(Received 22nd Apr 2019; accepted 12th Jul 2019)

Abstract. Understanding the shelterbelt development in northeast China over the past 30 years will provide a scientific decision support for its management in future. In this paper, Landsat images were selected to extract shelterbelt information covering three points in time (1990, 2000 and 2010). Shelterbelt density and landscape indexes (ratio of belt to patch, connectivity, and dominance) were introduced to analyze changes in landscape. Farmland landscape indexes (ratio of farmland to zone and fragmentation) were used to analyze the effect of farmland on shelterbelt distribution and change. The result showed that: (1) shelterbelt density had considerable spatial variation. These changes were strong correlated with land-use type. Farmland fragmentation was a main index which significantly affected the connectivity and evenness of shelterbelt, especially on connectivity; (2) shelterbelt density increased about 10% over the 30 years. This modest increase included two contrasting trends, an increase by 13.2% from 1990 to 2000 followed by a 2.8% reduction by 2010. Even the quantity reduced over 2000-2010, the qualities including connectivity and evenness were getting better overall. The temporal changes of shelterbelt density had little relationship with farmland changes. This research can provide valuable information for decision makers to guide and develop future policies.
Keywords: *shelterbelt structure, landscape index, geographic information system, remote sensing*

Introduction

In 1978, the Central Committee of the Communist Party of China launched an afforestation project known as the "Three Norths" (or 3N, referring to the North West, the North and the North East of China). The 3N is one of China's most important projects at a national level (Moodre and Russell, 1990).

Objectives of the 3N project are to control wind and sand erosion, enhance soil and water conservation, improve ecological environments, and produce multiple forest products. This project is acclaimed as China's "green great wall" and "world's best ecological project". Based on an investigation of the State Forestry Administration of China, the 3N framework was configured during past 30 years and the eco-environmental benefits have begun to appear in wind reduction, soil and water conservation, farmland protection, and sand dune fixation (Wang and Zhou, 2003).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1165511668

The Northeast shelterbelt is a part of the 3N project. Since the 1980s, China has invested substantial money and energy into its construction. The construction of eco-economic shelterbelts was popular in the late 1980s (Shan et al., 2018). By now, the third phase of 3N project has been completed, and the fourth phase is nearing completion. Researching and clarifying the development of the shelterbelt over the past 30 years can help identify problems of this area and provide a scientific decision support for shelterbelt management in the next phase.

Shelterbelts are used to reduce wind speed. They can help to control wind erosion, provide habitat for wildlife, protect crops and homes, and enhance the agricultural landscape (Brandle et al., 2004). The shelterbelts are in a network state on the agricultural landscape, the role of one shelterbelt is like a barrier, which is an important element in the landscape (Ding et al., 1993).

Because of their importance in the agricultural landscape, shelterbelt construction develops very rapidly. The studies were mainly focused on their structure, function and management (Fan et al., 2002). As researches expanding from field scale to landscape scale, geographic information system (GIS) and remote sensing (RS) technologies were widely used in shelterbelt research (Wiseman et al., 2009; Czerepowicz et al., 2012; Deng et al., 2013, 2017; Zheng et al., 2016). Using the principle of the landscape ecology and combining GIS and RS, landscape structure can be analyzed to accurately evaluate development and status at landscape scale. Zhou and Sun (1994) introduced landscape indexes (ratio of belt to patch, connectivity, circuitry, and dominance) to shelterbelt landscape research. These indexes were widely used to evaluate shelterbelt structure at landscape scale (Sun et al., 1997; Li et al., 2003; Guan et al., 2004; Yang et al., 2017). Based on these researches, Shi et al. (2011) developed a method evaluating the spatial heterogeneity of shelterbelts distribution at landscape scale. These researches well measured and evaluated the spatial distribution and heterogeneity in landscape, but they did not analyze the reasons behind these results. Kristensen and Caspersen (2002) analyzed the changes of shelterbelt network density, discussed the farmers' motives for shelterbelt planting in central Jutland. The results of this research provided insight into the driving forces behind shelterbelt planting and removal.

We found that, at landscape scale, the studies were mainly focused on evaluating the spatial distribution, there was few paper existed to study the changes of them, and further to regard the driving forces behind these distributions and changes. Shelterbelts are commonly planted on the farmland in the agricultural landscape. The changes of farmland may be one important factor to affect their changes. Therefore, the purpose of this paper is to research the temporal and spatial dynamics of shelterbelt planting in northeastern China, and analyze how the farmland affects the distributions and changes of them. Therefore, this paper investigates the changes of shelterbelt density and landscape indexes at three points in time (1990, 2000 and 2010). These times were chosen to cover the period of major shifts in shelterbelt planting strategies. The results provide insight into the spatial distribution and temporal changes of shelterbelt density, connectivity and distribution evenness across the study area, and understand the relationship of distributions and changes between shelterbelt and farmland. We suppose this analysis can provide valuable information for decision makers to guide and develop future shelterbelt planting policies.

Materials and methods

Study area

The boundary of northeast shelterbelt protection zone was determined by Three North Shelterbelts Construction Bureau of the State Forestry Administration of China. The area is about 584152 km^2. This zone is in eastern Inner Mongolia Autonomous Region and western Northeast China, and embraces Heilongjiang, Jilin and Liaoning provinces. Its extent is 115°–130°E and 40°–50°N (*Fig. 1*). There are very cold and long winter and hot and rainy summer. Agricultural disaster is mainly caused by windstorms and sandstorms, as well as droughts and floods. Winds from the southwest often reach 15–20 m/s in spring. Crop types are mainly maize, soybean, millet and sorghum (Zhu et al., 2010).

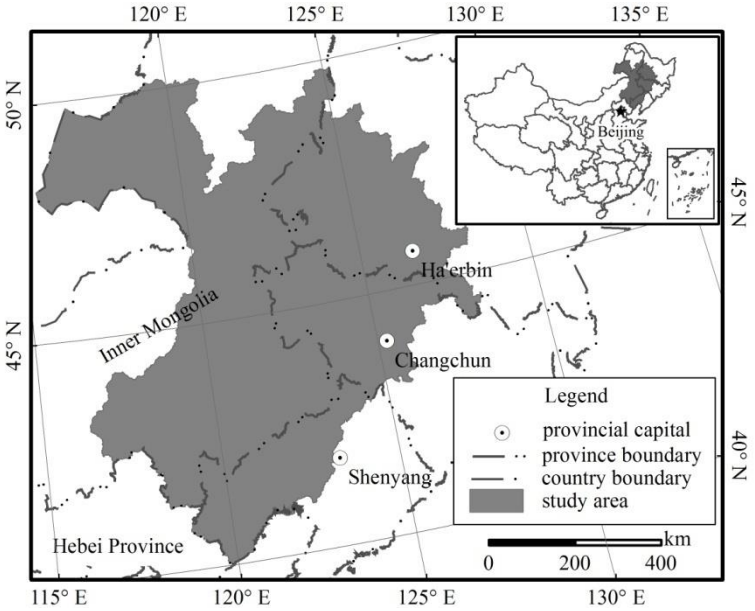

Figure 1. *The location of study area*

Data source

Shelterbelt data

Landsat series images of 30 m × 30 m spatial resolution were selected to extract shelterbelt information. Specifically, the 1990 images were acquired from Landsat-5 Thematic Mapper (TM) data, the 2000 images from Landsat-5 TM and Landsat-7 Enhanced TM (ETM) data, and the 2010 images from Landsat-5 TM data. For each time, it needed about 48 images to cover the whole study area. In order to accurately extract the information, optimal acquisition dates for images were in May, early and mid-June; second best were in early and mid-October. Considering the atmospheric difference of the images at different times, the atmospheric radiation was made based on each actual condition. Atmospheric radiation and geometric corrections were made for images with ENVI 4.8 software, and the estimated total root mean square error was less than one pixel.

Shelterbelt features in the Landsat images were sufficiently clear because of the moderate resolution and appropriate dates. Vector data were obtained as linear features

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1165511668

through manual interpretation via a computer interface with ArcMap 10.0 software. The result can be seen in *Figure 2*. Results were validated by field measurement and accuracy was greater than 95%.

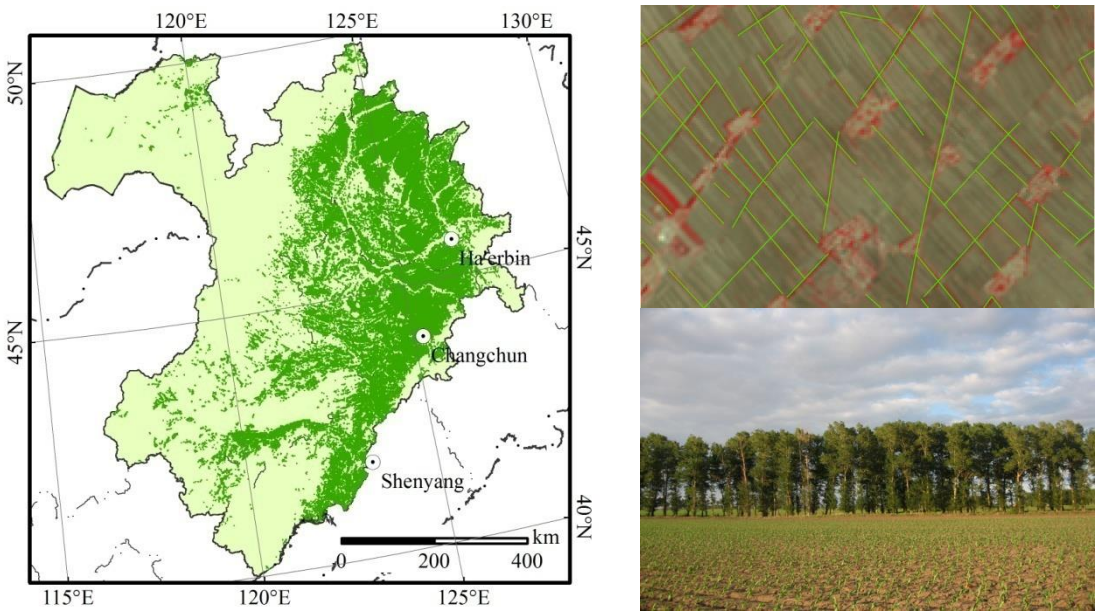

Figure 2. *The distribution of the shelterbelts, taken the shelterbelts in 2010 as example. Bottom right: the shelterbelt photographed in field. Top right: the shelterbelt in Landsat image. Left: the extracting result of shelterbelts in 2010*

Land use data

The indicators of land use interpretation were established according to the characteristics of the images, the second Chinese land investigation interpretation standard, expert knowledge, and other related geographic maps. The images were interpreted using the ArcMap 10.0 and the human-computer interactive method. Finally, land uses were classed into six types: farmland, grassland, forest, built-up land, water bodies and marsh. Data accuracy was validated by field surveys: 10% of the patches were chosen to perform accuracy assessment, the total precision was 90%, the precision of the farmland was more than 95%.

Zoning

The shelterbelt spatial distribution was related to site conditions. Therefore, we analyzed changes of the objects by the zoning method. Based on regionalization of Chinese agricultural natural resources and consideration of differences in topographic features, air temperature and precipitation, we separated the study area into seven zones. The result is shown in *Figure 3* and *Table 1*.

Landscape index of shelterbelt

The shelterbelts are in a network state in agricultural fields. Each shelterbelt interconnects and forms a network system. In the system, the junction of two or more belts or the end point of single belt are nodes. The connected edges between nodes are

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1165511668

belts. Ratio of belt to patch (*P*), connectivity (*Q*), and dominance (*D*) are introduced to estimate the landscape structure at regional scale (Zhou and Sun, 1994; Guan et al., 2004). We calculated these three landscape indexes to describe changes of the network in the study area between 1990 and 2010.

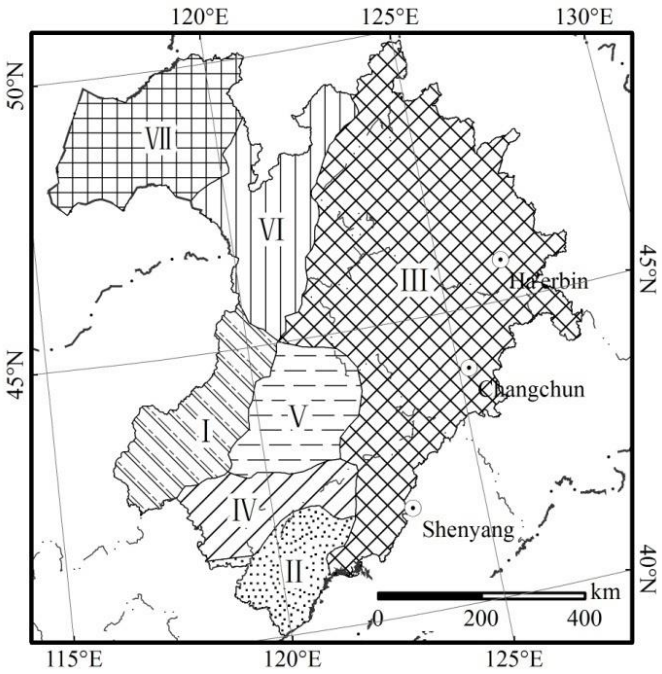

Figure 3. *Zones within the study area*

Table 1. *Description of site conditions in each zone*

Zone	Regionalization of agricultural natural resource	Topographic feature	Temperature condition	Precipitation condition
I	Pastoral and agricultural region in eastern Inner Mongolia Plateau	Medium-low mountain	Medium	Semi-arid
II	Agricultural, pastoral and forest region in Songliao Plain	Medium-low mountain	Warm	Semi-humid
III	Agricultural region in Songliao Plain	Flatland	Medium	Semi-humid
IV	Agricultural and pastoral region in eastern Inner Mongolia Plateau	Medium-low mountain	Medium	Semi-humid
V	Agricultural and pastoral region in eastern Inner Mongolia Plateau	Flatland	Medium	Semi-arid
VI	forest region in eastern Inner Mongolia Plateau	Medium-low mountain	Medium	Semi-humid
VII	Pastoral region in eastern Inner Mongolia Plateau	Upland plain	Medium	Semi-arid

(1) Ratio of belt to patch

This index is used to describe the abundance extent with aspects of area and number of networks, and measure the number of forest networks. The index is expressed as:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1165511668

$$P = \frac{S_b}{A} \quad \text{(Eq.1)}$$

where S_b is a reasonable area of the shelterbelt networks (km^2) and A is patch area which should to be protected in this state (km^2).

(2) Connectivity

This index is used to measure the formed condition. It is expressed as:

$$Q = \frac{N_a - (n-1)}{L_{MAX}(V)} \quad \text{(Eq.2)}$$

where $L_{MAX}(V)$ is the maximum number of belts; V is a reasonable node number; N_a is the sum of main and assistant shelterbelts; n is the number of patches that should to be protected.

(3) Dominance of forest network

This index is used to measure the occupied area, the number and the distribution evenness within the networks. Larger values of this index indicate a larger occupied ratio and vice versa. In other words, a smaller dominance index shows that the number of forest networks is insufficient or that its distribution is not uniform. The index is expressed as

$$D = \frac{1}{2} \cdot \left(\frac{R_d + R_f}{2} + R_c \right) \quad \text{(Eq.3)}$$

where R_d represents relative abundance in the network, R_f represents frequency in the network, and R_c represents coverage in the network.

Landscape index of farmland

The farmland area was extracted from land use data by GIS method. Ratio of farmland to zone (*PF*) and fragmentation (*CF*) are chosen to estimate the landscape structure of farmland in this paper. We calculated these two landscape indexes to describe distributions and changes of the farmland in the study area between 1990 and 2010.

(1) Ratio of farmland to zone

This index is used to describe the quantity or density of farmland in the zone, which is expressed as

$$PF = \frac{S_f}{S} \quad \text{(Eq.4)}$$

where S_f is the area of farmland in the zone, and S is the area of zone that farmland located in.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1165511668

(2) Fragmentation of farmland

This index is used to describe the degree of farmland fragmentation in the zone, which is expressed as

$$CF = \frac{N}{S_f} \quad \text{(Eq.5)}$$

where N is the number of farmland patches in the zone.

Results and discussion

Spatial distribution of shelterbelt density and landscape indexes

Shelterbelt density, expressed as shelterbelt length divided by zone area, is used to analyze spatial distribution in the study area. The results indicated that the spatial distribution at each time was similar, but shelterbelt density varied considerably by zone (*Fig. 4*).

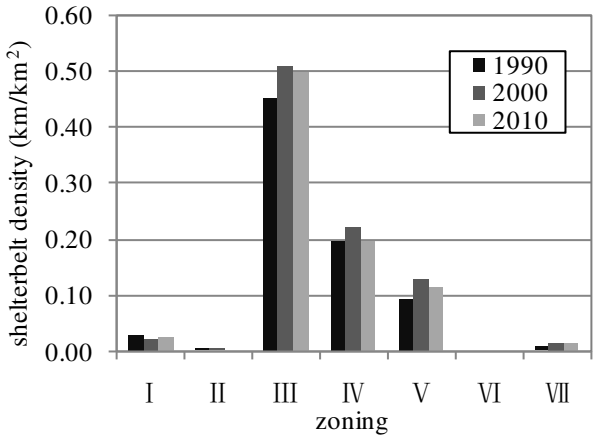

Figure 4. *Shelterbelt density in each zone*

Comparing shelterbelt density with site conditions in each zone, we found strong correlation between density and land-use type in the study area. The greatest shelterbelt density was in zone III, an agricultural region, it also had the largest area and the most shelterbelt length than other area. This was followed by zones IV and V, which were agricultural and pastoral regions. Then came zone I and VII, a pastoral or pastoral and agricultural region. Finally, with the smallest shelterbelt densities, zones II and VI, both were forest regions. We conclude that shelterbelt density decreased as land-use type transferred from agriculture to pastoral and then forest. This result is related to the shelterbelt protection function. That is, the main role of shelterbelt is to protect homes, crops and livestock by reducing wind speed, and the main land-use type is agriculture across the study area. In forest regions, windstorms and sandstorms are less frequent than the other regions, and lower shelterbelt densities there are reasonable.

Figure 5 showed the distribution of changes in landscape index between 1990 and 2010. Landscape distributions were similar in zones III, IV and V. We can see that *P*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1165511668

and *D* values in III were obvious higher than other zones, the seconds were IV and V, but *Q* was almost equal to IV and V, although it was still larger than other zones. The result indicated that, the numbers of shelterbelt were larger, the shelterbelt connectivity were better, and the shelterbelt distributions were more uniform in these three zones.

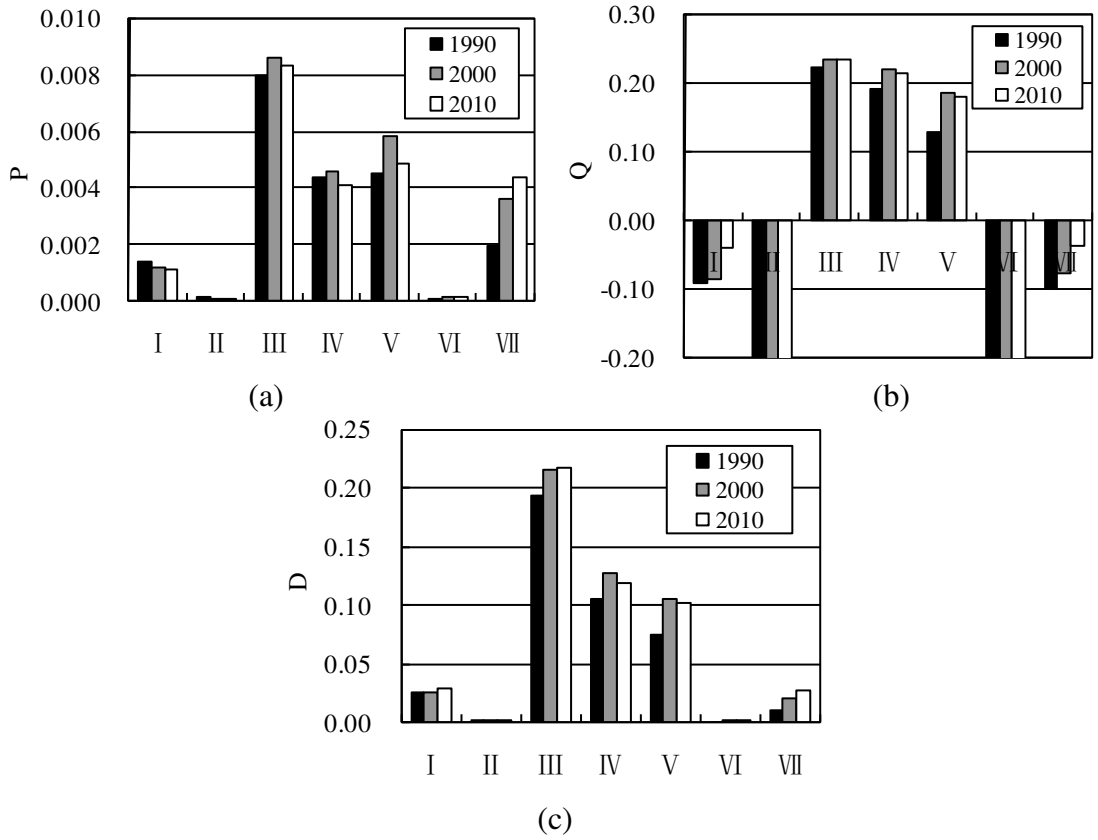

Figure 5. *The landscape indexes in each zone*

Compared with *Figures 4* and *5a*, they showed that *P* values in I and VII were higher than shelterbelt density in these zones. But they were still lower than III, IV and V. the reason for the lower landscape indexes in I, II, VI and VII was that forest or pastoral land was the dominant land-use type. Moreover, cropland was scattered in these zones, so shelterbelts in such land were fragmented.

Relationship of landscape indexes between shelterbelt and farmland

Shelterbelts are generally planted in the farmland, which may affect the shelterbelt landscape index. *PF* and *CF* were chosen as farmland indexes to analyze their relation with shelterbelt indexes. By calculating the mean value of each index in each zone, the relationship between landscape indexes of shelterbelt and *PF* showed in *Figure 6*. We can see that, the farmland density mainly affected the shelterbelt evenness (the coefficient of determination (R^2) was 0.638 between *D* and *PF*). The relationship between farmland density and shelterbelt number was not as obvious as we thought (R^2 was 0.364 between *P* and *PF*). By analyzed these two indexes in each zone, we found that two zones had opposite trend: in zone II, the *PF* value was high, which was the third one for all zones. But *P* value in this zone was the last. That because this zone

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1165511668

belonged to the agriculture, pastoral and forest transitional region, where land use type was more fragmental. Farmland fragmentation was a main factor to affect the *P* in this zone; the other was in zone VII, which had the smallest farmland density, the *P* value was up to the forth for all zone. This zone belonged to pastoral region and upland plain, where was more frequently affected by wind damage. For this reason, it may result that the shelterbelt spacing distance was closer than other areas. If we discarded these two zones, the relationship between these two indexes was increased to 0.775. Therefore, farmland density had some influences on shelterbelt number, but the main reason may be farmland fragmentation or site conditions.

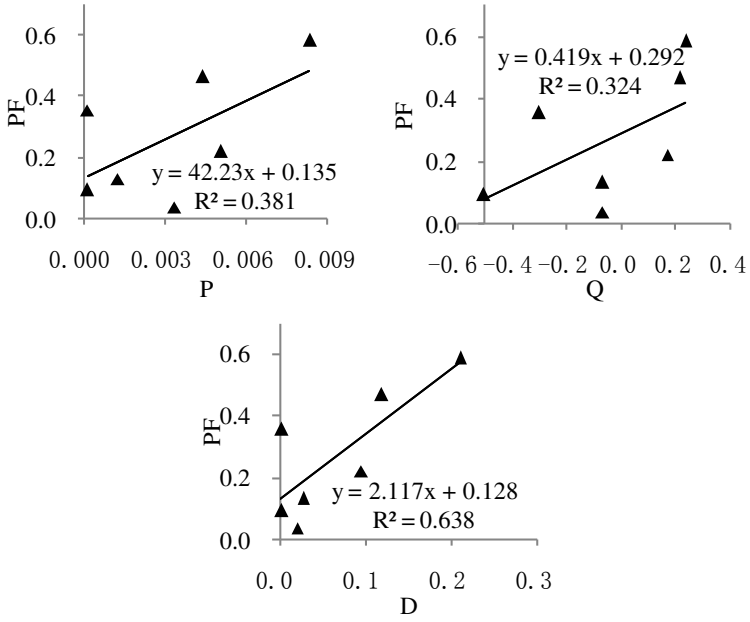

Figure 6. *The relationships between landscape indexes of shelterbelt and PF*

The relationship between landscape indexes of shelterbelt and *CF* showed in *Figure 7*. We can see that, R^2 was 0.568 between *P* and *CF*, which indicated that farmland fragmentation could affect the shelterbelt number. R^2 was 0.773 between *Q* and *CF*, and was 0.679 between *D* and *CF*, which indicated that farmland fragmentation could significantly affect the connectivity and evenness of shelterbelt, especially on connectivity. The result revealed that farmland fragmentation was a main index to affect the landscape pattern of shelterbelt. The lower of the farmland fragmentation, the higher connectivity and evenness of shelterbelt, and that may cause larger shelterbelt numbers.

Temporal change of shelterbelts density

Shelterbelt density increased by about 10% in the last 30 years, revealing that the number of shelterbelts were relatively stable over this period. The modest increase included two contrasting trends during the period: an increase by 13.2% from 1990 to 2000 followed by a 2.8% reduction by 2010. As a result of these changes, the density increased from 0.238 km/km^2 around 1990 to 0.269 km/km^2 around 2000. This then decreased to 0.262 km/km^2 around 2010. The changes of the density between 1990 and 2000, and between 2000 and 2010 can be seen from *Table 2*, the value was calculated

by shelterbelt lengths divided into total lengths in each zone. Such changes of the density were closely related to the 3N project. The first phase of this project was from 1978 to 1985. One of the main objectives in this phase was to plant more trees. The second phase from 1986 to 1996 aimed at strengthening gains made during the first phase (Moodre and Russell, 2003). For this reason, the shelterbelt density increased between 1990 and 2000. After 2000, many shelterbelts developed into over-mature forests and, because of destruction by humans, plant disease and insect pests, many shelterbelts were lost and the construction of the agro-forestry system entered updating phase. In this phase, many shelterbelts were updated, and sometimes they were too young to be recognized by remote sensing. Therefore, the density decreased between 2000 and 2010.

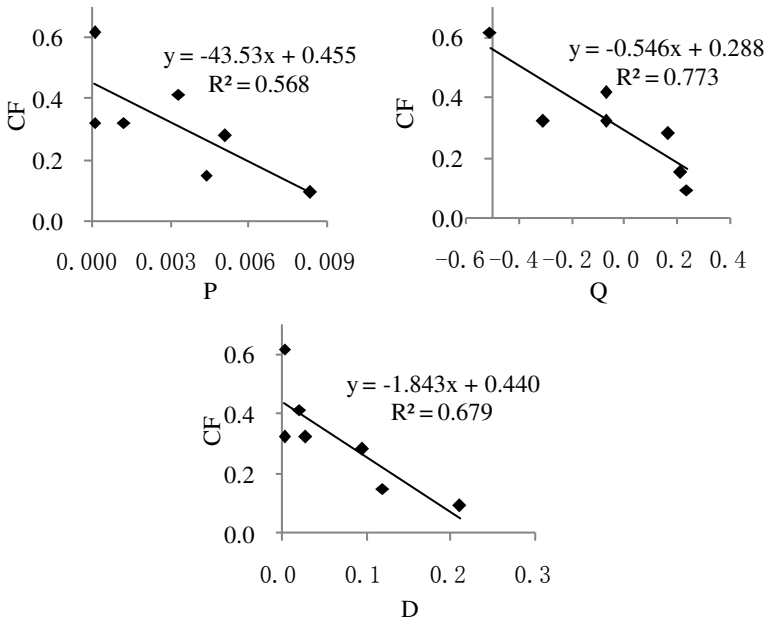

Figure 7. *The relationships between landscape indexes of shelterbelt and CF*

Table 2. *Shelterbelt changes from 1990 to 2000 and from 2000 to 2010*

Zone	Changes between 1990 and 2000			Changes between 2000 and 2010		
	Added (%)	Reduced (%)	Added in total (%)	Added (%)	Reduced (%)	Added in total (%)
I	28.7	52.4	-23.7	49.7	30.7	19.0
II	27.7	70.3	-42.6	20.4	39.3	-18.9
III	24.1	11.6	12.5	14.8	17.1	-2.3
IV	39.7	27.1	12.6	9.7	21.0	-11.3
V	48.8	10.6	38.2	12.5	23.5	-11.0
VI	50.6	18.9	31.7	63.3	44.2	19.1
VII	140.9	53.9	87.0	30.7	13.2	17.5
Average	26.3	13.1	13.2	14.8	17.7	-2.8

Added means new planted shelterbelts during this period; reduced means disappeared shelterbelts during this period; added in total means added minus reduced shelterbelts, "-" means reduced in total. The average value of the last row is calculated by changed divided total shelterbelts, not the average value of the seven zones

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1165511668

From *Table 2*, we can also find that between 1990 and 2000, the percent of the new planted shelterbelts was 26.3%, the fastest increased area was zone VII. The first reason was the shelterbelt density in 1990 was low in this area, and the second reason was that more shelterbelts were planted compared to the past time of this area. But we also seen that the reduced percent in VII was more faster, only second to II, the third was I. These three zones reduced faster than other areas obviously, which may be related to the site conditions. Between 2000 and 2010, the percent of new planted shelterbelts was lower than the first phase, but the disappeared shelterbelts more higher. The higher percent of added shelterbelts were in I, VI and VII, these areas were mostly belonged to pastoral or forest region. This means that the shelterbelt construction had been strengthened in these areas. Instead, Zones III, IV and V, had better shelterbelt density, the added percent was totally reduced, the shelterbelts needed to be timely updated in these areas.

The change of farmland area was produced by overlapping method. The result can be used to analyze the relationship between the changes of shelterbelt density and farmland. If the new planted shelterbelts were in the new added farmland, we considered the added shelterbelts were related to farmland, if not, there were other reasons. The same as the reduced shelterbelts. The results were shown in *Figures 8* and *9*.

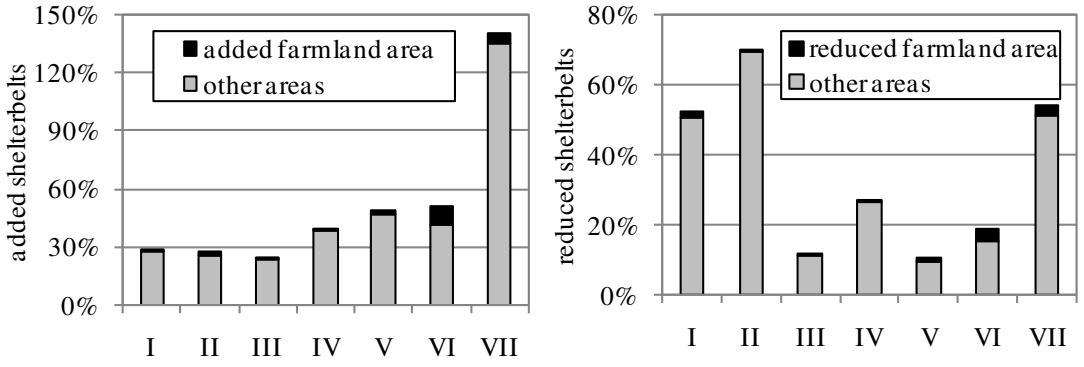

Figure 8. *The comparison between the changes of shelterbelt density and farmland from 1990 to 2000*

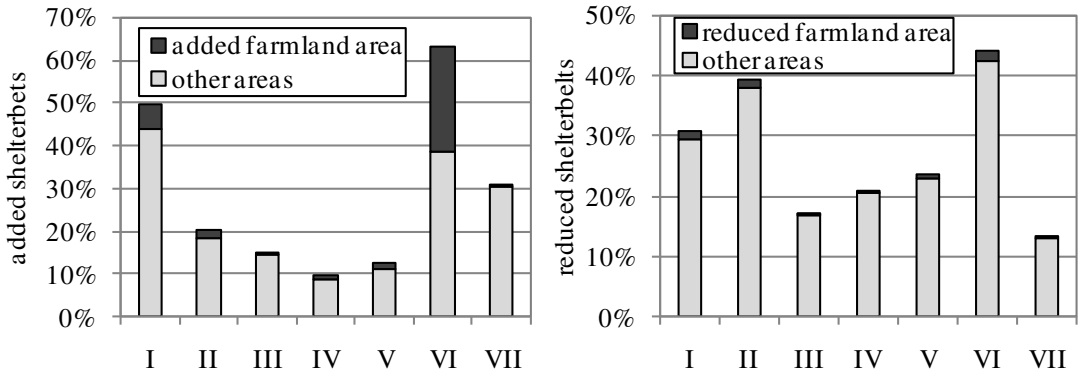

Figure 9. *The comparison between the changes of shelterbelt density and farmland from 2000 to 2010*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1165511668

Figure 8 showed that the changes of shelterbelts density had little relationship with farmland changes. The new planted percent was 26.3% between 1990 and 2000, only 0.9% of them were added in new added farmlands, the other 99.1% were added by other reasons. The reduced percent was 13.1% between 1990 and 2000, only 1.6% of them were reduced in reduced farmlands, the other 98.4% were reduced by other reasons. The similar results appeared between 2000 and 2010 (seen in *Fig. 9*), the added shelterbelts in new added farmlands were 2.5% for total added shelterbelts, and the reduced were 0.7%. We can conclude that the farmland changes were not the main factor to affect the changes of shelterbelt densities. The added shelterbelts were mainly related to the shelterbelt construction by managers. The reduced shelterbelts may be mainly caused by site conditions, or human destruction, which we did not discuss in this paper, and will be done in the future work.

Change analysis of landscape indexes of shelterbelt

The changes of landscape indexes of shelterbelt and farmland between 1990 and 2010 can be seen in *Table 3*. It indicated that between 1990 and 2010, the landscape indexes were increased totally. Although the *P* value reduced from 2000 to 2010, the change was not obvious. The most important was, the *Q* and *D* were more and more better during this period, which means that, even the quantity of the shelterbelt reduced between 2000 and 2010, the qualities including connectivity and distribution evenness were more better. This means that, after decades of construction, the landscape pattern of shelterbelt had been improved. But compared to the optimized network, it had many more harder works to do.

Table 3. *The landscape index changes of shelterbelt and farmland between 1990 and 2010*

	Shelterbelt	***P***	***Q***	***D***	**Farmland**	***PF***	***CF***
1990		0.0066	0.205	0.136		0.358	0.192
2000		0.0071	0.223	0.159		0.375	0.129
2010		0.0068	0.224	0.160		0.381	0.118

Table 3 also showed that the landscape indexes of farmland were more and more better. Farmland area was increased, and fragmentation was reduced. In order to understand the relationship of landscape indexes between shelterbelt and farmland, we calculated the changed of each index from 1990 to 2000 and from 2000 to 2010 in each zone respectively, and then analyzed the relationship of the landscape index changes between shelterbelt and farmland. The result showed that, there was no significant relationship between landscape index changes of shelterbelt and farmland during these periods.

