(Received 24th Jan 2019; accepted 21st Mar 2019)

Abstract. Artificial Neural Networks (ANNs) is a reliable and alternative method used specially in the growth characteristics of some fish species. The purpose of this work was to compare with length-weight relationships and Artificial Neural Networks, the length-weight relation of 415 (232 female and 183 male) *Alburnus mossulensis* captured from Murat River between January 2018 and December 2018. The total length and the weight of the fish changed between 7.2-19.9 cm (12.81±0.095) and 3.24-40.6 g (13.51±0.30) respectively. The length-weight relationships were determined for females, males and all individuals as $W=0.0097L^{2.812}$ ($R^2=0.95$), $W=0.0168L^{2.599}$ ($R^2=0.95$) and $W=0.0130L^{2.701}$ ($R^2=0.95$), respectively. The growth type of *A. mossulensis* was negative allometric growth for female, male and all individuals. Regression analysis showed that length has high significantly correlation with weight (R = 0.97, R^2 = 0.95, $F_{1,413}$ = 79550.3, P <0.001) and 95% remain in weight was due to length remain. t-test results was used for the importance condition of the regression coefficients (t=89.193, P<0.01). Length-length relations were highly significant with R^2 values greater than 0.97. The condition factor values were ranged between 0.430 and 0.975 for all individuals. According to the comparison of the results obtained with MAPE (%), ANNs provided better results than the LWRs. With this study, it can be seen that ANNs can be used as an alternative useful method for population parameters prediction.
Keywords: *ANNs, MAPE (%), length-weight relation, negative allometric growth, Murat River*

Introduction

Alburnus mossulensis is a freshwater fish species from cyprinid, inhabiting the Euphrates, Tigris and Ceyhan rivers and in their near basins in Iran (Kuru, 2004; Geldiay and Balık, 2007; Coad, 2010). Ergene (1993) studied the reproduction and growth of this species in the Euphrates Basin of Turkey. Başusta (Girgin) (2000) investigation and growth and changes of in blod cells this species living in Keban Dam Lake. Turkmen and Akyurt (2000) and Yıldırım et al. (2003) studied the population structure and growth properties of the species in Karasu River. Başusta and Cicek (2006) studied the length-weight relationships for this fish in Ataturk Dam Lake in southeastern Anatolia, Turkey. Yıldırım et al. (2007) studied the reproduction and growth of this species in the Euphrates Basin of Turkey. Ghorbani (2011) studied the reproductive biology and population dynamics of the fish in Bibi-Sayyedan River of Tigris basin in Iran. Mousavi-Sabet et al. (2013, 2014) determined the length-weight relationships of the fish in Iran. Esmaeili et al. (2014) studied the LWR in this species in Iran. Abdul-Razak et al. (2015) studied some biological aspects of this species in the southern reaches of Euphrates River, Iraq. Alkan Uckun and Gokce (2015) assessed the age, growth, and reproduction of *A. mossulensis* in Karakaya Dam Lake (Turkey). Keivany et al. (2015, 2016); Radkhah (2016) and Keivany and Zamani-Faradonbeh (2017) studied the length-weight relationship and condition factor of *A. mossulensis* in Beheshtabad River, Bibi-Sayyedan River, Hamzeh-Ali Spring and Jarrahi River.

DOI: http://dx.doi.org/10.15666/aeer/1705_1025310266

Keivany et al. (2017) studied the reproductive biology and morphological diversity of *Alburnus mossulensis* populations in Iran. Serdar et al. (2017) some population parameters of *Alburnus mossulensis* in the Karasu River.

ANNs have been used in differ branches of aquatic science and in biology more than in other sciences (Tureli Bilen et al., 2011). With ANNs models; Maravelias et al. (2003) estimated the distributions of demersal fish species, Mastrorillo et al. (1997) estimated the existences of small fish in a river, Park et al. (2003) estimated aquatic macro-invertebrate varieties, Obach et al. (2001) predicted population dynamics of aquatic insects, Joy and Death (2004) estimated and spatially mapping freshwater fish and assemblies of decapods and Benzer and Benzer (2016) fish population predicted. Benzer et al. (2015, 2017) and Benzer and Benzer (2018) predicted growth properties of crayfish (*Astacus leptodactylus*). Ozcan and Serdar (2018a) estimated some population parameters of tigris loach (*Oxynoemacheilus tigris*). Sangun et al. (2019) estimated body weight of *Sparus aurata* with artificial neural network. Many authors reported that ANNs gave better results than other methods (Tureli Bilen et al., 2011; Benzer et al., 2015, 2017; Benzer and Benzer, 2016, 2018; Ozcan and Serdar, 2018a). ANNs is an alternative method for other methods in non linear situations for predict modeling (Joy and Death, 2004).

This study is the first record ANNs as a new and alternative approach to predicting basic biological characteristics for *A. mossulensis* in Murat River. The results showed high proximity between the measured and predicted data. Predicted and observed values are compared by Mean Absolute Percent Error (%). The values obtained with Artificial Neural Networks are much closer to their real values. For this reason, in this study it can be concluded that ANNs model applied made a more effective and reliable analysis than other methods. The aim of this study is to show the reliability of ANNs, which is an alternative method for the calculation of length-weight relationships.

Materials and Methods

Murat River, which is born from Aladağ in the north of Lake Van, flows into the Palu and Keban Dam Lake. The coordinates of Murat River (Palu-Elazığ) sampling 1. stations (38°41'08.9"N, 39°52'51.9"E) and 2. stations (38°40'05.1"N, 39°50'59.5"E) are given in *Figure 1*.

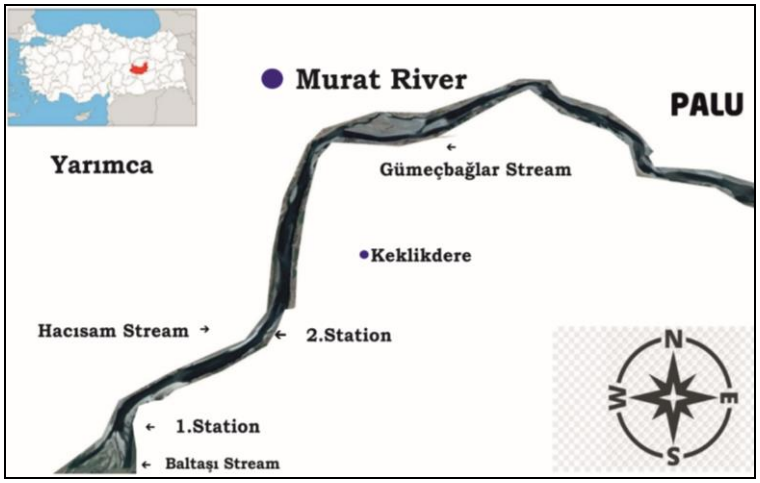

Figure 1. *Sampling stations of Murat River (Palu, Elazığ)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1025310266

Fishes were as monthly caught with gillnet by researcher and local fishermen during January 2018 and December 2018. Fishes were carried to the laboratory and fixed with 5% formaldehyde. Fish samples were measured for total length, fork length, standard length, weight and sexes identified by macroscopic observation of gonads; sex ratios were checked by a chi-square test (differed from 1:1).

The total length-weight relationship was determined with the below equation (*Eq. 1*) (Ricker, 1975). The degree of relation between the changeables was calculated with the determination coefficient, R^2 (King, 1995). (W is weight (W), L is total length (TL), a is the intercept, and b is the slope).

$$W = a*L^b \quad \text{(Eq.1)}$$

Length-length relationships were calculated with linear regression analysis (*Eq. 2*) (Zar, 1999).

$$TL=a+bFL,\ FL=a+bSL,\ SL=a+bTL \quad \text{(Eq.2)}$$

The condition factor values of fish are obtained by the below equation (*Eq. 3*) (W is weight; TL is total length and b is the coefficient of allometric of relationship) (Le Cren, 1951).

$$K=(W/TL^b)*100 \quad \text{(Eq.3)}$$

Artificial neural networks (ANNs) are biologically computer programs designed to adapt the human brain. ANNs identify the relationships in the data and learn through experiment and add their knowledge. An ANN is comprise of hundreds of single units, artificial neurons or processing elements. Neurons in a network are interconnected by the power of neural calculations. The behavior of these neural networks is determined by the transmission process and learning rule of their neurons. The activation signal is taked place transfer function to generate a single output of the neuron. Transmission process introduces non-linearity to the network. Throughout the course of the training, the connections are optimized until you reach the minimum and the best accuracy of the error. After the network is trained and tested, new data for output can be displayed (Agatonovic-Kustrin and Beresford, 2000). This model is an interrelatedness group of artificial neurons that process information in parallel. In general, an ANN is a system that varies according to internal and external information flowing through the network. Briefly summarized, neural networks are regression analysis, statistical, data-modelling tools used for modelling sophisticate relationships between inputs and outputs in data (Cabreira et al., 2009). Basically, there are 3 different layers in a neural network:

1. Input Layer (All the inputs are fed in the model through this layer (Length/weight, sex)).

2. Hidden Layers (There can be more than one hidden layers which are used for processing the inputs received from the input layers).

3. Output Layer (The data after processing is made available at the output layer (Weight/length)) (URL, 1); (*Fig. 2*).

The mathematical equation of the neuron model is as follows (*Eq.4*) (Krenkel et al., 2011). ($yi(k)$ is output value in discrete time k, F is a transfer function, $wi(k)$ is weight

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1025310266

value in discrete time *k* where i goes from *0* to *m*, *xi*(*k*) is input value in discrete time *k* where *i* goes from *0* to *m*, *b* is bias).

$$y(k) = F(\sum_{i=0}^{m} wi(k).xi(k) + b) \quad \text{(Eq.4)}$$

MAPE was used to compare ANNs and other methods. The smaller the MAPE values, the closer are the predicted values to the actual values (Benzer et al., 2017). MAPE is as follows equality (*Eq.5*). Yi is actual observation value, ei is difference between the actual value and the prediction value, n is number of total observations.

$$MAPE = \frac{1}{n}\sum_{i=1}^{n}\left|\frac{ei}{Yi}\right| x100 \ldots\ldots\ldots\ldots \quad \text{(Eq.5)}$$

Neural Network Toolbox of MATLAB (Ver R2016a) was used for ANNs. Created in MATLAB software are made up of three parts. These are "training", "testing", and "validation". In this study, for ANN model, 70% for training step, 15% for validation step and 15% for test step.

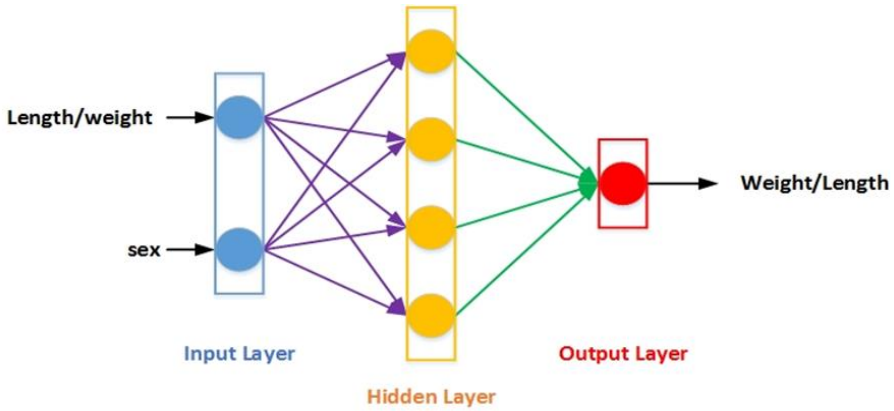

Figure 2. *Representation an ANN formed of 2 input layers, a hidden layer and an output layer to be estimated*

Results

A total of 415 (232 female and 183 male) specimens were caught in this study, the length and weight of females ranged from 8.7 to 19.9 cm (12.76 ± 0.12) and 5.0 to 40.60 g (13.32 ± 0.38) and those of males from 7.2 to 19.6 cm (12.82 ± 0.14) and 3.24 to 38.70 g (13.53 ± 0.45), respectively. The specimens were composed of 56% females and 44% males. The sex ratio of female to male was 1:0.79, chi-square test showed that significantly different from the expected 1:1 ratio ($P<0.05$). The difference in the lengths of females and males were not statistically important (*t*-test, $p>0.05$). The total length, weight-frequency is presented in *Figure 3*. The length group interval 11.0-12.9 cm (43.61%) and weight group 10.0-16.9 g (55.66%) were the most aboundant for all specimens. The females were larger in length and weight.

Length-weight relationships of *A. mossulensis* were found as $W=0.0097*L^{2.812}$, $R^2=0.95$, SE of $b=0.0025$ and 95% confidence intervals of $b=2.557$-2.836, *t*-test $P<0.05$ for females; $W=0.0168*L^{2.599}$, $R^2=0.95$ SE of $b=0.0028$ and 95% confidence intervals of $b=2.575$-2.865, *t*-test $P<0.05$ for males and $W=0.0130*L^{2.701}$, $R^2=0.95$ SE of $b=0.0019$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

and 95% confidence intervals of *b*=2.557-2.865, *t*-test *P*<0.05 for all individuals (*Fig. 4*); (*Table 1*). The growth type of *A. mossulensis* was negative allometric growth for female, male and all individuals. Regression analysis showed that length has high significantly correlation with weight (R = 0.97, R^2 = 0.95, $F_{1,413}$ = 79550.3, P<0.001) and 95% remain in weight was due to length remain. *t*-test results was used for the importance condition of the regression coefficients (*t*=89.193, *P*<0.01).

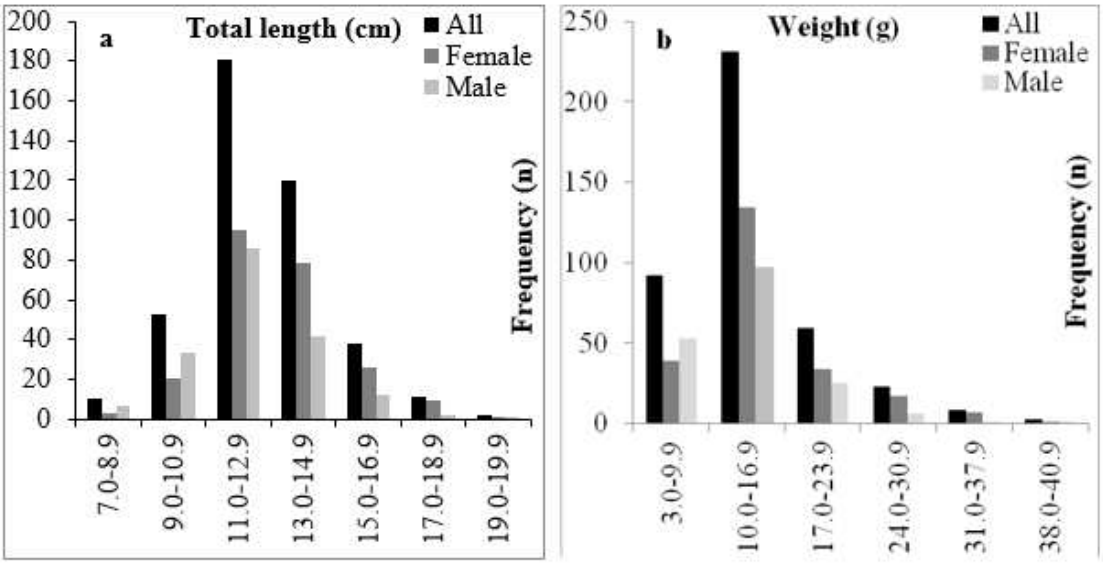

Figure 3. *Total-length (a) and weight (b) frequency of Alburnus mossulensis in Murat River*

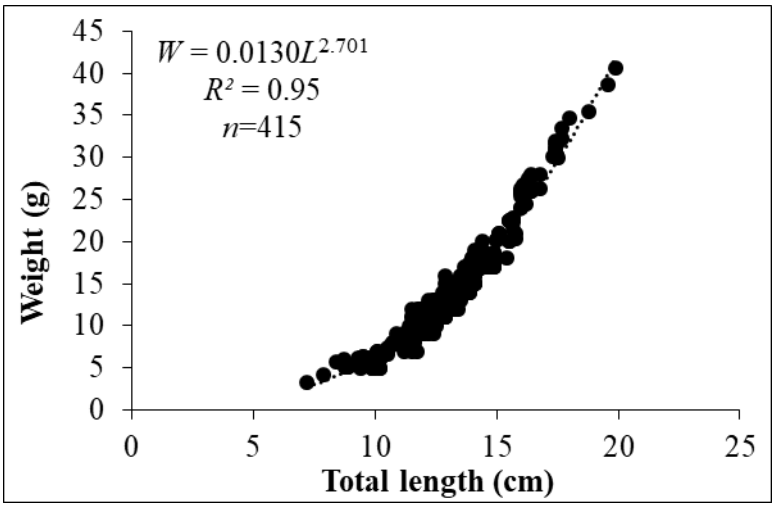

Figure 4. *Length-weight relationships of A. mossulensis for all individuals from Murat River*

The length and weight measurements, number of individuals (*n*), regression parameters *a* and *b* of the LWRs, 95% confidence intervals of *b,* coefficients of determination (R^2) and condition factor (*CF*) of the *A. mossulensis* were given in *Table 1*.

Regression analysis between the total, fork, standard length measurements for *A. mossulensis* sexes separately are shown in *Table 2*. Length- length relationships were highly significant with R^2 values greater than 0.97.

Figure 5 shows the coefficients of regression. The linear regression line, which is most appropriate between targets and outputs, is determined with a durable line.

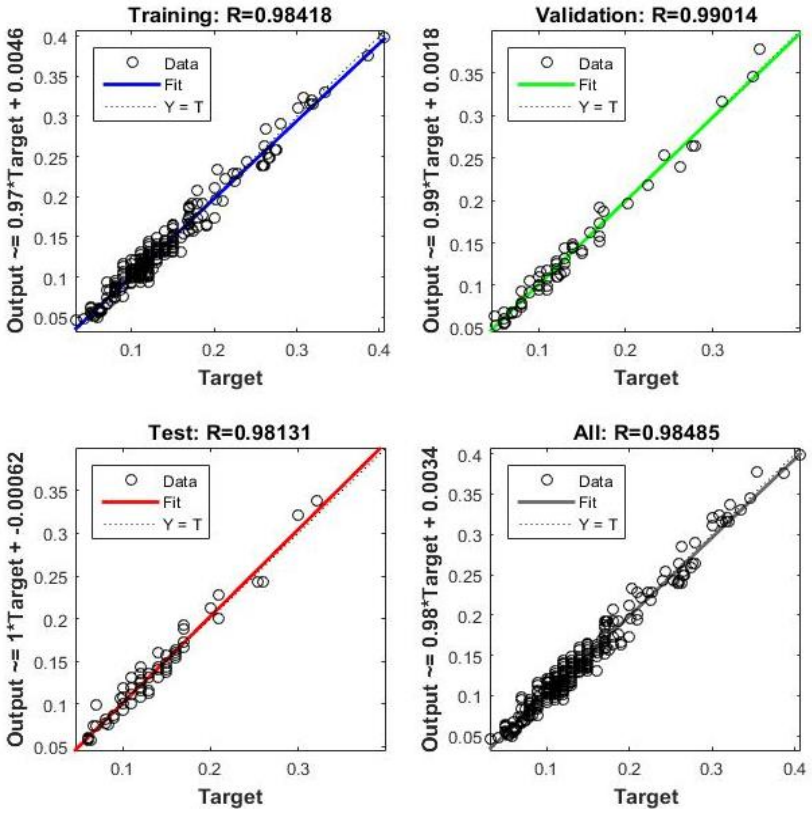

Figure 5. *Coefficients of regression in artificial neural networks model*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1025310266

R value shows the relationship between outputs and targets. According to *Figure 5*, the targeted output *R* value was 0.98418 for training, 0.99014 for validation, 0.98131 for testing and 0.98485 for corresponding all response. *R*=0.98485 value confirmes that the ANN output precise linear relevance with the target (excellently match). All these results confirm that the training gives the best results. Because all of the coefficients are close to 1, the accuracy of the training is highly acceptable and gave better predictions than regression relationship (0.98485) (*Fig. 5*).

Figure 6 shows the best validation performance. The mean squared error of all data (performance chart) is occurred on a logarithmically. The training mean squared error must have a declining trend in order for the training plot to shows an excellent training.

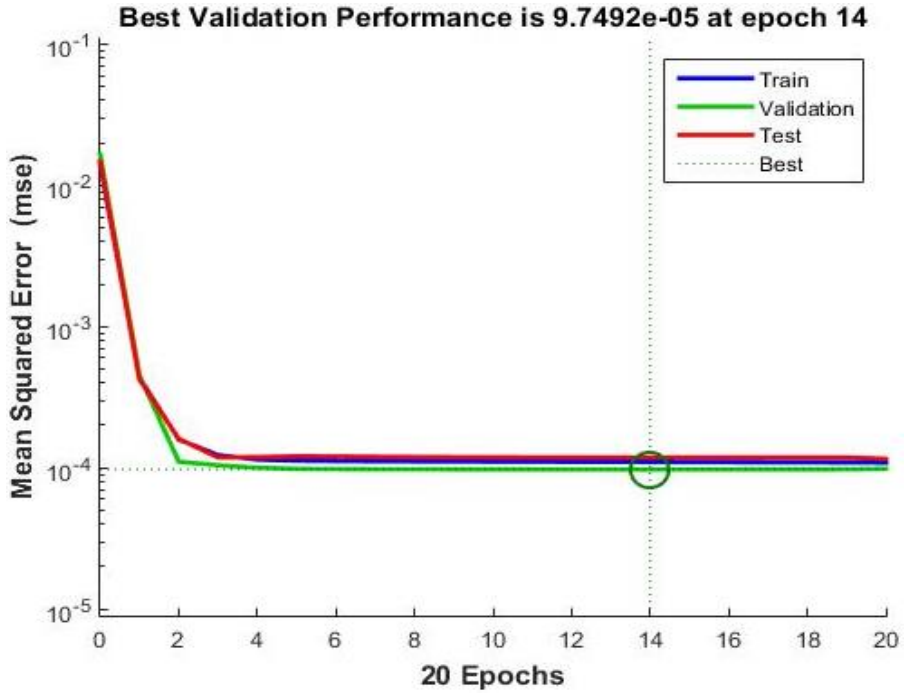

Figure 6. *Best validation performance of artificial neural networks*

In *Figure 6*, when the validation error increased to 20 epochs, the training was ended and the best validation performance was seen as 9.7492e-05 at 14th epoch. The optimum epoch is 20 for *A. mossulensis* there is no benefit to the system of increasing epoch after that.

Figure 7 shows the corresponding validation checks and the gradient of epochs. For the training state of artificial neural networks model, the validation checks was attained as 6, at epoch 20 and gradient=0.00032946, at epoch 20.

Actual values, ANNs and LWRs data of *A. mossulensis* are shown in *Table 3*. All values were classified by length groups and sexes. *Table 3* was obtained by comparison with ANNs and LWRs of *A. mossulensis*. The values we obtained with ANNs and LWRs were calculated one by one. It was determined that the ANNs MAPE (%) values were better than MAPE values calculated in length-weight relation.

Discussion

In this study, the maximum length for females was 19.90 cm and that for males was 19.60 cm; females are longer and heavier than males as seen in other fish species. The maximum total length reported for this fish from Ataturk reservoir was 38.20 cm (Başusta and Cicek, 2006), from Karakaya Dam Lake was 20.4 cm (Alkan Uckun and Gokce, 2015) and from Karasu River was 21.4 cm (Serdar et al., 2017).

Many researchers have found in different estimates for the length-weight relationship in fish. Le Cren (1951) because the oil and water content of the fish may vary depending on the temperature, stated that the length-weight relationship of the fish depends on the seasonal changes. It may also affect the *b* value in geographic location and environmental conditions such as and water temperature, which is the determining factor of feeding capacity, stomach fullness, disease and parasite loads (Bagenal and Tesch, 1978; Froese, 2006). Also, if the value of *b* is less than 3, the fish indicates negative allometric growth, and if the value of *b* is greater than 3, the fish indicates positive allometric growth (Weatherley and Gill, 1987). The *b* values reported for differ fish species ranged from 2.5 to 4.0 (Hile, 1936; Martin, 1949), 2 to 4 (Bagenal and Tesch, 1978) and 2.5 to 3.5 (Froese, 2006). In addition, high values of R^2 show that the length-weight relationships are linear observed range of values (*Table 4*). In the present study, length and weight relations of *A. mossulensis* were similar to those of Alkan Uckun and Gokce (2014) and Serdar et al. (2017).

	Male	0.0168	2.599	0.95	
	All	0.0130	2.701	0.95	

Length-length relationships are generally used for population parameters of fish species (Başusta et al., 2013; Ozcan and Serdar, 2018a, 2018b). LLRs were significant (P<0.001) for all individuals with all R^2 values greater than 0.97. These results are in agreement with those of Serdar et al. (2017) work done in the Karasu River.

Ergene, (1993) reported the mean condition factor as 0.86. Turkmen and Akyurt, (2000) reported it as 1.023 in males and as 1.047 in females. In this study, the max-min condition factors were 0.430-0.911 for females and 0.460-0.975 for males. The condition factor allows us to be informed about the physiological status of fish in relation to health (Kumolu and Ndimele, 2010). The fact that the condition factor is high shows that the environmental conditions are quite suitable for population dynamics studies (Blackwell et al., 2000). In this study, it can be said that the environmental

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1025310266

conditions are not suitable for *A. mossulensis* in this region since the condition factor value is less than 1.

The values obtained with Artificial Neural Networks are much closer to their real values (*Table 3*). ANNs is required for future predictions along with other methods. However, in the majority of these studies it is seen that the ANNs results are better than the results of other conventional methods (Brosse et al., 1999). In this study, according to results of *Table 3*, ANNs provided very good results compared to LWRs. Thus, ANNs can be used as an alternative and reliable method in fisheries for length-weight relation. MAPE values of the predict of ANNs for length and weight were 1.118 and 1.866 and the value of LWRs were 2.001 and 4.949. Lewis (1982) categorized models with a MAPE value of less than 10% as "very good" in predicting, 10%-20% as "good", 20%-50% as "acceptable" and over 50% are classified as "wrong and faulty" models. In many studies are determined that MAPE of ANNs values are quite low (Benzer and Benzer, 2016, 2018; Benzer et al., 2017; Ozcan and Serdar, 2018a).

According to Ekici and Aksoy (1993), *R* is successful when the values are between 0.95-1. In addition, Saleem et al. (2017), for a very good fit, the distribution of data should be along a 45° line indicating that the network outputs are equal to the targets. The forecasting of length-weight relation using artificial neural network was found to be 0.98485 as the *R* values for all individuals. With ANNs seen that the output tracks are very good targets for training (*R*-value = 0.98418), validation (*R*-value = 0.99014), and testing (*R*-value = 0.98131). These results show the success of the relationship between length-weight. With this study obtained high correlation coefficient (*R*) between the measured and predicted output variables, reaching up to 0.99 (validation).

Conclusions

The results of this study showed high proximity between the measured and predicted data. The values obtained with Artificial Neural Networks are much closer to their real values. For this reason, the ANNs model used in this study has a highly acceptable accuracy and reliability.

(Received 28th Jan 2019; accepted 6th Mar 2019)

Abstract. The paper presents results of a research conducted between 2010 and 2012 to determine the effect of the proportion of components in a mixture and harvest date on yield and chemical composition of field pea/oat (*Pisum sativum* L.*, Avena sativa* L.*)* mixtures. Two factors were examined in the study: factor I − proportion of components in a mixture: field pea 100%, oat 100%, field pea 75% + oat 25%, field pea 50% + oat 50%, field pea 25% + oat 75%; factor II − harvest date: the stage of field pea flowering and the stage of flat green pod of field pea. The following characteristics were examined: green matter yield of field pea/oat mixtures, nutrient content, NDF and ADF content. The results were statistically analysed. The highest fresh matter yield was produced by the 50% + 50% mixture of field pea and oat. Field pea/oat mixtures harvested at the stage of field pea flowering contained more total protein, crude ash and digestible nitrogen-free extracts. The mixtures harvested at the stage of flat green pod of field pea were higher in crude fibre, fibre fractions (NDF, ADF) and crude fat.
Keywords: *nutrient content, crude fibre, total protein, crude ash, fresh matter*

Introduction

Crop plants cultivated in mixtures usually produce higher yields compared to pure stands (Księżak and Staniak, 2013). It is the result of better utilisation of habitat conditions, including minerals and water from soil reserves. Spring cereals use roots to penetrate the surface soil layer whereas legumes reach the deeper layer. Also, plant species have different periods of critical demand for water and nutrients (Rutkowska and Pikuła, 2016).

Pisum sativum L. is a valuable component of legume/cereal mixtures. As the species includes various morphological forms (short or long stem, leafed and narrow-leafed), its potential to be mixed with spring cereals varies. Leafed cultivars seem to be the most suited to cultivation for green matter (Blagojevic et al., 2017). Oat may be a component mixed with field pea and sown on soils representing the rye good complex. One of its advantages is lower soil requirements compared with other cereal species (Shoaib et al., 2013).

A major issue which needs to be considered when cultivating legume/cereal mixtures is selection of an optimal harvest date which, paired with plant growth stage, makes it possible to rationally use the obtained yield. Also, when cultivating mixtures, one has to pay attention to nutrient content which determines the quality of harvested livestock feed. Feed digestibility is limited by plant cell wall components called fractions of neutral detergent fibre (NDF) and acid detergent fibre (ADF). Many authors (Rodrigues et al., 2008; Belanger et al., 2013; Stejskalova et al., 2013; Truba et al., 2017) believe

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1026710276

that modern livestock feeding systems (of cows in particular), take into account neutral detergent fibre (NDF) and acid detergent fibre (ADF) contents instead of or in addition to crude fibre. There are few works which assess the nutritive value of *Pisum sativum* L./*Avena sativa* L. mixtures in terms of the content of NDF and ADF fractions. The present paper is an attempt to at least partially fill this gap. The objective of the work is to determine the effect of the proportion of components in a mixture and harvest date on yielding and chemical composition of *Pisum sativum* L./*Avena sativa* L.

Materials and methods

Field research was conducted between 2010 and 2012 at the Zawady Experimental Farm (52°03' 39" N, 22° 33' 80" E) which belongs to Siedlce University of Natural Sciences and Humanities. The experimental soil was Albic Luvisol (Arenic), its reaction was neutral and it had average available phosphorus, potassium and magnesium contents. Humus content was 1.37%. The experimental design was a split-plot arrangement with three replicates. Two factors were examined in the study: factor I − proportion of components in a mixture: field pea 100%, oat 100%, field pea 75% + oat 25%, field pea 50% + oat 50%, field pea 25% + oat 75%; factor II − harvest date: the stage of field pea flowering, the stage of flat green pod of field pea. A detailed description of the mixtures and their sowing rates is as follows: field pea 170 kg∘ha^{-1}, oat 180 kg∘ha^{-1}, field pea 128 kg∘ha^{-1} + oat 45 kg∘ha^{-1}, field pea 85 kg∘ha^{-1} + oat 90 kg∘ha^{-1}, field pea 43 kg∘ha^{-1} + oat 135 kg∘ha^{-1}.

Each study years, the mixtures were preceded by winter triticale. In autumn, phosphorus and potassium fertilisers were applied at the rates of pure element dependent on the soil chemical composition, i.e.: 35.2 kg∘ha^{-1} P and 99.6 kg∘ha^{-1} K. In spring, nitrogen fertiliser, at the rate of 30 kg∘ha^{-1} N, was applied to all the units (excluding pure stand field pea) prior to seed sowing. An additional N rate, 50 and 30 kg∘ha^{-1}, was applied to oat and field pea/oat mixtures, respectively, at the stage of stem elongation. Seeds of field pea cv. Roch and oat cv. Zuch were sown in early April. Harvest was performed in late June (the stage of field pea flowering) and early July (the stage of flat green pod of field pea). During harvest, fresh matter yield was determined in each plot, and average fresh matter samples were collected to perform chemical analyses. The following characteristics were determined in the dry matter of the plant material sampled: total protein, crude ash, crude fibre and contents of fractions of neutral detergent fibre and acid detergent fibre (by near-infrared reflectance spectrometry NIRS using a NIRFlex N-500 spectrometer) as well as crude fat (by Soxlet method). Based on the determined nutrient contents, digestible nitrogen-free extracts were calculated as a difference between four components and the sum 1000.

Each characteristic studied was subjected to variance analysis appropriate for the split-block design. Tukey test was used to separate means when significant sources of variation had been found.

Results

The fresh matter yield content of field pea/oat mixtures

The fresh matter yield of field/oat was significantly affected by the experimental factors and their interaction (*Table 1*). The highest fresh matter yield was produced by

the 50% + 50% mixture of field pea and oat. Yields of the remaining mixtures were significantly lower. The yield of oat fresh matter was significantly higher compared with the 75% + 25% mixture. The highest fresh matter yield was produced by field pea grown in pure stand. Harvest date had a significant effect on fresh matter yield, it being higher for field pea/oat mixtures harvested at the stage of flat green pod of field pea compared with mixtures harvested at the stage of field pea flowering. An interaction was confirmed indicating that the highest fresh matter yield was produced by the 50% + 50% mixture of field pea and oat harvested at the stage of flat green pod of field pea, it being the lowest for pure stand field pea harvested at the flowering stage.

The total protein content of field pea/oat mixtures

Statistical analysis revealed a significant influence of the experimental factors and their interaction on total protein content in field pea/oat mixtures (*Table 2*). The highest concentration of total protein was recorded in field pea cultivated in pure stand. Mixtures had a lower total protein content; of these the 75% + 25% mixture had the highest content of this component. An increase in the proportion of oat in the mixture was followed by a decline in total protein content, it being the lowest in pure stand oat. Harvest date had a significant effect on total protein content in mixtures. Field pea/oat mixtures harvested at the stage of field pea flowering had a higher concentration of total protein than mixtures harvested at the stage of flat green pod. An interaction was detected which indicated that pure stand field pea harvested at the flowering stage had the highest total protein content, it being the lowest in pure stand oat and field pea/oat mixtures with the component proportion of 50% + 50% and 25% + 75% harvested at the stage of flat green pod of field pea.

The crude fibre content of field pea/oat mixtures

Crude fibre content in field pea/oat mixtures was significantly affected by the experimental factors and their interaction (*Table 3*). The lowest crude fibre content was determined in pure stand field pea, it being the highest in oat. The presence of oat in mixtures with field pea contributed to an increase in crude fibre content. Of the test mixtures, the highest crude fibre content was recorded in the 75 + 25% and 50 + 50% mixtures. Also, harvest date had a significant effect on crude fibre content in mixtures

which was higher in mixtures harvested at the stage of flat green pod of field pea than the stage of field pea flowering. An interaction between the experimental factors was confirmed. It indicated that the lowest crude protein content was characteristic of pure stand field pea and the 75 + 25% mixture, both harvested at the stage of field pea flowering, it being the highest in oat cultivated in pure stand and harvested at the stage of flat green pod of field pea.

The neutral detergent fibre (NDF) content of field pea/oat mixtures

Statistical analysis revealed a significant influence of the experimental factors and their interaction on the content of neutral detergent fraction (NDF) in field pea/oat mixtures (*Table 4*). The lowest NDF content was recorded in field pea cultivated in pure stand, it being the highest in oat. As the proportion of field pea in mixture was reduced and oat proportion increased, an increase in the NDF content was observed. Of the test mixtures, the lowest NDF content was determined in the 75 + 25% mixture. Harvest date had a significant effect on NDF content in field pea/oat mixtures. The content was lower in mixtures harvested at the field pea flowering stage than at the stage of flat

The acid detergent fibre (ADF) content of field pea/oat mixtures

The content of acid detergent fibre (ADF) was significantly influenced by the experimental factors and their interaction (*Table 5*). The lowest ADF content was recorded in field pea cultivated in pure stand and the highest in oat. The more oat was added to the mixture, the higher the ADF content. Of the test mixtures, the lowest ADF content was recorded in the 75 + 25% mixture of field pea and oat. A interaction was detected indicating that the lowest ADF content was characteristic of pure stand field pea harvested at the flowering stage, it being the highest in oat harvested at the stage of flat green pod of field pea.

The crude fat content of field pea/oat mixtures

Statistical analysis demonstrated a significant effect of the experimental factors and their interaction on crude fat content in field pea/oat mixtures (*Table 6*). The highest crude fat content was determined in pure stand oat, it being the lowest in field pea. An addition of oat to mixtures with field pea contributed to an increase in crude fat content. Of the test mixtures, the highest crude fat content was recorded in the 25 + 75% mixture. Harvest date had a significant effect on crude fat content in mixtures. More crude fat was determined in mixtures harvested at the stage of flat green pod of field pea compared with the flowering stage. An interaction was found: the highest crude fat content was determined in oat cultivated in pure stand and harvested at the stage of flat green pod of field pea, it being the lowest in field pea harvested at the flowering stage.

Table 6. *Crude fat content in field pea/oat mixtures (means across 2010-2012), g◎kg^{-1} d.m.*

The crude ash content of field pea/oat mixtures

Crude ash content in field pea/oat mixtures was significantly affected by the proportion of components in a mixture, harvest date and their interaction (*Table 7*). Pure stand field pea and the 75 + 25% mixture had the highest crude ash content, it being the lowest in pure stand oat. In the remaining mixtures, crude ash content was lower than in field pea, and it differed insignificantly from oat content. Harvest date had a significant effect on crude ash content in mixtures. A higher concentration of crude ash was recorded in field pea/oat mixtures harvested at the stage of field pea flowering compared with the stage of flat green pod of field pea. There was found an interaction between the experimental factors which indicated that the highest crude ash content was determined in field pea cultivated in pure stand as well as mixed with oat at the following proportions: 75 + 25% and 50 + 50% and harvested at the flowering stage, it being the lowest in oat and the 50 + 50% and 25 + 75% mixtures of field pea and oat harvested at the stage of flat green pod of field pea.

The digestible nitrogen-free extracts of field pea/oat mixtures

Statistical analysis demonstrated a significant influence of the experimental factors and their interaction on digestible nitrogen-free extracts in field pea/oat mixtures (*Table 8*). The highest content of digestible nitrogen-free extracts was determined in the 75 + 25% and 50 + 50% mixtures of field pea and oat, it being the lowest in pure stand

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1026710276

oat and the 25 + 75% mixture. Harvest date had a significant effect on digestible nitrogen-free extracts in field pea/oat mixtures.

Their concentration was higher in mixtures harvested at the stage of field pea flowering compared with the stage of flat green pod of field pea. There was found an interaction between the experimental factors indicating that the highest content of digestible nitrogen-free extracts was determined in pure stand oat harvested at the stage of field pea flowering, and the lowest in pure stand oat harvested at the stage of flat green pod of field pea.

Discussion

Legume/cereal mixtures are predominantly grown for grain and fodder seed but they can be successfully cultivated for green matter to be used as fodder for cattle. On light soils, which predominate in Poland, field pea and oat may be valuable components used for cultivation in mixtures. In the present study, the highest fresh matter yield was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1026710276

produced by the 50 + 50% mixture of field pea and oat. According to Huńady and Hochman (2014), mixtures of field pea (60%) with wheat or spring barley had the highest yields. Also Bedoussac and Justes (2009), Eskandari et al. (2009), Neuman et al. (2009), Kontturi et al. (2011), Księżak and Staniak (2013), Bojarczuk et al. (2014) and Neugschwandtner et al. (2014) demonstrated that mixed stands produce better yields than pure stands as mixtures are better at utilising changeable habitat conditions. In the experiment reported here, the fresh matter yield of the remaining mixtures was significantly lower although still higher than pure stand field pea. Harvest date had a significant effect on the fresh matter yield of field pea/oat mixtures. The yield was higher for mixtures harvested at the stage of flat green pod of field pea. Also studies by Staniak et al. (2012), Bojarczuk et al. (2014) and Rutkowska and Pikuła (2016) revealed that legume/cereal mixtures harvested at a later growth stage produced more biomass.

In the present study, the highest total protein content, crude ash content and digestible nitrogen-free extracts were found in pure stand field pea and in the 75 + 25% mixture of field pea and oat. Also Lithourgidis et al. (2006), Eskandari et al. (2009), Alizahed and Jat (2013), Huńady and Hochman (2014) Neugschwandtner and Kaul (2016) and Blagojevic et al. (2017) reported that leguminous plants grown in pure stand or constituting a high proportion in mixtures with cereals, oat in particular, produced the highest quality green fodder. In the study discussed here, pure stand field pea had the lowest crude fat content as well as the content of neutral detergent fibre (NDF) fraction and acid detergent fibre (ADF) fraction. Also Lithourgidis et al. (2006) found that common vetch cultivated in pure stand and in mixtures with spring triticale or oat had the lowest content of crude fibre and its fractions. In the study reported here, pure stand oat contained the most crude fibre, NDF, ADF and crude fat. According to many authors (Shoaib et al., 2013; Płaza et al., 2017), oat is the cereal that has the highest crude fat content. Also, cereals contain more crude fibre compared with legumes, which makes them less digestible. The factors which limit livestock feed uptake and digestibility include components of plant cell walls which are determined as fractions of neutral detergent fibre (NDA) and acid detergent fibre (ADF) (Belanger et al., 2013; Baert and Van Was, 2014; Truba et al., 2017).

Harvest date is a factor which affects nutrient content and, as a result, livestock feed quality. In the present study, field pea/oat mixtures harvested at the stage of field pea flowering contained more total protein, crude ash and digestible nitrogen-free extracts, which corresponds to findings reported by Lithourgidis et al. (2006), Shoaib et al. (2013), Płaza et al. (2017) and Uzun et al. (2017). In the experiment reported here, green fodder harvested at the earlier growth stage was of better quality, contained less crude fibre and fibre fractions, which made the green fodder more digestible. Research by Lithourgidis et al. (2006), Pires et al. (2006), Rondahl et al. (2006), Rutkowska et al. (2016) and Płaza et al. (2017) demonstrated that legume/cereal mixtures harvested at later development stages were of poorer quality. Primarily, they contained more crude fibre which reduces livestock feed digestibility. However, with fresh matter yield in mind, later harvest of legume/cereal mixtures, that is at the stage of flat green pod of field pea, should be encouraged. The highest fresh matter yield was produced by the 50 + 50% mixture of field pea and oat, and the most favourable chemical composition was determined for the 75 + 25% mixture.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1026710276

Conclusions

1. The highest fresh matter yield was produced by the 50 + 50% mixture of field pea and oat.

2. Field pea grown in pure stand and mixed with oat at the proportion of 75 + 25% contained the most total protein, crude ash and digestible nitrogen-free extracts.

3. Pure stand oat had the highest crude fibre content, NDF, ADF and crude fat.

4. Field pea/oat mixtures harvested at the stage of field pea flowering contained more total protein, crude ash and digestible nitrogen-free extracts whereas mixtures harvested at the stage of flat green pod of field pea had more crude fibre, NDF, ADF and crude fat.

5. For further research, the selection of other species of legumes and cereals for cultivation in mixtures should be recommended. It will be very important to broaden the research with the features that define the feed value of the mixtures, i.e. the digestibility of the organic matter and the digestibility of the dry matter. The green matter from mixtures of legume and cereal plants can be used for silage used in cattle feeding.

(Received 21st Feb 2019; accepted 15th May 2019)

Abstract. Biodiversity of Asarama estuary at Andoni flat in the Niger Delta was surveyed in the wet and dry seasons of 2016/17; in order to ascertain the diversity, composition and community structure of plankton. Qualitative plankton samples, were collected from different sources including surface water and analysed in the laboratory. The results for the analyses for water chemistry showed optimal to near high values for the parameters, which were within the normal range of normality in tropical brackish waters. Biodiversity analyses revealed eight divisions of phytoplankton in the given order; (bacillariphyta constituting 84% > cyanophyta 8% > chlorophyta 6%, > euglenophyta 1%, ≥ dinophyta 1%, > ochrophyta < 1%, ≥ charophyta < 1%, ≥ oligohymenophorea < 1%) and three groups of zooplankton which were cyclopoida (composed of 98% of the species), harpaticoida and rotifera (which had 1% of the constituent species each). Species diversity and composition were low for zooplankton and very high for phytoplankton. Meanwhile, unregulated boat traffic and illegal pollution with crude oil products pose major challenges to the biotic communities. Nutrient enrichment may perhaps become an issue in the near future if no monitoring efforts backed with legislature are imposed on the maricultural practices of bivalves at the upstream.
Keywords: *Andoni, inter-tidal, phytoplankton, salinity, zooplankton*

Introduction

Estuaries are shallow open systems that are strongly influenced by river inflows, mixing with the coastal ocean and exchanging sediment including the cleaning of the atmosphere and the water interfaces. They usually have distinct salinity gradients in their lower part and a tidal influence in their upper freshwater part providing specific hydrological properties when compared to rivers. Importantly, estuaries form transition zones between freshwater and marine environments, and are thus characterised by a large variability in their biophysical and chemical properties under both the influence of climate change and intense anthropogenic activities (Pearle et al., 2010; Lancelot and Muylaert, 2011; Yang et al., 2014). Asarama estuary is one of the most important navigable waterways in the far reaches within Andoni land and it connects several communities therein. Besides, it is exposed to both the natural factors and human exploitation activities daily (Ansa and Francis, 2007).

The estuarine environment represents an ecotone between freshwater and marine ecosystems and is influenced by both, but is in many ways more complex than either of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1027710292

them (Cearreta et al., 2000; Elliott and De Jonge, 2002; Elliott and McLusky, 2002; Yang et al., 2014). Both river flow and tidal motions drive the riverine and marine communities towards estuaries (Waniek et al., 2005) and hence shape the diversity and abundance of estuarine communities (Elliott and McLusky, 2002; Waniek, 2003; Froneman, 2004; Cloern et al., 2014). Despite the well-documented role of zooplankton in the transfer of carbon and energy, and in ichthyofaunal abundance, relatively few studies have dealt with the determinants of zooplankton assemblages in estuarine ecosystems (Carlsson et al., 1995; Dalal and Goswami, 2001; Tan et al., 2004; Thor et al., 2005; Hwang et al., 2010).

The productivity of any water body is determined by the amount of plankton therein as they are the major primary and secondary producers. Plankton communities serve as a base for the food chain that supports the commercial fisheries (Townsend et al., 2000; Godhantaraman et al., 2003; Conde et al., 2007; Davies et al., 2009; Ogbuagu et al., 2011). They are essential tools for biomonitoring programme (Davies et al., 2009) and as such their relative high abundance and diversity is crucial.

Some available studies in the Niger Delta brackish waters dealing with phytoplankton and zooplankton include Opute (1990) on the phytoplankton of Warri/Focados estuary in Delta State; Kadiri (2006) on the survey of phytoplankton on the western Niger Delta; Davies et al. (2009) on the phytoplankton of Elechi creek, and Ogbuagu et al. (2011) on the myco-plankton of Imo River in the Niger Delta).

There is a huge dearth of knowledge on the plankton communities of Asarama estuary regarding its checklist, diversity and community structure; as no such known study was documented prior to this work upon search. Hence, this study was timely and addresses the influence of environmental activities upon the composition, diversity and community structure of the plankton of Asarama estuary at Andoni flat in the Niger Delta. Therefore, the aim and objectives of this study were to document the diversity, community composition and the physicochemical environment associated with the plankton of Asarama estuary. We used Multivariate approach such as canonical correspondence (CC) analysis to test for the associations between plankton communities and the physicochemical environment in the study area.

Materials and methods

Study area

Asarama estuary at Adoni land in Rivers State is located within the coordinates (04°30’37”N, 007°27’05”E and 04°31’35”N, 007°28’44”E). It is a semi-diurnal tidal estuary system with a bridge across to other communities near shore (*Fig. 1*). The sampling stations (which are designated as points 1 to 5, in yellow ink along the water course on the map) were fixed by using a hand held Global Positioning System (GPS) and were maintained throughout the study period.

Sampling stations

The ecosystem is characterised by rich flora communities of white and red mangroves, Nipa palm forests and other halophytes. At station 1, is located a forest of mangroves named; Aso mangrove forest which is over 200 years old (personal communication, 2016). The forest is a host to several species of birds, monkeys, reptiles, bees and insects as observed during field studies. Stations 2 is rich in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1027710292

mangroves as well. Decapods and bivalves were commonly seen on mangrove branches here. Stations 3 is characterised by an admixture of white mangrove and nipa palms. The sediment was mostly silty and contained a lot of dead decaying organic matter like dead woods, dead leaves and dead shells of molluscs. Station 4 is located far downstream after the bridge by the fishing wooden traps. The substratum was a mixture of sandy-muddy bed. A film of soot from an illegal petroleum local refinery was observed on the water surface throughout the study. Station 5 is equally located downstream of station 4. A lot of nipa palms were found here with so much decomposition activities of the palm fronds and their seeds. The substratum was mostly muddy at the upper most reaches.

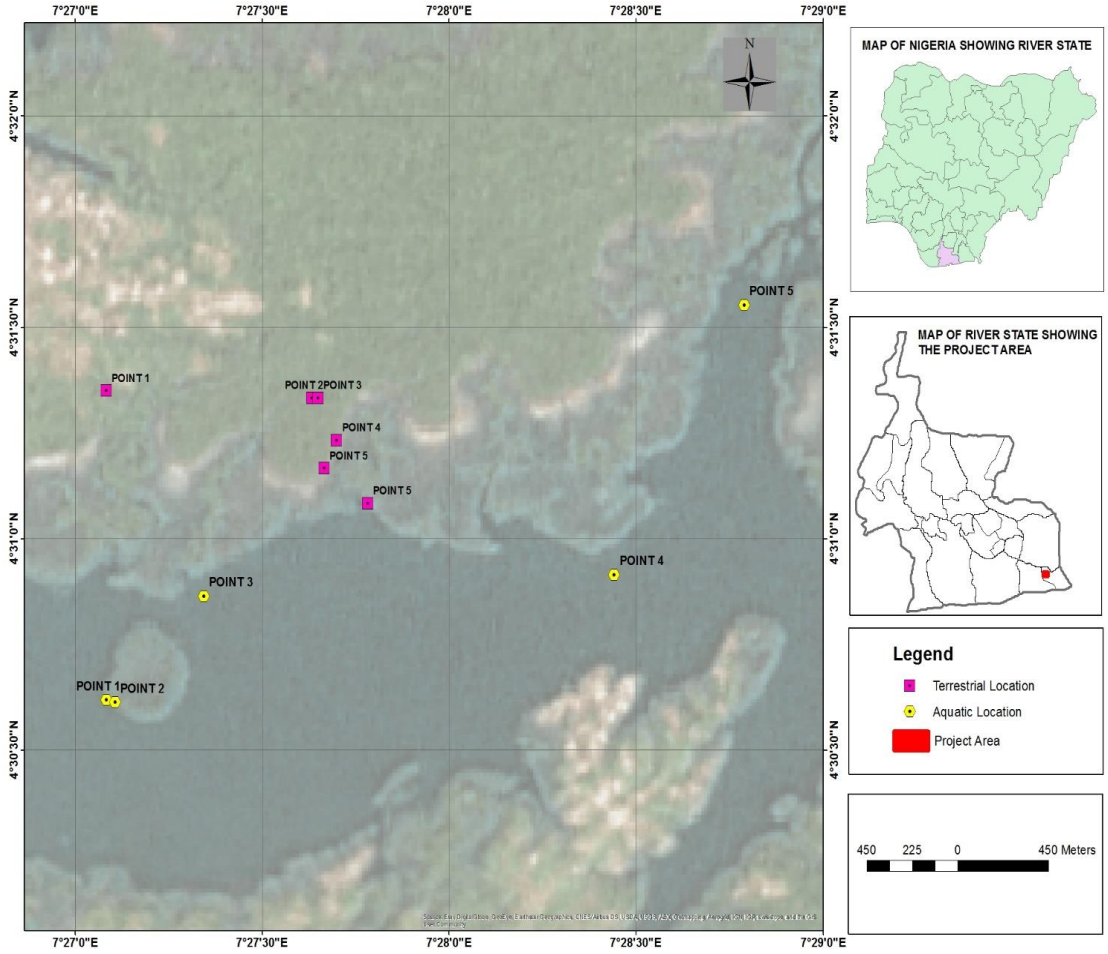

Figure 1. *Map of the study area*

Human activities and land used pattern

The major human activities in the locality include land and water transportations using cars, motor-bikes and boats, fishing with fish nets, gears and fish traps. Mariculture of Oysters (*Castrostrea* sp) and Periwinkles (*Tympanotonus fuscatus* Var. *Radular*) were predominant. At low tides particularly between 08:30 and 10:00 some of the locals were engaged in harvesting periwinkles indiscriminately without regulations.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1027710292

Illegal local refinery of petroleum products was observed far upstream off the estuary at the north-western bank which was emitting soot into the atmosphere.

Surface water sampling and analyses

Surface water samples were collected, preserved where applicable and analysed either in the field or laboratory according the methods of Eaton et al. (2005). A HANNAH field pH meter was used for the determination of pH in-situ. Turbidity was determined in the laboratory by using a HACH DR - 2000 spectrophotometer (Hach instrument). Salinity was determined in the laboratory by using HACHCO150 Model for Total Dissolved Solid/Conductivity/Salinity. This was determined using a HACHCO150 TDS/Conductivity/Salinity meter. Azide modification of Winkler's method was used to determine dissolved oxygen content of the water samples. Also, the Azide modification of Winkler's method was used to determine BOD content of the water samples. Nitrate was determined using HACH ER 2000 spectrophotometer. Determination of sulphate was done using a HACH DR 2000 spectrophotometer.

Plankton sampling and laboratory analyses

We used qualitative method to collect both phyto and zooplankton communities from the subsurface water in August 2016, the peak of wet season in the Niger Delta and March 2017 (driest month in the dry season) across five sampling stations (designated as points 1 to 5 on the map) by towing a 55 micron plankton net tied to a 25 HP engine-powered boat cruising at a speed of about 5 km h^{-1} for not more than 3 minutes in all. Plankton samples were then preserved with few drops of 10% buffered formaldehyde solution in 250 ml plastic bottles (polypropylene bottles) (Davies et al., 2009; Imoobe and Adeyinka, 2009). Samples were observed in the postgraduate laboratory of the Department of Animal and Environmental biology, University of Benin, Benin, Nigeria; using the Olympus binoculars microscope (CH). Identification and classification to species level where possible, was carried out with the appropriate literatures (Newell and Newell, 1966; Prescott, 1975; Needham and Needham, 1978 and Van De Velde, 1984; Jeje and Fernando, 1986).

Data analyses

Physicochemical data were subjected to the Analysis of Variance (One-way ANOVA) using SPSS (version 16.0). Plankton results were tested for biological diversity indices such as species richness, Shannon diversity index and species evenness with the aid of Palaeontological Statistics software (PAST 1.99 version) and canonical correspondence analysis (CCA) was also performed to test for any existing association between environmental condition and the biota (Hammer et al., 2001; Uwagbae et al., 2017). Plankton data were equally analysed by using basic tools for the measurement of central tendency such as graphics and percentage distribution.

Results

Physico-chemical environment of Asarama estuary

The physical and chemical condition of Asarama estuary surface water is presented in *Tables 1* and *2,* respectively.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

Significant < 0.05: significant difference

Air and water temperatures closely followed each other. The differences between air and water temperatures was not more than 4 °C. Mean air temperature ranged between 30 and 31 °C across the stations. Likewise water temperature varied from 27.75 °C at station 2 to 29 °C at station 4. There was however no significant differences between the two parameters ($P > 0.05$).

The mean spatial and temporal concentrations of hydrogen ion concentration (pH) values showed an alkaline condition ranging between 7.00 at station 5 and 7.30 at stations 2 and 3 respectively. The mean values across stations 1 to 5 in wet and dry seasons were between 7.06 and 7.32. Turbidity mean wet and dry season values ranged from 10.20 to 15.00 NTU. Turbidity mean concentration values were between 900 NTU at station 1 and 19.00 NTU at station 2. Electrical conductivity (EC) mean seasonal concentrations were between 5.22 $mScm^{-1}$ at station 5 and 9.37 $mScm^{-1}$ at station 2.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1027710292

Total hardness and nutrients (phosphate, sulphate and nitrate) exhibited condition tenable in the marine environment. Mean values of total hardness varied from 1075.00 mgL^{-1} at station 3 and 4 respectively to 1430.00 mgL^{-1} at station 2. Its mean concentration value in the water was between 1108.00 mgL^{-1} in the wet season and 1272.00 mgL^{-1} in the dry season. Nitrate and phosphates both had low range of values. The mean temporal and spatial concentration values were less than 0.5 mgL^{-1}. However, sulphate recorded very high values of between 386.00 mgL^{-1} during the wet season and 305.40 mgL^{-1} during the dry season. Sulphate mean concentration were between 254.00 mgL^{-1} at station 5 and 455.00 mgL^{-1} at station 2. The seasonal values of dissolved oxygen (DO) ranged between 7.18 mgL^{-1} in the dry season and 7.86 mgL^{-1} in the wet season. Mean values across the stations ranged from 7.21 mgL^{-1} at station 1 to 788 mgL^{-1} at station 5. Biological oxygen demand (BOD_5) seasonal values ranged from 1.23 mgL^{-1} in the dry season to 1.38 mgL^{-1} in the wet season. And mean values showed variations from 0.98 mgL^{-1} at station 1 to 1.89 mgL^{-1} at station 3.

Salinity mean concentrations varied from 3.20 ppm at station 5 to 4.95 ppm at station 1. Seasonal concentrations varied between 3.98 ppm in wet season and 4.90 ppm in the dry season.

Plankton studies

Both phyto- and zooplankton were characterised and presented in this section.

Phytoplankton

Phytoplankton analysis revealed a total of eight divisions dominated by the Bacillariphyta constituting about 84%. Others were in the order Cyanophyta (8%) > Chlorophyta (6%), > Eglenophyta (1%), ≥ Dinophyta (1%), > Ochrophyta (< 1%), ≥ Charophyta (< 1%), ≥ Oligohymenophorea (< 1%) (*Figs. 2* and *3*). The total number of individuals is represented by 9,276 individuals per meter squared, amongst 57 taxa. Phytoplankton taxa had higher percentage composition and distribution across the study stations except at station 5 and were significantly higher during the dry season of the study in 2017 (*Table 3*).

Zooplankton

The zooplankton taxa were poorly represented and distributed in three groups; Cyclopoida, Harpaticoida and Rotifera of the phylum Arthropoda and sub-phylum Crustacea. A total of 1,299 individuals per unit area represented in 15 taxa were recorded in this aspect of the study. The group Cyclopoida constituted 98% of species while Harpaticoida and Rotifera had 1% each. Taxa composition and distribution varied irregularly across the sampled stations (*Figs. 4* and *5*). Meanwhile, Rotifera was highest at station 5. There was no zooplankton recorded at station 4 throughout the study (*Table 4*).

Diversity indices for plankton

Biological diversity index for phytoplankton with respect to species richness was highest at station 1 and least at station 2. Species were only evenly distributed at stations 2 and 3. Meanwhile species dominance was highest at station 4 and Shannon diversity was least at stations 4 and 5 respectively (*Table 5*).

Application of canonical correspondence analysis (CCA) on the biota

We used Canonical correspondence analyses to characterise the relationships between the abiotic and biotic components of Asarama estuary.

For phytoplankton several associations were found at axis 2 of the CCA (*Fig. 6*). There was a positive association between phosphorus, sulphur and Ochrophyta species at plot 4. At plot 1, there was a positive association between pH and Charophyta. Meanwhile, Cyanophyta and Euglenophyta showed some positive correlations with nitrate respectively.

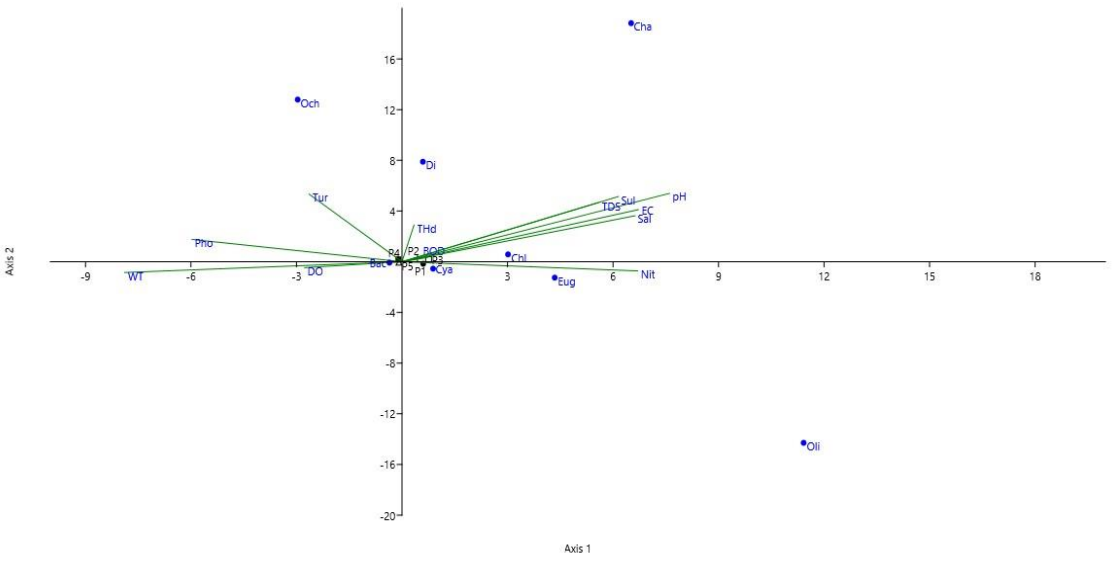

Figure 6. *Canonical corresponded analysis (CCA) for phytoplankton community*

However, for the zooplankton taxa (*Fig. 7*) there was a strong negative correlation between cyclopoida taxa and water temperature at axis 1. Also at axis 1, positive

DOI: http://dx.doi.org/10.15666/aeer/1705_1027710292

association between biological oxygen demand (BOD), dissolve oxygen (DO) and rotifers was observed. Importantly, pH, EC, salinity, turbidity, sulphate and nitrate showed strong negative association with harpacticoida taxa during the study.

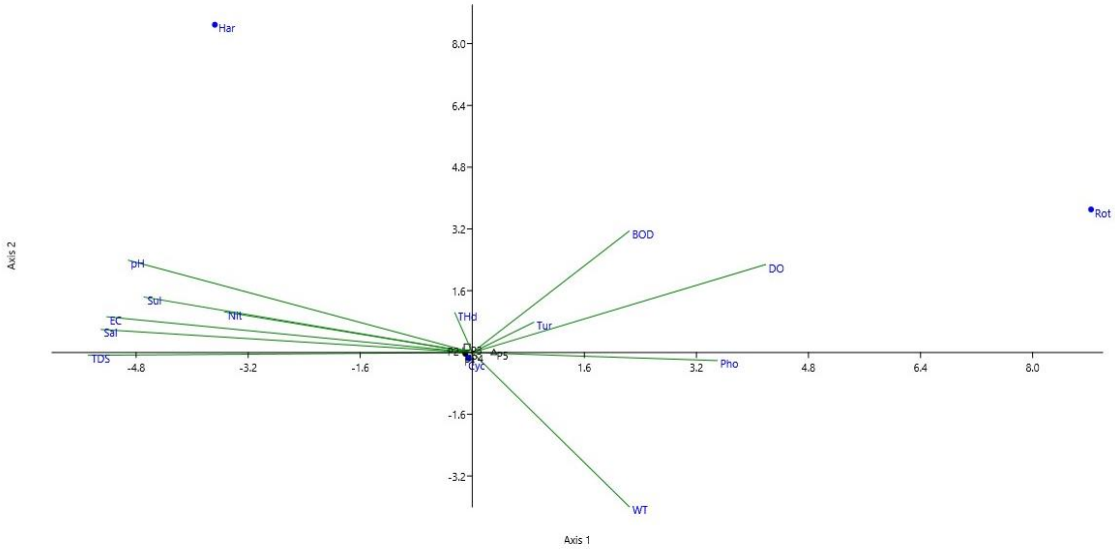

Figure 7. *Canonical corresponded analysis (CCA) for zooplankton community*

Discussion

The result of phytoplankton showed high species diversity, abundance and a robust community structure. In a given healthy aquatic environment, phytoplankton high population density is expected particularly in the shallow water depth rich in nutrient materials (Castro and Huber, 1997; Kadiri, 2006; Davies, 2009; Cloern et al., 2014; Dalu et al., 2016) except otherwise in contaminated or polluted waters. The dominance of Bacillariophyta division amongst the eight divisions recorded in this study corroborate the study by Kadiri (2006) and Egborge et al. (2001) in the western Niger Delta explaining that most inter-tidal waters in the zone are likely to be in this nature. Davies (2009) demonstrated that day light event (sun shine rays) play very important role in the production activities of both the primary and secondary producers as the latter is dependent on the former. The taxa among the division Bacillariophyta which were well represented across the study irrespective of the prevailing season were; *Bacillaria paradoxa, Flagillaria sp* and *Synedra acus* and were occasionally sampled at stations 1, 2, 3 and 5 respectively. The reason why the divisions Dinophyta, Ochrophyta and Oligohymenophorea recorded one species each throughout this study could not be well ascertained. However, the pattern of phytoplankton diversity is similar to what was reported (Kadiri, 2006) across waterways in the western Niger Delta of Nigeria. The pattern of diversity and species abundance observed in this study whereby some stations did not record any individual was affirmed by the output of the performance of diversity indices such as species richness and Shannon wiener diversity, and was earlier acclaimed (Kadiri, 2006 in the Niger Delta; and Lancelot and Muylaert, 2011). Environmental conditions such as temperature, pH, DO, BOD, salinity and EC in the surface water of Asarama estuary greatly influenced the production (particularly of phytoplankton), distribution and stability of the biotic community (typical for the zooplankton).

The zooplankton of Asarama estuary were in conformity to what have been documented for some coastal or brackish waters in the Niger Delta of Nigeria (Davies, 2009; Ogbuagu et al., 2011). Though, the zooplankton community structure had more taxa of the sub-class copepod which consist of the order cyclopoida and harpaticoida, and the class rotifer respectively. The dominance of copepods in this study as a finding is in consistency with some earlier studies (Kolo et al., 2001; Davies, 2009) in Nigerian coastal environments and Hwang et al. (2010) for a study in Taiwan. Zooplankton-cyclopoida was represented by seven species of which; *Thermocyclops neglectus and Mesocyclops bodanicola* were the most dominant and abundant species recorded across the five sampled stations. *Shizopera neglecta* (Harpacticoida) and the two species of Rotifers only (*Keratella hiemalis and Rotaria neptunia*) were recorded at station 4. We strongly attribute this phenomena to the presence of soot and oil film on the surface water which could perhaps inhibit the activities of primary producers. The restriction of the occurrence of Rotifers species to stations 3 and 5 only could not be fully ascertained in this study. Importantly, the dominance of copepods in a given aquatic environment as in this study, is an indication of a perturbed or stressed environment (Davies, 2009). Imoobe and Adeyinka (2009) reported a high species diversity for rotifers and copepods for an inland stream in Benin, Nigeria, which proved contrary to our findings for the same group of zooplankton. Environmental perturbation was found to be associated with Asarama estuary resulting from intense human activities such as transportation/navigation and over harvesting of periwinkle (*T. fuscatus)*. Despite the diversity of phytoplankton, the zooplankton diversity was low however, a situation that was least expected since Asarama estuary is typically a shallow inter-tidal ecosystem rich in nutrient resulting in high productivity in the littoral zone. However, we believe that the effect of vertical migration in zooplankton and the choice of sampling the subsurface water using qualitative method only could have accounted for the low zooplankton species abundance and species composition.

The application of canonical correspondence analysis in data analysis (*Fig. 7*) has been used as clarification method to establish any relationships or associations between biota and environmental variables in recent ecological studies (Lengendr and Lengendr, 1998; Yang et al., 2014 and Uwagbae et al., 2017). The positive association between BOD, DO and members of the rotifer group suggests that they have affinity for environment rich in dissolved oxygen as well as requiring low biological oxygen demand for decomposition activity. This finding was not farfetched from the observation in the Asarama estuary as there were a lot of decomposing woods and leaf litter, and dead mollusc shells in the river bed. The positive relationship that was observed between DO, BOD and rotifers was truly reflected at station 5 of *Tables 1* and *2* in which case, DO and BOD had higher mean concentrations. In addition, environmental perturbation was lesser at station 5 except for dead nipa palm trees remains. Meanwhile, the negative association or correlation between harpacticoida species with several environmental factors such as salinity, EC, nutrient and pH; foretell that they may be more tolerant to waters of very low salinity and electrical conductivity with moderate nutrient such as in inland waters. Conversely, it also suggested that total hydrocarbon content affected abundance of the already mentioned taxa. This is evident and further explains the phenomenon of the low species abundance at station 4 in particular. The same negative correlated relationship was observed for pH and rotifers, implying that they perhaps prefer habitats with non-acidic pH condition (i.e. between 6.8 and 8.2) which is contrary to our finding. Equally, at station 4, CCA proved that

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1027710292

cyclopoida-zooplankton were negatively influenced by water temperature, which is attributed to the total effect of direct sun heating of the littoral zone and the due to the absence of floral community that plays temperature regulation role by providing canopy effect as well as due to the presence of soot and petroleum slick on the water surface. The combination of these environmental factors can greatly influence the abundance, diversity and community structure of biota in any give aquatic ecosystem. The work by Lancelot and Muylaert (2011) satisfactorily explains the relationships between light, temperature and turbidity in shallow estuaries which supports our finding on the negative correlation between zooplankton and water temperature in the study area. However, it could also be attributed to the phenomena of tidal action still in shallow estuaries.

Conclusion

We conclude that the species diversity and composition for zooplankton was very low when compared with the result of the phytoplankton diversity in this study. The low zooplankton composition and diversity may be attributed to the phenomenon of vertical migration in shallow water coupled with the choice of sampling which was strictly restricted to the subsurface water considering the effect of sun rays on the shallow water in terms of increasing productivity.

However, the abundance of phytoplankton and diversity is attributed to the high effect of sun light and nutrient enrichment of the shallow estuary. Nevertheless, the indiscriminate human activities such as the unregulated transportation of goods and services, shipment of petroleum fractions from an illegal local refinery at upstream (though, they have relocated their activities as at early 2017) via wooden boats including bivalve mariculture, tend to pose danger to the biodiversity sustainability, and the environmental quality. Though this study is preliminary, we advocate that a major funded survey on the biodiversity of Asarama estuary should be carried out particularly on the influence of environmental factors on the fauna and flora organisms with a broadened scope. Besides, a comprehensive study on the physicochemical oceanography of Asarama estuary is of paramount importance amidst the rapid developments in the Niger Delta of Nigeria.

It is also very important to have a formal environmental legislature in place that seeks to protect the estuary and its kinds in the region, which allows its sustainable use of the resources amongst the locals. This way, the indiscriminate human impact on the environment would be greatly reduced sustainably.

Acknowledgements. We (particularly ARD and MAU) are very thankful to Duke University and Oak Foundation of the United States for the award of Duke University Marine Laboratory mini grant for marine conservation project, which greatly supported this work. We are grateful to the following persons: Obediah Owoh (Asarama community liaison officer and local curator), Godswill Amos (boat coxswain), Ikechuckwu Odoemenam (local diver) and Hakeem Okunola (taxi driver) for their various assistance during this project. We equally extend our thanks to Mr Isaac Adewole, a research fellow of the department of Animal and Environmental Biology, University of Benin, Benin for assisting in the laboratory work.

Abstract. In the current study there were 6 treatment of all combinations of two propagation methods (chipping and twin-scaling), two propagating bulb storage temperatures (pre-cooling and no pre-cooling), two hot-water treatments (hwt and no hwt). Treatments were applied to measure the effects on the propagation of *Narcissus tazetta* cv. "Ziva" bulbs. The major effects were those of propagation methods and pre-propagating bulb storage temperatures. Chipping, pre-cooling and hwt consistently affected the bulblet formation in both seasons and bulblet weight per chip in the first season only but had no effect on number of bulblets. Chipping method increased all parameters (bulblet formation, weight and circumference of bulblet and number of bulblets per chip, number and length of leaves and roots per-chip). However, chipping resulted in lager, but fewer bulblets than twin-scaling. Pre-cooling increased bulblet formation and both weight and circumference of bulblet in the first season only but reduced number and length of leaves and roots in the second one only. Hot-water treatment increased bulblet formation in both seasons but reduced number and length of leaves and roots in the first season only.
Keywords: *Narcissus, chipping, twin-scaling, bulblet, hot-water treatments, bulb storage temperature*

Introduction

Narcissus, a genus of the Amaryllidaceae family, consisting of about 62 species, classified into 12 sections (Kington1989). These bulbs are well known garden perennial, cut flowers, and can also be used as flowering potted plant. In addition to its horticultural values, the genus *Narcissus* provides numerous alkaloids, some of which exhibit pharmaceutical importance (Bastida et al., 2011). The natural vegetative propagation rate of narcissus under field conditions is very slow, with the mother bulb produce few daughter bulbs, approximately 1.6 bulbs per year (Rees, 1972, 1992). In vitro propagation through tissue culture has been successfully used for narcissus (Malik and Bach, 2017). However, compared to chipping and twin-scaling, in vitro propagation is costly. Chipping and twin-scaling are two of conventional propagation techniques for rapidly propagating narcissus bulbs, enabling an increase from 1 to 1000 in 5–6.5 years instead of 15–25 years (Hanks, 1993). In chipping, bulbs are divided into 8 or 16 longitudinal segments depending on bulb size, but these are not subdivided further (Andrade-Rodringuez et al., 2015; Kharrazi et al., 2107), while in twin-scaling are further divided by removing scale pieces in pairs by cutting through the attached basal plate. In this technique bulb is cut into 50 to 100 twin-scales, depending on its size (Hanks, 1993; Zahng et al., 2013). Pretreatment of bulbs may profoundly affect the bulblets production from chipping and twin-scaling. Studies found in literature have reported the successful use of hot-water treatment before narcissus bulb cutting to increase bulblet yields, and control bulb mite

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1029310301

(Hanks, 1993). However, bulb storage temperature, has been reported to increase (0–10 weeks at 5–30 °C; Hanks et al., 1986) or decrease (5 days at 35 °C; Rees and Hanks, 1984) bulblets production, to be without effect (5 weeks 9 °C; Hanks and Rees, 1978). This study aimed to investigate chipping and twin-scaling techniques and to determine the effect of bulb storage temperature and hot-water treatment on propagation of *Narcissus tazetta* to achieve a high yield of bulblets.

Materials and methods

Bulbs of paperwhite *Narcissus tazetta* cv. "Ziva" were obtained from a commercial source Sperli- GmbH. In an experiment there were 8 treatments, consisting of all combinations of two hot water treatments (hwt and non-hwt) two pre-cutting storage temperatures (pre-cooled and non-pre-cooled bulbs) and two methods for propagation (chipping and twin-scaling). On July 1st, 2014/2015 and 2015/2016 bulb were graded, single-nosed, round bulbs 12–14 cm in circumference were selected, cleaned and divided into two groups of 48 bulbs each. In the first group the bulbs were given a hot water treatment (hwt) at 43.5 °C for 3h, with 1.5% (v/v) formalin, while in the second one they were soaked in a tap-water with 1.5% (v/v) formalin (non-hwt). After drying, the bulbs were stored at ambient temperature (27 ± 3 and 20 ± 3 °C day/night, RH 67–70%) until 6 weeks, prior to bulbs cutting time. Both groups were further divided into two subgroups of 24 bulbs each, the first subgroup was moved to a controlled chamber at a constant temperature of 9 °C, RH 65–70% (pre-cooled bulbs), while the second one was left in the same ambient temperature (non-cooled bulbs) as described above until the start of the bulbs cutting treatments. On October 3rd in both seasons, half of the bulbs of each group were propagated by chipping technique, while the other half was propagated by twin-scaling. Finally, each experiment included 12 bulbs (3 replication × 4 bulbs).

Methods of bulb cutting

After removing the outer brown tunicated scales, and outer crust of basel plate, the top of bulbs was cut off for about 2.5 cm. For chipping, bulbs were longitudinally cut into eight equal sized segments. For twin-scale cuttings, segments of each bulb were divided into pairs of scales (twin-scales) by cutting through the basal plate, however the outer papery scales and the very small ones were discarded (stored to reject any outside the range 0.8–1.0 g) hence each segment gave about 4 twin-scales (Hanks, 1985). Both chips and twin-scales were dipped in a fungicide solution with 1% captan plus 0.4% benomyl (benlate) for 30 min. After dipping and draining, either 12 chips or 16 twin-scales were placed in thin polyethylene bags (20 × 30 cm) filled with 500 ml sterile *vermiculite* previously mixed with 40 ml sterile distilled water and sealed by ensuring air space at top. The bags were incubated in single layer in the dark at 20–22 °C and relative humidity of 70–80%. After 15 weeks of incubation, the bulblet formation calculated as the percentage of chips and twin-scales with visible bulblet, number of bulblets per chip and twin-scale, number and length (the longest, cm) of leaves and roots and circumference (cm) and weight (g) of each bulblet were determined. The experimental design was factorial in a complete randomized with three replicates. The data were subjected to statistical analysis and means were compared according to Duncan's multiple range test (Snedecor and Cochran, 1980).

The following is an explanation of the shape of the cutting methods used:

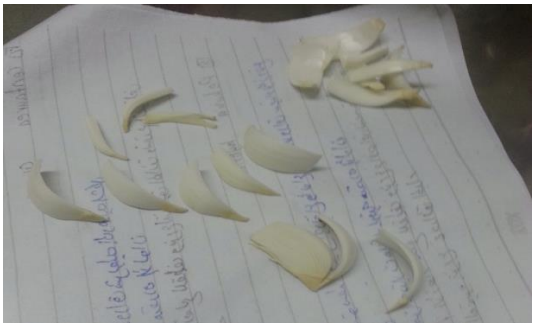
Chipping



Twin-scaling

Chips and twin-scales were dipped in a fungicide solution with 1% captan +0.4% benomyl (benlate) for 30 min

Thin polyethylene bags (20 x 30 cm) filled with 500 ml sterile *vermiculite* previously mixed with 40 ml sterile distilled water and sealed by ensuring air space at top

Results

Bulblet formation

Data presented in *Table 1* reveal that there were significant effect of propagation methods (chipping or twin-scaling), pre-propagating storage temperature (pre-cooled or non-pre-cooled bulbs) and hot-water treatment (bulb given hot-water treatment (hwt) or non hwt) on the percentage of bulblet formation. In comparison with the alternative treatments, chipping, pre-cooling, hwt increased bulblet formation in both seasons. The interaction between cutting methods, bulb storage temperature and hwt also

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1029310301

significantly affected bulblet formation in the second season only (*Fig. 1*). In this interaction, the bulblet formation of the chips was in 100% irrespective of the pre-propagating storage temperature or whether not hot-water treatment was performed. In twin-scales, the highest bulblet formation (96.67%) was obtained in bulbs given pre-cooling, hwt.

Table 1. *The effects of cutting methods (C.M), hot-water treatments (hwt), bulb storage temperature (S), and their combination on bulblet formation (%), circumference (cm) and fresh weight (FW) of bulblet (g), number of bulblets per propagules (No.), number and length (L, cm) of leaves and roots in the first and second seasons*

The fresh weight, circumference and number of bulblets:

Chipping method significantly increased fresh weight, circumference and number of bulblets in both seasons *Table 1*, while pre-cooling increased both fresh weight and circumference of bulblet in the first season only. However, hot-water treatment had no effect. In the first season the interaction revealed that, chipping method, pre-cooled bulbs produced a heavier maximum weight and circumference of bulblet than twin-scaling method, non-cooled bulbs (*Figs. 2* and *3*). However, chipping method, hwt produced a wider maximum circumference of bulblet than twin-scaling, hwt. There were also significant effects of cutting method, pre-propagating storage temperature and hwt on fresh weight of bulblet in the first season (*Fig. 2*). Chipping, pre-cooling and hwt produced bulblets that were heavier than those of twin-scaling, pre-cooling and hwt. There were non-significant effects of pre-cooling, hwt and all combinations on bulblet numbers per both chip and twin-scale in both seasons.

Number and length of leaves and roots per bulblet:

Data presented in *Table 1* show that, chipping method significantly increased number and length of leaves and roots in both seasons, while pre-cooling treatment in the second season and hwt in the first one significantly decreased both number and length of leaves and roots. However, the interaction revealed that pre-cooling resulted the shortest leaves in both the chipping and twin-scaling methods in the second season only (*Fig. 4*). However, hot-water treatment resulted the shortest roots per bulblet on the chipping method in the first season only (*Fig. 5*). In cooling-stored bulbs, number of leaves and length of roots, were declined with hot-water treatment in first season (*Figs. 4* and *5*).

Discussion

Chipping method consistently affected the bulblet formation and gave greater bulblet weight, circumference and number of bulblets per propagule. The advantage of propagation by the chipping method are simpler and rapid multiplication that produces large quantities of good quality bulb with a relatively short period, but it is less productive (Hanks, 1993). As known, chips had more scales and wider basal plate than twin-scales, suggesting that a higher content of nutrients was stored in the chips. However, the variation in bulblet formation, weight and circumference of bulblet and number and length of leaves and roots observed in *Table 1*, may be a result of variation in amount of food reserve (Hanks, 1985; Chen and Ziv, 2005; Zahng et al., 2013). The obtained results are similarly to the findings of Roxas et al. (2000) who reported that bulblet formation from cutting mother bulbs of *Lycoris* species into $^1/_4$ and $^1/_8$ sections (chips) was higher than that from $^1/_{16}$ sections. Thus, as pointed out by Seyidoglu and Zencirkiran (2008), Fenlon et al. (1990), Kharrazi et al. (2017) and Zhu et al. (2005) in several Amaryllidaceae species, a linear relationship between bulblet weight per chip and initial chip weight, based on parent bulb weight (which would reflect chip weight) and number of chips per bulb (cutting rate). Some species require a cold treatment for subsequent initiation and development of bulblet primordia and for rapid, synchronous growth (Khodorova and Boitel-Conti, 2013). The effect of previous bulb storage temperature on the performance of chips and twin-scales propagation was reported in earlier studies on *Narcissus*. Rees and Hanks (1984) found that pre-chipping storage temperature (5 days at 35 °C) reduced bulblet formation, whereas pre-cooling (5 weeks at 9 °C) alone or after a warm storage did not affected bulblets formation. Hanks et al. (1986) showed that pre-twin-scaling storage temperature (0–10 weeks at a range of 5–30 °C) produced bulblets in all cases, while the greatest bulblet formation was produced in bulbs stored at 15 and 30 °C for 6–7 weeks. Chen and Ziv (2005) reported that, in vitro, the twin-scales isolated from the *Narcissus tazetta* "Ziva" bulbs after 12 weeks in storage at 30 °C and a 6 weeks cold treatment at 15 °C produced high number of uniform adventitious buds and were able to regeneration on the semi-solid medium. They observed also that, higher starch levels were found to correlate to higher regeneration potentials in twin-scales. Our experiments show that, twin-scales required a cold treatment to induce bulblets formation more than those with chips. However, 86 and 100% (in both seasons, respectively) of chips produced bulblets, while bulblet formation for twin-scales did not reach 100% in any treatment, but 84.51 and 96.59% of twin-scales produced bulblets in pre-cooling treatment. Hot-water treatment is the established method for controlling nematodes and bulb scale mite in *Narcissus* planting stocks (Hanks, 1991, 1993). The effectiveness of hwt may vary depending on pre-hwt storage temperature and date of application. However, pre-hwt storage temperatures around 30 °C are used for preventing damage, lower temperatures are also effective if used for longer durations (Hanks, 1991). Vreeburg and van der Weijden (1987) stated that bulblet yields was greatest in bulbs given hwt (2 h at 43.5 °C) with formaldehyde before chipping with 5 days. In the study, bulblet formation was significantly greater due to either hwt or to pre-cooling and hwt interaction in both seasons, while there were insignificant differences in fresh weight and circumference of bulblet. Although, for Horticultural application or production purposes, twin-scaling method is used for propagation because of its potentially greater multiplication rates.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1029310301

Conclusion

The current study showed that in chipping technique the segments produce larger but fewer bulblets per bulb than those produce by twin-scaling and may reach flowering size more quickly. However, hot-water treatment, pre-cooling of bulbs before twin-scaling improved bulblet formation and yields. Although relatively labor-intensive, twin-scaling dose have an important role to play in bulking-up schemes, because of its potentially greater multiplication rate. On the other hand, in chipping method, size of parent bulb and number of chips per bulb must be taken into consideration.

(Received 12th Feb 2019; accepted 12th Jul 2019)

Abstract. The study aims to analyze the impact of urbanization and urban income on carbon emission, in the case of China. Panel data estimations use the data from 30 Chinese provinces from 1998 to 2016. Empirical result of urbanization confirms significant and positive coefficient, whereas, urban income has a negative coefficient. This illustrates that higher urbanization trend escalates the carbon emission, while this urban-based carbon emission can be controlled by increasing the per capita income of the urban population. Moreover, economic growth, industrialization, coal, and oil consumption are responsible for carbon emission, as reported by the significant and positive coefficients. The findings of the regional analysis are in line with the full sample results. Based on the results, the study provides practical implications for policy makers to curtail the environmental degradation process.
Keywords: *economic growth, industrialization, coal consumption, oil consumption, GMM*

Introduction

There are a number of challenges that are to be faced by the developing countries with the higher pace of economic growth such as, urbanization and greenhouse gas emission. The increase in urbanization leads to a higher demand for fossil fuels which ultimately results in higher carbon emission (Kumar and Madlener, 2016), but the contribution mechanism of urbanization in carbon emission varies due to underlying factors, such as economic condition, dependence on fossil fuels, industrialization, energy consumption etc. However, it is required to analyze the role of urbanization in carbon emissions for China, specifically. Furthermore, it is also important to study the factors that are helpful to control the urban based carbon emission.

A number of studies have been made in order to analyze relationship of urbanization and carbon emission (Parikh and Shukla, 1995; York, 2007; Kasman and Duman, 2015; Sun et al., 2016; Shahbaz et al., 2016; He et al., 2017; Ding and Li, 2017; Khoshnevis et al., 2018; Dai et al., 2018), the results have confirmed the role of urbanization in carbon emission. Several types of research have documented a positive relationship between urbanization and carbon emission (Parshall et al., 2010; Zhang and Lin, 2012; Fang et al., 2015; Hao et al., 2016; He et al., 2017; Ding and Li, 2017). On contrary, a number of researches have put forward the statement that the urbanization can be a reason for the decrease in carbon emission (Liddle, 2004; Mishra et al., 2009). Moreover, Martínez-Zarzoso and Maruotti (2011) confirmed a U-shaped association between urbanization and carbon emission.

Moreover, Xu and Lin (2015) have worked upon the effects of urbanization and industrialization on carbon emissions in China over the period of 1990-2011. The

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1030310311

regression estimations have reported U-shaped relationship. Likewise, a large number of studies has analyzed the relationship of urbanization and carbon emissions in accordance with Environmental Kuznets Curve (EKC). The study concluded that urbanization is in the favor of environmental development only if the economic development reached at a specific level (Martínez-Zarzoso and Maruotti, 2011; Hao and Peng, 2017; Yao et al., 2018). Recently, Chikaraishi et al. (2015) analyzed different factors that are responsible for urban-based carbon emission. For instance, the country's per capita gross domestic product and the ratio of service industries are one of the most important factors that influence the relationship between the urbanization and carbon emissions. Beside this, there are various factors that affect carbon emissions (such as, technological progress, energy consumption structure, economic development, and industrial structure (Jiang and Lin, 2012; Shahbaz et al., 2016; Waheed et al., 2018; Song and Wang, 2018).

Alkhathlan and Javid (2015) reported a non- linear trend between carbon emission and economic growth of Saudi Arabia, the reason for the positive relationship is the dependence on oil for energy, transportation and industrial activities. Kumar and Madlener (2016) confirmed that higher economic growth is among the major causes of carbon emission in India. Adewuyi and Awodumi (2017) reported that oil consumption and energy consumption have a significant impact on economic growth which further boosts the carbon emission. Previous studies have affirmed that industrialization is also a source of carbon emission (Sadorsky, 2013; Yuan et al., 2014; Lin et al., 2015; Zhu et al., 2017; Ding and Li, 2017; Liu and Bae, 2018).

In addition, the role of coal and oil consumption is considered as the main contributor to carbon emission in China (IPCC, 2014). As China is among the fastest growing economy as well as the biggest carbon emitter of the world (WDI, World Development Indicator, 2017); that is responsible for the around 30% of global carbon emission. According to the Information Energy Administration (2014), China is the second largest oil consumer in the world, the oil consumption of China 11.96 million bpd in 2015. Hence, on one side, the oil is important for economic growth, but, on the other side, the oil consumption has an adverse impact on the environment. The oil consumption, in form of industrial process, transportation, energy generation etc., is one of the main contributors of carbon emission. According to a recent statistics, the demand for oil will increase in the next few decades (Cook and Cherney, 2017). Coal is the main element of energy generation in China which contains around 65% of total energy mix (China Electric Council, 2016).

Previously, the studies have investigated the impact of economic growth, urbanization, industrialization, coal and oil consumption in carbon emission. However, after identifying the role of economic growth, urbanization, industrialization in carbon emission, current paper contributes to the existing literature through analyses the role of urban income to control the carbon emission, which is missed by the previous researches.

The current study has following objectives: the study analyzes the role of urbanization in carbon emission. Furthermore, the role of urban income to control the urban-based carbon emission is another objective. The main contribution of given study is to examine the role of annual average urban income to control the urban based carbon emission. It is known that the higher urbanization tends to boost the carbon emission by different channels: (i) forest need to cut down to extend the urban lands which causes to increase the carbon emission; (ii) higher urbanization triggers the industrialization,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1030310311

transportation and energy consumption etc. which are the major carbon emitters (Shahbaz et al., 2016; Ding and Li, 2017)[1]. In concise, higher urbanization directly or indirectly boost the carbon emission. On the other side, the urbanization trend is increasing since few decades and it will be higher in upcoming decades, as mentioned in *Figure 1*. However, it is required to explore the counter measures that support to reduce carbon emission that is caused by urbanization. On this basis, this study assumes that higher urban income enables the urban population to invest in eco-friendly products that require less energy (e.g. advanced energy efficient home appliances, hybrid or electricity vehicles etc.) that assist to control the environmental degradation process. However, it is clear that urbanization increases the rate of carbon emission as well as it can also contribute to the green technology and its innovation (Martínez-Zarzoso and Maruotti, 2011). Finally, the regional based analysis is used to examine the carbon contributors and the role of higher urban income to mitigate the carbon emission. The findings can assist the policy maker to define the environmental policies to control the carbon emission.

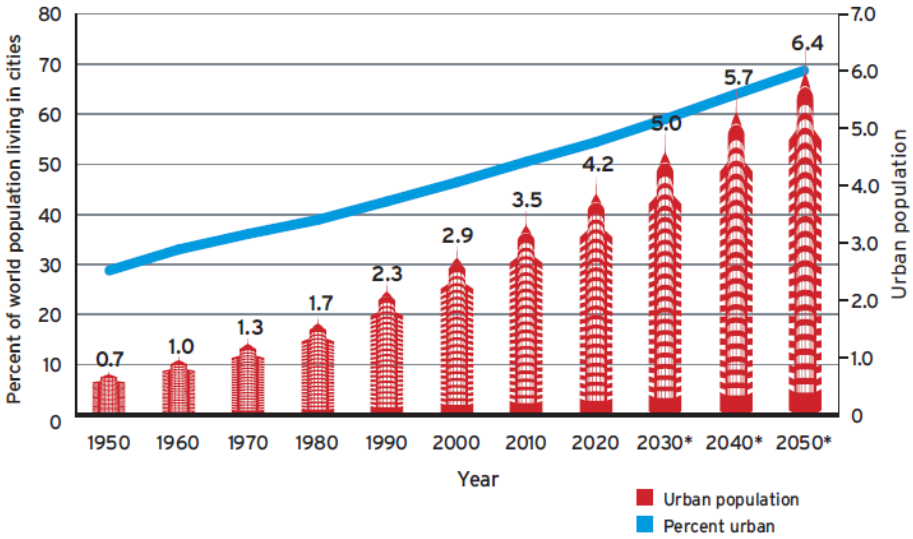

Figure 1. *Urbanization population and percentage of world population living in urban areas. (Source: UN, Department of Economic & Social Affairs, Population Division)*

Materials and methods

Current study investigates the urbanization, urban income, economic growth, industrialization, coal consumption and oil consumption on carbon emission. For empirical estimations, panel data of 30 Chinese provinces are collected over the period 1998 to 2016. Mainly, the paper concerns the role of urbanization on carbon emission and the corrective measures to reduce the urbanization based carbon emission in China. The bulk literature has confirmed the adverse effect of urbanization on carbon emission;

[1]Industrialization requires higher energy for operational activities that contribute in carbon emission, similarly, the waste of industries is also a source of carbon emission. The higher urbanization trend stimulates the buying of cars and the use of other transportation mean (Zhang, 2014), which use the fossil fuels and in turn increase the carbon level. Similarly, the urbanization increases the electricity consumption by city authorities for street lights, electricity sign boards and households (Shahbaz et al., 2016).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1030310311

higher urbanization leads to increase the carbon emission (York, 2007; Wang et al., 2016; Kasman and Duman, 2015; Shahbaz et al., 2016; He et al., 2017; Zhu et al., 2017; Yao et al., 2018). This adverse relationship can be due to multiple reasons: firstly, there is a need to cut down the forests to increase the urban land which reduces the carbon balance. Secondly, higher urbanization requires the higher energy to meet the electricity demands, for transportation etc., however, this higher energy consumption causes to boost the carbon emission. It is necessary to find practicable solutions to control the urban based carbon emission. In light of this, we propose that the government should increase the per capita income of urban people and motivate them to buy energy efficient and environmental friendly products. In such domain, we use two assumptions: firstly, the industries are producing green and energy efficient equipment for industrial and household uses. Secondly, the urban population are motivated to purchase latest green technology household items; meaning that higher per capital income enables them to have environmental friendly items. The general form of studied model is given below:

$$CO_2 = f(U, UI, EG, I, C, O)$$

The log form of model is below:

$$\ln CO_{2\,it} = \beta_0 + \beta_1 CO_{2\,i,t-1} + \beta_2 U_{it} + \beta_3 UI_{it} + \beta_4 EG_{it} + \beta_5 I_{it} + \beta_6 C_{it} + \beta_7 O_{it} + \varepsilon_{it}$$

where $CO_{2\,it}$ and $CO_{2\,i,t-1}$ is current carbon emission and lagged carbon emission in million tons (Mt), respectively, which is calculated by using energy consumption based methodology. Energy consumption based carbon emission follows Intergovernmental Panel on Climate Change (IPCC, 2006). U_{it} is the urbanization (10,000 people) and UI_{it} is the proxy of urban income which measured as per capita income in Yuan. EG_{it} is the economic growth measured as gross regional product for each province (100 million Yuan). I_{it} represents the industrialization measured in 100 million Yuan. C_{it} and O_{it} presents the coal consumption and oil consumption (10,000 tons).

Difference-GMM, system-GMM and dynamic mean group (DMG) are employed for econometric estimations. We emphasize on panel data estimations due to following reasons: firstly, it assists to control the heterogeneity issues; secondly, is deals with the increase in degree of freedom. Thirdly, it is useful to control the multicollinearity issues.

Results and discussion

Table 1 reports the empirical estimations of difference-GMM, system-GMM and dynamic mean group (DMG). The findings of difference-GMM confirm the significant and positive coefficients of lagged carbon emission, urbanization, economic growth industrialization, coal, and oil consumption. These findings imply that higher urbanization trend, economic and industrialization activities, coal and oil consumption in different economic sectors are the main culprits of environmental degradation in China. On contrary, the coefficient of urban income has reported statistically significant and negative coefficient, which validates our hypothesis that higher urban income causes to reduce the carbon emission. The reason for this relationship is that the higher

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1030310311

urbanization leads to the advance and green technology innovation (Mishra et al., 2009; Martínez-Zarzoso and Maruotti, 2011). However, the increase in urban income raises the chances that urban population buys advanced green technologies that are useful to control the carbon emission from urbanization.

CO_2 is lagged carbon emission, U represents the urbanization and UI is the urban income. EG mentions the economic growth, whereas, I is the industrialization. And C and U are the coal and oil consumption, respectively

System-GMM has reported similar results; the positive relationship of lagged carbon emission, urbanization, economic growth, industrialization, coal consumption and oil consumption (there is a slight difference; the coefficients of industrialization and oil consumption are statistically significant at 5% level). The coefficient of urban income is statistically significant and negative, at 1% level, which illustrates that higher carbon emission can be managed by increasing the urban income. The estimations of the dynamic mean group present the positive coefficient of urbanization, economic growth, coal consumption and oil consumption, whereas, industrialization turns out to be insignificant. The coefficient of urban income is still significant and negative.

Regional analysis

Empirical results of the regional analysis provide more insight that is useful for environmental policymakers, as the factors of carbon emission vary across different economic and geographical basis. The Chinese provinces are divided into six geographical regions to estimate the regional analysis. In *Table 2,* the coefficient of urbanization has reported significant and positive coefficients in five out of six regions, Southwest region reports insignificant coefficient. These significance and positive coefficients of urbanization exhibit that higher urbanization movement induces the carbon emission in most of the Chinese provinces. In case of urban income, the results are statistically significant and negative in five out of six provinces. The results confirm the role of urban income in carbon mitigation in most of the regions, however, it is suggested that urban-based carbon emission can be managed by increasing the per capita income of urban population. Moreover, motivate the urban population to have eco-friendly home appliances and vehicles.

Economic growth is a source of carbon emission in all six regions of China, as mentioned by the positive coefficients. The coefficients of industrialization are significant and positive in four out of six regions (North, Northeast, East and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1030310311

Southcentral), whereas, insignificant in two regions (Southwest and Northwest). It is not hard to conclude that industry is also responsible for higher carbon emission in China. Estimated results of coal and oil consumption mentioned statistically significant and positive coefficients in all six regions, which indicate that fossil fuels are among the main sources of carbon emission. As China is a developing economy that requires fossil fuels (coal and oil) for industrial process, transportation, electricity generation etc., however, it is quite difficult for China to suddenly replace the fossil fuels with renewable energy.

***, ** represents the significance level of 1% and 5%, respectively

Conclusion

There are two main objectives of given study: firstly, investigate the role of urbanization in carbon emission; secondly, examines the role of the urban income in carbon mitigation. The data from 30 Chinese provinces are used for empirical estimations that cover the time period of 1998-2016. Estimated findings have validated that higher urbanization causes the environmental degradation in China. In case of urban income, the coefficients present significant and negative results, which affirm our hypothesis that higher urban income likely to reduce the carbon emission by changing the buying behavior of urban population. The increase in income enables the urban population to have advance and green technology that uses less energy and have lesser emission than conventional technologies. The findings of economic growth, industrialization, coal and oil consumption are responsible for carbon emission in China. Similar findings are confirmed by regional based analysis; the higher per capita urban income assists to control the role of urbanization in carbon emission.

On the basis of above results, the study proposes significant policy implications that are useful to control the environmental degradation process. The study examines, the urban and central authorities should increase the urban income and motivate the urban population to acquire green technologies. The studies proposed that the government should impose the carbon tax on industries that force them to install carbon treatment plants. Lastly, the Chinese government needs to replace the non-renewable source of energy (coal and oil) to renewable energy (e.g. water, solar, wind, biomass etc.).

The authors have faced some limitations during the data collection and assigning the proxies; such as, the data before 1998 is missing in China statistical database which forces to limit the time series. For future studies, the authors can gather the previous

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1030310311

data by using some other available sources, to examine the robustness of results. Another limitation of current study is the base of two assumptions; firstly, the industries have to produce green and energy efficient equipment for industrial and household uses. Secondly, the urban population are motivated to purchase latest green technology household items; proposing that higher per capital income enables them to have environmental friendly items. However, for future direction, there is a strong need to find some alternate proxies to examine the role of urban income.

Abstract. To solve the problem of dust pollution caused by bench blasting in open-pit mines and to solve the current situation of blasting dust control efficiency in most open-pit mines, the blasting dust removal mechanism and migration law were studied in this paper. In this paper, taking the bench blasting in Fushun China open-pit mines as an example, a real-time simulation of blasting dust pollution in open-pit mines was conducted through the numerical simulation by Fluent software and field test using the theories of gas-solid two-phase flow and explosion mechanics. The results showed that in the stage of impact movement and mushroom cloud formation, the explosive gas produced by blasting expanded rapidly, and a large amount of dust rushed into the atmospheric space under the effect of blasting impact kinetic energy, and then diffused. The migration velocity of dust was very lowly without wind. The dust with a particle size of 60-100 μm settled slowly, and the dust with a particle size of below 40 μm settled with difficulty due to the strong disturbance by air flow. Based on the law of dust pollution, this paper provides a basis for the design of reasonable parameters of dustproof net and related parameters of remote mist emitter, and provides a theoretical and practical basis for the control of blasting dust in other open pit mines.
Keywords: *blasting dust, dust migration law, numerical simulation, gas-solid two-phase flow, strip mine*

Introduction

With the continuous expansion of production scale of open-pit mines, the problem of blasting dust pollution is becoming more and more serious. Blasting is mainly a process of rapid expansion of explosive gas with huge energy, in which a large amount of dust rushes into the atmospheric space under the effect of blasting impact kinetic energy, and then diffuses. The dust expands rapidly at the beginning of blasting, then gradually slows down, and finally tends to be stable. The dust of large particle size settles slowly, and most of the dust of small particle size diffuses slowly with the explosive gas (Jing et al., 2007; Ghose and Majee, 2001; Yang et al., 1996; Chen et al., 2013).

The local blasting dust concentration reached thousands of milligrams per cubic meter. Therefore, it not only endangers the health of workers, affects the normal operation of nearby production equipment, but also may endanger the health of surrounding residents (Baxter and Smith, 1993). A lot of studies have been done on explosive dust, for example, Jiang (2007) conducted real-time simulation of dust diffusion motion shape based on coal dust particle system, and developed BSMS simulation software. Their research has a lot of advantages, but due to the limitations of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1031310333

computer performance at that time, they failed to simulate the law of blasting dust pollution more visually. On the basis of summarizing the predecessors, in this paper, taking the bench blasting in Fushun China open-pit mines as an example, a reasonable simplification was conducted according to the actual conditions of blasting site, and a corresponding mathematical model was established, and the movement track of dust particles was tracked by Fluent software (Fu and Liu, 2017; Shen et al., 2017; Lenart, 2017), and the simulation results were analyzed, and simple and effective dust control measures were taken, finally, the dust control measures were tested through the numerical simulation and field test of dust (Zhang et al., 2018; Nongqwenga and Modi, 2017; Peng et al., 2018; Wang et al., 2018; Wu, 2016). By analyzing the law of dust pollution, the reasonable proportion of water stemming and solid stemming and the reasonable height of dust screen are calculated.

General situation of blasting dust pollution and determination of basic characteristics of dust in east open pit mine in Fushun, China

Description of the diffusion process of dust

Fushun China East Open-pit Mine is located in the northern temperate zone. It is located in the east longitude 99° north latitude 47°. The pit is 5.7 km long from east to west, 1.9 km wide from north to south, and covers an area of 9.2 km^2. The deep-hole loosening blasting was adopted in 32# station working face, and the blasting parameters are shown in *Table 1*. The blasting pile did not form an obvious blasting funnel in the original place after blasting, and the degree of crushing of blasting body can meet the requirements of subsequent collision transportation, improve working efficiency and service life of equipment.

Through the observation and data analysis on the blasting site of East Open-pit Mine, it was found that in the process of open-pit blasting, the blasting dust rushed into the atmospheric space after leaving the blasting body under the effect of blasting impact kinetic energy (Yang et al., 2018; Zamora Figueroa et al., 2017; Jiang et al., 2017). Dust movement in the atmosphere can be roughly divided into three stages: (1) impact movement stage; (2) mushroom cloud formation stage; (3) diffusion stage. In this stage, the dust particles generated and excited by blasting vary greatly in the movement state. Although it lasted a short time, the dust concentration was high, as the local blasting dust concentration reached thousands of milligrams per cubic meter, as shown in *Figure 1*.

Borehole depth	7-8 m	Burden	4.5 m

Materials and methods for testing the physical properties of dust

(1) Sampling requirements for testing the basic characteristics of dust

1) Sampling site for testing the basic characteristics of dust

a. Determination of dust concentration: the damage of dust to human body is determined by the concentration of free silica. Generally, the suspended dust 1.5 m above the ground (respiratory zone height) was determined;

b. Determination of dust dispersion: the dispersion of dust usually refers to a collection of percentages of particles with different particle sizes. Generally, the dust of different concentrations at different places were collected for many times.

2) The basic characteristics of dust in working face should be tested by taking into account the influence of air humidity, temperature, wind speed and so on. The following points should be considered in selecting the right time to test it:

a. The dust concentration was determined at the same place and the same wind speed.

b. The change value of dust concentration was determined at different times after blasting and the same wind speed.

In the course of testing the basic characteristics of dust, the following test instruments were used: AH-91A Dust Sampler produced in Wuxi (depending on the actual situation); glass fiber filters produced by Sephorlebo (Φ75 mm if the dust concentration was greater than 200 mg/m^3; Φ40 mm if the dust concentration was less than 200 mg/m^3); scales, tweezers, drying boxes, etc.

(2) Detection contents of dust dispersion

To deeply reveal the influence of dust on human body and equipment, and to design a more simple and effective dust removal scheme, we introduced the dispersion test.

1) Detection methods and specific contents

It was mainly detected by quantity and quality dispersion, and the observation method by microscope was most commonly used for the quantity dispersion. The dust sample was made into a standard sheet, tested by a microscope, and the content was calculated, and the dispersion was finally determined. *Equation 1* was used to calculate it:

$$P_{n_i} = (n_i / \sum n_i) \times 100\% \quad \text{(Eq.1)}$$

where: P_{ni}—Particle size dispersion; n_i—The sum of the number of dust particles of specified particle size, pcs; Σn_i—The sum of the number of dust particles of different particle sizes, pcs.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1031310333

Weight dispersion: within a given range, the ratio of the sum of the mass of dust particles contained in each particle size interval to the sum of the mass of total dust particles was usually expressed as a percentage. *Equation 2* was used to calculate it:

$$P_{wi} = \frac{wi}{\sum wi \times 100\%} \quad \text{(Eq.2)}$$

Where: wi—The sum of the mass of dust particles in a certain particle size range; Pwi—The percentage of the mass of dust particles in a certain particle size range, %.

2) Main test instruments

Perchloroethylene fiber filter membrane; butyl acetate solvent; glass slide; microscope; computer microimage processing system; etc.

Determination results of dust

Because of the particularity and danger of determination of dust, it was necessary to use advanced testing instruments and means to test the concentration and dispersion and other important parameters of dust in a comprehensive and systematic way, which provided an important basis for selecting suitable dust control schemes. The test results are shown in *Tables 2* and *3*. Dust particles are irregular in shape and the equivalent diameter of the dust is usually used to describe the size of the dust particles. Dust particles vary and the particle size of dust is in accordance with Rosin-Rammler distribution after experimental analysis. *Figure 2* is drawn from the test dust sampling results, and the median particle size value is the particle diameter $\overline{d}$ = 170 when Y_d = 0.368.

Table 2. *Dust concentration of 32# station working face on the blasting site*

Test number	Test site	Dust concentration mg/m³	Test time	Test condition
1	Station working face on the blasting site	306.7	10	60S after blasting, no wind
2		273.5	10	60S after blasting, no wind

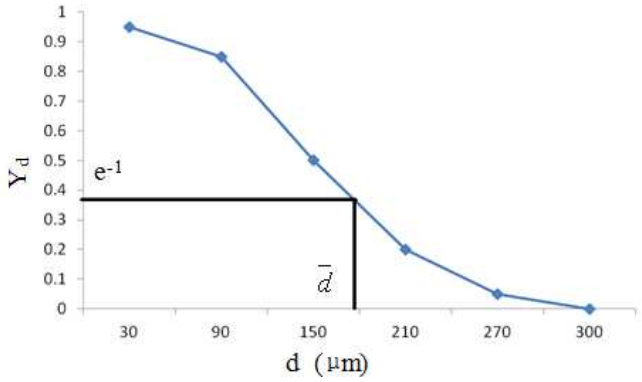

Figure 2. *Size distribution of accumulate particle quality of total dust*

Establishment of mathematical model and determination of parameters

According to the dust migration law, the discrete phase model of Euler-Lagrangian method was used to calculate the effect of turbulent velocity on particle motion by using random orbits.

Mathematical model of continuous phase flow field

(1) Turbulence model

It was generally recognized that the natural air flow was dominated by turbulent motion state, which thus directly affected the diffusion range of dust. It was necessary to briefly introduce the basic characteristics of turbulent motion.

Through a large number of tests, it can be concluded that: if the Reynolds number did not reach the critical value, we defined this flow as laminar flow (orderly flow between the flow layers); if the Reynolds number exceeded the critical value, we defined this flow as turbulence (chaotic and irregular flow of fluid). In the Cartesian coordinate system, the vector of velocity in the three coordinate axes (X-axis, Y-axis, Z-axis) was represented by u, v and w respectively, and the governing *Equations 3* and *4* can be expressed as:

$$div\vec{u} = 0 \tag{Eq.3}$$

$$\begin{cases} \dfrac{\partial u}{\partial t} + div\left(u\vec{u}\right) = -\dfrac{1}{\rho}\dfrac{\partial p}{\partial x} + v\,div\left(gradu\right) \\ \dfrac{\partial v}{\partial t} + div\left(v\vec{u}\right) = -\dfrac{1}{\rho}\dfrac{\partial p}{\partial y} + v\,div\left(gradv\right) \\ \dfrac{\partial w}{\partial t} + div\left(w\vec{u}\right) = -\dfrac{1}{\rho}\dfrac{\partial p}{\partial z} + v\,div\left(gradw\right) \end{cases} \tag{Eq.4}$$

where: grada=$\dfrac{\partial a}{\partial x}+\dfrac{\partial a}{\partial x}+\dfrac{\partial a}{\partial x}$; V—Kinematic viscosity coefficient, m^2/s; p—Pressure on a fluid microelement, pa.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1031310333

The pulsation can be taken into account by using the Reynolds averaging method, that is, the time average of the variable ϕ can be expressed as *Equation 5:*

$$\bar{\phi}=\frac{1}{\Delta t}\int_{t}^{t+\Delta t}\phi(t)dt \tag{Eq.5}$$

where: "–"—Time average; ϕ —Instantaneous value; $\bar{\phi}$ —Time average; ϕ' — Pulsation value. ϕ, $\bar{\phi}$, ϕ' —The three were as *Equation 6:*

$$\phi=\bar{\phi}+\phi' \tag{Eq.6}$$

If the instantaneous value was replaced by the sum of the time average and pulsation value that is following as *Equation 7:*

$$u=\bar{u}+u' \quad v=\bar{v}+v' \quad w=\bar{w}+w' \quad p=\bar{p}+p' \tag{Eq.7}$$

By substituting the *Equation* 7 in the *Equation* 3, *Equation* 4, the following formulas can be obtained:

1) Continuity equation (Almstedt, 2003)

Continuity equation is as *Equation 8*.

$$\frac{\partial}{\partial x_i}(\rho u_i)=0 \tag{Eq.8}$$

where: ρ —Gas density, km/m^3; u_i—Gas velocity vector.

2) Momentum equation (N-S equation)

Momentum equation is as *Equation 9.*

$$\frac{\partial}{\partial x_j}(\rho u_i u_j)=-\frac{\partial}{\partial x_j}\left(\mu\frac{\partial u_i}{\partial x_j}-\rho\overline{u_i'u_j'}\right) \tag{Eq.9}$$

where: xi—Coordinates in the x, y, z direction, m; ui—The velocity of gas in the x, y, z direction, m/s; p—Effective turbulent pressure, Pa; μ—Dynamic viscosity coefficient Pa•s.

(2) Standard k-ε equation model

The standard k-ε equation model was first introduced by Launder and Spalding in the late last century. Up to now, it is also very popular in the field of turbulence simulation. The turbulent dissipation rate ε can be expressed by *Equation 10:*

$$\varepsilon=\frac{\mu}{\rho}\overline{\left(\frac{\partial u_i'}{\partial x_k}\right)\left(\frac{\partial u_i'}{\partial x_k}\right)} \tag{Eq.10}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1031310333

The turbulent viscosity coefficient μ_t was a function of k and ε, that is, *Equation 11:*

$$\mu_t = \rho C_\mu \frac{k^2}{\varepsilon} \quad \text{(Eq.11)}$$

where: ρ— Gas density, kg/m^3; C_μ—Empirical constant; k—Turbulence kinetic energy, m^2/s^2; ε— Turbulent kinetic energy dissipation rate, m^2/s^3.

In the standard k-ε model, k and ε were two fundamental unknown quantities, and the corresponding transport equations were *Equations 12* and *13:*

$$\frac{\partial(\rho\varepsilon u_i)}{\partial x_j} = \frac{\partial}{\partial x_j}\left[\left(\mu + \frac{\mu_t}{\sigma_k}\right)\frac{\partial k}{\partial x_j}\right] + G_k + G_b - \rho\varepsilon - Y_M + S_k \quad \text{(Eq.12)}$$

$$\frac{\partial(\rho\varepsilon u_i)}{\partial x_j} = \frac{\partial}{\partial x_j}\left[\left(\mu + \frac{\mu_t}{\sigma_\varepsilon}\right)\frac{\partial \varepsilon}{\partial x_j}\right] + G_{1\varepsilon}\frac{\varepsilon}{k}\left(G_K + G_{3\varepsilon}G_b\right) - G_{2\varepsilon}\rho\frac{\varepsilon^2}{k} + S_\varepsilon \quad \text{(Eq.13)}$$

where: G_k— he generating term of turbulent kinetic energy caused by average velocity gradient; G_b—Turbulent kinetic energy caused by buoyancy; Y_M—Contribution of pulsation expansion in compressible turbulence; $G_{1\varepsilon}, G_{2\varepsilon}, G_{3\varepsilon}$—Empirical constants; $\sigma_k, \sigma_\varepsilon$—The Prandtl number corresponding to the turbulent kinetic energy k and dissipation rate ε; S_k, S_ε—User-defined source item.

When the fluid was steady-state incompressible, regardless of user-defined source item, G_b=0 , $G_{3\varepsilon}$=0 , Y_M=0 , S_k=0 , S_ε=0 , then the standard k-ε model were *Equations 14* and *15:*

$$\frac{\partial(\rho\varepsilon u_i)}{\partial x_j} = \frac{\partial}{\partial x_j}\left[\left(\mu + \frac{\mu_t}{\sigma_k}\right)\frac{\partial k}{\partial x_j}\right] + G_k - \rho\varepsilon \quad \text{(Eq.14)}$$

$$\frac{\partial(\rho\varepsilon u_i)}{\partial x_j} = \frac{\partial}{\partial x_j}\left[\left(\mu + \frac{\mu_t}{\sigma_\varepsilon}\right)\frac{\partial \varepsilon}{\partial x_j}\right] + G_{1\varepsilon}\frac{\varepsilon}{k}G_k - G_{2\varepsilon}\rho\frac{\varepsilon^2}{k} \quad \text{(Eq.15)}$$

where: $G_k = \mu_t \frac{\partial u_i}{\partial x_j}\left(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i}\right)$.

By deriving from experimental data and theoretical derivation, $G_{1\varepsilon}$ = 1.44, $G_{2\varepsilon}$ = 1.92, σ_k = 1.0, σ_ε = 1.3 were obtained.

The discrete phase model of Euler-Lagrangian method was adopted according to the dust migration law.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1031310333

Mathematical model of discrete phase

According to the force balance on the droplet (particle), the equation of motion of the particle in Lagrangian coordinate system can be obtained (O'Rourke, 1981; Jin, 2010; Guo, 2006; Luo and Shen, 2006) as *Equations 16* and *17:*

$$\frac{du_p}{dt} = F_D(u-u_p) + g_x(\rho_p - \rho)/\rho_p + F_x \quad \text{(Eq.16)}$$

$$F_D = \frac{18\mu}{\rho_p D_p^2}\frac{C_D \mathrm{Re}}{24} \quad \text{(Eq.17)}$$

where: u— Continuous phase velocity, m/s; u_p— Particle velocity, m/s; μ— Molecular viscosity coefficient of the fluid, Pa•s; ρ, ρ_p— The density of the fluid and the particle respectively; kg/m^3; D_p— Particle diameter, m; Re was a relative Reynolds number, which was defined as *Equation 18:*

$$\mathrm{Re} = \frac{\rho D_p |u_p - u|}{\mu} \quad \text{(Eq.18)}$$

The resistance coefficient $C_D = \alpha_1 + \frac{\alpha_2}{\mathrm{Re}} + \frac{\alpha_3}{\mathrm{Re}^2}$, α_1, α_2, α_3 was a constant, which was given according to the experimental results of smooth spherical particles.

The other method for determining C_D was *Equation 19:*

$$C_D = \frac{24}{\mathrm{Re}}(1 + b_1 \mathrm{Re}^{b_2}) + \frac{b_3 \mathrm{Re}}{b_4 + \mathrm{Re}} \quad \text{(Eq.19)}$$

The form factor was defined as $\varphi = s/S$, s was the surface area of the sphere of the same volume as the particle; S was the actual surface area of the particle. Then the above constants were *Equations 20–23:*

$$b_1 = 2.3288 - 6.4581\phi + 2.4486\phi^2 \quad \text{(Eq.20)}$$

$$b_2 = 0.0964 + 0.5565\phi \quad \text{(Eq.21)}$$

$$b_3 = 4.905 - 13.8944\phi + 18.4222\phi^2 - 10.2599\phi^3 \quad \text{(Eq.22)}$$

$$b_4 = 1.4681 + 12.2584\phi - 20.7300\phi^2 + 15.8855\phi^3 \quad \text{(Eq.23)}$$

If the particle size was below micron, the Stokes resistance formula was used as *Equation 24:*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1031310333

$$F_D = \frac{18\mu}{D_p^2 \rho_p C_c} \quad \text{(Eq.24)}$$

where C_c was the Cunningham correction coefficient, as *Equation 25:*

$$C_c = 1 + \frac{2\lambda}{D_p}[1.257 + 0.4e^{\frac{1.1D_p}{2\lambda}}] \quad \text{(Eq.25)}$$

where λ was the mean molecular free path.

Equation of motion of dust particle trajectory

The equation of motion of dust particle trajectory can be solved step by step in discrete time step. The particle velocity at every position on the particle orbit can be obtained by integrating *Equation 26.*

$$\frac{d_x}{dt} = u_p \quad \text{(Eq.26)}$$

By solving the governing equations on each coordinate axis, the discrete phase dust particle trajectory can be obtained.

Establishment of geometric model and generation of meshes

(1) Overview of the establishment of geometric model

To simulate and analyze the practical problems, it was necessary to establish a similar model to approximate the practical engineering problems, so we established a geometric model according to the actual situation of the receiving station.

(2) Division of meshes

The meshes adopted in this paper are shown in *Figure 3.*

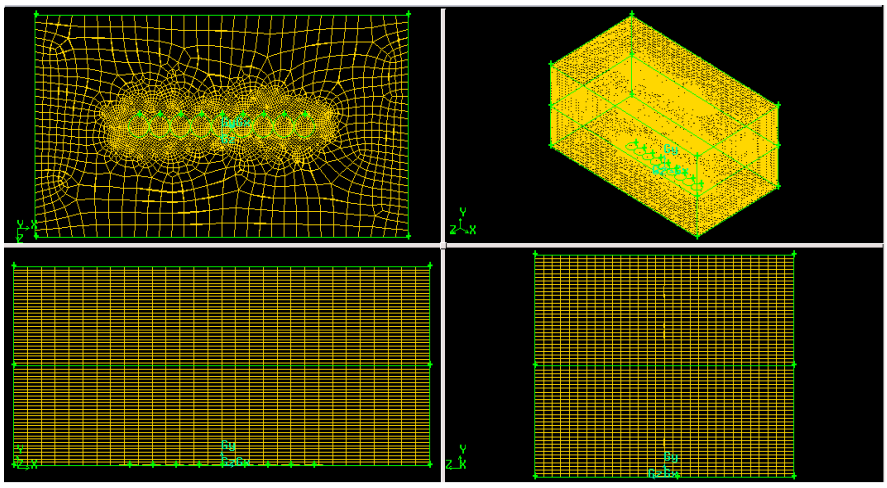

Figure 3. *3D mesh diagrams*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1031310333

Establishment of boundary conditions

(1) Establishment of continuous phase boundary conditions

The boundary conditions, wall boundary conditions, and inlet and outlet boundary conditions involved in the simulation are shown in the *Tables 4* and *5*.

Table 4. *Setting list of model*

Model	Define
Solver	Segregated Implicit Transient
Viscous model	k-ε
Energy	On
Discrete phase model	On

Table 5. *Setting list of operating conditions*

Operating conditions	Setting
Operating pressure (pa)	101325
Gravitational acceleration	X 0 Y 0 Z -9.8
Air density kg/m^3	1.225
Air viscosity Pa•s	0.000018
Dust density kg/m^3	1830
Pressure-velocity	SIMPLEC
Pressure discretization	Standard
Discretization	Second order upwind
Convergence criterion	0.001

(2) Establishment of discrete phase boundary conditions

The assumption of mathematical model of dust movement was that when facing complex dust particles, we need to understand the main characteristics of dust, and we can ignore some subtle characteristics which have little influence on the calculation results, which can not only simplify the calculation, but also show the migration law of dust correctly. Therefore, we made the following assumptions, as shown in *Table 6:*

1) The dust particles were perceived as spheres
2) Initial velocity of dust ejection
3) The interaction between dust particles was neglected
4) The dust ejected steadily instantly

Iterative calculation

The unsteady numerical simulation by Fluent software according to the parameters and boundary conditions given above showed good convergence. The partial residual curve is shown in *Figure 4.*

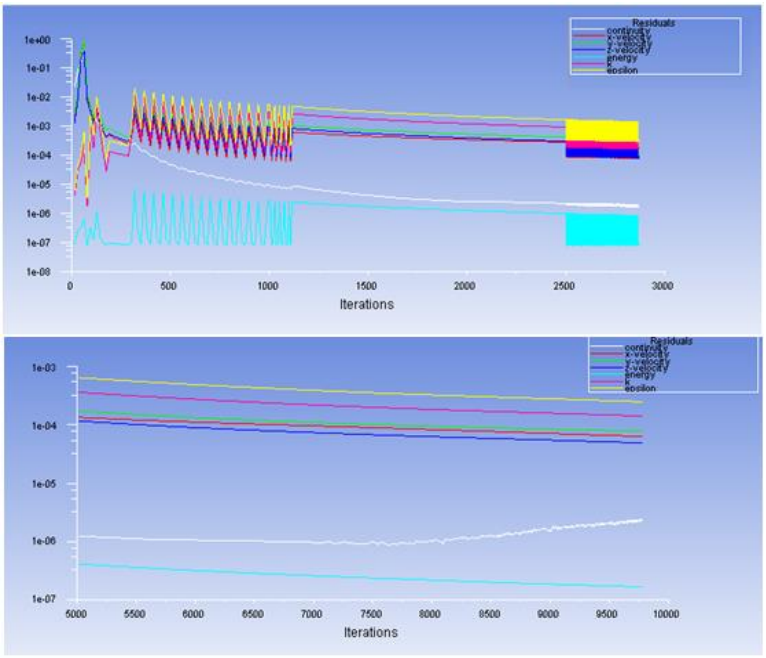

Figure 4. *Partial residual curve diagram*

The analysis and discussion of the numerical simulation results of blasting blowing dust law

To understand the movement state of dust more intuitively, a numerical simulation of the migration law of dust was conducted according to the field situation and relative conditions of blasthole arrangement (as shown in *Figs. 5* and *6*).

Dust particle trajectory diagrams at different times after blasting

The results showed that the change of the shape and migration velocity of dust was complex with the increase of time.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1031310333

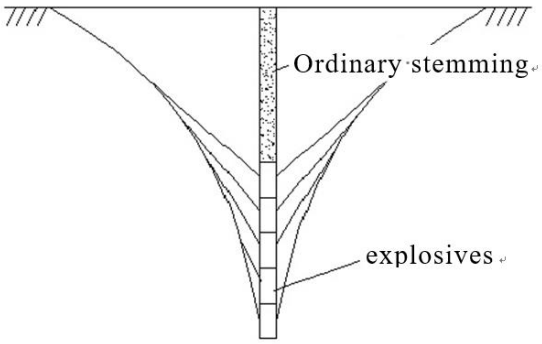

Figure 5. *Deep-hole blasting stress curve diagram*

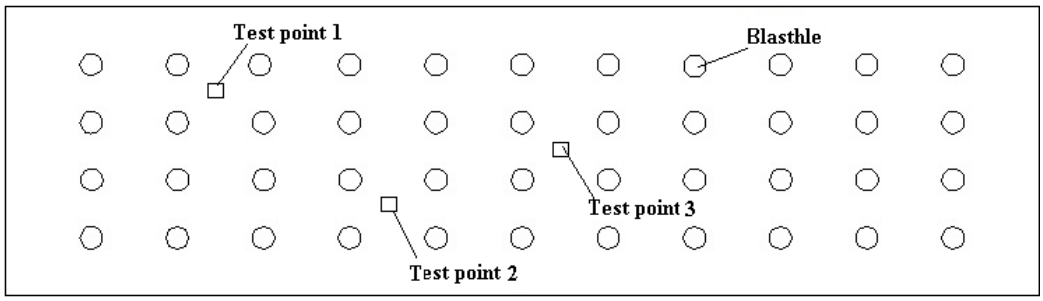

Figure 6. *Blasthole arrangement and test point diagram*

a. At the beginning of blasting, the initial velocity of dust was 50-65 m/s, and the average velocity of dust decreased to 30-40 m/s after the 0.1th second, and to 5-8 m/s after 0.5 s (*Fig. 7*), and to below 3.5 m/s after the 3rd second (*Fig. 8*). In the stage of impact movement of dust, the impact force was strong, the velocity of dust varied greatly. The inertia of dust particles was greater than that of gas phase, and the inertia of dust of large particle size was greater than that of dust of small particle size. Therefore, the front end of blasting dust cloud was dust particles, which moved by inertia.

b. With the increase of time, the velocity of dust decreased gradually under the effect of air resistance, and the average velocity of dust decreased to 1.04-2.78 m/s at the 6th second (*Fig. 9*), and was not obvious after the 6th second (*Fig. 10*), and became stable after this period of time. The heat carried by most of the explosive gases had basically been discharged into the atmosphere. Due to the release of huge blast energy, local pressure difference was produced, and a large amount of air came in because of the pressure difference, which slowly rose and diffused carrying dust.

c. The velocity of dust decreased to 0.6-1 m/s after the 25th second (*Figs. 11* and *12*) and varied slightly. Then, the diffusion stage began, and the range of dust pollution was also determined by this stage.

Dust concentration diagrams at different times after blasting

As can be seen from the dust concentration diagrams, the maximum dust concentration reached thousands of milligrams per cubic meter at the 0.1th second. At the 3rd second (*Fig. 13*), the maximum dust concentration reached 1,660 mg/m^3. The change of dust concentration in the inertial motion stage mainly depended on the change

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1031310333

of the velocity of dust inertial motion (*Fig. 14*). At the 25th second (*Fig. 15*), the maximum dust concentration was 459 mg/m^3, and the average dust concentration was 270 mg/m^3. After 35 s of settlement (*Fig. 16*), the maximum dust concentration was 339 mg/m^3, and the average dust concentration was 170 mg/m^3. At this point, some of the dust of large particle size began to settle, and the change of dust concentration was determined by both the diffusion and settlement velocity of the dust. The change of dust concentration was very slow at later time points (*Fig. 17*).

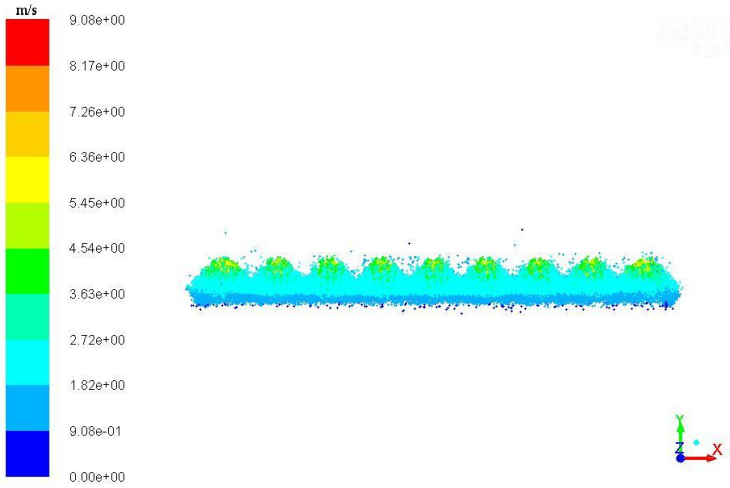

Figure 7. *Dust particle trajectory diagram (0.5 s)*

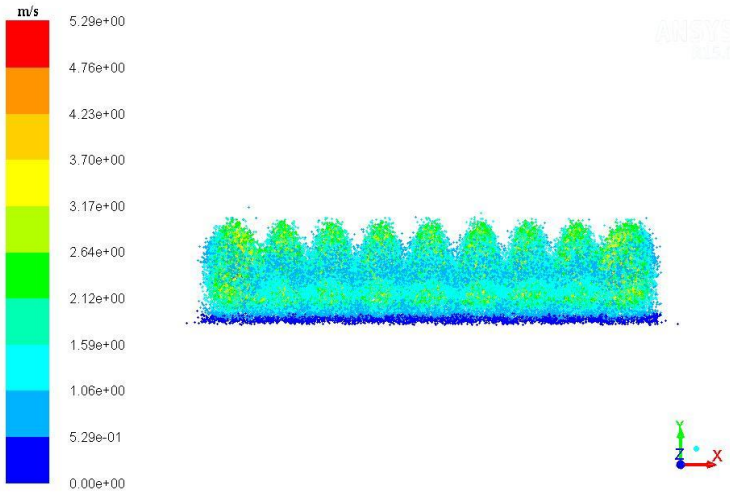

Figure 8. *Dust particle trajectory diagram (3 s)*

Dust particle size distribution diagrams at different heights at the same time after blasting

In the process of numerical simulation of dust, a disk area was established every 5 m in the vertical direction. By capturing the dust particles passing through every plane, the probability distribution diagrams of the discrete amount of average diameter of dust at different vertical heights were obtained. Through the interpolation fitting by tecplot

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1031310333

software, the probability distribution curve diagrams of dust particle size distribution at different heights were obtained. Through the analysis of each curve, it can be seen that at the 6th second (*Fig. 18*), the average diameter of the dust with a particle size of 200-300 μm was about 5-10 m. After the 25th second (*Figs. 19* and *20*), the settling velocity of the dust with a particle size of greater than 250 μm was very fast, and almost all of them had fallen to the ground. With the increase of vertical height of observation plane, the particle size of dust was becoming smaller and smaller, and the dust of large particle size can rapidly settle by its own gravity, but the dust of small particle size can suspend in the air for a long time under natural conditions. Due to the disturbance by air flow and the action of air resistance, the floating effect of the dust of large particle size decreased gradually. Some of the dust of large particle size settled by overcoming the buoyancy by its gravity, and the dust with a particle size of greater than 100 μm began to settle at a fast settling velocity with the increase of settling time. Almost all the dust with a particle size of about 250 μm fell to the ground after about 30 s, the dust with a particle size of 60-100 μm settled slowly, and the dust with a particle size of below 40 μm settled difficultly due to the strong disturbance by air flow.

Result verification

To verify the validity of the data, three test points were arranged at the blasting working face, and two direct reading dust testers were placed in each test point (the readings of the two testers were averaged). The dust concentration was measured at the 25th second (*Fig. 21*) and the 60th second (*Fig. 22*).

Figure 21. *Blowing dust after blasting (25 s)*

The test results are shown in *Tables 7* and *8*. In the 25 s after blasting, the average relative error of measured data and simulation data of three measuring points is 2.84%, 2.69% and 3.01%, both lower than 5%, in the 60 s after blasting, the average relative error of measured data and simulation data of three measuring points is 3.26%, 2.59% and 2.39% respectively, the relative error of measured data and simulation data of the test point 1, 2, 3 is under 5%, all show relatively reliable numerical simulation results and the reasonable model, The model can be used in subsequent studies to test the difficult law of blasting dust and its influencing factors.

Conclusions

(1) In this paper, a real time simulation of blasting dust pollution in open-pit mines was conducted through the numerical simulation and field test of dust. In the stage of impact movement of dust, a large amount of dust rushed into the atmospheric space instead of settling under the effect of inertia.

(2) Almost all the dust with a particle size of about 250 μm fell to the ground after about 30 s, and the dust with a particle size of 60-100 μm settled slowly, and the dust with a particle size of below 40 μm settled difficultly due to the strong disturbance by air flow.

Abstract. Micro-climatic factors of landscape green space have provided dynamic conditions and thermal conditions for the distribution of suspended particulate matters. In this paper, the data of greening rate and micro-climatic factor of 88 residential areas were acquired, by means of field survey, spot test and CFD (Computation Fluid Dynamics) analog simulation. Through analysis of the previous relevant theoretical research and work, with the greening rate of residential clusters in Chinese Shanxi Province Xi'an as the research object, this study has reasonably set the value of the greening rate and built the physical models of the greening rate. In this study, the relationship among the various factors was obtained by analyzing the measured data. Meanwhile, CFD numerical models were verified, and the influence of the greening rate on wind speed, turbulence characteristics and concentration of suspended particulate matters were simulated. Finally, it concluded that the optimal cluster plan is 35% and 40% greening rate, while the cluster plan of 0% and 25% greening rate is inappropriate.
Keywords: *green area ratio, residential groups, CFD simulation, suspended particulate matter*

Introduction

Winston Churchill, British Prime Minister, once said that we shape our dwellings and afterward our dwellings shape. There is no doubt that modern urban construction will change the climate and living environment and directly affect the quality of life of residents (Periáñez, 2005). Urbanization has now become the main theme of the world's social and economic development. From a worldwide perspective, the world's urban population only accounted for 3% in 1800. After the industrial revolution, urbanization accelerated development and up to 2000, the world's urban population accounted for 55%, which is also the first time in human history that the urban population is larger than the rural population. In the face of the global urbanization development, the population changes of all countries show different pace. As shown in *Figure 1*, in the developed countries, due to the early start of urbanization and the high level of urbanization, the infrastructure of villages and towns is relatively perfect. With the increasing demand for urban environmental quality, the growth of urban population tends to be stable, and the phenomenon of population flowing back to villages and towns makes the cities of developed countries suburbanized; however, in the developing China, the urbanization starts late, the level is low and the development speed is very fast. Because of the abnormal development of the urban economy, the urban population grows rapidly. In order to meet the needs of the fast-growing population, the urban starts to expand construction blindly and unrestrictedly, which leads to the rapid decline of the environmental quality, serious traffic congestion and poor living conditions and other environmental and social problems. In China, the growth of urban population

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1033510356

shows a sharp trend. As shown in *Figure 2,* in 1950, China's population was 545 million, of which only 12% was 654 million. In 2000, there were 453 million people in urban areas. It is estimated that by 2025, 851 million people will live in cities (World population forecast by United Nations: Demographic Data of 2009, http://esa.un.org/upod/wup/dov_highights.htm).

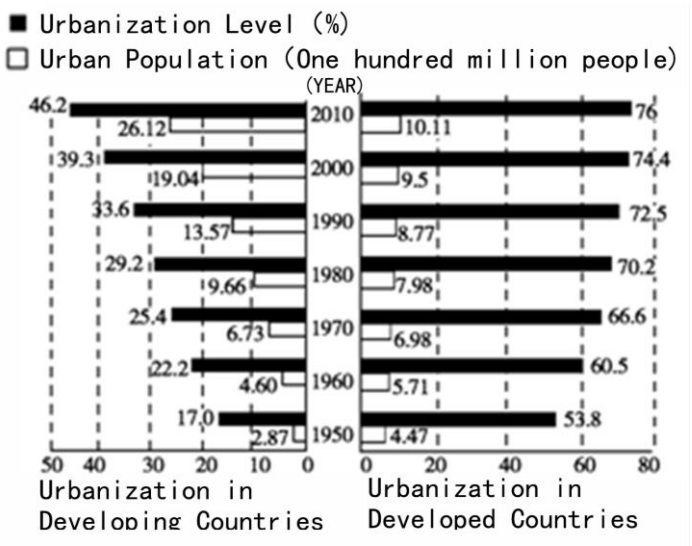

Figure 1. *World urbanization process*

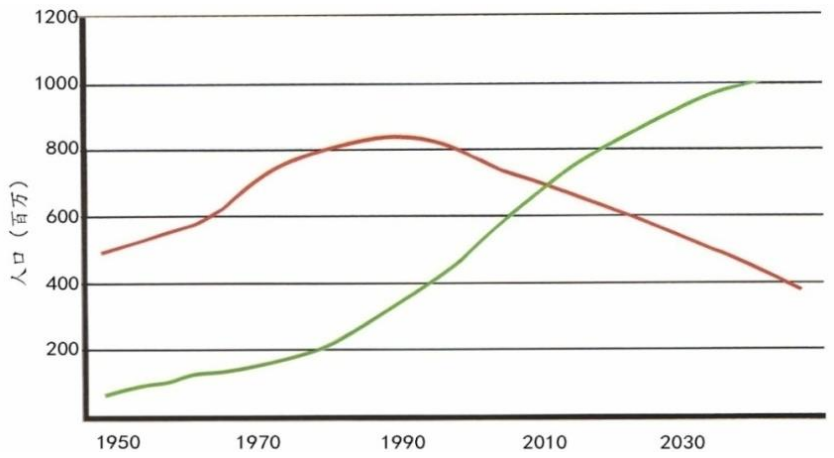

Figure 2. *The increase of rural population (red) and urban population (green) in China*

In the process of such rapid urbanization, not only the number of urban residents has increased, but also the urban land cover has been replaced by artificial paving materials from natural landforms. At the same time, the production and life of the city is maintained by the throughput of energy and raw materials (urban flow). In this process, it is inevitable to produce pollutant deposition in the form of energy and substance in the environment. These pollutants change the composition of urban atmospheric thermal structure and material form and affect urban climate and environment. Different forms and functions of urban areas form different local microclimates, which directly affect the quality of near-ground environment (*Fig. 3*). At present, the most concerned and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1033510356

discussed phenomenon of urban environmental pollution is haze, which has the greatest impact on human life and production. The air quality is related to the concentration distribution of suspended particulate matter, which has been paid close attention by scholars, managers and builders in various fields and even ordinary residents. There have been many pollution incidents about air pollution all over the world, which are due to the serious impact and harm of gaseous pollutants on local people in foggy weather or solid pollutants in bad weather conditions. In recent years, a wide range of haze in China has seriously affected the health and normal life of residents, whose fundamental reason is the atmospheric environmental pollution caused by suspended particulate matter. A large number of studies have also shown that the concentration of atmospheric suspended particulate matter, especially small particle size, has a significant impact on the health of human and animal respiratory system and shows a significant positive correlation. Particularly, small granule matters are very easy to adsorb organic pollutants, acid oxides, heavy metals, viruses and bacteria in the air, which are suspended in the atmosphere for a long time. It is harmful to human body and other animals through large-scale wind transmission (Ding, 2011; Peng, 2002).

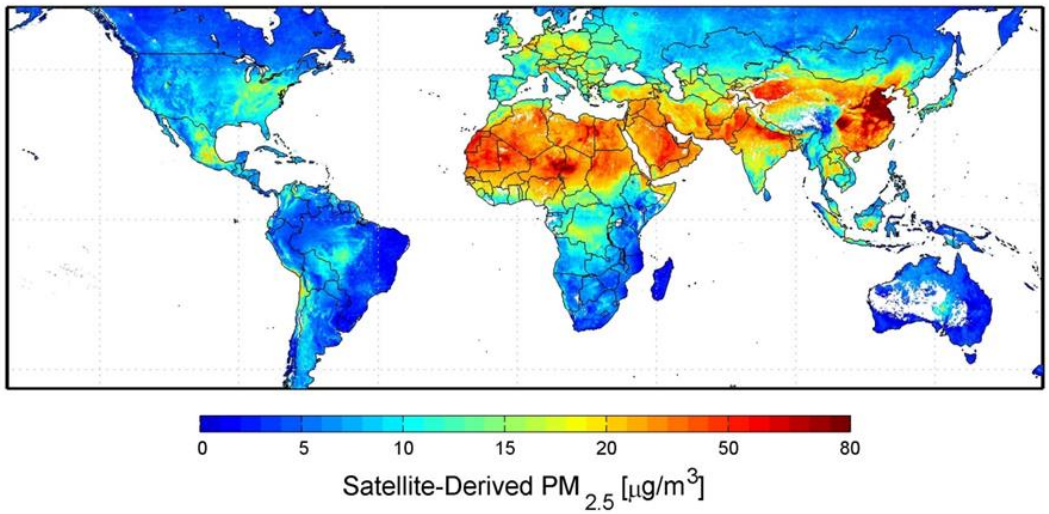

Figure 3. *Global air quality map released by NASA in September 2010*

Landscape garden is the most important place for urban activity and outdoor space in urban area, and the micro-climate changes in its spatial form affect the distribution of suspended particulate matters directly. *Figure 4* has shown the interactional relationship between climate and artificial environment. Climate acts on the environment where people live, people create an urban environment, which is better for living and production. However, with urban development and construction, urban spatial form conducts feedback to the atmospheric environment, where heat of the smooth and impervious underlying surface of the city conducts convection directly on the city surface due to lack of moisture and vegetation. The T thermal energy then rises and is transmitted to the atmosphere. Meanwhile, the nearby air temperature changes rapidly, enabling the city to be covered under the dry and warm lid. The difference between microclimate and the background climate occurs in certain areas of the city. In addition, under the influence of microclimate, a variety of special climatic phenomena, such as heat island and haze appearing in some areas and they differ from natural climate.

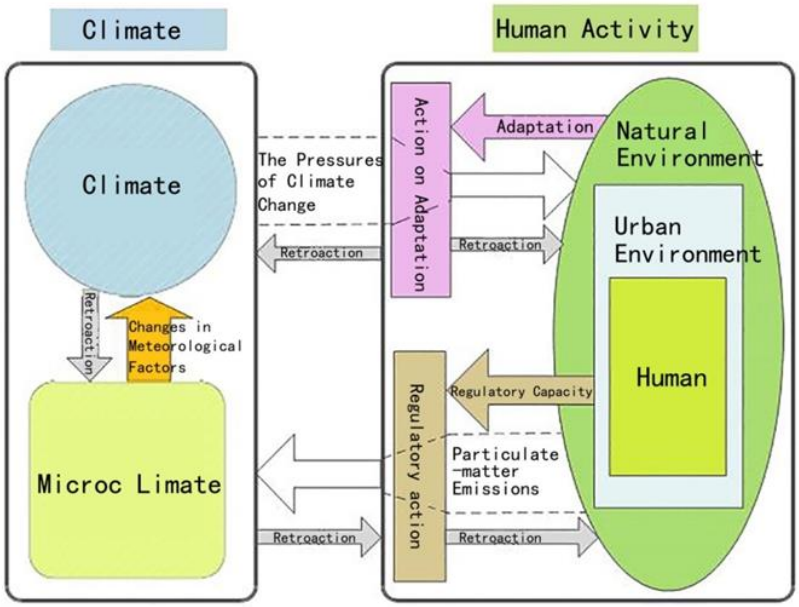

Figure 4. *Interaction among microclimate, climate and artificial environment (Dai Tianxing, 2006)*

According to aerodynamic equivalent diameter, air pollution particulate matters can be classified into TSP (≤ 100 μm), PM10 ≤ 10 μm) and PM2.5 (≤ 2.5 μm), etc., where the particulate matters with the grain size of less than 10μm are known as inhalable particulate matters. Since they closely relate to human health, they have raised extensive attention (Zhang, 2015). *Figure 5* shows data comparison of major air pollutants in Xi'an from 2007 to 2017, indicating that the concentration of inhalable particulate matters is far higher than SO_2 and CO_2, and the pollution is especially obvious in winter. Therefore, the inhalable particulate matters have become the major air pollutants, which cannot be ignored.

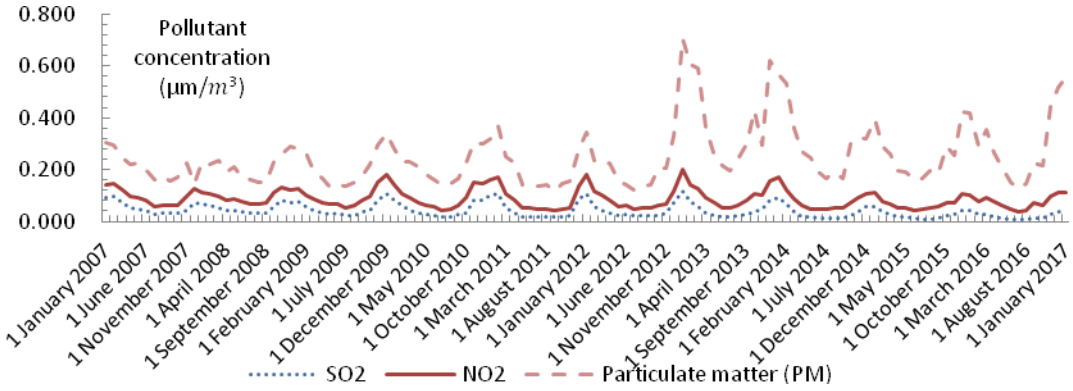

Figure 5. *Comparison of monthly mean concentration of air pollutants from 2007 to 2017 made by Xi'an Meteorological Bureau*

The concentration of ground pollutants is the major research object of this paper. This index mainly targets at the pollution of suspended particulate matters in people's

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1033510356

daily life. This is because human activities are mainly outdoor, while the outdoor ground pollutants directly harm human body. This index can be obtained via either air pollution level or field test. This paper conducted comparison of the PM2.5 concentration of the rigid pavement and green space in the Dependent's Area of Chang'an University, Xiaozhai Commercial District, Xi'an. This study collected data at 11:00 a.m. On each day from January 30, 2015 to March 23, 2015, which was obtained by the Meteorological Bureau. Moreover, what have been published by Xi'an Municipal Environmental Protection Bureau indicate that the law of the two are almost the same. However, the measured values are obviously greater than the published meteorological data. According to the *Technical Guidelines for Fugitive Emission Monitoring of Air Pollutants HJ/T55-2000* and *Ground Meteorological Planning* issued in 2004: the data of wind environment and pollutants are usually obtained through tests on the meteorological tower in suburb area, which is higher than 10 m. While the values in this paper were acquired at the human respiration altitude of 1.5 m away from the ground, as the near-surface concentration values, for which *Figure 6* shows the obvious difference between the two. Therefore, the practical research value of the measured values is greater (*Fig. 7*).

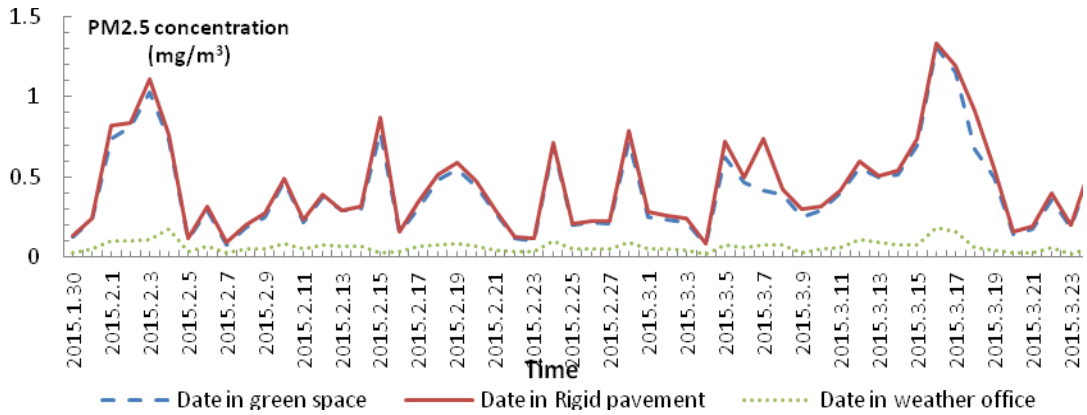

Figure 6. *Comparison of the measured data and published meteorological data of PM2.5 from January to March 2015*

In landscape garden, the dust settling effect of plants mainly results from the absorption and settling of particulate matters in the air by blocking the wind speed enabled by plant leaves. Buccolieri et al. (Nikolopoulou et al., 2001) found through wind tunnel test and CFD simulation that arbors on urban streets can improve wind environment and settle pollutants. However, due to different thickness of leaves and density of branches and leaves of various vegetation in greenbelts, dust retention differs per plant species It was found by Meir et al. (2000) through research that dust retention of trees and shrubs is far greater than that of lawns. In park green space and roadside green space, dust retention of shrubs per unit leaf area is higher than that of arbors. Many researches have proved that arbor leaves mainly retain large-grained flying dust, while shrubs set dust materially since they can better prevent pollution caused by the near-ground particulate matters (Zhou, 2001). In some researches, the relationship between the form of greenbelts and concentration of particulate matters is discussed from the perspective of the spatial arrangement of greenbelts. Feng et al. (2014) and Feng and Chu (2017) investigated and compared the urban green space, and concluded that pollutant dispersion presents positive relationship with green land area, and different green land area of residential areas, especially different trees and shrubs majorly contribute to dust retention of residential areas. There have been quite a few domestic and foreign scholars (Zhu et al., 2002; Che and Song, 2002; Su et al., 2002; Chai et al., 2002; Fanger and Toftum, 2002) with dedicated researches on the elimination rate of greenbelts of different structures towards particulate matters, with a consistent finding: under the same community structure, the effect of PM2.5 reduction by greenbelts is better than that of PM10 reduction.

The above research shows that suspended particulate matters are closely related to greening rate and characteristics of plant leaves due to the effect of microclimate. Moreover, dust retention of shrubs per unit leaf area is the best among other plant species. Therefore, by analyzing microclimate characteristics in this paper, shrubs were selected as the vegetation for research, and the design threshold of greening rate in residential clusters was preset reasonably, to study the distribution of PM2.5 of inhalable suspended particulate matters.

Materials and methods

Establishment of physical models

In this paper, residential quarters with 1,000-3,000 residents or 300-1,000 households in Xi'an were screened according to the study on the characteristics of urban residential clusters. Based on the scale characteristics of residential clusters, visit and investigation were carried out on 88 selected residential clusters in Xi'an, and the greening rate of the various community clusters were sorted out and analyzed. *Figure 8* indicates that the greening rate of the residential living clusters in Xi'an is mainly around the ranges of 30%, 35% and 40%.

It is expressly stipulated in the *Code of Urban Residential Areas Planning and Design GB50180-93 (2002)* that for the construction of new residential areas, the greening rate shall not be lower than 30%, and the greening rate shall not be lower than 25% for the reconstruction of old residential areas. It is stated by Article 14 in *Regulations of Xi'an Municipality on the Administration of Urban Greening* executed on June 1, 2014 that the greening rate of new residential areas shall not be lower than 35%, while the greening rate of residential areas under old city reconstruction shall be

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1033510356

5% lower in comparison, namely 30%. When building the models, the assumed greening rate of 25%, 30%, 35%, 40% and 0% shall be adopted combining the relevant standards and the practical cognitions of Xi'an to enhance the comparability of simulated results, as shown in *Figure 9*.

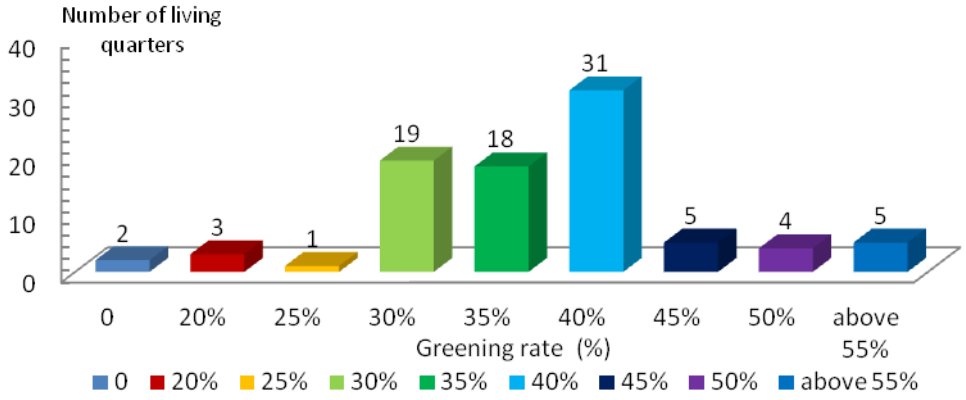

Figure 8. *Statistics of the greening rate in Xi'an through field survey*

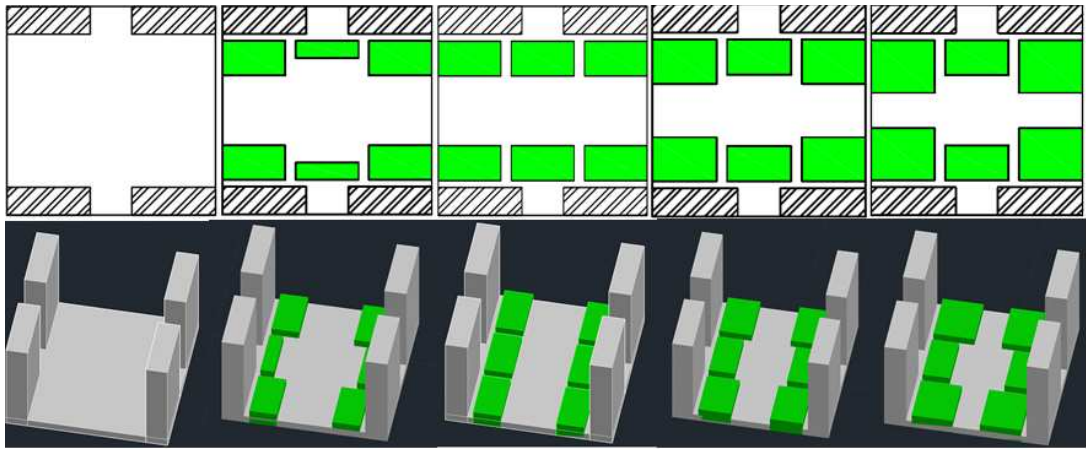

Figure 9. *Plane and aerial view of different greening rate models*

CFD numerical calculation model

According to the residential cluster space studied in this paper, Autodesk Simulation CFD was selected for the outdoor microclimate research thereof, given the fact that Autodesk Simulation CFD has high intelligence, strong automatic mesh generation technology, powerful analysis functions, high degree of humanization of post processing, and can conduct comparative analysis, etc. Its main functions are simulated analysis of fluid flow, heat transfer and movement (Hu, 2002). In this paper, the distribution of suspended particulate matters and flow field in the residential cluster space of different building height were simulated elaborately, with the powerful automatic mesh partitioning technology of the most common and mature turbulence model as well as Autodesk Simulation CFD, through the discretization and solution of differential equation.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

Standard* $k-\varepsilon$ *turbulence model

In the study on urban outdoor environment, the most frequently used model is the standard $\mathbf{k}-\boldsymbol{\varepsilon}$ turbulence model. Such model focus on the turbulent dissipation rate and turbulence function. Suppose that both the inside and outside of the flow field are turbulence, the viscosity between molecules are ignored, and the standard model $\mathbf{k}-\boldsymbol{\varepsilon}$ is built and functioning effectively (Hu, 2002; MOHURD, 2010). In this paper, this model was taken as the research model. As a semi-rational formula, its equation is as follows:

$$\frac{\partial k}{\partial t}+\frac{\partial}{\partial t_j}(u_j k)=\frac{\partial}{\partial t_j}\left[\left(v_0+\frac{v_t}{\sigma_k}\right)\frac{\partial k}{\partial x_j}\right]+G-\varepsilon \quad \text{(Eq.1)}$$

$$\frac{\partial \varepsilon}{\partial t}+\frac{\partial}{\partial t_j}(u_j \varepsilon) \quad =\frac{\partial}{\partial t_j}\left[\left(v_0+\frac{v_t}{\sigma_\varepsilon}\right)\frac{\partial \varepsilon}{\partial x_j}\right]+\frac{C_1 \varepsilon}{k}G-C_2\frac{\varepsilon^2}{k} \quad \text{(Eq.2)}$$

where k—turbulence energy; ε—turbulent energy dissipation rate; σ_k、σ_ε、$C_1$and C_2 —empirical constant; G—generation of turbulent energy, expressed as:

$$G=v_t\left(\frac{\partial u_i}{\partial x_j}+\frac{\partial u_j}{\partial x_t}\right)\frac{\partial u_i}{\partial x_j} \quad \text{(Eq.3)}$$

Discretization and solution of differential equation

The study in this paper has adopted the Finite Volume Method (FVM), with which, the entire computation field was first divided into several control volumes for mesh processing. Then, the differential equation was set for discretization processing with related schemes. Finally, the boundary conditions and initial conditions were supplemented, unknown parameters of all points of the space were solved, and a satisfactory result was finally obtained through repeated iteration. FVM has high computational efficiency, as it can indicate accurately integral conservation when the meshes are not very precise (Ma et al., 2017).

Mesh size and division

In the process of numerical simulation, mesh division of the models played an important part affecting the calculation of simulation values. To reduce the impact of the mesh boundary on its central area, and reduce the calculation of excessive loss due to oversize mesh, fineness of the mesh partition unit for the models of the residential areas was adjusted to around 0.3. In large blocks, Uniform Mesh was adopted, while Non-uniform Mesh was brought in small blocks, providing possibilities for depicting more precise flow fields.

Initial value of PM2.5 concentration field

The annual mean PM2.5 concentration of Xi'an in 2014 was higher than the secondary national ambient air quality standard by 1.17 times (Ma et al., 2017). The 24-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1033510356

h mean concentration of the 95th percentile was 194, higher than the secondary standard of the daily mean value of national ambient air quality standards by 1.59 times (Pape et al., 2014). The daily mean value of the monitoring points was 11-506 mg/m^3, and the maximum surpassing times was 5.75 times higher *(Code for planning and design of urban residential areas GB50180-2002, 2002)*. Since urban buildings have high density, the emission sources of single suspended particulate pollutants lead to low emissions. However, if they are in great quantity, emission sources can be considered as the spread mode of non-point source pollution (Feng and Wang, 2004). In this paper, only the background concentration of PM2.5 is considered, instead of the automobile exhaust or the influence of other complex surroundings. In the United States and Western Europe, the background concentration is about 3-5 μg/m^3, and 5 μg/m^3 (Sun et al., 2010; Peng Jiang, 2002; Salamanca et al., 2009) in Australia. There is still no public data available for China. According to the new *Ambient Air Quality Standard* published by Chinese government in March 2012, the value of 150 μg/m^3 executed previously is still reserved as the daily mean concentration limit of PM10, the daily mean concentration of PM2.5–75 μg/m^3 was set according to the proportion of PM2.5 to PM10–50% (Horemans, 2007; Zhao and Liu, 2001).

Experimental test

Summer experiment

The experiment was conducted from January 16 to 17, 2015. In this group of experiments, 88 residential areas of Xi'an were selected with two measurement points for each residential area. The central square, open place and the space between two buildings were respectively selected as measurement points. For each measurement point, there were 1056 data. The theoretical analysis has showed that the air humidity of the greenbelts increases through plant transpiration, and wind environment of some areas could be improved through photosynthesis. Therefore, concentration of PM2.5 would decrease along with the increase of greening rate. The data was separated for summarization. The single factor greening rate was taken as the major cause for comparison with the concentration of PM2.5, and a trend chart was drawn accordingly. The analysis of the design factors and the data of PM2.5 concentration of the 88 residential areas has showed that the greening rate is negatively related to PM2.5 concentration (*Figs. 10* and *11*).

Winter experiment

Selection of comparison group of green space rate

The comparison group compared the influence of green space rate on PM2.5 diffusion distribution under the same heat island and volume rate. As shown in *Table 1,* the locations are Jinduicheng Garden District and Shengshi Chang'an, which have similar volume ratios of 2.8 and 2.55 respectively and are located in Chang'an District in the northern suburbs of Xi'an. Chang'an District surrounds Xi'an City from the south and west and Qinling Mountains in the south. The intensity of heat island is weak and the concentration of PM2.5 is at a low level. The difference of green rate between the two districts is obvious of which the green space rate of Jinduicheng Garden District is only 18%, and that of Shengshi Chang'an is 65%. The location and detailed test points of the two districts are shown in *Figures 12* and *13* and *Table 2*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1033510356

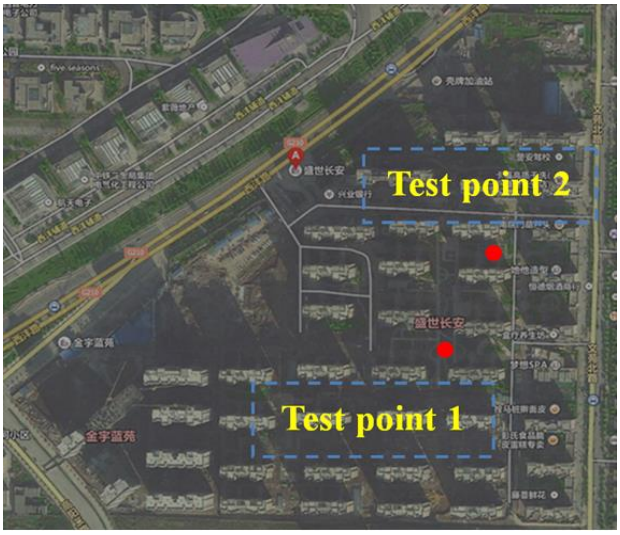

Figure 13. *Distribution of test points of Shengshi Chang'an*

Test of the influence of green space rate on PM2.5 concentration

During the experiment, every test point in each district is tested every hour. The test time is from 10:00 on January 15, 2015 to 10:00 on January 16, 2015. Detailed PM2.5 concentration analysis of the two districts is as follows:

It can be seen from *Figures 14* and 15 that the concentration of PM2.5 in Shengshi Chang'an is basically lower than that in Jinduicheng District, but during the period from 8:00 to 17:00 in the daytime, the construction site near Shengshi Chang'an has affected the high concentration of particulate matter in the district. The two residential areas are located in Chang'an District, where the intensity of heat island is weak and the volume ratio is basically the same. It can be seen that the difference of PM2.5 concentration between the two residential areas is caused by the difference of green space rate. Plants can alleviate PM2.5 pollution due to their retention on particulate matter. From the experimental data, it can be seen that green space can reduce PM2.5 concentration to a certain extent. As shown in *Figures 16* and *17*, as a whole, because the test point 1 is located in the open central square and the test point 2 is located in the hard ground between the two buildings where the ventilation is not smooth. Because the greening around the test point 1 is higher than that around the test point 2 which causes higher PM2.5 concentration of the test point 2. The data at 5:00 in Shengshi Chang'an are obviously higher, which may be caused by the passing cars.

To define the microclimate factors affecting PM2.5 concentration, this paper has introduced linear-regression analysis, to study the relationship among temperature, humidity, wind speed and PM2.5, by following 3 processes. Firstly, choose analyze → regression → linear, and activate the dialog boxes popping up in sequence. To follow that, there shall be further analysis. Finally, review the output; make the regression equation and inspection. The final analysis results are shown by *Table 3,* where, 3.126 is the constant term, while the coefficient of temperature, humidity, wind speed and PM2.5 concentration are respectively -2.198, 0.153, 0.045 and 0.190.

Since residuals are always assumed to obey normal distribution in the models, *Table 3* demonstrates whether the actual residuals after regression fit this assumption. Besides, it shows that the degree of influence imposed by various influencing factors on

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1033510356

PM2.5 concentration from high to low respectively: wind speed (m/s) > temperature (°C) > humidity (%RH), where wind speed exerts the greatest influence on PM2.5 concentration, while humidity exerts the lowest influence. Since it is difficult to subside PM2.5, gas pollution can be deemed as in the atmosphere, while wind speed is just a direct performance indicator of gas flow. Upon actual measurement, the most relevant micro-climatic factor of the distribution of PM2.5 concentration shall be wind environmental impact. Due to the difficult of PM2.5 reduction, increase of humidity has no significant effect on its settlement.

Results

Study in this paper conducted thermal pollution coupling calculation simulation of the greening rate of residential clusters in Xi'an, by building the physical model and CFD numerical calculation model. Furthermore, this paper has analyzed the effect of micro-climatic factors on improving the concentration distribution of suspended particulate matters through the influence of greening rate. After measurement

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1033510356

verification, micro-climatic factors of wind environment are found mostly related to PM2.5 concentration (Li et al., 2017; Tian et al., 2017; Liu et al., 2017). Therefore, during the simulation, comparative analysis was only made on wind speed, turbulence characteristics, PM2.5 concentration and the greening rate.

[a]Dependent variable: PM2.5 concentration

Wind speed

Figure 18 shows the planar wind speed distribution of different green land rates at an altitude of 1.5 m, under the condition of perpendicular to the northeast wind. *Figure 19* shows the comparison on the wind data of the gap between two green land parcels at an altitude of 1.5 m from north to south, at the fluid outlet on the west of the residential clusters. The comparison shows that wind speed in urban residential cluster space is negatively related to the greening rate. However, as the greening rate grows, its impact on wind speed weakens gradually. This is mainly because when the green land area is too large, airflow generated through transpiration of the plants can adjust the surrounding breeze or wind environment, and wind speed will not slow down linearly (Zamora Figueroa et al., 2017; Kmita et al., 2018). When the green land area is large enough, improvement made by the plants on the wind environment of the internal cluster space would be enhanced, and wind speed increases.

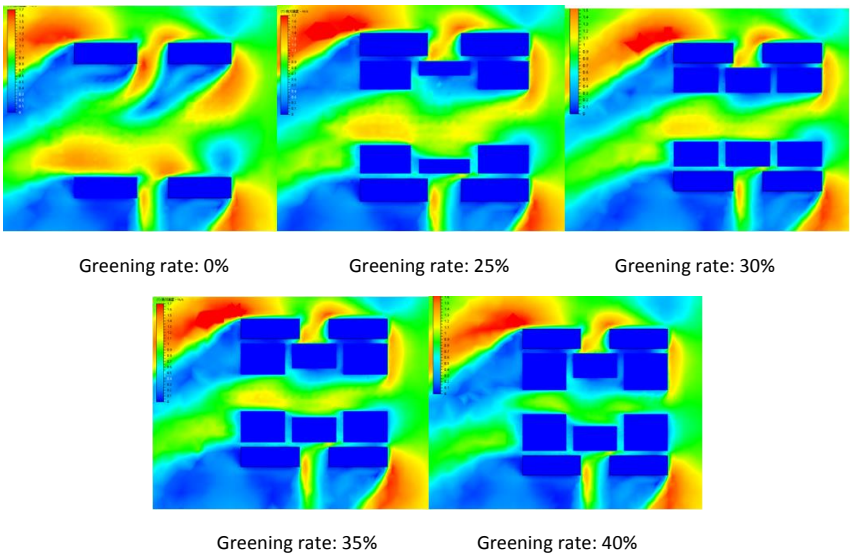

Figure 18. *Planar fluid spread of clusters with different greening rates at an altitude of 1.5 m*

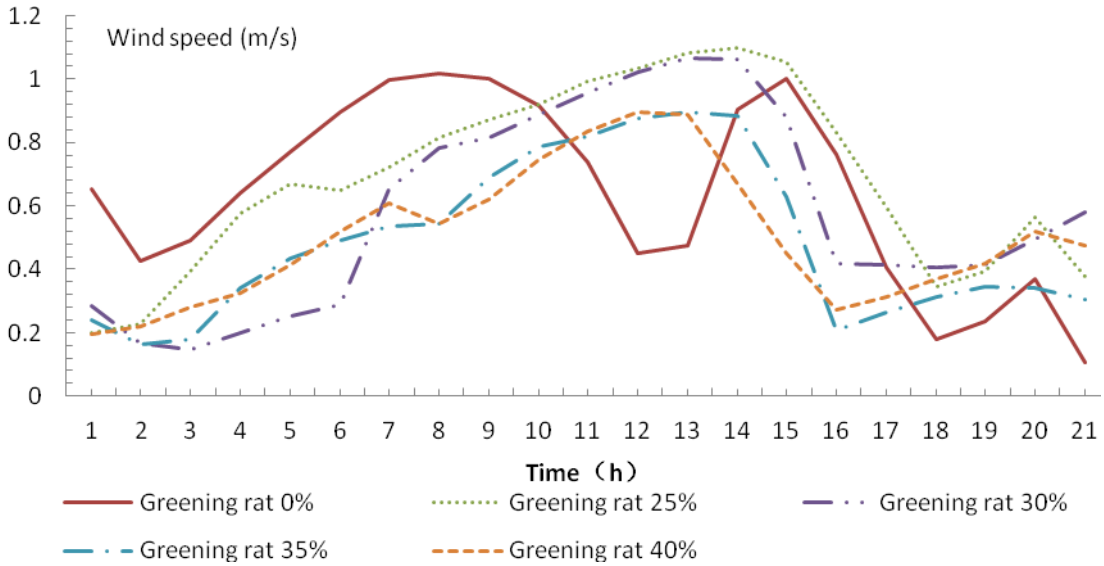

Figure 19. *Distribution of wind speed on the west-side air outlet in the cluster space with different greening rates at an altitude of 1.5 m*

Turbulence characteristics

Figure 20 shows a section view of each cluster on the west-side air outlet, indicating the influence of cluster space with different greening rate of fluid. When under the condition that the buildings are unchanged, it is clear that the degree of changes made by different green land area towards internal fluid of the space vary, and it is especially significant on the surface of the buildings.

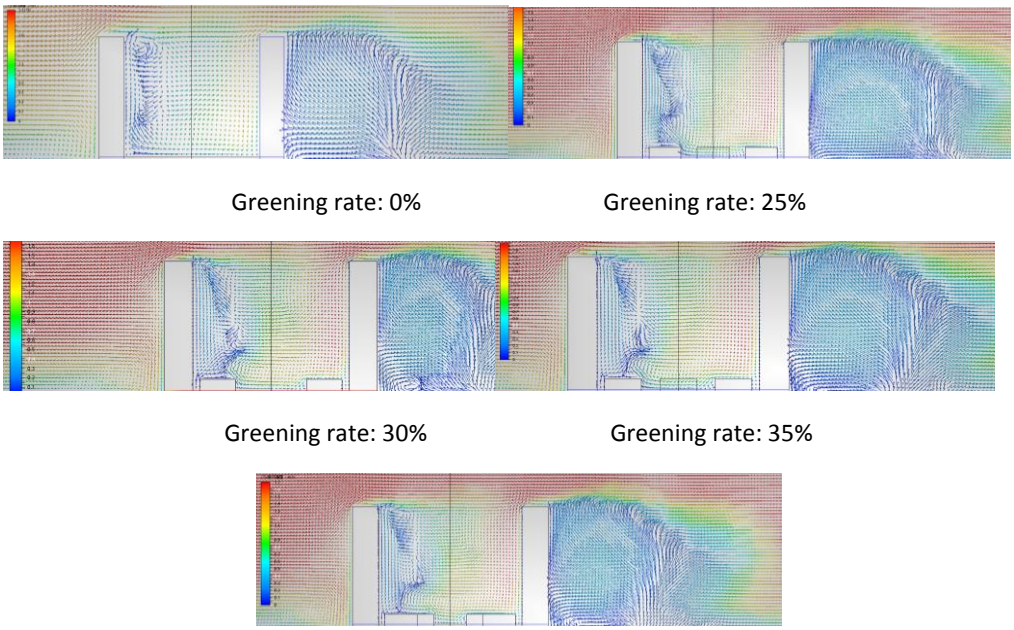

Figure 20. *Section view of wind velocity vector on the west-side outlet of fluid for clusters with different greening rates*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1033510356

Spread of pollutants in cluster space

Figures 21 and *22* show the planar fluid spread distribution of different greening rates at an altitude of 1.5 m and the concentration distribution of fine particulate matters. As demonstrated, the concentration data of particulate matters from north to south in the gap between two west-side green land parcels of planar clusters at an altitude of 1.5 m was selected for comparison that is shown in *Figure 22*.