Conclusion

The following conclusions are drawn from the analysis.

Shelterbelt densities varied considerably by zone. There is a close correlation between shelterbelt density and land-use type in the study area, with that density decreasing as the type transitioned from agriculture to pastoral and then forest.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1165511668

Distributions of shelterbelt in landscape index between 1990 and 2010 showed two opposing trends in seven zones. The reason for these results appeared closely connected to land-use type. Farmland fragmentation was a main index which had significantly effect on the connectivity and evenness of shelterbelt, especially on connectivity. Farmland density mainly affected the shelterbelt evenness. The shelterbelt numbers were affected by many factors, including farmland density, fragmentation and site conditions.

Shelterbelt density increased by about 10% over the last 30 years. After decades years of construction, the landscape pattern of shelterbelt had been improved. These changes of shelterbelt density had little relationship with farmland changes. The added shelterbelts were mainly related to the construction by managers. The reduced shelterbelts may be mainly caused by site conditions, or human destruction.

During the research, we found that the distribution and change shelterbelts were also closed related with the site conditions, like soil type, elevation, temperature and precipitation, which we did not discuss in this paper. In the future work, we will study the effect of site conditions on the changes of shelterbelt.

Abstract. In this paper, a catfish-effect multi-objective particle swarm optimization algorithm (CE-MOPSO) is proposed for optimizing the coordinative flow-sediment scheduling in a reservoir. In the proposed CE-MOPSO, the driven effect of catfish particles is introduced to improve the convergence and diversity of solutions. The performance of the proposed CE-MOPSO was verified using a classical bi-objective test function (ZDT3), and it was found that compared with MOPSO and Sigma-MOPSO algorithms, the CE-MOPSO showed better convergence to the true Pareto optimal fronts, and provided better diversity and uniformity for the Pareto frons with smaller values of convergence index and diversity index. After the successful validations in simulation studies, the proposed approach was then applied to a real case study in the Three Gorges Reservoir in China. Our results showed that the obtained Pareto solution set effectively approximated the true Pareto optimal frontier during the process of evolution. The scheduling results of CE-MOPSO revealed the relationship between power generation and sediment deposition in ten years and can be used to develop reservoir operation policies and plan sediment trapping and flow operations in real time. These results suggest that the proposed CE-MOPSO approach is efficient and effective in managing multi-objective water resources and hydrologic problems.

Introduction

Reservoir comprehensive utilization and sediment sluicing are contradictory in reservoir operation and management. Sediment deposition can reduce reservoir storage capacity, and subsequently cause decreases in the efficiency of flood control, hydropower generation, and navigation (Yoon, 1992; Yang, 2003). Therefore, the coordinated flow-sediment regulation is very important for effective and successful reservoir operation (Zhu, 1997; Han, 2003; Peng et al., 2014).

The aim of coordinated flow-sediment regulation in a reservoir is to seek maximum comprehensive benefits under the minimum sediment deposition. This can be considered as a multi-objective optimization problem (MOOP) with characteristics such as being multidimensional, dynamic, strong coupling, and nonlinear. In most previous studies, this multi-objective problem was usually solved by being transformed into a single-objective problem using vector optimization technologies, such as weighted method (Lian et al., 2004; Xiao et al., 2013), constraint method (Zhang and Feng, 1988; Xiang et al., 2010), Bayesian model averaging method (Duan et al., 2007; Yan and Moradkhani, 2014; Yan and Moradkhani, 2016), decomposition-polymerization method (Peng et al., 2004, 2014) and so on. However, the values of weight coefficients and constraint thresholds should be set subjectively in advance during the process of solving the model. A single set of fixed weights or constraint thresholds may result in only local optimum on the Pareto front. To obtain the global Pareto optimum, we need to run a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1166911686

good number of simulations to examine all the weight combinations or constraint threshold (Reddy and Kumar, 2009).

As an alternative, multi-objective particle swarm optimization algorithm (MOPSO) has been shown as a useful tool for solving large and complex MOOPs, due to its stochastic and implicitly parallel properties to search for multiple local optimal solutions and consequently, to obtain the Pareto optimal solutions set. However, the algorithm of MOPSO has some disadvantages including premature convergence, reduced individual diversity, and enmeshed local optimum (Reyes-Sierra and Coello, 2006). To overcome these issues, several improved MOPSO have been proposed. For instance, Mostaghim and Teich (2003) used a Sigma method in MOPSO for searching the best local guides to speed up the convergence towards the true Pareto front with better distribution. Coello et al. (2004) used a constraint-handling mechanism and a special mutation operator to enhance exploration capability of MOPSO. Reyes-Sierra and Coello (2005) improved the MOPSO with the use of the Pareto dominance and a crowding factor to select the leaders. Leong and Yen (2006) suggested to use an adaptive local archive to promote swarm's diversity and incorporated an adjusted population size to promote swarm's competition. Branke and Mostaghim (2006) proposed a few strategies for the selection of global guides. Abido (2008) employed a clustering technique to adjust the optimal Pareto set size. Recently, the MOPSO has been increasingly applied in the field of water resources. Reddy and Kumar (2007, 2009) presented an elitist-mutation MOPSO approach for solving optimal multipurpose reservoir operation problems. Azadnia and Zahraie (Azadnia and Zahraie, 2010) used non-domination sorting and crowding distance techniques in MOPSO and applied it to optimize reservoir operation with two objectives including water supply and sediment removal. Li and Lian (2008) improved the MOPSO with self-adjusting inertia weights and Pareto-optimal archive for optimizing the coordinate reservoir deposition and power generation in reservoir operation. Despite the advances in these studies, there is still room to improve the efficiency of MOPSO, and the application of MOPSO to the coordinative flow-sediment scheduling in a reservoir has remained a challenge.

To further enhance the robustness of MOPSO, we propose a catfish-effect MOPSO algorithm (CE-MOPSO) in this paper. The catfish effect introduces a driven effect of catfish particles on individuals (i.e. the sardine particles), which was studied in the PSO algorithm and proven that the introduced catfish particle can improve the performance of the PSO (Chuang et al., 2008, 2011; Ji et al., 2011; De Souza et al., 2014). By taking advantage of such catfish effect, this paper incorporates catfish effect mechanism into the MOPSO algorithm. Different from the work in references (Chuang et al., 2008, 2011; De Souza et al., 2014), in which catfish particles were added at the extreme points of the search region and replaced 10% of original sardine particles having the smallest fitness value, this paper suggests another way to generate catfish particles and a different way that catfish particles work. The proposed algorithm was applied to optimize the coordinative flow-sediment scheduling in a real reservoir. In summary, the main contributions of the proposed CE-MOPSO algorithm are as follows.

(1) In the CE-MOPSO, the catfish particles are generated from the external archive, which is used to store the intermediate non-inferior solutions (i.e., elite particles with greater fitness value during the optimization process). Thus, the generated catfish particles have greater vigor and competitiveness than sardine particles. When the diversity of particle swarm is less than a defined threshold, catfish particles are added into the search region. The added catfish particles have driven effect on sardine

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1166911686

particles, which make the sardine particles escape from them. Thus, the sardine particles may jump out of the "locked" status and be guided to moving towards new area of the search space. This helps the MOPSO algorithm improve the diversity of the population, and converge fast towards true Pareto fronts in further generations.

(2) The global optimal value of the sardine particle driven-influenced by catfish particles, is decided by the Sigma value of catfish particle, which is the second close to the Sigma value of sardine particle instead of the closest one. This contributes the CE-MOPSO avoid trapping in the local optimal solutions caused by the Sigma method and finding the global optimal solution with deeper search and increased convergence speed.

(3) The proposed CE-MOPSO performance is first compared with MOPSO (Coello et al., 2004) and Sigma-MOPSO (Mostaghim and Teich, 2003) algorithms through an optimization test with a bi-objective test function (ZDT3). The results show that the CE-MOPSO have better performance in convergence and diversity. Then, the proposed algorithm is applied to solving the optimization of reservoir flow-sediment regulation in a case study. Results show that the proposed CE-MOPSO is able to obtain a well-distributed Pareto optimal front, which can reflect the relationship between power generation and reservoir deposition.

The remaining sections are organized as follows. In Section 2, we establish a reservoir flow-sediment optimal dispatching model. The proposed CE-MOPSO algorithm is elaborated in Section 3 and its performance is verified in Section 4 by comparing it with the MOPSO and Sigma-MOPSO algorithms. A case study of using the CE-MOPSO is presented in Section 5. Finally, we conclude the paper in Section 6.

Materials and methods

Materials

The Three Gorges Reservoir (TGR) in China is taken up as a case study for analyzing non-inferior relationship between hydropower generation and sediment deposition. The Three Gorges dam is located in the upper reach of the Yangtze River, as shown in *Figure 1*. The TGR is the largest multi-purpose hydropower project in China, which has great benefits of flood controlling, power generation, navigation improving, water supply, etc. The TGR began to impound water on 1 June 2003, and was in full operation in 2009. The main features of the reservoir are given in *Table 1*.

The storage capacity of TGR is 393×10^8 m^3, and every 1 m increase in water head will bring TGR great benefit of power generation. Meanwhile, reservoir sedimentation is a serious issue in TGR operation and management, because it reduces TGR storage capacity and causes decreasing capability in flood control, hydropower generation, and navigation. Increasing power generation requires increasing the water head, which result in increase in sediment deposition. Power generation and reservoir sedimentation are contradictory in the TGR operation and management. Therefore, relationship between power generation and sediment trapping need to be revealed for effective reservoir operations.

The hydropower generation and sedimentation of TGR were calculated based on the 1961~1970 hydrological series. The time interval for the scheduling calculation is ten days in June to September and one month in other months. Therefore, the total number of time intervals is 20 in a year and 200 in ten years. The range of sedimentation calculation of the TGR was from Jiangjin to the dam site of the TGR, with the total

Mean annual power generation (10^9 kW·h)	847

Model formulation for reservoir flow-sediment optimal scheduling

In this study, the flow-sediment optimal scheduling model takes into account the non-inferior relationships between hydropower generation and sediment siltation, with the consideration of the constraints including reservoir flood control and navigation. The developed optimization model is generalized as follows.

Objective function

The optimal regulation model includes two objectives: maximize hydropower generation and minimize sediment deposition in reservoir. The mathematical functions of the objectives are expressed as follows (Peng et al., 2004; Yoo, 2009):

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1166911686

$$\max E = max\sum_{t=1}^{T}\eta H_t Q_t \Delta t / 3600 = f_1(\boldsymbol{X}) \quad \text{(Eq.1)}$$

$$\min V_s = min\sum_{t=1}^{T} V_{st} = f_2(\boldsymbol{X}) \quad \text{(Eq.2)}$$

where E and V_s denote hydropower generation and sediment that deposited in the effective capacity of reservoir for all scheduling intervals; T is the total number of intervals over the scheduling horizon; $f_1(\boldsymbol{X})$ and $f_2(\boldsymbol{X})$ are functions of the objectives E and V_s; $\boldsymbol{X}$ is an independent variable decided by reservoir operation mode; η represents power coefficient; Δt is duration of an scheduling interval; H_t and Q_t are hydraulic head and release passing turbines of hydropower plant in the tth scheduling interval; V_{st} is sediment deposited in a reservoir in the tth scheduling interval.

Reservoir sedimentation calculation

In the present study, the V_{st} is calculated by a one-dimensional mathematical model for unsteady flow and nonuniform sediment transport in a reservoir (Peng and Zhang, 2006). The governing equations are described as follows:

Flow continuity equation (van Rijn, 1993)

$$\frac{\partial A}{\partial t} + \frac{\partial Q}{\partial x} = q_i \quad \text{(Eq.3)}$$

Flow momentum equation (van Rijn, 1993)

$$\frac{\partial Q}{\partial t} + \frac{\partial}{\partial x}\left(\alpha_1 \frac{Q^2}{A}\right) + gA\frac{\partial Z}{\partial x} + g\frac{n^2 Q|Q|}{AR^{4/3}} = 0 \quad \text{(Eq.4)}$$

Nonequilibrium transport equation for suspended load (Han and He, 2015)

$$\frac{\partial(AS_k)}{\partial t} + \frac{\partial(QS_k)}{\partial x} = \alpha_k \omega_k B(S_{*k} - S_k) \quad \text{(Eq.5)}$$

Sediment carrying capacity equation for suspended load (Yang, 1993)

$$S_* = S_*(U, H, \omega, \cdots) \quad \text{(Eq.6)}$$

Sediment transport rate equation for bed load (Yang, 1993)

$$g_{bk} = g_{b*k}(U, H, d, \cdots) \quad \text{(Eq.7)}$$

Total bed deformation equation (Yang, 1993)

$$\rho' \frac{\partial Z_d}{\partial t} = \sum_{k=1}^{N_s} \alpha_k \omega_k (S_k - S_{*k}) - \sum_{k=N_s+1}^{N} \frac{\partial g_{bk}}{\partial x} \quad \text{(Eq.8)}$$

where t and x are temporal and spatial axes; Q is streamflow discharge; q_l is discharge of lateral flow; A, B and H are cross-sectional area, width and depth of streamflow, respectively; Z is water level; U is cross-sectional average velocity of streamflow; R is hydraulic radius; n is Manning's roughness coefficient; S_k is suspended sediment concentration of size group k, written as $S_k = p_k S$ in which p_k and S are size distribution and sediment concentration of suspended load; S_{*k} is suspended sediment-carrying capacity of the kth group, expressed as $S_{*k} = p_{*k} S_*$ in which S_* sediment-carrying capacity of suspended load, and p_{*k} is size distribution of S_*; α_k is saturation recovery coefficient for nonequilibrium suspended load transportation of kth size group; ω_k is settling velocity of kth size group of suspended load; g_{b*k} is the actual bed load transport rate of kth size group, written as $g_{b*k} = g_b\left(d_k\right) * p_k$ in which $g_b(d_k)$ is bed load transport capacity of kth size group, and d_k is particle size of kth size group; Z_k is depth of bed deposition; g is gravitational acceleration; ρ_s' is dry density of deposits or bed material; d is particle diameter of bed material, N_s is number of size groups of suspended load; N is number of size groups of total load.

Equations 3–8 can be solved by finite difference method. Solution process consists of two steps: Flow *Equations 3* and *4* were solved firstly, and sediment *Equations* 5 and *8* secondly. For details of the solution process, the readers are referred to (Peng and Zhang, 2006). The V_{st} in *Equation 2* can be calculated based on the computed result of Z_d in *Equation 8.*

Constraints

Water volume balance constraint

The water volume balance equation is expressed as

$$V_{t+1} - V_t = \left(Q_t - q_t - S_t\right)\Delta t \qquad \text{(Eq.9)}$$

where V_{t+1} and V_t are reservoir storages at the end and beginning of the tth interval, respectively; Q_t and q_t are inflow and outflow discharges during the tth interval; S_t is discharge of loss water in a reservoir during the tth interval.

Flood control constraints of reservoir

The flood control constraints of reservoir are expressed as

$$\mathrm{Z}_t \le Z_{\max}, q_t \le q_{\max} \qquad \text{(Eq.10)}$$

where Z_t is water level of reservoir at the end of the tth interval; Z_{max} is reservoir flood limiting water level; q_{max} is permissible discharge of streamflow at flood control point downstream of reservoir.

Navigation constraints

The navigation constraints of reservoir are expressed as

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1166911686

$$Z_t \geq Z_{\min}, q_t \geq q_{t\min} \quad \text{(Eq.11)}$$

where Z_{min} is navigable water stage in reservoir area; q_{tmin} is minimum discharge flow that meets the needs of navigation downstream of reservoir during interval t.

Water release ability limit of dam

The outflow discharging from reservoir is restrained by the maximum discharge capacity of dam discharge structure, which can be expressed as

$$q_t \leq q(Z_t) \quad \text{(Eq.12)}$$

where $q(Z_t)$ is flood peak discharge ability limit of dam at level Z_t.

Power constraints of station

The power constraints of station are expressed as

$$N_{t,\min} \leq \eta H_t Q_t \leq N_{t,\max} \quad \text{(Eq.13)}$$

where $N_{t,\min}$ and $N_{t,\max}$ are the upper and lower limits of plant power during interval t, respectively.

The proposed catfish-effect MOPSO algorithm

Catfish effect mechanism

The catfish effect originates from an effect observed by Norwegian fishermen when they introduced catfish into a holding tank for caught sardines. The added catfishes would stimulate the movement of sardines, thus making the sardines alive and fresh longer (Hu, 2004).

The catfish effect in this study is applied to the MOPSO algorithm and this method is called catfish-effect MOPSO algorithm (CE-MOPSO). At the early evolutionary stage of particle group, particles are treated as sardine's particles, and the Sigma method (Mostaghim and Teich, 2003) is used to search the space of solution with a fast convergence rate. When sardines group are trapped in a local optimum because of poor diversity, the catfish particles will be produced from the non-inferior solutions and be put into sardine particles. The generated catfish particles will trigger the driven influence on sardine particles, and guide sardine particles towards a new search region to improve the diversity in the population.

Implementation of CE-MOPSO

The detailed steps of the proposed CE-MOPSO algorithm are given below.

Step 1: Set the parameters including swarm population size N, maximum number of iteration K, and external archive size M. The external archive is used to store the generated non-inferior solutions that can be used to guide the search. The size of external archive determines the number of non-inferior solutions.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1166911686

Step 2: Initialize the population. Treat particles as sardine particles, and initialize particles in the population with random positions and velocities that meet the constrains. Initialize *M/2* non-inferior solutions and set them as the individuals in external archive.

Step 3: Calculate the fitness of each particle, and maintain the external archive based on the crowding distance of each non-inferior solution.

The equation used for computing the fitness of each particle with two-objective fitness function was expressed as follows:

$$\begin{cases} \mathrm{Fit}(f_1(\mathbf{x})) = \sum_{t=1}^{T} \eta H_t Q_t \Delta t / 3600 - M \sum_{l=1}^{L} W_l \\ \mathrm{Fit}(f_2(\mathbf{x})) = 1/\{\sum_{t=1}^{T} V_{st} - M \sum_{l=1}^{L} W_l\} \end{cases} \quad \text{(Eq.14)}$$

where M is penalty factor; W_l is the value that the tth constraint is violated; L is total number of constraints.

Generate non-inferior solutions according to the calculated fitness values of particles, and store the generated non-inferior solutions per iteration in external archive. If the number of non-inferior solutions in external archive exceeds the M, retain the individuals with larger crowding distance, thus maintain the diversity of non-inferior solutions. The crowding distance (d_j) of individual j in external archive was computed as follows (Reddy and Kumar, 2007):

$$d_j = \sum_{ob=1}^{O} \frac{|f_{ob}(j+1) - f_{ob}(j-1)|}{f_{ob}^{\max} - f_{ob}^{\min}} \quad \text{(Eq.15)}$$

where ob denotes the objective index; O is the total number of objectives; $f_{ob}^{\max}$ and $f_{ob}^{\min}$ denote the max and min values of objective function, respectively; $f_{ob}(j + 1)$ and $f_{ob}(j\text{-}1)$ are the values of objective function for individuals j-1 and j + 1, which are the two nearest to individual j.

Step 4: Determine the best value of each particle in population, and calculate the Sigma value of each individual in both population and external file as follows (Mostaghim and Teich, 2003):

$$\delta = \frac{f_1^2 - f_2^2}{f_1^2 + f_2^2} \quad \text{(Eq.16)}$$

where f_1 and f_2 denote the two objective functions' values of particle.

Step 5: Calculate the diversity of particle swarm at the kth iteration ($\xi(k)$) as follows:

$$\begin{cases} \xi(k) = \dfrac{div(k)}{div(0)} \\ div(k) = \sqrt{\dfrac{1}{Nm} \sum_{j=1}^{N} \sum_{i=1}^{m} \left[\dfrac{(x_i^j(k) - x_i^{j,gbest}(k))}{(Bu_i - Bd_i)} \right]^2} \end{cases} \quad \text{(Eq.17)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1166911686

where k is iteration number; j is serial number of particle; x_i^j is position in the ith dimension of particle j; $x_i^{j,gbest}$ is global best position in the ith dimension of particle j which exists in external archive, and its Sigma value is the second closest to the Sigma value of particle j; Bu_i and Bd_i denote the upper and lower limits of x_i^j.

Check whether the $\xi(k)$ is less than the scheduled threshold ξ_0. If $\xi(k) > \xi_0$, go to step 6, otherwise go to step 7.

Step 6: Determine the global optimal value of each particle using Sigma method (Mostaghim and Teich, 2003). If the sigma value of a particle in population is closest to the sigma value of an individual in external archive, the individual in external archive will be selected as the particle's global best position. Update the velocity and position of the jth particle as follows (Kennedy and Eberhart, 1995):

$$v_i^j(k+1) = \omega \times v_i^j(k) + c_1 \times r_1(x_i^{j,pbest}(k) - x_i^j(k)) + c_2 \times r_2(x_i^{gbest}(k) - x_i^j(k)) \quad \text{(Eq.18)}$$

$$x_i^j(k+1) = x_i^j(k) + v_i^j(k+1) \quad \text{(Eq.19)}$$

where ω is coefficient of inertia weight, which controls the influence of the particle previous velocity on its current one; c_1 and c_2 are learning factors; r_1 and r_2 are independent random numbers uniformly distributed in the interval [0,1]; v_i^j is the ith dimension velocity of particle j; $x_i^{j,pbest}$ is the jth particle's best position in the ith dimension.

Step 7: Generate catfish particles to promote the diversity of swarm particles.

Let C be the maximal number of catfish particles. If the number of non-inferior solutions is less than C, set all the non-inferior solutions as catfish particles. Otherwise, select C non-inferior solutions with larger crowding distance as catfish particles. The catfish particles are put into the sardine particle swarm as external competitive individuals. The added catfish particles, which act only at the current iteration and will be "dead" and removed from the particle swarm at next iteration, will trigger the driven influence on sardine particles. Thus, the search of solutions is affected by not only the guidance of global optimal value and individual optimal value, but also the driving of catfish particle. The renewed velocity of the jth particle is updated as follows:

$$\begin{aligned} v_i^j(k+1) = {} & \omega \times v_i^j(k) + c_1 \times r_1(x_i^{j,pbest}(k) - x_i^j(k)) + c_2 \times r_2(x_i^{j,gbest}(k) - x_i^j(k)) - \\ & Sat \times P \times sign(x_{Ci}^I(k) - x_i^j(k)) \times \exp\left\{-Q \times \left|x_{Ci}^I(k) - x_i^j(k)\right|\right\} \end{aligned} \quad \text{(Eq.20)}$$

where subscript C denotes catfish particle index; superscript I is a serial number of catfish particle which is closest to sardine particle j in dimension i, and is calculated as:

$$I = \left\{ l \,|\, \min_l \left(\left| x_{Ci}^I(k) - x_i^j(k) \right| \right) \right\} \quad \text{(Eq.21)}$$

Thus, the catfish particle nearest to each sardine particle in each dimension can be chosen at each iteration.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1166911686

Note that the fourth item in *Equation 20* is called the driven effect item. *Sat* is a binary variable, 0 or 1 stochastically that decides if sardine particles are driven-influenced by catfish particles, which can be expressed as:

$$Sat = \begin{cases} 0 & F_I^{k+1} > F_I^k \\ 1 & F_I^{k+1} \le F_I^k \end{cases} \quad \text{(Eq.22)}$$

where F_I^k is the fitness of catfish particle *I* at the *k*th iteration.

Parameters *P* and *Q* in *Equation 20* decide how hard catfish particles drive sardine particles. The nearer the distance between catfish particle and sardine particle is, the greater driven effect of catfish particle on sardine particle is. Consequently, sardine particles keep escaping from catfish particles, and catfish particles occupy around global best position rapidly.

It can be seen that the catfish effect mechanism described in *Equation 20* has two key points: (1) Global optimal value of sardine particle is decided by the Sigma value of catfish particle, which is the second close to Sigma value of sardine particle instead of the closest one. It prevents sardine particles from trapping into the local optimal solutions caused by the Sigma method and helps sardine particles find the global optimal solution with local depth search and increased convergence speed. (2) Including the guidance of global optimal value and individual optimal value, the search of solution was also affected by the driven effect of catfish particles. This makes sardine particles escape from catfish particles generated from non-inferior solutions, which can avoid the solution search concentrating near non-inferior solutions and falling into a "locked" status. Thus, the searching space is broadened and the diversity of solution is improved.

Step 8: Generate the newer particle according to the computed velocity and position.

Step 9: Take the maximum number of iteration as terminal condition of the algorithm. If the number of iteration is less than the maximum iteration, then go to step 3; otherwise end the search and output the non-dominated solution set from external files.

The flowchart of the CE-MOPSO is exhibited in *Figure 2*.

Results and discussion

Efficiency of CE-MOPSO algorithm

Before applying to a real case study, we first demonstrated the efficiency of the proposed CE-MOPSO algorithm through a bi-objective test function (ZDT3). We compared this algorithm with MOPSO (Coello et al., 2004) and Sigma-MOPSO algorithms (Mostaghim and Teich, 2003), and used two performance metrics to assess their performance.

Performance measures

Convergence index (γ) measures the distance of the obtained non-dominated solutions to the true Pareto front, which is written as (Tripathi, 2007):

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1166911686

$$\gamma = \frac{1}{n}\sqrt{\sum_{i=1}^{n} d_i^2} \qquad \text{(Eq.23)}$$

where n denotes the number of members in non-dominated solutions; d_i is the Euclidean distance between the ith member in non-dominated solutions and its nearest member in the true Pareto front. A smaller value of γ reflects better convergence toward the true Pareto front.

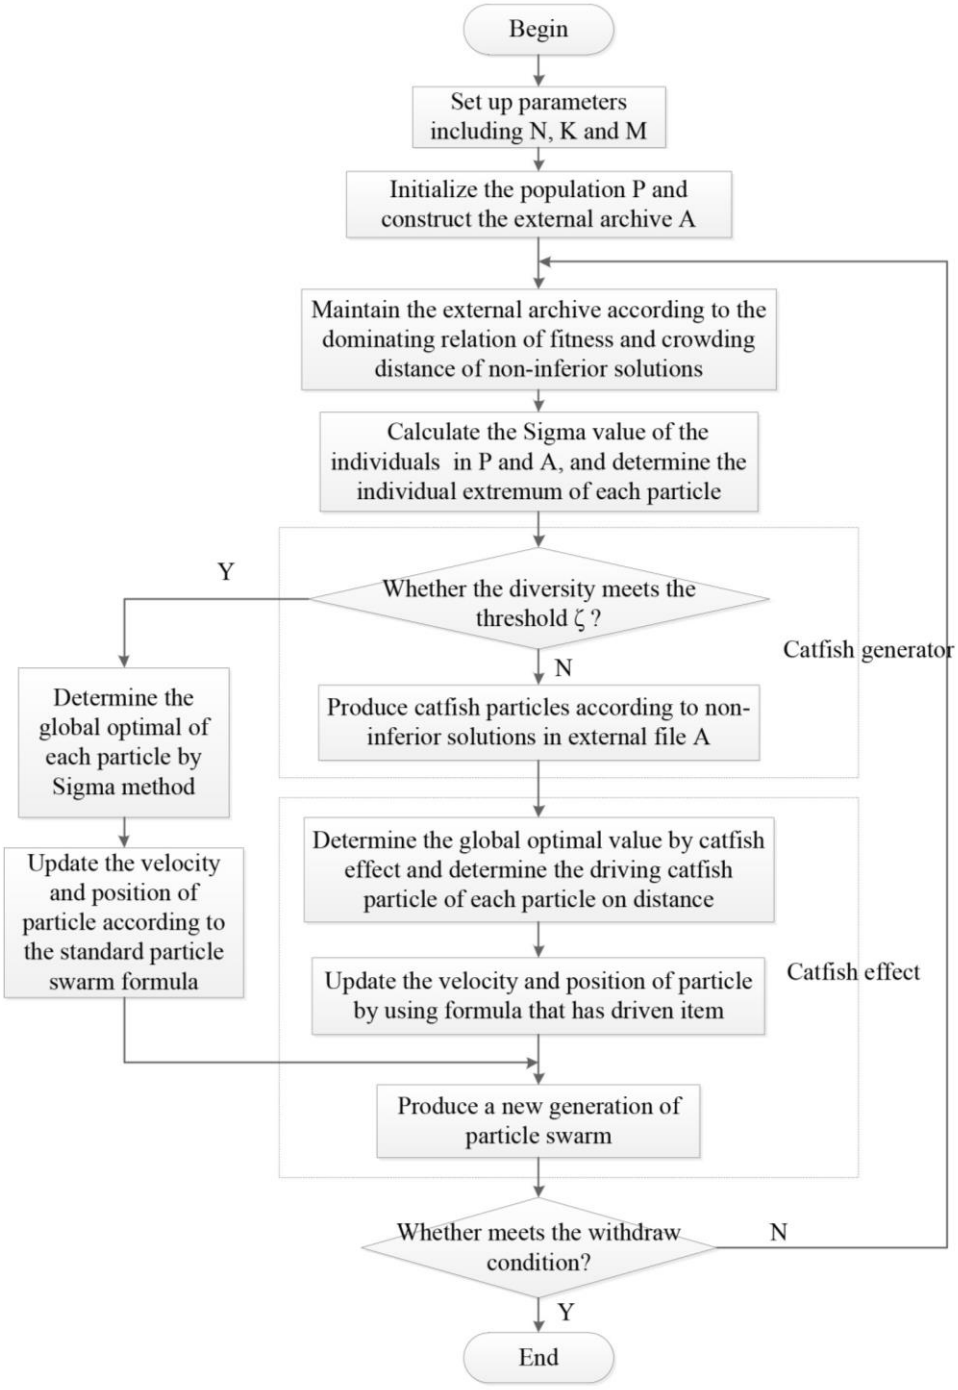

Figure 2. *The flowchart of the catfish-effect multi-objective particle swarm algorithm*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1166911686

Diversity index (Δ) indicates the spread along the non-dominated solutions, which is written as (Tripathi, 2007):

$$\Delta = \frac{d_f + d_l + \sum_{i=1}^{n-1} \left| d_i - \bar{d} \right|}{d_f + d_l + (n-1) \times \bar{d}} \quad \text{(Eq.24)}$$

where d_i is the Euclidean distance between adjacent solutions in the obtained non-dominated solutions set, and $\bar{d}$ is the average of all the d_i, which is expressed as $\bar{d} = \sum_{i=1}^{n-1} d_i / (n-1)$; d_f and d_l are the Euclidean distances between the extreme solutions and the boundary solutions of the obtained non-dominated set. The smaller the value of Δ, the more uniform the distribution of the non-dominated solutions.

Discussion of results

The following parameters were chosen for the three algorithms: population size $N = 50$, archive size $M = 100$, maximum number of iteration $K = 500$, learning factors $c_1 = c_2 = 2$, inertia weight $\omega = 0.9\text{-}0.5\ k/K$, in which k is the current iteration number. Relative diversity threshold of CE-MOPSO algorithm was set to $\xi_0 = 0.45$ (The calculated results showed that the evolution of the population stabilized in the vicinity of this value and the diversity of the population needed to be promoted).

Twenty independent runs are performed for each algorithm on ZDT3, and their average and variance values of the two metrics (γ and Δ) are presented in *Table 2*. It can be seen that the proposed CE-MOPSO algorithm outperforms MOPSO and Sigma-MOPSO algorithms for ZDT3 test problem, with the lowest average and variance values of the γ. It indicates that the CE-MOPSO achieves a faster convergence rate to the true Pareto optimal fronts than MOPSO and Sigma-MOPSO algorithms. Also, our proposed CE-MOPSO algorithm obtained the best results with respect to the Δ, with the smallest average and variance values of the Δ. This shows that the proposed CE-MOPSO can to attain a better distribution of solutions than the other two algorithms for ZDT3 test problem. Therefore, it can be concluded that the solutions obtained by CE-MOPSO have better performance in convergence and diversity. It should be mentioned that the CE-MOPSO consumes much more computation time than MOPSO and Sigma-MOPSO algorithms, because the catfish's driven effect makes sardine particles explore a deeper search space to promote the diversity in population, which will consume more time.

Table 2. *Results for ZDT3: γ, Δ, and the time required per iteration*

Test function	Index	MOPSO	Sigma-MOPSO	CE-MOPSO
ZDT3	γ (average)	0.00418	0.10205	0.00311
	γ (variance)	0.00000	0.00238	0.00000
	Δ (average)	0.83195	0.76016	0.33004
	Δ (variance)	0.00892	0.00349	0.00007
	Time (sec)	16.78	19.35	71.49

The resulting Pareto fronts produced by the three algorithms for ZDT3 function are presented in *Figure 3*. It is seen that compared with MOPSO algorithm, the solutions of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1166911686

Sigma-MOPSO had better convergence at two ends, but the distribution in the middle was rather dispersed with several gaps (*Fig. 3b*). The solutions of MOPSO algorithm were scattered at two ends, but the distribution in the middle was relatively continuous and uniform (*Fig. 3a*). Thus, the Sigma-MOPSO algorithm paid more attention to the convergence at two ends, but ignored the convergence quality and diversity of solution. Compared with the MOPSO and Sigma-MOPSO algorithms, the CE-MOPSO in *Figure 3c* can converge faster towards the true Pareto front, and produce the true Pareto front with better spread both at two ends and in the middle on this function. This also demonstrates that the proposed CE-MOPSO has obvious advantages in convergence and spread of solutions for ZDT3 test problem.

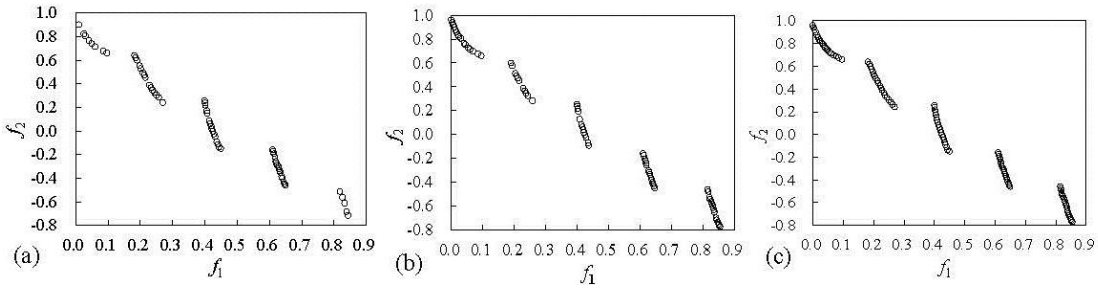

Figure 3. *Obtained Pareto fronts using (a) MOPSO, (b) Sigma-MOPSO and (c) CE-MOPSO on test function ZDT3*

Application

Case study

The one-dimensional numerical model for reservoir sedimentation was validated with other numerical results. The comparison of the computed sediment deposition for 10 years operation of the TGR was presented in *Table 3*. It is shown that the calculated sedimentation in TGR agreed well with the results calculated by Yangtze River Scientific Research Institute, the maximum relative error is 8.584% in the reach of Cuntan-Jiangjin. This indicated that the one-dimensional numerical model was accurate enough to model the sedimentation in the TGR.

Table 3*. Computed sediment deposition for 10 years operation of the TGR*

River reach	V_1 (10^8 m^3)	V_2 (10^8 m^3)	Relative error (%)
From the dam site to Fengdu	26.32	26.3	0.076
From Fengdu to Fuling	2.291	2.31	0.822
From Fuling to Changshou	1.146	1.2	4.500
From Changshou to Cuntan	0.327	0.337	2.967
From Cuntan to Jiangjin	0.213	0.233	8.584
From the dam site to Jiangjin	30.297	30.38	0.273

V_1 denotes the computed results by using the one-dimensional numerical model in the paper; V_2 denotes the computed results of Yangtze River Scientific Research Institute

Based on the designed operation scheduling of GTR, the main constraints were set as following: (1) Requirements of sediment flushing and constraints of flood control:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1166911686

considering improvement of flood forecast techniques and requirement of sediment flushing, limited water level of flood control is varied between 140 m and 145 m, maximum release discharge reservoir is 55,000 m^3/s. (2) Restrictions of minimum power and navigation: minimum power of plants in dry season is 4.99 million kilowatts (kW), water level controlled by navigation upstream of TGR in dry season is 155 m.

Select water level of TGR at each time step as decision variable, and one particle represents one of operation scheduling strategies of reservoir. Thus, each particle is expressed as:

$$X^j = (x_1^j, x_2^j, \cdots, x_t^j, \cdots, x_T^j) \quad \text{(Eq.25)}$$

in which x_t^j is the water level of reservoir during period t; superscript j denotes the serial number of particles; T denote total number of time step.

Results analysis

Ten independent runs were performed for optimizing the coordinative flow-sediment scheduling operation in the TGR by using the proposed CE-MOPSO. *Figure 4* shows the obtained optimal frontier of Pareto and its evolution process through 50, 100, 300, and 500 iterations of CE-MOPSO algorithm. It is shown that the non-inferior solution set is renewed during the process of evolution, and the obtained Pareto set effectively approximate to the true Pareto frontier. Comparing the obtained Pareto frontier result of 500 iterations with that of 300 iterations, it is basically the same in the central section of B-C and A-B area, but the distribution of the non-inferior solutions near A point of 500 iterative times are better than the result of 300 iterative times. The non-inferior solutions near B point has formed a more continuous uniform distribution than those of 300 iterative times. This indicates that the diversity of non-inferior solution set is improved with iterations by catfish effect mechanism, especially the non-inferior solutions are well-distributed at each end and inflection point of the optimal frontier.

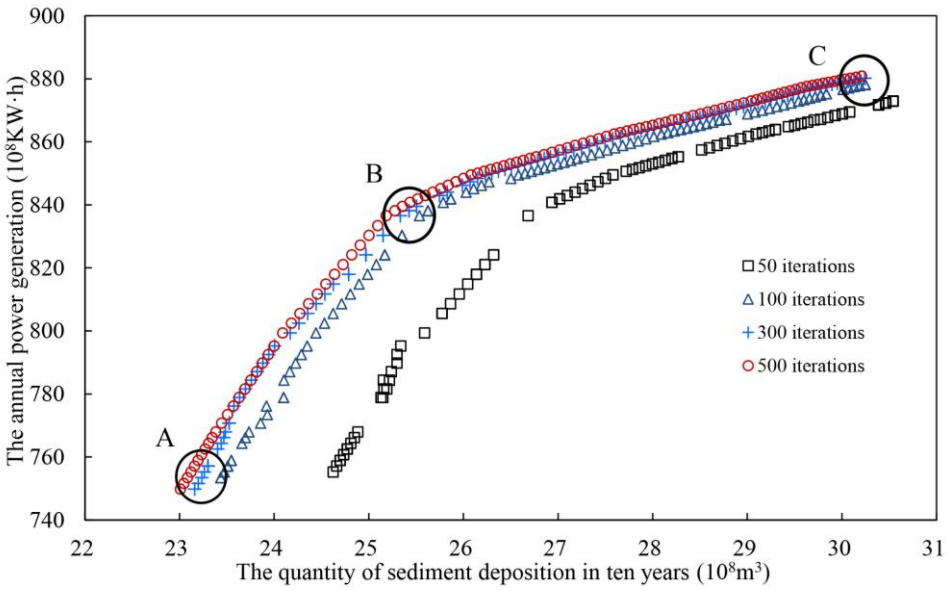

Figure 4. *The optimal frontier of Pareto and evolution process of the sedimentation in ten year and the annual average power generation*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1166911686

The Pareto optimal frontier shown in *Figure 4* also reflected the relationship between annual average power generation and sediment deposition in ten years. An increased hydropower generation resulted in an increased deposition in reservoir. The targets of increasing hydropower generation and decreasing reservoir sediment deposition are in contradictory ways. B point is an inflection point of the relationship between hydropower generation and sediment deposition of the TGR. In the section of A-B area, the rate of increasing power generation is greater than the rate of increasing siltation, while the rate of increasing power generation is smaller than the rate of increasing siltation in the section of B-C area. The inflection point B is very important for the selection of a non-inferior scheme in the TGR operation. For the schemes is in A-B area, increasing 1×10^8 kW·h power generation results in 0.025×10^8 m^3 sediment silting in the reservoir. For the schemes is in B-C area, increasing 1×10^8 kW·h power generation results in 1.08×10^8 m^3 sediment silting in the reservoir.

Figure 5 shows the non-inferior reservoir operation water level processes of the schemes corresponding to points A, B and C. In A scheme, since reservoir water level was lowered in flood season and did not reach the normal storage water level at the end of flood season that affects the power generation dispatch in non-flood season, both sediment deposition and power generation is the minimum in A scheme. In C scheme, due to the high water level operation in flood season, its power generation and sediment deposition is the maximum. The operation water level of B scheme in flood season is between A and C, which not only makes full use of lowering water level for sediment reduction in flood season, but also raising the water level to the normal storage level to ensure the power generation dispatch in non-flood season, so its power generation and sediment deposition is in the middle. This operation mode is different from traditional single-objective dispatch, which belongs to of multi-objective optimization of the coordinative water-sediment dispatch.

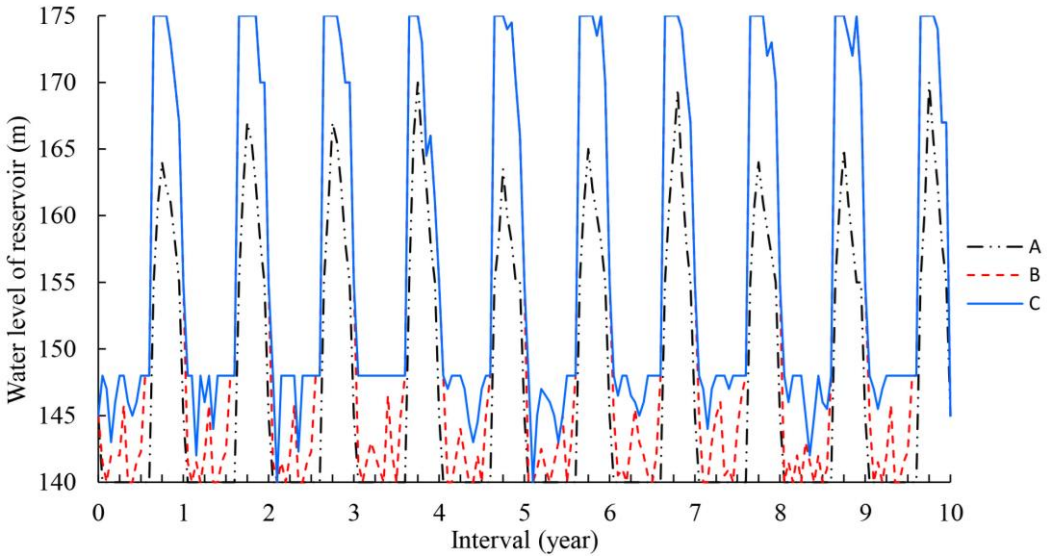

Figure 5. *Non-inferior reservoir operation level process of A, B and C schemes*

The mean annual power benefits and sedimentation represent short-term benefit and long-term benefits of the reservoir, respectively. If reservoir managers or decision makers focus on the life of reservoir that could play a long-term comprehensive

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1166911686

utilization benefit, the corresponding reservoir water level need to be lowed, such as scheme A. If decision makers focus on the short-term benefits of reservoir, the corresponding reservoir water level need to be raised, such as scheme C. The optimal scheme has better balance between power generation and reservoir sedimentation, and the obtained the non-inferior solutions can be used to formulate reservoir operation policies in practice. These policies can also be used to plan sediment trapping and flow operations.

Conclusion

In this paper, a catfish-effect multi-objective particle swarm optimization (CE-MOPSO) algorithm is proposed for optimizing the coordinated dispatch of water and sediment in a reservoir. Catfish particles, generated from the individuals in external archive, have greater vigor and more competitiveness than sardine particles. When added into sardine particles, the catfish particles have driven effect on sardine particles, which makes the sardine particles escape from them. By this, the sardine particles may jump out of the "locked" status, explore the search region, and improve the diversity of population. This helps the MOPSO algorithm to effectively guide the search towards the true Pareto front in further generations. In addition, the global optimal value of particle is second close to its Sigma value instead of the closest one. This prevents sardine particles from trapping into the local optimal solutions caused by the Sigma method, and helps sardine particles find the global optimal solution with local deeper search and increased convergence speed. The performance of CE-MOPSO in nonlinear numerical function optimization was first investigated with a test of classical bi-objective test function (ZDT3). The results were encouraging and promising in both computational efficiency and search efficiency when compared with the MOPSO and Sigma-MOPSO. The proposed CE-MOPSO was then applied to a multi-objective optimization of the coordinative flow-sediment regulation in the Three Gorges Reservoir. The obtained Pareto set effectively approximated the true Pareto frontier during the process of evolution. The scheduling results of CE-MOPSO reflected the tradeoff between power generation and sediment deposition in ten years, which is useful for making reservoir operation policies of sediment trapping and flow operations in practice. These results demonstrate that the proposed CE-MOPSO can provide efficient and effective solutions for the optimization of the coordinative flow-sediment scheduling in a reservoir.

However, in CE-MOPSO, we need to define the maximal number of catfish particles, which has some subjective. In the future, a better approach for selecting the maximal number of catfish particles is desired to make a balance between computation time and performance of the algorithm. In addition, we would like to compare CE-MOPSO with some other evolutionary algorithms and apply CE-MOPSO for solving higher dimensional optimization problems.

(Received 22nd Apr 2019; accepted 12th Jul 2019)

Abstract. Quarterly water quality monitoring data from 15 monitoring sites in Poyang Lake and the water level data from the Xingzi monitoring station in Poyang Lake from 2012 to 2016 were analyzed to determine (1) how the water quality changed both spatially and temporally and (2) how the changes of the water quality and eutrophication were related to variations in the water level. The results indicated that there were seasonal and interannual variations in the water quality of Poyang Lake. Dissolved Oxygen (DO) and Total Nitrogen (TN) reached maximum and minimum values in winter and summer, respectively. The maximum and minimum concentrations of Total Phosphorus (TP) were found in spring and summer, respectively. Chemical oxygen demand (COD) was slightly lower in spring and summer than in autumn and winter. Over the entire sampling period, the concentrations of ammonia nitrogen (NH_4-N), TP, and TN were highest in 2015. COD concentrations varied little interannually. Chlorophyll a concentrations were relatively uniform and did not show obvious seasonal variation. There was little spatial variation in the NH_4-N concentrations in spring and summer, but there was considerable variation between sites in autumn and winter; COD varied considerably between sites in spring and winter. COD and TP were not significantly correlated, but NH_4-N, TN, and the degree of eutrophication were negatively correlated, with water level changes in Poyang Lake.
Keywords: *Poyang lake, temporal, spatial, water level changes, TLI, eutrophication*

Introduction

Poyang Lake is the largest freshwater lake in China. Its drainage area, which extends over 16.22 × 104 km^2, accounts for about 9% of the Yangtze River Basin. It has an average annual runoff of 144 × 109 m^3, which accounts for about 15.5% of the Yangtze River's average annual runoff (Duan et al., 2016). Poyang Lake makes a significant contribution to the ecological functioning, ecological integrity, and regional management of the water resources of the Yangtze River Basin (Liu et al., 2016). The lake water quality can be recorded by examining the physical, chemical, and biological characteristics of the lake (Van Houtven et al., 2014). It is important to assess the quality of the lake water as it directly affects the safety of the water used by people living close to the lake and the quality of the groundwater. As the largest of all the lakes that are connected to the Yangtze River, its water quality will influence the ecological integrity and ecological functioning in the middle and lower reaches of the Yangtze River.

DOI: http://dx.doi.org/10.15666/aeer/1705_1168711699

Poyang Lake has multiple functions; for example, it provides water for irrigation and domestic needs, is a source of aquatic products, and is an important shipping route (Wu et al., 2017). In recent years, the water quality has been affected by industrial discharges, agricultural effluent, and domestic sewage, to the point and that the ecological function of the wetland has been compromised, with consequences for the water supply capacity of the lake. More pollutants from upstream and the lower water levels in the dry season together indicate that eutrophication will increase in Poyang Lake. In recent years, many researchers have studied spatial and temporal changes in the water environment and the trophic status in Poyang Lake. For example, Hu et al. (2010) using the Nimero index, found that the conditions in Poyang Lake were eutrophic because of excessive nitrogen and phosphorus in 2010. Wu et al. (2011) found that water quality of Poyang Lake has already undergone great changes after 2003, and it is showing a deterioration trend, while Gao et al. (2010) found that in 2010, the main pollutants affecting the water quality of the lake were TP and TN. The water level in Poyang Lake is affected by climatic conditions and human activities and, because it is directly connected to the Yangtze River, the seasonal fluctuations in the water level are quite pronounced. Therefore, the relationship between water level changes and eutrophication has definite implications for water resources management (Coops et al., 2003). In their study, Wu et al. (2014) used water quality indicators to examine the temporal and spatial changes in the water quality of Poyang Lake in 2017 and also examined how these changes were related to the water level. Wang et al. (2015) used SWAT and GIS to quantitatively estimate how the exchanges between the river and lake influenced the dissolved nutrient loads in Poyang Lake and also the spatial and temporal changes in the wetland vegetation in 2015. Liu et al. (2013) collected samples of surface water from the main part of Poyang Lake, the entrance of five rivers to Poyang Lake, and the dish-shaped sub-lake, and it was found that there was serious eutrophication in 2013. Ma et al. (2013) analyzed the changes in the water quality in Poyang Lake from 2008 to 2010 and used the load analysis method to determine the main sources of the pollution in the lake in 2013. Du et al. (2015) quantitatively analyzed the relationships between the water quality of Poyang Lake and the water levels during the wet and dry seasons in 2015. They found that the water supply was increasingly inadequate to meet the demands of the gradually more intensive industries and livestock and poultry breeding activities in the Poyang Lake area, that the surrounding environment had been destroyed, and the water quality in the lake had deteriorated rapidly. The spatial and temporal variations in the water quality of Poyang Lake and the trophic status of the lake have been intensively studied. However, few studies have focused on the relationship between water quality and the water levels in Poyang Lake, and very few studies have systematically analyzed how water levels influence the water environment.

In this study, five years continuum water quality monitoring data of Poyang Lake were analyzed and the trophic status was evaluated to find out how the water quality in the lake varied both spatially and temporally over recent years. The effects of water level changes on the spatial and temporal changes in the water quality and eutrophication in different seasons and at a range of spatial scales were also examined. The results of this study will provide useful information about how the water quality in Poyang Lake varies both spatially and temporally and how the water quality is related to the water level. This study will also provide support for making scientifically robust decisions about how to implement tools to control the pollution in the lake, restore the aquatic ecosystems, allocate and protect water resources in an effective way.

Materials and methods

Study area

Poyang Lake is in the northern part of Jiangxi Province, at the southern end of the middle to lower reaches of the Yangtze River. Poyang Lake has five main inflows (including the Raohe River, Ganjiang River, Fuhe River, Xinjiang River, and the Xiushui River) and drains into the Yangtze River from its northern end. Most of the lake's water area (97%) (Lai et al., 2014) is in Jiangxi Province. With Songmen Mountain as its boundary, the main body of the lake is to the south, while the channel that connects with the Yangtze River is at the northern end. Poyang Lake is 173 km long from north to south. It is between 3 and 74 km wide from east to west with an average width of 16.90 km. The lake basin slopes from the southeast to the northwest and the shoreline is approximately 1200 km long (Yao et al., 2018). The average water level in Poyang Lake is between 14 and 15 m (Liu et al., 2016) and there are considerable seasonal and interannual variations in the water level. Records show maximum annual variations between 9.59 and 15.36 m, and minimum annual variations between 3.80 and 9.79 m (Dai et al., 2016). The water level changes seasonally in Poyang Lake. During the dry season, the water level drops, and the beach is exposed; it then rises during the wet season and the landscape is very different from that in the dry season (Yuan et al., 2015). The water level in the lake is generally highest between June and August, and lowest between December to February (Lan, 2014).

Data sources

In this study, 15 monitoring stations were specifically chosen to account for the lake's unique hydrological conditions, shape, and different functional areas were set up in Poyang Lake, as shown in *Figure 1*. Samples were collected in January, April, July, and October of each year from January 2012 to December 2016. Data for the water level were obtained from the Jiangxi Provincial Hydrographic Bureau. Water level from January, April, July, and October at the Xingzi Monitoring Station from 2012 to 2016 were used to represent the average condition in Poyang Lake. The spatial distribution pattern of water quality is demonstrated using the data of 2012.

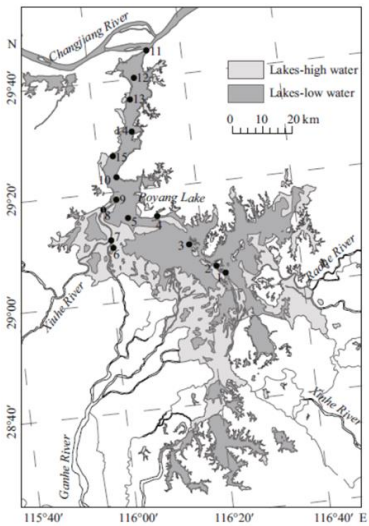

Figure 1. *Location and sampling point distribution of Poyang Lake*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1168711699

Water sample analysis

Lake surveys were conducted following the procedures outlined in The Lake Ecosystem Observation Method. The transparency was determined with a Secchi Disc (SD), chemical oxygen demand (COD_{MN}) was determined by acid potassium permanganate titration, TN concentrations were determined by ultraviolet spectrophotometry after digestion with alkaline potassium persulfate, TP concentrations were determined by ammonium molybdate spectrophotometry, and chlorophyll a (Chla) was determined after hot ethanol extraction.

Lake eutrophication evaluation method

The nutrient status of the lake was determined with the trophic level index (TLI), based on Chla, TP, TN, SD, and COD_{MN} (El-Serehy et al., 2018; Napiórkowska-Krzebietke et al., 2013; Trolle et al., 2014).

The numerical values of the trophic level index (TLI) for the Poyang Lake water were calculated using the following equation:

$$TLI(\Sigma) = \sum_{j=1}^{m} W_j \cdot TLI(j) \quad \text{(Eq.1)}$$

In which TLI = trophic level index; W_j = weight of the TLI parameter; m = Number of parameters participating in the evaluation.

$$W_j = r_{ij}{}^2 \left(\sum_{j=1}^{m} r_{ij}{}^2\right)^{-1} \quad \text{(Eq.2)}$$

In which r_{ij} = Correlation coefficient between each parameter and Chla parameter. The values are shown in *Table 1*.

Table 1. *A certain lake's parameter correlated* r_{ij} *and* $r_{ij}{}^2$ *of Chla**

Parameter	Chla	TP	TN	SD	COD_{MN}
r_{ij}	1	0.84	0.82	-0.83	0.83
$r_{ij}{}^2$	1	0.7056	0.6724	0.6889	0.6889

*From the calculation results of 26 major Chinese lake survey data

$$TLI(Chl) = 10(2.5 + 1.086 ln Chl) \quad \text{(Eq.3)}$$

$$TLI(TP) = 10(9.436 + 1.624 ln TP) \quad \text{(Eq.4)}$$

$$TLI(TN) = 10(5.453 + 1.694 ln TN) \quad \text{(Eq.5)}$$

$$TLI(SD) = 10(5.118 - 1.94 ln SD) \quad \text{(Eq.6)}$$

$$TLI(COD_{MN}) = 10(0.109 + 2.661 ln\, COD_{MN}) \quad \text{(Eq.7)}$$

When the TLI was less than 30, the lake was oligotrophic; TLI values of between 30 and 50 indicated oligotrophic/mesotrophic conditions; TLI values of between 50 and 60

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1168711699

indicated mild eutrophication; values between 60 and 70 indicate moderate eutrophication, while values greater than 70 indicate severe eutrophication.

Result and discussion

Temporal variations in the water quality in Poyang Lake

Information about seasonal variations in the various water quality indicators in Poyang Lake from 2012 to 2016 is presented in *Figure 2*. The concentrations and data for the four quarters indicate seasonal differences. The patterns in the concentrations of DO and TN were the same. DO and TN concentrations were lowest in summer (July) and highest in winter (January). The DO concentrations were 6.59 and 12.72 mg/L, while the TN concentrations were 1.50 and 2.40 mg/L in summer (July) and winter (January), respectively. The concentrations in spring (April) and autumn (October) showed little variation and fell between the maximum winter values and minimum summer values. The NH_4-N concentrations varied widely over the year and ranged from 0.16 to 0.51 mg/L. They were low in spring and summer and high in autumn and winter.

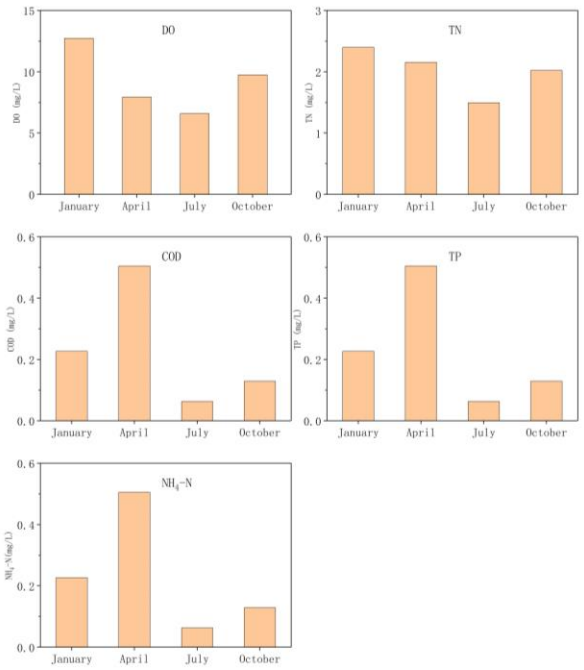

Figure 2. *Summary information about seasonal variations in the water quality indicators during the year*

There was considerable interannual variation in the various water quality indicators in Poyang Lake from 2012 to 2016, as shown in *Figure 3*. The concentrations of NH_4-N, TP, and TN reached maximum values of 0.56, 1.30, and 4.25 mg/L, respectively, in 2015 and these concentrations were considerably higher than those in the other years. The concentrations of these indicators were similar in the other years. The concentrations of NH_4-N and TN were about 50% higher in 2015 than those in the other years, while, compared to 2015, the concentrations of TP were much lower in the other

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1168711699

years and were generally below 0.3 mg/L. Concentrations of COD ranged from 2.24 to 3.15 mg/L and showed little between-year variation.

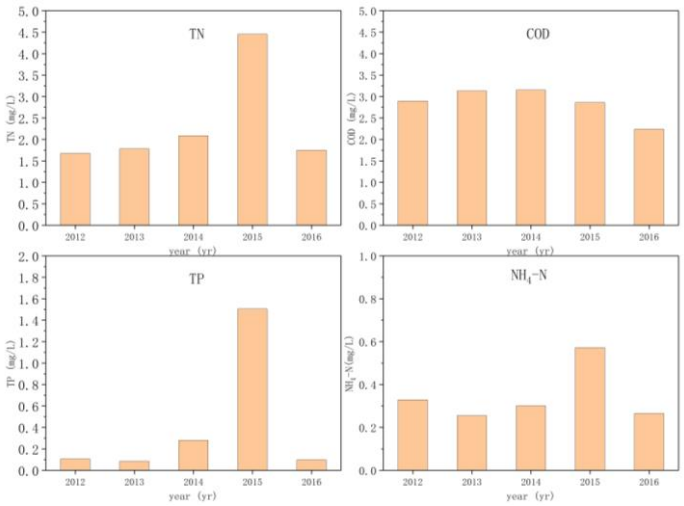

Figure 3. *Inter-annual variation in the water quality indicators*

Spatial variations in the water quality in Poyang Lake

The TN concentrations in Poyang Lake were high in autumn and winter and low in summer and autumn (*Fig. 4*). In winter (January), the TN concentration exceeded 2.0 mg/L across all of Poyang Lake, and did not differ significantly between the sampling sites. The TN concentration ranged from a minimum of about 1.8 mg/L in the western part of the lake and reached a maximum of about 3.0 mg/L in the southeastern part of the lake. In spring (April), the average TN concentration in the whole lake was relatively low and, at about 1.5 mg/L, did not differ significantly across the whole lake. In the northern part of the lake, the TN concentration reached a maximum of about 1.9 mg/L. The TN concentrations in summer and spring across the whole lake were similar. The average concentration in summer was about 1.5 mg/L and did not differ much across the whole lake, with high concentrations of up to 2.0 mg/L in only a few northern and central areas. In autumn (October), the TN concentrations were high in the south and low in the north. They were relatively low in the northern part (about 1.5 mg/L) in the channel that connected the lake to the river, and were relatively high (up to 2.0 mg/L) in the southern part of the lake.

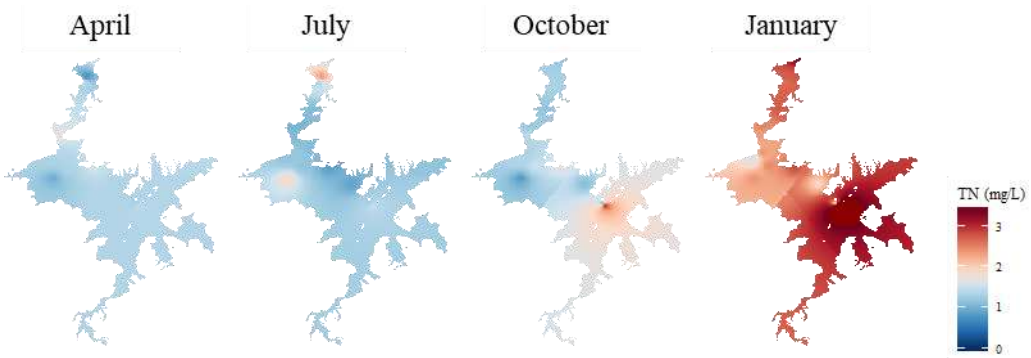

Figure 4. *Temporal and spatial distribution of TN in Poyang Lake*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1168711699

Similar to TN, the TP concentrations were high in autumn and winter and low in spring and summer (*Fig. 5*). In winter (January), the TP concentrations were higher in the southern part and lower in the northern part. The TP concentration reached 0.2 mg/L in the southern lake area, and was only 0.1 mg/L in the channel that connects the lake with the river in the north. In spring (April), the TP concentration showed little variation and was low across the whole lake (0.08 mg/L). The patterns in spring and summer (July) were similar. In summer, the concentrations were low (about 0.1 mg/L) and were relatively uniform across most of the lake, but were slightly higher (0.15 mg/L) in some areas, such as in the channel that connects the lake to the river in the north. The TP concentrations were highest in autumn (October) across the whole lake. The distribution of the TP concentrations in autumn and winter were similar, and were high in the south and low in the north. The TP concentrations in the lake were much higher in autumn than in winter, and exceeded 0.2 mg/L in most of the southern part of the lake, with concentrations greater than 0.3 mg/L in some places.

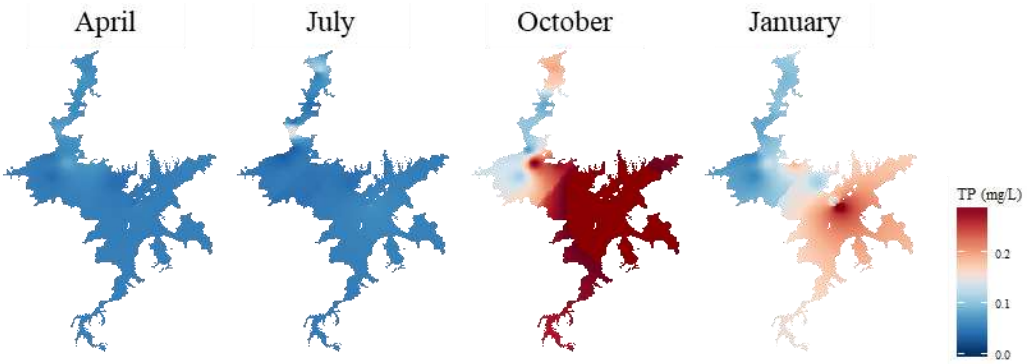

Figure 5. *Temporal and spatial distribution of TP in Poyang Lake*

Chlorophyll a was uniformly distributed in the lake both spatially and temporally (*Fig. 6*). The concentrations of Chla in the lake were lower in winter than in the other seasons, and were lower than 3.0 mg/L across the whole lake during the season. The concentrations of Chla were highest in the northwestern part of the lake. In summer (July), the Chla concentration reached a maximum value of about 15.0 mg/L at a monitoring station near Wucheng Town. The high values may attribute to the higher water consumption during summer in tourist towns, which results in higher pollutant loads, worse water quality, and causes algae to proliferate in the lake.

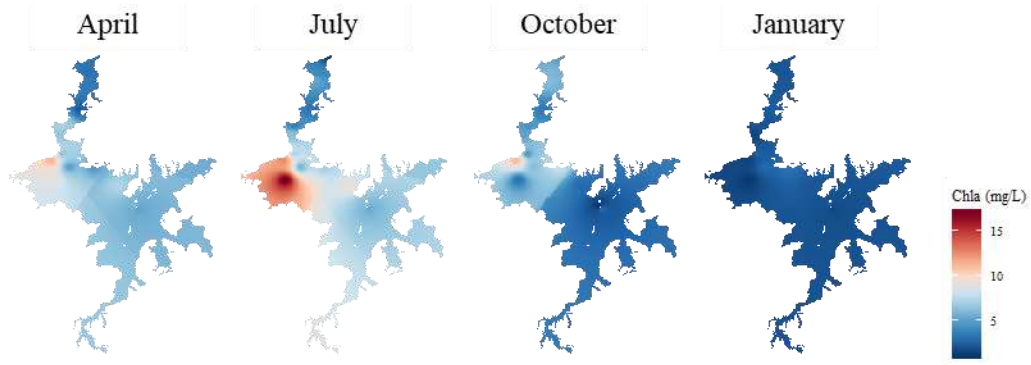

Figure 6. *Temporal and spatial distribution of Chla in Poyang Lake*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1168711699

The NH_4-N concentrations in Poyang Lake demonstrated little variation in spring and summer, and large variations in autumn and winter (*Fig. 7*). In spring, the NH_4-N concentrations were generally low, with an average of about 0.2 mg/L, and were relatively uniform across the lake. The spring and summer situations were similar. In summer, the NH_4-N concentrations were relatively uniform across the whole lake and averaged about 0.1 mg/L. In the autumn, the NH_4-N concentrations varied considerably across the lake and were high in the south and low in the north. The NH_4-N concentration was about 0.5 mg/L in the channel that connects the northern part to the river, and was about 1.2 mg/L in the southern part of the lake. By contrast in autumn, the concentrations were high in the north and low in the south in the winter. The concentrations reached a maximum of about 1.0 mg/L in the northern part of the lake, but were only about 0.5 mg/L in most of the southern part of the lake.

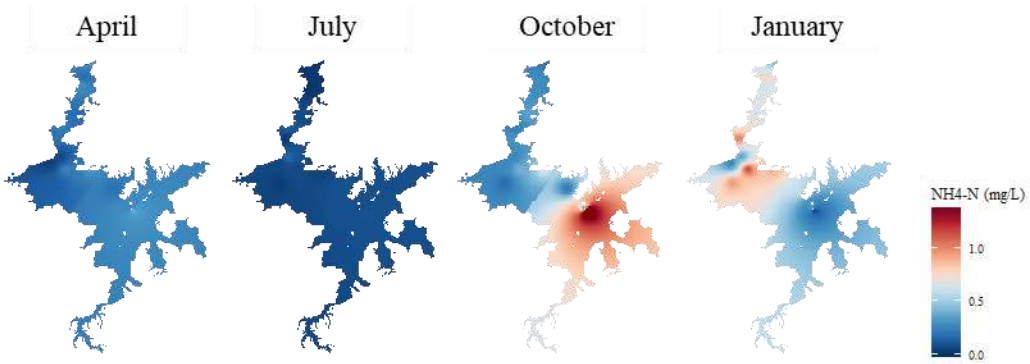

Figure 7. *Temporal and spatial distribution of NH_4-N in Poyang Lake*

The COD_{MN} in Poyang Lake showed considerable variation in spring and winter but varied little across the lake in summer and autumn (*Fig. 8*). In spring, the COD_{MN} was high in the north and low in the south. The COD_{MN} was high, up to 4.0 mg/L, in the channel that connects with the river channel in the north, but was about 3.5 mg/L in most of the southern lake. The COD_{MN} did not vary much throughout the lake in summer and autumn, and remained about 2.0 mg/L. Similar to the spring distributions, the concentrations were high in the north and low in the south in winter. The COD_{MN} reached 5.0 mg/L in the north where the lake was connected with the river channel, but was mainly between 3.0 and 3.5 mg/L in the southern part.