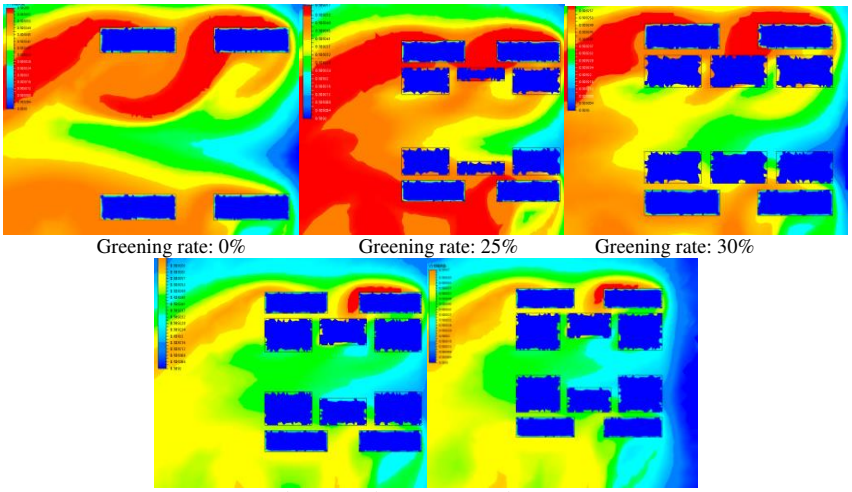

Figure 21. *Distribution of fine particulate matters of clusters with different greening rates*

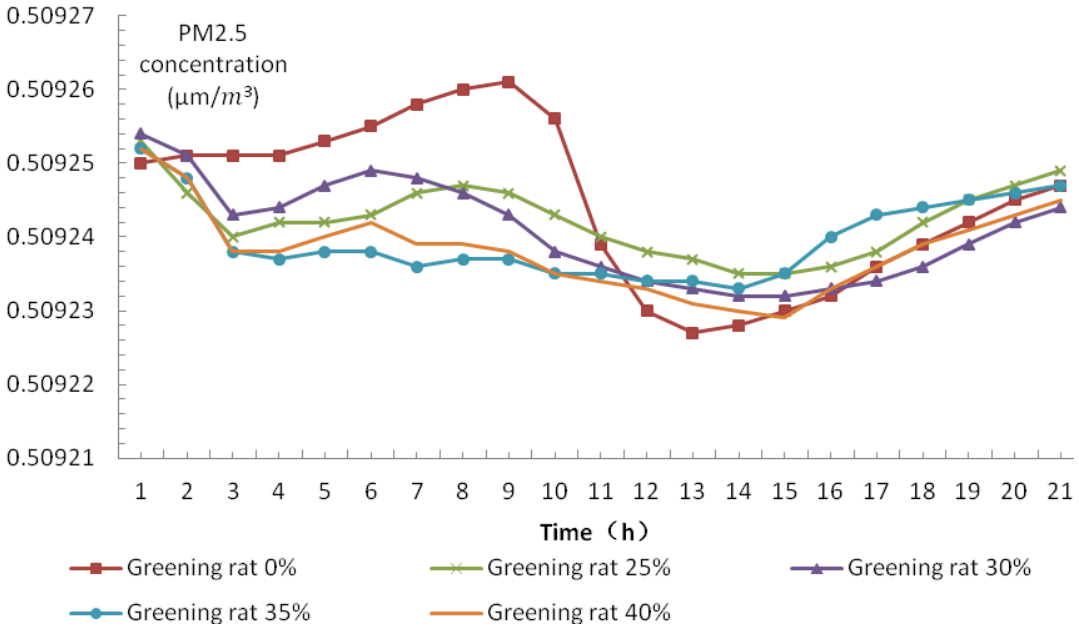

Figure 22. *Distribution of fine particulate matters on west-side air outlet in the cluster space with different greening rates at an altitude of 1.5 m*

The comparison discovers that the concentration of particulate matters in the space of urban residential clusters is negatively related to the greening rate, which is especially

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1033510356

significant in open space. However, a node appears. When a greening rate reaches a certain height, the concentration will decrease with the elevation of greenbelts, tending to be stable. This means that when the green land area reaches a certain height, excessively blocking and influencing field wind environment, wind speed will be largely reduced, dynamic factors for the spread of suspended particulate matters will wear off gradually, while the decrease of concentration of suspended particulate matters will also wear off gradually till reach the steady state.

Discussion

In the current residential group development process, in order to pursue the maximum unit area yield of commercial real estate, various types of residential areas are trying to approach or break through the volume ratio index and building density index defined by the regulatory plan to the maximum extent. Under the premise of determining the total building amount, the overall cluster layout cannot effectively combine local regional characteristics, climatic conditions and other factors, ignoring that the overall layout of residential areas will have a negative impact on the distribution of suspended particulate matter in the city.

The micro-climate environment has an important impact on the design of urban residential groups. Masatoshi M. Yoshino classifies the local climate dimensions in Japan, which can be concluded that the environmental factors of climate usually include temperature, solar radiation intensity, wind speed, humidity, etc. As shown in *Figure 23,* microclimate influences the surrounding environment and climate through the coupling of various climatic factors. Under the same solar radiation condition, influenced by the roughness of underlying surface, the greater the roughness of underlying surface, the more it can promote the flow and heat transfer of wind. By understanding the interaction principle between microclimate factors and urban underlying surface, we can find the characteristic factors of microclimate environment of residential groups (Chauhan et al., 2012).

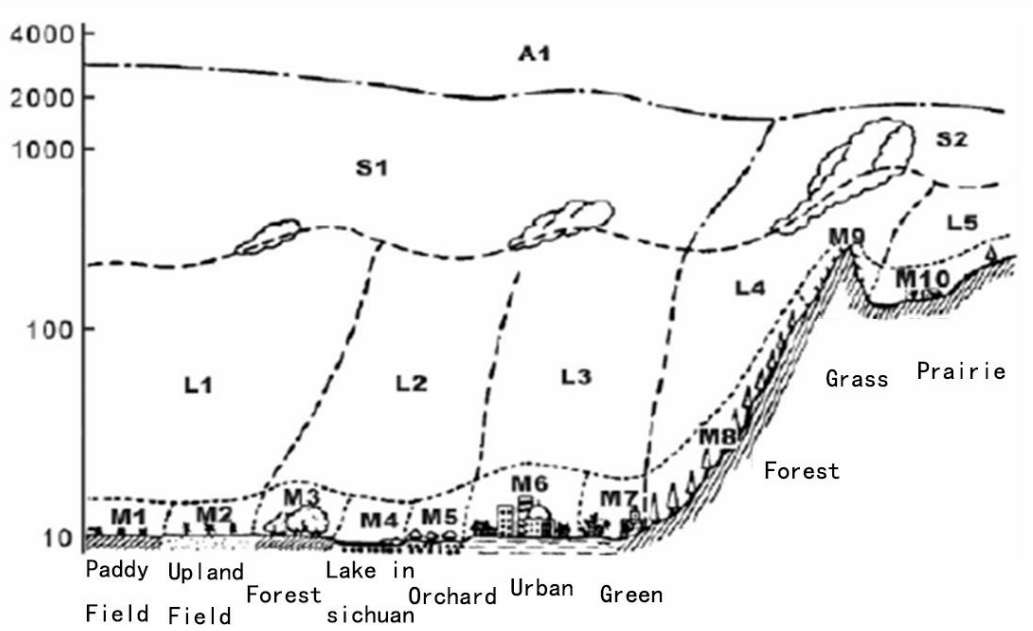

Figure 23. *Climate range map (Chauhan et al., 2012)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1033510356

Based on the research and analysis of the influence factors of microclimate, it is concluded that the microclimate factors which have great influence on the spatial form of urban residential groups are as follows: 1. Air circulation is reflected in the impact of the layout of buildings and buildings on microclimate. 2. Solar radiation and biological cooling are reflected in the change of microclimate caused by the absorption of heat radiation by greening vegetation communities. Vegetation can not only consume a lot of heat energy through transpiration in summer with intense sunshine radiation, but also increase the reflectivity of solar radiation by tree crowns. At the same time, plants can convert solar energy into biological energy, which reduces the fluctuation range of urban air layer. 3. Sun blocking effect refers to the use of buildings and trees, etc to shield the solar radiation, so as to reduce the absorption of solar radiation on the urban surface, so it will produce the climatic effect of reducing the environmental temperature in the shadows that appear in the shield (Sun et al., 2013); 4. Surface reflectance and temperature are reflected in the use of building surface materials and the impact of landscape paving materials on the temperature of microclimate 5. Evaporation and humidity; First of all, humidity is an important factor affecting natural ecological climate differences such as clouds, rain, fog and so on and is also an important factor affecting human comfort. In urban residential groups, this can increase and decrease air humidity through evaporation of underlying surfaces with different water seepage rates to achieve “passive” cooling (Sun et al., 2013). Many factors around residential group space influence the generation of microclimate, as shown in *Table 4*.

Table 4. *Signature characteristics of microclimate influencing factors and residential group composition factors*

Correlation factors	Signature characteristics	Effect on microclimate
Space shape	Plane form and elevation form	Air circulation
Green space	Greening Area, tree species	Wind speed reduction
Shaded condition	Buildings, trees	Direct radiation heating
Topographic roughness	Building distribution, average height, orientation and volume; extent of spatial openness	Scattering radiation warming
Surface reflectance	Building and ground material	Radiation warming
Evaporation of underlying surface	Green space and water body	Decalescence

The research in this paper was taken as a new method and new thought to conduct quantitative analysis and predict the microclimate with the greening rate of urban residential clusters, based on the spread of suspended particulate matters, further advancing the ecologicalization and scientification of the landscape architecture discipline. The findings of this paper have provided application value for the construction of similar areas. The following perceptions are summarized:

(1) Indication factors of this paper were set by combining the specific regional characteristics of Xi’an city. Therefore, in the future researches of other cities, such as Guanzhong, or even cities of lower temperature on average, the corresponding index parameters can be adjusted combining regional and cultural characteristics.

(2) Since spatial arrangement of urban greenbelts can be viewed from the plane and vertical plane perspectives, near ground microclimate is related to the greening

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1033510356

structure, quantity of greenbelts, spatial form of greenbelts and landscape pattern, etc., there are still factors in need of exploration in a further way.

(3) To certain extent, meteorological simulation software has relatively larger mesh calculation scale. Therefore, when studying micro-climatic factors, CFD is more suitable for the purpose of numerical simulation.

Conclusion

The increase of urban greenbelts and the improvement of urban underlying surfaces can realize the temperature reduction. On one hand, a great amount of greening volume can reduce the concentration of suspended particulate matters by alleviating heat island effect. On the other hand, greenbelts can greatly purify and retain particulate matters, and the wider range of greenbelts, the more effective.

In the space of residential clusters, different greening rates have been obtained through CFD simulation: concentration of particulate matters in the space of residential clusters is negatively related to the greening rate overall, and is especially significant in open space. However, a node appears. When the greening rate exceeds 40%, the degree of the concentration reduction with the elevation of greenbelts decreases, with the tendency to be stable. By making comprehensive analysis on the preferences of sectional turbulence characteristics and preferences of pollutant concentration of the cluster examples, this study has come to the conclusion that the optimal plan of greening rate is the cluster plan with the greening rate of 35% and 40%. The plan with the greening rate of 30% is optional, the plans with the greening rate of 0% and 25% are inappropriate, as shown in *Figure 24*.

Abstract. To investigate the effect of rooting medium, cutting type and auxin (indole butyric acid (IBA)) on rooting of pepino cuttings (*Solanum muricatum* Aiton), two separate experiments were carried out in a factorial based on completely randomized design. In the first experiment, the effects of two types of cuttings (middle and distal) and eleven rooting media, and in the second experiment, the effects of three levels of IBA (0, 500 and 1000 mg L^{-1}) and seven rooting media (selected based on the results of the first experiment) on the rooting rate of cuttings and some growth characteristics including root length, the longest root length, stem length, fresh and dry weights of root and plant were evaluated. The results of the first experiment showed that the distal cuttings showed better rooting than the middle ones. The highest number of roots (40.5) was found in peat moss + perlite rooting medium. The highest averages of root length and length of the longest root were related to the distal cuttings planted in water and then in peat moss + perlite medium. The greatest root fresh weight was recorded in cuttings planted in peat moss + perlite medium, and the highest root dry weight and plant fresh and dry weights were obtained in distal cuttings planted in peat moss + sand medium. The results of the second experiment also showed that the highest (66) and lowest (26.76) numbers of roots were due to peat moss + perlite and water media, respectively. The greatest root length and length of the longest root was observed in the treatment of 0 mg L^{-1} IBA in water medium which was higher than in other treatments Moreover, the highest root fresh and dry weights were related to a treatment of 500 mg L^{-1} IBA in peat moss + sand medium. In general, the most suitable combination for pepino cultivation is the use of distal cuttings treated with a concentration of 500 mg L^{-1} IBA and planting in the rooting medium of peat moss + perlite, followed by peat moss + sand medium.
Keywords: *IBA, peat moss + perlite medium, root number and length, distal cutting, root fresh weight*

Introduction

Pepino (*Solanum muricatum* Aiton), a member of the Solanaceae family, is a tropical and semi-tropical crop and native to the Andean Mountains. It is grown commercially in countries such as Bolivia, Colombia, Ecuador, Peru, Australia and New Zealand for its edible fruits, which are juicy, fragrant, sweet and rich in color and shape. It contains 92% water, low calories, high minerals, thiamine, niacin, riboflavin and ascorbic acid (Prohens et al., 1996; Sudha at al., 2011). Pepino is a greenhouse crop with growing season longer than most greenhouse crops and has a yield of 70-80 tons per hectare (Prohens and Nuez, 1999).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1035710369

Pepino propagation is possible through sexual and asexual methods, and most of the pepino cultivars are fertile and produce live seeds (5 to 30 seeds per fruit). Low percentage of seed germination, high levels of heterozygosity, and low quality of plants are the most important problems resulting from seed propagation (Pauli, 1988; Hernando and Leon, 1994; Pierik, 1997; Nemati and Tehranifar, 2007). There is not much information about the sexual reproduction of this plant, and generally reproductive propagation has been reported to be difficult and with low success. The germination rate of pepino seeds in soil has been reported to be only 4%, so cutting is the main propagation method of this plant (Bhardwaj et al., 1996; Hrbans et al., 1996; Prohens et al., 2005; Nemati and Tehranifar, 2007).

In various studies, it has been determined that type and position of cutting and rooting medium have a significant effect on the success of rooting. So that in some herbaceous species such as olive (Aboutalebi Jahromi and Hassanpoor, 2003) and *Azadirachta indica* (Palanisamy and Kumar, 1997), distal cuttings had better rooting than the middle or basal ones. Culture medium is composed of substances that can replace natural soil for plant growth, in which roots grow continuously by absorbing water and nutrients (Douglass et al., 2009). Use of culture media started in the 1960s by using organic substrates such as peat (Schie, 1997), and today the use of granulated substrates for planting greenhouse vegetables has become very common and becomes more important every year (Gül et al., 2005). An ideal growth environment for the plant should include features such as being affordable and accessible, appropriate efficiency for physical support of the plant, ability to store water and food, adequate oxygen exchange for root respiration, high water holding capacity and appropriate drainage. Moreover, culture medium should be free of pathogenic organisms (bacteria, nematodes, fungi and insects), weeds, toxic substances and chemical residues (pesticides) (Johnson et al., 1985; Cantliffe et al., 2003). Although different materials are used to prepare plants growth medium, the final selection of the material type depends on the inherent characteristics of the culture medium to maintain the desired growth of the plant (Verdonck et al., 1982). In a study, the effects of cutting type, different levels of naphthalene acetic acid and three substrates were investigated on sum of root length of 'Consuelo' pepino cuttings. Using middle cuttings treated with naphthalene acetic acid at concentration of 500 mg/l and planted in perlite medium was reported as the best combined treatment (Nemati and Tehranifar, 2007). Although use of cutting is considered as the main propagation method of pepino plant and many reports indicated that pepino cuttings stablish roots easily, none of them intensively compared rooting intensity of cutting type, effects of various rooting medium and growth regulators (IBA) on it. Moreover, there is a report on unsuccessful rooting and vegetation propagation of the cuttings of the plants grown from the seeds of the Ramses and Consuelo cultivars (Nemati and Tehranifar, 2007). Since low success of pepino propagation through seeds is a major problem in the development of this crop cultivation, this study was conducted to investigate the effects of rooting substrate, cutting type and different concentrations of indole butyric acid on the rooting of pippino cuttings of the 'Ramses' cultivar.

Materials and methods

In this research, in order to evaluate the effect of rooting medium, cutting type (cuttings position) and auxin (indole butyric acid) on rooting of pepino cuttings, two separate experiments were carried out based on a completely randomized design with

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1035710369

three replications in Ferdowsi University of Mashhad, Iran in 2016. In the first experiment, the effects of cutting type (distal and middle cuttings) and 11 rooting media including peat moss, perlite, cocopeat, sand, water, peat moss + perlite, peat moss + cocopeat, peat moss + sand, perlite + cocopeat, perlite + sand and cocopeat + sand were investigated on rooting of pepino cuttings (*Fig. 1*). Pepino seeds were purchased from Plant World Seed Company, UK, and planted in a greenhouse under temperature of 25°C and relative humidity of 50%.

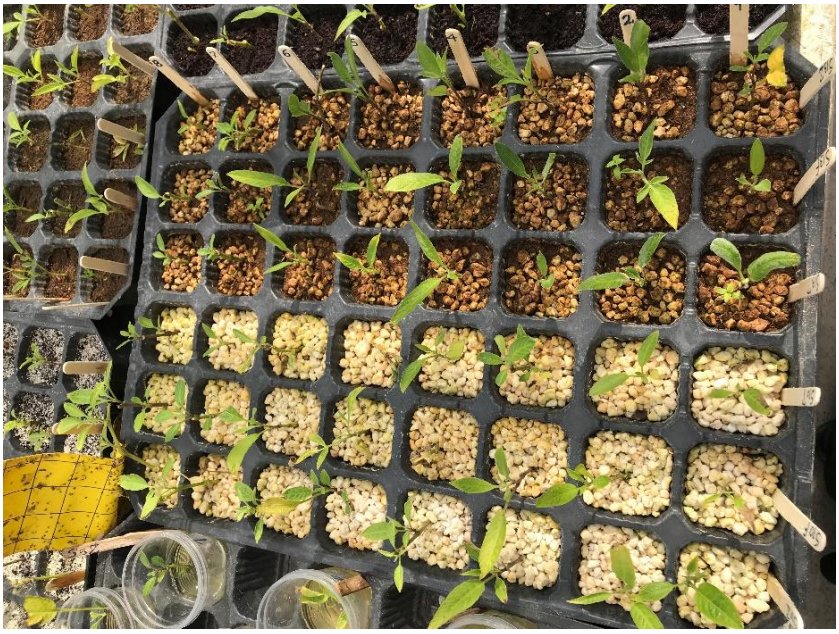

Figure 1. *Culture media and cuttings*

Two types of middle and distal cuttings with the length of 15 cm were prepared from the plants grown from seeds (seedlings) and planted in different media disinfected with benomyl fungicide. In the second experiment, the effects of different concentrations of indole butyric acid (IBA) (0, 500 and 1000 mg/l) and seven rooting media including peat moss, perlite, sand, water, peat moss + perlite, peat moss + sand and perlite + sand in six replications were evaluated on rooting of the cuttings and some growth parameters of pepino cuttings. Plants were grown in the greenhouse condition and temperature was set between 20ºC day/15ºC night and pots were tap watered each 3 days. It should be noted that the choice of cuttings type and rooting media in the second experiment was carried out based on the results of the first experiment. For this purpose, 5 cm of the basal portion of the cuttings was treated with different levels of indole butyric acid for 10 seconds, and after drying, they were planted in different rooting media disinfected with benomyl fungicide. After four weeks, characteristics including total number of roots, root length (cm), length of the longest roots (cm), root fresh and dry weight (g), stem length (cm) and plant fresh and dry weight (g) were evaluated. Data were analyzed using analysis of variance (ANOVA) procedure. The comparison of means were tested with the least significant difference test (LSD) at 5% probability level. The SAS software (version 9.3) was used for analysis.

Results and Discussion

Data showed that distal cuttings had better rooting. The highest number of roots and greatest root fresh weight were recorded in cuttings grown in peat moss + perlite medium. Moreover, the highest averages of root length and length of the longest root were observed in water and then in peat moss + perlite medium. However, the highest root dry weight and plant fresh and dry weights were obtained in distal cuttings planted in peat moss + sand medium. Investigating the effect of application of IBA on distal cuttings grown in seven media selected from the first experiment also showed that cuttings grown in peat moss + perlite and water media had the highest and lowest number of roots, respectively. Cuttings treated with 0 mg L^{-1} IBA and grown in water medium showed the greatest root length and length of the longest root. While, the highest root fresh and dry weights were observed under treatment of 500 mg L^{-1} IBA in peat moss + sand medium. Overall, distal cuttings treated with a concentration of 500 mg L^{-1} IBA and grown in the rooting medium of peat moss + perlite, followed by peat moss + sand medium were the best treatments for pepino vegetative propagation.

Effect of rooting medium and cutting type on rooting and growth characteristics of cuttings

Number of roots

Culture medium and cutting type had a significant effect on the total number of roots, while the interaction of medium × cutting type on this trait was not significant (*Table 1*). Based on the results of means comparison of simple effect of culture medium, the highest average number of roots (40.5) was observed in cuttings planted in peat moss + perlite rooting medium with no statistical significant difference from peat moss + sand. The lowest number of roots was obtained in peat moss + cocopeat medium. In other words, the number of roots in cuttings planted in peat moss + perlite and peat moss + sand was 1.7 and 2 times higher than the number of roots observed in peat moss + cocopeat medium, respectively (*Fig. 2*). The results of the simple effect of cuttings type showed that distal cuttings were more effective than middle ones so that the average number of roots in distal cuttings (31.4) was approximately 1.5 times that of middle ones (21.5).

Average root length, length of the longest root and stem length

Root length and length of the longest root were significantly affected by the culture medium, type of cutting and the interaction of culture medium × cutting type, while stem length was only affected by the interaction of culture medium × cutting type (*Table 1*). The results obtained from means comparison of the interaction of culture medium × cutting type showed that the highest averages of root length and length of the longest root were related to distal cuttings in water, while the lowest averages of root length and length of the longest root were observed, respectively, in middle and distal cuttings planted in peat moss + cocopeat medium. Besides, the greatest stem length was observed in cuttings planted in peat moss + sand medium and the shortest stem length was related to the cuttings planted in peat moss + perlite medium (*Table 1*).

The results of analysis of variance showed that fresh and dry weights of root were significantly affected by culture medium, cutting type and interaction of culture medium × cutting type, while fresh weight of the plant was affected only by culture medium and interaction of the culture medium × cutting type and plant dry weight index

was only affected by the culture medium × cutting type (*Table 2*). Based on the results of means comparison of the data, the greatest root and plant dry weights and plant fresh weight were related to distal cutting planted in peat moss + sand, while the lowest root dry weight was related to middle cuttings planted in cocopeat + perlite medium and the lowest fresh and dry weights of the plant were recorded in distal cuttings planted in cocopeat + perlite medium. Furthermore, the highest root fresh weight was related to distal cuttings planted in peat moss + perlite medium and the lowest root fresh weight was recorded in the middle cuttings planted in cocopeat + perlite and peat moss substrates (*Table 2*).

Effect of rooting medium and indole butyric acid on rooting and growth characteristics of seedlings

Total number of roots

The results of analysis of variance showed that total root number was significantly affected by culture medium and indole butyric acid, while the interaction effect of culture medium × indole butyric acid on this index was not significant (*Table 3*). Based on the results of means comparison, the highest average number of roots (66) was found in peat + perlite culture medium, which showed a significant difference from other substrates, while the lowest mean number of roots (26.7) was seen in water medium

(*Fig. 3*). In other words, the number of roots observed in distal cuttings of pepino planted in peat + perlite culture medium was about 2.47 times higher than what was observed in the cuttings planted in water medium (*Fig. 3*). The simple effect of indole butyric acid hormone showed that the highest number of roots was related to the cuttings treated with indole butyric acid at concentration of 500 mg/l, which showed a statistically significant difference from two other concentrations (0 and 1000 mg/l) (*Fig 4*).

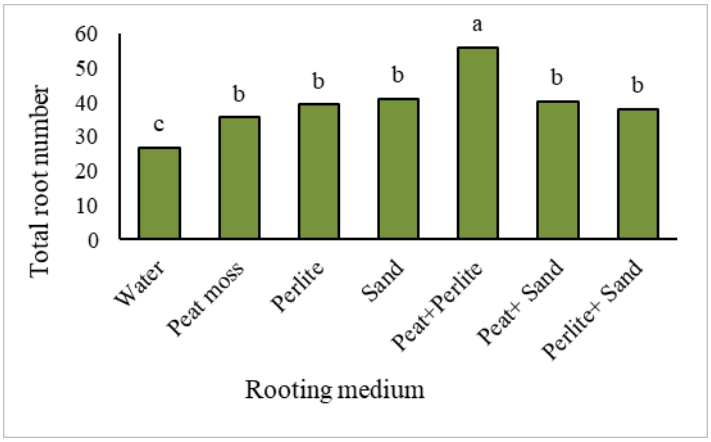

Figure 3. *Effect of rooting substrate on root number*

Average root length and length of the longest root

Mean root length and length of the longest root were significantly affected by the culture medium, indole butyric acid and culture medium × indole butyric acid interaction (*Table 3*). Among the different treatments, the greatest root length and the longest root length were related to 0 mg/l indole butyric acid in water, which resulted in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1035710369

a statistically significant difference compared to other treatments. The lowest root length and the shortest root length were obtained in 1000 mg/l indole butyric acid in perlite + sand medium and 0 mg/l indole butyric acid in sand medium (*Table 3*).

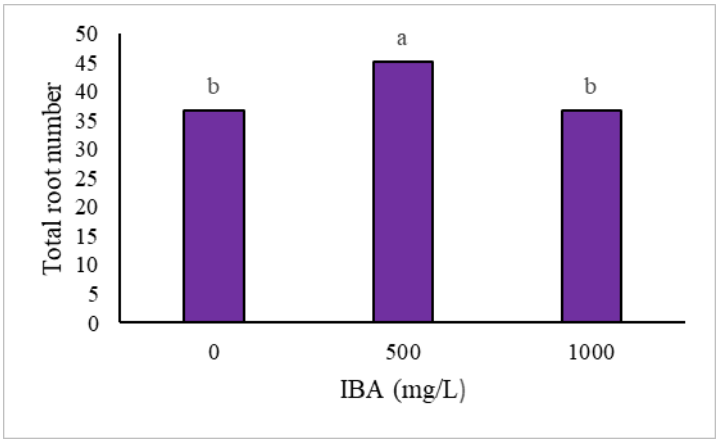

Figure 4. *Effect of indole butyric acid on root number*

Fresh and dry weights of root

Culture medium and culture medium × indole butyric acid interaction had a significant effect on root fresh and dry weights, while the simple effect of indole butyric acid on these two indices was not statistically significant (*Table 3*). The results of culture medium × indole butyric acid interaction showed that the highest root fresh and dry weights were due to the cuttings treated with 500 mg/l indole butyric acid in peat moss + sand medium. Moreover, the lowest root fresh and dry weights were recorded in the cuttings treated with indole butyric acid at concentration of 500 mg/l in water and sand substrates (*Table 3*).

Discussion

The results of the first experiment indicated better rooting of distal cuttings of pepino in comparison with the middle cuttings, and also greater suitability of peat moss + sand and peat moss + perlite substrates for rooting and vegetative growth of seedlings compared to other substrates. The significant effect of culture medium on different root characteristics such as number and length of root (Ercisli et al., 2005), weight, thickness, length and volume of root (Ahmad et al., 2000), and number of primary roots and amount of root dry matter (Kreen et al., 2002) has been reported in different studies. Culture medium is one of the most important indicators for successful rooting of cutting. Cuttings of azalea, privet and almond in a mixture with equal ratios of peat and sand had a remarkably good rooting, indicating that this combination (peat + sand) can be very useful for many cuttings which have poor rooting in either peat or sand (Hitchcock, 1928). Peat, perlite and sand substrates for rooting of tomato cuttings were more suitable than sand + soil + organic fertilizer mixture, so that the highest number of leaves and greatest fresh and dry weights of seedling were observed in peat medium and the longest root length and greatest seedling fresh weight were reported in peat and sand rooting media (Gül et al., 1993). Moreover, the increase found in rooting percentage and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1035710369

number of primary root in kiwifruit cuttings planted in peat + perlite medium was associated to proper water holding of this medium (Ercişli et al., 2002). Due to having suitable physical and chemical characteristics such as density, porosity, air capacity, water holding capacity, pH, electrical conductivity, cation exchange capacity and carbon to nitrogen ratio, peat is a suitable medium for planting most horticultural species (Abad et al., 2001). The maintenance of adequate ventilation in the rooting environment, along with reduced water losses from cuttings, is one of the important tasks of propagation systems. On the one hand, the presence of proper ventilation around the roots in culture media containing peat moss is effective in the induction and growth of roots in cuttings (Hartman et al., 1990; Jinks, 1995), and, on the other hand, the positive and desirable effect of peat moss + sand on rooting can be due to better water holding by this mixture compared to sand, as well as due to other potential benefits affected by peat moss (Hitchcock, 1928). Superiority of peat moss can be due to high cation exchange capacity and appropriate moisture holding. Use of perlite in combination with traditional media containing peat can be effective in plant growth and development due to better aeration (Smith and Hall, 1994).

The results of this study showed that root length in water medium was longer than other rooting media. In line with the results obtained in this study, Nemati and Tehranifar (2007) also reported that the total root length of pepino cuttings planted in perlite and water media was greater than that in other substrates. However, rooted cuttings in water medium did not have good establishment in soil. The effect of rooting media on the extension of the appeared roots was more than induction of rooting (Long, 1932). Although pepino can withstand flood conditions for several days (Prohens et al., 1996), formation of long roots in water medium can be a sign of flood stress (Gibberd et al., 2001; Grzesiak et al., 2014). These long roots are likely to be aerotropic roots that plant expands under flood stress conditions to search for air and oxygen (Gibberd et al., 2001).

Cutting position affects the rate of rooting success, so that better rooting of distal cuttings compared to middle ones has been reported in different plants, such as olive (Aboutalebi Jahromi and Hassanpoor, 2003) and neem (Palanisamy and Kumar, 1997), which is consistent with the results obtained in this study. As the plant grows older, the production of rooting inhibitors increases and there is a direct correlation between the reduction of rooting and tissues of lower cuttings (Paton et al., 1970). Phenols act as auxin cofactor, and reduction in rooting potential, along with aging of plants, can be due to the reduction of phenolic compounds (Khandan-Mirkohi et al., 2015). The absence of terminal bud in cutting and consequently depriving of cutting from internal auxin can lead to a decrease in the number of cells in root primordia. On the other hand, the aging of the root primordia and increase in the number of its cells reduce the effect of internal auxin, indicating greater rooting in juvenile cuttings with terminal bud (Haissig, 1972; Khandan-Mirkohi et al., 2015). Generally, the increase in rooting in distal cuttings containing terminal buds relative to cuttings with no bud can be attributed to high concentrations of internal rooting stimulator produced in the terminal bud and hence the pre-formation of a number of root initials affected by these materials (Davies and Hartmann, 1988; Hartman et al., 1990). Better rooting of distal cuttings in comparison with the middle ones can be due to the presence of higher auxin content at distal end of the shoot, so it is possible that auxin concentration decreases with increased distance from shoot tip and, consequently, rooting decreases (Palanisamy and Kumar, 1997).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1035710369

Based on the results of this study, rooting rate of pepino cuttings was influenced by the use of auxin hormone (IBA). The ability of cuttings for rooting is dependent upon phenolic compounds, enzymes and their auxin content (Loreti and Morini, 1985), so that success in rooting of some carnation species without application of plant growth regulators was related to their internal auxin (Guerrero et al., 1999). Auxin has a positive role in induction of rooting, formation of root initials, and increase of speed and percentage of cuttings rooting. Despite the synthesis of auxin in various plant organs (including young shoots and leaves), application of synthetic auxin for successful rooting and prevention of cutting death is useful (Štefančič et al., 2007; Kasim and Rayya, 2009). Through stimulating pericycle cells in the upper parts of root hairs, auxin hormone can stimulate the division of cell in this region and eventually lead to root formation (Hillman, 1984; Davies, 1995; Laskowski et al., 1995). Generally, the positive effect of auxin on rooting can be attributed to the increase of auxin-based food supply, increase of protein content and peroxidase enzyme activity (Husen and Pal, 2007) as well as its role in stimulating the division of the first cell of root initials (Hartman et al., 1990; Loach, 1996). In addition, the effect of rooting auxin hormone on the increase of root length can be due to the effect of this growth regulator on the stimulation of cell division.

Although it has been reported that pepino, due to the easy rooting of its cuttings, is mainly propagated vegetatively by using cutting and in most cases it is not necessary to use mist system or plant hormones (National Research Council, 1989; Spooner et al., 1993; Prohens et al., 1996), there is a report regarding unsuccessful rooting and vegetative propagation by using cuttings obtained from seedlings of Ramses and Consuelo varieties in Iran (Nemati and Tehranifar, 2007). Furthermore, the results of this study showed that application of rooting hormones can increase the success rate of pepino vegetative propagation. Use of IBA (especially at concentration of 500 mg/l) improved rooting and grwoth characteristics of seedlings in the present study. On the other hand, it has been shown that application of high concentration of IBA (1000 mg/l) in comparison with concentration of 500 mg/l decreased rooting and growth characteristics of seedlings, showing bell characteristic of hormones. Although IBA is one of the most effective compounds stimulating rooting in many species (Hartmann and Kester, 1990), its effect can vary based on the type of cuttings (Tworkoski and Takeda, 2007) and the concentration used. It has been reported that use of IBA at concentration of 1000 mg/l reduced the number of leaves and root fresh weight in lateral cuttings of tomato compared with the control (distilled water) (Gül et al., 1993). High concentrations of auxin can cause degradation of the basal tissues of cuttings, interference in hormonal balance in plant, damage to the cells, reduction of rooting, and inhibition of buds growth and even shoot development (Hartmann and Kester, 1990; Blythe et al., 2004; Ranjbar and Ahmadi, 2016).

Conclusion

Cutting position and type of culture medium influenced the success rate and percentage of rooting and different growth characteristics (number of roots, root length, length of the longest root, stem length, and fresh and dry weights of root and plant) in pepino cuttings. In conclusion, the results of the first experiment indicated the superiority of terminal cuttings over the middle ones and also more suitability of peat moss + perlite and peat moss + sand substrates compared to other substrates for the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1035710369

propagation of pepino. Study of the effect of auxin hormone and rooting medium in the second experiment showed that treatment of the cuttings with 500 mg/l IBA was more effective than concentration of 1000 mg/l. Peat moss + perlite and peat moss + sand substrates were more suitable than other substrates. In general, it was found in this study that the best treatment combination to increase the rooting of cuttings and to improve the growth characteristics of pepino seedlings is the use of terminal cutting, rooting hormone of IBA at concentration of 500 mg/l, and planting of cuttings in peat moss + perlite and peat moss + sand media. Finally, it is highly recommended that future investigators compare rooting of different cultivars of pepino simultaneously under different light and carbon dioxide regimes.

(Received 27th Sep 2018; accepted 16th Jul 2019)

Abstract. OBJECTIVE: To study the correlation between plant diversity and the physicochemical properties of soil microbes. METHODS: The determination of the chemical properties of farmland soil in the research area can be achieved by potentiometer method, automatic analyzer method, molybdenum-antimony anti-colorimetric method and gas chamber method. Based on the determination results, the relationship between plant diversity and soil microbial physical and chemical properties in the national nature reserve in rocky desertification area can be analyzed. RESULTS: The physical and chemical properties of soil in different grades of rocky desertification were significantly different. With the increase of rocky desertification, soil physical and chemical properties showed a response process from degradation to improvement. Soil organic matter, nitrogen, capillary water holding capacity, bulk density and porosity were significantly correlated with plant diversity, which played an important role in improving soil physical and chemical properties and promoting the restoration of plant diversity. Factor analysis showed that plant diversity at different levels in national nature reserves had different correlation with soil physical and chemical factors at different levels. The ratio between the significant correlation factors and the number of plants showed that the diversity of trees was greater than that of shrubs, and the diversity of shrubs was greater than that of herbaceous plants. Tree plant diversity factor plays a leading role. CONCLUSION: With the proposed method the physicochemical properties of soil microbes can be effectively studied.
Keywords: *plant diversity, soil, microbes, physical and chemical properties, rocky desertification, the related factors*

Introduction

Rocky desertification refers to the unreasonable social and economic activities of human beings in a fragile ecological environment, resulting in contradictions between people and land, vegetation destruction, soil erosion, gradual exposure of rocks, declining or even loss of land productivity, and presenting an evolutionary process or result similar to a desertified landscape (Steinauer and Tilman, 2016). The poverty-stricken population in the southwestern part of China is relatively concentrated, and the contradiction between people and land is very prominent (Bazerman et al., 2017; Jiang et al., 2017; Sun et al., 2016). Once the vegetation on the slope is destroyed, the soil erosion of the farmland is intensified, resulting in the loss of all the thin soil layers and serious rocky desertification, and the water and nutrient storage capacity is rapidly reduced. Rocky desertification has become a major ecological problem that restricts regional economic and social development in southwest China (He and Tang, 2016). Rock desertification governance has become an important part of Chinese social and economic construction. However, the current research on rock desertification restoration

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1037110388

ecology lags far behind the practice of rock desertification control (Thakur and Milcu, 2015). The restoration and reconstruction of rocky desert ecosystems seriously lacks the scientific support of relevant theoretical research, resulting in insignificant results of rocky desertification control. There are a series of problems such as simple structure, poor stability and weak resistance, which are difficult to maintain the governance results after the treatment of rocky desertification (Nyemb et al., 2018; Sudhan et al., 2018).

Species diversity is a manifestation of biodiversity at the species level, which can characterize the structural complexity of a biome, reflecting the structure type, organization level, development stage, stability level and habitat level of the community. It is an important organic component of biodiversity and is a research hotspot in the field of ecology (Zhalnina and Dias, 2015). At the same time, the restoration of species diversity is one of the most important features in the process of vegetation restoration. The farmland soil is an important part of the terrestrial ecosystem, and it is the carrier of many ecological processes of the ecosystem. It is an indispensable research content in the process of plant community renewal and succession. Through the study of the changes of soil physicochemical properties in the process of ecosystem succession under specific environmental conditions (Li and Zhang, 2015a), it will help to understand the interaction and mechanism of above-ground and underground interactions in the evolution of ecosystems, and then provide a scientific basis for the process of artificially regulating forest regeneration succession (Lloret and Mattana, 2015). But so far, although the research on the single ecological process of ecosystem is deep, the research on the correlation between ecosystem plant diversity and soil physicochemical properties is lack of in-depth research, and there is no research on the response of its spatial and temporal differentiation and its succession to rocky desertification (Camara et al., 2018; Shen et al., 2017; Xiao et al., 2018). After artificial regeneration and succession of rocky desertification environment, there is still a lack of research on what are the characteristics and trends of plant diversity and soil physicochemical properties, how the succession of artificial vegetation affects the evolution of underground farmland soil, and what kind of forest vegetation can be constructed to improve the soil properties of farmland in this area (Weidner and Koller, 2015). Therefore, this study in 2017, and national nature reserve in rocky desertification area as the research object, research on plant diversity and soil physical and chemical properties and their relations, and explore the plant diversity and changes of soil physical and chemical properties and their reaction mechanism, in order to provide theoretical support for forest ecological protection and ecosystem restoration and reconstruction of rocky desertification in Guizhou, even in Southwest China.

Material and methods

Overview of the study area

In this study, three typical rocky desertification areas and one national nature reserve as research areas are selected, which represents the different climates, topography, vegetation zoning and farmland soil conditions in a rocky desertification area.

The research area 1 is mainly located in the plateau mountainous areas of the Guizhou Province. The terrain is undulating and the elevation is 1400-1742 m. The annual average rainfall of the basin is 863 mm, the annual maximum precipitation is 995 mm, and the annual minimum precipitation is 618 mm. Rainfall is mainly distributed from July to September, accounting for 52% of the total annual rainfall. The

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1037110388

rock is dominated by carbonate-like limestone, with some Jurassic purple sand shale and shale distribution (Mellado-Vázquez and Lange, 2016). The farmland soil is dominated by yellow loam and purple sand. The vegetation is a subtropical evergreen deciduous coniferous and broad-leaved mixed forest, and the native vegetation is basically destroyed. It is now dominated by secondary forests (Kolton and Graber, 2016). The wild vegetation is vines, thorns, shrubs, which are mainly Pyracantha angustifolia, Rosa roxbunghii, Pyracantha fortuneana, Clematis florida and sporadic distribution of Cyclobalanopsis glauca, Pinus massoniana, Betula luminifera.

Study Area 2 is located in the township of the Guizhou Province, 12 km away from the county seat. The landform type is a typical plateau basin. The slope of the central part of the dam is slow, and the elevation in the basin is 1271-1451 m. The annual average rainfall of the basin is 1215 mm, and the rainfall is mainly distributed from April to August, accounting for 75% of the total annual rainfall. The rocks are mostly Triassic dolomite, argillaceous dolomite and shale. The farmland soil is dominated by yellow soil and yellow lime soil. Natural vegetation accounts for a small proportion of the area. The common arbor is mainly cedar (Vej and Lamentowicz, 2015), and the shrub layer is mostly typical limestone thorn bush, with Viburnum chinshanense, Pyracantha fortuneana, Rubus corchorifolius, and Rhamnus hemsleyana, etc., common species of the herbaceous layer are Imperata cylindrica, Miscanthus floridulu, Miscanthus sinensis, Arthraxon hispidus, Clematis florida, etc.

The study area 3 is located on the banks of the canyon of the Guizhou Province. The landform types are divided into two parts: the plateau area and the canyon area. There are mainly five types of landforms in the basin, and four types are karst landforms with an altitude of 450-1450 m. The difference is 1000 m. The annual average rainfall of the basin is 1100 mm, and the rainfall is mainly distributed from May to October, accounting for 83% of the total annual rainfall. The rocks are mostly Triassic dolomite, argillaceous dolomite and shale (Zhang and Johnston, 2017). The farmland soil is dominated by yellow soil and yellow lime soil. The vegetation is a subtropical evergreen deciduous coniferous and broad-leaved mixed forest, and the primary vegetation is basically destroyed. It is now dominated by secondary forests. The wild vegetation is vines, thorns, shrubs, which are mainly Pyracantha angustifolia, Rosa roxbunghii, Pyracantha fortuneana, Clematis florida and sporadic distribution of Cyclobalanopsis glauca, Pinus massoniana, Betula luminifera

Study area 4 is carried out in a certain test area of the Guizhou Province. The test area is located in a national nature reserve in the Guizhou Province. Except for a small amount of sand shale leakage, it is mainly composed of pure dolomite and limestone with exposed peak clusters, peak forests and Canyon landforms, as well as limestone soil and evergreen deciduous broad-leaved mixed forest (Zhou and Zhang, 2016). The test area belongs to the mid-subtropical mountain monsoon humid climate, with an average annual temperature of 15.3 °C, an average temperature of 5.2 °C in January, an average temperature of 23.5 °C in July, a growth period of 237 d, annual rainfall of 1752.5 mm, and concentrated distribution from April to October. The annual average relative humidity is 83%, and there are 827 species of 408 families and 408 genera of vascular plants, such as calcicole (Manglietia calcarea, Rhammus calcicolus, Cinnamomum calcarea, Phoebe calcarea, Stachyurus lipoensis, Camellia rubimuricata, Indosasa lipoensis, Acer liponsis, Hoya lipoensis and Tengia scopulorum), and national key protected plants (Handeliodendron bodimieri, Amentotaxus argotaenia,

Research methods

Sample setting

Based on the detailed investigation of the rocky desertification research area, five typical stages in the process of rock desertification succession are selected as the research objects, namely rockless desertification, potential rocky desertification, mild rocky desertification, moderate rocky desertification and intensity rocky desertification. The classification of rocky desertification is based on the results of expert research (Sun and Müllerschärer, 2015). For the five rocky desertification eco-environments, 45 research samples are set up in each of the four research areas, each of which has an area of 20 m × 20 m. The details of the sample are shown in *Table 1*. To analyze the physical and chemical properties of soil microorganisms, the basic information of the soil samples for the experiment should be clearly known. The basic information of the sample soil is given in *Table 1*.

In a national nature reserve, survey lines are set along the core area, buffer zone and test area, and the outer edge of the protected area. The number of forest survey plots established in different functional areas (interference levels) series are 12, 17, 9 and 3, respectively. One. The survey plot area is 20 m × 20 m, and the altitude, slope direction, slope position, slope, parent rock and farmland soil type are recorded (Baćmaga and Wyszkowska, 2016). Each plot is investigated for three layers of plants: arbor, shrub and grass. Diameter at breath height (abbreviated as DBH, the same below) ≥ 5 cm is classified as arbor and DBH < 5 cm is classified as shrub. The sample area is 10 m × 10 m in the arbor layer, 10 m × 10 m in the shrub layer, and 10 m × 10 m in the herb layer and the litter layer. The shrub layer, herb layer and litter layer are respectively set up three, representing that the development of each layer of plants or forest litter quantity is better, general, poor type. Among the vegetation survey indicators, the plants in arbor layer include the species name, DBH, tree height, number of plants, height under the branches, crown width and coverage, the plants in shrub layer include species name, ground diameter, height, number of plants and coverage, and plants in herbaceous layer include species, number of plants, height and coverage (Markowicz and Woźniak, 2015). The field sample is completed once in the first half of August of the survey year 2017.

Analysis of plant diversity

In October 2017, the density (strain/ m^2), average crown width (m^2 /strain) and coverage (%, That is, the proportion of the total area of the crown and the total area of all the trees), average DBH (cm/strain), average height (m/strain), and aboveground biomass are used to calculate community diversity (Yan and Zhang, 2016). The diversity measure indicators are:

Richness:

$$R = S \quad \text{(Eq.1)}$$

Shannon-Wiener index of diversity:

$$H = -\sum_{i=1}^{s} (Pi \ln Pi) \quad \text{(Eq.2)}$$

Uniformity index:

$$E = H / \ln S \quad \text{(Eq.3)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1037110388

Simpson dominance index, $D = \sum_{i=1}^{s} Pi^2$, S represents the total number of species in the community, Pi is the proportion of the number of individuals of species i to the total number of individuals in the community, i.e. $Pi = n_i / N$, n_i is the number of individuals of species i, N is the total number of individuals observed.

Collection of farmland soil samples and analysis of their physicochemical properties

(1) Collection of farmland soil samples in the rocky desertification research area

In the center of each plot, three sampling points are selected in a serpentine manner, and the spacing between the points is within 5 m. In October 2017, samples are taken 3 times at each point with a cutting ring (0-15 cm) and uniformly mixed to form a soil sample to be tested (Li and Zhang, 2015b). In a rocky desertification area, the farmland soil is very thin, and some of it is only about 15 cm. Therefore, it is used as a research object in the 0-15 cm farmland soil layer.

(2) Determination of soil physical properties in farmland

The volumetric weight, field water holding capacity, natural water content and capillary water holding capacity are determined by cutting ring method; total porosity is calculated by $p_t = 93.947 - 32.995 \times b$, b is bulk density, p_t is total porosity; capillary porosity is determined by cutting ring method; $p_o = p_t - p_c$ is used to calculate non-capillary porosity, p_o is non-capillary porosity, p_c is capillary porosity; permeability characteristics are determined by double-ring permeation.

(3) Determination of soil chemical properties in the study area

The pH value is determined by the potentiometer method using a water-to-earth ratio of 2.5:1. The organic matter is determined by oxidation of potassium dichromate with sulfuric acid to volumetric method; the whole nitrogen is potassium borate with copper sulfate as the selenium powder, and the automatic analyzer is determined by nitrogen analyzer. Hydrolyzed nitrogen is determined by alkali diffusion method; total phosphorus is determined by sulfuric acid for perchloric acid digestion and molybdenum anti-colorimetric method; effective phosphorus is determined by sodium bicarbonate extraction for molybdenum antimony colorimetric method; Hydrofluoric acid is determined by perchloric acid decoction flame photometer; available potassium is determined by flame photometric method using neutral ammonium acetate extraction (Ma and Baskin, 2017); farmland soil respiration is determined by gas chamber method.

(4) Collection and analysis of farmland soil samples in a national nature reserve

Combined with the plot survey, farmland soil sampling points are set up in each plot according to the three types of good, general and poor under-forest vegetation development. After removing the litchi cover layer of the sampling point, only the layer A of the farmland soil, or the layer A and the layer B, are sampled separately. The total weight of the soil sample of each layer is about 1 kg, and the soil sample is brought back to the laboratory under natural conditions. After air drying, the roots and gravel visible to the naked eye and the roots and coarse sand with a 1 mm mesh sieve are

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1037110388

removed, and the main chemical indicators of the farmland soil after grinding are determined (Baleshta and Simard, 2015). At the same time, according to the soil profile of farmland, the ring knife and sealant seal are extracted and brought back to the laboratory to analyze the main physical indexes of farmland soil, record the rock exposure rate of the sample plot, soil thickness, color, texture, root volume and amount of gravel.

Data processing and analysis

Drawing is performed using Excel software, and statistical analysis of variance analysis, t-test, multiple comparison (Duncan test), correlation analysis and principal component analysis are performed using SPSS 16.0 software (Økland and Nordbakken, 2016).

Calculation of plant diversity index:

Important value of arbor layer species:

$$IV = \frac{RD + RF + RT}{300} \quad \text{(Eq.4)}$$

In *Equation 4,* RD is the relative dominance, RF is the relative frequency, and RT is the relative density.

Species richness – Margalef index:

$$Mar = \frac{S - 1}{\ln N} \quad \text{(Eq.5)}$$

Ecological dominance – Simpson index:

$$Sim = 1 - \sum_{s=1}^{s} \frac{N_i(N_i - 1)}{N(N - 1)} \quad \text{(Eq.6)}$$

Information diversity – Shannon-Wiener index of:

$$Sha = -\sum_{s=1}^{s} P_i \ln P_i \quad \text{(Eq.7)}$$

Uniformity index – Pielon index:

$$Pie = \frac{H}{\ln S} \quad \text{(Eq.8)}$$

In the above equations, S represents the number of species, and N_i and N represent the number of species and all species, respectively

$$P_i = N_i / N \quad \text{(Eq.9)}$$

Results

Vegetation species composition and plant diversity of different grades of rocky desertification environment

Species composition

Vegetation species survey results show that the vegetation composition of rocky desertification environment is simple, and with the deepening of rocky desertification, the vegetation species composition shows a decreasing trend, and the Huajiang River with the highest degree of rocky desertification (Research Area 3) has the simplest vegetation community. There are only 8 families, 12 genera and 13 species in the layer, and there are only 10 families, 13 genera and 13 species in the wood layer. The richness of vegetation species in a rocky desertification area is also very low. Most species are 1 family, 1 genera and 1 species, and only 1 has Compositae, Rosaceae, and Gramineae. The families of Caprifoliaceae, Moraceae, Euphorbiaceae, and Rhamnaceae are mostly of many life types, indicating that these groups have better adaptation to the rocky desertification environment.

Among them, the Rosaceae species have more genus, species and life-type distribution in the potential and mild rocky desertification environment, but the distribution in the rocky desertification environment drops sharply, showing the adaptability of same species for different grades of rocky desertification environment has significant differences. The important value study of species also shows that there are significant differences between the established and dominant species of plant communities in different grades of rocky desertification. In the potential-light rocky desertification environment, species such as Saccharum arundinaceum, Robinia pseudoacacia, Ligustrum lucidum, and Artemisia dubia are dominant or established species of plant communities; In the light-moderate rocky desertification environment, the dominant or established species of plant communities are Miscanthus floridulus, Setaria viridis, Pteris multifida, Leptorhabdos parviflora, Viburnum propinquum, Itea yunnanensis and other species; in the moderate-intensity rocky desertification environment, the dominant species or plant species of the plant community are foxtail, Arthraxon hispidus, Broussonetia papyrifera, Lonicera japonica, Ampelocalamus calcareous, etc. *Table 2* shows the adaptability differences of rocky desertification environments at different levels.

Plant diversity

The plant diversity of four research areas was detected by Hashi Amtax NA8000 ammonia nitrogen automatic monitor. The following results were obtained. The results show that the four indices of plant diversity in rocky desertification environment are low (*Table 3*), indicating that the rocky desertification plant ecosystem has been destroyed, and the restoration succession is at a lower stage. The results also show that the four indexes of plant diversity in different grades of rocky desertification environment are significantly different: (1) The uniformity index of rockless desertification environment is significantly larger than the potential rocky desertification, and the potential rocky desertification is significantly larger than the mild, moderate and intensity rock desertification. (2) The environmental richness index of rockless desertification and mild rocky desertification is significantly larger than that of potential rocky desertification. (3) The environmental diversity index of rockless

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1037110388

desertification, potential rocky desertification and mild rocky desertification is significantly smaller than that of intensity rock desertification. There is no significant difference between rockless desertification, potential rocky desertification and mild rocky desertification. (4) The dominance index of potential rocky desertification environmental is significantly larger than other rocky desertification environments. It can be seen that among the four indices of plant diversity of rocky desertification environment, only the uniformity index change is significantly coupled with the succession of rocky desertification grade, showing a trend of decreasing with the increase of rocky desertification degree.

Table 2. *Adaptability differences of rocky desertification environment in different grades*

	Light-moderate rocky desertification environment	**Potential-light rocky desertification environment**	**Moderate-intensity rocky desertification environment**
Dominant species	Miscanthus floridulus, Setaria viridis, Pteris multifida, Leptorhabdos parviflora, Viburnum propinquum, Itea yunnanensis and other species	Saccharum arundinaceum, Robinia pseudoacacia, Ligustrum lucidum, and Artemisia dubia are dominant or established species of plant communities	foxtail, Arthraxon hispidus, Broussonetia papyrifera, Lonicera japonica, Ampelocalamus calcareous, etc

Table 3. *Plant diversity indices in different grades of rocky desertification environment*

Degrees of rocky desertification	**Evenness index**	**Richness index**	**Shannon-Wiener index**	**Dominance index**
Nil	12.65 ± 0.35a	12.65 ± 0.63a	2.26 ± 0.63ab	0.28 ± 0.09b
Potential	1.33 ± 0.26b	6.53 ± 0.35b	1.82 ± 0.52a	0.58 ± 0.09b
Low	0.38 ± 0.12c	12.17 ± 0.28a	2.48 ± 0.67ab	0.32 ± 0.08b
Middle	0.42 ± 0.11c	10.75 ± 1.02ab	2.91 ± 0.57bc	0.17 ± 0.05b
High	0.75 ± 0.13c	9.26 ± 0.67ab	3.28 ± 0.74c	0.13 ± 0.05b

The numerator value is the layer A of farmland soil and the denominator is the layer B of farmland soil

Correlation between plant diversity and soil physicochemical properties

The results of the correlation between plant diversity and soil physicochemical properties shows that (*Table 4*), there is a significant correlation between plant diversity in rocky desertification and soil physicochemical properties: (1) the richness index is negatively correlated with bulk density, total porosity, field water content, capillary water content, upper saturated permeability, organic matter, total nitrogen, total phosphorus and hydrolyzed nitrogen, and positively correlated with pH value, available potassium and soil respiration. (2) Diversity index is negatively correlated with bulk density, but positively correlated with total porosity, field water content, capillary water content, pH value, organic matter, total nitrogen and hydrolyzed nitrogen, and positively correlated with available phosphorus and available potassium. (3) The uniformity index had a significant negative correlation with pH and available phosphorus, a significant negative correlation with total phosphorus, a significant positive correlation with total potassium, and a significant positive correlation with soil respiration in farmland. (4)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1037110388

The dominance index has a significant negative correlation with capillary porosity, and has a significant negative correlation with field water holding capacity, pH value, total nitrogen, total phosphorus and hydrolyzed nitrogen, and a significant positive correlation with the lower layer saturated permeability. There is a significant positive correlation with non-capillary porosity. It can be seen that changes in soil physicochemical properties of farmland in rocky desertification environment can easily affect the characteristics of plant diversity.

Table 4. *Correlation between physical and chemical factors of rocky desertification and plant diversity*

Soil physical-chemical factors	Richness index	Shannon-Wiener index	Evenness index	Dominance index
Bulk density/(g/cm^3)	-0.454**	-0.408**	-0.013	0.174

(In the table, * means general correlation, ** means significant correlation.)

The degree of dimensionality of plant diversity index and soil main physical index of a national nature reserve is obvious (factor extraction value > 1.0), and the cumulative variance contribution rate of trees, shrubs, herbaceous plant diversity factors and other factors in soil layer A and layer B is 90.00%, 91.49%. The cumulative variance contribution of the water holding capacity factor dominated by soil density, maximum water holding capacity and field water holding capacity, and the porosity factor dominated by non-capillary porosity, capillary porosity and total porosity in layer A and B is 95.75%, 94.63%. The main chemical index value of the soil has a large dimensionality difference (factor extraction value > 0.5). The common factor includes the fertility factor dominated by organic mass, total nitrogen and hydrolyzed nitrogen, and the amount of cation exchange, exchangeable salt base and the total phosphorus-dominated nutrient factor, the nitrogen factor dominated by total nitrogen, exchangeable salt base and pH, and the layer A also has a phosphorus factor dominated by total phosphorus, available phosphorus and cation exchange, potassium factor dominated by

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1037110388

potassium, organic matter and hydrolyzed nitrogen, and phosphorus factor in soil layer B dominated by effective phosphorus and exchangeable salt base, potassium factor dominated by total potassium, available potassium and cation exchange. The cumulative variance of soil fertility, nutrient, nitrogen, phosphorus and potassium factors in layer A and B is 83.06% and 87.60%.

Changes in main physicochemical indicators of farmland soil in a national nature reserve

There are no significant differences in the main physical indices of farmland soils between different forest types (*Table 5*). Farmland soil density, capillary porosity and total porosity, as well as maximum water holding capacity and field water holding capacity shows a trend of layer A > layer B. The non-capillary porosity values in the type I, III and V show the trend of layer A > layer B, in line with the general law; analysis of type II and IV showing the trend of layer B > layer A is due to the fact that there are many fractures in the parent rock at the sampling point part of the farmland soil in 50% of the plot, and the underground erosion of the layer Bin farmland causes the non-capillary porosity to be higher, and the other 50% of the sample is still in the trend of layer A > layer B. Type IV forest land has high rock exposure rate, low farmland soil density value, non-capillary porosity and total porosity, and maximum water holding capacity and field water holding capacity; Type III forest rock has low bare exposure rate, thin soil layer, small farmland soil density value, non-capillary porosity and total porosity, and maximum water holding capacity and field water holding capacity. The rock exposure rate and soil physicochemical indicators of type I and II forests are middle and the change is large.

Table 5. *Change of main physical indexes of soil of different karst forest types*

Types	Profile property				Porosity			Water holding capacity	
	Slope/(°)	Bare rock rate/%	PD/cm	Density/ (g/cm^3)	Capillary porosity/%	Non-capillary porosity/%	Total porosity/%	Field capacity/ ($\times 10^2 g/kg$)	Maximum water capacity/ ($\times 10^2 g/kg$)
Study area I	13.66	34.4	17.8	1.138/1.212	45.95/42.32	7.50/4.84	53.45/47.16	4.172/3.520	4.927/3.989
Study area II	11.22	25.96	11.48	1.281/1.331	41.80/36.70	6.0/7.85	47.80/44.55	3.138/2.639	3.740/3.347
Study area III	15.67	15.67	11.33	1.086/1.360	48.70/40.00	6.57/5.83	55.27/45.83	4.353/2.921	5.107/3.420
Study area IV	16.25	69.5	12.25	0.958/1.203	56.30/44.78	3.08/4.50	59.38/49.28	5.743/3.810	6.384/4.106

In the table, the numerator value is the layer A of farmland soil and the denominator is the layer B of farmland soil.

There are no significant differences in the main chemical indices of farmland soils between different forest types (*Tables 6* and *7*). The pH value and total potassium content of farmland soil shows the trend of layer A < layer B; the trend of soil organic matter quality, cation exchange amount, exchangeable salt base amount, total nitrogen amount, total phosphorus amount, hydrolyzed nitrogen amount, available phosphorus amount and available potassium is layer A > layer B. The change trend of total phosphorus and total potassium in layer A and B layer of farmland soil is different from other types, among which 50% of farmland soil total phosphorus and 75% of farmland soil total potassium change are contrary to the general law, which is related to the heterogeneity of farmland soil sample sites and farmland soil heterogeneity and the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1037110388

underground erosion formed by the parent rock fissures. The soil fertility and nutrient index of type IV farmland are higher, the soil fertility and nutrient index of type III farmland are lower, and the soil fertility and nutrient index of type I, II and IV are middle, with larger variation.

Table 6. *Change of main soil fertility indexes of different karst forest types*

Types	pH	Organic mass/$(\times 10 g / kg)$	Cation exchange capacity/$(\times 10 cmol^{*} / kg)$	Exchangeable base amount/$(\times 10 cmol^{*} / kg)$
Study area I	6.55/6.62	6.32/3.34	3.89/2.44	1.08/1.07
Study area II	6.38/6.41	2.49/1.89	2.22/1.30	0.86/0.86
Study area III	6.05/6.22	6.14/2.16	4.24/2.82	1.50/1.18
Study area IV	6.46/6.63	5.95/3.40	6.30/4.63	3.34/3.08

The numerator value is the layer A of farmland soil and the denominator is the layer B of farmland soil.

Table 7*. Changes of main nutrient indexes of soil of different karst forest types*

Types	Total nitrogen content/(g/kg)	Total phosphorus content/(g/kg)	Total potassium content/ $(\times 10 g / kg)$	Hydrolysis nitrogen content/ $(\times 10^{2} mg / kg)$	Available phosphorus content/(mg/k)	Available potassium content/$(\times 10^{2} mg / kg)$
Study area I	2.63/2.52	0.30/0.29	3.99/4.02	2.65/1.64	2.76/1.85	1.68/0.91
Study area II	2.25/1.28	0.29/0.27	3.75/3.97	1.59/1.21	5.02/3.51	1.22/1.00
Study area III	4.87/0.98	0.22/0.13	4.15/4.38	2.97/0.90	1.65/1.46	2.54/1.32
Study area IV	4.92/2.02	0.35/0.40	4.53/4.38	3.10/1.51	2.13/1.56	2.49/1.51

The numerator value is the layer A of farmland soil and the denominator is the layer B of farmland soil

The correlation between different stratified plant diversity factors and soil physicochemical factors in different soil layers is different, which is consistent with the general characteristics of growth and development during the natural restoration process of trees, shrubs and herbaceous plants. According to the proportional relationship between relevant important factors and quantity in *Table 7*, the more nitrogen, phosphorus and potassium content in the study area, the richer plant diversity in the study area. The contents of nitrogen, phosphorus, potassium and other important factors in each class landform forest can fully explain the following results: The relevant significant factor-to-quantity ratios shows the trend of arbor layer (36.38%) > shrub layer (27.27%) > herb layer (18.9%), layer A in farmland soil (45.45%) < layer B (54.55%). The plant diversity factor of arbor layer plays a leading role.

Correlation between plant diversity index of arbor layer and soil physicochemical indicators in a national nature reserve

The correlation coefficient between the plant diversity index of forest arbor layer and the soil physicochemical index of farmland shows a trend of quadratic polynomial (QC) ≥ linear (SL). The significant indicators are 46.09% and 39.84%, respectively, showing the trend of the Layer A (QC = 21.88%, SL = 18.75%, the same below) < layer B (24.22%, 21.09%), Pielou index (14.06%, 13.28%) > Simpson index (12.50%, 10.94%) > Shannon-Wiener index (10.16%, 8.59%) > Margalef index (9.38%, 7.03%) as shown in *Table 8*. Among the related significant quantitative rate, the soil physical index of farmland is quadratic polynomial (66.67%) > linear (62.50%), layer A > layer

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1037110388

B, and the soil fertility index of farmland is quadratic polynomial (37.50%) > linear (31.25%), layer A > layer B, farmland soil nutrient index is quadratic polynomial (31.25%) > linear (22.92%), layer A < layer B in farmland soil. Significant correlations between plant diversity index in arbor layer and soil physical, fertility and nutrient indices are found. The logarithmic quantitative rate varies with species of diversity index, soil layers and types of physical and chemical indices, but the trend does not change with model types.

According to *Table 8*, based on the difference between the quadratic polynomial and the linear correlation between the plant diversity index and the farmland soil physicochemical indicators, it can be divided into three types. (1) The correlation is not significant, including farmland soil pH, total phosphorus and available phosphorus, the indicator rate is 53.91%, which is farmland soil layer A (28.13%) > B layer (25.75%)/Margale index (15.63%) > Shannon-Wiener Index (14.84%) > Simpson Index (12.50%) > Pielou Index (10.94%). (2) Only the significant type of curve correlation, including total potassium of layer B in farmland soil, etc., the indicator pair rate is 5.47%, showing the trend of layer A in farmland soil (2.34%) < layer B (3.13%), Pielou index (0.78%) < Simpson index (1.56%) = Shannon-Wiener index (1.56%) < Margalef index (2.34%).(3) Significant type of correlation. Both linear and quadratic polynomial correlations are significant, including farmland soil density, field water holding capacity and maximum water holding capacity, organic quality of layer A in farmland soil and available potassium of B layer. The indicator rate is 40.63%, which shows the trend of layer A (19.53%) < layer B (21.09%) and Margalef index (7.03%) < Shannon-Wiener index (8.59%) < Simpson index (10.94%) < Pielou index (13.28%).

Discussion

Discussion on the plant diversity of rocky desertification environment and the physicochemical properties of farmland soil

Compared with the experimental results of traditional methods, the results of this paper show that there is no obvious coupling relationship between the richness index, diversity index and dominance index of rocky desertification plant community at different levels and the succession of rocky desertification. This should be the result of human interference. After the natural state is superimposed by human activities, the natural law of vegetation restoration is disturbed. The change of evenness index has remarkable coupling relation with the succession of rocky desertification degree. With the increase of rocky desertification level, the evenness index showed a trend of gradual decrease, indicating that the evenness index of plant diversity should be an important basis for plant community evaluation in rocky desertification areas. The deterioration of rocky desertification environment leads to the decrease of plant diversity. The evolution of farmland soil properties under rocky desertification is not a process of degradation with the increase of rocky desertification level, but a gradual process of degradation and then improvement. The reason is the result of soil erosion of rocky desertification and soil nutrient accumulation of bare rocky desertification. With the increase of rocky desertification, the accumulation effect of bare rock increased gradually, and the input of soil nutrients in farmland increased. With the increase of rocky desertification, soil loss can be reduced, soil erosion is weakened, and soil nutrient loss of corresponding farmland is weakened. The combination of these processes leads to the gradual improvement of degraded farmland soils. The evolution process of the physical and chemical properties of farmland soil in rocky desertification is as follows: when forest vegetation is destroyed in rocky desertification environment, the loss of soil nutrients in farmland increases with the increase of soil and water loss, the input of organic matter in garbage decreases, the bulk density of farmland soil increases, nitrogen and water capacity decrease, and farmland soil degradation. The accumulation of nutrients and karst products in the atmosphere increased, and the input of organic matter and nitrogen in farmland soil increased. At the same time, with the increase of rocky desertification

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1037110388

degree, soil loss can be reduced, soil erosion weakened, soil nutrient loss in farmland reduced, soil nutrient and farmland physical properties gradually improved.

Discussion on plant diversity and soil physicochemical properties of a national nature reserve

In this paper, the distribution of the same type of cross-adjacent functional area exists in the forest type by the important value of the arbor layer species. Because the important value only reflects the dominant degree of the species in the community, does not reflect its growth and development stage, and there are different functional areas, the type of division can still be interpreted. The application of other indicators may better express the types of forests in different functional areas, but the main indicators and related trends of vegetation-farm soil systems will not change. In this paper, the significant differences in soil organic matter, total nitrogen, hydrolyzed nitrogen, available phosphorus and available potassium are different. The plant diversity index is similar to that of farmland soil. The correlation coefficient of the index value decreases or increases with the increase of the soil layer thickness. The correlation significant index shows the trend of the layer A < layer B, which is different from the non-natural secondary forest and similar to other natural secondary forests. It indicates that the correlation between forest plant diversity index and soil physicochemical index values is specific between soil layers.

Restoration and reconstruction of degraded ecosystems in rocky desertification area

The rocky desertification ecosystem has a simple vegetation community and a very low abundance. The rocky desertification environment has significant stress on its plant distribution. The plants in rocky desertification environment must have the characteristics of stone nature, calcium tolerance and drought tolerance, but also have a well-developed and strong root system, which has important guiding significance in the restoration and reconstruction of degraded ecosystems in rocky desertification area. The plants of Compositae, Rosaceae, Gramineae, Lonicerae, Euphorbiaceae and other plants are mostly distributed in rocky desertification environment, indicating that these groups have strong adaptability to rocky desertification environment, which provides an important reference for the application of vegetation restoration technology and the selection of pioneer species. Among them, the Rosaceae plants have more genus distribution in the potential and mild rocky desertification environment, while the number of species distributed in the intensity rocky desertification environment decreases significantly, indicating that the adaptability of adaptable species in different grades of rocky desertification environment are is significantly different. Therefore, in the process of controlling desertification and selecting species by rocky desertification, it is necessary to screen not only the species that adapt to the rocky desertification environment, but also the adaptive pioneer species for different grades of rocky desertification environment, so that it can achieve the expected goal of vegetation restoration in rocky desertification control. The degradation of fragile ecosystems is driven by strong human disturbances, with vegetation reduction as the cause, degradation of land productivity as the essence, and a composite process marked by similar desertification landscapes. The diversity and structural index of vegetation community in rocky desertification environment are low, and the stability is poor. Therefore, the vegetation with strong primitiveness and without disturbance should keep

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1037110388

the status quo and develop naturally. The disturbed rocky desertification ecosystem should supplement the post-successive propagules, paying special attention to the introduction of some top or sub-top species; secondary forest areas should be properly trimmed to maintain reasonable density, which is conducive to sexual reproduction and renewal chain as soon as possible. Recovery and rapid growth of forests promote the uniform distribution of species composition, rationalize the diversity, and achieve rapid restoration and formation of plant communities.

Conclusions

In this paper, a rocky desertification area and a national nature reserve are used as research objects to analyze the correlation effects of plant species diversity on the physicochemical properties of soil microbes. Three typical rock desertification areas and one national level nature protection are selected as the sample area. Through the collection and analysis of the physicochemical properties of the farmland soil samples in the rock desertification area, the results of the physical properties of the soils, such as the bulk density, field water capacity, natural water content, capillary water capacity, total porosity, capillary porosity, and non-capillary porosity, and the determination results of the chemical properties of the farmland soils such as pH, organic matter, total nitrogen, total phosphorus, total potassium, available phosphorus and available potassium are obtained. Based on this, the correlation between plant diversity and the physicochemical properties of farmland soil in the rocky desertification environment and the correlation between plant diversity and soil microbes in a national nature reserve are studied. After measuring the physicochemical indicators of farmland soil, the plant diversity index is calculated to study the physicochemical properties of farmland soils of different forest types. The change of index value is used to study the correlation between plant diversity of national nature reserve and soil microbes in farmland.

(Received 5th Dec 2018; accepted 1st May 2019)

Abstract. Livestock plays an important role in the economy of Pakistan. Small ruminants like sheep and goats, are highly susceptible to internal parasites, particularly gastrointestinal nematodes (GINs) including *Haemonchus contortus*. The present study was conducted in Pakistan to test the larvicidal and ovicidal activities with different concentrations of extracts of bulbs of domestic garlic (*Allium sativum*) and leaves of neem tree (*Azadirachta indica*) against *H. contortus*. In case of larval mortality, the highest mortality was recorded as 87% at 100% extract of neem leaves, while 100% extract of garlic bulb showed 67% mortality. The highest egg hatching inhibition (94%) was noted when neem leaves extract was used at 100% concentration, while in case of garlic extract, 100% concentration showed 80% inhibition of the eggs hatching. It was concluded that all the extracts of *A. indica* showed higher mortality and eggs hatching inhibition of *H. contortus* than *A. sativum*.
Keywords: *parasites, medicinal plants, eggs hatch assay, larval mortality assay*

Introduction

Agriculture always played a major role in the economy of Pakistan. In National Gross Domestic Product (GDP), agriculture contributes 24% in which share of livestock is 12%. According to the Ministry of National Food Security & Research the estimated population of domestic sheep (*Ovis aries*) was 30.5 million while domestic goats (*Capra aegagrus hircus*) were 74.1 million during 2017-18. It is also estimated that about 40000 tons of meat from sheep and 915000 tons from goats were obtained during the year 2017-18 (Economic Survey of Pakistan 2017-2018). But this important sector of agriculture is highly susceptible to gastrointestinal nematodes (GINs). Among GINs, *Haemonchus contortus*, a blood-sucking nematode that belongs to the family *Trichostrongylidae* and class *Secernentea,* causing a serious disease in small ruminants called Haemonchosis (Khattak et al., 2018).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1038910397

The clinical symptoms of this disease include hemorrhagic anemia, hypo-protein anemia, and parasitic gastroenteritis in animals especially in small ruminants like sheep and goats (Mola, 2018). *Haemonchus contortus* infestation causes major health problems including reduction in animal productivity in terms of meat, milk and wool. The major impacts of *H. contortus* in small ruminants are associated with the blood sucking activity that results in extensive blood loss (Bowman et al., 2009). Each parasite sucks 0.05 ml of blood per day. As a result, there is a decrease in total erythrocytes count, hemoglobin, packed cell volume, body weight, milk production and wool growth (Hepworth, 2006; Urquhart et al., 1996; Rasool et al., 1995). It is estimated that a sheep can lose 250 ml blood/day if infected with 5000 *H. contortus* worms. Life cycle of this parasite takes around 21 days to complete. Its life cycle is direct i.e. no secondary host is involved in cycle completion. Every adult female parasite lays 5000-10,000 eggs per day which are then passed out in the feces (Emery et al., 2016) as shown in *Figure 1*.

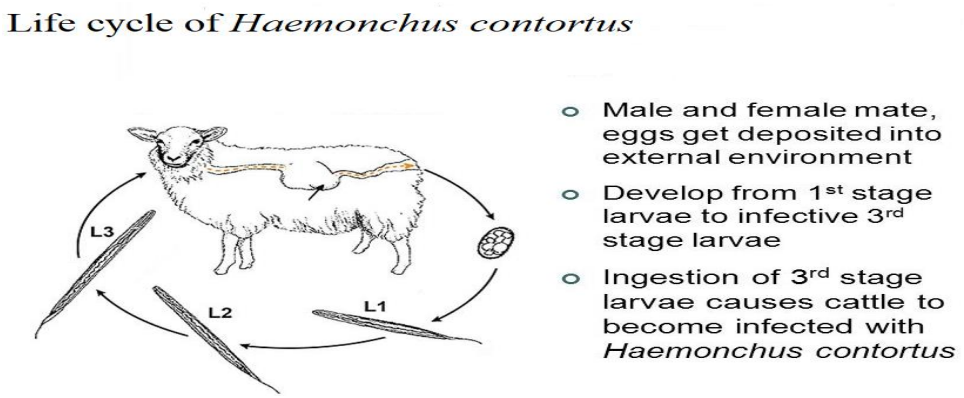

Figure 1. *Life cycle of Haemonchus contortus. (Reproduced from SlidePlayer.com)*

The frequent and un-judicial use of anthelmintic drugs has led to a growing problem of parasitic resistance against the conventional therapies. *Haemonchus contortus* is showing resistance to the most commonly used broad spectrum anthelmintics belonging to the classes; Benzimidazoles, imidazothiazoles and Macro cyclic lactones (Kaplan, 2004; Jackson and Coop, 2000; Sangster, 1999; Miller et al., 1987).

Garlic (*Allium sativum*) has been reported to be a parasiticide, amoebicide, larvicide and immune-stimulant (Duke, 2002). Essential oil of these plants can also be used as alternative or supplement to the current anthelmintics therapies (Anthony et al., 2004). Neem plant, (*Azadirachta indica)* is known for its medicinal properties and has been used against gastrointestinal nematodes and related problems in many parts of the world (Biswas et al., 2002). Therefore, the present study was designed with the objective to evaluate the anthelmintic properties of the crude extracts of Garlic and Neem plants against *H. contortus* in small ruminants.

Materials and methods

Sampling area

Adult *H. contortus* were collected from the infected abomasums of small ruminants from slaughter houses in district Kohat of Khyber Pakhtunkhwa, Pakistan as shown in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1038910397

Figure 2. The climate in Kohat is referred to as a local steppe climate. There is little rainfall throughout the year. This location is 33°34'47.1"N/71°26'29.3"E, elevation is 395 m/1296 feet and barometric pressure is 97KPa. The temperature here averages 22.8 °C. The average annual rainfall is 529 mm.

Figure 2. *Sampling area of district Kohat. (Reproduced from Google Maps)*

Collection and isolation of H. contortus

After collection of the adult parasites, female *H. contortus* worms were separated and placed in the Petri dish containing Phosphate Buffer Saline (PBS). Petri dish containing worms were kept in incubator at 37 °C. The identification of *H. contortus* was carried out on the basis of morphological features using standard keys (Urquhart et al., 1996) as shown in *Figure 3*.

Cultivation of infective larvae

After separation of female parasites from male parasites, eggs were recovered by grinding the female with pistol and mortar by adding 5 ml PBS. Eggs were incubated at room temperature for 72 h for the development of the infective larvae (L3). After cultivation, the infective larvae (L3) were maintained in the laboratory at 25-30 °C in sterile conditions.

Collection of plant materials

Fresh and healthy plant parts of Garlic (bulbs) and Neem (leaves) (disease free) were collected from various parts of the Khyber Pakhtunkhwa, Pakistan. After collection, the plants were washed with distilled water and dried with clean clothes and then kept in the laboratory for further processing.

Preparation of plant extracts

After drying, the plant materials were cut into small pieces followed by grinding into fine powder. The powdered material was mixed with methanol in conical flask and filtered through Whattman filter paper No. 1. The filtrate was then allowed to evaporate and make them concentrated.

DOI: http://dx.doi.org/10.15666/aeer/1705_1038910397

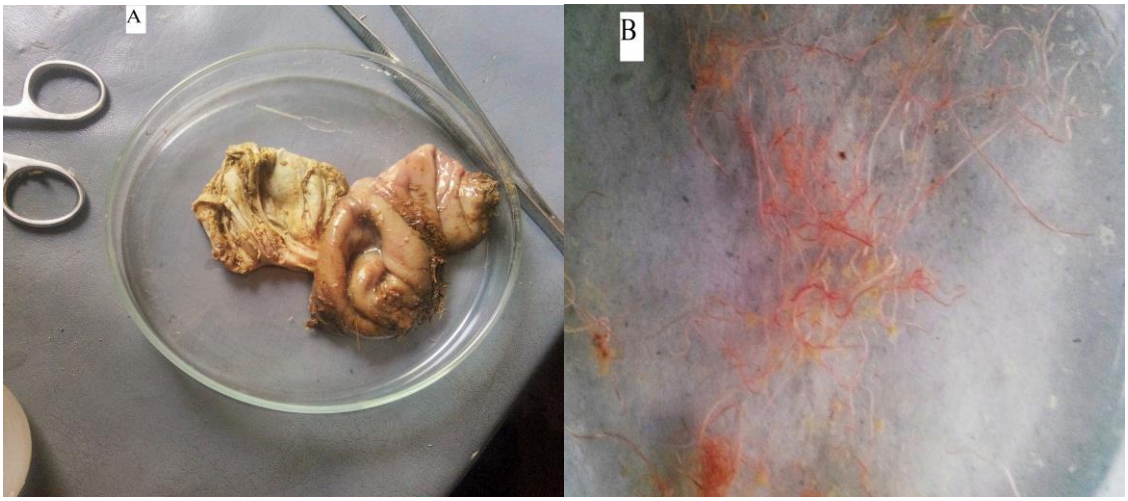

***Figure 3. A** Abomasum of infected sheep. **B** Adult worms harvested from infected abomasum*

Preparation of methanol extracts

10 gm of the Neem and Garlic powdered materials first weighted and then dissolved in 100 ml methanol solution in separate beakers in order to make 10% solution and mixed properly by magnetic stirrer for 15 min. The solutions were kept on rotary shaker for 24 h and the mixtures were then passed through Whattman filter paper No.1 to prepare filtrate. The filtrate was taken into cork labeled bottle in sterilized condition. Different concentrations of filtrate were made i.e. 50%, 25%, 12.5% and 6.25% by adding 2.5 ml PBS and 2.5 ml filtrate in separate petri dishes by serial dilution method. A 100% (5 ml) pure extract solution was taken as a mother solution having no PBS, where PBS (5 ml) was used as a control group.

Effects of plant extract on Haemonchus contortus

Mortality of *H. contortus* was checked after 6 h treatment to the various concentrations of Garlic (*Allium sativum*) and Neem (*Azadirachta indica*) extracts.

Statistical analysis

Student *t* test was used to statistically analyze the data and the significance level was kept as $P < 0.05$.

Results

Mean percentage mortality of L3 stage Larvae after 6 h post-exposure of various percentages of methanol neem extracts

The selected plants of different concentration of methanol extract, Neem (100%) was significantly effective against L3 stage larvae of *Haemonchus contortus.* The efficacy of methanol extracts of plants at different concentration presented in *Figure 4*. At 100% concentration, 87% mortality was observed. 53%, 43%, 37% and 23% mortality have showed by 50%, 25%, 12.5%, 6.25% concentrations, respectively. In case of L3, Neem showed highest mortality as compared to Garlic extract. In positive control there was 100% mortality as shown in *Figure 4*.

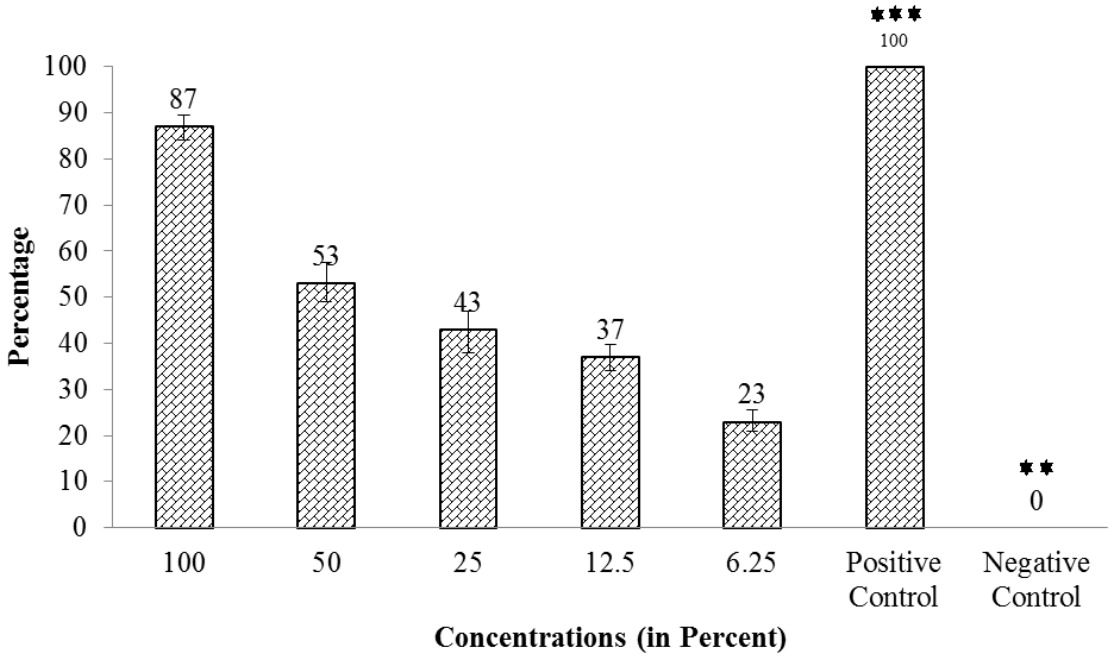

Figure 4. *Mean percent mortality of L3 stage larvae after 6 h post-exposure of various concentrations of methanol neem extracts*

Mean percentage mortality of L3 larvae after 6 h post-exposure against various percentages of garlic methanol extracts

It is evident from the data that Garlic diluted filtrate showed anthelmintics activity against L3 larvae but highest mortality has showed by 100% concentration which was noted as 67%. Moreover, 50%, 33%, 23% and 3% mortalities were shown by 50%, 25%, 12.5% and 6.25% solution, respectively. Whereas, in control group no mortality was noted as shown in *Figure 5.*

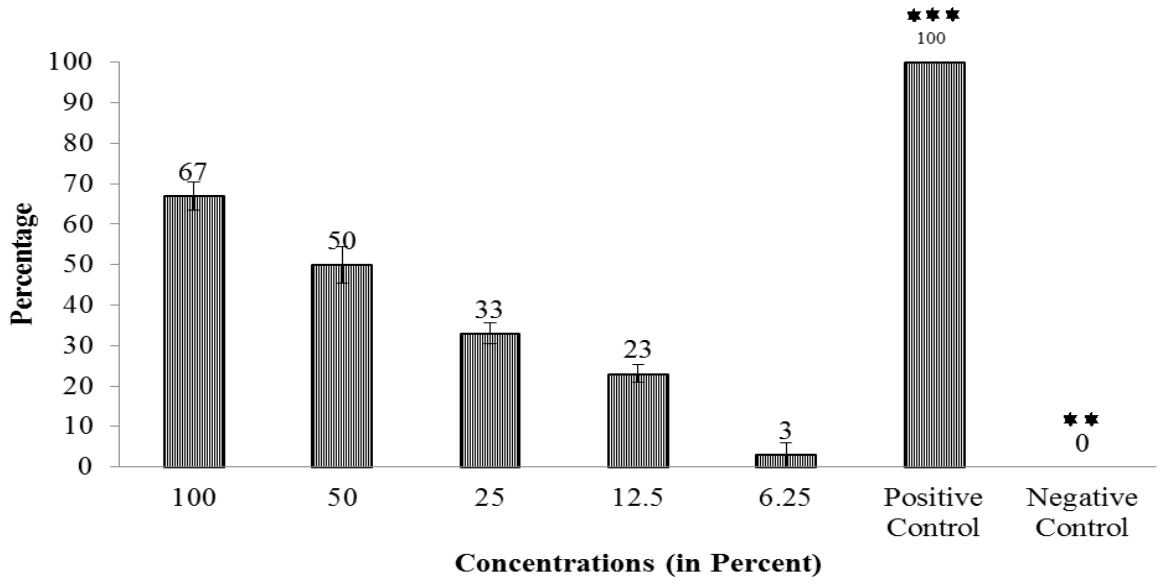

Figure 5. *Mean % mortality of larvae after treating 6 h with various concentration of methanol-based garlic extracts*

Percent inhibition of eggs hatching of H. contortus against Neem extract

At 100% Neem extract showed highest egg hatch inhibition which was 94% (*Table 1*). Second highest egg hatch inhibition was recorded for 50% methanol extract of Neem (72%), followed by 25% (54%) and 12.5% extract (33%). The lowest inhibitions were observed for 6.25% and 3.125% that were 20% and 8%, respectively.

Table 1. *Percent inhibition of eggs hatching of H. contortus against neem extract*

Concentration (%)	No. of egg inhibition in 1st trial	No. of egg inhibition in 2nd trial	No. of egg inhibition in 3rd trial	Mean of egg inhibition
100	94	96	92	94
50	75	70	72	72
25	58	53	50	54
12.5	35	32	33	33
6.25	20	18	21	20
3.125	8	9	7	8
Control	0	0	0	0

P = 0.9992 > 0.05, non-significant

Percent inhibition of eggs hatching of H. contortus against garlic extract

The 100% Garlic extract showed highest egg hatching inhibition i.e. 80% as shown in *Table 2*. At 50%, 25%, 12.5%, 6.25% and 3.125% egg hatching inhibition was recorded as 65%, 49%, 31%, 15% and 5%. The results infer that concentration is directly proportional to egg hatching inhibition**.**

Table 2. *Percent inhibition of eggs hatching of H. contortus against garlic extract*

Concentration (%)	No. of eggs after 3 days in 1st trial	No. of egg inhibition in 2nd trial	No. of egg inhibition in 3rd trial	Mean of egg inhibition
100	80	82	78	80

Discussion

To control *Haemonchus contortus*, common anthelmintics are applied but not enough to erase this parasite completely as it is reported to be resistant to all three broad spectrum families of anthelmintics viz. benzimidazole, lmidazothiazole and ivermectin and against drugs with narrow spectrum of activity such as salicylanilides anthelmintics (Kaplan and Vidyashankar, 2012; Eckert, 2008). *H. contortus* is one of the most prevalent nematode parasites of small ruminants i.e. sheep and goats (Coles et al., 2005). Keeping in view the importance of this blood sucker, there is need of alternative

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1038910397

methods other than common anthelmintics to prevent sheep and goats from this highly dangerous nematode parasite.

The present study was undertaken to check the mean percentage of egg hatching inhibition. Extract filtrate obtained from *Allium sativum* at different concentration showed mean of inhibited eggs of *H. contortus* in the range from 5% to 80% which is much similar when compared with work of (Hammad et al., 2012) who reported that there was a dose and time dependent antinematicidal activity of crude aqueous methanol extract (CAME) of *N. tabacum* leaves with estimated LC_{50} values of 0.566 in EHA. Another study conducted in Pakistan by (Sindhu et al., 2009) showed a similar result that in egg hatching test, based on the LC_{50} values, most effective plants (LC50 in ppm) in their order of activity were; *N. tabacum* (0.10), *S. lappa* (0.73), *A. indica* (1.73), *C. arvensis* (2.51), *T. chebula* (5.55) and *A. vasica* (15.74). The allicin may have an important role in penetration of nematode egg surface, resulting in death of juveniles inside hard and protective barriers. The Azadirachtin of *Azadirachta indica* may have an important role in penetration of nematode egg surface, resulting in death of juveniles inside hard and protective barriers.

The third stage larvae (L3) of *H. contortus* in the present study were treated with different concentrations of the selected plants. In case of larvae, the mortality was found to be 87% at 100% methanol *Azadirachta indica*. Whereas, in case of *Allium sativum* the highest mean percent mortality was 67% at 100% extract. The methanolic diluted filtrate extract of *Azadirachta indica* showed approximately same result to the published paper of Rahman (2002). Rahman (2002) recorded the highest efficacy of neem leaves in alcoholic extract whereas aqueous extract has the lower efficacy (92%) than alcoholic extract against gastrointestinal nematodiasis in goat. Sujon et al. (2008) also recorded that the efficacy of methanol extract of neem was 80% and 100% at 5% and 10% concentration, respectively. Niddhi et al. (2007), Rahman et al. (2011) and Radhakrishnan et al. (2007) also showed the efficacy of neem against Haemonchus contortus adult and L3 stage larvae.

Conclusion and recommendations

Medicinal plants traditionally used against *Haemonchus contortus* control showed therapeutic activity. The selected medicinal plants contain active agents especially Allicin in garlic and Azadirachtin in Neem. These plant extracts at absolute (100%) form have the ability to lower the *H. contortus* infestation in small ruminants i.e. sheep and goats. *Azadirachta indica* contain potent anthelmintics compounds and therefore this plant is strongly recommended for further research studies. Mode and mechanism of action of anthelmintics plants also need to be studied in detail.

Abstract. Ethnoecological knowledge refers to the local wisdom, innovations, traditional life style and practices of aboriginal communities. This knowledge also contributes a lot to understanding of conservation stata of culturally significant flora of a region. The present research work is the first one to focus on this particular aspect of cultural knowledge to assessing preliminary conservation status of 295 culturally significant plant species of district Tor Ghar. In such remote and less privileged areas interaction between plants and people is much stronger. Multistage random selection of 700 informants was made. The data was obtained through EPA, group discussion and semi structured interviews. The conservation status of all culturally significant plant species were assessed quantitatively by developing a new special mathematical relation that is CS = K (OC + AV + CE)/TF × RP. A scale was devised on the basis of CS value index and all 295 species were assigned to different IUCN categories. According to this classification 20 species were found critically endangered, 35 endangered, 56 vulnerable, 58 near threatened (rare) and 126 least concerned (secure). This categorization depicts a miniature of ethno-conservation of plants at local level. The current study leads to an enhanced understanding of cultural knowledge on mountain vegetation within the context of anthropogenic impacts and the role of indigenous communities in regional plant conservation strategies and future outlooks.
Keywords: *local wisdom, aboriginal, endangered, threatened, ethno-conservation*

Introduction

Biodiversity and culture of a region affect each other reciprocally. Local wisdom of communities popularly known as traditional knowledge, cultural knowledge, indigenous knowledge or local ecological knowledge. The body of knowledge usually includes understandings, beliefs, and practices that human societies develop longitudinally in relationship with their natural environment, and which are dynamic and co-evolving with social and ecological changes (Berkes, 2000; Zent, 2001; Von, 2011). This knowledge incorporates spiritual connections with the natural environment and the sustainable use of natural resources, and association between people, which are reflected in their language, narratives, social organisation, values, beliefs, and cultural

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1039910419

laws and customs (Andrews, 2006). Every aspect of life is touched and covered by the culture of a particular region. According to Larid (1999) culture facilitates the association between humans and their environment. The perception of culture provides the basis of scientific disciplines such as ecological anthropology and scientific concepts such as bio-cultural diversity (Berkes et al., 2000).

According to Declaration of Belem (1988) there is an "inextricable link" between biological and cultural diversity. The term bio-cultural diversity was coined to describe the concept indicating the link (Posey, 1999). Human beings and their societies are an essential part of biodiversity, and according to their way of utilizing natural resources, they can be promoters of its sustainable use or drivers of its loss (Calvo, 2003). Wild biological resources are especially important for populations in rural areas, because these people depend directly on the extraction of local species to fulfill part of their daily requirements, such as wood, food, medicine, and timber (Boom, 1987; Prance et al., 1987; Phillips et al., 1994).

Participation of indigenous communities in decision making related to natural resource management has been regarded as a potential effort that can boost local well-being without harming biodiversity and ecosystem functions (United Nations, 1992; Schwartzman et al., 2000; Adams and Hutton, 2007; Berkes, 2007).

Local communities have more close association with biodiversity and their cultural practices and life styles influence biodiversity greatly. According to Convention on Biological Diversity, local communities showing a socially and geographically defined group of people may not homogeneous, living close to biodiversity and protected areas. They may have customary rights of use, distinctive knowledge and skills and direct impact on biodiversity as individuals or groups of individuals. These people are also described as having a close and unique relationship to their natural resources as a community. Locals communities may be dynamic in response to changing rural conditions, and therefore, may change their cultural practices and their perspectives on the importance of natural resources and biodiversity (Wiersum and Shackleton, 2005).

In order to protect and manage a particular ecological system, its cultural context is considered to be the most important one. Human relation to the natural environment has so for been studied mostly in biophysical terms; but there is now a growing acknowledgment that societies themselves have created detailed procedures to conserve and manage their resources. These methods are entrenched in their cultural values that have to be taken in to consideration if sustainable and reasonable human development is to become a truth (Bridgewater, 2002). These new trends have resulted in a change from a top down to a more community- based approach which aims to work closely with local people, depend on their cultural knowledge, and contribute to their livelihoods (Grimble and Laidlaw, 2002).

The convention on Biological Diversity (CBD) from 1992 stressed on parties to respect, preserve, and maintain knowledge, innovations and practices of indigenous and local communities having traditional lifestyles relevant for the conservation and sustainable use of biological diversity, and facilitate their wider involvement with the approval of bearers of such knowledge, innovations and practices, and encourage the reasonable sharing of the gains obtaining from the use of such knowledge, innovations and practices (McNeely, 2000).

Global environmental conservation policies and discourses have been increasingly influenced since 1980s, either verbally or practically, by the idea that conservation demands the coexistence of humans and nature (Adams et al., 2004; Wells and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1039910419

McShane, 2004). According to Cotton (1996) over long time, indigenous people have developed their own locality specific knowledge on plant use management and conservation. The United Nations Convention Environment and Development (UNCED, 1992) mentioned the important roles that indigenous populations play in both the conservation and sustainable use of natural resources while in turn maintaining biodiversity. Current use of cultural knowledge in conservation led to the novel idea of "ethnoconservation" in the late 1990s which is now well known conservation approach around the world (Rajeswar, 2001; Jules et al., 2008; Negi, 2010).

In a context where numerous conservation goals must be attained, local ecological knowledge can be a donor to a multidisciplinary conservation approach as well as foster transdisciplinary approaches when locals become partners and co-workers (Aswani, 2018). Assessment of conservation status cannot be absolute and needs periodic revision but taking various criteria at a time validates the conclusion for a considerable period of time or for a specific geographic locality (Domínguez Lozano et al., 2003; Broennimann et al., 2005).

In the present investigation local ecological knowledge has been incorporated in IUCN red list and used as a tool for assessing conservation status of culturally significant flora of district Tor Ghar with special reference to the following objectives.

1. To assess the existing threats to culturally significant plants in the study area
2. To evaluate how the cultural values of plant biodiversity contribute towards conservation.
3. To quantify the local wisdom regarding conservation status of the flora

Materials and methods

Study area

District Tor Ghar, a rigorous mountainous area of northern Pakistan located between 34° 32' and 34° 50' N, and 72° 48' and 72° 58' E in Lesser Himalayas having strong cultural and traditional background besides rich plant biodiversity. The study area is inhabited by five well known tribes namely Basikhel, Akazai, Nusratkhel, Hassanzai and Medakhel (*Fig. 1*). Plants and peoples of the study area have close association and plants provide a number of societal benefits. Human culture is the main driver of plant biodiversity. Hence cultural knowledge was used as a tool for assessing conservation status of ethnospecies of the district.

Data collection

Villages of each tribal society as well as informants were selected randomly.700 informants shared their cultural knowledge related to conservation status through semi structured interviews, questionnaires, Ethnobotanical Participatory Appraisal (EPA) and group discussion.

Field trips

Extensive field trips of the study area were carried out during 2014 and 2015. Threatened and secure plant species were studied in their local habitats. Threatening factors and conservation efforts of indigenous tribes were recorded. Pressed, dried and poisoned specimens in triplicate deposited in herbarium of Hazara University, Mansehra, Pakistan.

DOI: http://dx.doi.org/10.15666/aeer/1705_1039910419

Figure 1. *Map of district Tor Ghar showing different tribal belts*

Data analysis

Recorded data from the questionnaires was shifted on Microsoft Excel sheet for further processing and evaluation. Whole conservation related data was analyzed successfully by developing a new simple mathematical relation named as CS equation.

Development of a new equation

A new mathematical equation was developed for assessment of conservation status, which is a novel approach in the field of ethnobiology for quantification of local wisdom. The idea was born during data collection and field visits that local wisdom if quantified properly to assessing conservation status of a plant species in a particular

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1039910419

area, it would depict its conservation in a better way. During the study it has also been observed that locals adopted conservatory measures for protecting plant biodiversity. They protect the plants of their interest from fire and grazing and also cultivate useful plants. In this regard, a questionnaire was designed to get maximum information from the locals about conservation status of culturally significant flora of the area. Availability for the last ten years was recorded (increased, decreased or persistent). Occurrence of a plant species (abundance, moderate or rare) was noted. The most cited three important threatening factors of the study area (over exploitation, fire and grazing) were enlisted. Similarly, information regarding regeneration potential (high, moderate and low) was gathered. Data obtained from informants was cross checked by direct field observations during extensive field trips and analyzed by the following mathematical relation developed first time by the authors (*Eq. 5*).

As Conservation Status (CS) of a species is directly proportional to Occurrence (OC), Availability (AV) and Conservation Efforts (CE). This may be expressed mathematically as:

$$CS \alpha OC + AV + CE \quad \text{(Eq.1)}$$

Similarly Conservation Status (CS) is also directly proportional to Reproductive Potential (RP) of a species and can be represented as follows:

$$CS \alpha RP \quad \text{(Eq.2)}$$

where CS is inversely proportional to Threatening Factors (TF) shown mathematically as:

$$CS \alpha 1 / TF \quad \text{(Eq.3)}$$

By combining *Equations 1, 2* and *3,* the following equation obtained:

$$CS \alpha (OC + AV + CE) / TF \text{ X } RP \quad \text{(Eq.4)}$$

By substituting the sign of proportionality with constant K, the final equation was thus obtained.

$$CS = K (OC + AV + CE) / TF \text{ X } RP \quad \text{(Eq.5)}$$

where CS is the conservation status of a plant species, OC is occurrence, AV is availability for the last ten years, CE is conservation efforts by locals, TF is threatening factors and RP is regeneration potential of a plant species in a particular habitat.

The constant K was assigned a value 1. Degree of occurrence was evaluated by giving values 3 for abundance, 2 for moderate and 1 for rare. Values for availability for the last ten years are 3 for increasing, 2 for persistent and 1 for decreasing. The most cited four conservation efforts by locals were considered in this equation and assigned a sum of value 4 to these (1 for each conservation effort). Conservation efforts are protection from grazing, cutting and fire. Cultivation of a plant species is also a conservation effort. Threatening factors considered in this formula on the basis of local perception were Over-exploitation, fire and overgrazing/overbrowsing. Each threatening

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1039910419

factor was assigned a value 3 for extensive, 2 for moderate, 1 for low and 0 for absence of a threatening factor. Similarly, the values assigned to regeneration potential were 3 for high, 2 for moderate and 1 for low.

All 295 culturally significant plant species of the study area were assessed by the equation of CS in order to quantify the local wisdom. Keeping in view the CS index values, a scale was devised for assigning IUCN categories to the flora under investigation.

2-scale for IUCN categories

On the basis of C S values index plant species were described according to IUCN classification as critically endangered, endangered, vulnerable, near threatened (rare) and least concerned (secure) (*Table 1*).

Table 1. *Scale for IUCN categories*

Name of category	C S values
Critically endangered	0.1 to 1
Endangered	1.1 to 1.5
Vulnerable	1.6 to 2.0
Rare	2.1 to 2.5
Least concerned (secure)	2.6 and above

Results

Conservation status of 295 plant species was assessed tribewise and mean value was calculated for each recorded species (*Table 2*).

NR: not reported, CS: conservation status, CE: critically endangered, E: endangered, V: vulnerable, R: rare, S: secure

Conservation status of herbs

Six species of herbs were found critically endangered (CE) showing CS values up to 1.0 These species are *Podophyllum emodi* (0.5), *Gentiana kurroo* (0.85), *Dioscoreadeltoidea* (0.88), *Incarvellia emodi* (0.96), *Arisaema utile* (1.0) and *Picris hieraciodes (1.0)* (*Fig. 2*). Thirteen species of herbs were mentioned as endangered ranging CS values from 1.1 to 1.5. Vulnerable species were found 31, rare 41 and secure 104 (*Table 2*).

Conservation status of shrubs

Among shrubs 9 species were found critically endangered. These were Skimmia laureola (0.48), Woodfordiafruticosa (0.78), Periploca aphylla (0.88), Hedra nepalensis (01), Nannorrhops ritchieana(01), Vitis jacquemontii (01), Viburnum grandiflorum (01) and Opuntia dillenii(01) (*Fig. 3*). Endangered species were recorded 4, vulnerable 15, rare 11 and secure 9 (*Table 2*).

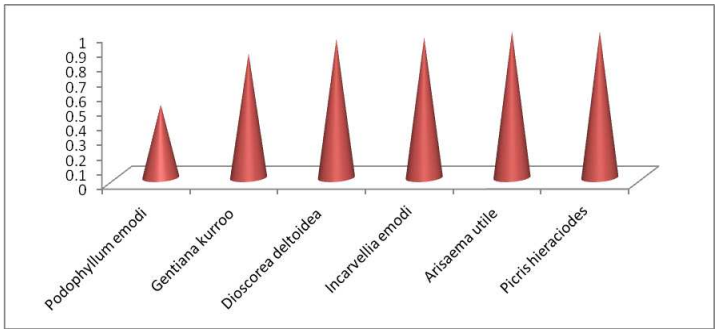

Figure 2. *Critically endangered herbs of district Tor Ghar*

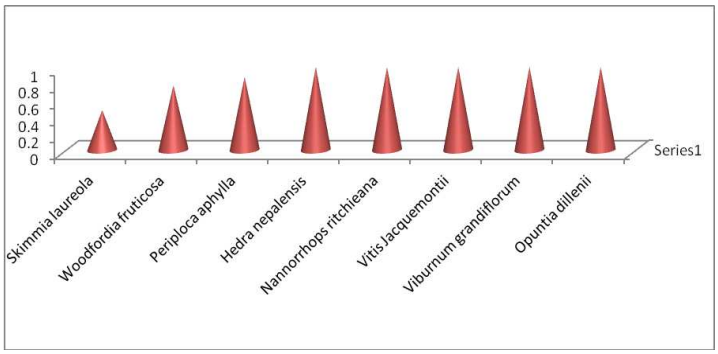

Figure 3. *Critically endangered shrubs of district Tor Ghar*

Conservation status of trees

Six trees species were declared critically endangered. These were *Cedrus deodara* (0.54), *Pistacia integerrima* (0.62), *Taxus wallichiana* (0.83), *Ficus carica* (0.91), *Cornus macrophylla* (1) and *Bauhinia variegata* (1) (*Fig. 4*). Eighteen species of trees were mentioned as endangered, 10 vulnerable, 6 rare and 13 secure (*Table 2*).

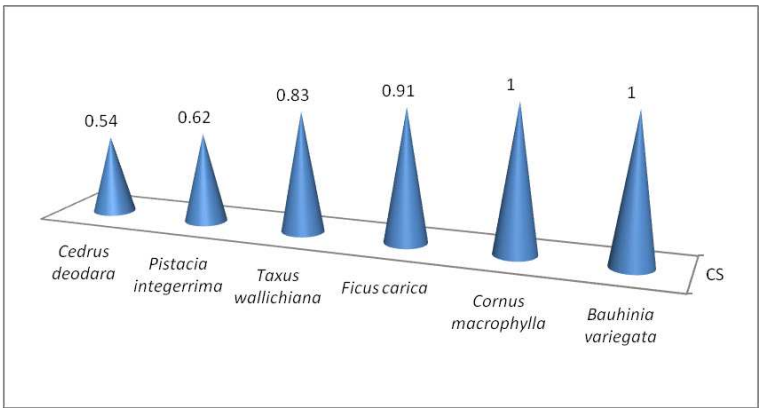

Figure 4. *Critically endangered trees of district Tor Ghar*

Herbs are found secure mostly in the region and least critically endangered whereas trees are more endangered and least critically endangered and rare. Shrubs are more vulnerable and least endangered (*Fig. 5*).

DOI: http://dx.doi.org/10.15666/aeer/1705_1039910419

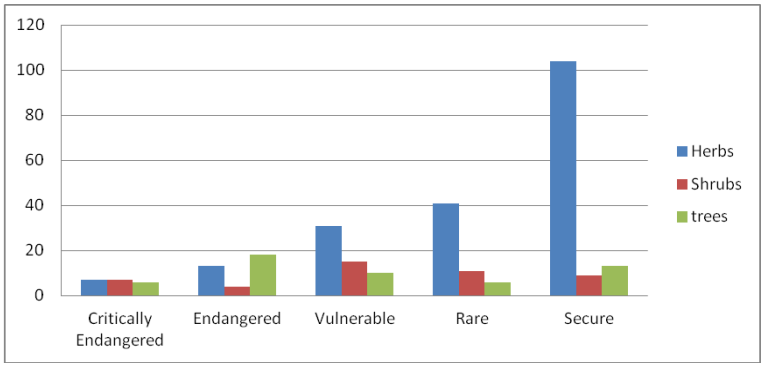

Figure 5. *Number of species of all life forms and IUCN categories*

Overall 20 species of all life forms were declared critically endangered, 35 endangered, 56 vulnerable, 58 rare and 126 secure (*Fig. 6*).

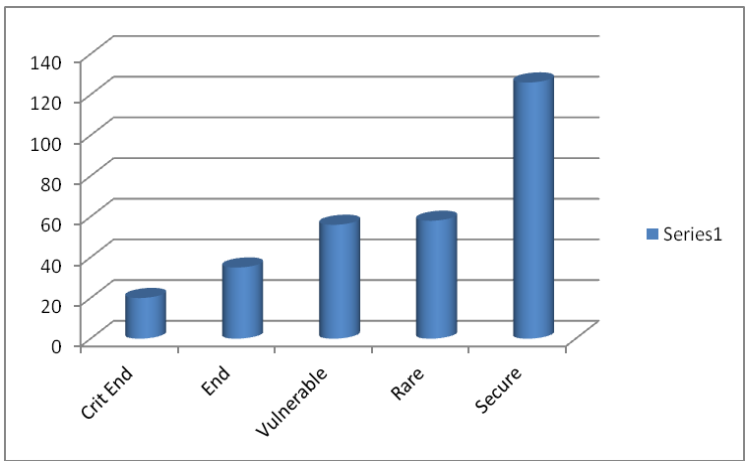

Figure 6. *Total number of species assigned to IUCN categories*

The percentage of threatened flora 38% (7% critically endangered, 12% endangered, 19% vulnerable) 19% near threatened (rare) was higher as compare to secure (least concerned) flora 43% (*Fig. 7*).

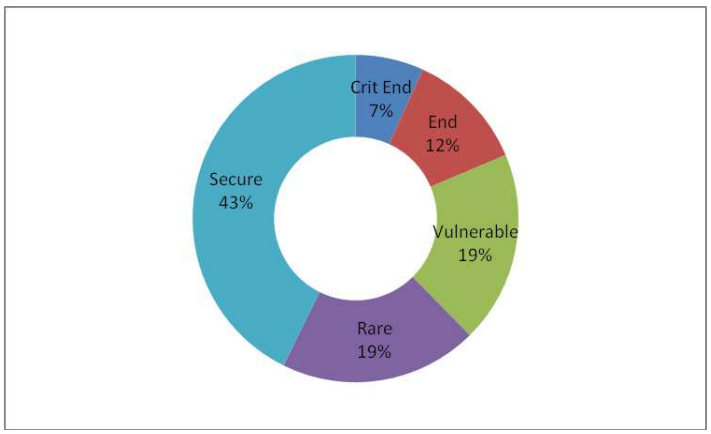

Figure 7. *Percentage of threatened and secure species of Tor Ghar*

Discussion

The current investigation finds out the role of ethnoecological knowledge in evaluating the conservation status of culturally significant flora of district Tor Ghar. The United Nations Convention Environment and Development (UNCED, 1992) also highlighted the important roles that indigenous peoples play in both the conservation and sustainable use of natural resources while in turn maintaining biodiversity. In the present study local wisdom was explored and conservation status of 295 plants species in terms of IUCN categories was calculated on the basis of newly developed equation. The results depict 7% critically endangered flora, 12% endangered, 19% vulnerable and 19% near threatened (rare). The rest of the flora that is 43% found secure (least concerned). Such categorization was also found in a number of other ethnobotanical studies (Gilani et al., 2006; Afzal et al., 2009; Haq, 2012; Akhter et al., 2013; Bibi et al., 2014; Shah et al., 2015). Hamayun et al., 2006) also evaluated conservation status of 49 medicinal plant species and found 24 species threatened. Out of which 9 were found endangered, 7 vulnerable and 8 rare. The study also revealed that locals particularly plants collectors had useful information about plants occurrence, distribution and sites of their maximum availability. This information was cross checked through field surveys and visits. The field observations include, range extent and area of occupancy, exploitation level, availability, habitat alteration, conservation efforts, plant collection methods, part collected, invasive species and threats to plant biodiversity. On the basis of these observations, the species were then categorized according to IUCN categories as critically endangered, endangered, vulnerable, rare (near threatened) and secure (least concerned).

The results obtained by applying this equation show accuracy and found in accordance with the majority of results of other studies conducted in adjacent areas as well as different parts of Pakistan. According to this equation six species of herbs were found critically endangered (CE) showing CS values up to 1. These species are *Podophyllum emodi* (0.5), *Gentiana kurroo* (0.85), *Dioscorea deltoidea* (0.88), *Incarvellia emodi* (0.96), *Arisaema utile* (1) and *Picris hieraciodes* (01). Thirteen species of herbs were mentioned as endangered ranging CS values from 1.1 to 1.5. Vulnerable species are 31 (1.6-2), rare 41 (2.1-2.5) and secure 104 (CS value above 2.5). Gilani et al. (2006) documented 21 ethnomedicinal herbs from AyubiaNational Park, district Abbottabad and found *Podophyllum emodi* and *Viola canescens*as vulnerable species due to overexploitation. While according to the findings of the present study *Podophyllum emodi* (0.5) is critically endangered but *Viola canescens* (2.7) is secure. *Podophyllum emodi* is under great harvesting pressure, showing minimum occurrence, availability for the last 10 years decreases and its regeneration potential could not keep pace with its overexploitation. Whereas *Viola canescens* shows the criteria of secure in this study. Afzal et al. (2009) studied that some plant species *Colchicum luetum, Bergenia ciliata, Pimpinella stewartii, Valleriana jatamonsii, Viola serpens* and *Dioscorea deltoids* etc. are rapidly depleting and may become locally extinct in near future. Some of these have also been reported and assessed in present investigation. *Colchicum luetum* (1.33), *Bergenia ciliate* (1.76) and *Valleriana jatamonsii* (1.92) were found vulnerable. While *Dioscorea deltoids* (.95) found critically endangered at local level.

Among shrubs 8 species were found critically endangered. These are *Skimmia laureola* (0.48), *Woodfordia fruticosa* (0.78), *Hedra nepalensis* (1.0), *Nannorrhops ritchieana* (1.0), *Vitis jacquemontii* (1.0), *Periploca aphylla* (01), *Opuntia dillenii* (01)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1039910419

and *Viburnum grandiflorum* (1). Endangered species are 4, vulnerable 15, rare 11 and secure 9 (*Table 2*).

Six trees species were declared critically endangered. These are *Cedrus deodara* (0.54), *Pistacia integerrima* (0.62), *Taxus wallichiana* (0.83), *Ficus carica* (0.91), *Cornus macrophylla* (1) and *Bauhinia variegate* (1.0). Eighteen species of trees were declared as endangered, 10 vulnerable, 6 rare and 13 secure (*Table 2*).

Similarly Haq (2012) also conducted ethnoconservation survey of 12 threatened species from district Battagram (adjacent district to Tor Ghar). These species were *Acer caesium, Betula utilis, Cedrus deodara, Opuntia dilleni, Paeonia emodi, Pistacia integerrima, Populus alba, Quercus glauca, Skimmia laureola, Taxus wallichiana, Ulmus wallichiana* and *Viscum album*. Their conservation status was assessed through direct field observation and the information gathered by locals. The present research work also declared 6 plants *Cedrus deodara, Opuntia dilleni, Pistacia integerrima, Populus alba, Skimmia laureola* and *Taxus wallichiana* as critically endangered species of district Tor Ghar.

Shah et al. (2012) explored *Olea ferruginea* along with mixed tree species of *Monotheca buxifolia* and *Acacia modesta* as dominant ethnoflora of sacred jungles of Kurd sharif and Sho of district Karak showing a traditional way of conserving plant biodiversity. Similar findings of this research show *Olea ferruginea* (2.78) and *Acacia modesta* (3.15) as secure species of the study area. *Olea ferruginea* is protected in graveyards and considered one of the most important sacred plant species of Graveyards and is not cut for any purpose. *Olea ferruginea*is also protected by locals from fire by making small circular stony walls around trees (Shah et al., 2015)

Ahmad et al. (2012) found 5 plants species critically endangered, 6 endangered, 10 vulnerable, 11 secure and 6 rarely distributed in Sharda, Neelam valley Azad Jammu and Kashmir. This study further revealed the over exploited species are *Aconitum heterophyllum, Geranium wallichianum, Ajuga bracteosa, Traxicum officinale, Quercus incana, Berberis lycium, viola canescens* and *Dyosporus lotus.* Majority of them are at the verge of local extinction due to extensive harvesting pressure. The CS values index also shows *Geranium wallichianum* (1.56), *Ajuga bracteosa* (02) and *Berberis lyceum* (02) as vulnerable species, whereas *Traxicum officinale* (2.13) and *Dyosporus lotus* (2.4) as rare species. Whereas *Quercus incana* (1.22) as endangered species *and viola canescens* (2.7) as secure species. The result of *viola canescens* (2.7) as secure species is only different. It may be due to its habitat adjustment or reduced overexploitation. Therefore, *viola canescens* (2.7) is not considered the threatened species of the district. The field observations also show its moderate occurrence.

In Chakesar valley district Shangala, a plant resource assessment project was carried out ethnobotanically to explore conservation status of some important medicinal plants. Conservation of 127 plant species was evaluated through IUCN criteria. Among these species 47 were endangered (E), 32 vulnerable (VU), 36 rare (R) and 12 species were infrequent (IF). Some of the important endangered species of the region are *Abies pindrow*, *Acer oblongum, Aesculus indica, Alnus nitida, Berberis kunawarensis, Celtis australis, Desmodium elegans, Hedrane palensis, Juglan regia, Olea ferruginea, Paeonia emodi, Picea smithiana, Pinus gerardiana, Pisticia integrima, Quercus semicarfifolia, Vibernum grandiflorum* and *Woodfordia fruticosa* (Shah and Hussain, 2012). When the results of this study were compared with the results of present research, majority of the species showed similarity in results and however, a few species showed different conservation stata e.g. *Abies pindrow, Alnus nitida, Celtis australis*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1039910419

and *Picea smithiana* were declared as endangered species while *Hedrane palensis, Vibernum grandiflorum* and *Woodfordia fruticosa* as critically endangered species of the research area. *Aesculus indica* was mentioned as vulnerable species of the district. In these results category of threatening is different. However, *Juglan regia* and *Olea ferruginea* showed different results being culturally significant species. These are well protected by local culture and therefore, attained the secure status. *Juglan regia* is the most popular wild edible plant of the study area. This tree species provides a number of services to the locals in the form of furniture wood, cosmetics and tasteful dry fruit having prolonged storage life. This important species is facing overexploitation pressure but due to cultivation and protection by locals showing secure status in the district Tor Ghar (Shah et al., 2015).

Akhtar et al. (2013) assessed ethnobotanically that *Aconitum violaceum, Colchicum luteum* and *Jasminum humile* as vulnerable due to over exploitation. According to the present study *Colchicum luteum* (1.33) is endangered and *Jasminum humile* (2.33) is rare. However, *Aconitum violaceum* was not reported by any tribe in the current study.

Bibi et al. (2014) pointed out the highest under pressure species *Caralluma tuberculata, Citrullus colocynthis, Malva neglecta* and *Mentha longifolia* in district Mastung of Baluchistan. *Caralluma tuberculata* (1.32) and *Citrullus colocynthis* (1.1) were also declared as endangered species, whereas *Malva neglecta* (3) and *Mentha longifolia* (4.49) as the most secured species of the area showing highest values of CS. *Malva neglecta* is an agricultural land associated plant species and is found abundantly in the study area. Similarly, *Mentha longifolia* was found secure and grows excessively near aquatic habitats of Tor Ghar.

Mussarat et al. (2014) indicated *Morus alba* and *Dalbergia sissoo* under great overexploitation pressure and threatened species in the area. While in the present exploration *Morus alba* (1.5) is endangered and *Dalbergia sissoo* (2.3) is rare. *Dalbergia sissoo* is under great overexploitation pressure especially for furniture wood. *Morus alba* is also depleting alarmingly in the region. No conservatory measures are taken to secure *Morus alba* in Tor Ghar.

Amjad et al. (2015) indicated *Ajuga bracteosa, Mallotus philippensis, Micromeriabiflora, Butea monosperma*and *Zanthoxylum armatum* as critically endangered in Kotli, Azad Jammu and Kashmir. The present research work show *Ajuga bracteosa* (2) as vulnerable, *Mallotus philippensis* (3.3) as secure, *Butea monosperma* (1.37) as endangered species and *Zanthoxylum armatum* (2.4) as rare species.

In the current study *Taxus wallichiana* (0.83) was found critically endangered while *Pinus wallichiana* (1.5) and *Abies pindrow* (1.33) were found endangered. The study of Adnan et al. (2006) also mentioned these species as rapidly decreasing species in Miandam vally of district Swat.

Cedrus deodara in this study showing (0.54) CS value and declared critically endangered. Sheikh et al. (2002) also pointed out that *Cedrus deodara* had completely eradicated from Naltar valley, northern western Karakorum range.

When the results of present study were matched with IUCN red list criteria at regional level two species were found critically endangered (CE) in the study area. These species were *Cedrus deodara* (0.54) and *Gentiana kurroo* (0.85). Two species were found Endangered/Threatened (EN) in the region i.e., *Picea smithiana* (1.33) and *Viburnum cotinifolium* (1.13). While *Geranium wallichianum* (1.56) and *Salvia moorcroftiana* (1.87) were mentioned endangered in IUCN criteria but vulnerable species at district Tor Ghar level. *Bergenia ciliata* (1.76) is vulnerable in IUCN list as

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1039910419

well as in the present research. *Pinus wallichiana* (1.5) was found endangered in this study but vulnerable in IUCN red list. *Viola canescens* (2.7) is considered as secure locally but vulnerable regionally. This species showed quite different conservation status from the published literature and IUCN red list indicating its conservation status secured locally.

Conclusion

Local ecological knowledge has been proved a successful tool for evaluating conservation stata of flora of the study site. This empirical study revealed that a higher proportion (57%) of flora is undergoing various degrees of threatening at local level that is 7% critically endangered, 12% endangered, 19% vulnerable and 19% rare in terms of IUCN categories. However, forty three percent flora of the district is secure. The findings of the present study indicating that flora of Tor Ghar is under high anthropogenic pressure. This is first ever attempt of quantifying the local wisdom regarding conservation status of the plants. Local perception of the flora also reflects its conservation status which may be considered in futures researches as base line study. The above discussion revealed that the mathematical relation designed during the study has been proved useful tool for evaluating ethno-conservation of local flora. The equation can be generalized and applied to any floristic area of the world. Conservation researchers should quantify the local wisdom while applying IUCN criteria to any floristic territory especially where anthropogenic disturbances are at alarming rate. This will reinforce the results and more clarify the picture of conservation status of plant biodiversity of a region.

Acknowledgements. Indigenous tribes of district Tor Ghar are highly acknowledged for their permission of gathering data and cooperation and guidance during field trips.

Conflict of interests. The authors declare that they have no competing interests.

(Received 5th Mar 2019; accepted 20th Aug 2019)

Abstract. The physical, microbiological quality parameters and plankton abundance have been monitored and evaluated in coastal waters of Fethiye Inner Bay, Turkey. The temporal and areal variations of quality parameters have been investigated through the monthly measurements at 14 locations between March 2016 and February 2017. The physical parameters measured throughout the water column were water temperature, salinity, pH, and turbidity. Besides, water samples were taken from the surface waters, and total coliform, fecal coliform, fecal streptococci, *Escherichia coli*, *Pseudomonas aeruginosa*, *Salmonella* detection, phytoplankton and zooplankton abundance analyses were performed in the laboratory. By using the related Turkish Standards Institution (TSE) standards, biochemical oxygen demand and dissolved oxygen levels were also determined. Results were evaluated to understand the microbiological water quality of Fethiye Inner Bay, by the Turkish Regulations for the Surface Water Quality (2016) and the Quality of Bathing Water (2006), and Directive 2006/7/EC on bathing water. For the evaluation of the results, geographic information systems (GIS) based HYDROTAM-3D that is the first coastal waters hydrodynamic, transport and water quality model developed in Turkey, was used (http://www.hydrotam3d.com/fethiye). A microbiological parameters database was established for Fethiye Inner bay coastal waters by using HYDROTAM-3D model water quality management system, accessible over the internet.
Keywords: *marine environment, pollution, HYDROTAM-3D, microbiological parameters, phytoplankton, zooplankton, biochemical oxygen demand, dissolved oxygen, Fethiye Bay*

Introduction

People take the water from the hydrological cycle for their vital and economic needs, and the water used returns back to the cycle. In this cycle, substances that enter the water cause the pollution by changing the physical, chemical and biological properties of the water. The main factors that accelerate water pollution are population growth and rapid industrialization (Liyanage and Yamada, 2017). Water is a vital source of infections that can be transmitted through the digestive system. Pathogenic bacteria and other microorganisms mix with water in feces and similar ways depending on many factors such as the geographical location of the region, infrastructure facilities, sewage processes, the socio-economic structure of the community. Viruses, pathogenic bacteria, and parasites can be found in the water as harmful biological agents for human health (Griffin et al., 2003).

The increasing use of water due to population increase and developing industrialization is a crucial factor accelerating water pollution. Pollutants discharged from the point sources such as domestic and industrial sea outfalls or discharged from the distributed sources also pollute the water resources and prevent other uses of receiving waters. Protection of water resources, development, prevention of deterioration in quality and sustainable use of water for long-term conservation of water resources is necessary.

Fecal coliforms and fecal streptococci are dangerous indicators of health associated with fecal contamination (Barcina et al., 1991). The main entranceway of enteric bacteria and viruses such as *Escherichia coli* to coastal areas is by urban and agricultural wastes (Rees et al., 2010). Enteric bacteria exposed to the marine environment simultaneously, different to their natural habitat, encounter a variety of abiotic and biotic challenges that is marked (Rozen and Belkin, 2001). Biotic stress arises from natural seawater microbiota, which are better scavengers for limited nutrients available and may also prey and graze on the enteric newcomers. Abiotic stress faced by enteric bacteria in seawater include sunlight temperature, pH, lack of nutrients, salinity, current and turbulence and (possibly) hydrostatic pressure (Troussellier et al., 1998; Barcina et al., 1991; Rozen and Belkin, 2001). Lack of water quality management of coastal waters can lead to both health and income losses at shellfish trade centers and fishing places (Rees et al., 2010). Continuous water quality management at coastal waters are vital for human health. In this study, measurements and evaluations of physical, microbiological quality parameters and plankton abundance were performed for Fethiye Inner Bay. The monthly variations of microbiological quality parameters were investigated through the site measurements conducted in between March 2016 and February 2017.

The Fethiye Bay is located in the Eastern Mediterranean coast of Turkey. It is a sheltered area against currents and waves approaching from north, west and southeast directions. Fethiye Inner Bay is an enclosed water body having limited water exchange from the openings on both sides of the Şövalye (Zeytin) Island located in the Fethiye Bay (Cebe, 2016) and it is surrounded by the town of Fethiye. The primary economic activity in the town is tourism. Besides the tourism, its economy is mainly based on agriculture and animal husbandry (Cebe, 2016). Due to the compatibility of climate and physical conditions, irrigated agriculture is mostly performed in the town. The drainage waters of agricultural lands flow to the waters of Fethiye Bay via Murt (Mersinli) and other channels. Low flushing rate of the enclosed Inner Bay waters increases the sensitivity to pollutants.

The wastewater of the Fethiye Town is transferred to the treatment plant and then discharged to the Inner Bay from the eastern part of the Şövalye (Zeytin) Island (*Fig. 1*). The treated wastewater is rich in nitrogen and phosphorus, and it has been discharged into Fethiye Inner Bay together with the agricultural drainage waters that are also rich in nitrogen and phosphorus salts carried by the Murt River. The pollution in Murt River alone has a potential to affect the inner bay of Fethiye. Also, seven channels discharge the agricultural drainage waters directly into Fethiye Inner Bay without any treatment or sedimentation (*Fig. 2*). Likewise, settlements located in the Şövalye (Zeytin) Island and in the west of the bay constitute one of the primary sources of pollution because they are not connected to the wastewater system, and are not subject to the treatment. Other sources of pollution are Fethiye Marina and wastewaters emptied from the boats (Yılmaz et al., 2017). In this study, it is aimed to determine the coastal pollution level in Fethiye Inner Bay, to analyze the temporal and areal changes of water quality parameters and establish a database for evaluations.

Measurements and analysis

The field study has been conducted monthly between March 2016 and February 2017, in the Fethiye Inner Bay coastal waters in Turkey shown in *Figure 2*. Fourteen

(14) measurement points were located at the site, and their names, water depths, and coordinates are listed in *Table 1*. Measurements of physical parameters were performed at every 2 meters throughout the water column. The total number of measurements at the site is 1164 for the water temperature, salinity, pH, and 168 for the turbidity, each repeated at least three times. Measurement devices used are listed in *Table 2*.

Figure 2. *Fethiye Inner Bay measurement points (Google Earth, 2018)*

Total coliform, fecal coliform, fecal streptococci, *Escherichia coli, Pseudomonas aeruginosa*, and *Salmonella* analysis have been performed in 168 water samples taken for the temporal and spatial analysis of the changes of the bacteriological water quality parameters in the coastal waters. Phytoplankton and zooplankton abundance analyzes have been carried out in the laboratory for water samples taken from the surface and the bottom layer at depths exceeding 8 m using plankton nets. Biochemical Oxygen Demand (BOD) and Dissolved Oxygen (DO) requirements were determined by the relevant Turkish Standards Institution (TSE) standards for comparison with the changes in bacteriological parameters.

Microbiological laboratory test-methods are given in *Table 3* (TS EN ISO 9308-1, 2014; TS EN ISO 16266, 2009; TS EN ISO 7899-2, 2000), BOD and DO test-methods are listed in *Table 4* (TS EN ISO 5814, 2012; TS EN ISO 10707, 2005). BOD and DO were detected in 168 and 1164 samples, respectively.

55-micron Hydro-Bios plankton nets were used through the water column vertically to collect phytoplankton and zooplankton samples during the study. Then, both phytoplankton and zooplankton samples were fixed with 4% formaldehyde buffer solution until counting and identification activities.

APHA Standard Methods (1995) were used during the counting of phytoplankton and zooplankton samples with Leica DM500 binocular microscope, and Sedgewick-Rafter Counting Chamber was employed as the counting chamber unit. The Sedgewick Rafter Counting Cells are designed primarily for the quantitative measurement of the exact number of particles in a precise volume of a fluid. This chamber itself is 50 mm in length, 20 mm in width and 1 mm in depth. The base part of the chamber is also grid marked with 100 x1 mm squares. Before transferring to the counting chamber, each sample was shaken at least 1 min, and 1 ml of sample were placed in the chamber. During the counting and identification, the number phytoplankton and zooplankton on each counting cell were recorded under the light microscope. Countings were repeated on 8 subsamples (Harris et al., 2000).

Physical parameters

Physical parameters were measured every 2 m from the surface to the bottom at each of the 14 stations. Salinity and temperature recorded at all measurement points are given in *Figure 3*. As a result of 12-month measurements carried out between March 2016 and February 2017, it was observed that the seawater salinity in Fethiye Inner Bay changed between 30.37 ppt (at F06) and 39.43 ppt (at F14) at the surface and the lowest salinity value was recorded in September, and the highest value was recorded in August. The salinity of surface waters is lower in all seasons than in the bottom layers. Towards the sea bottom from the surface, the average salinity increase is 4.35 ppt in the spring, 1.49 ppt in summer, 2.89 ppt in autumn, and 2.85 ppt in winter. Similarly, seawater temperatures were ranging in between 12.7 and 30.8 °C. The seasonal temperature averages decreased from the surface to the bottom of the water column from 20.7 to 18.6 °C in the spring, from 29.2 to 25.1 °C in summer, and they remained almost unchanged along the water column with a slight increase from 22.5 to 22.8 °C in the autumn and 16.8 to 16.8 °C in winter. Measured pH values ranged from 7.55 to 8.38.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1042110444

The surface layer pH and turbidities measured at all points are given in *Figure 4*. Turbidity recorded at point F14 (water depth is 46 m.) changed in between 0.54 and 3.2 ntu, whereas at all other points ranged in between 1.02 and 4.81 ntu. The lowest values were recorded in autumn. All turbidity values were less than 5 ntu that is the acceptable limit for recreational purposes in coastal waters.

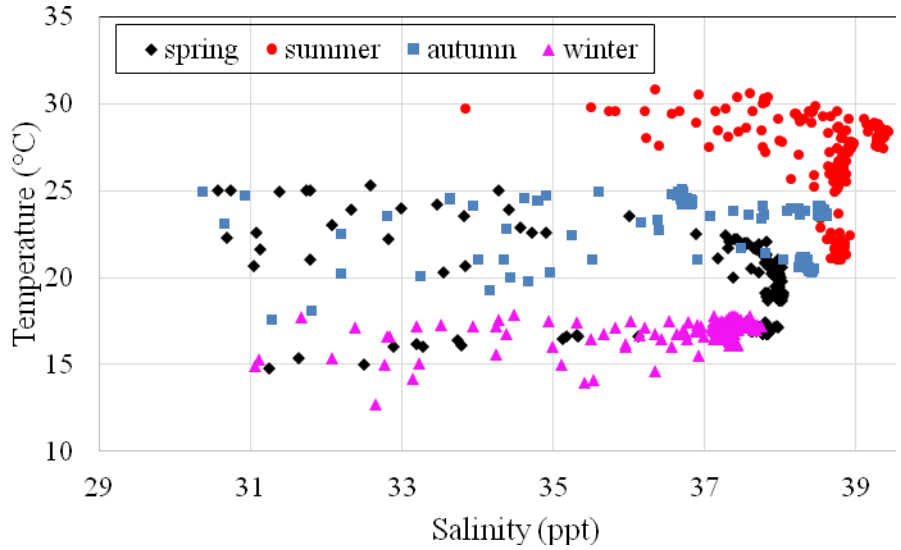

Figure 3. *Salinity and temperature recorded at all measurement points*

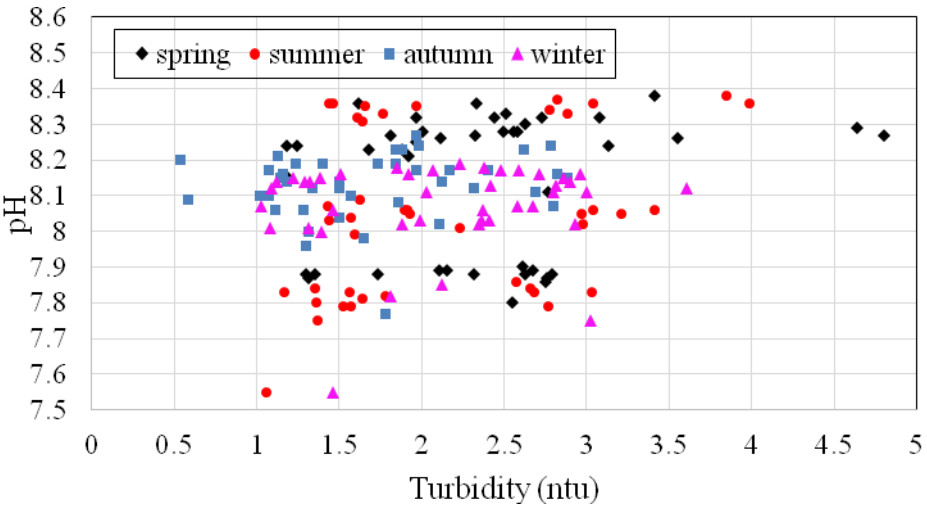

Figure 4. *Surface turbidity (ntu) and pH recorded at all measurement points*

Microbiological parameters

Coliform bacteria are bacteria that show the contamination of coastal waters. These bacteria are found in soil and plants as well as in the feces of warm-blooded animals. Such bacteria are fast-breeding species, and their presence indicates that disease-causing organisms (pathogens) from the feces of humans or animals could be existent in the coastal waters. Coliform bacteria are grouped as total coliform or fecal coliform

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1042110444

according to general characteristics. Total coliforms (TC) are common in soil or vegetation and do not show that water is contaminated by feces (Gao et al., 2015).

According to the 12-month measurements made between March 2016 and February 2017, the temporal changes in total coliform values at all measurement points are given in *Table 5*.

Table 5. *Temporal variations in TC (cfu/100 ml) at all measurement points*

Measured coliform bacteria values provide guidance value (500 cfu/100 ml) of the Quality Criteria Table to be provided by Bathing Water Quality for Swimming and Recreation purposes, Annex-1 of Regulation for the Quality of Bathing Water (2006). The 15.5% of samples were above the guide standard however they were all less than the mandatory standard (10000 cfu/100 ml). In 91.7% of the samples TC was recorded. According to measured values, it is seen that the total coliform bacteria density is low in Fethiye Inner Bay coastal waters. However, coliform contamination was found at the mouth of Murt River (F11), along with the Çalış Beach (F12, F13), and in holiday village swimming bay (F01, F02) during the rainy spring and winter months. While this pollution is lower than the mandatory standard, its presence suggests that there may also be pathogens from the feces of humans or animals in the water.

Coliform bacteria originate as organisms in soil or vegetation and the intestinal tract of warm-blooded animals (fecal coliform). Fecal coliform (FC) bacteria are indicators of fecal contamination and the potential presence of pathogens associated with wastewater or sewage sludge. The total group includes FC bacteria such as *Escherichia coli*, as well as other types of coliform bacteria that are naturally found in the soil. The presence of fecal coliform in water may indicate recent contamination of the water by sewage or feces which could contain other bacteria, viruses, or disease-causing organisms. This is why coliform bacteria are considered "indicator organisms"; their presence warns of the potential presence of disease-causing organisms and should alert the person responsible for the water to take precautionary action (Gao et al., 2015).

The temporal variations in fecal coliform values at all measurement points according to the 12-month measurements made between March 2016 and February 2017 are shown in *Table 6*.

Measured FC bacteria values satisfy the guide standard (100 cfu/100 ml) of the Regulation for the Quality of Bathing Water (2006), Annex-1: Quality Criteria Required for Swimming and Recreation Waters, only at F07 in all of the measurements. In 85.7% of the samples FC was recorded. The 21.4% of samples were above the guide standard. At F14, the FC count was almost three times higher than the mandatory level (2000 cfu/100 ml) in August. Measurements indicate that there is substantial fecal pollution in Fethiye Inner Bay coastal waters. The source might be wastewater, sludge, septage, or animal excreta, resulted from the intensive anthropogenic facilities.

Escherichia coli is a member of the fecal coliform group and a more specific indicator of fecal pollution and commonly used to identify the presence of pathogenic microorganisms (Feng et al., 2012). It can be found in the digestive system of humans and warm-blooded animals. They cause digestive system infection. It is most commonly transmitted to humans by swimming in or swallowing the polluted water. Its presence in seawater indicates the entrance of sewage (Craig et al., 2004). There is a strong correlation between the increased *E. coli* levels in recreational waters, and the gastrointestinal disease even though the vast majority of them are not pathogenic (Blaustein et al., 2013). The temporal variations in *E. coli* values at all measurement points according to the 12-month measurements made between March 2016 and February 2017 are given in *Table 7*.

No limit value is defined for *E. coli* in the Regulation for the Quality of Bathing Water (2006). According to the bathing water quality standards for coastal and transitional waters in Directive 2006/7/EC of The European Parliament and the Council, Annex I, excellent quality and sufficient values of *E. coli* are stated as 250 and 500 cfu/100 ml, respectively. Similarly, in "Standard Values Required for Coastal and Transitional Waters Used for Recreational Use" (Regulation for the Surface Water Quality, 2016, Annex-5, *Table 6*) provides a guide standard of 250 cfu/100 ml and the mandatory standard of 500 cfu/100 ml. Measurements indicate that in rainy spring and autumn, *E. coli* significantly increases. Along the beach (Çalış Beach, F12 and F13 Points), *E. coli* values have doubled to the mandatory standard. In 38.1% of the samples *E. coli* was recorded. The 3.6% and 1.8% of samples were above the guide standard and the mandatory standard, respectively.

Fecal streptococci (FS) are also known as enterococci and of intestinal origin. They are a more resistant group of bacteria to be used as fecal pollutant indicators (Sinton et al., 1993). Especially they live in sea waters longer. The temporal variations in FS at all measurement points according to the 12-month measurements made between March 2016 and February 2017 are presented in *Table 8*.

Table 8. *Temporal variations in FS (cfu/100 ml) at all measurement points*

Measured FS values at F01, F03, F05, F06, F07, F10, and F14, all satisfy the guide standard (100 cfu/100 ml) of the Regulation for the Quality of Bathing Water (2006), Annex-1: Table of Quality Criteria Required for Swimming and Recreation Waters. However, they exceed the guide standard at F02 in April, at F04 and F08 in January, at F09 and F13 in December and January, at F11 in April, May, September, and January, at F12 in May and January. All the measured values are less than the mandatory standard (1000 cfu/100 ml). In 66.1% of the samples FS was recorded. The 7.7% samples were above the guide standard.

Microbial degradation of waters used for drinking, irrigation or recreational purposes is monitored using concentration levels of fecal indicator bacteria (the United States Environmental Protection Agency, 2002). However, other bacteria, including gram-negative opportunistic pathogens of humans, *Pseudomonas aeruginosa*, and HPC bacteria, may also be useful in characterizing the quality of seawater (Carter et al., 2000). *P. aeruginosa* especially exists in coastal and transitional waters that interact with land (Kimata et al., 2004; Mena and Gerba, 2009). The increase in indicator bacteria in seawater and sediment has been associated with the risk of pathogenic microorganism-induced disease in humans (Donovan et al., 2008). Gastrointestinal diseases, skin infections, and risk of acute respiratory tract infections are increasing in people exposed through the recreational use of coastal waters intensified by indicator bacteria (Karbasdehi et al., 2017). Although not yet in Turkey, many regulations define measures to control *P. aeruginosa* pollution in recreational waters foreseeing such risks (Centers for Diseases Control and Prevention, 2014). The temporal variations in *P. aeruginosa* values at all measurement points according to the 12-month measurements made between March 2016 and February 2017 are summarized in *Table 9*.

Table 9. *Temporal variations in P. aeruginosa (cfu/100 ml) at all measurement points*

The highest values of *P. aeruginosa* as a pathogenic bacteria was measured at F12 in winter time. No limit value is defined in the regulations for this bacteria in coastal waters. In Italian regulations, it is defined as 1 cfu/100 ml (Guida et al., 2016) in swimming pool waters. *P. aeruginosa* was detected as well in the absence of the TC, FC and FS. In 76.2% of the samples *P. aeruginosa* was recorded.

Salmonella is a pathogenic bacterial species, and it is dangerous for human health. They may enter to coastal waters by land-based anthropological sources, wastewaters, surface flows and ballast waters of marine vessels (Altuğ, 2012). The temporal variations in *Salmonella* values at all measurement points according to the 12-month measurements made between March 2016 and February 2017 are given in *Table 10*.

Measured *Salmonella* values are generally at high levels. They exceed the limit value (0 cfu/100 ml) of the Regulation for the Quality of Bathing Water (2006), Annex-1: Table of Quality Criteria Required for Swimming and Recreation Waters. The highest values have been reached at F11, F14 and F02 in August. *Salmonella* was detected as

Plankton abundance

The temporal changes in the phytoplankton and zooplankton abundance values as number per ml (#/ml) at the surface layer of the water and at the depth of -8 m from the surface in Fethiye Inner bay are shown in *Tables 11–14* according to the monthly measurements between March 2016 and February 2017.

Table 11. *Temporal change of surface layer phytoplankton abundance (number per ml) at all measurement points*

Samples from F01 and F02 were dominated by Copepod and copepod nauplii individuals during March 2016. A few numbers of Cladocerans were also observed from the same sample. The dominance of Copepod and copepod nauplii groups were also observed between April and August 2016. Diatoms were the abundant phytoplankton group for the same period. While filamentous and green algae were dominated the April sample for F01 and F02, the system was shifted to filamentous

Samples from stations F03 and F04 were Copepod and copepod nauplii dominated during March 2016. Moreover, few Cladoceran individuals were spotted at samples from 4 m depth. Copepod and copepod nauplii were both the abundant groups at the same stations between April and August. Phytoplankton samples for the same stations were dominated with diatoms between March and August. Therefore, filamentous and green algae domination was observed during April and May 2016. While Copepod nauplii and Rotifera groups were dominant at F05 during March, Copepod, Copepod nauplii, and Cladocera groups were observed in April from the same spot. Moreover, Copepod and copepod nauplii abundance was observed between May and September. Diatoms were the dominant phytoplankton group in March for F05. Both filamentous algae and diatom were the observed during April as well. However, the system was shifted to filamentous algae dominance during May. Diatoms were the dominant group at August sampling.

Rotifer and Copepod nauplii were dominant at F06 during March sampling. However, Cladocera, Copepod and Copepod nauplii were found to be the dominant groups in April (2016). Afterward, the abundance of Copepod and Copepod nauplii groups were reached to their highest number from May to the end of August. Diatoms were the dominant phytoplankton group in March among all phytoplankton. Both filamentous and green algae were the most dominant groups together with diatoms in April 2016 samples. While the system was shifted to filamentous algae dominance at May, diatom abundance was observed in August samples.

Copepod and Copepod nauplii group were dominant at F07, F08 and F09 from April to the end of August. Cladocera individuals were also observed at F07 and F09 during the investigation of 8 m samples in April. Filamentous algae dominance was observed

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1042110444

between April and May for both stations, and a few individuals of green algae and diatoms were also observed in the same samples. Followingly, diatoms dominated the system during August. The abundant groups were Copepod and Copepod nauplii for F10, F11, F12 and F13 from April until the end of August. Additionally, Cladocera individuals were observed at F11 during April.

Diatoms, filamentous and green algae were found to be the dominant groups for the same stations in April. After that the system was first shifted to filamentous algae dominance during May, then diatom dominance was observed during August. Copepod and Copepod nauplii groups were dominant at F14 between March and August. Additionally, Cladocera individuals were observed in March and April samples. While the diatoms were dominant in March, the system was shifted to diatom, filamentous and green algae dominance in April. Filamentous algae abundance was observed in May, and diatom dominance was found during August.

Copepod and Copepod nauplii were the dominant zooplankton group at F02, F05, F06, F07, F08, F09, F10, F12, F13 and F14 during June. Moreover, some Cladoceran individuals were observed at F01 and F03. Copepod nauplii were the only zooplankton group that was observed at F11. If we summarize phytoplankton distribution, filamentous algae dominance was observed for all stations.

Copepod and Copepod nauplii were dominant zooplankton groups at F01 and F02 during September 2016 sampling. Additionally, Appendicularia individuals were observed in October at both stations for the same period. Copepod and Copepod nauplii were dominant zooplankton groups together with Cladoceran individuals for November 2016 and January 2017 samples. Copepod and Copepod nauplii were the abundant zooplankton groups as well as in March 2017 sampling. Henceforth, members of Rotifera, Cladocera and Appendicularia were observed in the sample. During the investigation of phytoplankton distribution of the stations, diatom dominance was observed for September and October 2016. Small amounts of diatoms and filamentous algae were dominated the November 2016 sample while January 2017 samples were full of green algae and a few diatom species. Diatom dominance was observed at all samples in March 2017.

Copepod and Copepod nauplii dominance was observed between September and November 2016 for F03 and F04. Additionally, a few Appendicularia class individuals were found in 4 m samples. The abundant groups were Copepod and Copepod nauplii for F03 and F04, and a small number of Cladocera individuals were found in January 2017 samples. Copepod, Copepod nauplii, Cladocera and Appendicularia individuals were observed in March for both stations as well. The phytoplankton samples of F03 and F04 were dominated by diatoms and a few dinoflagellates during September and November 2016. However, filamentous algae dominance were observed in November 2016 for the same spots. January 2017 samples were abundant with green algae and a few diatoms. Diatom dominance was observed at all samples in March 2017.

Copepod and Copepod nauplii were dominant between September and November 2016 for F05, F06, F07, and F08 together with a few Appendicularia class individuals. On the other hand, Copepod, Copepod nauplii, and Rotifera groups were mostly found in January 2017 samples with a small amount of Cladoceran and Appendicularia individuals. The same phytoplankton distribution pattern was observed for F05, F06, F07, and F08. While Diatoms and dinoflagellates were dominated the system during September and October 2016, filamentous algae abundance was found in November 2016 samples. Green algae were dominant in November 2016, and a few diatom species

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1042110444

were observed in January 2017. The system was shifted to diatom dominance during March 2017.

Copepod and Copepod nauplii were the dominant zooplankton groups for F09, F10, and F11 between September and November 2016. Also, Cladoceran and Appendicularia individuals were found in samples. Sampling points were dominated by Copepod and Copepod nauplii zooplankton groups during January 2017. However, Rotifera abundance was observed together with a few Cladoceran and Appendicularia individuals for March 2017. Phytoplankton distributions of the points showed the same pattern as F05, F06, F07, and F08.

Copepod and Copepod nauplii were the abundant zooplankton groups for F12, F13, F14, and F15 between September and November 2016. Additionally, Cladoceran and Rotifera individuals were observed in October 2016. Copepod and Copepod nauplii were found to be the dominant zooplankton groups in January 2017. Moreover, few Rotifera and Cladoceran individuals were observed in January 2017. Copepod and Copepod nauplii were the dominant zooplankton group in March 2017 together with a small number of Rotifera, Cladocera, and Appendicularia individuals. Phytoplankton distribution of the same stations showed diatom dominance with a few individuals of dinoflagellate for September and October 2016. Filamentous algae were dominant in November 2016. Green algae have dominated the samples during January 2017, and a few diatom species were found in the sample. Diatom abundance was observed in the system in March 2017 samples.

Dissolved oxygen and biochemical oxygen demand

Dissolved Oxygen (DO) level is one of the most critical parameters in monitoring water quality and is an essential indicator of water mass's ability to support healthy ecosystems (Manivanan et al., 2013). DO is the amount of oxygen present in molecular form to provide life in seawater. The DO can enter the marine environment, directly through mixing and diffusion, or as a by-product of photosynthesis. Therefore, the level of DO in the water may increase due to strong wind and wave motions and the presence of plants and algae. On the other hand, it decreases by respiration and decay. When the plant population is very intense, oxygen consumption increases. Organisms such as bacteria, phytoplankton, and zooplankton need oxygen and consume dissolved oxygen in large quantities. Degradation of organic matter is the most significant oxygen consumer in the system. In general, a dissolved oxygen level of at least 4 mg/L is required to support live life. In marine environments, chronic oxygen deficiency occurs when the DO amount is between 2.0 and 6.0 mg/l, and hypoxic conditions (acute oxygen deficiency) threaten livelihood occur when DO is lowered than 2.0 mg/l. When the DO level drops below 0.2 mg/l, anoxic or oxygen-free conditions occur (O'Boyle et al., 2009). As temperature and salinity increase, the oxygen concentration in the seawater decreases.

The 12-month measurements between March 2016 and February 2017 were made at every 2 m from the surface to the sea bottom. The temporal changes of DO measurements at the water surface and at -14 m below the surface are presented in *Tables 15* and *16,* respectively. The seasonal and annual averages of DO (mg/l) at all measurement points are summarized in *Table 17*. The measured dissolved oxygen values are in between 3.83 and 9.12 mg/l, and the values are decreasing in the summer when the temperature is the warmest. In summer, mean DO values are below 6 mg/l,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1042110444

and chronic oxygen deficiency condition is seen. All of the measurements were higher than 2 mg/l higher and hypoxic or anoxic condition was not observed.

Biochemical Oxygen Demand (BOD) is a measure of the amount of oxygen that is consumed by microorganisms to break down organic substances. As the water temperature values increase, the BOD values also increase. When the water temperature rises, photosynthesis rate of plants increases, plants grow faster and die. Decay the dead plants by the bacteria requires oxygen, and as a result, the BOD values rise. For this reason, the BOD values in the summer months are higher than the winter months values. The increase in nitrate and phosphate increases the rate of plant growth and death, and thus the organic pollutant load that will be broken down by bacteria in the marine environment. For this reason, the increase in nitrate and phosphate values is also effective in increasing BOD levels. As the BOD level rises, the dissolved oxygen (DO) values used by bacteria are reduced. In the months of intense rainfall, there is an increase in the mixing of the organic materials found in the soil with the sea water. Generally, in the uncontaminated waters, the BOD level is less than 4 mg/l, while it can reach 8-150 mg/l in the wastewater (Regulation of Surface Water Quality, 2016).

According to the 12-month measurements between March 2016 and February 2017, the temporal changes of the BOD values at the surface of Fethiye Inner Bay are presented in *Table 18*. All measured BOD values range from 2.3-6.8 mg/l.

In this study, a three-dimensional coastal waters hydrodynamic (Balas and Özhan, 2003), wave propagation, transport and water quality (Cebe and Balas, 2016) numerical model HYDROTAM-3D, was used and a water quality monitoring and evaluation database system based on geographical information system (GIS) was established. The database system is available at www.hydrotam3d.com/fethiye by username: fb and user password: fb. Coordinated and temporal access is provided to all data.

Results and discussion

The monthly variations of water quality parameters were investigated through the site measurements conducted in between March 2016 and February 2017. Once at every month, at selected 14 locations, water samples were collected, and total coliform, fecal coliform, fecal streptococci, *Escherichia coli, Pseudomonas aeruginosa, Salmonella* detection, phytoplankton and zooplankton abundance analyses were performed in the laboratory. By using the related TSE standards, biochemical oxygen demand (BOD) and dissolved oxygen (DO) levels were determined, and water samples were collected from surface and -8 meters below if possible. The physical parameters measured throughout the water column were water temperature, salinity, pH, and turbidity. Changes in parameters measured between March 2016 and February 2017 were summarized in *Table 19*.

Table 19. *The measured ranges of physical and chemical parameters suitable to water samples in Fethiye Inner Bay*

Number of samples	Parameters	Mean	Minimum	Maximum
14	Water Depth (m)	16.2	4.5	46
1164	Salinity (S, ppt),	37.5	30.4	39.4
1164	Temperature (T,°C)	21.4	12.7	30.8
1164	pH	8.09	7.55	8.38
168	Turbidity (Turb.,ntu)	2.08	0.54	4.81
168	Total coliform (TC, cfu/100 ml)	298	0	6090
168	Fecal coliform (FC, cfu/100 ml)	131	0	6090
168	Fecal streptococci (FS, cfu/100 ml)	28	0	800
168	*E. coli* (cfu/100 ml)	37	0	933
168	*P. aeruginosa* (cfu/100 ml)	174	0	3350
168	*Salmonella* (cfu/100 ml)	930	0	18550
1164	DO (mg/l)	6.4	3.83	9.12
168	BOD (mg/l)	4.2	2.3	6.8

Pearson correlation matrix and related p-values were carried out on all the data set of water samples to describe the relations between measured parameters. In *Table 20,* coefficient of correlations (r) were listed, and significant correlations at $p < 0.05$ were indicated. After examination of several scatter plots, it is decided to refer the correlation as a weak correlation if $0.1 < r < 0.3$, a moderate correlation if $0.3 < r < 0.5$ and a strong correlation if $0.5 < r < 1.0$.

According to the correlation analysis, it is seen that temperature shows a weak positive significant correlation with the salinity ($r = 0.28$), pH ($r = 0.15$) and turbidity ($r = 0.25$). In line with a moderate positive correlation ($r = 0.3$), as water temperature increases, zooplankton counts increases as well. pH values show a weak negative correlation with DO ($r = -0.17$) and phytoplankton counts ($r = -0.15$) and a weak and moderate positive correlations with turbidity ($r = 0.19$) and zooplankton counts ($r = 0.32$) respectively. Zooplankton shows a reduction in numbers at the lower pH levels.

*significant at $p < 0.05$

As the salinity of coastal waters decreases in rainy seasons, DO (r = -0.15) and phytoplankton counts (r = -0.27) increase and BOD decreases (r = 0.33). The measured DO decreases in the summer, as the water temperature increases. In 32% of the measurements, DO values are below 6 mg/l, and chronic oxygen deficiency condition is seen. DO and BOD values show a strong inverse relation (r = -0.61) as shown in *Figure 5*. DO values reach the highest values in the spring, while BOD values are the lowest. It is seen that, as phytoplankton counts (r = 0.43) increase and zooplankton counts (r = -0.45) decrease, DO increases in coastal waters of Fethiye Inner Bay. Whereas zooplankton counts show a positive moderate correlation with BOD (r = 0.35).

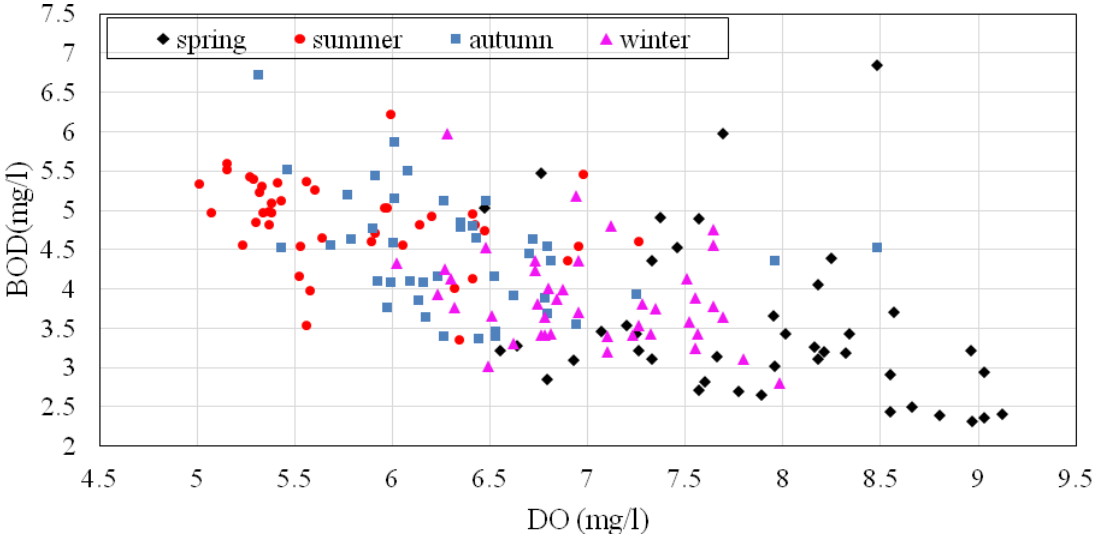

Figure 5. *Seasonal change of dissolved oxygen and biological oxygen demand*

BOD tends to increase in summer and autumn. This is due to the increase in microorganisms that requires dissolved oxygen to oxidize organic matter. BOD values

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1042110444

are higher than 4 mg/L in 55% of measured samples. It is seen that BOD values have a positive relation with TC (r = 0.34), FC (r = 0.24) and FS (r = 0.24). BOD increases as the concentration values of organic pollutants increase. As an example of this positive relation, timewise changes in BOD, total coliform, fecal coliform and fecal streptococci values at selected measuring points F06 and F12 are presented in *Figure 6*.

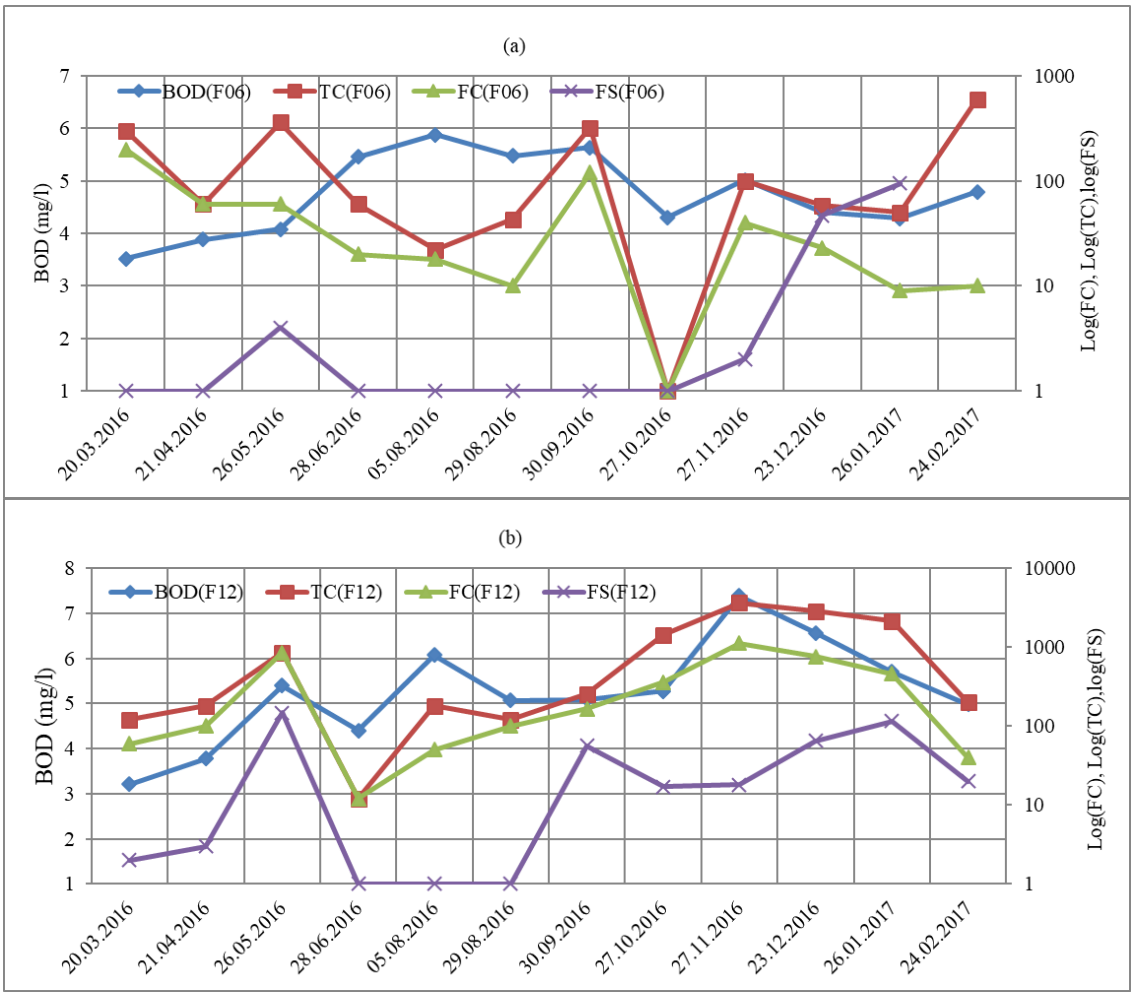

Figure 6. *Temporal changes in BOD, total coliform, fecal coliform and fecal streptococci values a) at point F06 b) at point F12*

It is seen that as TC amount increases, FC (r = 0.85) strongly increases and also FS (r = 0.17) shows an increase. In 91.7%, 85.7% and 66.1% of the samples TC, FC and FS were recorded respectively. In 15.5%, 21.4% and 7.7% of them were above the TC, FC and FS guide standards respectively. In 38.1% of the samples *E. coli* was recorded, and 3.6% and 1.8% were above the guide standard and the mandatory standard, respectively. It is seen that, FS amount has positive moderate correlation with phytoplankton count (r = 0.33).

In this study, "Spring Bloom" were observed between May and July which corresponds with the highest level phytoplankton abundance in the sampling points and the results are in line with Sverdrup's (1953) study (Colebrook, 1982; Martinez et al., 2011). During the "Spring Bloom", the amount of phytoplankton in aquatic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1042110444

environments increase significantly due to less stratification, more stable dispersion of temperature and higher availability of surface nutrients.

After the spring bloom season, there was a decrease in phytoplankton and increase in zooplankton in all samples. Measurements show that there is an inverse correlation between zooplankton and phytoplankton counts (r = -0.3). Zooplankton numbers were reached to their maximum between August and September, then started to decrease in October. Moreover, a few phytoplankton peaks were also observed in the end of the fall bloom. This pattern corresponded with an event called "Fall Bloom". According to literature, the stratified water column started to mix due to an increase in the atmospheric events that cause an increase in nutrient levels as well in the aquatic ecosystem which results with a bloom in phytoplankton levels for a short period (Sverdrup, 1953). In this study, fall bloom was spotted starting from October, and it lasted for three months.

According to the results of the study performed, the number of total coliform bacteria had a significant increase during May and September. All measured microbiological parameters frequently increase in spring and winter, often exceeding guide standards. In a study by Kim et al. (2000), it was shown that increase in bacterial populations tended to be seasonal, which was in line with results of this study. The observations in the current study showed that zooplankton samples were mostly dominated by copepods which had a low grazing control of bacteria. Correspondingly, it is thought that the bacterial growth is not controlled by zooplankton in this study.

In conclusion, land-based pollutants transported with increasing surface runoff are thought to cause an increase in microorganism concentrations. Swimming in Çalış Beach coastal waters (F12 and F13) might be dangerous for human health. Seasonal averages and high BOD values indicate that the Fethiye Inner Bay is under considerable threat of continuous pollutant loadings. Measurements all indicate that immediate measures should be taken to reduce the land-based pollution causing degradation of coastal water quality in Fethiye Inner Bay.

Acknowledgements. This study was carried out with the support given by the Scientific and Technological Research Council of Turkey (TUBITAK) under the scope of the Project (No: 115Y468) entitled as 'Monitoring and evaluations of water quality parameters in coastal waters'. Authors would like to thank employees of DLTM Software Technologies Limited Company due to their support for field measurements.

Abstract. Domestication of the crop plants has narrowed the genetic base of the crops and thereby mounting their exposure towards global climate change, disease and insect epidemics. Genetic variability of modern days crops must be broadened to make crop production more sustainable against various biotic and abiotic stresses which are posturing major threats to the world. It is therefore, crucial to identify novel additional sources of durable resistance. Wheat wild relatives have provided valuable sources of genetic diversity for various biotic, abiotic and quality components. In this respect wide hybridization has become a promising breeding method for introducing new variability in crop plants by using the crop wild relatives. In the present research work wheat-*Th. Bessarabicum* amphiploid, addition and translocation lines have been screened. These genetic stocks were exposed to 15% polyethylene glycerol (PEG) stress, to find out the drought tolerant addition and translocation lines by studying different physiological parameters. The screening of drought stress revealed that addition lines 2JJ, 4JJ, 5JJ, 7JJ and translocation line Tr-7 exhibited tolerance attitude towards water deficient conditions.
Keywords: *chlorophyll contents, proline, superoxide dismutase, drought tolerance, wheat (Thinopyrum bessarabicum) addition and translocation lines*

Introduction

The negative effect of non-living factors on the growth and development of living organism is termed as abiotic factors. Abiotic stress factors occurred naturally that may cause harm to the plants and animals in the effected area. Abiotic stress is the most destructive one concerning the growth and productivity of crops worldwide. It has also been found that abiotic factors are very harmful when they occur together in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1044510461

combinations (Milter, 2006). The most important abiotic stress factors include salinity, drought and water logging which cause harm to the plants.

Water deficit condition imposes severe influences on growth and development of plants by causing changes at the physiological, metabolic and molecular levels (Zu et al., 2017). Drought is the prolonged period without precipitation that is injurious to crops plants. It is the most important environmental factor that limits the plant growth and productivity than any other environmental stresses (Jones and Corlett, 1992). Approximately 32% of wheat growing culture faces different types of drought stress throughout the growing season in developing countries (Morris et al., 1991). About 15 million ha of cultivated land in Pakistan is affected by this environmental factor (Mujtaba and Alam, 2002). About one-third of the total annual cereal production is obtained from wheat alone. The response of plants for drought stress depends upon the severity, frequency, duration of exposure and the plant growth stage (Bray, 1993).

Germination, tillering and the reproductive stages are considered to be the most sensitive to drought in wheat (Passioura, 2007). The best way to encounter this problem is to develop high yielding drought tolerant crop varieties. Genetic diversity of cultivated plants has become drastically narrowed due to selection pressure in breeding programs thereby minimizing tolerance to environmental stresses (Nevo, 2004). Global warming followed by rising drought and salinity has threatened the world's food security. One of the economical and sustainable solutions for increasing crop stability and productivity is by making improvement in crops genetic structure for higher tolerance against abiotic stresses (Blum, 1998; Ashraf et al., 2009). This can be achieved by the utilization of several methods; one of the method is by identifying agronomically important novel genes and QTLs from the wild genotypes to improve the cultivars (Xie and Nevo, 2008).

The crop wild relatives that adapt to drought stress environment are expected to have genes or alleles for drought and salt tolerance. These drought tolerant genes and/or QTLs could be introgressed or cloned to increase crop tolerance (Araus et al., 2003). Addition of barley chromosome segment into wheat has shown tolerance to drought (Hoffmann et al., 2011). *Th. bessarabicum,* a wheat wild relative grows on the sea shore of the Crimea (Gorham et al., 1985) are highly salt tolerant. Wild relatives that show salt tolerance also exhibit drought tolerance (Farooq and Azam, 2001). Soil water potential is decreased in drought stress which ultimately reduces plants osmotic potential for water absorption by congestion of soluble carbohydrates and proline and in other words osmotic regulation is performed (Martin et al., 1993). Consequently osmotic regulation will help to improve plant growth and development in water stress (Pessarkli, 1999).

Drought tolerance can be enhanced if selection is made on the basis of physiological mechanisms or characters conferring tolerance. Drought stress tolerance in crop plants is associated with various physiological traits such as proline accumulation for osmoregulation (Nayyar and Walia, 2003; Larkunthod et al., 2018) increased activity of antioxidant enzymes like superoxide dismutase (SOD), peroxidases (POX) to protect membrane integrity (Sairam and Saxena, 2000) and various yield components (Majid et al., 2007; Lonbani and Arzani, 2011). One of the ways to develop drought tolerant crop, these parameters can be used to screen the genetic stock to identify the new sources of tolerance for developing drought tolerant crop species/varieties. Drought tolerant selection at seedling stage is mostly carried out through Polyethylene glycol (PEG)-treated hydroponic conditions which induce negative osmotic potential comparable with

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1044510461

moisture deficit stress (Robin et al., 2015). The aim of present experiment was to find out the suitable drought tolerant wheat-*Th. bessarabicum* genetic stocks. The evaluation was made on the basis of physiological responses like accumulation of proline, superoxide dismutase enzymes activity and chlorophyll contents.

Materials and methods

Plant material

The germplasm consisted of wheat-*Th. bessarabicum* addition and translocation lines along with some other drought tolerant and susceptible cultivated wheat varieties (Bano et al., 2012) as a check. The material was obtained from Wheat Wide Crosses Program at NARC Islamabad. Pedigree of these genetic stocks is given in *Table 1*.

Table 1. *Pedigree of wheat-Th. bessarabicum genetic stocks*

Chakwal-97, Punjab-96	Drought tolerant and susceptible wheat cultivars (Bano et al., 2012)

Laboratory procedure

The genetic stock was evaluated for several physiological and biochemical traits analysis in hydroponics with Polyethylene glycerol (PEG) induced drought under controlled environmental conditions of laboratory (*Fig. 1*). In the first phase, all the genetic stocks with two check cultivars were evaluated for drought analysis under two treatments namely control (Hoagland solution) and 15% PEG. Fifteen seeds/genetic stock were germinated in petri plates. After confirming the chromosomes number, the germinated seedlings of 3-4 days were shifted in small pot trays containing 2:3 of compost and sand. After 10 days, seedlings were transferred to holes on the 5 L hydroponics boxes containing half strength Hoagland's nutrient solution (Hoagland and Arnon, 1950). The pH of nutrient solution was maintained between 5.5-6.0 with 1N HCl

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1044510461

or KOH. Air pumps were fitted for providing oxygen to the roots throughout the growing period. For inducing drought, polyethylene glycol (PEG 6000) was used. Young leaf samples of three plants from each genetic stock were collected for different biochemical analyses after seven days of 15% PEG for drought stress.

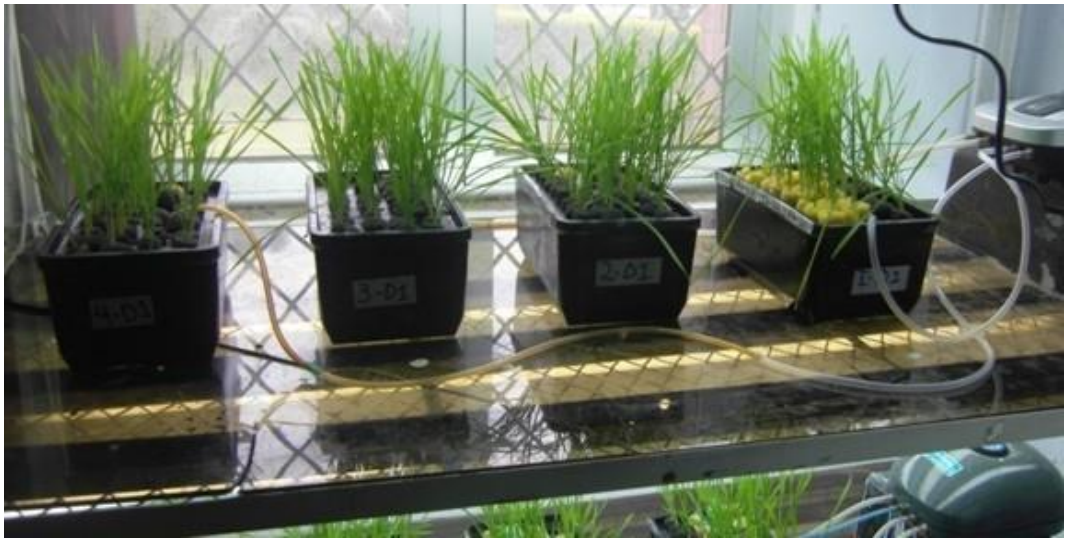

Figure 1. *Hydroponic experiments for screening tolerance against drought in Thinopyrum bessarabicum genetic stock at 15% PEG treatment*

Proline contents determination

Analysis of proline contents was done by the method of Bates et al. (1973). Fresh leaves of each sample weighing 0.25 g were homogenized in 10 mL of 3% aqueous sulfosalicylic acid and solution was filtered through Whatman 42 filter paper. 2 mL acid-ninhydrin and 2 mL of glacial acetic acid was added in filtrate and placed in a water bath for 1 h at 100 °C. After that the mixture was extracted with 4 mL toluene and readings were taken at 520 nm wavelength using a spectrophotometer.

Superoxide dismutase (SOD) determination

The SOD activity was calculated by measuring the ability of the enzyme to inhibit phytochemical reduction of nitrobluetetrazolium (NBT) according to the method of Giannopolitis and Ries (1977). Fresh leaf sample (0.25 g) was homogenized with 1 mL of 100 mML^{-1} sodium phosphate buffer containing 1% polyvinyl pyrollidone (PVP) in an ice bath. Then centrifugation was done at 10,000 rpm for 15 min at 4 °C. For SOD activity, the reaction mixture (3 mL) contained: K-Na-phosphate buffer (60 mM, pH 7.8), methionine (13 mM L^{-1}), riboflavin (12 mM L^{-1}), P-tetrazoleum blue (80 µM), EDTA (0.1 mM) and 100 µL of enzyme extract. The reaction mixture was left for 10 min under 15 W fluorescent light. After 10 min, light was switched off to stop the reaction. The absorbance of the mixture was measured by using spectrophotometer at A560 nm wavelength. For control the reaction mixture without the enzyme extract was utilized and a dark control mixture acted as a blank. One unit of SOD activity was taken as the quantity of enzyme that is able to inhibit tetrazoleum blue reduction by 50% as determined at 650 nm wavelength. SOD activity was expressed in arbitrary units per mg of fresh weight.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1044510461

Chlorophyll contents determination

Crude extract from each sample was taken and readings were measured at spectrophotometer (RS-110) at wavelength 645 nm and 663 nm immediately with care to minimize exposure to light. Chlorophyll contents were calculated according to Arnon (1949).

Statistical analysis

Completely Randomized Design (CRD) was followed with three replications. The data were analyzed by analysis of variance technique and comparison among treatment means was made by Least Significant Difference (LSD) test by using Statistix 8.1 computer software at $p \leq 0.05$.

Results

Proline contents

Statistical analysis showed significant differences among wheat-*Th. bessarabicum* genetic stocks at 15% PEG stress at $p \leq 0.05$ for proline contents (*Table 2*). In this experiment, free proline contents were increased in almost all the drought stressed-seedlings of wheat genetic stock (*Fig. 2*). Maximum increase was observed in 3JJ (99%) followed by 7JJ (96%) and 5JJ (93%) disomic addition lines and in amphiploid (90%) as compared to the non-stressed plants. These addition lines represented the increased proline contents as compared to CS parent and drought tolerant check cultivar Chakwal-97, while addition lines 1JJ and 2JJ represented minimum increase in proline contents. All the translocation lines showed increase in proline contents than that of CS parent and tolerant check cultivar Chakwal-97. Translocation line Tr-6, Tr-7 and Tr-5 showed maximum increase of 97%, 95% and 94%, respectively which is greater than that of the drought tolerant genotype Chakwal-97, CS parent and CS/*Th. bessarabicum* amphiploid.

Inter critical value for comparison was 2.8, while general critical value for comparison was 3.96

Superoxide dismutase (SOD)

Statistical analysis showed significant differences among wheat-*Th. bessarabicum* genetic stocks at 15% PEG stress at $p \leq 0.05$ for superoxide dismutase activity (*Table 3*). The result showed SOD activity enhanced significantly in all the genotypes. The magnitude of the increment was different in various addition and translocation lines (*Fig. 3*). Under drought stress, maximum SOD activity was recorded in amphiploid (96%), translocation line Tr-2 (71%), Tr-7 (75%) and addition lines 1JJ (87%), 2JJ (90%), 5JJ (85%), 7JJ (83%) showed maximum SOD activity which was higher than that of the drought tolerant genotype Chakwal-97 (56%). Other translocation and addition lines along with amphiploid showed high to medium increase in SOD activity.

Chlorophyll A contents

Statistical analysis showed significant differences among wheat-*Th. bessarabicum* genetic stocks at 15% PEG stress at $p \leq 0.05$ for chlorophyll A contents (*Table 4*). Drought stress reduced significantly on leaf chlorophyll A contents of wheat genetic stock (*Fig. 4*). Comparison of wheat genetic stock revealed that addition lines 1JJ (9.6%), 2JJ (17%) and 4JJ (12%) represented reduction in chlorophyll A contents as compared to control and drought tolerant check. Similarly translocation line Tr-7 (11%),

Tr-6(19%) closely followed by Tr-3 (21%) and Tr-4 (21%) depicted minimum reduction in chlorophyll A contents. On the other hand, addition line 5JJ represented an increase in chlorophyll A contents.

Chlorophyll B contents

Statistical analysis showed significant differences among wheat-*Th. bessarabicum* genetic stocks at 15% PEG stress at $p \leq 0.05$ for chlorophyll B contents (*Table 5*). Water deficit significantly reduced leaf chlorophyll B contents of all the wheat genetic stock (*Fig. 5*). Results revealed that all the wheat genetic stock addition lines 1JJ (24%), 4JJ (38%) 7JJ (39%) and translocation line Tr-1 (18%), Tr-9 (22%) represented the lowest reduction in chlorophyll B contents as compared to control and drought tolerant genotype. While addition line 5JJ (61%) and translocation line Tr-8 (61%) depicted maximum decrease in chlorophyll B contents.

Total chlorophyll contents

Statistical analysis showed significant differences among wheat-*Th. bessarabicum* genetic stocks at 15% PEG stress at $p \leq 0.05$ for total chlorophyll contents (*Table 6*). Results revealed that addition line 1JJ (14%), 2JJ (10%) and 4JJ (18%) showed minimum reduction in total chlorophyll contents, while addition lines 5JJ (24%), 6JJ (24%) and 7JJ (25%) depicted moderate decrease in total chlorophyll contents (*Fig. 6*). Similarly translocation lines Tr-5 and Tr-7 represented lower reduction in total chlorophyll contents.

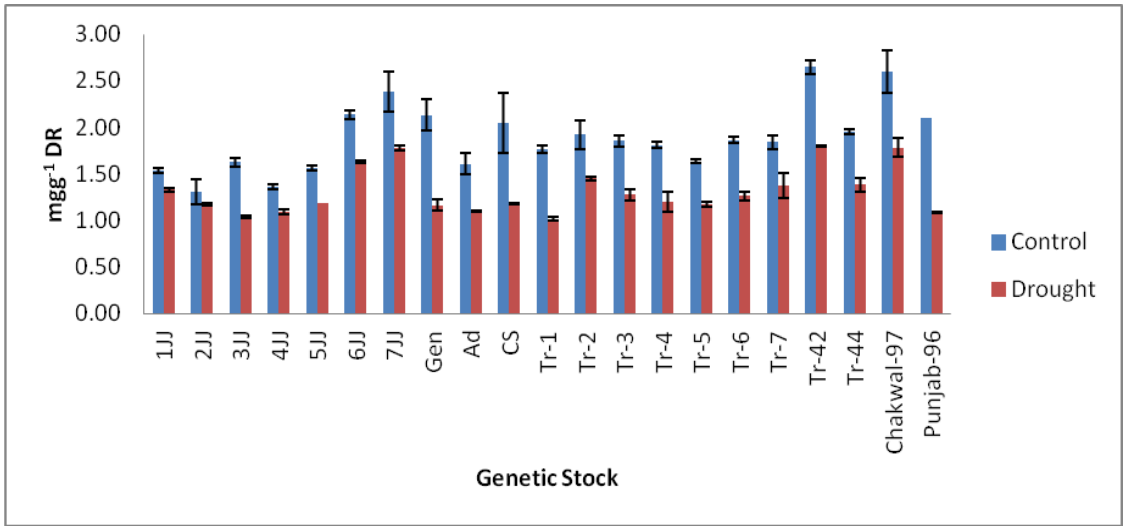

Figure 6. *Total chlorophyll contents in leaves at control and 15% PEG treatments*

Discussion

CS-*Th. bessarabicum* addition and translocation lines might possess tolerant genes for drought. Salt tolerant species might prove drought tolerant in the areas where water deficit prevails was inferred from the study of Farooq and Azam (2001). Whereas *Th. bessarabicum* (2n = 2x = 14, JJ or EbEb) is a perennial maritime wheatgrass that possesses salinity tolerances and can be an important gene source for wheat improvement (Gorham et al., 1985; William and Mujeeb-Kazi, 1993; King et al., 1997a). Majority of the traits associated with improved performance under drought stress have complex nature and controlled by several genes each having a small effect (Rebetzke et al., 2007; Yang et al., 2007).

Drought causes oxidative damages by producing reactive oxygen species (ROS) such as hydroxyls (OH), superoxide (O^{-}_{2}), peroxide hydrogen (H_2O_2). These ROS may initiate disturbance in lipid peroxidation, chlorophyll, protein oxidation, and nucleic acid (Scandalios, 1993). To combat the effects of drought–induced oxidative stress, plants develop complex mechanisms of antioxidant system via induction of drought tolerant genes (Bowler et al., 1992). Increase in ROS causes the enhanced SOD activity which is a major scavenger of O_2^- and it can catalytic the disproportionate reaction of superoxide radical anions into oxygen and hydrogen peroxide (Scandalios, 1993). As a consequence, H_2O_2 accumulation was possibly due to the activation of SOD. Thus, the balance between ROS and the antioxidative system is crucial for survival and adaptation to stress (Weng et al., 2015). Amphiploid, addition lines 1JJ 2JJ, 5JJ, 7JJ and translocation lines Tr-2, Tr-7 might have tried to maintain oxidative stress by exhibiting maximum SOD production. These addition lines possess 1J, 2J, 5J and 7J chromosomes pairs, while translocation lines have translocated segments of 1J and 5J from *Thinopyrum bessarabicum* chromosomes, respectively probably possess genes conferring resistance to drought via overproduction of SOD to scavenge ROS to protect against drought stress. SOD genes were mapped to the long arms of the homologous group-2 and group-7 chromosomes of wheat, respectively (Guohai et al., 1999). Zhao Xinhua et al. (2005) also found QTLs for SOD on chromosomes 1D, 2B and 5A of wheat. Higher SOD activity has also been reported in drought tolerant genotypes of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1044510461

wheat (Sariam and Saxena, 2000). Din et al. (2009) also reported enhanced SOD activity in drought tolerant germplasm of wheat.

Drought stress influences the transcription of some of the genes to synthesize different types of drought stress related proteins, and proline is one of them. Proline is a crucial protein that has a vital function in water stress tolerance. Free proline might be involved in membrane stabilization during water stress (Kocheva and Georgiev, 2003), or it might be a reserve of readily mobilizable N available upon relief of stress (Hare et al., 1998). It has been reported that proline accumulation in the cytosol might be enough for osmotic adjustment by activating other mechanisms, such as the formations of strong H-bonded water around protein for protecting protein structures and scavenger of free radicals (Rascio et al., 1994; Alia et al., 2001; Ghoulam et al., 2002).

Results showed that addition lines 3JJ, 7JJ, 5JJ and translocation lines Tr-5, Tr-6 Tr-7 exhibited the highest proline accumulation at 15% PEG treatment indicating that these addition and translocation lines might possess genes on *Th. bessarabicum* chromosomes/chromosomal arms, which were induced during water deficit condition to maintain their turgor through osmotic adjustment. Research studies have shown that drought stresses increased leaf proline contents as compared to the control in drought tolerant lines (Dehnavi et al., 2017; Larkunthod et al., 2018). It was indicated by Gariba et al. (1992) that chromosome 4B, 5A and 5D of wheat may carry genes associated with the control of proline accumulation induced by osmotic stress. Ma et al. (2008) indicated an enzyme P5CR is the last enzyme in the cascade for proline synthesis. The TaP5CR gene was located on chromosome 3D of wheat genome. Its expression was upregulated by salt, PEG, ABA and heat stress. On the basis of above mentioned observation it can be suggested that enhanced level of proline accumulation in 5JJ and 3JJ addition line might be due to extra dosage of genes associated with the control of proline accumulation present on 5J and 3J chromosomes of *Th. bessarabicum*. The 7JJ addition lines might possess some other genes on *Th. bessarabicum* chromosomes which might be involved directly or indirectly in enhancing proline accumulation under drought stress. While translocation line Tr-5 contains chromosomal segment of 4J, Tr-6, while Tr-7 contains 6JS and 5JS chromosomal arm of *Th. Bessarabicum*, respectively that might possess some more genes responsible for inducing stress tolerant genes and accumulation of the highest level of proline under drought condition. Accumulation of osmolyte like proline has also been noticed in variety of crop species. Transgenic tobacco plants over expressing proline synthesis genes have been claimed to induce osmotic adjustment and have increased drought tolerance (Kishore et al., 1995). Under stress condition, proline concentration has been shown to be generally higher in stress-tolerant than that of stress-sensitive plants in many plant species such as rice (Shereen et al., 2007), alfalfa (Petrusa and Winicov, 1997), maize (Sharp et al., 1994), pigeon pea (Waheed et al., 2006) and potato (Rahnama and Ebrahimzadeh, 2004).

Concentration of chlorophyll contents in chloroplast affects photosynthetic capacity of crops and thereby considered a significant adaptation trait under water deficit condition (Chernyad'ev and Monakhova, 2003). Tolerance to drought comprises of maintaining high chlorophyll contents under water deficit to support photosynthetic capacity of plants (Yasmin et al., 2013). Drought stress causes decrease in the contents of chlorophyll by producing ROS such as O_2 and H_2O_2, thereby causing lipid peroxidation which consequently results in chlorophyll destruction (Mirnoff, 1993; Foyer et al., 1994). It has been expressed that tolerant genotypes of wheat and corn possessed higher chlorophyll contents than that of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1044510461

sensitive genotypes during oxidative stress (Pastori and Trippi, 1992; Dehnavi et al., 2017). Disomic addition lines 1JJ, 2JJ, 4JJ possess a pair of 1J, 2J, 4J chromosomes and translocation lines Tr-7, Tr-6, Tr-3, Tr-4 possess chromosomal arms 5JS, 6JS, 3JS and 1JL, respectively from *Th. bessarabicum*, emphasizing the importance of these chromosomes/chromosomal arms in determining the tolerance of these genetic stock as these genetic stocks showed minimum reduction in chlorophyll A contents. While 5JJ addition line exhibited an increase in chlorophyll A contents under drought stress might possess gene(s) which were directly or indirectly involved in over expression of the chlorophyll A synthesis genes. It has also been found that the chlorophyll contents of leaves are increased in resistant cultivars under drought stress (Shahriari, 1999).

Reduction in chlorophyll contents of various crops has been previously reported by many researchers under drought stress. Results of chlorophyll B showed that addition lines 1JJ, 4JJ, 7JJ and translocation lines Tr-1 and Tr-9 exhibited minimum reduction in chlorophyll B, while addition lines 1JJ, 2JJ, 4JJ, 5JJ, 6JJ, 7JJ, amphiploid and translocation lines Tr-5 and Tr-7 depicted minimum decrease in total chlorophyll contents under water stress environment. Minimum reduction of chlorophyll B and total chlorophyll contents in these addition and translocation lines under drought stress might be linked to the presence of chromosomes/chromosomal arms from *Th. bessarabicum*.

It has been demonstrated that chlorophyll concentration in plants is a quantitative trait. Seven QTLs for chlorophyll contents on chromosomes 2B, 4A, 5B, 6A, 7A, and 7D under Nitrogen sufficient environment, while nine QTLs for chlorophyll contents on chromosomes 2D, 3A, 4B, 5B, and 6A when wheat seedlings are grown under nitrogen deficient environment were identified (Cao et al., 2004). Yang et al. (2007) mapped four additive QTLs controlling chlorophyll contents under water deficient and well watered on chromosomes 1A, 5A, and 7A in wheat. All these observations specify that controlling of chlorophyll contents in various environments is governed by multiple gene loci distributed on different chromosomes authenticating it as quantitative trait. Similar kinds of increased stress tolerance through presence of alien chromosomes of *Th. Elongatum* have also been reported by Taeb et al. (1993). Several alien substitution and translocation lines of wheat (*Triticum aestivum* L.) have shown genetic diversity for desirable traits of the alien donors (Rabinovich, 1998; Ko et al., 2002).

Conclusion

Wheat-*Th. bessarabicum* genetic stocks were given 15% PEG stress to evaluate their drought tolerance. The results indicated that amphiploid and the addition lines 1JJ, 5JJ, and translocation line Tr-7 have performed best in most of the physiological parameters studied in drought stress, and are considered to be tolerant under water stress condition. Other addition lines including 2JJ, 4JJ and 7JJ can be categorized as moderately tolerant to water deficit condition on the basis of their performance in traits studied under drought stress. These addition and translocation lines are recommended as sources of introducing drought tolerance into drought susceptible wheat cultivars.

(Received 20th Dec 2018; accepted 10th Apr 2019)

Abstract. Sustainable Conservation Standards (SCS) promote the need for preserving soil life system and minimal use of farm chemicals including fertilizer to replenish the soil. The standards also guide farmers to meet international food safety and production standards such as Global Good Agricultural Practices (GLOBALGAP). The study was conducted in Kenya examined and compared levels of compliance to Sustainable Conservation Standards between GLOBALGAP certified and Non-GLOBALGAP Certified farms. Also, the study examined profit efficiency between GLOBALGAP certified and Non-GLOBALGAP Certified farms. The sample size comprised of 429 randomly selected smallholder farmers from three major snap bean producing regions in Kenya. The result revealed that the majority of GLOBALGAP certified farmers were likely to comply to Sustainable Conservation Standards techniques such as low usage of pesticides, herbicides, and fertilizer than None GLOBALGAP certified farmers. The showed that compliance to SCS and food safety and production standards enables snap bean smallholder farmers to directly access advanced value chains and ultimately receive higher prices for produce. We conclude by noting that the cost of implementing international food safety and production standards is still expensive to smallholder farmers especially in Sub-Saharan Africa.
Keywords: *GLOBALG.A.P., food safety, production standards, conservation agriculture*

Introduction

Globally food production system has been experiencing the transformation that greatly impacts on the global food supply value chains (Muller et al., 2017). One of the primary concern for changes in the production system is climate change and its impending threats to food and nutrition security. The effects will probably impact more in the developing countries that heavily depend on agriculture for livelihoods. For instance in Sub-Saharan Africa, agricultural production is the major employer in rural areas and also cushions against perennial food shortages (Stevenson et al., 2014). In the region, majority of the farmers are considered to own small parcels of land and are poor with low financial resources to cushion them against the adverse effects of climate change. The second concern to global food production is intensive agricultural production that advocates for excessive use of external inputs. This has been noted to increase the degradation of soil, water, and genetic resources over time. The increase in degradation of national resources not only pose a threat to global food security but

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1046310474

destabilizes livelihoods of larger populations. A study by Tilman et al. (2011) noted that annually more than 10 million hectares of quality productive land is lost due to soil degradation process, this will affect more than 1.5 billion people who depend directly on the land.

Generally, the trends in the degradation of national resources are seen to be on the increase despite policies put in place to reduce the growing threats. In developing countries, the agricultural production system is facing an even greater magnitude of soil and water degradation in prime agrarian lands (Whitfield et al., 2015). In particular, smallholder farms are experiencing falling groundwater table, declining organic carbon and soil matter, intensive soil tillage, imbalance of soil nutrients, increase in the use of pesticides and herbicides. The factors are believed to have contributed to declining crop yields and the rising cost of production and high wages. While on the supply marketing chain, smallholder farmers are not only limited to access to advanced markets but are also experiencing low prices for agricultural commodities. Besides, farmers are facing pressure from consumer's increasing demand for higher food quality and safety standards (Annor et al., 2016).

To sustain food production, overcome modern agrarian challenges and ensure that producers have stable livelihoods, policies on the adoption of sustainable conservation standards have been promoted. Mainly sustainable conservational agricultural practices ensure that farmers observe i) surface-incorporation of crop residues ii) reduced tillage or soil disturbance iii) increase production of cover crops for both annual and perennial crops. The concept is aimed at enriching and promoting soil health by enhancing natural biological processes above and below the soil surface. Also, SCS emphasizes the need for preserving soil life system and allows for minimal use of farm chemicals, including fertilizer to replenish the soil. However, the chemicals inputs quantities used in Sustainable Conservation farming are lower in comparison to conventional farming (Milder et al., 2015).

Over the years' sustainable production standards have merged to be a promising response to challenges of the degradation of national resources. Most of the agricultural sustainable production standards mainly address issues related to environmental quality and biodiversity conservation (Bain et al., 2013). Globally agricultural sustainability conservation standards are applied in production of major crops such as cocoa (22%), palm oil (15%), and tea (12%), coffee (38%) sugar (3%), soybeans (2%), and other crops (Potts et al., 2014). Good Agricultural Practices (GLOBALGAP) production is one of the standards put in place to minimize the negative impact of agriculture on the environment while meeting consumer concerns of food safety. Specifically, GLOBALGAP aims to reduce the use of fertilizer, management of waste, minimize the use of pesticides and efficiently use of non-renewable resources. Also, the standards ensure farmers invest in worker's safety and traceability systems (Chan, 2016).

In Sub-Saharan Africa (SSA), land productivity and per capita food availability have been on the declining in comparison to other regions in the world. Declining soil fertility and high-cost inputs are mainly linked to low agricultural productivity in the region. The problem is more profound among poorly endowed smallholder farmers. Majority of the farmers lack knowledge, resources, and techniques to adopt sustainable agricultural production standards (Whitfield et al., 2014). Nevertheless, a considerable number of smallholder farmers have been supported and trained in sustainable conservation farming practices. Farmers targeting the export market have been forced by marketing agents to comply with agricultural conservation practices (Blaikie and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1046310474

Brookfield, 2015). On the contrary, large-scale farmers have resources to comply with the required food production standards easily. The concept of sustainable conservation standards is not only confined to improve environmental ecology and food safety but also archive acceptable profits sustained production level, and marketability of crops.

Studies in developing countries provide varied analysis of the increased competitiveness, in marketing and productivity in horticulture crops. While providing market linkage that has a positive impact on farmers' incomes, in most of the cases only farmers directly linked to advanced value chains tend to receive higher prices for their produce (Aasprong, 2013). Despite the associated benefits of being guaranteed market access, smallholder farmers are constantly under pressure to maintain sustainable production standards and sometime observe the set consumers food safety standards (Lockie et al., 2015). Prior studies have examined the returns on investments and social, economic benefits of horticultural crop production in developing economies (Henson et al., 2011). Conventionally, in Sub-Saharan Africa, farmers' profits are measured using financial gains in the form of gross margins. However, the techniques used don't show how exogenous factors such as farm characteristics, investments in sustainable conservation standards affected farms profit efficiencies levels.

In Asia, profit frontier function was used to estimate the profit efficiency of rice producers (Rahman, 2003; Chang et al., 2017). In computing profit efficiency, farmers can easily identify output level production, establish firms revenues and evaluate the benefits of investing in conservation agriculture (Abdulai and Huffman, 1998; Rahman, 2003). With this understanding, the objective of this study will examine variances in profit efficiency between certified GLOBALGAP farms and Non certified GLOBALGAP farms. Further, the study will examine utilization levels of sustainable conservation agriculture between certified GLOBALGAP farms and Non certified GLOBALGAP farms. The present study contributes to the debate on smallholder farmers producing efficiently in a perfectly competitive market while observing sustainable conservation agricultural production standards.

Materials and Methods

In Kenya, most of the snap beans are produced in the Central and Eastern regions. Snap beans are produced in well-drained silty loam to heavy clay soil that has pH range of between 6.5 to 7.5. Also, the beans grow well in optimum temperatures ranging between 20^{o}C and 25^{o}C. Snap beans do well in the altitude range of 1000 to 2100 meters. While the preferred rainfall for cultivation range is 900 to 1200 mm that is distributed throughout the year. Over the years there has been a decline in snap bean production that is mainly linked to i) erratic weather patterns, ii) declining soil fertility iii) use of banned pesticides such as dimethoate.

Study area and sampling procedures

The study employed multi-stage sampling technique to select 429 respondents who participated in the study. The first stage was purposively selecting major snap beans producing counties (Kirinyaga, Murang'a and Embu) in Kenya (*Figure 1*). A sampling frame of 3200 snap beans smallholder farmers from the three regions was obtained from ministry of Agriculture office. Using households sampling methodology formula 429 farmers were selected using simple random sampling procedure to participate in the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1046310474

study. The data used in the study was collected between June 2016 and September 2016 in three major snap beans producing Counties in Kenya.

Data was collected through household surveys involving a face-to-face interview; this allowed interviewers to make a clarification on questions and to probe the respondents for accurate answers. The questionnaire was administered in local languages, to farmers who were farming snap beans in the last six years. The enumerators only interviewed respondents who were above 18 years and made most farming decision in the household (household head or spouse, farm employee). The identified farmers answered a detailed questionnaire on snap bean farming management, production, harvesting, and marketing of the beans. Also, farmers were presented with probing questions on perceptions and knowledge awareness of sustainable conservation agriculture and Global Good Agricultural Practices Good Agricultural Practices (GLOBALGAP) (The respondents provided information on household characteristics, land size, social capital, as well as non-income indicators.

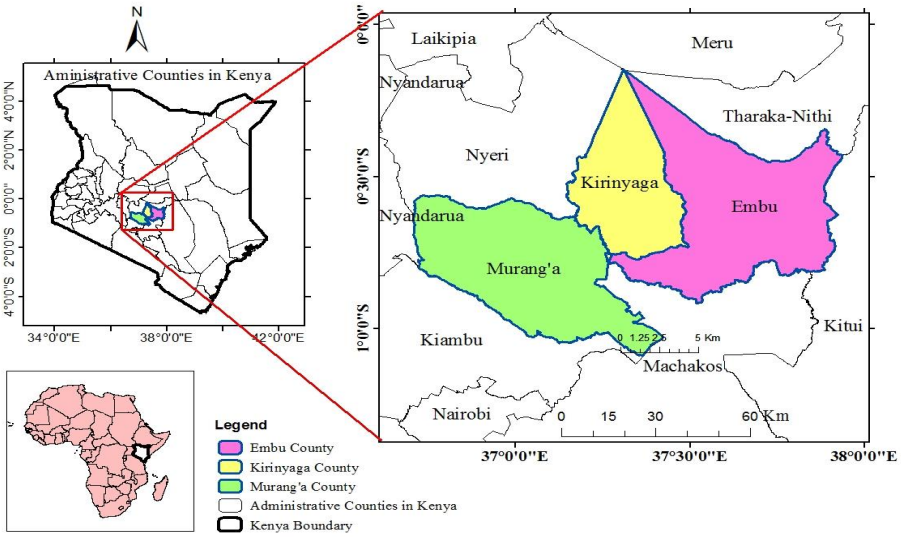

Figure 1. *Map of the study area*

Empirical analysis of profit efficiency

Traditionally, the farm production process has been measured using production function while efficiency has been estimated using deterministic or parametric approaches (Aigner et al., 1977; Van den Broeck et al., 1994). However, the profit frontier theory assumes that producers are always willing to maximize their profits, but not all are fully technically efficient. In a perfect competitive market, profits are assumed to be zero in the long run, producers operating at a negative profit are bound to exit the industry (Kumbhakar et al., 2015). Equally, if the profits are positive more will be attracted to in the industry. In the long run this increases market competition and drive profits to zero. Theoretically, firms are also seen to have short and long runs sequence of operating within profits as well as negatives. Thus profit efficiency is used in the present study to compare snap bean profit frontier function for certified GLOBALGAP farms and Non-GLOBALGAP farms in a perfectly competitive market.

Past studies in Africa and Asia have applied stochastic profit frontier models by considering estimation of the cost function (Ali and Flinn, 1989; Abdulai and Huffman,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1046310474

1998; Chang et al., 2017). However, there is the assumption that cost function ignores the variances of profits and cost. In addition, the profit function takes into account that commodity prices are not homogeneous for all producers. The efficiency estimated by profit function can be used to evaluate management efficiency of producing high-quality products. In this study, we use one-step estimation and a Translog profit function. The efficiency determinant factors are included as the inefficiency term and estimated with the selected estimation function. Rahman (2003) argues that one-step estimation solves the statistical problem of consistency. The profit frontier function can simply be expressed as;

$$1n\Pi_i 1n\pi_i = \alpha_0 + \sum_{j=1}^{j} \alpha_j lnx_{ij} + v_i - u_i \quad \text{(Eq.1)}$$

where Π_i is the profit of the ith farm, xi's are the cost of different production inputs such, seed, water, labor (hired and own) and fertilizers (manure and chemical fertilizers). The error component v_i is assumed to be random variables identical independently distributed (iii) $N(0, \sigma_v^2)$ that contains statistical noise. $u_i$denotes the Non-negative random accounting for profit inefficiency expected to be truncated at zero $N(0, \sigma_v^2)$ distribution. Technical efficiency enables us to know variables that affect farm inefficiency. The equation is written as;

$$u_i = \delta_0 + \sum_{k=1}^{k} \delta_d z_{ik} + \omega_i \quad \text{(Eq.2)}$$

Input costs and farm characteristics are assumed to influence the profit efficiency of both GLOBALGAP certified, and None GLOBALGAP certified farms, in the equation Zi are the explanatory variables that explain inefficiency. The list of inefficiency variables used in different models includes farmer's characteristics, distance to market, number of extension contacts, subsidy support, and farmer's group membership. Inefficiency is denoted by E [exp(-u)|υ], and is a truncated normal distribution as outlined by (Battese and Coelli, 1995; Kumbhakar et al., 2015).

Results and discussion

Socioeconomic characteristics of respondents

Table 1 presented descriptive statistics for the survey; in general farmers in the study allocated an average of 1.2 hectares of land to snap bean production. Also we noted that only 58% of the farmers produced snap beans with GLOBALGAP certification. Despite the fact that snap bean production venture require smallholder farmers to have skills to comply with the Good Agricultural Practices standards, only 40 percent received regular extension visit. Further results showed that only 47 percent of the farmers received subsidy support from marketers, saving and credit co-operatives groups, Governmental and Nongovernmental organizations. However, 24 percent of the farmers accessed credit from formal banks to invest in the snap bean production venture in the year of the survey.

Table 2 presented the difference in characteristics of GLOBALGAP certified and Non-certified farmers. The analysis revealed that farmers who had GLOBALGAP certification were older and had more years in education than the None certified

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1046310474

farmers. Farmers with fully GLOBALGAP certification owned 1.087 hectors of snap beans farm size while None GLOBALGAP farmers owned 1.433. Generally, farmers with GLOBALGAP certification incurred 176.29$ on the cost of inputs such as seedlings, fertilizers, and pesticides. Also, they had additional input cost on soil/water testing and preservation, hygiene and sanitation units, packaging crates and traceability systems. While the None certified GLOBALGAP farmers only incurred input cost of $132.68 mainly related to seedlings, fertilizers, and pesticides. Despite farmers with GLOBALGAP certification incurring high cost if inputs, they also received higher returns of $1008.27 compared to $307.32 received by None GLOBALGAP certified farmers. Further, we noted that none GLOBALGAP farmers incurred more cost in land preparation than GLOBALGAP certified farmers.

Table 1. *Definition of variables (Source: Research findings)*

Variables	Description	Mean	St.Dev
GAP certification	1 if a farmer has GLOBALGAP certificate otherwise 0	0.580	0.494
Age	Age of the Household Head in years	44.64	12.83
Education	Number of years of schooling	9.669	2.578
Farm size	Total farm size under snap beans in hectares	1.232	1.089
Co-operative membership	1 of farmers belong to farmers groups otherwise 0	0.765	0.424
Extension contact	1 if farmer visited extension services on Snap bean production other wise 0	0.408	0.492
Access to credit	1 if farmer received a loan to finance snap bean venture otherwise 0	0.242	0.429
Under contract farming	1 if farmer is under contract farming other wise 0	0.540	0.497
Years of GLOBALGAP certification	Years of GLOBALGAP has certification	2.840	1.802
Farmers subsidy support	1 farmer received support from NGO otherwise 0	0.471	0.499
Distance to market	Distance to collection center market in kilometers	4.379	3.345

Compliance to sustainable conservation standards

Figure 2, presented comparative analysis on the levels of compliance to sustainable conservation standards between GLOBALGAP certified and None certified farmers. Generally, the results indicated that more than 73 percent of the farmers applied water conservation techniques in their farms.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1046310474

Further results revealed that 45 percent of the GLOBALGAP certified farmers used organic fertilizer in comparison, only 17 percent of the None certified farmers. We noted that GLOBALGAP certified farmers were less likely to apply pesticides, herbicides, and fertilizer than None GLOBALGAP certified farmers. The results indicated that only 20 percent of None GLOBALGAP certified farmers applied soil conservation technique minimum tillage while 65.9 percent of the GLOBALGAP certified applied the technique.

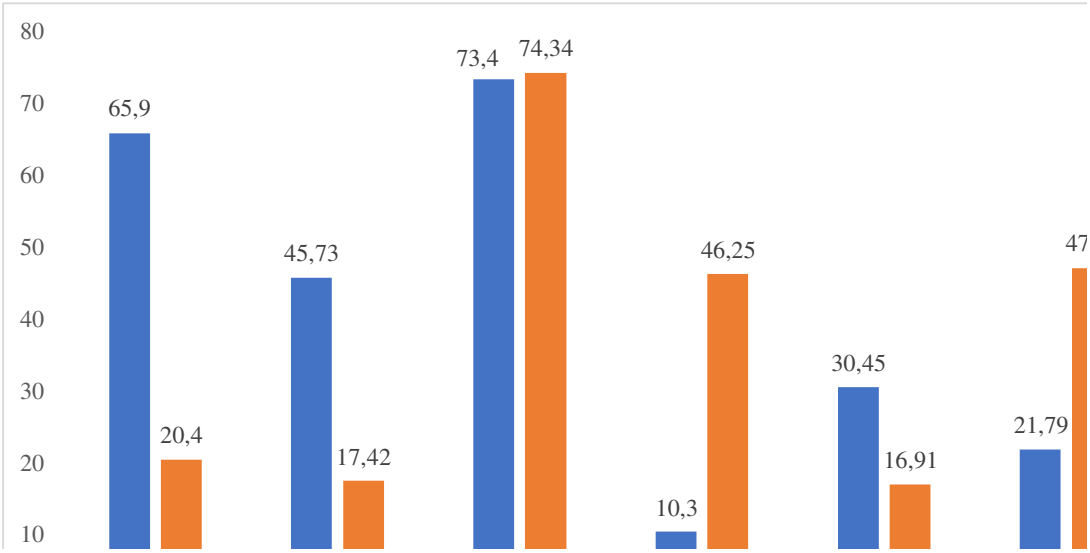

Figure 2. *Compliance to Sustainable Conservation Standards by Snap bean farmers*

Profit efficiency estimation

The maximum likelihood estimates of profit frontier function are presented in *Table 3*. The dependent variable is snap bean profits from the output of the whole year. The coefficient estimates parameter follows the normal profit function based on the assumption of a competitive market. The study results revealed that investing and complying to GLOBALGAP Ln(GAPC) farming standards negatively and significantly impacted profits of non- certified farmers. Also, General Input Cost (Ln GIC) negatively impact on none GLOBALGAP certified farms profits by 2.2%. Further results showed that land size would positively and significantly influence on profit efficiency of GLOBALGAP certified farms. While General Input Cost (Ln GIC) negatively impact on profits GLOBALGAP certified farms. Regarding characteristics that determine profit inefficiency, the results showed that farmers age, education years, years of GAP farming, distance to Market, GLOBAL GAP application in the farm, and contract farming would significantly influence on inefficiency for GLOBALGAP certified farms. While farmers age experience and distance to market determined on profit efficiency of Non- GLOBALG.A.P Certified farms

Table 4 shows the decile frequency distribution between GLOBALGAP certified, and non- GLOBALGAP certified farms. In general, the results revealed that the average measure of profit efficiency for GLOBALGAP certified farmers was 0.625 percent. This, implied that GLOBALGAP certified farmers got an average of about 62.5 percent of maximum profit potential.

This was gained due to production efficiency while the remaining shortfall of the discrepancy between observed profit and the frontier profit can be attributed to both technical and allocative inefficiencies as had earlier been confirmed by the likelihood ratio test. Further results showed non-GLOBALGAP farmers got an average of about 40.9 percent of maximum potential profit from snap bean venture.

Discussion

The main objective of this study was to examine the levels of compliance with sustainable conservation standards and estimate the profit efficiency of snap bean production between GLOBALGAP and Non-GLOBALGAP. The data was based on 429 smallholder farmers in Kenya. The comparative analysis on levels of utilization of sustainable conservation standards revealed that GLOBALGAP certified farmers were likely to apply soil conservation technique minimum tillage than Non-GLOBALGAP farms. Presently, extension messages in developing countries emphasize the use of reduced tillage. However, there, are indications that farmers are slow in adopting such practices (Luangduangsitthideth et al., 2018). Soil fertility experts recommend integration of organic matter from livestock and post-harvest crop waste to raise soil carbon levels. The study showed that the application of organic manure was less than 50 percent for both GLOBALGAP certified and Non- certified farmers. Previous studies reported that organic utilization of manure enhanced soil structure, improved soil carbon components while availing nutrients and mineral fertilizers to plants (Boström et al., 2015). We noted that low levels of inorganic fertilizer use by GLOBALGAP certified farms than for Non-certified farmers. Whitfield et al. (2015) reported that organic manure use improved the efficiency of fertilizer use by farmers.

The results of the study also indicated that the profit efficiency of GLOBALGAP certified farms was significantly higher than that Non-GLOBALGAP certified farms. The international food safety compliance literature showed that smallholder farmers in developing countries were locked out of the export market for non-compliance with sustainable conservation standards. In most of the cases, farmers were unable to meet requirements on environmental management, traceability standards, product safety, and the health safety of the workers (Kleemann et al., 2014). Thus, compliance with sustainable conservation standards such as GLOBALGAP would be prohibitive to farmers with low capital investment, a factor that affected the snap bean profit margins. Similarly, Lockie et al. (2013) reported that the use of safer pesticides required farmers to incur a higher cost of pest and disease management. Also, the cost of implementing GLOBALG.A.P certification could cost smallholder farmers up to 65 percent of the production cost (Muriithi et al., 2011). According to (Bain et al., 2013) compliance with sustainable production standards necessitated an increase in the cost of operation hence affecting the revenues.

The present study pointed out that farmer's group created inefficiencies for non-GLOBALGAP and GLOBALG.A.P Certified farms. However, Fernandez-Stark et al. (2011) study that farmers co-operatives are likely to get better returns when dealing directly with marketing companies or supermarket chains than middlemen. Also, collective action by farmer's organizations increased credit acquisition chances, the ability to negotiate prices, and market assurance. Supporting farmers with inputs, credit, and extension services resulted in reduced profit inefficiency, especially for GLOBALG.A.P certified farmers. The support services would help farmers to observe sustainable conservation standards required by buyers. Also, Aasprong (2013) notes that agricultural extension support system facilitated dissemination of suitable technologies to farmers reduced the inefficiency in Madagascar.

Conclusion

In conclusion, we noted that food production and certification standards such as GLOBALG.A.P significantly facilitate smallholder farmers to observe sustainable conservation practices. In particular, the standards help reduction in pesticide use, inorganic fertilizer use, minimum soil disturbance. However, the governments and other stakeholders in Sub-Saharan Africa have to mobilize and create awareness on the benefits of sustainable conservation standards. Also, there is a need to have a policy shift and address the perception that inorganic fertilizer is the panacea for smallholder productivity.

We also noted that smallholder snap bean farmers need to increase profit efficiency marginally. Much of the policy emphasis must be directed towards increasing compliance to sustainable conservation standards not only for the export target market but also local Kenyan market. However, high rejection rate resulting from Non-compliance sustainable conservation standards will likely lead farmers to produce for local market where they invest less and still get marginal profits from the snap beans. While compliance to sustainable conservation standards such as GLOBALG.A.P standards guarantees a ready market for the snap bean, there is need to scale up subsidies relating to sustainable conservation standards certification and compliance for snap bean venture to be more profit efficient. This will enhance smallholder's snap bean farmers in Kenya to efficiently produce and maintain competitiveness in the global market that is becoming more dynamic, especially with regards to environmental and food safety standards.

Abstract. In order to promote the understanding of the dynamic change characteristics of ecosystem flux in cold zone wetlands and to provide scientific basis for the accurate simulation of wetland flux, this study applied the eddy covariance (EC) flux measurement system for long-term continuous flux of Harbin Jinhewan Wetland Botanical Garden. A preliminary analysis of one-and-a-half-year measurements of water, heat, and CO_2 fluxes showed that: (1) The diurnal variation of CO_2 flux shows a single-valley character, and the annual variation is consistent with the vegetation growth trend; the diurnal variation of CO_2 concentration shows a single-peak and single-valley character, the annual change process is opposite to the vegetation growth trend. (2) The average daily CO_2 absorption rate of Jinhewan Wetland is only 0.13 mg/(m^2·s), with weak carbon sink function and great carbon sequestration potential. (3) The diurnal variations of sensible heat flux (SHF), latent heat flux (LHF) and Bowen ratio (except for winter) of Jinhewan Wetland are basically single-peaked; SHF is highest in spring and LHF is highest in summer; LHF is only smaller than SHF in winter, while in summer LHF is much larger than SHF and minimum is two times that of SHF.
Keywords: *Eddy covariance, sensible heat flux, latent heat flux, carbon dioxide flux, Bowen ratio*

Introduction

The exchange of mass and energy in the Soil-Plant-Atmosphere Continuum (SAPC system) plays an important role in global climate, environmental change, and hydrological and ecological processes (Chen et al., 2016; Wang, 1999). The mass exchange of water and CO_2 is the carrier for the biosphere to acquire and store energy, which is mainly achieved through the photosynthesis and transpiration of crops. CO_2 concentration also significantly affects the earth temperature. Heat exchange plays an important role in atmospheric movement, which affects the formation of weather and climate on a larger spatial scale (Wang et al., 2013). Observing and studying the relationship among ground-air water, heat and CO_2 exchange is of great significance to water cycle analysis, water resources management, and weather and climate forecast (Zheng, 2013). Since the 1980s, long-term observations of the fluxes have attracted extensive attention (Baldocchi et al., 2001).

The measurement methods for water, heat and CO_2 fluxes include Eddy Covariance (EC for short), BREB method (Bowen Ratio-Energy Balance, BREB for short), aerodynamic method, and profile gradient iterative method (Liu and Yu, 1997; Shen et al., 2005; Wang et al., 2009). Among them, the EC technique uses the sensor's measurement result of the wind speed fluctuation and a certain physical quantity pulsation in the atmosphere, and the fluxes of various substances and energy are obtained by calculating the covariance between them (Roland, 1991). This technique is simple, easy, and can be directly observed (Xu et al., 2008). With the rapid development

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1047510490

of measuring instruments and computing technology, the EC technique has been widely used in field observations (Liu et al., 2006), and it has achieved continuous, long-term, automatic observation of surface fluxes, while exerting minimal interference on the environment and ecosystems (Baldocchi, 2003). At present, the EC technique has become a standard method for measuring water, heat, and CO_2 fluxes, and is widely used for measurement of water, heat, and carbon fluxes between the earth's surface and atmosphere (Hutley et al., 2005; Kang et al., 2001). Many factors such as undulating terrain, unfavorable weather conditions will affect the accuracy of flux measurement results by using EC technique (Massman and Lee, 2002), and to some extent hinder the application of the technique. However, the study area is flat and the elevation difference is only 5 m. During the monitoring period, the temperature in the study area was between -30 and 30 °C, and the daily precipitation was within 21 mm (moderate rain), except for the two maximum days of 54 mm (storm) and 28 mm (heavy rain), with no adverse weather such as extreme temperatures and precipitation. Therefore, the effects of topography and climate can be ignored in this study.

Among the currently known terrestrial ecosystems, wetland, as one of the three largest ecosystems (land, sea, and wetland), is the second most important carbon stock next to the forest. Although accounting for only 6% of the land area (Gao et al., 2008), wetland stores 10%-30% of the carbon of the global terrestrial ecosystem (Nahlik and Fennessy, 2016; Smith et al., 2004; Edwards, 2001). At present, there is no conclusion on the carbon source/carbon sink function of wetlands (Shoemaker et al., 2015; Duman and Schäfer, 2018). The estuarine wetland of the Niuesi River in southern Texas has carbon sink characteristics under sufficient water conditions, but it appears carbon source characteristics when there is insufficient moisture (Heinsch et al., 2004). Affected by the wetland age, geographical location, climate and other environmental conditions, the wetland ecosystem will present a carbon source or carbon sink function accordingly (Kayranli et al., 2010). In addition, when the rate of methane released by sediments exceeds the rate of carbon sequestration in the plant photosynthesis, even reed wetlands with vigorous growth of vegetation will become carbon sources (Brix et al., 2001). The absorption of CO_2 in the Zoige wetland in southwestern China in 2008 and 2009 was 173 g/m^2/a and 292 g/m^2/a (Hao et al., 2001), respectively, and played a significant carbon sink function. Affected by tides, the Yangtze River estuary wetland alternates with the function of carbon sources and carbon sinks (Guo et al., 2009). In the alpine wetland ecosystem of the Tibetan Plateau, carbon absorption mainly occurred during the growing and withering stages of vegetation, while carbon release by respiration occurred during non-growing stage of vegetation (Cao et al., 2017). However, in the cold regions of northeastern China, long-term observations of wetland ecosystem fluxes are few (Chen, 1996; Yang and Lyu, 1999) and their research is not deep (He et al., 2006).

Jinhewan Wetland Botanical Garden is a demonstration area for the protection and restoration of aquatic ecosystems in Harbin, and is an important part of the ecological project of the "Hectares of Songjiang Wetland and Long-stretching Ecological Corridor". The water-heat cycle and the carbon source/carbon sink function of the wetland have an important effect on the protection and restoration of the ecosystem. This study used the EC flux measurement system to conduct long-term continuous observations of water, heat, and CO_2 fluxes at Jinhewan Wetland, and characteristics of changes in water, heat and CO_2 fluxes in the wetland was analyzed by using the monitoring results for one and a half year from August 1, 2015 to December 31, 2016.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1047510490

And then the characteristics of the water-heat cycle and the carbon source/carbon sink function are further analyzed, thus providing technical support for the protection and restoration of the ecosystem in the demonstration area.

Test area and instrument

Test area

The test area is located in Jinhewan Wetland Botanical Garden, Harbin, Heilongjiang Province, China (N 45°46'35.2"-45°46'58.9", E 126°29'07.7"-126°29'45.1"; see *Fig. 1*). Located on the left bank of the main urban area of Harbin, Songhua River, on the beach between the West Fourth Ring Bridge and the East Third Ring Bridge, it is 3,800 m in length, 1500 m in width, 3.5 km^2 in area, and 115 m-120 m in altitude. The extremely gentle terrain effectively avoids the influence of topographic relief on the accuracy of flux observations by using EC technique.

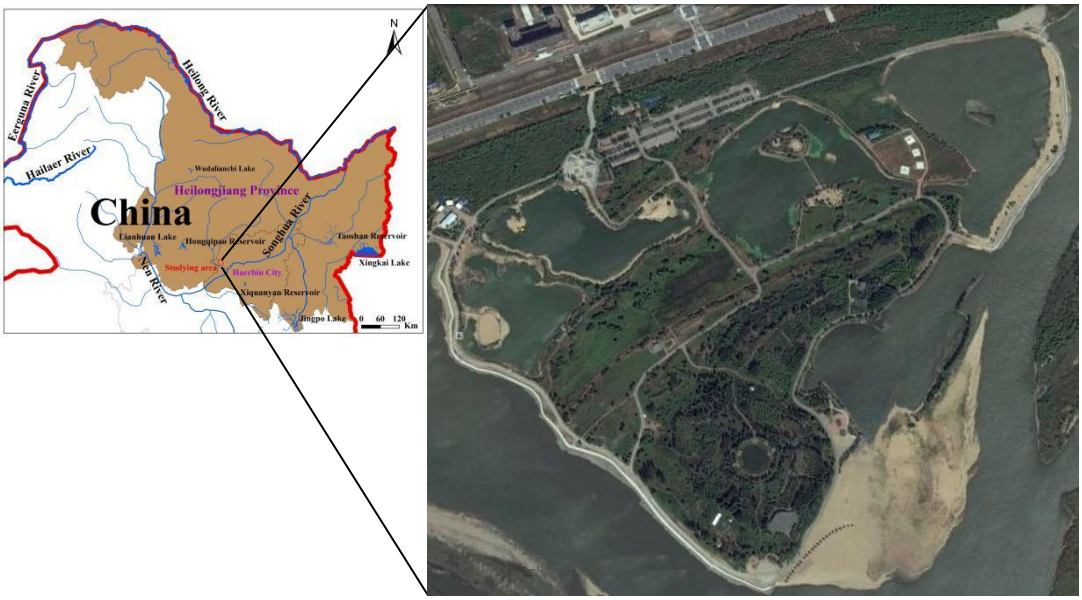

Figure 1. *Harbin Jinhewan Wetland Botanical Garden*

The test area is located in the middle temperate zone, which features a semi-humid continental monsoon climate with four distinct seasons, short winters and long summers. According to the meteorological data from 1951 to 2013, the average annual sunlight duration is 2636.3 h, and the annual sunlight rate is 55-66%. The average annual temperature is 3.2 °C, January is the coldest month, the average monthly temperature is -19.7 °C, and the extremely low temperature is -41.1 °C; in the hottest month in July, the average monthly temperature is 23.1 °C, and the extremely high temperature is 39.1 °C. The frost-free period averages 135 days. The average annual precipitation in Harbin City where the test area is located is 570 mm, and the maximum annual precipitation is 1015 mm. Affected by the alternating of southeast ocean air mass and the northwest continental air mass, the distribution of rainfall season is uneven. The average annual precipitation in June-September is 341.5 mm, accounting for about 60% of the whole year. Rainstorms are mostly concentrated in July and August, accounting

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1047510490

for about 84% of the year's heavy rain. The largest rainfall in history is 146.5 mm (July 28, 1914). The experimental area is surrounded by grasslands and pagoda wetland plants.

Data acquisition and processing

The EC technique can directly measure the water, heat, and CO_2 fluxes (Baldocchi et al., 2000) between the atmosphere and the earth's surface in the atmospheric boundary layer, of which the basic principle is to use atmospheric turbulence theory to collect CO_2 concentration, water vapor content, temperature, horizontal wind speed and vertical wind speed, and then to determine the CO_2 and water and heat fluxes between the surface and the atmosphere via statistical analysis of the data. The specific analysis process (Wang, 2012) is: within a certain average period, the turbulent transport flux of a scalar x is described by *Equation 1:*

$$Q_x = \overline{w\,(\rho x)} = \rho\,\overline{wx} \quad \text{(Eq.1)}$$

where the over-line indicates the time average; w is the vertical wind speed (m/s); ρ is the air density (kg/m^3), which is generally set to be constant within the average time period taken. Through Reynolds decomposition, each quantity is divided into two parts: average volume and pulse volume, as described in *Equations 2* and *3:*

$$w = \bar{w} + w' \quad \text{(Eq.2)}$$

$$x = \bar{x} + x' \quad \text{(Eq.3)}$$

Supposing that the time average of vertical wind speed is 0, that is, $\bar{w} = 0$

$$Q_x = \rho\,\bar{w}\bar{x} + \rho\,\overline{w'x'} = \rho\,\overline{w'x'} \quad \text{(Eq.4)}$$

Then CO_2 flux (F_C, mg•m^{-2}•s^{-1}), SHF (H, W/m^2) and LHF (LE, W/m^2) can be expressed as in *Equations 5, 6* and *7:*

$$F_C = \rho\,\overline{w'C'} \quad \text{(Eq.5)}$$

$$H = C_P\rho\,\overline{w'T'} \quad \text{(Eq.6)}$$

$$LE = \lambda\,\rho\,\overline{w'q'} \quad \text{(Eq.7)}$$

where is the CO_2 concentration fluctuating value (kg/kg); C_P is the air constant-pressure specific heat (J•kg^{-1}•K^{-1}), the general value is 1004.7 J•kg^{-1}•K^{-1}; T' is the ultrasonic virtual temperature fluctuation value (°C); λ is the latent heat of evaporation (J/kg); q' is the water vapor concentration (specific humidity) fluctuating value (kg/kg). ρ and λ are respectively calculated by the following formulas:

$$\rho = 100 \times \frac{P}{287.1 \times (T_a + 273.15) \times (1 + 0.61 \times q)} \quad \text{(Eq.8)}$$

$$\lambda = (2.501 - 0.00237 \times T_0) \times 10^6 \quad \text{(Eq.9)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1047510490

In *Equations 8* and *9,* P indicates the atmospheric pressure (hPa); T_a indicates the temperature (°C); T_0 indicates the surface temperature (°C).

In the actual calculation, the data first needs to be corrected (Webb et al., 1980; Wilczak et al., 2001; Finnigan et al., 2003) by removing the outliers caused by environmental factors such as rain, snow, dust and unstable power supply; then by performing slope correction and frequency loss correction, ultrasonic virtual temperature (humidity effect) correction for SHF, WPL correction for LHF and CO_2 fluxes (air density pulsation correction). Meanwhile, quality control and evaluation (Foken and Wichura, 1996) must also be carried out, such as whether the working status of the sensor is normal, whether the instantaneous value or the mean value is within a reasonable threshold, etc., and the similarity and stability of the final products (mainly the individual fluxes) need to be checked.

The eddy covariance (EC) flux measurement system was employed in this research, including the 3D ultrasonic anemometer–thermometer (CSAT3, Campbell Scientific Inc., USA), the fast-response infrared gas analyzer (Li-7500, LI- COR Inc., USA), and the data collector (CR5000, Campbell Scientific Inc., USA) and preprocessor (Eddy Reprocessing, or EdiRe, University of Edinburgh, UK, http://www.geos.ed.ac.uk/research/micromet/EdiRe). The measurement system was installed at the end of June in 2015, at the southwest corner in the Wetland Botanical Garden, with a location of N 45°46'40.3", E 126°29'23.9". This measurement has an installation height of 10 m from the ground, with a data acquisition frequency of 10 Hz and a set average period of 30 min. The main vegetation species at the measurement site are *Labiatae* and *reed*. The final data used to conduct analysis was recorded from August 1, 2015 to December 31, 2016, with a duration of one and a half years.

Results

In order to promote the understanding of the dynamic change characteristics of wetland ecosystems, we analyzed the daily changes and seasonal changes of CO_2 flux, CO_2 concentration, SHF, LHF and Bowen ratio (ratio of SHF to LHF) of Jinhewan Wetland based on one-and-a-half EC flux measurements.

Characteristics of changes in water and heat fluxes

Characteristics of daily changes in water and heat fluxes

January, April, July and October were selected as the representative months of the year (in which the data took the average of the data for October 2015 and October 2016) to analyze the average monthly diurnal variation of water and heat fluxes near the underlying surface ecosystem of Jinhewan Wetland in spring, summer, autumn and winter, and SHF and LHF were put in a contrastive analysis by using the Bowen ratio (the absolute value of which reflects the strong and week relationship between the sensible and latent heat exchange), as shown in *Figure 2*.

Sensible heat refers to the heat exchange in the form of turbulence that occurs between the atmosphere and the underlying surface due to temperature changes. Heat is positive when it is transported from the underlying surface to the atmosphere, and vice versa. The daily changes of SHF of Jinhewan Wetland throughout the year show single-peaked features. Before 8:30 in the morning of January, SHF was always negative, which is because the surface temperature is lower than the atmosphere at night, and heat

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1047510490

is transported from the atmosphere to the ground. The heat supplied to the ground is offset by the amount of radiation on the ground, making the temperature difference between surface and atmosphere stable. Therefore, the SHF floats up and down at -10 W/m^2. As the sun rises, solar radiation appears and gradually increases, and the ground continues to heat up, the temperature difference between the surface and the atmosphere begins to decrease and the SHF gradually becomes larger; SHF becomes positive at around 9:00, indicating that the surface temperature begins to rise above the atmosphere, and sensible heat is transferred to the atmosphere from the ground; then SHF increases rapidly and peaks at 12:00, indicating that the temperature difference between the surface and atmosphere reaches a maximum, as a result, the transport of sensible heat from the ground to the atmosphere achieves the highest rate of about 50 W/m^2; then the SHF decreases sharply, because the surface radiation of high-temperature surface is strong, and the solar radiation weakens again, as a result, the surface temperature drops rapidly and approaches atmospheric temperature as soon as 16:00, and the SHF is about 0 W/m^2; as ground radiation continues to cool down the earth's surface, the surface temperature begins to fall below the atmosphere, and sensible heat is transported from the atmosphere to the ground. The flux is negative, and it stabilizes after 17:00, indicating that the monthly SHF is positive for about 7 h. Due to the difference in sun rise and fall times in different seasons, the time course of monthly SHF change in April and July was different from that in January, where SHF starts to increase slowly from a negative value at about 5:00, and becomes positive at about 6:00 when the sensible heat starts to be transported from the ground to the atmosphere; it also reaches its maximum at around 12:00, which is close to 150 W/m^2 and 80 W/m^2 respectively; SHF is reduced to 0 W/m^2 at 18:00, and maintains a stable state of small-scale fluctuations by approaching 19:00; these two representative monthly SHF takes 12 h to be transported from the ground to the atmosphere. The rise of SHF in October was similar to that in April and July, and the decline was in sync with January; the peak was around 90 W/m^2, indicating that the monthly SHF is positive for 9 h. It can be seen that Jinhewan Wetland has the shortest SHF time in winter and the lowest peak value, while in the spring and summer, the SHF diurnal variation is more synchronous, the positive and negative flux values have the equal time. The peak value of spring flux is the highest, and the positive duration of SHF in autumn is slightly longer than in winter, and the peak value is close to summer, which is in the middle of the peak of the four seasons' flux.

Latent heat mainly refers to the heat energy absorbed or released from one phase to another by water under isothermal pressure conditions. When LHF is greater than 0 W/m^2, it mainly absorbs heat through soil evaporation and vegetation transpiration. When LHF is less than 0 W/m^2, heat is released mainly through dew, frost, and icing. The daily changes of LHF of Jinhewan Wetland in the four seasons also have a single-peaked feature, except that the feature is not significant in January. In January, in addition to the increase in LHF from about 0 W/m^2 to 10 W/m^2 in peak value between 10:00 and 16:00, it is reduced to 0 W/m^2, and LHF fluctuates up and down around 0 W/m^2 in 3/4 time of the entire day/night. In the other three representative months, LHF is greater than 0 W/m^2. Among them, LHF increases rapidly from 6:00 in April and October, reaching the peak 160 W/m^2 and 110 W/m^2 at 13:00, and then continues to decrease, and basically maintains between 20 W/m^2-40 W/m^2 from 20:30. July increases from 3:30 and peaks at around 220 W/m^2 before 13:00, and it also begin to fluctuate around 30 W/m^2 at 20:30. The results show that Jinhewan Wetland not only

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1047510490

transports water from the atmosphere to the ground during the night in winter, but also transports it from the ground to the atmosphere through evapotranspiration, indicating the strong water cycle characteristics of wetlands. In addition, the evapotranspiration is relatively weak in winter and is strong in spring and autumn, and during the summer daytime, due to the higher temperature, the evaporation of soil moisture can be promoted, and the vegetation also reduces its own temperature by enhancing transpiration, so the underlying surface evapotranspiration plays the most important role.

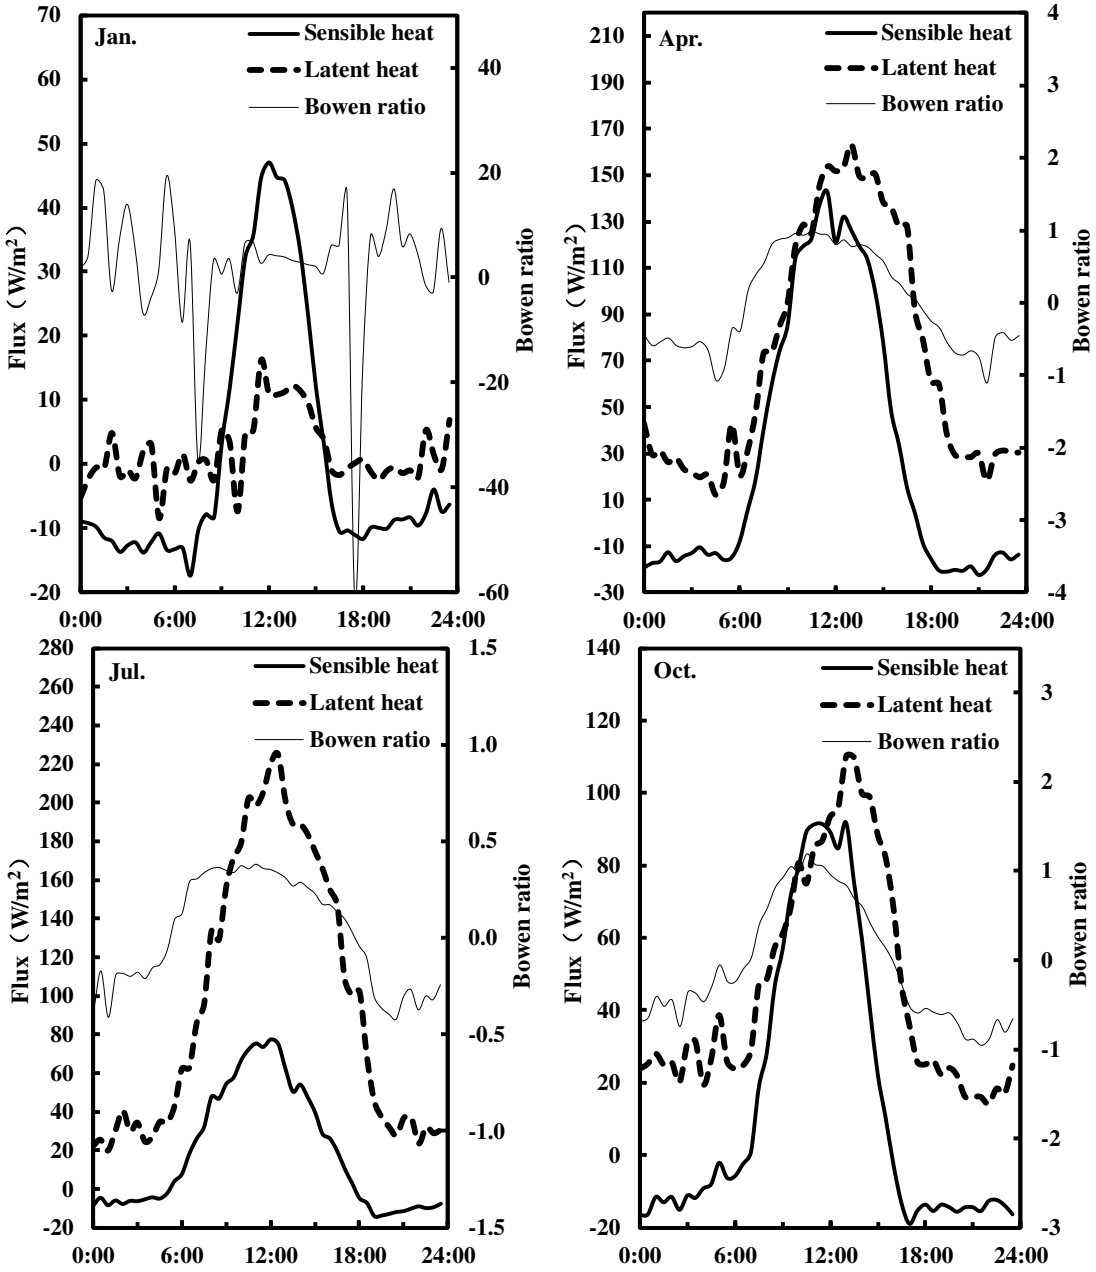

Figure 2. *Diurnal variation of monthly averaged water and heat fluxes in representative months from different seasons in Jinhewan Wetland*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1047510490

By analyzing the size of the Bowen ratio, the SHF and LHF at any time during the average monthly diurnal variation (without considering the energy transfer direction of the sensible heat and the latent heat, only considering the size of the flux) are compared. LHF is less than SHF only in January, and because LHF is very small and even less than 1 W/m^2, the fluctuation of the Bowen ratio (absolute value) in January is relatively large. Without considering extreme cases, the range of variation is 1-20. LHF is almost always greater than SHF during the monthly diurnal variation in spring, summer and autumn. Among them, in April and October, the Bowen ratio (absolute value) fluctuates in the range of 0-1 (except that LHF is slightly smaller than SHF at some time in October, and the Bowen ratio is within 1-1.1). The overall difference between LHF and SHF is relatively small. Bowen ratio (absolute value) is greater than 0.5 about 65% of the time, the two are almost equal especially between 9:00-12:00, and the Bowen ratio is above 0.92. In July, the fluctuation range of Bowen ratio (absolute value) is only 0-0.5, and LHF is much larger than SHF.

Seasonal changes in water and heat fluxes

According to the observations of Jinhewan Wetland from August 2015 to December 2016, the daily average water and heat fluxes were calculated, and seasonal variations of water and heat fluxes were analyzed according to the annual change process. *Figure 3a, b,* and *c* show the change of annual mean value of the sensible heat, latent heat, and Bowen ratio, respectively.

Over the nearly one-and-a-half-year observation period, the average daily SHF ranged from -49.97 to 90.63 W/m^2, and the annual average daily change was smaller (see *Fig. 3a*). Daily SHF averaged 13.78 W/m^2; in the winter (December-February), the average was the lowest, only 3.57 W/m^2; in the spring (March-May), the average was the highest, reaching 19.13 W/m^2; in the summer and autumn (June-August and September-November, respectively), the average daily SHF average was mediate, with summer slightly higher than autumn, at 18.65 W/m^2, and the autumn average was close to the average during the observation period, which was 14.71 W/m^2.

Average daily LHF fluctuated more intensively, ranging from -12.28 W/m^2 to 213.40 W/m^2 (see *Fig. 3b*). The average value over a one-year observation period was 50.27 W/m^2; Characteristics of daily average LHF was the same as SHF in winter, only 3.87 W/m^2, which is far lower than the average of the other three seasons; the summer average was as high as 91.40 W/m^2; average daily LHF during the spring and autumn determines the average value of the observation period, and it was always fluctuating around 50 W/m^2; seasonal averages were 70.88 W/m^2 and 42.77 W/m^2, respectively.

Dividing the daily average SHF by the daily average LHF, we can get the annual variation of the daily scale Bowen ratio during the observation period (see *Fig. 3c*). Except for the late autumn period (from November 13 to November 30 for 2015 and 2016) and winter, and due to the continuous fluctuation of the daily average LHF around 0 W/m^2, the Bowen ratio varied greatly and changed narrowly within -3.08-3.33 for most of the spring, summer and autumn. Bowen ratio not only varied greatly in winter, but also fluctuated drastically, with only 30% of the time ranging from -1 to 1, indicating that the daily average SHF in winter is generally greater than the daily average LHF; while in the summer Bowen ratio ranged from -0.40 to 0.68, the daily average LHF was not only larger than the daily average SHF, but also at least 1.47 times that of the latter; in the spring and autumn, the daily average LHF was usually greater than the daily average SHF, with 70% of the time Bowen ratio ranging from -1 to 1.

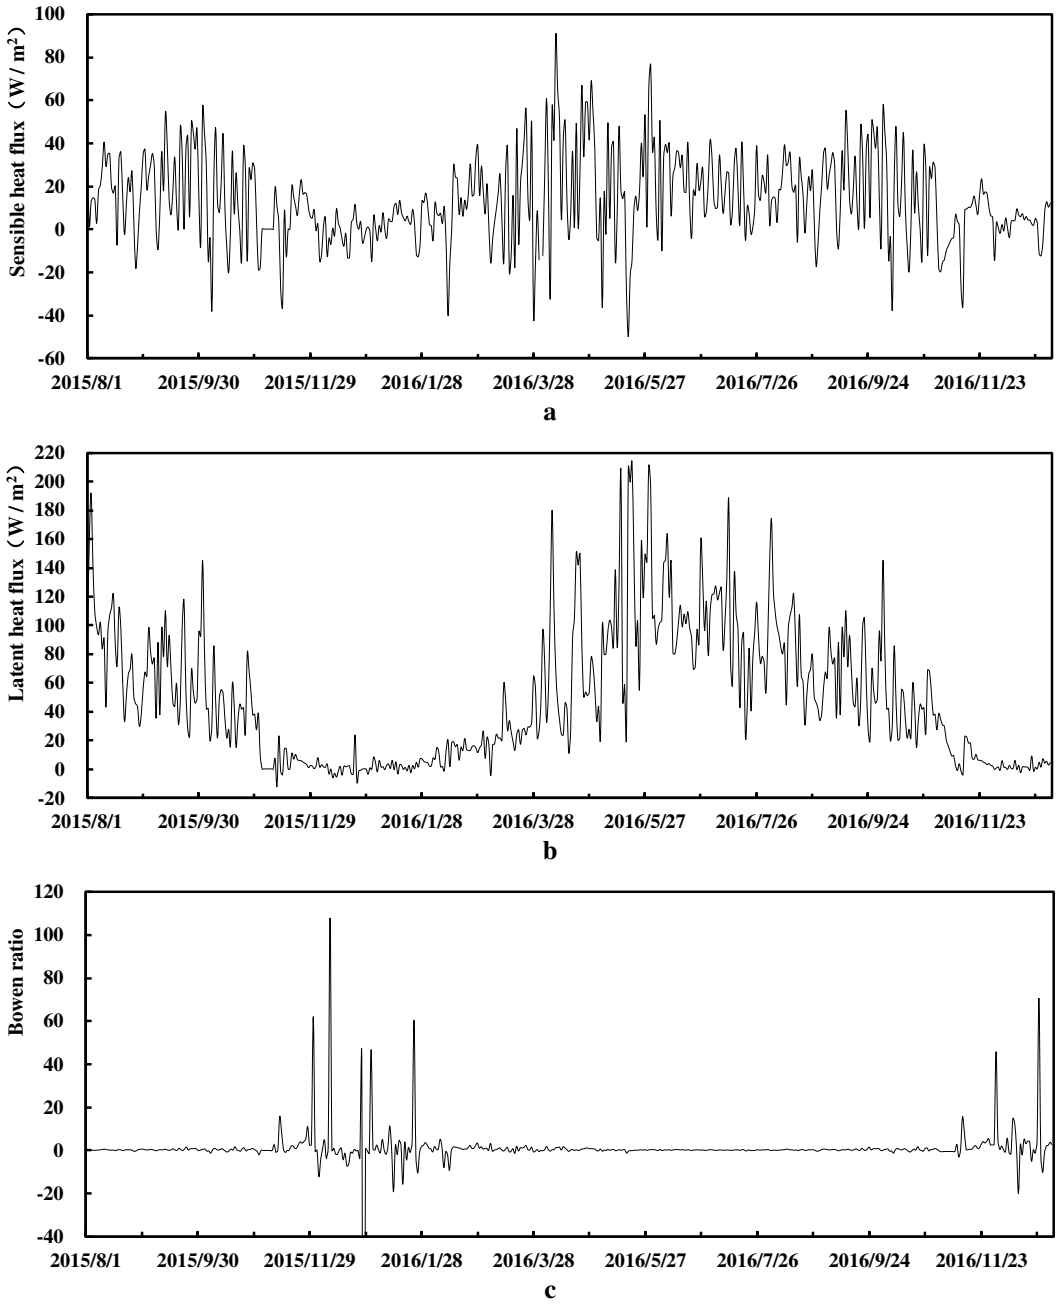

Figure 3. *Annual daily average change of Jinhewan Wetland sensible heat flux (a), latent heat flux (b) and Bowen ratio (c) during August 2015–December 2016*

Characteristics of CO_2 flux change

Figure 4 shows the average monthly diurnal variation and the average daily diurnal variation of the Jinhewan Wetland CO_2 flux in January and July. When the CO_2 flux is negative, it indicates that the surface absorbs CO_2 from the atmosphere due to photosynthesis and other reasons; when it is positive, it indicates that the surface releases CO_2 into the atmosphere under the effects of vegetation and soil microbial respiration. As can be seen from the figure, the CO_2 flux has the diurnal variation characteristics of the single-valley character. Due to the lack of sunlight at night, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1047510490

vegetation cannot absorb CO_2 via photosynthesis, instead they release CO_2 through stable respiration of vegetation and soil microorganisms, therefore the nighttime CO_2 flux is greater than 0 mg/(m^2•s) with little change. Jinhewan Wetland shows weak carbon source attribute, which fluctuates around 0.02 mg/(m^2•s) in January, and shows strong respiration with vigorous vitality of vegetation, and CO_2 flux fluctuates around 0.10 mg/(m^2•s); average annual CO_2 flux at night is about 0.05 mg/(m^2•s) and the maximum is 0.08 mg/(m^2•s). After sunrise, the vegetation begins to undergo photosynthesis, and as the sunlight increases, the photosynthesis intensity also slowly increases. The CO_2 absorption rate increases from 0 mg/(m^2•s) and gradually equals the release rate, and its flux begins to decrease and approach 0 mg/(m^2•s) step by step, which drops to 0 mg/(m^2•s) before 10:00 and 5:30 in January and July, and drops to 0 mg/(m^2•s) before 6:30 on an annual average. As sunlight becomes stronger, the rate of CO_2 absorption by vegetation through photosynthesis is greater than the release rate, and the CO_2 flux becomes negative and decreases. Jinhewan Wetland begins to play a carbon sink role; at noon time, the sunlight reaches the strongest and CO_2 flux reaches the least value, which reduce to -0.05 mg/(m^2•s) and -0.41 mg/(m^2•s) in January and July, respectively, and the average annual minimum flux is -0.13 mg/(m^2•s). As the sunlight weakens in the afternoon, photosynthesis is weakened and the CO_2 absorption rate begins to decrease. When it is again equal to the rate of CO_2 release, the flux turns to 0 mg/(m^2•s) again, reaching 0 mg/(m^2•s) after 15:00 and 18:00 in January and July, and averaging 0 mg/(m^2•s) after 17:30 on a yearly basis. Photosynthesis continues to weaken until it stops, and the respiration of vegetation and soil microorganisms begins to dominate. CO_2 flux increases again and becomes positive after being stable. In general, Jinhewan Wetland has a carbon sink function only 5 h a day in winter, and the CO_2 absorption rate is within 0.05 mg/(m^2•s). In summer, the carbon sink function is slightly stronger and it plays a carbon sink role for about 13 h per day. Absorption rate is relatively high, up to 0.41 mg/(m^2•s); the annual average carbon sink function is 11 h a day, and CO_2 absorption rate is up to 0.13 mg/(m^2•s), less than half of the highest absorption rate of Panjin wetland (0.3 mg/(m^2•s) (Wang and Zhou, 2006) that has the reputation of "the capital of wetlands".

To analyze the seasonal variation characteristics of CO_2 flux, CO_2 flux data with a time step of 30 min was taken for a 6 h sliding average treatment (as shown in *Fig. 5*). In the non-growing season of vegetation (from late autumn to early spring, approximately from November to March of the following year), CO_2 flux (absolute value) was small and it was greater than 0 in most of the time, indicating that vegetation photosynthesis was weak or even absent from photosynthesis during this period, atmospheric carbon exchange process is achieved mainly through vegetation and soil respiration. In the growing season of vegetation, the amplitude of CO_2 flux increased. In particular, during vigorous growth periods (July and August), vegetation has the most intense life activities: intense photosynthesis during the day brings rapid absorption of CO_2 and a large negative value of CO_2 flux; at night, vegetation respiration was also strong, and the release rate of CO_2 was also large. Regardless of whether CO_2 is transported from the atmosphere to the surface during the day or when CO_2 is transported from the surface to the atmosphere at night, the CO_2 flux during the vigorous growth of vegetation is higher than at the initial stage of growth (April to June) or at the end of growth (September and October), while the CO_2 flux in the growing season was higher than that in the non-growing season, and the change pattern of the year coincided with the vegetation growth trend.

DOI: http://dx.doi.org/10.15666/aeer/1705_1047510490

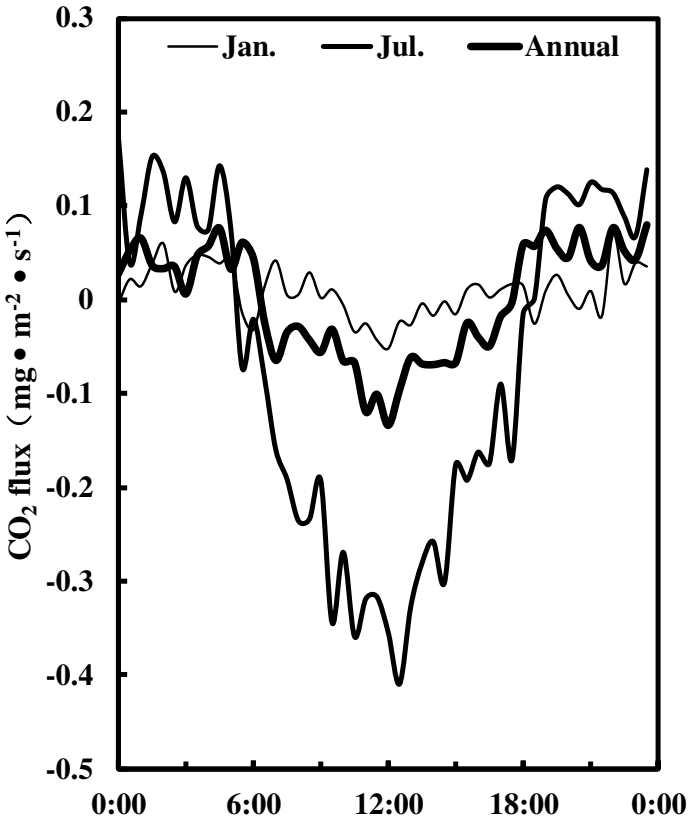

Figure 4. *Diurnal variation of monthly and yearly averaged CO_2 flux in Jinhewan Wetland*

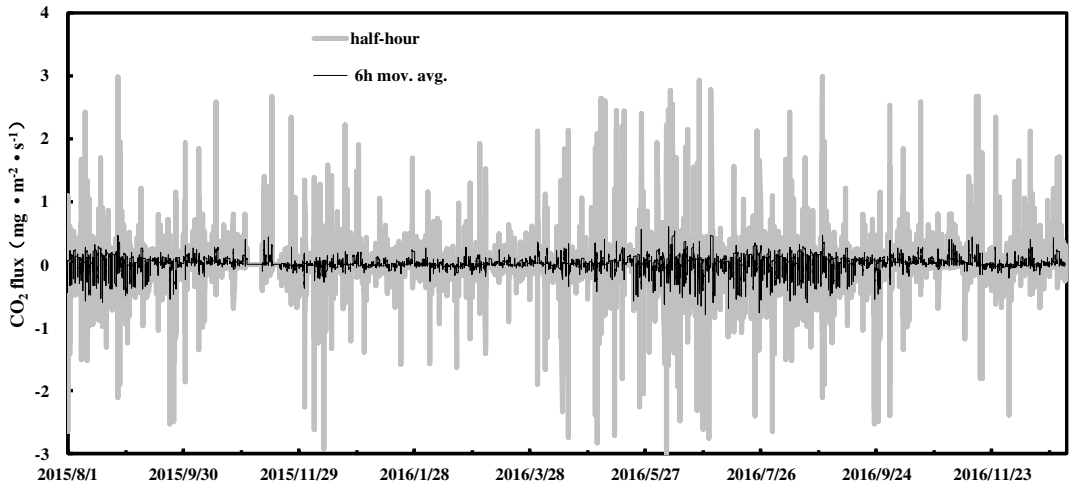

Figure 5. *Annual change process of Jinhewan Wetland CO_2 flux during August 2015–December 2016*

Characteristics of CO_2 concentration changes

The average monthly diurnal variation of the Jinhewan Wetland CO_2 concentration in January and July showed a single-peak and single-valley character (see *Fig. 6*). As a carbon source, the CO_2 flux of Jinhewan Wetland at night was always greater than 0 mg/(m^2•s), and near-surface CO_2 concentrations continued to accumulate, showing an

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1047510490

upward trend. After sunrise, with the CO_2 absorption from the photosynthesis of vegetation, when the CO_2 flux approaches 0 mg/(m^2•s), the concentration peaks: reaching 720 mg/m^3 at 8:00 in January, and 670 mg/m^3 at 4:30 in July, with an annual average peak value of 700 mg/m^3. As the CO_2 flux became negative, the wetland began to function as a carbon sink and the CO_2 concentration began to decrease. When the CO_2 flux increased to 0 mg/(m^2•s) due to the weakening of sunlight, the CO_2 concentration dropped to the bottom: reaching 670 mg/m^3 and 590 mg/m^3 around 16:00 in January and July, with an annual average of 650 mg/m^3. Then the CO_2 flux became positive and remained stable, so the concentration began to rise again. The difference between the peak value and bottom value of CO_2 concentration in July was greater than that in January, indicating that the photosynthesis and respiration of vegetation in summer had greater impact on CO_2 concentration than in winter. In summer, not only photosynthesis was strong from the strong sunlight, but vegetation was also in the growing season, with strong vitality and respiration.

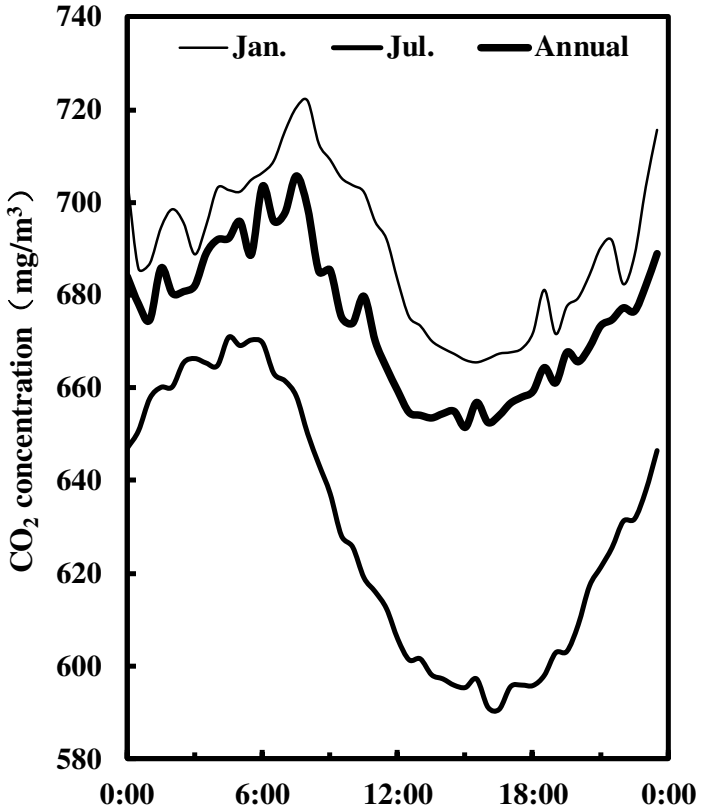

Figure 6. *Annual diurnal variation process of Jinhewan Wetland CO_2 concentration*

The seasonal variation characteristics of the CO_2 concentration is analyzed based on its 6 h rolling average data (see *Fig. 7*). The average CO_2 concentration during the observation period was 679.45 mg/m^3. Among them, the average CO_2 concentration during the vigorous growth period of vegetation was only 655.97 mg/m^3, and the CO_2 concentration was relatively stable, basically fluctuating within the range of 500-800 mg/m^3; while the average value of CO_2 concentration in other periods was 684.86 mg/m^3, with intense fluctuation and a maximum of 2000 mg/m^3.

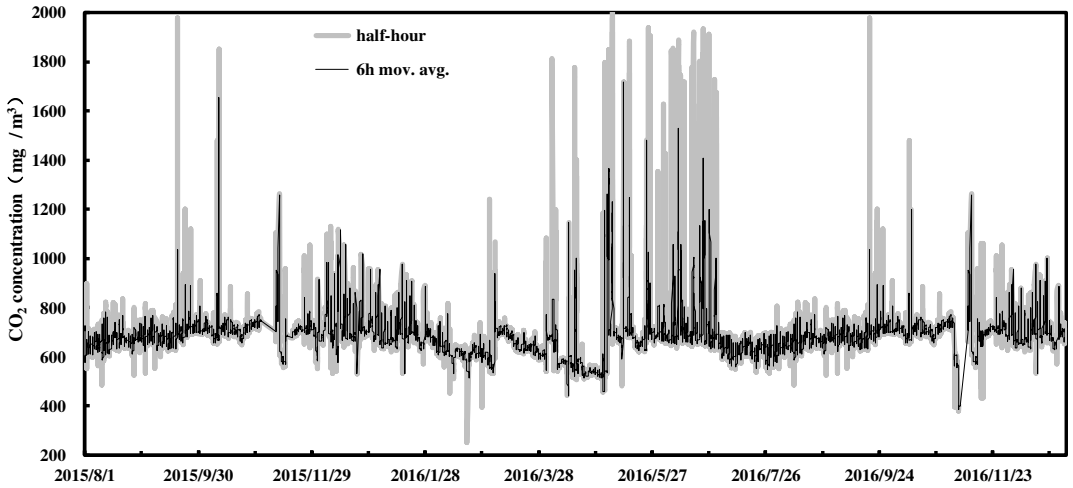

Figure 7. *Annual change process of Jinhewan Wetland CO2 concentration during August 2015–December 2016*

Discussion and conclusion

The material and energy exchange process on the ground-air interface of the cold zone wetland ecosystem in northeast China plays an important role in its climate change research and eco-protection. Jinhewan Wetland, as an example of Harbin's key ecological wetland for the protection and restoration of aquatic ecosystems, uses the EC flux measurement system to conduct long-term continuous flux observations. Based on the one-and-a-half year flux observations, this study initially analyzed the dynamic change characteristics of Jinhewan Wetland's water, heat, and CO_2 fluxes.

The SHF, LHF and Bowen ratio of Jinhewan Wetland basically has the characteristics of single-peaked diurnal variation; in summer, LHF is generally higher than in the other three seasons due to the highest temperature and strongest evapotranspiration; in spring, SHF is usually the largest because summer vegetation is in the vigorous growing period when most of the net radiation is consumed by strong evapotranspiration of vegetation, so SHF is smaller in summer than in spring; in case of the same season, LHF is smaller than SHF in winter, and LHF is almost always greater than SHF in the other three seasons; the two has the biggest difference in summer.

The diurnal variations of CO_2 flux and concentration show a single-valley character and a single-peak and single-valley character respectively. The annual average diurnal variation of flux shows that the daily maximum absorption rate of CO_2 is only 0.13 mg/(m^2•s), which is far less than the Panjin wetland and carbon sequestration has not been fully exerted. There may be two reasons. On the one hand, the Panjin Wetland has a warm temperate monsoon climate, where the temperate of Jinhewan Wetland in the mid-temperate zone is relatively cold. On the other hand, the Panjin Wetland meets the needs of the public for citizen activities by making small areas of land hardening based on natural plow fields and artificial paddy fields. While Jinhewan Wetland, with a higher degree of artificiality, takes into account the needs of the citizens for leisure and entertainment and their landscape functions, thus the green land area is relatively small and the vegetation coverage is low. In view of Jinhewan Wetland's weak carbon sink function, investment in vegetation construction can be increased and the potential for carbon sequestration in wetland ecosystems can be fully tapped. The annual change process of the flux is consistent with the vegetation growth trend, the more vigorous the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1047510490

vegetation growth, the greater the flux (absolute value), and the annual change process of the concentration is just the opposite. The dynamic change characteristics of Jinhewan Wetland's flux are similar to flux changes in forest, grassland, and farmland ecosystems (Song et al., 2004; Liu et al., 2006; Wang et al., 2009).

The preliminary analysis results show that Jinhewan Wetland has a large room for the improvement of water-heat cycle and carbon sink function, and can further promote its role in the water-heat cycle and carbon sink function by strengthening vegetation construction and expanding the green area. Many factors such as undulating terrain, unfavorable weather conditions will affect the accuracy of flux measurement results by using EC technique (Massman and Lee, 2002), and to some extent hinder the application of the EC technique. However, the study area is flat and the elevation difference is only 5 m. During the monitoring period, the temperature in the area was between -30 and 30 °C, and the highest monthly precipitation was 154 mm, with no adverse weather such as extreme temperatures and precipitation. Therefore, the effects of topography and climate in this study can be ignored (Eda et al., 2016; Evadzi et al., 2017; Kuang et al., 2017; Liu, 2018; Meng et al., 2018).

The material and energy exchange process on the ground-air interface plays an important role in its climate change research and eco-protection. Jinhewan Wetland, as an example of Harbin's key ecological wetland for the protection and restoration of aquatic ecosystems, by conducting long-term continuous monitoring on it, using ground-based fixed-point observation data and combining large-scale remote-sensing data, it is possible to achieve scale conversion of flux data from ground-based observations to surface mean values, thereby providing technical support for regulating regional microclimates, preventing soil erosion and protecting ecological environment (Wani et al., 2018).

EFFECTS OF DIFFERENT FERTILISATION TECHNOLOGIES AND CULTIVATION TECHNOLOGY ON SOIL ORGANIC CARBON CONTENT

LIU, T.

College of Economics and Management, Nanjing Agricultural University, Nanjing 210095, China (e-mail: ysghge@163.com)

(Received 27th Sep 2018; accepted 16th Jul 2019)

Abstract. Due to the different stability of organic carbon with different protection mechanisms, the response and evolution of organic carbon components of yellow loam paddy soil to long-term fertilization was studied. Our aim was to study the effects of organic carbon on soil fertility from two aspects: fertilization treatment protection mechanism and tillage treatment protection mechanism. The long-term test site is located in an agricultural science research institute in a certain province of China. The fitting analysis found that the content of soil organic carbon and its components increased with time between 2006 and 2014 under the four fertilization protection mechanisms. Except for biochemical protection of organic carbon, the linear increase of the remaining components of organic carbon is more obvious than that of single fertilizer (NPK) treatment. Compared with traditional tillage treatment, the organic carbon contents have increased by 22.9% and 21.8% respectively, and the organic carbon reserves have increased by 21.8% and 16.7%, respectively. The carbon sequestration rates are 0.09 and 0.06 T $C \cdot hm^{-2} \cdot a^{-1}$. Unprotected free organic carbon is the largest part of organic carbon in soil, and is most sensitive to fertilization.

Keywords: *protection mechanism; organic matter, soil fertility, yellow soil, physical protection, chemical protection, biochemical protection*

Introduction

Soil organic carbon is one of the most active carbon pools in the Earth's surface system, and it plays the important role in regulating the physical, chemical and biochemical processes of soil. It is not only the indicator for assessing soil fertility, but also the important part of the global carbon cycle. Organic carbon with different protection mechanisms has different bioavailability and fertility effects (Herencia and Maqueda, 2016). The scientific basis for the assessment of soil carbon sequestration potential in farmland soils in Southwest China is provided by studying the changes in organic carbon composition of different protective mechanisms of yellow paddy soil with long-term fertilization (Ouyang et al., 2017; Wang et al., 2016; Zhang et al., 2015).

Kang Rifeng's analysis of long-term monitoring data of 17 national arable land in the black soil region of Northeast China shows that after 10-26 years of evolution, the organic matter content has increased overall, which is 33.9% higher than that before monitoring (Kintché et al., 2015). Hu Mingfang studied the evolution of soil organic carbon in double-crop paddy fields in Poyang Lake area under long-term fertilization (Kunlanit et al., 2014). The results show that the carbon content increases with the fertilization period under organic fertilizer treatment, which is consistent with Xu Minggang's research on the law of change of soil organic matter. The organic carbon reserves of 0-20 cm ploughed layer estimated by GATTINGER show that the cumulative rate of SOC (Soil organic carbon) is 0.24-0.46 $t \bullet hm^{-2} \bullet a^{-1}$. The evolution characteristics of organic carbon components in grey desert soils under different fertilization models analyzed by Li Sheng (Li et al., 2016) shows that the organic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1049110507

carbon components show the significant increase trend under the long-term application of organic and inorganic fertilizers. In view of this, in accordance with the different solid-state mechanisms of organic carbon, the physical-chemical joint grouping method is proposed by the STEWART team to separate organic carbon into components of various protection mechanisms such as physical, chemical and biochemical protection. The role of soil micro-aggregates and minerals in the sequestration and transformation of organic carbon is emphasized, which provides the advanced method for the research on the changing characteristics of organic carbon and the transformation process.

At present, the research on the evolution characteristics of SOC under long-term fertilization mainly focuses on surface soil and particulate organic carbon, and has insufficient connection with SOC stability mechanism (Cruz Campas et al., 2017; Manjunatha et al., 2018). The differences and evolution characteristics of SOC components of different protection mechanisms are rarely noticed. Based on the previous work, the evolution characteristics of different stable organic carbons in time series are further revealed in this paper to explore their future trends.

As a sustainable agricultural technology, conservation tillage has far-reaching implications for improving soil fertility and carbon sequestration. SOC is the core material of soil nutrient cycling and fertility supply. The evolution law of the soil can reflect the difference of management measures. However, due to the obvious difference in carbon sequestration ability of different micro-aggregates in soil, the study on the evolution law of organic carbon is very important. At present, the research on farmland organic carbon at home and abroad mainly focuses on the protection mechanism of different tillage treatments (Amelian et al., 2018; Hu et al., 2017). The research on the law of soil organic carbon under the long-term tillage treatment protection mechanism needs to be strengthened.

Combined with long-term localization experiments and laboratory analysis, the physical-chemical of SOC combined grouping method is used to determine the content and distribution of unprotected organic carbon of free active, chemical protection and biochemically protection between micro-aggregates, and to analyze the role of soil micro-aggregates and mineral combinations in SOC sequestration and transformation. The change rate of organic carbon in yellow paddy soil with fertilization time and the effective of fertilization on improving SOC pool under different protection mechanisms are elucidated. At the same time, the carbon input and soil carbon sequestration of farmland under different tillage treatment mechanisms are analyzed, and the effects of long-term farming on the carbon reserves of 0-10 cm soil layer in farmland soil are discussed, these provide the reference for the improvement of soil fertility and the choice of carbon sequestration technology on the Loess Plateau.

Materials and methods

The general situation of the research area

The long-term test site is located in an agricultural science research institute in a certain province of China (106°39’52”E, 26°29’49”N). It is located in the hilly area of central Guizhou and has the subtropical monsoon climate with the average elevation of 1071 m and the average annual temperature of 15.3 °C, the annual average sunshine hours is about 1354 h, the relative humidity is 75.5%, the annual frost-free period is about 270 d, and the annual precipitation is 1100-1200 mm. The test site is yellow loess paddy soil, and the parent material is triassic limestone and sand shale weathering. It

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1049110507

began in 1995. In 1994, the basic soil samples were collected. The soil properties of the cultivated layer (0-20 cm) are: organic matter 31.15 g•kg^{-1}, total nitrogen 1.76 g•kg^{-1}, total potassium 13.84 g•kg^{-1}, alkali nitrogen 134.4 mg•kg^{-1}, available phosphorus 21.1 mg•kg^{-1}, available potassium 157.9 mg•kg^{-1}, and pH 6.6.

Methods

Experimental design

(1) Fertilization treatment

A ploughing field is selected as the experimental field. Before the experiment, the ploughing layer soil (0-20 cm) had a pH value of 8.70-9.10, and the conductivity is 0.362-0.702 dS/m, the mass fraction of organic carbon is 3.10-4.70 g/kg, the mass fraction of total nitrogen is 250-400 mg/kg, the mass fraction of organic phosphorus is 3.0-7.0 mg/kg, and the mass fraction of available potassium is 110.23 mg/kg. According to the needs, 5 fertilization treatments are selected from 11 treatment methods (Roy et al., 2018): control (CK), single application of chemical fertilizer (NPK), single application of organic fertilizer (M), low-level organic and inorganic fertilizer application (0.5MNPK) and the high amount of organic and inorganic fertilizers (MNPK) (Naab et al., 2015). The test uses the large-area comparison test with a plot area of 201 m^2 (35.7 m * 5.6 m) without repetition. The type of the applied organic fertiliser is: The chemical fertilizer is urea (including N 46%), superphosphate (including P_2O_5 16%), potassium chloride (including K_2O 60%); organic fertilizer contains C 413.8 g•kg^{-1}, N 2.7 g•kg^{-1}, P_2O_5 1.3 g•kg^{-1}, K_2O 6.0 g•kg^{-1}. The NPK treatment method is applied annually with N 165 kg•hm^{-2}, P_2O_5 82.5 kg•hm^{-2}, K_2O 82.5 kg•hm^{-2}, the annual application of organic fertilizer in the M treatment is 61.1 t•hm^{-2}; the amount of fertilizer applied by MNPK is the amount of fertilizer applied by M treatment plus NPK treatment. The amount of nitrogen applied by NPK treatment, M treatment, and 0.5MNPK treatment was the same (Qiu et al., 2014). The application amount of chemical nitrogen fertilizer is adjusted according to the nutrient content of organic fertilizer every year, as shown in *Table 1*. From 2002 to 2006, due to the destruction of the irrigation facilities at the test base, rice cultivation could not be satisfied and corn is replanted. The rice varieties planted are as follows: Jinma Stick (1995-1998), Nonghuhe (1999-2001), Xiangliangyou 875 (2007-2008), Yanyou United No. 2 (2009) and Maoyou 601 (2010-2014).

(2) Tillage treatment

The trial began in 1999 and the crop planted in the plot is rice. There are 4 treatments and 3 repetitions (Zhang et al., 2016). RT: When the rice is harvested, leave 10 cm, the straw and rice ears are taken away, and the soil is ploughed 20 cm after harvesting, and then simmered; NT: When the rice is harvested, leave 30 cm, and the remaining straw is threshed and left in the ground; SM: When the rice is harvested, leave 30 cm, and the remaining straw will be left in the ground after threshing. The soil will be separated by 60 cm and ploughed 30-35 cm after harvesting. CT: When rice is harvested, it leaves 10 cm, and the straw and rice ears are taken away. After harvesting, the soil is ploughed by 20 cm. Carry out the second ploughing, fertilize, simmer, and sow before planting. The fertilization amount of each treatment is N 150 kg•hm^{-2}, P_2O_5 105 kg•hm^{-2}, and K_2O 45 kg•hm^{-2}.

DOI: http://dx.doi.org/10.15666/aeer/1705_1049110507

Table 1. *Annual amount of pure nutrient treatment in each treatment*

Handle	Stable manure ($t•hm^{-2}$)	N ($kg•hm^{-2}$)	P_2O_5 ($kg•hm^{-2}$)	K_2O ($kg•hm^{-2}$)
CK	0	0	0	0
NPK	0	165	82.5	82.5
0.5MNPK	30.6	165	81	224.6
M	61.1	165	79.4	366.6
MNPK	61.1	330	161.9	449.1

Collection of samples

Soil samples of 0-20 cm of ploughed soil in each district are collected in October 2014. The zones are equally divided into 3 plots (67 m^2), and each plot is uniformly distributed to collect 5 points to form the mixed sample, and 3 soil samples are collected from each plot. After removing the animal and plant residues, mix them. After the soil sample is air-dried, pass through the sieve with the pore size of 2 mm and set aside. The same method is used to collect soil samples for 2006, 2008, 2010 and 2012. They are air dried and sealed in the ziplock bag.

SOC grouping and measuring method

By referring to STEWART and other methods, SOC is divided into four carbon pools, which are free active organic carbon, physically protected organic carbon, chemically protected organic carbon and biochemically protected organic carbon (Wang et al., 2014). The specific operation steps are as follows.

The first step is to group the micro-aggregates: air dried soil samples over the 2 mm sieve are placed in the microaggregate separator and 30 glass beads having the diameter of 4 mm are added. After the separator is operated for 20 min, the component remaining on the 250 μm sieve is coarse particulate organic matter, and the free colloidal particles could pass through the 53 μm sieve. They are then centrifuged at 900 r/min and 3200 r/min for 7 min and 15 min, respectively, and d-Silt and d-C lay are obtained, respectively.

The second step is density grouping: the microaggregate fraction obtained in the first step is floated by 1.70 $g•cm^{-3}$ of sodium iodide, and the float is fine particulate organic matter. The recombinant part is dispersed in 5 $g•L^{-1}$ six sodium polyphosphate solution for 18 h, passed through the 53 μm sieve, and left on the sieve as physical protective organic matter. The particles smaller than 53 μm are then separated by centrifugation to obtain μ-Silt and μ-Clay.

The third step is the acid hydrolysis process: all the particles and cosmid fractions are refluxed for 16 h in 6 $mol•L^{-1}$ HCl at 95 °C less than 25 mL. The acid hydrolysis solution is filtered off, and the residue is the biochemical protective organic component (NH-Silt and NH-C lay). The acidolysis moiety is the difference between the full component and the non-acidolytic component, namely the chemically protected organic component (H-Silt and H-Clay).

The elemental analyzer (Lehman, EA3000) is used to determine the carbon content.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1049110507

Calculation method

(1) Organic carbon reserve and micro-aggregate organic carbon reserve:

$$M_{soi1}=SOC\times BD\times H\times 10^{-1} \quad \text{(Eq.1)}$$

where M_{soi1} is the SOC reserve of 0-10 cm layer (t C•hm^{-2}); BD is the soil bulk density of 0-10 cm (g•cm^{-3}); H is the thickness of the soil layer, 10 cm;

$$M_i'=C_i\times SOC_i\times BD\times H\times 10^{-1} \quad \text{(Eq.2)}$$

where M_i' is organic carbon reserves of i-level micro-aggregates (t C•hm^{-2}); C_i is the relative mass fraction of the i-th micro-aggregates; SOC_i is the organic carbon content of the i-level micro-aggregates (g•kg^{-1}).

(2) The amount of straw carbon returned to the field and the amount of roots carbon returned to the field:

$$Y_{straw}=Y_{grain}\times\rho \quad \text{(Eq.3)}$$

where Y_{straw} is straw yield (t•hm-2); Y_{grain} is measured grain yield (t•hm-2); ρ is is straw grain ratio, taken 1.1.

$$Input-C_{straw}=Input-Y_{straw}\times C_{straw} \quad \text{(Eq.4)}$$

where $Input-C_{straw}$ is the amount of straw carbon returned to the field $Input-Y_{straw}$ is The amount of straw returned to the field. No-tillage and deep pine treatment are 100% of the yield, less tillage tradition and two sorghums is only 15% of the yield, and C_{straw} is the carbon content of the straw, which is 40%.

$$Y_{root}=\left(Y_{straw}+Y_{grain}\right)\times\alpha\times\beta \quad \text{(Eq.5)}$$

where α is the ratio of root to shoot, which is the ratio obtained after root exudates, and which is 0.6; β is the rate of returning to the roots, and the rate of returning the roots of 0-10 cm soil layer is 70%.

$$Input-C_{root}=Input-Y_{root}\times C_{root} \quad \text{(Eq.6)}$$

where C_{root} is the carbon content of the roots, which is 40%.

Data analyses

Data collation and mapping are performed using Excel 2016, and statistical analysis is performed using SPSS 24.0. All soil measurements are expressed as the average of 3 measurements. The least significant difference method (LSD) is used to test for differences between different fertilization treatments ($P < 0.05$) (Wentzel et al., 2015).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1049110507

The average annual rate of change is expressed by the slope of the equation. The linear function is used to fit the relationship between the total organic matter and its components in the soil and the times of fertilization, and to test the significance of the equation.

Experiment analyses

From 2006 to 2014, the changes of soil organic carbon in the original yellow soil paddy soil are shown in *Figure 1*. Under the condition of long-term fertilizer, the changes of soil organic carbon components in yellow soil paddy soil are shown in *Figure 2*. According to the statistical results of *Figure 2,* the ratio of soil organic carbon to total organic carbon under long-term fertilizer conditions (5-year average) is given, as shown in *Figure 3*. *Figure 4* shows the increasing trend of total soil organic carbon content under long-term fertilizer conditions.

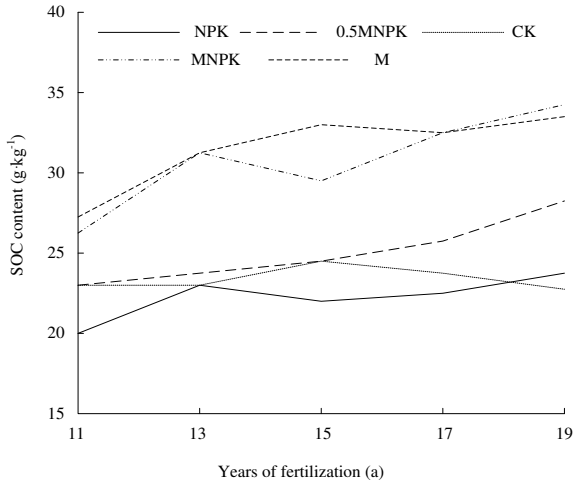

Figure 1. *Changes of soil organic carbon in yellow soil paddy soil from 2006 to 2014*

It can be seen from *Figure1* that the total organic matter content of the soil with 19 organic fertilizer is significantly higher than that of single fertilizer treatment and no fertilizer treatment, and the total organic matter is increased by 15-39%, and the increase of constant organic-inorganic application is the highest. Fitting analysis find that between 2006 and 2014, the SOC content of the four fertilization treatments increased with time, and the increasing trend of organic fertilizer treatment is more obvious than that of single fertilizer application. The annual average rate of increase of total organic matter content treated with organic fertilizer is 1.5-1.6 times and 3.5-3.7 times that of non-fertilizer and single-fertilizer treatment, respectively. This indicates that long-term application of organic fertilizer can significantly increase soil organic carbon content. In order to further verify this result, the annual growth rate of the total amount of organic carbon and its components in the paddy soil of yellow soil was calculated, as shown in *Table 2*.

It can be known from the results in *Table 2* that long-term application of organic fertilizer does increase the soil organic carbon content and can effectively increase rice yield.

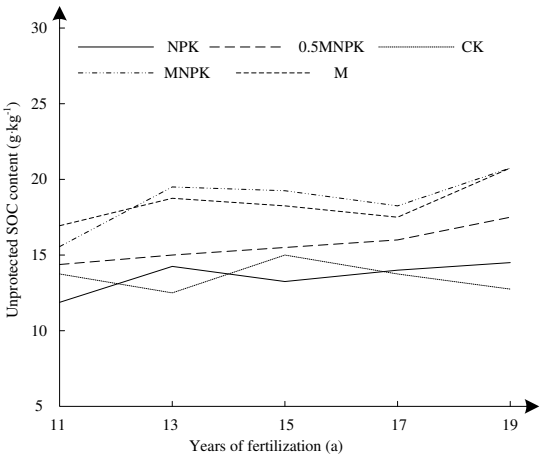
http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1049110507

Table 2. *Annual growth rate of total organic carbon and its components in yellow soil paddy soil from 2006 to 2014 under long-term fertilization*

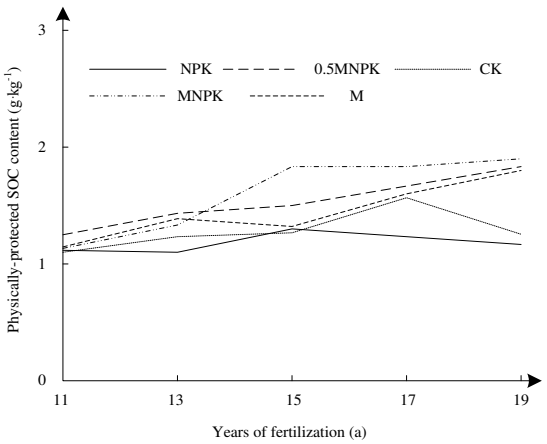
Treatment	CK	NPK	M	0.5MNPK	MNPK
SOC	0.17	0.39	0.62	0.59**	0.61*
Unprotected C	-0.02	0.25	0.38	0.33**	0.47
Physically protected C	0.02	0.02	0.08**	0.07**	0.09*
Chemically protected C	0.01	0.00	0.10*	0.07	0.17*
Biochemically protected C	0.12	0.13*	0.15	0.12*	0.09

*, **, respectively, indicated that the fitted linear equation reached a significant level ($P < 0.05$) and a very significant level ($P < 0.01$)

It can be seen from *Figure 2* that compared with no fertilizer application and single application of chemical fertilizer, the application of organic fertilizer significantly increased the soil free activity, physical protection and chemical protection organic carbon content ($P < 0.05$), and the increase amount is 18-61%, 30-44% and 27-56%. Among them, the increase of the organic-inorganic fertilization with the constant is the highest. In general, it can be seen that long-term non-fertilization and single-fertilizer treatment cannot maintain the turnover of the organic carbon pool, which is more detrimental to the accumulation of SOC components.

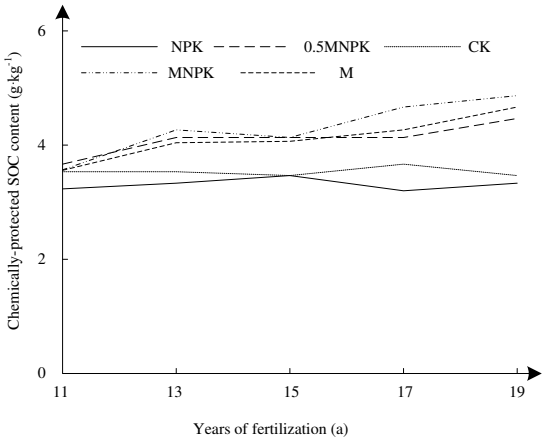


(a) Unprotected SOC content

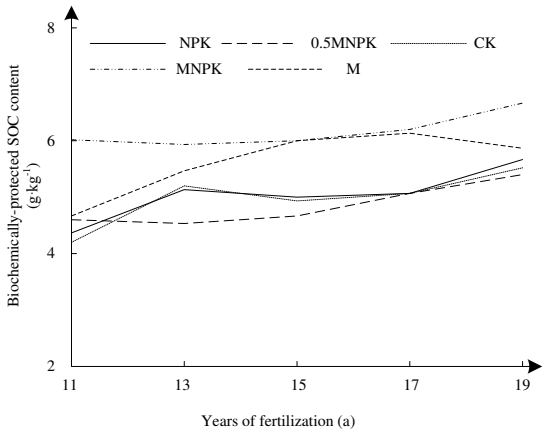


(b) Physically-protected SOC content

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1049110507



(c) Chemically-protected SOC content



(d) Biochemically-protected SOC content

Figure 2. *Changes of soil organic carbon fractions in yellow soil paddy soil during 2006 to 2014 under long-term fertilization*

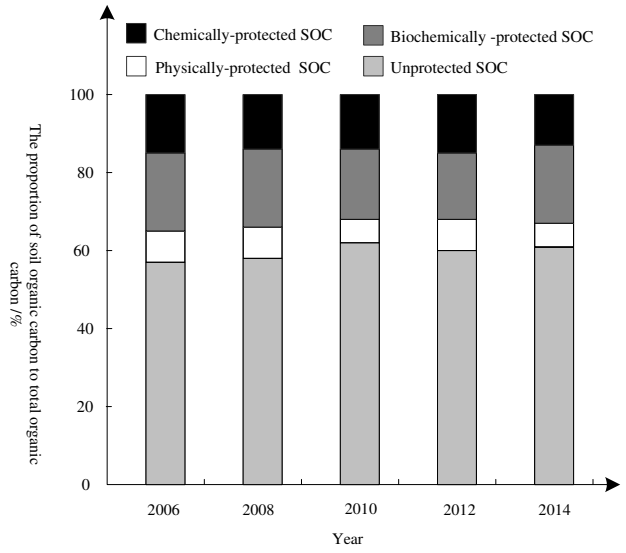


Figure 3. *The proportion of soil organic carbon to total organic carbon (average value of 5 years) under long-term fertilization*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1049110507

It can be seen that the difference in the ratio of organic carbon between the NPK treatment and the CK treatment is not obvious. In contrast, the ratio of organic fertilizer treatment is higher, and the ratio of the other two organic carbons is lower.

It can be seen from *Figure 4* that except for CK treatment, the SOC content and the fertilization time in other cases show the very significant linear positive correlation ($P < 0.01$). The SOC content under CK treatment increased by 3.7% compared with that in 2006; the annual growth rate of SOC content under chemical fertilizer treatment is 23.9% and 20.6%.

The annual growth rate of SOC content under organic fertilizer treatment is higher, ranging from 20.6 to 21.3%. This indicates that long-term application of organic fertilizer can significantly increase the SOC content.

Figure 4. *Growth trend of soil organic carbon content in yellow soil paddy field from 2006 to 2014 under long-term fertilization (n=15)*

It can be seen from *Table 3* that the effects of different fertilization treatments on soil carbon-N ratio are not significant. This indicates that the conversion relationship of soil carbon-N under various management measures tends to be stable with the change of fertilization years. It can be seen from the experiment that the soil carbon-N ratio of each fertilization treatment in 2006 is significantly higher than that of other years,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1049110507

indicating that land use patterns and farmland management changes can quickly affect the soil carbon-N ratio and quickly reach a new equilibrium. The general study suggests that the carbon-N ratio of dry-land is lower than that of paddy fields, but this study is different, and the reasons for further research are needed.

Table 3. *Soil carbon and nitrogen ratio in paddy fields under long-term fertilization (g/kg^{-1})*

Soil carbon and nitrogen ratio	CK	M	N	NPK	0.5MNPK	MNPK	Average value	Standard deviation
1995 year	11.7a	11.7a	11.8a	11.9a	11.1b	9.6c	11.3	0.9
1996 year	14.7a	10.5d	11.4c	10.8cd	11.4c	12.2b	11.8	1.5
2006 year	12.0d	18.2a	12.0d	15.2b	13.3c	15.4b	14.3	2.4
2008 year	11.8b	11.7b	10.1c	13.3a	10.5c	12.6ab	11.7	1.2
2010 year	10.5b	12.5a	9.3c	12.5a	11.0b	12.0a	11.3	1.3
2012 year	13.0a	12.6b	11.8cd	12.0c	11.5d	11.8cd	12.1	0.6
2014 year	12.3a	12.1a	12.6a	12.6a	11.9a	12.1a	12.3	0.3
Average value	12.3	12.8	11.3	12.6	11.5	12.2		
Standard deviation	1.3	2.5	1.2	1.4	0.9	1.7		

According to the analysis of *Figure 5,* there is no significant difference in soil bulk density of 0-10 cm layer in different long-term cultivation.

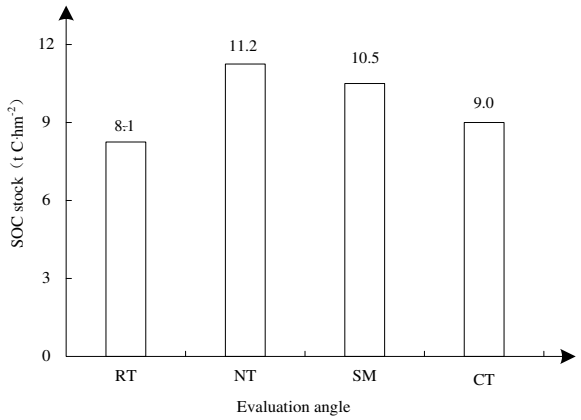

Figure 5. *Effects of long-term tillage on soil organic carbon content, capacity and organic carbon storage*

It can be seen from *Figures 6* and *7* that the carbon sequestration and carbon sequestration rate can be used as characteristic parameters for the evolution of organic carbon.

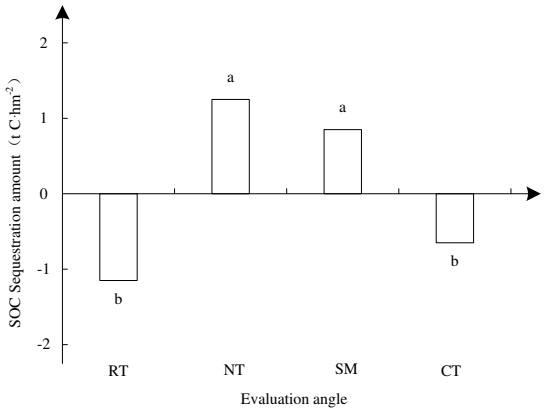

Figure 6. *Carbon fixation in long term different tillage treatment*

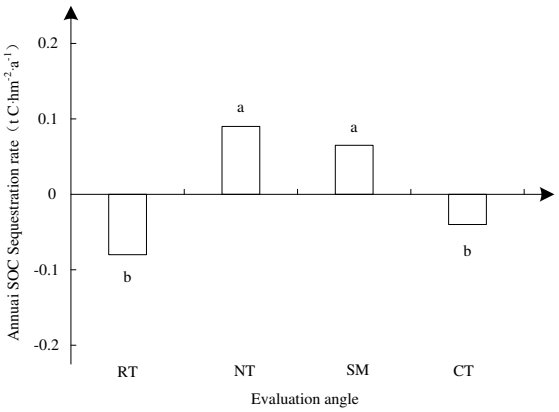

Figure 7. *Carbon fixation rate of long term different tillage treatment*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1049110507

This study showed that under 15 years of conservation tillage, the soil organic carbon content of no-tillage and deep pine treatment with straw mulching as the main feature showed the upward trend.

Taking the year of 2006-2014 as the influencing factor, the changes of soil organic carbon content in yellow soil paddy field were analyzed under the condition of no fertilizer and long-term fertilizer, respectively. In order to fully verify the effectiveness of the proposed method, the variance of the change of organic carbon content is calculated and counted, and the results are shown in *Figure 8.*

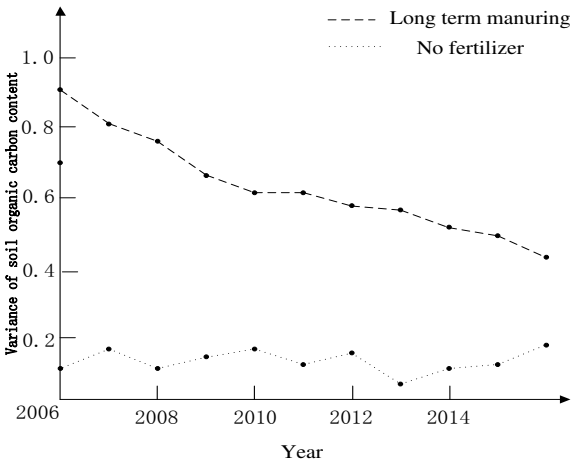

Figure 8. *Variance of soil organic carbon content*

Figure 8 shows that the variance of the change of organic carbon content is small under the condition of no fertilizer, and the influence of different years on the change of organic carbon content is small. Under the condition of long-term fertilizer, the variance of organic carbon content is larger, and the influence of different years on the change of organic carbon content is greater.

In order to further verify the effectiveness of the proposed method, the research accuracy of this method is compared with that of the traditional method, and the results are shown in *Table 4*.

Table 4. *Comparison of research accuracy*

Number of experiments/times	Paper method (%)	Traditional method (%)
5	89	76
10	88	75
15	90	74
20	92	72
15	93	80

The analysis *Table 4* shows that the research accuracy of this method is obviously higher than that of the traditional method, which shows that the research method has some advantages.

Discussion

Effect of NPK on soil organic matter composition

This study shows that in all treatments, the free active organic carbon belonging to high-activity organic carbon accounts for the relatively high proportion. It consists of unprotected coarse-grained organic carbon and fine-grained organic carbon, and is often used as one of the indicators of organic carbon change. Biochemically protected organic carbon and chemically protected organic carbon belong to the category of inert mineral-bound organic carbon (Song et al., 2015), which has strong stability. No change in chemically protected organic carbon indicates that long-term application of chemical fertilizer is not conducive to the accumulation of chemically protected organic carbon. The reason is that chemically protected organic carbon is mainly composed of humus, and the input of organic matter by NPK fertilizer is not enough to make up for its mineralization loss. During the period of 2006-2014, there was no significant change in physical protection of organic carbon under NPK treatment, indicating that it is less affected by chemical fertilizers.

Effect of single application of organic fertilizer on soil organic matter components

In this study, compared with single application of chemical fertilizer, the SOC and organic carbon content of each component were significantly increased with the fertilization period, which fully indicated its positive effect on increasing SOC reserves. The reason is that the application of organic fertilizer can not only increase crop yield, but also increase the direct input of carbon. This PANDEY et al study also shows that long-term application of organic fertilizer can increase the content of high-activity organic carbon and mineral-bound organic carbon in soil (Madejón et al., 2016). This PANDEY et al study also showed that long-term application of organic fertilizer can increase the content of high-activity organic carbon and mineral-bound organic carbon in soil. In this study, the proportion of mineral-bound organic carbon in the treatment with single application of organic fertilizer decreased slightly. The reason may be that the amount of soil fungi is increased in this case, so that the clay particles are converted into micro-aggregate particles. It increases the amount of animal and plant residues and secretions in the free active organic carbon. Yan Xiaogang et al. shows that the proportion of physical protection organic carbon in fluvo-aquic soil is 5.0-8.9%, which is mainly due to the physical protection of micro-aggregates, it reduces the decomposition of SOC by microorganisms and thus the effect of sequestering organic carbon.

Effect of NPK combined with organic fertilizer on organic matter components

The SOC content and annual variation of the MNPK treatment in this study are higher than 0.5MNPK treatment, which is consistent with most studies (Madejón et al., 2016). The SOC content mainly depends on the balance between the input and degradation of organic carbon, that is, the combination of constant organic fertilizer and chemical fertilizer. On the one hand, chemical fertilizer can increase microbial activity and increase crop root exudates.

On the other hand, organic fertilizer directly provides organic substances and promotes the increase of SOC. The study also shows that MNPK treatment improves the content of organic carbon in each component better than 0.5MNPK treatment, which

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1049110507

is consistent with the results of Zhang Jingye and Liang Shuming (Bahr et al., 2015). Yan Xiaogang's research shows that the content of free-particle organic carbon increased significantly under MNPK treatment, and there are differences in the proportion of organic carbon in each component under the same management measures and different fertilizer application rates. 0.5MNPK and MNPK still show the largest proportion of free active organic carbon. Compared with M treatment, their proportion of free active organic carbon is low. Because the long-term cooperation between NPK and organic fertilizers makes the non-protected active organic carbon form the stable Humin, it provides biochemical protection for organic carbon; it may also be that microbial metabolism promotes the accumulation of clay organic carbon.

Evolution characteristics of SOC in yellow soil paddy field under long-term fertilization

In this study, the SOC content shows the downward trend from 1995 to 2006. From 2006 to 2014, the SOC content under various conditions shows the very significant linear increase trend. This is due to changes in the farming system. Due to lack of water, the test site is changed to dry land during 2002-2006 and rice is replanted in 2007. The high permeability of dry land is conducive to the activity of soil microbes, resulting in the consumption of soil organic matter. The flooding and anoxic conditions of paddy fields inhibit their activities, which in turn is conducive to the accumulation of organic matter; on the other hand, paddy field conditions can effectively protect SOC. Other studies have also shown that the SOC content of paddy fields under the same conditions is significantly higher than that of dry land (Liu and Zhou, 2017).

Effect of long-term fertilization on carbon-N ratio in paddy yellow soil

Soil carbon-N ratio can reflect the coupling relationship between soil carbon and nitrogen, and is the important indicator for evaluating soil quality. The difference in soil carbon-N ratio between the fertilization treatments is not significant at around 12.3. This is consistent with the results of Luo Kun's research that the effect of fertilization measures on carbon-N ratio is not significant (Wander and Aref 2015). The soil carbon-nitrogen ratio is mainly related to the degree of soil organic matter. The carbon-nitrogen ratio of fresh organic matter tends to be higher, and the carbon-nitrogen ratio decreases with the increase of humification degree. Therefore, while increasing nitrogen input, the return level of carbon and nitrogen should be also paid attention. Vigorously promote the application of organic fertilizer and straw returning to maintain the stable increase in soil carbon-N ratio.

Carbon sequestration effect of conservation tillage

On the contrary, the less tillage treatment without straw returning decreased by 10.7%, which indicates that the conservation tillage of straw returning could increase soil organic carbon, while the no-tillage with reduced tillage frequency and intensity did not significantly improve organic carbon. Wang Chengji's research also shows that the organic carbon of conservation tillage with no increase in straw returning to the field is very small, and the no-tillage based on tillage management has great uncertainty on the accumulation of SOC in farmland.

DOI: http://dx.doi.org/10.15666/aeer/1705_1049110507

Conclusions

The results of this study indicate that the soil organic matter content of yellow loam paddy soil is still at low level, which has the large carbon sequestration potential and capacity. Free active organic carbon is the largest part of SOC. The combination of organic and inorganic fertilizers also significantly increased the unprotected free activity, physical protection and chemically protected organic carbon content of the soil, and the highest increase is achieved under the condition of constant organic-inorganic application. The effect of single application of chemical fertilizer on the increase of SOC content and total nitrogen content is relatively small. The alone application of organic fertilizer or organic and inorganic fertilizer could significantly increase the SOC content and total nitrogen content. When applying organic fertilizer, the application of nitrogen fertilizer is more conducive to soil carbon sequestration. When applying nitrogen fertilizer, it is more beneficial to soil nitrogen conservation and maintain proper carbon-N ratio and carbon-N coupling relationship. Therefore, the constant combination of organic and inorganic fertilizers is the most effective mode to increase soil organic carbon storage.

The organic carbon reserves of no-tillage and deep pine cover treatment is significantly higher than that of less tillage and traditional tillage, and the soil carbon sequestration increased significantly with the increase of cumulative carbon input. To maintain the stability of SOC reserves, the minimum of 2.4 t C•hm^{-2} carbon is required each year. Through long-term conservation tillage, the organic carbon storage of the soil and micro-aggregate in the high loess slope area is improved, which is the farmland management measure that is conducive to the increase of carbon in the soil.

(Received 27th Sep 2018; accepted 16th Jul 2019)

Abstract. A lot of efforts have been made in ecological assessment and applications. At present, Chinese government attaches great importance to regional economic development, so this research takes China as the research object. For this reason, a novel regional ecological assessment technology is proposed based on improved ELECTRE method. In the improved ELECTRE method, concordance index, non-concordance index, credibility index, consistent credibility, non-consistent credibility and net credibility are defined firstly, and the preference matrix, the relation of group individuals is also defined. Based on these definitions, it can be sorted for the quality of all alternatives according to the net credibility. Experimental results suggest that the proposed improved ELECTRE method is feasible and valid to the regional ecological assessment.
Keywords: *concordance index, non-concordance index, credibility index, consistent credibility, non-consistent credibility, net credibility, relation of group individuals, sort of group decision*

Introduction

In the eastern coastal areas and western areas to be developed in China, massive forest lands and wetlands have been damaged, leading to a situation of combined environmental pollution and massive ecological degradation (Anbari, 2003; Bi et al., 2015; Zuo et al., 2015). By ecological assessment, the key area for ecological environmental protection and restoration can be determined, ecological function zoning can be carried out, and proper protective measures and development plans can be made for different areas, to provide a scientific reference for determining urban development scale, land use arrangement and urban system configuration (Heilmann, 2013).

So far, a lot of efforts have been made in ecological assessment and application domestically and overseas (Nichols and Wahlen, 2004; Yang, 2015). The research contents include selection and analysis of sensitivity indexes of ecological environment, assessment of ecosystem service function and value, ecological risk analysis and pre-warning. The research range covers ecological sensitivity analysis under the context of global climate change, analysis of regional or watershed ecosystem dynamic change and difference, and provincial and municipal ecosystem assessment and ecological functional zoning (Zou et al., 2015; Zhao, 2003; Changdar et al., 2015; Lin and Lin, 2014). Diversified research methods have been adopted, such as ecological environment dynamic change monitoring and analysis with GIS and remote sensing monitoring technique, ecological environment sensitivity research based on fuzzy mathematical method, ecological environment vulnerability assessment with neural network method (Zhang et al., 2014; Belaqziz et al., 2013; Aloisio et al., 1997, 1999, 2005).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1050910523

Investigation and survey indicate that most researches on ecological assessment at home and abroad focus on areas at national, provincial or county (municipal) levels, and few on areas at lower levels (Karamchand, 2006; Tehraniana et al., 2006; Wen et al., 2015). This paper is intended to analyze the ecological sensitivity and ecological risk of Manas County in Xinjiang from the aspects of land cover type, vegetation coverage index, geographic and geomorphic data, meteorological data, and soil type, and plan the areas of county development suitability and put forward ecological planning suggestions for different areas on this basis (Xiang et al., 2008; He and Xing, 2012; Zhang et al., 2016).

In this paper, a novel regional ecological assessment technology is proposed using improved ELECTRE method. In the proposed method, concordance index, non-concordance index, credibility index, consistent credibility, non-consistent credibility and net credibility are defined firstly, and the preference matrix, the relation of group individuals is also defined. Based on these definitions, it can be sorted for the quality of all alternatives according to the net credibility. Experimental results suggest that the proposed improved ELECTRE method is feasible and valid to the regional ecological assessment.

Improved ELECTRE method

In order to be specific and not lose the generality, $C_j\,(j=1,2,\cdots,m)$ are all supposed to be benefit attributes. p_j, q_j and v_j signify strictly superior to the threshold value, indifference threshold value and veto threshold value respectively between projects on C_j, For the first kind of threshold value, suppose that p_j is less than the difference between values of project a_j and project a_k on C_j, then we consider that the relation between a_j and a_k is that the former strictly superior to the latter; for the second kind of threshold value, suppose that q_j is more than the difference between values of project a_j and project a_k on C_j, then it can be considered that there is indifference relation between these two projects; for the last threshold value, suppose that v_j is less than or equal to the difference between values of project a_j and project a_k on C_j (the value of a_k is more than a_j), then we can vote down that the overall level of a_j is superior to a_k, This shows that $0 \le q_j \le p_j \le v_j$,

The improvements of the proposed ELECTRE method can be summarized as follows. Three novel indexes, Concordance Index, Non-concordance Index and Credibility Index are defined. Based on these indexes, a new Preference Matrix is constructed. Also, the Consistent Credibility, Non-consistent Credibility and Net Credibility are established. At the final, one novel approach is proposed to the Relation of Group Individuals and Sort of Group Decision.

Definition of three indexes

(1) Concordance Index, which can be expressed as $c(a_i, a_k)$, This index refers to the supporting degree to thesis that 'the level of a_i is higher than a_k', which can be defined as

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1050910523

$$c(a_i, a_k) = \frac{1}{w}\sum_{j=1}^{m} w_j c_j(a_i, a_k) \quad \text{(Eq.1)}$$

where

$$w = \sum_{j=1}^{m} w_j \quad \text{(Eq.2)}$$

$$c_j(a_i, a_k) = \begin{cases} 0 & if \quad y_j(a_i)+p_j \le y_j(a_k) \\ 1 & if \quad y_j(a_i)+q_j \ge y_j(a_k) \\ \dfrac{y_j(a_i)+p_j-y_j(a_k)}{p_j-q_j} & other \end{cases} \quad \text{(Eq.3)}$$

This index refers to the degree that project a_i is superior to project a_k on C_j,

(2) Non-concordance Index, which refers to the denying degree to thesis that 'the level of a_i is higher than a_k', which can be defined as

$$d_j(a_i, a_k) = \begin{cases} 0 & if \quad y_j(a_i)+p_j \ge y_j(a_k) \\ 1 & if \quad y_j(a_i)+v_j \le y_j(a_k) \\ \dfrac{y_j(a_k)-y_j(a_i)-p_j}{v_j-p_j} & other \end{cases} \quad \text{(Eq.4)}$$

(3) Credibility Index, which refers to the credibility of that 'the level of a_i is higher than a_k', the value of which can be defined as

$$s(a_i, a_k) = \begin{cases} c(a_i, a_k) & if \quad \forall C_j, d_j(a_i, a_k) \le c(a_i, a_k) \\ c(a_i, a_k) \times \prod_{c_j} \dfrac{1-d_j(a_i, a_k)}{1-c(a_i, a_k)} & if \quad \forall C_j, d_j(a_i, a_k) > c(a_i, a_k) \end{cases} \quad \text{(Eq.5)}$$

Build the preference matrix

Every decision maker has his own point of view to judge and different preferences, so that they often use different dimensions and standards to make decisions (Duan et al., 2018; You et al., 2018; Liu et al., 2017; McKane et al., 2017). After finishing the ranking of alternatives by using ELECTRE-III method, we cannot simply use the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1050910523

average method or Borda method to integrate single decision result as the overall result, which does not conform to actual situations. Therefore, we need to put forward a new method to make the group reflect different dimensions and standards during the sorting process. Here, credibility index and the rating placement of project have greater relation with these dimensions and standards. We need to consider the following two questions at the same time: the relative interval of project while assigning the credibility index as $s(a_k, a_i)$ and $s(a_i, a_k)$, the relative rating placement of project on $s(a_i, a_k)$.

(1) Supposing that $\Delta Q_l(a_i, a_k)$ refers to the relative placement of project on (a_i, a_k) in the sort. $Q_l(a_i)$ refers to the order made by person l for project a_i. If there are m projects to be ordered, person l thinks that project a_i is the best among all the projects, then the $Q_l(a_i)$ is defined as 1. If person l thinks that project a_i is the worst one among all projects, then the $Q_l(a_i)$ is defined as m. There are five situations between the relative placement $\Delta Q^l(a_i, a_k)$ in ranking all projects and the project

$$\Delta Q_l(a_i, a_k) = \begin{cases} Q_l(a_i) >> Q_l(a_k) & if \quad Q_l(a_k) - Q_l(a_i) > \dfrac{n}{2} \\ Q_l(a_i) > Q_l(a_k) & if \quad 0 < Q_l(a_k) - Q_l(a_i) \le \dfrac{n}{2} \\ Q_l(a_i) = Q_l(a_k) & if \quad Q_l(a_k) - Q_l(a_i) = 0 \\ Q_l(a_i) < Q_l(a_k) & if \quad 0 < Q_l(a_i) - Q_l(a_k) \le \dfrac{n}{2} \\ Q_l(a_i) << Q_l(a_k) & if \quad Q_l(a_i) - Q_l(a_k) > \dfrac{n}{2} \end{cases} \qquad \text{(Eq.6)}$$

where $Q_l(a_i) >> Q_l(a_k)$ refers that person l thinks project a_i is much better than project a_k, $Q_l(a_i) > Q_l(a_k)$ refers that person l thinks project a_i is a little better than project a_k, $Q_l(a_i) < Q_l(a_k)$ refers that person l thinks project a_i is a little worse than project a_k, $Q_l(a_i) << Q_l(a_k)$ refers that person l thinks project a_i is much worse than project a_k,

When it is necessary to determine the quality sequence of projects, traditional ELECTRE method usually consider that there exists outranking relation while $s(a_i, a_k) \ge \lambda_{\max} - \beta$ is found, $\lambda_{\max} = \max_{a_i, a_k \in A} s(a_i, a_k)$, β is the intercepting threshold, the value of which is setting by decision makers themselves according to their own experience. Among all these outranking relations, the quality sequence of project a_i can be determined according to the difference between the number of outflowing directed arc of project a_i and the number of inflowing directed arc of project a_i. Therefore, there are four situations existed while defining the relative interval of credibility index $s_l(a_i, a_k)$ and $s_l(a_k, a_i)$ among each pair-projects

Zone I: $s_l(a_i, a_k) \ge \lambda_{\max} - \beta,\ s_l(a_k, a_i) \ge \lambda_{\max} - \beta$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1050910523

$$Zone\ II:\ s_l(a_i,a_k) \geq \lambda_{\max} - \beta,\ s_l(a_k,a_i) < \lambda_{\max} - \beta$$

$$Zone\ III:\ s_l(a_i,a_k) < \lambda_{\max} - \beta,\ s_l(a_k,a_i) \geq \lambda_{\max} - \beta$$

$$Zone\ IV:\ s_l(a_i,a_k) < \lambda_{\max} - \beta,\ s_l(a_k,a_i) < \lambda_{\max} - \beta$$

(2) Build the Preference Evaluation Matrix (*Table 1*). Preference Evaluation Matrix is used to measure the quality between project a_i and project a_k.

Table 1. *Preference evaluation matrix*

	Zone I	**Zone II**	**Zone III**	**Zone IV**
$Q_l(a_i) >> Q_l(a_k)$	$a_i O_s a_k$	$a_i O_s a_k$	$a_i O_w a_k$	$a_i O_s a_k$
$Q_l(a_i) > Q_l(a_k)$	$a_i O_w a_k$	$a_i O_s a_k$	$a_i I a_k$	$a_i O_w a_k$
$Q_l(a_i) = Q_l(a_k)$	$a_i I a_k$	$a_i O_w a_k$	$a_i B_w a_k$	$a_i I a_k$
$Q_l(a_i) < Q_l(a_k)$	$a_i B_w a_k$	$a_i I a_k$	$a_i B_s a_k$	$a_i B_w a_k$
$Q_l(a_i) << Q_l(a_k)$	$a_i B_s a_k$	$a_i B_w a_k$	$a_i B_s a_k$	$a_i B_s a_k$

$a_i O_s a_k$ refers that project a_i is much better (O_s) than project a_k; $a_i O_w a_k$ refers that project a_i is little better (O_w) than project a_k; $a_i I a_k$ refers that there is no difference (I) between project a_i and project a_k; $a_i B_w a_k$ refers that project a_i is little worse (B_w) than project a_k; $a_i B_s a_k$ refers that project a_i is much worse (B_s) than project a_k

Consistent credibility, non-consistent credibility and net credibility

(1) Consistent credibility $\Phi^+(a_i)$ indicates the degree that project a_i superior to other projects, which can be defined as

$$\Phi^+(a_i) = \sum_{a_k \in A} s(a_i,a_k), \forall a_k \in A \qquad \text{(Eq.7)}$$

(2) Non-consistent credibility $\Phi^-(a_i)$ is used to show the degree that other projects superior to project a_i, which can be defined as

$$\Phi^-(a_i) = \sum_{a_k \in A} s(a_k,a_i), \forall a_k \in A \qquad \text{(Eq.8)}$$

(3) Net credibility $\Phi(a_i)$ can express the difference between consistent credibility and non-consistent credibility, which can be defined as

$$\Phi(a_i) = \Phi^+(a_i) - \Phi^-(a_i)$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1050910523

It can be sorted of the quality for all alternatives according to the value of net credibility $\Phi(a_i)$. The greater the value of the net credibility $\Phi(a_i)$ of a project, the better the project is.

Relation of group individuals

(1) Group concordance index $C_G(a_i, a_k)$ refers to the credibility of supporting thesis that 'project a_i is better than project a_k' from the perspective of group, which can be defined as

$$C_G(a_i, a_k) = \sum_{l=1}^{m} v_l f_l(a_i, a_k) \quad \text{(Eq.9)}$$

where

$$f_l(a_i, a_k) = \begin{cases} 1 & if \quad a_i O_s a_k \\ 0.75 & if \quad a_i O_w a_k \\ 0.5 & if \quad a_i I a_k \\ 0.25 & if \quad a_i B_w a_k \\ 0 & if \quad a_i B_s a_k \end{cases} \quad \text{(Eq.10)}$$

(2) Group non-concordance index $D_G(a_i, a_k)$ refers to the credibility of denying thesis 'project a_i is better than project a_k' from the perspective of group, which can be defined as

$$D_G(a_i, a_k) = \sum_{l=1}^{m} v_l g_l(a_i, a_k) \quad \text{(Eq.11)}$$

where

$$g_l(a_i, a_k) = \begin{cases} 1 & if \quad \left(a_i B_w a_k \ or \ a_i B_s a_k\right) \& \left(Q_l(a_i) << Q_l(a_k)\right) \\ 0 & other \end{cases} \quad \text{(Eq.12)}$$

(3) Group credibility index $S_G(a_i, a_k)$ refers to the credibility of thesis that 'project a_i is better than project a_k', which can be defined as

$$S_G(a_i, a_k) = C_G(a_i, a_k) \cdot (1 - D_G(a_i, a_k)) \quad \text{(Eq.13)}$$

Sort of group decision

(1) Group consistency credibility $\Phi_G^+(a_i)$ refers to estimate the credibility that project a_i is better than other projects from the perspective of group, which can be defined as

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1050910523

$$\Phi_G^+(a_i) = \sum_{k=1}^{n} S_G(a_i, a_k) \quad \text{(Eq.14)}$$

(2) Group non-consistency credibility $\Phi_G^-(a_i)$ refers to estimate the credibility that other projects are better than project a_i from the perspective of group, which can be defined as

$$\Phi_G^-(a_i) = \sum_{k=1}^{n} S_G(a_k, a_i) \quad \text{(Eq.15)}$$

(3) Group net credibility $\Phi_G(a_i)$ refers to the difference between $\Phi_G^+(a_i)$ and $\Phi_G^-(a_i)$, which can be defined as

$$\Phi_G(a_i) = \Phi_G^+(a_i) - \Phi_G^-(a_i) \quad \text{(Eq.16)}$$

It can be sorted for the quality of all alternatives according to the value of $\Phi_G(a_i)$. In general, the greater the value of the group net credibility of a project, the better the project is.

Experimental results

In the experimental section, we take the Manas County (see *Fig. 1*) as the research object, which located at Xinjiang autonomous region, P. R. China. Manas County is located in the middle section of North Slope of the Tian-Shan Mountains, bordered by Hu-Tu-Bi County in the east, Shi-He-Zi and Sha-Wan city in the west, He-Jing County in the south, and Hoboksar Mongol Autonomous County in the north. In respect of geographical coordinates, it stretches from 43°28′29″ to 45°38′52″north latitude and from 85°41′16″ to 86°43′10″ east longitude. Manas County takes the shape of strip long from north to south and narrow from west to east. It is 235 km long to the most and 118 km wide to the most. The whole county covers an area of 10.196.4 km^2, and has seven towns, four villages, two farms and one station, as well as Xin-Hu Farm of the Sixth Agricultural Division of Xin-Jiang Production and Construction Corps, and four regimental farms of the Eighth Agricultural Division, namely 147 regiment, 148 regiment, 149 regiment and 150 regiment. Geomorphically, Manas County can be divided into three units from south to north, namely southern mountain area, central plan, and northern desert, of which the altitude ranges from 5,222 m to 650 m, from 650 m to 320 m and from 320 m to 280 m respectively. Manas County falls into the dry and semi-dry temperate continental climate region, of which the climate features are severe cold winter, hot summer, abundant sunshine, aridness, and little rainfall, with annual average temperature of 6.9 °C and average annual precipitation of 173.3 mm.

Basic data

The main data used in this research covers land cover type, Normalized Differential Vegetation Index (NDVI), geographic and geomorphic data, meteorological data, soil

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1050910523

type, distribution data of geological disaster, and administrative map. *Table 2* shows the data sources and details.

Table 2. *Data contents and sources*

Data name	Data source	Description
Land cover type	Institute of Geographic Sciences and Natural Resources Research, CAS	Vector data of year 2017
NDVI	Environmental and Ecological Science Data Center for West China, National Natural Science Foundation of China	SPOT VGT NDVI 1 km resolution data of year 2009-2017

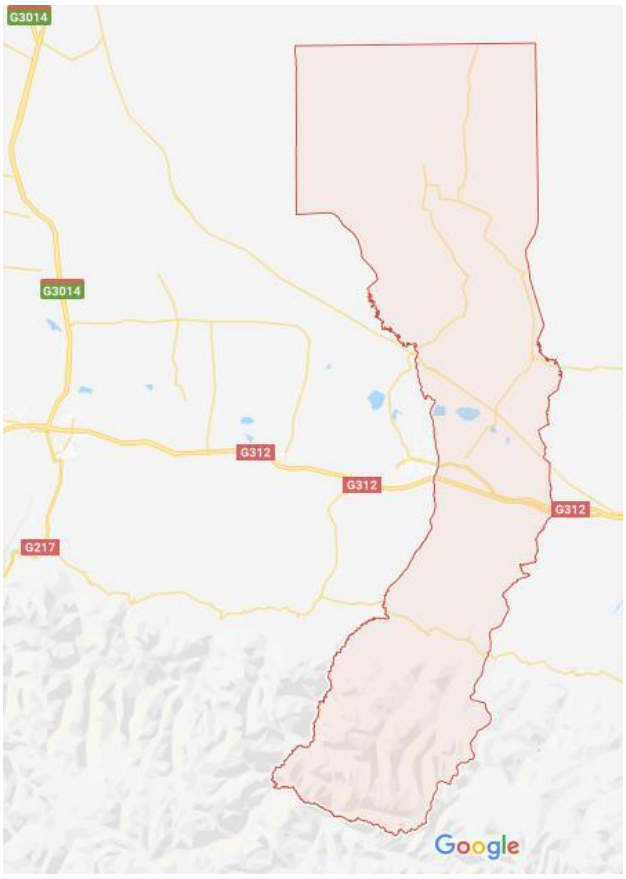

Figure 1. *The location of Manas County*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1050910523

Considering that the data is from different sources, it is necessary to preprocess the data before ecological analysis, including correction of remote sensing image data, scanning vectorization and registration of grid data, mergence and clipping of grid data based on administrative boundary map of county region. Essential data on the survey region has been generated with Xi-An trimetric projection zone coordinate system based on the preprocessed data.

Ecological sensitivity analysis

The term of ecological sensitivity analysis in this research refers to the level of sensitivity of inhabiting area of major species in an ecosystem to interference of human activity, or the adaptive capacity of inhabiting area of major species in an ecosystem to external disturbance, which, with respect to selection of ecological factor, complies with the principles of representativeness, reliability, combination of qualitative analysis and quantitative analysis, and data availability (Sheikhhosseini, 2018; Fang et al., 2018; Dong et al., 2018). For constructing the indicator system, comprehensive consideration of natural factors and anthropogenic influence has been taken, and the selected sensitivity assessment indicators including land cover factor, vegetation factor, slope, geomorphic type, and groundwater protection zone factor. For land cover factor, land-use type is taken as the assessment indicator, and national forest parks and major wetlands are taken into full consideration; for vegetation factor, NDVI is taken as the assessment indicator; for geomorphic factor, geomorphic division type is taken as the assessment indicator (Zhang et al., 2017; Obraczka et al., 2017).

In this research, the attributes of the assessment indicators are assessed, and a value ranging from 1 to 9 is assigned to each indicator. High value indicates high level of ecological sensitivity (as shown in *Table 3*, '/' indicates that it would contain non-relevant information). A weight is assigned to land cover factor, NDVI, slope, geomorphology, and underground water factor respectively, which is 0.4, 0.1, 0.2, 0.2 and 0.1 respectively. A 30 m × 30 m grid cell is taken as analytical unit, and the weighted sum of the factors is calculated with grid calculator in ArcGIS 9.3. Based on the calculations, the ecologically sensitive region is divided into five levels with 5-level division method, namely high sensitive area, relatively highly sensitive area, medium sensitive area, low sensitive area and non-sensitive area.

Table 3. *Manas County ecosystem sensitivity assessment indicator*

Item	1	2	3	4	5	6	7	8	9
Land cover	Urban	/	/	Farmland	/	Deseed	Grassland	Other	Forest, wetland
NDVI	≤ 0	/	(0, 0.25]	/	(0.25-0.5]	/	(0.50-0.75]	/	(0.75-1]
Slope	≤ 5°	/	(5°-15°]	/	(15°-25°]	/	> 25°	/	/

Ecological risk analysis

For purpose of this research, comprehensive ecological risk assessment method is adopted. According to field research and materials and documents, the three major ecological risks in Manas County include flood, desert, and geological disaster. An ecological risk assessment model has been built based on the results of risk exposure in combination with the intensity and frequency of risk. For the analysis, the collected research data is digitized first, and then further collated, verified and edited. On this basis, a database is built on the ArcGIS platform, and calculation and analysis are made according to the needs of assessment.

The flood types in Manas County mainly include snow (ice)-melted flood, rainstorm-type flood and blended-type flood. In the research, analysis is made on runoff of snow, rainstorm and small watershed, the probability of occurrence of flood is determined according to different catchment areas, and a certain area on both sides of river reach prone to flood is taken as the risky place. In the research on desertization risk, vegetation index, soil type, and average annual precipitation are taken as the assessment factors of desertization risk grade, and desertization risk classification is made. In the research on risk of landslide and debris flow, a geological disaster ecological risk formula of Manas County is established with slope, rainstorm and vegetation coverage as the assessment factors. At last, on the basis of main ecological risk analysis, the three risks set out above are normalized and graded respectively (as shown in *Table 4*), a weight of 0.40, 0.35 and 0.25 is assigned to flood risk, desertization risk and geologic risk respectively, and weighting calculation is conducted. Limited to human recognition, 1, 3, 5, 7, 9 are often used to distinguish the difference between two objects. Based on the results, the ecological risk area is divided into high risk area, relatively high risk area, moderate risk area, relatively low risk area and low area with the 5-level division method.

Table 4. *Manas County ecological risk assessment indicators*

Degree of risk	1	3	5	7	9
Flood risk	(0.04,0.08]	(0.08,0.17]	(0.17,0.33]	(0.33,0.58]	(0.58-1]
Desertization risk	(0.44,0.53]	(0534,0.60]	(0.60,0.65]	(0.65,0.70]	(0.70,0.85]
Geological risk	(0.11,0.25]	(0.25,0.34]	(0.34,0.45]	(0.45,0.56]	(0.56,0.80]

Suitability analysis of county development

According to the normalization with equal weight of the results of ecological sensitivity analysis and ecological risk analysis of Manas County and suitability analysis of county development, the highly ecologically sensitive area and highly ecological risk area are unsuitable for county development, relatively high ecologically sensitive area and relatively high risk area are barely suitable for county development, medium ecologically sensitive area and medium ecological risk area are moderately suitable for county development, and low ecologically sensitive area and low ecological risk area are highly suitable for county development. The ecology, safety, resources, environment and urban functions of areas unsuitable and barely suitable for county development are vulnerable, which are difficult to restore or will lead to heavy losses once being damaged. Proper control measures should be taken in areas moderately

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1050910523

suitable for county development according to the requirements of ecology, safety, resources and environment. Concentrated construction is feasible in areas highly or relatively highly suitable for county development.

Results of comprehensive ecological sensitivity analysis

According to the ecosystem sensitivity assessment indicators of Manas County, the highly sensitive area in the whole Manas County mainly covers the water conservation area in the south, wetlands in the central part, and desert in the north, and other areas most are moderately sensitive areas. The proportions of highly sensitive area, relatively highly sensitive area, moderately sensitive area, low sensitive area, and non-sensitive area to the total area of the survey region are 41.31%, 16.17%, 16.44%, 7.07% and 19.01% respectively.

Results of comprehensive ecological risk analysis

According to the ecological risk assessment system, the high-ecological-risk area of Manas County is mainly distributed in the south of Taxihe Village, the middle part and south of Qing-Shui-He Village, and the north of Guang-Dong-Di Village. The ecological risk level of the area along the downstream of Taxihe and the area along the downstream of Manas River is also relatively high, and that of other areas is low.

Results of suitability analysis of Manas County development

The suitability analysis results of county development are classified into five grades. The area highly suitable for county development mainly covers most areas of Manas town, Lan-Hou-Wan town, the west area of 147 regimental farm, Bei-Wu-Cha, the southeast of Liu-Hu-Di, as well as the east of 148 regimental farm, 149 regimental farm and 150 regimental farm; the area relatively highly suitable for county development mainly covers the middle part of the four regimental farms, the south of Lan-Zhou-Wan, Le-Tu-Yi and the south of Bao-Jia-Dian; the area moderately suitable for county development mainly covers Xin-Hu Farm and most area of Guang-Dong-Di village; the rest area is barely suitable or unsuitable for county development, mainly covering the northern desert, southern mountain, the area along Manas River and Taxihe, and reservoirs and swags in plain area.

Manas County construction regionalization

Manas County is regionalized according to the suitability analysis of Manas County development, by which the areas barely suitable or unsuitable for county development are classified into prohibited-construction areas, and the areas relatively highly or highly suitable for county development into construction-suitable areas. The prohibited-construction areas mainly cover the southern mountains, wetlands in the plain area, and the northern desert. The north slope of the Tian-Shan Mountains is highly sensitive water conservation area; most primeval forest and vegetation have been damaged in the process of bringing wasteland into cultivation; the area of the north desert has been put under proper control with the expansion of cultivated land and the construction of wind break, but it is still an ecologically sensitive area needing intensive protection. These areas set out above should be prohibited for development in urban construction (*Fig. 2*).

Conclusions

In this paper, relatively comprehensive ecological assessment of Manas County has been made through ecological sensitivity analysis and ecological risk analysis by combining expert knowledge with the analytic hierarchy process and bringing the spatial analysis capability of GIS into full play, providing new ideas for ecological quality assessment and urban development planning. In the scope of Manas County, the highly sensitive area is mainly distributed in the water conservation area in the south mountains, wetlands in the central part, and desert in the north; the proportions of highly sensitive area, relatively highly sensitive area, moderately sensitive area, low sensitive area, and non-sensitive area to the total area of the survey region are 41.31%, 16.17%, 16.44%, 7.07% and 19.01% respectively; the highly ecological risk area is mainly distributed in the south of Taxihe Village, the middle part and south of Qing-Shui-He Village, and the north of Guang-Dong-Di Village, as well as the middle and lower reaches of Taxihe and the lower reaches of Manas River. According to ecological sensitivity analysis and ecological risk analysis, county development suitability analysis has been made in this research, and the survey region is classified into prohibited-construction area, construction expansion restricted zone, and construction-suitable area on this basis. The construction of any unrelated building should be prohibited in the prohibited-construction area, measures should be taken to avoid occupying urban construction land in the constructive expansion restricted zone as far as possible, and rational development on the premise of ecological environmental protection is allowed in the construction-suitable area.

According to the ecological sensitivity analysis and ecological risk analysis, the middle and lower reaches of Manas River and the upper and middle reaches of Taxihe are flood-prone area, of which the comprehensive ecological safety assessment index takes on a down trend. A special fund allocated by the Ministry of Water Resources was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1050910523

used for flood control of Manas River in 2011. The feasible measures for flood control include consolidating the construction of small and medium size reservoirs and infrastructure of flood control and drainage of cities, and mitigating damage to Manas River and Taxihe. For severe desertification region, it needs to strengthen the construction of vegetation, river, road, and other ecological corridors in the junction zone between desert and city, to prevent desertification erosion. For the highly sensitive and risk areas such as the high mountains and gorge areas in Manas County, ecological emigration from the steep slope area along Manas River and Taxihe can be considered to resettle the scattered residents in an area of low ecological risk centrally. For county development, the construction of unrelated buildings should be prohibited in the prohibited-construction area; measures should be taken to avoid occupying urban construction land in the constructive expansion restricted zone as far as possible, or proper ecological assessment, compensation measures and the procedure for examination and approval should be subject to if it needs to occupy any urban construction land in special circumstance; the principles of construction following planning, optimal land utilization, intensive development, and rational exploitation on the premise of ecological environmental protection should be adhered to for the construction-suitable area.

Abstract. The present research aims to evaluate the effects of ammonium (NH_4^+), nitrate (NO_3^-) and phosphate (PO_4^{-3}) on oviposition preference, hatching rate, time to pupation, pupation rate, time to adult emergence, adult emergence rate and female to male ratio of *Culex quinquefasciatus* mosquito, under laboratory conditions. The mosquito preferred to oviposit in containers containing 5 ppm NH_4^+, 45 ppm NO_3^- or 30 ppm PO_4^{-3} solution. No significant effect of these polutants on egg hatching rate was observed. The larvae that existed in containers containing 5 ppm NH_4^+, 45 ppm NO_3^- or 30 ppm PO_4^{-3} solution reached earlier to pupal and adult stages. The presence of NH_4^+ (5 ppm), NO_3^- (45 ppm) or PO_4^{-3} (30 ppm) in aqueous medium, resulted in decreased time to pupation or adult emergence and increased pupation and adult emergence rates. The adults emerged from these larvae showed significantly higher female to male ratio as compared to control adults ($P<0.05$). From the findings of the present research, it is concluded that the levels of NH_4^+, NO_3^- or PO_4^{-3} set in effluents for wastewater reuse in agricultural irrigation by WHO (2006) are favorable for the survival and development of *Cx. quinquefasciatus* mosquito, however higher levels of NH_4^+, NO_3^- or PO_4^{-3} are not favorable for the survival and development of this mosquito. These results help in identification of concentration ranges of the ammonium, nitrate and phosphate that make the larval habitat favorable for survival and reproduction of *Culex* mosquitoes. This could be helpful in effective control of mosquito borne diseases.
Keywords: *oviposition preference, hatching rate, pupation rate, time to pupation, emergence rate, time to adult emergence, female to male ratio*

Introduction

Mosquito larval habitats are influenced by many physical, chemical and biological factors. The results of several studies have shown the relationship between habitat characteristics and mosquito larval abundance and distribution (Kenea et al., 2011). Ammonium (NH_4^+), nitrate (NO_3^-) and phosphate (PO_4^{-3}) are the well-known inorganic nutrient pollutants of water bodies. The NH_4^+, NO_3^- and other ionic forms of inorganic nitrogen enter the surface water bodies both from natural and anthropogenic sources (Wetzel, 2001; Rabalais, 2002). Phosphate is also an important inorganic nutrient in aquatic ecosystem and surface water receives it from various

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1052510541

sources such as agricultural use of fertilizers, domestic and industrial wastewater, and atmospheric deposition (Tchobanoglous and Burton, 1991; Grubb et al., 2000).

The inorganic nutrient pollutants such as NH_4^+, NO_3^- and PO_4^{-3} in mosquito breeding sites influences the development of mosquito larvae (Noori et al., 2015). Breeding sites with higher NH_4^+, NO_3^- and PO_4^{-3} concentration provide better microbial food source for mosquito larvae (Dowling et al., 2013). Knowledge of mosquito breeding habitats is useful for identifying the most productive water bodies in a given area and developing efficient control approaches (Noori et al., 2015). Noori et al. (2015) designed a mesocosm experiment for investigating the relationships between inorganic nutrient pollutants (i.e., NH_4^+, NO_3^- and PO_4^{-3}) concentrations and larval development of *Cx. quinquefasciatus*. High concentrations of nitrate and phosphate favored the larval development and survival rates. High NO_3^- concentration suppressed the development of female mosquito but favored the development of male mosquitoes. The adult mosquitoes which emerged in high NO_3^- concentration solution were found to be faster in development. It was further observed that in the absence of NO_3^-, the addition of PO_4^{-3} slow the larval development. Schletzbaum (2013), evaluated the influence of water nutrient pollutant on the sequence of larval hatching of two mosquito species, *Culex pipiens* and *Anopheles albopictus* in container habitats. Higher NO_3^- concentration in the larval environment resulted in larger *Anopheles albopictus* females and higher emergence rate and shorter time to emergence for *Culex pipiens*.

Increased level of different forms of inorganic nitrogen in water is toxic to fresh water invertebrates, fishes and amphibian (Hickey and Vickers, 1994; Camargo et al., 2005). Phosphate (PO_4^{-3}) toxicity with aquatic invertebrates has also been reported (Kim et al., 2013). According to Williams et al. (1986), the elevated levels of nitrates, ammonia and phosphorus in the surface waters (in both marine and fresh water), can affect invertebrate diversity in feeding grounds. According to the compendium of standards for wastewater reuse in the Eastern Mediterranean region, the maximum permissible concentrations of NH_4^+, NO_3^- and PO_4^{-3} in effluents for reuse in agricultural irrigation are 5, 45 and 30 ppm, respectively (WHO, 2006). Irrigation water for agriculture has the potential to create mosquito breeding habitats within the storage system for water along the water supplying channels or in the field that receive water.

Monitoring of pollutants in aquatic environment is necessary for investigating the status of pollution in such environment for protection of human life and wildlife. From environmental, ecological and economic point of view, regular assessment of the pollutant levels and their destiny in different media of environment is essential. Regulation and re-evaluation of the threshold levels of different pollutants set by different international and national organizations is very important. The present research aims to evaluate the effects of threshold levels of three inorganic nutrient pollutants (NH_4^+, NO_3^- and PO_4^{-3}) set by WHO (2006) compendium of standards for wastewater reuse in agricultural irrigation in the Eastern Mediterranean region on the life-history of a common and economically important insect (*Culex quinquefasciatus* Say, 182) in water under laboratory conditions. The study contributes to the science of the effects of increasing level of inorganic nutrient pollutants on insect populations.

Materials and methods

During the present research, the effects of NH_4^+, NO_3^- and PO_4^{-3} on oviposition preference, hatching rate and larval development of *Culex quinquefasciatus* (Say, 182) were studied in laboratory condition. During larval development, the effects of above inorganic nutrient pollutants on time to pupation, pupation rate, time till first appearance of adult, adult emergence rate, and female to male ratio were studied.

Required chemicals

The chemicals used included ammonium chloride (NH_4Cl) of Merck Co. (Darmstadt, Germany) for NH_4^+, sodium nitrate ($NaNO_3$) of Sigma-Aldrich (USA) for NO_3^- and sodium phosphate dibasic (Na_2HPO_4) of Sigma-Aldrich (USA) for PO_4^{-3}. The following are the detail of molar mass of the compounds and the related ions used during the present research:

- Ammonium chloride (NH_4Cl) molar mass is 53.5 g and contains 18 g of NH_4^+.
- Sodium nitrate ($NaNO_3$) molar mass is 85.5 g and contains 62 g of NO_3^{-1}.
- Sodium phosphate dibasic (Na_2HPO_4) molar mass is 144 g and contains 97 g of PO_4^{-3}.

Preparation of solutions

Initially 1000 ppm stock solution of each pollutant was prepared. For preparation of stock solution of 1000 ppm (1000 mg/L) of NH_4^+, 2.9 gram of NH_4Cl was required. For preparation of stock solution of 1000 ppm (1000 mg/L) of NO_3^-, 1.4 gram of $NaNO_3$ was required. For preparation of stock solution of 1000 ppm (1000 mg/L) of PO_4^{-3}, 1.5 gram of Na_2HPO_4 was required.

Laboratory rearing of Cx. quinquefasciatus

Experiments were conducted on the effects of NH_4^+, NO_3^{-1} and PO_4^{-3} on larval mortality, egg laying preference, egg hatching rate and larval development of *Cx. quinquefasciatus*. Laboratory colonies of *Cx. quinquefasciatus* were maintained during April and May 2016.

Laboratory conditions

The experiments were conducted during April and May 2016. Inside the laboratory, minimum temperature was $\geq$ 20°C and maximum temperature was $\leq$ 33°C. The laboratory was wide, well ventilated and receiving sun light at the day time through glass windows.

Bioassay for effect of inorganic nutrient pollutants on oviposition preference

According to the standards for wastewater reuse in the Eastern Mediterranean Region, the maximum permissible concentrations of NH_4^+, NO_3^{-1} and PO_4^{-3} in effluents for reuse in agricultural irrigation are 5, 45 and 30 ppm, respectively (WHO, 2006). Irrigation water for agriculture has the potential to create mosquito breeding habitats within the storage system for water along the water supplying channels or in the field that receive water. The present study aimed to investigate the effect of NH_4^+, NO_3^{-1} and PO_4^{-3} on oviposition preference of *Cx. quinquefasciatus* at the concentrations which are permissible in effluents for reuse in agricultural irrigation (WHO, 2006). The effect of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1052510541

NH_4^+, NO_3^{-1} and PO_4^{-3} on oviposition preference of *Cx. quinquefasciatus* was also studied at concentrations higher than WHO recommended concentrations of these nutrient pollutants in effluents for reuse in agricultural irrigation (WHO, 2006). Thus, two concentrations of NH_4^+ (5 and 10 ppm), NO_3^{-1} (45 and 90 ppm) and PO_4^{-3} (30 and 60 ppm) were tested for their effect on oviposition preference of *Cx. quinquefasciatus* gravid female adult. The main purpose was to investigate the effect of NH_4^+, NO_3^{-1} and PO_4^{-3} on oviposition preference of *Cx. quinquefasciatus* at concentrations which are permissible in effluents for reuse in agricultural irrigation (WHO, 2006). Three mosquito cages (cage 1-3) were used during this experiment (*Figure 1*).

Figure 1. *Picture showing mosquito cages used during the present research*

During the study of effect of NH_4^+ on oviposition preference of *Cx. quinquefasciatus* gravid female adult, two NH_4^+ solutions of 5 and 10 ppm (300 ml each) in two 400 ml polyethylene containers were placed in mosquito cage (45 cm × 45 cm × 45 cm). In addition, a control polyethylene container containing 300 ml non-chlorinated tap water was also placed inside the mosquito cage along with NH_4^+ solution. For studying the effect of NO_3^{-1} on oviposition preference, two NO_3^{-1} solutions of 45 and 90 ppm (300 ml each) in two 400 ml polyethylene containers were placed in mosquito cage. In addition, a control polyethylene container containing 300 ml non-chlorinated tap water was also placed inside the mosquito cage along with NO_3^{-1} solution. For studying the effect of PO_4^{-3} on oviposition preference, two PO_4^{-3} solutions of 30 and 60 ppm (300 ml each) in two 400 ml polyethylene containers were placed in a mosquito cage. In addition, a control polyethylene container containing 300 ml non-chlorinated tap water was also placed inside the mosquito cage along with PO_4^{-3} solution. The experiment was run in triplicate.

For each mosquito cage, 100 blood fed and gravid female adult mosquitoes (5 days of age after emergence from pupae) were caught from the existing laboratory colony of *Cx. quinquefasciatus* through mouth aspirator and then introduced into the cage. The gravid female mosquitoes laid egg into the containers after 2 or 3 days of introduction. The number of egg rafts laid by female mosquitoes in each jar was counted under stereo binocular microscope with digital camera (Labomed Inc, USA) so that to determine the effect of inorganic nutrient pollutants on the egg laying preference of *Cx. quinquefasciatus* female adult mosquitoes. Schematic of experiment on the effect of inorganic nutrient pollutants on oviposition preference and egg hatching rate is shown in *Figure 2*. Egg rafts and eggs within rafts have been shown in *Figures 3-4*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1052510541

Bioassay for effect of inorganic nutrient pollutants on egg hatching rate

The egg rafts laid by the gravid female mosquitoes during oviposition assays for NH_4^+, NO_3^- and PO_4^{-3}, hatched into first instar larvae. After two days of hatching, all the containers were brought out of the mosquito cages and the total number of eggs and the number of hatched out larvae were counted.

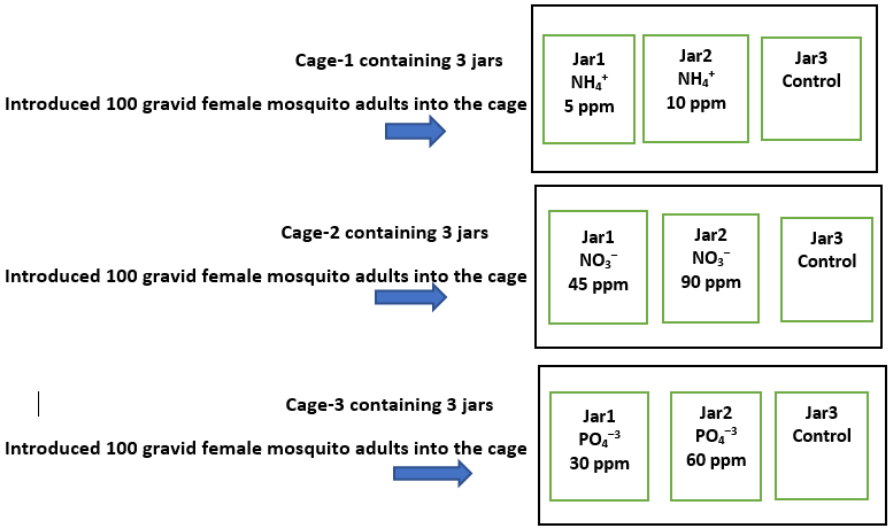

Figure 2. *Schematic of experiment on the effect of inorganic nutrient pollutants on oviposition preference and egg hatching rate*

Figure 3. *Egg rafts deposited by Culex quinquefasciatus during the present experiments*

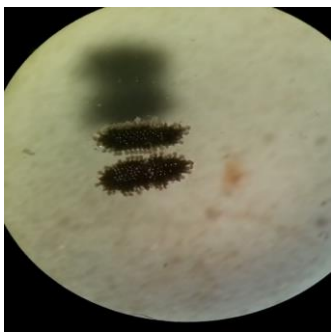

Figure 4. *Microscopic picture of Culex quinquefasciatus eggs in rafts taken during the present experiments*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1052510541

Bioassay for effect of inorganic nutrient pollutant on larval development

The effect of high concentration of NH_4^+ (5 ppm), NO_3^- (45 ppm) and of PO_4^{-3} (30 ppm) in water on larval development of *Cx. quinquefasciatus* were also studied as these concentrations are allowable according to a compendium of standards for wastewater reuse in the Eastern Mediterranean Region (WHO, 2006). The schematic of experiment on the effect of inorganic nutrient pollutants on larval development of *Cx. quinquefasciatus* is shown in *Figure 5*. Thus 5 ppm concentration of NH_4^+, 45 ppm concentration of NO_3^- and 30 ppm concentration of PO_4^{-3} were prepared in three 1000 ml polyethylene jars. The solutions were prepared from stock solutions in sieved pond water for ensuring the presence of natural communities of microflora (Noori et al., 2015). The volume of each testing solution was 500 ml. In addition, a control 1000 ml polyethylene jar containing only 500 ml sieved river water was also arranged. Dried leaf litter of *Chenopodium album* was collected along the boundary wall of University of Malakand as there was no history of pesticides application. The leaf litter was ground into powder. During this experiment, 100 mg of leaf litter powder was added to each jar including control jar for providing source of carbon (Schletzbaum, 2013; Noori et al., 2015).