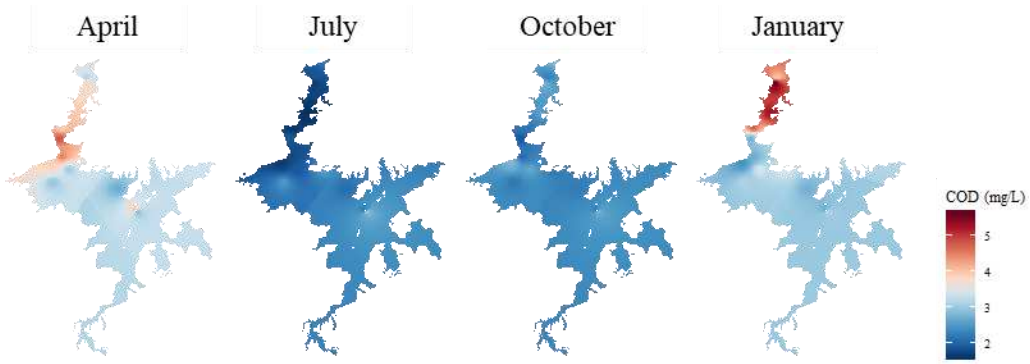

Figure 8. *Temporal and spatial distribution of COD_{MN} in Poyang Lake*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1168711699

The influence of changes in the water level on the water quality of Poyang Lake

The correlations between the concentrations of COD_{MN}, NH_4-N, TN, and TP concentrations and the water level in Poyang Lake at the Xingzi Hydrological Station are shown in *Figure 9*. There were no significant correlations between COD_{MN} and TP and the changes in the water level. The concentrations of NH_4-N and TN were strongly and negatively correlated with the changes in the water level, with correlation coefficients of 0.31 and 0.19, respectively ($p < 0.05$); the concentrations of NH_4-N and TN in the lake were affected by the water level, and the concentrations gradually decreased as the water level increased.

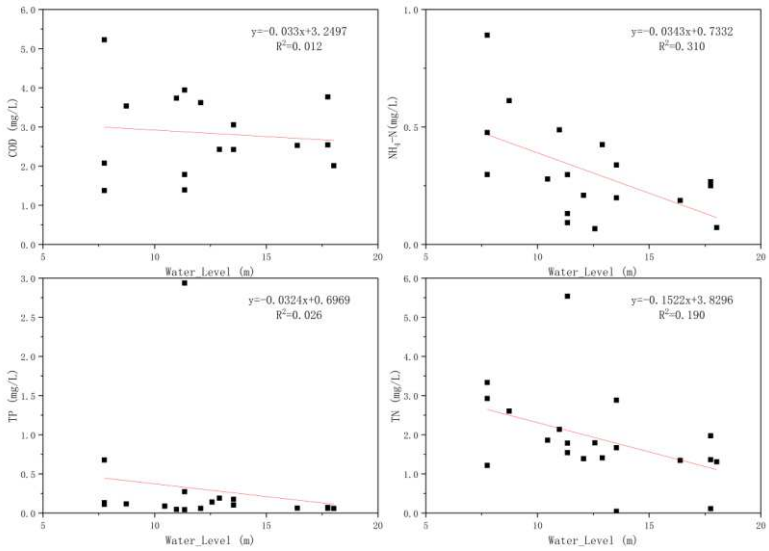

Figure 9. *Correlations between the water quality indicators and the water level*

The influence of changes in the water level in Poyang Lake on the degree of eutrophication

The average TLI in Poyang Lake was 48.35, which indicates mesotrophic conditions. There was little variation in the overall trophic status of the lake (*Fig. 10*). At Site 1, on the central/eastern part of the lake, the TLI reached a maximum of 50.20. At Site 7, on the northwestern/central part of the lake, the nutrient TLI was lowest at 45.65. The conditions at Site 1 and Site 5, which accounted for 13% of the sites, were mildly eutrophic, while the conditions at the remaining sites, or 87%, were mesotrophic. Poyang Lake is generally mesotrophic, and the trophic status does not show much spatial variation.

The TLI was negatively correlated with the water level ($R^2 = -0.62$), so that as the water level increased, the TLI, and also the degree of eutrophication, decreased accordingly. The TLI (Chla) and the water level ($R^2 = 0.24$) were weakly and positively correlated, but the TLI (TP), TLI (SD), and TLI (COD_{MN}) were negatively correlated with the water level ($R^2 = -0.52$, $R^2 = -0.41$, and $R^2 = -0.35$). As shown in *Figure 11,* there was a strong negative correlation between the TLI (TN) and the water level ($R^2 = -0.75$), so that, as the water level increased, the TLI decreased.

As the water level increased, the TLI decreased in areas affected by TN, TP, transparency, and COD_{MN}. Conversely, as the water level decreased, the TLI increased in areas affected by TN, TP, transparency, and COD_{MN}. In general, the TLI was negatively

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1168711699

correlated with the water level of Poyang Lake. The TLI was also negatively correlated with the water level. As the water level increased, the TLI decreased and vice verse.

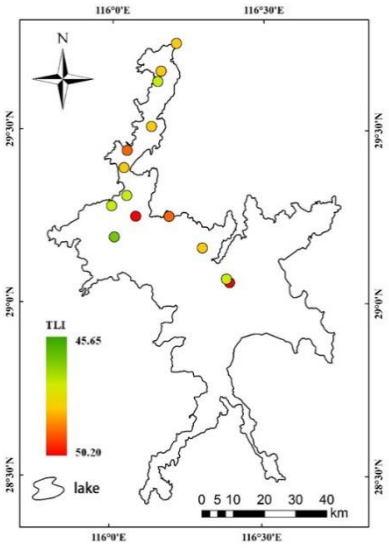

Figure 10. *Spatial distribution of the TLI in Poyang Lake*

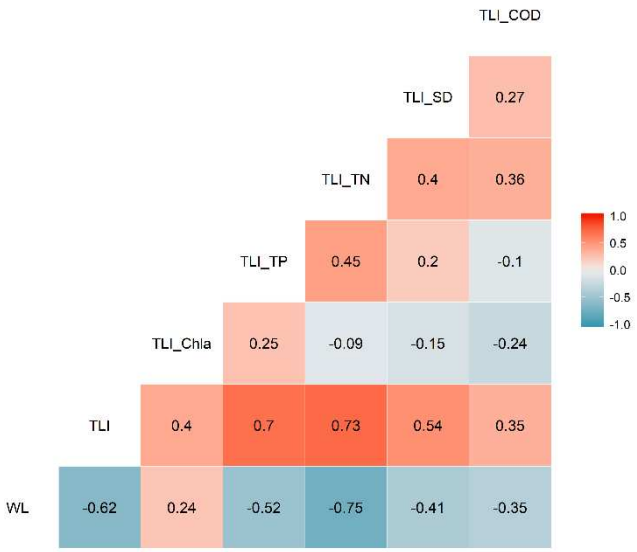

Figure 11. *The relationships between the TLI and various water quality indicators and water level (WL) in Poyang Lake*

Factors influencing temporal and spatial variations in the water quality in Poyang Lake

The water level regulates the structure and function of natural lake ecosystems. The water levels in lakes connecting with the Yangtze River change quite considerably over the course of a year. The large fluctuations in the water level of Poyang Lake will therefore affect the hydraulic retention time, the time taken for water to exchange, and the growth and energy exchange of phytoplankton. We found that, on an annual time

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1168711699

scale, the water level in Poyang Lake was highest in summer, the TLI was negatively correlated with the water level, and the fluctuation in the water level had the most important influence on TN. In the study of Poyang Lake from 2009 to 2014, Wu et al. (2017) found that the nutrients in the lake would be diluted in 2017 because of seasonal increases in the water level, thereby reducing the eutrophication in the lake. In the study of Poyang Lake from 2008 to 2012, Liu et al. (2014) confirmed that the trophic level was lower at higher water levels than at lower water levels in 2014. However, as the lake level and water volume decrease, sediment will be resuspended and nutrients will be released. The water level in Poyang Lake is higher in summer than in winter, so more sediment will be resuspended in winter than in summer, resulting in more serious eutrophication in winter than in summer. As shown in numerous previous studies, higher water levels will decrease eutrophication by Mao et al. (2014). In addition, Poyang Lake is connected to the Yangtze River. When the water level is high in summer, water is exchanged rapidly between them, so the degree of eutrophication is low. In winter, the water level is lower and it takes longer for the water to exchange, so the degree of eutrophication is higher. The change in the degree of eutrophication in the lake area following temporal changes in the water level can be explained by dilution of nutrients as the water level rises during precipitation, resuspension of sediments and release of nutrients when the water levels are low, and the time taken for water to turn over. The changes in the water level were correlated with the TLI for TN, TP, transparency, and COD_{MN}, and the factors that influenced the changes are consistent with those that influenced the TLI. The content of Chla is not related to changes in the water level, mainly because Chla is influenced by the water temperature, algal biomass, light, and suspended matter. The water level can, however, affect the light and the concentrations of suspended matter what is limited for shallow lakes.

The changes in the water level have little effect on how the trophic state varies spatially, and previous studies have not shown that the water level was related to the spatial distribution of the trophic state by Wang et al. (2013). The results of this study show that spatial variations in the trophic state of Poyang Lake are mainly affected by the pollutants transported into the lake from urban and industrial areas. There is no clear relationship between the water level of Poyang Lake and its trophic status. Some of the sampling points were in the main channel that connected the lake with the river. At these points, the water exchange is faster than in the main body of the lake and the self-purification ability is strong, so the pollutants gradually dilute and degrade; the degree of eutrophication is low and is only weakly related to the water level. Other monitoring points are polluted by agricultural, industrial, and domestic activities.

Conclusions

The water quality of Poyang Lake showed seasonal changes at the annual scale. The concentrations of DO and TN were lowest in summer and highest in winter, with little difference in spring and autumn. The concentrations of TP reached maximum and minimum values in spring and summer, respectively. COD was slightly lower in spring and summer than in autumn and winter. Concentrations of NH_4-N were low in spring and summer, and high in autumn and winter. The water quality of Poyang Lake also varied inter annually. Concentrations of NH_4-N, TP, and TN reached maximum values of 0.56, 1.30, and 4.25 mg/L, respectively, in 2015, but did not vary much in the other years. Concentrations of NH_4-N and TN were about 50% higher in 2015 than in other

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1168711699

years; TP concentrations were much higher in 2015 than in the other years, when they remained below 0.3 mg/L. The COD concentrations did not vary much between years.

There were seasonal spatial variations in the water quality in Poyang Lake. The TN concentrations across the whole lake in winter generally exceeded 2.0 mg/L, while in the spring and summer, the TN concentrations were about 1.5 mg/L. In the autumn, the TN concentrations were high in the south and low in the north. In winter, the TP concentrations were high in the south and low in the north. The concentrations of TP were low across the entire lake in the spring and summer. In autumn, the TP concentrations were much higher than in the winter, and were high in the south and low in the north. The NH_4-N concentrations in Poyang Lake were generally low at 0.2 mg/L, and showed little spatial variation across the whole lake. The NH_4-N concentrations across the whole lake were low in summer. In the autumn and winter, the NH_4-N concentrations in the lake were high in the south and low in the north, and high in the north and low in the south, respectively. In the autumn, NH_4-N concentrations were high in the south and low in the north, while the pattern was the opposite in winter. COD_{MN} in the lake in spring and winter was high in the north and low in the south. COD_{MN} did not vary significantly on the spatial scale in summer and autumn and was generally low.

Poyang Lake was mesotrophic, and the trophic status was relatively uniform. The TLI of Poyang Lake were negatively correlated with the water level. Of the water quality indicators, TN was most affected by the changes in the water level of Poyang Lake. On the temporal scale, the TLI of Poyang Lake was negatively correlated with the water level. The trophic status of Poyang Lake was spatially heterogeneous and was not affected much by the water level.

Abstract. Assessing the aquatic ecosystem health status of lakes has been the focus of lake studies for domestic and overseas researchers and water resource managers. Poyang Lake, which is one of the only two remaining large Yangtze-connected lakes in the middle reaches of Yangtze River in China, provides considerable ecosystem service functions, such as flood water storage, water supply for industrial and agricultural production, maintenance of the unique and diverse biota of the entire Yangtze floodplain ecosystem, maintenance of regional ecological balance and so on. However, due to the impact of climate change and human activities, Poyang Lake has experienced drastic hydrological changes, water quality decline and aquatic ecological function degradation in recent years. An assessment of the aquatic ecosystem health of Poyang Lake is of great importance. On the basis of the index system construction principles and a meta-analysis of previous research, this paper puts forward the index system for the ecosystem health assessment of Poyang Lake. The indices contains the three element layers of aquatic organisms, hydrologic characteristics and trophic status and the five indicators of ratio of cyanobacteria biomass to diatom biomass (CB/DB), diversity index of macrozoobenthos, lowest water level anomaly during the dry season, mean water level anomaly during rising season and trophic state index (TLI). Then, the thresholds of indicators are determined using empirical study, frequency analysis, standard specification and so on. Aquatic ecosystem health status is categorised into three groups: 'good', 'moderate' and 'poor'. The study could provide theoretical basis for identifying the causes of the lake aquatic ecosystem health degeneration and protecting the environment of Poyang Lake. This present study provides an attempt to quantify the aquatic ecosystem health in a large floodplain lake with dramatic hydrological variations and will give some impetus for floodplain ecosystem assessment and management worldwide.

Introduction

The global ecosystem has become increasingly destroyed since the 1960s, and human society is facing immense challenges concerning survival and development (Zeng et al., 1999). Ecologists have begun to pay attention to the issue of ecosystem health. In 1988, Schaeffer proposed the concept of ecosystem health measurement (Schaeffer et al., 1988), and domestic and foreign scholars have since initiated substantial research on the concept of ecosystem health and related concerns (Costanza et al., 1992; Rapport and Whitford, 1999). Ecosystem health assessments are common in the research fields of forests, rivers, oceans, wetlands and so on (Cui and Yang, 2002; Borja and Dauer, 2008; Davies et al., 2011). Lakes, as a crucial part of the terrestrial

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1170111716

surface system, serve as vital freshwater reservoirs and help conserve species gene pools on earth; they are also known for their ecological functions, including maintaining ecological balance of basins, supplying production and living water, and providing rich aquatic products, and thus have great ecological and economic significance to regional development (Yang et al., 1988). Since the introduction of the ecosystem health concept in the 1980s, the health assessment of lake aquatic ecosystems, as a key part of lake ecosystem management, has gradually become the focus of scholars, resource managers and environment managers at home and abroad (Xu et al., 2001, 2012; Kane et al., 2009). Ecosystem health assessment provides the theoretical basis for analysing the causes of lake ecosystem health degradation and the protection of lake water environment, which is also closely linked with the achievement of the virtuous cycle of lake ecosystems.

Many scholars at home and abroad have performed studies regarding the construction of the assessment index system and the determination of thresholds because they are crucial in the health assessment of lake aquatic ecosystems. The selected assessment indices mainly include two aspects. The first aspect on biological components, e.g. biomass, species, diversity indices, etc. (Xu et al., 2001; Jeppesen et al., 2011; Umi et al., 2018); Phytoplankton and macrozoobenthos are commonly selected for ecosystem health assessment (Lyche-Solheim et al., 2013; Sreeja, 2018). Eutrophication responses are mainly evaluated on phytoplankton, macrozoobenthos and large aquatic plants, whilst pH response is mainly assessed by macrobenthos and fish (Solheim et al., 2008); Large aquatic plants (Mjelde et al., 2013; Keto et al., 2006), macrozoobenthos (Baumgärtner et al., 2008), and fish (Sutela and Vehanen, 2008)) have been used to describe responses to hydromorphological alterations. The second aspect represents the systematic indices, which are constructed from aquatic biological components, such as eco-exergy, structural eco-exergy, ecological buffer capacity, entropy, etc. (Ludovisi, 2006; Ludovisi and Poletti, 2003; Kane et al., 2009). The primary assessment approaches include the comprehensive health indices (Xu, 2005; Shuai and Li, 2014) generated by index system weighting or algorithmic derivation and the water quality model-based method (Xu et al., 2013; Zhang et al., 2010; Banerjee et al., 2017; Qi et al., 2018). Poyang Lake is one of the only two remaining large Yangtze-connected lakes in the middle reaches of Yangtze River in China. Its ecosystem development is affected not only by pollutants and sediments within the lake but also by seasonal hydrological fluctuations, particularly the annual amplitudes of water levels that reach 8 m (Zhao and Tong, 2013), which can significantly affect lake structures and functions (Coops et al., 2003). In recent years, Poyang Lake has also been affected by ecological and environmental issues related to human activities. Water quality has declined and eutrophication has gradually increased, and these phenomena resulted in ecological problems such as potential hazards of cyanobacterial bloom breakout (Yang, 2012; Cheng and Li, 2006; Xu et al., 2012; Li et al., 2017; Zhang et al., 2018). Therefore, constructing a lake aquatic health assessment index system suitable for the hydrological variation characterisation of Poyang Lake and large Yangtze-connected lakes, scientifically determining assessment indicator thresholds, and evaluating lake aquatic ecosystem health are of great theoretical and practical significance. On the basis of the analysis of the ecological system and evolution characteristics of Poyang Lake, this study combines observed and acquired data to construct a preliminary aquatic ecosystem health assessment index for large Yangtze-connected lakes. Then, the aquatic ecosystem health assessment thresholds are determined by adopting the special value

method, frequency analysis method, normative standards and analogies, reference mode method and so on.

Materials and methods

Study area and data

Physical, chemical and biological variables were measured in Poyang Lake from 1984 to 2013. Data from 2007 to 2013 were supplied by the Lake Poyang Laboratory for Wetland Ecosystem Research of the Chinese Ecosystem Research Network, whilst other less and reference data were collected from previous studies (Committee, 1993; Xie et al., 2000). Water level data from 1951 to 2011 were collected from the Changjiang (Yangtze River) Water Resources Commission. The details of these datasets are shown in *Table 1* and *Figure 1*.

Table 1. *Summary of variables and number of sites sampled in a given month and year in Poyang Lake*

Year	Month and sites	Data
1984, 1987–1993	Details shown in previous studies (Committee, 1993; Xie et al., 2000)	Biological variables (density of phytoplankton, etc.)
2007	October, 24 sites	Physical, chemical and biological variables (SD, TN, TP, COD_{mn}, Chl-a, biomass and density of phytoplankton, macrozoobenthic)
2008	June, 35 sites	
2009–2011	January, April, July and October, 15 sites	
2012	January, April and October, 15 sites July, 97 sites	Physical, chemical and biological variables (SD, TN, TP, COD_{mn}, Chl-a, biomass and density of phytoplankton, macrozoobenthic)
2013	July, 106 sites	
1951–2011	January–December, seven sites (Xingzi, Duchang, Hukou, Kangshan, Wucheng, Tangyin and Boyang)	Water level

SD: Secchi disk depth (water transparency); TN: total nitrogen; TP: total phosphorus; COD_{mn}: chemical oxygen demand; Chl-a: chlorophyll a

Methods

The construction of the aquatic ecosystem health assessment index system for in this study was mainly determined on the basis of literature research and theoretical analysis. The primary approaches for determining the index thresholds can be divided into two categories, namely, through statistical analysis approaches, such as the frequency analysis method and the special value method, direct observation of reference state and the adoption of normative standards. All statistical analyses were performed with the Statistical Program for Social Sciences (SPSS-IBM, New York, NY) 13.0 software.

Results and discussion

Construction of aquatic ecosystem health assessment index system for Poyang Lake

Many studies have demonstrated that the health status of lake aquatic ecosystems of water bodies should be assessed from the perspective of biological elements and supporting hydro-morphological and physico-chemical elements, especially water level-related indices (Mjelde et al., 2013), and not only on the basis of some specific biological, physical or chemical indices (Xie et al., 2013; Xu et al., 2013; Ghosh et al., 2018). Therefore, as a large-scale Yangtze-connected lake, the construction of an aquatic ecosystem health assessment index system for Poyang Lake must also consider the status of biological elements and supporting hydromorphological and physico-chemical elements.

1. Biological indicators

Lake ecosystems mainly include aquatic organisms such as planktons, benthic organisms, large aquatic plants and fish, etc. The indicators most widely used are biomass, quantity, species structure, and so on. On the basis of the response of various aquatic organisms to stress and the aquatic characteristics of Poyang Lake, phytoplankton and macrozoobenthos are selected to characterise the lake's aquatic ecosystem health.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1170111716

(1) Phytoplankton: Phytoplankton is a critical indicator for the health assessment of lake aquatic ecosystems. Changes in algal species structure can reveal variations in the water environment (eutrophication, etc.) and lake ecosystems (Vanni, 1987; Paerl et al., 2013). The hydrological regime will affect the biomass, species composition, diversity and succession of phytoplankton (Wu and Guo, 2001). Lotic ecosystems are dominated by diatoms, whereas lentic ecosystems are dominated by cyanobacteria (De Emiliani, 2001). Relative to Taihu Lake, the phytoplankton characteristics in Poyang Lake are dominated by diatoms in the aspects of biomass and quantity, not cyanobacteria (Xu, 2013; Wu et al., 2013). But cyanobacteria bloom was also found at the centre part of the lake in 2011 (Xu, 2013). Dam construction in Poyang Lake has become controversial in recent years because of its adverse effects to water level fluctuations, and consequently, to the structure of phytoplankton (Liu et al., 2015). Many scholars have predicted the outbreak of cyanobacteria bloom after dam construction. Algal structural changes, particularly variation tendency in cyanobacteria proportion, are the primary focus of aquatic ecosystem health assessments for Poyang Lake. Constructing the ratio of cyanobacteria biomass (CB) to diatoms biomass (DB) can help determine the water environment of Poyang Lake and its aquatic ecosystem health characteristics.

(2) Macrozoobenthos: Macrozoobenthos are essential indicator organisms for monitoring human disturbance and lake pollution and thus ideal as natural monitors. The diversity index of macrozoobenthos has been widely adopted for the water pollution assessment of lakes and rivers (Shuai and Li, 2014; Xiong et al., 2003; Miler et al., 2013). The EU Water Framework Directive uses macrozoobenthos to monitor and evaluate the ecological health of lakes, as they are sensitive to water level amplitudes (i.e. water levels affect the abundance of macrozoobenthos) (Aroviita and Amalainen, 2008). The density of macrozoobenthos in Poyang Lake has drastically changed in recent years, as evidenced by the obvious decrease of molluscs (Cai et al., 2014), whilst the increased number of large animals have negatively affected the abundance of small marsh and long-horned snails (Ou et al., 2009). Large-scale sand mining and river scouring have also altered the macrozoobenthos habitat and influenced their community structures in recent years. Therefore, macrozoobenthos characterisation has been prioritised in the aquatic ecosystem assessment of Poyang Lake, and the diversity index of macrozoobenthos has been selected as the biological indicator.

Large aquatic plants and fish are also vital indicator species of aquatic ecosystem changes in Poyang Lake. However, large aquatic plants only appear in few branch areas of the lakes during the summer flooding season (Jian et al., 2015), and for the structure of fish species, there are certain similarities between Poyang Lake and Yangtze River Basin and the whole country (Hu, 2009). Hence, in this paper, we will not include large aquatic plant and fish species, considering their representativeness and substantial data availability.

2. Hydrological indicators

Habitat is commonly characterised on the basis of the following aspects: hydrology, water environment, lake morphology, and human activity or interference. The hydrological elements of Poyang Lake are relatively unique. For instance, water-level fluctuations are significant during the year, which greatly impact the lake's ecological environment. Subsequently, wetland area and distribution are directly affected, whilst the growth of aquatic organisms (e.g. phytoplankton and fish) are either directly or

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1170111716

indirectly affected. Therefore, hydrological element is selected as one of the habitat indicators for the aquatic ecosystem health assessment of Poyang Lake.

Previous studies have proposed that the indices for water level fluctuations include winter water level amplitude and spring flood amplitude (Hellsten, 2001; Keto et al., 2006, 2008; Mjelde et al., 2013), as they affect the species abundance of large aquatic plants (Keto et al., 2006), macrobenthos (Aroviita and Amalainen, 2006) and fish (Sutela and Vehanen, 2006). The communities of *carex–polygonum criopolitanum*, *carex–Phalaris arundinacea* and *Phalaris arundinacea–carex* in Poyang Lake are relatively sensitive to changes in water level conditions and largely affected by water level amplitudes (Zhang et al., 2012), and they have low tolerance to changes in hydrological conditions. The seasonal droughts in spring (rising season) and winter (dry season) over Poyang Lake in recent years have caused serious impacts on the wetlands and aquatic ecosystems of the lake (Yang, 2012). For instance, spring drought is disastrous to fish, as they lay eggs in large quantities due to the simulation of gonads by flowing water and aquatic plants. If the aquatic plants are exposed to non-water areas during April and May, fish reproduction will be seriously affected. The lowest water level during the dry season directly impacts the growth and distribution of wetland plants and the succession of vegetation belts, thus affecting the different ecosystem functions (e.g. wetland ecological function and migratory bird habitat function) of Poyang Lake (Hu et al., 2012). The lowest water level during the dry season will also influence the habitat of migratory birds, and its occurrence is averse to their protection (Qi and Zhang, 2014). Characterising the lowest water level in the spring drought and dry seasons of Poyang Lake is critical in evaluating the aquatic ecosystem health of the lake. Hence, the lowest water level anomalies during the dry season and the mean water level anomalies during the rising season are determined to characterise the lowest water level (dry season) and spring drought (rising season) of Poyang Lake.

Poyang Lake begins to recede in October and rise in April, as the flood season starts in June (Hu et al., 2007) whilst the dry season occurs from December to March the following year. The lowest water level anomaly during the dry season is expressed by the difference between the lowest water level of the dry season (December–March) and the mean value of the lowest water level of the dry season over multiple years. Meanwhile, the rising season anomaly is expressed by the difference between the mean water level of the rising season (April–May) and the mean of mean water level of the rising season over multiple years.

3. Water environment indicators

As discussed in the previous section (2. Hydrological indicators), water environment is one of the four elements of habitat, as its condition can directly impact the growth of aquatic organisms. Therefore, water environment is selected as another indicator of habitat. In the 1980s, Poyang Lake has entered the mesotrophic stage (Cheng and Li, 2006); at present, it is in light eutrophic stage (as reported by Environmental Bulletin in 2013). Water quality has gradually deteriorated because total nitrogen and total phosphorus have both exceeded the standard values. Eutrophication is one of the key issues of Poyang Lake and hence an important aspect of aquatic ecosystem health assessment. Here, the comprehensive nutrition state index (labelled as TLI) is selected as the indicator for the nutrition status in the aquatic ecosystem health assessment index of Poyang Lake.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1170111716

In summary, the aquatic ecosystem health assessment index system of Poyang Lake is constructed from three perspectives, namely, aquatic organism elements, hydrological elements and water environment elements (*Table 2*).

Table 2. *Aquatic ecosystem assessment index of Poyang Lake*

Objective layer	Element layer	Index layer	Index explanation	Index calculation method	Determination method of index thresholds
Health assessment of Yangtze-connected lake ecosystems	Aquatic organism elements	Ratio of cyanobacteria biomass to diatom biomass (CB/DB)	Characterise the primary productivity status of lakes and ecosystem succession	Measure, calculate	Reference mode method, frequency analysis method
		Diversity index of macrozoobenthos (DI)	Characterise the features of macrozoobenthos and reveal the changes of ecosystem	$DI = \sum_{j=1}^{m} ({}^{N_i}/_{N}) \log(\frac{N_i}{N}, 2)$	Normative standards and analogies
	Hydrological elements	Lowest water level anomaly during dry season (LWLa-D)	Evaluate the characteristics of lowest water level during dry season	Difference between lowest water level in December–March and mean of lowest water level over multiple years during dry season	Special value method, frequency analysis method
		Mean water level anomaly during rising season (MWLa-R)	Evaluate the characteristics of water level during rainy season (spring drought or not)	Difference between mean water level in April–May and the mean of mean water level over multiple years during rising season	Special value method, frequency analysis method
	Water environment elements	Trophic state index (TLI)	Characterise the state of nutrition of lakes	Reference (Wang et al., 2002)	Normative standards and analogies

TLI: Trophic state index; CB/DB: Ratio of cyanobacteria biomass to diatom biomass; DI: Diversity index of macrozoobenthos; LWLa-D: Lowest water level anomaly during dry season; MWLa-R: Mean water level anomaly during rising season

Determining the aquatic ecosystem health assessment thresholds of Poyang Lake

The threshold proposed by Robert in the 1970s (May, 1997) refers to the set of thresholds and breakpoints of multiple stable states based on the characteristics and functions of the ecosystem. The methods to determine thresholds include normative standards and analogies, special value methods, statistical models, mathematical models, physical models, etc. The threshold determination methods for specific indicators are shown in *Table 2*.

1. Ratio of cyanobacteria biomass to diatom biomass

Few related researches on the indicator exist at present. In this study, health assessment thresholds are determined by performing the time reference mode method and the frequency method. *Figure 2* shows the CB/DB ratio from 1984 to 2013. The values have increased year by year, and the ratio in 2013 is larger than that in 2012. By taking the state of Poyang Lake in 1984 as the reference state of 'good' (maximum value 1.22, minimum value 0.004, average value 0.16, median value 0.04), and combined with the histogram of the CB/DB ratio in the past 30 years (*Fig. 3*), the thresholds are determined to be as follows: 'poor' (> 0.6), 'moderate' (0.4–0.6) and 'good' (< 0.4).

2. Diversity index of macrozoobenthos

The diversity index of macrozoobenthos has been widely used in water quality assessments (Lu, 1985; Lv et al., 2009; Miler et al., 2013; Xiong et al., 2003).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1170111716

According to the Aquatic Biomonitoring Manual (State Environmental Protection Agency, 1993), the relationship between ecosystem health status and the macrozoobenthos Shannon diversity index can be divided into four pollution categories: H = 0 for 'severe pollution', 0 < H < 1 for 'heavy pollution', H = 1–2 for 'medium pollution' , H = 2–3 for 'light pollution' and H > 3 represents 'clean'. As shown in *Figure 4,* the diversity index of macrozoobenthos has a normal distribution, and the index with relatively high frequency is 0.8–2. The aquatic ecosystem health thresholds, which are determined on the basis of existing evaluation criteria and frequency methods, are as follows: 'poor' (0–1), 'moderate' (1–2) and 'good' (> 2).

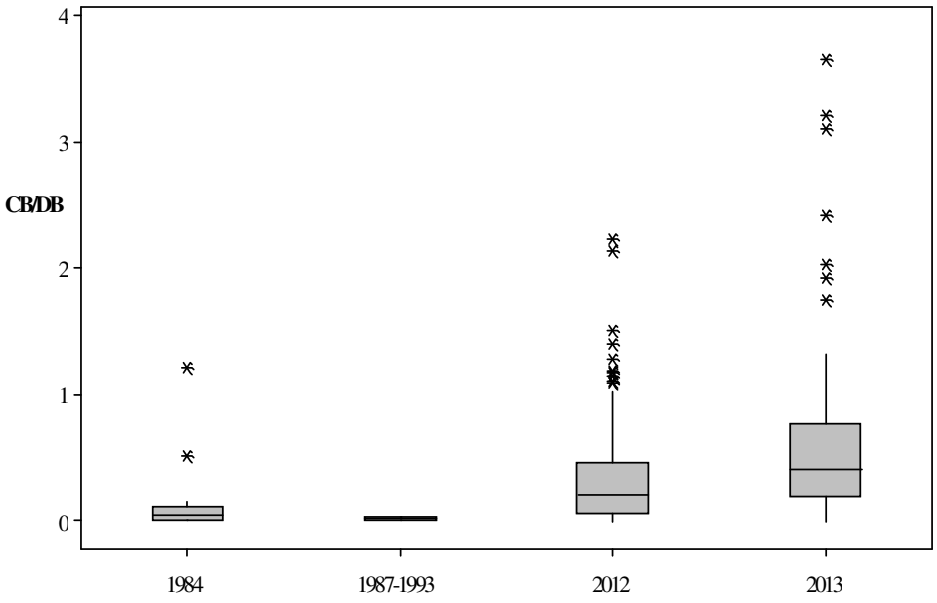

Figure 2. *Box-plot of CB/DB ratios of Poyang Lake in the recent 30 years (some data from previous studies (Committee, 1993; Xie et al., 2000))*

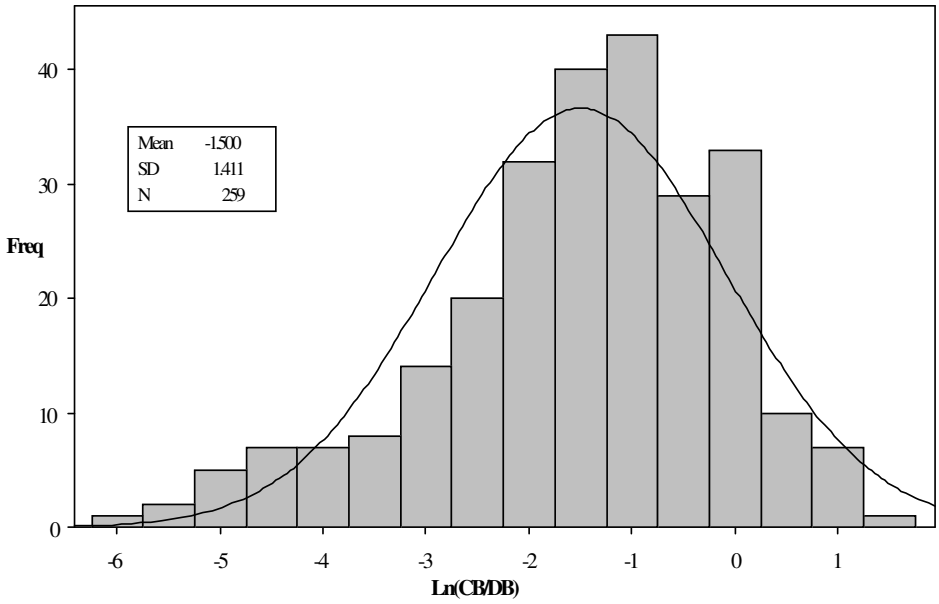

Figure 3. *Histogram of CB/DB ratios of Poyang Lake in the recent 30 years*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1170111716

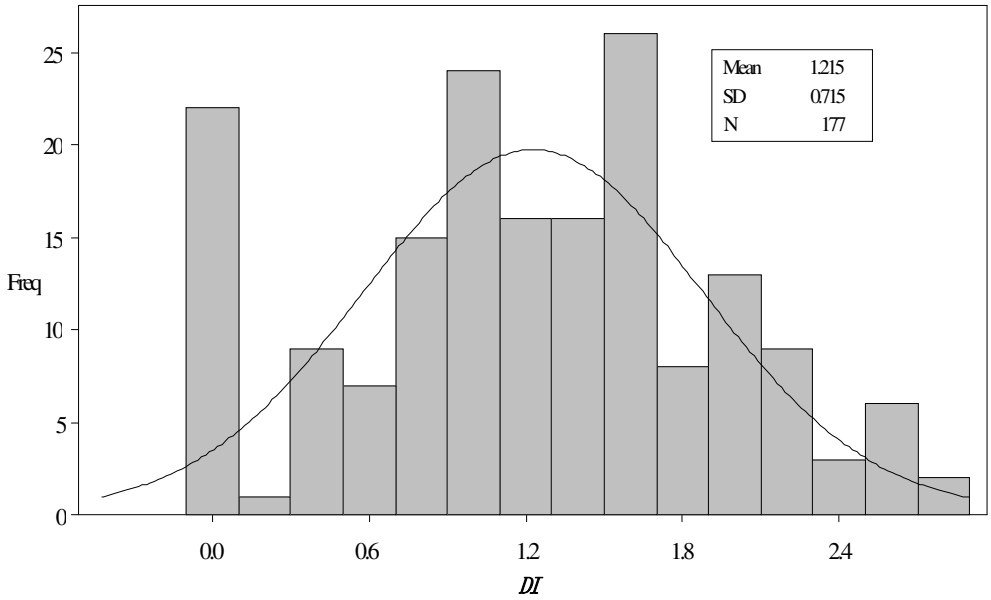

Figure 4. *Histogram of diversity index of macrozoobenthos of Poyang Lake in 2012–2013*

3. Lowest water level anomaly during the dry season

A statistical analysis of water level amplitudes during the dry season of Hukou, Xingzi, Duchang, Wucheng, Tangyin, Kangshan and Boyang stations for Poyang Lake from 1950 to 2011 was conducted. The amplitude variations of the seven stations are not significant, which is in accordance with the normal distribution. The average value is 0, the standard deviation is 0.7644 m, and the 5% and 95% tantiles are 1.34 m and −1.18 m, respectively (*Fig. 5*). In actual situations, the extremes of lowest water level during the dry season affect exposure time and area of wetlands. Exposure time directly affects the development of vegetation on the beach; it may be conducive to vegetative growth and may even result in the growth of new species of wetland ecological vegetation, but wetland degradation may occur if exposure time is too long (Ge et al., 2010). However, an extremely short exposure time over a small exposure area is unfavourable to the growth of wetland plants (Hu et al., 2010) and this will cause a series of ecological problems. Therefore, the extremes of lowest water level anomalies during the dry season signify an unhealthy state. In addition, the water level in Xingzi Station in 2008 was low with amplitude of −0.95 m during the dry season. The water levels in Duchang Station in 2008 and 2009 were low (e.g. 7.99 m in 2009, the lowest in history) with amplitudes of −1.49 m and −1.55 m during the dry season, respectively. In summary, the range of 1× standard deviation is determined to be from −0.5 to 0.5 m ('good'). The 5% and 95% tantiles (i.e. based on short plate effect, taking the minimum of absolute value) of 1× standard deviation is from 0.5 to 1.18 m and from −0.5 to −1.18 m ('moderate') and 'poor' if the value is less than −1.18 m or greater than 1.18 m, respectively.