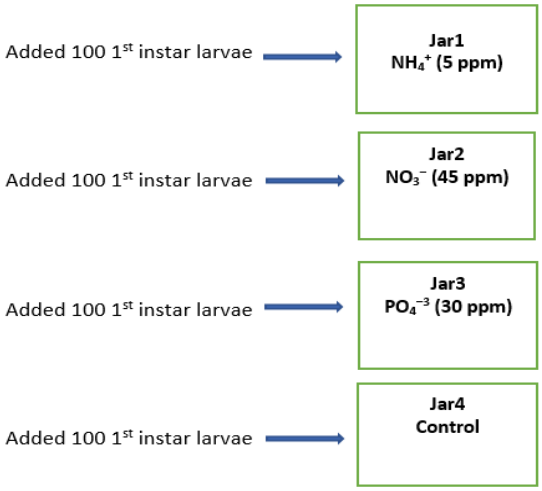

Figure 5. *Schematic of experiment on the effect of inorganic nutrient pollutants on larval development of Cx. quinquefasciatus*

One hundred newly hatched 1st instar larvae (a day after hatching) larvae of *Cx. quinquefasciatus* from laboratory colony were transferred to each polyethylene jar. This experiment was run in four replicates. The jars were capped with gauze to prevent the escape of emerging adult mosquitoes. The jars were daily checked for the appearance of pupae and adults. The observations were continued till all the larvae or pupae in all the jars have died or emerged as adults. The effect of NH_4^+, NO_3^- and PO_4^{-3} on time to pupation, pupation rate, time to adult emergence, adult emergence rate and female to male ratios were studied. All the mosquito adults were counted and the female to male ratio was determined by dividing the total number of female adults by the total number of male adults (Neira et al., 2014). Time to pupation or adult emergence was calculated by the following method (Kosalwat and Knight, 1987) (*Eq.1*):

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1052510541

$$T = \sum (D \times N) / \sum N \quad \text{(Eq.1)}$$

where T represents the average time to pupation or adult emergence (in days), D represents the number of days from day zero of exposure of first instar larvae to pupation or adult emergence and N represents the number of pupae or adults produced. *Figure 6* shows the pictures of egg, larval, pupal and adult stages of life history of *Culex quinquefasciatus* mosquito. The pictures have been taken in the laboratory during the present experiments.

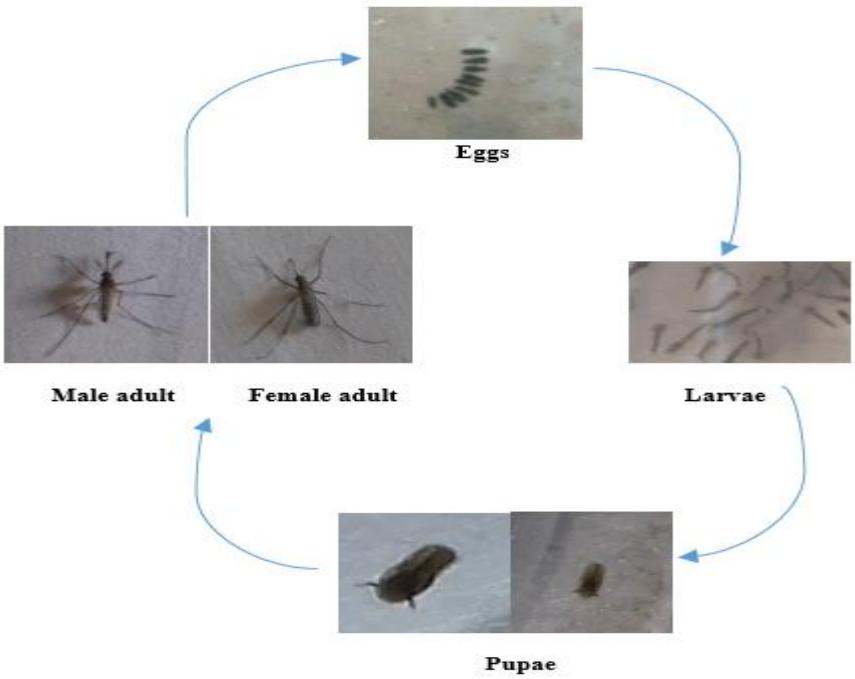

Figure 6. *Picture showing the egg, larval, pupal and adult stages of life history of Culex quinquefasciatus mosquito. The figure has been produced from the pictures taken in the laboratory during the present experiments*

Statistical analysis

The data was initially analyzed by normality test of Shapiro-Wilk. If the P value was less than 0.05 then the data was analyzed by Kruskal-Wallis test for comparison (Schlotzhauer and Little, 1987). When the P value in Kruskal-Wallis test was less than 0.05 then the Kruskal-Wallis test was followed by Bonferroni's post hoc test for pairwise comparison. The data was presented as the mean rank. If the value of P in normality test was greater than 0.05 then the data was analyzed by Dunnett's Test at P>0.05 significance level for assessing significant difference between control and each of the treatment solution. In this case the data was presented as mean with standard error. The LC_{50} values were compared by 95 % confidence limits overlap method (Wheeler et al., 2006).

Results

Oviposition preference of Cx. quinquefasciatus

The effect of NH_4^+ (5 ppm and 10 ppm), NO_3^- (45 ppm and 90 ppm) and PO_4^{-3} (30 ppm and 60 ppm) on oviposition preference of *Cx. quinquefasciatus* is shown in *Table 1*. Data is presented as means (with standard error of means) and mean ranks of egg rafts. Based on normality test of Shapiro-Wilk, the data was not normally distributed, therefore the data was analyzed by Kruskal-Wallis test at $P<0.05$ significance level for determining significant difference.

During the study of effect of NH_4^+ on oviposition preference, the Kruskal Wallis χ^2 value was 6.0 and the P value was 0.05. The overall test showed significant difference in the mean ranks of egg rafts across the control and treatment containers (5 ppm and 10 ppm NH_4^+ solutions). The mean rank of egg rafts in 5 ppm NH_4^+ solution container (mean rank = 8.0) was significantly higher when compared to control container ($P<0.05$). The control container and 10 ppm NH_4^+ solution container showed similar mean rank of egg rafts (mean rank = 3.5 each).

Table 1. *Effect of inorganic nutrient pollutants in water on oviposition preference of Cx. quinquefasciatus (n=3)*

Pollutants	Concentration	N. of egg rafts Mean± SE	Mean rank of egg rafts
Ammonium (NH_4^+)	Control	1.6±0.3	3.5
	5 ppm	7.3±0.7*	8
	10 ppm	1.6±0.6	3
			KW, χ^2=6.0
			P=0.05
Nitrate (NO_3^-)	Control	1.3±0.3	2
	45 ppm	8.0±1.2*	8
	90 ppm	3.6±0.3	5
			KW, χ^2=7.3
			P=0.03
Phosphate (PO_4^{-3})	Control	2.6±0.3	4
	30 ppm	12.7±1.8*	8
	90 ppm	2.3±0.3	3
			KW, χ^2=6
			P=0.049

KW - Kruskal-Wallis, *-.significantly different from the control at $P<0.05$ significance level in Kruskal-Wallis test

During the study of effect of NO_3^- on oviposition preference, the Kruskal Wallis χ^2 value was 7.3 and P value was 0.03. The overall test showed significant difference in mean ranks of egg rafts across the control and treatment containers (45 ppm and 90 ppm NO_3^- solutions). The mean rank of egg rafts in 45 ppm NO_3^- solution container (mean rank = 8.0) was significantly higher when compared to control container (mean rank = 2) ($P<0.05$). There was no significant difference ($P>0.05$) in the mean rank of 90 ppm NO_3^- solution container (mean rank = 5) and control container (mean rank = 2).

During the study of effect of PO_4^{-3} on oviposition preference, the Kruskal Wallis χ^2 value was 6.0 and P value was 0.050. The overall test showed significant difference in mean ranks of egg rafts across the control and treatment containers (30 ppm and 60 ppm PO_4^{-3} solutions). The mean rank of egg rafts in 30 ppm PO_4^{-3} solution container

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1052510541

(mean rank = 8.0) was significantly higher when compared to control container (mean rank = 4) ($P<0.05$). The mean rank of egg rafts of 60 ppm PO_4^{-3} solution container (mean rank = 3) was insignificantly lower ($P>0.05$) when compared to control container (mean rank = 4).

Hatching rate of Cx. quinquefasciatus

The effect of NH_4^+, NO_3^- and PO_4^{-3} on hatching rate of *Cx. quinquefasciatus* is shown in *Table 2*. Based on normality test of Shapiro-Wilk, the data was normally distributed, therefore the data was analyzed by Dunnett's Test at $P<0.05$ significance level for determining significant difference between control container and each of the inorganic nutrient pollutant solution containers. Data is presented as means with standard error of means. During this study, no significant difference in egg hatching rate of *Cx. quinquefasciatus* eggs was observed between the control container and any of the treatment containers ($P>0.05$).

There was no significant difference ($P>0.05$) in egg hatching rate between control and treatments

Larval development of Cx. quinquefasciatus

During the present research, the effect of 5 ppm NH_4^+, 45 ppm NO_3^- and 30 ppm PO_4^{-3} on larval development of *Cx. quinquefasciatus* were studied in the laboratory conditions. In addition, each container (including control) was also containing 100 grams leaf litter powder. The larval development study included the effect of above inorganic nutrient pollutants on time to pupation, pupation rate, time to adult emergence, adult emergence rate and female to male ratios. Following are the details:

Time to pupation of Cx. quinquefasciatus

The effect of 5 ppm NH_4^+, 45 ppm NO_3^- and 30 ppm PO_4^{-3} on time to pupation in *Cx. quinquefasciatus* is shown in *Table 3*. During this study, a total of one hundred first instar larvae were exposed to each nutrient pollutant. The value of significance in normality test of Shapiro-Wilk showed that the data is normally distributed, therefore the data was analyzed by Dunnett's Test (significance level=0.05) for determining significant difference between control and each of the inorganic nutrient pollutants. Data is presented as the mean and standard error of mean of four replicates. Each

DOI: http://dx.doi.org/10.15666/aeer/1705_1052510541

pollutant caused a decrease in time to pupation. The minimum number of days to pupation was observed for PO_4^{-3} solution (8.5±0.6 days) followed by NO_3^- (12.5±0.6 days), NH_4^+ (13.5±0.6) and control (14.5±0.6). The difference in time to pupation between the control and PO_4^{-3} solution container was significant ($P<0.05$). However, the difference between the control and the rest of the pollutants i.e., NH_4^+ or NO_3^- was insignificant ($P>0.05$).

Table 3. *Effect of inorganic nutrient pollutants in water on time to pupation in Cx. quinquefasciatus (n=4)*

Treatment	Days (Means ± SE)	95% Confidence Intervals		Minimum	Maximum
		Lower limit	Upper limit		
Control	14.5 ± 0.6	12.4	16.6	13.0	16.0

Pupation rate of Cx. quinquefasciatus

The effect of NH_4^+ (5 ppm), NO_3^- (45 ppm) and PO_4^{-3} (30 ppm) on pupation rate in *Cx. quinquefasciatus* is shown in *Table 4*. The value of significance in normality test of Shapiro-Wilk showed that the data is normally distributed, therefore the data was analyzed by Dunnett's Test (significance level≤0.05) for determining significant difference between control and each of the pollutants. Data is presented as the mean and standard error of mean of four replicates. Pupation rates in NH_4^+ solution container (52.0±9.9%) and PO_4^{-3} solution container (51.8±9.6%) were significantly higher ($P<0.05$) when compared to control containers (27.0±4.9%). Pupation rate in NO_3^- solution container (33.0±3.4%) was insignificantly higher than pupation rate in control container ($P>0.05$).

Table 4. *Effect of inorganic nutrient pollutants in water on pupation rate in Cx. quinquefasciatus (n=4)*

Treatment	Pupation rate (% Means ± SE)	95% Confidence Intervals		Minimum	Maximum

the data was analyzed by Dunnett's Test (significance level=0.05) for determining significant difference between control and each of the inorganic nutrient pollutants. Data is presented as the mean and standard error of mean of four replicates. The minimum number of days to adult emergence was observed for PO_4^{-3} solution (11.5±1.7 days) followed by NO_3^- (15.0±1.4 days), NH_4^+ (17.0±1.4 days) and control (18.5±2.08 days). The difference in time to adult emergence between the control and PO_4^{-3} or NO_3^- solution container was significant ($P<0.05$). However, the difference between the control and NH_4^+ was insignificant ($P>0.05$).

Adult emergence rate of Cx. quinquefasciatus

The effect of NH_4^+ (5 ppm), NO_3^- (45 ppm) and PO_4^{-3} (30 ppm) in water on adult emergence rate in *Cx. quinquefasciatus* is shown in *Table 6*. Data was presented as the mean and standard error of mean of emergence rates (n=4). The value of significance in normality test of Shapiro-Wilk showed that the data is normally distributed, therefore the data was analyzed by Dunnett's Test (significance level≤0.05) for determining significant difference between control and each of the pollutant solution.

Table 6. *Effect of inorganic nutrient pollutants in water on adult emergence rate of Cx. quinquefasciatus (n=4)*

Treatment	Emergence rate (%) (Mean ± SE)	95% Confidence Intervals		Minimum	Maximum
		Lower limit	Upper limit		
Ammonium (NH_4^+)	31.5 ± 4.4	17.5	45.6	22.3	40.01

Female to male ratio of Cx. quinquefasciatus

All the adults were counted and the percentage of female and male mosquitoes to the total number of adults produced were determined for each jar. Female to male ratio was obtained through dividing the number of female adult mosquitoes by the number of male adult mosquitoes. Data was presented as the mean of percentage of female and male *Cx. quinquefasciatus* mosquito and mean female to male ratio (*Table 7*). The value of significance in normality test of Shapiro-Wilk showed that the data is distributed normally, therefore the data was analyzed by Dunnett's Test (significance level≤0.05) for determining significant difference between control and each of the pollutant solutions.

Table 7. *Effect of inorganic nutrient pollutants in water on female to male ratio of Cx. quinquefasciatus (n=4)*

Treatment	% Female (Mean ± SE)	% Male (Mean ± SE)	Female to male ratio (Mean ± SE)
Control	42.9 ± 2.3	57.1 ± 2.3	0.7 ± 0.07
Ammonium (NH_4^+)	52.4 ± 0.9*	47.7 ± 0.9*	1.1. ± 0.94*
Nitrate (NO_3^-)	62.7 ± 2.2*	37.3 ± 2.1*	1.7 ± 0.13*
Phosphate (PO_4^{-3})	60.8 ± 1.2*	39.2 ± 1.2*	1.6 ± 0.08*

*- Significantly different from the control at P<0.05 significance level

The female to male adult ratio for NH_4^+, NO_3^- and or PO_4^{-3} solution container was significantly higher than control container (P<0.05). Maximum female to male ratio was observed for NO_3^- solution container that was 1.7±0.13 (62.7±2.2% females, 37.3±2.1% males). After NO_3^-, maximum female to male ratio was noted for PO_4^{-3} that was 1.6±0.08 (60.8±1.2% females, 39.2±1.2% males). The lowest female to male ratio was observed for control container that was 0.7±0.07 (42.9±2.3% females, 57±2.3% males).

Discussion

During the present study, the effects of NH_4^+, NO_3^- and PO_4^{-3} on oviposition preference, hatching rate and larval development parameters of *Cx. quinquefasciatus* were studied under laboratory conditions. During the study of effect of these pollutants on oviposition preference, the effect of two environmentally realistic concentrations of NH_4^+ (5 ppm and 10 ppm) on oviposition preference of gravid female adult *Cx. quinquefasciatus* was studied. Gravid female *Cx. quinquefasciatus* adults preferred the container containing 5 ppm NH_4^+ solution but did not prefer the container containing 10 ppm NH_4^+ solution or control container (containing only non-chlorinated tap water) (*Table 1*). For example, the number of egg rafts in the container containing 5 ppm NH_4^+ was significantly higher than control container where as the number of egg rafts in the container containing 10 ppm NH_4^+ was insignificantly lower than control container (P>0.05). Nguyen et al. (2012) observed higher number of mosquito egg rafts in water containing NH_4^+ above 2 ppm when temperature was high (> 32°C). They observed lower number of egg rafts at the same concentration of NH_4^+ when temperature was lower. During the present research, minimum temperature was ≥ 20°C and maximum temperature was ≤ 33°C in which NH_4^+ at 5 ppm concentration acted as oviposition attractant for *Cx. quinquefasciatus*. During the study of effect of NO_3^- (at 45 ppm and 90 ppm) on oviposition preference of *Cx. quinquefasciatus,* the results

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1052510541

show that gravid female *Cx. quinquefasciatus* mosquito preferred water bodies with lower NO_3^- concentration (45 ppm) for oviposition. Water without NO_3^- and water with higher NO_3^- concentration (90 ppm) were less preferred for oviposition. These results suggest that NO_3^- in water attract the gravid female *Cx. quinquefasciatus* mosquito for oviposition, however water with higher NO_3^- concentration is not highly preferred for oviposition by *Cx. quinquefasciatus* mosquito (*Table 1*). To the author knowledge, limited studies have been conducted on the effect of NO_3^- on the oviposition preference of mosquitoes. For example, Nguyen et al. (2012) studied seasonal, weather, nutrients, and conspecific presence impacts on *Cx. quinquefasciatus* mosquito in combined sewage overflows. It was observed that high NO_3^- concentration i.e. >1 ppm is associated with decrease in the number of oviposited egg rafts. During the present research, the same trend of association of decreased number of egg rafts with high NO_3^- concentration was observed. During the experiment of Grech and Juliano (2017), the female *Cx. restuans* mosquito laid more eggs in containers having low amount of plant detritus but high concentration of total dissolved nitrogen, however after some days the gravid female *Cx. restuans* preferred those containers for oviposition which were containing high amount of plant detritus but low concentration of total dissolved nitrogen and high phosphate concentration. They concluded that the concentrations of total dissolved nitrogen and phosphorus have differential effect on the oviposition preference of the gravid female *Cx. restuans*, and the mosquitoes favor different nutrients in different circumstances and do not always oviposit preferentially in containers rich in plant detritus. During the study of effect of PO_4^{-3} (at 30 ppm and 60 ppm) on oviposition preference of *Cx. quinquefasciatus*, the gravid female *Cx. quinquefasciatus* preferred the container for oviposition having lower PO_4^{-3} concentration (30 ppm), however they oviposited less number of egg rafts in containers containing no PO_4^{-3} (control) or containing higher concentration of PO_4^{-3} (60 ppm). A breeding site rich in PO_4^{-3} and NH_4^+ is an excellent larval habitat for *Cx. quinquefasciatus* (Nguyen et al., 2012). The NH_4^+ and PO_4^{-3} promote the growth of bacteria in breeding site; the bacteria serve as food source for mosquito larvae (Beehler and Mulla, 1995; Sunish and Reuben, 2001) and attract adult gravid female mosquito for oviposition (Beehler et al., 1994). Nguyen et al. (2012) studied the effect of seasons, weather, nutrients, and conspecific presence impacts on *Cx. quinquefasciatus* mosquito in combined sewage overflows. At lower PO_4^{-3} concentration, *Cx. quinquefasciatus* oviposited more eggs rafts, however at higher PO_4^{-3} concentration (>10 ppm), a decrease in the number of oviposited egg rafts was observed. Similar trend was observed during the present research. Agricultural fertilizers also influence the oviposition preference of adult gravid female mosquitoes. For example, Kibuthu et al. (2016) studied the effect of sub lethal concentrations of cypermethrin, glyphosate, ammonium sulfate and diammonium phosphate on oviposition preference of *Anopheles arabiensis* and *Culex quinquefasciatus* mosquitoes. Highest number of egg rafts were observed in diammonium phosphate and ammonium sulfate treatments.

During the study of effect of inorganic nutrient pollutants on egg hatching rate, no significant difference in egg hatching rate of *Cx. quinquefasciatus* in NH_4^+, NO_3^- or PO_4^{-3} solution container and control container was observed ($P>0.05$) (*Table 2*). To the author knowledge, there is no reported study about the effect of inorganic nutrient pollutants i.e., ammonium, nitrate and phosphate on the egg hatching rate in mosquitoes. The effect of temperature on hatching rate of mosquito eggs has been reported. For example, Oda et al. (1999) studied the effect of temperature on hatching

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1052510541

rate and adult survival of *Cx. pipiens molestus* and *Cx. quinquefasciatus*. The egg hatching rate of *Cx. pipiens molestus* became very low with rise in temperature, however no effect of temperature rises on egg hatching rate of *Cx. quinquefasciatus* was observed. Yang (2008) studied the effect of site deprivation on oviposition performance and egg hatching rate of naturally blood–fed gravid *Culex quinquefasciatus* in the laboratory. Gravid female adults failed to form egg rafts, and egg hatching rate decreased significantly. Vitek and Livdahl (2006) compared the hatching rates of *Ae. Albopictus* eggs in both field and laboratory settings. The hatching rates were compared for mosquitoes exposed to regular, periodic hatch stimulation and random hatch stimulation. The hatching rate in laboratory treatments was not significantly different from the field treatments. Ezeakacha (2015) reported increase in egg hatch rate of *Aedes albopictus*, *Aedes aegypti*, *Aedes triseriatus* and *Culex quinquefasciatus* with increase in relative humidity and egg storage period.

The present study also aimed to investigate the effect of NH_4^+, NO_3^-, and of PO_4^{-3} in water at concentration of 5 ppm, 45 ppm and 30 ppm, respectively, on larval development parameters (such as time to pupation, pupation rate, time to adult emergence, adult emergence rate and female to male ratios) of *Cx. quinquefasciatus*. During this experiment, 100 mg of leaf litter powder was added to each jar including control jar for providing source of carbon (Schletzbaum, 2013; Noori et al., 2015). During the study of the effect of NH_4^+ (5 ppm), NO_3^- (45 ppm) and PO_4^{-3} (30 ppm) on time to pupation, larvae of control container larvae took more days to reach pupation, however the larvae in the containers that were containing NH_4^+, NO_3^- or PO_4^{-3} reached earlier to pupation (*Table 3*). Among the inorganic nutrient pollutants, PO_4^{-3} caused a significant decrease in time to pupation when compared to control ($P<0.05$). To the author knowledge, very limited studies have been conducted on the effect of pollutants on time to pupation in mosquitoes. For example, Noori et al. (2015) studied the effect of NH_4^+, NO_3^- and PO_4^{-3} in water on larval development of *Cx. quinquefasciatus*. During their study, larvae that were exposed to phosphate at concentration range of 1 ppm to 12 ppm without leaf litter, took more time in reaching to pupation. During the present study, the phosphate solution which was also containing 100 gram of leaf litter powder, caused a decrease in time to pupation. This indicated that larvae exposed to higher phosphate concentration (30 ppm) in presence of leaf litter reach early to pupation.

During the study of effect of NH_4^+ (5 ppm), NO_3^- (45 ppm), and PO_4^{-3} (30 ppm) on pupation rate of *Cx. quinquefasciatus*, significantly higher number ($P<0.05$) of larvae reached to pupation in NH_4^+ and PO_4^{-3} solution containers when compared to control container (*Table 4*). These results agree with the findings of Sunish and Reuben (2001) as they reported a positive influence of ammonia nitrogen and PO_4^{-3} on aquatic stages of mosquitoes. Similarly, in another study, increase in the concentration of NH_4^+ or PO_4^{-3} was associated with increase in the number of *Cx. quinquefasciatus* larvae that reached to pupation (Noori et al., 2015). There was observed no significant effect of NO_3^- (at 45 ppm) on pupation rate when compared to control ($P>0.05$). Noori et al. (2015) also found no significant correlation between increase in NO_3^- concentration and pupation rate. The presence of NH_4^+, NO_3^- and PO_4^{-3} accelerate the multiplication of microorganisms (Sunish and Reuben, 2001) that in turn favors the survival of *Culex* larvae. Paul et al. (2006) suggested that higher concentration of phosphorus in agricultural stream is associated with faster breakdown rate of leaf litter. The faster breakdown rate of leaf litter in water bodies results in multiplication of microorganisms.

DOI: http://dx.doi.org/10.15666/aeer/1705_1052510541

Microorganisms in mosquito breeding sites constitute the major food source of mosquito larvae.

During the study of effect of NH_4^+ (5 ppm), NO_3^- (45 ppm) and PO_4^{-3} (30 ppm) in water on time to adult emergence of *Cx. quinquefasciatus*, in each of the NH_4^+, NO_3^- and PO_4^{-3} solution containers, the larvae took less number of days to reach to adulthood than in the control container (*Table 5*). The first instar larvae exposed to 45 ppm NO_3^- or 30 ppm PO_4^{-3} solution took significantly lower ($P<0.05$) number of days in reaching to adulthood when compared to the control. The larvae exposed to PO_4^{-3} took longer in reaching to adulthood. The larvae exposed to 5 ppm NH_4^+ solution took insignificantly higher number of days in reaching to adulthood when compared to control ($P>0.05$). The early emergence of adults in NH_4^+, NO_3^- or PO_4^{-3} solution containers (each containing 100 g leaf litter powder) can be attributed to increasing microbial activities (major food source of *Culex* larvae) (Sunish and Reuben, 2001; Paul et al., 2006).

During the study of effect of NH_4^+ (5 ppm), NO_3^- (45 ppm) and PO_4^{-3} (30 ppm) in water on adult emergence rate of *Cx. quinquefasciatus*, significantly higher number of adults emerged in NH_4^+, NO_3^- and PO_4^{-3} solution containers when compared to control container ($P<0.05$) (*Table 6*). Noori et al. (2015) reported the boosting effect of NH_4^+, NO_3^- and PO_4^{-3}on adult emergence rate of *quinquefasciatus*. Schletzbaum (2013) also reported the positive effect of NO_3^- concentration on adult emergence rate of *Cx. pipiens*. Agricultural fertilizers have also been reported for their effect on adult emergence rate of mosquitoes. For example, Kibuthu et al. (2016) observed significantly higher emergence rate of *Cx. quinquefasciatus* in diammonium phosphate treatment. The high emergence rate in NH_4^+, NO_3^- or PO_4^{-3} solution container can be attributed to increasing microbial activities (Sunish and Reuben, 2001; Paul et al., 2006).

During the study of effect of NH_4^+ (5 ppm), NO_3^- (45 ppm) and PO_4^{-3} (30 ppm) in water on female to male ratio of *Cx. quinquefasciatus*, the female to male adult ratio for each nutrient solution container was significantly higher than control container ($P<0.05$) (*Table 7*). Maximum female to male ratio was observed for NO_3^- and PO_4^{-3} solution container. To the author knowledge, very limited studies have been conducted on the effect of inorganic nutrient pollutants on female to male ratio in mosquitoes. For example, Noori et al. (2015) reported that high NO_3^- levels in water without leaf litter favored the development of male mosquitoes and suppresses the development of female mosquitoes. They suggested that the development of females might need more PO_4^{-3} than male development. But the findings of the present study suggest that high concentration of NH_4^+, NO_3^- or PO_4^{-3} favors the development of females. For the control container (containing only 100 grams leaf litter), the percentage of males was higher than the percentage of females (42.9±2.3% females, 57±2.3% males).

Conclusion

It is concluded that the levels of NH_4^+, NO_3^- and PO_4^{-3} recommended in effluents for wastewater reuse in agricultural irrigation by WHO (2006) are favorable for the survival and development of *Cx. quinquefasciatus* mosquito, however higher levels of NH_4^+, NO_3^- and PO_4^{-3} are not favorable for the survival and development of this mosquito. These results help in identification of concentration ranges of the NH_4^+, NO_3^- and PO_4^{-3} that make the larval habitat favorable for survival and reproduction of *Culex* mosquitoes. This could be helpful in effective control of mosquito borne diseases.

(Received 30th Jan 2019; accepted 22nd May 2019)

Abstract. A total of 10 sub-regions were identified and tree total volume equations were developed for economically important Dahurian larch species in northeast China (Daxing'an Mountain region/Heilongjiang province). These equations were based on a simple power function and adjusted to the forest inventory data volumes of three mountainous regions, including the northwest of northern slope of Yilehuli Mountains (NWYLHLM), the southeast of northern slope of Yilehuli Mountains (SAYLHLM) and the eastern slope of northern part of Daxin'an Mountains (NDXAM). The volume equations were tested to determine if differences by ecoregion were statistically significant. Results varied by species, volume and ecoregion suggesting that the relationship between tree volume and tree diameter of Dahurian larch (*Larix gmelinii* Rupr) tree species is significantly different between the three geographic regions, depending on local climatic, soil and ecological conditions. This implies that the provincial and regional models of volume-diameter relationships are not appropriate for predicting tree volume at ecoregional level. In addition, the use of an ecoregional specific model will lead to significant bias in predicting the total volume of trees. The ecoregion-based volume models developed in this study could provide more accurate information on tree growth and development to forest resource managers and planners.
Keywords: *Larix gmelinii, Heilongjiang, forest inventory, mountainous regions, ecoregions*

Introduction

Boreal forests, the second largest biome in the world, cover about one-third of the Earth's forest area (Jia and Zhou, 2018). Dahurian larch (*Larix gmelinii* Rupr) is a dominant tree species in Chinese boreal forest. It's one of the main timber species in China and forms large forests in northeast China, including the northeastern part of the Inner Mongolia autonomous region and the Daxing'an Mountain range (Jin et al., 2015). It's the most commercially cultivated timber species in northeastern China due to its ecological prevalence and its superior wood attribute. However, its timber quality is largely driven by the crown architecture, i.e., the number, size and distribution of branches. The majority of branch-level models in the literature are focused on planted forests, which have substantially different crown architecture than that grown in natural mixed forests (Dong et al., 2016). Therefore, the purpose of this study is to develop the total volume model for Dahurian larch in three forest regions of northeastern China.

Accurate estimation and determination of stem standing volume is very useful for both research and practical purposes in forestry and contributes to the efficient and sustainable management of timber resources (Barrio et al., 2007). When preparing a cut for sale, the estimate of the volume of trees to be felled is necessary. The cubage can be done on a tree, as in the case of the volume of large trees and can also be done on a stand with an estimate of the overall volume of wood made by type of wood. The cubing of standing timber is governed by the standard Afnor NF B 53-017 "Estimated

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1054310564

volume of standing timber" for estimating the "solid volume" of a standing tree (Limousin, 2011). Previous studies have shown that, total volume equation has been widely used throughout eastern North America (Honer, 1967). In a study conducted in 1998 (Shailer et al., 1998) in New Brunswick, Honer's volume equations were shown to best predict total volume from a set of almost 20 different published volume equations for nine important commercial species.

Recently Lee et al. (2017) reported that, Stem volume models using diameter at breast height (DBH) and height were developed for *Pinus densiflora*, *Pinus koraiensis*, and *Larix kaempferi*. The data were obtained from Gangwon, Gyeonggi, and North Gyeongsang provinces in South Korea, and the sample trees felled were used to provide the parameter estimates of volume equations. The combined-variable function, $V = a + bD^2H$, was shown to be the best model through the validation of the equation. Also, the model using only DBH, $V = aD + bD^2$ was also evaluated to be applicable in the field. Similarly, Tsega et al. (2018) reported as well that, Stem volume equations were fitted for *Cupressus lusitanica* in Gergeda Forest, Ethiopia using six different established equation forms. A total of 260 trees were measured for their diameter at breast height (*D*), total height (*H*) and stem volume using destructive sampling methods. The data set was randomly divided into equal size for equation development and equation validation. Five fit statistics comprising of the fit index, root mean square error, bias (%), absolute mean deviation and coefficient of variation were used to evaluate the performance of each equation. Among the different equations, the Schumacher and Hall function of the form $V = b_1 D^{b_2} H^{b_3}$, which estimates volume (*V*) using diameter at breast height and total height as predicting variables, performed best and was then fitted to the combined data set for prediction of volume over-bark of *C. lusitanica* in Gergeda Forest.

These models revealed higher accuracy when compared with previous studies. Both equations are considered to be easily used in the field. In the recent past, the principles of multifunction, multipurpose and ecologically based forest management were approved in China. Therefore, in order to help forest managers and practitioners realize the differences in these relationships among different sub-regions then subregion-based height-diameter models are very important.

Previous studies have also revealed that, there is ecoregion differences exist in the height-diameter relationships in Ontario (Zhang et al., 2002; Peng et al., 2004) and in West Virginia (Brooks and Wiant, 2008; Jiang et al., 2005) and local merchantable board foot, cubic foot and weight equations have been developed for six economically important hardwood species in central Appalachia. Equations were based on a simple power function and fit to volumes from the USDA Forest Service Forest Inventory Analysis data for West Virginia and parts of Ohio, Pennsylvania, Maryland, Virginia, and Kentucky. Five ecoregions were identified and the volume equations were tested to determine if differences by ecoregion were statistically significant with results varying by species, volume type and ecoregion (Brooks and Wiant, Jr., 2004). Akinsanmi and Akindélé (1995) noted that, sustainable management of forest resources requires adequate data collection. These actions make it possible for the manager to have indicators on wood potential in order to develop a consequent management plan. Palm (1982), Pauwels and Rondeux (1999) and Thibaut et al. (1998), revealed that the low values of the statistical parameters of validation are obtained with the formula of the truncated cone. The graphical analysis of the residues of the truncated cone model shows a good distribution of the residues. Consequently, Fonton et al. (2009) confirmed

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1054310564

the hypothesis of the succession of cone trunks along the stem of *Isoberlinia spp, Anogeissus leiocarpa* and *Danielli aoliveri* stems from the study by on the modeling of drum volume tree for sustainable management of forest ecosystems. Rondeux (1999), Laumans (1991), Thibaut et al. (1998) and Fonton et al. (2002) agreed with the findings of the models obtained in the Fonton study, expressing the volume as a function of diameter squared (D^2), are the most relevant for estimating individual tree volume. Finally, Bontemps et al. (2012) found that the estimation of forest-impaired biomass and forest productivity explained that environmental changes involve redefining and expanding the ecosystem services provided by forests, while aiming for the sustainability of their management. The quantification of timber and wood energy resources and the carbon storage function requires new methods of assessing forest volume and biomass.

In this current study, the test is based on the ecoregional statistical analysis from forest management data in Dahurian larch region, in the Daxing'an mountainous region located in northeastern China (Heilongjiang Province). For the purpose of this study again, there are many situations in forest mensuration when the use of local volume tables is useful (Brooks and Wiant, 2008). These may include but are not limited to cursory forest inventory applications as well as timber trespass evaluations when stem diameter is estimated from an existing stump diameter. This study uses forest inventory data from the Daxing'an Mountains region in Heilongjiang Province in northeastern China.

The objectives of this study are to evaluate whether ecoregion based volume cubic meter, total volume equations are statistically justified to test for differences between ecoregions for the one species selected and to evaluate the bias associated when a region wide model is compared to individual ecoregion models. Consequences of inappropriately applying provincial, regional or other regulations were also evaluated among the ten subregions.

Materials and Methods

Study area and data

The study was conducted in the cold temperate forest regions in Heilongjiang Province (Daxing'an Mountains; from 121° 12′E to 127° 00′E and from 50° 10′N to 53° 33′N) and eastern part of Inner Mongolia, in Northeastern China) (*Figure 1*). The elevation of the area ranges from 300 to 700 m above the sea level. The soil in this region is mostly Haplum-brepts or Eutroboralfs (or dark brown forest soil in Chinese Taxonomic System). The area experinces continental monsoon climate with mean annual rainfall ranges from 500 to 750 mm and mean annual temperature is from -1 to -2.8°C.

These temperate forests are dominated by White birch (*Betula platyphylla*), Amur linden (*Tilia amurensis*), Maple (*Acer mono*), Dahurian birch (*Betula davuria*), Mongolianoak (*Quercus mongolica*), Dahurian poplar (*Populus davidiana*), and mixed hardwood forest dominated by Amurlinden (*Tilia amurensis*), Maple (*Acer mono*), Manchurian ash (*Fraxinus manshurica*), Manchurian walnut (*Juglans mandshurica*), Mongolian oak (*Quercus mongolica*) and Manchurian elm (*Ulmus laciniata*) (Dong et al., 2014).

Data and methods

Ten subregions for conifer trees were identify for this study based on the work conducted by Brooks and Wiant (2008) in USA (*Table 1*).

A total of 5474 individual height-diameter measurements for four Conifer Forest tree species were collected in systematically/randomly selected square/circular (25.8 m x 25.8 m plots) using field Inventory from Daxing'an Mountains in the northeast of China (*Figure 1*). A county was assigned as part of a specific ecoregion if a majority of the land base fell within ecoregion boundaries. The selected ecoregions are a combination of the different subregions between them and the land base regions identified by the China Soil Conservation Service. In this study, only one species of tree, the Dahurian larch (*Larix gmelinii* Rupr*)* was selected, given the absence of some data for other tree species.

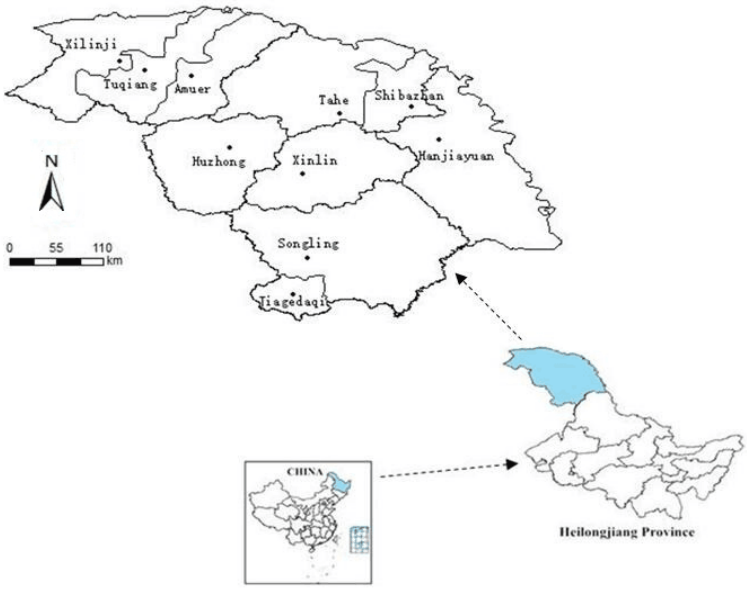

Figure 1. *The geographical location of study area and plot distribution in the Northeast China*

A total of 2411 destructively sampled Dahurian larch trees were used in this investigation. These trees were felled throughout the forest inventory areas of northeast China and all sampled trees were selected to ensure a representative distribution across a range of height and diameter classes within stands varying in density, height, site condition, age and stand structure. The data was then randomly divided into an adaptation dataset and a validation dataset (*Table 2*). For developing taper and individual tree volume equations the data set was initially used. Diameters at breast height were measured for all sampled trees (D, defined as 1.3 m above the ground) outside bark and total volume (V). Trees possessing broken tops, obvious cankers or crooked boles were excluded from the analysis. Summary statistics for tree diameter and total volume are provided for each subregion, the NDXAM, YLHLM-NW, and YLHLM-SA regions, and all data combined (Overall) in *Table 3*.

The three major regions employed are depicted in *Figure 1* above and include:

- Region1: The northwest of the northern slope of Yilehuli Mountains (NWYLHLM) which includes four subregions: Xilinji (XLJ), Tuqiang (TQ), Amuer (AME), Huzhong (HZ).
- Region2: The southeast of the northern slope of Yilehuli Mountains (SAYLHLM) which includes four subregions: Xinlin (XL), Tahe (TH), Shibazhan (SBZ), Hanjiayuan (HJY).

DOI: http://dx.doi.org/10.15666/aeer/1705_1054310564

- Region3: The eastern slope of northern part of Daxing'an Mountains (NDXAM), which includes two subregions: Songling (SL), Jiagedaqi (JGDQ).

D = diameter at breast height, SD=Standard of deviation

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1054310564

The individual tree database for each region was queried to select only those trees from the appropriate counties as well as selecting only those merchantable tree records having measured diameters and heights and non-zero volumes. The tree data selected was from the northwest of the northern slope of Yilehuli Mountains, the southeast of the northen slope of Yilehuli Mountains, the eastern slope of northern part of Daxin'an Mountains, located in Heilongjiang Province. The volume parameters examined included only total volume in cubic meter, as reported in the tree database. The number of trees species and ecoregions sampled after the combination of different ecoregions is shown in *Table 1*, and the state distribution parameter and the summary Tree diameter (DBH) statistics within volume (V) for regional and ecoregional datasets for Dahurian larch species are presented in *Table 3*. An initial evaluation was conducted using several families of nonlinear models to establish an appropriate volume model form (*Table 4*).

Table 3. *Summary statistics of tree diameter at breast (DBH), total height (H) and total volume (V) for regional and subregional data sets*

Table 4. *Volume equations used for model fitting and model validation*

Model code	Model of Volume Equations	Number of parameters
1	$V = aD^b$	2
2	$V = aD^bH^c$	3
3	$V = a(D^2H)^b$	2
4	$V = a+bD^2H$	2
5	$V = aD^2H$	1
6	$V = a1+aD^bH^c$	3

V = over-bark stem volume (in m^3), D = diameter at breast height (in cm), H = total tree height (in m), and a, b, c, and are parameters to be estimated from the data

Across all species and volume parameters, a simple power function proved to provide both consistent and accurate results (model code 2) and was thus selected as the basic model form for development (*Equation 1*):

$$V = aD^b H^c \quad \text{(Eq.1)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1054310564

Where V is volume in cubic meter (m^3), D is the tree diameter at breast height (DBH) (cm), H is the total height, a is the asymptotic parameter, b is the rate parameter, and c is the shape parameter. *Equation 1* was fit to (1) the Overall data (2411 Dahurian larch (*Larix gmelinii* Rupr) species of tree), (2) the region 1: The northwest of the northern slope of Yilehuli Mountains (NWYLHLM), (3) the region 2: The southeast of the northern slope of Yilehuli Mountains (SAYLHLM), (4) the region 3: The eastern slope of northern part of Daxing'an Mountains (NDXAM) and (5) each of the ten subregion separately. The PROC NLIN procedure in the Statistical Analysis System (SAS Institute, Inc. 1999) was utilized to estimate the model parameters and model statistics.

To test for differences between the overall model (region wide) and each ecoregion, a nonlinear extra sum of squares procedure was employed (Neter et al., 1996). This procedure involves the use of two indicator variables (k=2) who are needed in *Equation 2* for three regions in the full model form, while the reduced model form is represented by a three parameters model representing the volume relationship across all ecoregions (region wide). The full model form uses an indicator variable (k=2) approach to represent the tree regions.

- If region = NWYLHLM, $z_1 = 1$, $z_2 = 0$.
- If region = SAYLHLM, $z_1 = 0$, $z_2 = 1$.
- If region = NDXAM, $z_1 = 0$, $z_2 = 0$.

And to compare the difference of the volume relationships among different ecoregions, the non-linear extra sum of squares method was used (Bates and Watts, 1988; Huang et al., 2000). The method requires the fitting of full and reduced models.

The full model corresponds to different sets of parameters for each of the ecoregions involved, while the reduced model corresponds to the same set of parameters for all ecoregions.

Indicator (dummy) variables were used to facilitate the hypothesis tests as follows:

Test on the Overall model

In order to examine the sufficiency of the Overall model for the ten subregions, the full model for Darurian larch species and volume parameter was tested independently and is of the form:

$$V = \left(\alpha + \sum_{i=1}^{k} \alpha_i r_i\right) D^{\left(\beta + \sum_{i=1}^{k} \beta_i r_i\right)} H^{\left(\sigma + \sum_{i=1}^{k} \sigma_i r_i\right)} \quad \text{(Eq.2)}$$

Where:
V = volume parameter tested,
ri = indicator variable for ecoregion ri, i = 1,...,4,
D = tree dbh (in),
α,β, σ = parameters to be estimated from the data.
k= the number of indicator variables
The full model form has 10 parameters and an error sum of squares (SSEF) with N-10 degrees of freedom (dfF) where N is the total number of sample trees for each volume parameter and species tested. The form of the reduced model is that of *Equation 1* having three parameters and an error sum of squares (SSER) with N-3 degrees of freedom (dfR). The full model test has the following null and alternative hypotheses for each of the one species tests:
H_0: $\alpha_1=\alpha_2=\alpha_3=\alpha_4=\beta_1=\beta_2=\beta_3=\beta_4=\sigma_1=\sigma_2=\sigma_3=\sigma_4=0$ and
Ha: at least one parameter is not equal to 0.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1054310564

Rejecting the null hypothesis would indicate that the volume-diameter relationship is not the same for all ecoregions. Failure to reject the null hypothesis would indicate that the reduced model form *Equation 2* would be adequate for all ecoregions. These tests were conducted independently for each of the major species investigated.

In addition to the overall ecoregion tests, similar tests were conducted for each of the ten pairwise ecoregions comparisons for each of one species and three volume units examined. The same indicator variable approach was applied to the specific ecoregion comparison tests having a full model.

Test on the region against regions

To compare the volume relationship between the region and regions, the following full model was used

$$V = (\alpha + \alpha_1 r_1) D^{(\beta+\beta_1 r_1)} H^{(\sigma+\sigma_1 r_1)} \quad \text{(Eq.3)}$$

Where all variables and parameters were as previously defined. The full model form has three parameters and an error sum of squares (SSE_F) with N-4 degrees of freedom (df_F). The reduced model form is that of *Equation 1*. For each species and volume type tested, the full model test has the following null and alternative hypotheses:

H_0: $\alpha_1=\beta_1=\sigma_1=0$

and

Ha: at least one parameter is not equal to 0.

Rejection of the null hypothesis would indicate that the volume-diameter relationship is not the same between the three ecoregions being tested. Failure to reject the null hypothesis would indicate that a single model (*Equation 1*) could be used for both ecoregions for that species and volume type. These tests were conducted independently for each species and volume type combination.

To evaluate the differences between the three regions

A total of three regions pairs were formulated to test the pairwise differences between the three regions. The three testing pairs require three full models that take the form of *Equation 2*, and three reduced models that take the form of *Equation 1*. For example, to test the difference between region NWYLHLM vs SAYLHLM, one indicator variable (k=1) can be defined: if subregion = NWYLHLM, Z1 =1; and if subregion = SAYLHLM, Z1 = 0. Similarly, the full model (*Equation 2*) has 6 estimable parameters. To evaluate the overall differences among subregions nine indicator variables (k=9) are needed in *Equation 3* for ten subregions. They are defined as follows:

- If subregion = SL, z1 = 1, all other zi = 0.
- If subregion = JGDQ, z2 = 1, all other zi = 0.
- If subregion = XL, z3 = 1, all other zi = 0.
- If subregion = TH, z4 = 1, all other zi = 0.
- If subregion = HZ, z5 = 1, all other zi = 0.
- If subregion = SBZ, z6 = 1, all other zi = 0.
- If subregion = HJY, z7 = 1, all other zi = 0.
- If subregion = XLJ, z8 = 1, all other zi = 0.
- If subregion = TQ, z9 = 1, all other zi = 0.
- If subregion = AME, all other zi = 0.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1054310564

Test on the differences between the ten subregions

To test the pairwise differences between the ten subregions, a total of 45 subregions pairs for Dahurian larch species were formulated. The 45 testing pairs require 45 full models that take the form of *Equation 3*, and 45 reduced models that take the form of *Equation 1*. For example, to test the difference between subregions SL vs. XL, one indicator variable (k=1) can be defined: if subregions = SL, Z1 =1; and if subregion = XL, Z1 = 0. Similarly, the full model (*Equation 3*) has 6 estimable parameters. The reduced model takes the form of *Equation 1* with 3 parameters. The null and alternative hypotheses are:

H_0 (1): $a_1=b_1=C_1=0$

H_a (2): at the least one parameter is not equal to 0.

Rejecting the null hypothesis H_a (2) would indicate that there is a difference between the two subregions tested (subregion 1 (SL) and 2 (JGDQ) in this example).

Test statistic

The significance of the full and reduced model comparisons were based on an F-test of the form:

$$F = \frac{\frac{SSE_R - SSE_F}{df_R - df_F}}{\frac{SSE_F}{df_F}} \quad \text{(Eq.4)}$$

Where SSE_F is the error sum of squares of a full model with the degrees of freedom df_F, and SSE_R is the error sum of squares of a reduced model with the degrees of freedom df_R.

This test statistic is F-distributed for a non-linear model if the data used represent a large sample generally, the F-test is significant if the p-value for the test is less than 0.05.

In order to understand the consequences of inappropriate application of a volume model in different ecoregions, each of the ten models (global model, regional model 1 (NWYLHLM 1), regional model 2 (SAYLHLM 2), regional model 3 (NDXAM 3) (and 10 suregions models) was used to predict total volume of trees for each ecoregion.

And to quantify the magnitude of the prediction error when a specific region model is used, the average volume prediction error $(\bar{\varepsilon})$, the standard error of the prediction error (S_e), and the prediction bias as a percentage of average "real" volume (% bias) were calculated and defined as:

$$\bar{\varepsilon} = \frac{\sum_{i=1}^{m}(\hat{V}_i - V_i)}{m} \quad \text{(Eq.5)}$$

$$S_e = \sqrt{\frac{\sum_{i=1}^{m}(\epsilon - \bar{\varepsilon})^2}{m-1}} \quad \text{(Eq.6)}$$

$$Bias(\%) = {}^{\bar{\varepsilon}}/_{\bar{V}} \times 100 \quad \text{(Eq.7)}$$

Where:

m= number of tree volumes for each species and volume type,

V_i= data reported volume for tree i,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1054310564

$\hat{V}_i$= predicted volume for tree i,

$\bar{V}$= mean data reported volume for each species and volume type. In this case $\bar{V}$ is the mean of observed tree volume. The t-test is used to test the null hypothesis and demonstrate that the mean prediction error is zero by

$$t = \frac{\bar{e}}{S_e/\sqrt{m}} \quad \text{(Eq.8)}$$

Large values for these measures of prediction error would indicate situations where selection of an ecoregion specific model may be justified. Parameter estimates for *Equation 1* were obtained using SAS Proc NLIN (SAS 2002) for each species, ecoregion and volume type combination.

Results and Discussion

Estimation and validation of volume equations

The initial volume model development was completed with six candidate model forms. For all of the models, the significance of each parameter was tested and proved before and after weighting. The estimated parameters and their MSE-model mean squared error of the weighted models are presented in *Table 5* who is the parth of the data who help us to form the model.

Table 5. *Parameter estimations and model MSE of volume function for the regional and ecoregional models*

Note: N-sample size (number of tree), a, b, c-three parameters of volume model, MSE-model mean squared error

The volume equations were classified as two types of functions: volume = f(DBH) with an independent variable and volume = f(DBH, height) with two independent variables (*Table 4*) and the parameter estimates and fit statistics were computed by species and all equations (*Table 5*). For the volume equations with DBH, the parameter estimates were valid ($P < 0.05$), but the P-value of parameter b was not valid in Equation (model 1) for Dahurian larch. For this reason, Equation (model 1) failed to fit the model. Equation (model 3) had lower MSE than Equation (model 1).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1054310564

For the volume equations with DBH and height, parameter estimates of Equations (model 4) to (model 6) were firstly evaluated, and all parameters were valid ($P < 0.05$). Compared to other equations, however, Equations (model 3) and (model 5), especially for Dahurian larch, had fit statistics with high MSE. Meanwhile, Equation (model 6) estimated using nonlinear regression analysis predicted the volume with negative number when DBH was smaller than 10 cm, which indicated the instability of parameter estimates. For these reasons, Equations (model 5) and (model 6) failed to be the best fit equations in this study.

Equation (model 2) has valid coefficients and good fit statistics for Dahurian larch species and is considered as the best model to predict the total volume. This result corresponded to previous studies, which concluded that Equation (model 2), the so-called combined-variable function, is the best fit model (Burkhart, 1977; Amateis and Burkhart, 1987; Sherrill et al., 2011; Lee et al., 2017).

Fitting the total volume equations to regional and subregional data

The sample sizes, parameter estimates and mean square errors (MSE) for all models are provided in *Table 5*.

The four regional models (Overall, Region 1: NWYLHLM, Region 2: SAYLHLM and Region 3: NDXAM) have similar model MSEs. The parameters of the Overall model were similar to those of the regional model 1, due to the fact that regional1 data were 37.9% of the Overall data set with similar DBH and volume ranges for Dahurian larch species (*Table 3*). Among the ten ecoregional models, the lowest MSE value was found in the subregion 8 (XLJ) with a value of 0.00135. The parameter estimates also varied among the ten subregions, indicating that each ecoregion may have a different volume relationship from others.

Comparison of the total volume equations among subregions and between regions

Tables 1 and 6 show the testing results for the differences in Volume relationships between the Overall regions and among the ten subregions. *Equation 2* was used to test if the Overall model using all data combined was sufficient for the ten subregions.

Table 6. *F-test for testing difference between regions*

Regions	n	Full Model			Reduced Model			Extra sum of squares		
		SSE_F	PF	df_F	SSE_R	PR	df_R	$df_R - df_F$	PF	P_VALUE
Overal	**2411**	**30.9453**	**9**	**2402**	**32.3012**	**3**	**2408**	**6**	**17.5411**	**0.0000**
NWYLHLM - SAYLHLM	1673	22.7335	6	1667	23.3796	3	1670	3	15.7934	<. 0.0001
NWYLHLM - NDXAM	1653	22.4578	6	1647	23.1683	3	1650	3	17.3701	<. 0.0001
SAYLHLM - NDXAM	1496	16.6992	6	1490	17.4872	3	1493	3	23.4346	<. 0.0001

Note: N – sample size, SSE_F – error sum of squares of the full model, df_F – degrees of freedom of SSE_F, SSE_R – error sum of squares of reduced model, df_R – degrees of freedom of SSE_R, P is the number of parameters

The null hypothesis H_0 (1) was rejected (p-value < 0.0001), indicating that the Overall model was not sufficient to describe the volume-diameter relationships for the ten suregions. The difference between the different regions was also tested using *Equation 3* and the null hypothesis H_0 (2) was rejected (p-value < 0.0001). This means

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1054310564

that the difference in Volume relationships between the three geographic regions was statistically significant. A pairwise test revealed that there were differences in Volume relationships among ten subregions, i.e., the F-values ranged from 0.81 to 94.63 and all p-values were not less than 0.0001 (*Table 1*). Each ecoregion appeared to have a unique tree Volume relationship.

Prediction errors of applying subregional equation to each subregion

According to the tests above, there were significant differences among the ten subregions in the volume relationships. Inappropriately "applying" a volume model in these ecoregions may result in prediction biases. To understand the consequences, all fourteen models (Overall model, regional 1 model, regional 2 model, regional 3 model and ten subregional models) were used to predict total tree volume for each given ecoregion individually. The mean prediction error ($\bar{\varepsilon}$), the prediction bias (%), and the t-test for testing the null hypothesis that the mean prediction error equals zero are shown in *Tables 7 to 8*.

Table 7. *Prediction error of applying the overall model for each subregions*

Note: N – sample size, $\bar{V}$ – average of observed tree volume, $\hat{\bar{V}}$ – average of predicted tree volume from the model, S_e – standard deviation of prediction error

If the overall model was used to predict the volume of trees in each region, excessive or underestimated predictions were made for different ecoregions (The p values of the t tests would be less than 0.05 for each of the ten subregions). On average, the overall model under-estimated (i.e., positive Bias %) tree volume from 0.6% to 5.6% for subregions XL, TH and HZ, and over-estimated (i.e., negative Bias %) tree volume about -2% to -5.2% in subregions HJY and SBZ. In the three forest regions, the Overall model under-estimated tree volume in both subregion TQ (4,2%) to subregion XL (5,6%) (*Table 7*).

Prediction errors of applying regional and overall volume equations to each subregion

Applying the regional model to each subregion would result in similar patterns and magnitudes of the prediction errors as the Overall model. This model under-estimated tree volume in the NWYLHLM - TQ (1.6%). And over-estimated tree volumes in the NWYLHLM - XLJ (-9.8%), NWYLHLM - SBZ (-8.5%), NWYLHLM - JGDQ (-7.1%), NWYLHLM - HJY (-5.5%), NWYLHLM - SL (-4.2%), NWYLHLM - TH (-3.4%) and NWYLHLM - NWYLHLM (-1.8%).

Note: N – sample size, $\bar{V}$ – average of observed tree volume, $\hat{\bar{V}}$ – average of predicted tree volume from the model, S_e – standard deviation of prediction error

Again, larger under-estimations occurred in the NWYLHLM - XL (2.9%) (*Table 9*). This was expected because the estimated parameters of the Overall model were close to those of the three regional models (*Table 5*).

On the other hand, the regional model has not been able to overestimate the volume of trees in the ten ecoregions of the different regions (*Table 9*).

When the ten ecoregional models were applied to each ecoregion, they generally performed well in the ecoregions in which the models were developed (p-values for the t-

Note: N – sample size, $\bar{V}$ – average of observed tree volume, $\hat{\bar{V}}$ – average of predicted tree volume from the model, S_e – standard deviation of prediction error

These results are expected because different ecoregions have large differences in climatic, soil and ecological conditions. As Peng et al. (2004) and Rivas et al. (2007) indicated, part of the differences in dbh and volume models among tree species may be caused by differences in genetics, growth conditions and site quality. Recent studies with different species also indicated differences in ecoregion-based height diameter models (Huang et al., 1999; Peng et al., 2004; Brooks and Wiant, 2005). For our case, the updated Ecoregion classification of Dahurian larch region (*Figure 1*) provides comprehensive information on changes in ecoregion-species relationships along the ecological and macroclimatic gradients of different regions. These ecoregions are characterized by large climatic patterns (temperature and precipitation, for example), soil moisture and nutrient

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1054310564

regimes, and succession and vegetation types (Hills, 1959, 1960; CEC, 1997; ELC Working Group, 2000).

In general, Dahurian larch species are larger in forest subregions (JGDQ and AME), mainly due to climate, abundant rainfall and the longer growing season. For example, the average annual temperatures of the different ecoregions are between -1°C to -2.8°C and -28°C to 20°C, respectively in Daxing'an Mountains region. Moreover the average air temperatures in January and July are about -28°C and 20°C, respectively while the mean annual precipitation is relatively higher in Daxing'an Mountains region (500 to 750 mm). More detailed analysis of climatic characteristics for each ecoregion can be found in Dong et al. (2014). In addition, local ecological conditions (vegetation type) also affect species growth and productivity in these ecoregions. For example, in the ten subregions studied, it has been shown that the stand of the Dahurian larch species is the most dominant in relation to others species. The latter which is our study species comprises a total of 2411 individuals for all ten subregions compared to a total of 1324 trees in all ten subregions for *Betula platyphylla* species (BH), 445 trees for Siberian larch (SY) species, 1294 trees for Korean pine (ZZS). Subregion 2 (JGDQ) has the largest number of trees (524 trees for Dahurian larch species only).

Therefore, the combination of all climatic, environmental and vegetation factors plays an important role in determining the different volume relationships among ten subregions.

These results are consistent with the recent findings reported by Huang (1999) quoted by Liunjun et al. (2002) and Huang et al. (2000) for Lodgepole pine and white spruce in the boreal forests of Alberta.

Illustration of different graphics in Figure 2

The different figures below illustrate average prediction errors on diameter classes of 5 cm for the ten subregions. Clearly, the overall model's negative biases in some subregions were due to overestimation for large trees. The larger positive model biases in the two subregions (XL (second line on the left) and TQ (fifth line on the left)) are due to the underestimation of all trees by the global model.

This limitation was initial pointed by Thalmann (1965), where advanced evaluation methods based on confirmed technical bases are necessary. These graphs show the mean prediction errors (m^3) in diameter classes of 5 cm when the global model is applied to predict the volume of trees in each of the ten subregions.

Solid lines with solid symbols: diamond, square, triangle, asterisk and circle are used to represent subregions:

- First line (SL and JGDQ: 3E (circles), 3W (squares), 2S (triangles), 3S (asterisks) and 3W (circles)).
- Second line (XL and TH: 3E (circles), 3W (asterisk), 3W (squares), 3S (triangles).
- Third line (HZ and SBZ: 3E (triangles), 3W (triangles), 3W (circles), 3W (squares), 4W (asterisks), 2W (circles).
- Fourth line (HJY and XLJ: 3E (circles), 2W (circles), 4W (asterisks), 1W (squares), 1S (rod).
- Fifth line (TQ and AME: 2E (rods), 2E (circles), 2W (diamond), 5w (asterisks), 3W (squares).

Therefore, trends in prediction errors in the 5 cm of diameter classes were very similar for some regional model and the overall model.

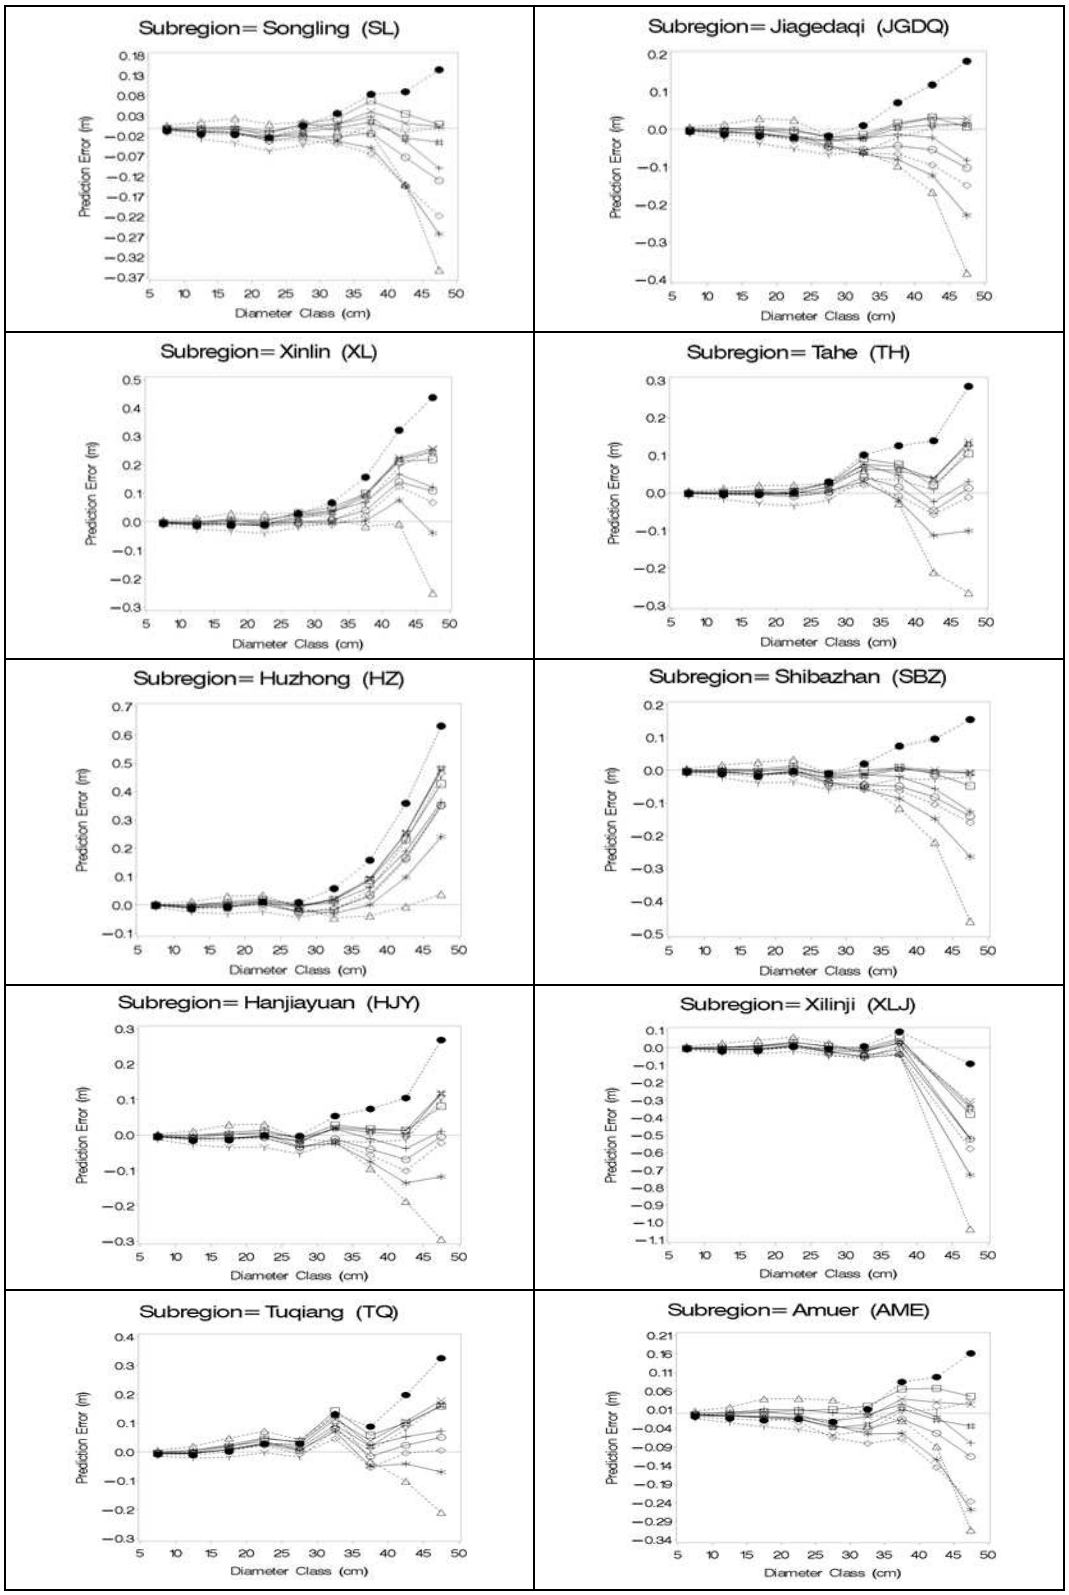

Figure 2. *Average prediction errors (m) across 5-cm diameter classes when each subregional model is applied to predict total volume in each of the ten subregions with symbols: SL (hash), JGDQ (square), XL (star),TH (circle), SBZ (X), HJY (plus), HZ (triangle), XLJ (dot), TQ (diamond) and AME (Y)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1054310564

On the other hand, other regional models overestimated tree volume (e.g. % bias) in some subregions of different regions including: HJY and SBZ and in others, underestimated, for example: XL, TH, HZ and finally TQ and XL. Some figures indicate that negative model biases result from overestimation of all trees in diameter classes of different subregions. The relatively high value for some subregions can be explained by the morphology of the Dahurian larch stem in the temperate mixed forests of the study regions.

Conclusion

With total tree volume equations being developed in the study for economically important hardwood species from northeastern China (Daxing'an Mountain region /Heilongjiang province), these equations were based on a simple function and adjusted to the forest inventory data volumes of three mountainous regions, including the north-west of the North Slope of the Yilehuli Mountains, the southeast of the North Slope of the Yilehuli Mountains, and the northeastern slope of the Daxin'an Mountains. Using dummy variables and an additional sum of squares procedure, the volume - diameter relationship was not the same for all ecoregions when tested by species and volume type. For ecoregion-specific comparisons, statistical differences in total volume were found across many ecoregions, which can be explained in part by the longitudinal, latitudinal, and elevation properties of differences between soils, the length of the season of growth and annual rainfall rate in the regions, which leads us to prove the significance of the relationship between the volume and diameter of the trees of the Dahurian larch tree species studied.

The main underlying factor is probably the differences in height-diameter relationships reported for the same ecoregions in northeastern China. Mean bias varied from -3.3% to 9.5% for (SL1), -0.9% to 9.2% for (JGDQ2), -9.9% to 2.1% for (XL3), -6.5% to 4% for (TH4), -12.9% to 5.1% for (HZ5), -2.8% to 9.3% for (SBZ6), -3.5% to 7.2% for (HJY7), -3.3% to 14.9% for (XLJ8), -9.8% to 3.9% for (TQ9) and -11.6% to 6.2% for (AME10) for the marketable value of timber in the three regions. Local tree volume equations specific to species and ecoregions are presented and can be easily used in wood intrusion situations. However, there are clear variations in volume relationships for Dahurian larch species in the ten subregions of the three regions studied in northeastern China (Heilongjiang Province). Inappropriate application of provincial or regional volume models to these different subregions can lead to significant errors in estimating tree height and total volumes. Ecoregion-based volume models can actually provide more accurate predictions of tree volume and height than models developed at the provincial or regional level.

Abstract. Homoarginine is a non-protein amino acid which is structurally similar to arginine. Research shows that homoarginine is produced in a small quantity in the body of humans and animals and it is suggested to be found in some organs such as the kidney, liver, brain and body fluids; blood and urine. Homoarginine is synthesized from arginine and lysine by the catalytic action of arginine: glycine amidinotransferase (AGAT) which is also responsible for the synthesis of guanidinoacetate, the precursor of creatine. High concentration of homoarginine has been reported to inhibit arginase which is a substrate in the synthesis of nitric oxide. Recent reports have also indicated that low homoarginine concentrations are a risk marker for cardiovascular diseases and death. More research needs to be done to improve knowledge on the physiological role of homoarginine and its application in clinical studies and pharmacy with the aim of coming up with possible medication and ways to combat cardiovascular diseases. This review seeks to summarize the role of homoarginine in the cardiovascular system.
Keywords: *arginine: glycine amidinotransferase, disease, nitric oxide, smooth muscle cells, synthesis*

Introduction

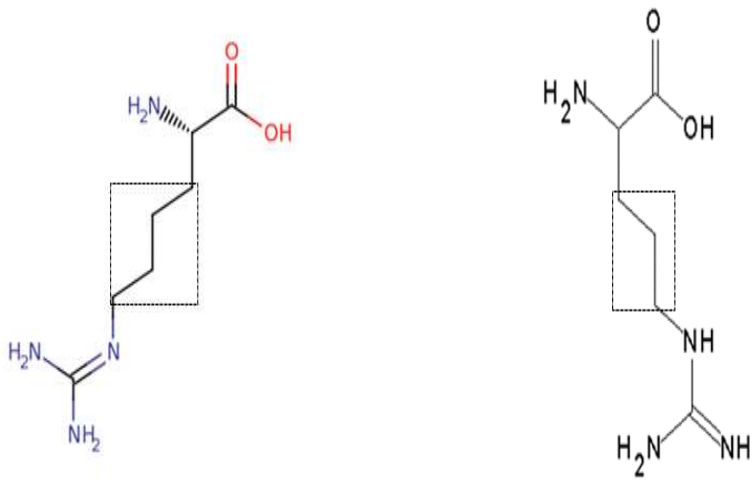
As a cationic amino acid, homoarginine has structural similarities to arginine (*Fig. 1*) and formed from lysine (Papageorgiou et al., 2015). Its synthesis occurs in the kidney and the liver (Ryan and Wells, 1964). The enzyme that is responsible for homoarginine synthesis remains unknown (Tsikas and Kayacelebi, 2014) however, it is assumed to be arginine: glycine amidinotransferase (AGAT) which may help in the synthesis of homoarginine from lysine and arginine in animals (Hou et al., 2015; Tsikas and Wu, 2015). According to research, homoarginine inhibits arginase and arginine transportation by cells (Hou et al., 2015). The level of homoarginine concentration in the body has been reported to be higher in children as compared to adults - children have a high level of protein synthesis to support growth (Atzler et al., 2014). Some researchers found that its concentration in the plasma declines with age, which results in cardiovascular, cerebrovascular diseases and death in animals and humans (Atzler et al., 2015; Hou et al., 2015). Studies have shown that homoarginine may impact nitric oxide metabolism, endothelial function, insulin secretion, and inhibit platelet aggregation; these are important for the maintenance of cardiovascular health (Bretscher et al., 2003; Stockebrand et al., 2015). Based on these functions, some scientists have showed that homoarginine is an independent risk biomarker of cardiovascular diseases (Tomaschitz

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1056510574

et al., 2014; Kayacelebi et al., 2015; Chafai et al., 2017; Seppälä et al., 2017). Current investigations on the usage of homoarginine in both human and animals in relations to different conditions such as disease states, growth promotion, nutrient transport and metabolism, foetal and neonatal growth and survival is increasingly gaining scientific attention. Homoarginine has been associated with different disease states in both human and animals however there are limited investigations involving homoarginine. Therefore, this current review seeks to summarize the role of homoarginine in the cardiovascular systems, including Atherosclerosis, Type 2 diabetes mellitus, and Stroke.

Synthesis of homoarginine

Arginine and asymmetric dimethylarginine (ADMA) are usually measured at the same time with homoarginine, which is a homolog of arginine (*Fig. 1*) (Teerlink et al., 2002; Davids et al., 2012b). Homoarginine is solid and it has a melting point of 213-215°C with a molecular weight of 188.231 g/mol. Its formation is endogenous (Seppälä et al., 2017). Some legumes are rich in nonprotein amino acids, including homoarginine; the grass pea (Lathyrus sativus L.), which is rich in homoarginine serves as food for humans and feed for domestic animals (Bell, 2003; Rao, 2011). Research shows that plasma concentration of homoarginine in healthy adults is about 2 μM (Hou et al., 2015; May et al., 2015; Hanff et al., 2016). A study on rats recorded 20 min as the half-life of homoarginine (Günes et al., 2017; Adams et al., 2019). It is known to play a role in the arginine/nitric oxide pathway by acting as a substrate (Haghikia et al., 2017). According to research, homoarginine's ability to inhibit either arginase or protein arginine methyltransferase (PRMTs) makes it increase the production of nitric oxide (Michel, 2013; Vogl et al., 2015) and this might have a positive impact on endothelial function (Valtonen et al., 2008). Recent reports have indicated that low homoarginine concentrations is a risk factor for cardiovascular conditions and death in people as well as kidney disease patients (Atzler et al., 2014; Pilz et al., 2014; Tomaschitz et al., 2014; Vogl et al., 2015).The physiological role of homoarginine is still being studied by some researchers.



Homoarginine Arginine

Homoarginine metabolism in vascular system

Metabolism of Homoarginine

Studies over the past fifty years have led to an understanding of some of the physiological and biochemical roles of homoarginine in humans and animals (Hou et al., 2015). Homoarginine is produced in a small quantity in the body of humans and animals (Hou et al., 2015). It is suggested to be found in some organs such as the kidney, liver, brain and body fluids; blood and urine (Valtonen et al., 2008). A research on the possible pathways for homoarginine showed that a mitochondrial enzyme found in the kidney, which is arginine: glycine amidinotransferase (AGAT), catalyses the transformation of glycine and arginine to guanidinoacetate (GAA) and ornithine, and GAA is methylated to creatine with the help of guanidinoacetate N-methyltransferase (GAMT) for energy metabolism. Homoarginine is produced when AGAT uses lysine instead of glycine (Davids et al., 2012a) (*Fig. 2*). In the urea cycle, homoarginine is formed when ornithine is replaced by lysine. The ornithine transcarbamoylase (OTC) enzyme is important in this metabolic pathway. This enzyme catalyses the transamidination of lysine which facilitates the production of homoarginine (Davids et al., 2012a). Homoarginine also inhibits arginase and acts as a substrate for NO synthase to form NO, which performs a critical function in vasodilation and is important in the regulation of blood pressure (März et al., 2010).

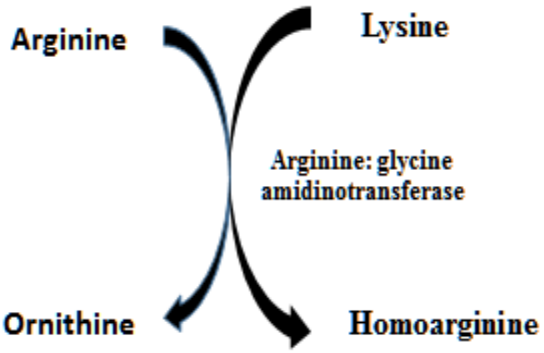

Figure 2. *A schematic diagram showing the synthesis of Homoarginine and Ornithine from Arginine and lysine using Arginine: glycine amidinotransferase*

Nitric Oxide and Nitric Oxide Synthases

Nitric oxide (NO) is formed during the complex oxidation reaction from arginine and oxygen (O2). NO is produced with the help of enzyme nitric oxide synthase (NOS), with the endothelial cells of blood vessels being its first location. The enzyme is called synthase, not synthetase, because there is no need of adenosine triphosphate (ATP) for its action (Arzumanian et al., 2003). The nitric oxide synthase plays active role in the production of NO. They are neuronal (nNOS), endothelial (eNOS) and inducible (iNOS). Oxygen, nicotinamide-adenine-dinucleotide phosphate (NADPH), tetrahydrobiopterin and flavin adenine nucleotides are known as the co-factors for NOS (Kassim et al., 2010; Tousoulis et al., 2012).

Expression of Neuronal NOS occurs in specific neurons in the brain with Ca^{2+} and calmodulin regulating the activities of enzymes (Zhou and Zhu, 2009). According to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1056510574

immunohistochemistry, nNOS could be located in the spinal cord, the sympathetic ganglia and adrenal glands, in kidney macula densa cells, and in the vascular smooth muscle (Förstermann et al., 1994). nNOS is known to play a role in physiological functions such as memory, learning, and neurogenesis (Zhou and Zhu, 2009). Research has shown that the central regulation of blood pressure in the central nervous system (CNS) is assisted by NO formed by nNOS (Sakuma et al., 1992; El karib et al., 1993). A data on human studies indicated that nNOS perform a significant function in vascular tone regulation (Melikian et al., 2009). When eNOS becomes dysfunctional, low level of nNOS expressed in the vascular smooth muscle cells maintains vasodilation (Schwarz et al., 1999). The endothelial cells are known as the site for endothelial NOS production. Research has also shown that the isozyme is found in cardiac myocytes, platelets, LLC-PK1 kidney tubular epithelial cells and certain neurons of the brain, and in (Förstermann et al., 1994). Numerous essential cardiovascular functions appear to be regulated by eNOS which serves as a homeostatic regulator. Endothelial NOS-derived NO stimulates soluble guanylyl cyclase and increases cyclic guanosine monophosphate (cGMP) in smooth muscle cells thereby dilates all types of blood vessels (Förstermann and Sessa, 2011). Blood pressure rises as a result of deletion of the eNOS gene (Huang et al., 1995; Shesely et al., 1996). The inhibition of platelet aggregation and adhesion to the vascular wall occurs when nitric oxide is released towards the vascular lumen (Alheid et al., 1987). Evidence has also indicated that endothelial NO inhibits leucocyte adhesion and vascular inflammation. An early event in the development of atherosclerosis is leucocyte adherence and therefore, NO may act against the onset of atherogenesis (Förstermann and Sessa, 2011). Expression of inducible NOS can be instigated by bacterial lipopolysaccharide, cytokines, and other agents (Förstermann, 2000). The production of high quantity of NO by inducible NOS occurs when induced in macrophages which indicates a major cytotoxic principle of those cells (Nathan and Hibbs Jr, 1991). Arginine is utilized by all isoforms of NOS as the substrate, with molecular oxygen and decreased NADPH being utilized as co-substrates (Förstermann and Sessa, 2011).

Functions of homoarginine in vascular system

Nitric oxide synthesis

Nitric oxide which has been studied extensively due to its health effects in the body is an inorganic molecule that exists in mammalian biology (Ziolo et al., 2001). The formation of nitrogen oxides occurs when NO; an unstable free-radical gas reacts rapidly with oxygen. It is soluble and has a molecular weight of 30.006 g/mol. Nitric oxide has a half-life of ~6–30 s (Tousoulis et al., 2012). The nitric oxide synthases catalyse the oxidation of arginine to produce nitric oxide in mammals. eNOS and nNOS are constitutively expressed and are referred to as Ca^{2+}-dependent enzymes (Förstermann and Sessa, 2011). It serves as a main paracrine and autocrine mediator of immune regulation and vascular relaxation in the body (Moncada, 1991). In the endothelium, nitric oxide serves as a central signal transduction pathway (Ignarro et al., 1999). Homoarginine is a weak substrate for nitric oxide synthase (NOS) and can produce NO. When homoarginine hinders the activity of arginase, it may increase arginine and NO production (Hrabak et al., 1994). Nitric oxide aids in blood pressure regulation, inhibition of platelet aggregation, platelet adhesion inhibition, and neurotransmission (Loscalzo and Vita, 2000; Atzler et al., 2015). Arginine performs

various functions in living organisms (März et al., 2010; Haghikia et al., 2017), but the roles of homoarginine need more research (Seppälä et al., 2017). A study suggested that homoarginine competes with arginine, which causes a decrease in NO synthesis (Alesutan et al., 2016). An intravenous homoarginine infusion research done on rats showed an increase in serum concentration of homoarginine and ornithine (Dellera et al., 2016). According to the results obtained, it was suggested that anti-proliferative effects may be exerted by homoarginine; increasing the release of NO from vascular cells (Durante, 2013; Dellera et al., 2016), and by ornithine; acting as an arginase inhibitor to increase NO availability (Durante, 2013; Dellera et al., 2016). Homoarginine plays an important role in NO synthesis even though its concentration is little in the serum and plasma of humans and animals.

Cardiovascular diseases

Vascular smooth muscle cells perform a major function in vascular diseases (Qiu et al., 2014). Studies have shown that the abnormal proliferation and migration of vascular smooth cells are the main constituents of hypertension, atherosclerosis and vascular sterosis after vessel transplant (Kockx and Knaapen, 2000; González-Navarro et al., 2010). Homoarginine is a less efficient NOS substrate than arginine, but competes with arginine for NO synthesis by hindering the regular production of NO (März et al., 2010). Research has reported that critical cardiovascular conditions are as a result of both high and low hArg levels whereas increased vascular resistance is as a result of high homoarginine levels. Prospective research indicated that cardiovascular death and stroke were caused by low homoarginine levels (Tomaschitz et al., 2014; Chafai et al., 2017; Seppälä et al., 2017). Endothelium plays a main role in the vasculature by ensuring the promotion and maintenance of a protective environment via endothelial cell-derived vasoactive factors (Guzik et al., 2004; Papageorgiou et al., 2015). Some scientists investigated on how low level of homoarginine is related to dilation and a reduced function of the left ventricle and their findings indicated that high homoarginine is linked to lower left ventricle thickening, higher ejection fraction and lower N-terminal pro B-type natriuretic peptide (NTproBNP) (Bahls et al., 2018).

Atherosclerosis

Atherosclerosis, a disease of the arterial wall occurs at sensitive areas in the main arteries (Insull Jr, 2009). It starts off by lipid retention, oxidation, and modification, which leads to incurable swelling and causes thrombosis or stenosis (Insull Jr, 2009). Many factors may cause atherosclerosis by their effects on low-density lipoprotein (LDL) particles and inflammation (De Groot et al., 2000; Tomkin and Owens, 2012). These factors often include tobacco smoking, hypertension, obesity, diabetes, and genetic susceptibility (Insull Jr, 2009). Aortic stiffness, the inverse measure of aortic distensibility (AD), is also known as a cardiovascular risk marker aside the common factors for atherosclerosis (Kronzon and Tunick, 2006; Haghikia et al., 2017). Atherosclerosis has been reported as a main cause of death and morbidity across the globe. Studies have shown that homoarginine promotes vascular calcification (Alesutan et al., 2016; Haghikia et al., 2017) and it may be involved in the pathogenesis of atherosclerosis (Seppälä et al., 2017). However, there are inadequate information on the association between low homoarginine concentrations and the occurrence of atherosclerosis.

Type 2 diabetes mellitus

Type 2 diabetes mellitus (T2DM) is a metabolic disorder which is distinguished by insulin deficiency, hyperglycemia, and insulin resistance (Olokoba et al., 2012). An interaction between genetic, environmental and behavioural risk factors can also cause this disorder (Chen et al., 2012). Recent evidence has reported that homoarginine concentrations were lower at higher age, lower body mass index (BMI), lower albumin, lower haemoglobin, and were lower in females as compared to males (Drechsler et al., 2011). Low homoarginine concentrations were also associated with a longer history of diabetes mellitus and higher levels of C-reactive protein (Drechsler et al., 2011). Low serum concentration of homoarginine is independently associated with T2DM patients that can lead to death.

Stroke

Stroke is as a result of the cessation of blood flow to the brain which can cause disability and death. Ischemic stroke is caused by thrombosis due to atherosclerosis. Some common risk factors associated with stroke are hypertension, stress and age. In the LURIC study, low serum homoarginine concentrations were found to be a novel risk factor for fatal strokes (Pilz et al., 2011). A recent report on a homoarginine supplementation in stroke-infected mice indicated a noticeable decrease in homoarginine in the plasma from AGAT null mice, which is related to an increase in the size of stroke (Choe et al., 2013). According to Choe et al. (2013), there was a decrease in the death rate of patients with ischemic stroke which was independently associated with high homoarginine levels recorded. In the Harburg Stroke Study, which involved 137 patients affected with ischemic stroke, it was reported that plasma homoarginine concentrations were significantly decreased in patients who were near death, nonfatal recurrent stroke and nonfatal myocardial infarction compared with those without the condition (Choe et al., 2012).

Conclusion

It has become evident that homoarginine is a new biomarker for cardiovascular diseases by its involvement in NO production. Low serum concentration of homoarginine has been reported in subjects suffering from cardiovascular, cerebrovascular and renal diseases as compared to healthy subjects. More research needs to be done to understand the physiological role of homoarginine and its application in clinical studies and pharmacy as a possible medication for the cure of associated diseases.

(Received 17th Jan 2019; accepted 2nd Jul 2019)

Abstract. This experiment was conducted in 7 different locations of Turkey (Diyarbakır/Dicle, Malatya, Mardin, Elazığ, Elazığ/Gezin, Iğdır and Hatay) and it was conducted on the black chickpea genotypes. The aim of this experiment is to determine the hydration capacity of black chickpea genotypes, seed ratio with hard seed coat, the weight of one hundred seed, the protein content in the grain, the fat content in the grain and the P, K, Ca, Mo, Fe, Zn, Cu and Mn (mg / kg) contents. In line with this aim, in 2015, it was carried out with three repetitions according to the Trial Plan of Random Parcels. At the end of the experiment, the obtained values were subjected to variance analysis and the differences among the means were tested according to the Duncan multiple comparison method. The difference among the genotypes in terms of hydration capacity was found to be statistically significant at 1%. The hydration capacities of genotypes varied between 0.9826-1.0856. While the genotype of Hatay has the highest hydration capacity, Gezin genotype was determined to have the lowest hydration capacity. In the study, no genotype was found to have seeds with hard seed coat (seed without water). All seeds are swollen as a result of taking water. The highest values were determined as follows: Iğdır genotype with a weight of 12.40 g for the hundred seed, Gezin genotype for the fat ratio in the grain and the ratio of protein in the grain is Elazığ genotype. The Elazığ genotype is prominent in terms of phosphorus, potassium, molybdenum, zinc and copper content in grain.
Keywords: *Cicer arietinum L., cooking time, hydration capacity, macroelements, microelemets*

Introduction

Chickpea (*Cicer arietinum* L.), which belongs to the genus *Cicer* of the family of legumes (Fabaceae), is a legume plant. Almost 10,000 years ago, wheat, barley, rye, peas, vetch and lentil plants together with chickpea, have been reported to be cultivated for the first time in the area called Fertile Crescent (in Turkish: Bereketli Hilal) (Redden and Berger, 2007). The chickpea genus is composed of some perennial species, such as *C. arietinum* L., as well as single-year species. The first chickpea plant cultivated in the area known as the old world is *Cicer arietinum* L. (Tanno and Willcox, 2006). Cultured chickpea *C. arietinum* L. diploid (2n = 16) is an edible legume plant (Sethy et al., 2006). According to a classification, plants in the genus *Cicer* are known to be single or multi-year. According to the morphological characterization, there are 39 species in the genus *Cicer* and after the revision studies, it was reported that *Cicer* genus consists of 44 species, 9 of which are single-year and 35 of which are multi-year (Van der Maesen et al., 2007). Total of 10 species belonging to the genus *Cicer* is located in Turkey and five of them are of endemic character (Öztürk, 2011).

As a result of research with genetic markers, it was detected that the Fertile Crescent Region, which is the homeland of chickpea, is the richest region in terms of chickpea

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1057510585

gene sources (Roorkiwal et al., 2014). Chickpea taxa shows to be most spread in Turkey in the following regions: Southeast Anatolia, Mediterranean, Eastern Anatolia and Aegean regions. The species spread in Turkey are: *C. arietinum, C. reticulatum, C. echinospermum, C. pinnatifidum, C. bijugum, C. incisum, C. montbretii, C. floribundum, C. isauricum, C. heterophyllum, C. uluderensis* and *C. anatolicum* türleridir (Van der Maesen, 1972; Öztürk, 2011; Akın, 2018) (*Fig. 1*).

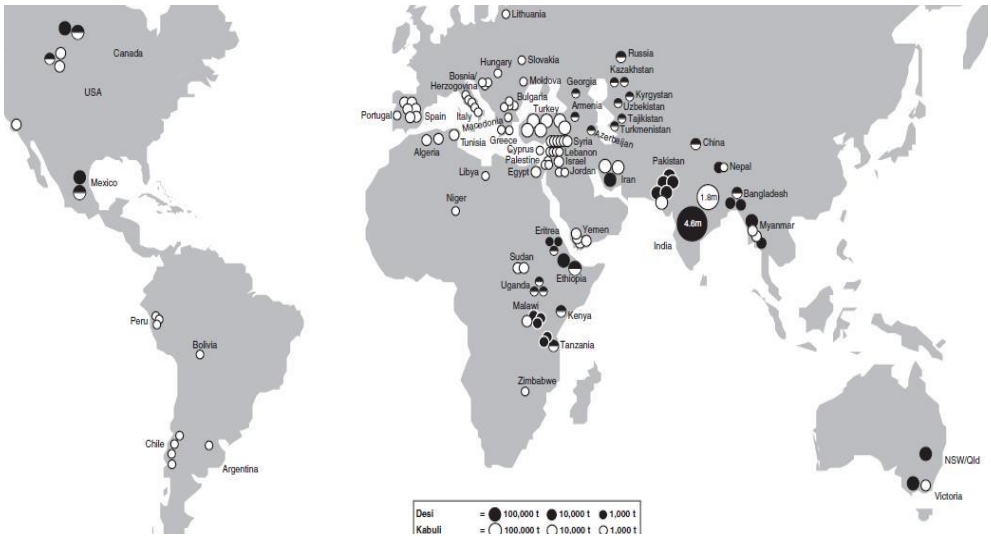

Figure 1. *Kabuli and Desi type chickpea production pattern of the world (Knights et al., 2007)*

Legumes contain high protein, low fat content, vitamins and minerals as nutritional values in their seeds (Pekşen and Artık, 2005). In addition, edible legumes contain 11% of insoluble dietary fibers that are beneficial for intestinal health due to their laxative effects (Anderson and Bryant, 1986; Marlett et al., 2002). Chickpea seed coat was found to be rich in dietary fiber and minerals. However, the contribution of the seed coat on nutritional benefits of the whole seed were determined to be limited (Savar and Karataş, 2017). If the benefits of chickpea in human nutrition are listed; Polyphenols are common constituents of foods of plant origin and major antioxidants in the human diet. These compounds possess diverse biological activities such as antioxidation, apoptosis, antiaging, anticancer, antiinflammation, antiatherosclerosis, cardiovascular protection, improvement of the endothelial function, as well as inhibition of angiogenesis and cell proliferation activity (Ozdemir, 2006; Han et al., 2007). Colored seeds contained up to 13-, 11-, and 31-fold more TPC (Total polyphenol content), TFC (Total flavonoid content), and antioxidant activity, respectively, than cream- and beige-color seeds. Thus, colored chickpea could be a potentially functional food in addition to its traditional role of providing dietary proteins and dietary fibers. colored chickpea might be considered a functional food in addition to its traditional role of providing dietary proteins. Colored chickpea might also contribute significantly to the management and/or prevention of degenerative diseases associated with free radical damage due to their high antioxidant activity. Due to their high antioxidant activity, future research should be conducted to verify that colored chickpeas can be used for management and/or prevention of degenerative disease (Segev et al., 2010).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1057510585

While chickpea is the second most sown and farmed legume in the world among the edible legumes, it is ranked first in our country (Anonymous, 2016). While India ranks first in terms of cultivation area and production, 2/3 part of the world chickpea production takes place in this country. In terms of cultivation area Turkey is fourth after Pakistan and Iran and third in terms of production.

According to the studies conducted, *Cicer* species in the flora of Turkey (Davis et al., 1988) was represented by 9 species. With the work done in the following years *C. uluderensis* (Dönmez, 2011), *C. reticulatum* (Ladizinsky, 1975) and *C. heterophyllum* (Constandriopoulos et al., 1972) species were identified in Turkey and had been added to the world scientific literature as new species. On the other hand; *C. floribundum* var. *Amanicola* in Osmaniye, *C. heterophyllum* var. *Kasanii* in Antalya and *C. incisum* subsp. *Serpentinica* in Erzincan are introduced to the scientific world with relevant study (Öztürk, 2011) and the total number of taxa spreading in Turkey increased to 15. This study conducted on chickpea plant which has been spreading widely in Turkey, showed that it is crucial to reserve the black chickpea as a genetic resource due to its resistance to diseases and adverse environmental conditions, quality parameters and active substances.

In this study, it is aimed to emphasize the importance of black chickpea, which is rarely grown and scarcely found in our country and to restore it to agriculture and human life by looking at some quality criteria and nutrient element contents.

Literature review

It is known that black chickpea which belongs to the Desi variety, also known as Bengal Gram in India, has high fiber content and low glycemic. In India, black chickpeas are highly involved in human nutrition. Black chickpea is not given the necessary importance in our country. Black chickpea, which is important in the eating habits of our ancestors, has lost its importance today and has even been used as animal feed by producers. Today, the cultivation of black chickpea covers a very small area and cannot be evaluated statistically. Black chickpea, which had been produced in the past years, is now being produced by some farmers in regions such as Malatya, Elazığ, Elazığ/Gezin, Diyarbakır/Dicle, Mardin, Iğdır and Hatay. This production is done to meet the farmer's own needs and is usually given as supplementary food in animal feed.

Yarmaca and mekaşer are local food names of Eastern Anatolia. As well as being directly used in food, black chickpea is also used as ‘yarmaca’ and ‘mekaşer’ after being put through certain processes. Black chickpeas are more delicious than other chickpeas. Black chickpea is a versatile legume and is widely used in India and the Middle East. It is consumed as a fast snack in meals, humus and curries, soups and salads in Turkey.

It is produced by some farmers in regions such as Malatya, Elazığ, Elazığ/Gezin, Mardin, Diyarbakır/Dicle, Iğdır, Hatay and is consumed by a certain part of the population and finds buyers at very high prices. They are either put into food after being boiled or are added into food as yarmaca (Malatya region) or mekaşer (Diyarbakır-Dicle region) after certain processes and consumed that way. In contrast to the positive aspects of food legumes such as high protein content, the length of cooking times is seen as a negation for their consumption. It was observed that the cooking time was closely related to the hydration capacity of the seed and that there was a positive relationship between the hydration capacity and the cooking time and that the varieties with high hydration capacity were more rapidly cooked (Williams et al., 1983; Manan et

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1057510585

al., 1987; Singh et al., 1991). For this reason, it has been tried to increase the hydration capacity of seed with various breeding and growing techniques in edible legumes (Rao and Vakil, 1985).

Materials and methods

Material

Black chickpeas obtained from Diyarbakır / Dicle, Malatya, Mardin, Elazığ, Elazığ / Gezin, Iğdır and Hatay were used in the experiment.

All genotypes have taken their names from the provinces and districts where situated in South East, Meditereinan and Eastern Anatolia regions of Turkey. All collected genotypes were grown with the same methods without fertilization in dry conditions. The aim of the study is to determine the nutrient content of genotypes grown under farmer conditions. 1 kg of samples were collected from each genotype. Materials were obtained from seeds grown by farmers in traditional methods.

Methods

The study was carried out with three repetitions according to the Trial Plan of Random Parcels.

Determination of hydration capacity, hard seed coat and hydration index (%)

In the study, seed weight was detected by weighing 50 seeds from each genotype and these seeds were placed in a 250 ml erlenmayer with a wide mouth then 100 ml demineralized water was added to the seeds and the mouth of the erlenmayer was covered with aluminum foil for 16 hours at room temperature (22-25˚C). Seeds that were kept at room temperature for 16 hours were taken from the containers at the end of this period and were kept for a short time between drying papers in order to remove the water on them. Then, if there had been non-swelling seeds, they were separated as hard-coated seeds and the hydration capacities and hydration indices of the varieties were determined after various calculations were made by weighing the wet weights of the remaining seeds. The following equation was used to determine the hydration capacity. Hydration index was also determined by calculating the hydration capacity against the original seed weight (Williams et al., 1986) (*Eq. 1*).

$$Hydration\ Capacity = \frac{Y-\left(X-\left(\frac{X}{100}\right)N2\right)}{N1-N2} \quad \text{(Eq.1)}$$

where

- Y = Wet Seed Weight.
- X = Dry Seed Weight.
- N_1 = Original Seed Count.
- N_2 = Hard-Coated Seed Count (Non-Water Drawing Seed Count).

Weight of one hundred seed, (g)

The grains were randomly weighed in four groups of 100 pieces, on a 0.01 g sensitive scale, and averages of one hundred seed, were calculated.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1057510585

Grain protein ratio (%)

After grinding the seeds, Kjeldahl method was applied and the amount of nitrogen was determined, and the resulting values were multiplied by 6.25 and the crude protein ratios in the grains of genotypes were detected.

Fat content in grain (%)

Spectra Star laboratory type NIR (Near Infrared) analyzer was used to determine the crude fat content in the grains of genotypes.

Determination of macro and micro nutrients in seeds

Phosphorus content in grain (%) was calculated according to Kacar (1984), with vanado molybdo phosphoric acid yellow color method. Mo, Fe, K, Ca, Zn, Cu and Mn (mg / kg) analyses were performed according to Kacar (1994).

At the end of the study, the obtained values were subjected to variance analysis and the differences among the means were tested according to Duncan's multiple comparison method ($P < 0.05$). In statistical analysis, information from Yurtsever (1984) and Düzgüneş et al. (1987) were used.

Results and discussions

The Duncan groups are shown in *Table 1*, which gives us the mean values of the weight of one hundred seed, protein content in the grain, fat content in the grain, hydration capacity, hydration index and the differences among the means belonging to the black chickpea genotypes grown in different locations in Turkey.

The weight of one hundred seed, is a genre specification and it shows significant changes compared to genotypes. As shown in *Table 1*, the average weight of one hundred seed, of genotypes used in the study ranged from 7.97-12.40 g. The lowest hundred seed weight was obtained from the Dicle genotype and the highest value was obtained from the Iğdır genotype. Karaköy (2008) reported that the weight of one hundred seed, of chickpeas varied between 37.6-51.5 g. The findings of this study were different with the findings of the researchers. The reason for this is that the black chickpeas used in this study have smaller grain size than the other chickpeas and they are not developed by any reclamation method.

The mean hydration capacity of the genotypes used in the study ranged between 0.9826-1.0856 g/seed and the lowest hydration capacity was detected in the Gezin genotype, but its difference from the Malatya genotype was not statistically significant. The highest hydration capacity was obtained from Hatay genotype and its difference compared to Mardin and Elazığ genotypes was statistically insignificant. In previous studies, it had been reported that the water absorption properties of legume seeds are related to seed size and seed coat thickness (Kaur et al., 2005). Toğay et al. (2001) stated in their study conducted within the chickpea varieties that have been registered in Turkey that the hydration capacity varies between 0.979-1.223 g/seed. In terms of this feature, the findings of the researchers seem to be supporting each other. In a study, unlike these research findings, the hydration capacity in Desi genus chickpea grown in Tunisia was found to be 0.64 g/seed (Ghribi et al., 2015).

As can be seen from *Table 1* the mean hydration index of the genotypes used in the study ranged from 16.23 to 23.66% and the lowest hydration index was obtained from

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1057510585

the Iğdır genotype but the difference between it and the Gezin genotype was statistically insignificant. The highest hydration index was obtained from the Dicle genotype. In this study, no statistical analysis was performed since there were no genotypes with hard seed coat among black chickpea genotypes. Considering the positive relationship between hydration capacity and cooking time reported in the previous studies regarding this topic (Williams et al., 1983; Manan et al., 1987; Singh et al., 1991), the Hatay genotype has been found to be more suitable for rapid cooking than the other varieties. The Gezin black chickpea genotype can be evaluated as the longest cooking type.

Table 1. *Duncan groups showing the average values and the differences among means of the weight of one hundred seed, hydration capacity, hydration index, protein content in the grain and fat content in the grain of the black chickpea genotypes grown in different locations in Turkey*

Genotypes	Weight of one hundred seed (g)*	Hydration capacity (g/seed)**	Hydration index (%)*	Protein content in the grain (%)*	Fat content in the grain (%)*
Dicle	7.97 d	1.0493 ab	23.66 a	19.60 c	3.25 c
Malatya	9.58 c	0.9986 c	21.30 b	19.58 c	3.17 c
Mardin	11.27 b	1.0583 a	18.56 c	19.75 c	3.20 c
Elazığ	10.98 b	1.0650 a	18.66 c	22.54 a	3.21 c
Gezin	11.55 ab	0.9826 c	16.50 d	19.91 c	3.55 a
Iğdır	12.40 a	1.0121 bc	16.23 d	19.33 c	3.37 b
Hatay	10.81 b	1.0856 a	19.53 c	20.83 b	2.93 d

**: $p<0.01$; *: $p<0.05$

The average protein content of the genotypes was varying between 19.33-22.54% and the lowest protein ratio was obtained from the Iğdır genotype, but the difference among it and the Dicle, Malatya, Mardin and Gezin genotypes was not statistically significant. The highest protein ratio in the grain was obtained from Elazığ genotype. Dry seed protein rate was stated to be between 12.4% and 31.5% (average 23%) (Özdemir, 2006). Dinç (2014) carried out an adaptation work with the chickpea varieties were registered in Turkey and the protein content in grain values were reported to vary between 20.32-24.5%. As a result of this study, the protein ratio values in the grain were found to be close to the values reached by different researchers like (Khan et al., 1995; Önder and Üçer, 1999; Erdin and Kulaz, 2014).

As it was seen on *Table 1*, the average fat content of genotypes in the study was 2.93-3.55% and the lowest fat content was obtained from Hatay genotype while the highest ratio was obtained from Gezin genotype. Özdemir (2006) stated the rate of the oil in chickpea seeds range between 3.8-12.2% and among the edible legumes, most oil was to be found in chickpeas. Şehirali (1988a) had reported that the fat content of chickpeas ranged from 1.5-6.8% while the adaptation study conducted by Dinç (2014) with the chickpea varieties which have been registered in Turkey, stated that the fat content in the grain varied between 4.01-4.93%. The low-fat content of black chickpea compared to other chickpeas is very important for low calorie nutrition and especially for cardiovascular diseases and cholesterol.

Duncan groups showing the mean values and the difference among mean values of black chickpea genotypes grown in different locations of Turkey in terms of iron,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1057510585

molybdenum, manganese, copper and zinc content are shown in *Table 2*. Duncan groups showing the mean values and the differences among the mean values obtained in terms of calcium, phosphorus and potassium content are shown in *Table 3*.

Table 2. *Duncan groups showing the mean values and the difference among mean values of black chickpea genotypes grown in different locations of Turkey in terms of iron, molybdenum, manganese, manganese, copper and zinc content*

Genotypes	Iron Content (ppm)*	Molybdenum content (ppm)**	Manganese content (ppm)*	Copper content (ppm)*	Zinc content (ppm)*
Dicle	50.15 c	2.36 bc	23.62 d	15.06 ab	58.58 b
Malatya	73.20 a	2.30 cd	30.27 c	15.81 a	46.59 bc
Mardin	43.20 cd	2.16 d	25.27 d	12.76 c	40.10 c
Elazığ	47.09 cd	2.50 ab	41.33 b	15.58 a	96.33 a
Gezin	61.69 b	2.43 abc	27.86 cd	13.52 bc	35.36 c
Iğdır	40.67 d	2.43 abc	28.13 cd	12.76 c	36.49 c
Hatay	49.45 cd	2.60 a	46.00 a	12.58 c	32.40 c

**: $p<0.01$; *: $p<0.05$

As shown in *Table 2*, the iron content of the genotypes used in the study ranged from 40.67-73.20 ppm and the lowest iron content was obtained from Iğdır genotype, while the highest iron content was obtained from Malatya genotype. Özdemir (2006) reported that an average of 6.6 mg (66 ppm) iron mineral exists in 100 gr seed. The iron content of black chickpea was also found to be within the average of iron content of other chickpeas. Due to the high iron and calcium content of chickpea, it is especially recommended for preschool children, pregnant and lactating women.

The effect of black chickpea genotypes on molybdenum content in grain was statistically significant at 1% level. Average molybdenum content of the genotypes used in the study ranged from 2.16 to 2.60 ppm and the lowest molybdenum content was obtained from the Mardin genotype, while the highest molybdenum content in the grain was obtained from the Hatay genotype.

The manganese content of the genotypes used in the experiment varied between 23.62-46.00 ppm and the lowest manganese content was obtained from the Dicle genotype. Its difference from Mardin genotype was statistically insignificant. Mut and Gülümser (2005) stated that manganese content varies between 19-20.42 ppm in zinc and molybdenum applications with bacterial inoculation in chickpea. The manganese content of black chickpea which had not been subjected to any fertilizer application, was even higher than the normal average rate of chickpea.

As shown in *Table 2*, the average copper content in the grain of genotypes used in the study ranged from 12.58 to 15.81 ppm, while the lowest copper content was obtained from the Hatay genotype, its difference compared to the Iğdır and Mardin genotypes were found to be statistically insignificant. The highest copper content in grain was obtained from Malatya genotype but its difference from Elazığ genotype was found to be statistically insignificant. Mut and Gülümser (2005) stated that the copper content of zinc and molybdenum applied together with bacterial vaccination in chickpea ranged between 10-11.67 ppm on average in studies. In the study conducted by the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1057510585

researchers, it is believed that the low content of manganese and copper is due to the applied zinc fertilizer.

The mean zinc content of the genotypes used in the study changed between 32.40-96.33 ppm and the lowest zinc content was obtained from Hatay genotype. Its difference from Iğdır, Gezin and Mardin genotypes was found to be statistically insignificant. The highest zinc content in grain was obtained from Elazığ genotype. Legumes are rich in zinc content and chickpea is reported to contain an average of 3.4 mg of zinc (Anonymous, 2015). It was observed in this study that zinc content of black chickpea is also quite high.

As can be seen in *Table 3*, the calcium content of the genotypes used in the study varies between 0.28-0.58%. Even though the lowest calcium content was obtained from Dicle genotype, the difference between it and Elazığ genotype was statistically insignificant. The highest calcium content in grain was obtained from Mardin genotype. Özdemir (2006) reported that the average calcium content in 100 gr seed is 185.6 mg (0.185%) while Şehirali (1988b) stated that there were 33-1980 mg of calcium in 100 grams of chickpea.

Table 3. *Duncan groups showing the mean values and the difference among mean values of black chickpea genotypes grown in different locations of Turkey in terms of calcium, phosphorus and potassium content*

Genotypes	Calcium content (%)*	Phosphorus Content (%)*	Potassium Content (%)*
Dicle	0.28 c	0.33 c	1.13 bc
Malatya	0.32 bc	0.28 d	1.02 cd
Mardin	0.58 a	0.29 d	1.00 d
Elazığ	0.31 c	0.42 a	1.20 ab
Gezin	0.45 b	0.43 a	1.30 a
Iğdır	0.35 bc	0.34 bc	0.97 d
Hatay	0.40 bc	0.36 b	1.25 a

*: $p<0.05$

The phosphorus content of the genotypes used in the experiment changed between 0.28-0.43% and the lowest phosphorus content was obtained from Malatya genotype but the difference between it and Mardin genotype was found statistically insignificant. The highest phosphorus content in grain was obtained from Gezin genotype and its difference from Elazığ genotype was not statistically significant. Özdemir (2006) reported that the phosphorus content in chickpea was 342.9 mg (0.34%) in 100 gr seed. The phosphorus content of black chickpea also appears to be around average values.

As shown in *Table 3*, the potassium content of the genotypes used in the study ranged from 0.97% to 1.30% and the lowest potassium content was obtained from the Iğdır genotype and the difference between it and the Mardin genotype was found to be statistically insignificant. The highest potassium content in grain was obtained from the Gezin genotype and the Hatay genotype was also in the same group.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1057510585

Conclusion

The hydration capacity, which is an important criterion in chickpea consumption, was measured in studied chickpea genotypes. In genotypes with low hydration capacity, water is absorbed in a long time and the duration of cooking of seeds is increased. Hard seed crusted seeds cannot absorb water as fast as normal seeds, cannot germinate or cook quickly. As a result of this study, it was detected that the best black chickpea genotypes are the Hatay and Elazığ genotypes in terms of hydration capacity and cooking characteristics. These genotypes are good sources of genes with respect to their hydration capacity during breeding work. In addition, the resistance to anthracnose, which is known to be the most important factor limiting yield in chickpeas, especially in early planting and in areas with high humidity, should be considered. Elazığ genotype is prominent in terms of fat content in the grain, protein content in the grain, phosphorus, potassium, molybdenum, zinc and copper content. In terms of healthy eating; black chickpea has a high protein content, low fat content and rich in especially calcium, iron and zinc. In this way, it is very important that it regains its rightful place by taking part in nutrition programs.

Abstract. To fully understand and evaluate the impact of lead and cadmium on the surrounding soil pollution in tailings from gold ore dressings, 36 soil samples were collected at different depths near an abandoned concentrating mill in a gold mining area. By examining the lead and cadmium contents in the soil samples, the degree of lead and cadmium pollution over the soil profile was analyzed at different sampling points. Meanwhile, 12 typical plant samples, including *Bulrush (Phragmites communis (Cav.) Trin. ex Steud.), Capillary Wormwood (Artemisia capillaris), Heteropappusaltaicus (Artemisia gmelinii)* and *Stipa (Stipa capillata Linn.)* were collected at the soil sampling point. The lead and cadmium contents were determined in the aboveground and belowground organs, and the enrichment and transfer coefficients of each plant sample were calculated. The results showed that both lead and cadmium were moderately polluted within 0-10 m of the tailing dump. The lead and cadmium contents over the depth profile of 0-30 cm were higher at depths of 0-10 cm and 20-30 cm than at 10-20 cm. *Heteropappusaltaicus* showed more significant enrichment and transfer effects and large coverage and can thus be used as the phytoremediation material for the remediation of Cd- and Pb-polluted soil around tailing slag.
Keywords: *tailing slag, lead and cadmium pollution, phytoremediation, enrichment, migration*

Introduction

Mine tailings are by-products of mineral processing, usually, they are rich in significant quantities of heavy metals (Wang et al., 2017a). In modern society, heavy metal pollution in agricultural soil from mining has been becoming serious and widespread (Marrugo-Negrete et al., 2017; Yang et al., 2018). The National Communique on Soil Pollution Survey Bulletin issued in April 2014 showed that the soil environment in China was negative, and the environmental problems of industrial and mining wasteland were in evidence. Inorganics were the main type of pollution. Inorganic cadmium (Cd) and lead (Pb) pollutants were found in excesses of 7.0% and 1.5%, respectively in China (Luo and Tu, 2018). In 16.1% farmland soils, heavy metals

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1058710597

have exceeded the environmental quality standard (Mahar et al., 2016). The processes of industrial production, mining development, sewage irrigation and rock weathering are the main ways heavy metals enter the soil ecosystem (Pascaud et al., 2015; Sankhla et al., 2016; Ashraf et al., 2017; Jing et al., 2018). Pb and Cd also cause damage to human health. Heavy metals are difficult to decompose through biological cycling and energy exchange and are difficult to remove, resulting in heavy-metal-contaminated soils (Arora et al., 2015; Mahar et al., 2016; Wang et al., 2017b). Shaanxi province is rich in mineral resources. The development of mineral resources has brought great economic benefits as well as serious environmental problems. As the deposits are mostly related to or associated with metals, one can assume the metal smelting process leaches heavy metals. In addition, a single mining mode is mostly used in China at present, which coupled with the low recovery rate and the comprehensive utilization rate, is not only a great waste of resources but has also led to serious ecological destruction and environmental pollution.

Phytoremediation technology can be used for in situ remediation (Filippis, 2015) and is a clean, green and environmentally friendly technology for the treatment of heavy-metal-polluted soil. Compared with other technologies, phytoremediation does not cause secondary environmental problems but instead increases the soil organic matter content (Sarwar et al., 2017; Fiorentino et al., 2017; Ashraf et al., 2017), and the repair period is short and adaptable, making phytoremediation suitable for repairing large areas (Taj and Rajkumar, 2016; Kim et al., 2019).

Although some results in the scientific literature have shown that some plants have cumulative effects on Pb and Cd, there are large differences in growth status and enrichment characteristics under different geographical climates. Through the determination of heavy metals in Pb- and Cd-contaminated soils and surrounding plants in gold mining areas, several plants with tolerance to heavy metal pollution or the ability to enrich heavy metals were screened to provide a scientific reference for applying phytoremediation technology to heavy metal pollution in mining areas.

Materials and methods

Description of the research area

The research area is located in Yao Shang Village, Taiyao Town, Tongguan County. The geographic coordinates are E34°30′56″~34°31′21″, N110°19′23″~110°19′56″ (*Fig. 1)*. The small gold mining area in the Qinling Mountains is the second largest gold-producing area in China. It mainly exploits quartz-veined gold deposits and has a warm, temperate continental monsoon climate with four seasons, with an annual average temperature of 13ºC, sunshine duration of 2269 hours and frost-free period of 190 days. The ore dressing tailings were stacked at random along the river and bank slope, causing soil and water pollution.

Sample collection

Collection of plant samples

Sampling was carried out on August 23th and 24th, 2016. A total of 4 sampling sites of 10 m, 30 m and 50 m to the north of the tailing pile and slag pile were set up, and square sample boxes were used to investigate plants near the sampling points and collect a number of typical plants along with the roots, such as *Bulrush, Capillary*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1058710597

Wormwood, *Heteropappusaltaicus* and *Stipa*. For each plant sample, 3 to 5 plants with similar growth periods that were well developed were selected from the area and packed in kraft paper bags for analysis.

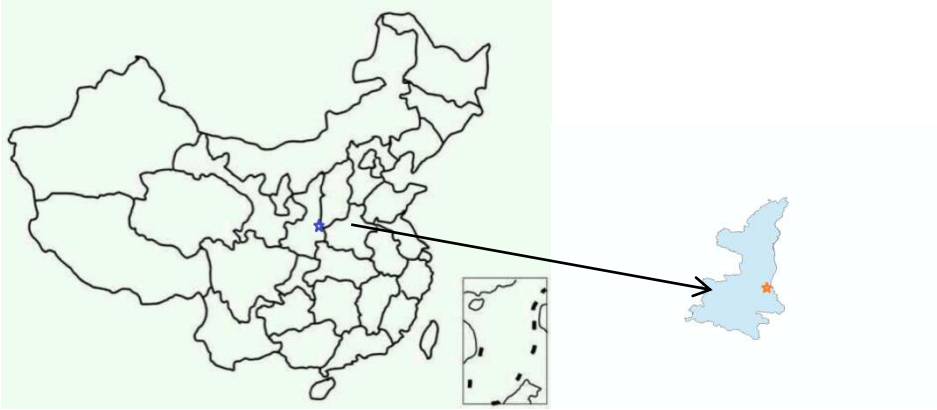

Figure 1. *Description of the research area*

Collection of soil samples

The tailings slag stacked in low-lying areas not far from the road in the open air. The top of the tailings slag was basically equal to the the height of the roadbed. The tailings slag thickness is about 30-40 cm, and it seems to be landfilling construction waste down there. Soil samples were collected by the plum sampling method along the main wind direction. The plum sampling method picks five samples based on the shape of a plum along with the center point at the diagonal intersection. At each sampling point, soil samples of 0-10 cm, 10-20 cm, 20-30 cm were collected (three times) and the remaining sample was approximately 1 kg using the quartile method. Soil samples were sealed in a plastic bag to avoid sample contamination. The sampling location and the surrounding environment were recorded accurately, and a total of 36 tailings (N34°30′58″ E110°19′45″) and 36 soil samples were collected.

Sample processing and determination

Treatment and determination of plant samples

The plant samples were separated into aboveground and underground organs, which were then treated separately. The samples were cleaned and washed with deionized water and placed in an oven at 105ºC for approximately 30 min. Then, the temperature was adjusted to 75°C until reaching a constant plant weight, which was taken as the dry weight (g) (Environment Pollution Analysis Method, 1987). The samples were milled by agate mortar and then sieved with a 0.25 mm nylon sieve. Weighed samples of approximately 0.5 g were placed in a polytetrafluoroethylene digestion tank along with 65-68% nitric acid and 30% hydrogen peroxide for digestion of the heavy metals to make them easy to measure. An AAS Zeenit 700P atomic absorption spectrometer was used to determine the Pb and Cd contents in the aboveground and underground organs. The reagents used in the test were excellent grade, with strict quality control.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1058710597

Treatment and determination of soil samples

The soil samples were air-dried, crushed and ground with wood rods, sieved (<0.149 mm), and stored until measurement (Hu et al., 2014; Zhu et al., 2015; Vogelmann et al., 2015) of the Pb and Cd contents by the method outlined in GB/T 17141-1997. The pH was measured on the basis of NY/T 1377-2007.

Method for evaluation of heavy metal pollution

The grade II soil environmental quality standard was used as the evaluation criterion of soil Pb and Cd geoccumulation indices. The geoccumulative index (I_{Geo}) was used to evaluate the degree of Pb and Cd pollution. The I_{Geo} (*Eq.1*) was obtained in accordance with Muller (1969).

$$I_{Geo} = log_2\left(\frac{c_i}{kB_i}\right) \quad \text{(Eq.1)}$$

In the formula, I_{Geo} is the geoccumulation index, c_i is the measured mass concentration of heavy metal I (mg kg^{-1}), B_i is the environmental background level of the measured element (soil environmental quality standard grade II, in *Table 1*), and k is a correction factor because the diagenesis may cause a change in the background value (generally k =1.5) (Wang et al., 2015). According to the I_{Geo}, the pollution levels of heavy metals can be classified (*Table 2*), the higher I_{Geo} is, the more serious of the pollution.

Table 1. *Descriptive statistics of the Pb and Cd concentrations (mg kg^{-1}) in the tailings of the study area*

Distance from tailing slag	Elements	pH	Range (mg kg^{-1})	Mean (mg kg^{-1})	Standard deviation	Grade II of GB 15618-1995(mg kg^{-1})
0 m	Cd	7.48-7.60	0.47-5.34	2.64	2.51	0.6
	Pb		2506.90-3369.92	2471.70	1117.38	350
10 m	Cd	7.53-7.90	3.42-9.00	5.91	2.84	0.6
	Pb		1779.29-2612.68	2231.01	421.09	350
30 m	Cd	8.00-8.11	0.17-0.39	0.26	0.12	0.6
	Pb		32.12-75.61	71.40	37.36	350
50 m	Cd	7.54-7.84	0.16-0.47	0.33	0.16	0.6
	Pb		28.02-175.19	100.13	73.63	350

Table 2. *Heavy metals geoaccumulation index graduation standard*

I_{Geo}	Grade	Pollution level
≥5	6	Serious
4~5	5	Heavy
3~4	4	Biased
2~3	3	Moderate
1~2	2	Mild
0~1	1	Light
＜0	0	No pollution

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1058710597

Data processing

Plant bioaccumulation factor (BCF) was calculated by *Eq.2*:

$$BCF = \frac{C_p}{C_s} \quad \text{(Eq.2)}$$

In the formula, BCF is the bioaccumulation factor, C_p is the concentration of Pb or Cd in the ground or underground part of the plant (mg kg^{-1}), C_s is the content of Pb or Cd in the soil (mg kg^{-1}), BCF is an important index to measure the heavy metals enrichment capacity. The larger BCF is, the higher the enrichment efficiency of the plant. The larger BCF indicates the stronger mobility of the heavy metal.

The plant transfer coefficient (TF) was calculated as *Eq.3*:

$$TF = \frac{F_i}{R_i} \quad \text{(Eq.3)}$$

where TF is the transfer coefficient, F_i is the concentration of Pb or Cd in the ground part of the plant (mg kg^{-1}), R_i is the content of a certain element in the underground part of the plant (mg kg^{-1}).

Results and Discussion

Evaluation of soil pH and Pb and Cd accumulation indices

The pH values of the tailing samples and soil samples were all greater than 7.5 (*Table 1*). The Pb and Cd concentrations in the 0-30 cm soil samples are given in *Table 1*, along with the Pb and Cd geoccumulative pollution indices of the soil samples. The average and range of Cd and Pb concentrations in the samples taken from different distances from the tailing dumps were compared with the grade II limits (GB 15618-1995). The ratios of the average concentrations of Pb and Cd in the tailing samples to the standard limits were 7.06 and 4.40, respectively. At a distance of 10 m from the tailings, the samples had values of 9.85 and 6.37. The Cd and Pb concentrations in these samples significantly exceeded the soil environmental quality standard grade II.

The average geoccumulative indices of Cd and Pb were calculated by *Eq.1*. The average geoccumulative indices of Cd and Pb in the tailing slag were 0.82 and 1.72 (*Fig. 2*), respectively, which corresponded to mild and moderate pollution levels, respectively. The average Cd and Pb geoccumulative indices of the soil samples taken 10 m from the tailing slag indicated partial to moderate pollution. The average Cd and Pb cumulative indices of the soil samples taken 30 m and 50 m from the tailing slag were negative, indicating no pollution. The results showed that there were different degrees of Cd and Pb pollution in the tailing dumps itself and within 10 m of the tailing pile.

Pb and Cd concentrations in soil

The mean concentrations of Pb and Cd at different soil depths are presented in *Figures 3 and 4*. In this section, we analyzed the Pb and Cd concentrations at depths of 0-10 cm, 10-20 cm and 20-30 cm at each sampling point. Soil taken 30-50 m from the tailing slag showed much lower Pb and Cd concentrations than soil 0-10 m from the tailing slag (*Figures 3 and 4*). The contents of Pb and Cd in the tailings changed greatly

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1058710597

from surface to the lower layer. The average contents and the maximum values of Pb and Cd in the soil profiles of all layers were lower than the grade II soil environmental quality standards. However, the concentrations of Pb in the tailings in each section were higher than soil environmental quality standard (dotted lines). The content of Cd at 0-20 cm soil depth taken 0 m and 30-50 m from the tailing slag was no pollution. The concentration of Cd at a depth of 20-30 cm was 8.9 times that of 0.6 mg kg^{-1} obtained in soil taken 10 m from the tailing slag. At a distance of 0 m, the average concentrations of Pb and Cd in the 20-30 cm section reached 3369.9 and 5.34 mg kg^{-1}, respectively. After comparison with the literature, the cause of the above phenomenon may be that Pb and Cd were present in a migratable state and a bound state in the tailings, and the precipitation and oxidation of the surface layer promoted migration from the surface layer to the lower layer, resulting in the accumulation of Pb and Cd in the lower layer (20-30 cm) (Adeyi and Torto, 2014).

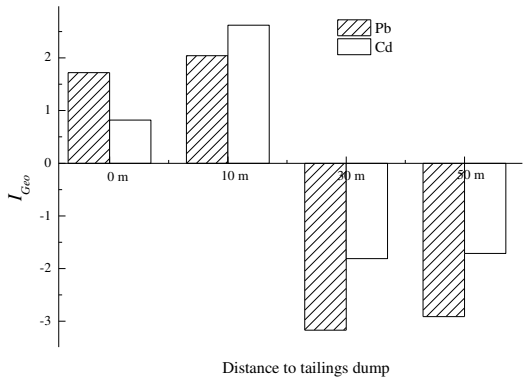

Figure 2. *The average I_{Geo} of Pb and Cd at different distances from the tailings dump*

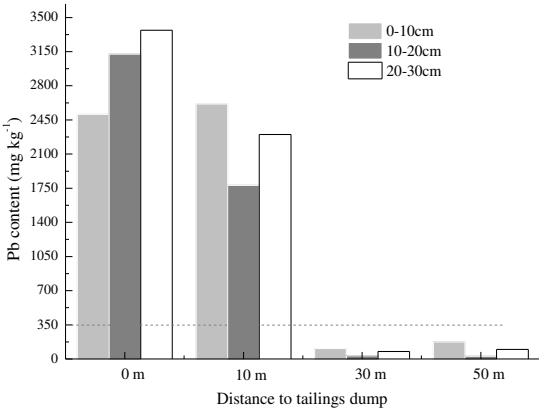

Figure 3. *The average contents of Pb in soil profile at each sampling point*

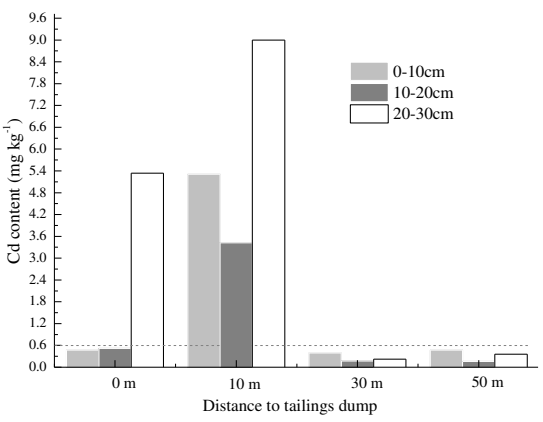

Figure 4. *The average contents of Cd in soil profile at each sampling point*

The average concentrations of Pb and Cd in the 0-10 cm soil were higher than those in the tailings. It is possible that the tailings accumulated for a long time, which led to the larger Pb and Cd accumulation at a depth of 20-30 cm at the sampling point. The main reason for the high concentrations of Cd and Pb in the 0-10 cm layer was that the location of the sampling point was affected by gusts of dust and particle sedimentation.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1058710597

This might also be because the tailing pile pressure accounts for a large area of land, and the accumulation time of tailings was different.

Based on the above analysis, the Pb and Cd concentrations in the study area were highest 0-10 m from the tailing dump, and the maximum Pb and Cd concentrations were 9.6 and 15 times higher, respectively, than those given by GB15618-1995 (pH>7.5). The over-standard rates of Pb and Cd at the sampling points within an area of 0-10 m from the tailing dump were 100% and 83.3%, respectively. In the range of 30-50 m from the tailing dump, the Pb and Cd contents in the soil were lower than the environmental quality standard for soils, though the background soil in Shaanxi has a Pb content higher than 11.5 mg kg^{-1} (Xue et al., 1986).

The results showed that there were significant differences in Cd content in different depths (p=0.043<0.05). The Cd content of heavy metals did not change with the distance from the tailings slag (p=0.161>0.05). There were very significant differences in Pb content in different depths (p=0.000<0.01). The Pb content of heavy metals did not change with the distance from the tailings slag (p=0.31>0.05).

Distribution of Pb and Cd in various plant organs

In this section, the effects of Pb and Cd enrichment and transfer to plants at a distance of 10 m from the tailings dump were analyzed and compared with the corresponding soil environment (*Fig. 5*).

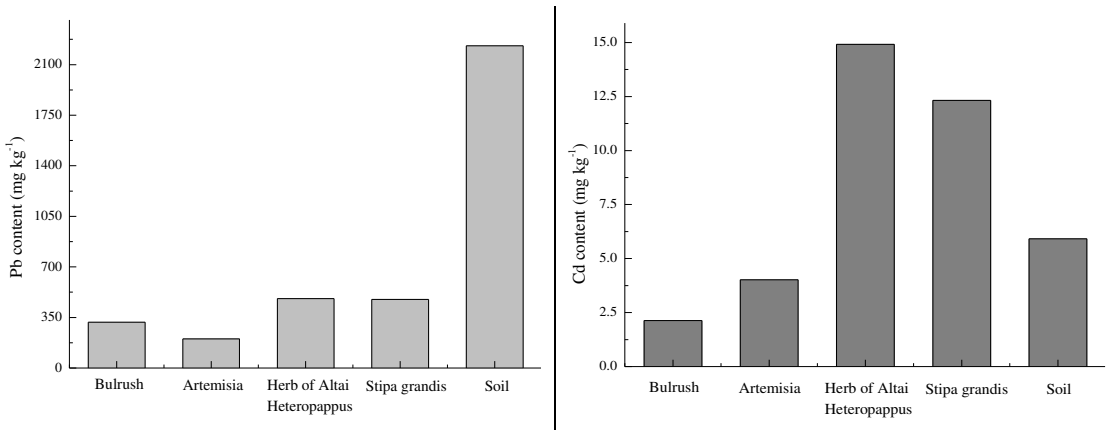

Figure 5. *Comparison of Pb and Cd concentrations and soil concentrations 10 m from tailings slag*

The bioaccumulation factor (BCF) and transfer coefficient (TF) of *Bulrush (Phragmites communis (Cav.) Trin. ex Steud.) (Poales family), Capillary Wormwood (Artemisia capillaries) (Compositae family), Heteropappusaltaicus (Artemisia gmelinii) (Compositae family), Stipa (Stipa capillata Linn.) (Gramineae family)* 10 m from tailing slag are shown in *Table 3*. The BCF and TF were calculated by *Eq.2* and *Eq.3*, respectively.

From *Table 3*, we can see that the values of the BCF of Cd for *Heteropappusaltaicus* and *Stipa* were more than 1 and the BCF of Pb was less than 0.3. Among the four plants, the BCF of Pb was similar for *Heteropappusaltaicus* and *Stipa*, and the two plants had similar Pb enrichment abilities. The TFs of *Capillary Wormwood, Heteropappus-altaicus* and *Stipa* for Pb and Cd were higher than 1.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1058710597

The Cd and Pb distributions in various plant organs taken at a distance of 10 m from the tailing slag are shown in *Table 4*. At the sampling point 10 m from the tailing slag, the Cd and Pb concentrations in different organs of *Bulrush, Heteropappusaltaicus* and *Stipa* were compared. The results showed that the stem and leaves had higher Pb and Cd accumulation than the roots. *Heteropappusaltaicus* leaves had the highest Pb accumulation. Taking the results of *Table 3* and *Table 4* into consideration, *Heteropappusaltaicus* had better Pb and Cd accumulation ability. There might be two reasons for this. *Heteropappusaltaicus*, *Capillary Wormwood* and *Stipa* were the dominant crops around the tailing slag and thus had adapted to their growth environment and formed a specific tolerance mechanism. In addition, the stems and leaves of the *Heteropappusaltaicus* plants were covered with villus. These special physiological characteristics play a certain role in the accumulation of Cd and Pb, therefore, the Cd and Pb contents in the stem and leaf were generally higher than those in the underground organs. *Heteropappusaltaicus* had a large coverage in the local area. Theoretically, extraction this plant could reduce the degree of Cd and Pb pollution in soil around the tailing slag.

Table 3. *Plant bioaccumulation factor (BCF) and transfer factor (TF)*

One group of plants for phytoremediation lied in their excellent heavy metal accumulation capacity. Research had showed that Asteraceae species had the ability to remove heavy metal concentrations (Bolan et al., 2014). Some of them can absorb heavy metal ion in their tissues but usually have less biomass and slow growth rate. Because of the cosmopolitan distribution and local ecological adaptability (Rahman et al., 2008), Asteraceae could be used for removal the heavy metal pollutants. Nikolić and Stevović (2015) reported that family Asteraceae includes multiple species with phytoremediation potential including *T. vulgare (L)*, *T. parthenium (L.)* and *T.*

DOI: http://dx.doi.org/10.15666/aeer/1705_1058710597

balsamita (L.) and *S. transcaspicus Nevski.* owes the ability to remove heavy metals. Xiao et al. (2018) observed that the coverage of Asteraceae family and herbs were most in the heavy metal pollution aera and *Symphytum officinale Linn.* has the ability to accumulate Cd and Pb. In the research of Hesami et al. (2018), the heavy metal uptake ability of 16 plants shoot from family Asteraceae was investigated by calculating (BCF), (TF) and the phytoremediation potential were evaluated. The maximum shoot concentrations of Pb (162 mg kg^{-1}) were found in *Taraxacum officinale F.H.Wigg* and Cd (13 mg kg^{-1}) in *Crepis sp*. The maximum BCF of Pb and Cd were 0.326 and 1.787, respectively. Comparing the results with the BCF of *Heteropappusaltaicus*, the BCF of Pb and Cd were 0.224 and 2.97, respectively.

Conclusion

The soil 30 m and 50 m from the tailing dump was not polluted by heavy metals. Soil 0-10 m from the tailing slag showed different degrees of Cd and Pb contamination, whereas soil 10 m from the tailings slaghad moderately high Cd and Pb concentrations.

The Cd and Pb concentrations at depths of 0 to 30 cm were analyzed. The Pb and Cd contents in the tailings gradually increased from the surface to the lower layer. It is possible that the tailings accumulated fora long time, which led to the larger accumulation of Pb and Cd at a depth of 20-30 cm at the sampling point. The high Pb and Cd contents in the surface layer (0-10 cm) may be due to the location of the sampling point, which was affected by gusts of dust and particle sedimentation, and large area of the tailing pile. There were significant differences in Cd (p=0.043<0.05) and Pb (p=0.000<0.05) content in different depths, respectively.

Among the four tested plants, *Heteropappusaltaicus* showed a strong comprehensive Cd and Pb transfer ability and can be used as a phytoremediation plant for Cd and Pb soil pollution around tailings slag. Based on the existing research results, taking soil Cd and Pb 10 m away from tailings slag as an example, the soil contaminated by heavy metals is restored to a safe planting level, which will require equal dry weight plants and take at least 5 years under ideal conditions of equal enrichment efficiency. But it is worth noting that each part of the plant has a certain enrichment effect on heavy metals. If the plants are not properly treated, it may lead to the re-entry of heavy metals enriched by plants into the soil system. These heavy metals are mostly soluble and will cause severer harm. Selecting more dominant plants of family Asteraceae for phytoremediation of environmental pollutants is the final target.

(Received 1st Mar 2019; accepted 21st May 2019)

Abstract. To illustrate the internal micro-mechanism of macro-properties for soft rock and sand compound soil. The compound soil with the mixing ratios of soft rock to sand 1:1, 1:2 and 1:5 which planted in six years, and the ratio of 1:2 planted in one, five and six years were characterized by scanning electron microscope (SEM) to observe the micro structures. The results showed that (1) in the 1:1 compound soil, the silt particles and sandy particles accounted for about 62.5% and 37.5%. Compared with sand, the content of silt particles in 1:1 compound soil increased by about 26%, while the sandy particles decreased by about 26%. (2) The coarse sandy particles (0.25~1 mm) decreased from 9.2% for 1:2 compound soil planted in one year to 2.0% that planted in six years. In contrast, the fine silt particles (0~0.01 mm) increased from 20.7% to 32.6%. With increasing wheat planting years, soil particles of compound soil became finer, which was consistent with the situation that adding soft rock into sand. (3) After six-year wheat planting, the number of soil aggregate for 1:5 and 1:1 compound soil were 1.0 and 2.5. While the number of soil aggregate was 2.0 for 1:2 compound soil after one-year wheat planting, which increased to 8.0 after six-year wheat planting. With the increase of soft rock into sand or wheat planting years, the number of soil aggregate increased also, thus the soil quality was greatly improved.
Keywords: *micro-mechanism, SEM, soil particles, soil aggregate, long-term planting*

Introduction

Soft rock refers to the interbed rock which is composed of thick sandstone, sand shale and argillaceous sandstone of Paleozoic Permian, Mesozoic Triassic, Jurassic and Cretaceous (Bazhenov et al., 1993; Martin et al., 1999; Zhang et al., 2009a). Soft rock is as hard as stone without water, while as soft as mud when it meets water. Water and wind erosion is poorly tolerable for soft rock, which can lead to a large amount of soil loss and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1059910610

thus a disaster for local people (Yang et al., 2014). Soft rock is mainly distributed at the junction of Shanxi, Shaanxi and Inner Mongolia where partly overlaps with Mu Us Sandy Land. Soft rock and sand presents interphase distribution there (Zhang et al., 2009b). Sandy soil there is loose and has no structure which results in serious leakage of water and fertilizer and soil erosion problem. It has been proposed that soft rock can be blended with sand to form compound soil, which compensates the shortcomings in the structure of sandy soil that can be further used for planting (Wang et al., 2013). Compared to sand, the texture of compound soil has been improved (Zhu et al., 2017) and the water and fertilizer holding capacity has been significantly increased (Han et al., 2012; Wang et al., 2014, 2016).

The study of soil microstructure is helpful to the further understanding of soil properties and its intrinsic mechanism. Currently, scanning electron microscopy (SEM) is usually applied for studying the microstructure of soil (Montes et al., 2005; Sayen et al., 2009; Romero, 2013; Lin and Cerato, 2014; Jiang et al., 2014;). Chang et al. (2015) directly observed the morphology of sand, clay, and Red Yellow soil treated by Xanthan gum with SEM, showing the connection mechanism of Xanthan gum with soils of different particle sizes. SEM and energy dispersive spectrometer (EDS) can be jointly used for semi-quantitative analysis of matter elements. Ramamurthy and Kannan (2009) studied the effects of atmospheric pollution by analyzing heavy metals in soil and plants collected from an industrial area with SEM-EDS method. Through this, a perceptible variation in the trace element concentration of samples in different seasons can be found. For the study of soft rock, Li et al. (2016) used SEM to observe the microstructure of soft rock geopolymer materials and discussed the influences of fly ash content and curing age on the mechanical properties and microstructure of soft rock geopolymer material. However, the microstructure of soft rock and sand compound soil is still unclear. The study of the microstructure of compound soil is also helpful for improving the macro properties of compound soil by laying the theoretical and technical foundation in the micro level, which provides efficient support for the resource utilization of soft rock.

In this work, soft rock, sand and compound soil were observed by SEM to study the effect of mixing ratio and wheat planting year on the soil microstructure. Compound soil with the mixing ratios of soft rock to sand 1:1, 1:2, and 1:5 which planted in six years, and the ratio was 1:2 planted in one year, five years, and six years were characterized by scanning electron microscope (SEM) to observe the micro structures. Microstructures of soil with different treatments were qualitatively compared. Statistical analysis of the micro images showed the variation trends of particle size and aggregate number, etc., as a function of mixing ratio and wheat planting ages. The application of SEM can not only determine the microstructural changes observed in the soil, but also simultaneously determine the main components of the cement material in the process of sand becoming soil, and compare the particle size distribution information measured by laser particle size analyzer to reveal relationship between the microscopic and Macroscopic composite soil.

Materials and methods

Materials

Soft rock and sand were collected from Yuyang District, Yulin City (108.58°E to 110.24°E, 37.49 °N to 38.58°N). The altitude ranges from 1000 to 1600 m. The area is in medium-temperate arid climate zone. All the experimental fields were artificially sown. The tested wheat variety was Xiaoyan 22, with an average 1000-grain weight of 38 g and a wheat germination rate of 90.1%. The wheat yield is 150 kg / hm^2 and the line spacing is 20 cm. Before wheat planting, apply the base fertilizer (diammonium phosphate 300 kg / hm^2, urea 150 kg / hm^2). Winter irrigation treatment of urea 150 ~ 225 Kg / hm^2, spring application of urea 150 ~ 225 kg / hm^2, irrigation 3 times, winter irrigation 1 time, spring irrigation 1 time, filling period 1 time, chemical weeding 1 time in spring, a spray three defense after heading.In addition, soft rock and sand compound soil after six-year wheat planting with three proportions (1:1, 1:2, 1:5, respectively) and compound soil with ratio of 1:2 after one-year, five-year and six-year crop cultivation were collected respectively. Sample information was given in *Table 1*.

Table 1. *Details of soil samples*

Sample	Mixing Ratio of Soft Rock to Sand	Wheat Planting Year
Soft Rock		
Compound Soil	1:1	6
Compound Soil	1:2	1
Compound Soil	1:2	5
Compound Soil	1:2	6
Compound Soil	1:5	6
Sand		

Methods

The microscopic structure of collected soil samples was characterized by FEI Q45 SEM. Soil samples with a good flat surface were prepared on the sample stage, which were observed at the voltage of 25 kV. The magnification times gradually increased and photographs were taken at magnification times of 100, 500, 1000 and 2000, respectively. The obtained surface microstructure images of soil samples were analyzed and processed. The particle size was measured by the Nano Measure software. Specifically, the scale on the picture was used as a reference, and then lines were crossed on the maximum diameter of all the soil particles, including the attached clay and silty particles, to obtain the particle size. The measurement results were output and the number of particles classified by size into several levels was counted. Through the picture, the number of aggregates and other sample information were also obtained. The soil particle size composition, the number of aggregates, etc., were plotted as a function of mixing ratio of compound soil or wheat planting year.

According to the X-ray diffraction method, clay mineral samples with particle size less than 10 μm and less than 2 μm in 1:2 compound soil with wheat planting years of 1 year, 5 years and 6 years were extracted according to the Stokes settlement theorem. A clay mineral sample having a particle diameter of less than 10 μm is used for determining the total relative content of clay minerals; a clay mineral sample having a particle diameter of less than 2 μm is used to determine the relative content of each clay mineral.

Results and Discussion

Micro-morphology of compound soil

Microstructure of compound soil with different mixing ratios

The texture of soft rock and sand compound soil with different proportions has been studied by laser particle size analyzer (Zhu et al., 2017). The volume of soil particles with different grain sizes was measured by laser, so as to obtain the percentage of each grain size. Compared with this indirect measurement method, it was more intuitive to measure the particle size through micro-image obtained by SEM. In addition, the morphology of the soil particle surface and the interface between particles can be seen.

Fig. 1 showed the SEM images of compound soil with different proportions after wheat planting for six years. *Fig. 1(a-d)*, *Fig. 1(e-h)*, and *Fig. 1(i-l)* respectively illustrated the composite soils with ratios of 1:1, 1:2, and 1:5. The magnification times for images from top to bottom were 100, 500, 1000, and 2000, respectively. From the images of lower magnification times (100 and 500 times), it can be seen that there was more cementing matter between soil particles under the ratio of 1:1. As the content of sand increased, the particles became dispersed and the cementation material became less. In the images with higher magnification times of 1000 and 2000 times, it showed that there were more matter attached on the surface of soil particles under the ratio of 1:1 and 1:2 than that with the ratio of 1:5. With the increasing content of soft rock, the particles mostly presented face contact to each other and more cementing materials bonded them together, maintaining certain content of pores and good agglomeration property.

Microstructure of compound soil with different wheat planting ages

Fig. 2 showed the images of compound soil with the ratio of 1:2 which planted in different ages under SEM. *Fig. 2(a-d)*, *Fig. 2(e-h)* and *Fig. 2(i-l)* were the images of compound soil with one-year, five -year and six-year wheat planting ages, respectively. The magnification times from top to bottom were 100, 500, 1000 and 2000 times, respectively. In lower magnification images of 500 and 1000 times, it can be seen that the surface of soil particles after one-year planting was relatively smooth, while with the increasing wheat planting years, more attachments appeared on the surface of soil particles. Higher magnification images (1000 and 2000 times) indicated that the soils were relatively dispersive after one year wheat planting. The inter-particle boundaries

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1059910610

were clear and cementing matter was less. In contrast, the compound soil planted in five and six years presented closer connection, smaller pores and richer intergranular cementation. This was due to the increase of soil organic matter content during several years of crop cultivation, such as irrigation and fertilization. In addition, root exudates, soil biological activities and their products, and humus etc. can make the soil agglomeration better, so that the soil structure improved remarkably.

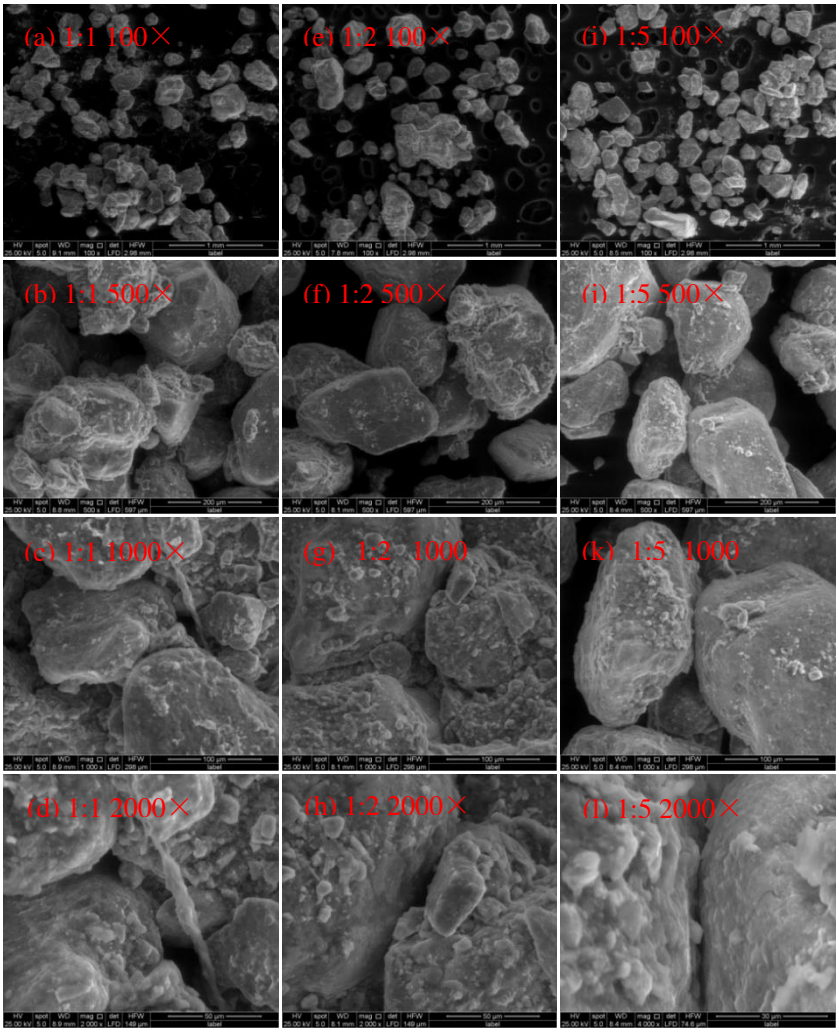

Figure 1. *SEM images of soft rock and sand compound soil with different ratios after six-year wheat planting. The ratios of soft rock to sand were 1:1, 1:2, and 1:5 for (a-d), (e-h), and (i-l), respectively. The magnification times were 100, 500, 1000, and 2000 respectively for (a, e, and i), (b, f, and j), (c, g, and k), and (d, h, and l)*

By section analysis of compound soil aggregates, backscattered electron imaging and X-ray energy spectrometer analysis showed that the elemental composition of cemented materials in compound soil was mostly O, Mg, Al, Si, K, Ca, Fe. In combination with Oades' research on soils with low organic matter content and high clay mineral and iron-aluminum oxide content, it is found that the formation of agglomerates mainly

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1059910610

depends on the cohesive force of cosmids and the cementation of iron-aluminum oxides. It is believed that the cemented material in the compound soil is mainly clay mineral and is closely packed between the bone particles.

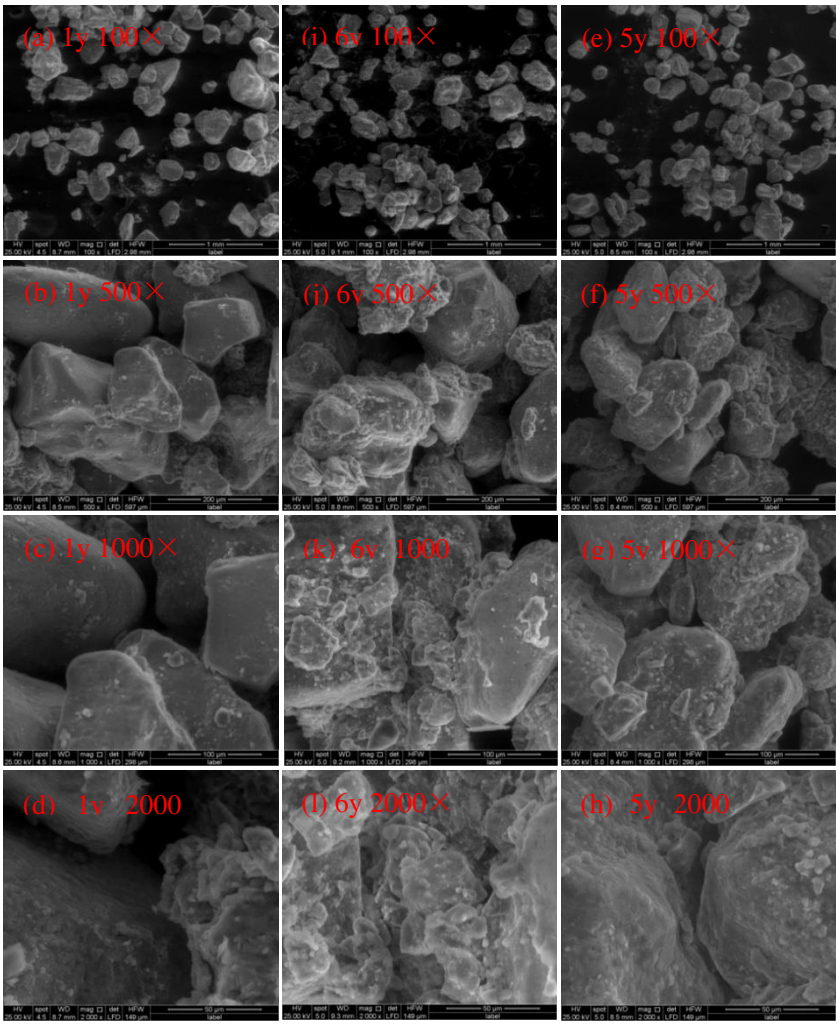

Figure 2. *SEM images of soft rock and sand compound soil with different wheat planting years. The ratio of soft rock to sand was 1:2, and the wheat planting years were one year, five years, and six years for (a-d), (e-h), and (i-l), respectively. The magnification times were 100, 500, 1000, and 2000 respectively for (a, e, and i), (b, f, and j), (c, g, and k), and (d, h, and l)*

According to the XRD analysis, the content of clay minerals in the compound soil increased with the increasing wheat planting years, shown as *Table 2* and increased from 18.2% after wheat planting in 1 year to 22.4% after 6 years wheat planting, which greatly improved the cementing property of the compound soil. There is a significant difference between the compound soil of 5 years and 6 years and the initial stage of compounding. The clay minerals in the compound soil were mainly water-sensitive illite-montmorillonite mixed layer, which accounts for 49~51% of clay minerals, and the proportion of different kinds of clay minerals was similar.

Particle gradation of compound soil

According to the soil texture classification of United States Department of Agriculture (USDA) (Drzymala, 2000), the range of sandy particle size 0.05 to 1 mm, while in this paper, the sandy particle was divided into fine sandy particles (0.05~0.25 mm) and coarse sandy particles (0.25~1 mm). The particles whose size ranged from 0.002 to 0.05 mm were called silty particles and that smaller than 0.002 mm were called clay particles. Since the resolution capacity is not enough for the Nano Measure software to distinguish the clay particles, the 0 to 0.05 mm particles were all denoted as silty particles in this work, in which 0 ~ 0.01 mm and 0.01 ~ 0.05 mm particles were denoted as fine and coarse silty particles, respectively.

Particle gradation of compound soil with different mixing ratios

As shown in *Fig. 3*, the content of sandy particles in sand was more than 63.5%, and the content of fine silty particles (0~0.01 mm) was only 2.3%. The content of sandy particles in soft rock was about 19.6%, and the content of fine silty particles was up to 32.3%. In addition, the content of coarse silty particles was also very high, about 48.1%.

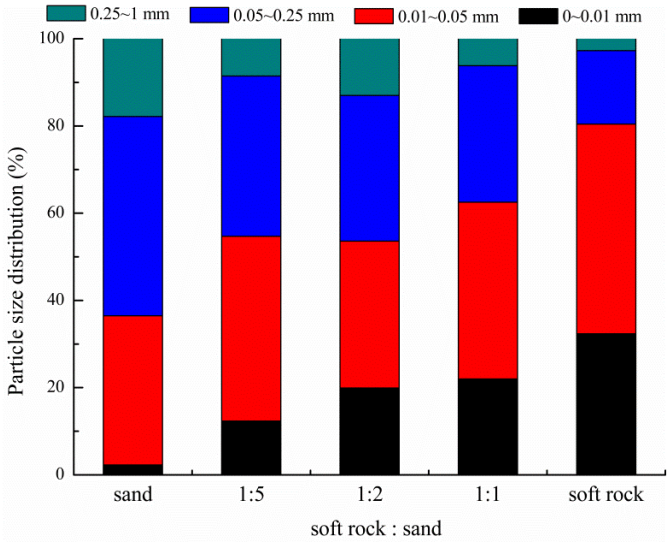

Figure 3. *The particle size distribution of soft rock and sand compound soil with different mixing ratios after six-year wheat planting*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1059910610

By comparison, the measurement results of particle size by SEM and laser particle size analyzer (Zhang et al., 2015) were basically the same. It indicated that the riched fine particles in soft rock made up for the lack of fine particles in sand. The content of sandy particles in compound soil with the ratio of 1:1 was about 37.5%, in which about 6.2% was coarse sandy particles, and the content of silty particles was about 62.5%, in which the fine silty particles was about 40.5%. Compared with sand, the content of silty particles increased by about 26%, and the content of sandy particles decreased by about 26%. The particle size distribution of compound soil can be altered by adjusting the proportion of soft rock and sand. With the adding soft rock into sand, the percentage of coarse particles decreased while the fine particles increased. Furthermore, the trend was more obvious with the increasing proportion of soft rock in sand. The mixing of soft rock and sand not only significantly improved the soil texture but also increased the content of fine particles, which was beneficial to the formation of soil agglomeration and capillary pores, so as to enhance the water retention capacity of soil.

Particle gradation of compound soil with different wheat planting ages

Fig. 4 displayed the particle size distribution of compound soil with the ratio of 1:2 as a function of wheat planting year. It can be seen that the content of coarse sandy particles decreased with the increase of wheat planting period, from 9.2% for one-year tillage to 2.0% for six-year tillage.

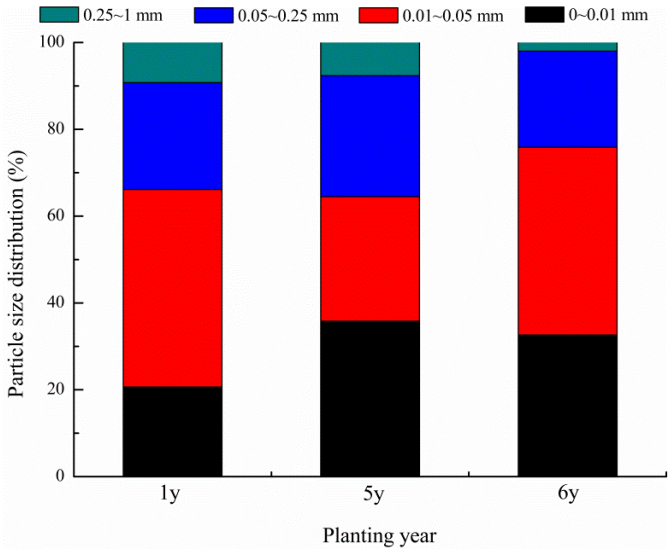

Figure 4. *The particle size distribution of soft rock and sand compound soil (the ratio is 1:2) with different wheat planting years*

Besides, the content of fine silty particles increased from 20.7% for one-year wheat planting to 32.6% for six-year wheat planting. With the increase of tillage time, the content of sandy particles decreased while silty particles increased, which was attributed to the comprehensive actions of tillage, irrigation, and activities of crop root, animal and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1059910610

microorganism. By comparing the particle size distribution of compound soil after five-year and one-year wheat planting, it can be found that with the increasing wheat planting years, the coarse sandy particles crushed into fine sandy or silty particles and coarse silty particles crushed into fine silty particles under the action of root and microorganisms. Thus, the content of coarse sandy and coarse silty grains decreased, while the content of fine sandy and fine silty grains increased. After six-year wheat planting, soil particles continued to become finer gradually, therefore, the content of coarse and fine sandy granules declined, and the content of coarse and fine silty particles increased, which was conducive to the rational distribution of soil particles, the formation of pore structure with good performance of ventilation, water permeability, fertilizer holding, etc. Thus, the land quality was improved.

Aggregation characteristics of compound soil

Fig. 5 was the mean number of coacervates in multiple images (the magnification times was 100) of compound soil after six-year wheat planting as a function of the mixing ratio. With the increase of soft rock in sand, the number of coacervates also increased, raging from 1 for the ratio of 1:5 to 2.5 for the ratio of 1:1. From the ratio of 1:5 to 1:1, the number of coacervates increased by 75.0% and 42.9%, respectively.

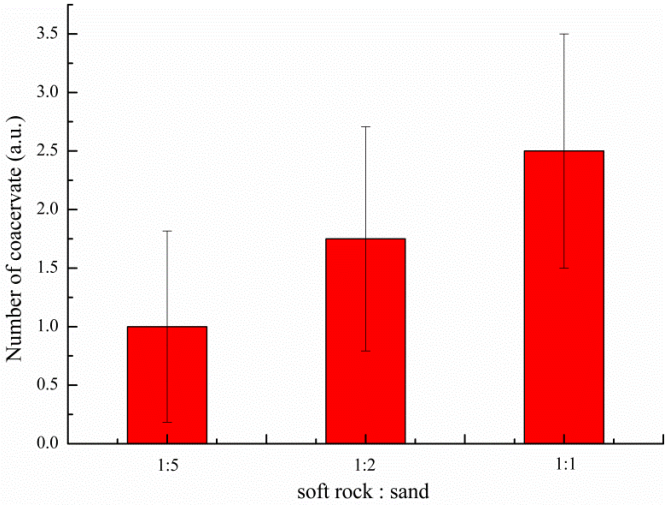

Figure 5. *The number of coacervate of soft rock and sand compound soil with different ratios after six-year wheat planting*

Fig. 6 was the mean number of coacervates in 100 times magnification of compound soil with ratio of 1:2, which plotted as a function of wheat planting year. With the increase of the wheat planting period, the number of coacervates increased too, varying from 2 for one-year wheat planting to 8 for the six-year wheat planting. Among three wheat planting, the increase in the number of coacervates was 100.0%. In terms of the relationship between particle size and formation of aggregates, it was considered that the more the fine particles, the stronger the soil aggregation ability. Aggregation refers

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1059910610

to the process of agglomeration of soil particles resulted from various forces. The main external forces included the effects of plant roots, fossorial animals, soil tillage, alternation of dry and wet, and alternation of freeze and thaw, etc. Section 3.2.1 indicated that after six years wheat planting, with the increasing proportion of soft rock in the compound soil, the content of sandy grains decreased while the silty grains increased. The finer particles would accelerate the formation of aggregates, which was consistent with the result shown in *Fig. 5*. It can be seen in section 3.2.2 that with the increasing wheat planting years, for the compound soil with the ratio of 1:2, the soil particles became finer, which was beneficial to the formation of aggregates.

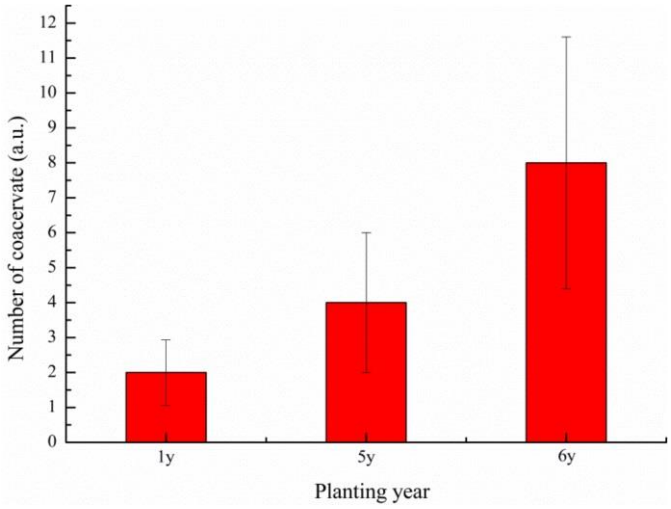

Figure 6. *The number of coacervate of soft rock and sand compound soil (the ratio was 1:2) with different wheat planting years*

In *Fig. 6*, the number of aggregates increased with the increasing wheat planting ages, resulting from the inserting, cutting, squeezing effect of plant roots and fossorial animal during the wheat planting period. In addition, the enwinding of mycelium to the soil particles played a role as forming power (Aspiras et al., 1971; Tisdall and Oades, 1980), and mycelial secretion played an important role of cementing soil particles (Martin et al., 1955). Timely and reasonable cultivation, intertillage, raking, repression and other measures with chopping, squeezing and other effects would also be conducive to the formation of aggregates.

Conclusion

The improvement effect of sandy soil properties by mixing soft rock and sand into compound soil was studied with the mono-factor analysis method under SEM. The samples were compound soil planted in six years with mixing ratio of 1:1, 1:2, 1:5, respectively, and compound soil planted in one, five and six years with the ratio of 1:2. The effect of mixing ratio and wheat planting ages on microstructure and properties of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1059910610

compound soil was analyzed. It was found that with the increasing amount of soft rock in compound soil, the soil particles became much more fine. The grain composition of sandy soil was significantly improved by adding of soft rock. The content of silty particles for compound soil planted in six years with the ratio of 1:1 increased by 26% compared to the sandy soil, and the sandy particles decreased by about 26%. With the increase of wheat planting period, due to farming activities and activities of plant roots and soil microorganisms, etc., soil particles of compound soil continuously got finer, and the distribution of particle size became more reasonable. The content of coarse sandy particles decreased from 9.2% for one-year wheat planting to 2.0% for six-year wheat planting, while the content of fine silty particles increased from 20.7% to 32.6%. With the increasing content of soft rock in compound soil or the wheat planting period, the number of soil aggregates increased, raging from 1 for 1:5 ratio to 2.5 for 1:1 ratio planted in six years, and from 2 for one-year wheat planting to 8 for six-year wheat planting whose ratio was 1:2. In conclusion, soil quality has been improved with the addition of soft rock or the increase of planting years. Finally, the analysis of microstructure for compound soil laid a good foundation for the study of the inherent mechanism of macroscopic performance.

(Received 1st Mar 2019; accepted 21st May 2019)

Abstract. Agricultural non-point source pollution of aquifer, lake, riverbank and other ecosystems is caused by chemical fertilizer, pesticide, animal manure and other organic or inorganic pollutants through surface runoff and farmland leaching in agricultural production. The non-point source pollution has the characteristics of wide distribution, concealment, randomness, hysteresis and complex formation mechanism, and thus it is difficult to study and control this type of pollution. Understanding the mechanism of agricultural non-point source pollution and comprehensively being aware of the pollution sources are of great theoretical and practical significance for future research. In this paper, the mechanism of agricultural non-point source pollution was analysed in terms of rainfall and runoff process, soil erosion process, pollutant migration and transformation, and so on. In addition, the sources and sinks of nitrogen, livestock and poultry pollutants, pesticides, plastic film and other pollution sources were discussed, and the results could be informative for the formulation of agricultural sustainable development policies.
Keywords: *non-point source pollutants, agricultural runoff, livestock and poultry raising, pesticide pollution, contaminant transport, geographic information system*

Introduction

With the continuous strengthening of human economic activities, water environmental pollution has become a global problem. According to the types of pollution, it is divided into point source and non - point source. Point source pollution has been effectively treated by controlling industrial wastewater and urban sewage, but the problem of non-point source pollution has not been effectively solved. Agricultural non-point source pollution is caused by the non-point-source pollutants including chemical fertilizers, pesticides, livestock and poultry manure, and farmland leachate, produced in agricultural production processes (Wang et al., 2007). In recent years, agricultural non-point source pollution has been worsened and drawn more attention. Agricultural non-point source pollution can lead to surface water eutrophication and groundwater pollution, threatening aquatic habitats. Hence, it has been regarded as one of the main pollution sources of surface water and groundwater (Ma et al., 2003). Compared to point source pollution, non-point source pollution has a wider space-time range, greater uncertainty and affected by many factors such as geographical conditions, climate conditions, soil structures and vegetation coverage, thus increasing the difficulty of research, decontamination and management (Pei et al., 2010; Babin et al., 2016). At present, many scholars have studied on the agricultural non-point source pollution, and governments have also been involved in the management and abatement of agricultural non-point source pollution.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1061110621

At present, the pollution composition is rapidly transformed in China (Chen et al., 2004). Especially, the excessive application of nitrogen and phosphorus fertilizers in China rural area has caused serious environmental problems. Because Livestock-poultry farming and domestic sewage was not centralized and treated, a large amount of manure was directly disposed of into the water body through surface runoff generated by rainstorm. Consequently, the problem of agricultural non-point source pollution in a watershed was aggravated. In this paper, pollutant sources and process and mechanism on non-point source pollution were reviewed and the information obtained could be beneficial for the formulation of agricultural sustainable development policies in China.

Sources of pollutants

Sources and sinks of nitrogen

In order to comprehensively understand the current situation of total nitrogen pollution in the water source area of the Middle Route Project of the South to North Water Diversion and effectively grasp the sources of pollution and formulate systematic countermeasures, Xin and Xu (2018) carried out the field monitoring and data collections of 7 reservoir sections, 16 reservoir tributaries and 62 typical reservoir bays in Danjiangkou Reservoir area. The environmental issues resulting from nitrogen have been extensively studied (Jacobsen et al., 2016; Walters et al., 2017), but most of the studies only focused on a specific problem, and rarely conducted comprehensive studies on the various links of nitrogen cycles in watersheds (Rowe et al., 2016). Therefore, the understanding of the nitrogen cycles in watersheds is usually one-sided and not qualified to provide scientific information for the decision-making of environmental management in the watersheds (*Table 1*).

Table 1. *China's pesticide application and main grain production from 2010 to 2016 (10^4t)*

Item	2010	2011	2012	2013	2014	2015	2016
Pesticide	175	179	181	180	181	179	175
Staple food	54648	57121	58958	60194	60703	62144	61625

Sha et al. (2018) carried out model analysis on the characteristics of the load flux and source composition of the total nitrogen pollutants in the water body, employed The regional nutrient management model (ReNuMa) to model the total nitrogen source apportionments of Lianjiang River and estimate the future pollution fluxes and contribution proportion under changed climate conditions, which were further compared to current status to estimate the response of watershed non-point source pollution to climate change. To date, the research on the deposition of atmospheric nitrogen has not been sufficiently done in China. Thus, the basic data are insufficient, and the research methods and technologies are still developing. At present, merely scattered data of rainwater nitrogen contents in China have been reported, and the quantitative studies on the dry and wet deposition intensities, space-time distribution and the sources of atmospheric nitrogen at watershed scales have not been documented (Singh and Pandey, 2018). Collected surface water samples from Guanzhong area, Shanxi, in the Weihe River Basin so as to prevent and control the nitrate nitrogen (NO_3^- - N) pollution of the surface water in the watershed. For this purpose, Zhang et al. (2018) have done the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1061110621

hydrochemical assessment and nitrogen isotopic measurement to determine the pollution levels of nitrate by identifying its main pollution sources on the water surface. Limited by experimental conditions, the applications of stable nitrogen isotopes in the identification of atmospheric nitrogen deposition and nitrogen sources of surface water were rarely attempted in China (Xiao and Liu, 2002).

Livestock and poultry breeding pollutants

After the reform and opening in China, the livestock and poultry breeding industry in China has been developed rapidly (Qian et al., 2018), but some of the farms possessed poor equipment and bad management, resulting in pollution problems because of livestock and poultry waste (Huang et al., 2006). China began to recognize the harm of livestock and poultry waste to environment in 1990s (Wang et al., 2017a). However, the research on this kind of pollution was still developing in China. Ji et al. (2017) took the total nitrogen emission from livestock and poultry breeding in the Zhexi Reservoir Basin as the research object, calculated the water environment capacity and the total nitrogen pollutant emission load of livestock and poultry breeding on the small watershed scale, and determined the response relationship between the environment capacity of the river basin and the total nitrogen emission of the livestock and poultry according to the pollutant discharge contribution rates of different industries. Wang et al. (2017b) conducted hotspot analyses for total and respective livestock numbers in China for the years 1992, 2002, and 2012. Based on these analyses, the main livestock pollutants of the hot spot provinces were estimated using the discharge coefficient method. In order to characterize the spatial distribution of non-point source pollution in the Yanghe Reservoir watershed, based on land use, agricultural management, and other data, Chen et al. (2018) calculated the load of four pollutants (TN, TP, NH_3-N and COD). Pollutant sources included domestic wastewater, solid waste, livestock and poultry breeding, chemical fertilizer loss, soil erosion and urban runoff. The spatial distribution of sources was analyzed using ArcGIS. In practice, the rapid development of livestock and poultry breeding in China has significantly affected the regional environmental quality (Xu et al., 2018), and the surface water and groundwater in certain regions have been largely polluted. Due to the lack of understanding of the various loss routes of livestock and poultry breeding waste and the quantitative migration rules of nutritional elements, the environmental pollution issues ascribed to livestock and poultry breeding have not been quantitatively studied, which affects the development of livestock and poultry pollution management regulations.

Pesticides pollution

Excessive unreasonable application of pesticides causes pollution (Vryzas, 2018; Yang et al., 2018). According to the literatures, more than 84% of peasants applied pesticides in excess of the standards (Li and Yin, 2001). As a result, highly toxic and highly persistent pesticides would be discharged into the environment, polluting crops, soil, atmosphere and water (Yang et al., 2009). The excessive application leads to the majority of pesticides were discharged into the soil and atmosphere (Lai, 2017). Hu et al. (2016) collected rice and soil samples from 11 counties and cities around Poyang Lake according to the pollution status of organic chlorine pesticides (OCPS) pollution in rice and soil in the area around Poyang Lake, and used Gas chromatograph - electron capture detector (GC-ECD) technology to determine organo chlorine residue. The OCPs from the rice samples were evaluated with the health risk assessment model. With the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1061110621

aim of ecological restoration for surface water that suffered from pesticides and domestic waste water pollution in a agricultural village, Jin et al. (2017) established a Vallisneria natans and Hydrilla verticillata demonstration area in August 2015, and evaluated the effect of submerged vegetation restoration on the control of seven pesticides, the recovery of macrozoobenthos and the reduction of conventional water quality indicators. At present, the relative research in China mainly focused on the highly persistent organ chlorine pesticides (Yuan et al., 2003; Kang et al., 2003). Because of their persistence, the pollution effect of organochlorine pesticides residues on the soil in China will last for a long time. In addition, at present, the research on widespread and highly toxic organophosphorus pesticides (Wu et al., 2018; Chahkandi et al., 2019) focused on the development of detection methodology and analysis of the residues over vegetables, fruits and crops (Wan et al., 2004; Yang et al., 2004).

White pollution

Since the 1980s, agricultural film mulching technology has been widely applied. This technology has brought economic benefits but caused serious environmental problems (Yang et al., 2009). The agricultural film has remarkable effects in resisting natural disasters, expanding planting area of crops and increasing yields. Meanwhile, the plastic residues harm the environment and soil (Yan et al., 2006). A large amount of residual agricultural film was dispersed in soil and could not be degraded, which not only reduced the permeability, water content, and drought resistance of farmlands, but also seriously affected the growth of plant roots and water-fertilizer transport, resulting in the reduction of crops yields (Hu and Zhang, 2003). To date, the number and distribution of agricultural film residues in local regions and the harm to soil and crops growth have been extensively studied, but long-term, systematic and large-scale follow-up studies and observation experiments are still insufficient.

Mechanism study

Surface runoff

The runoff formed by rainfall is a carrier for non-point source pollutants migration and transformation (Ma, 2019). Thus, the characteristics of runoff generation and confluence as a response to rainstorm events were usually investigated from the points of view of hydrology and hydrodynamics. At the beginning, a typical SCS-CN model (Soil Conservation Service-Curve Number, USDA-SCS, 1972) was usually adopted in the research on non-point source pollution. Afterwards, Lutz revised the SCS method by taking the soil moisture conditions (such as basic flow factor) in the early stage into account, which renders the Lutz method more accurate in the simulation of hydrological parameters. During the same period, a number of watershed hydrological models were also developed (Villamizar and Brown, 2016), such as the Stanford Watershed Model (SWM) (Crawford, 1996). In the early 1960s, the excess storage, excess infiltration and integrated runoff generation theories were proposed in China (Hu and Lu, 2019). These theories have been gradually applied in the studies on the non-point source pollution. In addition, in view of the small number of non-point source pollution monitoring data in China, Li (2000) proposed a simple and practical average-concentration algorithm for estimating the non-point source pollution load in watersheds based on the formation process of pollution. Liang et al. (2005) used a small-scale artificial rainfall simulator to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1061110621

launch natural heavy rain experiments in four typical land-use types around the Guanting Reservoir. On the basis of the experiments, the migration process of nitrogen and phosphorus along with rainstorm runoff and runoff sediments was studied, and the loss rates of total nitrogen and total phosphorus in different land-use types were also estimated. In order to investigate effects of under different vegetation coverage (0%, 15%, 30%, 45%, 60%, 75%, 90%), slope lengths (3 m, 4 m, 5 m) and fertilizer treatments (control (CK) and compound N-P-K fertilizer (CF)) on runoff producing processes and nitrogen loss, Wu et al. (2019) conducted an artificial simulated rainfall experiment.

Soil erosion

Soil erosion issue is common in the world, and it affects the production and livings of people (Yuan et al., 2019). Soil erosion is one of the primary forms of agricultural non-point source pollution (Zhang et al., 2019). In the late 1960s, the Universal Soil Loss Equation (USLE) was prevalent in the simulation and estimation of long-term average soil loss in the erosion processes of slope lands (Wischmeier and Smith, 1978). Huang et al. (2003) predicted the non-point source pollution load discharged into the Yahekou reservoir using the USLE equation, which taking six factors of rainfall, soil erodibility, slope length, slope, and crop and management measures into account. This model was continuously revised and extended until a Revised Universal Soil Loss Equation (RUSLE) model (Daniel et al., 1994) was developed. Wang (2006) adopted the RUSLE equation and SCS hydrological model to estimate the nitrogen and phosphorus pollution loads in the Chaohu Lake Watershed. Zhou et al. (2015) systematically evaluated and analyzed the risks of agricultural non-point source pollution in the Ashi River Watershed based on a modified universal soil loss equation (MUSLE) model. In the early 1980s, a WEPP (Water Erosion Prediction Project) model was proposed to study the mechanism of soil erosion. On the basis of the meteorological data and soil erosion moduli of field runoff plots in Huajiang demonstration area in 2006 and 2010, Long et al. (2014) estimated the annual average soil erosion moduli at different rocky desertification levels, and evaluated the applicability of the WEEP model in Karst rocky desertification area. Likewise, on the basis of the meteorological data and monitoring data of field runoff plots in an experimental station in Binxian County, Heilongjiang Province in 2008, Liu et al. (2010) estimated the secondary rainfall runoff and soil loss in the black soil area of Northeast China using the WEPP model, and evaluated the applicability of WEPP model by comparing with the measured data. Wang et al. (2019) selected seven sub-basins of the Chaohu Basin as the target area, established a sediment delivery distribution model to quantitatively estimate the particulate phosphorus loading modules (PPLM) of the Chaohu Basin in 2015 and determined the differences in the loss of particulate phosphorus and their causes under different land use patterns.

Migration and transformation of pollutants

The migration of non-point source pollutants refers to the process of non-point source pollutants diffusing from the soil circle to other circles (Lu and Xie, 2018), especially the hydrosphere, under the action of external forces (rainfall, irrigation, etc.). Some of the agricultural non-point source pollutants were discharged into ditch wetland systems along with field drainage. After the interception and reduction by the ditch wetland systems, the residual pollutants were eventually discharged into rivers, lakes

DOI: http://dx.doi.org/10.15666/aeer/1705_1061110621

and other water bodies (Wei et al., 2016), causing pollution to the surface water environment (Chen, 2000). A series of studies have been launched on the relationships between nitrogen and phosphorus loss due to farmland rainfall runoff and farmland tillage patterns, crops growth seasons, rainfall characteristics, land utilization, topographic conditions and vegetation cover (Hong et al., 2007). Liu et al. (1988) investigated the non-point source pollution in the Yuqiao Reservoir Watershed of Tianjin City and the results showed that vegetation was a key factor restricting the spatial variability of non-point source pollution (*Figure 1*).

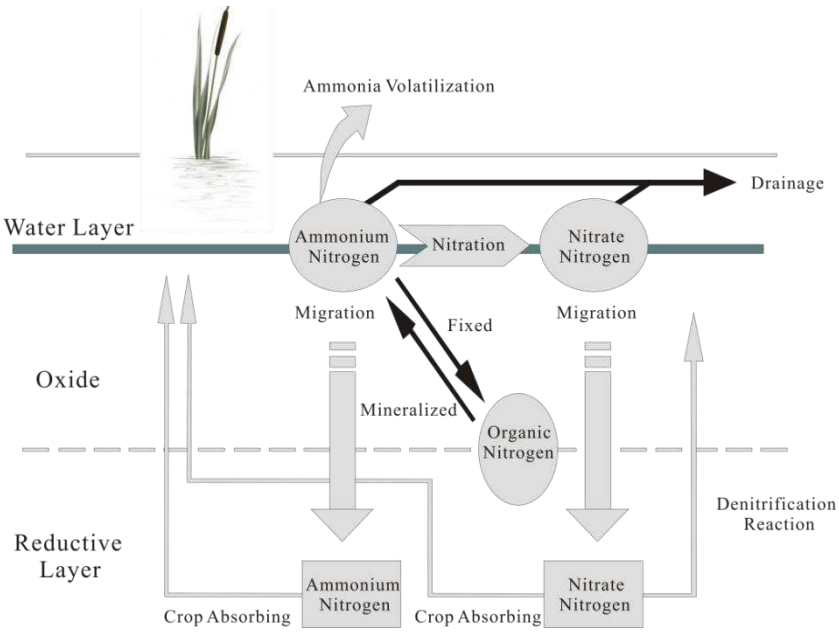

Figure 1. *Conversion of ammonium and nitrate nitrogen*

Shen et al. (2014) conducted a simulated experiment to determine the interception effectiveness of runoff, sediment, nitrogen, and phosphorus by artificial grass-like Vegetative filter strips (VFS) with different widths. The results indicate that grass VFS are very effective in reducing runoff, sediment, nitrogen, and phosphorus and controlling agricultural non-point source pollution. Kang et al. (2018) investigated and analysed the characteristics of application and surface runoff loss of nitrogen and phosphorus fertilizers in nine cities of Fujian Province during the years of 1985 to 2016. Additionally, they analysed the risk grades of farmlands pollution due to nitrogen and phosphorus fertilizers considering nitrogen and phosphorus fertilizers runoff loss, rainfall and river network density. At the same time, the spatial distribution characteristics of nitrogen and phosphorus contaminated regions were presented through the geographic information system (GIS) analysis. Li et al. (2017) divided paddy field water into surface and subsurface waters. The leaching of surface water and the dissolved solute NH_4^+, NO_3^- and PO_4^{3-} within it were calculated using water-balance method. Water in the soil was simulated numerically from transient flow equation, from which Li et al. (2017) calculated the discharge rate to drainage ditch. Water flow in the drainage network was simulated using the wave equation and the biochemical reaction of the solutes was described by first-order kinetics.

Conclusions and prospects

The mechanism of non-point source pollution was discussed in terms of rainfall and runoff processes, soil erosion process and pollutants migration and transformation processes in this paper. In addition, the non-point-source pollutant sources were analysed in terms of nitrogen sources and sinks, livestock and poultry breeding pollution, chemical fertilizer and pesticide pollution, and white pollution.

The future research should embark on the following: First, the basic monitoring should be enhanced because the agricultural non-point source pollution research should not be separated from field tests and monitoring data. Therefore, the field test, monitoring and management are required to be reinforced, and the correlations between the database of different regions and different watersheds should be increased. Secondly, the pollution research models suitable for China's situations should be established; the agricultural non-point source pollution research models suitable for China's different regions should be established; the agricultural non-point source pollution research in regions without data or with data difficult to derive should be done. Thirdly, the cross-research between related subjects and related fields should be conducted; the agricultural non-point source pollution research should be closely related with geography, ecology, economics, management and other disciplines.

Agricultural non-point source pollution control and management will be a long-term and gradual process, and we can make efforts in the following aspects. First, the simple and cheap alternative technology is the key to the control of agricultural non-point source pollution. Finding alternative economic, simple and feasible technical system to control agricultural non-point source pollution, establishing causality between economic behavior and pollution hazard is the basis of formulating control policy. Second, the promotion and demonstration project operation management mechanism.These include the construction of agricultural non-point source pollution control demonstration area, the formulation of agricultural non-point source pollution control project long-term management mechanism, the establishment of long-term supervision institutions and strengthening the construction of farmers' professional organizations. Third, there should be different management policies for different pollution sources. For example, the use of chemical fertilizers and pesticides can be controlled by levying taxes, subsidizing agricultural environmental policies and insuring against risks. Fourth, we should promote modern agricultural technologies, raise the level of agricultural production, implement multi-dimensional innovation, and comprehensively promote the prevention and control of agricultural non-point source pollution.

The mechanisms of agricultural non-point source pollution have been greatly developed. The relationships between the pollution and sustainable development of agriculture as well as the negative influences of the pollution on ecological environment and human health have been well agreed. The relative results have effectively promoted people's understanding of the serious environmental consequences of agricultural non-point source pollution.

(Received 1st Mar 2019; accepted 21st May 2019)

Abstract. *Microcystis* occurs as colonies in natural waters and always disaggregates into unicellular cells in the laboratory. Cadmium (Cd) could stimulate *Microcystis* colony formation in the laboratory. To elucidate the mechanism involved in cadmium-induced colony formation of *Microcystis*, microcystin (MC) changes and proteomic responses in *M. aeruginosa* treated with seven concentrations of Cd (0, 0.0125, 0.0250, 0.0500, 0.1000, 0.2000 and 0.4000 mg/L) for 40 h were studied. The results showed that seven concentrations of Cd except 0.4000 mg/L Cd could significantly induce colony formation ($P < 0.05$), and the Cd-induced colony-stimulating effects were accompanied with the increased intracellular MC-RR production. A total of 1170 proteins, including seven MC biosynthesis-related enzymes and seven polysaccharide biosynthesis-related enzymes, were identified using 2D-LC-MS/MS combined with isobaric tags for relative and absolute quantitation (iTRAQ). 0.4000 mg/L Cd could downregulate all the identified enzymes involved in MC and polysaccharide biosynthesis while most of these enzymes were upregulated during Cd-induced colony formation. Cd might stimulate *Microcystis* colony formation via increasing the biosynthesis of MC and polysaccharide.
Keywords: *cyanotoxin, polysaccharide, heavy metal ions, iTRAQ, Cyanobacteria colony*

Introduction

Cyanobacteria blooms have been paid more and more attention all over the world for their toxic impacts on freshwater environments and human health (O'Neil et al., 2012). *Microcystis* is a common cyanobacterial genus forming blooms (Shen and Song, 2007). In natural freshwaters, *Microcystis* cells always aggregate into colonies (Zhu et al., 2016). Colony formation provides *Microcystis* with a competitive advantage in preventing zooplankton grazing, viral and bacterial attack (Yang and Kong, 2012). However, the mechanism involved in *Microcystis* colony formation remains poorly understood.

In laboratory cultures, *Microcystis* is hard to keep colonial phenotype and colonial *Microcystis* usually disaggregates into single cells or a few paired cells (Huisman et al.,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1062310636

2018). Previous studies have identified that zooplankton grazing pressure (Yang et al., 2012), ultraviolet radiation (Sommaruga et al., 2008), heterotrophic bacteria cocultivation (Shen et al., 2011), low light intensities and temperatures (Li et al., 2013) could stimulate colony formation of *Microcystis* cultured in the laboratory. Moreover, we found that the contents of lead (Pb), cadmium (Cd), chromium (Cr), aluminium (Al), ferrum (Fe), and manganese (Mn) in *Microcystis* cell were significantly positive with the colony size in natural freshwaters (Bi et al., 2015). Cd(II) could promote *Microcystis* colony formation in an appropriate concentration range (Bi et al., 2016). Moreover, Gan et al. (2012) found that microcystin (MC, a typical cyanotoxin), supplementation in medium could enhance the size of *Microcystis* colony and depletion of MC could dramatically decrease colony size. Different from above external biotic and abiotic environmental factors, MC released by toxic *Microcystis* might act as an internal signal factor influencing the aggregation of *Microcystis* cells.

Proteomics, the large-scale analysis of proteins, can link the upstream genome and the downstream metabolome (Wilmes and Bond, 2009). Proteomic analysis has been widely applied in reflecting functional protein dynamic responses of cyanobacteria under stress (Alexova et al., 2016). According to the proteomic responses of *M. aeruginosa* to N or P starvation, Yue et al. (2015) found that N limitation enhanced the expression of several proteins relating to cellular C metabolism and fixation while P limitation downregulated the proteins involved in protein synthesis and the assimilation of C and N. Proteomic response of *M. aeruginosa* revealed that long-term exposure of amoxicillin could affect the cellular biosynthesis process and the metabolism of nucleoside phosphate and carbohydrate (Liu et al., 2016).

To make clear how heavy metals affect colony formation of *Microcystis*, *M. aeruginosa* were treated with seven concentrations of Cd for 40 h, and their changes in the colony formation, intracellular MC contents and proteomic responses were investigated. The results will help us reveal the impact of heavy metals on the breakout of *Microcystis* blooms in natural waters.

Materials and methods

Algal culture conditions

M. aeruginosa FACHB-905 was purchased from the Institute of Hydrobiology, Chinese Academy of Sciences. Algae were cultured in BG11 medium (without EDTA) under a L:D (12 h: 12 h) cycle at a light intensity of 40 μmol/m^2/s at 25 °C. Stock solution of $CdCl_2$ (Merck, Germany) was added to algae cultured to the exponential phase, and the final concentrations of Cd were prepared as follows: 0.0125 (Cd_A), 0.0250 (Cd_B), 0.0500 (Cd_C), 0.1000 (Cd_D), 0.2000 (Cd_E) and 0.4000 mg/L (Cd_F). The culture without Cd was used as control group (CK). All groups were done in triplicate, and the initial density of *M. aeruginosa* was 5.2 $\times 10^6$ ind/L. After 40 h, samples were taken from algal cultures to study changes in cell densities, colony numbers, MC content and proteomic analysis.

Counting algal cell density and colony

Algal cell density and colony were counted using a hemocytometer under microscope. Samples were collected 1 cm below the medium surface, and the flasks

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1062310636

were shaken up slightly before sampling. Algal phenotype was classified as unicellular, two-cell aggregation and colony (aggregation of ≥ 3 cells).

Intracellular MC extraction and analysis

Intracellular MC was extracted and measured according to the method of Bi et al. (2017) using high-performance liquid chromatography (SPD-M20A, Shimadzu, Japan) equipped with a Shim-Pack VP-ODS column (250 mm × 4.6 mm). MC-RR was identified by its characteristic UV spectra and retention time, and spiked with purified standards of MC-RR (Sigma, USA).

Proteomic analysis

Sampling, proteins extraction and iTRAQ labeling

Samples were extracted with Lysis buffer (8 M Urea, 40 mM Tris-HCl or TEAB, pH 8.5) containing 2 mM EDTA and 1mM PMSF, and then added with 10 mM DTT after being kept on ice for 5 min, then were sonicated at 200 W for 1 min. After centrifugation (25000 g, 4 °C) for 20 min, the supernatants obtained were incubated at 56 °C for 1 h and cooled to room temperature, then incubated with 55 mM IAM (for alkylation) in darkness for 45 min, and then centrifuged (25000 g, 4 °C) for 20 min. Protein concentrations were quantified using Bradford method. The protein solution (100 μg) with 8 M urea was diluted 4 times with 100 mM TEAB. For iTRAQ analysis, proteins were digested with Trypsin Gold (Promega, Madison, WI, USA) with a protein-to-trypsin ratio of 40:1 at 37 °C overnight, and peptides were desalted with a Strata X C18 column and vacuum-dried. The peptides were dissolved in 30 ul 0.5 M TEAB via vortexing. ITRAQ labeling reagents recovered to ambient were transferred and combined with proper samples. Peptide labeling was performed using ITRAQ Reagent 8-plex Kit. The labeled peptides with different reagents were combined and desalted with a Strata X C18 column and vacuum-dried, the above experimental method refers to Wiese et al. (2007).

Peptide fractionation, HPLC, mass spectrometer detection

After being reconstituted with buffer A (5% ACN, 95% H_2O, adjusting pH to 9.8 with ammonia) to 2 mL, labeled peptides were fractioned using a Shimadzu LC-20AB HPLC pump system equipped with a high pH RP column at a flow rate of 1 mL/min with a gradient of buffer B (5% H_2O, 95% ACN, adjusting pH to 9.8 with ammonia): 5% for 10 min, 5-35% for 40 min, 35-95% for 1 min, 95% for 3 min, 95-5% within 1 min followed by 5% buffer for 10 min. Chromatograms were recorded at 214 nm, and fractions were collected at 1-min intervals. In total, 20 fractions were collected and vacuum-dried, dissolved in buffer (2% ACN, 0.1% FA in water) and centrifuged at 20,000 g for 10 min. Supernatants were loaded onto a C18 trap column using a LC-20AD nano-HPLC instrument (Shimadzu, Kyoto, Japan) and eluted, then separated with an analytical C18 column packed in-house at a flow rate of 300 nL/min with the following gradient of buffer (2% H_2O and 0.1% FA in ACN): 8-35% in 35 min; 35-60% in 5 min, 80% for 5 min, 80-5% in 0.1 min and equilibrating for 10 min. Data was acquired with a Triple TOF 5600 System equipped with a Nanospray III source (SCIEX, Framingham, MA, USA) and a pulled quartz tip emitter (New Objectives, Woburn, MA). This procedure was carried out by Beijing Genomics Institute

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1062310636

(Shenzhen, China), the above experimental method refers to Olson et al. (2013) and Lyu et al. (2016).

Protein identification, quantification and data analysis

For an MS/MS Ions Search, each query represented a complete MS/MS spectrum. The common protein databases: NCBInr, SwissProt (Magrane and UniProt Consortium, 2011), and UniProt were used for protein identification. ITRAQ quantification was applied by BGI's IQuant (Wen et al., 2014). Proteins with 1.2-fold change and Q-value less than 0.05 were determined as differentially expressed protein. Genes were annotated by using BLAST* (Altschul and Gish, 1996) against Clusters of Orthologous Groups of proteins database (COG) (Tatusov et al., 2003) and Kyoto Encyclopedia of Genes and Genomes database (KEGG) (Kanehisa et al., 2006). We set Cd_A/CK, Cd_B/CK, Cd_C/CK, Cd_D/CK, Cd_E/CK, Cd_F/CK, as comparison group.

Statistical analysis

Data expressed as means ± SD were subjected to one-way analysis of variance (SPSS ver. 10.0) to determine differences among groups, and least significant difference multiple-range test was used to determine significance differences ($P < 0.05$).

Results and discussion

Effects of Cd on the growth, colony formation and intracellular MC-RR content of M. aeruginosa

As shown in *Figure 1A,* with the increasing Cd concentrations, cell densities of *M. aeruginosa* increased first and then decreased, and the maximum cell density appeared in *M. aeruginosa* exposed to 0.0250 mg/L Cd. As compared to CK, all tested concentrations of Cd except 0.4000 mg/L Cd could significantly induce colony formation ($P < 0.05$), and 0.1000 mg/L Cd showed the best inductive effects (*Fig. 1B*). Intracellular MC-RR contents of *M. aeruginosa* exposed to 0.0250, 0.0500, 0.1000 and 0.2000 mg/L of Cd increased significantly as compared to CK (*Fig. 1C*). Cd could contribute to *M. aeruginosa* cells aggregation, and the Cd-induced colony-stimulating effects accompanied with the increased intracellular MC-RR contents. In our previous research, it was observed that the *Microcystis* colonies with smallest size in natural waters had the highest MC cellular production which decreased with the increasing colony size (Bi et al., 2017), suggesting toxic *Microcystis* might play a vital role in *Microcystis* colony formation via MCs production. Based on our above results, we speculated that Cd could increase the production of MC which acted as an internal signal stimulating the colony formation.

Proteomic analysis of M. aeruginosa exposed to Cd

A total of 405114 spectrums were generated, 7766 peptides and 1170 protein were identified (*Table A1*). According to the distribution of COG classification, it was found that in *M. aeruginosa* FACHB-905 genome, the number of genes relating to energy production and conversion (C), amino acid transport and metabolism (E), carbohydrate transport and metabolism (G) and cell wall/membrane/envelope biogenesis (M) was more than that of other function related genes (*Table A2*). Among all the KEGG

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1062310636

pathways, biosynthesis of secondary metabolites, antibiotics and amino acids accounted for 22.46%, 14.08% and 9.42%, respectively (*Table A3*).

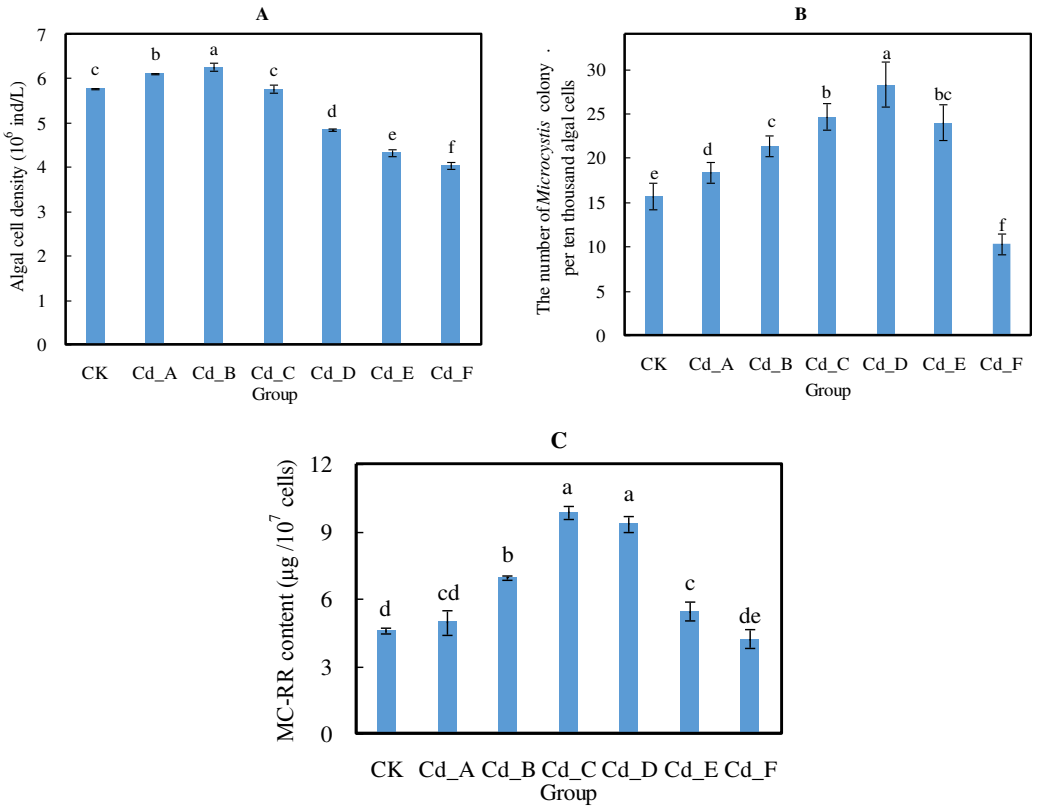

Figure 1. *Effects of Cd on the growth (A), colony formation (B) and intracellular MC-RR content (C) of M. aeruginosa*

MCs are synthesized by a large, modular enzyme complex, including peptide synthetases McyA, McyB, and McyC, a polyketide synthase McyD, two hybrid enzymes (McyE and McyG) consisting of peptide synthetase and polyketide synthase modules, and enzymes putatively involved in the tailoring (McyJ, McyF, and McyI) and transport (McyH) of MCs (Tillett et al., 2000). As shown in *Figure 2,* a total of seven MC biosynthesis-related enzymes, including McyB, McyC, McyD, McyE, McyG, McyI, and McyJ were identified using proteomic analysis. Consistent with the changes in MC-RR, 0.4000 mg/L Cd downregulated all these seven identified MC biosynthesis-related enzymes. 0.050 mg/L Cd upregulated all indentified MC biosynthesis-related enzymes except McyG, and 0.0125 mg/L Cd upregulated all indentified MC biosynthesis-related enzymes except McyJ. Other concentrations of Cd regulated MC biosynthesis-related enzymes to different degree. All tested concentrations of Cd except 0.4000 mg/L Cd could upregulated the expression level of McyC while McyD expression of *M. aeruginosa* exposed to 0.0125-0.0500 mg/L Cd was upregulated (*Table A4*).

Both soluble and total carbohydrates in colonial *Microcystis* cells and sheaths were significantly higher than those in disaggregated cells (Zhang et al., 2007). In colonial *Microcystis,* extracellular polysaccharides (EPS) were the main constituents of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1062310636

sheaths relating to cell aggregation (Plude et al., 1991). Previous researches have proved that biotic and abiotic factors could stimulate polysaccharide production (Xu et al., 2016; Yang et al., 2007). We also found that the contents of intracellular polysaccharide and bound extracellular polysaccharide in Cd-induced *M. aeruginosa* colony increased significantly, which could stimulate aggregation of algal cell and eventually promote colony formation (Bi et al., 2016). Many genes were involved in polysaccharides synthesis pathway, such as *capD*, *csaB*, *tagH*, *rfbB*, and *epsL* (Thurlow et al., 2009). Proteomic analysis showed that all identified polysaccharide biosynthesis-relate enzymes were downregulated in *M. aeruginosa* exposed to 0.4000 mg/L Cd which led to decreased colonies (*Fig. 3*). All concentrations of Cd except 0.4000 mg/L triggered upregulation of capsule biosynthesis protein CapD and sugar ABC transporter substrate-binding protein while rfbB NAD-dependent dehydratase and lipid-A-disaccharide synthase of *M. aeruginosa* exposed to 0.0125-0.0500 mg/L Cd were upregulated. These upregulated polysaccharide biosynthesis-relate enzymes might be responsible for Cd-induced increase in polysaccharides.

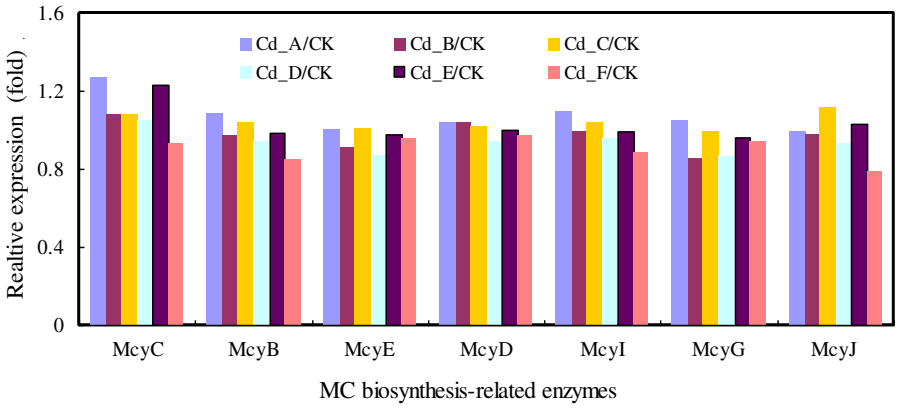

Figure 2. *Cd-induced changes in the expressions of MC biosynthesis-relate enzymes of M. aeruginosa*

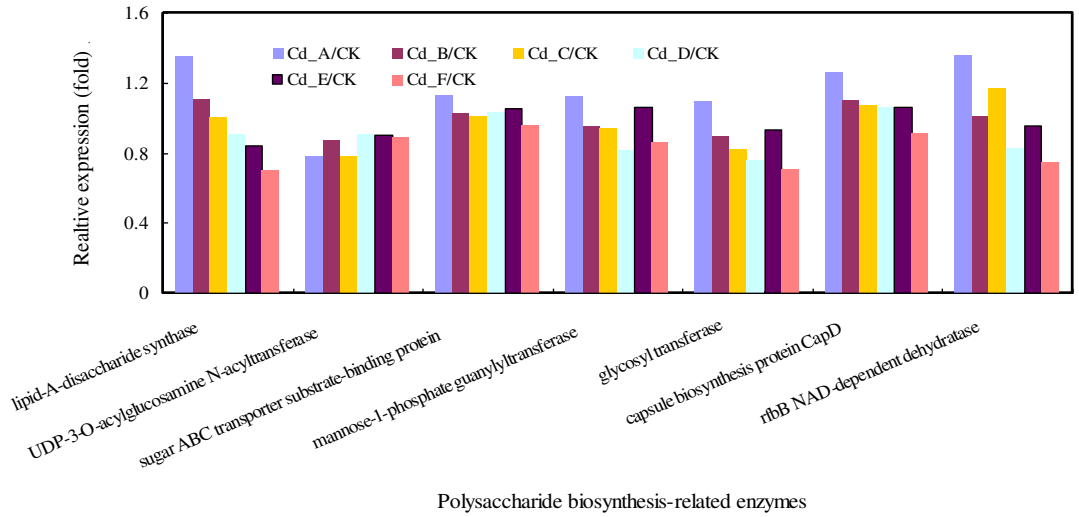

Figure 3. *Cd-induced changes in the expressions of polysaccharide biosynthesis-relate enzymes of M. aeruginosa*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1062310636

The strong competition advantages of *M. aeruginosa* in plankton system are based on its high photosynthetic activity (Amorim et al., 2017). Cd remarkably influenced the porphyrin and chlorophyll metabolism (*Fig. 4*), and photosynthesis (*Fig. 5*) in *M. aeruginosa*. 16 related proteins were upregulated or downregulated significantly in *M. aeruginosa* exposed to 0.4000 mg/L Cd. The expression level of heme oxygenase and ferredoxin: protochlorophyllide reductase increased in all groups, thus preventing or minimizing ROS-induced damages (Zhou et al., 2006). Furthermore, the expression level of magnesium-protoporphyrin IX monomethyl ester cyclase, radical SAM protein, glutamate-tRNA ligase, photosystem II extrinsic protein and ATP synthase increased by more than 27% in *M. aeruginosa* exposed to 0.0125 and 0.0500 mg/L Cd. The increased global effects on photosynthesis could help *M. aeruginosa* enhancing the carbon fixation and energy transfer, and thus promoting the synthesis of polysaccharides and colony formation. When the Cd contention was up to 0.0500 mg/L, the expression level of allophycocyanin subunit beta/alpha and universal stress protein UspA increased by 1.5 fold as compared to the control group, thus protecting DNA against oxidative damage (Bhat and Madyastha, 2001).

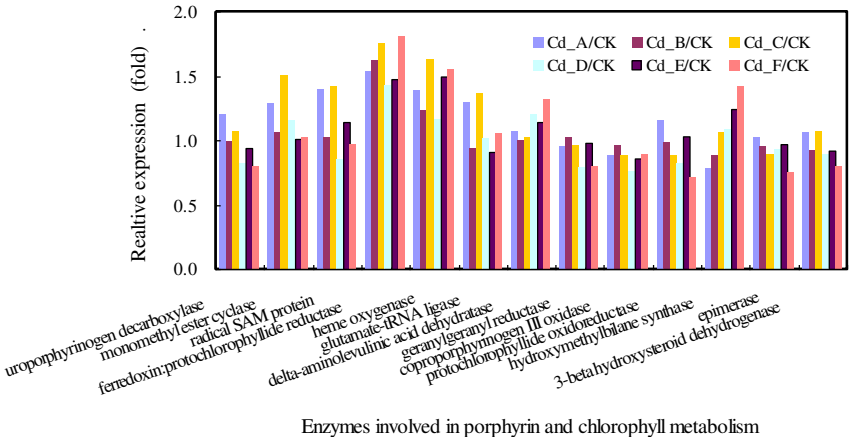

Figure 4. *Cd-induced changes in the expressions of enzymes involved in porphyrin and chlorophyll metabolism of M. aeruginosa*

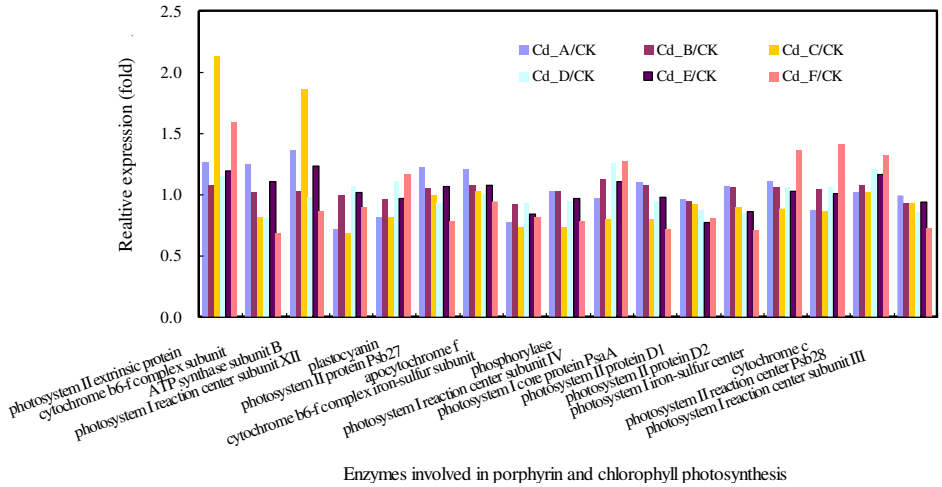

Figure 5. *Cd-induced changes in the expressions of enzymes involved in porphyrin and chlorophyll photosynthesis of M. aeruginosa*

DOI: http://dx.doi.org/10.15666/aeer/1705_1062310636

Consolidate all our findings about the effects of heavy metal ions on the *Microcystis* colony formation, we believe that *Microcystis* could bioaccumulate heavy metal ions, such as Cd, in natural waters, and appropriate heavy metal ions enriched in *Microcystis* cell could promote the synthesis and secretion of polysaccharide and MC in *M. aeruginosa* by upregulated polysaccharide and MC biosynthesis-related enzymes. Heavy metal ions could increase *Microcystis* colony formation in natural waters with the assistance of low concentration of MC, which may act as an important internal signal stimulator.

Conclusions

Proper concentration of heavy metal ions could induce *Microcystis* colony formation. Heavy metal ions could increase *Microcystis* colony formation in natural waters with the assistance of low concentration of MC, which may act as an important internal signal stimulator. Further intensive study should be carried out to reveal the mechanism of synergistic reaction of MC and heavy metal ions.

Abstract. In our study, zeolite, sepiolite, vermiculite and biochar were added to high-concentration lead-contaminated soils, respectively, and the metal fractions, toxicity leaching amount and leaching characteristics of lead (Pb) in soils were studied after 30 d. Besides, the feasibility of chemical immobilization to reduce Pb was investigated. In the soil immobilization experiments, compared with the control, the toxicity leaching amount of soils added zeolite, sepiolite, vermiculite and biochar decreased. The decreasing ratios were 40.12%, 41.28%, 25.50%, and 16.04%, respectively. It is clear that the treatment of zeolite showed the best effect. And the group matching curing agents (GMCAs) with a mass ratio of 2:1 for zeolite and sepiolite was the best, of which the Pb content in soil leaching solutions decreased by 41.4%. Meanwhile, through soil column leaching experiment, compared with the control, the pH of leachates generally increased, and the electrical conductivity (EC) of leachates presented a falling trend. The Pb content of accumulated leachates from treatments decreased, and the best effect treatment was at a mass ratio of 1:2 for zeolite andsepiolite with the highest decrease rate at 93.35%. And the immobilization effect was further verified. Therefore, the addition of curing agents could decrease the bioavailability and migration of Pb.

Introduction

With the advancement of industrial and agricultural modernization, soil heavy metal contamination has become an extremely important and serious global environmental problem in recent decades (Liu et al., 2014). Pb is a common heavy mental pollutant owning to the fact that excessive intake of Pb can damage nerve and human organs such as kidney and liver, increasing the risk of cancer (Taylor et al., 2014; Cao et al., 2015; Schwab et al., 2005). Pb can easily be complexed with soil colloids and adsorbed on oxides and clays because of its hard degradation, limited soluble and chronicity in soils (Suman et al., 2005; Putra et al., 2013). In

DOI: http://dx.doi.org/10.15666/aeer/1705_1063710654

recent decades, due to the industrial pollution caused by human activities such as electroplating, atmospheric deposition from combustion of leaded gasoline, metal smelting and coal mining, Pb concentration in soil has increased dramatically (Tai et al., 2013). Consequently, it is urgent to develop a method for the remediation of Pb-contaminated soils.

At present, the remediation methods of Pb-contaminated soils mainly focus on soil washing, electrodialysis and phytoremediation due to their outstanding effects (Amrate et al., 2005; Gupta et al., 2013; Xu et al., 2014; Suzuki et al., 2014). Although these methods may be effective to remediate Pb-contaminated soils, they usually tend to be expensive and time-consuming (Suman et al., 2005). On the contrary, immobilization as a main potential soil remediation technique has received considerable attention (Hwang et al., 2008; Kumpiene et al., 2008).

The immobilization of heavy mental is a remediation technique applied to decrease the mobility of elements by adding curing agents in soils, so that reducing the bioavailability and solubility of heavy metals (Mcgowen et al., 2001; Mignardi et al., 2012). Soil immobilization technique has been successfully applied to radioactive waste, sediment, and industrial sludge. Compared with other technologies, this technology can be applied widely and the processing time is short. Curing agents have different curing mechanism for heavy metals, such as soil pH, ions exchange, adsorption, coordinating action, co-precipitation, etc. (Suman et al., 2005). However, most studies on heavy metal immobilization treatments aimed at single curing agent remediation, rarely considering GMCAs remediation or verifying further immobilization effect by soil column leaching experiment.

Therefore, this study on batch immobilization experiments and soil column leaching experiment were conducted by selecting four kinds of curing agents, including zeolite, sepiolite, vermiculite and biochar. The purposes of the study were:(1) to compare immobilization effects of different curing agents on Pb-contaminated soils so that screening out the feasible curing agents; (2) to study the leaching characteristics and the rules of migration and transformation of Pb-contaminated soils under different treatments, and to assess the influence of the soils on the surrounding environment after immobilization.

Materials and methods

Soil sample and curing agents

The topsoil layer (0–20 cm) of the tested soil was collected from one battery plant in Chongzhou, Sichuan, China (30°34'N, 103°34'E). The collected soil was dried at room temperature, and then the uniform soils were obtained through a 2 mm nylon mesh. Zeolite, sepiolite, vermiculite and biochar were used in the immobilization experiment. Zeolite is an artificial zeolite. Sepiolite particle diameter is ≤ 74 um. Vermiculite particle size is 0.5~1.5 mm, 12 h after soaking by 7.5% potassium nitrate solution at 600~800 °C heating 5 to 7 min, and then through 100 mesh. Biochar particle size is less than 150 microns to corn starch and coconut shell as raw material, under the environment of low oxygen content at 600 °C high temperature pyrolysis, and then through 100 mesh. All reagents obtained as chemical pure were used in the study. All the solutions were prepared by deionized water. The physical and chemical properties of soil are shown in *Table 1*.

Design of experiment

Design of single curing agent immobilization experiment

Soils samples (50 g) were placed in the beakers (100 mL) and then curing agents (zeolite, sepiolite, vermiculite, and biochar) were added to them, respectively. Batch leaching experiments were conducted at different curing agent concentrations from 0 to 16 $g \cdot kg^{-1}$. Then each beaker was added 20 mL water. The soils dried at room temperature for 2 weeks were sampled by quartering, and then the uniform soils were obtained through a 2 mm nylon mesh. The soil were screened by 100 meshes, dried and frozen, then placed on the conductive adhesive. The morphological characteristics of the materials were observed by scanning electron microscopy (SEM) (JSM-6510LV). Afterwards, effect of curing agents on Pb immobilization in soil was tested by Toxicity Characteristic Leaching Procedure (TCLP). And the concentration of lead ion in filtrate was measured by Atomic Absorption Spectrophotometer (AAS) (AA800, America). In this experiment, three parallel samples were used for each data.

Design of GMCAs immobilization experiment

Soil samples (50 g) were placed in the beakers (100 mL) and then added different curing agents according to *Table 2*. Batch leaching experiments were carried out at curing agent concentration 8 $g \cdot kg^{-1}$. Two kinds of curing agent in each group matching were set at three ratios of 1:1, 1:2 and 2:1. Then each beaker was added 20 mL water. The soils dried at room temperature for 2 weeks were sampled by quartering, and then the uniform soils were obtained through a 2 mm nylon mesh. Afterwards, effect of GMCAs on Pb immobilization in soil was tested by TCLP. And the concentration of lead ion in filtrate was directly determined by AAS.

Design of soil column leaching experiment

Preparation of acid rain

According to the pH of average rainfall and acid rain monitoring data in Southwest China during the period from 1995 to 2003 (Mei, 2006), the simulated acid rain was prepared. The chemical composition of rainfall was presented in *Table 3*. Simulated acid rain leaching experiment was carried out by adjusting pH and compounding the main anion and cation concentrations according to the rainfall characteristics of Southwest China. The acid rain solution (*Table 4*) was prepared by selecting corresponding salts and calculating its mass on the basis of ion composition and equivalence relation. The solution mixing sulfuric acid and nitric acid was compounded by the rainfall of Southwest China, in which the molar ratio of SO_4^{2-} to NO_3^- was 3:1 (Tang, 2006). And the pH of rainfall solution was set at 4.7 and was adjusted by adding diluted NaOH or/and HNO_3 solution.

Table 3. *The chemical composition and ion content of rain in Southwest China (umol/L)*

Ions	NH_4^+	Na^+	K^+	Ca^{2+}	SO_4^{2-}	Mg^{2+}	NO_3^-	Cl^-	F^-

Table 4. *A variety of salt content in acid rain (mg/L)*

Salts	$MgCl_2 \cdot 6H_2O$	$CaSO_4 \cdot 2H_2O$	KNO_3	NaF	$(NH_4)_2SO_4$	NH_4NO_3
Content	2.731	19.120	2.519	0.974	10.130	0.951

Soil column leaching experiment

Soil samples (200 g) were placed in the beakers (500 mL) and then added single curing agents and GMCAs pre-screening. Batch leaching experiments were carried out at curing agent concentration 8 $g \cdot kg^{-1}$. The soils after immobilization dried at room temperature for 2 weeks were sampled by quartering, and then the uniform soils were obtained through a 2 mm nylon mesh. Then soil column leaching experiment was carried out. Soil column leaching apparatus was shown in *Figure 1*. The soils reacted for a certain time by using intermittent leaching to approach the natural rainfall state. The leachates kept leaching at 8 h every other day, which was collected for 10 times (a total of 1000 mL). Batch soil column leaching experiments were conducted to explore the effects of leaching variables including pH value, EC and the concentration of Pb in soils. Afterwards, the soils after leaching dried naturally at room temperature were sampled by quartering, and then the uniform soils were obtained through a 2 mm nylon mesh so that determining the fractions of Pb in soils. The concentration of lead ion in the solution was directly measured by AAS. Moreover, de-ionized water should be used to make the soil column saturated and moist before leaching.

Experimental analytical methods

Soil pH value was determined with H_2O at a 1:2.5 soil solution ratio. Soil organic carbon, total phosphorus and total nitrogen were measured by the Walkley–Black titrations, Digestion-Mo-Sb Anti spectrophotometric method and Kjeldahl method,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1063710654

respectively (Bremmer and Mulvaney, 1982; Nelson and Sommers, 1996). The ammonium acetate method was applied to measure cation exchange capacity (CEC) in soils (Rhoades, 1982). The soil digestion method was applied to determine total heavy mental concentration at a volume ratio of 1:2:2 for HNO_3–HCl–$HClO_4$ mixture (Zhang et al., 2013). The exchangeable, reducible, oxidizable, and residual fractions ofPb in soils were determined to use the optimized Bureau of Reference (BCR) three-step sequential extraction procedure before and after leaching (Nemati et al., 2011; Pueyo et al., 2008). To determine the amount of Pb leaching in soil, America Environmental Protection Agency's TCLP was used (U.S. EPA, 1986). The concentration of Pb in the solution was measured by AAS. And soils after immobilization experiments were photographed by SEM operating at 15 kV.

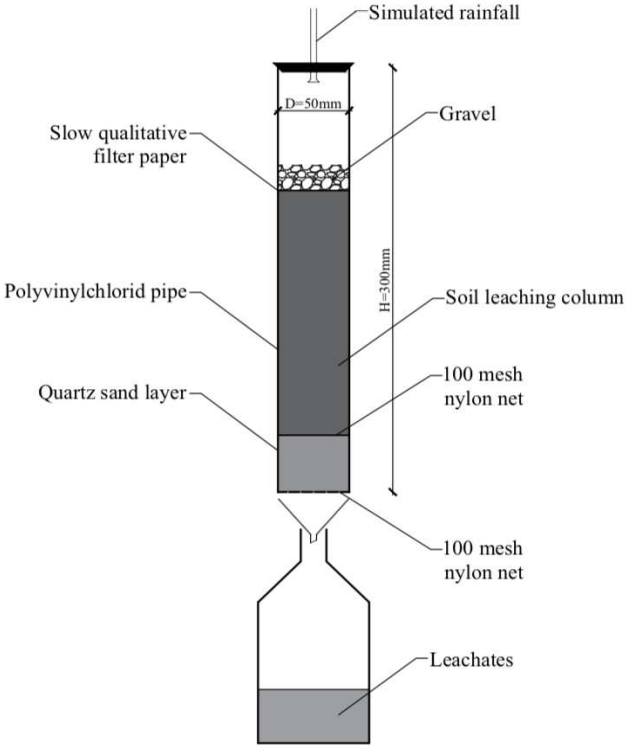

Figure 1. *Apparatus of soil column leaching experiment*

Statistical analysis

Statistical data analysis was done with software SPSS Version 19.0. The data were analyzed by Pearson's correlation analysis using a two-tailed test with significance levels of 0.05 and 0.01.

Results and discussion

Effect of single curing agent on Pb immobilization in soil

SEM analysis of soil after adding single curing agent

As shown in *Figure 2*, the soil samples were photographed by SEM before and after immobilization. It showed that new metal-containing phase was not found after adding

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1063710654

curing agents in soil by SEM analysis. And the surface particles presented a smoother morphology than the control soil. Therefore, results suggested the dissolution may not be the main immobilization mechanism for heavy metals. Moreover, the reduction of water solubility for heavy metal in soil was mainly attributed to surface ion exchange and co-precipitation, corresponding mineral crystals were formed to make the surface smoother. Similar results also found in the studies of He et al. (2013). It might be due to the addition of curing agents reacting with Pb in soils to form corresponding lead minerals, which were crystals, so the surface appears smoother. Similar results were also found in Mignardi et al.'s (2012) study. However, there is little difference between different curing agents, of which the mechanism needs to be further explored.

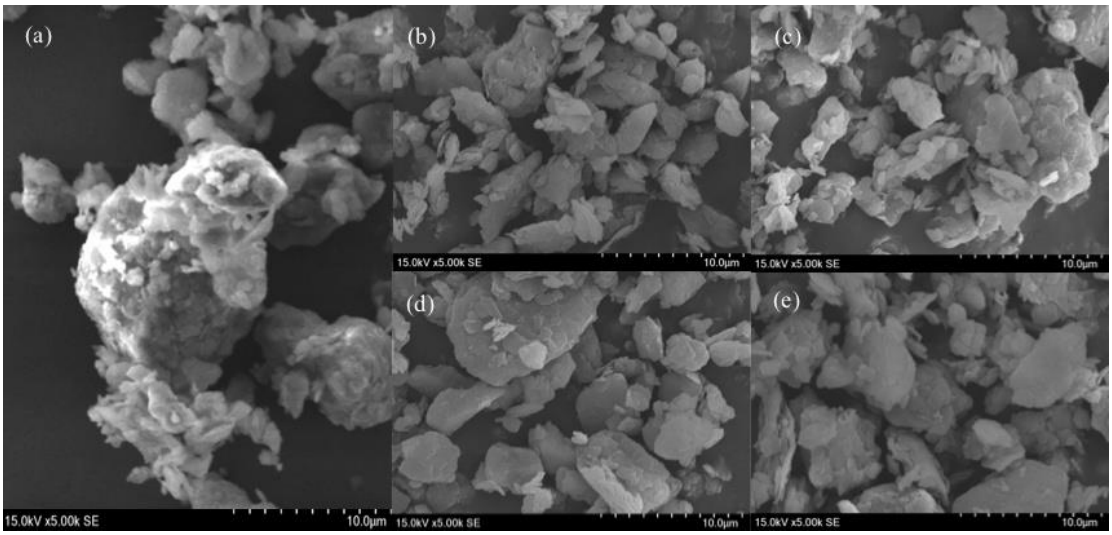

Figure 2. *SEM images of the control and the tested soil (a, the control soil; b, the soil added zeolite; c, the soil added sepiolite, d, the soil added vermiculite; e, the soil added biochar)*

Effect of single curing agent on soil pH value

As shown in *Figure 3,* the addition of zeolite, sepiolite, vermiculite, and biochar influenced the soil pH differently. With the concentration of curing agents increasing, soil pH increased gradually. Soil pH increases from 6.71 to 7.67, 6.95, 7.20, 6.92 for four curing agents, respectively, when the concentration of curing agents is 16 g/kg. It showed that zeolite influenced the soil pH most in four curing agents, of which the pH increase was 0.96. The increase of pH value was mainly due to the fact that the zeolite was a shelf-shaped silicate mineral of alkali and alkali earth metals, containing a large amount of Na^+, K^+, Ca^{2+}, Mg^{2+} ions, which could exchange with H^+ and Al^{3+} ions in the soil solution (Chi et al., 2017).

The pH of soil plays an important role on the remediation of heavy metal contamination. Generally speaking, with the increase of pH, the absorption capacity of heavy metals in soils will enhance. Because heavy metals will form hydroxide precipitates in soil solution as the OH^- increases (Begum et al., 2013; Elliott and Brown, 1989). Organic matter and Fe-Mn oxide are considered as the main carrier for heavy metal adsorption in soils, which can bind more strongly with heavy metals, so that reducing the bioavailability and biological activity of heavy metal in soils (Zhou et al., 2010).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1063710654

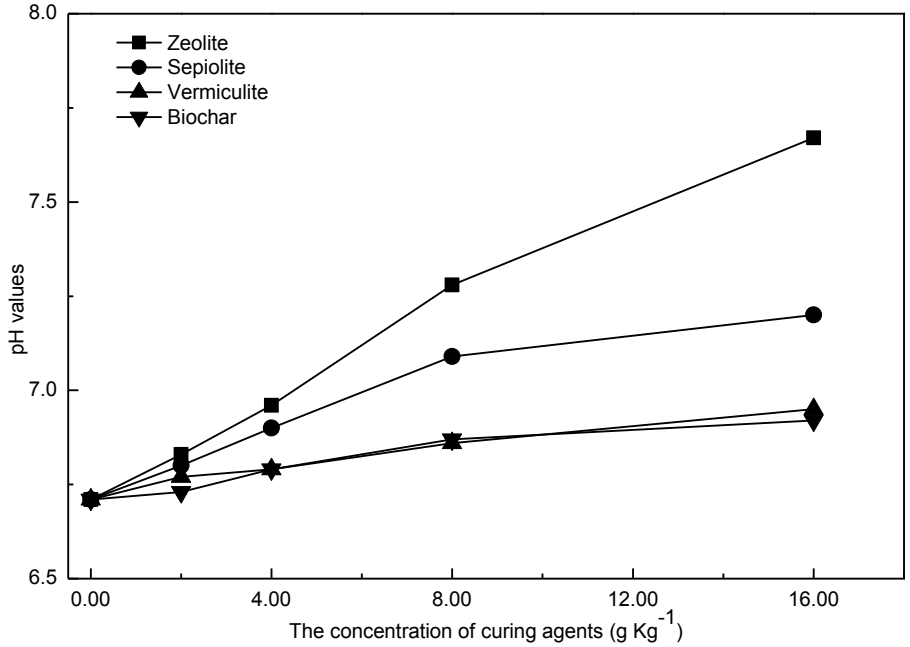

Figure 3. *Effect of curing agents on soil pH value*

Effect of single curing agent on Pb immobilization in soil

As shown in *Figures 4* and *5,* four kinds of curing agents could reduce the exchangeable Pb contents and Pb leaching amounts efficiently. Zeolite, sepiolite, vermiculite and biochar could reduce the exchangeable Pb contents. When the concentration of curing agents was 16.0 g/kg, the exchangeable Pb contents reduced by 93.59%, 100%, 59.35%, 46.91%, respectively. The activity of soil heavy metals depended on the exchangeable fraction (Zhou et al., 2010). Moreover, zeolite, vermiculite and sepiolite could decrease the Pb leaching amount (*Fig. 5*). The Pb leaching amount gradually reduced with further increasing of the curing agent concentration from 0 to 16.0 g/kg. When the concentration of zeolite, vermiculite and sepiolite all reached 16.0 g/kg, Pb leaching amount reduced by 40.12%, 25.50%, 41.28%, respectively.

Compared four kinds of curing agents, zeolite and vermiculite could reduce the exchangeable Pb contents, which inhibited the activity of Pb in soils. Moreover, zeolite and sepiolite could reduce Pb leaching amount effectively. The less leaching amount indicated that only less Pb took away with the surface runoff, which was less harmful to the environment. Above all, sepiolite was the best for Pb immobilization in soil, followed by zeolite and vermiculite. Sepiolite could absorb heavy metal ions or complexes with opposite charges in soil to reduce the activity and migration of heavy metals because of its large specific surface area and unique pore structure (Shirvani et al., 2006). Meanwhile, due to the layered chain structure of the crystal, some heavy metal ions would be absorbed into the interlayer crystal structure to become solidified ions so as to achieve solidification (Sun et al., 2012).

Through single factor correlation analysis, it can be found that the amount of four curing agent, soil pH value and curing effect indicators have a certain correlation. *Table 5* shows that soil pH value is significantly or extremely significantly positively

correlated with the amount of four curing agents applied. The reduction of exchangeable Pb contents in soil and the immobilization efficiency are positively correlated with the amount of four curing agents applied. *Table 6* shows that soil pH value is significantly or positively correlated with the reduction of exchangeable Pb contents in soil and the immobilization efficiency after applying curing agent. To some extent, the increase of soil pH reduced the bioavailability and migration of Pb in soil, inhibited the activity of heavy metals, and stabilized Pb in soil.

Effect of GMCAs on Pb immobilization in soil

Effect of GMCAs on soil pH value

It can be seen from *Figure 6* that, compared with the control (pH 6.71), single curing agents could increase soil pH, among which the zeolite increased soil pH most by 0.57. GMCAs could also increase the soil pH, but the increasing effect was not as good as single curing agents. Among all GMCAs, A5, A13 and A22 possessed a better capacity to increase the soil pH. The pH was increased by 0.36, 0.33, and 0.30, respectively. Therefore, GMCAs showed a general effect in adjusting soil pH.

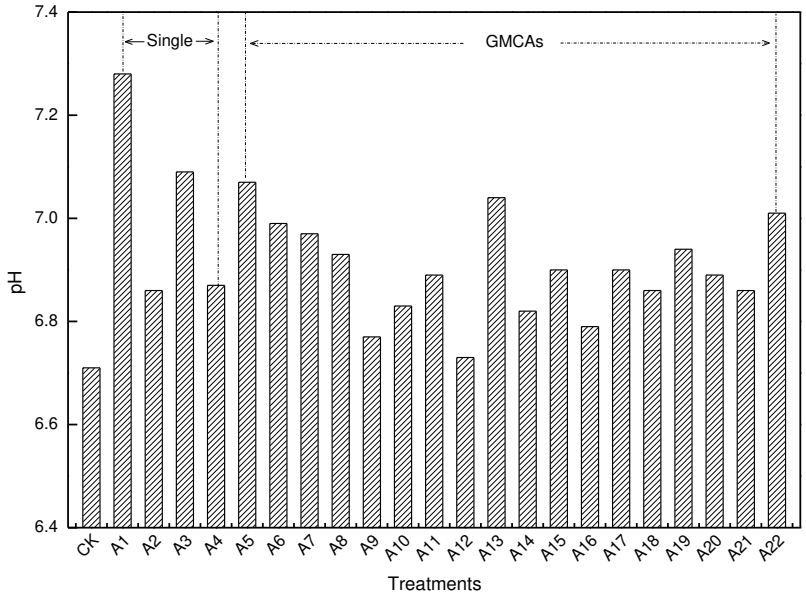

Figure 6. *Effect of different treatments on soil pH value*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1063710654

Effect of GMCAs on Pb immobilization in the soil

As shown in *Figures 7* and *8*, when the concentration of GMCAs was 16.0 g/kg, the various treatments showed different curing efficiency. Besides, different mass ratios of curing agents also performed differently in the same GMCAs. Among all treatments, the GMCAs with a mass ratio of 1:2 or 2:1 for zeolite and sepiolite were the best, and the treatments of these GMCAs decreased the exchangeable Pb contents in soils by 90.2%, 86.4%, respectively. Moreover, A7 and A10 decreased Pb contents effectively in soil leaching solution by 41.4%, 42.1%, respectively. Obviously, zeolite mixing with sepiolite at a mass ratio of 2:1 could immobilize the soil Pb effectively. The combination of zeolite and sepiolite had synergistic effect. Similar results were also found in the studies of Liu (2014).

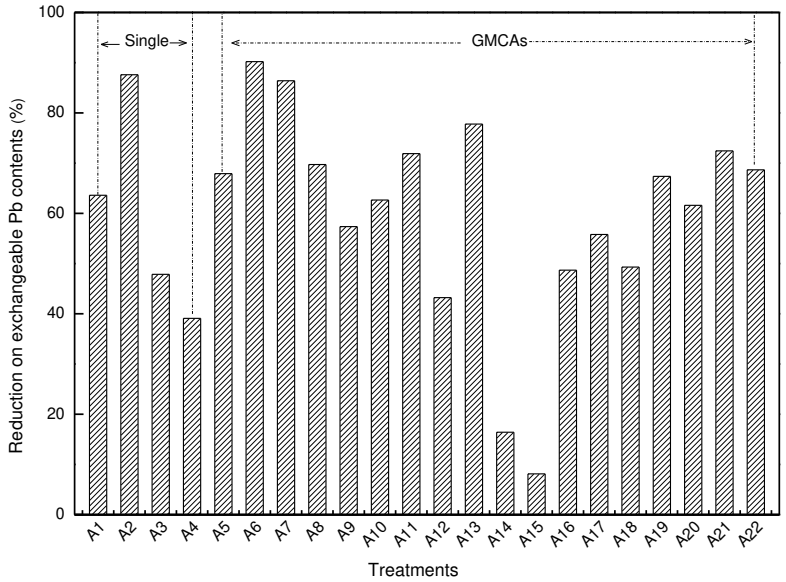

Figure 7. *Effect of GMCAs on exchangeable Pb contents in the soil*

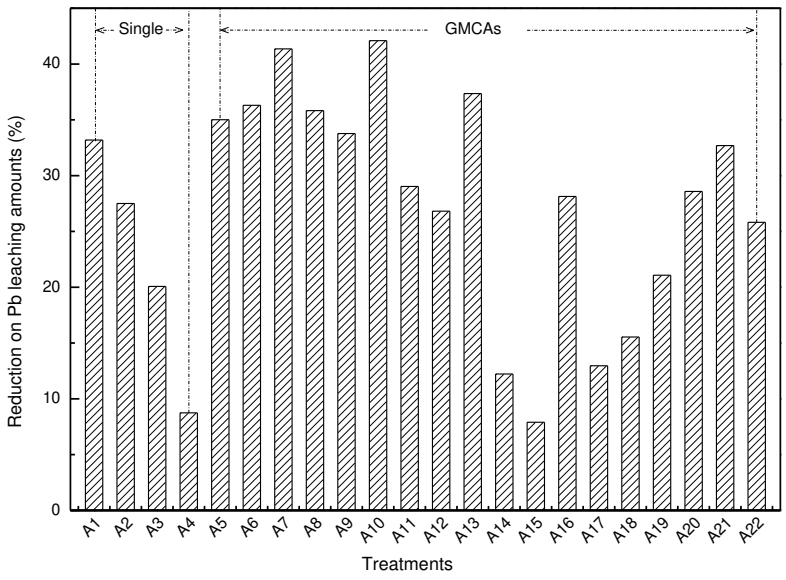

Figure 8. *Effect of GMCAs on Pb leaching contents in the soil*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1063710654

However, compared with the single curing agent, two curing agents at different ratios have different effects on Pb in soil. Some of them have synergistic effects, while others have antagonistic effects.

The result and analysis of soil column leaching experiment

Variation of pH in leachates with leaching times

Considering the effects of curing agent immobilization preliminarily, soil column leaching experiment was conducted by choosing four single curing agents and four different kinds of GMCAs according to *Table 7*.

The results of soil leachates pH from different treatments were shown in *Figure 9,* which gave the change of the pH during the soil column leaching experiment. Compared with the pH of the control, the pH of other treatments was higher than the original leaching solution. Moreover, the pH of the leachates first increased and then decreased with the increase of leaching times. The maximum pH of the leachates was inconsistent in different times, but basically appeared after the fourth leaching. This is mainly determined by the rate of neutralization and exchange reaction between exchangeable base ions and H^+ input through acid rain. With the continuous reaction of exchangeable base ions and H^+ input, the pH of exchangeable base ions begins to decrease slowly after the complete exchange of exchangeable base ions in the mid-leaching stage. However, because the soil contains a large number of buffer ions, the decrease of pH is relatively small (Zhang et al., 2007; Yu et al., 2001; Fang, 2016; Ma, 2007). In addition, the anions contain in acid rain also coordinate with the hydroxyl groups on the surface of soil particles. Hence, under leaching of leachates, the hydroxyl group enters the solution and consumes H^+, which leads to the increase of pH of soil leachates (Xu et al., 2004). It indicated that the addition of curing agents was beneficial to alleviate the effect of acid rain and improved the soil buffering properties (Yu et al., 2001).

Among the different treatments, the most obviously increasing of pH was B1, followed by B6, and the third was B5. The maximum change of pH could reach 0.69, which occurring at the 5^{th} time of leaching. For B2, B3, B4, B7 and B8, the increase of pH was lower than B1, B6 and B5. It showed that the addition of zeolite has the greatest influence on soil pH, which indicated that zeolite increases the cation exchange capacity in soil and adsorbs the hydrogen ions in original solution, thereby increasing pH of leachates.

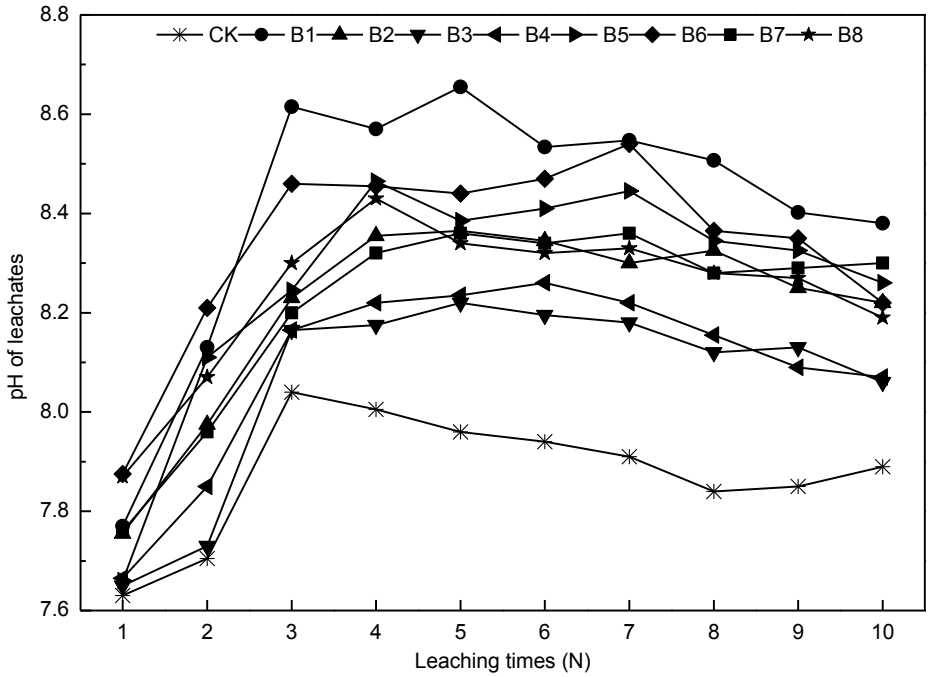

Figure 9. *Changes of pH with leaching times in leachates*

Variation of EC in leachates with leaching times

The EC of soil can be used to characterize soluble salt content in soil, and the content of soluble salt in soil shows a great effect on the EC of soil (Sun, 2000). The EC of each treatment was shown in *Figure 10* with the leaching of simulated acid rain (pH 4.7). It could be seen that the change of EC in each treatment was approximately the same, and leachates for the first time showed the highest EC. With the increase of the leaching times, the EC rapidly reduced. There was the highest rate at the beginning, and then their concentration was close to equilibrium and remained almost constant with further leaching. It showed that the release of base cation in soil gradually reduced with the increasing of the leaching times, and the initial release quantity was the largest, and then it flattened out. The EC changes can be divided into two stages: rapid decline and slow decline to a steady state. The early stage may be related to the rapid release of various base ions on the soil surface, some soluble oxide particles adsorbed on the soil surface and soluble salts into aqueous solutions. In the later stage, the exchangeable ions in soil become less and less, and the process of slowly releasing and tending to equilibrium is achieved (Zhang et al., 2007; Fang, 2016). At the same time, most of the curing agents are mineral materials. After acid rain leaching, a certain degree of weathering occurs to release the corresponding base ions. Some of them are lost with the leachates, and the other part is adsorbed in the soil, so the conductivity trend tends to balance finally. In addition, acid rain causes a large number of salt-based ions to dissolve, and H^+ in acid rain replaces salt-based ions in soil colloids. This may also explain that the leachates pH will decrease with the increase of leaching times (Zhang et al., 2007).

From *Figure 10* it could also be seen that the initial EC of each treatment was higher than CK under the leaching of simulated acid rain, indicating that the EC could increase the content of soluble salts and also could reduce the release of base cation after adding curing agents in soils (Rhoades et al., 1990).

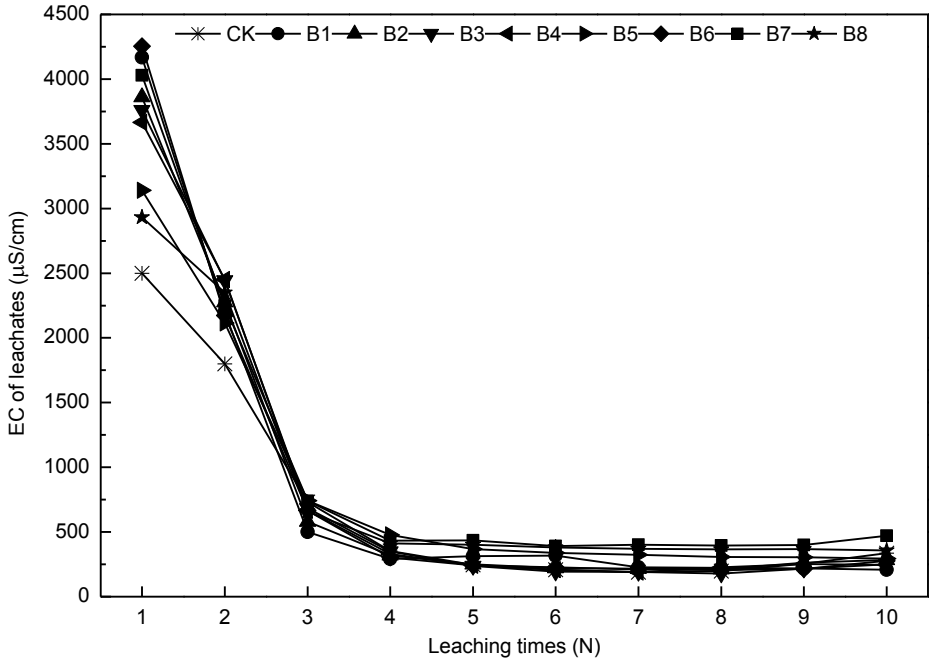

Figure 10. *Changes of EC with leaching times in leachates*

Correlation analysis was conducted between Pb content, pH, conductivity and leaching times in leachates under simulated acid rain leaching conditions, and the results were shown in *Table 8*.

Table 8. *The correlation coefficient of leaching times, pH, EC and Pb content*

The Pb concentration of leachates	Leaching times	pH	EC
CK	-0.804**	-0.725*	0.979**
B1	-0.838**	-0.794**	0.940**
B2	-0.853**	-0.872**	0.943**
B3	-0.902**	-0.805**	0.933**
B4	-0.881**	-0.845**	0.963**
B5	-0.717*	-0.918**	0.926**
B6	-0.758*	-0.848**	0.995**
B7	-0.813**	-0.901**	0.943**
B8	-0.650*	-0.879**	0.907**

**Extremely significant correlation ($p \leq 0.01$). *Significant correlation ($p \leq 0.05$)

On the whole, Pb content in the leachates is significantly negatively correlated with pH. It may be due to the loss of soluble Pb carbonate in the process of acid rain leaching. With the increase of leaching times, at the beginning, Pb in the water-soluble and exchangeable states was released quickly due to acid rain leaching, and then Pb carbonate was also dissolved by H^+ reaction, leading to loss, so there was a significant correlation (Shi et al., 2013). At the same time, the Pb content of leachates is significantly negatively correlated with the number of leaching times, and extremely significantly positively correlated with EC.

Influence of leaching on curing agent immobilization

The change trend of Pb concentration in leachates with leaching times was shown in *Figure 11* under the leaching of simulated acid rain. It indicated the Pb concentration significantly reduced with the increasing of leaching time when the leaching time was ≤ 2. With further leaching, the rate of reduction decreased. The Pb concentration of B5 decreased most slowly, which decreased from 5.86 μg/L to 0.61 μg/L.

Compared with the control (CK), the Pb concentration of leachates significantly reduced after adding curing agents in soils under the leaching of simulated acid rain. The Pb concentration of the control was 190.23 μg/L. And the maximum concentration of Pb after adding curing agents was 106.89 μg/L. The Pb content of accumulated leachates from B1 to B8 significantly decreased, and the decreasing rate was 76.03%, 73.01%, 44.02%, 44.74%, 83.97%, 79.64%, 61.82% and 55.21%, respectively. The highest decrease rate was 83.97% resulted from the treatment of zeolite mixed with sepiolite at a mass ratio of 1:2. Curing agent treatment can significantly reduce the leaching of lead in soil under acid rain conditions (Linet al., 2009). Similar results also found in the studies of Tao et al. (2015) and Rao et al. (2013).

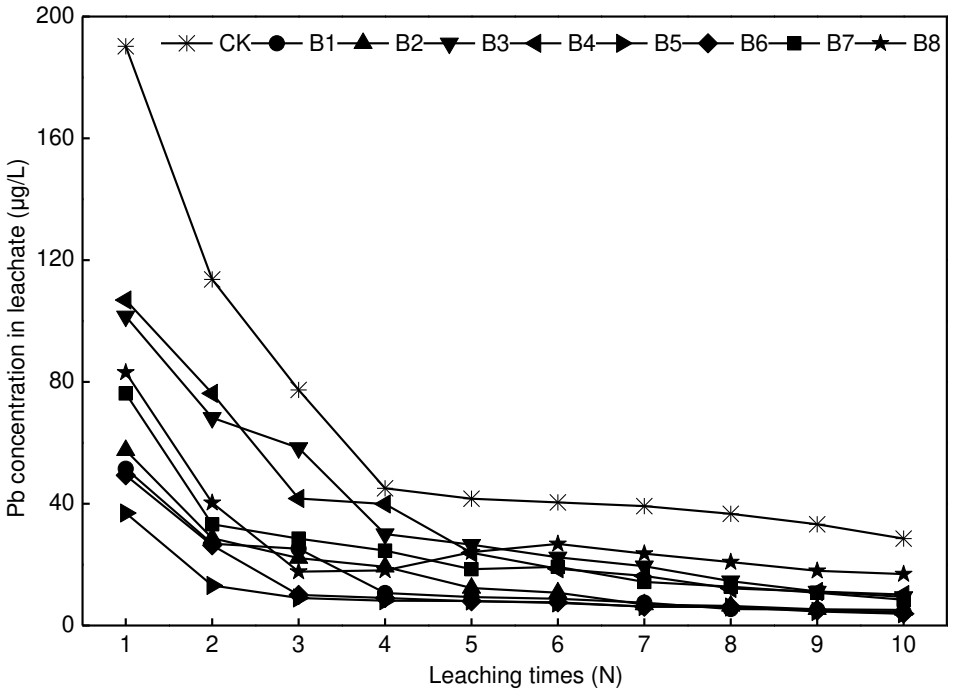

Figure 11. *Changes of Pb concentration with leaching times in leachate*

Influence of leaching on Pb fractions

The fractions of Pb in soil were determined by the BCR procedure before and after leaching. The changes of Pb fractions before and after leaching were presented in *Figure 12*. It indicated that the exchangeable Pb amount increased and the residual Pb amount decreased after leaching.

With the addition of different curing agents, the change of reducible and oxidizable Pb amount was not obvious, of which some increased and some decreased. Our results suggested that the residual Pb contents gradually transformed into exchangeable Pb,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1063710654

reducible Pb and oxidizable Pb contents with the increasing of leaching times. In other words, simulated acid rain could activate the fractions of Pb, which increased its bioavailability and migration. However, the addition of curing agents could decrease the leaching Pb amounts, thus reducing the harm to the ecological environment around the soil (Brown et al., 2004; Geebelen et al., 2003).

The exchangeable Pb amount of nine treatments (CK and B1-B8) in soil leaching solutions increased by 9.95%, 6.69%, 6.98%, 7.44%, 7.81%, 4.56%, 6.54%, 9.19% and 7.84%, respectively. Among all treatments, the minimum increasing rate was the treatment of B5. That is to say, the activating ability of simulated acid rain was relatively small, namely this treatment posed the minimum potential side-effects to the ecological environment around the soil.

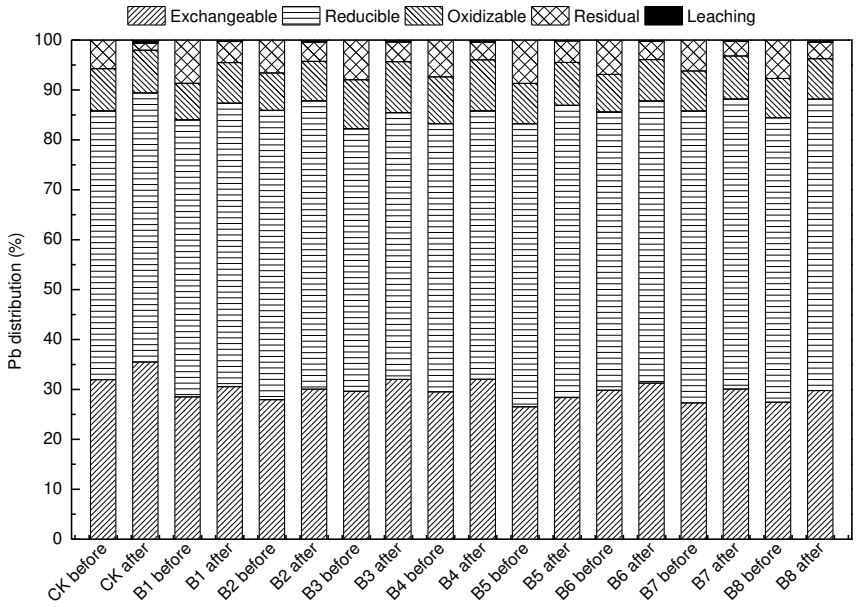

Figure 12. *Comparative distribution of Pb in soil for different treatments before and after leaching*

Conclusion

Four kinds of curing agents showed a better immobilization effect when further increasing of the concentration of curing agents. Compared with the control, the toxicity leaching amount of soils added zeolite, sepiolite, vermiculite and biochar decreased. The decreasing ratios were 40.12%, 41.28%, 25.50% and 16.04%, respectively. Moreover, the soil pH value was significantly or extremely significantly positively correlated with the amount of four curing agents applied. The soil pH value was significantly or positively correlated with the reduction of exchangeable Pb contents in soil and the immobilization efficiency after applying curing agent. The treatment of zeolite showed a best effect on reducing toxicity leaching amount of Pb in soil. Among various GMCAs, zeolite mixing with sepiolite at a mass ratio of 2:1 was the best agent which could immobilize Pb effectively. Under the leaching condition of pH 4.7, the pH of leachates generally increased compared with the control, and the EC of leachates presented a falling trend. The Pb content of accumulated leachates from treatments was decreased, and the highest decrease rate was 83.97%. The residual Pb contents

DOI: http://dx.doi.org/10.15666/aeer/1705_1063710654

gradually transformed into exchangeable Pb, reducible Pb and oxidizable Pb contents with the increasing of leaching times. Moreover, Pb content in the leachates was significantly negatively correlated with pH, significantly negatively correlated with the number of leaching times, and extremely significantly positively correlated with EC. For all treatments, the treatment of zeolite mixing with sepiolite at a mass ratio of 1:2 showed a best effect on reducing leaching amount of Pb in soil. Meanwhile, the activating ability of simulated acid rain was relatively small, namely this treatment posed the minimum potential harm to the ecological environment around the soil. That is to say, the addition of curing agents could decrease the bioavailability and migration of Pb, thus reducing the harm to the ecological environment around the soil. In addition, the mechanism of Pb immobilization and the modification of curing agents need to be future explored.

(Received 1st Mar 2019; accepted 21st May 2019)

Abstract. Between 25th July and 19th August 2013, Amur River basin received some of its most extreme precipitation on record. The floods caused by the heavy rain brought affected Amur River and its 4 major tributaries. Hailun and Hailar stations break daily maximum precipitation record with 153.6 mm in 30th July, and 85.8 mm in 27th July, respectively. Based on daily precipitation observations at 25 stations from 1954 to 2014, the trends, periodicities and abrupt changes of five extreme precipitation indices in Amur River basin were investigated to the Spatiotemporal Characteristics of the extreme precipitation. Area-averaged annual total wet-day precipitation (PRCPTOT), maximum 1-day precipitation amount (Rx1day), maximum 5-day precipitation amount (Rx5day), very wet days (R95) and extremely wet days (R99) had non-significant trends. By wavelet analysis for annual PRCPTOT, Rx1day, Rx5day, R95 and R99 series, the real part wavelet phase of main periods were mostly located at positive peaks in 2013, which were corroborated by abrupt change analysis. Multi-cycle superimposition of main periods is possibly the main cause for extreme precipitation in 2013. The record-breaking daily precipitation data improve 100-year recurrence interval (111.47 mm) to 130.61 mm in Hailun and raise 100-year recurrence interval from 78.95 mm to 87.91 mm in Hailar.

Introduction

Climate change is a severe issue all around the world, which received a lot of attention. The studies in the mean value for temperature and precipitation have made very rich and detailed achievements in different regions, such as China (Qian and Zhu, 2001; Shi et al., 2007), Italy (Moonen et al., 2002), Iran (Tabari and Talaee, 2011), Chile (Kumar et al., 1992), and South Africa (Minetti et al., 2003). The extreme climate events always accompanied by the disasters and the life and property losses directly (Easterling et al., 2000a; Changnon et al., 2000; Griggs and Noguer, 2002), attracts more and more interests of international organizations and scientific research personnel in recent years (Allen et al., 2015; Bordi et al., 2007; Furió and Meneu, 2011). Extreme events, generally defined as the extreme low or high values in the range of observation data (Field et al., 2012), are considered more important and necessary than the study of the mean values referred to human and natural system (Aguilar et al., 2009; Katz and Brown, 1992). As climate changes present poor-rich effects on different regions, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1065510669

intensity and frequency of the extreme events also show different variation characteristics on geographically. In particular, the extreme precipitation indices present both negative and positive trends in India (Revadekar and Preethi, 2012; Preethi et al., 2011) and China (Wang and Zhou, 2005; Fu et al., 2013). It is generally that the changes in precipitation is the result of global atmospheric circulation in large spatial and temporal scales (Trenberth, 1999), and easily affected by monsoon (Li and Liu, 2006; Turner and Slingo, 2009), the Arctic Oscillation (Scaife et al., 2008), El Niño (Easterling et al., 2000b; DeFlorio et al., 2013) and other factors in the small term, but the relations between extreme indices and these factors are not the focus in our analyses and detailed research will be considered in future.

As one of the most important international rivers in East Asia with plenty of water, vast area and diversity of ecological features, Amur River has been concerned universally. The main factor caused the 2013 flood is the big amount of moisture poured on the Amur River basin, influenced by the East Asian monsoon, the Siberia High, high-pressure of the Pacific Ocean, the Arctic oscillation (AO) and so on (Danilov-Danil'yan and Gel'fan, 2014). Therefore, it is necessary to explore the spatiotemporal characteristics of the extreme precipitation events and take measures to cut back the damage from the events.

The five extreme precipitation indices were chosen to identify the changes of extreme precipitation events firstly: PRCPTOT, Rx1day, Rx5day, R95 and R99, which were recommended by World Meteorological Organization (WMO), United Nations Environment Programme (UNEP), et al. (Tao et al., 2018; Li et al., 2018). Secondly, the Mann-Kendall test was used to calculate the magnitude of the trends for five extreme indices, and evaluate whether the trend is significant or not. Then the periodicities of the extreme indices were analyzed by wavelet transform, and the abrupt changes were detected by Mann-Kendall method. Compared with the results of the trends and periodicities, the changes of the five extreme indices time series were analyzed, and the changes could partly reveal the causes of the 2013 extreme precipitation. Finally, the extent of the 2013 extreme precipitation was measured by analyzing the typical station, and some conclusions were given. This paper aims to provide a reference for international river-related countries to deal with extreme weather events through the study of extreme precipitation in the Amur River Basin.

Study area and data

Study area

The Amur River (*Fig. 1*), with the other name as Heilong River in Chinese, has the tenth largest basin area on earth (Nicholson et al., 2014). The Amur River basin has an area of 1.86 million km^2 which covers the territories of Mongolia, Russia, China and North Korea. In addition to its transboundary location, the Amur River basin can be characterized by contrasts between other geographic aspects: Russia and Asia; continental and monsoon climates; and southern dense and northern sparse populations. The climate of eastern Amur basin is humid monsoon temperature climate, which impact can reach the northernmost latitude on earth (Semenov et al., 2014; Yu et al., 2013). The climate of areas in the west of this basin (upper reach of the Amur River) is sheltered from monsoon influence and arid. The arid western portion of this basin is smaller compared with the more humid eastern portion.

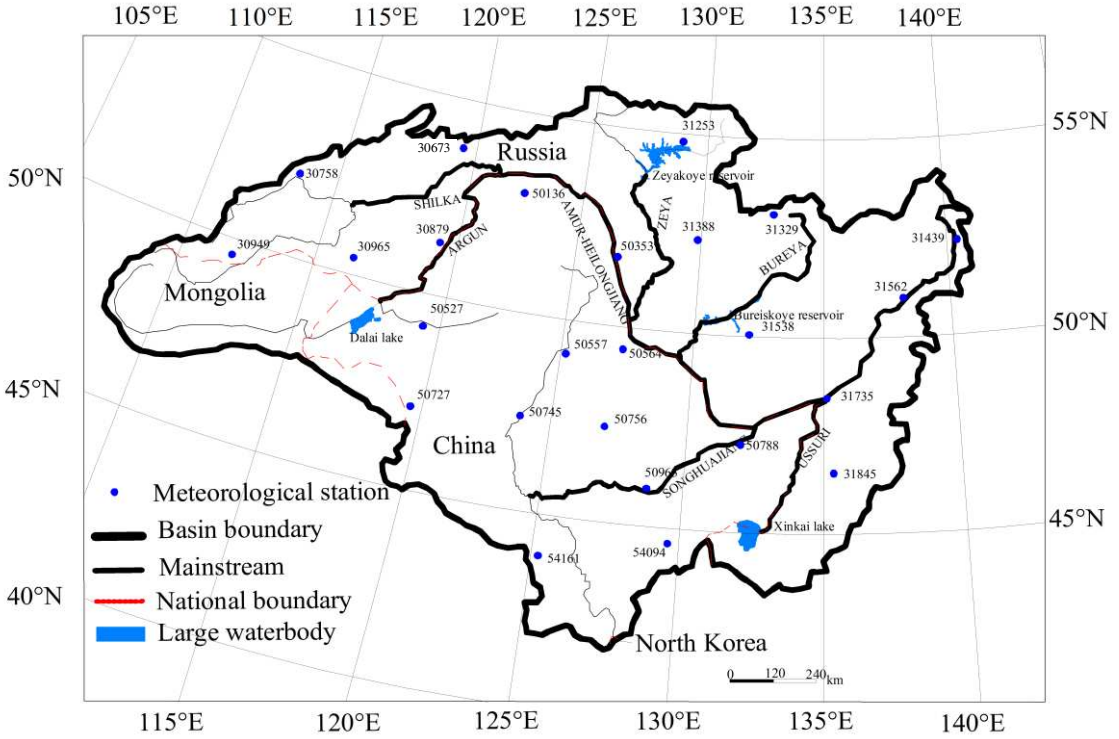

Figure 1. *Locations of the 25 meteorological stations in the Amur River basin*

Long-term observed precipitation data

The daily precipitation data from 1954 to 2014 were collected in 25 stations of which the 12 stations in China and 13 stations in Russia. *Figure 1* presented the geographical location of the stations and more information were shown in *Table 1*. The Chinese station data was provided from the National Climate Center, China Meteorological Administration, and the station data of Russia came from Russian Federal Service for Hydrometeorology and Environmental Monitoring. The data collected from authoritative departments in China and Russia are measured daily data of meteorological sites. Data quality control is necessary in the calculation and detecting the trends and periodicities of the extreme precipitation indices (Huang et al., 2013; You et al., 2014), although these data has been detected by primary quality control. The RHtestV.4 software package (http://etccdi.pacificclimate.org/software.shtml) was employed for homogeneity assessment (Wang, 2008a, b; Wang and Feng, 2013).

Methodology

In this study, five indices were chosen for variations evaluation of the extreme precipitation in Amur River basin, the definitions of these indices were presented in *Table 2,* and all these indices are from the core indices which were recommended by the Joint CCI-CLIVAR Expert Team for Climate Change Detection Monitoring and Indices (ETCCDMI) and applied in different countries (Liu et al., 2015; Altinsoy et al., 2013). These indices were used widely to study the variations of extreme climate events in many regions of the world.

Table 2. *Definitions of five precipitation indices*

Index	Indicator name	Definitions	Units
PRCPTOT	Annual total wet-day precipitation	Annual total PRCP in wet days (RR ≥ 1 mm)	mm
Rx1day	Max 1-day precipitation amount	Monthly maximum 1-day precipitation	mm
Rx5day	Max 5-day precipitation amount	Monthly maximum consecutive 5-day precipitation	mm
R95	Very wet days	Annual total PRCP when RR > 95th percentile	mm
R99	Extremely wet days	Annual total PRCP when RR > 99th percentile	mm

The RClimDex software was employed to carry out the calculation of extreme precipitation indices. The non-parametric Mann-Kendall test (Ahmad et al., 2015; Yin et al., 2016; Yue et al., 2002) was used to estimate the magnitude of indices trend and verify whether the trend is significant. The Kendall slope is computed as *Equation 1:*

$$\beta = \mathrm{Median}\left(\frac{x_i - x_j}{i - j}\right) \quad \text{(Eq.1)}$$

Where $1 < j < i < n$ and β indicates the trend rate, and the unit is mm/year in this study. The threshold of significance test was set to 0.05 when assessing the trends of extreme indices.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1065510669

Wavelet analysis (Lau and Weng, 1995), as an effective method to detect the periodicity in time series, was used to explore the extreme precipitation indices time series. In this study, Morlet wavelet was as the mother wavelet, to participate in the wavelet transform (Liu et al., 2015; Dai et al., 2003). The original data should be z-score standardized to eliminate the randomness before wavelet transform. The continuous transform is computed as *Equations 2–4:*

$$W_f(a,b) = |a|^{-\frac{1}{2}} \int_{-\infty}^{+\infty} f(t)\overline{\psi}\left(\frac{t-b}{a}\right)dt \quad \text{(Eq.2)}$$

$$\psi(t) = e^{ict}e^{-t^2/2} \quad \text{(Eq.3)}$$

$$\mathrm{Var}(a) = \int_{-\infty}^{+\infty} \left|W_f(a-b)\right|^2 db \quad \text{(Eq.4)}$$

Where *f(t)* is the extreme precipitation indices times series, $W_f(a,b)$ is the coefficient of wavelet transform, a and b are scale and time parameters, respectively. $\psi(t)$ is the morlet wavelet function, and Var(a) reveals the fluctuations of a in the annual indices series. When $c = 6.2$, the periodicity $T \approx a$, so c was set to 6.2 in this study. By the graph of Var(a) varying with a, the main periodicities can be marked by the peaks corresponding to a.

The generalized extreme value distribution (GEV) (Furió and Meneu, 2011; Burke et al., 2010), derived from the characterization of extreme event, was employed to fit the annual Rx1day series. The distribution formula is computed as *Equation 5:*

$$G(z;\mu,\theta,\sigma,\xi) = \exp\left\{-\left[1+\xi\left(\frac{z-\mu}{\sigma}\right)\right]^{-1/\xi}\right\} \quad \text{(Eq.5)}$$

Defined on $\{z:1+\xi(z-\mu)/\sigma>0\}$, $-\infty<\mu<\infty$ (location parameter), $\sigma>0$ (scale parameter) and $-\infty<\xi<\infty$ (shape parameter). The profile likelihood method is more reasonable to be used to estimate the multi-year return levels and 0.95 confidence intervals, compared with the maximum likelihood method (Huang et al., 2013).

Results and discussion

General characteristics of precipitation extreme indices

The changes of Percentage of precipitation anomalies in the area-averaged time series for five extreme precipitation indices were shown in *Figure 2,* and the basic statistical data was performed in *Table 3*. The changes of 5 indices are almost consistent, while the R99 fluctuate severely. The anomaly percentage of R99 varies from 73.50 to -80.76, while other indices fluctuate between -30 and 30. In particular, the variation coefficient (0.30) of R99 is largest, while PRCPTOT, Rx1day, Rx5day, and R95 are 0.10, 0.08, 0.09 and 0.18, respectively.

Figure 3 shows the distribution for the multi-year mean of extreme precipitation indices from 1954 to 2014 in the Amur River basin. Most of the extreme precipitation events generally occurred in the southeast of the Amur River basin, while the south area

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1065510669

are higher than other area for Rx1day. Spatially, the maximum value of the multi-year mean of extreme precipitation indices generally occurs in the south, while the minimum value generally occurs in the north. Specifically, the maxima of PRCPTOT, R95 and R99 occur in Krasnyj Jar Station (southeast of the basin), and the maxima of Rx1day and Rx5day occur in Changchun Station (southwest of the basin). The minima of PRCPTOT, Rx5day, R95 and R99 occur in Kyra Station (northwest of the basin), and the minimum value of Rx1day occurs in Mogoca Station (northwest of the basin). Particularly, the distributions are similar to the distribution pattern of the annual precipitation in Liu's view, although his study area is just one part of the Amur River basin (Liu et al., 2015).

Figure 2. *Percentage of precipitation anomalies changes in the time series for five extreme precipitation indices during 1954 to 2014 (comparison with the averages of 1954~2014). (PRCPTOT-annual total wet-day precipitation, Rx1day-maximum 1-day precipitation amount, Rx5day-maximum 5-day precipitation amount, R95-very wet days, R99-extremely wet days)*

Table 3. *Statistical information for five extreme precipitation indices time series*

Indices	Mean (mm)	Standard deviation	Coefficient of kurtosis	Coefficient of variation	Maxima (mm)	Minima (mm)	Range (mm)	Range/ mean (%)
PRCPTOT	500.69	49.16	-0.19	0.10	619.28	399.27	220.01	43.94
Rx1day	46.84	3.86	0.03	0.08	56.26	38.7	17.56	37.49

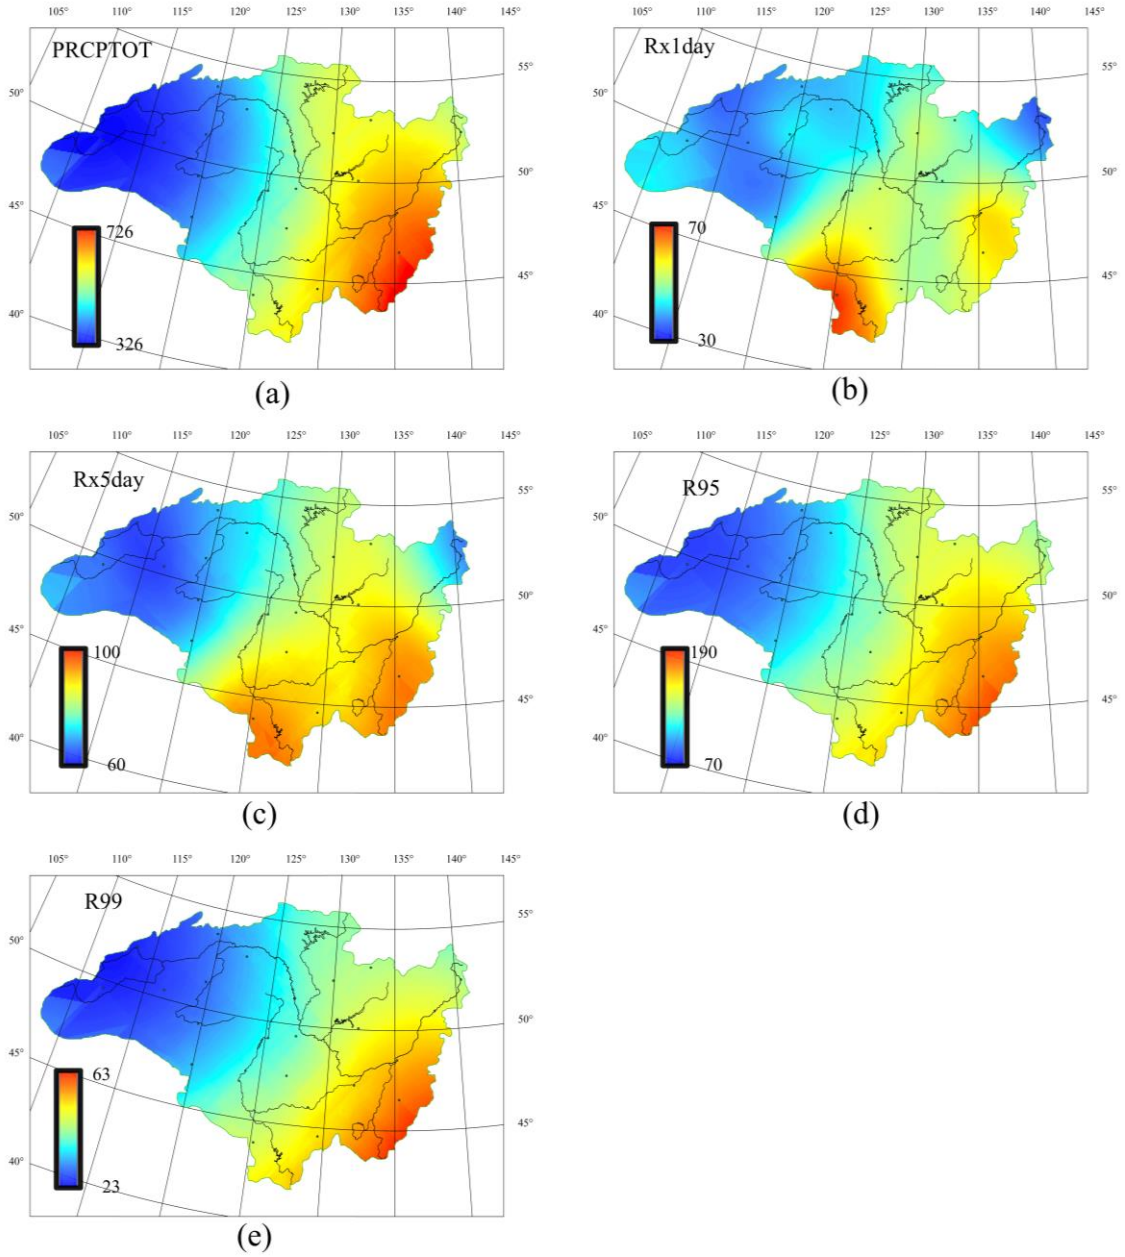

Figure 3. *Spatial distribution for the multi-year mean of extreme precipitation indices from 1954 to 2014 in the Amur River basin (unit mm). (PRCPTOT-annual total wet-day precipitation, Rx1day-maximum 1-day precipitation amount, Rx5day-maximum 5-day precipitation amount, R95-very wet days, R99-extremely wet days)*

Trends of extreme precipitation indices

For the five indices, the area-averaged trends are weak and statistical non-significant, the Kendall slopes for PRCPTOT, Rx1day, Rx5day, R95 and R99 are -0.28, 0.02, -0.04, 0.01 and 0.09 mm/year, respectively. For the spatial trends results (*Fig. 4*), only Nizhnetambovskoe station, the trends of Rx1day, Rx5day, R95 and R99 are notable and positive significantly, while the other stations fluctuate weakly in all indices during the study period.

DOI: http://dx.doi.org/10.15666/aeer/1705_1065510669

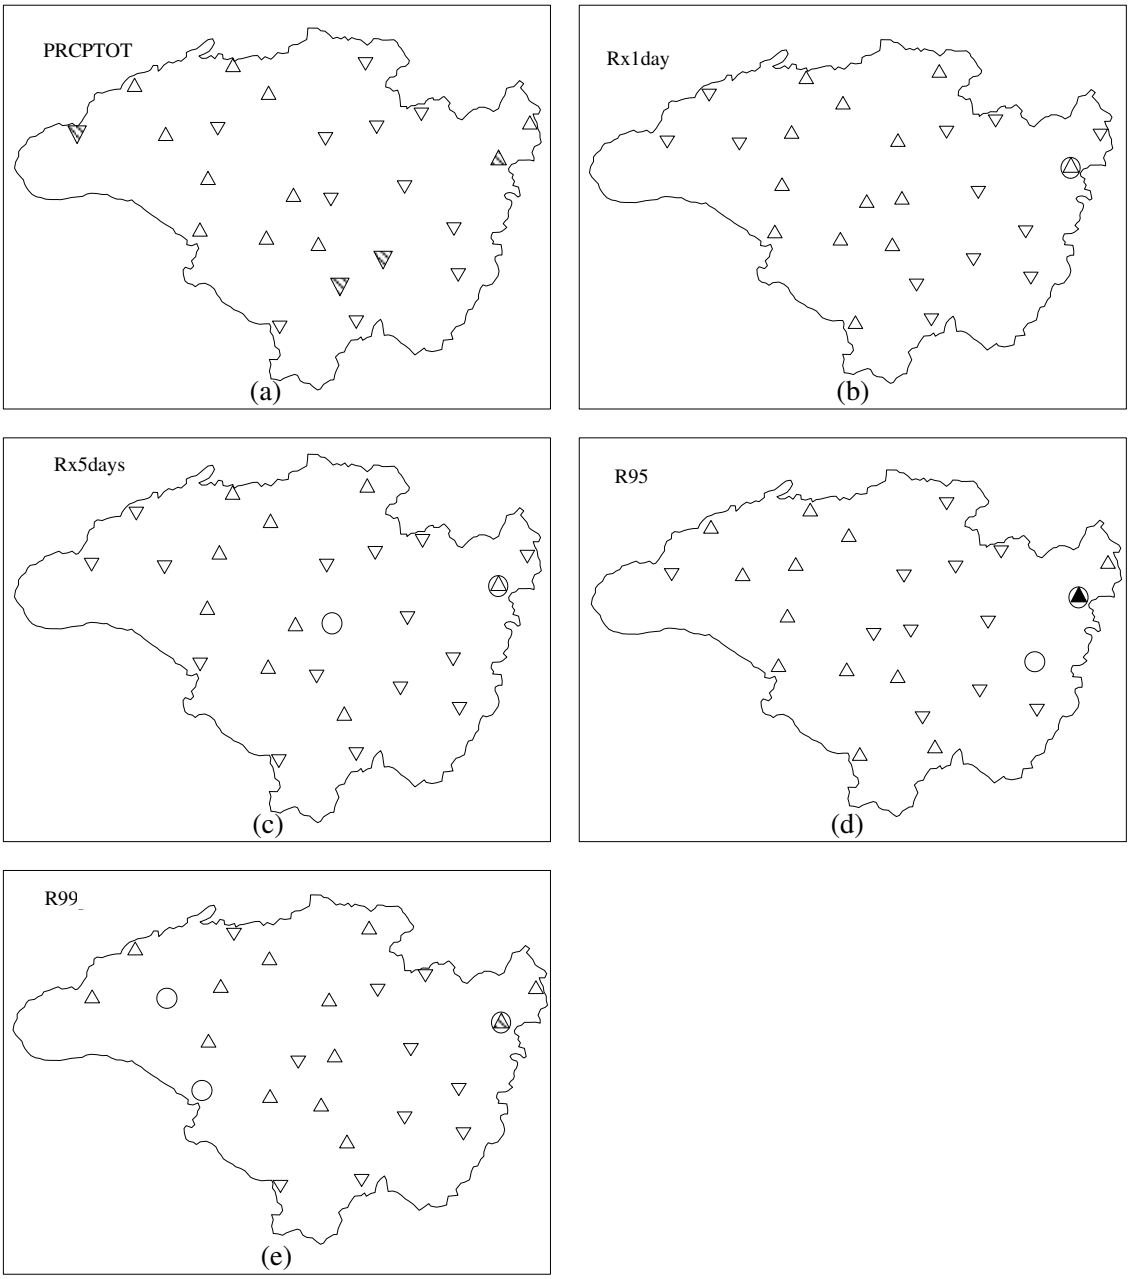

Figure 4. *Spatial pattern of trends for the extreme precipitation indices for 25 stations from 1954 to 2014 in the Amur River basin (▲,◬, ◭, ○, ▽, ▼, ▼ indicate $\beta > 2$ mm/year, $1 < \beta \leq 2$ mm/year, $0 < \beta \leq 1$ mm/year, $\beta = 0$, $-1 < \beta < 0$ mm/year, $-2 < \beta \leq -1$ mm/year, $\beta \leq -2$ mm/year, respectively; the triangles that are rounded indicate significant trend at 0.05 level). (PRCPTOT-annual total wet-day precipitation, Rx1day-maximum 1-day precipitation amount, Rx5day-maximum 5-day precipitation amount, R95-very wet days, R99-extremely wet days)*

Periodicities of extreme precipitation indices

Wavelet analysis is employed to judge the periodicities of the extreme precipitation indices. For PRCPTOT, three peaks can be found in the Periodicities diagnosis graphs of annual area-averaged indices series and they are located at time scale of 4, 13 and 29a. As the peak value means the oscillation strength, the first main period is 29a, and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1065510669

the second and third are 13 and 4a respectively. The main periods are 30, 19 and 5a for Rx1day, 30, 14 and 6a for Rx5day, 30, 13 and 4a for R95, and 28, 11, 18 and 6a for R99, respectively.

Figure 5 shows the wavelet transform real part variation course of annual area-averaged indices series. The size of amplitude responses the periodic obviousness, and the amplitude of the first main period of 29a are larger than those of 13 and 4a in *Figure 5a*. For PRCPTOT, the amplitude of 13a time scale becomes gradually smaller in the entire study period, and even weaker than 4a after 1990. It reveals that the periodicity of 4a timescale was more obvious than 13a after 1990. Besides, the positive real part phase means abundant PRCPTOT, while the negative real part phase indicates scarce PRCPTOT. Taking 13a time scale as example, abundant PRCPTOT occurred in 1957-1962, 1969-1974, 1992-1998 and 2010-2014.

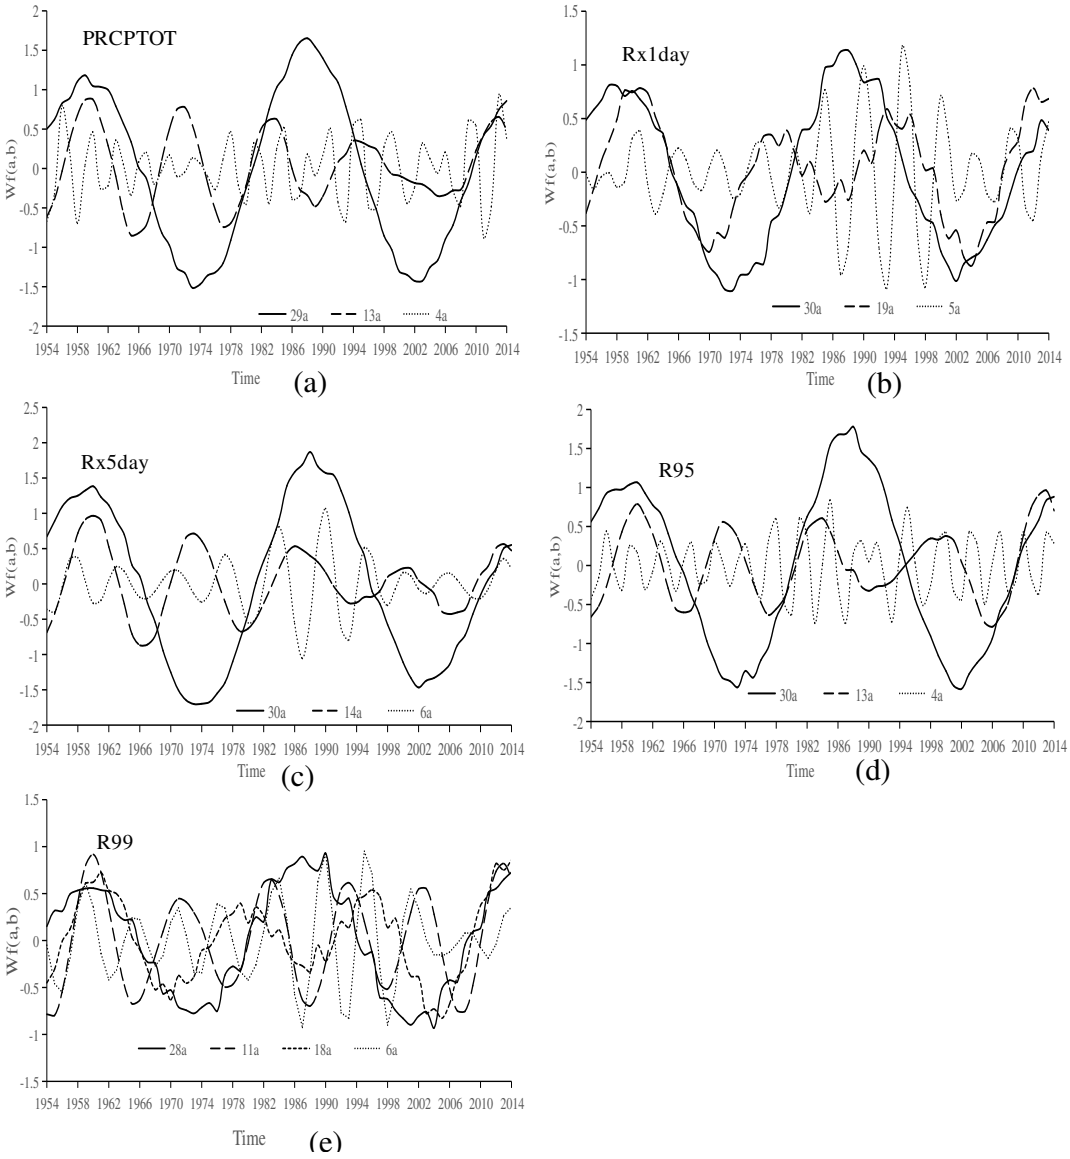

Figure 5. *The wavelet transform real part variation course of annual area-averaged indices series (PRCPTOT-annual total wet-day precipitation, Rx1day-maximum 1-day precipitation amount, Rx5day-maximum 5-day precipitation amount, R95-very wet days, R99-extremely wet days)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1065510669

Overall, the periodicities analysis of the annual extreme precipitation indices explains the cause of the extreme precipitation in Amur River basin in 2013. For PRCPTOT, Rx1day, Rx5day, R95 and R99, the real part wavelet phase of main periods were mostly located at positive peaks in 2013.

Abrupt changes of extreme precipitation indices

The Mann-Kendall method is used to perform abrupt change testing on extreme precipitation indices, which is widely used in hydrometeorology. *Figure 6* shows the Mann-Kendall abrupt change test of the five extreme precipitation indices from 1954 to 2014. It can be seen from the figure that there are similar abrupt change characteristics in the five extreme indices, with two change points around 1963 and around 1989. Both of these change points correspond to the peak of the first main period in *Figure 5,* which indicates that there is a certain relationship between the abrupt change and the periodic variation of the sequence. In addition, the lines of Rx1day, R95 and R99 have intersections in 2013, 2014 and 2012, respectively, while the other two indicators will intersect at the end of the evaluation period, which is almost the same as the peak of the first main period in *Figure 5*.

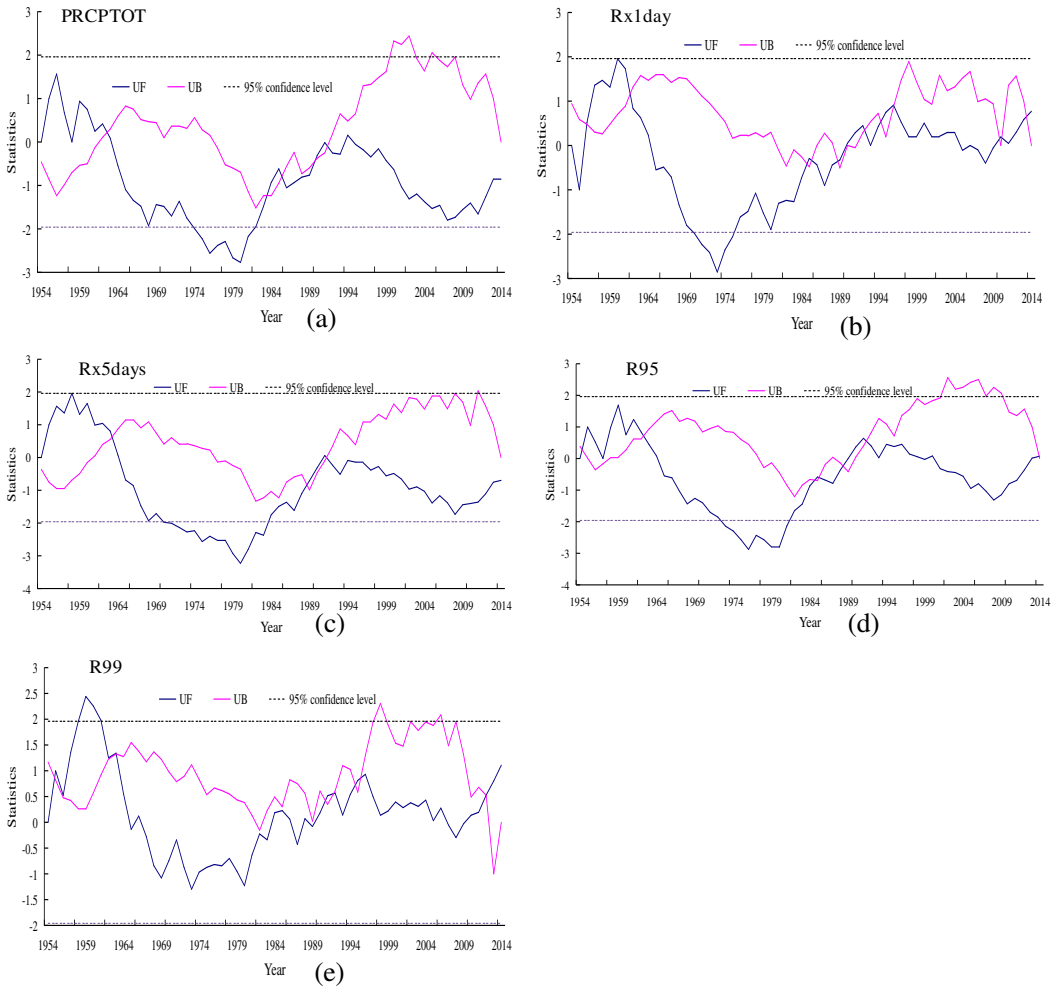

Figure 6. *The Mann-Kendall abrupt change test of annual area-averaged indices series. (PRCPTOT-annual total wet-day precipitation, Rx1day-maximum 1-day precipitation amount, Rx5day-maximum 5-day precipitation amount, R95-very wet days, R99-extremely wet days)*

Extreme precipitation analyses at typical stations in 2013 floods

The Hailun and Hailar Stations received record-breaking observations of daily maximum precipitation in 2013. The GEV distribution was fitted to the annual Rx1day series of Hailun and Hailar, and the profile likelihood method was employed to estimate the 10/50/100-year return levels (*Table 4*). For Hailun station, the record-breaking data (153.6 mm) was around 100-year return level in the evaluation period of 1954-2012, and improve the 10/50/100-year return levels (76.37, 100.90 and 111.47 mm) to 89.14, 114.62 and 130.61 mm. For Hailar station, the record-breaking observation (85.80 mm) was also around 100-year return level in the period of 1954-2012, and the 10/50/100-year return levels (51.99, 70.45 and 78.95 mm) were raised to 54.21, 76.80 and 87.91 mm.

Table 4. *The 10/50/100-year return levels and 0.95 confidence intervals (mm) estimated by the profile likelihood method for annual Rx1day series*

Region	Time series	10 years	50 years	100 years
Hailun	1954-2012	76.37(68.63,89.33)	100.90(87.37,136.47)	111.47(94.21,162.38)
	1954-2013	89.14(79.71,97.33)	114.62(94.96,161.45)	130.61(104.34,199.60)
Hailar	1954-2012	51.99(46.51,61.84)	70.45(59.46,101.75)	78.95(64.35,126.00)
	1954-2013	54.21(47.91,65.77)	76.80(63.16,115.72)	87.91(68.94,138.21)

This study analyzes the temporal and spatial variation characteristics of extreme precipitation indices for the trend, periodicity and abrupt change analysis of five extreme precipitation indices. The results of the trend, periodicity and abrupt change analysis are also mutually corroborated, indicating to some extent the correctness of the results of the analysis. This study has certain similarities with the results of other scholars studying Northeast Asia, but other scholars are limited by the availability of data, and the scope of research is limited to China (Deng et al., 2018; Liu et al., 2015) or Russia (Vyshkvarkova and Voskresenskaya, 2018). In addition, some scholars use large-scale meteorological products to analyze extreme precipitation (Zhu et al., 2018; Tao et al., 2018). Based on the analysis of spatio-temporal distribution characteristics of extreme precipitation, this paper uses GEV distribution to analyze the impact of the extremes on the return levels of typical stations by comparison two periods with or without the value of 2013, which is helpful to further understand the numerical value of the single extreme value for the entire evaluation period. Furthermore, the causes of extreme precipitation are not studied in this paper, and it is expected to be demonstrated in future research..

Conclusions

1. Generally, the changes of annual PRCPTOT, Rx1day, Rx5day, R95 and R99 series are almost consistent, while the R99 with the largest variation coefficient (0.30) fluctuate severely.
2. For PRCPTOT, Rx1day, Rx5day, R95 and R99 indices, not only area-averaged but also individual stations have weak and non-significant trends except for the Nizhnetambovskoe Station.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1065510669

3. It was reasonable to use wavelet analysis to explore the periodicities for annual PRCPTOT, Rx1day, Rx5day, R95 and R99 series, and the real part wavelet phase of main periods were mostly located at positive peaks in 2013. It means that the periodicities of the extreme precipitation indices are the main cause for 2013 extreme precipitation event than the trends.
4. The correlation coefficients among PRCPTOT, Rx1day, Rx5day, R95 and R99 varied from 0.50 to 0.84, and all have passed 0.01 significant level.
5. The Hailun and Hailar stations suffered from record-breaking daily maximum precipitation in 2013, and their 10/50/100-year return levels were raised from 76.37/100.90/111.47 mm and 51.99/70.45/78.95 mm to 89.14/114.62/130.61 mm and 54.21/76.80/87.91 mm, respectively.

Abstract. Anaerobic fermentation is one of the effective ways to achieve the harmless, resource-reducing and reducing of kitchen waste. In this paper, the oxygen content under initial conditions in the anaerobic fermentation process of kitchen waste was changed by experiment (for micro-oxygen pretreatment). It was verified that trace oxygen can optimize the anaerobic fermentation system and increase the rate of anaerobic fermentation. Through the study of the gas production characteristics of the micro-oxygen experiment group, by using the Logistic model and the modified Gompertz model, the R^2 is above 0.99, and the fitting effect is better. The first-order hydrolysis model was combined with different particle reaction kinetic models to obtain a modified first-order gas production model. The results show that the air intake is suitable for the cylindrical particle model. The corresponding R^2 and k values for the air intake from 0 ml to 20 ml are: $\ln(y_m) + \ln(k) = 0.98298$, $k = 0.04339$; $\ln(y_m) + \ln(k) = 0.96149$, $k = 0.04706$; $\ln(y_m) + \ln(k) = 0.98219$, $k = 0.04611$; $\ln(y_m) + \ln(k) = 0.94356$, $k = 0.05039$; $R^2 = 0.9327$, $k = 0.05149$; the fitting effect is better. The population growth model and the modified primary gas production model can better describe the effect of oxygen content change on anaerobic fermentation gas production, and have important significance for the application of anaerobic fermentation in actual production and life processes.
Keywords: *kitchen waste, microaerobic pretreatment, kinetic analysis, population model, modified first-order gas-generation model*

Introduction

Waste and pollution of kitchen waste is a worldwide economic and environmental problem. Per capita production of 95-115 kg of kitchen waste per year in Europe and North America exceeds one third of the total food produced in the region. China is due to population base. Larger, with the rapid increase in the amount of organic waste and municipal sludge produced in recent years, the amount of kitchen waste produced in China reached 95 million tons in 2015, and the average daily waster output was as high as 260,000 tons per day The per capita annual output is 73 kg (Zeng, 2017). One of the effective ways to treat kitchen waste by anaerobic digestion has many advantages: Anaerobic digestion of food waste has many advantages: the generated biogas is an alternative to fossil fuels and thus can ease the energy shortage problem; processed biogas can be used as organic fertilizer, enabling a resource utilization of food waste; the process only produces a little amount of secondary pollution. Therefore, anaerobic digestion of food waste is in line with the "reduction, resource recovery, non-toxic" principle for waste treatment. Overall, this waste treatment process is not only environment-friendly, but also can promote a sustainable economic development (Melikoglu and Webb, 2013).

In the current research background, the three models commonly used in the study of organic matter hydrolysis kinetics model are the first-order hydrolysis model, the Monod model and the Contois model. Huang et al. (2017) used kitchen waste and activated sludge as substrates for anaerobic fermentation, and used the first-order kinetic model to fit the methane production and predict the late methane production, The predicted value and the actual measured value have less error; Sun et al. (2016) carried out anaerobic digestion experiments using cow dung and corn stover as raw materials, and simulated the Gompertz model. The R^2 of the fitting equation of cow dung and corn stover were 0.983 and 0.991, and the predicted and experimental measured values were 12.3% and 1.7%. Miao et al. (2014) and Syai-churrozi et al. (2013) also fitted anaerobic digestion methane production of cyanobacteria, pig manure and distiller's grains based on the revised Gompertz model, providing a scientific assessment method for predicting the methanogenic potential of various raw materials in the future, but the revised Gompertz model can only characterize the gas production potential of the fermentation substrate, and it is difficult to reflect the influence of influencing factors such as organic load and hydraulic retention time on the gas production rate. Liu et al. (2017) established the PSO-SVM anaerobic digestion gas production prediction model by controlling the temperature, pH, oxidation-reduction potential, and influent organic load as the input, and the gas production as the output, which improved the accuracy of the model. Jurado et al. (2016) first pretreated the pig manure by aqueous ammonia soaking method, and based on the ADM1 kinetic model, the anaerobic fermentation of the pretreated pig manure was fitted. The results show that the ADM1 model has poor prediction ability for anaerobic fermentation process after aqueous ammonia soaking treatment. The reason may be that the hydrolysis rate of the treated pig manure is increased, and the hydrolysis constant needs to be revised to meet the requirements. Lauwers et al. (2013) and other studies have shown that the ADM1 model is suitable for a single matrix substrate, the practical application process is more complicated, and the ADM1 model is more difficult to apply.

As a key factor in the anaerobic fermentation process, oxygen concentration has a significant impact on the generation of biogas. By changing the concentration of oxygen, the activity of the microflora in the system can be manipulated. Thus, increasing the biological activity of aerobic microorganisms and facultative anaerobic microorganisms in the anaerobic fermentation process represents a means for regulating the gas-generation in the system. However, there is currently no systematic kinetic model established for the anaerobic fermentation process of kitchen waste with microaerobic pretreatment, and both the kinetic and mechanistic analyses are lacking (Mata-Alvarez et al., 2000; Forster-Carneiro et al., 2008; Pavan et al., 2000). To this end, in this study, we established three models, namely, a population growth model, a modified Gompertz model and a modified first-order gas-generation model. With them, we explored the impact of oxygen concentration on the microaerobic pretreatment process and system gas-generation. Based on our data, we also provided suggestions for the subsequent industrialization of the process.

Materials and methods

Experimental materials

The raw materials used in this experiment mainly include kitchen waste and inoculated sludge, which were collected from the Southern District Canteen of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1067110683

Shenyang Aerospace University and the sewage treatment plant in north Shenyang City (Liaoning province), respectively. First, mix the different kitchen wastes (including taro, vegetables, meat, eggs and other proteins). Remove other materials such as bones and paper scraps from the kitchen waste, stir them with a blender, and store them in cold storage; The inoculated mud was taken from the anaerobic digestion sludge of the sewage treatment plant in the northern part of Shenyang City, Liaoning Province.

Experimental methods

A wide-mouth reagent bottle (1 L) was used as the anaerobic fermentation tank (*Fig. 1*). The raw material for anaerobic fermentation was kitchen waste (simulation), and a certain amount of inoculated sludge was added to the anaerobic digestion tank. Anaerobic digestion was carried out in a water bath at 37 °C. Five parallel groups were set up. Group 1 was used as a control and it was carried out as a standard anaerobic fermentation. Groups 2–5 were experimental groups, and 5 ml, 10 ml, 15 ml, and 20 ml of air were respectively inflated to create different microaerobic conditions. The biogas generation in each group was measured once a day, and the total amount of biogas generation in each group was also calculated. The experimental period is 50 days, of which 1-10 days is the adaptation period. At this time, the microorganisms are in the adaptation stage, also called the start-up stage, mainly by hydrolyzing the fermenting bacteria group to act on starch and cellulose. Hydrogen-producing bacterial bacteria convert monosaccharides into volatile fatty acids (VFAs), H_2 and CO_2. 31-50 days is the deceleration period and the decay period. Since a large amount of organic matter in chicken manure and straw is consumed, the microorganisms enter the endogenous respiration stage and begin to sleep or die.

Model establishment

A kinetics model for anaerobic fermentation

The hydrolysis kinetics model is mainly classified according to the type of organic matter and the hydrolysis process. There are three major categories: the ones based on organic matter concentration, the ones based on organic matter composition and the ones based on organic surface area. The most commonly used organic-concentrations-based hydrolysis kinetic models are the Monod model, the Contois model, and the first-order hydrolysis model.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1067110683

The Monod model was proposed by the founder of modern cell growth kinetics, Monod, in 1942. This model describes the relationship between the limiting substrate concentration of cells and their growth rate during the equilibrium and log phase of the microbial growth.

The Contois model was proposed about 20 years later than the Monod model. It describes the growth of microorganisms over time. The Contois model was first applied to the hydrolysis process of the soluble organic matters in aerobic activated sludge, and later developed also for the anaerobic fermentation process of organic particulates. The Contois model is a modified Monod model, which assumes that saturation constant is proportional to the initial concentration of the substrate. However, this model also has disadvantages: for example, it does not consider the influence of temperature on the rate of hydrolysis (Rao and Singh, 2004; Fang and Yu, 2002; Song et al., 2004).

First-order hydrolysis model is the simplest model for the hydrolysis of organic matters. It assumes that the concentration of unhydrolyzed organic matter is proportional to the hydrolysis rate; thus, this model is not suitable for the lag phase. By comparing the actual anaerobic fermentation process with the simulation, First-order hydrolysis model is considered as the model of choice for simulating the hydrolysis of organic particulates (Rao and Singh, 2004). It can be improved by introducing the concept of specific surface area of hydrolyzed particles into the model (Song et al., 2004). Although the hydrolysis characteristics of the specific components in the hydrolysis model are not particularly clear because of the different compositions of organic particulates, the kinetic model regarding the mixture as a hydrolyzed whole, compared to the conventional one, undoubtedly provides some clues for future studies.

Anaerobic fermentation kinetics models for the SBR system

Population growth model

The Logistic equation is:

$$P = \frac{P_{max}}{1 + exp\left[\frac{4R_{max}(\lambda - t)}{p_{max}} + 2\right]} \quad \text{(Eq.1)}$$

where P is the cumulative amount of methane generation (ml/gVS) at time point t; Pmax is the potential maximum methane generation (ml/gVS); Rmax is the maximum methanogenic rate (ml/gVS/d); t is the reaction time; and λ is the delay time (d).

The modified Gompertz equation is:

$$M = P \times \exp\left\{-\exp\left[\frac{R_m \times e}{P}(\lambda - t) + 1\right]\right\} \quad \text{(Eq.2)}$$

where M is the accumulative amount of methane generation at time point t (ml/gVS); P is the potential maximum methane generation (ml/gVS); Rm is the maximum methanogenic rate (ml/g/VS/d); t is the reaction time; and λ is the delay time (d).

It can be seen from these two equations that the P, Pmax, and Rmax in the Logistic equation represent the same as the kinetic parameters, M, P and Rm in the modified Gompertz equation. In this study, we performed nonlinear regression analysis (a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1067110683

function incorporated in the origin 8.0 software) of the kinetic parameters in the Logistic equation and the modified Gompertz equation.

First-order gas-generation model

Because of the proportional relationship between degradable organic matter and methane generation derived the first-order gas-generation model based on previous studies (Vavilin et al., 2008):

$$\frac{1}{t}\ln\left(\frac{dy_t}{d_t}\right)=\frac{1}{t}\left(\ln\left(y_m\right)+\ln k\right)-k \qquad \text{(Eq.3)}$$

where y_m is the theoretical methane generation per unit degradable organic matter (ml/gVS); y_t is the methane generation per unit degradable organic matter at time point t (ml/gVS); t is the reaction time (d); k is the hydrolysis constant (d^{-1}).

By combining *Equations 2* and *3,* we obtained the $Ln(y_m) + ln(k)$ and the k value of the corresponding organic matter, which were used for the following analysis.

Modified first-order gas-generation model

The modified first-order gas-generation model is based on the modified first-order hydrolysis model. Modified first-order hydrolysis models include pellet particle model, cylindrical particle model, and spherical particle model. The conclusions are shown in *Table 1*.

Table 1. *The conclusions of three hydrolysis models*

Pellet particle model	Cylindrical particle model	Spherical particle model
$c = c_0 e^{-kt}$	$c = c_0\left(\frac{1}{2}kt+1\right)^{-2}$	$c = c_0\left(\frac{2}{3}kt+1\right)^{\frac{3}{2}}$
$\frac{dc}{dt} = -kc$	$\frac{dc}{dt} = -k\frac{c^{\frac{3}{2}}}{c_0^{\frac{1}{2}}}$	$\frac{dc}{dt} = -k\frac{c^{\frac{5}{3}}}{c_0^{\frac{2}{3}}}$

For our modified first-order gas-generation model, we referred to the first-order hydrolysis model, and used cumulative methane generation to indicate the degree of hydrolysis of the substrate. Considering the proportional relationship between the gas generation rate of anaerobic fermentation and the degradation rate of organic matter, and the initial generation rate in the SBR system is 0, we have:

$$G=\frac{\alpha}{c_0}\left(c_0-c\right) \qquad \text{(Eq.4)}$$

Putting the conclusions shown in *Table 1* into *Equation 4,* we have:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1067110683

$$G = \alpha\left(1 - e^{-kt}\right) \quad \text{(Eq.5)}$$

$$G = \alpha\left[1\text{-}\left(\frac{1}{2}kt + 1\right)\right] \quad \text{(Eq.6)}$$

$$G = \alpha\left[1\text{-}\left(\frac{2}{3}kt + 1\right)^{\frac{3}{2}}\right] \quad \text{(Eq.7)}$$

where t is the reaction time (d); k is the Hydrolysis constant (d^{-1}); c is the concentration of volatile solid matters (gVS); c_0 is the initial concentration of the volatile solid matters (gVS); G is the cumulative biogas generation (mL/gVS); α is the conversion rate of the volatile solid matters (mL/gVS). *Equations 5, 6* and *7* correspond to pellet particle, cylindrical particle, and spherical particle models, respectively. Using origin 8.0, we did a linear regression analysis to compare the hydrolysis constants of these models.

Experimental result analysis and model verification

Statistical analysis of experimental results

Through the statistics of the cumulative gas production of each group of experiments, it can be seen that the gas production of the system is lower under different micro-oxygen concentration conditions in the initial stage of the experiment. This is because the anaerobic digestion of kitchen waste is in the adaptation stage at the beginning of the experiment, and the activity of methanogens and other strains in the system is low; as the experiment progresses, the daily gas production begins to rise gradually. Each system of different oxygen concentrations reached the first peak around day 10, 511 ml (5 ml), 490 (10 ml), 607 (15 ml), 586 ml (20 ml), 498.5 (0 ml). Since a large amount of substrate is decomposed into small molecular organic substances and cannot be consumed in time, a large amount of organic acid accumulation changes the neutral environment suitable for the growth of methanogens, thereby inhibiting the activity of methanogens, resulting in a decrease in daily gas production. As the experiment progressed, the methanogens passed the inhibition phase and the gas production gradually recovered. The system of different oxygen concentrations reached the second peak of gas production around the 20th day, and then the gas production between different systems will also fluctuate slightly until the end of the experiment.

In the meantime, the gas production conditions of different oxygen concentration systems show different rules. Each system reached the first peak of gas production around the tenth day. At the beginning of the experiment, the daily gas production of the 20 ml experimental group was up to 586 ml, and the daily gas production of the 0 ml blank experimental group was only 314 ml. Therefore, the gas production rate of the 20 ml micro-oxygen test group at the initial stage of the experiment was higher than that of the 0 ml blank test group. This is because the presence of trace oxygen makes the system a small amount of organic matter consumed by aerobic bacteria in the initial stage of fermentation, so that the accumulation of organic acids is less, and the inhibitory effect on methanogens in the system is reduced. According to the statistical analysis of the data, it can be seen that since the initial materials are the same, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1067110683

cumulative gas production of each group is about 11.5 L. However, the experimental period of the micro-oxygen test group was shorter than that of the control group, and the reaction rate was faster as the oxygen content increased. The 0 ml control group entered the late stage of the experiment at about 40 days, and the 20 ml group entered the later stage of the experiment when it was about 25 days old, and the reaction rate increased by 37.5%. The experimental results show that micro-oxygen pretreatment can accelerate the reaction rate of anaerobic fermentation, which is of great significance to the actual production and life.

Discussion of the Logistic equation and the modified Gompertz equation

During the experiment, the other influencing factors (Temperature, pH, Organic matter concentration, Mass transfer efficiency) were constant, and the change in the gas-generation was achieved by manipulating the concentration of the air that was inflated. The data were input into the original 8.0 software for nonlinear fitting. The results were shown in *Figure 2*. It can be seen from *Table 2* that the fitting based on the Logistic equation gave high R^2 values (all > 0.99), indicating a well-fitting effect of the equation; thus, the anaerobic fermentation process can be accurately simulated. On the other hand, the Gompertz equation also performed very well, with only one R^2 value below 0.99 (R^2 of the 5 ml data), and it therefore also can be employed for the fermentation with microaerobic pretreatment (*Table 3*). Nevertheless, a detailed comparison between these two equations suggests that the Logistic equation performs slightly better (Duan et al., 2016).

Table 2. *The fitting parameters of the Logistic equation*

Microaerobic level	P_{max} (ml/gVS)	R_{max} (ml/gVS)	λ(b)	R^2	RMSE
0 ml	163.0659	4.9061	6.6926	0.9987	2.7806
5 ml	155.7169	5.5464	7.0825	0.9966	5.3478
10 ml	149.8337	4.8603	6.0728	0.9961	2.9435
15 ml	172.0383	6.1555	4.2376	0.9982	2.2739
20 ml	177.7048	7.3598	5.9396	0.9981	5.7349

Table 3. *The fitting parameters of the Gompertz equation*

Microaerobic level	P_{max} (ml/gVS)	R_{max} (ml/gVS)	λ(b)	R^2	RMSE
0 ml	192.9103	4.4659	4.8080	0.9966	1.7100
5 ml	173.8075	5.0624	5.3332	0.9881	2.8803
10 ml	167.6019	4.5520	4.6021	0.9974	2.3736
15 ml	186.169	5.7861	2.8244	0.9917	4.7257
20 ml	188.7640	6.9479	4.6672	0.9902	2.5224

As indicated by the R^2 values, the Gompertz equation had a better fitting effect for the 5 ml group and 10 ml group, whereas the Logistic equation had a better performance for 0 ml, 15 ml and 20 ml groups. Meanwhile, we can also conclude that under good fitting conditions, 20 ml of air intake had the highest gas-generation potential. This shows that the addition of a proper amount of oxygen can increase the activity of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1067110683

facultative anaerobic bacteria in the system. These "active" bacteria subsequently promote the anaerobic digestion process, increasing the degradation efficiency of the substrate and improving the gas production potential of the whole system (Pontes and Pinto, 2006; Garcia-Ochoa et al., 1999).

Analysis of the first-order gas-generation kinetics model

Using the equation of the first-order gas-generation model, the fitting diagrams were shown in *Figure 3*. Except for 0 ml and 10 ml groups, the R^2 values were all greater than 0.97 (i.e., other R^2 values were below 0.97), indicating it was not able to simulate the experimental data.

The k represents the degradation rate of the degradable portion of the substrate: the lower the value of k, the slower the reaction rate; otherwise, the faster the reaction. It can be concluded from *Table 4* that the k value of the 0 ml group is the highest (k = 0.00012), indicating that the reaction of this group was the fastest. The second highest k value (0.000051), which is only slightly lower, was found in the 5 ml group. The 20 ml group had the lowest reaction rate (k = 0.000010). These data also showed that in the 0 ml group, gas-generation peaked at the early stage of the experiment.

Table 4. *Parameters of the first-order gas-generation model for each group*

Microaerobic level	Parameters		
	$\ln(y_m) + \ln(k)$	k	R^2
0 ml	1.30019	0.00012	0.9843
5 ml	1.31103	0.000052	0.9608
10 ml	1.2613	0.000026	0.9824
15 ml	1.38128	0.000051	0.95225
20 ml	1.46557	0.000010	0.93532

y_m represents the amount of biogas generated by the reaction, and k represents the speed of the reaction. Neither y_m nor k along can fully characterize the gas -generation from the kitchen waste. However, $\ln(y_m) + \ln(k)$, a parameter combining y_m and k, can indicate the availability of the degradable part of the substrate. Therefore, it can be considered as an indicator of the methanogenesis characteristics, which include the speed of gas-generation and the amount of gas-generation. Thus, the larger this value, the better the gas-generation characteristics of the corresponding experimental group (Linke, 2006).

While the value of k obtained in our study can directly indicate the speed of reaction in each experimental group, to have a more comprehensive comparison, we also checked the value of $\ln y_m + \ln k$ for each group, which can directly indicate the methanogenesis characteristics. In our data, 20 ml group had the highest $\ln y_m + \ln k$ value (1.46557), suggesting it is of relatively optimal methanogenic characteristics in comparison with the other four groups. This is consistent with the conclusions drawn by using the Logistic equation. For other groups, from high to low, their $\ln y_m + \ln k$ values were 1.38128 (15 ml), 1.31103 (5 ml), 1.30019 (0 ml), and 1.2613 (10 ml). These data clearly demonstrate that the addition of micro-oxygen, if not destroying the microaerobic environment, can promote the degradation of the substrate and increase the methane yield.

Analysis of the modified first-order gas-generation model

Using the models described above, we revealed that the 5 ml experimental group had the longest delay time (8 d), followed by the 0 ml group (7 days) and the 20 ml group (6 days). The groups with the shortest delay time were the 10 ml and 15 ml groups (both 5 days). As mentioned previously, the modified first-order gas-generation model was derived from the modified first-order hydrolysis model, and the first-order hydrolysis model does not include the lag phase when estimating the hydrolysis constant k. Consequentially, for the anaerobic fermentation process with a significant lag phase, the estimation of the hydrolysis constant must exclude the lag period. The k values are

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1067110683

listed in *Table 5*. Our data suggest that cylindrical particle model is suitable for every oxygen concentration, followed by the pellet particle model, and the last is the spherical particle model. The hydrolysis constants of the cylindrical particle model for each concentration (from 0 ml to 20 ml) were 0.04339, 0.04706, 0.04611, 0.05039 and 0.05149, respectively.

Table 5. *Parameters of the modified first-order gas-generation model for each group*

Microaerobic level	Model	Pellet particle model	Cylindrical particle model	Spherical particle model
0 ml	R^2 K(1/d)	0.8841 0.0350	0.9830 0.0434	0.7987 0.0462
5 ml	R^2 K(1/d)	0.8641 0.0403	0.9615 0.0471	0.7692 0.0548
10 ml	R^2 K(1/d)	0.8911 0.0391	0.9822 0.0461	0.8008 0.0528
15 ml	R^2 K(1/d)	0.9035 0.0478	0.9436 0.0504	0.8046 0.0680
20 ml	R^2 K(1/d)	0.8810 0.0493	0.9327 0.0515	0.7778 0.0701

Based on the above analysis, including the ones for the lag phase and the modified first-order gas-generation model, the complete periodic equations can be obtained by inputting the value (from Population growth model) and the k value (from first-order gas-generation model) into the equation. For each group, they are:

$$G_1 = \begin{cases} -0.0351t^4 + 0.7142t^3 - 5.0891t^2 + 15.3286t, 1 \le t \le 7 \\ 163.0659\left[1 - \left(\frac{1}{2} \times 0.0434t + 1\right)\right], 8 \le t \le 46 \end{cases}$$

$$G_2 = \begin{cases} 0.0094t^5 - 0.2385t^4 + 2.3185t^3 - 10.6587t^2 + 23.0191t, 1 \le t \le 8 \\ 155.7169\left[1 - \left(\frac{1}{2} \times 0.0471t + 1\right)\right], 9 \le t \le 46 \end{cases}$$

$$G_3 = \begin{cases} -0.0761t^4 + 1.1732t^3 - 6.3810t^2 + 14.6148t, 1 \le t \le 5 \\ 149.8337\left[1 - \left(\frac{1}{2} \times 0.0461t + 1\right)\right], 6 \le t \le 46 \end{cases}$$

$$G_4 = \begin{cases} 0.2469t^3 - 3.4825t^2 + 16.5419t, 1 \le t \le 5 \\ 172.0383\left[1 - \left(\frac{1}{2} \times 0.0504t + 1\right)\right], 6 \le t \le 46 \end{cases}$$

$$G_5 = \begin{cases} 0.4875t^3 - 5.072t^2 + 17.5546t, 1 \le t \le 6 \\ 177.7048\left[1 - \left(\frac{1}{2} \times 0.0515t + 1\right)\right], 7 \le t \le 46 \end{cases}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1067110683

Notably, this model is a modified model, which takes the lag phrase into consideration, thus better describing the individual stages of the anaerobic fermentation process. We anticipate that our analysis may guide the development of microaerobic pretreatment process and provides a theoretical basis for the kinetics analysis of sequencing anaerobic fermentation.

Conclusion

- Three Kinetic models of anaerobic fermentation of kitchen waste with microaerobic pretreatment were established. Among them, the Logistic model and the modified Gompertz model could better simulate the process since most of the R^2 values were higher than 0.99. Judging from the simulation results, the experimental group in which 20 ml of air were inflated had the largest gas generation capacity.
- For the modified first-order gas-generation model, the cylindrical particle model was suitable for every air concentration. The corresponding $\ln(y_m) + \ln(k)$ values and k values for each group are: 0 ml group, $\ln(y_m) + \ln(k) = 0.98298$, $k = 0.04339$; 5 ml group, $\ln(y_m) + \ln(k) = 0.96149$, $k = 0.04706$; 15 ml group, $\ln(y_m) + \ln(k) = 0.98219$, $k = 0.04611$; 20 ml group, $\ln(y_m) + \ln(k) = 0.94356$, $k = 0.05039$; 20 ml group, $\ln(y_m) + \ln(k) = 0.9327$, $k = 0.05149$. It is worth noting these results were obtained from three simulations for each group. Every experimental group had a significant lag phrase. The longest lag phrase was 8 d for the 5 ml experimental group, followed by the 0 ml group (7 days) and the 20 ml group (6 days). The groups with the shortest delay time were the 10 ml and 15 ml groups (both 5 days). Based on the modified first-order gas-generation model, the entire periodic equation taking the lag phrase into consideration was also generated.

(Received 1st Mar 2019; accepted 21st May 2019)

Abstract. Taking the Central Plain City Cluster of China as the research object, and using the center-of-gravity coupling model, unbalance index, and coordination measure model, this paper analyzed spatial and temporal evolution characteristics of coordination between urban population, built-up area, and economy in 2008-2016, and predicted their overall development trend in combination with the Logistic model. It obtained following results: (i) The growth rate of urban economy is faster than that of urban population and built-up area, and the stage characteristics and spatial differences of their evolution are significant. (ii) On the whole, the shift direction of population is opposite to that of built-up area and economic gravity, the coordination between population and built-up area and economy gradually declines, while the shift direction of built-up area is the same as that of the economic center-of-gravity, and the coordination between built-up area and economy is gradually strengthened. The unbalance index of population, built-up area and economy is on the rise, while unbalance index of population and built-up area remains stable. (iii) The spatial difference characteristics of the coordination between them are significant. Specifically, the coordination is poor between population and built-up area and economy, while the coordination is good between built-up area and economy. (iv) According to the prediction, the overall size of urban population, built-up area and economy of the Central Plain City Cluster will be 29.4 million, 4,355 km^2, and 4.549 billion yuan in 2026, and such prediction is very believable.
Keywords: *urbanization, center of gravity coordination model, unbalanced index, coupling,* coordination degree, logistic prediction

Introduction

As the world's fastest-growing economy, since the reform and opening up, China has been accelerating in the urbanization process, and both the speed and scale of its urbanization are unprecedented (Chan and Yao, 1999; Niu et al., 2014; Feng et al., 2014). According to the estimation by the Development Research Center of the State Council of China, the peak rate of urbanization in China is 70%-75%, and it will get close to 67% by 2030. In other words, in a long period of time in the future, China's urbanization process will still maintain a high development speed, and the city scale will be further expanded. Therefore, how to maintain coordinated and orderly development will become particularly important in the process of high-speed urbanization.

As an important characterization of the urbanization process, population, built-up area and economy have close connection and interaction in the scale, speed, structure, quality and benefits of urbanization (Shi, 2015; Wang et al., 2014). Urbanization should

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1068510702

be a complex process of interaction and coordinated development of the three-dimensional integrated system of "population – built-up area – economy". However, in the process of rapid urbanization development of small and medium-sized cities in China, there appear various problems such as excessive accumulation of population, low intensive use of urban land, lopsided industrial structure, and extensive economic development, leading to the imbalance between population, built-up area, and economic system (Di et al., 2016; Lin, 2007, 2006; Friedmann, 2010). Such imbalance has greatly restricted further development of China's urbanization (Fan et al., 2014; Tang, 2013). In this situation, the study on coordinated development of population, built-up area, and economy has great realistic significance for healthy and sustainable development of urbanization.

Some studies have shown that urbanization is the spatial and temporal evolution of regional socio-economic processes, mainly reflected in population, economy, space and society (Ameen et al., 2015; Liu et al., 2014). In the process of urbanization, any subsystem in the population, the built-up area, and economy gets ahead or lags behind the development of other subsystems will lead to an imbalance in the overall development of urban society (Chen, 2008; Liu and Yamauchi, 2013; Holden and Otsuka, 2014). With reference to the above studies, we believe that the healthy and sustainable development of the economy, population, and built-up area is the coordinated development of "population – built-up area – economy". Some scholars such as Henderson and Cohen demonstrated the importance of the coordination of urban population and economy to the healthy development of urbanization; they pointed out that population urbanization is the core and economic urbanization is the driving force, and the quantitative relationship between population urbanization and economic urbanization determines the basic trend and economic benefits of urbanization, while the lag of the development of built-up areas will lead to various problems of resources and environment (Henderson, 2002; Cohen, 2008; Ravallion et al., 2007; Murakami et al., 2005; Ameen et al., 2015). Based on the relatively independent and non-inclusive variables of urban built-up area and urban population, Yang Yanzhao et al. built the relationship model between urban built-up area expansion and population growth, and evaluated the coordination between urban built-up area expansion and population growth (Yang et al., 2013; Zhou et al., 2016). They found that the rapid expansion of built-up areas, as the main type of urban development, has weakened the coordination between built-up area expansion and population growth. From the perspectives of regional structure, construction land structure, and urban scale structure, Wang Chengxin et al. analyzed the relationship between urban population growth and built-up area expansion in China, and found that there is a significant regional and structural difference between urban population growth and built-up area expansion (Wang et al., 2016).

Some existing studies also explored methods of urban measurement. Using Logistic regression, Zhang Leqin et al. measured the relationship between urban built-up area expansion and economic development (Zhang et al., 2014). Using exploratory spatial data analysis and coupling coordination model, He Sanwei et al. analyzed the coupling coordination type and spatial distribution of population, land and economic urbanization in Beijing-Tianjin-Hebei region, and found that most cities have difficulties in achieving a good level of coordinated development (He and Shao, 2018). Different scholars have different judgment criteria for coordination, but the research results have indicated that there are obvious spatial differences in the coordination relationship

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1068510702

between population, built-up area and economic urbanization subsystems, and the uncoordinated phenomenon is very prominent. Through the above findings, we have a deeper understanding of the changes in the relationship between the development of urbanization subsystems and the spatial distribution of the coupling coordination state. However, there are still some shortcomings in the existing studies. (1) There are few studies on urban scale measurement, and most studies focus on the expansion model, model and dynamic mechanism (Xu et al., 2007; Liu and Yang, 2011). Some scholars discussed from the perspective of the population and built-up area (Li et al., 2011; Liu and Wang, 2011). There is no prediction about the urban population, the built-up area, and the future trend of the economy, so it is impossible to formulate preventive policies for relevant issues. (2) In terms of the research area, many studies focus on China's coastal areas (Li et al., 2018; You et al., 2017; Wang et al., 2018), but few studies care about the inland urban city cluster in the process of rapid urbanization, and such areas are exactly the areas with prominent problem in the coordination between the urban population, built-up area, and economy. This is mainly because there is still no clear definition of the theoretical connotation of urbanization coordination in the academic circle (*The concept of coordination comes from the "coordinated development of urban and rural areas" proposed by the central government. As a part of the harmonious society theory, it describes the state of balanced development between urban and rural areas.*). Besides, there is no criterion for measurement indicator system. In addition, the coordinated development is a description of dynamic interactions, and the specific evaluation conclusions need to be combined with local situations, so it is difficult to unify the weight of indicators. With reference to the existing studies, we believe that the population - built-up area - economic urbanization subsystems have the same effect on the overall coordinated development. Therefore, we used the proportion of the population, build-up area, and economic growth rate of each city to that of the Central Plain City Cluster to characterize the contribution share of each subsystem. If the contribution share of each subsystem is consistent, it will be deemed to be the theoretical optimal state. The Central Plain City Cluster is a central inland region of China with rapid urbanization. Problems exposed in the process of its urbanization development are representative. Thus, study on the coordination of "population - built-up area - economy" of this region is helpful for deeply understanding the quality and rules of its urbanization development, and has great realistic significance for healthy and sustainable development of the regional urbanization. On the basis of studies both at home and abroad, considering the relationship between population size, GDP and built-up area of the Central Plain City Cluster, we established a mathematical model to measure the coordination between urban population, built-up area and GDP of the Central Plain City Cluster. Besides, we introduced the center of gravity model and the imbalance index to study the spatial and temporal evolution characteristics and coordination relationship of the population, built-up areas and economy of 30 provincial cities in the Central Plain City Cluster in 2008-2016. Finally, using the Logistic model, we predicted the future development trend of urban population and built-up area in the Central Plain City Cluster of China, in the hope of providing certain references for properly adjusting the relationship between urban population, land use, and economic development, and promoting the coordinated development of urbanization.

Overview of the study area

The Central Plain City Cluster is located in the central eastern of China (*Fig. 1*). As an intersection of "two horizontal lines and three vertical lines" urbanization strategy, it is a core growth pole for undertaking the industrial transfer of foreign countries and China's eastern regions, resource output of western regions, and driving the development of central and western regions of China. This region has excellent natural endowments, the terrain is mainly plain, with hills and mountains; human resources are abundant, the industrial system is complete, and the advantages of industrial clusters are obvious and the innovation ability is continuously enhanced; the transportation location is superior, the three-dimensional transportation network is gradually improved, and all-direction accessible comprehensive transportation hub based on the railway transportation is gradually forming; urban system is complete, and it is gradually forming the coordinated development pattern of large, medium and small cities and small towns. The *Development Plan for Central Plain City Cluster*, issued by the State Council of China on December 28, 2016, clearly defined the scope of this region, and divided this region into 6 zones according to the city type and regional industrial structure: Zhengzhou Metropolitan Zone, Core Development Zone, Northern Trans-regional Coordinated Development Demonstration Zone, Eastern Industrial Transfer Demonstration Zone, Western Transformation and Innovation Development Demonstration Zone, and Southern High Efficiency Ecological Economic Demonstration Zone. By the end of 2016, the area of Central Plain City Cluster was 287,000 km^2, the total population was 162.1082 million, the GDP was 6,034.372 billion yuan with the per capita GDP of 37,200 yuan, making this region become the fourth growth pole of Chinese economy, following the Yangtze River Delta, the Pearl River Delta, and Beijing-Tianjin-Hebei economic circle. Therefore, how to realize the spatial optimization and coordinated development of population, built-up area and economy is an important issue confronted by the Central Plain City Cluster.

Study method and data source

Study method

Center of gravity coordination model

In this study, we adopted the center-of-gravity model and center-of-gravity spatial coupling trend to reflect the overall coupling trend of the growth of population, built-up area, and economy of 30 cities in Central Plain City Cluster. The center-of-gravity model is as follows (Zhou et al., 2016):

$$G_I(x, y) = \frac{\sum_j^n (Q(x_j, y_j))}{\sum_j^n I_j} \quad \text{(Eq.1)}$$

where G_I denotes the center of gravity of urban population, built-up area or economy; I = 1, 2, and 3 denotes population, built-up area, and economy, respectively; n denotes the number of study areas; I_j denotes the population, built-up area or economy of the j-th city; x_j and y_j denote the longitude and latitude of the j-th city.

Using the overlapping of spatial distribution and the consistency in track of center-of-gravity changes, we observed the spatial coupling trend in center of gravity of 30 cities in Central Plain City Cluster. The overlapping of spatial distribution can be calculated with the following formula (Zhou et al., 2016):

$$S = \sqrt{(\Delta x_G)^2 + (\Delta y_G)^2} \quad \text{(Eq.2)}$$

where S denotes the distance of center of gravity between urban population and built-up area, between population and economy, and between built-up area and economy; x_G and y_G denote the longitude and latitude of the center of gravity; closer distance means higher overlapping.

The consistency in track of center-of-gravity changes can be calculated with the following formula (Zhou et al., 2016):

$$C = \cos\theta = \frac{(\Delta x_A \Delta x_B) + (\Delta y_A \Delta y_B)}{\sqrt{(\Delta x_A^2 + \Delta y_A^2) + (\Delta x_B^2 + \Delta y_B^2)}} \quad \text{(Eq.3)}$$

where $\cos\theta$ denotes the cosine value of the vector angle θ of displacement of the center of gravity of urban population and built-up area, population and economy, and built-up area and economy in this time point relative to that in last time point, and it is in the range of [-1,1], and higher value means greater consistency of variation; Δx and Δy denote variation of the longitude and latitude of the center of gravity of this time point relative to the last time point. In this paper, Excel 2007 software is used to process data and charts.

Unbalance index

In order to study the distribution of urban population, built-up area and economy, with reference to previous studies, we constructed an unbalance index characterizing the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1068510702

overall balance of urban population, built-up area, and economy. The unbalance index can be calculated with the following formula:

$$U = \sqrt{\frac{\sum_{i=1}^{n}\left[\frac{\sqrt{2}}{2}(X_i - Y_i)\right]^2}{n}} \quad \text{(Eq.4)}$$

where U denotes the unbalance index, n denotes the number of study unit, X_i and Y_i denote the proportion of population and built-up area, population and economy, and built-up area and economy to the total amount. The unbalance index reflects the coupling relationship between population and built-up area, population and economy, and built-up area and economy. The smaller the U value, the more balanced the distribution. In this paper, Excel 2007 software is used to process data and charts.

Spatial coordination measure model

The coordination degree is an indicator reflecting the degree of internal dependence of different factors. It can be used to judge the degree of interdependence and close relationship between urban population, built-up area and economy. Its function is:

$$C = \frac{X + Y}{\sqrt{X^2 + Y^2}} \quad \text{(Eq.5)}$$

where C is the coordination degree, representing the coordination degree between population and built-up area, between population and economy, and between built-up area and economy, with the value in the range of [-1.4142, 1.4142], the higher the C value, the better the coordination; X and Y denote the proportion of urban population, built-up area, and growth rate of economic scale to the total population, total built-up area, and growth rate of total economic scale, respectively. According to the proportional relationship between population, built-up area and economy, we divided the coordination degree into four types: $C \geq 1.3868$ means coordinated (difference below 0.5 times), $1.3868 > C \geq 1.3416$ means relatively coordinated (difference 0.5-1 times), $1.3416 > C \geq 1.2649$ means relatively uncoordinated (difference 1-2 times), and $C < 1.2649$ means uncoordinated (difference above 2 times). In this paper, Excel 2007 software is used to process data and ArcGIS 10 software is used to visualize the calculation results.

Logistic prediction model

Predicting the trend of changes in the urban population, built-up area, and economic scale is favorable for the control of urban size and making the development plan. In view of this, using Logistic model, we predicted the development trend of urban population, built-up area and economy, to provide theoretical recommendations for the promotion of urbanization construction in a scientific and proper manner. The Logistic growth model is as follows:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1068510702

$$S_t = \frac{S_{max}}{1+(S_{max}/S_0-1)e^{-k_s t}} \quad \text{(Eq.6)}$$

where S_{max} denotes the maximum of simulated object, and k_s denotes the initial growth rate of simulated object. In this paper, Excel 2007 software is used to process data and charts.

Data source

The basic data involved in this study included population, built-up area and economy. For the population indicator, we took the resident population of the urban area; for the built-up area indicator, we used the area of the built-up area; for the economic indicator, we used the urban GDP. All data were selected from *China Urban Construction Statistical Yearbook (2008-2016).*

Result analysis

Characteristics of spatial and temporal evolution

Characteristics of temporal evolution

In 2008-2016, the urban population, built-up area, and economic scale of Central Plain City Cluster showed a linear growth trend. Specifically, the population increased from 20.68 million to 24.65 million, with an average annual growth rate of 2.22%; the built-up area scale increased from 2,073 km^2 to 3,031 km^2, with an average annual growth rate of 4.87%; the economic scale increased from 660.5 billion yuan to 1,775.4 billion yuan, with an average annual growth rate of 13.16%. From *Figure 2* it can be seen that the growth rate of urban population, built-up area and economy of Central Plain City Cluster showed a fluctuating trend.

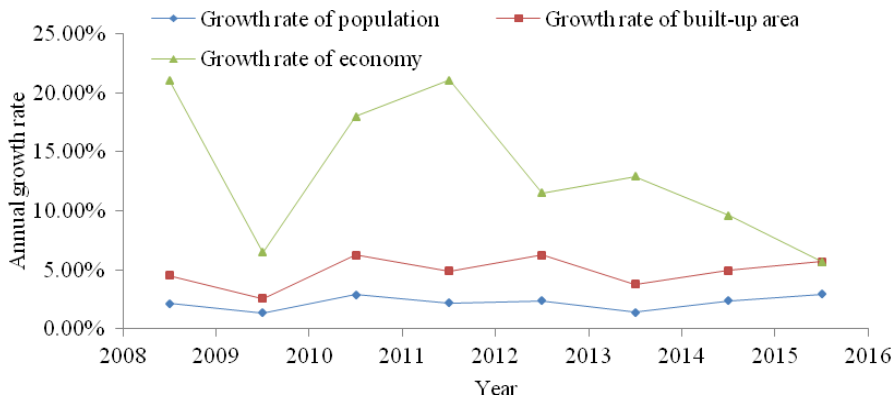

Figure 2. *Growth rate of urban population, built-up area, and economy of Central Plain City Cluster in 2008-2016*

Specifically, the variation trend of growth rate of built-up area expansion and population was basically consistent, while the growth rate of economy showed a significant decline. In 2008-2010, due to the impact of the international financial crisis, urban economic growth rate declined rapidly, the urban construction rate slowed down,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1068510702

the employment opportunities decreased, leading to a decline in the growth rate of population and built-up area. In 2010-2014, with the support of the state policy of vigorously promoting urban infrastructure construction, a new round of urban development and industrial park construction drove the rapid economic development, which consequently led to the expansion of urban built-up area and the population agglomeration. Although external capital stimulus has promoted economic development in a short term, urban development lacks internal motivation, so that the growth rate of urban population, built-up area and economy fluctuated. In 2014-2016, the national economic stimulus policy came to an end, and the economic growth rate declined. With the gradual improvement of urban functions, urban population and built-up area entered a steady growth stage. On the whole, the variation in growth rate of urban population, built-up area and economy was not in the same proportion, the economic growth rate was the highest and the population growth rate was the lowest.

Characteristics of spatial evolution

Figure 3 depicted the spatial distribution of growth rate of urban population, built-up area, and economy of Central Plain City Cluster.

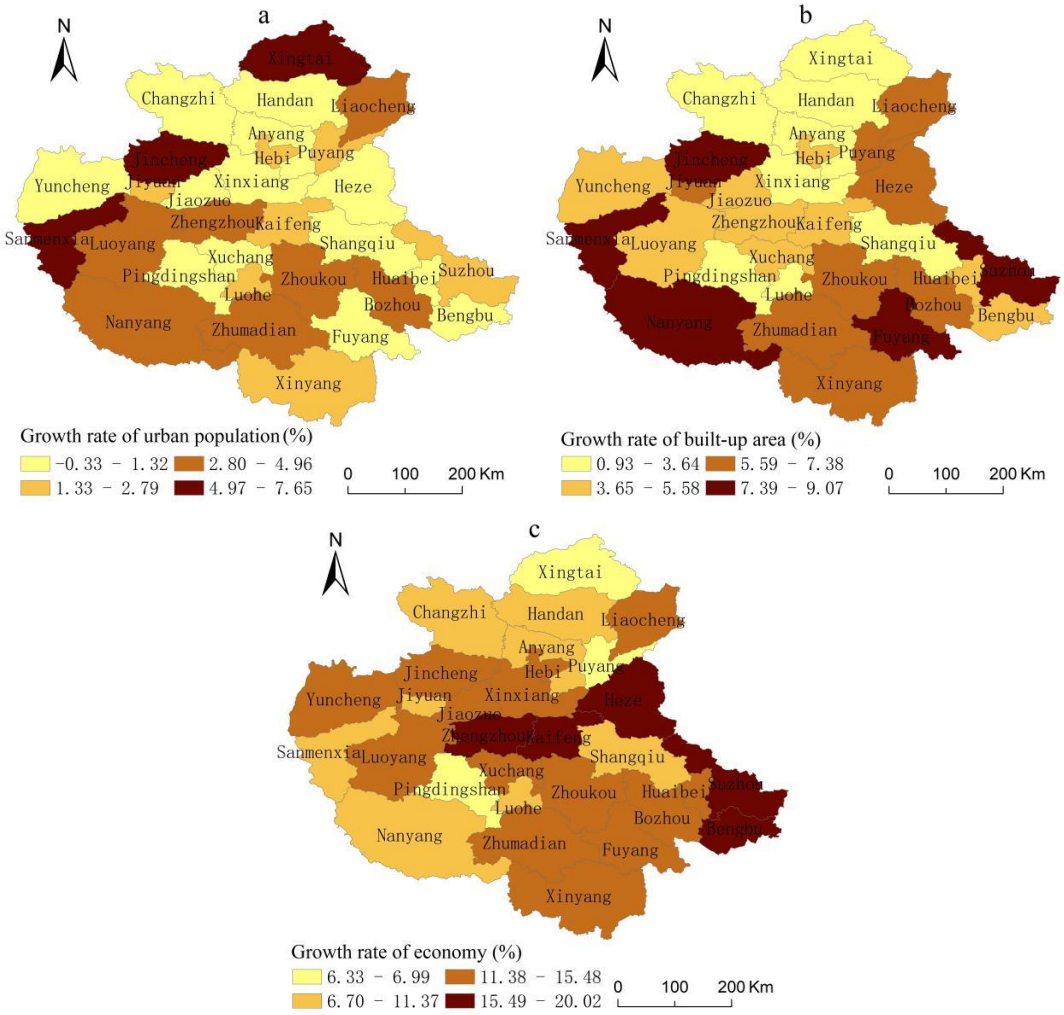

Figure 3. *Spatial distribution of growth rate of urban population (a), built-up area (b), and economy (c) of Central Plain City Cluster in 2008-2016*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1068510702

It showed significant spatial difference in growth rate of population, built-up area, and economy. In the study period, the growth rate of urban population was mainly concentrated in the range of 1.33-2.79% and 2.80%-4.96%, accounting for 43.33% and 23.33% of the total number of cities respectively; the growth rate of population of different cities was relatively close to each other. In terms of built-up area rate, the number of cities in different grades is basically the same. The growth rate of built-up area was mainly concentrated in the range of 3.65%-5.58%, and both were in the Midwest of the city cluster, accounting for 30% of the total number of cities. In general, the growth rate of built-up area is faster than that of urban population. Driven by the tide of urbanization, land finance has become an essential means or urban development. The growth rate of urban economy was mainly concentrated in the range of 12.27%-16.22%, accounting for 50% of the total number of cities. The cities with faster economic growth were concentrated in the central and western parts of the Central Plain City Cluster, mainly because, except Zhengzhou Metropolitan Zone, the Eastern Industrial Transfer Demonstration Zone, Western Transformation and Innovation Development Demonstration Zone, and Southern High Efficiency Ecological Economic Demonstration Zone realized collaborative development, forming a multi-regional development pattern.

Analysis of coordination evolution

Overall coordination trend

(1) Coordination trend of the center of gravity

According to *Equation 1,* the track of changes in urban population, built-up area, and economic center of gravity is calculated (*Fig. 4*). From *Figure 4,* it can be seen that the center of gravity of urban population, built-up area, and economy of Central Plain City Cluster was located in the northwest of the geometric center of gravity.

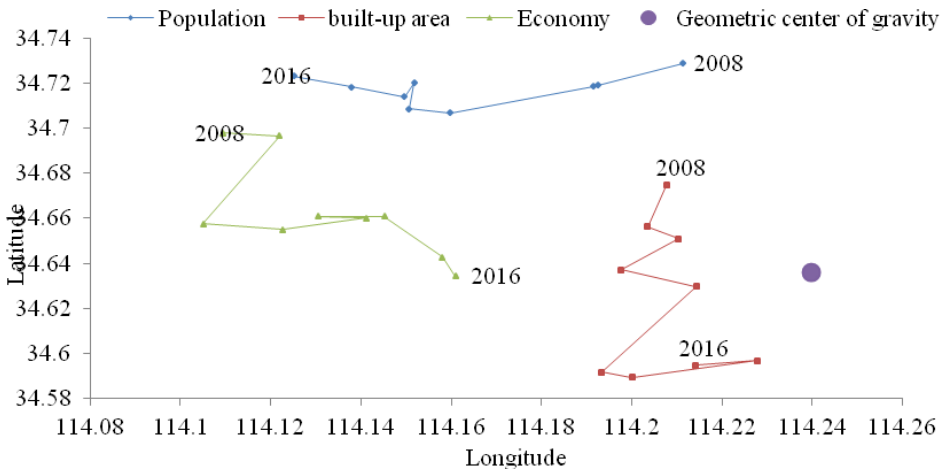

Figure 4. *Moving tracks of center of gravity of urban population, built-up area, and economy of Central Plain City Cluster in 2008-2016*

In 2008-2016, the center of gravity of urban population moved about 6.7 km to the west, with annual average moving distance of 1.33 km; the center of gravity of urban population moved about 8.37 km to the south, with annual average moving distance of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1068510702

1.98 km; the center of gravity of urban economy moved about 9.16 km to the southeast, with annual average moving distance of 1.85 km. On the whole, the moving distance of three centers of gravity was small, indicating that the distribution of population, built-up area, and economy of cities of Central Plain City Cluster was basically reasonable. Combined with *Figure 3,* the movement direction and growth rate distribution of the center of gravity were basically consistent in the urban population, built-up area, and economy; the growth of built-up area was mainly concentrated in the regions of south of Yellow River, and the center of gravity moved to the south, close to the geometric center of gravity; the center of gravity of population generally moved to the west due to influence of southwestern cities with faster population growth including Nanyang, Luoyang, Sanmenxia, and Zhengzhou; the center of gravity generally moved to the southeast due to the influence of cities with faster economic growth rate of central and southeastern cities.

According to *Equations 2* and *3,* the spatial overlapping and variation consistency in the center of gravity of urban population, built-up area and economy is calculated (*Fig. 5*).

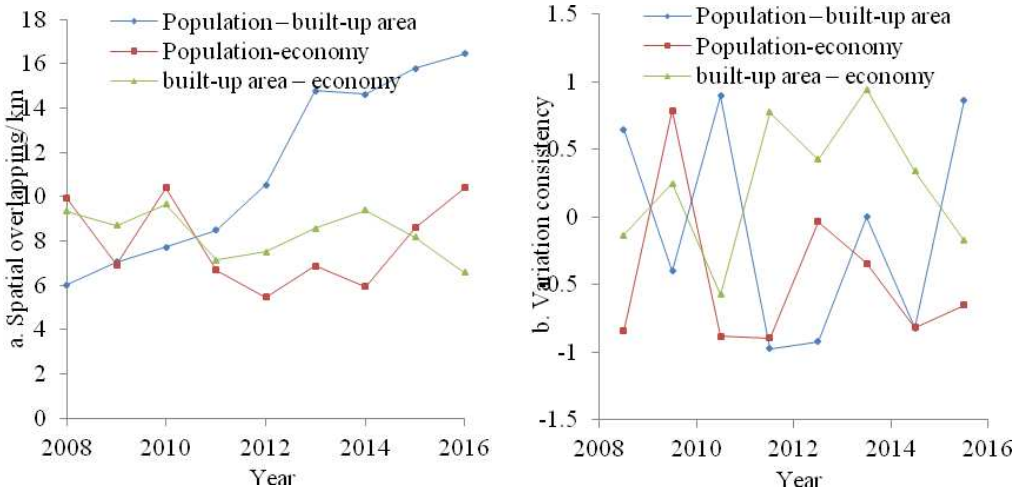

Figure 5. *Spatial overlapping (a) and variation consistency (b) of center of gravity of urban population and built-up area in Henan Province*

From *Figure 5,* it can be seen that: (i) The center-of-gravity distance between population and built-up area was generally on the rise, increasing from 6 km in 2008 to 16.5 km in 2016, with the average value of 10.9 km; the center-of-gravity overlapping was getting worse, and the coordination was declining; the variation consistency of the center of gravity between population and built-up area showed alternate changes of "the same direction – opposite direction", the variation consistency index was generally -0.12, indicating that the center of gravity of population and built-up area moved in the opposite direction and the distance between the centers of gravity was constantly increasing. (ii) The center-of-gravity distance between population and economy showed a general trend of "decline – rise", increasing from 9.9 km in 2008 to 10.4 km in 2016, with the average value of 8.1 km; the center-of-gravity overlapping showed a small fluctuation; the variation consistency index of the center of gravity between population and economy was negative (-2.69), indicating that the centers of gravity moved in the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1068510702

opposite direction, and the distance between the centers of gravity first increased then decreased, the coordination was poor. (iii) The center-of-gravity distance between built-up area and economy showed a declining trend, from 9.3 km in 2008 to 6.6 km in 2016, with the average value of 8.4 km; the center-of-gravity overlapping declined; the variation consistency of the center of gravity between built-up area and economy showed alternate changes of "the same direction – opposite direction", the variation consistency index was generally 2.32, indicating that the centers of gravity generally moved in the same direction, and the coordination gradually became greater.