4. Mean water level anomaly during the rising season

A statistical analysis on mean water level anomaly during the rising season of Xingzi, Duchang, Hukou, Kangshan, Tangyin, Wucheng and Boyang Stations was conducted. The findings, which accord with normal distribution, show a mean value

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1170111716

of 0.014 m and a standard deviation of 1.042 m (*Fig. 6*). The 5% and 95% tantiles are 1.80 m and −1.50 m, respectively. In actual situations, spring drought will affect fish breeding and wetland vegetation. The larger the MWLa-R is, the unhealthier the state will be. In the past 60 years, spring drought occurred five times since 2000, particularly in 2004, 2005, 2008, 2009 and 2011. The mean water level anomalies during the rising season in Xingzi Station for the abovementioned years are −1.44, −1.08, −1.53, −0.95 and −4.2 m. In Hukou Station, the corresponding anomalies are −1.35, −1.02, −1.34, −0.67 and −3.94 m. In Duchang Station, the corresponding values are −1.21, −0.80, −1.62, −1.15 and −3.24 m. In Wucheng Station, the corresponding values are −1.01, −1.25, −1.43, −1.12 and −3.73 m. In summary, the range of 1× standard deviation is determined to be from −1.03 to 1.06 m ('good'). The 5% and 95% tantiles (i.e. based on short plate effect, taking the minimum of absolute value) of 1× standard deviation is from 1.06 to 1.5 m and from −1.50 to −1.03 m ('moderate') and 'poor' if the value is less than −1.5 m or greater than 1.5 m, respectively.

5. Comprehensive nutrition state index

The comprehensive nutrition index is used to evaluate the nutritional status of water bodies, and it includes the five variables of Chl-a, TN, TP, COD_{mn} and SD. According to the literature (Wang et al., 2002), a TLI of < 30 means 'oligotrophic', 30–50 means 'medium nutrition', and > 50 means 'eutrophication'. The thresholds are determined on the basis of the histogram of the comprehensive nutritional status of Poyang Lake in the past six years (*Fig. 7*). The thresholds can be determined as follows: 'poor' (> 50), 'moderate' (40–50) and 'good' (< 40).

In summary, the evaluation thresholds for the aquatic ecosystem health assessment index system of Poyang Lake can be divided into the following three levels: 'good', 'moderate' (sub-healthy) and 'poor' (*Table 3*).

Conclusions and prospects

The assessment index system for Poyang Lake presented in this paper comprises the following elements: CB/DB ratio and diversity index of macrozoobenthos for the aquatic organism index; lowest water level anomaly during the dry season and mean water level anomaly during the rising season; and the comprehensive nutrition state index with three habitat indicators. The frequency analysis method was conducted, normative standards and analogies were considered, and the special value method was performed to initially determine the thresholds for the health assessment of Poyang Lake's aquatic ecosystem. The three grades ('good', 'moderate' and 'poor') can help provide the research basis for further evaluating the aquatic ecosystem health of the large Yangtze-connected lakes, such as Poyang Lake.

This work is a preliminary study on the index system and the thresholds for the aquatic ecosystem health assessment of large-scale Yangtze-connected lakes. Thus, optimisation and adjustment are still needed. Only the indicators of phytoplankton, macrozoobenthos, and habitat (hydrology and water environment) were considered. In the future, ecological indicators (e.g. migratory fish) and thermodynamic oriented ecological indicators (e.g. ecological energy and structural ecological energy) shall also be covered. Considering that large proportions of fish in these lakes have similar ecological compositions, excluded; however, this approach may have affected the comprehensive assessment of aquatic ecosystem health of Poyang Lake in this study. Moreover, due to the hydrological rhythm ('ample flow, short water') in Poyang Lake, and large aquatic plants mainly appear in few branch area of the lake during the rising season, they are not easily accessible. That is to say, the related data are hardly got. Thus, this study did not consider aquatic plants for the time being, but future research will be conducted to improve this limitation. The indicators on hydrologic elements were determined on the basis of existing data, and further in-depth research and screening can be performed to construct more appropriate indicators. The thresholds of indices were determined on the basis of available data, but some of the important information, especially biological data, was limited. Having access to a wealth of information can help optimise this aspect of the research. In addition, the values of the indicators for Poyang Lake vary greatly with the seasons. Thus, this study only determined the mean threshold value. A further deepening of the research scope is needed for the large Yangtze-connected lakes, such as Poyang Lake, considering their obvious seasonal differences.

(Received 22nd Apr 2019; accepted 12th Jul 2019)

Abstract. Dahuofang Reservoir is an important drinking water source. Hunhe, Suzihe and Shehe are three main input rivers, the water quality of which directly affects the water safety. Traditional water quality analysis often adopts a single analysis method, which can only judge the rising or falling trend and trend degree of a certain parameter. The calculation process of multi-section and multi-index trend analysis is quite complicated with a large workload. Thus, in this paper, Nemerow index evaluation method was used to evaluate the water quality, 24 indicators being screened to 8, greatly reducing calculating workload. Then, trend analysis was made by seasonal Kendall test method. The results show that the Nemerow indices of TN in the three river sections were 6.94, 6.68 and 6.30, exceeding 38.8%, 33.6% and 26% of serious pollution standard (5.0) respectively, and with a highly significant upward trend. Those of fecal coliform were 17.42, 3.12 and 2.79 respectively. Beizamu section was seriously polluted, exceeding 248.4% of serious pollution standard (5.0). Gulou section belonged to heavy pollution, exceeding 4% of standard (3.0). Taigou section was also polluted, exceeding 39.5% of standard (2.0). Therefore, effective measures should be taken to control TN and fecal coliform concentrations in the three sections.
Keywords: *water pollution, indicator screening, Nemerow index evaluation, seasonal Kendall test*

Introduction

According to the Chinese Water Resources Bulletin 2017, the per capita water resource amounts to only 2300 m^3 in China, only a quarter of the world average, belonging to water shortage country. With the development of industry, acceleration of urbanization and the expansion of population, China face with a very severe environmental situation. Class I to III water quality section of the main watershed of the country accounts for 67%, while inferior V accounts for 12.9%. Among which, the Haihe River Basin is a serious pollution, and the Yellow River, Huaihe and Liaohe Basins are moderately polluted (Ministry of Water Resources, 2017).

In the 1960s, under rapid industrial development, China ignored the protection of the ecological environment, causing different levels of environmental pollution and ecological damage, resulting in frequent occurrence of water pollution accidents. The obvious increasing trend of water pollution accidents is a direct threat to the security of drinking water supply. Water pollution has become a major obstacle on the road of sustainable development in China. In the 19th National Congress of CPC, it was clearly pointed out that we should strengthen the construction of water resources and other infrastructure, adhere to the construction of ecological civilization, create a good living environment for the people, and contribute to the global ecological security. River water quality assessment is the most important basic work in the process of water environment management and improvement. Therefore, the evaluation of river water quality and the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1171711729

analysis of the trend of water quality are of great significance to the control of water environmental pollution, the construction of ecological civilization and the guarantee of ecological security.

At present, the commonly used water quality evaluation methods include single factor evaluation method, index evaluation method, fuzzy evaluation method, artificial neural network evaluation method, grey clustering method and so on. The single factor evaluation method is to evaluate each water quality monitoring indicators in the water separately, and determine the comprehensive water quality level in the measured area according to the level of the worst individual water quality indicators. The evaluation method is simple to operate (Yin, 2008). The index evaluation method is generally divided into Nemerow index method, comprehensive pollution index evaluation method, water pollution index method and so on (Liu, 2010). The index evaluation method selects the indexes and evaluation criteria according to the use of water, so as to obtain the index value of a single water quality indicator. If a comprehensive evaluation is required, the weight of each indicator needs to be determined to calculate the water quality index, and the water quality evaluation is performed (Liu, 2016). The fuzzy evaluation method is to convert the qualitative analysis into quantitative calculation by the membership degree theory of fuzzy mathematics, and evaluate the water quality grade. This method combines different weight determination methods to avoid the subjectivity of the selection of weight coefficients, making the evaluation results more reasonable, but the calculation process is more complicated (Pan, 2002). Artificial neural network is a complex nonlinear science. It is introduced into the field of water quality assessment, which can fully utilize the high-speed computing power, learning ability and fault tolerance of neural networks, improve the accuracy of water quality evaluation, and avoid human factors in weight selection. However, this method requires a large amount of complete data, and the more complete the data, the higher the accuracy. The gray clustering method is based on the whitening function possessed by the clustering index of different clusters, and the clustering objects are summarized to find the maximum clustering coefficient. The clustering sample level is the water quality level. This method is used for clustering weighting by judging the grey, whitening degree of the system and the comprehensive influence of various pollution indicators, to make the weight determination method more reasonable (Yuan, 2003).

Huang (2013) and Ma (2014) evaluated the water quality of Dahuofang Reservoir in Liaoning Province by using fuzzy evaluation method and BP neural network method respectively, and drew the conclusion that the water quality in the reservoir area was class II level, while in Hunhe River and Suzihe River were all class III level and there was a certain eutrophication risk. It is mainly caused by livestock and poultry breeding, fertilizer use and sewage discharge. Zhou (2015) used the grey clustering evaluation method based on index transformation value to evaluate the water quality of the study area, which overcomes the shortcomings of randomness, ambiguity and uncertainty due to multi-index coupling in the calculation process. After verification, the results are reasonable and accurate. But in the verification process, this method only focuses on the water quality of the study area. Whether it can be popularized or applied remains to be verified. Luo and Wu (2016) put forward the improved Nemerow index evaluation method, in addition to considering the weight of each pollution index; we also pay special attention to the monitoring factors with higher weight to make comprehensive evaluation of water quality. The Nemerow index method has a simple mathematical process and is easy to calculate. It can be used to understand whether the water quality

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1171711729

meets the requirements. Therefore, the Nemerow index method is widely used in water quality evaluation. However, there are still some shortcomings in the classification of water quality, such as being affected by human factors, and no strict corresponding relationship between this division standard and the national standard level. Guan (2017) proposed pollution index method based on the CRITIC weight, and built a water quality evaluation model. Using CRITIC method to determine the weight takes into account the difference and conflict between the indicators on the weight, is an improvement of the entropy weight method, can objectively determine the weight value. This method overcomes the one-sided problem of single factor evaluation, and the calculation process of weight determination is relatively simple. But the method is more dependent on water quality monitoring results.

For water quality trend analysis, the commonly used statistical test methods include seasonal Kendall test, Daniel test, Spearman rank correlation coefficient method, etc. (Gao, 2013). The seasonal Kendall test is a generalization of the Mann-Kendall test (Mann, 1945; Kendall, 1975). In recent years, its calculation process has been gradually improved and applied to the trend analysis of water quality of major rivers. The results are scientific and reasonable. Although this method can determine the rise and fall tendency and trend degree of water quality parameters, it cannot reflect the result of water quality evaluation. Meng (2015) used the seasonal Kendall test to analyze the trend of water quality in the main stream of Minjiang River, pointed out the change trend of the four indicators of chemical oxygen demand (COD), five days biochemical oxygen demand (BOD_5), total phosphorus (TP) and ammonia nitrogen, analyzed the reasons, and proposed corresponding treatment measures. However, the reasons for selecting these four indicators for analysis were not explained. Pang (2017) analyzed the variation trend of groundwater quality in Guanghua Basin using the Spearman rank correlation coefficient method. This method is relatively mature at present, but it can only judge the variation trend from the past to the present and cannot represent the real change of the pollution factor in the future period. Guo (2017) used Daniel test method to analyze the trend of water quality of Nanhai reservoir in Zhangwu. The rank correlation coefficient for statistical tests was compared with Spearman rank correlation coefficient to analyze the variation trend. However, this method requires sufficient available data, while the seasonal Kendall test is not affected by missing measured values. At present, for the study of water quality analysis, people often only pay attention to unilateral water quality evaluation or trend analysis, ignoring the shortcomings of the multi-section and multi-index trend analysis process. Therefore, in this paper we combined water quality evaluation with seasonal Kendall test method. According to the evaluation results, the indexes to be evaluated were selected, which greatly reduced the calculation amount, made up for the deficiency that seasonal Kendall test cannot reflect the evaluation results, and reflected the changing trend of river water quality more intuitively.

Materials and methods

Materials

Dahuofang Reservoir is an important drinking water source of Shenyang, Fushun, Anshan, Liaoyang and some other central cities. It belongs to zonal-valley-type reservoir, about 35 km long in west-east direction, 4 km wide at its widest point, and 0.3 km wide at its narrowest point at the water surface. The project is a large-type

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1171711729

reservoir with a maximum depth of 37 m, maximum water storage area of 114 km^2, and a maximum storage capacity of 2.268×10^9 m^3. The annual average water evaporation in the basin is about 1100~1600 mm (according to the 20 cm scale evaporative dish). The average annual inflow is about 789.36 m^3/s, and its wet season is from April to September. The basin above Dahuofang Reservoir belongs to Hunhe River Basin, Suzihe River Basin and Shehe River Basin, and belongs to the mixed area of agriculture and forestry. In Hunhe River Basin, there are 3.45×10^5 population in Qingyuan County and 3.94×10^4 hm^2 cultivated area. The domestic sewage reaches 1.74×10^4 t/d, due to the existence of chemical mines such as Qingyuan Limestone Mine, lead to the industrial sewage reaches 1.32×10^4 t/d, and the total amount of sewage in the county is 3.06×10^4 t/d. The annual application amount of chemical fertilizer in Qingyuan County is 1.8×10^4 t, pesticide application amount is 280 t, and the dosage of film is 200 t, which caused the loss of most of the chemical substances and thus polluted the water environment. In Suzihe River Basin, there are 3.08×10^5 population in Xinbin County and 5.10×10^4 hm^2 cultivated area. The sewage can be basically treated by a sewage treatment plant. The domestic sewage treatment capacity reaches 1.61×10^4 t/d. In this basin, the pesticide application amount is 2.55 kg/hm^2, lower than the national standard. In Shehe River Basin, there are3.83×10^4 population and 4.78×10^3 hm^2 cultivated area. It is a river with the best water quality in the upstream rivers since there is no large-scale enterprise. The three rivers upstream of Dahuofang Reservoir are the main water sources of the reservoir, with Hunhe River accounting for 52.7% of the water storage, Suzihe River accounting for 37.1%, and Shehe River accounting for 10.2% (Dahuofang Reservoir Chronicles, 2006). The location map of Dahuofang Reservoir and upstream watershed is shown in *Figure 1*.

Figure 1. *Location map of Dahuofang Reservoir and upstream watershed*

In this study, the Beizamu section on Hunhe River, the Gulou section on Suzihe River and the Taigou section on Shehe River were taken as the main monitoring sections on the three input rivers upstream of Dahuofang Reservoir. The water quality monitoring data from 2003 to 2015 were analyzed. The original data were obtained from the monthly average water quality monitoring data of the three monitoring sections from April 23, 2003 to December 7, 2015 provided by the Fushun Hydrology Bureau of Liaoning Province.

The water quality of the three sections ranged from good to bad: Taigou section > Gulou section > Beizamu section. In 2015, there are six indicators that exceed the standard of the national surface water class II in Beizamu section: total nitrogen

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1171711729

(TN) 100%, fecal coliform count 100%, dissolved oxygen (DO) 23.3%, ammonia nitrogen 22%, five-day biochemical oxygen demand (BOD_5) 16.7%, total phosphorus (TP) 10%. There are two indicators that surpass the standard of the national surface water class II in Gulou section: total nitrogen (TN) 100%, fecal coliform count 5%. There are two indicators that exceed the standard of the national surface water class II in the Taigou section: total nitrogen (TN) 100%, dissolved oxygen (DO) 1.7%. The National Surface Water Quality (NSWQ) classification standards (Ministry of Environmental Protection, 2002) are presented in *Table 1*.

Table 1. *Chinese national surface water quality classification standards (GB3838-2002)*

Indicators	Classification				
	I	II	III	IV	V
DO ≥ (mgL^{-1})	7.5	6	5	3	2
Permanganate ≤ (mgL^{-1})	2	4	6	10	15
BOD_5 ≤ (mgL^{-1})	3	3	4	6	10
COD ≤ (mgL^{-1})	15	15	20	30	40
Ammonia Nitrogen ≤ (mgL^{-1})	0.15	0.5	1.0	1.5	2.0
TN ≤ (mgL^{-1})	0.2	0.5	1.0	1.5	2.0
TP ≤ (mgL^{-1})	0.02	0.1	0.2	0.3	0.4
Fecal Coliform Count ≤ (10^{-1} mpn 100 mL^{-1})	200	2000	10,000	20,000	40,000

Methods

In the study of water quality trend analysis, people often use only a certain trend analysis method to analyze the water quality of a river, and then get the trend of water quality change. However, in this paper, the trend of water quality in 3 sections of three rivers in the upstream of Dahuofang Reservoir will be analyzed. There are 8 indicators to be evaluated for each section, altogether 24 indexes. If the seasonal Kendall test method is used alone, the calculation amount will be large. The Nemerow index method is simple in calculation and widely used in water quality assessment. Therefore, the Nemerow index evaluation method was used to evaluate the water quality. According to the evaluation results, the polluted indicators were screened out. The seasonal Kendall test was applied to the selected indicators, which reduced the amount of calculation and made up for the shortcomings of seasonal Kendall test method which can not reflect the evaluation results. Thus, the trend analysis results were obtained, which was also the innovation of this paper.

Nemerow index evaluation method

The Nemerow index evaluation method is based on the single factor index evaluation method to evaluate water quality. The single factor index evaluation method is a method to determine the water quality category by comparing the measured concentration of a certain pollution index with the evaluation standard of the pollution index. Each water quality monitoring indicator is evaluated separately, and the category of the worst single water quality index is selected to determine the comprehensive water quality category of the measured area. The main pollution factors in river water could be determined by single factor index evaluation. The evaluation index F_i is calculated as follows:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1171711729

(1) For the water quality factors whose evaluation criteria are constant values, the evaluation index is calculated by *Equation 1*.

$$F_i = \frac{C_i}{C_0} \quad \text{(Eq.1)}$$

where F_i is the evaluation index of monitoring indicator i in river water, C_i is the measured concentration of indicator i (mg L^{-1}), and C_0 is the evaluation criteria of indicator i.

(2) For the water quality factors whose evaluation standards are interval values (such as PH value), the evaluation index is calculated by *Equations 2* and *3*.

$$P_{pH} = \frac{7.0 - pH}{7.0 - pH_{sd}} \quad \text{If } pH \le 7.0 \quad \text{(Eq.2)}$$

$$P_{pH} = \frac{pH - 7.0}{pH_{su} - 7.0} \quad \text{If } pH \ge 7.0 \quad \text{(Eq.3)}$$

Herein, P_{pH} is the evaluation index of pH, dimensionless; pH is the measured value; pH_{sd} is the lower limit value of the standard; pH_{su} is the upper limit value of the standard.

When Fi is less than 1, it means the river water body is not polluted. When F_i is greater than 1, it means the river water body has been polluted. The greater the F_i is, the more serious the pollution is (Luo and Zhang, 2016). In particular, the situation of dissolved oxygen (DO) is just the opposite.

For Nemerow index method, firstly, a series of Fi values of indicators were calculated by single-factor evaluation method based on the ratio of measured concentration and standard value of selected water quality indicators; then Nemerow pollution index was obtained according to the maximum and average value of Fi. Compared with the corresponding grade standard index (Luo and Wu, 2016), the evaluation grade can be determined to judge the pollution situation. The calculation method is shown in *Equation 4*.

$$P = \left[\frac{(F_{\max})^2 + \left(\bar{F}\right)^2}{2} \right]^{1/2} \quad \bar{F} = \frac{1}{n}\sum_{i=1}^{n} F_i \quad \text{(Eq.4)}$$

where P is the Nemerow index of river water quality monitoring indicators; F_{max} is the maximum F_i value of indicator i; and $\bar{F}$ is the average of F_i of indicator i. Particularly, for DO concentration index, the F_{max} in the formula should be changed to F_{min}, that is, the minimum F_i value of indicator i.

It can be seen that Nemerow index is a comprehensive evaluation of river water quality based on the single-factor index method, which is different from the traditional single-factor index method. On the premise of judging pollution according to the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1171711729

NSWQ, the possible pollution indicators are evaluated, so that the number of water pollution indicators can be effectively deleted to reduce the calculation workload of the seasonal Kendall test.

Seasonal Kendall test

The seasonal Kendall test is a method based on the Mann-Kendall test, which is used to analyze the variation trend of water quality over the years with incomplete measured water quality data, low accuracy of data or regularly changing values with seasons (Onoz, 2003). The test statistic (S) is calculated by *Equations 5* and *6*.

$$\mathrm{sgn}(x_j - x_i) = \begin{cases} 1 & x_j - x_i > 0 \\ 0 & x_j - x_i = 0 \\ -1 & x_j - x_i < 0 \end{cases} \quad \text{(Eq.5)}$$

$$S_p = \sum_{i=1}^{n-1} \sum_{j=i+1}^{n} \mathrm{sgn}(x_j - x_i) \quad \text{(Eq.6)}$$

Herein, x_i and x_j are the measured values of pollutant concentration in month p each year; S_p is the S value in month p, p = 1, 2, ...12.

The null hypothesis H_0 of seasonal Kendall test is a random variable, independent of each other in time. Assuming that the water quality data over 12 months have the same probability distribution, S_p approximately obeys the normal distribution under zero assumption. The expression of its mean and variance are shown in *Equations 7* and *8*.

$$\mathrm{E}(S_\mathrm{p}) = 0 \quad \text{(Eq.7)}$$

$$Var(S_p) = \frac{n_p(n_p - 1)(2n_p + 5) - t_p(t_p - 1)(2t_p + 5)}{18} \quad \text{(Eq.8)}$$

where n_p and t_p are the number of measured values and missed values at month p, respectively.

For the whole p months, $S = \sum_{p=1}^{12} S_p$, $Var(S) = \sum_{p=1}^{12} Var(S_p)$. If n is no less than 10, and S satisfies the normal distribution feature, then its standardized variance Z is described as *Equation 9*.

$$Z = \begin{cases} \dfrac{S-1}{[Var(S)]^{1/2}}, S > 0 \\ 0, S = 0 \\ \dfrac{S+1}{[Var(S)]^{1/2}}, S < 0 \end{cases} \quad \text{(Eq.9)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1171711729

The calculated Z value is compared with the standard normal distribution table with two-sided confidence levels. If $|Z| \le Z_{\alpha/2}$ at the α level of significance, H_0 should be accepted. According to the relevant research results (Robert, 1984), the critical value of significance level α is 0.1 and 0.01. If $\alpha \le 0.01$, $|Z| \ge Z_{\alpha/2}$, the test is highly significant; if $0.01 \le \alpha \le 0.1$, $|Z| \ge Z_{\alpha/2}$, the test is significant. If S > 0, it shows a significant upward trend; if $S < 0$, it shows a significant downward trend; if $S = 0$, there is no obvious variation trend.

Results

Results of Nemerow index evaluation

The data of the main monitoring sections of three rivers in the upstream of Dahuofang Reservoir from 2003 to 2015 were analyzed. Compared with the NSWQ (GB3838-2002), according to the grade II water quality standard, 8 major pollution indicators per section were screened out, which were DO, permanganate index, BOD_5, Chemical oxygen demand (COD), ammonia nitrogen, TN, TP and fecal coliform. Therefore, there are 24 indicators to be evaluated for the three monitoring sections. According to the measured concentration of each indicator, the F_i value of the corresponding year was obtained, and its average value and maximum value was calculated, thus the Nemerow pollution index was obtained. The results are shown in *Table 2*.

Table 2. *Nemerow pollution index*

Indicators	Beizamu section			Gulou section			Taigou section		
	$\bar{F}$	F_{max}	P	$\bar{F}$	F_{max}	P	$\bar{F}$	F_{max}	P
DO	1.53	1.72	1.63	1.60	1.88	1.75	1.59	1.87	1.73
Permanganate	0.86	1.31	1.11	0.65	1.05	0.87	0.53	0.82	0.69
BOD_5	0.60	1.05	0.86	0.47	0.69	0.59	0.39	0.51	0.45
COD	0.84	0.93	0.89	0.77	0.94	0.86	0.72	0.82	0.77
Ammonia nitrogen	0.76	1.34	1.09	0.47	1.28	0.96	0.41	0.85	0.67
TN	6.05	7.73	6.94	5.25	7.85	6.68	5.17	7.27	6.30
TP	0.44	0.98	0.76	0.35	0.93	0.70	0.29	0.55	0.44
Fecal coliform	5.89	23.93	17.42	1.62	4.11	3.12	1.40	3.69	2.79

If the P value of DO is greater than 1, it is indicated that dissolved oxygen is a clean index. By comparing with the classification criteria for pollution grade of Nemerow water quality index (see *Table 3*), the clean indicators were excluded, the indicators belonging to different degrees of pollution were retained, and the pollution indicators of the three sections was reduced from 24 to 8 (see *Table 4*).

Table 3. *Classification criteria for pollution grade of Nemerow water quality index*

P	< 1	1-2	2-3	3-5	> 5
Water quality level	Clean	Light pollution	Pollution	Heavy pollution	Serious pollution

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1171711729

Table 4. *Screened indicators and pollution levels*

Sections	Indicators	P Value	Pollution Level
Beizamu	Permanganate	1.11	Light pollution
	Ammonia nitrogen	1.09	Light pollution
	TN	6.94	Serious pollution
	Fecal coliform	17.42	Serious pollution
Gulou	TN	6.68	Serious pollution
	Fecal coliform	3.12	Heavy pollution
Taigou	TN	6.30	Serious pollution
	Fecal coliform	2.79	Pollution

It is obvious that:

(1) In Beizamu section, the Nemerow indexes of TN and fecal coliform were 6.94 and 17.42, respectively, which belonged to serious pollution. The Nemerow indexes of permanganate index and ammonia nitrogen were 1.11 and 1.09, respectively, which belonged to light pollution. Other indicators were all clean indicators;

(2) In Gulou section, the Nemerow index of TN was 6.68, which belonged to serious pollution. The Nemerow index of fecal coliform was 3.12, which was a heavy pollution. Others were all clean indicators;

(3) In Taigou section, the Nemerow index of TN was 6.30, which was a serious pollution. The Nemerow index of fecal coliform was 2.79, belonging to pollution. Others were all clean indicators.

In order to further verify the variation trend of the above pollution indicators, the seasonal Kendall test was conducted on the selected 8 indicators.

Results of seasonal Kendall test

According to the evaluation results of Nemerow index method, seasonal Kendall test was performed on the following indicators: permanganate index, ammonia nitrogen concentration, TN and fecal coliform in Beizamu section; TN and fecal coliformt in Gulou section; TN and fecal coliform in Taigou section. The test results are shown in *Table 5*.

The test results showed that Z values of TN in the three sections were 2.945, 4.951 and 5.133, respectively, with a highly significant upward trend, while the other indicators showed no significant variation trend.

Discussion

The above analysis results reveal that:

(1) TN and fecal coliform in Beizamu section belong to serious pollution, exceeding the pollution standards (the minimum standard index is 5.0) by 38.8% and 248.4%, respectively. Permanganate index and ammonia nitrogen are light pollution, exceeding 31% and 34% of the minimum pollution standards (1.0), respectively. These four pollution indicators are consistent with the main pollution indicators determined by Huang (2013) using the fuzzy evaluation method. Firstly, the Hunhe River Basin where the Beizamu section is located has a large population (3.45×10^5 people), and a large amount of domestic sewage (1.74×10^4 t/d), which leads to the excessive number of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1171711729

fecal coliform bacteria. Secondly, the upstream industrial mines (e. g. Qingyuan Limestone Mine) still exist, and the industrial wastewater discharge is large (1.32×10^4 t/d) and the treatment is not timely, resulting in slight pollution of permanganate index and ammonia nitrogen. Pang (2017) also mentioned the reason why the ammonia nitrogen concentration exceeded the standard in the analysis of groundwater quality in Guanghua Basin. Thirdly, the cultivated land area of Hunhe River Basin is relatively large (3.94×10^4 hm^2). Due to the large use of pesticides and fertilizers, the TN exceeds the limit, which leads to the risk of eutrophication in water.

Table 5. *Seasonal Kendall test results*

Sections	**Indicators**	**S**	**VarS**	**Z**	α **= 0.1** $Z_{\alpha/2}$=1.645	α **= 0.01** $Z_{\alpha/2}$=2.576	**Water quality trends**
Beizamu	Permanganate	28	1878.0	0.62	<	<	No trend
	Ammonia nitrogen	-61	1414.0	-1.596	<	<	No trend
	TN	114	1472.7	2.945	>	>	Highly significant increase
	Fecal coliform	43	1766.0	0.999	<	<	No trend
Gulou	TN	191	1472.7	4.951	>	>	Highly significant increase
	Fecal coliform	-69	1766.0	-1.618	<	<	No trend
Taigou	TN	198	1472.7	5.133	>	>	Highly significant increase
	Fecal coliform	-41	1822.0	-0.937	<	<	No trend

(2) TN in Gulou section belongs to serious pollution, exceeding the pollution standard (the minimum standard index is 5.0) by 33.6%. Fecal coliform belongs to heavy pollution, exceeding 4% of the minimum pollution standard (3.0). This is due to the fact that the Suzi River Basin, where the Gulou section is located, has a large population (3.08×10^5 people) and a large amount of domestic sewage (1.6×10^4 t/d). However, there are sewage treatment plants in the area, which can discharge domestic sewage after treatment. Therefore, the quantity of fecal coliform is significantly less than that of Beizamu section, but there is still a certain degree of pollution. The number of fecal coliforms in the Aibihu Lake Wetland Nature Reserve has also shown a significant downward trend after the establishment of sewage treatment plants and the treatment of domestic sewage to meet the discharge standards (Ren, 2011). In addition, the cultivated land area in the Suzi River Basin (5.1×10^4 hm^2) is larger than in the Hunhe River Basin, and the application of pesticides and fertilizers is more, resulting in serious pollution of TN.

(3) TN in Taigou section belongs to serious pollution, exceeding the pollution standard (the minimum standard index is 5.0) by 26%. Fecal coliform belongs to pollution, exceeding 39.5% of the minimum pollution standard (2.0). This is due to the population of Shehe River Basin where the Taigou section is located is small (38,381 people), the cultivated land area is also small (4776.5 hm^2), and there is no

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1171711729

large-scale industrial enterprise in the upstream. Therefore, compared with the Hunhe River Basin and the Suzi River Basin, the water quality is better. This conclusion is consistent with the research result of Shi (2004). However, because of the discharge of domestic sewage and the use of pesticides and fertilizers, the TN and fecal coliforms are still polluted to varying degrees.

(4) TN concentration in the three sections of Beizamu, Gulou, Taigou all show a highly significant upward trend, while the other indicators show no significant change trend. Fang (2017) analyzed the change trend of TN concentration in the Beizamu section of Hunhe River and drew the same conclusion. This change is associated with the large-scale application of chemical fertilizers in the upstream farmland. Among the fertilizers applied in the study area, the nitrogen content accounts for 49.5% of the total content (Tang, 2016). The large amount of chemical fertilizers has resulted in nitrogen residue in soil, and with the surface runoff flowing into rivers. The TN concentration has a highly significant upward trend due to the long-term excess of nitrogen. The interannual variation curves of the TN concentration in the three sections from 2003 to 2015 (*Fig. 2*) also shows a significant upward trend, which is consistent with the above analysis conclusion.

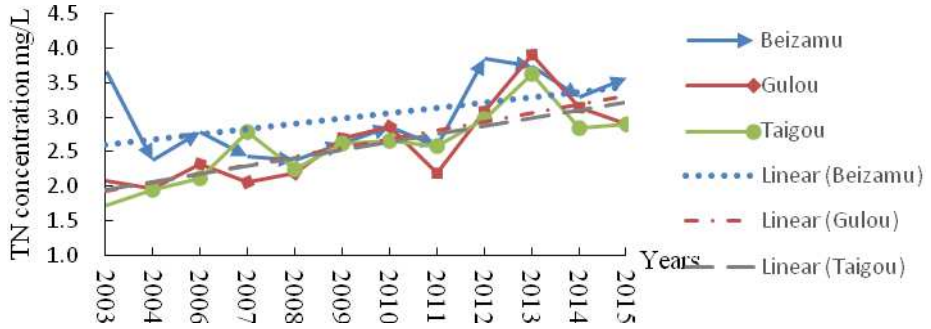

Figure 2. *Interannual variation curves and linear analysis of total nitrogen concentration in three sections from 2003 to 2015*

Conclusions

Based on the monitoring data of water quality in the upstream of Dahuofang Reservoir from 2003 to 2015 and according to the NSWQ, the water quality evaluation and water quality variation trend analysis were carried out to Hunhe River, Suzihe River and Shehe River, the three major rivers upstream of Dahuofang Reservoir. The Nemerow index method was used to preliminarily evaluate the river water quality at the three sections of Beizamu, Gulou and Taigou. 8 indicators of each section, totaling 24 indicators, were compared with the pollution grade classification standard of Nemerow water quality index. Among the original 24 pollution indicators, according to the evaluation results, the clean indicators were eliminated, the pollution indicators of different degrees were retained, and the indicators were reduced from 24 to 8. Then seasonal Kendall test method was applied to test the 8 indicators, and to predict the variation trend of water quality.