(2) Evolution of unbalance situation

According to *Equation 4,* we calculated the unbalance index of population and built-up area, population and economy, and built-up area and economy of Central Plain City Cluster. The calculation results were shown in *Figure 6.*

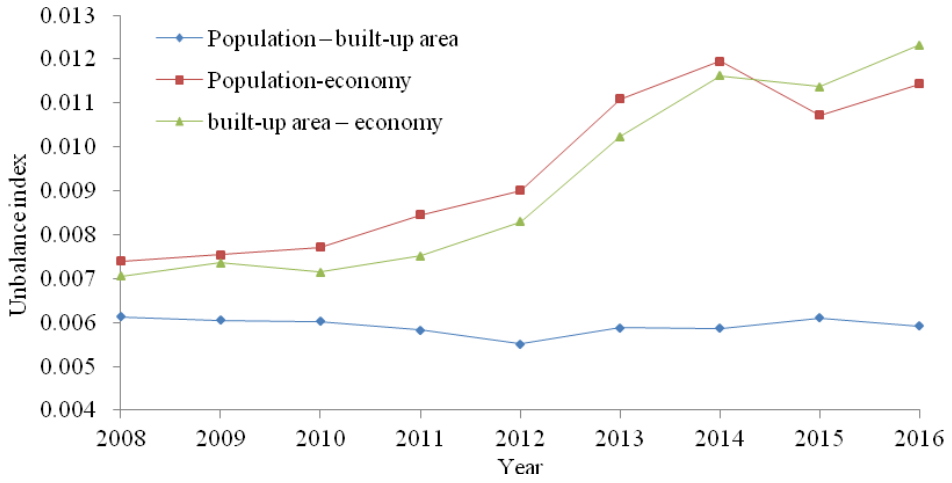

Figure 6. *Unbalance index of population, built-up area, and economy of Central Plain City Cluster*

Generally, the urban population–economy, and built-up area – economy unbalance index showed a fluctuation trend of "rise – decline – rise", and the variation trend of both was basically consistent, while the population - built-up area unbalance index was basically stable, showing a trend of "slow decline – slow rise". (i) In the study period, the population – built-up area unbalance index remained basically the same, with an average of 0.0059, indicating that the population and built-up area elements realized a balanced development in space. (ii) On the whole, the population–economy unbalance index rose from 0.0074 to 0.0114, and the built-up area – economy unbalance index rose from 0.0071 to 0.0123. Main reason was as follows: when carrying out the transfer of eastern industries, central core cities did not realize the corresponding agglomeration of population, so that the unbalance appeared between population, built-up area, and economy in space, till the urban population agglomeration effect became gradually stronger in the late period, then the spatial distribution balance of population and economic elements got gradually strengthened. For small and medium-sized cities, because built-up area expansion rate was much higher than the economic growth rate, the spatial distribution of built-up area and economic elements became out of balance.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1068510702

Trend of spatial coordination

According to *Equation 5,* we calculated the coordination (*C*) between population and built-up area, between population and economy, and between built-up area and economy of 30 cities in Central Plain City Cluster, and divided the coordination into coordinated, relatively coordinated, relatively uncoordinated, and uncoordinated types (*Fig. 7*).

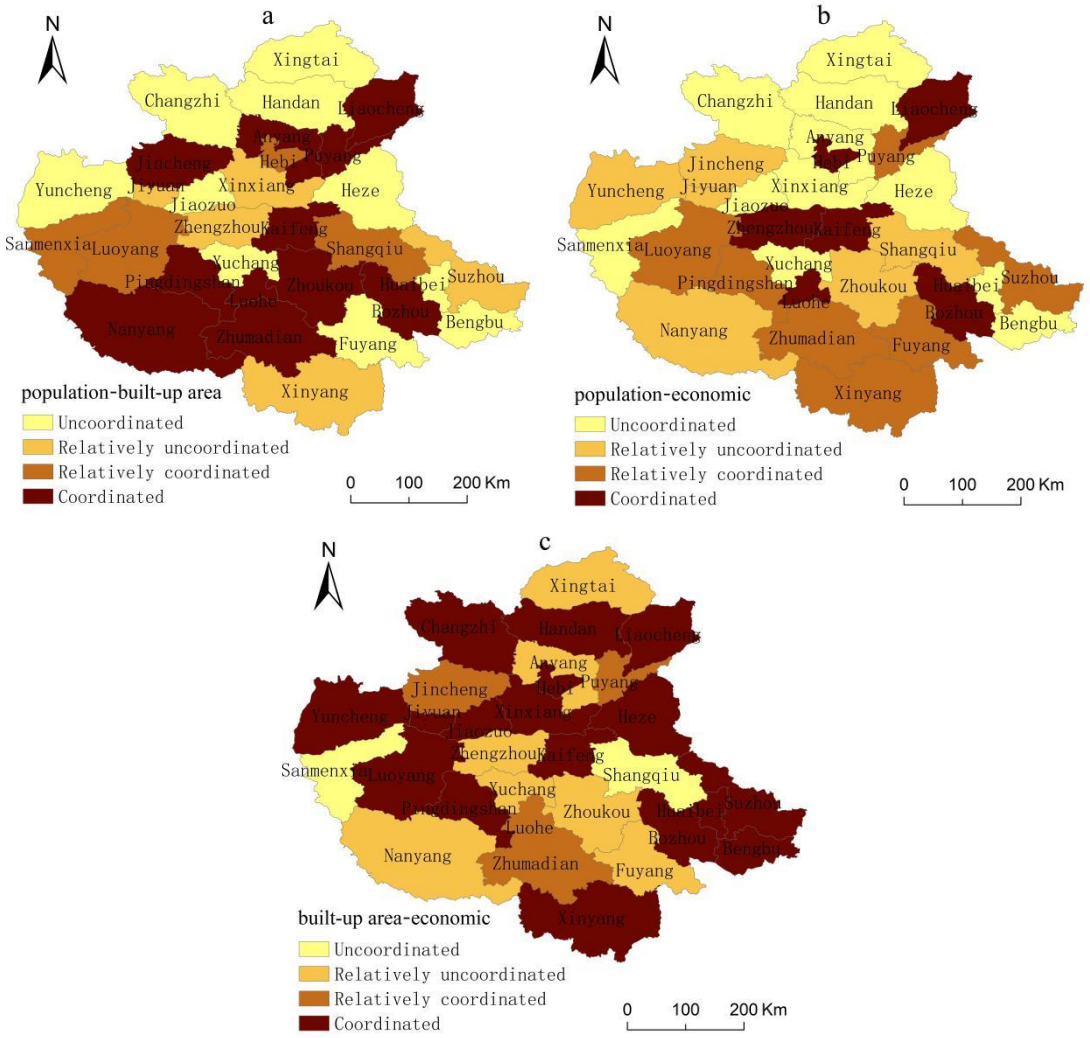

Figure 7. *Spatial distribution of population (a), built-up area (b) and economic (c) scale of 30 cities in 2008-2016*

(i) In the study period, the coordination relationship between population and built-up area of 30 cities in the Central Plain City Cluster was mainly coordinated and uncoordinated types, accounting for 36.67% and 33.33% of the total number of cities, respectively. The coordinated cities were mainly concentrated in the southern and northern parts of the City Cluster, and basically located in the transition area from the core city circle to edge city circle. They not only avoided the flow of urban population to Zhengzhou and outside Henan Province, but also avoided the problem of weak economic development due to geographical location, so the relationship between

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1068510702

population and built-up area was relatively balanced. Uncoordinated cities were mainly concentrated in the northern part, basically the fringe areas of the City Cluster. These cities received weak radiation of core city circle. Driven by the tide of urbanization, the built-up area expansion in these cities was faster than the population growth. Relatively coordinated and relatively uncoordinated cities were few and mainly distributed along the Longhai (Lianyungang-Lanzhou) Railway, accounting for 13.33% and 16.67% of the total number of cities, respectively.

(ii) The coordination relationship between population and economy was mainly uncoordinated type, accounting for 36.67% of the total number of cities. The number of coordinated, relatively coordinated and relatively uncoordinated cities is roughly equal, 20%, 23.33%, and 20%, respectively. Uncoordinated cities were mainly distributed in the northern part of the City Cluster, namely, north of the Yellow River. The expansion of Zhengzhou Metropolitan Zone and construction of all-direction accessible township industrial axis and belt promoted economic development of northern area and also made it absorbed numerous people from other places, so that urban economic growth of northern area was rapid but the population agglomeration was slow. Coordinated cities were scarcely distributed, mainly because these cities had high economic level, were located far from Zhengzhou, and situated in status of local core cities. The relatively coordinated and relatively uncoordinated cities were mainly distributed in the south of the Yellow River. These cities had stable economic development and population growth, and the relationship between economy and population was basically coordinated.

(iii) The coordination relationship between built-up area and economy was mainly coordinated type, accounting for 56.67% of the total number of cities. Relatively coordinated, relatively uncoordinated, and uncoordinated cities accounted for 13.33%, 23.33%, and 6.67% of the total number of cities, respectively. Roughly opposite to the coordination relationship between population and economy, the built-up area – economy coordinated cities were basically distributed along the Longhai Railway and the north of the Longhai Railway, while the relatively uncoordinated cities were basically distributed in the south of the Longhai Railway.

Logistic growth model

Urban development has its inherent laws. Predicting the development trend of population, built-up area and economy in the future urban development process has important realistic significance for rationally determining the scale of a city and coordinating the development of urban population, built-up area and economy. On the basis of the data of population, built-up area, and economy during 2008 (t = 1) and 2016 (t = 8), According to *Equation 6,* using the Brute Force search method, we established the Logistic prediction model for urban population, built-up area, and economy of the Central Plain City Cluster:

$$P_t = \frac{19648.15}{1 + 8.5822\, e^{-0.0217t}} \quad \text{(Eq.7)}$$

$$A_t = \frac{7936.97}{1 + 3.0806\, e^{-0.0695t}} \quad \text{(Eq.8)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1068510702

$$E_t = \frac{74577.44}{1+11.7325e^{-0.1531t}} \quad \text{(Eq.9)}$$

where P_t denotes the population size, A_t denotes the built-up area scale, and E_t denotes the economic scale. The goodness of fit of the model R^2 is higher than 0.97, so the fitting results are very credible. This model can reconstruct the population, built-up area and economic scale of the Central Plain City Cluster in 2008-2016 and predict the value of the following ten years (Chen and Zhang, 2014). As shown in *Figure 8,* the growth of each variable strictly followed the Logistic growth law, and the reconstruction results were very close to the actual scale of each variable. According to the prediction results, by 2026, the population, built-up area and economic scale of the Central Plain City Cluster were 29.4 million, 4,355 km^2, and 4.549 billion yuan, respectively, increasing by 4.75 million, 1,324 km, and 2.777 billion yuan, respectively compared with 2016. In 2016, the actual per capita built-up area was 123 m^2, the per capita GDP was 720,000 yuan, and the average built-up area GDP was 586 million yuan; in 2026, the per capita built-up area was 148 m^2, the per capita GDP was 154,700 yuan, and the average built-up area GDP was 1.045 billion yuan. On the whole, in the next decade, the urban population, built-up area and economic scale of the Central Plain City Cluster would show a steady growth trend, among which the economic growth rate will be the fastest, followed by the built-up area growth rate, and the slowest was the population growth rate.

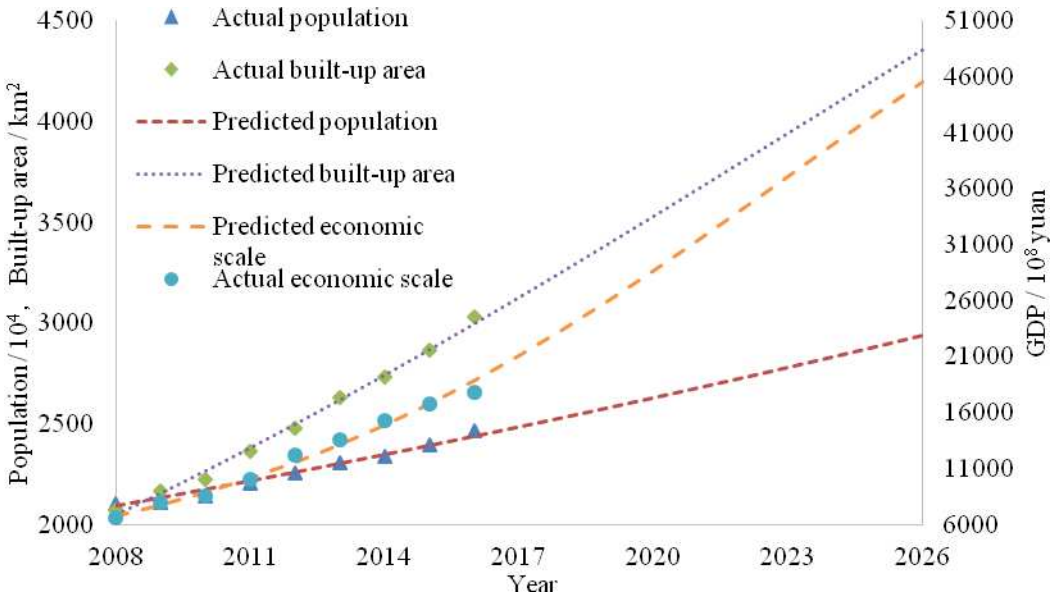

Figure 8. *Prediction of urban population, built-up area, and GDP of Central Plain City Cluster (2008-2026)*

Discussion

On the basis of previous studies, we analyzed the spatial and temporal evolution characteristics of the coordination of population - built-up area - economy of the Central Plain City Cluster and came up with some implications and conclusions. The

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1068510702

urbanization problem of the Central Plain City Cluster is mainly reflected in two aspects. First, the expansion of the urban built-up area leads to occupation of large area of farmland around the city, no guarantee for the life of landless farmers, and imbalance between the population growth, economic growth, and built-up area expansion. These are similar to the situation in other regions of China. Second, compared with the Yangtze River Delta, the Pearl River Delta, and the Beijing-Tianjin-Hebei region, the core cities of the Central Plain City Cluster are less efficient in promoting the surrounding areas. Once there the relationship between the population, built-up area, and economic development of surrounding areas is not coordinated, there will be adverse spatial effect between cities, which will be more unfavorable for the integrated development of the region. Therefore, it is necessary to improve the efficiency of economic growth, reduce the input of such productive resources as land, adjust the industrial structure, increase urban employment, and promote the coordinated and sustainable development of urbanization.

At present, there is still no unified standard for the evaluation system of urbanization coordination measurement. Combining the existing studies, we supplemented the existing theoretical connotation of "urbanization coordination" and stressed that the population - built-up area - economic urbanization subsystems have the same effect on the overall coordinated development. Besides, we built a preliminary framework for analysis of the urbanization coordination, namely, using the proportion of the population, build-up area, and economic growth rate of each city to that of the city cluster to characterize the contribution share of each subsystem; if the contribution share of each subsystem is consistent, it will be deemed to be the theoretical optimal state. The measurement of urban scale is very complicated. In this study, we calculated the future trend of urban population, built-up area and economy from the city cluster level and obtained reasonable results, indicating that our technical ideas are feasible and can be promoted. The calculation results can be used as an important reference for understanding the evolution process and future trend of the relationship between urban population, built-up area, and economy. Considering the complexity of urban scale prediction, especially the imbalance of urbanization development will reduce the accuracy of Logistic prediction, it is necessary to further explore a more comprehensive and effective technical method.

For example, the ecological factor should become an important indicator in the evaluation system of urbanization coordination. Both domestic and foreign theories of sustainable development of cities emphasized three important evaluation indicators "ecology, society, and economy". However, there is still no definite conclusion about how to quantify the weight of each indicator, and this is a difficult but important point of study. Therefore, we attempted to analyze the coordination between population and built-up area, and the conclusion can be used as a reference indicator for the evaluation of human settlement environment. However, we did not explore the coordinated relationship between ecological environment and urbanization. This is a weak point of our study. In the future study, we should analyze the urbanization and the connotation of the ecological environment from the perspective of complexity, and accordingly propose a reasonable analytical framework to explain the coordination mechanism between urbanization and ecological environment from multiple dimensions, so as to make clear the coordinated development relationship between urbanization and ecological environment, and ultimately promote the sustainable urban development.

Conclusions

Taking the Central Plain City Cluster as the research object, and using the center-of-gravity coupling model, unbalance index, and coordination measure model, this paper analyzed spatial and temporal evolution characteristics of coordination between urban population, built-up area, and economy in 2008-2016, and predicted their overall development trend according to the Logistic model. The results shown are as follows:

(i) The growth rate of urban population, built-up area and economy of Central Plain City Cluster shows a fluctuating trend. The economic growth is faster than that of population and built-up area. The variation trend of growth rate of built-up area expansion and population is basically consistent, while the growth rate of economy shows a significant decline, and the stage characteristics and spatial differences of their evolution are significant.

(ii) From the macro perspective, the shift direction of population is opposite to that of built-up area and economic gravity, the coordination between population and built-up area and economy gradually declines, while the shift direction of built-up area is the same as that of the economic center-of-gravity, and the coordination between built-up area and economy is gradually strengthened. The unbalance index of population, built-up area and economy is on the rise, while unbalance index of population and built-up area remains stable.

(iii) The coordination between population and built-up area and between population and economy is poor, with the population – built-up area and population –economy coordinated cities accounting for 36.67% and 20% of the total number of cities. The coordination between built-up area and economy is good, with built-up area – economy coordinated cities accounting for 56.67% of the total number of cities. The coordination between these three items presents significant spatial difference characteristics.

(iv) According to the prediction, the growth of each variable strictly follows the Logistic growth law, and the reconstruction results are very close to the actual scale of each variable. According the prediction, the overall size of urban population, built-up area and economy will be 29.4 million, 4,355 km2, and 4.549 billion yuan in 2026, and such prediction is very credible.

(Received 1st Mar 2019; accepted 21st May 2019)

Abstract. This study developed hydrologic models based on satellite remote sensing data from 2002 to 2010. Daily meteorological and hydrological data (1959-2010) were used as model inputs to analyse the relationships between meteorological factors and water area, and to calculate the daily water area and mean reduced water area on an annual basis to analyse the trend of changes. By analysing BCC-CSM1-1 model data, the study derived a qualitative assessment of the future water area of the Poyang Lake Basin, China. The following results were found. (1) The water area had shrunk substantially since the 1990s, especially during the 2000s. Because of aridification, the water area had decreased by 22.5% from 1845 km^2 in the 1980s to 1430 km^2 in the 2000s. (2) Since 1990, the first day of its wet season had become delayed and the final day had advanced. Generally, the number of wet season days had reduced while that of the dry season has increased. (3) In all future scenarios, extreme events were projected to occur more frequently, suggesting dramatic volatility in water resources and great frequency of droughts, which would exacerbate the shrinking of Poyang Lake and represent a severe threat to its water security.
Keywords: *Poyang Lake, water area, wet season, dry season, RCPs scenario*

Introduction

Although wetlands cover only about 6% of the earth's surface, they provide many services for humans, such as food, water, recreation and space for living. Climate change is recognized as a threat to the health of wetland systems. Major changes in global climate can be summarized as follows: (1) changes in total precipitation and precipitation pattern; (2) increase temperature and evapotranspiration, especially in high latitude; and (3) an increase in extreme climate events (IPCC, 2013; Junk et al., 2013). These changes will certainly induce variations in the structure, pattern, and function of wetlands by modifying temperature, precipitation, hydrology, and evapotranspiration (Erwin and Gardner, 2009). In North America, climate change will change rainfall patterns, thus affecting runoff and groundwater inflows to wetlands. In general, a decrease in precipitation or an increase in evapotranspiration will result in less-frequent flooding of existing wetlands. The magnitude and rate of climate change could alter the hydrology of the Great Lakes and affect wetland ecosystems. Because of an increased frequency and duration of low water levels, key wetlands are at risk, particularly those that are impeded from adapting to the new water level conditions by man-made structures or geomorphic conditions (Sierszen, 2012).

In China, especially in north China, it is difficult to predict the loss of the wetlands because of the climate change. As the global mean temperature continues to increase, the glacier in Qinghai-Tibet Plateau accelerates dissolution. The area of some wetlands has shrunk, while some wetland areas have increased, such as Ulan Ula Lake (Yan et al., 2014). But in south China, due to the combined effect of human activities and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1070310716

climate change, the wetland area is shrinking, such as Dongting Lake, Poyang Lake and so on (Liu et al., 2013; Cheng et al., 2016).

Located on the southern bank of the middle and lower reaches of the Yangtze River, Poyang Lake is the largest freshwater lake in China. It covers an area of 162,200 km^2 and it accounts for 9% of the Yangtze River Basin. The lake is one of the 10 largest ecological reserves in China and it is a major global ecoregion, as designated by the World Wide Fund for Nature. It plays an essential role in the protection of worldwide biodiversity, management of ecological security, safeguarding of people's livelihoods and property, and implementation of national water resource strategies (Hu et al., 2007). However, because of the impacts of climate change and anthropogenic activity, the wetland of Poyang Lake has "aged" rapidly in recent years, as evidenced in the lake sediments and by the shrinking of the lake and wetland areas (Jie et al., 2007; Qian and Dan, 2010; Jian et al., 2014).

The development of remote sensing technology has enabled extensive analysis of the water area of Poyang Lake to be conducted. For example, Zhang et al. (2012) adopted satellite remote sensing data acquired during 1991-2000 to analyze the water area dynamics of Poyang Lake. Using statistical analysis to couple the water area data with water levels measured by hydrologic stations during the same period, they established a relationship between water area and water level that modeled water area changes well, despite inherent errors between the wetland and water areas based on the remote sensing analysis. Dai et al. (2013) compared Landsat images of Poyang Lake from around 1990 and 2000 and they reported a substantial reduction in water area.

This study used remote sensing data to analyze the change of area of Poyang Lake's main body and its adjacent waters during 2000-2010. The objectives were to determine the relationship between meteorological conditions and water level, simulate the daily water area of Poyang Lake's wetland from 1959 to 2008, and discuss its annual trend of change over the past 50 years. Furthermore, the study adopted future Representative Concentration Pathways (RCPs) scenario data provided by the BCC-CSM1-1 model, developed by the National Climate Center of the China Meteorological Administration. These projections were used to discuss potential changes in climatic and basin factors, surface runoff and hydrologic extremum, and the potential impact of temperature change on the water area of Poyang Lake. The findings constitute a reference for the provision of management solutions by decision-making departments and science-based suggestions for sustainable socioeconomic development.

Data

Meteorological data

Daily meteorological data from Jan. 1, 1959 to Dec. 31, 2010 were provided by the Meteorological Bureau of Jiangxi Province. The dataset comprised almost complete and regular data records (20:00 to 20:00 Beijing time) from a reasonably dense and well-distributed network of 79 meteorological stations located within the lake basin (*Fig. 1*). Missing temperature and precipitation data in some stations records accounted for $\leq 0.5\%$ of the total dataset. The missing data were compensated based on inverse distance weighting using data from the nearest four stations (Appleton and Adlam, 2012); therefore, the missing data were considered not to compromise the mean value and the total value calculated on annual and monthly bases.

DOI: http://dx.doi.org/10.15666/aeer/1705_1070310716

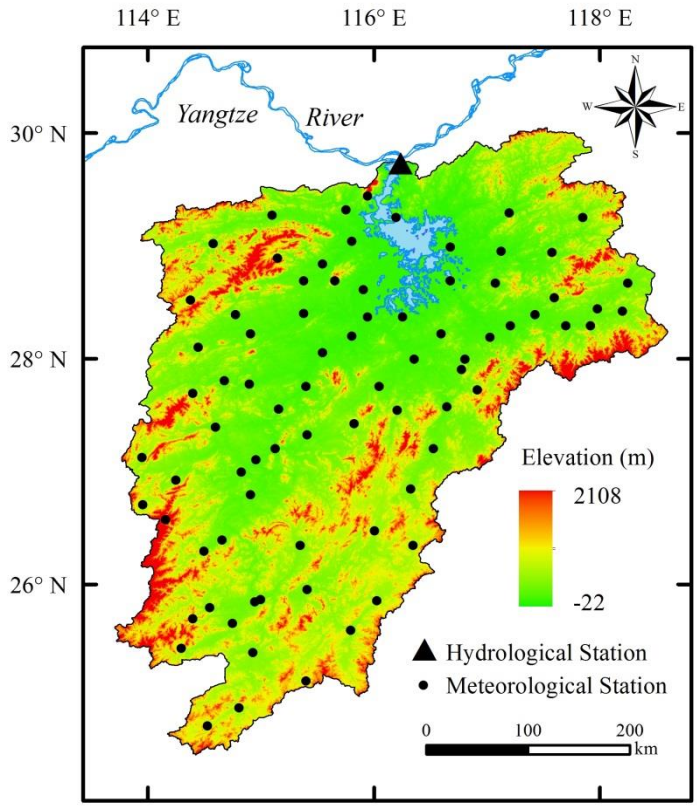

Figure 1. *Meteorological and hydrological (Hu Kou) stations in the Poyang Lake Basin*

Hydrological data

The Hukou Hydrologic Station is the control station located at the point where Poyang Lake discharges into the Yangtze River. The data recorded at Hukou reflect the level of Poyang Lake, which is governed by the levels of both the Yangtze River and the five major rivers that flow into the lake (*Fig. 1;* Hu et al., 2010). The hydrological data used in this study comprised daily water levels (Wusong Elevation) from 1961 to 2010 recorded at Hukou and Xingzi stations, provided by the Water Resources Department of Jiangxi Province.

Satellite remote sensing image data

The satellite remote sensing data of the water area of Poyang Lake (2002–2010) comprised 130 images acquired from the Poyang Lake Satellite Remote Sensing Data Bulletin released by the Meteorological Institute of Jiangxi Province. *Figure 2* shows the water area of Poyang Lake measured by remote sensing on June 4, 2010.

Climate model data

To predict future global and regional climate change, future emissions of greenhouse gases and sulfate aerosols need to be considered and these are included in the Special Report on Emissions Scenarios. In 2014, the IPCC suggested the use of radiation intensity per unit area to reflect Representative Concentration Pathway (RCP) scenarios

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1070310716

over the next 100 years. Different RCP scenarios (e.g., high, medium, and low) can be chosen based on projections of greenhouse gas emissions and equivalent CO_2 concentrations (IPCC, 2014; Metz et al., 2007).

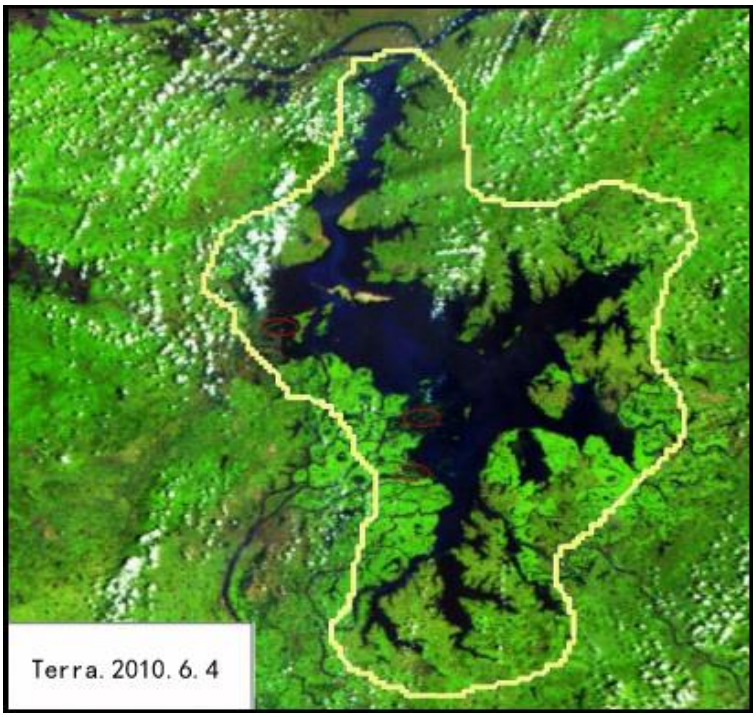

Figure 2. *Remote sensing image of Poyang Lake, acquired on June 4, 2010*

The study used data from the BCC-CSM1-1 model, developed by the National Climate Center. The model included three scenarios: RCP26, RCP45, and RCP85 with data resolution of 1° × 1°. The data comprised four parameters: mean temperature, highest and lowest temperatures, and precipitation spanning from Jan. 1, 1980 to Dec. 31, 2060. The model has been compared with other global climate models proposed for IPCC AR5, and it has been found to have better capacity in simulating climate (National Climate Center, 2012) in the monsoon belt of East Asia. Analysis of a control run of the BCC-CSM1-1 model by Zhang et al. (2011) and by Xin et al. (2013) indicated that it could satisfactorily reproduce the temperature and precipitation in China.

The simulation capability of the BCC-CSM1-1 model in terms of the daily temperature and precipitation in the area of Poyang Lake from 1986 to 2005 can be assessed using a Taylor diagram (Taylor, 2001; Xu et al., 2016). Comparisons of the correlation coefficients and the root mean square deviations of the observed data (1986–2005) with the BCC-CSM1-1 simulated data (1986–2005) show whether the model results are applicable to the Poyang Lake Basin. The Taylor diagram presented in *Figure 3* shows the correlation coefficients for the temporal and spatial distributions of temperature are 0.68 and 0.67, respectively, while those for precipitation are 0.58 and 0.45, respectively. All the root mean square deviations are < 0.5. Therefore, the BCC-CSM1-1 model is considered capable of simulating the daily temperature and precipitation at the station level for 1986–2005, indicating the suitability of the simulation data for the analysis of the spatiotemporal variations of temperature and precipitation.

Methodology

Classification of water area

This study classified the water area of Poyang Lake using the following scheme. The historically largest water boundary was taken as its outer boundary and its historically smallest water boundary was adopted as its inner boundary. We considered the area outside the outer boundary as land not submerged by water and the area inside the inner boundary as land covered by the lake. The water boundary of the lake moves within the outer and inner boundaries on a daily basis. The area between the water and inner boundaries was defined as the expanded water area and the area within the outer and water boundaries was defined as the reduced water area (see *Fig. 4*).

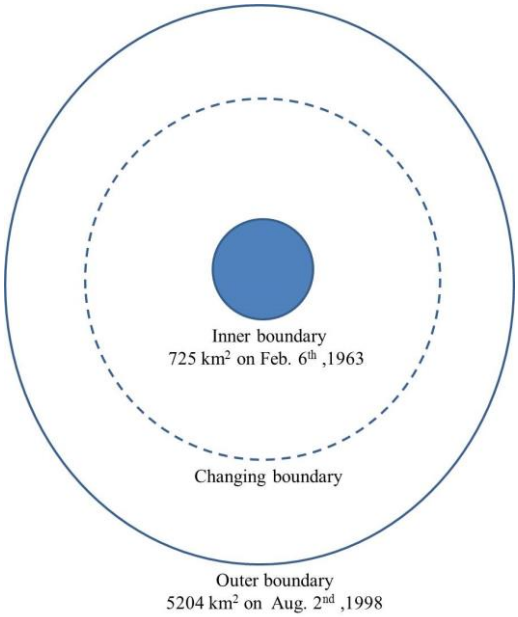

Figure 4. *Schematic of definition of water area of Poyang Lake*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1070310716

Water area model of Poyang Lake

Land reclamation constitutes a major process via which the land resource of lake areas in the southern plains of China has been developed and exploited. The harnessing of reclaimed land to develop agriculture (Zhang et al., 2015) has long been practiced in the wetland area of Poyang Lake. Since the founding of the People's Republic of China, unchecked land reclamation has been undertaken. For example, the area of reclaimed land in the 1950s, 1960s, and 1970s was 394.9, 793.4, and 211.7 km^2, respectively. However, by the 1980s, the situation was more controlled with only 66.9 km^2 of land reclaimed. Since the flooding that occurred in 1998, a policy of returning farmland to lakes has been phased in (Zhu and Kang, 2017). By the end of 2001, 900,000 residents had been resettled and the water area increased by over 1000 km^2. To avoid the influence of anthropogenic activity on the water area of Poyang Lake, this study used data collected from 2002 to 2009, after the return of farmland to the lake had been completed. These data included 98 samples of water area measured by remote sensing, water level measured at Hukou Station, and mean temperature and precipitation measured by the meteorological stations surrounding the Poyang Lake wetland. Stepwise regression analysis (Arunajadai, 2009) revealed the strongest correlations between the water area determined by remote sensing and water level measured at Hukou Station, and between the 30-d accumulative mean temperature and accumulative precipitation. We established a functional relationship between water area, Hukou water level, and meteorological conditions as below:

$$Y = -1.029X1 + 0.202X2 + 312.476X3 - 991.585 \quad \text{(Eq.1)}$$

where Y is the simulated water area of Poyang Lake, X_1 is the 30-d accumulative mean temperature, X_2 is the 30-d accumulative mean precipitation, and X_3 is the water level at Hukou Station on that day. Based on 14 sets of remote sensing data of water area, water level measured at Hukou Station, and meteorological data, it was verified that this model could satisfactorily simulate the water area of Poyang Lake with a correlation coefficient of up to 0.986 and mean relative error of only 5.6% (*Table 1*). No significant difference between simulated and measured data by F-test. In general, the simulation achieves the desired effect.

Inputting the data on temperature, precipitation, and water level at Hukou Station during the study period into *Equation 1* produced the largest and smallest water areas of 5204 (August 2, 1998; Hukou water level: 22.53 m) and 725 km^2 (February 6, 1963; Hukou water level: 5.91 m), respectively. Therefore, this study adopted 5204 km^2 as the outer boundary and 725 km^2 as the inner boundary.

Results

Changing trends of drought and flood of the Poyang Lake Basin

To analyze the trend of change of the Poyang Lake wetland, we supposed the water area within the outer boundary and within the inner boundary was S_{MAX} and S_{MIN}, respectively, and the water area on a certain day was S. Therefore, we defined the following:

$$S_{\text{expanded lake area}} = S - S_{MIN}$$

and

$$S_{\text{reduced lake area}} = S_{\text{MAX}} - S.$$

We used *Equation 1* to calculate the daily water area from 1959 to 2008. Its difference from the outer and inner boundaries was determined as the daily expanded or reduced water areas, respectively. *Figure 5* shows the annual mean expanded or reduced water areas. According to the statistics in the Chronicle of Meteorological Disasters in China—Jiangxi Volume (CMA, 2010) and the Yearbook of Climate-Related Disasters in China (CMA, 2014), basin-wide severe flooding occurred in 1970, 1973, 1975, 1995, and 1998. Taking 1998 as an example, 1329 villages and towns from 79 counties (cities or districts) were badly affected with direct economic losses of RMB38.714 billion. Basin-wide severe drought has occurred in 1963, 1971, 1972, 1978, 1986, 1988, 2001, 2003, 2004, 2006, and 2007. Taking 2007 as an example, 352,000 ha of crops were affected by drought and 64,000 ha of winter crops could not be sown. Overall, 760,000 people and 310,000 large livestock lacked adequate supplies of drinking water.

Table 1. *Simulation tests of the water area of Poyang Lake in 2010*

Average						5.6

The time series of changing wetland area presented in *Figure 5* reflects the occurrence of flood and drought disasters in the Poyang Lake Basin. *Figure 5* shows that since 1990 the wetland area of Poyang Lake has had a trend of reduction. Particularly since 2000, several severe droughts have exacerbated this trend (the trend passed the 0.01 reliability test). The water area of Poyang Lake has shrunk substantially from the 1990s, especially during the 2000s. Because of aridification, the water area has shrunk by 22.5% from 1845 km^2 in the 1980s to 1430 km^2 in the 2000s.

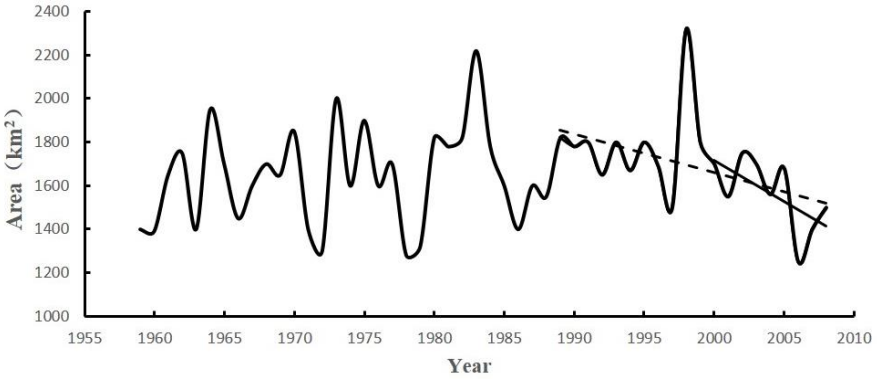

Figure 5. *Temporal variation of wetland area of the Poyang Lake Basin (1959–2008)*

Changing trend of wet season of Poyang Lake Basin

The wet and dry seasons of the Poyang Lake Basin were determined based on the water level at the Xingzi Hydrologic Station. When its water level was > 13.39 m, we considered the area to be in the wet season and the first day of such an occurrence was denoted the first day of the wet season (final day of the dry season). When its water level was < 10.22 m, we considered the area to be in the dry season and the first day of such an occurrence was denoted the first day of the dry season (final day of the wet season). The period between the first and final days of the wet season was called the wet season of Poyang Lake. Using daily hydrological data from Xingzi Station (1959–2009), we calculated the annual first and final days of the wet season and the number of wet season days.

According to *Figures 6–8*, the first day of the wet season of Poyang Lake has had a tendency to become delayed (the trend passed the 0.05 reliability test). Conversely, the final day of the wet season of Poyang Lake has had a tendency to become advanced (the trend did not pass the reliability test). Generally, the number of days of the wet season of Poyang Lake has decreased since 1990 (the trend passed the 0.05 reliability test). This reduction has led to large-scale wetland loss and degradation, stunting the growth and development of both plants and animals. Taking the dry season from August 2006 to April 2007 as an example, it is evident that the eco-environment of the lake area has been influenced by the effects of climate change. Droughts have given rise to serious ecological issues, including the drying up of lake branches, degradation of lakeside wetland, and desertification of the lakebed.

Climate prediction

Data from the BCC-CSM1-1 model, developed by the National Climate Center, is capable of simulating the climatic conditions of the Poyang Lake Basin. Based on systematic analyses, Zhan et al. (2013) verified the capability of the BCC-CSM1-1 model in simulating the spatial and temporal trends of temperature.

Temperature prediction

As shown in *Figure 9,* under the three future climate change scenarios (RCP2.6, RCP4.5, and RCP8.5), the annual mean temperature of the Poyang Lake Basin would increase to different extents from 2011 to 2060. It would increase the least under the RCP2.6 scenario and it would increase the most under the RCP8.5 scenario. The rates of temperature rise under the RCP2.6, RCP4.5, and RCP8.5 scenarios would be 0.26, 0.37, and 0.44 °C/a, respectively. The mean temperature, however, would be highest (17.7 °C) under the RCP4.5 scenario and lowest (16.9 °C) under the RCP8.5 scenario.

Precipitation prediction

As shown in *Figure 10* and *Table 2*, under the three RCP climate change scenarios, precipitation in the Poyang Lake Basin from 2011 to 2060 would not change overall, although interannual fluctuation would be apparent. The annual mean precipitation would be lowest under the RCP8.5 scenario, while it would be similarly relatively

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1070310716

higher under the RCP2.6 and RCP4.5 scenarios. In terms of interdecadal precipitation distribution, the trends seen under the RCP2.6 and RCP4.5 scenarios would be consistent with a W–shaped pattern, i.e., reflecting a process of "fall–rise–fall." Under the RCP8.5 scenario, the Poyang Lake Basin could experience a prominent trend toward a hotter and wetter climate.

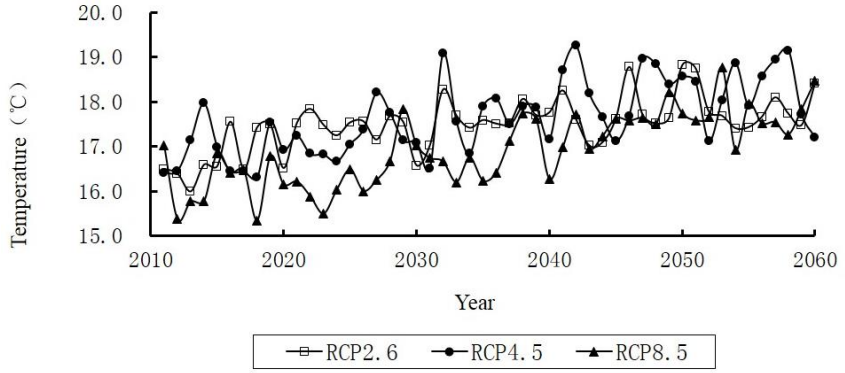

Figure 9. *Temporal variation of annual mean temperature under different RCP scenarios (2011–2060)*

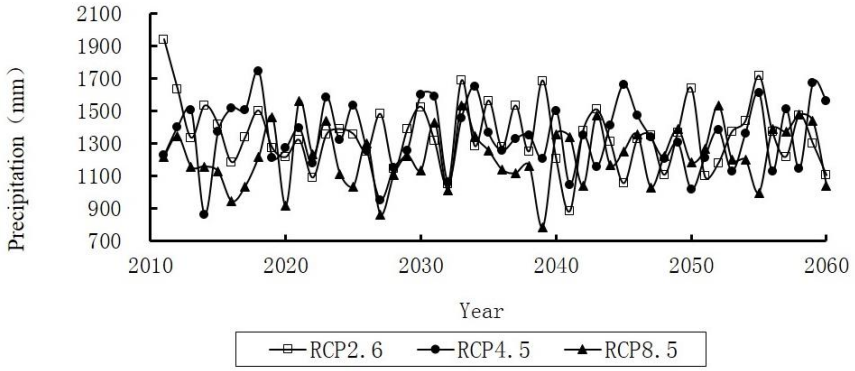

Figure 10. *Temporal variation of annual precipitation under different RCP scenarios (2011–2060)*

Table 2. *Decadal annual precipitation of the Poyang Lake Basin under different RCP scenarios (2011–2060)*

Precipitation (mm) / Scenarios	2010s	2020s	2030s	2010s	2010s	2011-2060
RCP2.6	1437	1329	1385	1292	1326	1354
RCP4.5	1362	1323	1376	1296	1371	1345
RCP8.5	1157	1200	1212	1245	1290	1221

Changing trend of precipitation extremum

Extreme precipitation events can be represented by two quantiles, e.g., the 10th and 90th percentiles of annual precipitation (Guan et al., 2015; Zhang et al., 2015). *Table 3*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1070310716

lists the threshold values of extreme events in the Poyang Lake Basin. It is shown that from 2011 to 2060, dry years with 10% probability of occurrence would increase obviously under all three RCP scenarios but the increase would be greatest under the RCP4.5 and RCP8.5 scenarios. Over the past 50 years, wet years with 10% probability of occurrence remained largely constant under the RCP2.6 scenario but they decreased in number in both the RCP4.5 and the RCP8.5 scenarios. In general, under all three scenarios, extreme events would be expected to occur more frequently, suggesting dramatic volatility in water resources and greater frequency of droughts, which would exacerbate the shrinking of Poyang Lake and represent a severe threat to its water security.

Table 3. *Frequency of extreme events in the Poyang Lake Basin from 2011 to 2060 under the different RCP scenarios*

Extreme precipitation from 1981 to 2005 (mm)		**Extreme precipitation from 2011 to 2060 (mm)**		
The 10th percentile	**The 90th percentile**		**Times lower than the 10th percentile**	**Times higher than the 10th percentile**
1098	1607	RCP2.6	6	5
		RCP4.5	10	1
		RCP8.5	13	2

Conclusions and discussion

The Poyang Lake Basin is sensitive to the effects of climate change. Particularly since the 1990s, it has witnessed a rapid rise in temperature, fewer rainfall days, and increased precipitation intensity, which have increased the frequencies of floods in summer and of droughts in spring and autumn (Wang et al., 2009; Wei et al., 2015). Since the 2000s, with even greater temperature rises and slight falls in amounts of precipitation, the Poyang Lake Basin has faced severe challenges of aridification and shrinkage of the lake area. Based on hydrological data from the Wuhe and Xingzi stations (1956–2007), a study by Min and Dan (2010) yielded almost identical results to those derived from the present work.

1. A statistical model built using hydrological and meteorological data was verified capable of reflecting changes in the water area of Poyang Lake. Based on the difference between the water area and the outer and inner boundaries, this study redefined and reclassified the area of the Poyang Lake wetland. The results showed that the change of wetland area satisfactorily reflected the variation between flood and drought throughout the entire basin. Since 1990, and particularly since 2000, acute reduction of the wetland area has accelerated its aridification.

2. Using the water level of the Xingzi Station as a benchmark, the first and final days of the wet season (first and final days of the dry season) of Poyang Lake were analyzed. It was found that since 1990 the first day has become delayed and that the final day (first day of the dry season) has advanced. The number of wet season days has decreased significantly and the wetland area is in the process of dramatic shrinkage.

3. Under the RCP2.6, RCP4.5, and RCP8.5 scenarios, it was discovered that the temperature from 2011 to 2060 would continue to rise in the Poyang Lake Basin. Although the precipitation amounts would remain similar, extreme droughts would occur with greater frequency and the water area would fluctuate more substantially,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1070310716

which would exacerbate the shrinkage and degradation of the water area, introducing greater instability to the ecological system.

Irrespective of whether based on observed or remotely sensed data, previous research has largely agreed that the area of Poyang Lake has shrunk from the 1960s to the 2000s (Min and Dan, 2010; Feng et al., 2011; Gan and Liu, 2011). However, considering the influence of the Three Gorges Dam (Wu et al., 2011; Mei et al., 2015; Liu et al., 2017), the future of the Poyang Lake Basin is more difficult to forecast. Based on future climate data, this study predicted exacerbation of the shrinkage of Poyang Lake. To overcome inadequacies identified in this research, our future work will use additional climate model data and a hydrological model to consider the effects of the Three Gorges Dam.

Abstract. This study aims to analyze the effects of plant growth regulator on the chlorophyll fluorescence characteristics and yield of spring maize under different planting densities in Northeast China. 'Dongnong 253' was used as the material in this experiment and was planted at the densities of 5, 6, 7 and 8 plants m^{-2}. The plants were sprayed at the jointing stage with the "Yuhuangjin" plant growth regulator. The results showed that increasing the planting density effectively increased the production of the maize populations, while it led to a decrease in the chlorophyll content, angle between the stem and leaf (ABSL) in the ear leaf, single plant dry weight and photosynthetic efficiency, as well as increases in the plant height, ear height and lodging risk. The application of "Yuhuangjin" decreased the plant height and ear height and increased the dry matter accumulation per plant and lodging resistance, increased the ABSL in the ear leaf, reduced the degree of overshadowing in the prophase, extended the duration of high leaf area index (*LAI*), delayed the senescence process of the leaf and improved the canopy aeration and transmittance capability. The application of "Yuhuangjin" improved the photosynthetic capacities and maintained higher stable photosynthesis by significantly improving the chlorophyll fluorescence parameters, such as *Fv/Fm*, *Y(II)*, and *qP* and decreasing *Y(NO)* and *qN*. This study showed that the highest yield was 11428.18 kg ha^{-1} after the "Yuhuangjin" treatment at the planting density of 7 plants m^{-2}. This experiment provided theoretical and experimental evidence for the effect of increased production from the use of plant growth regulator and high-density planting cultivation on spring maize in Northeast China.

Keywords: *maize, high-density planting, chlorophyll fluorescence characteristics, photosynthesis rate, Yuhuangjin, yield*

Introduction

Maize (*Zea mays* L.) plays an important role in ensuring world food security (Dong et al., 2013; Li et al., 2017). Increasing planting density is important to increase maize yields. The demand for maize is increasing with the rapidly increasing demands for food, livestock feed and bio-fuel at the global scale. Previous researchers have conducted extensive work in improving maize yield potentials and increasing yields per unit area (Diallo et al., 2015; Li et al., 2016; Biswas and Ma, 2017; Ren et al., 2017a). Previous studies have shown that increasing population density is an important method to achieve high yields (Rutger and Crowder, 1967; Roy et al., 2014). The analysis of 37 super-high-yield fields between 2006 and 2007 showed that the yields reached 15000 kg ha^{-1} in the high yield field, the densities were in the range of 79725~84630 ears ha^{-1} (Chen et al., 2008). However, the current density of maize in the United States is generally 8 plants m^{-2} or higher. Dense planting is the main measure used to improve maize yields (Zhao et al., 2006; Benari and Makowski, 2016). The

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1071710730

structure of the canopy group becomes poor with the increase in planting density, and increased density can cause the plants to shade each other. Increasing the planting density will also increase the competition for light, water and nutrients between plants (Kang et al., 2011; Farhad and Mehdi, 2015; Ren et al., 2017b). With the planting density increases, the individual plants in the group will shade each other, which will deteriorate the permeability of the canopy, decrease the photosynthetic performance, increase the plant height and increase the risk of lodging (Li et al., 2007; Sangakkara et al., 2012).

The maize in the area of Northeast China experiences low temperatures and rainy environments, which enable the root system to resist falling. Plant growth regulator is a synthetic substance that has the function of plant hormones (Yan et al., 2009). Plant growth regulator can effectively regulate the growth and development of plants and can effectively regulate the structural characteristics of the canopy. It is easy for the root system to fall in the later stages of growth and development, and this will cause many production cuts (Liao et al., 2014). Plant growth regulator technology can lower the height and ear height of maize plants (Meng et al., 2016). Plant growth regulators can enhance the anti-lodging ability, improve the chlorophyll content in leaves and prolong the duration of high leaf area index (*LAI*) values (Cheng and Liu, 2017). Plant growth regulator can truncate the elongation of internode cells, lower the center of the maize plant, increase the roughness of the stalks, improve the anti-lodging capacity (Fan et al., 2017), improve the leaf photosynthetic characteristics, photosynthetic efficiency and the rational distribution of assimilation products (Zhang et al., 2014). Moreover, plant growth regulator can also promote the absorption of the maize root system, promote the delivery of root secretions to the ground and promote the formation of grain yields (Cicchino et al., 2013).

Photosynthesis is the basis of plant growth and development (Inamoto et al., 2015). The photosynthetic rate is an important index that can reflect the photosynthetic capacity of a plant. The process of photosynthesis is composed of a series of complex photophysical and photochemical processes. During these processes, part of the light energy losses is released in the form of fluorescence. Chlorophyll fluorescence is closely related to photosynthesis (Hwang and Choo, 2016; Zhang et al., 2017).

"Yuhuangjin" plays an important role in the increase of maize planting in China. The plant growth regulator "Yuhuangjin" was provided by Fujian Haolun Biology Engineering Technology Co. Ltd, China. Its total effective component contents are the mixture of 3% diethyl aminoethyl hexanoate and 27% ethephon. Maize in Heilongjiang Province faces problems related to how both production and anti-lodging capacity can be synergistically increased. Previous researchers have conducted extensive work on the application of "Yuhuangjin", and it plays an important role in the mining potential of planting. In this experiment, we combined dense planting and plant growth regulator to study the photosynthetic characteristics of maize and the effects on yield. The results also provided an experimental basis for the reasonable application of "Yuhuangjin" in China.

Materials and methods

Experimental materials and treatments

The present experiment was carried out from 2013 to 2014 at the Xiang Fang experimental base, Northeast Agricultural University, Heilongjiang Province at 45°42′N

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1071710730

latitude and 126°36′E longitude. The soil is a typical black soil (typic hapludoll in USDA soil taxonomy). The soil contained organic matter (25.25 g kg^{-1}), total nitrogen (N) (1.70 g kg^{-1}), available potassium (K) (179.35 mg kg^{-1}), rapid available phosphorus (P) (65.34 mg kg^{-1}), and alkali hydrolysable nitrogen (N) (118.21 mg kg^{-1}). The climate in the region is temperate continental monsoon. The weather data from 2013 and 2014 are provided in *Table 1*.

Table 1. *Daily mean values of the weather variables at the experimental site during the six months of the maize growing season in 2013 and 2014*

Month	Average temperature (°C)		Precipitation (mm)		Sunshine hours (h)	
	2013	2014	2013	2014	2013	2014
April	4.4	10.3	10.8	6.1	202.3	267.0
May	17.9	14.3	73.5	91.4	240.7	127.5

[a] Precipitation and sunshine are monthly sums, while temperature is a monthly mean of daily means

Maize was hand-sown at 7 cm depth and 70 cm row distance on May 1 in 2013 and May 1 in 2014 in a plot size of 84 m^2. The supply trial variety was ‘Dongnong 253’. The tested planting densities were 5 plants m^{-2}, 6 plants m^{-2}, 7 plants m^{-2} and 8 plants m^{-2}. Using the same density of rope, 20 ml of "Yuhuangjin" was added to 30 kg of water. The solution was sprayed on six leaves and one bud, and water was used as a control. Diammonium phosphate (250 kg), urea (75 kg), and potassium sulfate (150 kg) were used as seed fertilizer, and nitrogen fertilizer was applied per hectare during the jointing stage.

Measurement of leaf area index (LAI)

The leaf area was measured using three randomly selected maize plants in each plot at the silking stage. The length and maximum width of each leaf were measured with a ruler. Leaf area index (*LAI*) = single plant leaf area × the number of plants per unit of land ÷ unit land area.

Measurement of chlorophyll content (SPAD)

The CCM-200+ (Beijing Aozuo Ecology Instrument Co, Ltd) chlorophyll meter was used to measure the relative chlorophyll content in leaves. In each treatment phase, three plants with uniform leaf ages were selected and marked. The determination time was between 8:30 and 10:00 am, and the ear-leaf content of each reproductive period was measured. The leaf tip, leaf center and leaf base of the leaves were determined, and the mean values were calculated as the determination value of the blade. The three measured values of each treatment were calculated, and the average value was taken as the *SPAD* value of the treatment. In the subsequent measurements, the marked plants were selected for measurement.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1071710730

Measurement of net photosynthetic rate of leaves (Pn)

The net photosynthetic rate of the leaves was determined between 9:00 and 11:00 am, and a hand-held photosynthetic rate meter instrument CI-340 (Zealquest Scientific Technology Co., Ltd.) was used to measure the ear-leaf content. The mean value of the three measured values was used as the measured value for the treatment.

Measurement of chlorophyll fluorescence parameters

The middle of the selected plant was measured to determine the chlorophyll fluorescence parameters, and the measurement was collected between 8:30 and 10:00 am. First, a leaf clip was used to hold the middle of the ear leaf, and the ear leaf was kept in the dark treatment for 20 minutes; then, the leaf clip operation steps were followed. The mean value of the three measurements was taken as the measured value. The *PSII* maximum quantum yield (*Fv/Fm*), actual quantum yield (*Y(Ⅱ)*), non-regulating performance dissipation quantum yield (*Y(NO)*), non-photochemical quenching parameters (*qN*), and photochemical quenching parameters (*qP*) were calculated. The measurement instrument was a portable modulated chlorophyll fluorometer (PAM-2500) (KANGGAOTE Science and Technology Co., Ltd).

Measurement of biomass and yield

To determine the biomass and yield, two consecutive four-meter lengths were selected for each process. The rows per ear, number of ear, kernels row, number of row and hundred grain weight were calculated. After harvest, 20 ears were selected to calculate the kernels row, number of row, hundred grain weight, and the theoretical yield. The biomass was determined by the drying method, and the stalks and grains were dried separately. Each process was repeated three times, and the results were averaged.

Statistical analyses

According to the analysis of variance principles, data were statistically analyzed following standard statistical methods using Microsoft Excel 2010 and SPSS 12.0. Differences between treatments were determined by a posteriori Tukey's test at a significance level of 0.05.

Results

Effects of plant growth regulator on leaf area index of spring maize in different planting densities

During the reproductive process, the *LAI* first showed an increasing then a decreasing trend in both treatments (*Table 2*). The *LAI* peaks appeared around the time of silking, and the *LAI* also increased with the increase in planting density. In the "Yuhuangjin" treatment, the peak *LAI* values were 0.89% (5 plants m^{-2}), 3.95% (6 plants m^{-2}), 1.23% (7 plants m^{-2}) and 8.74% (8 plants m^{-2}) lower than the peak *LAI* values in the water treatment. From the silking stage to the dough stage, the *LAI* values were 3.75% (5 plants m^{-2}), 6.47% (6 plants m^{-2}), 7.14% (7 plants m^{-2}) and 14.60% (8 plants m^{-2}) lower than the peak values in the water treatment.

Effects of plant growth regulator on chlorophyll SPAD in the leaves of northeast spring maize under different planting densities

From the silking stage to the dough stage, the chlorophyll *SPAD* value decreased in the two treatments (*Table 3*). In the water treatment, the *SPAD* value decreased in every growth period with the increase in density. From the silking stage to the dough stage, the *SPAD* value declined by 16.72% (5 plants m^{-2}), 23.52% (6 plants m^{-2}), 25.01% (7 plants m^{-2}) and 25.73% (8 plants m^{-2}).

	8	66.64±4.06^{bcd}	62.50±2.86^{b}	55.51±2.71^{abc}

In the "Yuhuangjin" treatment, the *SPAD* value was higher than that in the water treatment in every growth period. The *SPAD* value in the "Yuhuangjin" treatment was higher than that in the water treatment by 7.14% (5 plants m^{-2}), 9.19% (6 plants m^{-2}), 7.85% (7 plants m^{-2}) and 8.77% (8 plants m^{-2}) at the silking stage. From the silking stage to the dough stage, *SPAD* value declined by 18.52% (5 plants m^{-2}), 16.54% (6 plants m^{-2}), 12.30% (7 plants m^{-2}) and 16.71% (8 plants m^{-2}) in the "Yuhuangjin" treatment. Except for the 5 plants m^{-2} density, the "Yuhuangjin" treatment decreased the chlorophyll degradation rate at varying degrees in the later stages of procreation.

Effects of plant growth regulator on the net photosynthetic rate (Pn) of leaves of northeast spring maize under different planting densities

From the silking stage to the dough stage, the net photosynthetic rate of the leaves decreased gradually in both treatments (*Table 4*). In the water treatment, the net photosynthetic rate was 43.29 μmol m^{-2} s^{-1} (5 plants m^{-2}), 40.42 μmol m^{-2} s^{-1} (6 plants m^{-2}), 38.79 μmol m^{-2} s^{-1} (7 plants m^{-2}) and 37.59 μmol m^{-2} s^{-1} (8 plants m^{-2}) at the silking stage. When the planting density increased, the net photosynthetic rate decreased. Compared to the 5 plants m^{-2} density, the net photosynthetic rate in the other densities reduced by 6.64% (6 plants m^{-2}), 10.40% (7 plants m^{-2}) and 13.17% (8 plants m^{-2}). At various densities, the net photosynthetic rate decreased by 46.23% (5 plants m^{-2}), 44.47% (6 plants m^{-2}), 44.72% (7 plants m^{-2}) and 49.70% (8 plants m^{-2}) from the silking stage to the dough stage.

Table 4. *The effects of plant growth regulator on the Pn of spring maize leaves under different planting densities in Northeast China*

Treatment	Density (plants m^{-2})	Jointing stage	Trumpet stage	Silking	Grain filling stage	Dough stage
Water	5	15.93 ± 0.09^{b}	29.40 ± 1.80^{b}	43.29 ± 1.31^{bc}	35.05 ± 0.88^{b}	23.28 ± 0.88^{cd}
	6	14.50 ± 0.16^{d}	26.53 ± 0.91^{de}	40.42 ± 0.32^{d}	32.22 ± 0.42^{e}	22.44 ± 0.43^{de}

	6	15.99 ± 0.09^{b}	29.28 ± 0.70^{b}	44.28 ± 0.32^{b}	34.80 ± 0.32^{bc}	25.28 ± 0.32^{b}
	7	15.84 ± 0.16^{bc}	28.41 ± 0.49^{bc}	42.65 ± 0.66^{c}	33.66 ± 0.74^{cd}	24.18 ± 0.38^{c}
	8	15.60 ± 0.22^{c}	27.16 ± 0.96^{cd}	39.99 ± 0.22^{de}	32.52 ± 1.05^{de}	19.87 ± 0.69^{f}

The net photosynthetic rate was higher in the "Yuhuangjin" treatment than in the water treatment in every growth period. The peak values were 46.81 μmol m^{-2} s^{-1} (5 plants m^{-2}), 44.28 μmol m^{-2} s^{-1} (6 plants m^{-2}), 42.65 μmol m^{-2} s^{-1} (7 plants m^{-2}) and 40.00 μmol m^{-2} s^{-1} (8 plants m^{-2}) at the silking stage. The net photosynthetic rates in the "Yuhuangjin" treatments were higher than those in the water treatment by 8.15% (5 plants m^{-2}), 9.55% (6 plants m^{-2}), 9.95% (7 plants m^{-2}) and 6.39% (8 plants m^{-2}).

From the silking stage to the dough stage, the net photosynthetic rate declined by 43.42% (5 plants m^{-2}), 42.90% (6 plants m^{-2}), 43.29% (7 plants m^{-2}) and 50.33% (8 plants m^{-2}). The net photosynthetic rate in the "Yuhuangjin" treatment was higher than that in the water treatment by 13.79% (5 plants m^{-2}), 12.64% (6 plants m^{-2}), 12.80% (7 plants m^{-2}) and 5.08% (8 plants m^{-2}) at the dough stage.

Effects of plant growth regulator on chlorophyll fluorescence parameters of the leaves of northeast spring maize under different planting densities

From the silking stage to the dough stage, the *PSII* maximum quantum yield showed a declining trend in the two treatments (*Table 5*). The *Fv/Fm* declined by 3.16% (5 plants m^{-2}), 3.40% (6 plants m^{-2}), 3.19% (7 plants m^{-2}) and 3.41% (8 plants m^{-2}) from the silking stage to the dough stage in the water treatment. The *Fv/Fm* declined by 3.07% (5 plants m^{-2}), 3.28% (6 plants m^{-2}), 2.65% (7 plants m^{-2}) and 2.17% (8 plants m^{-2}) from the silking stage to the dough stage in the "Yuhuangjin" treatment. Compared

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1071710730

with the water treatment, the *PSII* maximum quantum yield in the "Yuhuangjin" treatment decreased by a small amount. At the same time, the "Yuhuangjin" treatment increased the *PSII* maximum quantum yield.

With the increase in density, the *Y(II)* of the two treatments showed a decreasing trend (*Table 6*). From the silking stage to the dough stage, the *Y(II)* in the water treatment reduced by 7.04% (5 plants m^{-2}), 47.64% (6 plants m^{-2}), 47.40% (7 plants m^{-2}) and 57.49% (8 plants m^{-2}). The *Y(II)* in the "Yuhuangjin" treatment reduced by 42.44% (5 plants m^{-2}), 45.44% (6 plants m^{-2}), 46.38% (7 plants m^{-2}) and 53.42% (8 plants m^{-2}) from the silking stage to the dough stage. The "Yuhuangjin" treatment reduced the decrease in *Y(II)* in the later stages of procreation. Compared with the water treatment, the *Y(II)* in the "Yuhuangjin" treatment increased at varying degrees. In the silking stage, the *Y(II)* values in the "Yuhuangjin" treatment were 0.71% (5 plants m^{-2}), 1.32% (6 plants m^{-2}), 0.67% (7 plants m^{-2}) and 3.80% (8 plants m^{-2}) higher than those in the water treatment. In the dough stage, the *Y(II)* values in the "Yuhuangjin" treatment were 9.46% (5 plants m^{-2}), 5.58% (6 plants m^{-2}), 2.61% (7 plants m^{-2}) and 13.73% (8 plants m^{-2}) higher than those in the water treatment.

With the progress of procreation, the two *Y(NO)* treatments generally showed upward trends (*Table 7*). In the same growth period, the *Y(NO)* values of both treatments also increased with increasing density. Compared to the plant growth regulator treatment, the *Y(NO)* in the water treatment increased by 21.01% (5 plants

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1071710730

m^{-2}), 24.26% (6 plants m^{-2}), 34.38% (7 plants m^{-2}) and 41.60% (8 plants m^{-2}) from the silking stage to dough stage. The "Yuhuangjin" treatment increased the *Y(NO)* by 19.63% (5 plants m^{-2}), 18.78% (6 plants m^{-2}), 21.03% (7 plants m^{-2}) and 24.50% (8 plants m^{-2}) from the silking stage to the dough stage. The "Yuhuangjin" treatment reduced the *Y(NO)* at varying degrees. In the silking stage, the water treatment reduced the *Y(NO)* by 1.07% (5 plants m^{-2}), 4.16% (6 plants m^{-2}), 4.32% (7 plants m^{-2}) and 5.14% (8 plants m^{-2}) compared to the "Yuhuangjin" treatment. In the dough stage, the water treatment reduced the *Y(NO)* by 2.20% (5 plants m^{-2}), 8.39% (6 plants m^{-2}), 13.83% (7 plants m^{-2}) and 16.61% (8 plants m^{-2}) compared to the "Yuhuangjin" treatment.

With procreation, the *qN* values of the two treatments generally showed upward trends at the different densities (*Table 8*). From the silking stage to the dough stage, the *qN* value of the water treatment increased by 0.39% (5 plants m^{-2}), 0.43% (6 plants m^{-2}), 0.43% (7 plants m^{-2}) and 0.44% (8 plants m^{-2}). The *qN* value of the "Yuhuangjin" treatment increased by 0.37% (5 plants m^{-2}), 0.42% (6 plants m^{-2}), 0.41% (7 plants m^{-2}) and 0.44% (8 plants m^{-2}) from the silking stage to the dough stage.

The "Yuhuangjin" treatment reduced the increase of the *qN* value and enhanced the photosynthetic performance of the leaves. With the increase in densities, the *qN* values of the two treatments showed increasing trends. In terms of the plant growth regulator,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1071710730

the *qN* values of the blades declined under the "Yuhuangjin" treatment. In the dough stage, compared with the water treatment, the "Yuhuangjin" treatment resulted in low *qN* values of 6.83% (5 plants m^{-2}), 3.20% (6 plants m^{-2}), 6.75% (7 plants m^{-2}) and 5.63% (8 plants m^{-2}).

With the increase in densities, the *qP* values of the two treatments gradually decreased after the silking stage (*Table 9*). The water treatment reduced the *qP* values by 7.49% (5 plants m^{-2}), 37.15% (6 plants m^{-2}), 44.84% (7 plants m^{-2}) and 57.25% (8 plants m^{-2}) from the silking stage to the dough stage. The "Yuhuangjin" treatment reduced the *qP* values by 34.91% (5 plants m^{-2}), 36.31% (6 plants m^{-2}), 42.47% (7 plants m^{-2}) and 53.83% (8 plants m^{-2}) from the silking stage to the dough stage. Compared with the water treatment, the "Yuhuangjin" treatment exhibited varying degrees of improvement. In the silking stage, the maximum *qP* values were 2.05% (5 plants m^{-2}), 3.60% (6 plants m^{-2}), 4.56% (7 plants m^{-2}) and 4.94% (8 plants m^{-2}) higher than those in the water treatment.

Effects of plant growth regulator on yield of spring maize in different planting densities in northeast China

With the increase in densities, the water treatment first exhibited an increasing then decreasing trend in the yield (*Table 10*). The highest yield was measured in the 7 plants m^{-2} density (12346.40 kg ha^{-1}), which was 34.94%, 12.89% and 9.58% higher than the yields in the 5 plants m^{-2}, 6 plants m^{-2} and 8 plants m^{-2} densities, and these differences were significant.

Compared with the water treatment, the production in the "Yuhuangjin" treatment increased, and the highest yield was measured in the 7 plants m^{-2} density (13290.95 kg ha^{-1}), but this difference was not significant. Compared with the water treatment, the yields in the "Yuhuangjin" treatment increased by 6.14% (5 plants m^{-2}), 0.48% (6 plants m^{-2}), 7.65% (7 plants m^{-2}) and 3.81% (8 plants m^{-2}). With the increase in density, rows per ear, kernels row and hundred-grain weight did not obviously change, and the differences were not significant. For the "Yuhuangjin" treatment, the differences between row and kernel numbers of the different densities were not significant, while the hundred-grain weight increased, but not significantly.

Discussion

The main factors of maize yields include effective ear number, spike number and grain weight per unit area. The effective ear number of the group is easiest to control and is one of the main ways to increase maize yields. With the increase in density, the yield first increased and then decreased, the ear rows and the line grain number decreased, and kilo-grain weight decreased (Gilberto et al., 2013; Li et al., 2014; Niyogi, 2017). In this experiment, the changes in the yields at different densities in the two treatments are consistent with the results of previous studies. The maximum yields in both treatments occurred at the 7 plants m^{-2} density. The maximum yields were 10618.44 kg ha^{-1} (water treatment) and 11428.18 kg ha^{-1} ("Yuhuangjin" treatment). Compared with the water treatment, the "Yuhuangjin" treatment increased the yields by 0.24% (5 plants m^{-2}), 0.49% (6 plants m^{-2}), 7.63% (7 plants m^{-2}) and 7.70% (8 plants m^{-2}). The differences in the ear rows and the line grain number were not obvious. The experiment also showed that the "Yuhuangjin" treatment mainly increased the hundred-grain weight, which influenced the yield.

The formation of maize yield is a group production process and not simple individual accumulation. The production of a maize population is related to the *LAI*, canopy characteristics, photosynthetic productivity and assimilation products of the entire population (Khoshbakht et al., 2017). During the growth period, the *LAI* exhibited a curve with a single peak, and the peak *LAI* was reached in the silking stage. With the increase in density, the maize yield mainly depends on the photosynthetic characteristics of the leaf groups, especially the photosynthetic capacity of the upper part and the duration of high light. In this experiment, the change in the LAI with density was consistent with the results obtained by Bian (Bian et al., 2011) and the spraying of "Yuhuangjin" reduced the *LAI*. The *LAI* values in the "Yuhuangjin" treatment were 0.89% (5 plants m^{-2}), 3.95% (6 plants m^{-2}), 1.23% (7 plants m^{-2}) and 8.74% (8 plants m^{-2}) lower than those in the water treatment. Spraying "Yuhuangjin" can reduce the leaf area of the colony, and it can also reduce the mutual shading between individuals within a group and improve the permeability of the group. The positive effects of the "Yuhuangjin" treatment are greater than the losses caused by the decreases in the leaf area. From the silking stage to the dough stage, *LAI* decreased by 3.75% (5 plants m^{-2}), 6.47% (6 plants m^{-2}), 7.14% (7 plants m^{-2}) and 14.60% (8 plants m^{-2}) compared to the water treatment. The aging process slows in the later stages. With the increase in density, the *LAI* of the group also increased. Increased densities also increased the supply levels of the source. The pre-control effect of "Yuhuangjin" on the leaf area of the group increased the permeability of the group and delayed the aging process of the leaf blades.

Chlorophyll is an important material in the photosynthesis process. Chlorophyll is involved in the absorption of light energy by a plant and the conversion process. The change in chlorophyll content can be reflected in the blades during the aging process. The chlorophyll content can also reflect the photosynthetic performance and is closely linked to the yield formation (Ma and Dwyer, 1998). Increasing the planting density can decrease the chlorophyll contents of individual plant leaves in a group, and it can reduce the production capacity of single plants. The "Yuhuangjin" treatment increased the chlorophyll content of the leaves and increased the photosynthetic capacity of the leaves. The living environment of an individual plant worsens with the increase in the number of maize plants number per unit area. These density increases will result in the decrease of the net photosynthetic rate of the group. The results of the "Yuhuangjin" treatment in this experiment show that the net photosynthetic rate of the blades is improved by using "Yuhuangjin". The function time of the blade is extended, which created the conditions necessary for higher yields.

The light energy absorbed by the photosynthetic apparatus is mainly utilized in the following ways: to promote photochemical reactions, to dissipate in the form of heat energy and to emit in the form of fluorescence. These three paths are interrelated with each other. The fluorescence signals emitted by plant bodies contain rich photosynthetic information that can be used to predict crop yield potentials (Gong et al., 2006). With the increase of densities, the relative chlorophyll content (*SPAD*) will decrease, and plant growth regulators can improve the chlorophyll content of maize leaves (Li et al., 2011). This study shows that the *SPAD* value of the plants treated by "Yuhuangjin" increased at different degrees under different densities. The *SPAD* values in the "Yuhuangjin" treatment were 7.14% (5 plants m^{-2}), 9.19% (6 plants m^{-2}), 7.85% (7 plants m^{-2}) and 8.77% (8 plants m^{-2}) higher than those in the water treatment. By regulating the canopy structure of the group, "Yuhuangjin" reduced the shading of the plants and increased the light energy intercepted by the ear leaves. These conditions laid the foundation for the synthesis of chlorophyll. With the increase in density, the filling stage was reflected in the *PSII* center of the ear, while the *qP* and *qN* increased. A suitable planting density can help improve the apparent quantum efficiency of maize leaves, and it can increase the primary photochemical efficiency, *PSII* quantum yield, and photochemical quenching coefficient. A suitable planting density can also reduce the photochemical quenching coefficients of the blades (Yang et al., 2009). The chlorophyll fluorescence parameters of the "rod and three leaves" under the two strains showed a unique phenomenon. The "Yuhuangjin" treatment increased the photosynthetic capacity, and the actual quantum yield increased significantly (Xu et al., 2008). With the increase in densities, the *Fv/Fm*, *Y(II)* and *qP* decreased, while the *Y(NO)* and *qN* increased in the water treatment. This result suggested that increasing planting density can lead to worse population canopy conditions and can lower the fluorescence yield. Spraying "Yuhuangjin" increased the *Fv/Fm*, *Y(II)* and *qP*, while it decreased the *Y(NO)* and *qN*. The "Yuhuangjin" treatment improved the maximum quantum yield, improved the ability of the leaves to adapt to strong light, reduced the chemical quenching parameters, enhanced the leaf physiological functions and improved the utilization of energy and the actual quantum yield of the blade. Compared with the water treatment, the "Yuhuangjin" treatment resulted in smaller decreases in *Fv/Fm*, *Y(II)* and *qP*, higher reductions in *Y(NO)*, and reductions in the *qN*. Spraying "Yuhuangjin" delayed the senescence of the leaves and increased the duration of high photosynthetic efficiency, which laid the foundation for higher yields. The changes in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1071710730

the net photosynthetic rate and chlorophyll fluorescence parameters of the leaf blades showed a unique phenomenon. Increasing the planting density can reduce the photosynthetic capacity of individual plants in the population. Spraying "Yuhuangjin" can improve the photosynthetic capacity of individual plants.

Conclusion

In the water treatment, the *LAI* increased, and the *SPAD* value of the group decreased with the increase in density. The group yield first increased and then decreased. The maximum yield was 10618.44 kg ha^{-1} (7 plants m^{-2}). The *Pn* decreased, and the chlorophyll fluorescence parameters *Fv/Fm*, *Y(II)* and *qP* decreased, while *Y(NO)* and *qN* increased. In the "Yuhuangjin" treatment, the *LAI* declined, the *SPAD* increased, the *Pn* increased, the chlorophyll fluorescence parameters *Fv/Fm*, *Y(II)* and *qP* increased, and the *Y(NO)* and *qN* decreased. The maximum yield was 11428.18 kg ha^{-1} (7 plants m^{-2}). The "Yuhuangjin" treatment slowed the aging process of the leaves, improved the photosynthetic capacity of the leaves and increased production. In maize production, it is important to pay more attention on obtain high yields by increasing the planting density in Heilongjiang Province. We still have a lot of work to do to reveal the effects of plant density and plant growth regulators on the physiological and molecular levels of maize.

(Received 1st Mar 2019; accepted 21st May 2019)

Abstract. Quality control is the most critical issue for Chinese medicines (CMs) as its increasing acceptance all around the world. This study measure and analyse the pollution of nine kinds of velvet antlers, which is one of the classical Chinese medicines, in different species and parts of Cervus Nippon and Cervus Elaphus in China. Following the relevant Chinese national standards to evaluate the pollution, we employed the Quick Easy Cheap Effective Rugged and Safe multiresidue method (QuEChERS), combinating with gas chromatography (GC), for the analysis of the organochlorine pesticides (OCPs) in velvet antler. The Inductively Coupled Plasma Mass Spectrometry (ICP-MS) method was used to detect lead, cadmium, copper and arsenic in nine kinds of velvet antlers. The content of mercury and the pollutants in the nine kinds of velvet antlers were all in line with the Chinese Pharmacopoeia. However, these results showed that velvet antler as the unique animal medicine also has a certain amount of pesticide residues, and the individual detection indicators in antler, such as heavy metal copper, are high, which suggests that, we still need to conduct reasonable testing and analysis of heavy metals and pesticide residues in velvet antler before giving it to patients to ensure the safety of clinical application.
Keywords: *organochlorine pesticides, heavy metal, Chinese medicines, medication safety*

Introduction

Traditional Chinese medicine (TCM) is one of the important components of the traditional medicine in the world. Chinese medicinal materials are rich and widely distributed in China. The Chinese medicinal materials have been accepted by the vast majority of patients because of the characteristics of mild pharmacology, specimens and treatment, persistent drug effects and small side effects (Huie, 2002). With a growing number of reports announcing that excessive heavy metals and pesticide residues in Chinese medicinal materials have came out, the quality of Chinese medicinal materials has becoming paid more and more attention. The contents of harmful elements, pesticide residues and microorganism have become an important cause of serious influence on the export of Chinese medicinal materials and the modernization of traditional Chinese medicine (Iavicoli et al., 2009). Therefore, accurately detecting and limiting the amount of harmful substances such as heavy metals and pesticide residues is the key to ensure the safety of medication and to promote the internationalization of Chinese medicine (Efferth and Kaina, 2011).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1073110742

At present, the most toxic heavy metals are arsenic, cadmium, mercury and lead in environmental pollution, food safety and quality control of Chinese medicinal materials. However, heavy metals are parts of the natural environment. They are found in air, water and soil. In the process of Chinese herbal medicine, heavy metals can enter the medicinal materials through their growth environment, and then lead to heavy metal pollution through biological enrichment. The heavy metals in deer products are mainly derived from feeds which are fed, obviously this problem needs to be paid more attention during the processing and production, but it is often unavoidable. In addition, the production and processing of Chinese medicine preparation, the transportation and storage processing could also be polluted, these problems are accumulating and cause the heavy metal pollution of Chinese medicinal materials aggravating rapidly.

Pesticide residues, among the other potentially toxic compounds can be found in velvet antlers. According to the research status in recent years, pesticide residues in Chinese herbal medicines are universal (Kang et al., 2016; Yang et al., 2013), and organochlorine pesticide residues occupy a large proportion. The use of OCPs as insecticides and biocides has been widespread in agriculture and public health since the 1940s, and most of OCPs are resistant to photochemical, biological and chemical degradation for a long period of time (Yohannes et al., 2014). They persist in various media and some can be transported over long distances to regions where they have never been used. The use of most OCPs is now prohibited in China, but their low biodegradability means that they can still be detected in the environment (Barriada-Pereira et al., 2003). The nature drugs from animal body may also be polluted in the process of formation, such as exposing to pesticides and other routes.

Moreover, Chinese herbal medicines may also be exposed to pesticides and contaminated during transportation, storage and processing (Ting et al., 2013). In addition, the pesticide residues in Chinese medicinal materials are likely to be enriched in the traditional Chinese medicine preparation by processing. Which are easily accumulated in the body by patients already infirm, posing a threat to drug safety. Therefore, the determination of pesticide residues has been included in the Chinese medicine inspection methods and quality standards formulated by WHO.

Velvet antler as the animal medicine is a kind of immature horn of most male deer family, which is widely distributed all over the world. China is one of the largest amount of numbers and species of deers, including Sika deer, Wapiti, elk and so on. Velvet antler is the only regenerable mammalian organ (Li et al., 2014, 2016). It has special structural features, grows periodically and falls off each year, leaving no scars on the wound, the growth rate is very fast, reaching 1-2 cm per day. As a TCM, the pharmacological effects of velvet antler are enduring, which frequently performed to prevent and treat of osteoporosis (Tseng et al., 2014; Zhang et al., 2013), promoted cell proliferation (Xiao et al., 2017), repaired liver damage (Chunhua et al., 2017), anti-fatigue (Jang et al., 2014), anti-oxidation (Chunhui et al., 2017), anti-inflammatory (Ma et al., 2017; Lee et al., 2015) and showing other pharmacological activities. The composition of antler is extremely complex, the quality of different types of antler can be wildly different. In general, it can be divided into inorganic elements, organic components and bioactive ingredients.

The processing of velvet antler is according to the needs of Chinese medicine and pharmacy, putting dried velvet antler into Chinese Herbal Slices or other forms, for clinical use or variety of dosage forms. The Chinese Pharmacopoeia records two types of processing methods for velvet antler, “powder of velvet antler” and “tablets of velvet

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1073110742

antler". Take the velvet antler, lick the hair, scrape it, smash it into pieces, grind it into fine powder, then get the powder of velvet antler. The processing of tablets of velvet antler is more complicated: Take the velvet antler, lick the hair, scrape it, and wrap the body with a cloth belt, injecting hot white spirit from the small hole in the wound surface, continue to add spirit, until the run through or the liquor is slightly steamed, cross-cut, flattened and dried (China Pharmacopoeia Committee, 2015). The velvet antler is transected and the transverse section is divided into skin layer, interstitial layer and medulla layer from the outside to the inside. According to the industry standard NY/T1162-2006 promulgated by the Ministry of Agriculture, the velvet pieces made from the tip to the base can be divided into four parts: wax piece, powder piece, yarn piece and bone piece.

At present, the main extraction methods used in the analysis of pesticide residues are: ultrasonic extraction, microwave assisted extraction, supercritical fluid extraction, solid phase extraction, solid phase microextraction, accelerated solvent extraction, liquid phase microextraction, QuEChERS and so on. Among the above, QuEChERS is a novel sample preparation methodology for pesticide multiresidue analysis which was developed between 2000 and 2002 and firstly reported in 2003 (Anastassiades et al., 2003). Although it is a very new method, it has already been widely accepted by pesticide residue analysts in the international community, and a lot of publications already deal with this method in its original form or variations of it (Hu et al., 2012). QuEChERS has been validated for the extraction of OCPs in completely different matrices of TCM (Xu et al., 2011).

In order to solve the problem of quality and safety in the development of Chinese medicinal materials, the new technology of detection of pesticide residues, such as modern spectral analysis, chromatography analysis, spectrum and chromatography, is rapidly developing (Kong et al., 2015; Tadeo et al., 2012). The commonly used methods are GC, gas chromatography-mass spectrometry, high performance liquid chromatography, liquid chromatography mass spectrometry and so on. Among which, GC has become one of the most important analysis methods in agricultural residue detection because of its good stability, high sensitivity, good selectivity and ability to separate a variety of substances at the same time. GC can be used to meet the detection requirements of different kinds of pesticides by selecting different detectors. It is often used to detect the pesticide residues with small relative molecular weight, low boiling point and good thermal stability. Because of the content of heavy metals in Chinese herbal medicines is generally low, it is necessary to select suitable analytical instruments and methods for testing. The ICP-MS is characterized by high sensitivity, high accuracy, low detection line, rapid analysis, and simultaneous determination of various elements (Jiang et al., 2014). It is the most effective method of elemental analysis recognized currently. It has been included in the Chinese Pharmacopoeia as one of the methods for determining lead, cadmium, arsenic, mercury and copper in Chinese herbal medicines (China Pharmacopoeia Committee, 2015).

Materials

Sampling

In order to ensure the current pollution situation, samples were chosen: New Zealand plum velvet antler powder, red powder, wax tablets, Jilin sika deer antler red powder, yellow powder, wax tablets, Jilin red deer pilose antler powder tablets, sand tablets, wax

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1073110742

tablets both are purchased from a farm in Shuangyang District, Changchun City, Jilin Province, China. The feeding method is captive. (*Fig. 1*). The fodder are mainly corn, soybean and bean cake, and the roughage are silage corn stalk, grass and leaves. All the samples were ground and passed through 80-mesh sieve and stored at -20 °C prior analyses.

Experimental method

Pesticide analysis by GC

Preparation of standard solution

All OCP standards (α-BHC, β-BHC, γ-BHC, δ-BHC, o, p'-DDD, p, p'-DDD, o, p'-DDT, p, p'-DDT, Pentachloronitrobenzene (PNCB) were purchased from the National Standards Research Center. A mixed stock solution was prepared by dissolving exact amounts of powdered samples in mixture of methanol and toluene (3:1, v/v) at a concentration of 100 ng/mL, and then diluted to a mixed standard solution with a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1073110742

concentration of 10 ng/mL. A series of standard solutions with concentrations of 1, 5, 10, 50, and 100 ng/mL were prepared and the calibration curves were established after measurement.

Extraction and clean-up

Extraction and clean-up were carried out according to the QuEChERS method (Anastassiades et al., 2007). Nine samples were separately added to liquid nitrogen, ground and passed through a 80-mesh sieve. 0.5 g of sample was weighed into the 15 mL centrifuge tubes. The main extraction involved the addition of 1.5 g of sodium acetate, 10 mL of acidum aceticum-water-acetonitrile (1:4:95, v/v). The tube was closed and shaken vigorously by hand for 2 min. Then, 1.5 g of anhydrous $MgSO_4$ (burned in a high-temperature muffle furnace for 4 h) was added to the suspension. The tube was closed, shaken vigorously by hand for 2 min, and centrifuged for 5 min at 3000 r/min.

For clean-up, 1 mL of the upper organic phase was transferred into a 2-mL centrifugation tube already containing 25 mg PSA, 25 mg GCB and 150 mg anhydrous $MgSO_4$. The tube was closed, shaken vigorously by hand for 2 min, and centrifuged for 5 min at 12000 r/min. An upper organic phase was taken and concentrated by nitrogen to 200 μL for injection.

GC analyses

The measurement conditions were as follows: TG-5 quartz capillary column; The column temperature was maintained at 120 °C for 1 min, and then ramped at 6 °C min^{-1} up to 180 °C and kept for 2 min, then at 10 °C min^{-1} up to 280 °C and kept for 2 min; Detector temperature: 300 °C; Injector temperature: 230 °C; Carrier gas: N_2; Flow rate 40 mL/min; The sample injection volume was 1 μL, no splitting and external standard method for quantification.

Chemical analysis of the mineral composition

Preparation of standard solution

The elements standard solutions were prepared by 5% nitric acid solution diluting stock solution of 1000 μg/mL As, Cd, Pb, Hg and Cu (purchased from National Nonferrous Metals and Electronic Materials Analysis and Testing Center) to prepare a mixed standard stock solution with a concentration of 1000 μg/L. The mixture was further diluted to a mixed standard solution of 0.5, 1, 2, 10, 20, 50 μg/L and stored at 4 °C. Then the calibration curves were established after measurement.

Extraction

The heavy metals including As, Cd, Pb, Hg and Cu were analyzed by using ICP-MS. Before the analysis, samples were digested by using a microwave digestion system. Nine samples were separately added to liquid nitrogen, ground and passed through 80-mesh sieve. The sample was accurately weighed 0.5 g, placed in a microwave digestion tank and added 8 mL of nitric acid. The digestion procedures were carried out in a microwave oven according to the digestion setting (*Table 1*). After the temperature of the digestion solution dropped below 60 °C, the digestion tank is taken out. The samples were cooled to room temperature and ultrapure water was added to a total volume of 25 mL. The samples were stored at 4 °C before analysis.

DOI: http://dx.doi.org/10.15666/aeer/1705_1073110742

ICP-MS analyses

The measurement conditions were: Plasma gas flow: 15.0 L/min; Spray chamber temperature: 2 °C; Auxiliary gas flow: 0.85 L/min; He gas flow: 5 mL/min; Carrier gas flow: 1 L/min; RF power: 1450 W; Data sampling mode: peak capture mode; Sampling depth: 8 mm; Number of sweeps: 100 times.

Table 1. *Microwave digestion procedure*

Step	Set temperature (°C)	Heating time (min)	Duration (min)
1	130	4	5
2	160	4	10
3	210		15

Statistical analysis

All data are expressed as average value of concentration and standard deviation. Descriptive statistics of the determined results were calculated by using MS Office Excel software, and the Excel add-in "Data Analysis suite" was applied for the linear regression analysis.

Results and discussion

Pesticide residue test results

Figure 2 shows typical gas chromatograms of standards for the nine pesticides. The calibration curves were obtained using the linear least squares regression procedure of the peak area versus the concentration. The results show that the concentration has a good linear relationship with the peak area, and the linearity is greater than 0.99. The calibration curves were enough for the detection OCPs in samples. The nine samples were extracted, clean-up and measured according to the method described in the section "Pesticide analysis by GC", while the OCPs were well separated (*Fig. 2*).

Nine velvet samples were quantified according to the peak area external standard method to calculate the residual amount of various organochlorine pesticides in the sample (*Fig. 3*). In this work, *Table 2* shows that the concentrations of contaminants detected in the nine samples did not exceed the maximum allowable residue limits (MRLs) which specified in the Chinese Pharmacopoeia (total BHC < 200 μg/kg and total DDT < 200 μg/kg) (Chinese Pharmacopoeia Commission, 2015).

The residual levels of some OCPs in environment seem to remaining approximately twenty years at least. In general, plant medicinal materials are in direct contact with the soil, so the pesticide content of botanicals is relatively high. During this study, the levels of OCPs in the nine samples were found to be in accordance with Chinese Pharmacopoeia standards. However, there is still a certain amount of pesticide residues in the antler, which indicates that the possibility of pesticide residues in animal drugs, and should be tested before giving to patients to ensure the medication safety. In addition, data support is provided to continually correct reasonable maximum residue limits (MRLs).

Heavy metal test results

^{63}Cu and ^{75}As with ^{72}Ge as the internal standard, ^{111}Cd with ^{115}In as the internal standard, ^{201}Hg and ^{208}Pb with ^{209}Bi as the internal standard. During the measurement, the internal standard samples tube were always inserted into the internal standard solution, and the samples tube of the instrument were inserted into the mixed standard solution with a concentration of 0.5, 1, 2, 10, 20, 50 μg/L and nine velvet samples for measurement. As *Table 3* showed that the calibration curves of the five heavy metal elements have a good linear relationship, and the correlation coefficients (r) were all above 0.99.

Table 3. *Standard curves and linear relations*

Measuring element	Regression equation	r
Cu	y = 3.2998x - 0.8663	0.9968
As	y = 0.0377x + 0.0113	0.9995
Cd	y = 0.0064x + 0.0167	0.9992
Hg	y = 0.0024x - 0.0013	0.9998
Pb	y = 0.0088x - 0.0034	0.9996

The results of determination of heavy metals were shown in *Table 4*, which can be seen that the nine velvet samples contain a certain amount of heavy metals and the content of Cu was relatively high. In addition, the heavy metal content of the wax sheet was higher than other parts of the velvet antler. In particular, Jilin plum velvet wax tablets have the highest content of heavy metals.

This study revealed that the contents of heavy metals from nine samples are in line with the permissible limits, but the level of Cu in the samples was generally higher, and the heavy metals remaining of the wax tablets were higher than the other parts of the antler. Food chain in the ecosystem is a process, which stored chemical energy in organic matter conducting layer by layer. The absorption and enrichment of heavy metal in CMs are the important factors causing the potential quality problems of clinical application. In the natural world, green plants are almost at the end of the bio-chain.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1073110742

Heavy metal elements are absorbed by green plants and transported step by step along the chain, enforce accumulating and generating bio-magnification effects. Compared with green plants, animals are at the top of the bio-chain, which is more likely to be contaminated by heavy metals and harmful elements. The wax is the tip of the antler, thus the accumulation of heavy metals and harmful elements is higher. From this point of view, comprehensive and objective evaluation of the content of heavy metals in animal drugs can provide realistic data support for the safety of medication.

Table 4. *The content of 5 kinds of heavy metals in velvet antlers (n = 3)*

Antler species	Concentration (mg/kg)				
	Cu	**As**	**Cd**	**Hg**	**Pb**
Limit of detection	20	5	1	1	10
Jilin plum velvet wax tablets	4.577 ± 0.18	0.200 ± 0.014	0.011 ± 0.005	0.014 ± 0.007	0.688 ± 0.074
Jilin plum antler red powder	2.556 ± 0.13	0.103 ± 0.025	0.003 ± 0.0007	0.022 ± 0.014	0.372 ± 0.032
Jilin plum antler yellow powder	2.675 ± 0.16	0.093 ± 0.031	0.003 ± 0.0004	0.013 ± 0.003	0.512 ± 0.071
Jilin horse velvet wax tablets	5.065 ± 0.22	0.092 ± 0.01	0.001 ± 0.0003	0.008 ± 0.002	0.098 ± 0.002
Jilin horse velvet sand	1.033 ± 0.092	0.117 ± 0.011	0.001 ± 0.00	0.010 ± 0.001	0.588 ± 0.018
Jilin horse antler powder tablets	0.905 ± 0.06	0.062 ± 0.017	0.001 ± 0.00	0.010 ± 0.001	0.624 ± 0.049
New Zealand sika antler wax tablets	4.428 ± 0.11	0.109 ± 0.025	0.003 ± 0.0011	0.011 ± 0.005	0.104 ± 0.019
New Zealand sika antler powder	2.197 ± 0.15	0.041 ± 0.009	0.005 ± 0.002	0.113 ± 0.025	0.116 ± 0.16
New Zealand plum antler red powder	2.573 ± 0.17	0.172 ± 0.067	0.012 ± 0.003	0.275 ± 0.035	0.279 ± 0.008

Interestingly, studies have shown that there are excessive Cu and Cd contents in corn and soybean crops in Jilin Province (Liang et al., 2011). Therefore, we have reasons to suspect that the presence of heavy metals in velvet antlers may be enriched by food, and the food pathway only affects the content of heavy metals in antler. It could be related to the process of transportation and storage, so the reasons for the existence of heavy metals in antler must be further investigated to ensure the medication safety.

Conclusions

As a natural medicine, TCM has been favoured by patients because of its less side effects, good curative efficiency and medicine safety, which has been recognized and accepted by the international community gradually. TCM is a group of special products used by doctors to prevent and treat diseases, it would be rare for such plants or animal can use both as food and medicine to produce toxic effects on human body. It is the uniqueness of traditional Chinese medicine. However, due to the possibility that CMs may be contaminated by toxic and harmful substances during planting, processing, storage and so on, these pollution poses a certain threat to human health, which in turn affects the safety of its use. Animal medicine refers to the whole or parts of the body, the physiological or pathological product of the animal, the processed products, and the like, has taken a place for thousands of years. “Shen Nong’s Herbal Classic” contains 365 kinds of drugs, including 67 kinds of animal drugs, and the number of animal drugs in the “Compendium of Materia Medica” increased to 461 kinds. Animal medicine has the characteristics of strong activity and high curative effect, which is an indispensable component of TCM. Nowadays, there are many pharmacological studies on animal

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1073110742

drugs, but studies on safety issues such as residues of harmful substances are rare. Only a few analytical methods for determining pesticide residues in TCM have been reported.

Velvet antler is one of the representative animal drugs in TCM. Chinese deer industry has made great progress after continuous development. However, problems such as lack of talents, backward technology, extensive management, new technologies and methods have not been well promoted and applied in production practice are still exist. The world's leading exporters of velvet antler are New Zealand, Canada and Russia, of which New Zealand deer Antler has the greatest impact on Chinese antler industry.

The results show that although several OCPs detected in this subject have been banned for a while, some pesticide residues still can be found in velvet antlers. The content of heavy metal Cu in velvet antler is high, meanwhile the heavy metal pollution in the part of wax sheets is the worst, and provide a reference data for the further studies focused on the safety of herbal preparations. In addition, the source of heavy metal and pesticide pollution in antler is likely to be related to the management of farms, the processing of feed, medicine, transportation, storage and so on. Pharmacopoeia has only specified the source and type of deer antler, the method of identification, as well as the production methods of antler slices and powder. But the specification and quality description of the products of deer antler is too macroscopic; the identification method is too simple and not specific. Obviously, antler as traditional Chinese medicine needs to be further developed, clear breeding and regulatory standards should be established as soon as possible. Improving the more targeted analytical methods are useful for developing realistic MRLs and other regulatory guidelines for managing pesticide heavy metal residues in TCM products.

(Received 1st Mar 2019; accepted 21st May 2019)

Abstract. Soil organic matter (SOM) plays an important role both to condition soil properties and to mitigate climate change. SOM change pattern after intensive tillage is still not well revealed. Taking Sanhu Farm, Jiangling County, Hubei Province, China as a case area, based on topsoil survey samples of 1990, 1994 and 2000 respectively, the spatial distribution pattern and temporal change of SOM content was analyzed. The results show that (1) SOM content successively decreased with the increase of land exploitation history; (2) topsoil SOM value of the three survey years showed a similar spatial pattern whereby the highest SOM value was distributed in the center, and SOM value decreased incrementally as the distance from the center increased, which showed the SOM values were negatively correlated to the altitude of study area; (3) there was an overall tendency for the maximum or minimum value of SOM to approach to the average value over time; (4) SOM concentration changes were influenced by crop systems changes related to the price of crops and related policies. The study depicts SOM variability after the reclamation from virgin land to arable land at a landscape scale, which may contribute to research revealing spatial distribution patterns and controlling elements of SOM change.
Keywords: *land reclamation from lakes, SOM change pattern, land exploitation history, the kriging interpolation, spatial autocorrelation, crop systems*

Introduction

Soil organic matter (SOM) is the largest source of SOC, which is a key element to soil quality for its far reaching effect on soil physical, chemical and biological properties (Laik et al., 2009; Nadi et al., 2017). As an important feature of soil, even in small amounts, organic matter is very important to keep soil healthy (Osman, 2013). It has tremendous biological significance for providing food for microorganisms, storing nutrients, retaining water, and performing as a soil conditioner and aggregating agent (Manlay et al., 2007; Osman, 2013). The Soil surface comprises the largest carbon stock in terrestrial ecosystems, and soils to 1 m depth contain 74% of the total terrestrial C stocks (Lal, 2004; Batjes, 2016; Vitharana et al., 2019). The global soil organic carbon (SOC) pool is estimated to amount to 1200-1600 Pg carbon in the upper 1 m (Batjes, 1999), representing 2.5 times the carbon pool in vegetation, or 2 times the amount of carbon in the atmosphere. Change of soil organic matter (SOM) content under intensive

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1074310757

tillage has becomes a pivotal concern in soil research as an option for mitigation of climate change (Schulp et al., 2008b; Das et al., 2008).

Insight in variability of SOM quality and quantity is required to quantify the greenhouse gas mitigation potential of the landscape (Schulp et al., 2008a). Research shows that there is a direct link between SOM content and human impact, observed in land use patterns or land management systems, for example (Smith et al., 2000; Lettens et al., 2005; Abdollahi et al., 2014; Gmach et al., 2018; Wood et al., 2018). SOM contents are generally lower after intensive tillage (Degryze et al., 2004; Lettens et al., 2004a; Gerzabek et al., 2005; Papienik et al., 2007), especially the surface soil organic carbon and total nitrogen contents in cultivated areas (Schulp et al., 2008b; Barrett et al., 2015; Wood et al., 2018). Afforestation by different plantations increased soil C pools to different magnitudes (Laik et al., 2009; Kukuļs et al., 2019). Alternative management systems, like reduced tillage or organic farming, have been introduced that are considered to lead to more sustainable land use and increased sequestration of atmospheric C into agricultural soils (Pulleman et al., 2000). However Dutch research highlights some relationships between the SOM content variability and land condition before its exploitation. It is not a universal rule to lower SOM contents after intensive tillage (Webb, 1998; Schulp et al., 2008b; Abdullah, 2014).

At landscape scale, patterns of management, land use or land use history might better present the spatial variability of SOM pools (Veldkamp et al., 2001; Dendoncker et al., 2004; Schulp et al., 2008b) while soil and groundwater may dominate over other factors that influence SOM pools (quality and quantity) at a national scale. At temporal scales up to a few decades, SOM content changes are observed following land use conversions (Lettens et al., 2004b; Falloon et al., 2006; Gmach et al., 2018). Intensive cultivation is often exerted to land in China to support the large population. Soil pedons and characteristics including SOM contents are quite different to the natural ones under the Chinese special management patterns.

In this paper, we will try to reveal how the SOM contents have been changed under intensive tillage at landscape scale, using Sanhu Farm as a case study area, which belongs to Jiangling County, Hubei province, China. This site has been reclaimed farmland from a lake since 1960 and is currently dominated by anthrosols (Wang et al., 2010).

Materials and Methods

Case study area

Sanhu Farm (30°10'-30° 16' N, 112°29'-112° 35' E) is located in southeast of Jiangling County, Hubei province in central China, with an area of 63.5 km^2 (*Fig. 1*). There are 14,812 people in Sanhu Farm and 55.49% of them are peasants. The percentage of forest cover is only 1.92%. The max distance from north to south inside the farm is 11.2 km while from east to west is 7.75 km. The area is characterized by a subtropical humid monsoonal climate. The average monthly temperature reaches a maximum of 27.2°C in July and a minimum of 3.5°C in January. The average annual temperature is 16.1°C and the average annual precipitation is about 1100 mm. The altitude of Sanhu Farm ranges from 25.1 m to 29.3 m, with an average altitude of 25.8 m (Yellow Sea Height System). The relief of the farm is like a shallow dish, a little lower at the center and higher at the surrounding boundary. At the same time, it tilts

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1074310757

southwardly with a slope of about one five-thousandth. The parent soil material of Sanhu Farm is Quaternary sediments of fluvial or lacustrine deposits.

Sanhu Farm was once one of the Four Lakes in Jianghan Plain. Jianghan Plain is located in the middle reach of the Yangtze River basin where the Han River meets the Yangtze. This part of the basin was formed mainly by the alluviation and deposition of sediment from these two rivers. Jianghan Plain is one of the most important commodity grain and oil production bases of China and it is distinguished by its numerous shallow lakes. There were 1,141 lakes during the 1960s, but this number was reduced to 752 lakes in 1990s. There is a Four-Lake Area in Jianghan Plain, which named for the four biggest lakes of Jianghan Plain, one of which was Sanhu Lake which no longer exists (only two larger lakes remain of the original four). Sanhu Farm was named after Sanhu Lake.

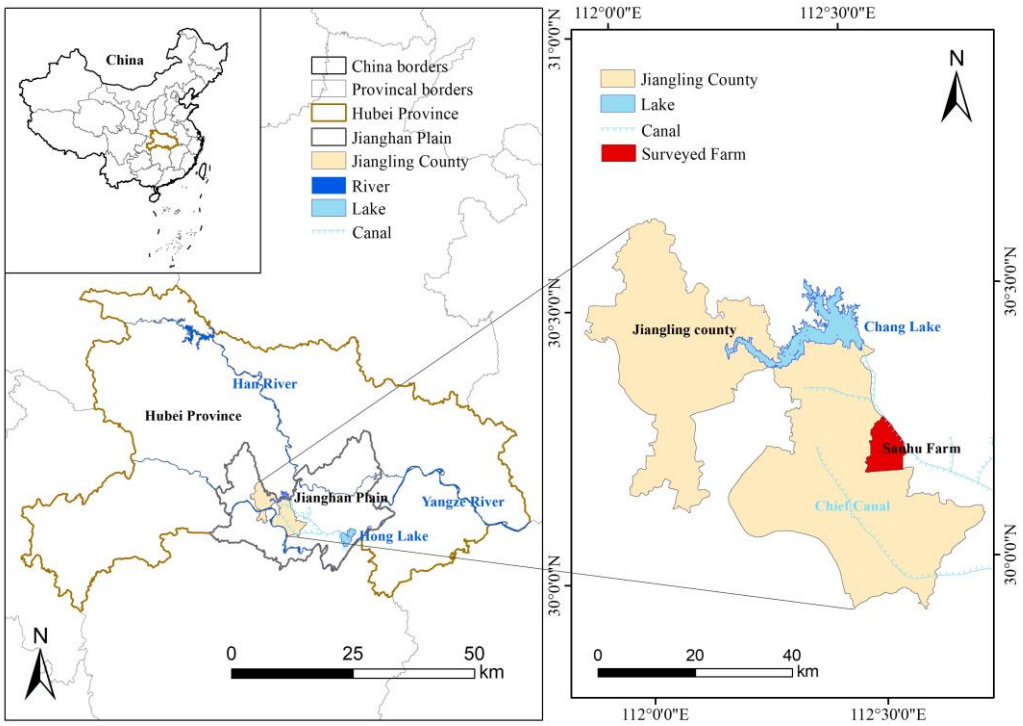

Figure 1. *Location of Sanhu Farm*

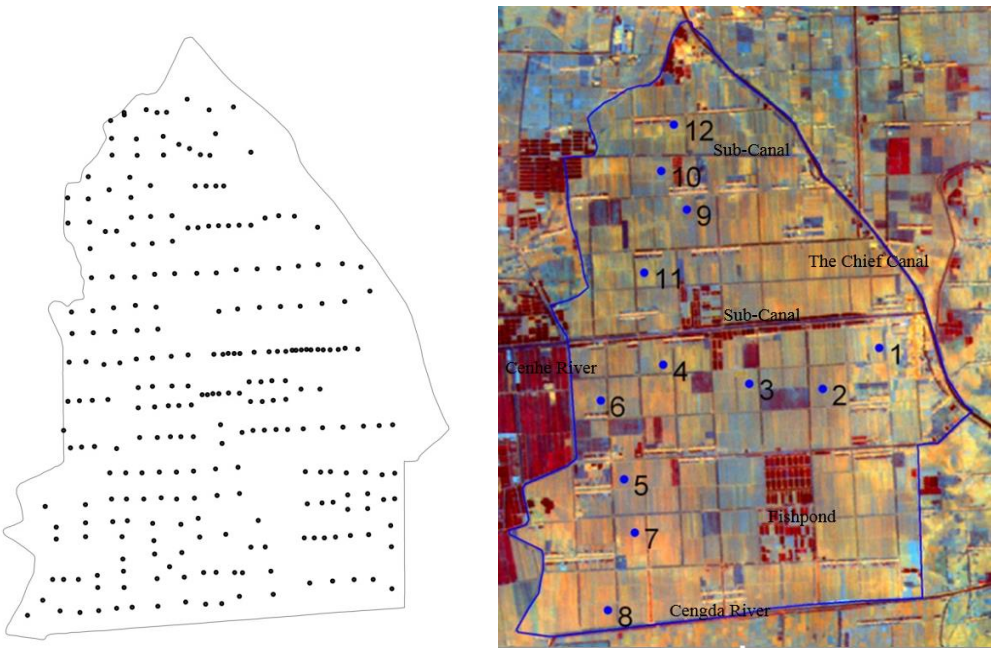
The plan of reclamation of Sanhu Lake began from 1960 just after the fulfillment of the construction of the Chief Canal of the Four Lake Area. There were two main objectives of the reclamation of Sanhu Farm. Firstly, there was a famine nationwide in China from 1958 to the early 1960s, and relieving the food problem was of utmost importance at that time. Secondly, many people were suffering from schistosome, a disease develops in the slack water environments. The reclamation of Sanhu Lake effectively addressed both of these concerns.

The Sanhu Lake area went through three land reclamation periods before reaching its present pattern. In the first stage, from 1962 to 1965, there were 33 km^2 of cultivated land reclaimed. In the second stage, from 1971 to 1973, 16.5 km^2 were reclaimed. In the third stage, from 1975 to 1979, 14 km^2 were reclaimed. By the end of 1979, the present pattern of Sanhu Farm had been formed.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1074310757

Three sides of Sanhu Farm is bound by water bodies, that is, Chief Canal of Four-Lake Area (8.6 km) on the east, Cengda River on the south and Cenhe River on the west. There is a well-developed water drainage system in Sanhu Farm, consisting of 7 main canals, 28 sub-canals and hundreds of ditches, which is connected or controlled by culverts and Watergates Developed Artificial Water Systems: numerous canals and ditches (*Fig. 2*). The water drainage system has been efficient to drain logged water to the outside canals and to irrigate the farmland, as well. So the area maintains the outline of Sanhu Lake.



(a) Topsoil Samples *(b) Soil Profiles*

Figure 2. *Distribution Map of Topsoil Samples (a) or Soil Profiles (b)*

Before 1994, the main crop in Sanhu Farm was rice because of the enacting of the national policy "Food for the Program", due to the national famine from the late 1950s to the early 1960s. After 1994, most of the paddy land was changed to dry crops which were harvested twice per year (cotton and rapeseed, respectively). However, the area of paddy has been expanding again as a result of the National Commissariat Allowance Policy from 2004 and the rising price of rice (Wang et al., 2010), but the speed of expansion has been restricted due to the degradation of the local drainage system. As a result, it is necessary to study the variation of SOM caused by the fluctuation of land use and management and to evaluate the impact of land use change on soil properties and climate change at a landscape scale.

Data collection and processing

Soil samples processing and analyzing

Some temporal and typological data were sampled and collected, including soil survey data of topsoil random samples without spatial information from both 1980 (643 samples) and 1987 (516 samples), soil survey data of topsoil with spatial information of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1074310757

262 random samples from 1990, 1994 and 2000, and soil horizontal sampling analysis data of 12 profiles from 2008 which have spatial points corresponding to former data.

Soil samples collection and pre-treatment were all carried out from October to November just after the harvest of rice in order to keep the seasonal consistency of the soil samples. Every topsoil sampling data was a mixture of arable horizon. 12 soil profiles (1.0 m wide×0.8 m thick×1.1 m deep) were dug at locations shown in *Fig. 2*. The geographic coordinates of every profile were recorded by GPS as well as photos of the landscape where the soil profiles were taken. Samples from every soil horizon in each profile were collected using a cutting ring. All soil samples were put in sterilized Kraft paper sacks with plastic bags outside to prevent water volatilization and were transported to a laboratory and kept at lower temperature. Samples were allowed to air dry and passed through a 1 mm bore diameter sieve first. One-fourth volume of every soil sample was collected for chemical analysis after passing through a 0.1 mm bore diameter sieve. The external heating method ($K_2Cr_2O_7$ at 0.4 mol/L-H_2SO_4) was used to determine the SOM content of all samples in the laboratory (Walkley and Black, 1934; Mirzaee et al., 2016; Singh et al., 2019).

Geographical data collection and data spatialization

A GIS based database of the study area was constructed containing a DEM of 1:10000 (1980), soil survey data of topsoil, and soil horizontal sampling data of several profiles and tables of soil survey data. The spatial system of the database is the Xi'an Geodetic Coordinate System 1980, Gauss-Krueger Projection. All the soil survey data with spatial information were digitalized in the format of DBF. According to the spatial information of the geographic coordinates of topsoil samples or soil profiles, the DBF data were converted to the point layer of the distribution of topsoil samples (*Fig. 2a*) or soil profiles (*Fig. 2b*) where the background is a TM image of May, 2005.

The kriging interpolation for the SOM spatial-temporal pattern prediction

There were 262 topsoil point observations from 1990, 1994 and 2000 which had exactly location information corresponding to the three different years. A DBF file of SOM content of 262 topsoil samples of the three years was connected to the point layer of the distribution of topsoil samples respectively under the ArcGIS10 platform environment. Then the Kriging interpolation technique was applied to depict the spatial pattern of SOM of the three years. The Kriging interpolation method is based on geostatistical models that include autocorrelation-that is the statistical relationships among the measured points. Kriging is a multistep process, includes exploratory statistical analysis of the data, variogram modeling, creating the surface, and (optionally) exploring a variance surface. The first step for the Kriging interpolation is to select the best fitted model which standardizes the mean near to zero, makes the Root-Mean-Square as small as possible, makes the average Standard Error near to the Root-Mean-Square, and standardizes the Root-Mean-Square Standardized near to one. Considering factors of error covariance analysis of every model type synthetically, the Exponential model best fits to identify the SOM for 1990 and the Spherical model best fits to identify the SOM for 1994 and 2000.

Results and analysis

The total trend of SOM concentration change

The average SOM concentration of every survey year was calculated by Excel according to all the topsoil random samples (*Table 1*). *Table 1* shows that the mean SOM concentration decreased from 1980 to 2008 with an average decrease rate of 1.01 g/kg per year. At the earliest stage, the SOM concentration decreased rapidly with a highest average yearly decrease rate of 2.57 g/kg. At the following stages, the mean yearly SOM decrease rate fluctuated under 0.78 g/kg. It tells us the SOM concentration successively decreased with the increase of the exploitation history.

Table 1. *The average concentration of SOM (Unit:g/kg)*

Year	1980	1987	1990	1994	2000	2008	Total
Types of Samples	topsoil	topsoil	topsoil	topsoil	topsoil	profile	
Spatial Located?	no	no	Yes	Yes	Yes	Yes	
Number of Samples	643	516	262	262	262	12	
SOM of topsoil	54.0	36.0	35.4	32.9	29.4	25.6	
Annual decrease rate	/	2.57	0.20	0.63	0.58	0.78	1.01

The samples of 1990, 1994 and 2000 were co-located in the three survey years, so the data may show more objective information. The annual decrease rate of SOM content was 0.63 g/kg from 1990 to 1994, and 0.58 g/kg from 1994 to 2000. The decrease of the former period was more rapid than that of the later period. The value of SOM greatly affects the soil productivity. Usually the SOM concentration value can be divided into three main grades as POOR, MEDIUM and ABUNDANT. When the SOM concentration value falls between 20-40 g/kg, it is MEDIUM; below 20 g/kg, POOR; above 40 g/kg, ABUNDANT. Sample numbers and percentages of every SOM concentration grade of the three survey years are shown in *Table 2*.

Table 2. *Sample numbers and percentage of every SOM concentration grade*

Year	Sample Numbers			Sample Number Percentage		
Grade	<20 g/kg Poor	[20-40g/kg] Medium	>40g/kg Abundant	<20 g/kg Poor	[20-40g/kg] Medium	>40g/kg Abundant
1990	32	155	75	12.2	59.2	28.6
1994	46	143	73	17.6	54.6	27.9
2000	19	193	51	7.3	73.7	19.5

Among the 262 samples, there are 75 samples graded as ABUNDANT in 1990, 73 samples in 1994, but only 51 samples in 2000; The percentage of samples graded as ABUNDANT decreased from 28.6% in 1990 to 19.5% in 2000. In the other end, there are 32 samples graded as POOR in 1990, 46 samples in 1994, but only 19 samples in 2000 (*Table 2*). In the long run, the SOM concentration differences of samples decreased after the land reclamation and intensive tillage.

The prediction of SOM spatial patterns and analysis

The distribution maps of the topsoil organic matter of the three survey years were depicted (*Fig. 3*) through the Kriging interpolation based on the topsoil sampling point

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1074310757

distribution layer under ArcGIS 10.1 platform with selected appropriate models (*Table 3*), and with 10 classes divided by Natural Breaks rule with a slight artificial interference. The maps (*Fig. 3*) show us that there was a high SOM center located in the south-middle part of the study area running through all the three survey years. In 1990, the SOM values decrease incrementally as the distance from the high SOM center increases. Compared with 1990, the highest SOM region of 1994 shrank considerably. By 2000, the highest SOM region divided into two centers, and the top two SOM classes (Legend) no longer existed, which were component classes of the SOM distribution maps of the former two survey years.

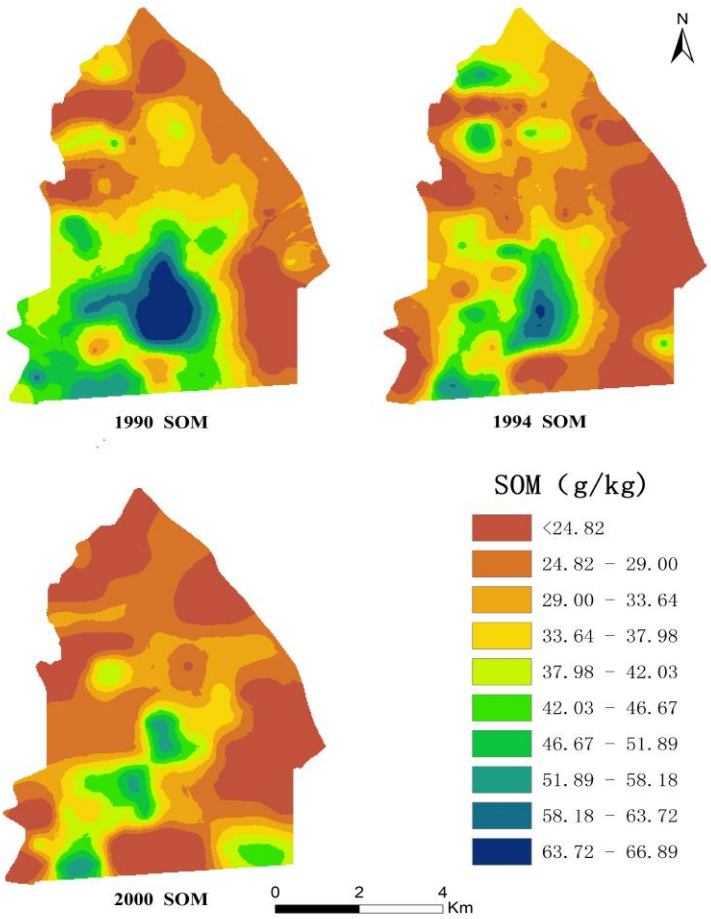

Figure 3. *The spatial pattern of SOM of topsoil of Sanhu Farm*

The selected model of 1990 is the Exponential and that of the other two years is the Spherical. The performance of Kriging models depends on spatial autocorrelation of the topsoil organic matter. The Range (*Table 3*) tells the scope that spatial autocorrelation works, which is one of the principles to set samples. Distances of neighboured samples are all less than the Range value, so the Kriging models can be used reliably.

The ratio of Nugget/Partial Sill (*Table 3*) reveals the factors that may affect the spatial autocorrelation of the SOM distribution. When the ratio is smaller than 0.25, the spatial autocorrelation of the SOM distribution is very strong and the SOM distribution is mainly controlled by structural factors such as climate, soil parent material, landform,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1074310757

etc. When the ratio is bigger than 0.75, the random factors affect the SOM distribution more, such as fertilization, cropping pattern, etc. According to *Table 3*, the SOM spatial pattern of 1990 and 2000 were more decided by the structural factors, while that of 1994 was more decided by random factors.

Considering the area of Sanhu farm is only 64 km^2, the climate type does not change and its influence on the distribution of SOM can be omitted. So for the Suhan Farm area, we think that the landform and the soil parent material are key structural factors for SOM distribution. Meanwhile, Sanhu lake was a lake formed by low-lying land where the Yangtze river and its tributaries are found (He, 2002). The soil parent material changes with the distance from the center of the lake to the rivers. When the sample site is nearer to the center of the lake, the soil parent material has more clays; when it is nearer to the rivers, the soil parent material has more sands. In another words, the soil parent material is quite uniform with the height of the study area. On the other hand, the random factors in the Sanhu Farm area related to human activities, among which the cropping pattern was the key factor to influence the SOM spatial pattern.

Table 3. *Parameters of semivariogram fitted to SOM distribution patterns*

Year	Model	Nugget	Partial Sill	Range	Nugget/Partial Sill
1990	Exponential	0.312	1.651	3577.776	0.189
1994	Spherical	0.973	1.118	2161.201	0.870
2000	Spherical	0.082	0.628	2150.335	0.131

Driving factors of the SOM spatial pattern changes

Both structural and random factors affect the SOM spatial patterns. The SOM spatial pattern and its change are controlled by the mixture of the two types of factors. *Table 3* shows that the SOM spatial patterns of 1990 and 2000 are affected more by the structural factors while that of 1994 is affected more by random factors. We think the elevation is the key structural factor and the cropping system is the key random factor.

The SOM Spatial Patterns of the study area have been controlled by the micro-landform constantly. This area was reclaimed through a lake, the Sanhu Lake. It was formed by the extraction of lake water to the Main Canals, so the study area basically kept the landform of the Sanhu Lake. The elevation of study area is between from 25.1 m to 29.3 m (*Fig. 4*). Most of this area has a height of around 26-27 m. The center part of the former lake was lowest with the richest deposit of peats, a rich source of SOM. That's why there is always a high SOM value at the center (*Fig. 3*).

When the relation between the SOM values and the elevation was analyzed (*Fig. 5*), it was found that the SOM values in the three survey years all had a strong negative correlation with the height. In the other words, in different survey years, between the elevation and the SOM value, there showed a similar pattern in which the SOM values decreased as the height increased, though every survey year's decreasing gradient was slightly different. The decreasing gradient of 1990 was 0.2656; that of 1994, 0.2574; that of 2000, 0.3263. The SOM values of 2000 decreased with the decrease of height more rapidly than that of the other two survey years. Though the decreasing gradient of 1990 was quite similar to that of 1994, the value of 1994 was the smallest.

The SOM values of samples with their corresponding heights were used to make a scatter diagram (*Fig. 6*). The diagram clearly shows the pattern of the changes of the SOM values during different periods after the land reclamation and intensive tillage.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1074310757

The red triangles in *Fig. 6* represent the SOM values of 1990, blue 1994 and green 2000. It is important to note that the highest SOM value is not just for the site with the lowest height. Rather, the mean value of SOM decreased constantly along the three survey years (*Table 4*). Compared to the SOM values of the three survey years, the data from 1994 had the highest standard deviation (*Table 4*) and the biggest ratio of Nugget/Partial Sill (*Table 3*), which was affected more by human activities.

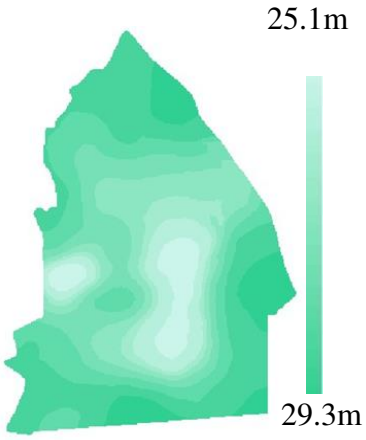

Figure 4. *The DEM of study area*

	Elevation	SOM_2000	SOM_1994	SOM_1990
Elevation	1.0000

	0.0000	0.0000	0.0000	

Figure 5. *Relationship of SOM concentration and elevation*

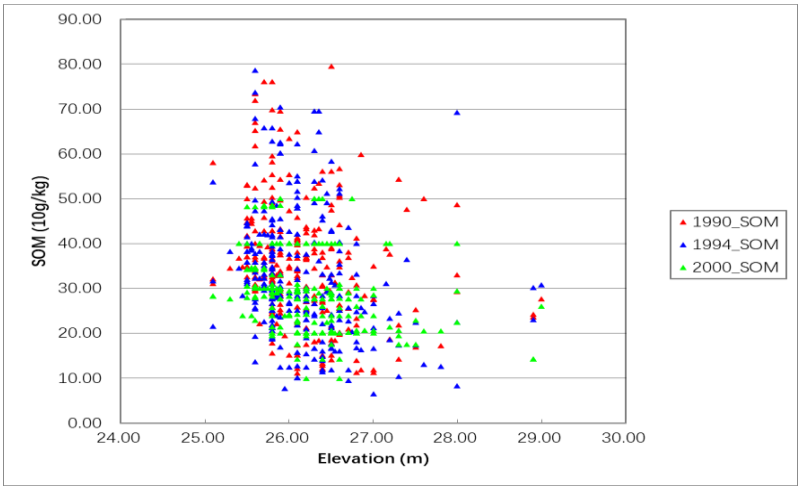

Figure 6. *Relationship between elevation & SOM concentration of every survey year*

When the cropping system and its changes were considered (*Fig. 7*), the cause of the speciality of the SOM spatial pattern from1994 can be identified. From 1980 to 1990, the paddy land accounted for 56.35% of the total arable land and the dry land accounted for 43.65% (*Fig. 7a*). By then early rice and late rice were planted in rotation in paddy land while the dry land was rotated by wheat, rapeseed and soybean. But from 1991 onward, China assigned cotton production responsibility nationally and the government supplied loans with low or free interest to encourage cotton planting. Additionally, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1074310757

price of cotton rose 10% in 1993 and continued to rise in 1994. This policy had strongly affected the cropping system of Sanhu Farm. The paddy land changed to dry land for cotton planting continuously in 1991. Until 1995, almost all paddy land was changed to dry land, where the paddy land accounted for 4.18% of the total arable land, and the dry land accounted for 95.82% (*Fig. 7b)*. The cropping system had been cotton and rapeseed in rotation from then. In 1998, however, the price of cotton depreciated significantly, and the government reformed the circulation system of cotton the following year. Cotton was no more the nationally critical materials, and the risk of cotton planting was no longer the joint responsibility of government and peasants (Sun, 2005). But the cropping system of Sanhu Farm had changed very little for the degeneration of irrigation system guaranteed the rice production till 2008 we did our last field investigation to the area.

Table 4. *The classical statistical features of SOM concentration data of Sanhu Farm*

Year	Sample Number	Mean (g/kg)	Standard deviation	Coefficient of variation (%)	Maximum (g/kg)	Minimum (g/kg)
1990	262	35.45	13.38	0.38	79.50	11.10
1994	262	32.92	14.36	0.44	78.70	6.50
2000	262	29.42	8.59	0.29	50.00	10.00

So 1994, a period of cropping system change emerged, which is why the ratio of Nugget/Partial Sill of SOM spatial pattern was very high (*Table 3*). We may suppose that, when the cropping system was steady and uniform, the micro-landform was the key controlling factor of the SOM spatial pattern of Sanhu farm. But as the cropping system changed, the influence of human activity can't be neglected for the SOM distribution. Regardless of whether the cropping system was steady, the amount of SOM decreased continuously after reclamation and intensive cultivation.

Discussion

Our research concerns two significant issues of the soil science domain.

The first issue is to ascertain the influencing factors and their influences on soil quality (Cambardella et al., 2004; Karlen et al., 2013a; Ontl et al., 2015) or carbon accounting (Ratayake et al., 2016).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1074310757

Many researchers suggest that soil quality is influenced by inherent (such as parent material, climate, and topography) and anthropogenic (such as tillage and crop rotation) factors (Karlen et al., 1998; Schwanghart et al., 2011). Research teams from the USDA mainly focus on changes in soil quality indicators through long-term care or maintenance of the plots for elaborately designed tests of tillage operations over several decades (Cambardella et al., 2004; Karlen et al., 2013b). Karlen et al. (2013b) verified their hypothesis that long-term moldboard plowing would have the greatest negative effect on soil quality indicators, and they put forth that less aggressive tillage systems or cropping systems could significantly improve soil quality/health. Cambardella et al. (2004) found that soil quality degradation with tillage depends upon landscape position, suggesting that soil quality increases on the backslope, and that shoulder landform elements are responsible for higher watershed-scale soil quality in the ridge-tilled watershed. Ontl et al. (2015) analyzed the influence of different bioenergy cropping systems on soil aggregation and particulate organic matter. The result showed that root system properties of crops and soil texture influenced the shift of iPOM-C concurrently, and cropping system effects were not consistent among positions across landscape.

SOM is a very important indicator of soil quality (Cambardella et al., 2004). We emphasized spatial patterns and temporal change of SOM with sampling data from three different years, while the USDA observed changes in many indicator variables of soil quality among positions across landscape, or under different cropping systems and tillage types, by comparing soil layered sampling data from a single year. They elaborately designed different scenarios of cropping systems and tillage types on different plots which was helpful to get the oriented results, but we analyzed a real-world cropping system altered by the farmers' wills, and concomitantly affected by both the market and policy. Our study area Sanhu Farm was virgin land before the reclamations of the 1960s, so it supplied a nice perspective to observe the impact of anthropogenic factors. In a spatial visual style, our research supported the hypothesis that soil quality is influenced by inherent and anthropogenic factors.

In another aspect, previous researches on carbon counting achieved some creative results. Rice cropping under waterlogged conditions enhances the soil organic matter (SOM) accumulation (Lal, 2002; Ratnayake et al., 2016). Wu (2011) reported that SOC accumulation in paddy ecosystems was faster and more pronounced than in other arable ecosystems. Kölbl et al. (2014) found that lower lands with water logging get greater accumulation of SOC in soil. Ratnayake et al. (2016) went further to find that different upland crops make limited contribution to carbon accumulation, while rice fields in the lower land landscape exhibit greater potential to store SOC in terms of carbon sequestration compared with upland cropping systems. Our research results were in accord with theirs. Furthermore, we found that the upland cropping systems also generate a smaller standard deviation.

Another issue is on the spatial modelling of SOM (SOC) and model accuracy (Miller et al., 2016; Ratnayake et al., 2016), which mainly focus on sampling density, efficiency, and the simulating precision of models. Previous research designed the rules for model selection which were used in our research in the preceding introduction, and the average distance of sample sites was about 350 m, which satisfied the sampling distance need (>2150 m) of every model (*Table 3*). Kriging models we used for simulating the spatial-temporal change of SOM rely on spatial autocorrelation, which perform best when the distance between points is minimized and only appropriate to use for making predictions between points, and they are considered inappropriate for

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1074310757

extrapolating beyond the extent of sampling points (Miller et al., 2016). So, near the boundary of Sanhu Farm the simulating error of SOM is relatively higher than the remaining area for there is no sample outside of the boundary. The biggest advantage of the Kriging technique over many classical statistical procedures is that it incorporates the spatial correlation of the data. Considering the sampling rule of different years was the same, and we mainly cared about the change of SOM, and the boundary area was quite limited, so we did not discuss the possible error of the boundary area in our calculation.

Conclusion

SOM plays a very important role both to condition soil properties and to mitigate climate change. Sanhu Farm with an area of 64 km^2, which was a lake before the 1960s, was used as our study site to observe SOM variability after intensive tillage of the virgin land. Based on 262 topsoil survey samples of 1990, 1994 and 2000 respectively, the SOM spatial distribution pattern, as well as the temporal change of SOM content of the corresponding years, were analyzed.

The SOM content successively decreased with the increase of the land exploitation history. From 1990 to 2000, the sample numbers of SOM grade in Abundant had decreased from 28.6% to 19.5%; the SOM grade in Poor decreased from 12.2% to 7.3%; but the Medium grade increased from 59.2% to 73.7%. We depicted the topsoil SOM distribution maps of the three survey years with an appliance of a same legend of 10 classes divided by Natural Breaks rule under ArcGIS 10 (*Fig. 7*). Compared with the map of 1990, the distribution area of the top grade shrank greatly by 1994, and the top two grades were disappeared by 2000. there was an overall tendency for the maximum or minimum value of SOM to approach to the average value over time.

The altitude of Sanhu Farm thus played a controlling role throughout the three survey years.The SOM concentration of each survey year was negatively and significantly (at 5 percent level) correlated with the elevation. The topsoil SOM distribution of the three survey years showed a similar spatial pattern whereby the highest SOM concentration value grade was distributed in the center, and the SOM value decreased incrementally as the distance to the center increased ,which showed the SOM values were negratively correlated to the altitude of study area.

SOM concentration changes were influenced by crop systems changes which were affected crop prices and related policies. In particular, the crop system change from rice to cotton influenced the decrease of SOM significantly.

Abstract. In this study, heavy metal cadmium ions (Cd^{2+}) in water environment were studied, and the existing Cd^{2+} colorimetric system was simplified. Based on colorimetry and spectroscopy, a portable analyzer for rapid detection of Cd^{2+} was developed. This study simplifies the tedious and complex pre-processing and completes the colorimetric experiment. The measuring instrument is mainly divided into an optical path module and a circuit module. The optical path module converts the concentration of cadmium ions into an optical signal, and the circuit module realizes functions of converting, amplifying, data processing, viewing management data, and uploading data of the optical signal. After the detector was completed, several system performance analyses were performed, and low power consumption, anti-interference, and repeatability tests were taken to verify the accuracy of the measurement. The experimental results show that the determination coefficient of the model and the chemical value of the colorimetric reaction is $R^2 = 0.934$, the detection limit is 0.1047 mg/L, the detection range is 0.1~1 mg/L, and the variation coefficient of cadmium content index is less than 1.0%. The test results show that the tester has good accuracy and repeatability. At the same time, compared with other related instruments, the meter also has the advantages of multiple functions, small size, portability, convenient use, and low power consumption.
Keywords: *cadmium ion, colorimetry, spectroscopy, analyzer, rapid detection*

Introduction

With the rapid development of modern industry, the danger of heavy metal pollution has become increasingly prominent. Cadmium is a highly toxic heavy metal and is a non-essential toxic element of the human body. It is called the "first of the five poisons" (Bairi et al., 2014; Chansuvarn, 2012). As early as 1974, the United Nations Environment Programme (UNEP) and the International Committee for Work Health and Heavy Metals identified it as a key pollutant . Numerous studies have shown that cadmium is carcinogenic, and the International Agency for Research on Cancer (IARC) classifies cadmium as the first class of human carcinogens (Chen et al., 2014; Chen et al., 2015). Wastewater containing cadmium is discharged into the environment. Cadmium has a strong enrichment effect in aquatic animals. Fish can be enriched 100,000 times. Once absorbed by the human body through the food chain, cadmium will selectively accumulate liver and kidney (Kim et al., 2012). Cadmium can also hinder the metabolism of bones, which is the main culprit for "pain sickness" (Fang,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1075910766

2016). Therefore, it is especially important to study the efficient detection of cadmium ion concentration.

The current detection methods are: atomic emission spectroscopy, mass spectrometry, fluorescence analysis (Georgiev et al., 2014; Ghasemi, 2009), electrochemical analysis method (Han, 2013), spectrophotometry (Mohanty et al., 2018), atomic absorption spectrometry (Han et al., 2014; HJ-763, 2015). Atomic absorption spectroscopy (Huang et al., 2013; Huang et al., 2012) overcomes the shortcomings of the traditional method, which has the advantages of low detection line, easy operation, and fast analysis speed (Kai, 2015) However, the range of atomic absorption bands is narrow, and it is difficult to analyze complex samples. Spectrophotometry is simpler to choose from, simple and fast to operate, and has a wider range of applications, but it is relatively low in accuracy. Electrochemical analysis methods (Li, 2006), although the detection efficiency is high, the accuracy accuracy is limited. Mass spectrometry (Li, 2008;Mohan et al. ,2018) can quickly detect metal concentration on the basis of a small amount of reagents (Rajalakshmi, 2011;Banerjee et al. ,2008), but it has limitations in the field of organic mass spectrometry. The application of various methods provides different ideas for cadmium ion detection. (Wanget al. , 2003;Ying ,2013)

In recent years, there have been many research results for the measurement of cadmium ion colorimetry. Yuan Aiping used dry ashing to dissolve ash with warm 0.2 mol/L sulfuric acid, and added dithizone-carbon tetrachloride as a masking agent to eliminate copper interference in the matrix and used for cadmium in fish and meat foods. The detection limit of the method was 0.12 μg/L, and the recovery was 86%-112%. Fan Yueqin et al. studied the color reaction of the new reagent 4-methyl-2,5-disulfonylphenyldiazoaminoazobenzene with cadmium . In the presence of TritonX-100, the reagent forms a red complex with cadmium in a buffer solution of $Na_2B_4O_7$-NaOH at pH 10.5~11.5. The maximum absorption wavelength is 526 nm and the apparent molar absorptivity is 2.5×105 $L \cdot mol^{-1} \cdot cm^{-1}$. This study combines colorimetry and spectroscopy to simplify the complex and cumbersome pre-processing of colorimetric methods, transform Cd^{2+} into measurable compounds, construct detection models, and apply the model to portable spectrometers to develop low cost. Low detection limit, simple pre-treatment, suitable for a variety of heavy metal rapid detection instrument.

Materials and methods

Materials

The heavy metal cadmium ion (Cd^{2+}) was used as the research object. The test materials included dithizone, carbon tetrachloride, sodium tartrate, sodium hydroxide, hydroxylamine hydrochloride and distilled water. The instruments used are pH meters, beakers, electronic balances, centrifuge tubes, and the like. The test principle is that in a strong alkali sodium hydroxide solution, Cd^{2+} in the water sample can react with dithizone to form a red complex.

In the colorimetric experiment, dithizone was used as a color developer, and the solvent was carbon tetrachloride (CCl_4). In the experiment, sodium potassium tartrate solution was used as a masking agent to exclude magnesium, iron, calcium and aluminum ions to prevent these ions from forming hydroxide precipitates in an alkaline environment (Alfonso,2010; Zhang et al,2010). The colorimetric reaction can be carried

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1075910766

out under a strong alkaline environment and adjusted with a sodium hydroxide solution. As a color developing agent, dithizone has a molecular formula of $C_{13}H_{12}N_4S$, a blue-black crystalline powder, which is easily oxidized by air and can be protected by a hydroxylamine hydrochloride solution. (Zhang et al, 2015;Zhao et al,2011) Carbon tetrachloride is a colorless solution with large specific gravity, low viscosity, non-toxicity and good chemical stability. It is selected as a solvent for dithizone solution. After the dithizone is dissolved in carbon tetrachloride, the solution is blue-green, and the red complex formed by the colorimetric reaction with cadmium is obviously different, which meets the requirements of the colorimetric reaction.(Wu et al, 2015;Sponza et al,2011)

Methods

The specific test steps are as follows:

Solution preparation: test to simulate cadmium-containing water, prepare 66 gradients of cadmium solution from 0.001 to 1 mg/L with standard solution; configure 1 mg/L dithizone use solution, use carbon tetrachloride as solvent; configure 20% The hydroxylamine hydrochloride solution is used as a reducing medium; 10% sodium potassium tartrate solution is used as a masking agent; the colorimetric reaction can be carried out under a strong alkaline environment, and the sodium hydroxide solution is used for adjustment.

The maximum wavelength of the absorption of the magenta liquid after the reaction was measured by a visible spectrophotometer V-1300 was 530 nm, and did not change with the change of the concentration. Therefore, this study chose 530 nm as the incident light center wavelength.

The optical path portion is composed of an LED light source, a fiber optical path, and a silicon detector. The required light source band of the circuit is 530 nm. Select the LED plus filter to achieve the required narrow-band light source to ensure the monochromaticity of the light source. The filter has relatively stable performance, high transmittance, and can be well matched to the established model. After comparison, this study selected the LED light source of model E505-06 from Japan EPETEX and the filter of 530 nm center wavelength of INTOR Company of USA.

In order to enable the monochromatic light source to emit parallel light and vertically illuminate the detector, and simplify the structure of the instrument, this study uses a fixed fiber collimator as the optical path, and realizes the connection between the reaction black box and the circuit, as shown in *Figure 1*. One end of the fiber is the incident end, and the outside is a metal sleeve, which is used to fix the filter and the LED light source, to ensure the stability and reliability of the light source, and to reduce the experimental error. The structure is shown in *Figure 2*. In this study, a cuvette with a diameter of 1 cm was used as the absorption cell to carry the sample.

Figure 1. *Structure diagram of fiber channel*

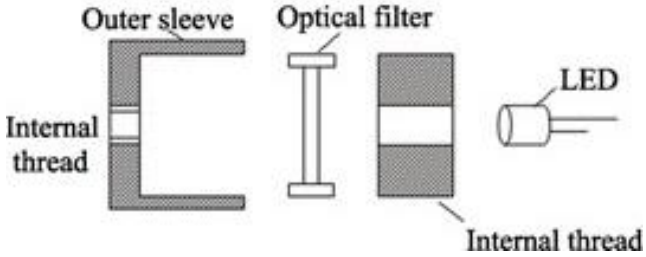

Figure 2. *Schematic diagram of metal sleeve*

The circuit module is mainly composed of a power supply circuit, a detection and amplification circuit, a keyboard circuit, a liquid crystal display circuit, etc., to realize conversion of an optical signal, amplification of an electric signal, attenuation of noise, and data processing and display functions. The instrument uses TI's low-power 16-bit microcontroller MSP430F149 as the controller of the system, with a 16-bit reduced instruction set to meet the rapid detection design of the analyzer.

The measuring instrument adopts a silicon material photodiode detector with a spectral response range of 300 to 1100 nm, and the model number is PS0308 (product of FIRST SENSOR, Germany), which effectively ensures the linearity of the instrument. Since the design circuit of this study works in a low frequency environment and requires good linearity, the photodiode is selected to work in zero bias mode without dark current error, and there is no need to design a reverse voltage bias circuit.

This design adopts full dot matrix graphic liquid crystal display CSME-12864, which has the advantages of low voltage, low consumption and good backlight mode. At the same time, this design uses membrane keyboard to realize functions of viewing, measuring, flipping, deleting, storing data, etc. powered by.

Results

The partial least squares method is combined with the above four different partitioning methods, combined with the MSC pretreatment method to establish a mathematical model of cadmium ion concentration and absorbance. The model has several evaluation indicators, and the model results are intuitive and specific through specific index values. Analysis, the results are shown in *Table 1*.

Table 1. *Comparison of different modeling set partitioning methods combined with PLS cadmium ion concentration prediction model*

Modeling set partitioning method	Main factor	Modeling set		Forecast set		RPD
		Rc	RMSECV	Rp	RMSEP	
RS	3	0.9427	0.1094	0.9131	0.1317	2.5074
KS	2	0.9619	0.0792	0.9201	0.1246	2.6101
SPXY	4	0.9662	0.0768	0.7068	0.1850	1.4455
Duplex	5	0.9550	0.0970	0.9549	0.0863	3.6142

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1075910766

From the analysis of *Table 1,* it can be known that the RS method divides the modeling set, the range does not cover all the samples, is not representative, and the established model is not stable enough. The model established by the Duplex method has the best detection and detection results. The RMSECV and RMSEP are 0.0970 mg/L and 0.0863 mg/L, respectively, which are small, and are smaller than other models. The RPD value is 3.3142 over 3, indicating that the model predicts better. Therefore, Duplex is selected as the model selection method of modeling set, and the PLS model of cadmium ion concentration is established by MSC pretreatment method. The model and prediction map of the obtained model are shown in *Figures 3* and *4,* and the sample is evenly distributed in the curve. Left and right, achieved a good prediction effect.

The test method is to prepare a set of lead standard solution 0.001~1 mg/L a total of 66 sets of gradient solution. The measurement was carried out by using a 530 nm light source with a bandwidth of 10 nm, and the linear regression analysis was obtained. The modeling results and test results are shown in *Figure 3.*

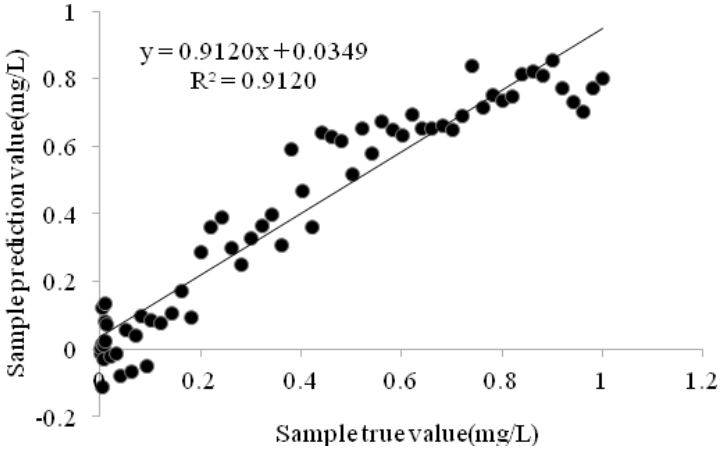

Figure 3. *Correlation between the actual value of Cd^{2+} concentration and the modeling set of predicted values*

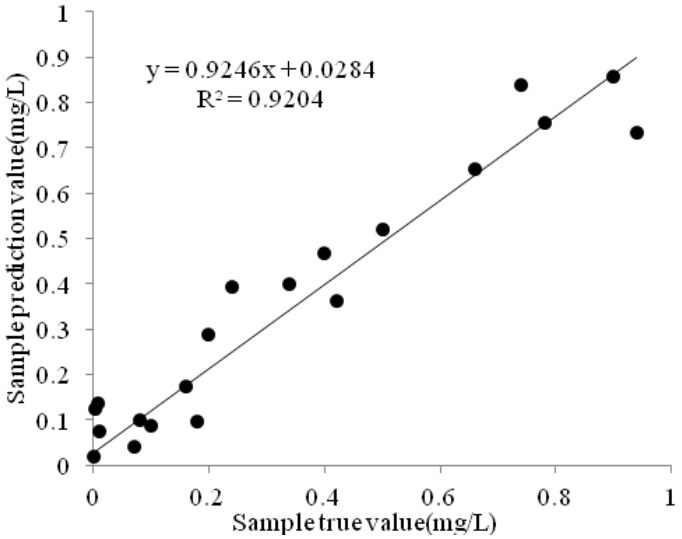

Figure 4. *Correlation between the true value of Cd^{2+} concentration and the validation set of predicted values*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

The design is based on the colorimetric reaction of dithizone with cadmium ions, masking the interference of other heavy metal ions with masking agent, and optimizing the reaction environment, including pH, temperature and other influencing factors. The whole instrument is composed of optical path module and circuit module. The linear measurement range of the instrument is 0.1~1 mg/L, which can measure the low concentration of cadmium ions and achieve a certain precision. The national surface water environmental quality standard for cadmium ions is 0.01 mg/L, and the instrument meets the testing standards. The detection range of dithizone spectrophotometry in national standard is 0.01~0.3 mg/L. The detection range of this method meets the standard requirements, and the experimental operation is simple. Compared with the spectrophotometer, the optical path system of the instrument is simple in design, and the main structure is composed of LED, filter and optical fiber. The measurement room has good shading performance, can shield the influence of stray light, and has simple and reliable design. The instrument passed the repeatability test with a coefficient of variation of less than 1% and hardware and software anti-interference measures to make it have certain stability. The tester has certain innovations. The actual experimental verification results show that the prototype of this design has good repeatability and stability, and can be used for the measurement of cadmium ions in water.

Discussion

By comparing the detection range of the method to meet the standard requirements, the experimental operation is simple. Compared with the spectrophotometer, the optical path system of the instrument is simple in design, and the main structure is composed of LED, filter and optical fiber. The measurement room has good shading performance, can shield the influence of stray light, and the design is simple and reliable. The instrument passed the repeatability test with a coefficient of variation of less than 1% and hardware and software anti-interference measures to make it have certain stability. The tester has certain innovations. The actual experimental verification results show that the prototype of this design has good repeatability and stability, and can be used for the measurement of cadmium ions in water.

Conclusion and recommendation

In this study, heavy metal Cd^{2+} was used as the research object to simplify the existing Cd^{2+} colorimetric system, and a portable analyzer for Cd^{2+} rapid detection was developed.

(1) By analyzing the physicochemical properties of Cd^{2+} and the colorimetric reaction of cadmium with dithizone, the experimental scheme for the color reaction of dithizone with water-weight Cadmium metal in alkaline environment at normal temperature was determined, and a masking agent was used. Mask other ion interference.

(2) The detection range of the analyzer in this study is 0.1~1 mg/L, the coefficient of variation is less than 1%, and the repeatability test results are good. At the same time, the analyzer has simple and stable structure, low power consumption and portability. Further research on this analyzer can be carried out in future work to achieve rapid detection of various heavy metals in the actual water environment.

(Received 1st Mar 2019; accepted 21st May 2019)

Abstract. *Zostera marina* is a perennial seagrass that is widespread on temperate coasts around the world. Some studies have showed that the presence of *Z. marina* in marine environments influences the microbial communities in sediment collected from Shuangdao Bay of China. To investigate the impact of *Z. marina*, the environmental factors and microbial communities in sediments collected in the eelgrass beds and adjacent unvegetated area, were examined. Several environmental factors and microbial communities composition differed significantly between the two areas. The content of total-phosphate and NH_4^+-N in the sediments of eelgrass beds were lower than the sediments of the unvegetated area, while the bacterial abundance and diversity in eelgrass bed were greater than that of unvegetated area. The most abundant bacteria found in sediments were Proteobacteria, Bacteroidetes, Planctomycetes and Acidobacteria, while the bacterial community structures were significantly different between the two areas. The changes found in the environmental factors and microbial communities were mainly attributed to the presence of *Z. marina*. This study may provide further understanding of the effects of *Z. marina*, which may be vital to the regulation of the marine environment.
Keywords: *Zostera marina, environmental factors, microbial communities, marine sediments, marine environment*

Introduction

Seagrasses are a unique group of plants that comprise 60 monocotyledonous angiosperm species (Hemminga and Duarte, 2002) that grow in coastal sediments in shallow coastal zones (Fonseca, 1998; Lebreton et al., 2012). *Zostera marina* is one of the most common seagrasses and distributed mainly in temperate regions of the northern hemispheres (Short et al., 2007; Zhou et al., 2015). Eelgrass meadow can provide a valuable habitat and food source for many invertebrates and fishes (Gillanders, 2006).

In recent years, many studies on *Z. marina* have focused on its biological processes that are related to photosynthesis, nitrogen fixation and restoration (Goodman et al., 1995; McGlathery et al., 1998; Marion, 2010). Eelgrass link sediment and nutrient cycles providing several vital coastal ecosystem functions (Harlin et al., 1981), so their protection and restoration are important. Many bacterial species found in the sediments of eelgrass bed are absent in sediment habitats outside of eelgrass bed (Campbell et al., 1990; Shieh et al., 1997). Several studies showed that bacteria inhabit the roots of the eelgrasses (Kuo et al., 1981; Kurtz et al., 2003; Küsel et al., 1999; Nielsen et al., 1999) and may form synergistic relationships. Eelgrass can excrete amino acids and sugars from their roots, thereby create suitable niches for a wide variety of microorganisms in the rhizosphere (Lee et al., 2000; Holmer et al., 2001; Jensen et al., 2005). Double

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1076710779

gradient denaturing gradient gel electrophoresis (DG-DGGE) was used to investigate several factors' impact on bacterial community diversity, and the results suggests that vegetation and season exert stronger controls on microbial community structure (James et al., 2006). Jensen et al., found that eelgrass can affect microbial processes in the rhizoplane via the excretion of amino acids and sugars. Significant differences in the bacterial communities associated with the roots and the bulk sediment associated with *Z. marina* have been found (Jensen et al., 2007), and the presence of roots could favour the growth of particular bacteria. Few studies to date have examined the effects of the eelgrass meadow on the environmental factors and bacterial communities.

In this study, we used a variety of methods to measure the environmental factors in sediments collected from eelgrass meadow and unvegetated area. We then characterized the richness, diversity, similarity, and composition of the microbial communities. In addition, root-specific bacteria were also analysed.

Materials and methods

Study area and sampling

Shuangdao Bay is located in Weihai, which lies within the Shandong Peninsula in northern China (N37°28.5′-37°29.2′, E121°57.5′-122°58.5′). The sample S1 (N37°29.087′, E121°58.267′) was collected from the sediments in eelgrass meadow, while sample S2 (N37°29.045′, E121°58.286′) was collected from the sediments in adjacent unvegetated area (*Fig. 1*). S0, S40, and S80 were collected from the sediments of a single plant. The sediment taken from the root of *Z. marina* was designated S0 (N37°29.073′, E121°58.306′), and the sediments taken from 40 and 80 cm away from the root were designated as S40 and S80, respectively. The S40 and S80 samples are a mixture of four samples taken from the circumference of the sampling zone. Samples were collected in April 2015.

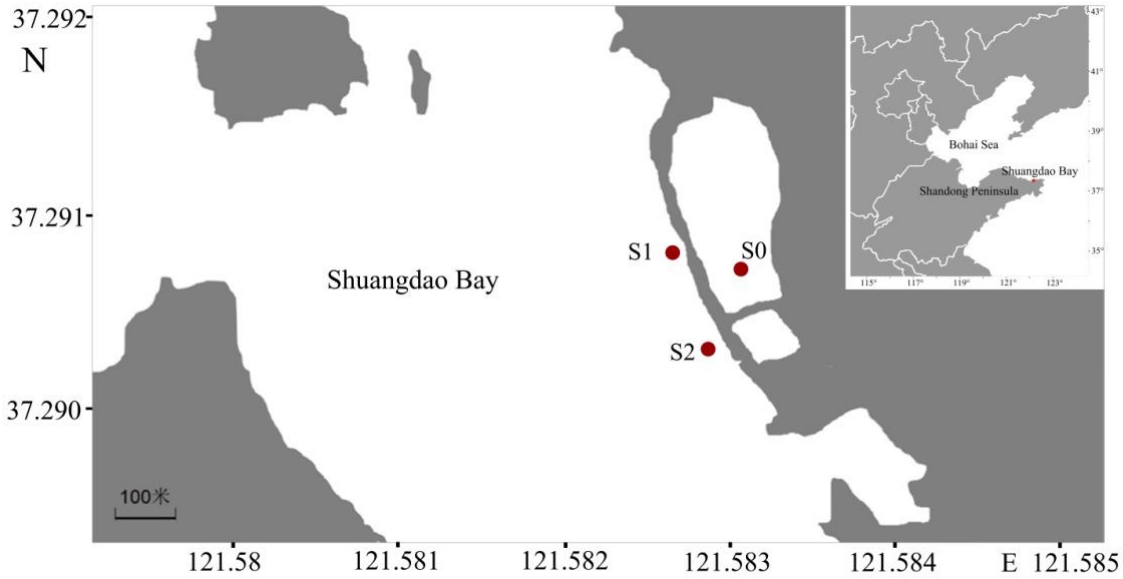

Figure 1. *Sampling area in Shuangdao Bay, Shandong Peninsula, China. Sediments were sampled in eelgrass beds (S1) and in adjacent unvegetated area (S2)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1076710779

In each sampling location, a composite sediment sample was collected at a depth of approximately 0–10 cm using a bottom sampler. Each fresh composite sample was subdivided into two subsamples, one of which was stored at -80 °C prior to bacterial 16S ribosomal ribonucleic acid (rRNA) gene sequencing, while the other was freeze-dried and tested to determine the levels of elemental factors that included salinity and nutrition factors such as sediment organic matter (SOM), total-nitrogen (TN), total-phosphate (TP), NO_3^-, NO_2^-, NH_4^+, PO_4^{3-} and water-soluble sulfide (WS).

Determination of environmental parameters in sediment

The contents of SOM and WS were determined by using the muffle furnace heating methodand $BaSO_4$ turbidimetry (Lv et al., 2018), respectively; three replicates were performed for each measurement. The TN/TP extract solution was obtained using a simultaneous preparation method (Li et al., 2007) and the contents of TN and TP were determined by using zinc cadmium reduction and the phosphomolybdenum blue method, which utilizes the reduction of ascorbic acid for specific ions according to the oceanographic survey GB17378.5-2007, respectively. NO_3^- was determined using zinc cadmium reduction, while NH_4^+ was detected using the indophenol blue method described in GB17378.5-2007. One-way ANOVA (Wolfram Mathematic 11.3) was used and the LSD-t tests were performed to compare TN, TP, WS, SOM, NH_4^+ and NO_3^- between different samples. Differences were deemed significant at $P < 0.05$ and extremely significant at $P < 0.01$. Values are means ± SD (n = 3).

DNA extraction, clone library construction, PCR amplification and high-throughput sequencing

The PowerSoil DNA Isolation Kit (TineGene Limited Company, Shanghai) was used to extract the genomic DNA. The DNA library was established using a two-step PCR amplification method, and the sequencing was conducted on an Illumina Miseq 16S rDNA system. The PCR primer sequences used to amplify the V4-V5 region within the bacterial DNA are shown in *Table 1*. The 16S rDNA sequences of S1 and S2 have been deposited in the NCBI Sequence Read Archive under accession number PRJNA506488. The 16S rDNA sequences of S0, S40 and S80 have been deposited in the NCBI Sequence Read Archive under accession number SRP158072.

Data analyses

Paired-end reads were assigned to each sample based on their unique barcode and were truncated by cutting off the bar code and primer sequence. Split sequences for each sample were merged using FLASH V1.2.7 (Magoc and Salzberg, 2011), and the splicing sequences were called raw tags. Quality filtering on the rawtags was performed under specific filtering conditions to obtain the high-quality clean tags according to the QIIME quality-controlled process (Caporaso et al., 2011). The tags were compared with the reference database using UCHIME algorithm (Edgar et al., 2011; UCHIME, 2011) to detect chimera sequences, and then the chimera sequences were removed, finally obtaining the effective tags. Using the USEARCH and Perl scripts, the sequences retained were analyzed following the UPARSE pipeline to generate an operational taxonomic unit (OTU) table and pick representative sequences (Edgar, 2013). The sequences with a length shorter than 200 bp and singletons were removed. The retained sequences were were aligned with the 16S rDNA sequences using Silva 119 (http://www.arb-silva.de/) in order to annotate the species based on 97% sequence similarity using the average neighbour method. Taxonomical assignments of OTUs were executed using MOTHUR 1.33.3. OTU abundance information was normalized using a standard sequence number corresponding to the sample with the least sequences. Rarefaction analysis was performed to compare the relative levels of OTU richness across all sediment samples at an OTU cutoff of 0.03 (Xu et al., 2017). Principal components analysis (PCA) of the PCORD5 is used to examine the relationship between the microbial community (phyla) and environmental factors. All data are tested for normal distributions before ANOVA. Figures are prepared by PCORD5.

Results

Determination of environmental factors in sediment

Compared with S2, the contents of TP (LSD-t = 113.12, $p < 0.01$) and NH_4^+ (LSD-t = 7.41, $p < 0.01$) in S1 were significantly reduced, while the contents of other factors have no significant differences (*Fig. 2*). To explore whether these differences were caused by the presence of eelgrass, we examined these environmental factors in the sediment near its roots (S0), as well as 40 cm (S40) and 80 cm (S80) from the roots. The contents of NH_4^+ (LSD-t = 0.007825, $p < 0.05$) and TP (LSD-t = 0.02093, $p < 0.05$) in S0 were lower than that of S40 and S80 (*Fig. 3*). In conclusion, the sediment in eelgrass meadow contains lower levels of TP and NH_4^+ than that of unvegetaed area.

Microorganism richness and diversity

After processing, 33424 and 27009 high-quality sequences were obtained from S1 and S2, respectively. A total of 9640 OTUs were obtained for the samples at 3% dissimilarity (*Table 2*). The abundance indices (Chao and Ace indexes) of S1 were both higher than that of sample S2, while the diversity indices (Shannon and Simpson indexes) were lower than that of sample S2. These results suggested that the bacterial abundance and diversity in the sediment of eelgrass meadow were greater than that of unvegetated area. In the same way, we measured the microorganism richness and diversity in S0, S40 and S80. After processing, 72720, 53733 and 25842 high-quality sequences were obtained from these samples, and a total of 15232 OTUs were obtained

DOI: http://dx.doi.org/10.15666/aeer/1705_1076710779

(*Table 2*). As shown in *Table 2*, the bacteria diversity and richness in the sediment near the roots (S0 and S40) were greater than that of sediment far from the roots (S80).

Comparison of microbial communities among different samples

To assess the variation in the microbial communities, the compositions of taxa at the phyla and class levels are represented in a pie chart (*Figs. 4* and *5*). A significant difference in bacterial community was found between eelgrass beds and adjacent unvegetated area. At the level of phyla (*Fig. 4)*, the most abundant phylum represented within each sample was Proteobacteria, which comprised 48% and 53% of the reads from S1 and S2.

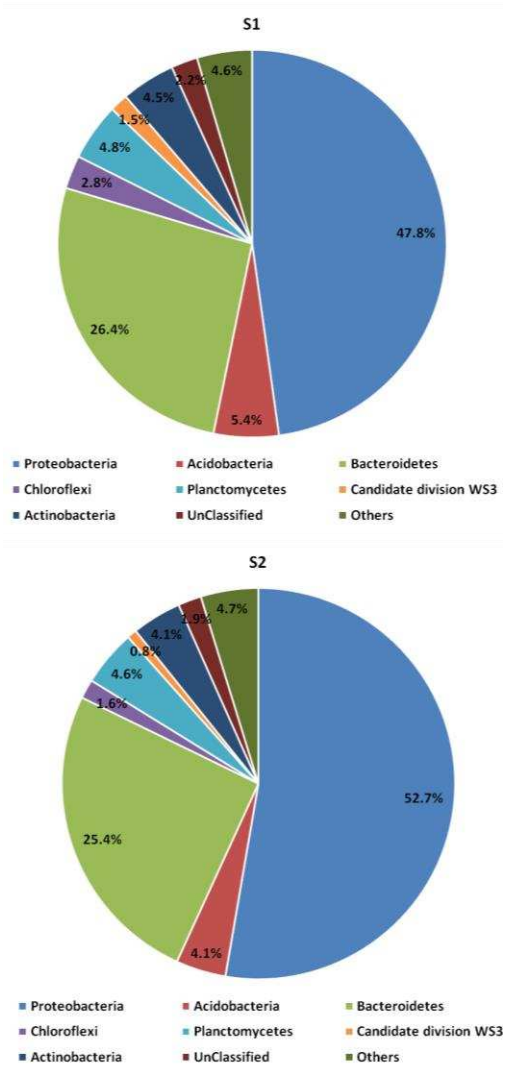

Figure 4. *The diagram for different samples's microbial communities at phylum level*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1076710779

The relative abundances of Proteobacteria, Gemmatimonadetes, Cyanobacteria and Chlamydiae were higher in the sediment of eelgrass meadow, while the relative abundances of Bacteroidetes, Firmicutes, Deferribacteres, Planctomycetes and Chlorobi were higher ($P < 0.05$) in the sediment of adjacent unvegetated area. At the level of class (*Fig. 5)*, the relative abundance of Gemmaproteobacteria was higher in the presence of eelgrass, while the relative abundances of Alphaproteobacteria, Flavobacteriia, Sphingobacteriia and Planctomycetacia were higher ($P < 0.05$) in the absence of eelgrass.

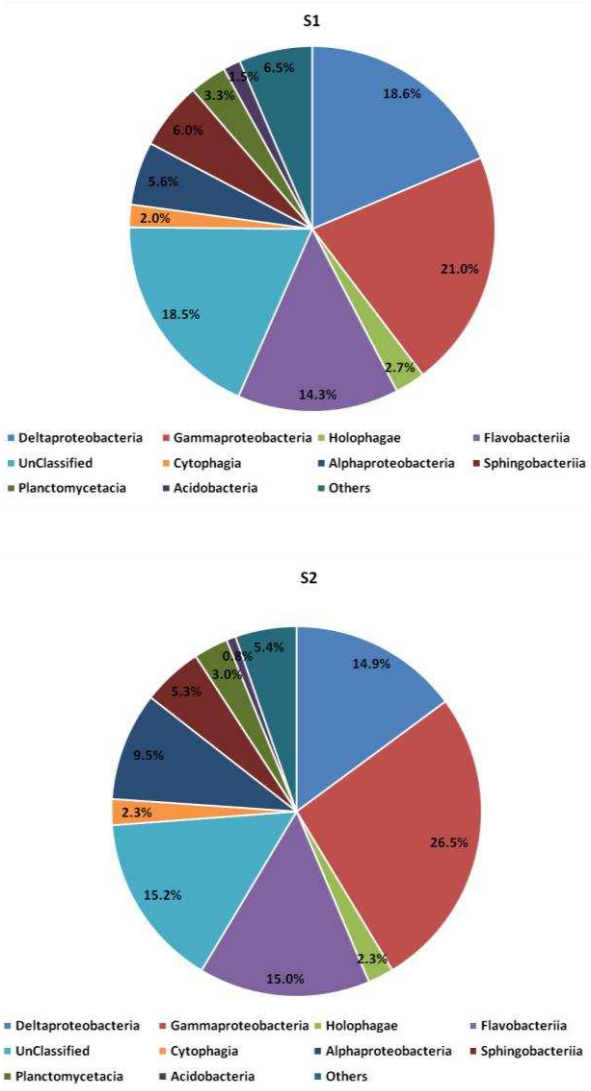

Figure 5. *The diagram for different samples's microbial communities at class level*

Microbial community and environmental conditions

Sediment properties are listed in *Figures 2* and *3*. The sediment in eelgrass meadow had much lower TP and NH_4^+ contents. The PCA analysis showed that PC1 and PC2 explained 56.246% and 18.277% of the bacterial phyla, respectively. The changes of microbial community composition in S1 and S2 were mainly attributed to NH_4^+, NO_3^- and TN (*Fig. 6*).

Root-specific bacteria

To obtain the root-specific bacteria of eelgrass, we analysed the OTUs specifically detected in S0. The results showed that there were 2654 unique OTUs detected within the roots of *Z. marina*, and the OTU size was 3464. Among these, 601 OTUs were identifiable at the family level, 302 at the genus level, and 11 at the species level. At the family level, the identified bacteria were Alicyclobacillaceae, Anaerolineaceae, Desulfobacteraceae, Desulfobulbaceae, Flavobacteriaceae, Planctomycetaceae and Spirochaetaceae. At the genus level, the identified bacteria were *Coxiella*, *Desulfococcus*, *Desulfobulbus*, *Acidiferrobacter*, *Geobacter*, *Sulfurovum*, *Rhodopirellula* and *Spirochete*. The eleven identified species were *Bacillus hwajinpoensis*, *Bacillus algicola*, *Brevundimonas bullata*, *Brevundimonas vesicularis*, *Paenibacillus provencensis*, *Roseiovarius aestuarii*, *Labrenzia marina*, *Lewinella nigricans*, *Sphingomonas paucimobilis*, *Ruditapes philippinarum*, and *Stenotrophomonas acidaminiphila*.

Discussion

Influence on environmental factors

The sediment in eelgrass meadow contains low levels of TP and NH_4^+ (*Figs. 2* and *3*). In this study, the content of NH_4^+ was significantly lower in eelgrass meadow which may be due to the vigorous ammonium absorption process in the roots (Hemminga et al., 1994). The contents of the other environmental factors such as organic matter have no significant difference in eelgrass meadow and unvegetated area which is consistent with previous research (Xu et al., 2016). From the above results, we speculate that nitrogen metabolism and phosphorus metabolism in the sediments inside eelgrass meadow are more vigorous than those outside eelgrass meadow, while there is no significant difference in carbon metabolism and sulfur metabolism. These environmental factors are considered to have been influenced by the presence of eelgrass, then influence the growth of particular bacteria.

DOI: http://dx.doi.org/10.15666/aeer/1705_1076710779

Variation in the bacterial community and ecological functioning

The coverage index for all of the samples in this study was estimated to be between 84.3% and 92.1%, which indicated that the results of the high-throughput sequencing most likely encompass most of the microbial organisms in the sediment. The richness and diversity analysis indicated that the bacterial abundance and diversity in eelgrass meadow were greater than in the unvegetated areas (*Table 2*), which may be related to the metabolic cycle or root exudates of *Z. marina*.

Proteobacteria is the most abundant phylum of bacteria in many coastal areas (Hu et al., 2014; Li et al., 2016). In the present study, this phenomenon is laso observed, and the dominance of *Proteobacteria* does not change in different samples (*Fig. 4*). In this study, the microbial community structures were analyzed on the basis of two approaches: eelgrass meadow analysis (*Figs. 4* and *5*) and single eelgrass analysis (*Fig. 7*). The two different approaches did not return similar result. The results suggested that the bacteria communities in sediment were complex. The results indicate that the first approach is more representative of the effect of eelgrass on microbial communities in sediments, as the effects of individual plant is limited.

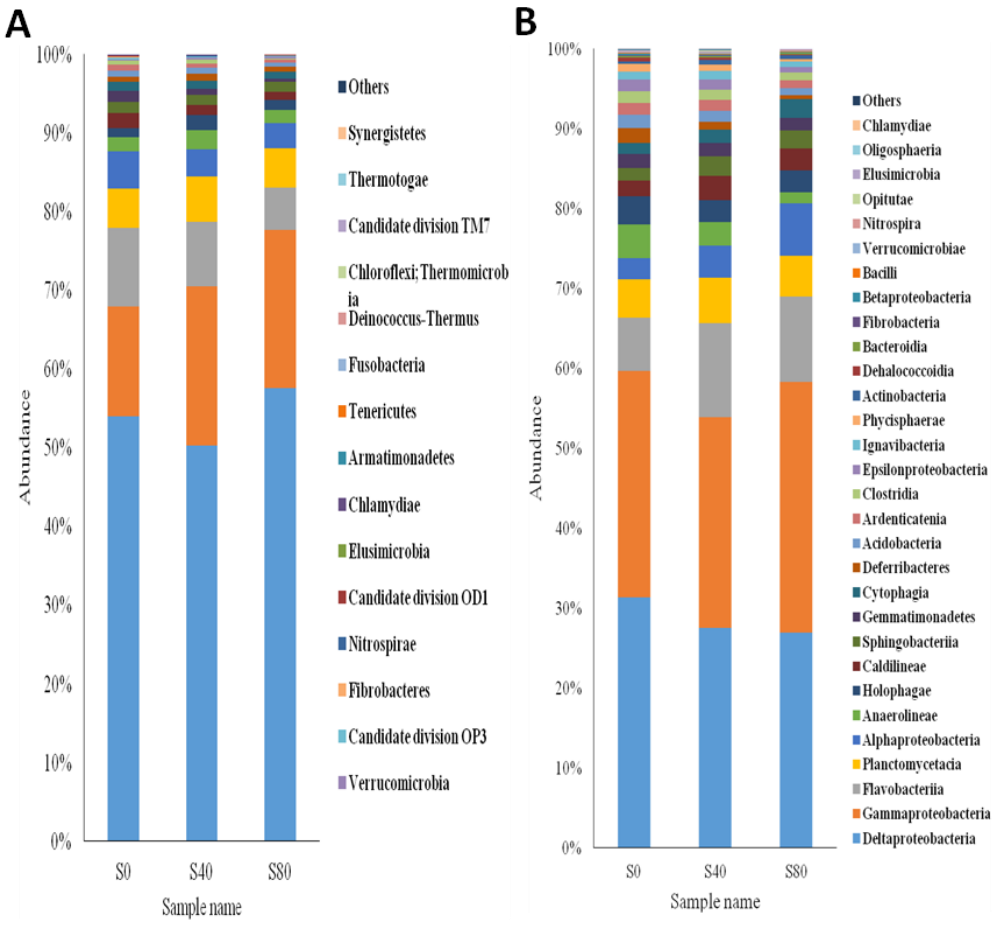

Figure 7. *The diagram for different samples' microbial communities at phylum level (A) and class level (B)*

Nutrient loading was reported to regulate the shifts in microbial structure and diversity in sediment along the river (Wang et al., 2018). Previous studies reported that

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1076710779

microbial biomass in saline environments was increased by an addition of easily decomposable substrate (Yan and Marschner, 2012), and TN is the main factor increasing the microbial biomass (Li et al., 2016). In this study, the S1 (in eelgrass meadow) and S2 (in unvegetated area) sites had apparently different bacterial phylum structure, which was found to be attributed to NH_4^+, NO_3^- and TN (*Fig. 6*). On the basis of the environmental properties results, we believe that NH_4^+ content in sediment influence the microbial community structure of eelgrass meadow.

Root-specific microorganisms

Root-specific microorganisms were analyzed through single eelgrass analysis. The results showed that there were 2654 unique OTUs detected within the roots of *Z. marina*, while there were 5735 OTUs detected. The result indicated that the microbial community structure and diversity in the area near the roots of eelgrass are significantly different from the surrounding environment. There abundance of *Rhodopirellula* in habitats with eelgrass was lower than that of unvegetated area. As a kind of Planctomycetes, *Rhodopirellula* has an anaerobic ammonium oxidation function (Wecker et al., 2010). It is speculated that the nitrogen cycle in sediments with eelgrass is more vigorous, and the conversion of ammonium is more rapid, which is also consistent with the ammonium content of the sample S1 below the sample S2 (*Fig. 2*). The microorganisms specifically detected in the roots of eelgrass may be closely related to their growth, which reflect the influence of eelgrass meadow on environmental factors and microbial community.

Based on the current and previous studies, we proposed that microbial community composition was closely related to environmental factors which may be influenced by the presence of eelgrass. However, more studies are needed on whether the sediments' microbial community compositions in different areas have the same trend.

Conclusions

Based on the measurements of the environmental factors, the sediments in eelgrass meadow have low levels of NH_4^+ and TP. The abundance and diversity of the microorganisms in the sediment with eelgrass were greater than in the sediment without eelgrass. In addition, significantly differences were observed in the microbial community composition between eelgrass meadow and unvegetated aera. Therefore, we speculate that the changes in the structure of the microbial community in the sediments with eelgrass are closely related to the vigorous N and P metabolism.

Abstract. Effect of exogenously applied Silicon (Si) and Thiourea (TU) were examined in fodder beet plants under saline conditions. Seedlings growth of three fodder beet genotypes (Jamon, Monro and Tarine) were maintained in pots containing soil salinized with 300 mM NaCl dissolved in irrigation water. Two levels of Si (100 mgL^{-1}, 200 mgL^{-1}) and TU (150 mgL^{-1}, 300 mgL^{-1}) respectively were applied exogenously through leaves of 40 to 50 days old pots transplanted fodder beet plants. Salinity stress significantly suppressed plant growth and fresh biomass and as well as altered some physiological parameters like total chlorophyll content, K^+, Na^+, and K^+/Na^+ ratio in all the investigated fodder beet genotypes. Yet, these reductions were higher in Tarine followed by Jamon than those of Monro. However, both treatments of Si and TU as foliar application were effective in mitigating the adverse effects of salinity stress on shoot growth and improvement in fresh weights of Monro. Salinity stress increased leaf Na^+ contents, whereas K^+ contents and K^+/Na^+ ratio decreased in fodder beet plants under saline regime. These reductions were improved by Si and TU application, increased the K^+ uptake and K^+/Na^+ ratio through ion selectivity and ultimately triggered activity of anti-oxidant enzymes: Superoxide dismutase (SOD), Peroxidase (POD), and Catalase (CAT) and proline accumulation needed to thrive best in saline stress conditions. The beneficial effects of applied Si and TU were reflected in the form of enhanced fodder beet growth as well as improvement in various physiological traits and antioxidant defensive mechanism.
Keywords: *fodder beet, winter fodder crop, salt stress, silicon, thiourea*

Introduction

Salinity intrusion is one of the major environmental issues throughout the world and a huge number of hectares of marginal lands also have limited the scope for crop production (Dasgupta et al., 2015). Salinity and drought are two of the most genuine abiotic stresses, which signify a threat on crop productivity worldwide (Guo et al., 2014). In many parts of the world, a significant region of watered arable land has been confronting a major issue of salinization. Even though it is very difficult to accurately determine the increasing salinized area and its phenomenon however, it was estimated that round about 20-21% of irrigated land (45 million ha) which contributes the on third of the world's coproduction is mainly salt affected (Shrivastava et al., 2015). The productivity of most crops was reduced by soil salinity, in spite of the fact that to a changing degree relying on species (Hussain et al., 2016). Pakistan has about 16.80 million ha irrigated agricultural area in which 6-7% is categorized as strongly Saline, 9-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1078110791

10% slightly saline, 3-4% moderately and 6% miscellaneous, while 72% is listed as non-salt affected land (Khan etal., 2017). Salt stress has great impact on major and minor crop's yield and reduce up to 50% yield in many arid and semi-arid areas of the world (Dugasa et al., 2016). Production of practically every conventional crop around there is significant decreased under saline soil conditions. Henceforth the introduction of non-traditional salt tolerant fodder crops in these areas could be an appropriate alternative.

Fodder beet is salt tolerant crop when contrasted with other fodder and forages, similar to that it can be effectively grown on salt influenced lands and fed as fodder in numerous European countries and in Egypt. Farmers generally use all parts roots and leaves as animal feed, directly in fresh form or processed (Sakr et al., 2014). The cultivation of fodder beet crop on marginal lands gives a remarkable benefit to farmers in the form of high economic yield production on such type of barren lands (Abdallah et al., 2008). The beet crop is utilized by amalgamation with straw in European and in other different countries of the world. Both the underground part roots and above part leaves are used as animal feed, however the tuberous roots of fodder beet are mainly utilized as primary feed for animals (El-Sarag et al., 2013).

Some beneficial mineral supplements have been determined by different researchers which can balance the unfavorable impacts of salt stress. On earth crust after the oxygen, silicon is found the 2nd most abundant element and exist as 8th common element in nature (Sahebi et al., 2015). A number of ways like fertilizer or bio-stimulant silicon can be used which plays a vital role in plant growth development and yield productivity under various stress conditions (Sawas and Ntatsi, 2015). Silicon supplementation into the solution culture enhanced wheat development and K^+/Na^+ with reduction in Na^+ and upgraded K^+ take-up. It is useful for plants from numerous points of view as it enhances plant water status in setting of relative water content and transpiration rate, improves the hurtful impacts of salt stress on chlorophyll and plant biomass in both leaves and roots, it brings down fundamentally the Na^+ uptake by (Liu et al., 2015). The supplementation of Silicon under salt stress conditions has the ability to mitigate the adverse effects of Na^+ and uptake by plants by increasing the K^+ concentration and with the resultant increase in K^+/Na^+ ratio (Xu et al., 2015). Exogenous application of different concentrations of Silicon to salt stressed aloe sensitive plants and tolerant plants significantly improved the K^+ content in roots and translocation to leaves and other parts of plants consequently raising the K^+/Na^+ ratio, while decrease the Na^+ uptake and its translocation (Garg et al., 2016).

Thiourea is a nitrogen and sulfur containing compound and is being utilized for the improvement of crops yield. Addition of thiourea significantly improves plant's root and shoot weight, tallness and number of leaves and leaf area, which directly results in the enhancement of plant's growth and development under various stresses condition (Parveen et al., 2015). Thiourea has the ability to improve entire plant growth, by enhancing cellular development of plants under salt stress (Ikram and Javed, 2015). Saddiqui et al. (2006) also reported that exogenously applied Thiourea altogether enhanced the fresh and dry weights grown under salt stress condition.

The current research was undertaken to test the hypothesis that (1) Thiourea and Silicon exogenous application enhanced fodder beet salt tolerance both by improving the plant biomass and decreasing the ion toxicity; (2) Thiourea and silicon improved the plant water balance by enhancing the proline accumulation; (3) Both treatments alleviated the ion toxicity by triggering antioxidant enzymes which are involved in scavenging reactive oxygen species and ion homeostasis.

Materials and methods

Land preparation and nursery raising

A plot sized 2×2 m^2 was prepared for nursery raising of Fodder Beet genotypes. For seeds sowing, the seedbed was prepared by thoroughly mixing one part Farm Yard Manure (FYM) and two parts soil as collected from AP horizon of the Agriculture Research Farm, The University of Haripur. Phosphorus 120 mg kg^{-1} as single super phosphate and half dose of the nitrogen (60 mg kg^{-1} N) as urea were applied as starter dose for fodder beet genotypes at time of Nursery preparation. Remaining ½ of the N was applied in two equal splits, i.e. 30 mg kg^{-1} N was applied 15 days after sowing (DAS) and the remaining at 30 DAS. and the nursery plot was then irrigated immediately. The nursery was left for 45 days after sowing to develop their growth and irrigations were provided at 7 days intervals subsequently.

Pot filling and nursery transplantation

A surface soil (0-20 cm), clay loam soil, (Gee and Bauder, 1986) was collected from Agriculture research farm area Department of Agricultural Sciences, The University of Haripur, Pakistan. The soil contained 1.20 mg Kg^{-1} of total dissolved salts, 0.55% organic matter (Nelson and Sommers, 1996), 0.20% calcium chloride (Leoppert et al., 1996), 8.7 mgL^{-1} available Pphosphorous. Growth media was prepared by filling pots measuring (height 22 cm, base diameter 24 cm and top diameter 27.5 cm) with a mixture of field soil and Farm yard manure in 3:1 ratio. The base of each pot was covered with polyethylene bags in order to develop salinity stress condition.

Plant growth and treatments application

At field capacity, five plants were transplanted on 1st March, 2017 in each pot, replicated thrice using Completely randomized design (CRD) for each fodder beet variety. In order to develop salinity stress, 300 mM NaCl solution was applied to the growth medium of Twenty days old transplanted after transplantation in pots Twenty days after transplantation in pots, a dose of 300 mM NaCl solution was applied to each pot in order to develop salinity stress. All pots were placed in green house and Twenty days after salt application, Calcium silicate (Si) and Thiourea (TU) were applied exogenously on Fodder beet genotypes. Two levels of Si and TU at 100 mgL^{-1}, 200 mgL^{-1} and 150 mgL^{-1}, 300 mgL^{-1} respectively were applied at 40 days after transplantation in pots, nonetheless one treatment in each fodder beet variety was kept control in the absence of Si and TU application. At 60th day of transplantation in pots, the plants were harvested and roots were cleaned from soil for data recording of fresh shoot, root weight and length of shoot, root and total biomass. The third fresh leaf of each fodder beet plant was harvested at the end of experiment for K^+, Na^+ concentration, K^+/Na^+ ratio, proline content estimation and the activity of antioxidant enzymes (SOD, POD and CAT).

Statistical analysis

Data of the present study were subjected to analysis using Two-Way ANOVA according to Abdi and Williams (2010), using Statistix 8.1. The differences among means were tested using Tukey's Honest Significant Difference test at 0.01% probability level. Mean values were presented as mean value with standard errors calculated from three replications.

Results

Growth parameters

Shoot length and root length of all fodder beet genotypes reduced significantly ($P \leq 0.01$) under salinity stress (*Table 1*). However, the reduction in shoot length and root length was much lower in Jamon and Tarine respectively than all other fodder beet genotypes. Exogenously applied Silicon and Thiourea significantly improved the growth of fodder beet genotypes as compared to non-treated plants under salt stress conditions. Silicon and Thiourea increased the shoot length in Monro with Si @ 200 mg L^{-1} being statistically at par with Tarine under TU @ 300 mg L^{-1} application. Similarly, the root length of Jamon plants increased under Si @ 100 mg L^{-1} whereas TU @ 300 mg L^{-1} application increased root length of Monro plants as compared to other treatments.

Values in columns having the same letter are not significantly different at $p \leq 0.05$

Shoot weight and root weight was significantly different ($P \leq 0.01$) of all fodder beet plants grown with salinity in root environment (*Table 1*). However, the reduction in shoot weight and root weight due to root zone salinity was much lower in Tarine compared to other fodder beet genotypes. The exogenous application of silicon and Thiourea significantly affected the fodder beet shoot and root weight under saline conditions. The highest shoot weight and root weight was recorded with Silicon and Thiourea application in Monro which was statistically at par with Jamon. Imposed root zone salinity significantly affected ($P \leq 0.01$) the total biomass in fodder beet plants (*Table 1*). Salinity stress caused maximum reduction in biomass of Tarine plants as

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1078110791

compared to other fodder beet plants. Both Silicon and Thiourea were found to increase the total biomass under salt stress conditions. Monro produced maximum biomass under Silicon @ 200 mg L^{-1} and Thiourea @ 300 mg L^{-1} followed by Jamon under Silicon @ 100 mg L^{-1} and Thiourea @ 150 mg L^{-1} (*Fig. 1*).

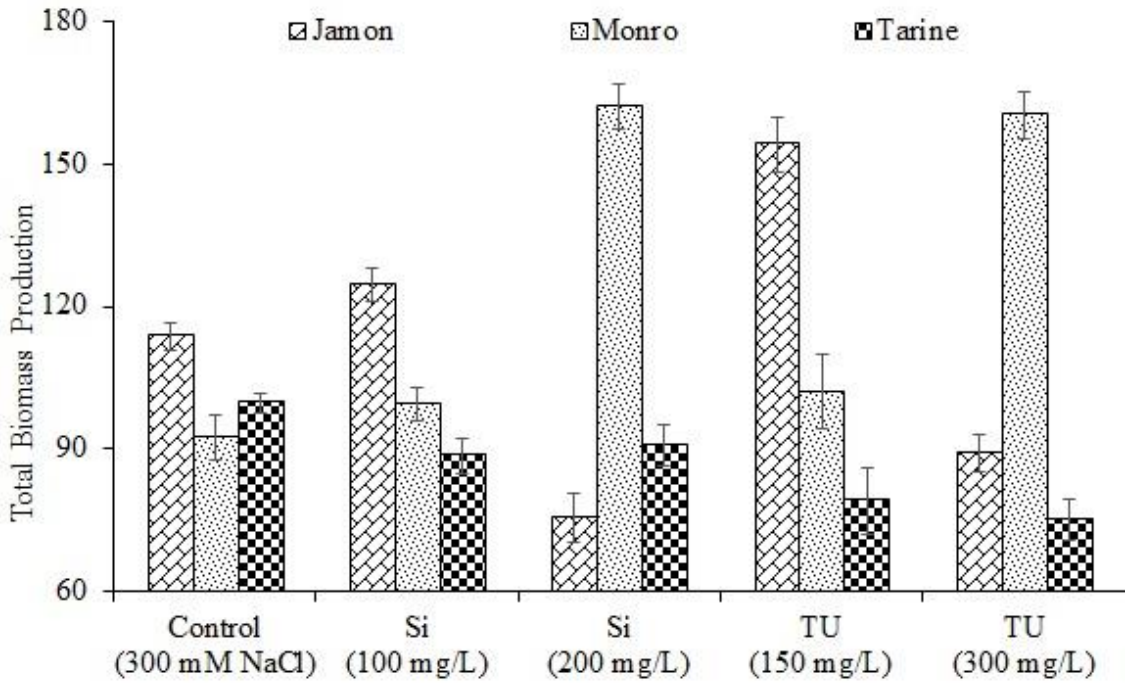

Figure 1. *Increase in total biomass production in fodder beet genotypes grown under salt stress conditions at different levels of silicon and thiourea. The bars indicates standard error (±SE) of mean (n = 3). All means are significantly different at p ≤ 0.05*

Physiological parameters

In all fodder beet plants, the potassium ion concentration was found significantly affected ($P \leq 0.01$) under salt stress conditions (*Table 2; Fig. 2*). The highest K^+ concentration was observed in Tarine under salt stress. Plants perform better in K^+ ions accumulation as Silicon and Thiourea were exogenously applied as compared to control treatment. The higher K^+ concentration in fodder beet shoots was recorded under exogenous application of Silicon @ 200 mg L^{-1} and Thiourea @ 150 mg L^{-1} in Tarine, statistically at par with Monro under control treatment. Root zone salinity significantly ($P \leq 0.01$) enhanced the sodium concentration in fodder beet shoots. The maximum Na^+ concentration was depicted in Monro under saline conditions. However, Silicon and Thiourea exogenous application were found to decrease the Na^+ ion accumulation in fodder plants under salt stress conditions as compared to control. Monro recorded with lowest Na^+ accumulation under Silicon @ 200 mg L^{-1} statistically at par with Tarine and Jamon under Silicon @ 100 mg L^{-1} and Thiourea @ 300 mg L^{-1} respectively. Monro recorded highest in K^+/Na^+ ration under Silicon @ 200 mg L^{-1} followed by Jamon under Thiourea @ 150 mg L^{-1} exogenous application respectively. Data revealed significant variation ($P \leq 0.01$) among fodder beet genotypes regarding proline accumulation under

DOI: http://dx.doi.org/10.15666/aeer/1705_1078110791

saline conditions (*Table 2*). Salinity stress significantly reduced proline accumulation in Monro compared to other fodder beet genotypes. Both Silicon and Thiourea were found to positively influence proline accumulation in Fodder beet plants. Deceasing salinity stress also decreased proline accumulation in Tarine under Silicon @ 100 mg L^{-1} and Thiourea @ 300 mg L^{-1}, statistically at par with Janom and Monro under Thiourea application @ 300 mg L^{-1} respectively.

	Tarine	2.81 ± 0.70	3.09 ± 0.87	2.98 ± 0.79	2.59 ± 0.64	2.93 ± 0.766

Values in columns having the same letter are not significantly different at $p \leq 0.05$

Anti-oxidant enzymatic activities

Anti-oxidant enzymes activity (SOD, POD and CAT) were significantly affected ($P \leq 0.01$) by induced salt stress in all fodder beet genotypes (*Table 2; Fig. 3*). Highest SOD and POD activity was found in Jamon while Tarine recorded higher CAT activity than rest of the genotypes under imposed salinity stress. Exogenous application of both Silicon and Thiourea enhanced the activity of antioxidant enzymes in fodder beet genotypes under salinity stress than that of untreated plants (control). Nonetheless, SOD, POD and CAT activity were increased significantly in fodder beet plants under Silicon @ 200 mg L^{-1} and Thiourea @ 150 mg L^{-1} when applied exogenously under salt stress conditions.

Discussion

The salinity stressed produced adverse effects on plants growth as mostly expressed as osmotic stress, explicit ion toxicity, damage to cellular membranes, vital nutrient deficiency and trigger in oxidants, etc. (Ashraf, 2009). To overcome salinity stress effects in plants, researchers are using various bio-stimulants which have been reported to influence various physiological processes (Perveen et al., 2014). In current study, the foliar application of silicon and Thiourea enhanced the growth of all Fodder beet plants as grown under salt stress condition. Various growth parameters including root and shoot length, root and shoot fresh weight, and total biomass were enhanced by Silicon and Thiourea under salt stress conditions (*Table 1*). Similar results to our research study have also been observed (Anjum et al., 2011) in two different wheat genotypes grown under 130 mM salt stress conditions. Likewise, some prior reports supported our results and revealed that Thiourea application mitigates the adverse effects of salinity and hence improved the final grain yield of many crops like, cereal crops (Sahu et al., 2006) and potato (Mani et al., 2012). Various research studies stated that exogenously applied Nitrogen containing compounds e.g. Thiourea has significant impact on the synthesis of green photosynthetic pigments which ultimately associated with high biomass production in salt stress conditions (Ashraf and Harris, 2013). Both Silicon and Thiourea exogenously applied are directly involved in the cellular osmotic adjustment of plants, which leads to enhance the biomass production of plants under salt stress condition (Burman et al., 2004; Seckin et al., 2009).

Figure 3. *Mechanism of silicon and thiourea mediated salinity tolerance in fodder beet*

Present study showed that salt stress caused the increased accumulation of Na^+ in shoots and roots of fodder beet genotypes. Due to presence of high concentration of Na^+ content, reduction was recorded in the concentration of K^+ which ultimately reduced the K^+/Na^+ ration in plant's tissues. The physiological window of ideal K^+ uptake by plants limits within the sight of expanding measure of Na^+. In the current research exogenous application of Silicon and Thiourea on fodder beet plants enhanced the K^+ and K^+/Na^+ by reducing Na^+ uptake (*Table 2; Fig. 2*). Silicon is also reported as to enhance the K^+/Na^+ ratio under salt stress (Al-aghabary et al., 2004). A critical decrease saw in Na^+ take-up demonstrates that TU-induced tolerance is because of salt stress mitigation strategy (Srivastava et al., 2011). To become salt stress tolerant, plants adopt various strategies and mechanisms like proline accumulation, formation of mannitol and glycine betaine etc which plays an important role in various plants processes just like, scavenging of Reactive Oxygen species in salt stress (Ali and Ashraf, 2011), stabilization of cell's membrane (Ashraf and Ali, 2008) and Osmotic adjustment of plants (Ashraf and Foolad, 2007). In this study, Tarine performed best in proline accumulation under salt stress conditions. Maximum proline content was found by Silicon exogenous application @ 100 mgL^{-1} (*Table 2; Fig. 3*). Silicon application improves proline and protein accumulation which ultimately trigger antioxidative defense mechanisms and decreases the lipid peroxidation under salt stress (Al-aghabary et al., 2004). Production of Reactive Oxygen Species such as SOD, POD, and hydroxyl radicals mainly damage the plants at cellular level which thrive in saline growth medium (Ashraf et al., 2009). In the current study we have detected that salt stress induces the SOD, POD and CAT activities as to alleviate salt stress in fodder beet plants. The exogenous application of Silicon and Thiourea showed to activate these activities more efficiently against salt stress conditions for ideal plant growth and development (*Table 2; Fig. 3*). Some prior studies concluded that Thiourea induced enhancement in the activities of antioxidant enzymes like, SOD, POD and CAT with remarkable decrease in Oxidative stress generated by the presence of Salinity stress

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1078110791

(Hammed et al., 2013). Likewise, another study also suggested that exogenous application of Thiourea in salt stress condition significantly lowered oxidative damage caused by ROS rather than unsprayed plants (Srivastava et al., 2011). It has been demonstrated recently that Silicon mitigates oxidative stress by stimulation of antioxidants, both enzymatic and non-enzymatic (Savvas and Ntatsi, 2015), such as superoxide dismutase (SOD), catalase (CAT), ascorbate peroxidase (APx), peroxidases (POD), and ascorbate (AA) etc. Li et al. (2016) showed that the provision of Si exogenously increased the SOD, POD and CAT activity of *Glycyrrhiza uralensis* seedlings grown under salt stress, after 20 days of treatment. Our research findings are analogous to earlier research studies which revealed that exogenously applied silicon can increase the anti-oxidant enzymatic activities such as; superoxide dismutase (SOD), peroxidase (POD) and catalase (CAT) under saline regimes.

Conclusions

Salt stress caused reduction in growth attributes, physiological and biochemical parameters of fodder beet plants. However, exogenously application of silicon and Thiourea improved to some extent stress tolerance in fodder beet plants by improving growth parameters as well as proline content, K^+ content, K^+/Na^+ ratio and decreasing Na^+ content in the shoots under saline conditions. Among all the three fodder beet genotypes evaluated under salt stress condition, Monro performed best having maximum SOD, POD and CAT activities. It was able to thrive best under saline conditions and hence produced prolific biomass, followed by Jamon and Tarine respectively. Furthermore; Silicon @ 200 mgL^{-1} and Thiourea @ 150 mgL^{-1} was found most effective in mitigating the salt stress conditions. To further investigate the salt ameliorating ability of silicon and Thiourea, a field experiment with more number of fodder beet genotypes is suggested.

Compliance with ethical standards. There is no potential conflict of interests and authors confirm that the field studies did not involve endangered or protected species.

(Received 8th Mar 2019; accepted 3rd May 2019)

Abstract. The potential of cucumber (*Cucumis sativus* L.) genotypes for salt tolerance was investigated in a pot experiment under a lath house conditions. Salt stress substantially reduced plant growth and physiological traits in cucumber plants. On other hand, increase in accumulation of organic solutes i.e., proline as well as activity of anti-oxidant enzymes like SOD, POD and CAT were also observed. However, salinity also caused ionic imbalancement in studied genotypes and lead towards high leaf sodium and chloride (Na^+, Cl^-) content along with a significant reduction in leaf K^+ and Ca^+ levels. On the behalf of percent increment or reduction in observed, cucumber genotypes Marketmore & Green long were found to be salt resistant, while Summer green and 20252 catagerized as salt sensitive. Tolerant genotypes effectively maintained better dry biomass and high Ca^+ and K^+ content with least Na^+ and Cl^- in their leaves exposed to salt stress. Furthermore, maximum accumulation of proline contents and greater activity of antioxidants (SOD, POD and CAT) results in improved tolerance under salinity which indicate that salt tolerance induced in cucumber is greatly connected with level of organic osmolytes and antioxidant defense system.
Keywords: *photosynthesis, salinity tolerance, glycinbetaine, salinity stress, superoxide dismutase, peroxidase*

Introduction

Increasing salinity is threat for vegetable production, particularly in irrigated areas where 40% food of the world's is produce (Sarwar et al., 2016, 2017). Some vegetables i.e., onions, cucumbers, tomatoes, peppers and eggplants are sensitive to salinity (Yamaguchi and Blumwald, 2005; Sarwar et al., 2017). Stepien and Klobus (2006) and Sarwar et al. (2018) stated that cucumber considered is an important vegetable for human nutrition and diet and it is source of vitamins and dietary fiber; it has been used for 3,000 years in its native areas of Asia and Africa (Gopalan et al., 1982). But melicious impact of salt stress on cucumber crop caused a severe reduction in crop growth and yield (El-shraiy et al., 2011; Sarwar et al., 2016, 2017). Cucumber growth significantly affected by salinity higher than 25 mM, which caused a reduction in yield upto 13% (Chartzoulzkis, 1992; Dorota, 1997). Soil salinity is a very serious threat being faced by agriculture sector of the world as it restricts the plant growth and yield (Qin et al., 2010; Mahboob et al., 2017; Sarwar et al., 2017) modulates leaf gas

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1079310806

exchange traits (Maeda and Nakazawa, 2008) enhanced cell membranes leakage (Dogan et al., 2010) and caused nutrient deficiency (Yang et al., 2008).

Salt stress resistance in plants depends on types of salts which are present in soil, plant growth conditions, genotype, age and management practice (Sheekh-El et al., 2002; Ashraf et al., 2010) it prompts osmotic and ionic stress which affect the morpho-physio and biochemical modifications at cellular level (Murphy and Durako, 2003). Higher amount of salts in soil, reduced the water potential of plant cell and soil which restrict the plant roots to absorb necessary water (Lloyd et al., 1989) that lead dehydration and ultimately cause death of the cell. Soil salinity means Na^+ and Cl^- ions are dominant and higher level of such ions leads to ionic toxicity in salt sensitive crops (Garcia-Sanchez et al., 2002). Maximum amount of toxic ions in saline environment inhibits absorption of the essential nutrients i.e., K^+, Ca^+ and Mg^+ (Hasegawa et al., 2000) and moreover enhance the concentrations of toxic ions Na^+ or Cl^- in plant cells which results in enhanced permeability and/or destabilization of cellular membranes by subsituting Ca^+ and K^+ (Grattan and Grieve, 1992). Photosynthetic activity of plant decreased due to modulation in stomatal conductance under salinity (Sarwar et al., 2017). Loss of turgor by osmotic effect of salinity resulted in stomata will close, reduce the supply of carbon dioxide to leaves of plants. Though, in calvin cycle more reduction in photosynthetic rate was also reported due to degradation of green pigments; decreased leaf area by reducing photosynthetic enzyme activity (Misra et al., 1997; Ashraf et al., 2010). Salinity-induced oxidative stress has toxic reactions like, mutation, degradation of protein and lipid peroxidation that impaired photosynthesis (Mccord, 2000). Salinty and drought tolerance mechanism in plants comprises balance between osmotic adjustment, ions concentrations, osmotic adjustment is a water balance in cell due to accumulation of proline, sugars and their role as an osmolyte for osmotic adjustment. Sugars alcohols i.e. mannitol and sorbitol, and glycinebetaines are bring into mainly protect the protein of cytoplasm or keep away cell membranes desiccation (Ashraf et al., 2010; Balal et al., 2012).

Keeping in view the malicious impact of salt stress on plants, the objectives of our study were to figure out the physiological, biochemical and chemical responses of cucumber genotypes on scientific basis for elucidating the fundamental mechanisms involved in salt tolerance. Such information is also key for suggesting a suitable crop cultivar for salt-affected soils. Furthermore objective of this study was to determine the fluctuations in ionic homeostasis of cucumber genotypes in response to Nacl salinity.

Material and methods

Current investigation was planned to find out the potential of cucumber genotypes for their salt tolerance under lath house conditions (30–35°C and relative humidity 40-50%) in University of Agriculture, Faisalabad- Pakistan. Four contrasting cucumber genotypes (Marketmore, Green long, Summer green and 20252) have varying degree of salinity tolerance were used for this study. A sand culture experiment was comprised with seven treatments and replicated four times, every treatment contain 12 pots; so, total 84 pots were used for this study. Before start of experiment, seeds of uniform size and identical color were selected and sterilized by using 3% solution (v/v) of sodium hypo-chlorite for ten minutes. Distilled water was used to rinsed the seeds and air-dried the seeds at 25°C. Eight cucumber seeds were sown in each 9 L plastic pot, after one week of emergence, thinning was carried out to maintain four plants in each pot. Plants

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1079310806

were irrigated after two days interval, half strength Hogland solution was used as a nutrient source twice in a week. Salt stress was based on Nacl (MERCK, CAS #-7647-14-5), NaCl stress was imposed at 40 days old crop after sowing. Six levels of salinity were investigated i.e., (Control- no stress), 2, 3, 4, 5, 6 and 7 dS m^{-1} NaCl. To avoid the osmotic shock, salt stress was imposed by gradual increments untill final concentrations reached for each treatments. The levels of salinity were maintained through out the experiment by recording EC and pH of the growing media. After one weeks of NaCl induction data were recorded for evaluation.

Growth characteristics

Five plants selected from each treatment to calculate the morphological traits, e.g. shoot/root length of cucumber plants with meter rod. Fresh weight of both shoot/root was weighed by an electrical balance (g). For dry weight determination these shoot/root were placed in oven at 70ºC temperature for 72 hours and mean values were calculated.

Leaf gas exchange attributes

The gaseous characteristics were estimated with Infrared Gas Analyzer by the described method of Sarwar et al. (2017).

Chlorophyll contents (SPAD)

For each plant, quantification of chlorophyll were taken from fully expanded third to forth young leave (Khan et al., 2003).

Membrane leakage (%)

Membrane leakage was assessed by the procedure of Lutts et al. (1996). Ten leaf discs of approximately same size were selected from young fully expanded leaf. After washing to remove dirt from leaf, little leaf discs were dipped in test tube having 10 ml distilled water and these tubes leave for 24 hour under room temperature followed by the determination of (EC_1) of electrolyte rich solution with the help of EC meter. Later on, the samples were shifted to water bath at 72ºC for 20 minutes and subsequently cooled at room temperature. The EC of diffused tissues (EC_2) was recorded. Membrane leakage was deliberated as ratio between EC_1 and EC_2 and expressed into %age.

Antioxidant enzymes and proline contents

Superoxide dismutase activity was assessed via proposed procedure of (Giannopolitis and Ries, 1977). Catalase and peroxidase were determined by the method of Chance and Maehly (1955). Whereas proline and glycinebetaine were quantified by the techniques of Bates et al. (1973) and Grieve and Gratan (1983).

Determination of ionic content (Na^+, K^+ and Ca^+)

The concentrtion of sodium, potassium and calcium were quantify according to method of digested leave samples The content of Na^+ and K^+ in extracted solution was estimated by flame photometer (Model Jenway PFP-7; UK). A graded series of standards (ranging from 10- 100 mg L^{-1}) of Na^+ K^+ and Ca^+ were prepared to draw standard curves used to quantify final concentration.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1079310806

Determination of Chloride

For determination of chloride ions, grounded plant material (1 gram) was taken in 50 ml test tube having 20 ml of distilled water and heated in an oven for overnight at 66°C. Then this solution filtered with "Whatmann-40 filter paper" and quantify of content with the help of Cl^- analyzer (Model: Corning-920, Germany).

Statistical analysis

The collected data was statistically analyzed under Completely Randomize Design (CRD) with factorial arrangement using (ANOVA) analysis of variance technique by Statistix 8.1 by implying HSD (Tukey's Test).

Results

Plant growth attributes

The present results revealed that increasing salt stress significantly and gradually reduced plant biomass in response of shoot/root length, fresh/dry weight and no. of leaves per plant. However, this decline was minimum in Marketmore, Green long genotypes who maintained better shootand root length, fresh and dry biomass by retaining maximum no. of leaves/plant as comparison to Summer green or 20252 genotypes (*Figs. 1, 2, 3a*).

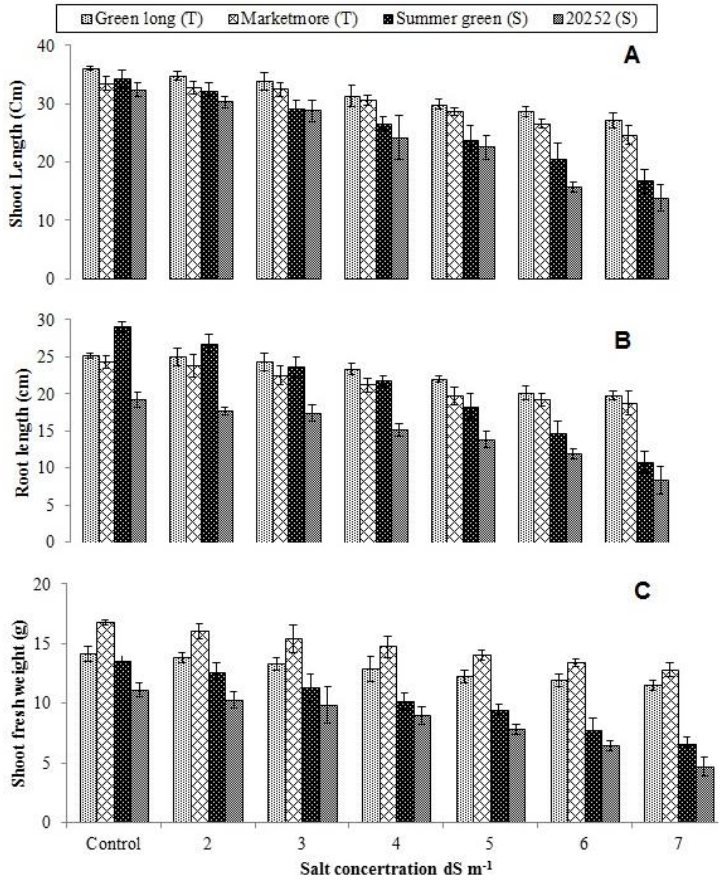

Figure 1. *Effect of salt stress on (a) shoot length (b) root length (c) Shoot fresh weight (g)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1079310806

Among the genotypes, Greenlong effectively neutralized the negative impects of salinity on plant growth and performed better than other genotypes under all salinity treatments. Hence, maximum shoot fresh weight was exhibited by market more under all experimental conditions. Cucumber 20252 showed maximum sensitivity towards salinity at all concentrations of salt stress and failed to manage considerable no. of leaves which produced lower shoot/root lengths with minimum fresh/dry weights.

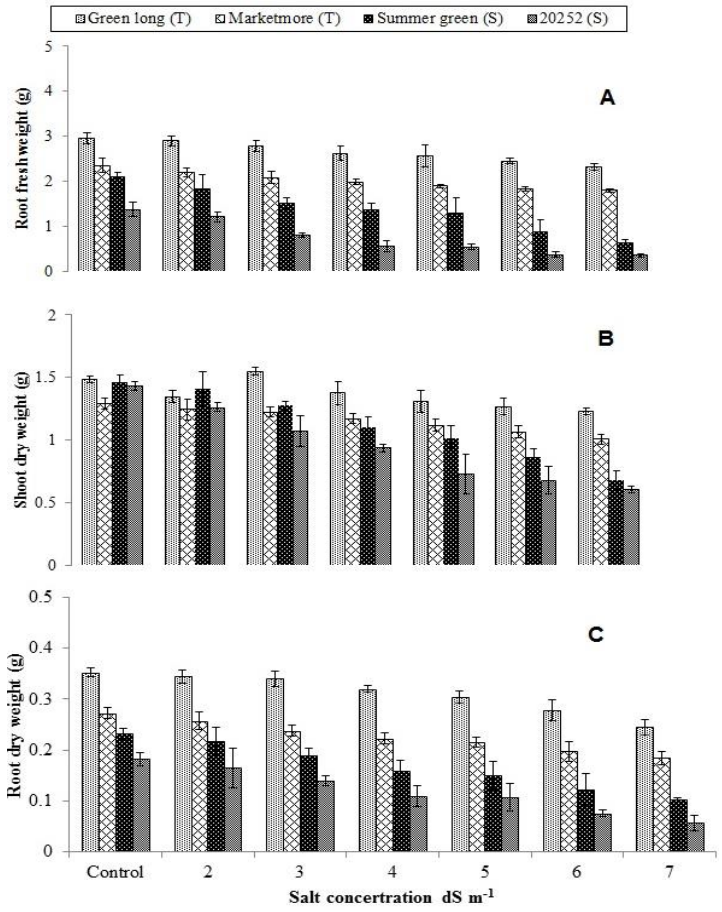

Figure 2. *Effect of salt stress on (a) Root fresh weight (b) Shoot dry weight (c) Root dry weight*

Leaf gas exchange attributes and chlorophyll content (SPAD)

Gas exchange attributes meaningfully decreased in tested cucumber genotypes (*Fig. 3*) at all salt levels however, significant decline in photosynthesis was induced by 6 dS m^{-1} salinity (*Fig. 3b,c*). Under highest salt level 7.0 dS m^{-1}, maximum reduction in gas exchange attributes were noted for Summer green or 20252 whereas, lowest for Marketmore or Green long in comparison to their controls. Increasing salt level caused decline in gas exchange attributes in tested genotypes, but higher decreased in these parameters was noted for genotype 20252 which is followed by Summer green. Maximum photosynthetic and respiration rate was exhibited by Marketmore under all salinity levels that is statistically at par with green long and behaved alike. Whereas, genotype 20252 showed highest stomatal conductance up to 3 dS m^{-1} salt stress but Green long maintained better stomatal conductance and improved water use efficiency even at higher level of salinity which is followed by Marketmore. Likewise, all the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1079310806

evaluating genotypes illustrate significant degradation of leaf chlorophyll in answer to elevating salt stress (*Fig 4c*). Maximum decline was observed at 7 dSm^{-1}. Thus, Green long and marketmore produced maximum chlorophyll under all level of salinity which expressed their capacity to tolerate salinity stress. Contrarly, high levels of salinity significantly affected stay green ability of Summer green and 20252 by reducing chlorophyll pigment. Lowest chlorophyll content was recorded for same genotypes at highest stress of 7 dSm^{-1}.

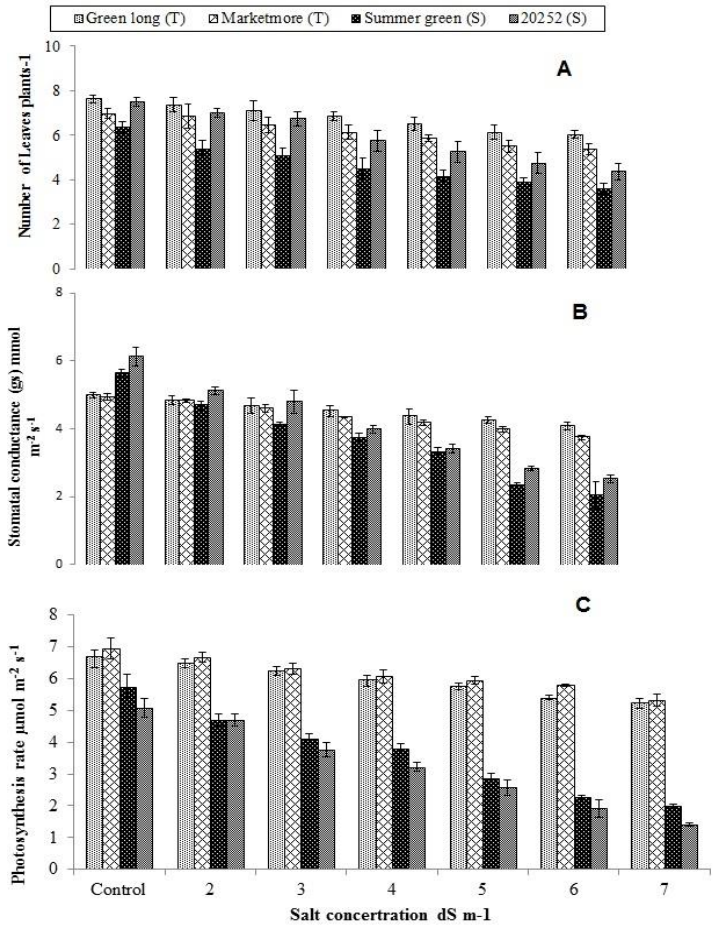

Figure 3. *Effect of salt stress on (a) number of leaves plant^{-1} (b) Stomatal conductance (c) Photosynthesis rate*

Electrolyte leakage(%)

It is obvious from data that all the cucumber genotypes showed a significant enhancement in electrolyte leakage when subjected to salt stress. Hence, the gradual increase in electrolyte leakage was observed with rising level of salinity and maximum increase was noted at 7 dSm^{-1} stress in genotype (20252) that was statistically at par with Summer green and behaved alike. Among the genotypes, Marketmore and Green long maintained better membrane stability and resulted in minimum electrolyte leakage under all salinity treatments over non-saline control. It indicates that electrolyte leakage % that can be used as potential approach for evaluating salt stress tolerance in cucumber plants.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1079310806

Antioxidant enzymes and osmolytes

It is clear from presented data that imposition of different salts concentration had a significant impact on the production of proline content and enzymatic activities in tested cucumber genotypes (*Fig. 5b,c*). However, maximum accumulation of proline and antioxidant activity was observed at highest saline level (7 dSm^{-1}). In case of genotypes, highest activities of CAT, SOD, POD and proline was demonstrated by Marketmore that was proceeded by green long genotype on exposure to all salinity treatments. Whereas, summer green was unable to produce better proline content as presented in *Fig. 6* and releaved minimum values for proline at all stress levels. Likewise, lowest activities of SOD, CAT, POD antioxidant were also exhibited by summer green as compared to other genotypes uder control and salt stress as well (*Figs. 5 and 6*).

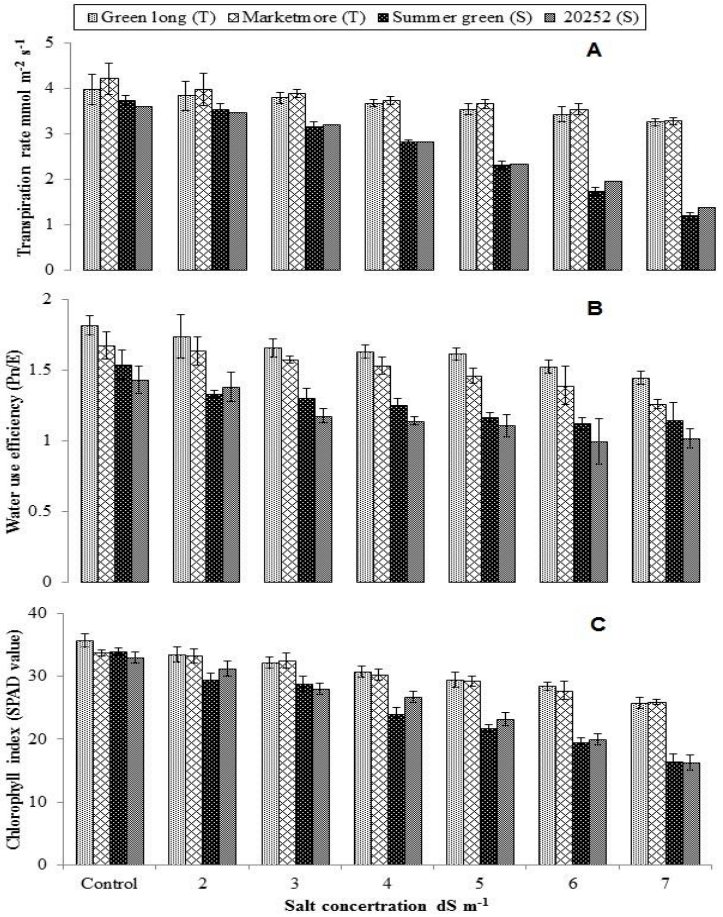

Figure 4. *Effect of salt stress on (a) Transpiration rate (b) Water use efficiency (WUE) (Pn/E) (c) Chlorophyll contents*

Leaf inorganic osmolytes

It is cleared from the results that rising levels of salinity modulated the concentration of in-organic osmolytes (Na^+, Cl^-, K^+, and Ca^+) in all cumcumber genotypes grown under salt stress (*Table 1*). Among the genotypes, 20252 and Summer green leaves had accumulated maximum contents of Na^+ and Cl^-, respectively, whereas Marketmore showed least build up of Na^+ and Cl^- contents in leaves in addition to improved

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1079310806

deposition of ionic content of K and Ca that was followed by green long under all saline regimes. These outcomes showed that at 70 mM level of salinity, cucumber genotypes Marketmore and Green long presented least increment in Na^+ and Cl^-, however, Summer green and 20252 exhibited maximum accumulation of these ions which indicated that resistant genotypes had lowest level of Na^+ and Cl^- in their leaves in comparison to sensitive cucumber genotypes. It can be concluded from the findings of this experiment is (Summer green or 20252) categorize as sensitive genotypes whereas, (Marketmore or Green long) are categorized as salt tolerant cucumber genotypes.

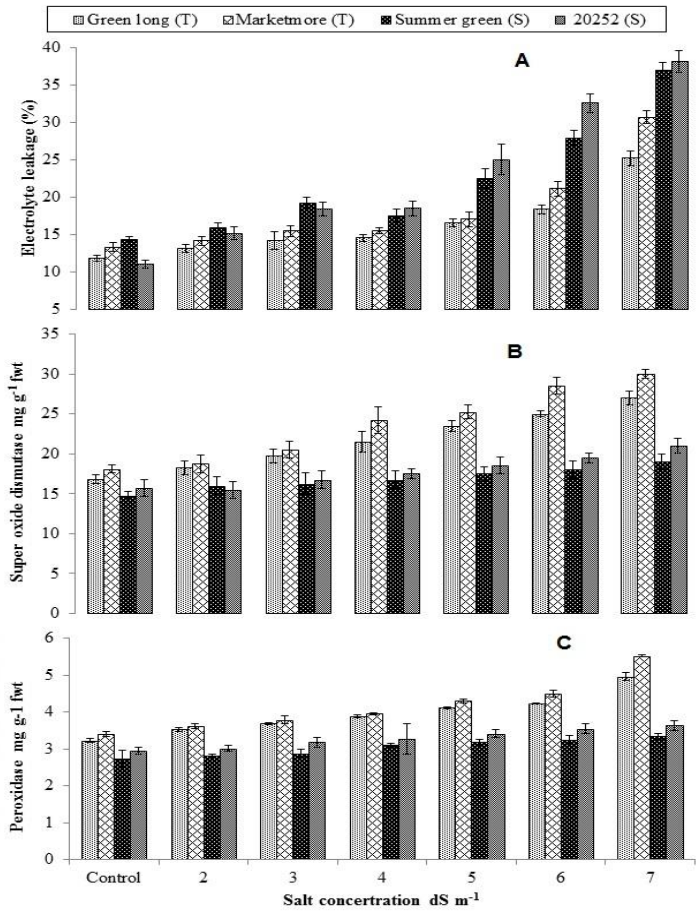

Figure 5. *Effect of salt stress on leaf (a) Electrolyte leakage (%) (b) Superoxide dismutase activity (c) Peroxidase activity*

Discussion

Inhibition in plant growth and development is very usual phenomena under salinity stress (Ashraf et al., 2009; Mahboob et al., 2017; Sarwar et al., 2017). Results illustrated that salts significantly decreased the root/shoot length, their fresh/dry biomasses and number of leaves per plants in all studied cucumber genotypes (*Figs. 1,2* and *3a*). Under stressed condition variation in total number of leaves $plant^{-1}$ is a important prevalence (Zhu et al., 2001). In present study, studied cucumber genotypes such as Marketmore and Green long was presented was little affected by salinity and presented maximum number of leaves while sumer green and 20252 failed to produce better number of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1079310806

leaves under saline conditions. Likewise reduction in leaves per plants were also observed by (Hassine and Lutts, 2010) in potato crop and (Bakht et al., 2011) in maize plant. Such decline in number of leaves in term of salt stress might be because of negative effects of salts on cell elongation mechanisms (Ashraf and Harris, 2004; Iqbal and Ashraf, 2005; Sawar et al., 2017).

The tested cucumber genotypes showed significant decreased in plant fresh and dry biomasses on exposure to various levels of salinity (*Fig. 2*), which established by the results of Mahboob et al. (2016) in *Triticum aestivum* (Noreen and Ashraf, 2008; Ashraf, 2009; Sarwar et al., 2016) in sunflower. However, under salt stress reduction in plant biomass might be due to lot of factors e.g, lack of turgor potential maintenance, sodium and chloride ions toxicity and variabilities in metabolic pathways. In the meantime, such factors disturb the gas exchange attributes that is ultimatelly cause decline in the activity of photosynthetic pigments (Sarwar et al., 2017). Subsequently, in this investigation reduction in plant biomass was due to decline in photosynthesis rate and a strong positive correlation was observed amongst dry weight of plants and gas exchange traits which revealed that those genotypes attained maximum dry biomass had higher rates of *gs* and *Pn.* The present results explained that photosynthesis was reduced due to maximum level of Na^+or Cl^- ions in plant cell which exhilarated the lethal impact on physiological mechanisms and functioning of leaf stomata. Bano (2010) also finds the same decreased in gas exchange traits in rice, when its exposed to saline stress. Results revealed that "Marketmore and Green long" presented lowest decreased in *Pn* and *gs* as compared to "Summer green and 20252", thus these attributes can be used as a screening tool for the salinity tolerance in cucumber plants. The previous researchers reported that the saline stress induced significant differences in *gs Pn* and *E* in sunflowers, rice and olive and these types of physiological traits can be measured as a potential signs of salinity tolerance (Nishimura et al., 2011). Since, salt stress have great impact on stomata function by losing the turgidity of guard cells ultimatelly it reduced transpiration rate in cucumber plants (Stepin and Klobus, 2006). Our findings are in agreement to Tezara et al. (2002), they described that sunflower showed a significant reduction in *E* on exposure to water stress. On the other hand, salts stress restrict the availability of various essentials nutrients to plants especially K^+ ions (Najafi et al., 2007; Mahboob et al., 2013) and K^+ is responsible for guard cell turgidity (Burman et al., 2003) so under salinity, variabilities in guard cell functioning may be reduced *gs* and *E* in cucumber plants. Those cucumber genotypes which keep the constant transpiration rate and stomatal conductance under stressed environments were successful to regulate them osmotically through production of glycinebetaine and proline. Thus, it is clear that Marketmore and Green long genotypes of cucumber have salt tolerance potential due to higher production of proline in plant cell. Increase in production of such osmoprotectant under salinity reported that for Seepweed and Glasswort by Moghaieb et al. (2004), in Maiz by Hajlaoui et al. (2010) and Mahboob et al. (2013). In this study, reduction in chlorophyll contentsdue to substitution of Mg^{2+} ions by toxic Na^+ ions,that caused the denaturation of chlorophyll. Under salinity in cotton crop same results were reported by Meloni et al. (2003) and in Maiz stated by Mahboob et al. (2013). In literature a positive relationship was observed amongst chlorophyll contents production and plant biomass growth. It is showed that salinity fragmented the cell membranes to a smaller extent in resistant genotypes in comparison to sensitives. In genotypes Marketmore and Green long were showed the sign of little electrolyte leakage; might be tolerant genotypes presented lower H_2O_2 and least (EL) than sensitives, this trait electrolyte leakage can be used to determine the saline stress damage's and potential of tolerance in plants. Likewise, Noreen and Ashraf (2009) complied different cucumber genotypes to many salt concentrations and observed a increment in LPO and H_2O_2 level with various salt concentrations. Higher activities of SOD, POD and CAT detoxify the (ROS) in plant cell (Sekmen et al., 2012). So, salt tolerance potential is connected with the production

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1079310806

of antioxidant enzymes activities (Balal et al., 2012). Same findings were comparised in this study a constant activities of antioxidant in tolerant cucumber genotypes with high potassium and calcium ions in their leaves, in results higher plant biomass, maximum photosynthesis activities as comparison to sensitive genotypes. As a result K^+ and Ca^+ ions concentrations can used as a screening parameter for the estimation of salt stress tolerance in cucumber cultivars. Conclusion of this findings is that saline stress had negative impact on the growth and yield of cucumber plant and potential of salinity tolerance is greatly connected with the quantity of proline contents and Ca^+, K^+ ions that play vital part in osmotic adjustment under salinity.

Conclusions

Salt stress harmfully affect the morpho-physiological and biochemical traits of cucumber genotypes by producing osmotic stress, ionic toxicity, altered stomatal functioning, impaired photosynthesis and restricted K^+ availability. Salt resistant cucumber genotypes were able to avoid most of the harmful implications of salt stress by Na^+ exclusion and maintenance of favorable levels of K^+ and Ca^{2+} that helped stabilize photosynthetic pigments and photosynthetic machinery under salinity stress resulting in comparatively better functioning and growth than salt sensitive genotypes. These cucumber genotypes can also serve for future studies dealing with salinity tolerance in cucumber, besides their worth in breeding programs and cultivation on soils where salinity seems inevitable

ASSESSMENT OF INVASIVE PLANT SPECIES, *OPUNTIA* SPP. (PRICKLY PEAR) IN RAYDAH PROTECTED AREA, ASEER, SAUDI ARABIA

ALWADAI, H. M.

Department of Biology, College of Science, King Khalid University, Abha, Saudi Arabia (e-mail: hmalwadai@kku.edu.sa; hmwadei@gmail.com; phone: +966-17-241-7242; fax: +966-17-241-8412)

(Received 9th Mar 2019; accepted 13th Jun 2019)

Abstract. Raydah protected area in an important declared protected area in Aseer area, Kingdom of Saudi Arabia that is rich in biodiversity, and provides habitat for nine of the ten indigenous bird species in the kingdom. Invasive plant *Opuntia* spp. in Raydah could threaten the natural balance among the indigenous species and thereafter affect the biological components of the ecosystem. This study evaluates the prevalence of invasive species and vegetation cover trends in Raydah protected area to identify possible interventions to conserve and protect the protected area. The results provide important and necessary information for the conservation and management of the Raydah Area and the Aseer Area's south-western highlands. The study has demonstrated the potential of sentinel sensor for detection and mapping of invasive species such as *Opuntia* spp. with desirable accuracy. This encouraging result demonstrated the feasibility of developing a semi-automated process for mapping and analysing the distribution of *Opuntia* spp. and found better results compared to multispectral data with very high resolution. Assessment of the current situation of the *Opuntia* spp. in the protected area will provide scientific data base for future management plans to combat and control invasive plants and protect the protected area from their adverse effects.
Keywords: *ecosystem, biodiversity, Sarawat Mountains, Juniperus procera, Sentinel satellite data*

Introduction

Invasive plants pose significant threats to natural ecosystems (Gurevitch and Padilla, 2004), biodiversity (Gaertner et al., 2009), forests (Peerbhay et al., 2016), rangelands and agricultural productivity (Pimentel et al., 2005). In addition, invasive plants are known to reduce the abundance of native plant species (Gaertner et al., 2009), alter soil properties (Pejchar and Mooney, 2009), and homogenize the biodiversity of invaded landscapes (Joshi et al., 2004). Invasive species are the species, subspecies that occur outside their natural range and potential for dispersal, and include any part of those species that may survive and then reproduce (Turlings, 2000). The non-native species invasion process took place in three phases: arrival, establishment and spread.

The southwestern parts of the Kingdom of Saudi Arabia have witnessed negative impacts of invasive species on forest ecosystems over the past few decades. Among them, the *Opuntia* spp. is one of the most serious invasive plant species, colonizing large forest areas in the highlands of the Sarawat Mountains in the southwestern parts of the kingdom. It is rich in dense vegetation as part of the southwest mountain ecosystem of the Sarwat, and constitutes the highest density of vegetation and diversity in the kingdom. The Sarwat southwest mountains' main high altitude species include *Juniperus procera*, the main dominant species with a density of 95 percent at elevations of 2000-3000 m above sea level (Aref et al., 2013). It grows in lower elevations with other tree species, such as *Acacia* spp., *Oleaeuropaea* ssp. Africana (Mill.) P. Green. *Ziziphus spina christi* and *Tamarix aphylla* (El-Juhany and Aref, 2013). El-Juhany and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1080710822

Aref (2013) noted that the following species of tree were reported only in the Aseer region: *Dobera glabra, Adenium obesum, Mimusop slaurifolia, Ficussy comorus* and *Tamarindus indica.*

In the southwestern highlands, Thomas et al. (2016) reported many invasive species such as *Opuntia* spp. To evaluate changes in vegetation and the spread of invasive species, it is therefore important to evaluate the status in the Raydah protected area. Invasive species are usually introduced from their native range to new plant species, either intentionally (Surendra et al., 2013) or accidentally, expanding into natural areas and disrupting native plant communities. They are equipped to adapt to new habitats, and with reproductive capacity they can grow aggressively. In the absence of natural enemies, their ability to compete and grow vigorously enables them to expand aggressively. These alien species are usually introduced into an ecosystem through seeds in imported soil, traveller fruits, deliberate introduction of certain species for their products, services or values, dispersal of seeds by natural means, and disposal of waste or soil containing alien plant seeds. Invasive species may have been introduced through human interference in the southwestern highlands of the kingdom and expanded due to clearing vegetation of large areas for road expansion, grazing and felling and removal of endemic forest trees.

Invasive plant expansion Raydah may have catastrophic effects on the habitat of the protected area in terms of overgrowth and displacement of native plants, resulting in disruption of the natural balance of native plant communities. Possible major consequences could include:

- Altering the plant species density and extinction of some species.
- Reducing the genetic base of the endemic species (resulting from biotic and abiotic stresses).
- Impact the balance and composition of endemic plant species - dependent wildlife components.
- Biodiversity reduction can adversely affect wildlife and alter natural processes such as fire or intensity and water flow.

Assessment of the current situation in the Raydah protected area will indicate and reveal the gravity of the situation and indicate possible interventions to control the invasive species Many methods have been developed to control or eradicate invasive species dependent on: available resources, plant species and habitat, and spread severity. These methods include: chemical control of invasive species by systematic herbicides, biological control by imported enemies, mechanical control by machines and hand tools, physical control (hand pulling, water drainage, flooding, burning and shading), or a combination of these methods (Integrated Management). Accordingly, this study address the situation of the invasive species in Raydah, with the general aim of conserving Raydah protected area, as part of an important ecosystem in the southwestern highlands of the kingdom, from their danger and threats. The unique plant association that provides habitat for nine of the ten indigenous bird species of Saudi Arabia should be managed and protected from the aggressiveness of the alien species.

Remote sensing data of high resolution have received considerable attention for invasive species inventory. The multi-date satellite imagery facilitates the monitoring and identification of phenological changes. It may be useful to integrate satellite information with other attributes in GIS to predict the spread of invasive species. Remote sensing of invasive plants has only been successful if the invasive is in a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1080710822

riparian, grassland, desert environment, aquatic and wetland where the lack of a tree cover enables the sensors to see the invasive plant unhindered (Bradley and Mustard, 2006). Thus, hindered invasive poses a challenge. Many researchers used hyperspectral data to detect and map invasive species (Lawrence et al., 2004). A practical advantage of using hyperspectral imagery to map invasive species is its capability to determine relative or unmixed components, which can be particularly useful in determining the percentage of species coverage (Peerbhay et al., 2016; Peerbhay et al., 2015; Curatola Fernandez et al., 2013). As noted above, the success of alien invasion remote sensing depends on their unique spectral signatures being identified, facilitated by differences in biophysical and biochemical characteristics (Matongera et al., 2016). Numerous studies (e.g. Matongera et al., 2016; Peerbhay et al., 2016; Niphadkar and Nagendra, 2016; Rocchini et al., 2015; Bradley, 2014; Boyd and Foody, 2011; Joshi et al., 2004) have explored approaches to remote sensing to optimize AIP detection and mapping.

The study aims to evaluate the prevalence of invasive species and vegetation cover trends in Raydah protected area to identify possible interventions to conserve and protect the protected area. The results may provide important and necessary information for the conservation and management of the Raydah Area and the Aseer Area's southwestern highlands. The specific objectives of this study were: to evaluates the usefulness of Sentinel satellite dataset for *Opuntia* spp. detection and mapping with emphasis on automatic information extraction techniques, establishing a phenological trend for the extraction of understory invasive plant data from temporal Sentinel satellite data (i.e. *Opuntia* spp.), assessing the usefulness of Sentinel sensor for the detection and mapping of *Opuntia* spp.

Literature review

Invasive species are defined as those non-native species that threaten ecosystems, habitats and species (Convention on Biological Diversity, 2008). They have great impact and influence on of the global environmental change (Pysek and Richardson, 2010), seriously affecting ecosystem services that are important to human welfare (Branco et al., 2015; Hejda et al., 2009). Their threats to plant diversity was reported to increase in past decades (Pimentel et al., 2001), due to the increase in exchange of plant material, and consequently their genetic materials among countries (Van Wilgen et al., 2008). Their effect was ranked as second to human interferences in the cause of species endangerment and extinction (IUCN, 2011). The reported hazards include direct threats to human health, and loss or alteration of goods and services regarding fishery, farming, forestry, drinking water, hydrology, climate stabilization, pollination, culture and recreation (McNeely, 2005; Lovell et al., 2006). The invasive species affect and threaten biological diversity by reducing genetic variation and narrowing gene pools to the extinction of endemic species (Sax and Gaines, 2008). Consequently, costs associated with their impacts are very high worldwide.

The management of invasive alien species present a significant challenge for the conservation authorities. The main principles applied to managing invasive species may include: Prevention of invasive species from entering the ecosystem, regular monitoring and rapid response, eradication, and or containment if eradication is not realistic. Some control methods were suggested that range from chemical, biological, physical, manual and integrated management system. Berhanu and Tesfaye (2006) described the dilemma of *Prosopis* dilemma (an aggressive invasive species) and some controlling methods.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1080710822

Similarly, invasive species can affect plant diversity in the Kingdom, and reach reaches its woodlands, forests, grasslands, agriculture lands, islands and inhabited areas (Thomas et al., 2016). They may have significant impacts on ecosystems and agriculture areas by eliminating or displacing many native species, particularly the highlands. The prevailing warm climate and the humid areas can enhance their spread in the kingdom by accelerating rapid seedling growth compared to native populations as indicated by Griffith et al. (2014).

Thomas et al. (2016) stated that "Approximately 37 alien plants have been reported from various habitats of southwestern region, majority of which are associated with specific plant associations". They indicated that on the higher elevations (800 to 2700 m) the common exotics according to severity are: "*Opuntia* spp., *N. glauca, Argemone ochroleuca, T. minuta, Verbesina encolioides, Tridax procumbens, Lantana camara, Amaranthus spinosus, Xanthium spinosum, Cenchrus setigerus* and *Bidens aurea"*. Further on, they indicated that six species have increased their distribution range both in the lowlands and highlands, and are therefore considered most troublesome ones in Saudi Arabia. The stated species in a descending order of were "*P. juliflora (Leguminosae), O. dellenii (Cactaceae), N. glauca (Solanaceae), T. portulacastrum (Aizoaceae), O. ficus-indica (Cactaceae) and Argemone ochroleuca (Papaveraceae)*".

The entry of invasive species to the highlands of Aseer Area could be attributed to human interferences like clearance of native plants for roads, as mentioned by Kingston and Waldren (2003). This is evident in the presence of some exotics along road sides in the southwestern high ranges (Thomas, 2016). Also, the highlands of Aseer Area was subjected to overgrazing (Abulfatih et al., 1989) and felling of forest trees that could have contributed to spread of opportunistic invasive species. Economic costs from invasive species include direct costs through reduction of ecosystem productivity and management costs. Indirect costs can occur through reduction in services and revenues. The key to reduce the threats and costs of invasive species damage and management is by early detection and rapid response. Warrag et al., 2019 reported the status of dieback of *Juniperus procera* (African pencil cedar) in natural stands and plantation in Alsouda highlands Saudi Arabia that is near to the studied location. They stated that with time, the NDVI showed a growing trend of greenness, especially in high rainfall seasons. The slope aspect effect was evident in the vegetation's dieback severity and greenness as detected by NDVI data.

Material and methods

Study area and field survey

Raydah watershed area, in an important declared protected area in Aseer area, Kingdom of Saudi Arabia (*Fig. 1*). Among the other protected areas in the kingdom, it has unique plant association and diversity in the highlands of the Sarawat Mountains in the southwestern parts of the kingdom (Mallick, 2016). The studied area is located between latitude of 18°10'50.859"N and 18°13'2.58"N and longitude of 42°21'58.042"E and 42°24'56.197"E and elevations 1330 to 2827 m.a.s.l.

The main features of Raydah protected area is described in Saudi Wildlife Authority as follows:

- It covers an area of 12.17 km^2.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1080710822

- It protects dense stands of Juniper (*Juniperus procera)*.
- Its unique plant association provides habitat for nine of the ten indigenous bird species of Saudi Arabia.
- Also, the protected area attracts Caracal Lynx, and Arabian wolf.

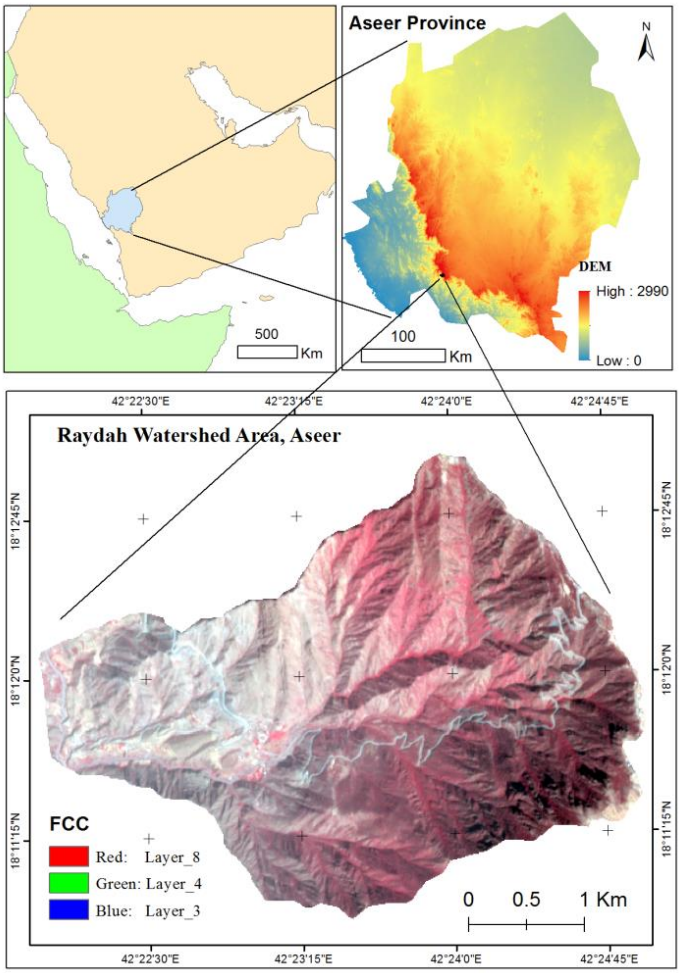

Figure 1. *Study area*

Sarawat Mountains in the south-western parts of the kingdom receives the highest southwestern monsoon annual rainfall in KSA, with variable annual patterns (Vincent, 2008). Precipitation is mainly from March to June during spring and summer growing seasons (Wheater et al., 1989; Mallick et al., 2014), and mean on the minimum of daily average temperature and mean on the maximum of daily average temperature are 19.3 °C and 29.70 °C, respectively. Rainfall data was obtained from the meteorological station situated 8 km northwest of the study area (Al-Sooda Station no. 00028, 18° 15' 08" N (latitude) and 42° 24' 15.7" E (longitude).

Ground surveys were conducted during 9th February 2019 to 23rd February 2019 for the understanding and distribution of vegetation classes and invasive plants. *Figure 2* shows the pictures of important location, in which Juniper procera were severely affected due to *Opuntia* spp. invasive species. The 50 × 50 m size of the sampling areas screened during the field survey.

Data processing

The Sentinel-2 level-1C satellite datasets (Level 1C Radiometric and geometric corrections including ortho-rectification and global reference system spatial registration with accuracy of sub-pixels) over the Raydah protected area were used to prepare the Normalized Difference Vegetation Index (NDVI) and Land Use and Land Cover (LULC) maps. The Sentinel-2 L1C product DNs are unsigned integer values of reflectance that that can be multiplied by 10,000 to achieve TOA reflectance values. DEM acquired from ALOS PALSAR Radiometrically Terrain corrected (RTC) DEM. From DEM, elevation (1330-2827 m, with the mean of 2070 m), slope angle (0° to 89.54° with the mean of 29.08°) have been calculated using ArcGIS software. For the generation of texture features, the gray level co-occurrence matrix (GLCM) method (Haralick, 1986) with 3 × 3 pixel window size was used. The NIR band of Sentinel data generated six texture features, mean, variance, contrast, homogeneity, dissimilarity and entropy as input images. The mean, contrast, homogeneity and variance characteristics displayed maximum information and were therefore taken as classification input images. For maximum likelihood classification, the common training sites selected from the sentinel image were used. For classification accuracy assessment, the classified images were field-checked at 152 locations.

Results and discussion

Temporary analysis of September, February and April Sentinel satellite dataset (*Fig. 3*) was conducted to determine a trend in vegetation phenology and to detect changes in the composition and structure of the community. *Juniperus procera* forest maintained significant foliage during the month of June, resulting in high reflectance from the upper canopy and hindering under-story reflection. From June to October, therefore, it was not possible to separate *Opuntia* spp. from the story. Therefore, for

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1080710822

further analysis, Sentinel images were not used. The *Juniperus procera,* once established, individual trees can survive in hot and dry conditions, but in areas with low rainfall, trees are usually poor in shape and small in size. Where rainfall exceeds *Juniperus procera* dominated forests are gradually replaced by moister types of evergreen forests in which *Juniperus procera* becomes increasingly common. This region has the highest average rainfall in Saudi Arabia distributed over 4-6 months during the spring (Aug and Sept and summer growing seasons (March-June), while negligible rainfall during the rest of the year (Wheater et al., 1989; Mallick et al., 2018). Due to partial leaf shedding in the month of February, the under-story reflection also added to the overall reflection (appearing in light reddish tones on standard false color composite (FCC)).

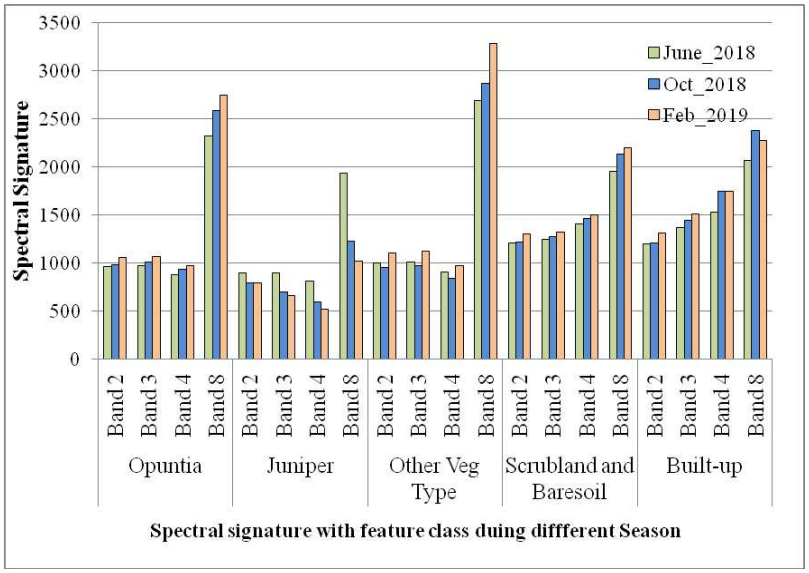

Figure 3. *Spectral reflectance of feature classes in June 2018, Oct. 2018 and Feb. 2019*

Although vegetation was visible in the February image under the story, it was not possible to delineate boundaries. Maximum reflection from vegetation occurred in the month of June - October due to full extent (moister types of evergreen forests) in evergreen tree (Sidr tree (*Ziziphus spina-christi*) and *Juniperus procera* forests (*Fig. 4*). This pattern in reflection showed that the data acquired between February were suitable for detecting *Opuntia* spp in the studied area. Every year, the best month varies due to annual temperature and precipitation differences. Statistically compared the Sentinel satellite data for various vegetation classes (*Table 1*). *Opuntia* spp's CV was slightly higher than *Juniperus procera*, indicating that discrimination against *Opentia* spp was possible to facilitate more accurate discrimination. *Table 2* shows the separability of different classes. In bands 3 and 8 of Sentinel data, the 2000 transformed divergence (TD) value showed very good separability of *Opuntia* spp from *Juniperus procera*. The 1997 and 1998 TD values between *Opuntia* spp and other tree (incl. Sidr tree) in bands 3 and 8 showed good separability, respectively. The texture classification was helpful in distinguishing the *Opuntia* spp from *Juniperus procera* successfully. In the vegetation classes, Band 8 of Sentinel data had the maximum variability compared to the other three bands (*Tables 1* and *2*). Band 8 of Sentinel data was therefore selected to analyze texture to extract *Opuntia* spp.

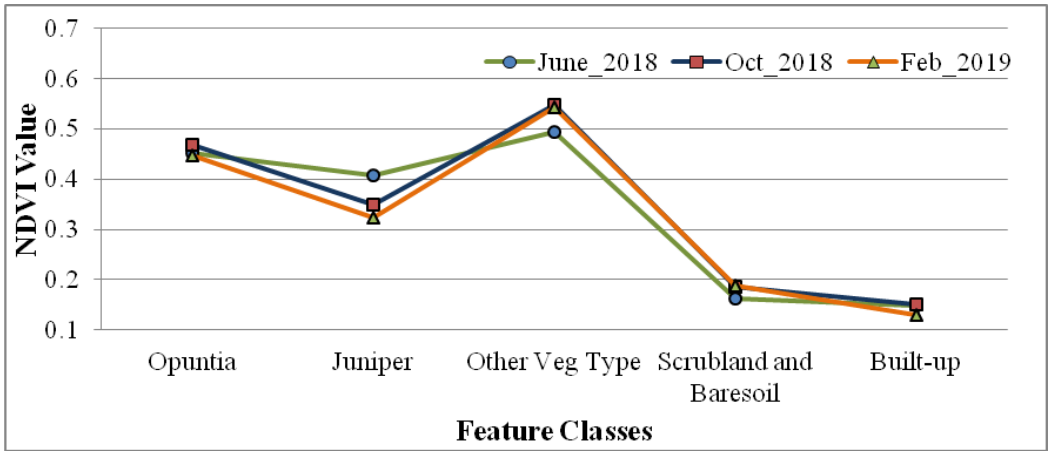

Figure 4. *NDVI value of different feature class over different period*

Taking into account the objectives, Sentinel satellite dataset were used to prepare the feature class map for the study area, i.e. built-up, exposed rocks, scrublands, *Juniperus procera, Opuntia* spp. and other tree (incl. Sidr tree). The total area of each category of feature class and percentage was calculated and presented in table. *Figure 5* shows the feature class type and the built - up area that also includes the road network lined from east to west direction and the building is mainly located in the western part of the study area towards the low land area. The *Juniperus procera* (45%) was the most dominant class in 2019, followed by scrublands (30.62%), exposed rocky area (12.66%) and *Opuntia* spp. (9.33%) shown in *Table 3*. Accuracy assessment was also evaluated to study the performance of the Sentinel sensor in feature class detection (specifically *Juniperus procera* and *Opuntia* spp.) for the classified output (*Table 4*).

Table 3. *Area (ha) of feature class estimated from the output of Sentinel sensors*

Sl. No	Feature class	Area in ha	Percent %
1	Built-up	17.70	1.45
2	Exposed rocks	154.93	12.66
3	Scrublands	374.61	30.62
4	*Juniperus procera*	550.54	45.00
5	*Opuntia* spp.	114.13	9.33
6	Other tree (Incl. Sidr)	11.53	0.94
Total area		1223.44	100.00

Table 4. *The producer's and user's accuracies*

Sl. No	Feature class	Producer's accuracy	User's accuracy
1	Built-up	76.52	92.85
2	Exposed rocks	93.15	94.61
3	Scrublands	88.90	92.47
4	*Juniperus procera*	96.14	94.82
5	*Opuntia* spp.	94.69	95.72
6	Other tree (incl. Sidr)	87.65	91.02

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1080710822

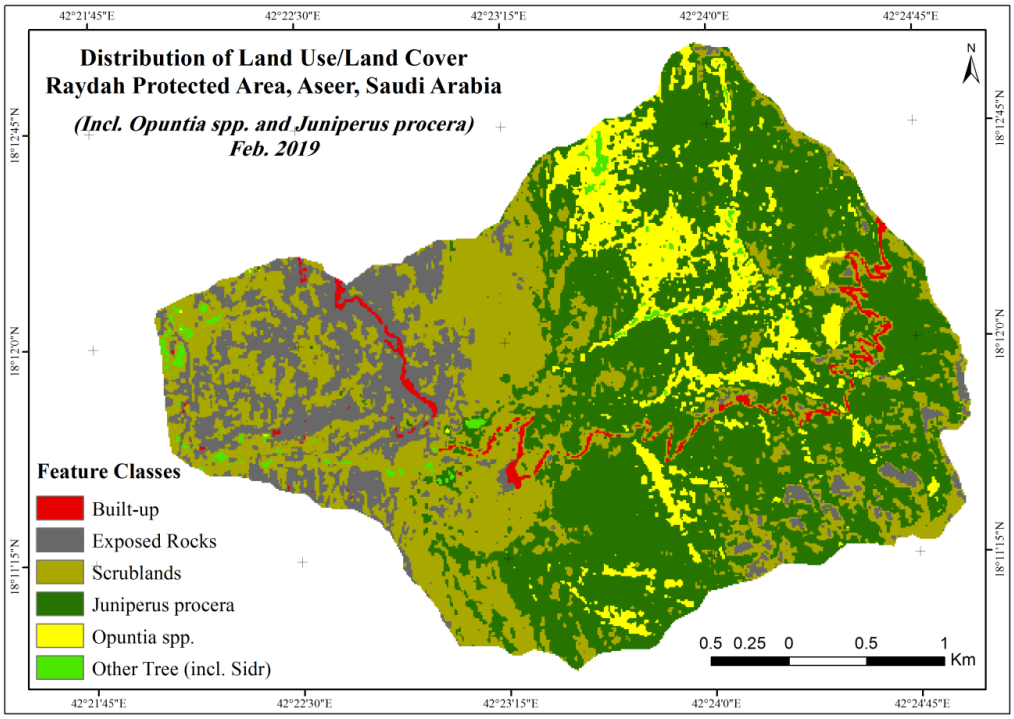

Figure 5. *Distribution of land use/land cover in Raydah protected area, Saudi Arabia*

The relationship between feature class and topography was analyzed using DEM. Figure shows the results of analysis of feature class in 2019 according to elevation (height). According to *Figure 6, Juniperus procera* are mostly located in regions with 1951-2827 m of height (Friis, 2009; Negash, 2010). It found as the dominant species in Raydah protected montane vegetation or mixed with other evergreen forests such as Sidr tree (*Ziziphus spina-christi*). The *Opuntia* spp. Mostly located in the regions with 1951-2550 m of height. Similarly, scrubland areas, mainly in regions with height of 1330-1950 m. This may be due to soil depth, week geology, and denuded high slope. With increasing altitude, the rock exposed class decreases.

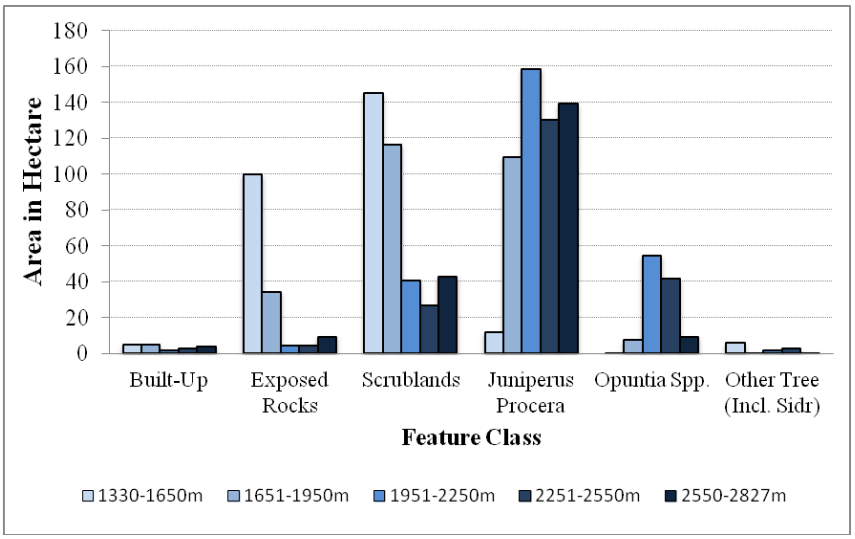

Figure 6. *Feature class according to elevation range*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1080710822

The gradient of the slope influences the feature classes distribution in studied area. *Table 5* shows the statistical analysis of slope analysis with feature class at the particular elevation range. The Juniper procera having large variation of slope gradient (ranged approx. 80°) between 1951 and 2827 m of elevation range. Whereas in *Opuntia* spp. It is found that the variation of slope gradient is low (ranged approx. 48°) between 1951 and 2550 m of elevation range. This finding shows that the growth and expansion of *Opuntia* spp. maximum at the moderate slope gradient (*Fig. 7*). It will be noted that the amount of moisture (water) intake tends to slightly decrease with slope increase. On the more gentle slopes, especially the 1.15° slope or less, the largest intake of water was found. That the degree of slope affects the infiltration. Therefore, it can be concluded that the slope factor influences and accelerates the growth and expansion of *Opuntia* spp. in the studied area.

BLT = Built-Up; EX = Exposed Rocks; SCR = Scrublands; Jun. Pro = *Juniperus Procera*; Op. Sp = *Opuntia* spp; OT = Other Tree (Incl. Sidr)

Over the past few decades, the southwest part of the Kingdom of Saudi Arabia has experienced negative impacts of invasive species on forest ecosystems, the *Opuntia* spp. among them. It is one of the most severe invasive plant species, colonizing large forest areas in the Sarawat Mountains highlands in the southwestern parts of the Kingdom. Assessing the current situation in the protected area of Raydah will indicate the gravity of the situation and indicate possible interventions to control the invasive species.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1080710822

Remote sensing data of high resolution have received considerable attention for invasive species inventory. The image of the multi-date satellite, i.e. Sentinel dataset facilitates phenological change monitoring and identification. In order to predict invasive species spread, it may be useful to integrate satellite information with other attributes in GIS.

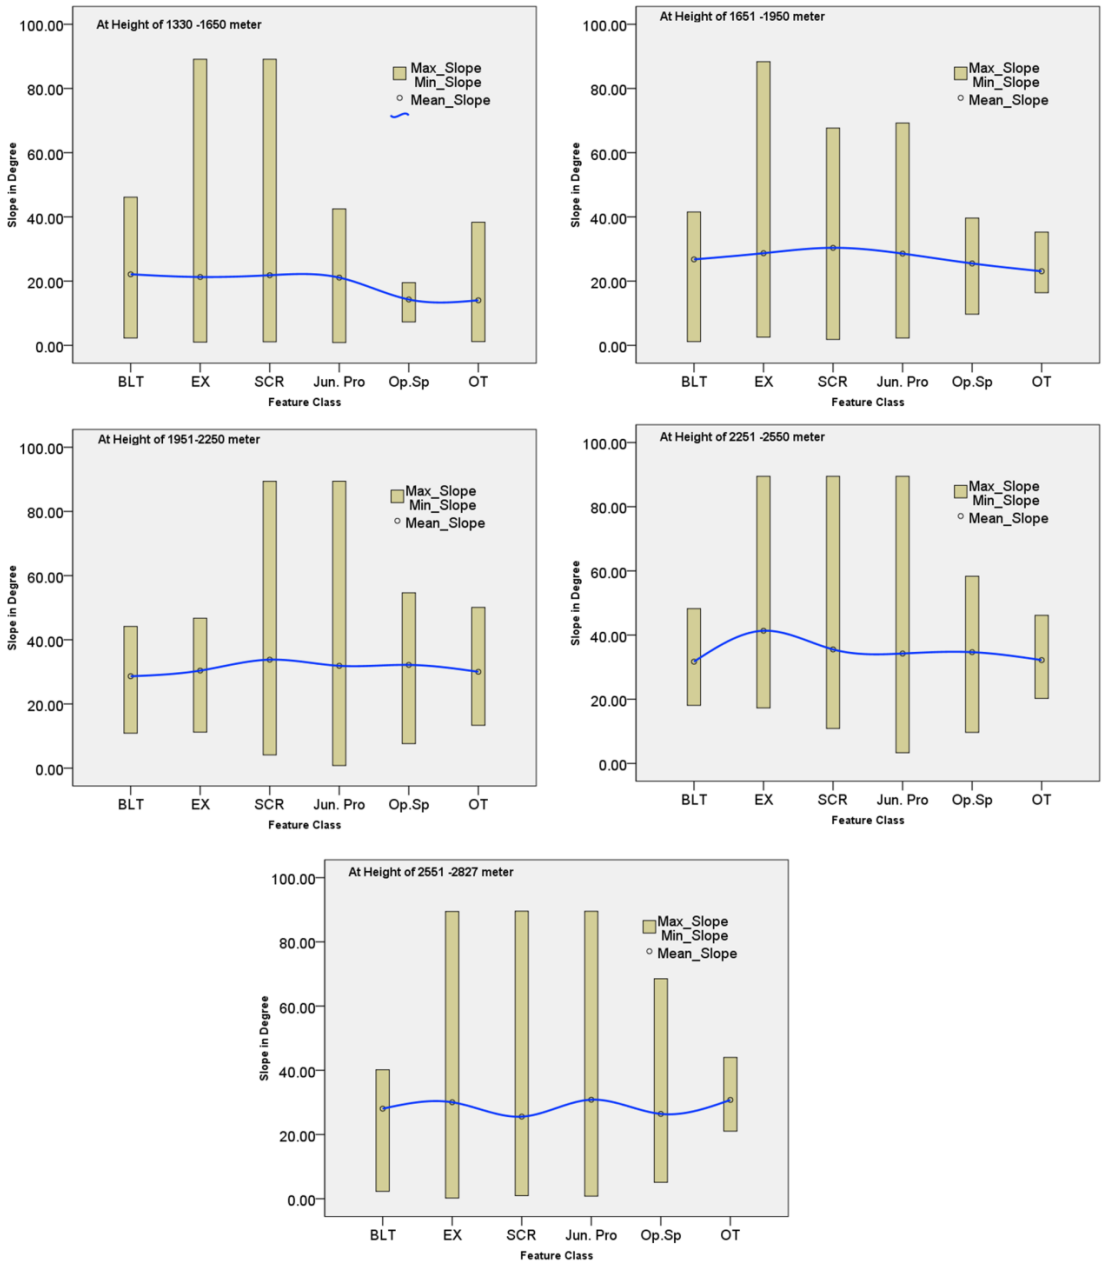

Figure 7. *Graphical representation of slope in degree (min, max and mean) at different feature classes*

The results of this study showed that *Juniperus procera* (45%) was the most dominant class in 2019, followed by scrublands (30.62%), exposed rocky area (12.66%) and *Opuntia* spp. (9.33%). The relationship between feature class and topography was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1080710822

also analyzed using DEM. *Juniperus procera* are mostly located in regions with 1951-2827 m of height. It found as the dominant species in Raydah protected montane vegetation or mixed with other evergreen forests such as Sidr tree (*Ziziphus spina-christi*). The *Opuntia* spp. mostly located in the regions with 1951-2550 m of height. Similarly, scrubland areas, mainly in regions with height of 1330-1950 m. This may be due to soil depth, week geology, and denuded high slope. With increasing altitude, the rock exposed class decreases. The gradient of the slope influences the feature classes' distribution in studied area. *Juniper procera* has large variation of slope gradient (ranged approx. 80°) between 1951 and 2827 m of elevation range. Whereas in *Opuntia* spp. It is found that the variation of slope gradient is low (ranged approx. 48°) between 1951 and 2550 m of elevation range. It can be concluded that the slope factor influences and accelerates the growth and expansion of *Opuntia* spp. in the studied area.

Conclusions

Raydah protected area in an important declared protected area in Aseer area - Kingdom of Saudi Arabia that is rich in biodiversity, and provides habitat for nine of the ten indigenous bird species in the kingdom. Invasive plant species in Raydah could threaten the natural balance among the indigenous species and thereafter affect the biological components of the ecosystem. Assessment of the current situation of the invasive plants in the protected area will provide scientific data base for future management plans to combat and control invasive plants and protect the protected area from their adverse effects.

In this study, the temporal data (i.e. June, Oct and February months) were used to establish a trend in vegetation phenology and changes in species community composition and canopy structures. Comparison of the data from these three months revealed that February was adequate month to detect under story *Opuntia* spp. Maximum reflection from vegetation occurred in the month of June - October due to full extent (moister types of evergreen forests) in evergreen tree (Sidr tree (*Ziziphus spina-christi*) and *Juniperus procera* forests where as during February is shows less reflectance over Sidr tree (*Ziziphus spina-christi*) and *Juniperus procera* forests. This pattern in reflection showed that the data acquired between February were suitable for detecting *Opuntia* spp in the studied area. Every year, the best month varies due to annual temperature and precipitation differences. *Opuntia* spp's CV was slightly higher than Juniperus procera, indicating that discrimination against *Opuntia* spp was possible to facilitate more accurate discrimination. The study demonstrated the potential of sentinel sensor for invasive species such as *Opuntia* spp to be detected and mapped with desirable accuracy. This encouraging result demonstrated the feasibility of developing a semi - automated process for mapping and analysing the distribution of *Opuntia* spp in forest areas and found better results compared to multispectral data with very high resolution.

(Received 13th Mar 2019; accepted 16th Jul 2019)

Abstract. This study was carried out to determine the effect of wheat bran as added to canola silage on the fermentation and in vitro organic matter digestibility. Canola was harvested and ensiled with 5% and 10% wheat bran in glass silos. With each treatment three parallel investigations were performed. Chemical, microbiological analyses and in vitro cellulase method were conducted on the silage which was opened on the 60th day of storage. According to the analysis of the control, 5% and 10% wheat bran treatments, crude protein reached 14.31%, 14.71% and 15.66%; ammonia-nitrogen reached 91.53, 85.43 and 85.34 g/kg TN; metabolisable energy reached 7.94, 8.27 and 8.51 MJ/kg KM; while organic matter digestibility was 61.45%, 63.93% and 62.92%, respectively. In conclusion, addition of wheat bran can increase dry matter content of canola silage.
Keywords: *canola, additive, silage quality, OM, digestibility*

Introduction

Canola seeds are mentioned frequently because of their contribution to the biodisel production. Canola is one of the oilseed plants that belong to brassica sp. Canola has tolerance to low temperatures and salinity (Sovero, 1993; Francois, 1994). Canola may be used as silage, straws, stubble and stover for roughage source in ruminant nutrition because of its palatability, and low levels of rejection (Sovero, 1993; Francois, 1994; Kincaid et al., 2012; Reta et al., 2015). Brassicas have metabolisable energy from 2.8 to 3.3 mcal/kg DM and dry matter digestibility of 81 to 89% before blooming (Hall and Jung, 2008; Barry, 2013). However, there are very restricted research studies about nutrient composition of canola forages. Sånchez-Duarte et al. (2011) reported a slight increase in feed consumption of eight month elder heifers fed with a 21% canola silage ratio, compared with heifers in the control group. Silage process is a method that contributes to diminish anti-nutritional effects concerning Brassicas and allows conservation without affecting nutritional value (Fales et al., 1987). But it requires an additive for proper conservation. Brassica forage contains 80-95% water (Lambert et al., 1987; Guillard and Alison, 1988). High moisture forages tend to lose their nutrients during ensiling. Canola forage must be wilted to 60-65% moisture before ensiling (Balakhial et al., 2008). A little scientific literature investigates the effect of wheat bran addition on the feed value and in vitro OM digestibility of canola silage. Addition of wheat bran can increase dry matter content of canola silage thanks to its relatively high dry matter content. The main objective of this study was to determine the effects of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1082310829

different level of wheat bran addition on feed value and in vitro OM digestibility of canola silage.

Materials and methods

The study was conducted in 2016 in Tekirdağ (41.0 ºN, 27.5 ºE), western Turkey located at about 5 m altitude above sea level and with a total precipitation of 482 mm on average and an annual mean temperature of 10.5ºC. Caravel which is a kind of winter canola was sowed in October 2016. Canola forage was harvested when 2/3 of the were blooming. Forage was chopped 1.0-1.5 cm theoretical length of cut. Silage materials were divided into three trial groups for the control, 5% wheat bran and 10% wheat bran. The material mixed with additive was pressed in 36 (1.0-1 liter) glass jars (Weck, Wher-Oftlingen, Germany) equipped with lids that enabled gas release only. The jars were stored under constant room temperature (20±1ºC). Three jars per treatment from all groups were sampled on day 60 for pH, dry matter, water soluble carbohydrates, lactic acid (DM, WSC, LA) content measurement and LAB, mold and yeast enumeration.

Analytical procedure

Chemical analyses were performed on triplicate samples. The fresh and silage samples were dried at 60ºC for 72 h in a fan-assisted oven. After drying, samples were ground through a 1 mm mesh screen for chemical analysis. The dry matter (DM) was determined by drying the samples at 105ºC for 16 h. Crude protein and ash contents of samples were determined according to the methods of AOAC (2012). Hemicellulase, cellulase, dry matter digestibility and relative feed value was determined by calculation. Neutral detergent fibre (NDF), acid detergent fibre (ADF) and acid detergent lignin (ADL) content determined as described by Van Soest et al. (1991). Metabolisable energy (ME) content of fresh and silage samples were calculated from the chemical composition TSE (1991). In vitro organic matter digestibility of samples was determined according to the methods of Aufrère and Michalet-Doreau (1988). Ammonia nitrogen (NH_3-N) and pH values fresh and silage samples were determined according to MAFF (1986). Lactic acid (LA) was determined by the spectrophotometric method of Barker and Summerson (1941). Water soluble carbohydrate (WSC) contents of experiment were determined by spectrophotometer (Shimadzu UV-12ol, Kyoto Japan) after reaction with the Anthrone reagent (MAFF, 1986). Microbiological analyses were performed according to the methods reported by Seale et al. (1990). Accordingly as the incubation medium; MRS agar was used for LAB and malt extract was used for yeast and mold. LAB, mould and yeast counts of samples were obtained at 30 °C following 3 days incubation period. Lactic acid bacteria (LAB), yeast and mold counts of the samples were converted into logaritmic coloni forming unit (cfu/g).

Statistical analysis

Statistical analyses were performed with the general linear model (GLM) procedure of Duncan's multiple range test performed with the Statistical Analysis System (2005) Software (SAS, Cary, N.C.).

$$Y_{ij} = \mu + a_i + e_{ij} \quad \text{(Eq.1)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1082310829

where
Y_{ij} = studied traits; μ = overall mean; a_i = fixed effect of the treatment; e_{ij} = random effect.

For all statistical comparisons, a probability level of $P < 0.05$ was accepted as statistically significant. When significant associations were identified, the mean values for each effect were contrasted using Duncan test.

Results and discussion

The results of the chemical analysis of fresh and ensiled canola are given in *Table 1*. In the study, dry matter and crude protein contents of canola silages ranged between 21.79-28.82% and 14.31-15.66%, respectively, and the dry matter and crude protein contents of canola silages increased significantly with the increase of wheat bran usage rate ($P < 0.01$). The reason for this increase in silage dry matter and crude protein content is that the dry matter and crude protein content of wheat bran is higher than that of canola. DM content was higher compared with that reported by Balakhial et al. (2008), Kincaid et al. (2012) and Limón-Hernández et al. (2019). Limón-Hernández et al. (2019), reported a CP of 145 g/KM DM that is slightly lower than our mean content of 148 g/kg DM. The CP content of canola silages was higher than that provided by most of conserved cereals that have 60 to 100 g/kg DM. For that reason silage could meet the requirements of ruminants (Van Soest, 1994; NRC, 2000). Besides, the addition of wheat bran to the canola significantly decreased the crude ash and ammonia nitrogen of the silages ($P < 0.05$). The pH value of silages, water-soluble carbohydrates and lactic acid contents were not affected by the addition of additives ($P > 0.05$). The pH value (4.5) was higher than (3.9) reported by Limón-Hernández et al. (2019). Balakhial et al. (2008) reported pH value 4.8 that is higher than our mean value (4.5). In the study conducted by Balakhial et al. (2008), it was reported that the addition of urea to the canola silage increased pH and ammonia concentration of the silage and thus the silage quality was adversely affected. The research findings show that wheat bran supplement has a positive effect on silage quality.

The microbiological composition of the canola silage is given in *Table 2*. The number of lactic acid bacteria increased as the amount of wheat bran decreased, while the number of yeast and mold increased. Silage fermentation is a complex process

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1082310829

which depends on many factors. The silage characteristics that contribute to a good fermentation are: dry matter content, physiological properties of epiphytic bacteria and, most importantly, the quantity of soluble carbohydrates (Zanine et al. 2010). The decline in pH values inhibit the spoilage microorganism proliferation, which allows the silage nutritive values to be preserved. Thus, the best silage forages are the ones with high water soluble carbohydrate content, which should be sufficient to promote the fermentation and produce enough acid to preserve the silage. In the present experiment, content of WSC in all ensiled canola forages (4.2% DM, *Table 1*) was lower than the 6 to 7% content which is recommended for theoretical requirement to achieve well preserved fermentation (Wang et al. 2009). Thus the canola without additives was adequate for producing good quality silages.

Values with different letters in the same column are statistically different (P<0.05 and 0.01). NDF: neutral detergent fiber; ADF: acid detergent fiber; ADL: acid detergent lignin; OMD: Organic matter digestion; DMI: dry matter intake; RFV: relative feed values

The degradation of the cell wall components in silages is thought to be resulted from the fact that the wheat bran has low NDF and ADF content and accelerates the activity of lactic acid bacteria in the environment, being a source of carbohydrates. The NDF and ADF findings were similar with Balakhial et al. (2008); and higher than Limón-Hernández et al. (2019) findings. Kincaid et al. (2012) reported a lower value of NDF

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1082310829

(29.82%) which can be attributed to an early harvest (60-70 days after sowing). Feeding behavior of animals, feed consumption, feed digestibility and feed conversion to animal products vary depending on the quality of feed (Van Soest, 1994).

Feed quality is determined by the relative feed value (RFV) index developed for clover in the USA and used in other roughages (Bozkurt, 2011; Canbolat, 2013). Neely et al. (2009) reported that RFV of canola silage was double that of corn, alfaalfa silage and more than three times higher than triticale silage. The lowest RFV was found as 97.24 in control group canola silage, whereas the RFV significantly increased with the addition of wheat ($P < 0.05$). The highest DDM ratio of silages was found as 62.08% and 5% in wheat bran group and the lowest DDM ratio was found as 56.80% in lean canola silage. DMI ratios of silages ranged between 2.21-2.38% and DMI ratio was found to be significantly higher in the groups with the addition of wheat bran than in the control group of canola silage. It is reported that increase in NDF, ADF and ADL levels, which are found in the structure of feeds and slow down the digestion, causes satiety and limits the feed consumption of animals (Canbolat and Karaman, 2009; Canbolat, 2013). The findings of this research also support this. The DDM and DMI values determined in the study were found to be similar with the findings of Canbolat and Karaman (2009) and Bozkurt (2011), who studied different legume feeds. In a study investigating the effects of urea and molasses on the quality of feed as an additive to canola silage, it was determined that the addition of molasses improved the quality of silage decreasing the content of ADF and NDF, but lowered the DDM value (Balakhail et al. 2008). DMI findings were slightly lower than Paula et al. (2017) findings. In the study, the addition of wheat bran to canola silage was found to increase the DMI value.

Organic matter digestion (OMD), metabolic energy (ME) contents of canola silages were determined and given in *Table 4*. Organic matter digestibility and metabolic energy values of canola silages increased with the addition of wheat bran. The highest organic matter digestibility was determined as 63.93% in canola silages with the addition of 5% wheat bran, while the highest metabolic energy value was found in the group with the addition of 10% wheat bran ($P < 0.05$). OMD findings were slightly lower than reported by Balakhial et al. (2008), Kincaid et al. (2012), Paula et al. (2017) and Limón-Hernández et al. (2019).

Conclusion

The results of this study show that canola forage has suitable nutrient composition. Therefore, it can be used for dairy cattle nutrition. It allows conservation without

affecting its nutritional value. High moisture content of canola forage is one of the dangerous factors concerning canola silage quality. It requires an additive for proper conservation. Addition of wheat bran improved DM and DDM content of canola silage.

(Received 14th Mar 2019; accepted 21st May 2019)

Abstract. Determining the temporal change in avian population is crucially important in order to understand whether their population is increasing or decreasing. The information about population parameters will help in conservation and protection efforts of avian species in future. Hence, the present study was carried out to determine the temporal changes in avian species in the 2014/15 and 2018/19 periods in urban waterlogged area of Hyderabad district Sindh, Pakistan. The highest relative abundance (28229 bird individuals representing 50 species and 14 families) was detected in 2018/19 rather than in 2014/15 (17454 individuals representing 38 bird species and 12 families). Out of the 50 bird species detected in 2018/2019, 30 were migrants (18965 individuals); 15 residents (5370 individuals), and 5 resident–migrants (3897 individuals) and while in the case of 2014/15 period, 22 species were migrants (11547 individuals), 15 residents (5247 individuals) and one resident–migrant (660 individuals). IUCN and BirdLife Status indicated that one migrant species was critically endangered; two species Rare/Accidental/Vulnerable and the rest of the 23 species were of the least concern. All resident bird species were totally protected (LC) while one resident–migrant species was data deficient. Foraging guild structure indicated that omnivore (32.489%) and Piscivore (12.808%) were the most dominant guilds of 2018/19 rather than 2014/15 while Carnivore was absent in detections of 2014/15. Alpha diversity analysis indicated that urban seasonal waterlogged was more diverse, rich and evenly distributed in 2018/19 than 2014/15. The findings of this study indicated that urban seasonal waterlogged area is suitable habitat (foraging sites and stopover) for a wide array of waterbird species especially migrant birds to refuel, rest, and forage.
Keywords: *waterbirds, population parameters, native, threatened, BirdLife*

Introduction

Waterbirds are directly or indirectly depend on the aquatic environment and foraged either near water body's edges or banks or on the surface. They are bioindicators of aquatic ecosystems due to cause–effect association with different microclimate and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1083110843

vegetation composition. Waterbirds may exploit broad scale of habitat, responded quickly to any environmental change either microclimate or vegetation structure and composition. Waterbird can be easily detected and identified (i.e., they showed their presence through vocalization). They can be surveyed more efficiently over the large spatial scale, e.g., presence, abundance, and influenced by surrounded habitats as compared to other animals.

The urban seasonal waterlogged areas are the undeveloped residential low-lying landscape within the city that received the water from domestic sewage and rainfall drain. They are characterized with shallow water overlying the interspersed soil and dominated either by submerged and emergent aquatic vegetation (Zhang et al., 2010). Waterlogged areas have been considered highly productive habitats for diverse fauna species, such as birds, amphibians, reptiles and mammals (Ehrenfed, 2000; Gibbs et al., 2005; Van der Walk, 2006). Due to loss and degradation of natural wetland areas, urban sewage has become a hotspot habitat for a wide array of waterbird species, i.e., waterfowls, waders, grebes, gulls, cormorants, terns to refuel, rest, and forage. These areas provide an important stopover foraging habitat for migrant as well as resident waterbird species due to high productivity (Hoffmann and Dodson, 2005). The other reason could be that, these areas are rich in fishes, amphibians, aquatic invertebrates (i.e. snails, worms, larvae of dragonflies, and water beetles that mostly occurs in soft damp soils, ditches, ponds), and organic matter.

It has been stated that more than 50% of the world's population inhabit in cities (Mackintosh and Davis, 2013) that may cause huge domestic sewage. A rapid increased in urbanization i.e., draining and infilling of wetland for development may also have caused the disappearing of wetlands from landscape (Sutula and Stein, 2003). The loss and degradation of wetland areas have increased runoff from urban sewage and industrial plants, which has adversely affected the hydrology of waterways and the remaining rest of wetlands (Catford et al., 2007; Vermoden et al., 2009; Davis et al., 2010). It has also been reported that more 50% of natural wetlands had been lost and degraded (Fraser and Keddy, 2005) that caused almost 40% of migrant bird species (i.e., 200 bird species) to be declined worldwide (BirdLife, 2015).

Previously, no study has been conducted to examine the temporal changes in avian population parameters inhabiting urban seasonal waterlogged areas. Hence, this study was conducted to examine the temporal changes in the avian population (i.e., relative abundance, diversity, status, and foraging guild structure) that utilizing the urban seasonal waterlogged areas.

Materials and methods

Study Area

These urban seasonal waterlogged areas lie in within the heart of the city 25^0 22' 45" N and 68^0 22' 06" E along the east bank of the Indus River, Hyderabad Sindh, Pakistan (*Figure 1*). Hyderabad city is densely populated, i.e., 2.323 million urban inhabitants and covers a total area of 3,198 km^2. It received monsoon rainfall from mid–April to late June and mostly remains warm (i.e., 50^0F to 119^0F) year–round, but sometimes temperature may fall at 34^0F during winter. The urban seasonal waterlogged areas are undeveloped residential wastelands that are under control of the cantonment board. These areas encompass the ditches and low laying grounds that receive water from domestic sewage and rainfall.

Birds Survey

It has been known that avian populations fluctuate from time to time and habitat to habitats (Schieck, 1997; Blake and Loiselle, 2001). Determining the temporal changes is highly essential to understand the trends in avian population in the wetland areas (Thompson et al., 2002; DeSante et al., 2005). For this reason, the Distance Sampling Point Count Method is one of the most common quantitative survey technique that has been widely used to examine the temporal changes in avian populations (i.e. relative abundance, foraging guilds, and diversity) inhabiting different habitats (Verner and Purcell, 1999; Codesido and Bilenca, 2000). This method involves the visual and auditory detection of birds with fixed or variable radius plots, and it provides detailed information on avian population parameters (Verner and Ritter, 1985; Mills et al., 2000). The design of this study was encompassing of the following factors: (i) suitability for habitats, such as open water bodies and vegetated areas, i.e. submerged vegetation; (ii) suitability for surveying cryptic, shy, and skulking species; (iii) suitability for species–rich populations; (iv) suitability in situations where human access was restricted; and (v) areas best situated for bird–habitat studies.

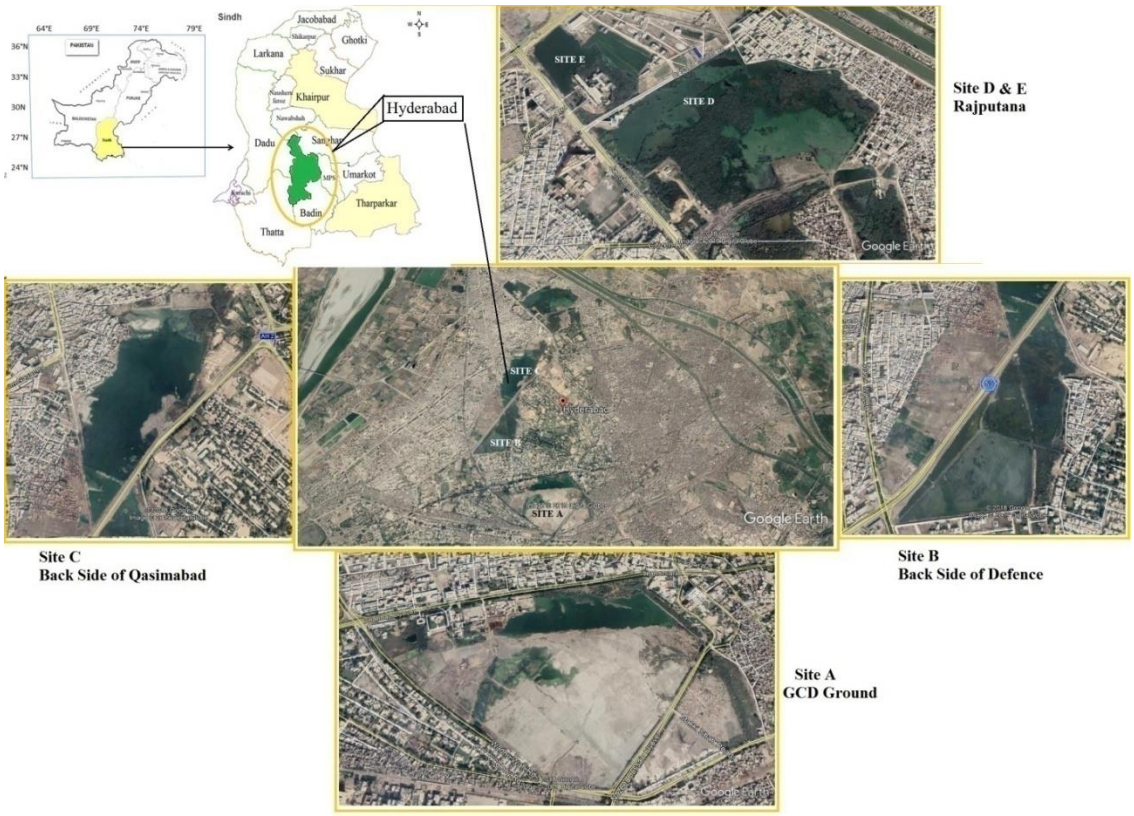

Figure 1. *Location map of the study area*

Avian species inventories at five selected sites were carried out from September 2014 to February 2015 and September 2018 to February 2019 employing Distance Sampling Point Count method. A total of 150 point count stations (i.e., in site 30 point count stations) were fixed at 300 m intervals along the edges of water bodies to avoid double counting the same bird individuals at more than one station (Meadows et al.,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1083110843

2012; Wijesundara and Wijesundara, 2014; Adams et al., 2015). The birds were surveyed at each point count station for 15 minutes during each visit. The surveys were carried out during 0750–1100 hrs. This period of time is appropriate as most of the avian species remain active in search of food. The sampling methodology was followed as described by Richardson et al. (2001), Buckland et al. (2004), Aborn (2007), Nadeau et al. (2008), and Yu-Seong et al. (2008).

Data Analysis

Relative abundance revealed the common or rare species inhabiting in a particular area. It is the percentage composition of particular bird species among all detected bird species utilizing the waterlogged area (Simon and Okoth, 2016; Walag and Canencia, 2016; James and Bright, 2017). Relative abundance (%) of avian species was determined to employ the following formula;

$$\text{Relative Abundance} = \frac{ni}{N} \text{ X } 100 \qquad \text{(Eq.1)}$$

where, n*i* = is the number of individuals in the *i*th bird species, N = is total detected numbers of individuals of species detected in urban seasonal waterlogged areas (Bibby et al., 2000; Hubbell, 2001; McGill et al., 2007).

Avian diversity was analyzed using the Community Analysis Package (PCA) Version 4.0 by Henderson and Seaby (2007). The reliability of data of tested through Shapiro–Wilk normality test (Analytical Software version 8.1) by Razali (2011).

The status of avian species was identified and confirmed with the help of IUCN RedList and BirdLife International checklist.

Results

Relative Abundance

The results of 2018/19 stated that urban waterlogged areas had attracted highest relative abundance (i.e., 28229 bird individuals equal to 61.793%) representing 50 species and 14 families as compared to 2014/15 (i.e., 17454 bird individuals equal to 38.207%) represent 38 species and 12 families. This indicated that 23.586% higher numbers of bird individuals were detected in 2018/19. Furthermore, twelve new avian species namely; Common Teal – *Anas cerca*, Green–winged Teal – *Spatula discors*, Mallard – *Anas platyrhinchos*, Gadwall – *Meraca strepera*, Great Cormorant – *Phalacrocorax carbo,* Brown–headed Gull – *Larus brunnicephalus,* Black Kite – *Milvus migrans,* Bar–tailed Godwit – *Limosa lapponica,* Spoon–billed Ibis – *Platalea leucorodia,* Pied Avocet – *Recurvirostra avosetta,* Solitary Sandpiper – *Tringa solitaria,* Spotted Sandpiper – *Actitis macularius,* and White–tailed Lapwing – *Chettus ialeucura* were detected in 2018/19 as compared to 2014/15 (*Table 1*).

In addition, the results obtained using the One–Way ANOVA and Tukey's HSD test showed that the avian relative abundance of the urban seasonal waterlogged area was significantly different in the 2018/19 and 2014/15 periods (i.e., F_1, 86 = 4.46, $P < 0.05$; CV = 2/81).

Relative Abundance of Migrant, Resident, Resident-Migrant Bird Species

Notably, 18965 bird individuals of 30 migrant species representing 6 families were detected in 2018/19 as compared to 11547 bird individuals of 22 species and 5 families detected in 2014/15. Likewise, 5370 individuals of 15 resident species were detected in 2018/19 and 5247 individuals of 15 resident species in 2014/15. However, 5 resident–migrant bird species (i.e. 3897 individuals) were detected in 2018/19 while 660 bird individuals of *Himantopus himantopus* resident–migrant species (i.e.) were detected in 2014/15. Out of 30 migrant bird species, one species was critically endangered; two species Ra/A/Vu (Rare/Accidental/Vulnerable) and the rest 23 species were least concern based on IUCN Status. All resident bird species were totally protected and one resident–migrant bird species as data deficient (*Table 2*).

Foraging Guilds Structure in the 2018/19 and 2014/15 Periods

Notably, the findings of foraging guild structure 2018/19 stated that currently, urban seasonal waterlogged areas had attracted a higher number of bird individuals than previous years (i.e., guild omnivore; 32.489% in 2018/19 and 17.562% in 2014/15). Likewise, the higher relative abundance of guild Piscivore was detected in 2019 (12.808%) rather than 2014/15 (7.292%). On the contrarily, lower number of bird individuals of guild Carnivore/Piscivore/Insectivore were detected in 2019 (4.188%) rather than 2014/15 (5.472%). Moreover, the member of guild Carnivore was detected in 2018/19 but no individuals of Carnivore was documented in 2014/15 period (*Table 3*).

Comparison of Diversity Indices

The results of the alpha diversity analysis indicated that urban seasonal waterlogged areas had attracted higher diversity of avian species in 2018/19 rather than 2014/15 (*Table 4*).

Discussions

The urban seasonal waterlogged areas investigated in this study encompasses of 30.0% rush and sedge aquatic plants while rest is shallow water open areas devoid of aquatic vegetation. Rush and sedge plants serve as hiding cover for avian species while open water areas as foraging grounds. The shallow water is rich in food resources, such as fishes, amphibians, insects, crustaceans and aquatic plants which is the major diet of avian species especially waterfowl, seagulls, cormorant, grebes, plovers, sandpipers, stilt, and egrets.

Urban seasonal waterlogged areas are a highly important habitat for a wide array of waterbirds and terrestrial birds. Their importance depends on many factors, namely; size, connectivity to surrounding areas, diversity of vegetation, water quality, occurrence of food resources and disturbance. Besides, determining the temporal changes in avian population parameters is highly important to obtain the population trend of different avian species utilizing these areas. Evidently, the results of the diversity analysis in the study indicated that the bird diversity during consequent time period might vary depending on the habitat suitability, richness of food resources, and feeding guilds in the wetland reserve.

Evidently, the results of population parameters are noteworthy, in comparisons; the higher relative abundance, bird species, foraging guilds, and diversity indices were detected in the 2018/19 rather than 2014/15 period. This indicate that urban seasonal waterlogged areas has becomes more attractive habitat with the passage of time for avian species as compared to previous years. The recording of higher relative abundance, species composition, foraging guilds, and diversity indices could be that these areas are less disturbed even though they are located within the heart of the city. Because nobody hunting in these areas due to under administration of cantonment board. The other reason might be that these areas are rich in fish fingerlings, amphibians, insect larvae, and organic matter. These food resources are the major diet of waterbird as well as terrestrial bird species. The third reason could be that natural wetland areas of the Hyderabad have lost due to conversion into agriculture fields, water pollution, and aquaculture ponds, and urban settlements. Due to these reasons, urban seasonal waterlogged areas of the Hyderabad serve as an alternate habitat for a wide array of waterbird as well as terrestrial bird species, especially in winter.

Furthermore, it was observed that the relative abundance of waterbird was influenced by vegetation structure, food resources, and water level that affected the habitat selection. This could be that these factors indicated where and how the waterbirds used the urban waterlogged areas. For example; waterfowl, grebes and cormorant often

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1083110843

utilized open water areas devoid of aquatic vegetation for foraging (waterfowls, sandpipers, lapwings, stilts, cormorants, terns, and egrets) and dead fallen trees for perching (cormorants and egrets). Likewise, egrets, herons, sandpipers, plovers, and lapwings selected shallow waters for foraging and substrate for perching and avoided the deep waters. This could be that deep water may restrict their prey accessibility and reduced the prey–capturing success (Gawlik, 2002; Brönmark and Hansson, 2005).

Additionally, it was also observed that the richness and diversity of food resources may regulate the distribution and diversity of waterbird species in aquatic habitat (Johnson and Sherry, 2001; Sutula and Stein, 2003). Furthermore, this study highlighted that waterbird species are habitat specialist, they often selected habitat that offers ideal foraging and perching sites, shelter from predator and harsh weather. Relatively, water depth, vegetation structure and composition, richness and diversity of food resources, and dead fallen trees in urban waterlogged areas play a significant role in foraging guild structure (Kiviat and MacDonald, 2004; Benassi et al., 2007; Guadagnin et al., 2009; Tsai et al., 2012).

Conversely, seven foraging guilds were recorded in 2018/19 and six foraging guilds in 2014/15 period. Apparently, the recording of seven feeding guilds of the avian species in urban waterlogged areas in the 2018/19 showed that this seasonal fragile habitat provided suitable food and foraging sites for a wide array of avian species (i.e., waterbirds and terrestrial birds). Furthermore, the results of foraging guild structure revealed that urban seasonal waterlogged areas are rich in food diversity, vegetation structure, and water level that may play a crucial role to attract a higher diversity of avian species especially waterbirds. It was observed that piscivore, i.e., cormorant, egrets, heron, and kingfishers preyed on fishes especially in shallow waters, omnivore i.e., waterfowls foraged on animal (fishes, amphibians, invertebrates, etc.) and plant matter (aquatic plants) that floating at the surface of the water or occurs in shallow waters, insectivore, i.e., stilt, sandpipers, and lapwing, etc mostly preferred shallow water and soft mud to prey on aquatic invertebrates (Guadagnin et al., 2009).

Furthermore, the results foraging behavior also indicated that the waterbirds and terrestrial birds inhabiting in urban waterlogged areas were highly variable in their morphological structures, foraging behavior, and food capturing tactics, and habitat selections. The members of each foraging guild varied in their food selection due to morphological differences, bill and tarsus size, water depth and habitat preferences.

Conclusions

The findings of this study indicated that urban seasonal waterlogged area is suitable habitat (foraging sites and stopover) for a wide array of waterbird species especially migrant birds to refuel, rest, and forage. Unfortunately, these fragile areas have been shrinking at an alarm rate due to urban development. For conservationist, dealing with the human and maintaining the functional waterlogged ecosystem is the greatest challenge to conserve and protect these fragile aquatic habitats. The existence, sustainability, and future of avian species directly depend on protection and conservation of the urban waterlogged areas of Hyderabad and across the country. Hence, it is strongly recommended that the urban seasonal waterlogged areas should be declared as wetland reserve (wetland of global importance) due to harboring a variety of migrants as well as native waterbird species that belong to different taxonomic groups.

(Received 14th Mar 2019; accepted 24th May 2019)

Abstract. The present study aimed at the characterization of various strains of phosphate solubilizing bacteria (PSB) purified on Pikovskaya (PVK) agar medium, containing insoluble tricalcium phosphate (TCP). Maximum phosphate solubilization index (PSI) was calculated from 1.1 to 4.57 cm from clear halo zones around the microbial growth on the PVK. 26 highly efficient purified PSB isolates were also found effective for potassium solubilization on Aleksandrov medium. Maximum potassium solubilization index (KSI) was calculated as 1.1-4.66 cm. The phosphate and potassium solubilization is linked to the production of low molecular weight acids by bacterial cells. Therefore change/decline in the pH of liquid cultures was also observed and maximum decrease was recorded as 3.25 in 9AS strain. Most efficient strains were characterized by ribotyping and based on sequence studies were identified under genera *Klebsiella, Enterobacter, Bacillus,* Marine bacterium*, Staphylococcus,* and *Serratia*. Their sequences obtained MF465778, MF465779, MF465782, MF465781, MF465777, and MF465783, respectively (GenBank). Bio-fertilizing efficiency and possible plant growth promoting effect of selected PSB was evaluated by applying in potato (*Solanum tuberosum* L.) rhizosphere in trial field. An increase of, two-fold yield in plant height, number of lateral shoots, number of roots and root length was observed by *Bacillus licheniformis*, *Serratia marcescens*, and *Staphylococcus warneri*, as compared to un-inoculated controls. These results indicate that the isolated strains bear great potential to be used as source of bio fertilizer in crop fields.
Keywords: *PSB, KSB, biofertilizer, potato trial field, molecular characterization*

Introduction

Phosphorus (P) being an essential macro nutrient is indispensable for plant's growth (Leticia et al., 2015). Unlike nitrogen, there is no atmospheric reservoir available to augment its quantity in soil. Phosphorus in soil is present both in the form of organic and inorganic phosphates. Inorganic phosphates form large mineral complexes with other metals in the soil. While on the other hand, organic phosphates, which constitute 20-80% of total phosphorus contents in soil, are present as immobilized and insoluble phosphates (Diep et al., 2013). Phosphorus that is absorbable by plant roots exists in scarce amount in soil. The amount of P deviates between 200-2000 kg P/ha at upper 15 cm soil layer, having an average amount of about 1000 kg present in soil but its available quantity is a lower fraction of phosphorus available (Ali et al., 2013; Jahangir et al., 2016), that is roughly 10μM in different soils (Nobandegani et al., 2015). A recent

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1084510859

investigation suggested that although 95-99% of all phosphoric amount is in insoluble forms, however only 0.1% of it, is in plant's accessible form (Ali et al., 2014, 2016; Awais et al., 2017; Surapat et al., 2013). Thus, plants need assisting agents to convert immobilized and insoluble phosphorus into a form that can be absorbed readily through roots.

Nature has richly supplied the agricultural soils with phosphate solublizing bacteria (PSB). These bacteria are one of the many other types of Plant growth-promoting bacteria (PGPB) which aid plant growth and development through various mechanisms (Glick, 2001). PSB are found to convert insoluble phosphates, in a form accessible to plants, such as orthophosphate (Leticia et al., 2015), through solubilization and mineralization. Animal dung has long been used to increase the P contents of soil ignoring the microbial communities and their roles (Sharma et al., 2011). Thus, PSB application to increase the rhizospheric phosphorus levels by solubilization of re-precipitated P forms is favored (Shekhar et al., 2000; Sadiq et al., 2013). In addition, application of KSB biofertilizers is not only associated with the improvement of soil fertility but also increases the crop yield. It also assists in shielding the plants from hazardous diseases plus lowers the solicitation of various synthetic fertilizers being expensive. Application of the PSB also minimizes the cost of the synthetic fertilizers in a much eco-friendly manner (Sindhu et al., 2010; Sheng et al., 2003; Zameer et al., 2015).

The purpose of the present study aimed for the isolation and molecular characterization of efficient PSB strains through ribotyping. The potential of potent strains for the development of plant growth is also evaluated in natural open environment on potato trial field that showed significant results. The Present investigation reports *Bacillus licheniformis*, *Serratia marcescens*, and *Staphylococcus warneri* are potential candidates to develop economical source of phosphate fertilizers that enhance plant growth and also help to reuse the fixed soil phosphate.

Materials and methods

Soil sampling

To isolate growth promoting rhizobacteria, soil samples were collected from crop rhizosphere of different agricultural areas of Punjab in the months of August-October. Soil adhering to plant roots was taken from about 20-24 cm depth. The soil samples were collected in disinfected polythene bags and were carried to the research laboratory of the Centre for Applied Molecular Biology (CAMB) Lahore. Soil samples were kept at 4 ± 1 °C until further use.

Purification of PSB strains from rhizospheric soils

For the isolation of PSB strains, the tiny roots with adhering soil were removed weighing about 1 g (per sample) in a formerly sterilized mortar. 6 ml of normal saline was poured in individual sample and crushed moderately with sterilized pestles. The soil suspension from each sample was serially diluted by 10x factor in saline water to get better isolation. Serially diluted soil samples, 10 µl of diluent was spread on synthetic Pikovaskaya (PVK) agar medium (Merck, B.N. #JE2JF62127), and was sterilized at 121 °C and 105 kPa for 15 min, incubated at 28 °C (binder, MB64585923, 240 V and 50/60 Hz). After initial incubation of 48 h, single colonies that produced halo

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1084510859

zones were repeatedly streaked on PVK agar plates until purified cultures were obtained. Purified cultures were preserved in 20% glycerol at -80 °C.

Phosphate solubilization

Single colonies of purified PSB isolates were inoculated into 10 ml LB broth medium in 50 ml separate culture tubes. LB medium contained Tryptone (DIFCO#0349000), 10 g/L; NaCl, 10 g/L; Agar (bioworld#40100044-1), 15 g/L and Yeast Extract (Fluka#0001415579), 5 g/L, and was sterilized at 121 °C and 105 kPa for 15 min. For obtaining the optimal growth, these cultures were incubated overnight at 28 °C in constant shaking incubator (New Brunswick scientific classic C24KS). For pin point inoculation 10 µl of each of this fresh grown culture was dripped in the middle of respective labelled PVK agar plates and incubated for 7 days at 28 °C. The phosphate solubilization index (SI) of phosphate solubilizing bacteria was calculated on seventh day using the following formula:

$$\text{PSI} = \frac{\left(\text{Colony diameter} + \text{halo zone diameter}\right)}{\text{Colony diameter}}$$

Based on higher phosphate solubilization index, 11 superior isolates were selected for further characterization.

Potassium solubilization

The efficient PSB isolates with higher PSI were also analyzed for assessing their proficiency to dissolve bounded potassium. The solubilization of potassium was assessed by the same protocol and formula as the phosphate solubilization; however, Aleksandrove media was used to calculate the potassium solubilization index (KSI). This modified Aleksandrove medium/L contained $CaCO_3$: 0.10 g, Glucose: 5.0 g, $MgSO_47H_2O$: 0.50 g, $FeCl_3$: 0.006 g, $Ca_3(PO_4)_2$: 2.0 g, Insoluble Mica powder (insoluble potassium source): 3.0 g and Agar: 20.0 g, and was sterilized at 121 °C and 105 kPa for 15 min. Disinfected water was used for medium preparation with pH adjustment of 5.5-5.7.

pH change

Single purified colony of all PSB isolates was inoculated in 10 ml of PVK broth to assess the pH change of the medium. Cultures were incubated in the shaker incubator (New Brunswick scientific classic C24KS) at 120 rpm and 28 °C for ten days along with un-inoculated control. The pH of isolate was measured by a pH meter (Bante, 210) on 1st, 3rd, 7th and 10^{th} day of incubation.

Molecular characterization of PSB strains based on 16SrRNA conserved regions

11 superior isolates (based on their solubilizing efficiency) were selected for molecular characterization. Bacterial DNA was extracted using a buffer (50 ml) that contained 5 M NaCL, 5 ml; 0.5 M EDTA, 5 ml; Tris of pH 7.9, 5 ml and autoclaved distilled water, 35 ml. Other reagents of protocol include Phenol Chloroform Isoamylalcohol (25:24:1), 10% SDS, 70% Ethanol, Isopropanol and glass beads. 10 ml of sterilized LB broth medium was inoculated with single colony of each of the 11 PSB isolates in aseptic conditions. Cultures were incubated overnight, in shaker incubator at 28 °C to obtain

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1084510859

optimal growth. After incubation, the culture was dispensed into 1.5 ml microcentrifuge tubes and cells were harvested from each culture by tight centrifugation at 3000 rpm for about 10 min. Cell pellets were resuspended in DNA extraction buffer (500 µl/1.5 ml of each culture) and dispensed in correctly labeled 1.5 ml micro centrifuge tubes. Each tube was given a heat shock up to 65 °C for the duration of 30 min. After cooling for 5 min, 100 µl of 10% SDS was added and were again given the 65 °C heat shock for 10 min. After cooling for about 5 min, added the 200 µl of glass beads along with 200 µl of PCI. Each sample was subjected to vortex after 1 min incubation in freezer. After repeating this step three times, samples were centrifuged on 14000 rpm for 10 min and their supernatants were collected in a new 1.5 ml microcentrifuge tubes and added with equal volume of Isopropanol. Further, tubes were centrifuged at 14000 rpm for 10 min. Pellet was saved and washed with 500 µl of 70% Ethanol on 14000 rpm for 7 min. After washing, DNA pellets are dried for about 10 min at room temperature and then resuspended them in the 50 µl nuclese-free water and stored at -20 °C 4 µl of each sample was run on 11% agarose gel using 1 µl of 6X loading dye in 1XTAE buffer. Each sample of DNA was also quantified through nanodrop analysis. PCR was optimized to amplify 16S rRNA gene sequence using a universal primer (Laticia et al., 2015):

FORWARD PRIMER: 5'- GAGAGTTTGATCCTGGCTCAG-3'

REVERSE PRIMER: 5'- CTACGGCTACCTTGTTACGA-3'

Annealing temperature and other amplification conditions were optimized in Gradient thermal cycler (BIO-RAD T100^{TM}). PCR reaction mixture contained 100 ng/µl of template (4 µl of 14AS DNA), 1mM dNTPs, 1X PCR Buffer, 1.0 picomol, each of Forward and Reverse Primers, 2.5 mM $MgCl_2$, and 0.5 U of Taq Polymerase (Thermo Scientific). Final volume made up to 20 µl with nuclease free H_2O. The cycling conditions included initial denaturation at 95°C for 3 min followed by 35 incubation repeats of 45 s denaturation at 95 °C, 45 s annealing at gradient of 54 °C, 55 °C, 56 °C, 57°C, 58 °C, 59 °C and 1 min extension at 72 °C with the final extension of 7 min at 72 °C and infinity hold at 4 °C. After optimization, same cycling conditions were practiced for amplification of 16SrRNA gene sequences from all six best performing strains. PCR products were run on 1% agarose gel along with 100 bp DNA ladder (Thermo Scientific#SM0323) in 1XTAE buffer. Amplified bands were purified using Invitrogen, Purelink^{R} Quick Gel Extraction Kit # K2100-12).

Purified 16S rRNA PCR products were sequenced by DNA core facility of the CAMB. Sequence data was analyzed and used for molecular identification of the studied PSB strains. The obtained sequences were BLAST, aligned and compared with the standard sequences in NCBI of all bacterial lineage based on information related to 16SrRNA gene sequences available on the online portal of National Center for Biotechnology Information GenBank (http://www.ncbi.nlm.nih.gov/). Further analyses were made on MEGA 6, and the phylogenetic trees for PSB strains were constructed through neighbor-joining method.

Trial field experiments of PSB isolates on potato crop

Bacillus licheniformis, Staphylococcus warneri, and *Serratia marcescens* (14 AS, Rl, and 5Bl respectively) were applied in the rhizospheric region of 25 abiotic stress tolerant potato plants (Sante) in a trial field to test their biofertilizing efficiency in the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1084510859

natural environment. Field trial study was conducted in the area of CAMB specified for potato trial field within trial field premises of CAMB during October-January 2017.

The trial field land was prepared by using different irrigational practices and was supplied with essential amount of fungicide and inorganic fertilizers for adequate crop growth. The soil of trial field was sandy loam and an adequate quantity of organic matter was mixed during softening of soil. The pH of trial field soil was 6.5 on the day of plantation. No extra fertilizer was applied during whole experiment. All other requirements of the field including watering and soil softening were provided as per need of the crop. The Lab grown complete plants of tissue cultured transgenic Sante variety (possessing Dehydrin-10 gene of Eucalyptus) was shifted to the trial field. Following the plantation pattern of Skogsmyr (1994), the plants were planted (shifted) to trial field soil at distance of 0.25 to 0.5 m. Overnight grown bacterial culture (10 ml per plant) was applied to the rhizosphere soil of plantlets in three repeated treatments on 7th, 21st, and 50th day of plantation. The potato field was harvested on 90^{th} day after shifting the plants into trial field from laboratory. The number of survived plants per experimental units, number of lateral shoots per plant, total number of roots and tubers (of all sizes) per plant, maximum root and shoot length per plant were measured and recorded for all three treatments and, negative control lanes.

Statistical analysis

The obtained experimental data were analyzed statistically by using Statistix software version 8.1 and the results were expressed as the mean. Means and standard errors (SE) separation was accomplished by LSD. Statistical analysis of the results was performed by using general linear model (GLM) and one-way analysis of variance (one-way ANOVA) up to 5 levels to access whether the different PSB isolates had a significant effect on plant growth parameters. Significance of the effect of treatment was determined by the magnitude of the value ($P < 0.05$).

Results and discussion

Purification and phosphate solubilization potential of PSB

Phosphate Solubilizing Microbial colonies that were purified on the Pikovskaya (PVK) agar medium containing insoluble tri-calcium phosphate (TCP), (*Fig. 1*). Insoluble P was consumed by all isolates to different extents but eleven samples namely 2CQlV, 2CQll, 2CQlll, 2CQV, 9AS, 2CQVl, 14AS, GRl, GRll, 5BI and 17AS exhibited greater halo zones on PVK agar plates, hence showed higher PSI (*Fig. 2*). 14AS showed highest halo zone measured as 3.2 cm with the PSI of 4.57cm. Whereas the lowest halo zone measurement was recorded as 1.1 cm in 3SQII. Similar methodology related to isolation and screening of PSB has been reported by scientists (Sadiq et al., 2013; Zameer et al., 2016; Jahangir et al., 2016). Values of Phosphate solubilizing index (PSI) based on their colony diameter and clear zones, differed for different PSB isolate. Similar results were stated by Yasmin et al. (2011).

K solubilization potential of the PSB isolates

PSB isolates with higher PSI were also evaluated for potassium solubilization efficiency. These potassium solubilizing microbes increase plants growth as a result of solubilization of insolvable K minerals like mica and feldspar (Sheng et al., 2003). All

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1084510859

of the tested PSB isolates consumed Aleksandrov medium yielding various sized colonial growth while 3SQIV isolate showed disperse pattern of growth. While, 14 PSB isolates namely 2CQII, 2CQV, 2CQIII, 63dII, 2CQIV, 5GQI, 2CQVI, 2CQVIII, 9AS, GRII, 14AS, GRl,17AS and 5B1 were found to be capable of solubilizing K from insoluble K-bearing minerals source and the zone of solubilization was measured from 4.66 to 1.1 cm (*Fig. 3*). The research by Zhang and Kong (2014), also demonstrated the ability of the potassium solubilization from insoluble potassium. Maximum measurement of the colony and halo zone diameter was recorded by 2CQVI (1.7 cm) and 2CQVIP (1.1 cm) respectively (*Fig. 3*). The overall highest recorded value of KSI was shown by 2CQVl as 4.66 cm (*Fig. 3*). The distinct patterns of P and K Solubilization on respective growth media for comparative efficiency of PSB isolates are presented in (*Figs. 4* and *5*).

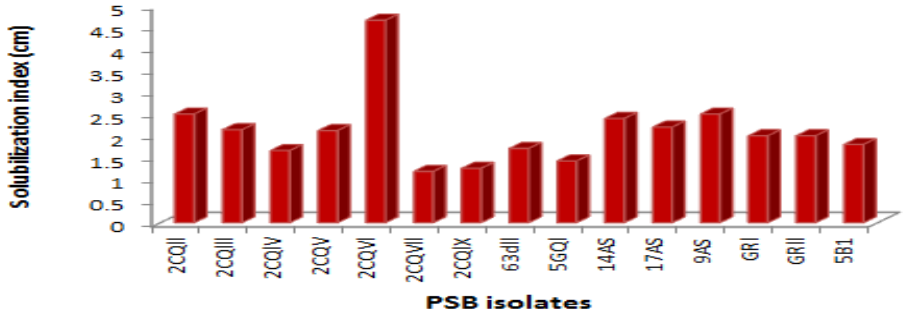

Figure 3. *KSI of selected PSB isolates on Aleksandrov medium*

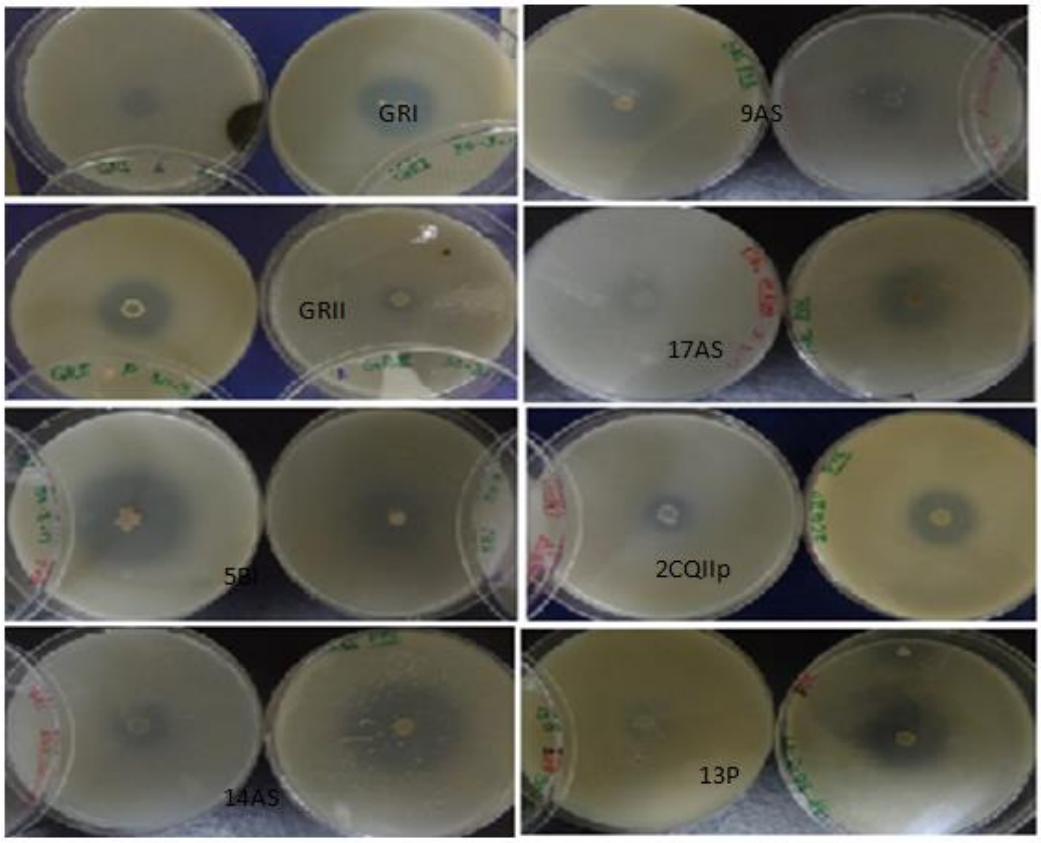

Figure 4. *Comparison of some PSB isolate's Solubilization index (SI) on Pikovskaya's and Aleksandrov media*

pH change

A successive decrease in all of the isolates was observed on 1st, 3rd, 7th and 10th days. Maximum recorded acidic value was of 9AS (3.25) depicting the highest medium discoloration because of breakdown of insoluble precipitates of tricalcium phosphate (*Fig. 6*). However, 5 cultures 2CQlll, 2CQlV, 2CQVl, 2CQX and 63dll, showed distinct patterns of PH change by giving much lower pH values at start then a bit increase in these values on successive day but showed overall trend towards acidic property (*Fig. 6*). The results of the presented study are in close accordance with the findings of

Molecular characterization/identification of bacterial isolates

For molecular characterization, genomic DNA of 9AS, 2CQll, 2CQlll, 14AS, 2CQlV, 2CQV, 17AS, 2CQVl, GR1, 5B1 and R1 PSB isolates was extracted and used as template for 16SrRNA amplification with universal primer set. DNA of 2CQlll isolate was used as a template for optimizing the primer set's annealing temperature and run its gradient PCR. It displayed the single prominent band at 54 °C, 55 °C and 56 °C

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1084510859

of approximately 1.2 kb size (*Fig. 7*). Following the optimized recycling conditions ribotyping PCR was carried with genomic DNA of 6 potent isolates 2CQll, 14AS, 2CQlll, 17AS, Rl and 5Bl as templates. In all strains PCR products of 1.2 kb was observed (*Fig. 8*). After ribotyping, the data for sequence analyses of PCR products were obtained from the DNA core facility of the CAMB and used it for molecular identification through in silico analysis. Thus by equating the 16SrRNA sequence database with all available data of gene bank through BLAST homology, inferred the isolates identification. On the base of close relations, experimental PSB isolates 2CQll, 14AS, 2CQlll, 17AS, Rl and 5B1 were identified as *Enterobacter* sp., Marine Bacterium, *Klebsiella* sp., *Bacillus licheniformis, Staphylococcus warneri* and *Serratia marcescens,* with the sequence similarity of 95%, 93%, 93%, 94%, 96% and 96% respectively. Accession no was obtained by submitting their sequence data to NCBI. The identified PSB isolates are mentioned in *Table 1*. Phylogenetic trees were constructed by MEGA 6 software, shown in the *Figure 9*. Similarly, different PSB from the plant rhizosphere have been purified, characterized and reported by other researcher (Tariq et al., 2014; Dar et al., 2014; Rodríguez et al., 2000).

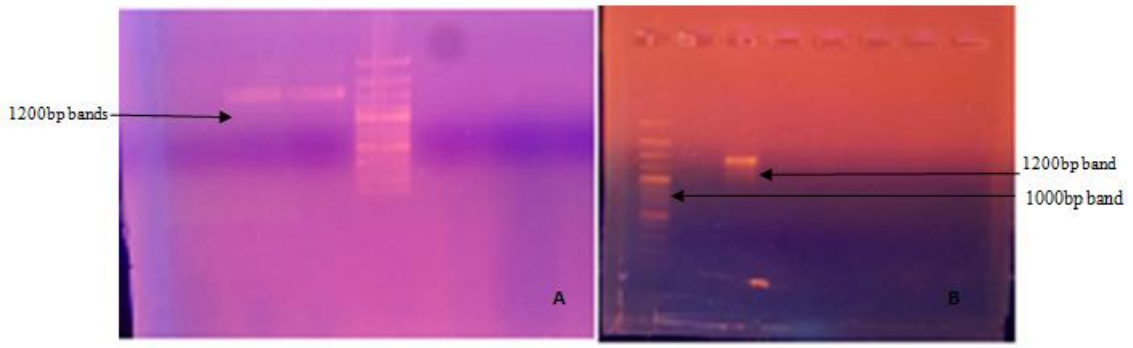

Figure7. *Gradient PCR displaying ribotyping PCR result (1% Agarose gel) of about 1200 bp band (A) at 54 °C and 55 °C (B) at 55 °C with DNA of 14AS (100 bp DNA ladder)*

Field efficiency of CAMB biofertilizing agents in natural environment (on potato trial field)

To evaluate their efficiency as phosphate biofertilizers in natural environment, three bacterial strains, the *Bacillus licheniformis* (14AS), *Serratia marcescens* (5B1), and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1084510859

Staphylococcus warneri (R1), were studied under natural environmental conditions. All three strains were found effective biofertilizers as more than double yield of potato tubers was obtained (*Figs. 10F*). Similar results were also reported by Malboobi et al. (2009) who evaluated efficiency of PSB on potato field trail and found significant yield in the growth of potato crops. Plants and tubers from control lanes and lanes treated with these three strains were compared. Very healthy and vigorous potato plants were observed in the experimental lanes that were treated with CAMB biofertilizer and showed significant results (*Table 2*). Harvesting of trial field with accumulated yield from all treatments and negative control are also shown in picture (*Fig. 10*). Significant differences ($P < 0.005$) were observed between the values obtained for plant growth, number of lateral shoots, number of roots and root length of potato plants as compared to un- inoculated control plants (*Table 2*). These findings are in close accordance of Sadiq et al. (2013) who have performed pot experiments of similar nature. They have applied PSB isolates in the rhizosphere of sugarcane plant and found positive impact of PSB isolates on the plant growth. Mayak et al. (2014) have performed experiments on stress tolerance effect of rhizobacteria on tomato. They isolated plant growth promoting rhizobacteria from soil and applied selected strain (*Achromobacter piechaudii*) in tomato rhizosphere in salty soil conditions. During their study they found that application of bacteria caused enhanced growth of tomato plants. Further they have linked enhanced salt stress tolerance of tomato plants with enhanced uptake of potassium and phosphorous. Findings of Mayak et al. (2014) and Hosni et al. (2016) support the outcome of presented study. Furthermore, our study explains that rhizospheric application of plant growth promoting bacteria (phosphate and potassium solubilizing bacteria) enhance absorbable phosphate and potassium in the root area of plants. Similar results have also been reported by many others who have concluded up with enhanced overall plant production in the influence of PSB application in rhizosphere of pot and trial field plants (Khalid et al., 2004; Çakmakçi et al., 2006; Wu et al., 2005). The results reported by Wu et al. (2005) have reported the highest biomass and seedling height in the plants of *Zea mays* trial field treated with PSB. Although several studies have been reported on the plant growth promoting effect of PSB in trial field, this is the first report on the rhizospheric application of PSB in the trial field of transgenic potato variety. The plants of treated lanes possessed dehydrin-10 gene of Eucalyptus globulus for tolerance against multiple abiotic stresses and produced about three folds enhanced potato yield and biomass over untreated lanes. The survival of tissue cultured plants in trial field lanes treated with PSB was also amazing and the higher survival rate may also be linked with antifungal activity of PSB strains as described by Jahangir et al. (2016).

Conclusion

The effects of this study demonstrated that Phosphate Solubilizing Bacteria play a vital role in plant nutrition, convert the insoluble phosphorus into the available form to the florae and used as biofertilizers for agricultural crops. Phosphate solubilizing bacteria identified by molecular characterization performed efficiently in natural environment and more than double potato yield was obtained as compared to untreated control plants in potato trial field. On the basis of this investigation, further studies are necessary to investigate possible synergistic effects of rhizospheric bacteria since the use of these bio-fertilizers can be used in an ideal harvesting system with a control effects on the environment sustainable manner in agricultural soils. Furthermore, use of these beneficial microbes not only reduces need of phosphate fertilizer for crop plant

DOI: http://dx.doi.org/10.15666/aeer/1705_1084510859

rather it plays some important role in plant growth parameter. Therefore, more research is needed to investigate the Phosphate Solubilizing Bacteria (PSB) as bio-inoculants to enhance the sustainable management of soil and agriculture that could help in economic stability and environment friendliness.

Acknowledgements. Very passionate thanks are paid to Mr. Islam Khan (CEMB) for his generous help. We are also very thankful to the CAMB DNA Core Facility (especially Mr. Muhammad Usman and Mr. Muhammad Akram) and Proteomics Lab CAMB for their kind cooperation during execution of this work.

Abstract. Through the optimal design of groundwater monitoring networks, it is possible to obtain the maximum level of information for certain variables (water level, some quality indicator parameters, and/or the presence of some contaminant) at minimum cost; the methodologies for this kind of designs follow a procedure to discard wells that provide redundant information. The information collected by monitoring networks is fundamental for supporting decision making that aims for a sustainable management of groundwater. In this paper, an existing methodology for the design of optimal groundwater quality monitoring networks is modified to include a new algorithm that allows to obtain alternative spatial distributions of the wells that provide the highest level of information, expressed in terms of the estimated uncertainty over an estimation grid. Additionally, different weights can be assigned to each monitoring site and to the analyzed variable(s) within the objective function in order to accomplish specific objectives without a significant loss of information. The final result represents a significant improvement to the original methodology by adjusting the spatial coverage of the optimal monitoring network to satisfy specific objectives.

Introduction

Groundwater is a vital resource for human beings; it provides 50% of the total water used worldwide (WWAP, 2016). This data shows the dependence of people on groundwater, mainly in regions with extensive cropping areas for food production and industrial activities (Li et al., 2015).

Considering the importance of groundwater, it is necessary to know, in detail, the spatial distribution of the groundwater flow systems and its physical-chemical characteristics to improve its management (Esquivel et al., 2015; Kim et al., 2007). It is relevant to assure sustainable levels of groundwater quality when it is used for water supply (Yang et al., 2018). The implementation of groundwater quality monitoring programs is of paramount importance; for instance, it was detected that in almost 15% of the monitoring stations in Europe, the standard for nitrates in drinking water established by the World Health Organization (WHO) was exceeded (WWAP, 2018). It is possible to characterize the groundwater quality in some areas of interest (AOI) by measuring some physical-chemical parameters of water extracted by wells and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1086110882

estimating the spatial distribution of their concentrations; however, the costs and time involved in visiting and sampling all the existing wells are often not economically viable; specially in low income countries.

The optimal design of groundwater monitoring networks is an alternative to reduce time and costs associated to the acquisition of data to accomplish specific objectives (Júnez-Ferreira et al., 2016a); in addition the development of a sustainable strategy for groundwater extraction management is required.

The methodologies for the optimal design of groundwater monitoring networks can be subdivided in three main groups: 1) those based on elements of hydrogeological conceptual models, 2) those that execute data analysis with statistical techniques, and 3) those that use groundwater flow numerical models (Júnez-Ferreira et al., 2016a; Loaiciga et al., 1992; Herrera and Pinder, 2005; Zhang et al., 2005). The latter can be considered as the most robust framework, since it does not only consider hydrogeological aspects (as group one) but also takes into consideration groundwater levels evolution (in space and time). It is important to note that some methodologies combine aspects of two or the three groups.

The hydrogeological framework usually uses a Geographic Information System (GIS) in order to incorporate as much areal information as possible of the hydrogeological factors that control the groundwater functioning such as geology, recharge and discharge zones, rainfall data, groundwater levels, land use/land cover images derived from satellites, among others (Singh and Katpatal, 2017; Zhou et al., 2013). The statistical-based methodologies usually employ a variance-based objective function evaluated by an optimization method, they are commonly based on spatial and/or spatiotemporal geostatistical techniques, entropy theory, harmonic series models and principal component analysis (Mirzaie-Nodoushan et al., 2017; Júnez-Ferreira et al., 2016b; Andricevic, 1990; Kim et al., 2007; Júnez-Ferreira and Herrera, 2013), some of them are multicriteria (Hosseini and Kerachian, 2017a, b). The combination of hydrogeological criteria through the use of GIS and statistical techniques has been used in (Baalousha, 2010; Uddameri and Andruss, 2014; Sizirici and Tansel, 2015; Júnez-Ferreira et al., 2016a; Alizadeh and Mahjouri, 2017). The methodologies based on a numerical flow model include optimization methods and are always combined with a GIS (Kim, 2015) or with statistical estimation methods such as the Kalman Filter (KF), Monte Carlo simulations (Herrera and Pinder, 2005; Zhang et al., 2005; Kollat et al., 2011; Luo et al., 2016; Jiang et al., 2018), or can have characteristics of the three groups of methodologies for the optimal design of groundwater monitoring networks (Nobre et al., 2007).

Most of these methodologies require a large amount of information about the study site that includes a comprehensive database of sampling campaigns, geological data, and an advanced understanding of flow systems.

In those areas with scarce data, it is necessary to implement methodologies to start with the data generation. In the literature, the KF or different types of kriging have been widely used as estimation methods for the design of optimal monitoring networks oriented to the reduction of the estimate error variance in areas with few hydrogeological data (Júnez-Ferreira et al., 2016a; Júnez-Ferreira and Herrera, 2013); however, the spatial distribution of the wells with higher priority selected by these methodologies preferably covers the central area of a pre-defined estimation grid, frequently assigning a lower priority to those wells located at the periphery of the study area. This is considered as a deficiency because a poor spatial coverage of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1086110882

monitoring network may lead to the undesirable extrapolation of the monitored variable(s) at those areas. In addition, a resilient monitoring network in regard to sampling station distribution, in practice could be easier to implement and to explain to stakeholders. The design of an optimal monitoring network results in an academic exercise not feasible to real-world limitations (data availability, budget), hence the implementation of alternative methodologies is advisable (Bode et al., 2018).

In Mexico there are 653 administrative aquifers, 105 of them have been classified with intensive abstraction resulting in negative environmental effects such as the ongoing deterioration of water quality (Esteller et al., 2011), sea water intrusion problems, presence of brackish water (CONAGUA, 2017), and high fluoride and arsenic concentrations in groundwater (Banning et al., 2012; Cardona et al., 2018). However, the natural evolution of the groundwater quality has not received the required attention as a tool for management planning.

Mexico and a number of countries around the world are involved in the Sustainable Development Goals (SDG) to address global challenges such as environmental (water) degradation. Specifically, goal 6: Clean Water and Sanitation, indicator 6.3.2: Proportion of water bodies with good water quality requires the implementation of groundwater monitoring networks to compile data for some core parameters at existing sampling stations (UN WATER).

The lack of properly designed wells for groundwater quality monitoring purposes makes necessary employing the available long screened production wells. The spatial distribution of these production wells depends on factors such as the location of irrigation lands and populated areas. Therefore, it is relevant for water management institutions to consider methodologies that contribute to the design of optimal groundwater monitoring networks, with water quality data obtained from production wells. This is an important issue for making decisions regarding groundwater sustainable development, not only in Mexico, but in several other countries around the world.

This paper proposes a methodology for the design of multivariable groundwater monitoring networks. The approach includes 1) irregular shape estimation grid according with the spatial sampling station distribution 2) a ponderation grid map based on sampling station density per unit area 3) the definition of an objective function that considers simultaneously, the ponderation grid map, priority determination for any water quality parameters included in the monitoring network and/or for sampling stations and a KF for the reduction of the estimate uncertainty for each variable provided by the selected sampling stations. The methodology allows obtaining alternative spatial distributions of the wells that provide the highest level of information, expressed in terms of the estimated uncertainty over an estimation grid.

Materials and methods

The methodology presented in this paper is based on that proposed in Júnez-Ferreira et al. (2016a); the original methodology selects the optimal monitoring positions by using spatial correlations expressed as covariance matrices derived from semivariogram models obtained through geostatistical analyses to data of groundwater quality parameters. The optimization of the monitoring network is carried out by successive inclusions employing the KF as the estimation method, minimizing a function called the joint total (JT) normalized variance of the estimation error (Júnez-Ferreira et al., 2016a).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1086110882

This methodology requires of a spatial estimation grid where the objective function is evaluated. During the optimization process, the addition of weights to the groundwater quality parameters, or different densities in the estimation grid have been useful to satisfy specific objectives, like assigning a higher priority to contaminated sites or to highly dangerous parameters (Júnez-Ferreira et al., 2016a; Esquivel et al., 2015).

For the proposed methodology, the objective function incorporates the spatial coverage of the available sampling stations (by means of a supplementary function, SF) besides a modified version of the joint total (JT) normalized variance of the estimation error. The modified JT, besides having a weight for each groundwater quality parameter includes a weight for each sampling station, this new algorithm is now called the weighted joint total normal variance of the estimation error (WJT). Both, the WJT and the SF are weighted in order to define different alternatives of the spatial coverage for the selected monitoring networks without a significant loss of information.

The objective function (OF) (*Eq. 1*) for the proposed methodology is:

$$OF = \mathrm{V} \times \mathrm{WJT} + W \times \mathrm{SF} \quad \text{(Eq.1)}$$

where V and W are the weigthing factors for the WJT and the SF, respectively; $V + W = 1$. Based in Júnez-Ferreira et al. (2016a) to obtain WJT, the KF is implemented through the use of $\hat{\mathrm{q}}^0$and P^0 that represent an initial state vector and the initial error covariance matrix, respectively. The KF process employs the following equations (*Eqs. 2, 3* and *4*):

$$\hat{\mathrm{q}}^{n+1} = \hat{\mathrm{q}}^n + \mathrm{K}_{n+1}(\mathrm{z}_{n+1} - \mathrm{H}_{n+1}\hat{\mathrm{q}}^n) \quad \text{(Eq.2)}$$

$$\mathrm{P}^{n+1} = \mathrm{P}^n - \mathrm{K}_{n+1}\mathrm{H}_{n+1}\mathrm{P}^n \quad \text{(Eq.3)}$$

$$\mathrm{K}_{n+1} = \mathrm{P}^n\mathrm{H}_{n+1}^{\mathrm{T}}(\mathrm{H}_{n+1}\mathrm{P}^n\mathrm{H}_{n+1}^{\mathrm{T}} + \mathrm{r}_{n+1}) \quad \text{(Eq.4)}$$

where K_{n+1} is the Kalman gain, H_{n+1} is the sampling matrix, z_{n+1} is the measurement vector, and r_{n+1} is the measurement error covariance. Superscripts refer to the number of measurements employed in the estimation; subscripts are used to indicate the transition when a new measurement is going to be used in the process.

The spatial covariance matrix for each parameter is calculated as follows (*Eq. 5*):

$$C(h) = C(0) - \gamma(h) \quad \text{(Eq.5)}$$

where $C(h)$ represent the covariance matrix, $C(0)$ is the variance for each analyzed parameter, and $\gamma(h)$ is the variogram model function.

The WJT value is calculated with (*Eq. 6*):

$$\mathrm{WJT} = \sum_{p=1}^{np} \sigma_{w,p}^2 \times \alpha_w \times \alpha_p \quad \text{(Eq.6)}$$

where $\sigma_{\mathrm{w,p}}^2$ represents the normalized estimate error variance (located at the principal diagonal of the corresponding updated covariance matrix) at each estimation position

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1086110882

for the p parameter, when the w well has been sampled, α_w represents the w well weight, α_p represents the p parameter weight, and np is the number of parameters.

The main advantages of this proposal are: a) it considers the possibility of obtaining alternative monitoring networks designs oriented to a desired spatial coverage b) it allows the assignation of different weights to a particular sampling point, which gives the opportunity to take into account specific hydrogeological conditions such as contaminated areas without affecting, within the optimization procedure, those wells located around this specific sampling point.

Custom estimation grid

As part of the proposed methodology, it has been developed an algorithm for the generation of a custom estimation grid (CEG). The KF estimates will be obtained and the OF evaluated at the CEG; it offers advantages when compared to a regular grid as implemented in commercial software such as XTools Pro 18 (XTools Pro), create fishnet (ArcGIS) and sampling design tool (Buja, 2012) because it avoids extrapolation areas since it is an adjusted envelope of the sampling points.

The definition of the CEG starts with the calculation of the distance between the extreme coordinates of the wells (maximum distance), followed by the calculation of the grid density with half the maximum distance divided by ten; this density (separation between the grid nodes) is selected to draw a rectangular grid that covers all the area where the wells with available data are located, an initial value of 0 is set to all these nodes. The CEG will be composed by values different than 0, the following procedure is carried out from the top (North) to the bottom (South) row of the original rectangular grid to the assignation of these values:

1. Values of 1 are assigned to the nodes that are next to the wells.
2. For each row it is given a value of 2 to the nodes that are between those with a value of 1.
3. A value of 3 is assigned to the nodes in empty rows to connect the nodes with values different to 0.
4. Values of 4 will be assigned to the nodes with an original value of 0 in such a manner that each row of the CEG cannot be longer one node to the West and one node to the East than the next row at the south.

The flowchart and pseudocode for this process are shown in *Figure 1*.

The colours in *Figure 2* are directly related to the value that indicates in which part of the algorithm the node for the CEG was selected.

Supplementary function

For the case study, the SF is proposed trying to establish a higher priority to those wells that have influence over the highest number of nodes of the estimation grid, and at the same time, with small influence of the other wells on their estimates (i.e., there is a poor spatial coverage of wells at that area). For that purpose, it is necessary to define a Custom Smooth Grid (CSG) based on the CEG and the maximum range used in the semivariogram models. For each node of the CEG, it is calculated the sum of wells located at a distance less than the model range, obtaining the values of the CSG (*Fig. 3*).

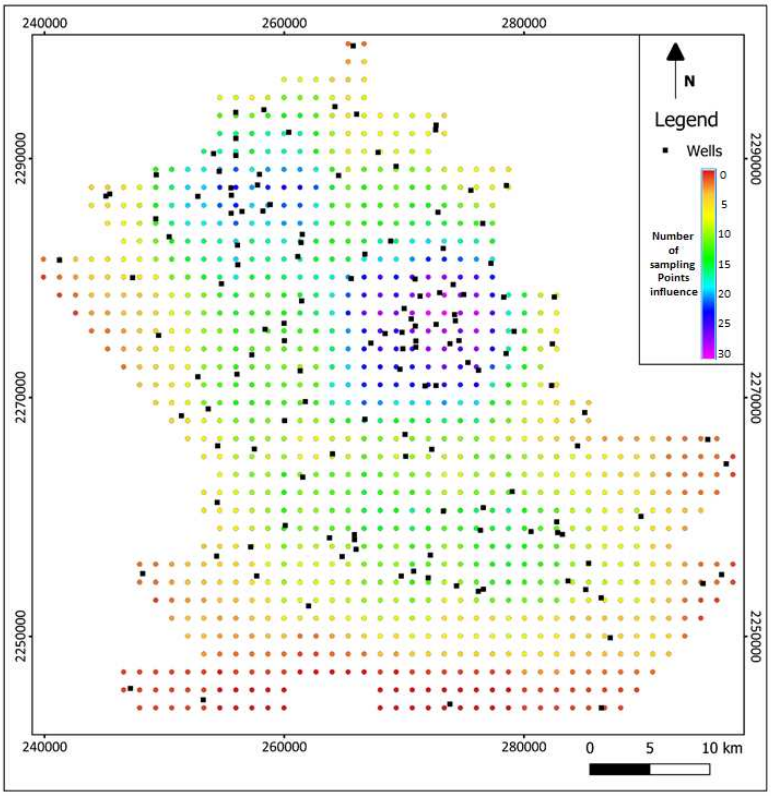

Figure 3. *Custom Smooth Grid (CSG)*

The SF is defined as follows:
The lower values in the CSG represent zones with a poor spatial coverage of wells.
The formulas for the values of the CSG are (*Eq. 7*):

$$ie_{w,p} = \sum_{n=1}^{nn} node_n \quad \text{(Eq.7)}$$

where $ie_{w,p}$ represents the influence of the well w over the nodes of the CEG, corresponding to the p parameter, $node_n$ is 1 when the node is inside a circumference with center on the w well and radius equal to the range of the semivariogram model in the p parameter; $node_n$ is 0 when the node is outside the circumference, nn is the total number of nodes in the CEG (*Eq. 8*);

$$iw_{n,p} = \sum_{w=1}^{nw} well_w \quad \text{(Eq.8)}$$

where $iw_{n,p}$ represents the influence of the sampling wells over the node n, corresponding to the p parameter, $well_w$ is 1 when the well is inside a circumference with center on the n node and radius equal to the range of the semivariogram model in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1086110882

the p parameter, $well_w$ is 0 when the well is outside that circumference, nw is the total number of sampling wells (*Eq. 9*);

$$inw_{w,p} = \sum_{n=1}^{nn} (iw_{n,p} \times r_{n,p}) \quad \text{(Eq.9)}$$

where $inw_{w,p}$ represents the influence of the sampling wells over circular zones of the CEG, $r_{n,p}$ is 1 when the node is inside a circumference with center on the w well and radius equal to the range of the semivariogram model in the p parameter, $r_{n,p}$ is 0 when the node is outside the circumference (*Eq. 10*);

$$f_{w,p} = \frac{\alpha_w}{ie_{w,p} \times inw_{w,p}} \quad \text{(Eq.10)}$$

where $f_{w,p}$ represents the w well factor for the p parameter (*Eq. 11*);

$$ff_w = \sum_{p=1}^{np} f_{w,p}\alpha_p \quad \text{(Eq.11)}$$

where ff_w represents the w well final factor, np represents the total number of parameters considered in the network design.

In the case study, it is proposed that $SF = ff_w$.

Results

Case study: hydrogeological setting

In order to evaluate the performance of the proposed methodology, it was applied for the design of a monitoring network in the "El Bajío" Region of Central Mexico (*Fig. 4*). The Bajío Region, specifically the Irapuato-Valle aquifer has become recently a focus of attention due to the intensive water extraction regime for agricultural, population, and industrial use. Groundwater extraction (about 600 × 10^6 m^3/year) through more than 2900 production wells in the area supports the water supply for more than 900,000 inhabitants in urban and rural areas, the irrigation of approximately 60,000 hectares and the water consumption for a refinery, a power production plant and several industrial parks (Comisión Nacional del Agua, 2015; Esteller et al., 2011; Gómez and Sandoval, 2004). The rock units in the study area include a sequence of Mesozoic plutonic and vulcano-sedimentary rocks affected by several metamorphism stages and Tertiary intrusive rocks outcropping in the Sierra de Guanajuato located at the North of the study area that constitutes the hydrogeological basement. The Tertiary sequence include volcanic (ignimbrites, lava flow and tuffs) and continental sedimentary rocks (conglomerates and basin fill sediments). The Oligocene volcanic sequence is comprised of andesite and rhyolite; the overlying Miocene and Pliocene volcanic rocks are mainly andesite and basalt associated with the Mexican Neo-volcanic Belt (Nieto-samaniego et al., 2012). From the Oligocene, the Sierra de Guanajuato underwent a rapid uplift, the main geologic structures are NW-SE trending normal faults, displacing

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1086110882

more than 500 m the Oligocene volcanic sequence (Gómez et al., 1989; Nieto-samaniego, 1990). During this stage of deformation, several faults were reactivated, the N-S (Taxco-San Miguel de Allende fault) and NE-SW trending directions, together with the "El Bajío" Fault with NW-SE trend, formed half grabens, leading the formation of the "El Bajío" region (Botero-santa et al., 2015). At the same time, the erosion from the mountains led to transfer clastic material to the graben structure. The deposition of basin fill sediments in the graben structure produced a granular permeable regionally unconfined aquifer with a maximum thickness of 350 -400 m. Basin fill sediments are inter-bedded poorly consolidated fluvio-lacustrine sediments, including sands, inter-bedded sandy-clay and silts. From pumping test data, typical hydraulic conductivity values for that aquifer are 1 to 10 m/day (Júnez-Ferreira et al., 2016a). The Tertiary volcanic rocks are cut by a set of NW-SE and N-S normal faults, creating the possibility of a fractured heterogeneous aquifer (200-300 m thickness). The basaltic Pliocene rocks outcropping in the southern portion of the study area are in contact with the basin fill sediments, they confirm an unconfined aquifer with hydraulic conductivity values from 6 to 18 m/day (Júnez-Ferreira et al., 2016a). The Oligocene and Miocene volcanic rocks below the basin-fill sediments can also constitute a deep aquifer, fractured conditions along the NW-SE trending structures have been identified in deep wells (600-700 m deep) producing thermal groundwater (well-head temperature 35-45 °C).

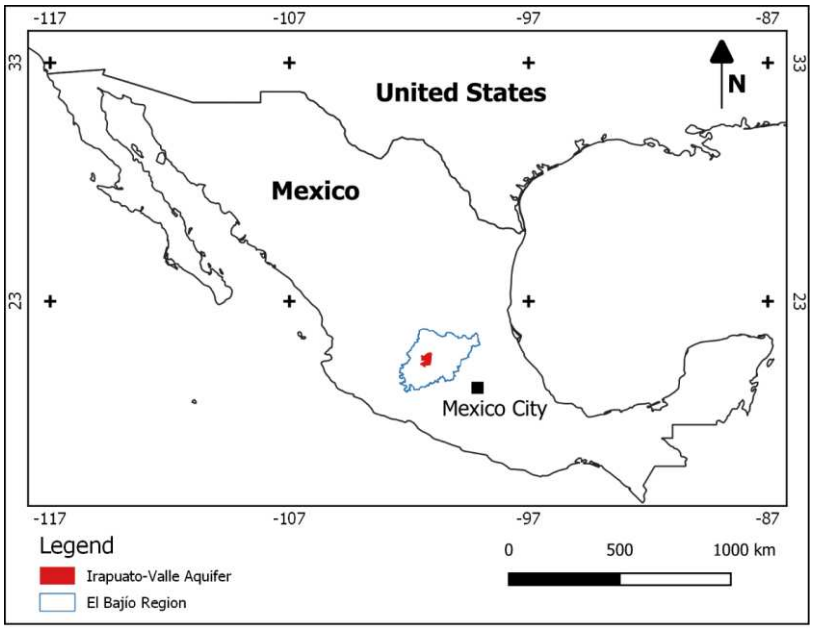

Figure 4. *Location map of the study area. (Sources: Simplified El Bajío Region map modified Suárez-mota and Villase, 2015; Irapuato-Valle Aquifer from National Water Information System, 2019; countries boundaries from Tapiquén, 2019)*

A sampling campaign for groundwater quality determination was carried out in December 2003 for laboratory measurement of 20 physicochemical parameters and in situ measurements of six field parameters (Júnez-Ferreira et al., 2016a), a total of 140 water samples were taken in production wells from the study area. A map displaying the sampled wells is presented in *Figure 2* (UTM coordinates datum WGS84, Zone 14N). Wells ranging from 46 to 700 m deep (mean 180 m, standard deviation 115 m), most of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1086110882

them screened along the saturated length of the well, promoting intra-well artificial mixing. This implies that sampled water represents a mixture of several water-bearing layers. It was identified that water in recharge areas is HCO_3-Ca dominant type (650 mg/L of total dissolved solids in average). Along the groundwater flow, water chemistry evolves to dominant HCO_3-Mix and HCO_3-Na. Groundwater quality analysis indicates the contribution of geogenic and anthropogenic contamination sources. The volcanic rocks, especially those of rhyolitic composition and the basin fill sediments derived from them, are potential trace element sources specifically for Arsenic. The water samples were analyzed for arsenic composition (mean 0.011 mg/L, max. 0.083 mg/L), 35% of the samples exhibit concentrations in excess of the WHO guideline value (0.010 mg/L) (*Fig. 5a*). Dissolved arsenic is usually found as arsenic (III) in reducing environments, which usually develops at some depth within aquifers, while near the water table oxic condition prevails (Appelo and Postma, 2005). There is a lack of vertical water quality profiles information in wells, for this reason it is not possible to demonstrate the existence of any vertical transition between oxic and anoxic conditions in the tapped aquifer. However, aerobic and oxic conditions (dissolved oxygen above 1 mg/L, Eh values above 100 mV) were detected in all the groundwater samples, suggesting that oxic conditions should prevail in most of the water bearing geologic formations tapped by the production wells. Considering that the sample depth could be assigned to mid-well screen depth, no correlation between sample depth and arsenic values was identified ($R^2 = 0.07$), indicating that dissolved arsenic is not explained by desorption from Fe-(hydr)oxide minerals in reducing conditions (*Fig. 5b*). Most of the high arsenic water samples are associated with HCO_3-Na dominant type, indicating that leaching from volcanic rocks with rhyolitic composition is a major control. Evidence from north-central Mexico suggests that dissolution of volcanic glass of felsic composition seems to be the dominant process for arsenic release into groundwater (Banning et al., 2012); the concentration in the central and northwest region of the study area seem to be derived from this source. The basin fill sediment constitutes an additional source; arsenic values above the WHO drinking water standard in the southwest region of the study area are probably derived from the basin fill sediments. Decarbonatization of basin-fill sediments could constitute an additional process for arsenic mobilization (Banning et al., 2012). The identification of groundwater impacted from anthropogenic sources, considered water types such as Cl-Mg, Mixed-Ca, Mixed-Na, and SO_4-Mixed; they exemplify impacted groundwater by diffuse contamination. Impact of diffuse contamination produced by irrigation can be evaluated with a combination of indicators, such as chloride, sulphate, nitrate, phosphate among others (Cardona et al., 2008). Chloride is a conservative solute; it is useful to detect the infiltration of diffuse contamination from agricultural activities. In addition, electrical conductivity is a function of the total concentration and charge of the ions; the relationship between them is approximately linear in most of the cases. The relation between chloride and electrical conductivity for water samples from the study area is shown in *Figure 6*. The characteristics of the local surface water and wastewater are presented as an additional reference. Despite the scatter, there is an evident general trend for most of the samples, suggesting that infiltration of wastewater modify to some extent groundwater composition. A few samples are not following the general trend, especially high electrical conductivity values with low chloride values; for these samples high alkalinity values (> 500 mg/L $CaCO_3$) linked with low nitrate

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1086110882

concentration (about 4-5 mg/L N-NO_3), suggest a limited influence of irrigation return flow or wastewater infiltration.

From the above considerations, the methodology proposed in this paper was applied for the design of an optimal groundwater quality monitoring network oriented to characterize the spatial distribution within the study area of only three parameters of the database presented in Júnez-Ferreira et al. (2016a): arsenic, chloride and electrical conductivity. Six cases were analyzed: 1) $V = 1$ and $W = 0$ within the OF ("100 – 0"), 2) $V = 99.999$ and $W = 0.001$ ("99.999 – 0.001"), 3) $V = 99.995$ and $W = 0.005$ ("99.995 – 0.005"), 4) $V = 99.99$ and $W = 0.01$ ("99.99 – 0.01"), 5) $V = 0.5$ and $W = 0.5$ ("50 – 50") and 6) $V = 0$ and $W = 1$, but in this case the optimization procedure is applied in such a manner that the highest priority in wells is assigned to the highest estimate error variance ("Worst" case). For the six cases $\alpha_w = \alpha_p = 1$.

Geostatistical analyses

As a result of the geostatistical analyses carried out to the selected groundwater quality parameters, semivariogram models for each parameter were obtained (*Table 1*). With these models, covariance matrices were derived and normalized for each parameter and used in the optimization process, using the CEG and the CSG values.