The results show that the order of water quality of the three sections is: Taigou section > Gulou section > Beizamu section. The TN concentrations in the three sections

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1171711729

belong to serious pollution and have a highly significant upward trend. The fecal coliform floras of the three sections are polluted to varying degrees, and the pollution in Beizamu section is the most serious. Therefore, the application of pesticides and fertilizers should be reduced as far as possible, non-point source pollution should be controlled, and eutrophication of water body should be prevented. At the same time, effective measures must be taken to ensure that domestic sewage treatment meets the discharge standards.

Abstract. The fraction and distribution characteristics of phosphorus in the sediments of Sancha Lake were studied using the SMT Phosphorus fraction method and its influencing factors were discussed. According to the research results, total phosphorus (TP) content in the sediments was 270.00-3,722.80 $\mu g \cdot g^{-1}$, the organophosphorus (OP) content was 64.00-774.43 $\mu g \cdot g^{-1}$, the inorganic phosphorus (IP) content, a main phosphorus fraction, was 164.00-3,006.99 $\mu g \cdot g^{-1}$, accounting for about 69.32% of TP, the HCl-P content, a main phosphorus fraction of IP, was 125.00-2,474.04 $\mu g \cdot g^{-1}$, accounting for about 69.19% of IP, and the NaOH-P content was less, i.e. 51.00-689.72 $\mu g \cdot g^{-1}$, accounting for about 30.73% of IP. Different phosphorus fractions had obvious temporal and spatial variation; all the sampling sites showed a general trend where the phosphorus fraction content was higher in winter and lower in summer, similar in spring and autumn. The content of organic matter in the sediments had significant correlation with OP, NaOH-P had significant correlation with Fe in the sediments, between HCl-P in the sediments had significant correlation with Ca, APA had significant positive correlation with OP. However, the pH, TN, dissolved oxygen and temperature had no significant correlation with various phosphorus fractions.
Keywords: *phosphorus fractions, spatial and temporal distribution, sediment, Sancha Lake, eutrophication*

Introduction

Phosphorus is the main restrictive factor (Zhang et al., 2012) of Lake Eutrophication, and most phosphorus nutrient salt entering into lakes will eventually be stored in the sediments under various conditions, forming endogenous pollution (Zhu et al., 2004). The fraction of phosphorus in the sediment has an important effect on its migration and transformation mechanism (Fan et al., 2010; Hupfer et al., 1995; Chuai et al., 2014; Li et al., 2014). The distribution characteristics of phosphorus in the sediments have already been confirmed to have a direct relation to the internal load of the lake, and different fractions and contents of phosphorus in the sediments play different roles in Lake Eutrophication (Yang et al., 2013; Zhou et al., 2013). Therefore, the analysis of different fractions of phosphorus in the sediments of a lake and their temporal and spatial distribution characteristics is of great significance to further research Lake Eutrophication. This paper mainly studied the fractions, contents, temporal and spatial distribution of phosphorus in the sediments of Sancha Lake, and discussed the factors influencing the content distribution of each phosphorus fraction, so as to provide data and theoretical support for further research on the mechanisms of lake eutrophication of Sancha Lake.

Materials and methods

Brief introduction to study area

Sancha Lake is located in Tianfu New Area of Sichuan Province, east longitude 104°11′16″ to 104°17′16″, north latitude 30°13′08″ to 30°19′56″, its average depth is 8.3 m, and the maximum depth is 32.5 m. The area is under subtropical moist monsoon climate, the annual average temperature is 15.2 to 16.9 °C, and the annual average rainfall is 786.5 mm. Sancha Lake water mainly derives from the Minjiang River which accounts for about 80%, and the rest of about 20% comes from the rainfall and two streams (Tiaodeng River and Longyun River). The drainage area above the dam site is 161.25 km^2, the average runoff depth is 275.1 mm, and the average sediment discharge through surface runoff is 200,000 t. Sancha Lake and its surrounding are an important part of "International Tourism Culture Area with Two Lakes and One Mountain" in Tianfu New Area. Sancha Lake is the source of drinking water for population in Sancha Town. Moreover, it can maintain biodiversity, store water, prevent and control flood, and adjust surface runoff and climate. According to the characteristics of lake and different human activities, Sancha Lake is divided into five functional areas as shown in *Figure 1*: (I) Main runoff area of lake; (II) Highly dense area of original cage culture; (III) Adjacent human activity intensive area; (IV) Relatively dense area of enclosure culture of Dahu Lake; (V) Tail water area of reservoir. According to the monitoring results of many years, the COD_{Cr} and BOD_5 of the waters of Sancha Lake decline year by year, while TN and TP have been rising, the corresponding chlorophyll increases year by year while transparency declines year by year, showing that the eutrophication has been formed in Sancha Lake (Li, et al., 2019).

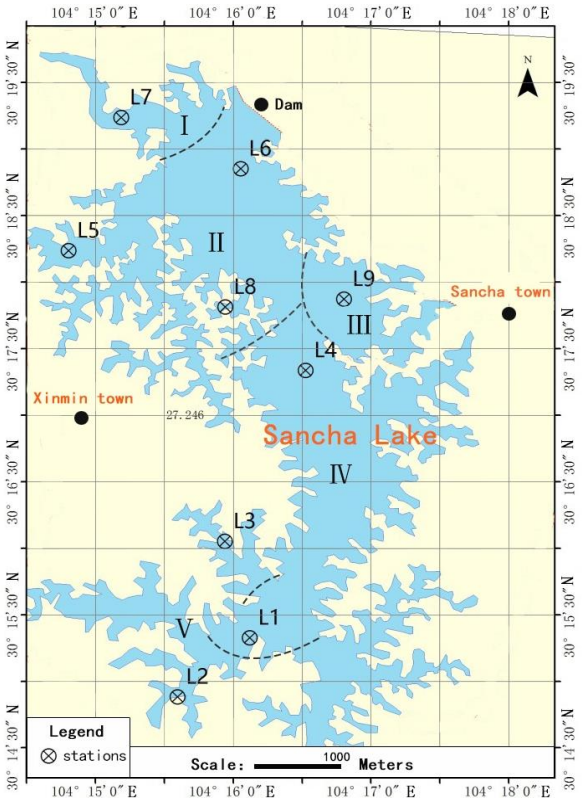

Figure 1. *Sampling sites in the Sancha Lake*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1173111743

Sample collection and pretreatment

According to the distribution characteristics of the sediments of Sancha Lake and eutrophication status (Jia et al., 2013), 9 sampling sites as shown in *Figure 1* were selected, and the latitude and longitude of sampling sites were determined by GPS. In January (winter), April (spring), August (summer) and November (autumn) of 2016, the surface sediment at the bottom of Sanch Lake at each sampling site was collected using a grab bucket, then the surface sediment (0-5 cm) was collected using a organic glass column and placed in a clean sealed polyethylene bag. Three parallel samples of each sampling site were collected and mixed as the representative sample of such sampling site, and then they were stored in an ice box at 4 °C and brought back to the lab. One part of the sediment samples was immediately used for isolation of microbes and counting cultivation experiment, and the other part was grinded using a 100-mesh screen after freeze drying, and then packed in a sealed bag for the determination of phosphorus fraction and its physicochemical properties. Meanwhile, the overlying water at the bottom of the sediments of each sampling site was collected using an airtight water sampler for analysis of the index of water environment.

Determination method

The various fractions of phosphorus in the sediments were determined using the SMT chemical continuous extraction method (Ruban et al., 1999, 2001) recommended by European Standards Committee. The contents of TP, IP, OP, NaOH-P and HCl-P in the sediments were determined using the ammonium molybdate spectrophotometric method (Huang et al., 2003) Three parallel samples were determined for each fraction and then their average value was selected. Alkaline phosphatase activity (APA) was determined using the Anupama method (Anupama et al., 2008). The alkaline phosphatase can catalyze and hydrolyze p-nitrophenyl phosphate (p – NPP) to produce steady yellow p-nitrophenol (PNP). Therefore, the production rate of PNP was measured using the colorimetric method, as an index of alkaline phosphatase activity (APA). The specific methods were as follows: Firstly, about 0.5 g of wet sediments was selected and placed in a sterilized reaction tube, then 10 ml of Tris-HCl buffer with the pH of 8.4 and 0.5 $mol \cdot L^{-1}$ concentration was added to the tube and blended well at 37 °C for 1h of reaction, then 2 ml of NaOH solution with 1 mol/L concentration was added to terminate the reaction, supernatant was filtered by centrifugation, 600 nm of solution was selected for colorimetric determination and the result was converted into the activity of dried mud of unit mass, and the PNP solution with different concentration was used to made the standard curve.

Total organic carbon (TOC) in the sediments was determined as per the regulations of On the Determination of Total Organic Carbon in Sediments issued by Chinese GB/T 19145-2003 (General Administration of Quality Supervision, Inspection and Quarantine of China, 2003). The Fe, Al and Ca were determined as per the regulations of Monitoring and Distinguishing Method for Water and Wastewater issued by National Environmental Protection Bureau (State Environmental Protection Administration of China, 2002). The moisture content was determined using the weight-loss method, namely the sediment was put at 105 °C and dried to constant weight. The pH, temperature and electrical conductivity of the overlying water were determined using an HI991301 portable multi-parameter temperature meter, and the dissolved oxygen was determined using an HQ3OD portable dissolved oxygen meter.

DOI: http://dx.doi.org/10.15666/aeer/1705_1173111743

Data analysis

Data analysis was conducted by Excel 2003 software and SPSS19.0. Correlation analysis was conducted using the Pearson correlation analysis to determine the relationship between fractions of phosphorus in the sediments and physicochemical properties.

Results

Physicochemical properties of the sediments and overlying water

The pH of the overlying water ranged from 7.15 to 8.73, averaging 7.53, 7.25, 7.91 and 8.54 in spring, summer, autumn and winter, respectively, alkaline in winter and weakly alkaline in spring, summer and autumn; the temperature ranged from 11.1 °C to 27.6 °C, averaging 18.90 °C, 26.0 °C, 20.9 °C and 13.2 °C in spring, summer, autumn and winter, respectively, with a temperature difference of about 13 °C in winter and summer, and not obvious temperature difference in spring and autumn; the DO ranged from 4.10 to 9.90 $mg \cdot L^{-1}$, averaging 6.57 $mg \cdot L^{-1}$, 4.60 $mg \cdot L^{-1}$, 6.45 $mg \cdot L^{-1}$ and 9.42 $mg \cdot L^{-1}$ in spring, summer, autumn and winter, respectively, like temperature, it had huge temperature difference in winter and summer, and not obvious temperature difference in spring and autumn. The content of moisture in the sediments ranged from 55.47% to 82.7%, averaging 73.48%, 70.42%, 73.14% and 73.46% in spring, summer, autumn and winter, respectively, changing slightly in the four seasons; the TOC in the sediments ranged from 13.7 to 36.3 $mg \cdot g^{-1}$, averaging 23.3 $mg \cdot g^{-1}$, 27.68 $mg \cdot g^{-1}$, 23.71 $mg \cdot g^{-1}$ and 22.4 $mg \cdot g^{-1}$ in spring, summer, autumn and winter, respectively, higher in summer and lower in winter, similar in spring and autumn; the TN in the sediments ranged from 1.2 to 3.1 $mg \cdot g^{-1}$, averaging 1.92 $mg \cdot g^{-1}$, 2.57 $mg \cdot g^{-1}$, 2.04 $mg \cdot g^{-1}$ and 1.73 $mg \cdot g^{-1}$ in spring, summer, autumn and winter, respectively, as with the variation laws of the TOC, it was higher in summer and lower in winter, similar in spring and autumn; the Fe in the sediments ranged from 25 to 128.4 $mg \cdot g^{-1}$, averaging 43.93 $mg \cdot g^{-1}$, 37.98 $mg \cdot g^{-1}$, 47.33 $mg \cdot g^{-1}$ and 61.46 $mg \cdot g^{-1}$ in spring, summer, autumn and winter, respectively; the Al in the sediments ranged from 4.72 to 21.67 $mg \cdot g^{-1}$, averaging 10.94 $mg \cdot g^{-1}$, 10.38 $mg \cdot g^{-1}$, 11.22 $mg \cdot g^{-1}$ and 13.43 $mg \cdot g^{-1}$ in spring, summer, autumn and winter, respectively; the Ca in the sediments ranged from 7.20 to 59.9 $mg \cdot g^{-1}$, averaging 32.74 $mg \cdot g^{-1}$, 32.86 $mg \cdot g^{-1}$, 37.34 $mg \cdot g^{-1}$ and 35.39 $mg \cdot g^{-1}$ in spring, summer, autumn and winter, respectively. From the seasonal variation of contents of Fe, Al, Ca in the sediments, it can be seen that the Fe content varied significantly in summer compared with winter, while the Al and Ca contents did not vary significantly with the seasons.

Temporal and spatial variation of content of phosphorus in the sediments

Content and distribution characteristics of TP in the sediments

As shown in *Table 1*, the content of TP in the sediments averaged 504.00-2,380.00 $\mu g \cdot g^{-1}$, 270.00-1,376.00 $\mu g \cdot g^{-1}$, 543.00-2,436.00 $\mu g \cdot g^{-1}$ b and 688.70-3722.80 $\mu g \cdot g^{-1}$ in spring, summer, autumn and winter, respectively, highest in winter, followed by spring and autumn, and lowest in winter, which was higher than Poyang Lake (689.34 $\mu g \cdot g^{-1}$), Yao Lake (987.93 $\mu g \cdot g^{-1}$) and Guanting Reservoir (1,268.93 $\mu g \cdot g^{-1}$) (Xiang et al., 2010; Jiang et al., 2016; Li et al., 2005), and higher when compared with

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1173111743

other similar lakes. From *Figure 2* it can be seen that different sampling sites had significantly different TP content and the same sampling site had significantly different TP content in different seasons, all the sampling sites showed a general trend where the phosphorus fraction content was higher in winter and lower in summer, similar in spring and autumn, which was due to the fact that vigorous growth of plankton of the waters had great demand for phosphorus in summer and the plankton of the waters conducted excessive decomposition of phosphorus in the sediments in the absence of phosphorus of the waters (Xie et al., 2003). The content of TP in L8, L6 and L5 of the highly dense area of original cage culture and L9 of the adjacent human activity intensive area was high, of which, it was highest in L8 and L9, reaching 3,723 $\mu g \cdot g^{-1}$ in L8 in winter; the content of TP in L4 and L1 of the relatively dense area of enclosure culture of Dahu Lake was relatively high, reaching 1,200 $\mu g \cdot g^{-1}$ in winter; the content of TP in L7 of the main runoff area of lake and L2 and L3 of the tail water area of reservoir was low compared with other sampling sites, of which, the content of TP averaged 643 $\mu g \cdot g^{-1}$ in L2, a sampling site with minimum pollution, which belongs to a moderately polluted area in accordance with EPA standard.

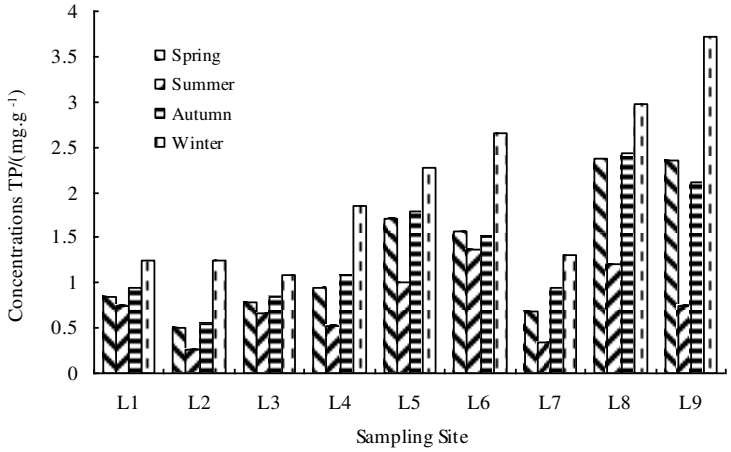

Figure 2. *Seasonal variation of content of TP in different sampling sites*

Content and distribution characteristics of IP in the sediments

As shown in *Table 1*, the IP content was 431.00-1,627.00 $\mu g \cdot g^{-1}$, 164.00-900.00 $\mu g \cdot g^{-1}$, 291.00-1, 568.00 $\mu g \cdot g^{-1}$ and 531.95-3, 006.99 $\mu g \cdot g^{-1}$ in spring, summer, autumn and winter, respectively, accounting for about 69.32% of TP, thus IP was the main factor influencing the TP variation. IP mainly included two phosphorus fractions namely NaOH-P and HCl-P, presenting HCl-P > NaOH-P in spring, summer, autumn and winter, showing that HCl-P was the main factor influencing the IP variation. As shown in *Table 2*, the correlation analysis indicated that there was significant correlation between IP and TP ($P < 0.01$). As shown in *Figure 3*, the spatial distribution of IP in spring, summer, autumn and winter was similar to that of TP, with basically same high value point, except for L5 and L6 in which the IP content of L5 was higher than that of L6. *Table 1* showed that the NaOH-P content was 144.00-592.00 $\mu g \cdot g^{-1}$, 51.00-371.00 $\mu g \cdot g^{-1}$, 168.00-504.00 $\mu g \cdot g^{-1}$ and 197.02-689.72 $\mu g \cdot g^{-1}$ in spring, summer, autumn and winter, respectively, averaging 32.84%, 38.64%, 36.44% and 27.00% of IP, respectively, changing slightly in summer and autumn, and low in winter may be due to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1173111743

the fact that weak reduction condition was favorable for NaOH-P to release to the overlying water on account of low oxygen content in the waters. In the spatial distribution, as shown in *Figure 3*, the content of NaOH-P in the sediments of L9 of the adjacent human activity intensive area was high, followed by L8, L6 and L5 of the highly dense area of original cage culture, and similar to TP in spatial distribution in other sampling sites in spring, summer, autumn and winter. The HCl-P content was 234.00-1,433.00 $\mu g \cdot g^{-1}$, 125.00-545.00 $\mu g \cdot g^{-1}$, 278.00-1,063.00 $\mu g \cdot g^{-1}$ and 330.98-2,474.04 $\mu g \cdot g^{-1}$ in spring, summer, autumn and winter, respectively, averaging 71.33.00%, 63.17%, 69.52% and 76.74% of IP, respectively, thus HCl-P was the main constituent of IP, changing slightly in summer and autumn, highest in winter, and low in summer may be due to the fact that the microorganism activity was highly favorable for HCl-P to release to the overlying water, showing the characteristics (Lau et al., 2002) of the sediments in eutrophic lakes. As shown in spatial distribution diagram 5, the HCl-P content was similar to TP in spatial distribution in spring, summer, autumn and winter, with basically same high value point.

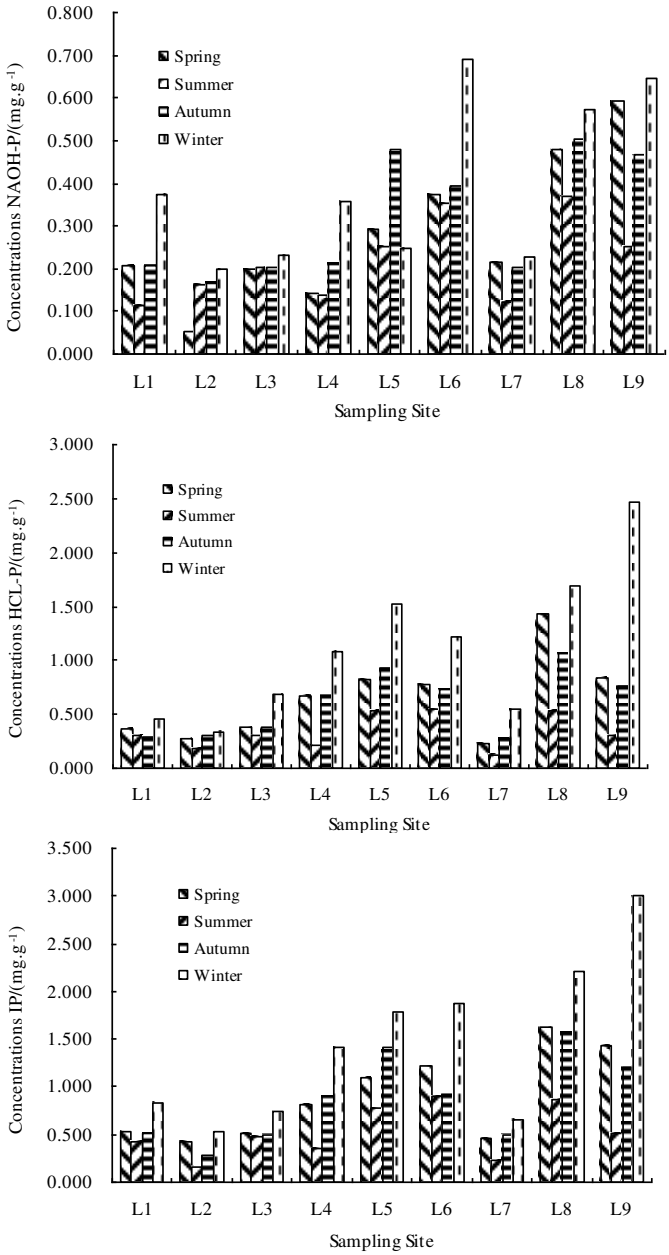

Figure 3. *Seasonal variation of contents of NaOH-P, HCl-P and IP in the sediments in different sampling sites*

Content and distribution characteristics of OP in the sediments

As shown in *Table 1*, the OP content was 110.00-848.00 $\mu g \cdot g^{-1}$, 64.00-360.00 $\mu g \cdot g^{-1}$, 172.00-868.00 $\mu g \cdot g^{-1}$ and 177.15-774.43 $\mu g \cdot g^{-1}$ in spring, summer, autumn and winter, respectively, averaging 32.84%, 38.64%, 36.44% and 27.00% of TP, respectively, lower than IP of TP, however, the content of OP in the sediments was rich, higher than that of the same type of lakes such as Taihu, Chaohu and Longgan Lake (Fan, et al., 2007). As shown in spatial distribution *Figure 4*, in terms of OP content, L8 of the highly dense area of original cage culture and L9 of the adjacent human activity intensive area were high, L6 and L5 of the highly dense area of original cage culture were lower than that of L8 in the same area, L7 of the main runoff area of lake was higher than L4 of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1173111743

relatively dense area of enclosure culture of Dahu Lake, which may be due to the fact that the organic matter was deposited in this area, and L2 and L3 of the tail water area of reservoir were the lowest. Furthermore, like TP, all the sampling sites showed a general trend where the phosphorus fraction content was higher in winter and lower in summer, similar in spring and autumn.

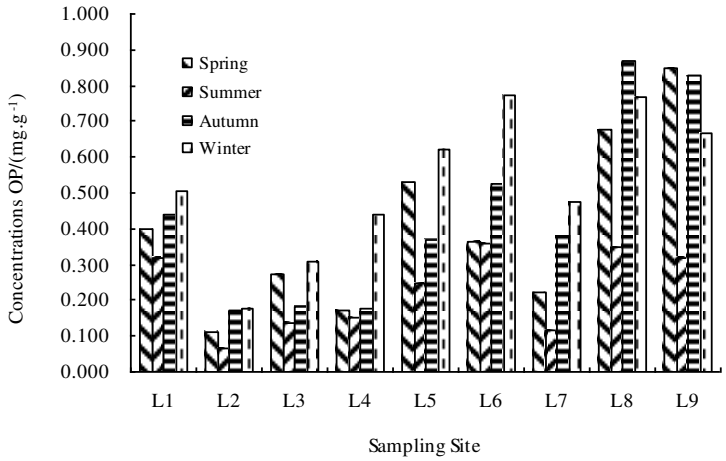

Figure 4. *Seasonal variation of content of OP in the sediments in different sampling sites*

Temporal and spatial variation of alkaline phosphatase in the sediments

The alkaline phosphatase (APA) in the sediments ranged from 1.40 to 9.80 μmol·g^{-1}·h^{-1}, averaging 5.63 μmol·g^{-1}·h^{-1}, 6.86 μmol·g^{-1}·h^{-1}, 5.89 μmol·g^{-1}·h^{-1} and 4.17 μmol·g^{-1}·h^{-1} in spring and summer autumn and winter, respectively. From *Figure 5*, it can be seen that the APA of different sampling sites in summer was higher than that in winter, and similar in spring and autumn. The study showed that the enzyme activity was high in summer due to high temperature and low in winter due to low temperature (Wilczek et al., 2005), and the temperature increase can increase the affinity between enzyme and substrate, thus leading to enzyme catalytic rate increase (Chróst and Rai, 1993); in addition, the metabolic rate of microorganism will increase with the increase of temperature and then induce the microorganism to produce more enzyme (Wallenstein et al., 2010), therefore, the APA in the study area showed obvious seasonal variation. In the spatial distribution of APA, like OP, L8, L6 and L5 of the highly dense area of original cage culture and L9 of the adjacent human activity intensive area were high, followed by L1 of the relatively dense area of enclosure culture, L7 of the main runoff area of lake was higher than L4 of the relatively dense area of enclosure culture of Dahu Lake, and L2 and L3 of the tail water area of reservoir were the lowest. It can be seen that the high APA of the highly dense area of original cage culture and the adjacent human activity intensive area indicated that the APA was closely related to the input of pollutants (Zhang et al., 2007), in culture dosing and human activity area, the more nutrients input, the more organic phosphorus or enzymatic hydrolysis phosphorus increase, thus inducing the higher APA, such a mechanism was known as the substrate inducing mechanism (Li et al., 2007). Therefore, APA can be used as an indicator of the degree of sediment pollution to a certain extent (Huang et al., 2013). By correlation analysis, it can be seen that the APA had a significant correlation ($P < 0.05$) with OP only in winter, while poor correlation with other phosphorus fractions.

Discussion

Distribution characteristics of different phosphorus fractions in the sediments of Sancha Lake

The phosphorus fractions in the sediments are closely related to the migration process of phosphorus to the overlying water, therefore, comprehending the distribution characteristics of different phosphorus fractions in the sediments has important practical significance to control the internal source pollution and reduce the endogenous phosphorus release. In this study, 9 sampling sites were selected as the representative samples of the sediments, and statistical analysis was conducted for the composition of different phosphorus fractions. The OP, NaOH-P and HCl-P in the sediments of Sancha Lake averaged 30%, 20.5% and 49.5% of TP, respectively, suggesting that HCl-P was the main constituent of phosphorus, followed by OP, while NaOH-P, mostly easily to release and with most biological activity, was the lowest. The decomposition of NaOH-P was closely related to the environmental conditions such as oxidation-reduction potential, while the morphological transformation and release process of HCl-P and OP were mostly related to the microorganism. Previous studies have indicated that microorganism dissolves HCL-P by secretion of organic acid, while phosphatase secreted by microorganism is an indispensable mediator of OP degradation pathway (Wu and Zhou, 2005). Therefore, in the sediments of Sancha Lake that are rich in HCl-P and OP, microorganism should play an important role in the migration and transformation process of phosphorus. The distribution characteristics of phosphorus fractions of different sampling sites were different, L8 of the highly dense area of original cage culture had high OP content, accounting for approximately 49% of TP, which was significantly higher than the average level of the whole lake, L9 of the adjacent human activity intensive area had high NaOH-P content, accounting for approximately 36% of TP, L6 and L5 of the highly dense area of original cage culture also had high OP content, averaging close to 40%, L1 and L4 of the relatively dense area of enclosure culture of Dahu Lake had low OP and NaOH-P contents, but high absolute content of HCl-P, which may be due to the fact that the fish of the upper water consumed and absorbed the phosphorus of the waters in the growth process, thus promoting the release of OP and NaOH-P in the sediments, and L2 and L3 of the tail water area of reservoir had low OP, NaOH-P and HCl-P contents on account of little

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1173111743

water flow and low pollution. Since OP and NaOH-P were phosphorus with release potential, so L8 and L9 had the most endogenous phosphorus release potential, meanwhile, L6, L5, L4 and L1 could exhibit strong phosphorus release capability under appropriate environmental conditions such as high temperature and hypoxia.

Correlation between different phosphorus fractions in the sediments of Sancha Lake

Correlation between different phosphorus fractions in the sediments of Sancha Lake was as shown in *Table 2*. TP had significant correlation with four phosphorus fractions, among which, the coefficient of correlation between TP and OP was higher, presenting extremely significant correlation, suggesting that the variation of content of TP in the sediments of Sancha Lake was closely related to OP fluctuation. IP had extremely significant correlation with HCl-P and positive correlation with NaOH-P, but not significant correlation, which may be due to the fact that the microbial activity was highly favorable for HCl-P to release to overlying water. IP had extremely significant negative correlation with OP, suggesting a presence of mutual transformation between IP and OP. HCl-P had significant negative correlation with OP, suggesting that the orthophosphate released from decomposition of these two phosphorus fractions may transform towards fraction of each other under suitable environmental conditions. Furthermore, there was significant negative correlation between HCl-P and NaOH-P, two main phosphorus fractions of IP.

Correlation between different phosphorus fractions in the sediments of Sancha Lake and physiochemical factors

Correlation between different phosphorus fractions in the sediments of Sancha Lake and physiochemical factors was shown in *Table 3*. Based on isothermy, Zhou et al. (2005) discovered, after investigating the sediments of Taihu Lake, that the influence of pH on phosphorus adsorption was an inverted "U" shape, and positive correlation on phosphorus analysis. the pH of the sediments of Sancha Lake was neutral leaning alkalinity, i.e. weakly alkaline in the four seasons, and had significant correlation with HCl-P phosphorus fractions, while the content of organic matter in the sediments had significant correlation with OP, such similar laws were also found by Huang et al. (2005) in studies on lake and reservoir. NaOH-P had significant correlation with the content of Fe in the sediments, whose formation was closely related to the adsorption and binding of iron and aluminum compounds, HCl-P in the sediments had extremely significant correlation with Ca. APA had extremely significant positive correlation with TP and OP and significant positive correlation with IP, which was basically in agreement with the results of a study by Jiang et al. (2011), who concluded that the APA had significant correlation with TP, IP and OP in the sediments. Other studies have suggested a complex relationship between APA and OP, and Xue et al. (1995) suggested that if the IP produced by enzymolysis of ALP was used by the biological organisms in the sediments, then the APA had positive correlation with OP; if the IP produced by enzymolysis of ALP moved upward into the overlying water, then the APA had negative correlation with OP. While Huang and Huang (1999) pointed out that the dissolved IP and small molecule OP concentration were the main factors influencing the APA variation because the APA jumped to high value when the dissolved IP or small molecule OP were almost depleted. Therefore, the relationship between the APA

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1173111743

and phosphorus was uncertain, which may be associated with the biological effect, physicochemical conditions of the sedimentation and nutrient content.

In addition, the TN, dissolved oxygen, temperature will also have an impact on the phosphorus fractions and phosphorus content, but their correlation was not significant, which may be related to water power, environmental media conditions and biological effect.

Table 3. *Coefficients of correlation between different phosphorus fractions in the sediments and physicochemical properties (n = 36)*

	TN	TOC	Fe	Al	Ca	PH	O2	T	APA

Conclusions

(1) The content of TP in the sediments of Sancha Lake ranged from 504.00 to 2,380.00 $\mu g \cdot g^{-1}$, 270.00 to 1,376.00 $\mu g \cdot g^{-1}$, 543.00 to 2,436.00 $\mu g \cdot g^{-1}$ and 688.70 to 3,722.80 $\mu g \cdot g^{-1}$ in spring, summer, autumn and winter, respectively. The contents of all phosphorus fractions were highest in winter, followed by spring and autumn, and smallest in winter. In the four seasons IP was the main phosphorus fraction of TP, averaging about 69.52% of TP, in which HCl-P was the main phosphorus fraction, averaging 71.8% of IP, and OP averaged about 29.50% of TP.

(2) In the spatial distribution, different sampling sites had significantly different phosphorus fraction content and the same sampling site had significantly different phosphorus fraction content in different seasons, all the sampling sites showed a general trend where the phosphorus fraction content was higher in winter and lower in summer, similar in spring and autumn. The contents of all phosphorus fractions were basically same, high in the highly dense area of original cage culture and adjacent human activity intensive area, relatively high in the relatively dense area of enclosure culture of Dahu Lake, and low in the main runoff area of lake and tail water area of reservoir.

(3) Correlation analysis showed that the content distribution of phosphorus in the sediments was influenced by many factors in the sedimentary environment, exhibiting different correlation in different seasons. TP had extremely significant correlation with APA and significant correlation with Ca, OP had extremely significant correlation with APA and significant correlation with TOC, HCl-P had extremely significant correlation with Ca, NaOH-P had significant correlation with Ca and Al, IP had significant correlation with Ca, and pH, TN as well as dissolved oxygen and temperature of the overlying water will also influence the phosphorus fractions and phosphorus contents, but their correlation was not significant.

(Received 22nd Apr 2019; accepted 4th Jul 2019)

Abstract. Five-year-old 'Fuji' (*Malus domestica* Borkh.) apple trees grafted on MM-106, M-9, M-26, and MM-111 in a commercial orchard in Çanakkale (Turkey), were used for determination of fruit quality and aroma volatiles. Fruits were sampled at the commercial harvesting stage at the end of September in 2015 and 2016. Fruit quality characteristics and aroma volatiles changed significantly in apples grown on four different rootstocks. The largest fruits (212.2 g) with highest total soluble solids (18.40%) were obtained from the trees on M9 rootstock. According to chromatography analysis, a total of 51 volatiles were detected in 'Fuji' fruits. Ester compounds were a major part of total volatiles in the fruits. The highest total ester content was obtained from the trees on M9 rootstock, whereas the lowest was from MM106 rootstock. 2-Methylbutyl acetate and ethyl 2-methylbutanoate were the main ester compounds in the fruits considering all volatiles. The total ester concentration in the total volatile compounds in the 'Fuji' apples grafted on the M9 rootstock was 95.52%. This rate was 91.28% for the M26 rootstock, 91.04% for the MM111 rootstock and 88.30% for the MM106 rootstock. The study concluded that the M9 rootstock enhances the aroma content of 'Fuji' apples.
Keywords: *pomology, quality, chromatography, ester compounds, SPME*

Introduction

The total world apple production for 2016 was 89,329,179 metric tons. China, USA, Poland, Turkey, Iran and Italy had the greatest shares of apple production. In Turkey, apples are grown in almost all parts of the country, and there was a total 3,032,164 metric tons of apple production in 2017 (FAOSTAT, 2018). The most widely-grown varieties of apples in Turkey are 'Starking Delicious', 'Golden Delicious', 'Amasya', 'Jonathan', 'Granny Smith', 'Red Chief', 'Braeburn', 'Pink Lady', 'Gala' and 'Fuji' (Özçağıran, 2005). 'Fuji' apples are one of the popular apple varieties frequently grown mostly in China, Japan, Brazil, USA, New Zealand and Spain. Besides its high fruit quality, 'Fuji' apples are long-lasting fruits. It is reported that the significant aroma compounds in 'Fuji' fruits are ethyl 2-methylbutanoate, 2-methylbutyl acetate and hexyl acetate (Echeverría et al., 2004). Aroma has been known since ancient times (Vicentini et al., 2018). Aroma is of capital importance for quality characteristics in apples. Aroma is the foremost characteristic that influences the purchase decision of a consumer about apples. There are numerous studies on volatile compounds that contribute to the flavour of an apple and more than 300 volatile compounds have been identified through chromatography techniques (Dimick and Hoskin, 1983). One of these techniques, GC-MS, helps to investigate phenolic and polyphenolic compounds in plant species (Zishan et al., 2017). Ester compounds are the main components of apple flavour (Paillard, 1990).

The selection and use of rootstock is vital. It has great impact on the characteristics of the apple variety grafted on the rootstock. It also affects yield, biotic and abiotic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1174511756

stress conditions, and quality characteristics of fruits. Many researchers have examined and published several studies on the impact of rootstocks on yield and fruit quality in apples. The most widely used rootstocks in the world are M9, MM106, MM111, and M26 (Jackson, 2003). The M9 rootstock is the most commonly used dwarf rootstock for high density planting. Apple seedling rootstocks produce trees about 35 to 40 percent larger.

According to the literature, there is no specific research concerning the comparison of aroma compounds for different widely-used apple rootstocks. This study was performed in 2015-2016 and seeks to compare the aroma volatile compounds that contribute to the flavour of 'Fuji' variety grafted on different rootstocks.

Materials and Methods

The 'Fuji' orchard was established with a row and intra-row spacing of 3 meters to 1.5 meters for the M9 rootstock, 3 meters to 2 meters for the M26 rootstock, 4 meters to 3 meters for the MM106 rootstock and 6 meters to 5 meters for the MM111 rootstock in 2010. The orchards where the fruit samples were collected, are located in the district of Lapseki, Çanakkale, Turkey (*Fig. 1*).

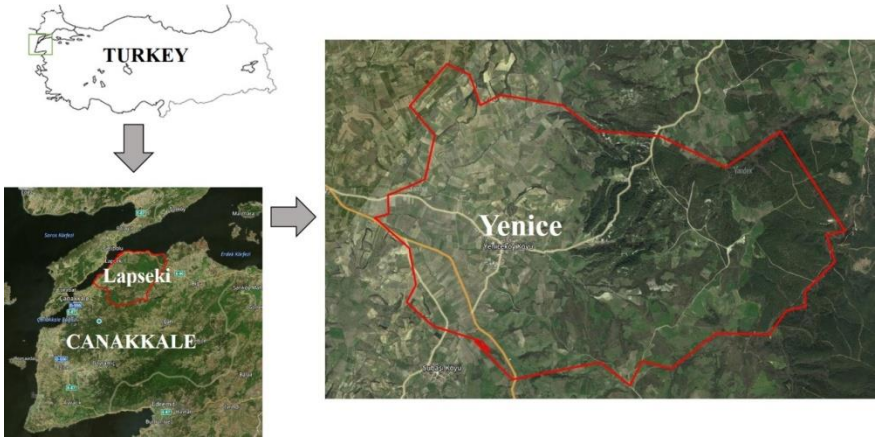

Figure 1. *Study area*

The region is well known for high quality pome fruits and stone fruits production and located at the nortwest of Turkey. In this region annual apple production is approxmately 115.000 tons. Different planting distances are used for commercial apple production due to rootstock effects on tree sizes. Application of fertilizers, pesticides, irrigation schedule were arranged according to the Global GAP certification programme for apple producers in Lapseki-Çanakkale. All the applications were made at the same time and same concentrations. The soil texture was generally clay-loamy and the reaction was slightly alkaline (pH 7.2). GPS coordinates of experimental site is 40º19'48'' N, 26º43'47'' E and elevation is 49 m above sea level.

Collection of fruit samples

The fruits of the 'Fuji' trees grafted on different rootstocks were collected in 30 September, in accordance with commercial harvest criteria. The fruits were sampled during 2015 and 2016 harvesting seasons. The fruits collected did not have any harmful

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1174511756

symptoms or suffer from any disease. These fruits were then transferred to the laboratories and prepared for pomological and chromatography analyses. Five trees from each rootstock / Fuji combinations were used for fruit sampling and 20 fruits from each trees were harvested for further analyses. So, one hundred fruits were used for each rootstock / Fuji combinations.

Evaluation of fruit quality characteristics

Fruit weight of 'Fuji' apples (g) was calculated considering the average value of 20 fruits by individual weighing with a 0.01 g precision digital balance (Model 612, Sartorius). Flesh firmness was measured on two paired sides of each fruit by removing a 1 mm thick disk of skin from each side of the fruit using a penetrometer (Model FT-327, Effegi). Total soluble solids (TSS) in the fruit juice were measured with a digital refractometer (PR-101, Atago) and expressed as °Brix. Titratable acidity (TA) was determined by using a sample of the juice from 20 fruits. The juice samples were diluted with distilled water (1:2) and titrated to pH 8.2 with a benchtop pH meter (InoLab pH 7110, WTW) with 0.1 N NaOH. The results were expressed as g malic acid/100 g fresh weight (FW).

Volatile extraction and GC/MS conditions

For headspace sampling, SPME fibres coated with polydimethylsiloxane–divinylbenzene (Supelco Co., Bellefonte, PA, USA) were used as described before by Wang et al. (2009). The fibre was activated according to the manufacturer's instructions. The headspace solid phase microextraction method was used for the isolation and concentration of volatiles. For each extraction, 2 g of the pulp and 0.6 g NaCl were placed in a 4 ml capped vial. The vial was placed in a 45°C water bath with a magnetic stirrer to warm to constant temperature, and the SPME fibre was exposed to the headspace of the sample to adsorb the analyses for 30 min. The fibre was then introduced into the heated chromatograph injector port.

The identification and quantification of volatile compounds in the samples were performed on a Shimadzu QP2010 Plus GC-MS (*Fig. 2*) using the method described by Wang et al. (2009) with a slight modification.

Figure 2. *Shimadzu QP 2010 Plus GS-MS system for chromatography analyses of volatiles*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1174511756

Separations were done with a DB-WAX column (60 m × 0.2 mm, i.d., and 0.25 µm, film thickness; J & W, USA), which was preconditioned at 250°C for a period of 2 hours. Helium was used as the carrier gas (3 ml/min). The analysis was conducted following the program at 40°C for 2 min, 40-150°C (3°C/min), then 150-220°C (10°C/min), and 250°C (5 min). The temperature of the injector was 250°C. The interface between GC and MS was at 250°C. Electron impact ionization was at 70 eV, EI mode, and the filament current was 0.25 mA. The ion-source temperature was 200°C. The scan range was 35-425 aMU.

Statistical analysis

Differences between strains were evaluated with analysis of variance using the SAS General Linear Model procedure: PROC GLM procedure of SAS (version 6.12; SAS Institute, Cary NC) (SAS, 1997). When this analysis was statistically significant (Ftest), mean separation was performed using the Tukey Test.

Results

The 'Fuji' apple trees budded in mid-March under the ecological conditions where the study was performed, and came into full bloom by April 20th. The harvest was gathered on September 30th in both years. The total number of days between full bloom and the harvest date was 152 to 158 days. *Table 1* and *Fig. 3* present the results from the pomological analysis of the fruit samples obtained in both years.

Among the 'Fuji' apple varieties grafted on different rootstocks, the fruits grafted on M9 were 212.20 grams in weight, which was the highest fruit weight. The apples with the highest fruit width were 82.43 mm grafted on M9, whereas those with the lowest fruit width were the ones grafted on MM111. Further, the apples with the highest fruit length were 67.59 mm grafted on M9, while those with lowest fruit length were 47.19 mm grafted on MM111. The fruits grafted on MM106 had the highest fruit firmness of 7.00; on the other hand, the fruits grafted on M9 and MM111 had lowest fruit firmness of 4.96. The fruits with the highest amount of soluble solids were grafted on the M9 rootstock with 18.40%, while the fruits with the lowest amount of soluble solids were grafted on MM111 with 12.40%. The highest pH value in the fruits was 4.70 grafted on MM106, while the lowest pH value in the fruits was 3.80 grafted on the MM111. The apples with the highest total acidity values were grafted on MM111 of 0.90%, while the apples with the lowest total acidity values were grafted on M9 of 0.48%.

The 'Fuji' apples grafted on M9 have an average fruit weight of 283.96 grams, fruit width of 84 mm, fruit length of 73.6 mm, 12.96% soluble solids, 0.59% total acidity and pH of 3.91 (Baytekin and Akca, 2011). Another study found that the 'Fuji' variety grafted on the M9 rootstock had a fruit weight of 197.33 grams and 16% soluble solids (Ünivar and Pırlak, 2016). Various researchers have reported the positive effects of the M9 rootstock on fruit weight (Nicolai, 1998; Brown and Wolfe, 1999; Autio and Krupa, 2001; Marini, 2002).

Volatile aroma compounds

The chromatography analyses of the fruit samples obtained from the apple trees grafted on different rootstocks successfully revealed the volatile compounds. *Table 2* presents the results for the volatile compounds and amounts of the samples from 2015. *Table 3* shows the results of the samples from 2016; *Table 4* presents the average results for both years.

Based on the results from 2015 and 2016, there were a total of 51 volatile compounds identified in both years. The aroma profiles in 2015 and 2016 were similar since the climate conditions in these two years were similar. The analyses concluded that 22 of the compounds were ester compounds; 17 of them were alcohol compounds; 7 of them were acid compounds and 5 were aldehyde compounds.

The total aroma amount of the fruits examined in the year 2015 varied between 275.13 µg/kg and 559.58 µg/kg. The aroma compounds in the 'Fuji' apples on the M9 rootstock were 2.03 times more than those on the MM106 rootstock (*Table 2*). The total ester content in the 'Fuji' fruits on the M9 rootstock was 535.02 µg/kg, whereas the MM106 rootstock had the lowest ester content of 242.29 µg/kg. This was also the case for 2016 (*Table 3*). In 2016, the total volatile compounds from M9 amounted to 542.05 µg/kg, while the total volatile compounds from MM106 amounted to 300.92 µg/kg. As for the ester compounds, those from M9 were 517.34 µg/kg and those from MM106 were 266.49 µg/kg. Considering the average values, the total volatile compounds in the 'Fuji' fruits on the M9 rootstock amounted to 550.89 µg/kg. The M9 rootstock was followed by MM111 (409.16 µg/kg), M26 (352.00 µg/kg), and MM106 (288.15 µg/kg) (*Table 4*). That being said, it can be argued that compared to other rootstocks, the M9 rootstock has an enhancing effect on the aroma content of the 'Fuji' fruits (*Fig. 4*).

*MSD: Minimum Significant Difference on Tukey multiple range test by $p<0.01$, NS: Non-Significant

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1174511756

The total ester concentration in the total volatile compounds of the 'Fuji' apples grafted on the M9 rootstock was 95.52%. This rate was 91.28% for the M26 rootstock, 91.04% for the MM111 rootstock and 88.30% for the MM106 rootstock. Ester compounds are the main components of apple flavours and constitute 85 to 95% of the total volatile compounds (Paillard, 1990). Isoleucine, an amino acid, plays an important role in the synthesis of ester compounds. A greater availability of isoleucine amino acid increases the concentration of ester compounds (Sugimoto et al., 2011). Thus, it seems that the dwarf M9 rootstock has an increasing effect on the amount of isoleucine.

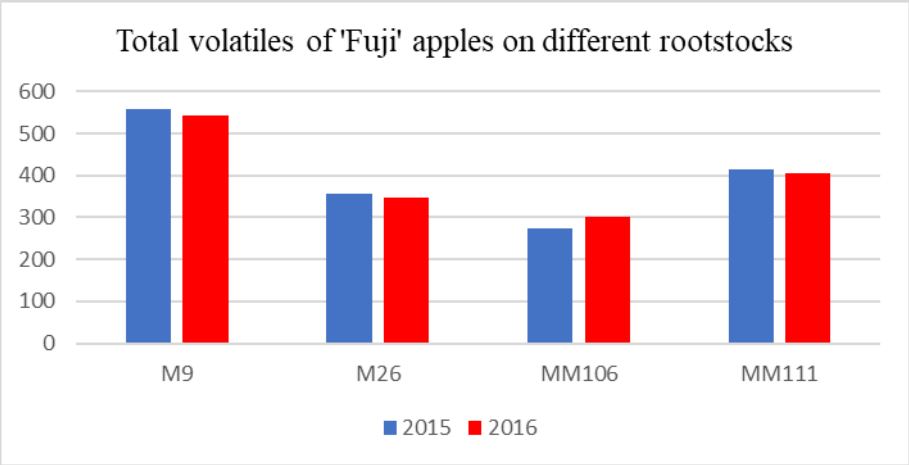

Figure 4. *Total volatiles of 'Fuji' apples on different rootstocks in two years*

In the year 2015, the ratio of 2-methylbutyl acetate compound in the 'Fuji' varieties grafted on M9 was 45.48% in all ester compounds and 43.49% in all volatile compounds; in 2016, this rate was 48.45% in all ester compounds and 46.24% in all volatile compounds. Further, in the year 2015, the ratio of 2-methylbutyl acetate compound in the 'Fuji' varieties grafted on M26 was 38.53% in all ester compounds and 35.20% in all volatile compounds; in 2016, this rate was 40.04% in all ester compounds and 36.52% in all volatile compounds. As for the MM106 rootstock, the ratio was 39.85% in all ester compounds and 35.10% in all volatile compounds in 2015, and it was 45.52% in all ester compounds and 37.66% in all volatile compounds in 2016. Lastly, for the MM111 rootstock, the ratio was 35.10% in all ester compounds and 32.01% in all volatile compounds in 2015, and it was 33.92% in all ester compounds and 30.83% in all volatile compounds in 2016. The other important ester compound in the 'Fuji' apples was ethyl 2-methylbutanoate. In the fruit samples obtained in 2015, the amount of this compound was 185.45 µg/kg for the M9 rootstock, 125.76 µg/kg for the M26 rootstock, 124.78 µg/kg for the MM111 rootstock, and 90.45 µg/kg for the MM106 rootstock (*Table 2*). In 2016, the amount was 162.47 µg/kg for the M9 rootstock, 121.52 µg/kg for the MM111 rootstock, 118.44 µg/kg for the M26 rootstock, and 96.78 µg/kg for the MM106 rootstock (*Table 3*). In the year 2015, the ratio of ethyl 2-methylbutanoate in the 'Fuji' varieties grafted on M9 was 34.66% in all ester compounds and 33.14% in all volatile compounds; in 2016, this rate was 31.40% in all ester compounds and 29.97% in all volatile compounds. Further, in the year 2015, the ratio of ethyl 2-methylbutanoate compound in the 'Fuji' varieties grafted on MM106, where the compound was found at the lowest amount, was 37.33% in all ester

DOI: http://dx.doi.org/10.15666/aeer/1705_1174511756

compounds and 32.88% in all volatile compounds; in 2016, this rate was 36.32% in all ester compounds and 32.16% in all volatile compounds. The average amount of the compound was 173.96 µg/kg for the M9 rootstock, 123.15 µg/kg for the MM111 rootstock, 122.10 µg/kg for the M26 rootstock and 93.62 µg/kg for the MM106 rootstock (*Fig. 5*).

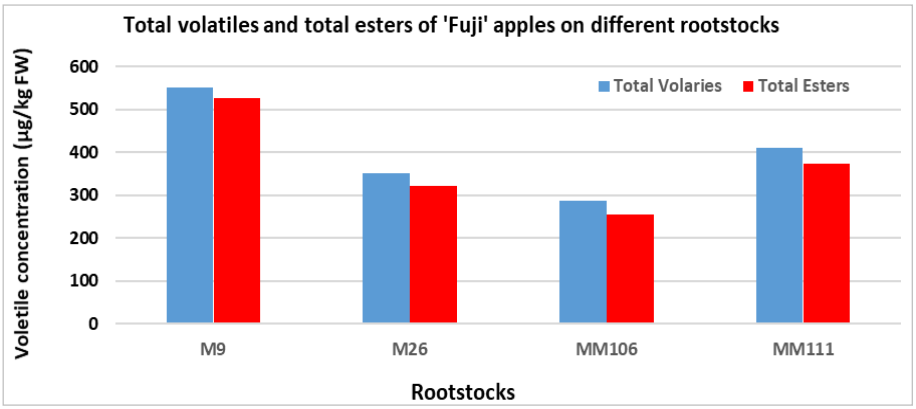

Figure 5. *Comparison of total volatiles and total ester concentrations of 'Fuji' apples grafted on different rootstocks in two years*

Besides, hexyl acetate and butyl propanoate are also notable among the ester compounds. Based on the average amount of these compounds, the 'Fuji' fruits obtained from the M9 rootstock yielded different results compared to other rootstocks (*Table 4*). Several researchers reported that esters are the main component groups of apple flavour (Echeverría et al., 2004; Mannucci et al., 2017). A study by Qin et al. (2017) identified 64 compounds based on the aroma profile of 'Fuji' apples gathered from 43 different regions in China. The researchers identified 43 ester compounds and the proportion of ester compounds in the total aroma compounds was 89.9%. As for the total amount of alcohol, the fruits collected from the MM111 rootstock had the highest amount of alcohol in both years (25.29 and 25.45 µg/kg). The M9 rootstock had the lowest amount of alcohol, which was 16.53 µg/kg and 16.51 µg/kg, respectively (*Table 2* and *Table 3*). Lower amounts of acidic compounds, which are among volatile compounds, were obtained compared to the amounts of the other main compound groups. In terms of the total acidic compounds, acetic acid identified in the MM111 rootstock was highest (*Table 4*). The amount of acetic acid in this rootstock was 1.40 µg/kg in 2015 and 1.32 µg/kg in 2016 (*Table 2* and *Table 3*).

Following esters and alcohols, aldehydes were the volatile compound group with the next highest level. Hexanal and [E]-2-hexanal were the compounds with the highest values in this group. The MM106 rootstock had the highest average value in terms of the total amount of aldehyde compounds (11.66 µg/kg). The lowest amount of aldehyde was found in the fruits on the M9 rootstock (7.40 µg/kg) (*Table 4*).

The results of this two-year study showed that the M9 rootstock has positive impact on the aroma profile of the 'Fuji' apples. It is remarkable that the M9 rootstock considerably increases the amount of ester compounds particularly.

Discussion

Wang et al. (2005) analysed the volatile compounds of conventional and organically cultivated 'Fuji' apple varieties on GC-MS using SPME method. As a result, 64 compounds were found in organic system and 51 compounds were found in control fruits. Tao et al. (2011) used the GC-MS with SPME method to determine the aroma components in eight apple varieties. As a result, 28 esters, 3 alcohols and 2 alkane compounds were determined. A study by Kviklys et al. (2014) revealed that the total phenol content of the M9 rootstock was higher than the M26 rootstock. However, they reported that there was no distinctive difference between different rootstocks in terms of the total phenol content. Unlike the total phenolic compounds, the amount of volatile compounds varied between rootstocks.

Although the effect of rootstocks on the quality characteristics of fruits has been analysed in different varieties, the studies about their impact on aroma profile are extremely low in number. Seker et al. (2017) reported the positive effects of the 'GF677' rootstock on the aroma profile of 'Cresthaven', a peach variety. Further studies may focus on the effect of rootstocks on aroma profile in different apple varieties.

Conclusion

Rootstocks may have great effect on aroma compound formation due to different carbohydrate and fatty acid metabolism pathways. So, utilization of different rootstocks should be considered for specific aroma compound improvements in apples.

Abstract. The aim of this study was to analyze the impact of various systems of soil tillage and nitrogen doses on the mineral composition of the grain of the common winter wheat cultivar (*Triticum aestivum* ssp. *vulgare*), cv. Azra selected for the conventional intensive production. The field experiment was conducted on luvic chernozem in completely randomized blocks. Wheat was grown under three soil tillage systems: conventional tillage, mulch tillage and no-tillage, and the experiment included two doses of N fertilization (60 and 120 kg ha^{-1}). Concentrations of eighteen elements (As, Al, Ba, Ca, Co, Cr, Cu, Fe, Hg, K, Mg, Mn, Ni, S, Sr, P, V and Zn) in wheat grain samples were determined by means of inductively coupled plasma with optical emission spectrometry (ICP–OES). The results indicated that concentrations of the studied elements in the wheat grain were significantly affected by the tillage systems and fertilization rates ($p < 0.001$), as well as by the interaction of these two factors. A smaller dose of nitrogen fertilizer (60 kg ha^{-1}) had a significantly better impact on the concentration of macro- and microelements in the wheat grain than the dose of 120 kg N ha^{-1}. The reduced tillage systems and lower nitrogen rates in nutrition had a better effect on the increase of the content of the studied elements in the wheat grain than the conventional cultivation which applied higher nitrogen rates.
Keywords: *wheat grain, production system, fertilization, macroelements, microelements, ICP-OES*

Introduction

Wheat (*Triticum aestivum* L.) is one of the most significant cultivated species and the staple food for more than 50% of the global population (Rizwan et al., 2016). The average per capita consumption of wheat in developed countries and developing countries amounts to 95 kg and 61 kg, respectively (FAO, 2016). In Serbia, the average per capita consumption of wheat is 180 kg, which is significantly higher than the consumption rates in most European countries (USDA, 2017). Due to its high global

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1175711771

consumption in the form of different food products, wheat is considered to be an important source of minerals in the everyday human nutrition.

The bioavailability of microelements in cereals is generally low (Kan, 2015; Dapkekar et al., 2018) and the concentrations of trace elements that are valuable for human nutrition steadily decrease with an increase in yield, which has adverse consequences, including 'hidden hunger' (Cakmak et al., 2010). Approximately half of the global population has zinc deficiency, and anaemia induced by iron deficiency is the most common phenomenon in Europe (Kan, 2015; Winiarska-Mieczan et al., 2019). In this context, the increase of micronutrient concentrations such as Fe and Zn in cereal grain has become a high-priority research area (Cakmak et al., 2010; Kutlu, 2018). Certain heavy metals (Zn, Cu and Ni) are necessary for biological processes in the human organism and they represent integral and catalytic components of proteins and enzymes, but they can be toxic in an overdose (Tiwari and Lata, 2018). On the other hand, toxic or non-essential elements such as As, Cd, Cr and Pb have no biological function in the human body and can be harmful for human health even in extremely low concentrations in case of long-term exposure (Lei et al., 2015; Zhang et al., 2019). What is more, these metals are responsible for the depletion of certain essential elements (Abbas et al., 2017).

The optimal application of fertilizers is an important factor for obtaining high yield and high quality products. Among the elements of mineral nutrition, nitrogen has the most important role in forming the yield (Litke et al., 2018), quality and utilizable value of the wheat grain (Blandino et al., 2016). Numerous studies have shown that the application of nitrogen fertilizer can promote the accumulation of certain microelements in the wheat grain, such as Fe and Zn (Kutman et al., 2011; Singh et al., 2018). This effect is explained by the fact that the sufficient supply of nitrogen increases the content of proteins in the grain, and the proteins are where Fe and Zn are accumulated (Barunawati et al., 2013). Similarly, previous research has shown that the concentration of Fe and Zn has a significant positive correlation with the content of proteins and P in the wheat grain (Zhao et al., 2009).

There has recently been an increasing interest in reduced soil tillage, stimulated by ecological and economic reasons (Sharma et al., 2011). According to some authors, the methods of reduced soil tillage increase soil density and inadequate distribution of nitrogen, phosphorus and microelements (Klikocka and Marks, 2018), which can consequently affect the uptake of mineral matter and thus influence the yield and crop quality. However, Stanislawska-Glubiak and Korzeniowska (2012) did not determine significant differences between various tillage systems regarding the content of microelements in wheat plants, except in respect of P and Mg in the early growth phases when the concentration of these elements was higher in the NT and MT systems than in CT. A similar study indicated that the NT system did not lead to the impairment of the quality of wheat and maize grains in terms of the primary mineral content, which is extremely significant for the nutritional value of the wheat grain (Stanisławska-Glubiak and Korzeniowska, 2012).

Scientific literature is still deficient in information regarding the impact of tillage on the chemical content of the wheat grain. Thus, the aim of this research was to determine the impact that tillage systems and different fertilization rates, within the applied cultivation technology, had on the differences in the content of the studied elements in the wheat grain of the cultivar Azra.

Materials and methods

Field experiment

The examination of the effects of different tillage systems and fertilization rates on the content of macro- and microelements in the wheat grain was conducted at the research field "Radmilovac" that belongs to the Faculty of Agriculture (44°45' N, 20°35' E, Serbia) in the growing season of 2016-2017. The soil type was luvic chernozem (WRB, 2014), with the following characteristics: $pH_{(H2O)}$ 8.04, total content of N 13%, available forms of phosphorus 22.18 mg P_2O_5 100 g^{-1} dry weight and potassium 19.10 mg K_2O 100 g^{-1} dw, content of humus in the topsoil layer 2.45%.

The study used the winter cultivar of common wheat (*Triticum aestivum* ssp. *vulgare*), cv. Azra, selected for the conventional intensive production. Cv. Azra is a winter hardy cultivar of medium late maturity. It is very well-resistant to *Erysiphe graminis* DC. and well-resistant to *Puccinia striiformis* f. sp. *tritici* (*Pst*). Its hectolitre weight amounts to 80 - 85 kg, protein content is 11.5 - 13.0%, and it belongs to the B1-B2 quality group. The previous crop was maize (*Zea mays* L.).

A two-factor field trial was arranged using split plot design in three replications, with the area of the elementary plot amounting to 6 m^2. The examined factors were tillage and fertilization. Three different tillage systems were used and two levels of fertilization were applied (*Fig. 1*).

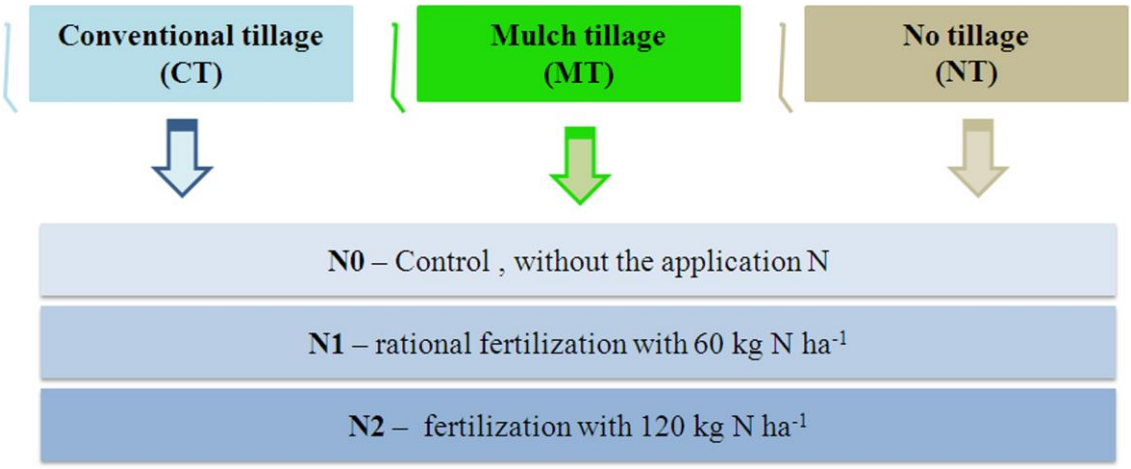

Figure 1. *Experiment design*

1. Conventional tillage (CT) - ploughing using a mouldboard plough at 25 cm and pre-sowing tillage using a disc harrow and a harrow,
2. Mulch tillage (MT) - tillage performed using a chisel plough at 25 cm with more than 30% of maize crop residues on the soil surface and the pre-sowing tillage using a disc harrow and a harrow,
3. No tillage (NT) - seeds were sown directly into unploughed soil, with the complete maize crop residues left on the surface.

Basic fertilization by NPK fertilizers was conducted during the autumn in the same quantity for all treatments. Spring fertilization was performed in the tillering phase using the KAN mineral fertilizer (25-27% N) and it differed in terms of pure nitrogen

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1175711771

quantities. Sowing was conducted on October 28th, 2016 with the crop density of 650 seeds m^{-2}. Standard cultivation measures in wheat production were applied and harvest was performed on June 29th, 2017.

Grain sample preparation for chemical analysis

In the grain of Azra cultivar, concentrations of macroelements: calcium (Ca), potassium (K), magnesium (Mg), phosphorus (P) and sulphur (S), as well as microelements: aluminium (Al), arsenic (As), barium (Ba), cobalt (Co), chromium (Cr), copper (Cu), iron (Fe), mercury (Hg), manganese (Mn), nickel (Ni), strontium (Sr), vanadium (V) and zinc (Zn) were determined.

The representative samples were made using a random square method as described by Korunović and Stojanović (1989). The wheat grain samples were ground in the laboratory mill SJ-500 (producer "Metron"), and then prepared for the chemical analysis. Both soil and grain samples were subjected to the process of "wet digestion" as described in our previous work (Popović-Djordjević et al., 2019).

The determination of the content of the elements was performed using the inductively coupled plasma-optical emission spectroscopy (ICP–OES) analysis. The analysis was conducted using the instrument Thermo Scientific iCAP 6500 Duo ICP (Thermo Fisher Scientific, Cambridge, UK). The calibration of the instrument was performed by means of two certified multielement ICO-OES standards: Multi–Element Plasma Standard Solution 4, Specpure® (Alfa Aesar GmbH & Co KG, Germany) and SS–Low Level Elements ICV Stock (10 mg L–1K) (VHG Labs, Inc–Part of LGC Standards, Manchester, NH 03103 USA). The analytic process was verified by the certified reference material EPA Method 200.7 LPC Solution (ULTRA Scientific, USA). The correlation of the measured concentrations with the certified values amounted to 96-104%.

Statistical analysis

Data processing was performed in the SPSS statistical package. The method for analyzing the variance (*F test*) for dual factor examination was used, and the significance of differences between the treatments was tested with the LSD test at the significance level of $p < 0.05$. Statistical data are given in *Table A1* in the *Appendix*.

Results

Concentration of macroelements in the wheat grain

The total content of the examined macroelements, as well as their average values are presented in *Table 1*. The total content of macroelements detected in the NT system (9968.11 mg kg^{-1}) was higher ($p < 0.05$) than in the MT and CT systems, by 1.7% and 5.3%, respectively. Differences in the treatment by means of nitrogen fertilization were also significant, where the content of macroelements in the control (9968.11 mg kg^{-1}) was higher by 2.3 and 3.2% than at the N1 and N2 levels, respectively.

The concentration of the examined macroelements, expressed in mg kg^{-1}, was in the following order: P (4058.89) > K (3350.33) > Mg (1169.55) > S (996.89) > Ca (171.33). The analysis of variance showed the statistically significant variability of macroelement concentrations among the studied tillage systems, as well as among the rates of nitrogen fertilization (*Table A1*). Considering the differences in the tillage

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1175711771

systems, the results indicate that the lowest concentration of all studied macroelements was detected in the CT system. The highest concentration of Ca (178.67 mg kg^{-1}), K (3410.33 mg kg^{-1}), Mg (1236.33 mg kg^{-1}) and P (4167.00 mg kg^{-1}) was detected in the NT system, while the highest concentration of S (1016.33 mg kg^{-1}) was found in the MT system.

Data are expressed as mean ± standard deviation (n = 3)

The concentration of macroelements in the grain significantly varied depending on different levels of nitrogen fertilization (*Tables 1* and *A1*). In the control group, there was a significantly higher concentration of P (4150.00 mg kg^{-1}), K (3403.33 mg kg^{-1}) and Mg (1210.33 mg kg^{-1}) than in the N1 and N2 variant. The highest concentration of Ca (176.00 mg kg^{-1}) was in the cases when the dose of 60 kg N ha^{-1} was applied, while the sulphur concentration in N2 (1007.33 mg kg^{-1}) was higher by approximately 2% than in the N0 and N1 variants (*Fig. 2*).

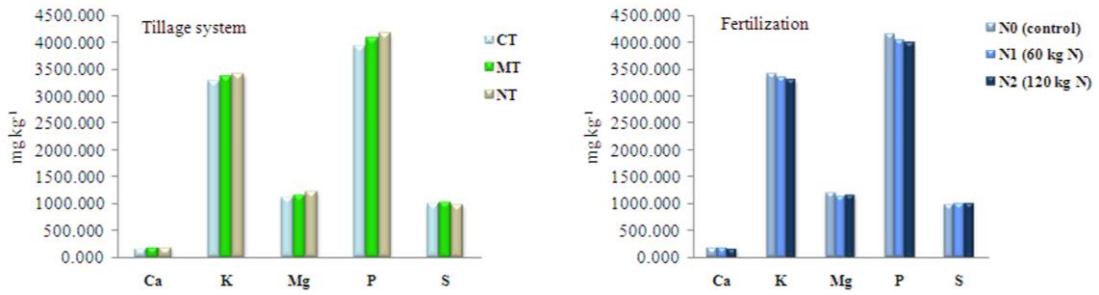

Figure 2. *Changes of macroelement concentration (mg kg^{-1}) in the grain within different tillage systems and levels of fertilization*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1175711771

Observing the interaction between the tillage systems and the levels of nitrogen fertilization, it can be noticed that the highest average value of Ca (189 ± 4 mg kg^{-1}) was recorded in the NT system with the N0 variant, and it was significantly higher than in other tillage systems and levels of nitrogen fertilization. It is interesting that the differences in the K concentration were not significant between the CT system with the N0 variant (3652 ± 34 mg kg^{-1}) and the NT system with the N2 variant (3627 ± 11 mg kg^{-1}). On the other hand, the concentrations of Mg (1300 ± 7 mg kg^{-1}), P (4470 ± 14 mg kg^{-1}) and S (1031.0 ± 1.0 mg kg^{-1}) in the CT system with the variant N0 were significantly higher than in other tillage systems and fertilization levels. The obtained results indicate that the reduced tillage and/or application of lower nitrogen rates do not decrease the macroelement contents in the wheat grain (*Fig. 2*).