Table 1. *Semivariogram models used for the generation of the groundwater monitoring network*

Parameter	Model	Nugget (u^2)*	Sill (u^2)*	Range (m)
Electrical conductivity	Spherical	0	125097	6792
Arsenic	Spherical	$6.5x10^{-5}$	0.000142	4685
Chloride	Spherical	60.98	1490	6515

*u in (mg/L) for arsenic and chloride, in (μmhos/cm) for electrical conductivity

Discussion

The methodology proposed by Júnez-Ferreira et al. (2016a) considered the selection of sampling points by choosing the well positions that minimize the estimate error variance of the selected indicator parameters with the option to include priority zones according to the groundwater quality data. The optimization process is supported by a Kalman filter to calculate WJT. The comparison between Júnez-Ferreira et al. (2016a) and the methodology proposed in this paper was carried out for various weighted values of the Kalman filter and the ponderation map proposed also in this new methodology. For the first case (100 – 0), the 100 indicates the percentage used for the calculations of the WJT with the Kalman filter and 0 the percentage of the SF; meaning that this is the equivalent of the Júnez-Ferreira et al. (2016a) methodology.

Figure 7 shows the percentage of reduction of the initial WJT that is obtained on the CEG each time a new well is added to the monitoring network for the six analyzed cases. The fastest reduction in the WJT is, as expected, produced for case "100 – 0", on the other hand, the lowest reduction corresponds to what we called the "Worst" case. The introduction of non-zero values to the SF produces a slower reduction in the WJT compared to the "100 – 0", it can be shown that assigning the same weight to both functions of the OF ("50 – 50") results in a reduction of the WJT that is found approximately in the middle of the "100 – 0" and the "Worst" cases. Assigning a very small weight to the SF produces almost the same estimates than in the optimal case in terms of the estimate uncertainty value ("100 – 0"); however, a different set of wells is now selected.

Figure 8a shows that for the "100 – 0" case, the first 10 positions are selected mainly at the central part of the cloud of the sampling stations, when the optimal monitoring network includes 30 positions; it extends to cover a larger area of the cloud of available sampling stations. However, it does not include positions in the periphery. An optimal monitoring network with 50 positions reaches some of the peripheral sampling positions with a high density at the central zone of the cloud.

Even though a priority order was assigned to all the monitoring wells, only those with the highest priority will be monitored in an optimal scheme since they achieve the highest reduction in the estimation grid uncertainty. In order to compare the set of wells selected for cases "100 – 0", "99.999 – 0.001", "99.995 – 0.005", "99.99 – 0.01", and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1086110882

"50 – 50", an analysis of *Figure 8* was done, where 10, 30 and 50 wells comprise the selected monitoring networks for each case. The resulting monitoring network for the "worst" case is not analyzed further; their WJT values were only used as a reference in *Figure 7,* to visualize how close the different cases are to the best and worst possible estimation scenarios.

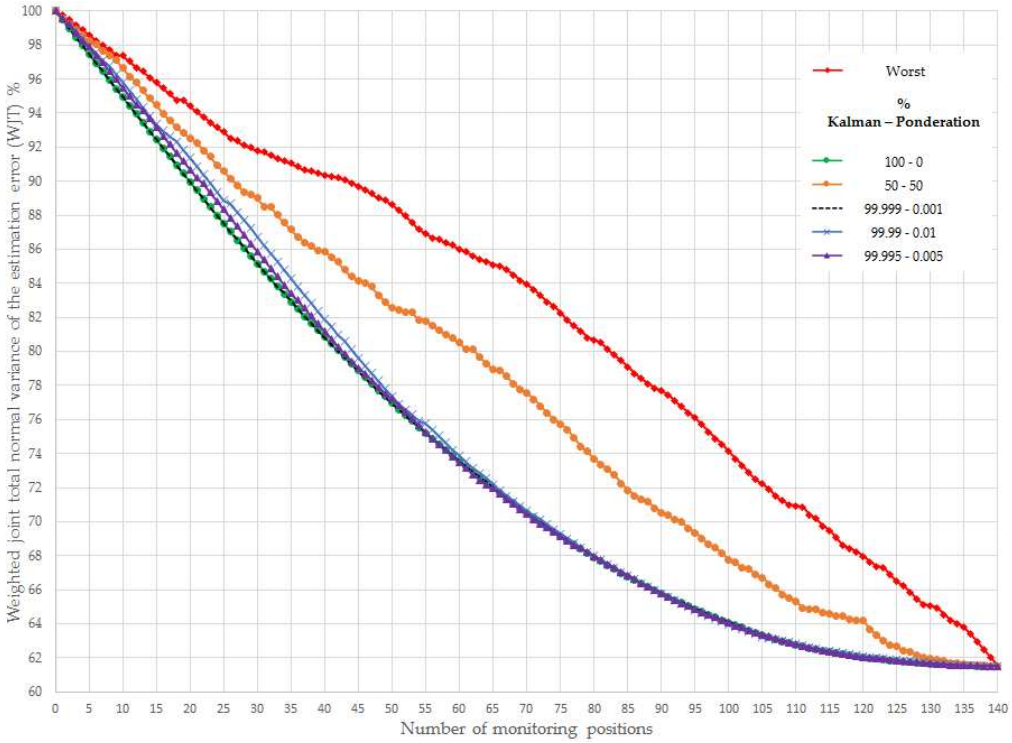

Figure 7. *Comparison of the WJT (%) vs number of monitoring positions*

When analyzing the "99.999 – 0.001" case (*Fig. 8b*), the first 10 positions are slightly biased to the south, including some of the peripheral wells. When 30 positions are selected, the wells are more homogeneously distributed within the cloud of points, but unlike the "100 – 0" case, the peripheral well with a priority value of 27 is included. With 50 positions, the same spatial coverage than the "100 – 0" case is virtually obtained.

For the "99.995 – 0.005" case shown in *Figure 8c,* the first 10 positions are notoriously biased to the extreme Southern part; only the position with a priority value of 9 is located at the Northwest. For 30 positions, the distribution is considerably better, with small areas uncovered at the central part. Finally, with 50 positions, the spatial coverage is better than in cases "100 – 0", "99.999 – 0.001", considering various wells at the Western periphery. The increase in the WJT value when selecting 50 wells for the "99.995 – 0.005" and the "100 – 0" cases is of 0.25%, this means that the loss of information is minimum for this alternative.

In *Figure 8d* it can be shown that for the "99.99 – 0.01" case, the first 10 and 30 selected positions are more biased to the south compared to the previously analyzed cases. When 50 positions are included in the monitoring network, the coverage is very similar to *Figure 8c;* however, the WJT value has increased in 0.40% with respect to the "100 – 0" case.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1086110882

The "50 – 50" case (*Fig. 8e*), is clearly biased to the selection of wells along the Southern periphery when 10 positions are included in the monitoring network. The selection of 30 wells now includes the Western periphery and one well is selected at the North. When 50 positions are selected, the monitoring networks is denser at those peripheral zones, leaving the central part of the cloud uncovered.

Conclusions

Various methodologies for the design of optimal groundwater monitoring networks are based on the reduction of the estimated error variance of the variable(s) involved in the design; these estimates are obtained over an estimation grid. In most cases, the shape of the estimation grid is square or rectangular; therefore, at poorly sampled peripheral areas, the estimates are extrapolations. On the other hand, these methodologies are biased to assign a higher priority to those wells that have more influence over a larger number of nodes of the estimation grid, thus assigning a low priority to those wells closer to the periphery of the estimation grid (Júnez-Ferreira et al., 2016a).

When the design is oriented to reduce the estimated error variance only, without assigning specific weights to the nodes of the estimation grid, the monitoring network could fail in covering some pre-defined priority zones or wells with valuable information. Therefore, it is necessary to evaluate alternative designs to consider those areas or sites of interest, minimizing the loss of information when estimating with the selected optimal monitoring network.

The proposed methodology includes a new algorithm for the definition of the estimation grid that takes into account the shape of the cloud of available sampling positions, trying to avoid extrapolation. The inclusion of a supplementary function in the optimization procedure allows the monitoring design to achieve a better spatial coverage, especially at the periphery of the estimation grid, without having a significant loss of information. The objective function considers also the assignment of weights to the wells; this aspect is important when some of them have been previously identified as relevant.

Through this methodology, it is possible to analyze alternative designs in which the spatial coverage of the monitoring networks changes, but its estimates are close to the optimal in terms of the estimate error variances.

Geochemistry evolution, along with groundwater flow in thick heterogeneous aquifers can be interpreted by specific methodologies; hydrogeochemistry is useful to solve questions of origin and attenuation of geogenic and anthropogenic contaminants. The proposed methodology considers statistical techniques to analyze the spatial distribution of specific water quality parameters as a result of sampling campaigns. In this regard, the understanding of groundwater chemical evolution and/or impacts of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1086110882

diffuse contamination with the monitoring network is beyond of the scope of the proposed methodology. This methodology is useful for the selection of the most convenient set of sampling stations in selected areas from a number of alternatives, it was specifically oriented for the implementation of drinking water monitoring networks. Once the monitoring network is designed, the collected data will include information from the whole selected area, data redundancy will be avoided and WTJ customized accordingly for example with financial resources and/or available time. The implementation of this methodology should facilitate to decision makers the classification of water quality in aquifers.

(Received 22nd Mar 2019; accepted 13th Jun 2019)

Abstract. This study aims to detect the factors which are effective on the adoption and the implementation of the agricultural innovations by the farmers who are focused on the beekeeping in the Milas district Muğla province of Turkey. For this aim, a questionnaire is made with 62 farmers who are determined with the method of proportional sampling. The method of Logistic Regression Analysis is used with the aim of the determination of the factors which are effective on the implementation of the innovations related to the beekeeping by farmers. According to the results of the analysis, it is determined that young farmers, farmers who have problems related to production, who are members of cooperative and who do not store the honey implement the agricultural innovations which are related to beekeeping more.
Keywords: *beekeeping, agricultural extension, innovators, adoption, farmers*

Introduction

The growing population in the world increases the demand for foodstuffs. No doubt, this situation creates a pressure on ecosystem. As it is not easy to increase the areas of agricultural production, it will be possible to meet the demand for foodstuffs by increasing the fertilization of agricultural production. The most important way of increasing agricultural fertilization is to develop modern agriculture technologies and agricultural innovations. As it known, agriculture is the most important source of income and livelihood for people who live in rural areas. For this reason, to be able to increase the fertilization, it is quite important to reach the developed technologies and agricultural innovations to the rural areas.

Rogers (1976) defines innovation as an idea, implementation or an object which is approved as new by an individual or a respective department. So, everything which the individual perceives for the first time has the characteristics of being new for that individual (Özçatalbaş and Gürgen, 1998). Some characteristics of innovations affect their adoption. General characteristics of innovations can be classified in five groups. These groups are; usefulness, suitability, simplicity, trialability and observability (Cinemre and Demiryürek, 2005).

Innovations are accepted as critical for socio-economic development as they contribute to the growth in industry, trade and economy in every society. Innovation contributes to the fertilization, productivity, quality and competitiveness (Mutsvangwa-Sammiea et al., 2018). The adoption of agricultural innovations is an important factor to increase

agricultural fertilization, ensure food security, provide comprehensive growth and reduce poverty (Gebremariama and Tesfaye, 2018). The adoption of new technologies in terms of input and agricultural implementations has vital importance for the growth of agricultural sector. Together with the adoption of new technologies, the fertilization of land and labour force increases, natural sources are used effectively (Peter et al., 2018).

The time between the introduction of an innovation and the implementation of it is called "adoption process". Generally, the adoption of innovations takes time. It is detected that the adoption of innovations is not an instantaneous behaviour or act but a process which involves a series of acts and requires a specific time period. For example, the plantation of a new kind of a seed or the purchase and the use of a new drug when they are found out for the first time cannot be expected. Time is needed for this and this process sometimes lasts quite long (Cinemre and Demiryürek, 2005). All the individuals of rural population do not accept an innovation simultaneously. A part of the society becomes more eager in accepting and can adopt it years later when compared to the others (Özkaya, 1996).

One of the ways of minimizing the costs in businesses is to use new technologies which are effective on the cost. The implementation of technology in the businesses of husbandry hinges upon the degree of adoption of these innovations by the society in which these businesses take place (Türkyılmaz et al., 2003). The adoption and the propagation of innovations is a subject about which there are so many intensive debates and which does not lose its currency not only in agricultural area but also in branches such as health, marketing, business management, communication, sociology and geography (Aktaş, 2005).

Innovations in agricultural extension are new or improved inputs or methods which are handled in the process of agricultural production in an attempt to create behavioural change over farmers and obtain the desired result. The generalization of an innovation and making it be used by so many farmers can be possible by carrying out various agricultural extension activities effectively and within a long time period.

Agricultural innovation is not just a matter of adopting new technologies. It also necessitates a balance between the new techniques and alternative organization types (Klerks et al., 2012). It is accepted that the decision of adopting innovations is correlated with the social, economical and psychological characteristics of potential adopters. In adopting the innovations, not only the characteristics of the individuals but also the characteristics of the innovation are important (Longo, 1990). Adopting agricultural technologies is a complicated process because of the multidimensional nature of the technologies and mutual relations between the different explanatory factors (Jensen et al., 2014). The characteristics of the farmer and the agricultural enterprise, bio-physical characteristics of the agricultural enterprise, financial and administrative characteristics of the agricultural enterprise and the other factors occurring out of the farmers are effective on the decision of adopting new technology (Yigezu et al., 2018). When the litterateur is examined, it is seen that a great number of factors are effective on the adoption of the innovations by farmers.

Beekeeping is not seen as a source of side income for agricultural businesses any more rather it is seen as a main income source. Turkey occupies the first places in the world in terms of both the bee possession and the production of bee products. According to the 2018 data, the number of the beekeeping businesses in Turkey is 81.300 and the number of hives is 8.108.424. In 2018, the total amount of honey produced is 107.920 tons and the total amount of beeswax is 3.987 tons (TÜİK, 2018).

DOI: http://dx.doi.org/10.15666/aeer/1705_1088310897

The aim of this study is to determine the implementation circumstances of innovations by farmers who are focused on beekeeping in the Milas district. In this context, the factors which are effective on the decisions of the farmers in terms of implementing innovations will be detected by examining the circumstances of following and implementing the innovations by farmers.

Materials and Methods

The primary material of the study composes of 62 questionnaires which are made with the farmers in 9 villages in the Milas district in Muğla province. Moreover, the previous research on the subject has been capitalized on to a great extent. The questionnaires were administered in April-May 2017.

In this study, purposive sampling method is used in choosing the villages with which the questionnaire is made. The study of questionnaire is made in 9 villages composing of Karahayıt, Sakarkaya, Akçalı, Çukurköy, Gölyaka, Kapıkırı, Fesleğen, Kalem and Karacahisar in which beekeeping is performed intensively in the Milas district Muğla province of Turkey (*Figure 1*).

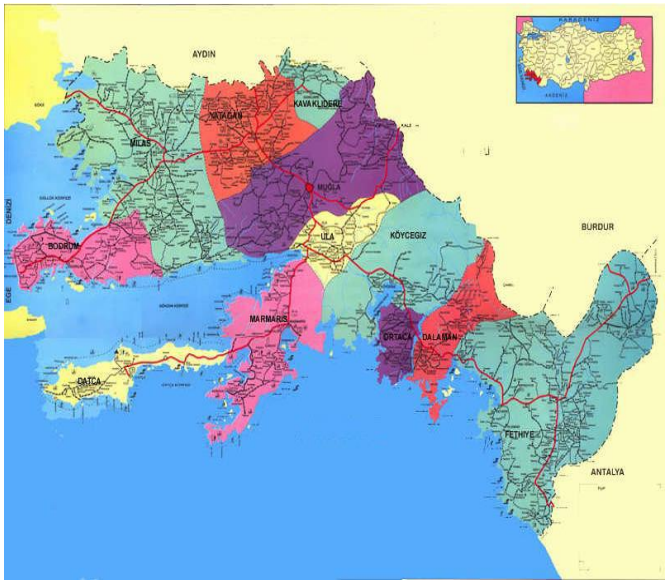

Figure 1. *Map of Muğla Province (Source: Anonymous, 2004)*

According to the information taken from Milas Agriculture and Forestry District Directorate, 721 farmers perform beekeeping activities in the district and these 721 farmers constitute the main population of the study (Anonymous, 2017). In the research, farmers who are determined with the proportional sample size are interviewed (Newbold, 1995). 90% confidence interval and 10% error margin are grounded on in the research. In *Equation 1*; n is the sample size, N is the population size, p is the ratio of the studied feature in the main population (the ratio of the beekeepers who implement innovations is accepted as 50% as it is desired to reach the maximum sample size and p=0.5 is taken).

$$n = \frac{Np(1-p)}{(N-1)\sigma_P^2 + p(1-p)} \qquad \text{(Eq.1)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1088310897

According to the calculation, the total number of the farmers who are to be interviewed is calculated as 62. The range of the applied questionnaires according to the districts is given on *Table 1*.

Table 1. *Villagers with whom the questionnaire is made in the scope of the research*

TOTAL	62

Logistic regression analysis method is used in the research with the aim of determining the factors which are effective on the circumstances of adopting the innovations by farmers. The aim of the model is to create the most suitable model by also paying regard to the level of the relation between the dependent variable and the independent variable or variables when the dependent variable (Y) is bivalent or classified (Önder and Cebeci, 2002). Logistic regression is a method from which is benefited in detecting the cause and effect relation with explanatory variable when categorically; the response variable is observed in dual, trio and multiple categories. It is a regression method which helps perform the classification and appointment transactions in which the expected value of response variable is obtained as probability in accordance with the explanatory variables (Everest, 2015).

Logistic regression does not deal with estimating the value of dependent variable. Instead of this, the probability of taking the value of 1 of dependent variable is tried to be estimated. As the obtained result is a value of a probability, it can only take values between 0 and 1 (Alpar, 2011). The model of logistic regression estimates the result as any value between 0 and 1 and tries to detect the probability of being 1 of dependent variable (Hosmer and Lemeshow, 2000). The logistic regression model used in the study is given in the *Equation 2*.

$$\pi(x) = P(Y = 1 / X = x) = \frac{e^{\beta_0+\beta_1X_1+\beta_2X_2+...+\beta_pX_p}}{1+e^{\beta_0+\beta_1X_1+\beta_2X_2+...+\beta_pX_p}} = \frac{1}{1+e^{-(\beta_0+\beta_1X_1+\beta_2X_2+...+\beta_pX_p)}} \qquad \text{(Eq.2)}$$

where X: is the data matrix in relation to the independent variable and X = x is (when the value of X is known) the probability of the occurrence of the event (Y = 1) π. β = refers to constant, βi = refers to the to be estimated parameter for every explanatory (independent) variable, Xi = refers to the i^{th} independent variable. Logit conversion is applied to the logistic regression function which is given in the equilibrium and is not linear and it is linearized. When the model is fixed according to the datas of the study, *Equation 3* is formed. Accordingly, b1 shows how much alteration 1 unit alteration in independent variable x causes in dependent variable (Aldrich and Nelson, 1984).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1088310897

$$g(x) = In\left[\frac{\pi(x)}{(1-\pi(x))}\right] = Ine^{\beta_0+\beta_1 X} = \beta_0 + \beta_1 X ... \quad \text{(Eq.3)}$$

In the research, a model which can identify the relation between the dependent and independent variables by using the least variables to have the best accord and which can be accepted as true statistically is established (Ertan and Gök, 2012). The farmers who implement the innovations related to beekeeping are coded as 1 and the farmers who do not implement the innovations are coded as 0. The functional form of the regression model estimating the factors which are effective on the adoption of the agricultural innovations by beekeepers is as in the following.

Y = f (X1, X2, X3, X4, X5, X6, X7, X8, X9, X10, X11, X12, X13)

Y; The circumstance of implementing the agricultural innovations yes; 1, no; 0 (Dummy).
X1; The age of the business manager.
X2; Educational level of the business manager.
X3; Beekeeping experience of the business manager.
X4; The amount of honey production.
X5; The circumstance of the business managers to get a loan yes; 1, no; 0 (Dummy).
X6; The circumstance of record keeping of the business yes; 1, no; 0 (Dummy).
X7; The circumstance of the business managers to have the information about the domestic market yes; 1, no; 0 (Dummy).
X8; The circumstance of the business managers to have the information about the foreign market yes; 1, no; 0 (Dummy).
X9; The circumstance of the business managers to have a problem about the production of bee products yes; 1, no; 0 (Dummy).
X10; The circumstance of the business managers to have a problem about the marketing of bee products yes; 1, no; 0 (Dummy).
X11; The circumstance of the business managers to be a member of the cooperative yes; 1, no; 0 (Dummy).
X12; The storage circumstance of the produced honey yes; 1, no; 0 (Dummy).
X13; The circumstance of participation in agriculture fairs yes; 1, no; 0 (Dummy).

Results

Socio-economical characteristics of beekeepers

The socio-economical characteristics of the farmers have important effects on their adoption of the innovations. Therefore, socio-economical characteristics of the beekeepers are examined. The ages, time periods of agricultural experience, time periods of beekeeping experience, education levels of the beekeepers, the number of hives and the sources of income take place among the socio-economical characteristics which are examined in the research.

It is detected that 41.94% of the producers are older than 51, 50% of the producers are at the age of 35-50 and 8.06% are younger than 35. As it is seen from these results, half of the beekeepers are at the age range of 35-50. The age average of the beekeepers is found as 48. It is seen that 61.29% of the beekeepers have the experience of agriculture for more than 21 years. It is detected that 12.90% of the beekeepers deal with the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1088310897

agricultural production for less than 10 years, 25.81% of the beekeepers deal with the agricultural production for 10-20 years. It is seen that 45.16% of beekeepers have had the experience about beekeeping for more than 21 years. It is detected that 32.26% of beekeepers perform beekeeping for less than 10 years and 22.58% of beekeepers perform beekeeping for 10-20 years. It can be stated that the level of education can be effective on the information sources that the farmers who perform beekeeping use. According to the datas of the questionnaire, it can be said that the majority of the beekeepers are the graduates of primary school (80.65%). 14.52% of the beekeepers are the graduates of secondary/high school and one beekeeper is the graduate of college. It is detected that 33.87% of the beekeepers have less than 100 hives, 40.32% of beekeepers have 100-200 hives and 25.81% of beekeepers have more than 201 hives. It is seen that 74.19% of the beekeepers earn their lives only with agriculture and 25.81% of the beekeepers, together with agriculture, deal with some other job activities out of agriculture (*Table 2*).

The information needs and the information sources of farmers about beekeeping

Rogers states that innovations are adopted at five stages (Rogers, 1983). These stages are: awareness, interest, evaluation, trial and adoption. Farmers need information quite intensively especially at the stages of awareness and interest. Therefore, it is vital that the needs for the information should be detected for farmers to decide about innovation and these needs should be met, the information should be provided truly and on time for the farmers to adopt the agricultural innovations.

In the current study, it was found that the beekeepers are in need of information about various subjects related to beekeeping. It was determined that 79% of the farmers who took place in the research need information about beekeeping. The major need for information is about disease and pest control. 64.5% of the farmers need information

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1088310897

about disease and pest control. 32.3% of the farmers need information about marketing and 27.4% of the farmers need information about bee production (*Table 3*).

Table 3. *The subjects that the farmers need information about beekeeping*

Information sources play an important role over getting into touch with new technologies, being aware of the information, creating an interest, making understanding easy and encouraging farmers to adopt (Pandey, 2014). In the study, it was determined that the beekeepers obtain information from different sources. In the research, Agriculture and Forestry District Directorate comes first as an information source of the farmers (38.7%). 37.1% of the farmers consult to the union of beekeepers and 24.2% of the farmers consult to their friends and relatives (*Table 4*).

Table 4. *Information sources of the farmers*

The points of view of farmers towards agricultural extension

Innovativeness which is an adoption and implementation of an idea in a society for the first time is really important for the extension of the innovations. The aim in agricultural extension is to increase the number of innovators (Cinemre and Demiryürek, 2005). For this reason, the determination of the points of view of the farmers towards agricultural extension/extensionists is quite important as the agricultural extension/extensionists play an important role in the access and the implementation of innovations by farmers. Because the more powerful is the relation between the farmer and extensionist, the more high is the possibility of adopting the innovations by farmers. In the study, it was found that the beekeepers are not much in contact with extensionists. While 22.6% of farmers state that they do not get into touch with the extensionists, 53.2% of the farmers state that

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1088310897

they get into touch with the extensionists twice a year (*Table 5*). While 89.6% of the producers (48 producers) who state that they get into touch with the extensionists for the aim of getting information find the information that they get useful, 10.4% of the producers does not find the information useful.

Table 5. *The frequency of getting into touch with extensionists by farmers for the aim of getting information about beekeeping*

	n	**%**
Once a week	1	1.6
Once a month	6	9.7
Once in three months	5	8.1
Once a year	2	3.2
Twice a year	33	53.2
Thrice a year	1	1.6
I do not get into touch	14	22.6
Total	62	100.0

It can be argued that the beekeepers' contacts with extensionists generally occur in the village. The proportion of the farmers who say that "I get into touch with the extensionists when they come to the village" is found as 45.2% on the other hand, the proportion of the farmers who say that "I get into touch with the extensionists when I have a problem" is found as 32.3% (*Table 6*). 22.6% of the farmers states that they never get into touch with the extensionists.

Table 6. *The circumstance of getting into touch with the extensionists*

	n	**%**
I get into touch with the extensionists when I have a problem	20	32.3
I get into touch with the extensionists when they come to the village	28	45.1
I never get into touch	14	22.6

When the places where the beekeepers and extensionists get in contact were examined, it was found that nearly half of the contacts occurred in the tea house of the village. With a proportion of 45.2%, the village's tea house comes first for the farmers as a place for getting into touch with extensionists. The proportion of the farmers who state that they get into touch with the extensionists at Agriculture and Forestry District Directorate is detected as 45.2% (*Table 7*).

It can be stated that mass communication is effective on the adoption of innovations. The most important reason of this is that the attentions of the farmers can be drawn to the innovation and a specific level of knowledge about innovation can be created (Sezgin, 2010). It is detected in the research that 91.9% of the farmers watch agriculture programmes at the television while 37.1% of the farmers listen to the agricultural programmes at the radio. 59.7% of the farmers state that they read books, magazines and newspapers about agriculture. In the research, the proportion of the farmers who use internet for agricultural purposes is found as 24.2% (*Table 8*).

Demonstrations show a group that how a new work is done or how an old work is done better (Cinemre and Demiryürek, 2005). Demonstrations are some of the extension methods which enable farmers to learn by hearing, seeing and practicing. Demonstrations are accepted as the most effective method at the operations of agricultural extension and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1088310897

they are used quite prevalently (Yurttaş and Atsan, 2007). In the research, the proportion of the farmers who attend the demonstrations about beekeeping is found as 16.1%. While the proportion the farmers who attend the course/seminar about beekeeping is detected as 24.2%, the proportion of the farmers who attend conference/panel activities is detected as 40.3% (*Table 8*).

Table 7. *The place of getting into touch with the extensionists by farmers*

I never get into touch	14	22.6

*The total is over 100% as there are answers more than one

Table 8. *The circumstances of the farmers to attend various activities*

	n	**%**
Watching agriculture programmes at television	57	91.9
Attending agriculture fairs and exhibitions	39	62.9
Reading materials like book, magazine, newspaper, leaflet etc. about agriculture	37	59.7
Being informed via telephone or sms about agriculture	34	54.8
Attending the farm or home visits	26	41.9
Attending the conference-panel activities	25	40.3
Listening to the programmes about agriculture at the radio	23	37.1
Using internet with the aim of agriculture	15	24.2
Attending course-seminar activities	15	24.2
Attending demonstration activities	10	16.1
Attending the trips with the aim of agriculture	6	9.7
Attending the competitions with the aim of agriculture	2	3.2

Agriculture fairs are important agricultural activities which provide information to the farmers about the new techniques and technologies in the agricultural sector. Farmers find the possibility to practice the new technology instantly thanks to the demonstration areas created at the fairs (Çukur and Çukur, 2017). It is detected in the research that 62.9% of the farmers attend the agriculture fairs and exhibitions (*Table 8*).

Results of Logistic Regression Analysis

The proportion of the farmers who state that they follow the innovations about beekeeping is found as 69.4%. 61.3% of the farmers state that they implement the innovations about beekeeping.

The ages of the farmers, the circumstances of the farmers to have a problem about production and the circumstances of them to be a member of a cooperative are found significant at 0.05 level of significance and the circumstance of storing the honey is found significant at 0.10 level of significance statistically, at the logistic regression analysis which is done for the aim of the determination of the factors which are effective on the implementations of agricultural innovations about beekeeping by farmers. That is, it is determined that young farmers, farmers who have problems related to production, who

Discussion

In this study which aims to determine the implementation of innovations by farmers who perform beekeeping at the district of Milas, it is determined that a great deal of the farmers adopt and implement the innovations about beekeeping (61.3%). In the research which is done by Kızılaslan and Ünal (2013), similar results are found and it is determined that 67.2% of the farmers implement the new agricultural informations and techniques. According to the research done by Kızılaslan (2009), the proportion of the farmers who state that they sometimes implement the innovations is detected as 71.67%. On the other hand, according to the research done by Özçatalbaş (2000), it is detected that the level of adopting the innovations at the majority of producers is under the level of intermediate and the proportion of the producers who have high adopting level is 8.7%. In the research done by Udofia and Edet (2016) at Ethiopia, the proportion of adopting the modern beekeeping techniques by beekeepers is found quite low and it is determined that only 16.80% of the beekeepers adopt modern beekeeping techniques. According to the research done by Chambo et al. (2018), more than half of the beekeepers adopt more than 74% of the suggestions about the harvest and after harvest. According to the research done by Kumar (2013), farmers adopt 45.71% of the innovations about bee feeding and 36.66% of the innovations about migratory beekeeping. These proportional differences occurring between the levels of adopting the innovations can arise from the differences at the personal characteristics of the beekeepers, social structure and the economical and financial situations of the beekeepers.

As there are differences between the levels of adopting the innovations by beekeepers, there are also differences in the factors which are effective on the adoption of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1088310897

innovations. In this study, it is detected that young farmers, farmers who have problems related to production, who are the members of the cooperative and who do not store the honey implement the agricultural innovations related to beekeeping more. According to the research done by Wodajo (2011), getting loan, the education level of the father of the family and attending the demonstrations have positive effects on the adoption of modern hives by farmers. In the research done by Adgaba et al. (2014), it is determined that farmers who have a crowded family, who have a high level of education and young farmers adopt the usage of modern hives more easily.

One of the most important factors in adopting the agricultural innovations by farmers is, no doubt, the practices of agricultural extension. In the research done by Fadare et al. (2008), it is detected that the proportion of adopting the innovations by beekeepers is low and the greatest reason of this is the low level of relation between the farmer and extensionist. According to the findings obtained from the research, it can be said that farmers do not get into touch with the extensionists very often. It is detected in the research that 53.2% of the beekeepers get into touch with the extensionists twice a year. In the research done by Ahmad et al. (2007), the majority of the farmers (82.5%) do not visit the local agricultural extension office. In the research done by Jan et al. (2008), the proportion of the farmers who says that "last year, extensionist came to the place that I live" is found as just 2.5%. In the research done by Kenea (2008) in Kenya, it is determined that 58.8% of the farmers did not get into touch with the extensionists last year, 38.8% of the farmers get into touch with the extensionists at least once a year and 8.5% of the farmers get into touch with the extensionists at least once a month.

The age of the owners of the business is an important factor in adopting the innovations. It is determined at the end of the research that the level of adopting the innovations by young farmers is higher and this result shows a parallelism with the data of litterateur. In the research done by Boz et al. (2011) and Sezgin et al. (2010), it is determined that there is an important relation between the age and the adoption of innovations.

In the research, it is determined that being a member of the cooperative has an important effect on the adoption of agricultural innovations by farmers. In the research done by Kolade and Harpham (2014) and Wossen et al. (2017), the same result is detected.

It is detected that an important part of the farmers (89.6%) finds the information that they get from the extensionist useful. In the research done by Apantaku et al. (2016), same results are found and it is detected that 53% of the farmers think that agricultural extension services develop the agricultural activities, 94% of the farmers think that agricultural extension services help farmers be educated about the better agricultural techniques. According to the research done by Muktar et al. (2016) in Nigeria, 10% of the farmers find the agricultural extension quite useful in terms of their production, 8.8% of the farmers find it useful and 45% of the farmers find it partially useful. In the research done by Yalçın and Boz (2007), it is emphasized that the importance of district and provincial directorates of agriculture, in terms of extension, decreases in the region.

First of all, farmers need to get true and confidential information about innovation to be able to adopt the innovations. It is detected in the research that an important part of the beekeepers needs information about illness and pest control and marketing. Similarly, in the research done by Sıralı and Doğaroğlu (2004), it is determined that 45.94% of beekeepers needs information about illness, pest and the control of them. According to the research done by Awino et al. (2018), farmers need information about the illnesses

and pests which affect the bees and producing and marketing the bee products. In the research done by Ibegbulem (2014), it is stated that farmers need information about the sources of the plants on which the bees gather pollens.

Today, farmers use mass communication (television, radio, internet, newspaper, book, magazine etc.) quite intensively to be informed about agricultural innovations and get information about new technologies. In the research, the proportion of watching agricultural programmes at television by farmers is found high and the proportion of listening to the programmes about agriculture is found relatively low. It is determined in the research done by Ahmad et al. (2007) that the proportion of farmers who regard radio as an information source is 83.75% and the proportion of farmers who regard television as an information source is 82.50%. In the research done by Akinbile and Alabi (2010), the proportion of the farmers who listen to the radio to update their knowledge is found as 75% and the proportion of the farmers who watch television to update their knowledge is found as 69.2%. In the research done by Anastasios et al. (2010) in Greece, it is detected that 80.41% of the farmers have television. According to the research done by Sezgin (2010), 41.4% of the farmers follow the programmes about agriculture at television/radio regularly.

59.7% of the farmers state that they read books, magazines and newspapers about agriculture. Similar results are found in the research done by and the proportion of the farmers who read newspaper is found as 61.7%. In the research done by Ijatuyi (2016) in Nigeria, it is detected that 18.75% of the farmers regard newspaper as a source of information. In the research done by Wangu (2014), it is detected that 30.6% of the farmers regard newspaper as a source of information and 9.2% of the farmers regard agricultural magazines as a source of information.

Approximately one fourth of the farmers who join in the research use internet for the aim of agriculture. Similar results are found in the research done by Okwu and Iorkaa (2011) and the proportion of the farmers who use internet for the aim of getting information is found as 23.9%. In the research done by Akinbile and Alabi (2010), the proportion of the farmers who use internet for the aim of getting information is found a bit low as 11.7%. In the research done by Anastasios et al. (2010) the proportion of the farmers who use the internet is found as 15.10%.

Conclusion

Consequently, the managers of the businesses should be young, the member of the cooperative and the farmers who do not store the honey to adopt and implement the innovations faster in the businesses of beekeeping in the district of Milas in Muğla province and accordingly, to perform a more fertile and profitable beekeeping by using modern agricultural techniques and technologies. Besides this, it should be remembered that the farmers who have a high level of information about agriculture, who are open to the innovations and the outer world and who trust the extensionists contribute to the development of beekeeping more. For this reason, performing the agricultural extension activities with the aim of increasing the levels of innovativeness of the beekeepers by considering their present situation is thought to be quite useful.

(Received 24th Mar 2019; accepted 2nd Jul 2019)

Abstract. Antibiotic resistance, which is emerging among pathogenic bacteria, is a leading cause of treatment failure worldwide with particular reference to developing countries. Thus, there is a need to explore and discover novel antimicrobial agents. The objective of this study was to investigate antibacterial activity of spider web metabolites and characterize certain antibacterial compounds. Web solvent extract (methanol, ethanol and acetone) was biologically screened for antibacterial activity against seven multiple drug resistant bacteria including three Gram negative bacteria (*E. coli, A. baumannii,* and *S. typhi*) and four gram positive bacteria (*S. aureus, Bacillus, E. faecalis and S. pneumonae*) using well diffusion test. Solvent extracts with the concentrations of (3.3 mg/ml 4.95 mg/ml 6.6 mg/ml 8.25 mg/ml 9.9 mg/ml and 11.55 mg/ml) were used to check the efficiency against MDR bacteria. Solvent extract of web metabolites exhibited significant activity against all seven MDR bacteria, by producing clear growth inhibition zones ranging in diameter from 04 to 22 mm. Considerable activities was exhibited against *E. faecalis* (22 mm), *E. coli* (14 mm) *and S. typhi* (15 mm). Acetone solvent extracts showed high antibacterial activity against most MDR bacteria. Solvent extracts with concentrations less than 5 mg/ml did not exhibit sufficient activity. Higher activities were related to concentrations higher than 6 mg/ml. Findings of the current study indicated that spider web metabolites may show promising antimicrobial activity against MDR bacteria. Additionally, the results suggest that spider web may be a broad spectrum antimicrobial agent, wherein its individual constituents contribute to its antimicrobial activity.
Keywords: *antibiotics resistance, antibacterial metabolites, solvent extracts, MDR, Pakistan*

Introduction

A lack of proper antimicrobial agents capable of controlling the incidence of infectious diseases is a major issue facing the health sector worldwide. An increase in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1089910908

microbial diseases resistant to antibiotics has reached worrisome proportions in the biosciences field (Cassini et al., 2018). Discovery of the first antibiotic, followed by technological advances in antimicrobial drug research, led to the protection of millions from microbial diseases. In the history of antibiotics, the first ever contribution was made by Sir Alexander Fleming who, in 1928, discovered that Penicillin derived from molds was capable of inhibiting bacteria. Following the discovery of this highly appreciated antibiotic, several other antibiotics were also discovered and used to treat infectious diseases (Davies et al., 2010)**.** However, towards the end of the 1900s, emergence of antimicrobial resistant species together with the capacity for resistant gene transfer between species became a cause for major concern in the life sciences community (Amare et al., 2011). The Emergence of MDR bacteria capable of resisting antibiotics directly and indirectly is the direct result of all these factors. Furthermore, extensive use of antibiotics during the past few decades, led to the application of selective pressure on vulnerable bacteria, favouring the survival of resistant strains, few of which are resilient to more than one antibiotic (Arason et al., 2002).

The emergence of MDR bacterial species increased gradually over the years. Currently numerous studies have described various pathogenic bacterial species including *Salmonella typhi, Acinetobacter baumannii, Staphylococcus aureus, Enterococcus faecalis, Streptococcus pneumonae* and *Escherichia coli* as highly antimicrobial resistant. These bacteria, which cause many different infectious diseases, are resistant to multiple antibiotics and cannot be treated with traditional antibiotics as reported in many studies (Singhal, 2014; Doi, 2015; Da Silva, 2016; Megan, 2016; Nilsson, 2012; Wattanathum, 2003; Noble, 1992). These strains may be untreatable in the near future unless substitute or novel antimicrobials are developed. Novel antibiotics may be derived from natural sources such as plants, animals or their secretions in the form of molecules and compounds. Spider web metabolites comprise different molecules which appear to be antimicrobial according to studies (Vollrath et al., 2000). Spider silk is also attracting attention due to its antimicrobial properties. There have been unsubstantiated reports regarding the antimicrobial potential of spider silk (Wright et al., 2012). This report indicated that microbes were unable to grow on spider silk due to its acidic properties, suggesting that spider silk either prevented. Biofilm formation by microorganisms or were bacteriostatic or bactericidal in nature (Saleem et al., 2010). Additionally, bacteriostatic activity of spider silk has also been attributed to the presence of potassium nitrate, which inhibits the growth of microbes such as *Bacillus subtilis* and *E. coli* (Chakraborty et al., 2009). Antibacterial and antifungal activity of spider webs is mentioned in literature. However, antimicrobial potential of spider webs against multi drug resistant bacteria (MDR) has not yet been examined in Pakistan. Multi-drug resistant (MDR) organisms are a global threat. Antibiotic resistance accounts for hundreds of thousands of deaths annually (Johan et al., 2018). Spider web been traditionally used as an antiseptic in rural areas of Pakistan, while Atypus spider webs were used by people in the Carpathian Mountains as a topical antiseptic (Wright et al., 2012). This was considered to be helpful as a disinfectant.

The aim of this study was to investigate antibacterial activity of spider web metabolites and characterize certain antibacterial compounds. Different concentrations of web extract were used against previously identified MDR bacteria. This study will be helpful to kill drug resistant bacteria and discovery of the novel antibiotics.

Materials and methods

Sampling

The current study and sampling of web were done in the district Kohat, Khyberpakhtunkhwa, Pakistan. Previously identified and characterized clinical bacterial isolates of *Salmonella typhi, Staphylococcus aureus, Enterococcus faecalis, Acinetobacter baumannii, bacillus, Streptococcus pneumonae,* and *Escherichia coli* were recruited for this study. These previously identified isolates were basically from chronic wounds origin. The samples were forwarded for re-culturing and re-identification. Biochemical test used for identification are given in details in *Table 1*.

Table 1. *Biochemical identification of test isolates*

Pathogens	Cell morphology		Biochemical tests				
	Shape	Gram	Cat	Oxi	Ind	DNase	Cit
Bacillus	Rod	+ ve	+ ve	variable	-ve	-ve	+ ve
A. baumannii	Rod	-ve	+ ve	-ve	-ve	-ve	+ ve
S. Aureus	Cocci	+ ve	+ ve	-ve	-ve	+ ve	+ ve
S. Typhi	Rod	-ve	+ ve	-ve	-ve	-ve	-ve
E. coli	Rod	-ve	+ ve	-ve	+ ve	-ve	-ve
S. pneumonae	Cocci	+ ve	-ve	-ve	-ve	-ve	-ve
E. faecalis	Cocci	+ ve	+ ve	-ve	-ve	-ve	+ ve

S. aureus = *staphylococcus aureus, S. Typhi* = *salmonella typhi, S. Pneumonae* = *streptococcus Pneumonae, E. faecalis* = *Enterococcus faecalis.* Cat = catalase, Cit = citrate, Ind = indole, Oxi = oxidase

Antibiotic resistance patterns

Antibiotic resistance patterns of the isolates were determined via the Kirby-Bauer disk diffusion method (Bauer et al., 1966) according to the recommendations of the Clinical and Laboratory Standard Institute (CLSI) (Shallu et al., 2015). The isolates were treated with a total of 11 antibiotics as follows; Clarithromycin, Doxycycline, Cefoperazone sulbactam, Cefoxitin, Kanamycin, Nitrofurantoin, Penicillin, Levofloxacin, Ciprofloxacin, Oxacillin and Clarithromycin. Briefly, Mullen-Hinton agar was prepared. A 0.5 McFarland turbidity standard equivalent to inoculation of a bacterial suspension was prepared and inoculated. Following 48 h of incubation, the diameters of inhibition zones around the disks were measured using a graduated ruler and results were interpreted according to CLSI guidelines.

Collection, processing and metabolites of spider web

Spider webs were collected from garages and ceilings of unused buildings in the district of Kohat, Pakistan. Webs were washed with distilled water in the laboratory and cleansed of other redundant ingredients and dust. Clean and wrapped web was air-dried at room temperature and preserved in ampoules. Organic solvents, such as methanol, ethanol and acetone, were screened for possible extraction of web metabolites which were to be tested against MDR species or specific pathogens considered sufficiently important or suitable for exploration (Tshipamba et al., 2018).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1089910908

Pure web metabolites were extracted using standard methodology. Pure web portions weighing 6 g each were introduced into falcon tubes, each containing 60 mL of acetone, methanol, ethanol and distilled water, and set on an orbital shaker at different angles for 2 weeks. After shaking liberated excessive amounts of metabolites, solvents were filtered into a beaker. The filtrate of solvent extract was placed in a large beaker and allowed to evaporate for one week. Following evaporation, the solidified extract was dissolved in 6 mL DMSO and kept it in sterile falcon tubes.

Screening of webs

Biological screening of antimicrobial properties of the web metabolites was performed via the well diffusion method. Muller Hinton Agar (MHA) media was used to assess susceptibility patterns of isolated bacteria by applying solvent extracts using well diffusion (Jaja et al., 2018).

Results

All isolates of *S. typhi, S. aureus, E. faecalis, A. baumannii, bacillus, S. pneumonae* and *E. coli* were re-identified via culture characterization, gram staining and biochemical testing.

Antimicrobial sensitivity pattern of bacterial isolates

Antimicrobial patterns of isolated bacterial pathogens were determined using 11 different antibiotic groups. *E. coli*, *S. typhi* and *A. baumannii* showed resistance to 7 antibiotics widely used against these pathogens, whereas *S. aureus* was resistant to 8 antibiotics. *S. pneumonae* was resistant to 6 antibiotics. However, *Bacillus* and *E. faecalis* were resistant to 6 antibiotics (*Table 2*). After confirming MDR patterns of these pathogens, aqueous acetone, ethanol, and methanol extracts of spider web were evaluated in *vitro* against *Acinetobacter, bacillus, S. aureus, S. typhi, E. faecalis, S. pneumonae* and *E. coli.*

Table 2. *Assessment of test isolates*

Antimicrobial activity of solvent extract against MDR bacteria

A total of 6 trials were conducted to test the anti-MDR effects of web, using different solvent concentrations against each MDR bacterium. Following 24 h, a significant portion of 9.9 mg/ml and 11.55 mg/ml solvent extract concentrations showed prolific activity while those concentrations that were less than 9.9 mg/ml did not display sufficient activity. Activity was measured by zone of inhibition around the wells. The highest inhibition zone (22 mm) was recorded for *E. faecalis* while the lowest zone (04 mm) was formed against *E. coli* (*Fig. 1*).

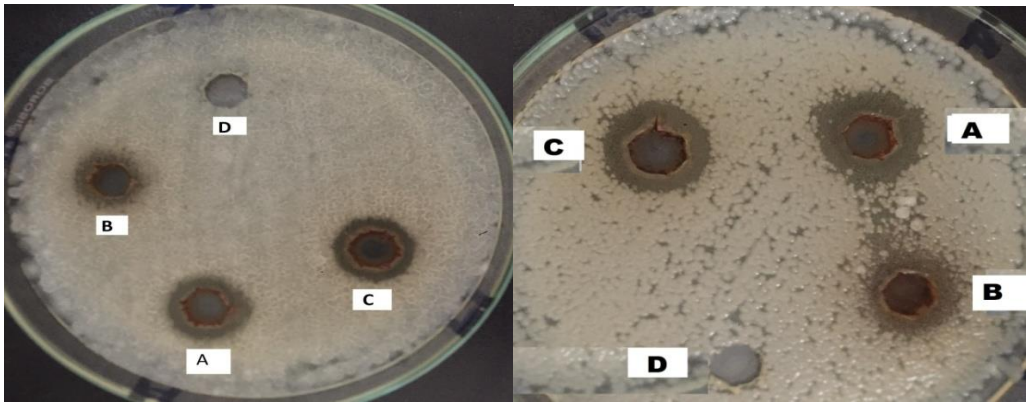

Figure 1. *Antimicrobial activity of the spider web was evaluated by means of well diffusion method by using different organic solvents acetone, ethanol and methanol as compared with control respectively (A, B, C and D). The web extract residues with different concentration (3.3 mg/ml 4.95 mg/ml 6.6 mg/ml 8.25 mg/ml 9.9 mg/ml and 11.55 mg/ml) showed promising activity. The presence of inhibition zones was measured, recorded and considered as indication for antibacterial activity. After 24 h a significant fragment of trials 9.9 mg/ml and 11.55 mg/ml solvent extract concentration showed proficient activity while the rest less than 9.9 mg/ml did not show enough activity. Activity was measured by zone of inhibition around the wells. The highest zone of inhibition (22 mm) was recorded for Enterococcus faecalis while lowest zone (04 mm) was formed against E. coli*

Anti-MDR bacterial potential of spider web metabolite extracts of the organic solvents acetone, ethanol, and methanol was analyzed. Solidified solvent extracts were dissolved in DMSO. An extract of distilled water was incorporated as the negative control**.** Results were described based on two parameters; organic solvents, and solvent extract concentrations.

Screening based on organic solvents

Spider silk was screened using different organic solvents to extract the web metabolites.

(i) Acetone

Acetone extract showed activity against all MDR bacteria, but higher activity was recorded against *E. coli, E. faecalis, and S. aureus*. The highest zone of inhibition (15 mm) was recorded for *E. coli,* whereas *E. faecalis, S. aureus, and S. typhi* each

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1089910908

exhibited 12 mm inhibitory zones on average. Inhibitory zones of 10, 09, and 07 mm were recorded for *Bacillus, S. pneumonae* and *A. baumannii,* respectively (*Table 3*).

Table 3. *Antimicrobial activity of web with the acetone extract*

Pathogens	Zone of inhibition (mm) of acetone extract					
	3.3 mg/ml	**4.95 mg/ml**	**6.6 mg/ml**	**8.25 mg/ml**	**9.9 mg/ml**	**11.55 mg/ml**
Bacillus	-	-	-	-	-	10
S. aureus	-	-	-	7	9	12
S. typhi	-	-	-	8	-	12
Acinetobacter	-	-	-	-	7	9
E. faecalis	-	-	-	13	13	13
E. coli	-	-	-	14	14	15
S. pneumonae	-	-	-	-	05	07

(ii) Ethanol

Ethanolic extract showed the highest inhibition zone (17 mm) against *bacillus.* The second highest zone of inhibition (15 mm) was recorded for *A. baumannii*. However, the inhibitory zones of *S. aureus, S. typhi* and *E. coli* were 12, 10 and 10 mm, while *S. pneumonae* showed resistance upto some extent, its zone of inhibition was 08 mm. *E. faecalis* appeared to be resistant to ethanol extract as shown (*Table 4*)

Table 4. *Antimicrobial activity of web with the ethanol extract*

Pathogens	Zone of inhibition (mm) of ethanolic extract					
	3.3 mg/ml	**4.95 mg/ml**	**6.6 mg/ml**	**8.25 mg/ml**	**9.9 mg/ml**	**11.55 mg/ml**
Bacillus	-	-	-	-	16	17
S. aureus	-	-	07	09	10	12
S. typhi	-	-	-	05	05	10
Acinetobacter	-	-	-	-	-	15
E. faecalis	-	-	-	-	-	-
E. coli	-	-	-	-	7	10
S. pneumonae	-	-	-	-	5	8

(iii) Methanol

The highest zone with methanol was recorded against *E. faecalis* (22 mm). Methanolic extracts showed average class inhibition zones against other MDR bacteria as follows; *S. aureus* (12 mm), *Bacillus* (13 mm), and *A. baumannii* and *S. typhi* 11 mm). The lowest inhibitory zones (06 mm) were recorded for *E. coli* and *S. pneumonae* (*Table 4*).

Screening based on solvent concentration

Web solvent extracts with the following solvent concentrations were tested; 3.3 mg/ml, 4.95 mg/ml, 6.6 mg/ml, 8.25 mg/ml, 9.9 mg/ml and 11.55 mg/ml. Sufficient activity was recorded only for concentrations ranging from 9.9 to 11.55 mg/ml.

DOI: http://dx.doi.org/10.15666/aeer/1705_1089910908

(i) Inhibition zones with 11.55 mg/ml

The highest inhibition zone (22 mm) was recorded for the concentration of 11.55 mg/ml for *E. faecalis* with the methanolic extract, whereas the second highest zone of inhibition was recorded for *Bacillus* (17 mm) with the ethanolic extract. Both *A. baumannii* and *E. coli* showed 15 mm inhibitory zones while the pathogens *S. aureus* and *S. typhi* showed zones of 12 mm. Additionally, *S. pneumonae* showed a10 mm zone (*Table 4*).

(ii) Inhibition zones with 9.9 mg/ml

Solvent extracts with concentrations of 9.9–11.55 mg/ml showed high efficiency. The highest inhibition zone (16 mm) was recorded for *Bacillus* with ethanolic extract. *E coli* appeared to be more susceptible to acetone extract of 9.9 mg/ml as it produced a zone of 14 mm. Another high inhibition zone (13 mm) was recorded for *E. faecalis,* while11 mm inhibitory zones were observed against *S. typhi and S. aureus* and 06 and 07 mm inhibitory zones were recorded for *A. baumannii* and *S. pneumonae,* respectively (*Tables 3, 4* and *5*).

Table 5. *Antimicrobial activity of web with the methanol extract*

Pathogens	Zone of inhibition (mm) of methanol extract					
	3.3 mg/ml	4.95 mg/ml	6.6 mg/ml	8.25 mg/ml	9.9 mg/ml	11.55 mg/ml
Bacillus					10	12
S. aureus					11	13
S. typhi	-	-	-	07	11	11
Acinetobacter	-	-	-	-	-	11
E. faecalis	-	-	-	-	08	22
E. coli	-	-	-	-	04	06
S. pneumonae	-	-	-	-	06	06

Discussion

Accessibility to various antibiotics following the initial discovery of penicillin, initiated great enthusiasm in modern medicine (Sulaiman et al., 2014). The discovery of antimicrobials was one of the noteworthy discoveries in the history of microbial diseases. Following the discovery of antibiotics, humans became mostly free of harmful, deadly diseases. As a result of this medical miracle, people are able to live safe and healthy lives (Levy and Marshall, 2004). Currently, scientists are searching for natural sources of antibiotics that may help to develop antimicrobial agents against MDR bacteria. Novel antimicrobials have always been developed from natural sources. These sources may be microorganisms, plants and animals such as spiders and their metabolites. Spider silk is frequently cited as having antimicrobial properties in addition to several other scientifically verified biomedical properties (Chakraborty et al., 2009). Most studies on biomedical and mechanical properties of spider webs also mention their antimicrobial properties. Several studies describing antimicrobial properties of spider webs, may surface in literature reviews but these properties have not been tested against MDR bacteria. To our knowledge, this is the first study which addresses this crucial issue.

In this study, silk of common house spiders was investigated for its qualitative antimicrobial potential. Aqueous, acetone, ethanol and methanol web extracts were tested against MDR bacteria including *S. typhi, S. aureus, E. faecalis, A. baumannii, bacillus, S. pneumonae* and *E. coli.* We determined that silk from the common house spider may act as an antimicrobial agent under various *in vitro* conditions. The studies related to antimicrobial potential of spider silk has been previously reported (Saleem, 2010; Laxminarayan, 2003). Web solvent extracts appear to be effective against all the MDR bacteria. Maximum inhibitory effects of all bacteria corresponded to concentrations ranging from 9.9 mg/ml and 12.55 mg/ml following after 24 h incubation period.

The most significant inhibition zone (17 mm) corresponding to increased activity was recorded against *bacillus* following 24 h of incubation. However, after 24 h, activity was not significant and decreased. Web extracts showed significant activity against *E. coli*, *Bacillus, S. aureus* and *S. pneumonae* as indicated by the diameter of their inhibition zones, which confirmed the findings of other studies, in which inhibition zones were; *E. coli* (8 mm) *B. subtilis* (14 mm), *S. aureus* (16 mm) and for *Streptococcus* species (12 mm) (Wright et al., 2012).

Among all MDR bacteria tested, *S. aureus* appears to be susceptible to minimum concentrations as well as maximum concentrations of solvent extracts. *E. faecalis* appears to be resistant to all solvent extracts to some extent.

Spider silk comprises certain constituents having antimicrobial potential such as potassium hydrogen phosphate, compound potassium nitrate and amino acids. These amino acids display broad spectrum activity, especially against a diverse group of microorganisms, including gram positive and gram negative bacteria and fungi (Gomes et al., 2011). Antimicrobial peptides bind to the lipid bilayer membrane of bacteria. Through this interaction bactericidal peptides attain an amphiphilic three-D configuration whereby its positive side interacts directly with negatively charged lipid head-groups resulting in the formation of pores in the bacterial membrane (Havard, 2006).

Thereby**,** potassium hydrogen phosphate lowers pH to approximately 4 by releasing protons into the aqueous solution, causing it to turn acidic. Such low pH prevents microorganisms from digesting web constituents (Case et al., 1999). Consequently, microorganisms are unable to degrade the web easily. Potassium nitrate is a web constituent that prevents protein from denaturing in the acidic condition**.** Therefore, the above stated components make spider silk a good agent for preservation.

Spider silk constituents show potential as novel preservative agents which may be useful in food, pharmaceutical and diary industries, among others. These are efficient and moderately in expensive with increased shelf life and reduced side effects. Silk producing genes of spiders may be manipulated to obtain higher yields of better quality silk, which may be utilized for industrial purposes.

Conclusion

Spider web metabolites used in this study displayed promising antimicrobial activity against MDR bacteria. Results indicate that spider web may function as a broad spectrum antimicrobial agent. Individual components responsible for its antimicrobial activity should be evaluated via cell culture assays for toxicity, as well as via NMR and HPLC for their molecular structure.

Abstract. Wetlands are considered as one of the most important ecosystems on the Earth. Rapidly urbanizing, being an intense way of human activities, has brought significant impact on the ecological functions of urban wetlands. This study focused on the urban wetland ecosystem in the Nanjing Jiangbei New Area, China, and presented a dynamic integrated approach to assess the monetized value of its services. A classification decision tree model was adopted to interpret the Landsat TM/ETM/OLI images to obtain the LUCC data of urban wetlands in different years. Then an integrated approach was employed to correct the equivalent values and their prices of various ecosystem services, dynamically evaluating the value of wetland ecosystem services. The results showed that the overall value of the wetland ecosystem services of the Jiangbei New Area was 893.99 million USD, 1365.63 million USD and 1016.46 million USD in 2002, 2009 and 2015, respectively. Among the service categories, the regulating service reaches the most and the provisioning service contributes the least to the total value. According to the analysis of annual valuation results, it was inevitable that the ecological conditions of wetlands in the rapidly urbanizing area would deteriorate and the capability to provide ecosystem services would degenerate. This research suggests that rapid urban development should adopt an ecosystem service oriented strategy to align sustainable utilization with conservation and to recognize the interaction between the wetland ecosystem services and the forces of urbanization.
Keywords: *LUCC, TCT, VTM, ecosystem services value, regulating services*

Introduction

As Millennium Ecosystem Assessment (MA) pointed, ecosystem services are the benefits people obtain from ecosystems. Every part of Earth produces a bundle of ecosystem services. These include provisioning services such as food and water; regulating services such as flood control; cultural services such as spiritual and recreational benefits; and supporting services, such as materials cycling (MA, 2003). All the services that the ecosystem provides maintain the conditions for life on Earth. Being known as the "kidney of the Earth", the wetland ecosystem is one of the most valuable ecosystems. As a significant land-water interacted ecosystem, the wetland provides us a multitude of benefits, including supply of materials, water storage, environmental protection, flood control, soil maintenance, climate regulation and maintenance of biodiversity, etc.(Keddy, 2010; Sharma et al., 2015; LePage, 2011). It also provides essential materials and ecological benefits to support life and economic growth in urbans and cities (Azous and Horner, 2000; Sullivan et al., 2014; Parker et al., 2018). As previous studies have shown, land-use and land-cover change (LUCC) caused

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1090910927

by human activities have significant impact on the urban wetland ecosystem (Zorrilla-Miras et al., 2014; Šabić et al., 2018). Around the globe, disorganized land use and development have led to a decrease in the total area covered by wetlands (Gardner et al., 2015), and to problems such as debilitated wetland structures and soil erosion, with urbanization exacerbating the decrease of wetland resources (Ehrenfeld, 2000; Kentula et al., 2014; MA, 2005; Davidson, 2014; Sica et al., 2016).

The impacts of human activities on ecosystems have increased rapidly in the last few decades. While a part of these activities can be considered beneficial to human well-being, there is increasing evidence of adverse effects, especially in areas with a concentrated population such as cities and urbans. Protection and recovery of urban wetland resources entails increased awareness of the ecological value of wetlands among the public, for which it is necessary the assessment of the value that wetland ecosystem services provide (Zhang et al., 2017a).

The concept of ecosystem services has been drawing more and more attention in the global community since the 1990s. On the basis of previous research (Costanza et al., 1997; Daily, 1997; Costanza and Mageau, 1999; De Groot et al., 2002; Costanza et al., 2014), MA put forward a guiding solution classifying ecosystem services into four categories: provisioning services, regulating services, cultural services and supporting services, and performed an assessment about them (MA, 2003, 2005a, b). Research on the value of ecosystem services provides an efficient tool to compare them and estimate the effect of environmental policies (McPherson, 1997; Tyrväinen and Miettinen, 2000; Jim and Chen, 2009). In this case, the assessments of urban wetland ecosystem services could specify the substantial contribution of this intricate system to human well-being. Meanwhile, the value-related studies also provide the conditions for the further research and practice of decision-making about urban wetland resources management.

According to existing publications, China has lost nearly 33% of its wetlands from 1978 to 2008 (Niu et al., 2012). The total area of wetlands in 2014 was 3.4 million hectares smaller than in 2003, an 8.82% decrease, and wetlands used for urban construction increased nearly tenfold (Geng, 2014). In recent years there have been efforts by Chinese researchers to probe into the field of valuation of wetland ecosystem services, with mainly focused on the comprehensive valuation of urban wetland ecosystem services, the value of ecosystem services of specific urban wetlands or the value of specific services, among others (Li and Wei, 2015; Xue et al., 2015; Cao et al., 2017; Zhang et al., 2017b, 2014, 2015a; Yang and Liu, 2018).

An assessment of the ecosystems services and their relation to human well-being requires an integrated approach. This enables a decision process to determine which service or set of services is valued most highly and how to develop approaches to maintain services by managing the system sustainably (MA, 2003). Nevertheless, due to limitations in data and research methodologies, research on dynamic monitoring of urban wetlands is still scarce, while in-depth quantitative and comparative studies on the value of ecosystem services are not available, making it difficult to provide a basis for urban planning and management (Zhang et al., 2017a). Based on previous methodologies published by Constanza et al (1997, 2014), Xie and other Chinese researchers optimized a unit area and equivalent value-based system, which is called Value Transfer Method (VTM), to assess the monetized value of ecosystem services (Xie et al., 2001, 2008, 2010, 2015a, b). This optimization was done to increase the reliability of the results and to provide a basis for building an efficient valuation system of ecosystem services of urban wetlands.

LUCC (land use/land cover change) analysis has already been recognized as an effective way to monitor changes in wetlands in a remote manner (Frohn et al., 2012). Through a discrimination method that combined the use of spectral information and supportive information, this study presents a comprehensive way that increases the precise level of land cover classification to improve accuracy of spatial information acquisition from the wetlands in research area. The study presented herein aims to develop an urban wetland ecosystem service valuation system based on the VTM combining modified equivalent values and LUCC data. It is an empirical study using the Nanjing Jiangbei New Area in the Jiangsu province in China as the study case.

Materials and methods

Research area

The Nanjing Jiangbei New Area in the Jiangsu province is located between 30°51′N and 32°27′N (latitude), 118°21′E and 119°03′E (longitude). It consists of three regions-Pukou District, Liuhe District and Baguazhou Sandbank, covering a total area of 2451 km^2, about 37% of the total of Nanjing (*Fig. 1*). With many rivers, polders and ponds, this area used to have abundant wetland resources which, however, were considerably reduced due to rapid urbanization and excessive reclamation. According to the "Overall Planning of Jiangbei New Area (2014-2030)", the urbanization rate of this new area is expected to reach 90% in 2030, while it was 66.3% in 2014, which means that urbanization initiatives will be accelerated and thus impose larger threats to the wetlands within the area.

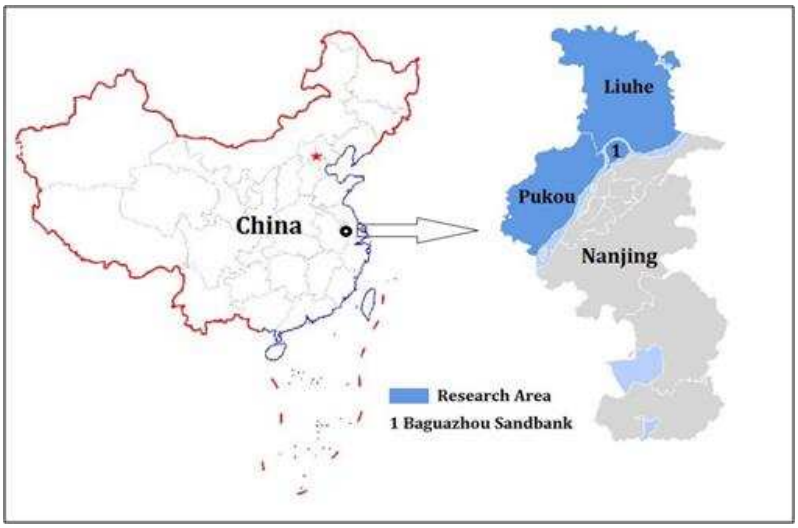

Figure 1. *The location of research area*

Remote sensing image processing

Data used in this study are remote sensing data collected in three periods during cloudless days in adjacent date (*Table 1*), including Landsat TM/ETM/OLI images captured in 2002, 2009 and 2015. The WGS-1984 coordinate system and the UTM projection are used to correct the images, and pre-processing steps including radiative correction, geometric correction and extraction of interested regions are taken before

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1090910927

utilization of the data. In light of the distribution of wetlands in the Jiangbei New Area and their main types, we took into consideration the features of valuation of remote images and put forward a system of classification of wetlands in the area (*Table 2*).

Table 1. *Remote sensing data source*

Satellite/sensor	Number of wavelengths	Resolution (m)	Date of obtain	Track number

Table 2. *Wetland classification system in research area*

Type of wetland	Main features
Lake wetland	A large area of planar water, including lakes, large reservoirs, etc.
River wetland	Regional permanent freshwater rivers
Pond wetland	Mainly refers to a small area of aquaculture water, irrigation reservoirs, etc.
Paddy fields	Mainly refers to paddy fields, also includes a small amount of cultivation of lotus root, artemisia and other aquatic plants arable land

Using spectral signatures, geometric features and environmental conditions of the main types of wetlands, our study followed the principle of "regional analysis followed by type recognition" and built a decision tree model of comprehensive indicators (*Fig. 2*).

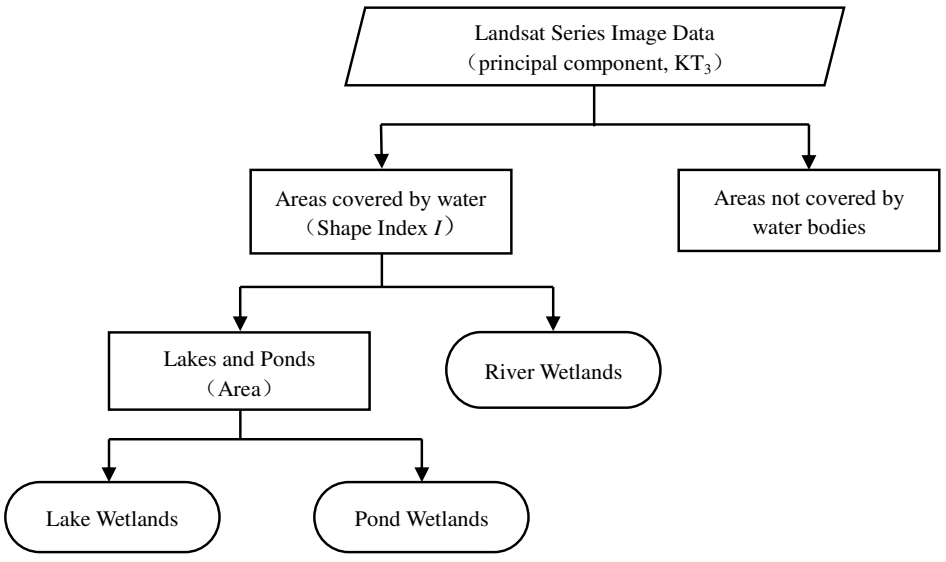

Figure 2. *Decision tree model for wetland information classification and extraction*

In the model, the Tasseled Cap transform (TCT), also known as Kauth–Thomas (K-T) transform, is performed to preprocess the images. The essence of TCT is similar to the principal component analysis by taking linear combinations of the original spectral

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1090910927

bands (Mostafiz and Chang, 2018). TCT is a widely used metric capable of capturing scene characteristics in related coordinate directions in a defined feature space and provides a mechanism for data volume reduction with minimal information loss and its spectral features can be directly associated with the important physical parameters of the land surface (Crist, 1985; Yarbrough et al., 2012). Consequently, the TCT conducting in TM imagery has been widely applied for ecological monitoring and other environmental studies, and its reliability and accuracy have been generally recognized (Zhang et al., 2002). In the studies of interpretation of land surface images, the TCT is usually employed to establish an automatic classification and recognition system (Thenkabail and Wu, 2012).

Valuation methods

Equivalent values

The MA definition follows Costanza and his colleagues in including both natural and human-modified ecosystems as sources of ecosystem services, and classify ecosystem services using categories of provisioning, regulating, cultural, and supporting services (MA, 2003). Among these services, 1) provisioning services refer to the products obtained from ecosystems, including food, fiber, wood, fresh water, etc.; 2) regulating services refer to the benefits obtained from the regulation of ecosystem processes, including gas regulation, climate regulation, soil erosion control, water purification and waste treatment, etc.; 3) cultural services are the nonmaterial benefits people obtain from ecosystems through spiritual enrichment, cognitive development, reflection, recreation, and aesthetic experiences, etc., 4) supporting services refer to those that are necessary for the production of all other ecosystem services, including primary production, production of oxygen, soil formation and retention, materials cycling and provisioning of habitat, etc.

Based on the previous studies, a basic equivalent system for ecosystem service value accounting is proposed by Xie and other Chinese researchers, within a basic idea of VTM (Xie et al., 2001, 2008, 2010, 2015a, b). Since 2008, the method has been optimized and improved many times, and its research adaptability has been fully proved. With the equivalent value per unit area of the ecosystem services set as the basis in the study (Xie et al., 2010, 2015), we could calculate the monetized value per unit area according to the price of the average national crop production. The equivalent values per unit area of different ecosystem services in 2015 are presented (*Table 3*).

Correction of equivalent values of water supply and flood control

Adapting to the specific situation of the study area, *Equation 1* is used to amend the equivalent values of two sub-category services, water supply and flood control. Considering both services are related to the hydrological processes of wetland ecosystems, the amount of precipitation is employed as a reliable modifying factor to amend the equivalent values.

$$R_i = W_i / \overline{W} \quad \text{(Eq.1)}$$

where R_i stands for the correction coefficient of equivalent values of water supply and flood control services in Region i, W_i refers to the annual precipitation in Region i, and $\overline{W}$ refers to the average annual precipitation in the whole nation.

Correction of equivalent value of soil maintenance

The ratio between the soil maintenance amount per unit area in the study regions and nationwide average level is taken as the correction coefficient of the equivalent value of the soil maintenance service. The equation is presented as *Equation 2:*

$$S_i = E_i / \bar{E} \quad \text{(Eq.2)}$$

where S_i stands for the correction coefficient of the equivalent value of soil maintenance in Region i, E_i refers to the soil maintenance amount per unit area in Region i, and $\bar{E}$ refers to the average amount of nationwide soil maintenance per unit area.

In most studies, the Universal Soil Loss Equation (USLE) is generally used to calculate the amount of soil erosion as it is a widely used mathematical model that describes soil erosion processes. The USLE was developed from erosion plot and rainfall simulator experiments. The USLE is composed of six factors to predict the long-term average annual soil loss in different situations. The equations take the simple product form as *Equations 3* and *4:*

$$SP_x = R_x \cdot K_x \cdot L \cdot S_x \cdot \quad \text{(Eq.3)}$$

$$SA_x = R_x \cdot K_x \cdot L \cdot S_x \cdot C_x \cdot P_x \quad \text{(Eq.4)}$$

where SP_x refers to the potential amount of average annual soil erosion, SA_x refers to the actual amount of average annual soil loss, while R_x, K_x, $L \cdot S_x$, C_x and P_x represent the rainfall erosivity factor, the soil erodibility factor, the land form factor, the land cover

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1090910927

and management factor and the land conservation measure factor, respectively. In addition, the potential amount of average annual soil erosion is a quantitative expression of the theoretical soil loss in the absence of vegetation and other management means.

According to *Equations 3* and *4,* we could obtain *Equation 5* to calculate average annual soil maintenance amount (SM_x):

$$SM_x = R_x \cdot K_x \cdot L \cdot S_x \cdot (1 - C_x \cdot P_x \quad \text{(Eq.5)}$$

Calculation of total values

The post-correction monetized value per unit area of each wetland ecosystem is calculated based on the equivalent values, the fundamental equivalent price and the correction coefficient. And the total value of ecosystem services is worked out based on the area of different types of wetlands in the research area. We first make calculations for different regions and then add them up to calculate the total value. The equation for this calculation is shown as *Equation 6:*

$$ESV = \sum A_{ki}\, m_{ki}\, n_{ki}\, C \quad \text{(Eq.6)}$$

where ESV refers to the amount of ecosystem services value (USD/a), A_{ki} refers to the area (hm^2) of Type *k* wetland in Region *i*; m_{ki} is the equivalent value of Type *k* wetland in Region *i*; n_{ki} is the correction coefficient of the equivalent value of Type *k* wetland in Region *i*, and C refers to the fundamental equivalent price of ecosystem services per unit area (USD/(hm^2·a)).

Results

LUCC data

Landsat images were often used to extract LUCC data, and land surface water is often identified by TCT (Mcfeeters, 1996; Chandrasekar et al., 2010; Adam et al., 2014; Fu and Burgher, 2015; Friedl et al., 2018). Meanwhile, the significant effectiveness of TCT in classification and extraction of wetland image has also been proved (Jiang et al., 2015; Luo and Tao, 2017; Mostafiz and Chang, 2018). The TCT method enhances the spectral information content of Landsat data for different implications of the earth's surface. Typically, there are three generally used dimensions in TCT, consisting by brightness (measure of soil), greenness (measure of vegetation), and wetness (measure of moisture) (Yarbrough et al., 2012; Adam et al., 2014; Fu and Burgher, 2015; Mostafiz and Chang, 2018). In this study, the water-covered areas were identified by the third principal component, KT_3 (wetness, mainly reflects the humidity information of ground objects), before extracting information of different types of wetlands according to the area and shape. Meanwhile, the area of paddy fields is taken as described from the yearbooks of Liuhe, Pukou and Baguazhou in different years. The results of the remote extraction and classification are shown below (*Figs. 3, 4* and *5*), and the areas of different types of wetlands are presented (*Table 4*).

Following the results from the extraction and classification of remote images from 2015, we identified the sampling sites through an stochastic method based on the proportion that each of the three types of wetlands (rivers, lakes and ponds) takes up in the total area of wetlands. On that basis, we verified the accuracy of extraction results

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1090910927

through comparison between the land use map and site surveying data. As the results of accuracy tests by the confusion matrix show, the classification accuracy rate of rivers and lakes are high, reaching 97.33% and 94.21%, respectively; while the extraction accuracy of ponds is lower, standing at 82.31%. The overall classification accuracy of the extraction results is 86.50% and the overall Kappa coefficient is 0.8433.

Table 4. *Area of wetlands in different years*

Wetland types	Regions	2002		2009		2015

	Liuhe	26677.00	17.96	27300.00	18.38	26100.00	17.58
	Baguazhou	2333.00	41.66	2333.00	41.66	2333.00	41.66
	Jiangbei	38572.00	15.74	38199.33	15.59	36859.67	15.04
Total area	Pukou	13359.50	14.68	13501.39	14.84	10400.01	11.43
	Liuhe	32106.62	21.62	35232.69	23.73	31760.73	21.39
	Baguazhou	2488.16	44.43	2516.46	44.94	2457.17	43.88
	Jiangbei	47954.27	19.57	51250.54	20.91	44617.91	18.20

According to the interpretation results and relevant statistical data (*Figs. 3, 4,* and *5; Table 4*), during the three research periods, the total area of wetlands in Jiangbei New Area in 2002, 2009 and 2015 are 47954.27 hm^2, 51250.54 hm^2 and 44617.91 hm^2 respectively, accounting for 19.57%, 20.91% and 18.20% of the total land area respectively.

According to the dynamic change of the total wetland area in Jiangbei New Area, the total wetland area increased slowly during the period of 2002-2009 and decreased continuously during 2009-2015. On the basis of the long-term change from 2002 to 2015, the total wetland area decreased by 0.54% annually on average, showing a slowly decreasing trend on the whole. From 2002 to 2009, the area of other types of wetlands increased significantly except for paddy field wetlands, the most obvious increasing was shown as the average annual growth rate of river wetlands (7.54%) and pond wetlands (6.14%). From 2009 to 2015, by contrast, the area of all types of wetlands decreased relatively rapidly, and the average annual reduction rate of pond wetlands was the most significant (-8.63%).

Correction results

Fundamental equivalent price

Within the Value Transfer Method, the economic value of productivity per unit area of farmland is utilized as the basis of fundamental ecosystem service price calculating in unit area. Computation based on relevant data, the economic value of crops production per unit area in China in 2010 was 3406.5 RMB/hm^2 (Nie, 2011; Xie et al., 2015b; Zhang et al., 2016), converting to 503.21 USD/hm^2 according to the average exchange rate of RMB against US dollar in 2010 (6.7695). We obtained the corrected price of the standard equivalent by calculating the ratio between the value of crops production per unit area in Nanjing and the same value nationwide in 2010 (Nanjing Statistical Bureau, 2012), after which we then obtained a correction coefficient of 1.38. As a result, the economic value of the fundamental equivalent of ecosystem services per unit area in Nanjing was 4700.97 RMB/hm^2, converting to 694.43 USD/hm^2 according to the average exchange rate mentioned above.

Correction coefficients

Through the calculation of the ratio of annual precipitation in the Jiangbei New Area and the national average level, we obtained the correction coefficients for the equivalent values of the services of water supply and flood control (*Table 5*).

In 2010, the soil maintenance amount per unit area in China was 208.88 t hm^{-2} a^{-1} (Rao, 2015). The average soil erosion modulus (actual amount of average annual soil loss) in the Pukou District over several years was 2465 t km^{-2} a^{-1}, that in the Liuhe

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1090910927

District was 2357 t km^{-2} a^{-1} and 3546 t km^{-2} a^{-1} in the Baguazhou Sandbank, while the average *CP* value over those years in Nanjing was 0.0483 (Ma et al., 2011). Using *Equation 5* to calculate, we find that the average soil maintenance amount over those years in the Pukou is 485.70 t hm^{-2} a^{-1}, and that for the Liuhe and the Baguazhou Sandbank are 464.42 t hm^{-2} a^{-1} and 698.70 t hm^{-2} a^{-1}, respectively.

Table 5. *Correction coefficients of equivalent value of water supply and flood control services*

Year	Average annual precipitation in China	Annual precipitation & correction coefficients in Pukon		Annual precipitation & correction coefficients in Liuhe		Annual precipitation & correction coefficients in Baguazhou	
2002	660 mm	1083.6 mm	1.64	980.2 mm	1.49	1105.7 mm	1.68
2009	591.1 mm	1174.2 mm	1.99	1055.1 mm	1.78	1368.9 mm	2.32
2015	648.8 mm	1508.1 mm	2.32	1300.4 mm	2.00	1535.8 mm	2.37

Using the ratio between the average Soil maintenance amount in each region and the national average level, we calculated the correction coefficients of the equivalent value of the Soil maintenance service in the Pukou District, the Liuhe District and the Baguazhou Sandbank, which are 2.33, 2.22 and 3.34, respectively.

Valuation results

Using the previously stated *Equation 6* for the calculations, the results for the valuation of wetland ecosystem services in 2002, 2009 and 2015 in the Jiangbei New Area in Nanjing are presented (*Tables 6, 7* and *8*). The ecosystem services of wetlands in this area reached its highest value in 2009 at 1365.63 million USD, and reached its lowest in 2002 at 893.99 million USD, with the 2015 value of1016.46 million USD in the middle.

To sum up, the value of ecosystem services of wetlands in the Jiangbei New Area presents a variable trend: it moved up sharply from 2002 to 2009, with an annual increase rate of 7.50%, but underwent a tangible drop from 2009 to 2015, with an annual decrease rate of 4.26% (*Fig. 6*).

The category-related components of ecosystem services of wetlands in the Jiangbei New Area are presented (*Table 9*). Among the presented components, the regulating service plays a vital role, taking up about 90% of the total value and even up to 95.81% in 2015, while the provisioning service contributes the least to the ecosystem services, with the proportion being negative in 2002 and 2015, accounting for the major losses in the ecosystem services of urban wetlands.

Table 9. *Category proportion of the wetland ecosystem services value*

Year	Provisioning services	Regulating services	Supporting services	Cultural services
2002	-1.30%	90.16%	8.35%	2.80%
2009	0.17%	89.96%	7.36%	2.51%
2015	-3.52%	95.81%	5.78%	1.93%

Discussion

The change and composition of value

The importance or "value" of ecosystems is viewed and expressed differently by different disciplines, cultural conceptions, philosophical views, and schools of thought (MA, 2003). The monetization of the value of ecosystem services is a more intuitively way to help people understanding the significance of ecosystem services to human well-being.

According to the valuation results, the value of ecosystem services of wetlands in the Jiangbei New Area reached 893.99 million USD, 1365.63 million USD and 1016.46 million USD in 2002, 2009 and 2015, respectively. In general, these results have the characteristics of temporal discretization, with notably changes in the values among different time periods, implicating a variable state of the wetland ecosystem. Among the three regions, Pukou shows the least stability with the sharpest and most obvious fluctuations over time. Consistent with findings of Zhang et al. (2015b), the change of wetland ecosystem service value is directly related to the change of land use pattern. Land use changes generally can be defined as a human-induced process that has great consequences for landscape and related ecosystems (Sawut et al., 2013).

Similar to the findings in Chaohu Lake Basin (Zhang et al., 2015b), the regulating service performances the core part of the ecosystem services of wetlands in study area. In this category, the flood control service has the highest value, which reflects the structural and functional stability of wetlands ecosystem is of vital importance for the ecological security in the Jiangbei New Area. Yet, the regulating services cannot be perceived or recognized directly by human observation. Located along the northern bank of the Yangtze River, the Jiangbei New Area is rich in precipitation and consists mainly of hilly lands; the landscapes and land covers have been largely damaged, leaving the area susceptible to inundation and waterlogging. Therefore, the regulating services, especially the flood control service, of the urban wetland ecosystem, deserves more attention as a key of the regional ecological security guarantee system.

The provisioning service contributes the least to the total value, with its contribution rate being negative in 2002 and 2015. This result is not consistent with the findings in Chaohu Lake Basin, Lakeside Wetland Park and other areas (Zhang et al., 2014, 2015b, 2017; Li and Gao, 2016). In previous research cases, the value calculation includes farmland, woodland and other types, so the provisioning service value is relatively high. Nevertheless, the land use type structure of our study area is different from that of lake basins, wetland parks or metropolis. Paddy fields and ponds wetland are the main components of production system in the study area. According to the calculation results, the value of the water supply service in 2015 was -78.37 million USD, mainly because the paddy fields take up the largest proportion in the total area of wetlands in the study area and these fields are largely water-consuming during the production process. Nonetheless, analysis of the hydrologic process of the paddy fields shows that these

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1090910927

fields are critical in water conservation (Xie et al., 2008) and, in particular, play an important role in underground water supply and water storage during floods; its function in water conservation has been included as a factor in the service type of flood control (Xie et al., 2015a, b). Therefore, respect to the direct benefits that humans receive from ecosystems, the water provisioning service of the paddy fields is obviously smaller compared to the water provisioning of other types of wetlands.

The impact of urbanization

Previous research has proved that regional massive urbanization had serious implications on the provision for ecosystem services, whether they be provisioning services or regulating services (Ai et al., 2015). Similarly, our research findings sufficiently proved that disorganized urbanization poses severe threats to the urban wetland ecosystem. A better understanding of the value of ecosystem services will facilitate protection and recovery of wetland resources in urban sprawl areas (Li et al., 2014). The rapidly urbanizing in Jiangbei New Are is acting as a violent form of human activity and causing obvious land use changes resulting in a great effect on the wetland ecosystem services.

According to this study, the area of wetlands in Pukou and the value of their ecological services witnessed a sharp drop between 2009 and 2015, because against the backdrop of fast urbanization driven by the planning of a new city center, wetlands were encroached and the original landscapes were destroyed, debilitating the ecosystem services. In the future, urban planners of Pukou should pay more attention to the ecological functions of urban wetlands, prevent the impertinently wetland occupying, protect and recover key wetlands and closely monitor wetland ecosystems in the city to build a stable ecosystem and support the development of the city center. Meanwhile, though there are no obvious losses in the value of ecosystem services of wetlands in Liuhe, protection and regional recovery of wetlands in this region should be given attention to maintain and improve the value of wetland ecosystem services. In particular, lake wetlands in the northern part of Liuhe and pond wetlands in the basin of the Chu River in the region's center should be protected and properly utilized to avoid severe value losses caused by future rapid urbanization, as Pukou has experienced.

Conclusion

This study has presented a dynamic model system to assess the value of ecosystem services of urban wetlands. Following the principle of "regional analysis followed by type recognition", our study developed a decision tree model for the automatic classification and extraction of remote images of urban wetlands. In addition, based on analysis of the spatial distribution and surrounding environment of urban wetlands, the model employed certain regulating factors to correct the fundamental price and the equivalent values, dynamically evaluating the value of wetland ecosystem services in different years in the research area. The study demonstrates that this approach is suitable for ecosystem services valuation in regional spatial scale and could accomplish a fast and convenient monitoring of the value of urban wetlands, supporting decision-making activities in urban management. Based on this study case, the application of VTM could be modified in other urban scale ecosystems.

The analysis empirically demonstrated that regional massive urbanization had serious implications on the provision for urban wetland ecosystem services. In the past period,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

the local government of the Jiangbei New Area applied special stress on the construction of infrastructure in localized regions to pursue a high level of quality to the economy and urban development, yet ignored the effective protection of the wetlands ecosystem there. It was inevitable that the ecological conditions of wetlands in the rapidly urbanizing area would deteriorate and the capability to provide ecosystem services would degenerate.

The valuation results would also provide a more appropriate reference to decision makers, and draw more attention to the importance of wetland systems in the field of urban ecological security, seeking the synchronized development of human well-being and the nature. Specifically, the valuation can help the regional policy maker (i.e., government, community) to aware the value of ecological resources and formulate or adjust policies accordingly to protect and restore ecosystem services in one particular area. The results suggest that rapid urban development should adopt an ecosystem service oriented strategy to align sustainable utilization with conservation and to recognize the interaction between the wetland ecosystem services and the forces of urbanization. The local administrators and planners should pay enough attention to analysis the value change in and maintain the capability of wetland ecosystem services in urban area. There is an urgent need for conducting the conservation and rehabilitation of urban wetland as key policies in the regional planning, while scientific appraisal can serve as the basis for policy formulation and valuation. Therefore, to evaluate urban wetland ecosystems correctly and frequently is of great significance.

Abstract. Environmental conditions have a great influence on the growth and development of weeds and, consequently, on their ability to compete, and changing these conditions can be effective in weed management. For this purpose, an experiment was carried out in 2016 and 2017 in the greenhouse of the Faculty of Agriculture and Natural Resources, University of Mohaghegh Ardabili, Iran. The studied factors were four weed species Red root pigweed (*Amaranthus retroflexus)*, Jimsonweed (*Datura stramonium)*, Russian knapweed (*Acroptilon repens* L*)* and Catchweed (*Setaria verticilata*) and three irrigation periods to field capacity (irrigation daily (control), irrigation once in every three days and irrigated once every six days). Results showed that with increasing irrigation period, Leaf Area Index (LAI), Relative Growth Rate (RGR), Weed Growth Rate (WGR), Net Assimilation Rate (NAR) and Total Dry Matter (TDM) decreased. The extent of decrease in growth indices was different between weeds C3 and C4. Total dry matter of Catchweed and Red root pigweed responded to increased irrigation periods less than others. In control irrigation, Jimsonweed growth indices were higher than other weeds, but to exert stress and increasing irrigation periods, Red root pigweed was more successful and a stronger competitor.
Keywords: *weeds management, environmental conditions, growth analysis, drought stress, irrigation period*

Introduction

Weeds are a hidden foe for crop plants, interfering with their functions and suppressing their growth and development. Hence, weeds have been documented as serious plant pests since the ancient times. Environmental factors influence weed growth and composition of arable weed species, therefore need more accurate estimations of the damage potential of arable weeds to develop effective weed control strategies while maintaining crop yield (Zimdahl, 2013; Peters et al., 2014). The purpose of the study of physiological characteristics is to describe or explain how the plant reacts to environmental conditions (Beech and Norman, 2002). One of the major problems in the production of agricultural products is the competition of weeds over growth resources, especially water stored in the soil (Monaco et al., 2002). In addition to weeds competition, drought stress is another factor in reducing production. Drought is one of the most important environmental stresses that has destructive and harmful effects on different plant growth stages, organ structure and activity (Eslami et al., 2012). In different experiments, humidity and temperature are mentioned as the most influential environmental factors on the growth of weed seedlings (Benvenuti et al., 2001). Results of Chauhan and Johnson (2010) showed that with increasing drought stress, the vegetative and reproductive characteristics of barnyard grass weed (*Echinochola cruss- galli L.*) decreased. Webster and Grey (2008) reported that under drought stress the biomass of *Commelina benghalensis* decreased. In research studies on the effect of irrigation periods (1, 3, 6, 9, 12 and 15 days) on weed growth characteristics of *Echinochloa colona* and *Rottboellia cochinchinensis*, it was found that

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1092910940

in general, with prolonging irrigation periods, height, number of leaves, number of stems, dry weight of shoot, root dry weight and seed production of these weeds decreased (Chauhan and Johnson, 2010 and Chauhan, 2013). Since changes in weeds growth indices have been considered less than environmental conditions change, so this experiment was conducted to evaluate the effect of irrigation periods on growth indices of Red root pigweed (*Amaranthus retroflexus)*, Jimsonweed (*Datura stramonium)*, Russian knapweed (*Acroptilon repens L)* and Catchweed (*Setaria verticilata*).

Materials and methods

The experiment was carried out as a factorial experiment based on randomized complete block design with five replications in the greenhouse of the Faculty of Agriculture and Natural Resources, University of Mohaghegh Ardebili, Iran during 2016 and 2017. The studied factors were four weed species; Red root pigweed (*Amaranthus retroflexus)*, Jimsonweed (*Datura stramonium)*, Russian knapweed (*Acroptilon repens L)* and Catchweed (*Setaria verticilata*) and three irrigation periods to field capacity (irrigation daily (control), irrigation once in every three days and irrigated once every six days). Weed seeds were collected from the surrounding farms. For planting nylon 12 L pots (26 × 36 cm) were filled with agricultural soil until sufficient growth conditions were provided for the roots. The amount of soil within each pot was 10 kg. The soil characteristics are shown in *Table 1*. Weed seeds were planted at a depth of 1 cm and immediately irrigated to field capacity. Roots of the same Russian knapweed were cultivated horizontally at a depth of 4 cm. Four pots were considered for each treatment in each replication, in order to destructive sampling. After germination of seeds, different irrigation periods were performed. Sampling started from the four-leaf stage of the plants and repeated once every 10 days. For this purpose, the plants were cut from soil surface, and after measuring the leaf area and their number, they were dried in an oven for 48 h at 75 °C. The roots were also separated from the soil by washing and their weight and length were measured. The length of the root was measured by measuring the longest root length with a ruler. Also, in measuring root dry weight, the root system of the plant was washed after being placed in an oven with a numerical scale of 0.001. To exit healthy roots, the soil is poured into nylon pots, at the end of the work, the pots were placed in the water pond and the root soil was washed out. For the above characteristics, analysis of variance and comparison of mean of cultivars were performed using SAS software.

Table 1. *Soil physical and chemistry properties*

pH	EC (Ms/cm)	OM %	Soil texture	Clay	Silt	Sand
7.8	366	1.74	Clay loam	36.72	34.56	28.72

Growth analysis parameters such as Total Dry Matter (TDM), Relative Growth Rate (RGR), Weed Growth Rate (WGR), Leaf Area Index (LAI), and Net Assimilation Rate (NAR) were measured using the following relationships (Rosal et al., 1984), and the charts were drawn with the help of Excel software.

$$TDM = e^{(a1 + b1t + c1t2 + d1t3)} \quad \text{(Eq.1)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1092910940

where TDM, total dry matter (g/m^2), was obtained by weighing the total dry matter of the plant in square meter.

$$LAI = e^{(a2 + b2t + c2t2 + d2t3)} \quad \text{(Eq.2)}$$

where LAI: leaf area index, by measuring the leaf area with the help of the device leaf area meter, and was calculated using the formula LAI = LA / P.

$$LDW = e^{(a3 + b3t + c3t2 + d3t3)} \quad \text{(Eq.3)}$$

where LDW: Green leaf dry weight (g or mg). Weight of green leaves dried in the oven, also, whose surface was calculated, weighed and noted. The other growth indices were calculated with the help of the following values.

$$WGR = RGR \times TDM \quad \text{(Eq.4)}$$

where WGR: Weed growth rate ($g\ m^{-2}\ d^{-1}$).

Weed growth rate is the derivative function of the total dry matter in unit of time (t) or multiplication RGR in TDM.

$$WGR = (b1 + 2c_1t + 3d_1t^2)\ e^{(a1 + b1t + c1t2 + d1t3)}$$
$$RGR = TDM/CGR \quad \text{(Eq.5)}$$

where RGR: Relative growth rate ($gg^{-1}d^{-1}$). Relative growth rate is the derivative of natural logarithm function of total dry matter in unit of time (t) or the result is the division of TDM on CGR.

$$Ln\ TDM = a1 + b1t + c1t2 + d1t3$$
$$RGR = b1 + 2c1t + d1/2t3 \quad \text{(Eq.6)}$$
$$NAR = CGR/LAI$$

where NAR: net assimilation rate ($gm^{-2}\ d^{-1}$).

$$NAR = (b1 + 2c1 + 3d1t2)\ e^{(a1-a2) + (b1-b2)\ t + (c1-c2)\ t2 + (d1-d2)\ t3}$$

Results and discussion

Weeds growth rate (WGR)

The results showed that WGR was affected by irrigation periods and for all weed species was at its peak for the first irrigation periods (control) in both 2016 and 2017 years in Jimsonweed 7.5 and 8.5 $g.m^2$ d, red root pigweed 5.5 and 6.2 $g.m^2$. d, Russian knapweed 4 and 4.3 $g.m^2$. d and Catchweed 3.3 and 2.9 g.m2. d. Regarding the logical and direct relationship between LAI and WGR, these results were consistent with the results obtained for LAI and showed that drought stress affects leaves development, dry matter production and growth rate. The changes trend in the growth rate of weeds in all treatments was relatively similar (*Fig. 1*). In control irrigation, WGR collapsed after reaching its peak at (45 to 54) days after planting the examined species. But for the second irrigation period the start of WGR collapse happens on 32-40 days, and for the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1092910940

third irrigation period on 30 to 32 days. It seems that weeds, under severe water shortages, take action by falling leaves to reduce evapotranspiration, before reaching their maximum growth, and thus lose their Carbohydrate factory. As can be viewed, WGR decreases in the third irrigation period earlier than another period. Investigating *Figure 1* shows that there is a difference between the four weed species in terms of WGR. In the irrigation control, Jimsonweed has a maximum growth rate. The reason for this can be pointed out the high level of leaf area index, which that caused the sunlight more and better to use. Jimsonweed retains its leaf area, it showed more ability to reach maximum WGR, because it makes more carbohydrates and receives better radiation. Whatever growth rate of the weed has, its ability is increased to compete with the crop. Because in this case, weed can more effectively overcome the canopy of the crop and maximize the use of limited resources available (Sadeghi et al., 2009). By increasing the irrigation period, the amount of CGR in weeds decreased. Nevertheless, the extent of this reduction is accompanied by some changes. As can be seen in *Figure 1,* by applying stress and increasing the irrigation period, the decrease in the growth rate of Jimsonweed and Russian knapweed weeds is greater than that is of Red root pigweed and Catchweed. In fact, it is quickly impacted by stress. This can be attributed to the fact that the two weeds are C3 plants. In fact, under conditions of water shortage and drought stress, C3 weeds have less competitive power than C4 weed (Sadeghi et al., 2009). From among the two weeds of the C4, Red root pigweed has a high resistance to stress. With regard to the direct relationship between WGR and LAI, it can be concluded that red root pigweed with a high leaf area can reach to a high WGR, because it makes more carbohydrates with the receipt of better radiation (Karim Zadeh Asl et al., 2004).

Therefore, it can be concluded that Jimsonweed can be problematic in the field under stressless conditions and continuous irrigation or regular rainfall, but if rainfall reduces or irrigation is low, the weeds flora will be changed and red root pigweed will be problematic. Also, it was found out that the weed growth rate is important at the time of applying a weed management strategy, including the use of herbicides.

$$WGR = (b1 + 2c1t + 3d1t2)\, e(a1 + b1t + c1t2 + d1t3)$$

$$WGR = RGR \times TDM$$

DOI: http://dx.doi.org/10.15666/aeer/1705_1092910940

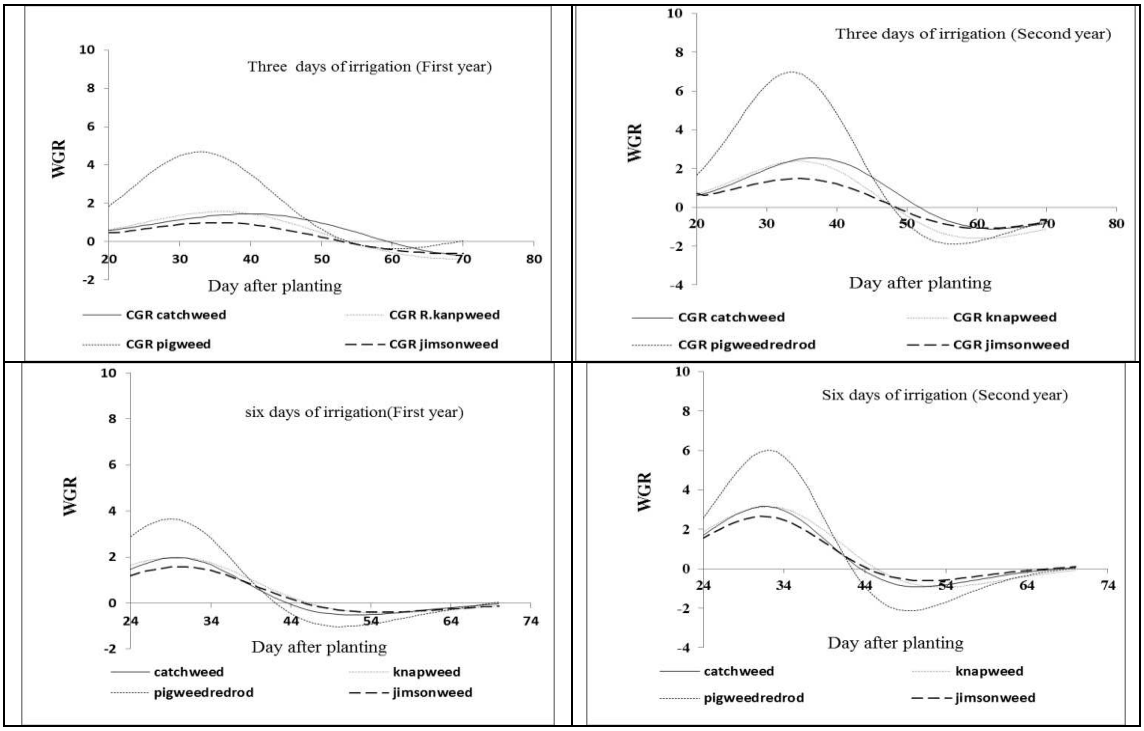

Figure 1. *The effect of irrigation period on the changes trend in weed growth rate during the growing season*

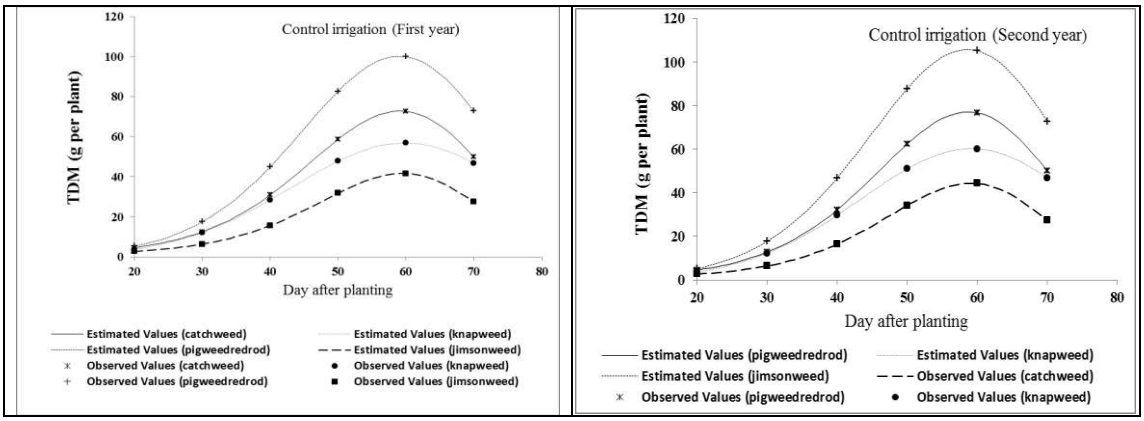
Total dry matter (TDM)

The results showed that in two years of experimentation, weed total dry matter declined with increasing irrigation period (*Fig. 2*). In all of the sampling, in the two years, Jimsonweed had the highest total dry matter (100 and 110 g per plant) in irrigation control. With increasing irrigation period (3 and 6 days) and applying drought stress and water shortage conditions, decreasing of Jimsonweed total dry matter was more intense. Catchweed and Red root pigweed total dry matter, changed less afoul and declined under stress conditions. This can be attributed to the fact that the two weeds are C4 plants. In fact, C3 weeds have less competitive power than weed C4 under conditions of water shortage and drought stress.

$$TDM = e^{(a1 + b1t + c1t2 + d1t3)}$$



http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1092910940

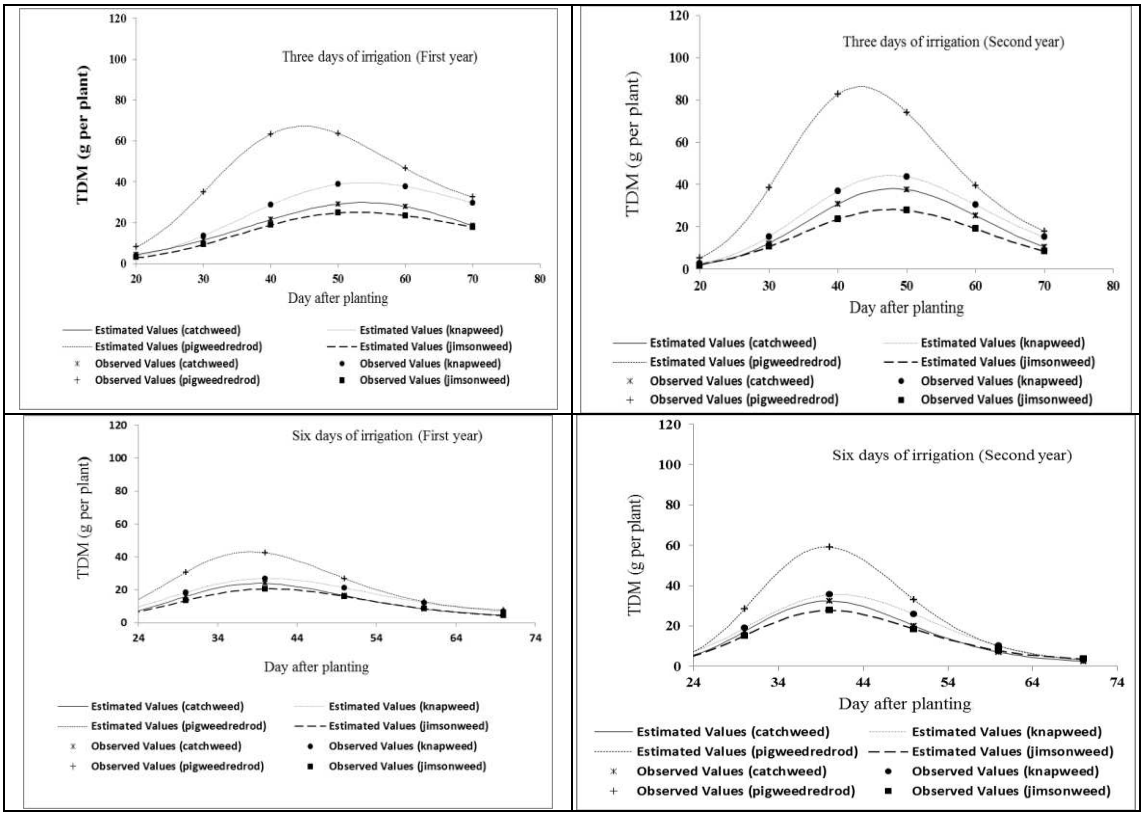


Figure 2. *The effect of irrigation period on changes trend in weed total dry matter during the growing season*

Leaf area index (LAI)

In the irrigation control, LAI is at its peak at all weeds examined. Jimsonweed (6 and 6.5), Red root pigweed (4.5 and 5), Russian knapweed (5.5 and 7.5) and Catchweed (2.3 and 2.7). In the meantime, LAI Jimsonweed is higher than other weeds. As seen in *Figure 3,* with the onset of stress and applying irrigation periods of 3 and 6 days, LAI reduced all weeds, and in 3 days, in both years, in Red root pigweed, Jimsonweed, Catchweed and Russian knapweed, it reached (3.8 and 5, 1.7 and 2, 1.5 and 2, 1.4 and 1.6) and in 6 days (2.4 and 3.2, 1.4 and 1.9, 1.9 and 2.5, 1.5 and 1.7) respectively. It is clearly that water shortage influence on plant morphology for example loss leaf number and leaf area reduction. Therefore, the results can be justified. Although the LAI begins to collapse after its peak, but it is becoming more intense with increasing irrigation periods.

Rawson and Turner (1982) concluded during the experiment that the number of leaves in sunflowers under drought stress was less than in non-stressed cultivars, also, the leaf area increased with increasing number of irrigation period. The main symptom of drought stress at the stage of growth is the reduction of the number and size of leaves. If the water shortage continues, the lower leaves fell and plant height will be significantly lower than normal.

$$LAI = e\ (a2 + b2t + c2t2 + d2t3)$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1092910940

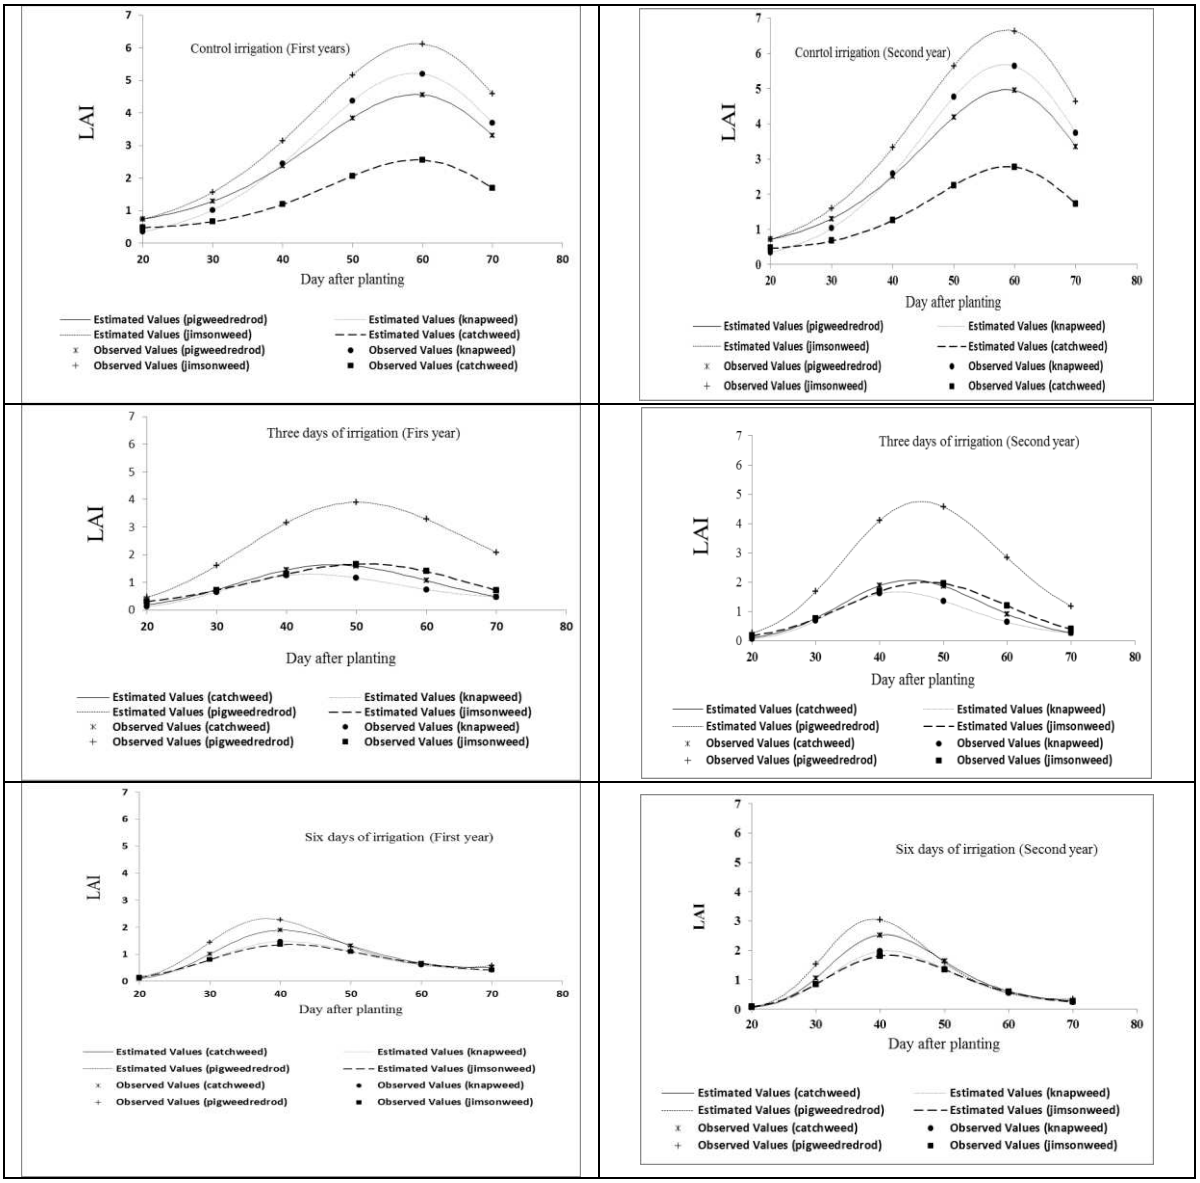

Figure 3. *The effect of irrigation period on changes trend in leaf area index during the growing season*

Figure 3 shows that Jimsonweed leaf area index is at a higher point than other weeds, but by applying irrigation periods, LAI reduction in Jimsonweed is more intense and it arrived less than the Red root pigweed leaf area index. Regarding what is seen from this curve in an environment without stress, Jimsonweed has better leaf area development and more potential for dry matter production than other weeds. Better leaf development allows the carbohydrate factory to be more productive and more competitive than other weeds. But by applying irrigation periods and increasing irrigation periods, it gives its place to the Red root pigweed.

Relative growth rate (RGR)

The results showed that in all irrigation periods, RGR was decreasing trend and with increasing irrigation periods, the rate of reduction of RGR also increased. RGR in all

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1092910940

weeds in the first irrigation periods at 68-73 days after planting, for the second and third irrigation periods at 50-60 and 41-44 days after planting, respectively, was zero. Six days irrigation gets zero faster than three days and control treatment (*Fig. 4*). Human et al. (1990) stated that RGR changes have decreased mode relative time, but its slope depends on environmental factors. Drought stress causes premature aging of the plant and this mechanism for that is the plant as soon as complete its growth period to escape dryness (Kochaki and Sarmadnia, 1990). Yegappan et al. (1982) has also achieved similar results. It seems with longing irrigation periods, the RGR faster reaches to zero.

$$RGR = TDM/CGR$$

$$Ln\ TDM = a1 + b1t + c1t2 + d1t3$$

$$RGR = b1 + 2c1t + d1/2t3$$

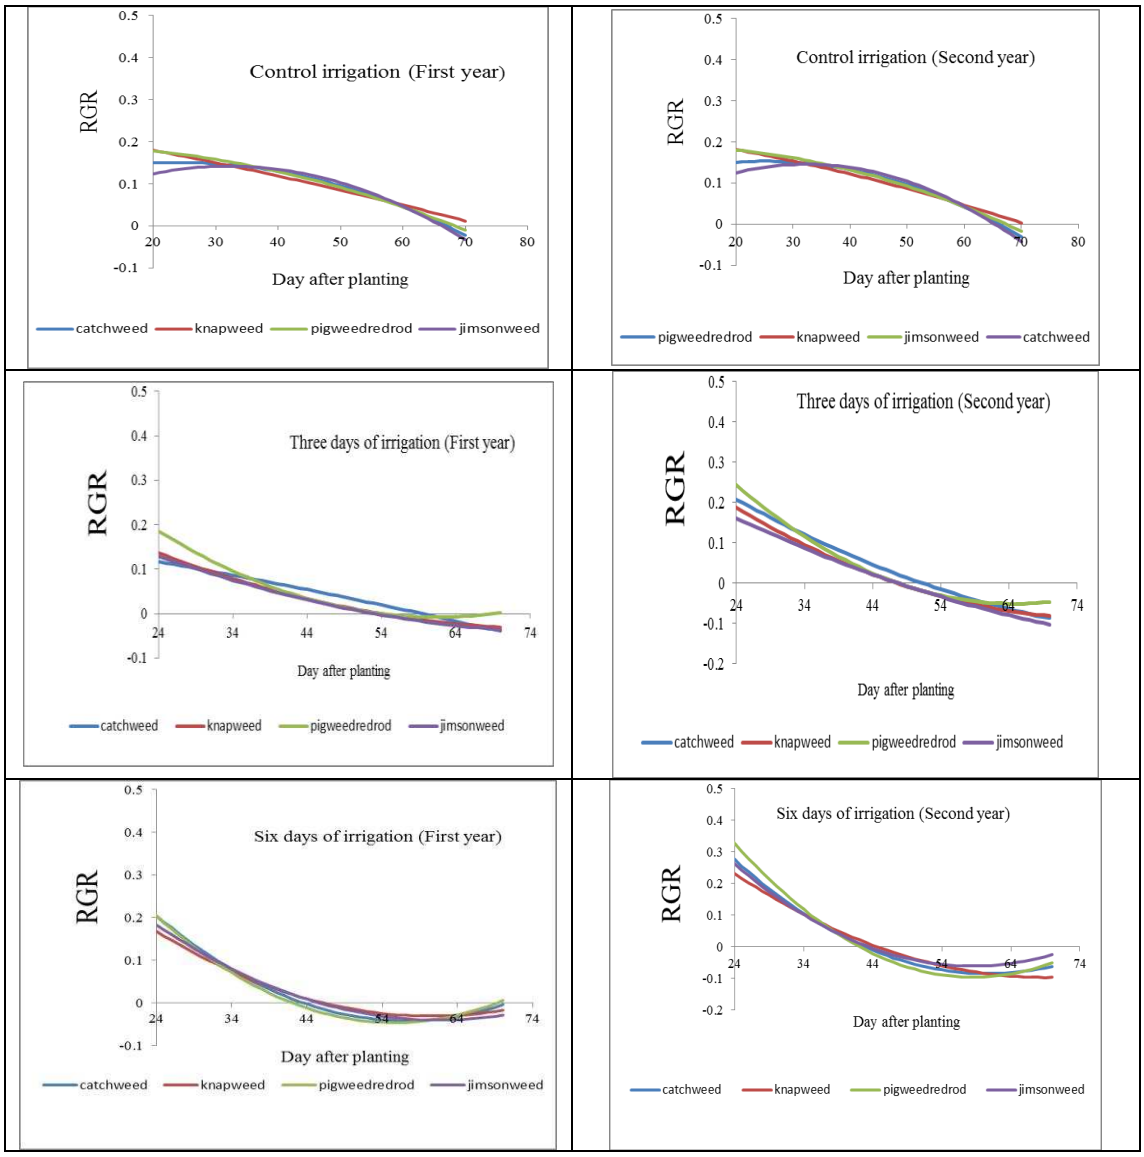

Figure 4. *The effect of irrigation period on relative growth rate of weeds*

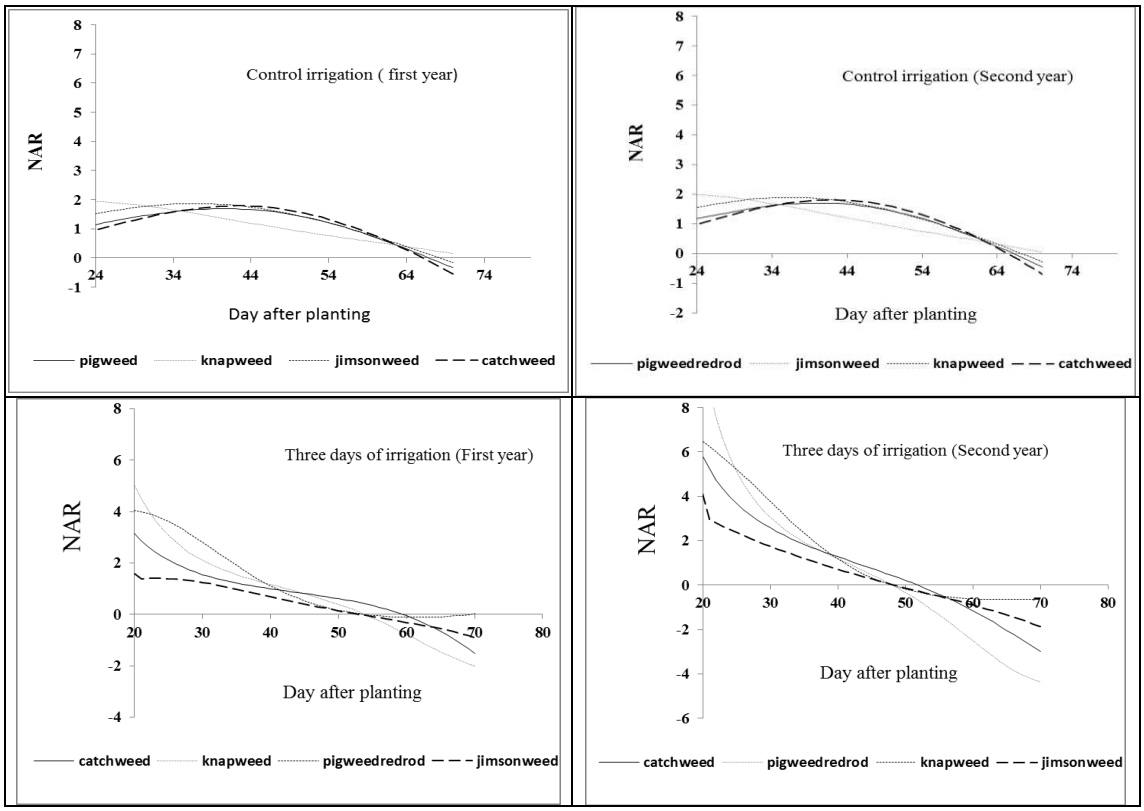
http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1092910940

Net assimilation rate (NAR)

NAR starts the descent trend for all periods of irrigation, however, the slope falling of NAR was slower in control than other both irrigation periods (*Fig. 5*). Given that in normal mode, Nar decreases due to shading leaves, but in treatments under stress, even though, photosynthesis capacity is reduced due to the closure of stomata as a mechanism to combat water losses, however, due to the shortage of leaves numbers and lower leaf area, little shading is observed in less irrigated treatments. This results are controversial with the results obtained for LAI. The photosynthesis restriction under the influence of irrigation shortages has a greater effect on the falling of the NAR, than the shading of leaves, and that is the cause of an intensive slope falling of the NAR in long irrigation periods. Wise et al. (2013) stated that drought stress, which causing reduces in the leaf water potential to -15bar, reduces pure photosynthesis by up to 50%, and the reason for this is the lack of stomatal conductivity due to the closure of the stomata. They also stated that cyclic and noncyclic photophosphorylation and electron transfer decrease under drought stress where the leaf water potential reaches between -10 to -11 atmospheres. However, water shortages affect enzymes of the dark reaction of photosynthesis. With the results, it can be said that in treatments under stress, with less shading leaves due to the lack of leaf area development, and photosynthesis limitation, single leaf photosynthesis is reduced and the effect of this factor is greater than that is of the shading leaves.

$$NAR = CGR/LAI$$

$$NAR = (b1 + 2c1 + 3d1t2)\, e^{(a1 - a2) + (b1 - b2)\, t + (c1 - c2)\, t2 + (d1 - d2)\, t3}$$



http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1092910940

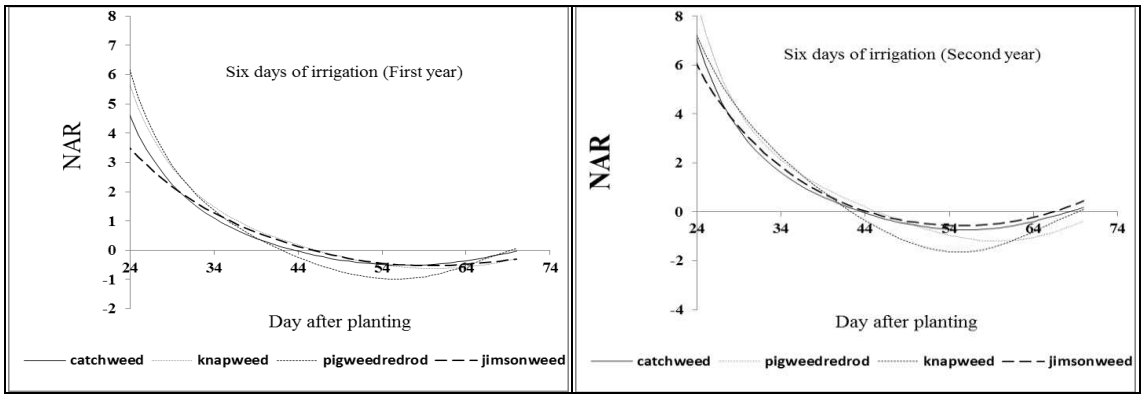


Figure 5. *The effect of irrigation period on net assimilation rate of weeds*

Related traits to root and plant height

ANOVA analysis was shown in *Table 2*. According to *Table 3* in all sampling, in both years, Jimsonweed in control irrigation, and followed that, Red root pigweed has the highest height. Russian knapweed was the shortest plant among the species. By applying drought stress and increasing irrigation periods, the height of all weeds decreased, but the decrease in Jimsonweed height was higher than the Red root pigweed. This act can be attributed to the photosynthetic system of both plants. In conditions of water shortage and drought stress, C3 weeds has less competitive power than C4 weeds. Regarding the rate of weed height increase under normal conditions, Jimsonweed is stronger than other weeds and the optimum time to control it may be short. But, in drought stress conditions, the height of the Red root pigweed is higher and the control of the Red root pigweed is in the priority. Also, in the case of root weighing traits, in all weeds, with increasing irrigation period, root dry weight decreased. Nevertheless, the root length showed an increasing trend. During drought stress, soil layers are depleted from moisture, the root system penetrates into the depths of the soil (Klepper, 1990), and root density under stress conditions is much higher than in non-stress conditions. When exposed to drought stress, the plant allocates more dry matter to the root system to increase the absorbing ability of the roots, as a result, changes in the morphological characteristics of the roots are created, such as increasing the length of the roots per unit of weight (Aerts and Chapin, 2008).

Setaria verticilata	Control	0.90fgh	17.89c	31.28b
	3 day	0.53gh	23.53b	20.87e
	6 day	0.32h	32.76a	15.76f
Acroptilon repens	Control	3.43d	13.52d	21.18e
	3 day	2.81de	17.33c	15.178f
	6 day	1.59efgh	17.67c	11.91g

Conclusion

The results showed that all indices decreased by increasing irrigation period. Red root pigweed showed more tolerance to long irrigation period than others. Thus in dried condition red root pigweed can be weed dominant. Unlike, Jimsonweed showed a better growth in control.

Abstract. The aim of our research was to study certain microorganisms living in the root areas of plants growing in stressed habitats such as mining sites. In the present study, the distributions of arbuscular mycorrhizal fungi (A.M.F.) spores in the root rhizospheres of certain plants (*Onopordum acanthium*, *Festuca glauca, Euphorbia helioscopia* L., *Plantago lanceolata* L., *Salvia officinalis*, *Mentha pulegium* L., *Verbascum thapsus* L. and *Crocus sativus* L.) that are prevalent around the Seydişehir Aluminum Plant Bauxite Deposit (SAPBD) were examined along with the infection rates of these spores in the plant roots, and the morphological definitions of these spores were presented. The highest values in the number of arbuscular mycorrhizal spores, arbuscular mycorrhizal infection rate, dehydrogenase, catalase, urease enzyme activities, the total number of bacteria, the vesicle and arbuscule rates, and also the DSE (dark septate endophyte) fungal structures were obtained from the plant *Euphorbia helioscopia* L., and the soils taken from its rhizosphere. The most prevalent spore species detected in the soils sampled from the Bauxite Mine sampling area were *Glomus* sp., *Acaulospora* sp. and *Archaeospora* sp. Fluctuations were observed in the arbuscular mycorrhizal infection rates of the roots depending on the species of the plants.
Keywords: *mycorrhizal infection rate, spore number, mine area, morphological identification, Seydişehir*

Introduction

Fungi play a central role in many microbiological and ecological processes, influencing soil fertility, decomposition, the cycling of minerals and organic matter, as well as plant health and nutrition (Finlay, 2008). Different symbiotic mycorrhizal associations between plants and fungi occur, almost ubiquitously, throughout a wide range of terrestrial ecosystems. Mycorrhizae are very common in disturbed areas, which indicates their positive role in establishing and building the plant community. There are several studies reporting the role of mycorrhizae in stressed habitats (Kumar et al., 2003). Furthermore, mycorrhizal associations are essential to the colonization of nutrient-deficient soil heaps left after mining

Soil contamination by heavy metals is an issue of major importance in industrialized areas. The detrimental effects of heavy metals on soil's biochemical and biological properties have been reported in the past and microbes are the pioneer of the living creation and play a vital role in mine restoration (Singh et al., 2011b; Li et al., 2012; Ma et al., 2016) High concentrations of metal in soil are toxic to bacteria and fungi, but the roots of most plants growing in polluted soils are colonized by A.M. fungi (Shetty et al., 1994a). This is an indication of the ability of A.M. fungi to develop tolerance to contaminants. Most studies aimed at evaluating the relationship between AMF and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1094110961

plants in soil contaminated with high metals have found increased tolerance and reduced damage in mycorrhizal plants (Shaker-Koohi, 2014). The species richness of AMF in mining areas has also been reported to be inversely related to soil high metal levels. The metals Zn, Cu, and Pb (Klauberg-Filho et al., 2002); Pb and Zn (Zarei et al., 2010); and Al, As, Ba, Cd, Cr, Cu, Pb, Se, Sr, and Zn (Biró et al., 2005) are some of the metals involved in reducing the diversity of mycobionts. However, despite the apparent exclusion of species and increased dominance imposed by the environmental damage generated by mining, AMF communities are rarely composed of less than 10 species. In areas of bauxite mining in Brazil, the number of species was found to vary from six (Melloni et al., 2003) to 21 (Silva et al., 2005).

When metals are at toxic concentrations in soil, mycorrhizal rather than non-mycorrhizal host plants are able to colonize these polluted sites (Shetty et al., 1994a, b). Thus, mycorrhizal colonization may be the key to plant survival in contaminated environments by enhancing metal resistance in plants and also by improving the uptake of essential nutrients. Nevertheless, metal resistance in A.M. fungi has not been extensively investigated with respect to their host plants (Meharg and Cairney, 2000). These studies demonstrate that plants are able to adapt quickly. Arbuscular mycorrhizal fungi, which are associated with most plant species and can serve as intermediaries for the uptake of soil nutrients, might be particularly important in mine tailings (Taheri and Bever, 2010). For example, Cumming and Ning (2003) found that A.M. fungi conferred Al resistance to *Andropogon virginicus* L. reducing Al uptake and translocation in host plants. The response of plants to mycorrhizal colonization combined with toxic metal exposure varies depending on plant species, fungal community, biotic and abiotic conditions, concentration of toxins, and pH. This suggests complex interactions involving many variables (Dietterich et al., 2017; Maynard et al., 2018).

Yet, few studies have examined plant response in terms of the adaptation of their symbionts, particularly in comparison to unadapted communities (Taheri and Bever, 2010). Furthermore, the impact of A.M. fungi community on soil quality is important in that it helps us to understand the function of the ecosystems. Relevant studies can provide important guidance for maintaining the balance of the soil-plant system and the development of sustainable agriculture (Huang et al., 2014). Mycorrhizal infection can increase the absorption of various mineral nutrients by the host plants (Smith et al., 2011; Wang et al., 2011), improve the host plant's water utilization efficiency under drought conditions (Augé, 2001; Huang et al., 2011; Tian et al., 2013), improve the host plant's resistance to salinity and heavy metals (Bothe et al., 2010; Garg and Kaur, 2013) and improve the host plant's resistance to disease. (Wehner et al., 2010; Meyer et al., 2013) Since one part of the morphological structure of A.M. fungi is located in the plant roots, and the other part in the soil, its infection will inevitably affect both the host plant and soil ecology. Studies on the distribution and infection rates of mycorrhizal spores in mining areas around the world and also studies to determine the types of spores are gaining more importance with each passing day. However, there are no studies on the mycorrhizae that exist in mining areas in Turkey. So, we determined the rate of mycorrhizal colonization in the plant root, the number of mycorrhizal spores in the plant rhizosphere and conducted the morphological identification of mycorrhizal spore species in various different plants growing in the vicinity of an aluminum mineral deposit. In doing so, we endeavored to make a general contribution to knowledge about the mycorrhizal state of these particular areas.

Materials and methods

Description of the sampling site

This study was carried out in an opencast mine site at the Seydişehir Aluminum Plant Bauxite Deposit (SAPBD), in Konya, Turkey (N 12 76 53, E 40 07 27 and 1671 m). This mining area is called the "Mortaş Bauxite Deposit". The Mortaş Bauxite Deposit is one of the largest bauxite deposits in the West Taurus Mountains and is located near Keçili village (the new name of the village is Madenli) located 15 km south of Seydişehir, and it occurs along the unconformity between Lower and Upper Cretaceous limestone layers (Atabey, 1976; *Fig. 1*).

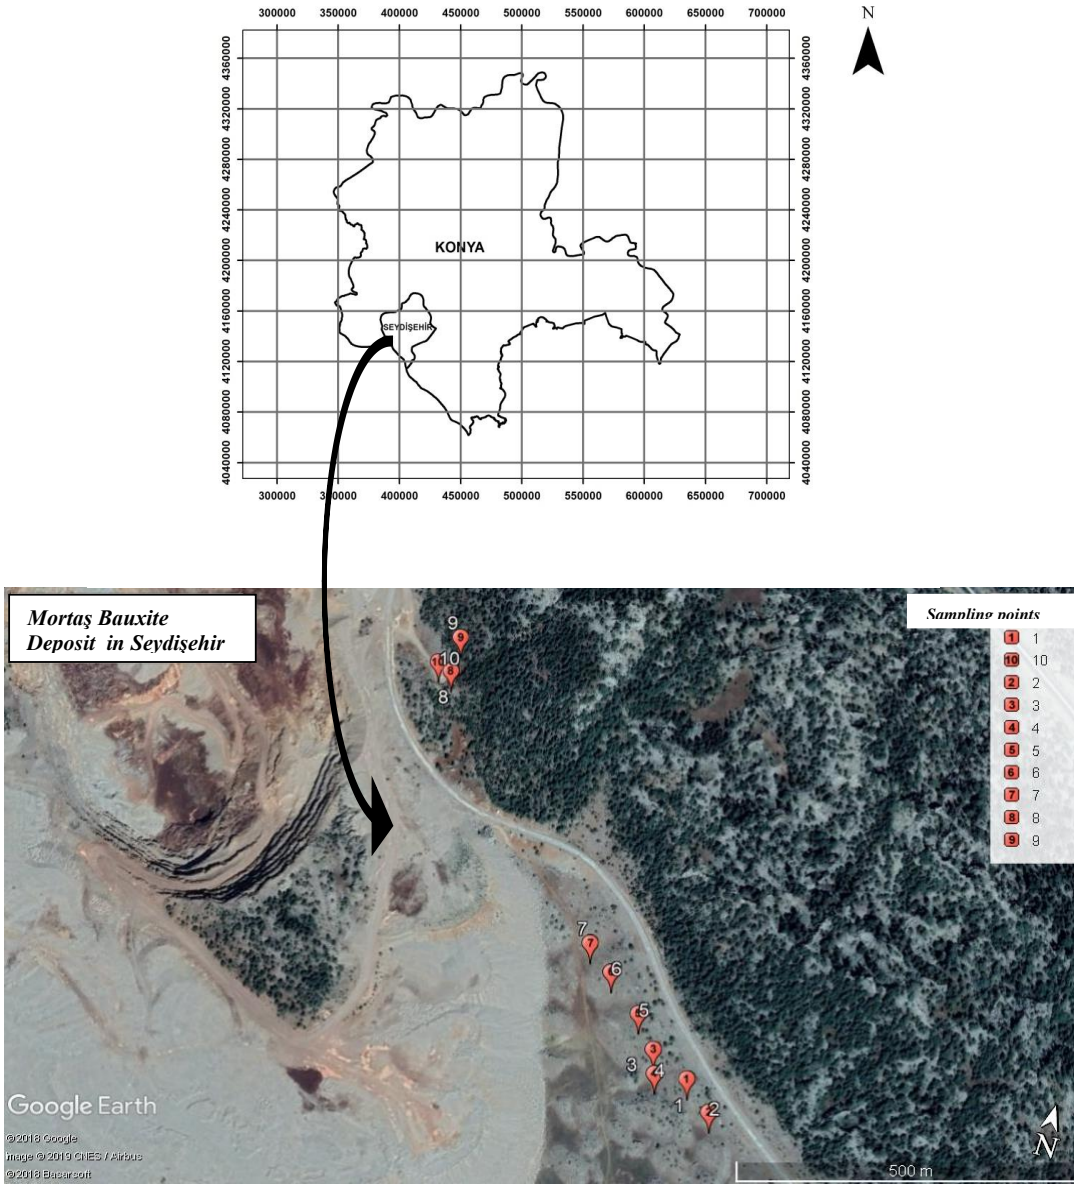

Figure 1. *Research area (Seydişehir Mortaş Bauxite Deposit) and locations of sampling points*

The Seydişehir-Akseki-Alanya district is of major economic importance and was investigated in the early 60's by A. Egger, who produced an unpublished detailed map

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1094110961

of the regional geology of the area. The Seydişehir deposits contain a total of 26.3 million tons of high-alumina boehmite bauxite at 55–67% Al_2O_3. Detailed exploration of the Seydisehir deposits by ETI Aluminum established a reserve of boehmitic bauxite measuring 25.8 million tons at 57–58% Al_2O_3, 6 million tons of which have already been mined (Öztürk et al., 2002).

The mean meteorological data of Seydişehir District (where the sampling area is located) for the study period (January–December 2017) were obtained from the 8th Konya Provincial Directorate of Meteorology. According to the data, the mean maximum temperature was 18.6 °C; the mean minimum temperature was 6.61 °C; the average temperature was 12.60 °C and the temperature distribution was generally around the seasonal norms throughout the year. Total annual precipitation was 746.40 mm with 53.89% of this precipitation occurring in the winter season, and 20.72% in fall. The periods of summer and spring were arid. In the locality, annual average wind velocity is 1.5 m/s. Dominant wind direction is north- northwest and average velocity of the winds blowing from this direction is 1.2 m/s. The averaged soil temperature in the locality is 16.1 °C in 5 cm depth; 15.8 °C in 10 cm depth; 15.1 °C in 20 cm depth;15.6 °C in 50 cm depth; and 15.6 °C in 100 cm depth.

Soil sampling and hosts

Soil samples were taken through random sampling in autumn in 2017. The samples were taken from soil layers at 0 to 20 cm below the surface (where the plant roots are the most extensive and thus the activities of microorganisms are the highest) using a spade to collect about 1 kg of soil. A quantity of the sampled soils was kept at +4 °C in a refrigerator so that microbiological analyses could be made. Later, the sampled soils were dried in air and passed through a 2 mm sieve in preparation for other analyses (some physical and some chemical). The number of soil samples was based on the number of the most prevalent perennial plants (The species were Asteraceae: *Onopordum acanthium subsp. acanthium* (1), Poaceae: *Festuca glauca syn F. cinerea F. ovina var glauca* (2), Euphorbiaceae: *Euphorbia helioscopia* L. (3 and 9: The same plant was sampled at a different distance to the pit), Plantaginaceae: *Plantago lanceolata* L. (4 and 8: The same plant was sampled at a different distance to the pit), Lamiaceae: *Salvia officinalis* L. *and Mentha pulegium* L. (5 and 6 respectively), Scrophulariaceae: *Verbascum thapsus* L. (7), Iridaceae: *Crocus sativus* L. (10). Samples of three of each of the aforementioned plants were taken from the sampling area, and the means of the values obtained from the three plants were used in the analyses. Plant names, localization and heights are presented in *Table 1*. The plants were described by Davis (1965-1985). In this study, the total number of plants is 10, but there are 8 different plants in these 10. Three and eight are the same, and also four and nine are the same plant varieties and they are indicated as different sample numbers since those are sampled from different locations.

Some microbiological, physical and chemical properties of the studied site soils

The taken soil samples were air dried and passed through a 2 mm sieve before being analyzed in the laboratory. The analyses were conducted to determine soil characteristics, such as electrical conductivity (EC), pH, $CaCO_3$, organic matter, and texture. The electrical conductivity (EC) and pH of the samples were determined using an electrical meter and a pH meter, respectively (Richards, 1954). $CaCO_3$ percentage

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1094110961

was determined according to Hızalan and Ünal (1965); organic matter according to Jackson (1958); texture according to Bouyoucos (1995) by means of the hydrometer method. Total nitrogen was determined according to Bremner (1996) using the Kjeldahl method, and available phosphorus was determined by the Olsen method (Olsen et al., 1954). Ammonium acetate solution (1 N, pH 7) was used to determine exchangeable Ca, Mg and K (Thomas, 1982). Available Fe, Cu, Mn and Zn were determined by atomic absorption spectrophotometry using DTPA extraction methods (Lindsay and Norwell, 1978). The sampled soils were subjected to microbiological analyses with their natural moisture content. The oven dry weights of the soils were determined and calculations were made according to the oven dry soil weight. Soil respiration was determined according to Isermeyer (1952); total bacteria and fungi count were determined according to the soil dilution and plate count method (Drews, 1983). The dehydrogenase activity (DHA) of the soils was determined according to Thalmann (1968); catalase activity (CA) was measured using the method by Beck (1971); urease activity was assayed using the method by Hoffmann and Teicher (1961). The percentage of root colonization was calculated by the gridline intersect method and, when the amount of roots was low by the slide method (Giovanetti and Mosse, 1980). The percentage of AM colonization was calculated as the number of segments infected out of 100 segments that were examined under a stereo microscope at 40X magnification (Giovanneti and Mosse, 1980). All the soil analyses and measurements were carried out in triplicate and the mean values were used in the statistical analysis.

Table 1. *The plants sampled around SAPBD, and the coordinates and height above sea level of the locations from where they were taken*

No	Name of plant	Coordinate	Altitude (m)
1	*Onopordum acanthium* (Asteraceae)	37°16’15.76”N, 31°53’50.61”E	1,611
2	*Festuca glauca* (Poaceae)	37°16’14.37”N, 31°53’52.53”E	1,611

10	*Crocus sativus* L. (Iridaceae)	37°16’33.98”N, 31°53’27.20”E	1,687

Assessment of arbuscular mycorrhizal fungi colonization and spores

The root samples were cleaned carefully with deionized water and stained using the method described by Phillips and Hayman (1970), and the percentage colonization was calculated using the gridline intersect method (Giovanneti and Mosse, 1980).

The spores were quantified and characterized according to the sieving and decanting procedure developed by Gerdeman and Nicolson (1963) and INVAM (2004). Spore quantification was examined under a stereomicroscope (Olympus SX 60 trinocular microscope) at 40X magnification. For spore observation and identification, the spores

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1094110961

were mounted on glass slides and identified to genus level, whenever possible, using a compound microscope (Euromex-Novex B-Series) at 100-400X magnification, based on the descriptions in Brundrett et al. (1996) and the information from the INVAM website (INVAM, 2004).

Data analysis

The data obtained were statistically analyzed using one-way analysis of variance and the means were separated by Duncan's multiple range test ($P < 0.01$ and 0.05) using Minitab 16 software. Correlation analysis was also performed. Correlation coefficient (r^2) was calculated between soil chemical features and mycorrhizal parameters (Minitab, 1997).

Results and discussion

Physical and chemical properties of the site soil

The means and standard deviations of some physical and chemical properties of the soil samples taken in three replicates from the rhizosphere soils of 10 plants (8 different plants) sampled around the SAPBD are given in *Table 2*.

Table 2. *Results of some chemical analyses and textures belonging to the soils of plants sampled around SAPBD*

Soil number	pH	EC µS/cm	Org. mat. %	$CaCO_3$ %	Texture
1	7.23 ± 0.01	160.47 ± 1.37	2.31 ± 0.04	2.62 ± 0.08	Loam
2	7.23 ± 0.01	299.33 ± 1.96	4.63 ± 0.01	4.36 ± 0.00	Silty loam
3	6.50 ± 0.26	165.40 ± 1.05	5.27 ± 0.04	1.69 ± 0.12	Loam
4	7.10 ± 0.01	140.83 ± 0.65	1.97 ± 0.01	2.68 ± 0.04	Loam
5	7.36 ± 0.04	151.97 ± 0.19	2.26 ± 0.07	3.78 ± 0.09	Loam
6	5.80 ± 0.01	145.77 ± 0.54	2.00 ± 0.04	6.05 ± 0.12	Sandy loam
7	7.17 ± 0.01	128.23 ± 0.49	1.69 ± 0.01	6.63 ± 0.08	Sandy loam
8	7.21 ± 0.01	113.73 ± 1.04	3.00 ± 0.01	50.68 ± 1.53	Sandy clay loam
9	5.77 ± 0.01	134.74 ± 1.29	4.97 ± 0.01	40.38 ± 0.99	Sandy loam
10	6.92 ± 0.06	131.26 ± 1.13	2.91 ± 0.04	26.47 ± 1.19	Sandy clay loam

Regarding the soil characteristics of the survey area: pH varied between 5.77 and 7.36, organic matter content between 1.69 and 5.27%, electrical conductivity between 113.73 and 299.33 dS/cm, and percentage of $CaCO_3$ between 1.69 and 50.68; texture classes were Loam, Silty Loam, Sandy Loam and Sandy Clay Loam (*Table 2*).

In addition, the contents of some micro and macro elements found in the soils sampled are presented in *Table 3*.

Root colonization of A.M. fungi

The roots of all 10 host plants were colonized by A.M. fungi, but the degree of colonization varied both among plant species and dependent on soil properties (*Table 5*). Typical A.M. fungal structures, i.e. arbuscules and vesicles (*Fig. 2a-c, f*) were

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1094110961

observed in the roots of all host plants but moniliform cell and dark septate endophytic fungal hyphea (*Fig. 2d-e*) were observed only in the roots of *Euphorbia helioscopia* L. (Euphorbiaceae). The colonization of vesicles varied from 0.00% to 83.54%, the colonization of arbuscules varied from 79.34% to 100%, and the colonization of hyphae varied from 0.00% to 60.33%. The highest vesicle and arbuscule rates were obtained from *Euphorbia helioscopia* L. (83.54%-100%), and the highest hyphae rate was obtained from *Festuca glauca* (60.33%). Statistically significant differences were observed among the rhizospheres of different plant species ($P < 0.01$ and $P < 0.05$) (*Table 4*). The mycorrhizal structures (arbuscules, vesicles and hypha) and also spore percentages were significantly higher (87.67 number/10 g soil) in the *Euphorbia helioscopia* L. compared to other plants and other rhizosphere soils.

Table 3. *Results of some macro and micro nutrient elements belonging to the soils of plants sampled around SAPBD*

Soil number	N %	P_2O_5 mg kg^{-1}	K_2O mg kg^{-1}	Ca mg kg^{-1}	Mg mg kg^{-1}	Fe mg kg^{-1}	Cu mg kg^{-1}	Zn mg kg^{-1}	Mn mg kg^{-1}

Among the mycorrhizal parameters examined in plant roots, a positive correlation was found between vesicle rate and arbuscule rate at a significant level ($P < 0.01$, $r = 0.6447$), and a significant and positive correlation ($P < 0.05$, $r = 0.5009$) was also found between vesicle rate and dehydrogenase activity. In addition to the positive and significant relationship between arbuscule rate and vesicle rate ($P < 0.01$), a positive and significant relationship was again detected between arbuscule rate and the number of spores per screen opening 50-100 μm in diameter ($P < 0.01$, $r = 0.6306$), and there was also a positive and significant relationship between arbuscule rate and urease enzyme activity ($P < 0.01$, $r = 0.3932$). By contrast, a negative and significant correlation was detected between arbuscule rate and hyphae rate and between arbuscule rate and root length ($P < 0.05$, $r = -0.3784$ and $r = -0.5362$, respectively in *Table 5*).

The photographs of the different formations exhibited by arbuscular mycorrhizal and DSE fungal colonization observed in plant roots are shown in *Figure 2a-f.*

Of the mycorrhizal structures, the vesicle and arbuscule formations are shown in *Figure 2a, c* and *f,* coiled intraradical hyphae (large arrow) are shown in *Figure 2b,* moniliform cells are shown in *Figure 2d*. Mycelia of dark septate endophytes (DSE) accompanied the A.M. fungi colonization, and were observed in only one plant species (Zubek et al., 2011). Dark septate endophytic fungal hyphea are shown in *Figure 2e.* All of these formations were obtained from the roots of the plant *Euphorbia helioscopia* L.

Spore density of A.M. fungi

The total A.M. fungi spore density ranged between 24.33-87.67 count/10 g soil in the rhizosphere zone of the ten host plants. The highest A.M. fungi spore density was observed in the rhizosphere of the plant *Euphorbia helioscopia* L., and the lowest A.M. fungi spore density (24.33-26.00-26.00 count/10 g soil) was obtained in the rhizosphere of *Verbascum thapsus* L. and *Plantago lanceolata* L. (Two plants sampled). On the other hand, the distribution of spore numbers varied according to sieve size and plant variety. The highest spore counts were taken from smaller size (38-50 µm) while the lowest spore counts were taken from larger size (>250 µm) sieves.

Considering all sieve sizes, the highest spore count in the 38-50 µm sieve was found at the rhizosphere region of *Onorpodum acanthium* (46.67 number/10 g soil), the highest spore count in the 50-100 and 100-250 µm sieves was found at the rhizosphere region of *Euphoria helioscopia* L. (39.00-32.00 number/10 g soil) and the highest spore count in the > 250 µm sieve (6.67 number/10 g soil) was found at the rhizosphere region of *Mentha pulegium* L. (*Table 4*).

As can also be seen from *Table 5*, the correlation analysis carried out in the study revealed that there was a positive and significant relationship between the total number of spores and the number of spores remaining in the 30-50 µm sieve, and also between the total number of spores and the microbial respiration value and the total number of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1094110961

bacteria ($P < 0.01$, $r = 0.6969$, $r = 0.7609$, $r = 0.7404$, respectively). Similarly, a positive and significant relationship was again found ($P < 0.01$) between the total number of spores and the number of spores remaining in the 100-150 μm sieve, and between catalase urease enzyme activities and the total number of fungi ($r = 0.4558$, $r = 0.5233$, $r = 0.4169$, $r = 0.5425$, respectively) (*Table 5*).

Evaluation of certain biological properties of the research area soil

Certain mycorrhizal parameters, as well as microbiological properties of the research soils, were analyzed. In this scope, the dehydrogenase, catalase and urease activities of the soils, total number of fungus, bacteria, and microbial respiration values were determined. Of the parameters mentioned above, the highest values in terms of dehydrogenase, urease and catalase activities, vesicle-arbuscule rates, and the total number of mycorrhizal spores were obtained from the root rhizosphere of the plant *Euphorbia helioscopia* L. In addition, as the result of the distribution of the total number of mycorrhizal spores with respect to sieve diameter, the highest number of spores remaining on the 50-100 μm and 100-250 μm sieves were also obtained from the rhizosphere of the same plant. Also, DSE fungal structures were determined from the root rhizosphere of the plant *Euphorbia helioscopia* L. Of the interpretations regarding the significance levels and degrees of the bilateral relationships between the analyzed biological parameters, those that are related to mycorrhizal parameters were presented above. The correlation analyses conducted on the root length data showed that there was a significant ($P = 0.05$) and positive (0.4911) relationship between root length and hypha rate; a significant ($P = 0.05$) and negative (-0.5362) relationship between root length and arbuscule rate; also, a significant ($P = 0.01$) and negative relationship between root length and the number of spores remaining on the 50-100 μm sieve. While a significant ($P < 0.05$) and positive (0.4203) correlation was determined between dehydrogenase enzyme activity and urease enzyme activity, again a positive ($r = 0.4963$) correlation was found at the same level ($P < 0.05$) between dehydrogenase activity and total number of bacteria. It was determined that there was a positive correlation ($P < 0.01$) between catalase enzyme activity and microbial respiration, and the number of spores remaining on the 35-50 μm sieve ($r = 0.7995$, $r = 0.7047$, respectively); also a positive correlation ($P < 0.05$) was found between catalase enzyme activity and the number of spores remaining on the 50-100 μm sieve, and hypha rate ($r = 0.4092$, $r = 0.4313$ respectively). From another enzyme analysis carried out in the soil, it was determined that there was a significant and positive correlation ($P < 0.05$) between urease enzyme activity and number of spores remaining on the 50-100 μm sieve, dehydrogenase enzyme activity, and total number of bacteria ($r = 0.5339$, $r = 0.4203$, $r = 0.5497$, respectively) (*Table 5*).

Determination of morphological diagnosis of A.M. fungi

Morphological identifications were made for A.M. fungi spores that were isolated from the rhizosphere zones of the plants sampled from mining areas. The A.M. fungal spores counted in the study were found to belong to three different mycorrhizal fungi genera and the counting results were compared to one another. The plants that were in symbiosis with *Acaulospora*, *Glomus* and *Scutellospora* were found as *Onopordum acanthium, Euphorbia helioscopia* L., *Plantago lanceolata* L., and *Crocus sativus* L.. The highest number of mycorrhizal spores was detected in *Glomus* sp. The present study recorded a total of three A.M. fungal genera: *Glomus* sp. (*Fig. 3a*, *3i*),

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1094110961

Acaulospora sp. (*Fig. 3b, 3d, 3e, 3h*) and *Entrophospora* sp. (*Fig. 3c, 3f, 3g*). *Acaulospora* sp. was the most frequently occurring genera (66.67%) followed by *Glomus* (22.22%) and *Entrophospora* sp. (11.11%).

Discussion

From all of the findings, it can be said that both the distributions of mycorrhizal spores in the soil and the infection rates they formed in the plant roots may vary in the same plant and soil even in short term intervals. For this reason, the data obtained from microbiological studies in which mycorrhizal distribution and infection rates are determined can only represent the moment of collection and are valid for only a short period of time. Since microbiological parameters can be affected by various factors and the action mechanism is again a living organism system, the cycle of effective factors is both quick and fluctuated.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1094110961

In addition, although the distances among the locations where the mining area plants used in our study were sampled were not very far, differences were still observed in the mycorrhizal parameters measured in the soils and the plants, and also in the results of the analyses of the activities of other microorganisms, and these differences were found to be statistically significant ($P < 0.05$), which confirms the statements explained above. As a matter of fact, the distribution of A.M. fungi in different ecological regions and their relations with soil properties and native plants have been investigated by several researchers (Cooke et al., 1993; Janardhanan, 1994; Aliasgharzadeh et al., 2001; Shi et al., 2007; Bi et al., 2019).

It is established that variations in A.M. fungi distribution, spore density and colonization with different host plant species are generated by a variety of mechanisms, including variation in host species and their phenology, mycorrhizal dependency, soil properties, host plant-mediated alteration of the soil microenvironment, or other unknown host plant traits (Eom et al., 2000; Wang et al., 2004). In addition, species and isolates of A.M. fungi differ in their tolerance to adverse physical and chemical conditions in soil (Augé, 2004; Daei et al., 2009; Barea et al., 2013). In our study, the highest values in terms of both mycorrhizal and other microbiological parameters were obtained particularly from the plant *Euphorbia helioscopia* L. This finding could be explained by the fact that this plant has a different physiology and thus a different mechanism compared to the others. Early reports revealed that plants of *Euphorbiaceae* contain many kinds of secondary metabolites, such as triterpenoids (Biesboer et al., 1982; Teresa et al., 1987), diterpenoids (Sahai et al., 1981; Yamamura et al., 1989; Öksüz et al., 1995; Madureira et al., 2004) steroids (Biesboer et al., 1982), lipids (Biesboer et al., 1982; Teresa et al., 1987), flavonoids and tannins (Durrani et al., 1987; Zhang and Guo, 2006). In addition to various medical and known properties of the plant, researchers conducted and have been continuing to carry out several studies on the use of the plant in agriculture and on its insecticide properties (Uzair et al., 2009). However, there are no studies on the potential of arbuscular mycorrhizal organisms that have a mutualistic symbiotic association with the root of *Euphorbia helioscopia* L. in the soil and their effects on the infection of mycorrhizal fungus spores in the plant root. For this reason, the data obtained in the present study could serve as a base for the future studies on similar topics.

In terms of the parameters examined in the study; although the values obtained from *Euphorbia helioscopia* L. were found to be higher compared to other plants, mycorrhizal fungus spores were observed in the root rhizospheres of all the plants examined in the study.

The spore numbers in the rhizosphere soil ranged between 24.33-87.67 spores per 10 g^{-1} dry soil. The average spore count recorded was 53.99 spores per 10 g^{-1} dry soil (*Table 4*).

In terms of the parameters examined in the study, although the values obtained from *Euphorbia helioscopia* L. were found to be higher compared to other plants, mycorrhizal fungus spores were observed in the root rhizospheres of all the plants examined in the study.

In the same way, arbuscule, vesicle, and hypha formations, which are among mycorrhizal parameters, were detected in the roots of all the plants. The A.M. fungi infection rate ranged between 0-83.54% (vesicle rate), 79.34-100% (arbuscule rate) and 0-60.33% (hypha rate) and the mean A.M. fungi infection rates recorded were 44.61-88.33-26.60% as vesicle, arbuscule and hypha rates, respectively.

DOI: http://dx.doi.org/10.15666/aeer/1705_1094110961

In addition, as can be seen from the correlation values in *Table 5*, there is a very strict and positive interaction between the mycorrhizal spore distribution in the soil and the other microbiological parameters of the soil analyzed in the study. The effect of soil enzymes is particularly noticeable in this interaction. Soil enzyme activity has been widely used to evaluate soil management effects (Dick, 1994; Bandick and Dick, 1999; Utobo and Tewari, 2014). The application of microorganism quantity and soil enzyme activity when investigating the effects of mycorrhizal fungi on soil ecosystem functions can improve our understanding of the correlation between mycorrhizal fungi and soil ecosystem functions. Many studies have shown that mycorrhizal colonization may affect the soil microbial communities either directly or indirectly through root exudates (Nuccio et al., 2013; Zubek et al., 2013). Camprubi et al. (1995), Kieliszewska-Rokicka (2001); Nadgórska-Socha et al. (2006); Fernández et al. (2012) investigated the effects of mycorrhizal fungi on soil biological quality by observing soil enzyme activity. In this paper, vesicle, arbuscule, and hypha rates also showed a relationship particularly with soil enzymes in addition to other microbiological parameters. The interactions of vesicle, arbuscule, and hypha rates with the enzymes in the soil were found to be different from one another. That is, a positive and significant correlation ($P < 0.01$) was found between the vesicle rate determined in the plant roots and dehydrogenase enzyme activity, between arbuscule rate and urease enzyme activity, and between hypha rate and catalase enzyme activity. This interaction of mycorrhizal formations in the plant root with the presence of enzymes outside the root could be attributed to the fact that the enzymes mentioned have an effect on the existence of organic matter in the soil.

As a matter of fact, the finding that among the nine plants used in the study, the highest results for certain biological analyses were generally obtained from the root rhizosphere of the same plant could be explained by the fact that the plant has a specific structure and also that the soil in which it grows has a high content of organic matter, with this organic matter being a source of substrate for the enzymes mentioned above. Thus, urease is an extracellular enzyme that provides the hydrolysis of urea reaching the soil in various ways (plant residuals, animal tissues, and fertilizers). After these enzymes are produced by the soil microorganisms to decompose the nutrient substances, they are kept by colloids of soils such as clay and organic matter and can sustain their activities independent of the microorganism cell producing these enzymes. The distribution of urease activity in the soils in the study area is shown in *Table 4*. In the soils studied, the values of urease activity were obtained between 8.71–77.87 μg per N g dry soil^{-1} and it was seen that the highest activity occurred in the soil taken from the rhizosphere of the plant *Euphorbia helioscopia* L. (*Euphorbiaceae*) (no.9), which had the lowest pH (5.77), while the lowest activity was observed in the soil taken from the rhizosphere of the plant *Verbascum thapsus* L. (*Scrophulariaceae*). Similar values of urease activity were also obtained by Douglas and Bremner (1971), Klein and Koths (1980), Bolton et al. (1985), Kızılkaya et al. (1998a, b), and Garcia et al. (2000), Qian et al. (2012) and Bi et al. (2019).

On the other hand, dehydrogenase activity is used when assessing total microbiological activity in soils. However, this enzyme activity is not generally associated with the total number of microorganisms. Dehydrogenase activity is largely affected by environmental factors such as soil moisture and temperature, and by soil properties such as organic matter (Carpenter et al., 1995; Lipson et al., 1999). Therefore, the activity of this enzyme yields its microbiological activity at the moment when the soil sample is taken. However, the highest dehydrogenase activity was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1094110961

obtained from the soil in which the highest urease enzyme activity was obtained, i.e. from the rhizosphere soil of the plant *Euphorbia helioscopia* L. (*Euphorbiaceae* (no.9) as 14.27 μg TPF per 1 g dry soil^{-1}. This rhizosphere soil had a high number of mycorrhizal spores (83 in 10 g soil^{-1}) and the highest number of bacteria (26 × 10^5 kob/ml). The distribution of dehydrogenase activity in the study area soils is shown in *Table 4*. The results obtained from dehydrogenase activity of this paper were close to Ross (1970), Bolton et al. (1985), Kızılkaya et al. (1998b, c), Garcia et al. (2000), Qian et al. (2012).

Catalase activity is a criterion used when assessing aerobic microorganisms in soils. Therefore, the catalase activity of soils indicates the desire of soil microorganisms to live in aerobic conditions. Catalase activity varies depending on the aeration condition of soils, O_2 concentration in the soil air, and the number of microorganisms (Schinner et al., 1996; Smith and Read, 2008). The distribution of catalase activity of the common plants existing in the rhizosphere soils around the SAPBD is shown in *Table 4*.

It was found that the catalase activity of the common plants in the rhizosphere soils around the SAPBD ranged between 0.6-7 ml O_2 per 5 g dry soil^{-1} and that the soil with the highest activity was that of the plant *Euphorbia helioscopia* L. (Euphorbiaceae) (no.9). It was also found that this soil had the highest organic matter content (5.27%) and the lowest $CaCO_3$ content (1.69%). In the literature Kızılkaya et al. (1998b, c), Garcia et al. (2000), Abdel Latef and Chaoxing (2011) also found their results in this range. In addition, Samuel et al. (2008) reported in their study that catalase activity was higher in the 0-20 cm part of the soil, i.e. in its top layer where there are more oxygen and more organic matter. Hence, they suggested that alternation had positive effects on the enzyme activity compared to monoculture.

The values regarding the CO_2 production of the soils sampled from the rhizosphere zones of the common plants around the SAPBD are shown in *Table 4*. Carbon dioxide production is used as an indicator of microbial activity in the soil. While heterotopic–qualified microorganisms in the soil decompose the organic matter, they produce CO_2. This process continuing in the soil is also referred to as soil respiration. Although all conditions (moisture, temperature, etc.) affecting the soil microorganisms affect the amount of CO_2, soil organic matter is the main soil property affecting the CO_2 production (Cheng, 1999). It was found that the CO_2 production in the rhizosphere soils of the prevalent plants around the SAPBD ranged between 31.62–73.06 mg CO_2 10 g dry soil^{-1}, and the soil with the highest CO_2 production was again detected in the rhizosphere soil of the plant *Euphorbia helioscopia* L. (Euphorbiaceae) (no.3), which had the highest organic matter content (5.27%) and the lowest lime content (1.69% $CaCO_3$). Kızılkaya et al. (1998c) investigated the microbiological properties of the soils of the Harran Plain and found that CO_2 production varied between 4,5–70,3 mg CO_2 per 100 g soil^{-1}, Kızılkaya et al. (1998b) found that CO_2 production varied between 15.50–68.50 mg CO_2 per 100 g soil^{-1} in the forestry soils of Samsun-Alaçam and Kohler et al. (2009), Wang et al. (2017), Papp et al. (2018) found similar results.

On the other hand, three different spore species (*Glomus* sp., *Acaulospora* sp. and *Entrophospora* sp.) belonging to A.M. fungi were identified in the rhizosphere zones of the 10 plants. In the present study, since the spores isolated from the root rhizosphere region were directly prepared as slides without performing trap culture, a very clear image could not be taken from the spores and methodologically the spores could be identified only based on genus.

Conclusions

This is the first study that has attempted to describe the diversity and distribution of A.M. fungi in the mine area rhizosphere soils in Turkey. Mycorrhizal parameters (infection rate, spore count, and morphological identification) were not examined on a very large number of host plants. Only the host plants that are dominant in the sampling area and in the sampling season were collected. The plants that were sampled around mine areas are available in every season, i.e. they do not exhibit any change. The plant species that are prevalently existent around Seydişehir Aluminum Plant in the autumn period.

In conclusion, the findings of this study emphasize the need for an understanding of the ecology of A.M. fungi in various ecosystems and soils for the successful selection and introduction of A.M. fungal species and strains for particular environments. A.M. fungi spore population in the soil and spore colonization in the plant root may change depending on seasonal variation, soil properties, host plant variety and the mechanism of the host plant (He et al., 2002; Bohrer, 2004).

In the present study, significant correlations were found both among the microbial parameters in the soil and among certain properties of the soil in general. The presence of life forms in a soil and their activity are among the most important indicators of that soil's health and quality. As a matter of fact, although the present study was carried out on soil and plant samples around a mining area, the high number and activity of the microorganisms in the soil in the sampling period could be due to the prevalence of non-culture plants growing in the soil in the study area.

In addition, of the three spore genera mentioned above, *Acaulospora* in particular was found to be not only a spore genus dominant in the plant root rhizospheres, but also a spore genus with a high infection rate in the plant roots from which it was isolated.

This gives rise to the opinion that this spore genus contains spore species that are potentially important for the areas in the vicinity of bauxite deposits, and that the use of these spore species in the rehabilitation of the soils that possess similar conditions could yield useful results. For further studies, the symbiosis of plant *Euphorbia helioscopia* L. with arbuscular mycorrhiza and with other fungi should be considered in studies involving stressed environments. In addition, the authors suggest that the benefits of symbiosis for stressed environments should be investigated in detail.

Abstract. Sprinkling water is applied in shorter irrigation intervals and lighter irrigation applications in arid areas. The water-saving irrigation is the primary method of local agricultural production. Since chemical fertilizer is the primary emission source of nitrous oxide (N_2O), it is appropriate to verify the general influence of water-saving irrigation on N_2O. Results of the study, conducted in a potato field as the experimental site for two consecutive years, using two different irrigation systems – namely, furrow (FI) and sprinkling-irrigation (SI) with a mineral N fertilizer (NF) and a control without any fertilizer (Control) are reported. The N_2O emission fluxes with NF were higher than those of the control in each irrigation system. On plots where the NF was applied, mean emissions fluxes of N_2O was 152.02 μg/(m^2 hr) in FI, 36.53μg/(m^2 hr) in SI from 2016 to 2017. The reduction of N_2O emissions from SI was due to the lower amount of water applied every time and the lower NO_3^--N and NH_4^+-N of soil associated with SI. This work showed that SI is a method that helps save water and mitigates emissions of the atmospheric N_2O pollutants compared to FI.
Keywords: *greenhouse gas, moisture, fertilization, emission factor, potato field*

Introduction

Nitrous oxide (N_2O) is one of the most significant long-lived greenhouse gases in the atmosphere. The atmospheric N_2O concentration has increased from 270 ppbv (10^{-9} volume ratio) in 1750 to 324 ppbv in 2011, resulting in an increase of 0.17 W/m^2 in radiative forcing. Especially from 2007 to 2011, N_2O concentration in the atmosphere increased linearly at an annual average rate of 6% (IPCC, 2013; Schilt et al., 2014). Agricultural production is the primary source of N_2O emission (Robertson et al., 2000). Agricultural emissions accounted for about 56% of the total anthropogenic atmospheric N_2O emissions in 2005 (US-EPA, 2006). The water strategy is one of the essential factors that affect the emissions of N_2O from agricultural soils. In irrigated soils, the amount of water used and its distribution in the soil influence moisture temporally and spatially. Consequently, different moisture content determines the processes that control

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1096310976

the amount of N transported, N mineralized such as NO_3^--N leaching within the soil. The changes on water and nitrogen in the soil affect the temporal and spatial distribution for various forms of nitrogen and the formation of N_2O. These irrigating systems, for instance, furrow (FI) or sprinkling irrigation (SI), significantly influence the movement of water in the soil because vertical and lateral infiltration are produced simultaneously (Auxiliadora et al., 2018; Naghedifar et al., 2018).

In arid and semiarid areas, FI is one of the most traditional surface irrigation systems because many crops that do not grow in water for long periods are suitable for this irrigation method. Under FI, water is delivered into each strip at a high amount from a head at its upper end to promote the rapid dissolution of fertilizers because of soaking in large quantities of water (Naghedifar et al., 2018). After the irrigation with long intervals and heavy application depths, water flows through the macropores, and most of the soil volume is wetted, temporarily creating the high ratio of anaerobic microsites, even if the small ratio of the ridge top may remain dry.

SI is one of the most popular methods of irrigation worldwide as an efficient and economically viable alternative (Ezequiel et al., 2018), because it offers the precise controlling of irrigation water amount and uniformity to decrease water and N losses (Lorenzo et al., 2018; José et al., 2018). Sprinkling water is applied on shorter irrigation intervals and lighter irrigation applications. Canopy induced irrigation water redistribution, which influenced the spatial and temporal variability of water in the soil. Irrigation water reaches the surface of the soil after it passes through the developed crop canopy, like precipitation. The wetted front in the soil surface moves downward under capillarity action and only a small part of the soil volume is nearly saturated due to the uniformity of irrigation (Naghedifar et al., 2018; Zapata et al., 2018). The wetted front from the soil surface advances slightly into the soil during sprinkling irrigation (Laura et al., 2008). Consequently, increasing the amount of water from different irrigation systems increases the wetted volume and shape in the soil, which mainly depends on the quantity and rate of applied water. The hydraulic properties in the irrigated soil determine the horizontal and vertical infiltration of water (Li et al., 2003; Vázquez et al., 2005). In previous studies, although the influences of moisture on crop growth have been very well recorded in SI and FI systems (Davidson, 1991; Granli and Bockman, 1994), the effects of these different wetted patterns in the soils on N_2O emissions are not known. So far, the information on N_2O emissions and the related importance do not appear in the comparison between sprinkling and furrow irrigation soils.

We assumed that the irrigation methods will influence N_2O emissions because of the different wetted forms in the furrow and sprinkling irrigation soils. In the sprinkled soil, the applied water at low water amount may be beneficial to more aerobic than anaerobic environment. The advance of the wetting front may produce pulses of N_2O from the furrow-irrigated areas, similar to those observed after irrigation when soil was dry (Diego et al., 2017). Therefore, we doubt that the differences of water distributed between SI and FI soils may occur the different states in N_2O emissions. In our studies, the objectives were to compare N_2O emissions in the soils from a potato field with furrow and sprinkling irrigation, and to assess how the two irrigation systems modulated the N_2O emissions and emission factor of N_2O. In this experiment, the results would help to develop the strategies to mitigate N_2O emissions from the soils fertilized with chemical fertilizers in irrigated agriculture.

Materials and methods

Description of the study site

The experiment was implemented during the 2016–2017 at the potato experimental farm in the suburbs of Hohhot, Inner Mongolia (latitude 40°45′34″N, longitude 111°41′56″E), in the middle of Inner Mongolia Plateau located in the hinterland of the Asian continent (*Fig. 1*). The soil was a Calcic Haploxerept with a sandy clay loam texture (Soil Survey Staff, 1992). Some physico-chemical properties in the upper (0–30 cm) horizon of the soil were: pH, 7.79; organic matter, 0.93 ± 0.2 g/kg; bulk density, 1.25 ± 0.2 g/cm^3; clay, 32%; silt, 20%; and sand, 48%; $CaCO_3$, 8.54 ± 0.1 g/kg. The mean annual precipitation is 335 mm and the mean annual temperature is 6.7 °C (averages for the previous 15 years).

Figure 1. *The experimental site and equipments used to collect gases in the potato field*

Experimental design and field management

The experiment was arranged according to a split-plot design. Two main plots (600 m^2) were selected in the experimental field with two treatments. Every main plot was divided into six subplots (5×10 m) in a randomized complete block design with three replicates. The main-plot treatments were different irrigation systems: furrow and sprinkling irrigation. Each mainplot was also split according to the fertilizer treatment applied:(i) N, P, and K compound fertilizer and urea as a chemical fertilizer (NF, 390 kg N/ha) and (ii) a control without any fertilizer (Control). The amount of applied fertilizer is the local range used by farmers for potato crops (360–410 kg N/ha). Fertilizers were applied by hand and immediately incorporated into the upper 15 cm of the soil using a rotovator. Sprinkling irrigation is often used to apply soluble fertilizers, in small amounts, as and when irrigated. Per subplot included five pressure-compensated sprinkling irrigation lines spaced 90 cm apart. Each sprinkling irrigation line was fitted with a solid set consisting of six full circle impact sprinklers (Elgo 80B2, made in Israel) with a wetting radius of 10 m, spaced 2.8 m apart, mounted on 1.30 m risers. A water meter (LXS-20C, TEFEN Manufacture, Nahsholim, Israel) was installed in the main pipe to measure sprinkling water amount in each experimental plot. This method is a popular practice in local farmers.

The experimental site for the furrow irrigation involved five furrows in each subplot, which were spaced 90 cm apart and ploughed 30 cm deep. The furrows were enclosed at the end of each experimental site, as irrigation water was intercepted to prevent it from flowing out of the field. The subplots were independent, but irrigated at the same time. The furrows were constructed using a seeding machine. The amount of used

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1096310976

irrigation water was recorded by water meter on each irrigated subplot after fertilizer application.

A potato crop (*Solanum tuberosum* L. *cv. Favorita*) requiring about 105 days to reach maturity was planted by potato seeder on May 25th, 2016 and May 15th, 2017. The potatoes were planted on the raised beds 0.3 m high and 0.6 m wide, with the top of 0.3 m bed wide and with a 0.20 m spacing between plants in a row and sowing rate of 2250 kg/ha. The time for potatoes to be harvested is September.

Irrigation management