Concentration of microelements in the wheat grain

The total content of microelements in the wheat grain and their average concentrations are presented in *Table 2*. The research results showed that the microelement content in the grain was affected by the tillage system and fertilization rate, as well as by the interaction of these factors (*Table A1*). There is a small but significant difference regarding the microelement content between the CT system (103.691 mg kg^{-1}) and NT system (102.048 mg kg^{-1}). Considering the differences between the rates of nitrogen fertilization, it can be noticed that the total content of microelements in the N2 variant (76.096 mg kg^{-1}) is significantly lower than in N1 (108.229 mg kg^{-1}) and N0 (104.880 mg kg^{-1}).

The concentrations of Al, Cr and Hg were below the limit of detection (LOD) in all studied grain samples of Azra cultivar. The concentrations of detected microelements, expressed in mg kg^{-1}, were in the following order: Fe (38.10) > Zn (27.90) > Mn (22.26) > Cu (3.87) > Ba (2.65) > Sr (0.83) > V (0.35) > Ni (0.29) > As (0.11) > Co (0.06).

The content of Fe detected in the NT system (46.170 mg kg^{-1}) was significantly higher than in the MT (23.390 mg kg^{-1}) and CT system (44.740 mg kg^{-1}). The highest concentration of Fe in the amount of 47.330 mg kg^{-1} was detected in the variant of fertilization with the smaller dose of nitrogen (60 kg ha^{-1}), while the lowest concentration (20.200 mg kg^{-1}) was detected in the application of nitrogen at the rate of 120 kg ha^{-1} (*Fig. 3*). The interaction of the examined factors indicates that the highest Fe concentration (101.3 ± 1.0 mg kg^{-1}) was obtained in the NT system with the N0 variant, and it was significantly higher than in other tillage systems and fertilization levels (*Table 2*).

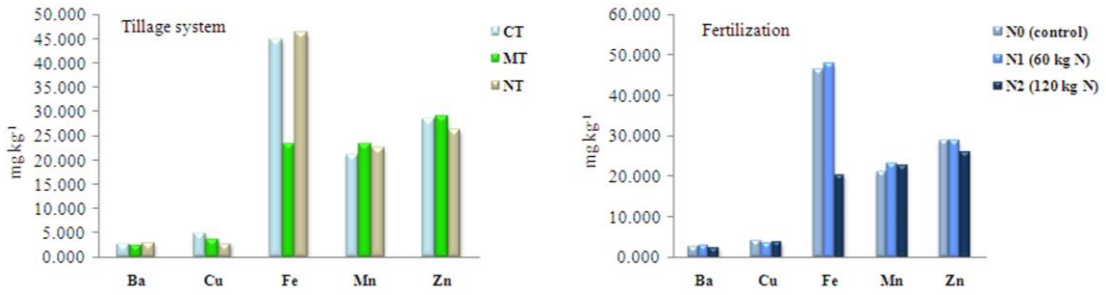

Figure 3. *Changes of Ba, Cu, Fe, Mn and Zn concentration (mg kg^{-1}) in the grain within different tillage systems and levels of fertilization*

Al, Cr and Hg were below LOD; Data are expressed as mean ± standard deviation (n = 3)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1175711771

Significant differences between the tillage systems were also detected regarding the concentration of Zn. In the NT system (26.210 mg kg^{-1}) it was lower by 9.7% and 7.9% than in the MT and CT systems, respectively. Considering the variants of nitrogen fertilization, Zn concentration was significantly lower than in the control, particularly in the N2 variant (10.2%). Observing the interaction of the examined factors, it can be noticed that the highest Zn concentration was detected in the CT system with the control variant (34.21 ± 0.06 mg kg^{-1}), in the MT system with the N1 variant (31.95 ± 0.02 mg kg^{-1}), and in the NT system with the N2 variant (28.14 ± 0.10 mg kg^{-1}) (*Table 2*).

When it comes to Mn, there were also significant differences regarding the tillage system and fertilization rate. The highest Mn concentration was detected in the MT system (23.233 mg kg^{-1}), and it was higher than in the CT and NT systems by 10.1% and 3.6%, respectively. The Mn concentration in the N1 variant (23.200 mg kg^{-1}) was higher than in the N0 and N2 variants by 10.1% and 3.2%, respectively.

The application of the conventional tillage system resulted in the significantly higher concentrations of Cu (5.066 mg kg^{-1}), Ni (0.553 mg kg^{-1}) and Co (0.103 mg kg^{-1}) than in the NT and MT systems, while there were no significant differences regarding nickel and cobalt between the NT and MT systems. It was also noticed that the concentrations of Cu and Ni in the grain decreased with the increased rate of nitrogen fertilization. Therefore, the highest concentrations of these microelements were detected in the variant N0 (4.170 mg kg^{-1} and 0.490 mg kg^{-1}). The concentration of Co in the wheat grain was the highest when the application of nitrogen was at the rate of 60 kg ha^{-1} and the differences between the variants N0 (0.041 mg kg^{-1}) and N2 (0.034 mg kg^{-1}) were not significant.

The highest Ba concentration was detected in the NT system (2.893 mg kg^{-1}), which was higher ($p < 0.05$) by 20.2% and 8.9% than in the MT and CT systems, respectively. Significant differences were also obtained at different fertilization rates. The Ba concentration in the N2 variant (2.417 mg kg^{-1}) was lower by 6.1% and 18.5% than in the control and N1 variant, respectively.

The content of Sr in plants is highly variable. The research results showed that the Sr concentration in the grain was the lowest in the CT system (0.725 mg kg^{-1}), and it was lower than in the MT and NT system by 17.7% and 16.5%, respectively. When it comes to the differences in fertilization rates, the lowest Sr concentration (0.789 mg kg^{-1}) in the grain was detected when applying the dose of 60 kg N ha^{-1}, while its concentration was the highest (0.851 mg kg^{-1}) at the rate of 120 kg N ha^{-1}.

The highest concentrations of V were detected in the MT system (0.531 mg kg^{-1}) and at the nitrogen application at a rate of 60 kg ha^{-1} (0.543 mg kg^{-1}). The intensity of soil tillage had an impact on the increase of As content, while the application of N fertilizers decreased the concentration of this trace element in the wheat grain (*Fig. 4*).

Discussion

A high yield of good quality is based on the proper use of agro-technical measures, primarily on the appropriate soil tillage and adapted crop fertilization. In modern agriculture, it is important to understand the effects of these measures since they can affect the product quality (Klikocka and Marks, 2018), and also contribute to the protection and preservation of soil fertility.

DOI: http://dx.doi.org/10.15666/aeer/1705_1175711771

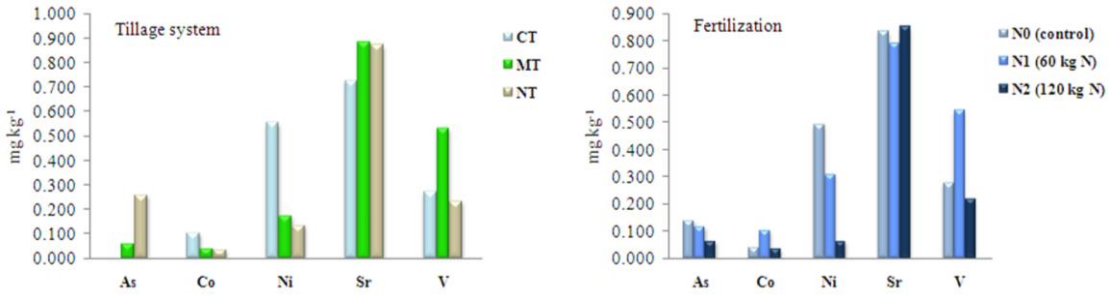

Figure 4. *Changes of As, Co, Ni, Sr and V concentration (mg kg^{-1}) in the grain within different tillage systems and levels of fertilization*

It was determined that the mineral content in the wheat grain, cv. Azra, differed significantly depending on the tillage system. The grain originating from the NT system had a significantly higher content of macroelements than in the MT system (1.7%) and CT system (5.3%). The highest concentrations of Ca (178.67 mg kg^{-1}), K (3410.33 mg kg^{-1}), Mg (1236.33 mg kg^{-1}) and P (4167.00 mg kg^{-1}) were detected in the NT system ($p < 0.001$), while the highest S concentration (1016.33 mg kg^{-1}) was found in the wheat grain cultivated in the MT system ($p < 0.05$). The obtained results suggest that the reduced tillage systems can have a positive effect on the concentration of macroelements in the wheat grain. According to De Vita et al. (2007), the NT system is more efficient than the CT in arid environments since it decreases the evaporation of moisture from soil surface, which ensures its better availability to plants. Furthermore, Wozniak (2010) states that the reduced tillage and lowered rates of N fertilizers increase the content of minerals in the wheat grain.

Nitrogen has a crucial role in the vegetative growth and crop quality (Faizy et al., 2017; Litke et al., 2018). However, the intensive application of mineral fertilizers has different local and global effects on the environment and human health. The research results have shown that the lowest average concentrations of Ca (165.33 mg kg^{-1}), K (3301.33 mg kg^{-1}) and P (3986.67 mg kg^{-1}) were detected in the variant with the highest rate of nitrogen fertilization (120 kg ha^{-1}). Studying the nitrogen application in protected areas, Bar-Tal et al. (2001) concluded that the application of larger doses of nitrogen decreased the assimilation of Ca, which is probably a consequence of the increased concentration of NH_4^+. Other studies showed that higher rates of N fertilizer application increased the content of phosphorus and potassium in the wheat grain (Gaj and Gorski, 2014; Faizy et al., 2017), which can be affected by numerous factors such as assortment, crop maturity, soil type and content, fertilizer type and rate (Jākobsone et al., 2015; Kan, 2015). In this study, fertilizer application did not have a positive effect on the increase of Mg concentration in the wheat grain. Nutrition treatment at the N rates of 60 and 120 kg ha^{-1} had similar values of Mg content, and they were significantly lower than in the control treatment (1210.33 mg kg^{-1}). Considering the studied macroelements, only S had a detected rise of concentration connected to the increase of N fertilizer dose. Similarly, Jamal et al. (2010) stated that there was a high positive correlation between the nitrogen and sulphur contents in wheat.

The analysis of variance of the obtained results showed that tillage had a statistically significant effect on concentration of microelements in the grain of cv. Azra. The highest ($p < 0.05$) concentrations of Fe (46.170 mg kg^{-1}), Ba (2.893 mg kg^{-1}) and As (0.257 mg kg^{-1}) were detected in NT, while the concentrations of Zn (29.027 mg kg^{-1}),

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1175711771

Mn (23.233 mg kg^{-1}), Sr (0.881 mg kg^{-1}) and V (0.531 mg kg^{-1}) in the MT system were significantly higher than in the CT and NT systems (*Figs. 3* and *4*). Arsenic is an environmental and food-chain contaminant, and inorganic As is a class-one carcinogen (Zhao et al., 2010). Wozniak and Makarski (2012) underline that the availability of microelements in well aerated soils is lower than in the less aerated ones, so it can be concluded that the multiple aeration of ground in the ploughing system depresses the availability of Zn and Cu, unlike in the ploughless tillage. The assimilation of Fe, Cu, Mn and Zn in the reduced tillage systems is easier not only for wheat but also for weeds in the calcareous soil (Taghizadeh et al. 2014). In addition, Santiago et al. (2008) found out that there was a higher concentration of Mn, Cu and Zn in the plants cultivated in the NT system than in the ones from CT and MT systems. Higher concentration of Mn in the conditions of reduced tillage (23.233 mg kg^{-1} and 22.433 mg kg^{-1}) than in the case of conventional tillage (21.100 mg kg^{-1}) can be explained by the better moisture content in the soil in MT and NT systems, which was confirmed by other studies (Wozniak and Makarski, 2012). The decrease of mineral content in the food is considered to be related to the intensive agricultural practices which can result in their depletion from the soil (Kan, 2015).

Reduced tillage increases the content of organic matter and preserves soil fertility more than the conventional management practices (De Sanctis et al., 2012). Rizwan et al. (2016) say that organic amendments could be used to reduce the uptake of toxic trace elements by crop plants. The research results have shown that the lowest concentrations of microelements such as Co (0.036 mg kg^{-1}), Cu (2.813 mg kg^{-1}) and Ni (0.136 mg kg^{-1}) were detected in the NT system (*Figs. 3* and *4*). Other authors also underlined the tendency of heavy metals to make stable compounds with the organic matter and thus lower their bioavailability (Kabata Pendias, 2011).

Understanding the interactions between nitrogen and other elements is the key for the improvement of the efficiency of fertilizer application (Domagała-Świątkiewicz and Gąstoł, 2013). The highest total content of microelements (108.229 mg kg^{-1}) was recorded with the nitrogen application at a dose of 60 kg ha^{-1}, while the lowest (76.096 mg kg^{-1}) was detected when the dose of 120 kg ha^{-1} was applied. Also, the lowest concentrations of Ba (2.417 mg kg^{-1}), Co (0.034 mg kg^{-1}), Ni (0.064 mg kg^{-1}), V (0.217 mg kg^{-1}), Zn (26.000 mg kg^{-1}) and Fe (20.200 mg kg^{-1}) were detected when applying the highest nitrogen dose (*Figs. 3* and *4*). The average Ba concentration in plant tissues ranges between 2 and 13 mg kg^{-1} and the higher concentrations of Ba are found in the plants from aridic zones (Kabata Pendias, 2011), whereas V is relatively easily taken up from acid soil, and some studies show that it is related to the process of biological nitrogen fixation (Bjekić, 2014). Fe availability to plants is dictated by the redox potential and pH soil reaction. In soils of higher pH, Fe is oxidized and is mostly in the form of insoluble ferric oxides which are less available to plants (Morrissey and Guerinot, 2009). In this case, the nitrate form of nitrogen (brought by a higher fertilization rate) probably increased pH and thus lowered the Fe uptake by plants. Zhao et al. (2009) underlined that Zn and Fe concentrations were significantly and positively correlated with P content, which was confirmed in this study since the lowest values of all three elements were detected in the N2 variant.

On the other hand, numerous authors state that larger doses of N fertilizer increase the microelement content in wheat, and some of the studies include the combined application of nitrogen and certain microelements (Klikocka and Marks, 2018; Kutman et al., 2011). Years-long research has shown that the application of higher nitrogen rates

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1175711771

leads to the increase in Fe, Zn and Cu concentrations, but it does not affect Mn concentration in the wheat grain (Shi et al., 2010). Later studies showed that the applied forms of N fertilizer had different effects on Mn content in plants (Klikocka and Marks, 2018). Svećnjak et al. (2013) reported that the content of trace elements depended primarily on the bioavailability of the minerals, but that different wheat cultivars could absorb different element levels from the soil, and that the same wheat cultivar could absorb different mineral levels from different soils.

The results have shown that Ni concentration (0.064 mg kg^{-1}) in the grain was the lowest in the variant with the highest rate of nitrogen application (*Fig. 4*), which can be the consequence of soil acidity, organic matter content and sorption capacity (Shaheen et al., 2017; Wlasniewski et al., 2019). The study of Wlasniewski et al. (2019) did not record a significant impact of mineral nutrition on the varying of nickel quantities in the wheat and barley grain, but it noticed a certain tendency of reducing the content of this metal in the wheat grain with the increase of NPK dose (Wlasniewski et al., 2019).

Conclusion

The results of the research have shown that the tillage system and level of nitrogen fertilization in top dressing, as well as the interaction between these two factors had an important effect on the content of macro- and microelements in the grain of winter wheat cultivar Azra. The lowest content of the examined macroelements, as well as the highest concentration of microelements Co, Cu and Ni, was observed in the grain produced in the CT system. On the other hand, the highest concentrations of microelements Fe, Ba and As were detected in the grain produced in the NT system. In the grain from the MT system, the concentrations of Mn, Sr, V and Zn were the highest in comparison with two other tillage systems. Significant differences in concentrations of macro- and microelements were detected in the grain produced with different levels of nitrogen fertilization. The highest total content of macroelements, as well as highest concentrations of Mg, K and P, was detected in the control. In the grain treated with a smaller dose of nitrogen (60 kg ha^{-1}), the highest total content of microelements, as well as the highest concentrations of Co, Ba, Fe, Mn and V, was detected. The obtained results indicated that reduced tillage and/or reduced nitrogen fertilization did not cause the reduction in macroelement content in the grain. Moreover, it had a positive effect on the content of nutritionally important minerals (Ca, Cu, Fe, K, Mg, Mn, P and Zn) in respect to the conventional tillage system with higher levels of nitrogen applied.

Abstract. This study analyzed the relationships between environmental parameters and benthic macroinvertebrate faunas. Invertebrate richness, Shannon-Wiener diversity, functional-group and CCA were used to evaluate conditions of waterbodies of the Hu-lan Estuary Natural Wetland Reserve and its hinterlands. We measured 10 physicochemical variables and collected 165 species belonging to 6 functional feeding groups (FFGs) during spring, summer and autumn. Some of the physicochemical factors changed with seasons. Nitrate nitrogen, total nitrogen and total phosphate significantly varied with seasons ($p < 0.05$), unlike water temperature, depth, pH, dissolved oxygen, chemical oxygen demand, Ammonia nitrogen and electronic conductivity ($p > 0.05$). The taxa richness of benthic macroinvertebrates did not vary significantly within the sites ($p = 0.508$); while the Shannon-Wiener diversity showed significantly difference ($p < 0.01$) within the sites over these three seasons. Gathering-collectors were the most abundant macroinvertebrate FFG assemblages all over the sites, though there's no significant difference in the total abundance of 6 functional feeding groups identified among the sites during spring, summer and autumn ($p = 0.677$, $p = 0.681$, $p = 0.302$, respectively). Our CCA results indicated positive correlations of macroinvertebrate community compositions with environmental variables in the Hu-lan Estuary Natural Wetland Reserve and its surrounding waters.
Keywords: *taxa richness, Shannon-Wiener diversity, functional feeding groups, water parameters, canonical correspondence analysis*

Introduction

Wetlands suffer from anthropogenic pressure and therefore are altered with respect to their physicochemical composition and species diversity (Rivera-Usme et al., 2015). They are essential for the maintenance of biodiversity that depends on the wetlands for their water supply. These aquatic systems are fragile because of high population densities subsequent to accelerated urban development that seriously threatens most of its wetlands (Rivera-Usme et al., 2015). Anthropogenic activities have severely affected the condition of wetlands worldwide (Wilkins et al., 2015; Tan and Beh, 2016). Physical alteration, habitat loss, water withdrawal, pollution (Cao et al., 1997; Morse et al., 2007), overexploitation and the introduction of exotic species all contribute to the decline in freshwater species and water quality as well (Tan and Beh, 2016). The stream

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1177311788

community structure is a result of both long-term environmental factors and short-term critical conditions of short duration (Morse et al., 2007); and an experienced stream biologist with good knowledge of normal and stressed stream community structures often can evaluate the water quality of a stream with considerable accuracy just after a few minutes' examination of its fauna (Hilsenhoff, 1977).

Benthic macroinvertebrates are an important component of the aquatic ecosystem and reflect a multitude of physical, chemical, and biological stream features allowing them to be excellent indicators of stream health (Hilsenhoff, 1977; Allan, 2004); i.e, the impacts of stressors such as organic pollution, toxins, and physical habitat alterations or foodweb links at higher trophic levels such as fish and birds (Cummins, 1992). Among members of the aquatic environments, they are probably best suited because they are numerous in almost every stream, and they are readily collected and identified, and they are not very mobile, and generally have life cycles of a year or more (Hilsenhoff, 1977). Monitoring wetland ecosystems using aquatic macroinvertebrates has been an effective tool for documenting changes in community health (Lenat, 1987; Plafkin et al., 1989). Some macroinvertebrate indices of stream health have been identified as most useful and efficacious. These include the EPT taxa richness-Ephemeroptera, Plecoptera, Trichoptera- (Lenat and Penrose, 1996), and total benthic macroinvertebrate taxa richness (Plafkin et al., 1989). The effective use of EPT or taxa richness measures for monitoring water quality in China requires richness rating systems to be developed by biologists (Lenat, 1994). However, physicochemical monitoring tools are usually expensive and can only be used at limited site number and they are, thus, unable to achieve computation of distribution patterns (Swaminathan, 2003). Hence, biological monitoring is considered one of the alternatives which is a useful as a rapid assessment instrument to check up the status of water quality (Tan and Beh, 2016). Changes in benthic macroinvertebrate fauna with water pollution (Morse et al., 2007), have been documented and measured in several instances using various aspects including biomass, density and composition (Cao, 1997).

Benthic macroinvertebrate functional feeding-group analyses were developed initially for streams (Cummins, 1973, 1974) as key components of the river continuum concept (Vannote et al., 1980). Various ratios of the functional groups have been successfully used as surrogates for ecosystem attributes to assess the ecological condition of flowing water environments (Masese et al., 2014; Fu et al., 2016; Shabani et al., 2019). The evaluation is based on easily observed morphological and behavioral attributes associated with feeding (functional-feeding groups, FFGs) and modes of attachment, concealment, and locomotion (functional-habit groups, FHGs), together with life history patterns and drift propensity (Merritt et al., 2002).

In this paper, we determined the functional group composition of benthic macroinvertebrate fauna and modeled relationships between benthic macroinvertebrate metrics and environmental factors in the Hu-lan Estuary Natural Wetland Reserve and its surrounding waters to evaluate the effects of environmental characteristics on benthic macroinvertebrate assemblages.

Materials and methods

Study area

The Hu-lan Estuary Natural Wetland Reserve is located in the southern part of Hu lan district, Harbin city in Heilongjiang Province, Northeast China (*Fig. 1*); and extends

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1177311788

along of the north bank of Songhua River from East to West band. The Hu-lan River enters the estuary of Songhua River and reaches the Dadingshan dam. The natural reserve extends between 45°53'44" and 46°54'04" N latitude and between 126°41'00" and 127°15'00" E longitude. The length of the reserve from East to West is 63.5 km, with a width of 21.3 km from North to South (Liu, 2012). It covers around 192.62 km^2. The annual temperature average is 3.3°C, with mean annual precipitations of 500.4 mm (Liu, 2012). The Hu lan Estuary Natural Wetland Reserve was created in 2008 and mainly aims to protect wetland ecosystems and endangered waterfowls. The wetland is rich in biological resources with more than 465 species of plants and 348 species of vertebrates, including fishes, amphibians, reptiles, birds and mammals (Liu, 2012). According to the Classification Criteria of Nature Reserve Types and Grades of the People's Republic of China (GB/T15629-93), the Hu-lan Estuary Natural Wetland Nature Reserve belongs to the inland wetland type and natural ecosystem category. Ashihe River is an important tributary of Harbin section of Songhua River in Hu-lan Estuary. The upper reaches of Ashihe River are alpine forest streams and the middle reaches of the river pass through a large area of farmland to reach the Harbin city and join the Songhua River (Liu, 2012).

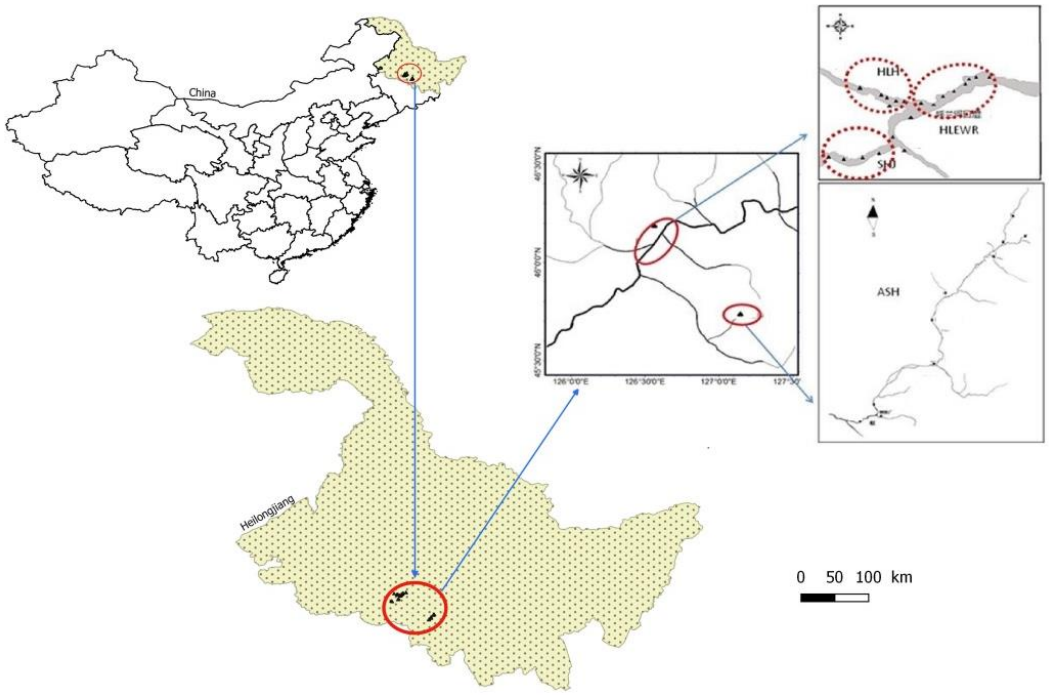

Figure 1. *Map of study site with the sampling locations in China*

Sampling of physical and chemical parameters

Four sampling locations were selected, including the Songhua River along Harbin (SHJ: N45°45'29.2″ and E126°45′10.4″, sites 1-3, 13-14), the Ashihe River upstream (ASH: N45°16′38.7″and E127°39′23.1″, sites 4-12), the Hu-lan river downstream (HLE: N45°55′33.1″ and E126°46′35.8″, sites 15-22) and the Hu-lan estuary wetland reserve (HLEWR: N45°55′31.3″ and E126°55′53.3″, sites 23-30). Physicochemical water conditions were determined in spring, summer and autumn in 2009. Water temperature

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1177311788

(WT, °C), pH, electronic conductivity (EC, mS/m) and dissolved oxygen (DO, mg/l) were measured in situ with a multiparameter probe. Water depth (m) was measured using Secchi disk and longline method when biological samples were collected. 500 ml of water were sampled at each site per season and put in labelled plastic containers, and then taken to the Laboratory of Hydrobiology, where nitrate nitrogen (NO_3^--N, mg/l), Ammonia nitrogen (NH_3-N, mg/l), total phosphate (TP, mg/l), total nitrogen (TN, mg/l) and chemical oxygen demand with permanganate index (COD_{Mn}, mg/l) were determined following the Chinese national water quality standards method GB3838-2002.

Benthic macroinvertebrate sampling

Several qualitative and quantitative sampling tools are designed to sample benthic macroinvertebrates (Barbour et al., 1999; Merritt et al., 2008). In this study, we used qualitative (D-frame net and handle net) and quantitative (Surber sampler: 0.09 m^2 and Petersen grab sampler: 1/16 m^2) sampling tools to collect the benthic macroinvertebrates from each of the four sampling locations. We used 500-μm mesh D-net and handle-net type devices at each site, the nets were dragged against the water flow over an area of 1 m^2 while large substrates were gently rubbed or kicked for 3-5 minutes with hands or feet, respectively, to dislodge free-living and burrowing macroinvertebrates from benthic substrates. Surber type sampling devices of 30 cm wide × 30 cm long with 0.09 m^2 catching area and a net of 500 μm in mesh size were placed along the river substrate to catch any organisms dislodged initially and carried downstream at low velocities; and the animals were subsequently swept by the water and caught in the net. We also used the Petersen sampler in wetland sites to collect macroscopic macroinvertebrates in sand, gravel, marl, or clay.

All samples were transferred into labelled plastic bags and preserved in 95% ethanol. Taxonomic determinations were conducted in the Laboratory of Hydrobiology using identification keys of Thorp and Covich (1991), Morse et al. (1994), Merritt et al. (1996), Tong (1996), and Dudgeon (1999). Each taxon was assigned to a general functional group according to their trophic specializations, as categorized by Cummins and Klug (1979), Morse et al. (1994), Vannote et al. (1980), Merritt et al. (1996), and Barbour et al. (1999). The FFGs identified were scrapers (SC), that are herbivores and feed on periphyton; shredders (SH), that feed on coarse particulate organic matter (CPOM); gatherers/collectors (GC), that consume fine particulate organic matter (FPOM); filterers/collector (FC), which filter FPOM in the water column; omnivores (OM), or those which simply do not fit neatly into the other categories; and predators (PR) that feed on other living organisms (Rivera-Usme et al., 2015).

Data analysis

The benthic macroinvertebrate taxa richness and Shannon-Wiener diversity were computed for each site and sampling season using PAST software (Hammer et al., 2001; Hammer and Ryan, 2008). Differences in benthic macroinvertebrate taxa richness and Shannon-Wiener diversity among sampling sites during spring, summer and autumn were tested using the ANOVA or Kruskal-Wallis tests in R software, and tests were considered significant at the $p < 0.05$ level. Canonical correspondence analysis was performed using CANOCO 4.5 software and Pearson correlation test (SPSS, version 16.0) to model on the correlation between benthic macroinvertebrate metrics and environmental factors. For data which fitted to the normal distribution, one-way

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1177311788

ANOVA and Tukey's honestly significant difference (HSD) tests, followed by Levene's test of homogeneity of variance were performed for multiple comparisons. On the other hand, data which did not fit to the normal distribution were submitted to the non-parametric Kruskal-Wallis test to evaluate the relationships between water quality variables and macroinvertebrate community metrics among sites over three seasons.

Results and discussion

Environmental variables

Table 1 shows the mean values of ten water parameters measured in the Hu-lan estuary wetland sites and its surrounding waters. Some of the physicochemical factors changed among seasons. Nitrate nitrogen (NO_3^--N), total nitrogen (TN) and total phosphate (TP) significantly varied with seasons (Kruskal-Wallis test, $p < 0.05$); unlike water temperature (WT), depth, pH, dissolved oxygen (DO), chemical oxygen demand with permanganate index (COD_{Mn}), Ammonia nitrogen (NH_3-N) and electronic conductivity (EC) which did not vary significantly (Kruskal-Wallis test, $p > 0.05$). Shabani et al. (2019) also found NO_3^--N, TN and TP concentrations significantly varied with seasons in the waterbodies of Sanjiang plain wetlands. Maloney and Feminella (2006) also recorded the highest mean value of water temperature in summer in the Southeastern plains ecoregion of central western Georgia, USA. Ortiz and Puig (2007) also found the highest mean value of water temperature in summer at the downstream reach in a Mediterranean stream. Shabani et al. (2019) also reported the highest mean value of water temperature in summer in the Sanjiang plain wetlands, obviously as the warmest season.

Benthic macroinvertebrate communities

A total of 165 benthic macroinvertebrate species belonging to 16 orders were recorded during the study period (*Appendix 1*, *Table 2*). Insects were the most species-rich group, with 8 orders (Trichoptera, Ephemeroptera, Plecoptera, Diptera, Heteroptera, Odonata, Coleoptera and Neuroptera), and 41.8% of the species belonged to order of Dipterans (*Table 2*). Limnodrilus hoffmeisteri (Tubificida) was considerably abundant in the Hu-lan estuary wetland and the surrounding Waters. 78 species were

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1177311788

collected in the Hu-lan river downstream (HLE) followed by the Ashihe River upstream (ASH) with 71 species, the Songhua River along Harbin (SHJ) with 59 species and the Hu-lan estuary wetland reserves (HLEWR) with 52 species (*Appendix 1*). The benthic macroinvertebrate taxa richness of in these four regions did not vary significantly during the three seasons (ANOVA results, $p = 0.5081$; *Fig. 2a*). While the Shannon-Wiener diversity showed high significant difference (Kruskal-Wallis test, $p = 0.0019$, *Fig. 2b*) within the sampling zones during these three seasons.

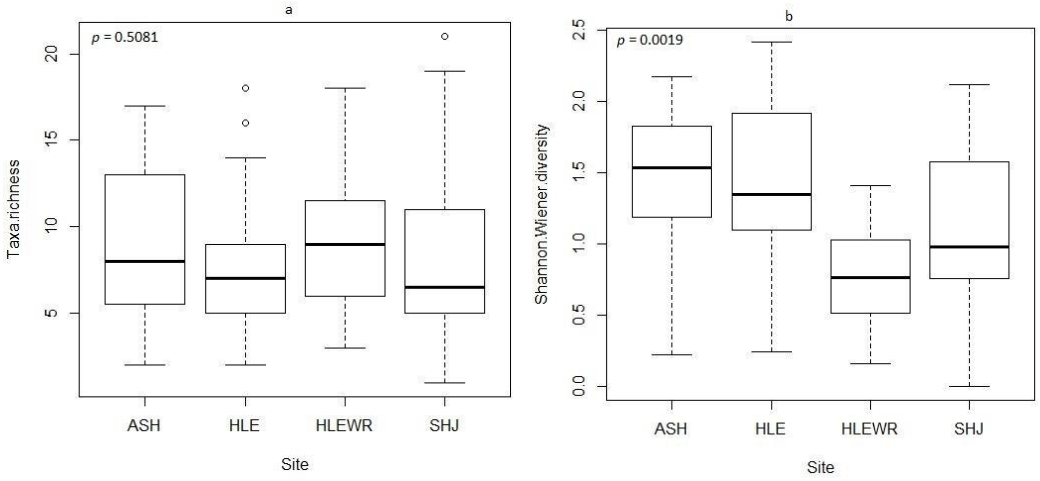

Figure 2. *Comparison of mean values of macroinvertebrate taxa richness (a) and Shannon-Wiener diversity (b) at sampling sites. ASH = Ashihe River upstream, HLE = Hu-lan river downstream, HLEWR = Hu-lan estuary wetland reserve, SHJ = Songhua River along Harbin*

Our results contracted with those of Šporka et al. (2006) in the stream of the Carpathian Mountains of central Europe; Wang et al. (2007) in Taihu lake watershed, Changzhou area; Zhao et al. (2012) in the bed sediment of the Yellow River; Pan et al.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1177311788

(2013) in the Upper Yellow and Yangtze Rivers; Zhang et al. (2014) in streams and rivers of lake Taihu Basin; Pham (2017) in Saigon river and its tributaries, Vietnam; Rosser and Pearson (2018) in tropical streams; Shabani et al. (2019) in the wetlands of the Sanjiang plain, who reported that aquatic insects were the most species-rich group and occurred in almost all of the sites. Their dominance may depend on the availability of allochthonous organic detritus from riparian structure (Vannote et al., 1980).

Benthic macroinvertebrate functional feeding groups

Figure 3a,b,c report the percentage contributions of the various benthic macroinvertebrate FFGs at the sites during the three seasons. Gathering-collectors (GC) were the most dominant benthic macroinvertebrate FFG assemblages within all sites in spring and autumn. They also dominated the benthic communities in the HLEWR and SHJ in summer. Filtering-collectors (FC) and predators were the most abundant in the ASH and HLE, respectively in summer. It appeared that there's no significant difference in the total abundance of these six functional feeding groups among the sites during spring, summer and autumn (Kruskal-Wallis rank sum test, p = 0.677, p = 0.681, p = 0.302, respectively). Pan et al. (2013) also found that gathering-collectors were the predominant macroinvertebrate FFGs in the source region of the Yangtze River. Fogelman et al. (2018) also reported that the gathering-collectors were the most dominant in the macroinvertebrate collection from the Susquehanna River, USA.

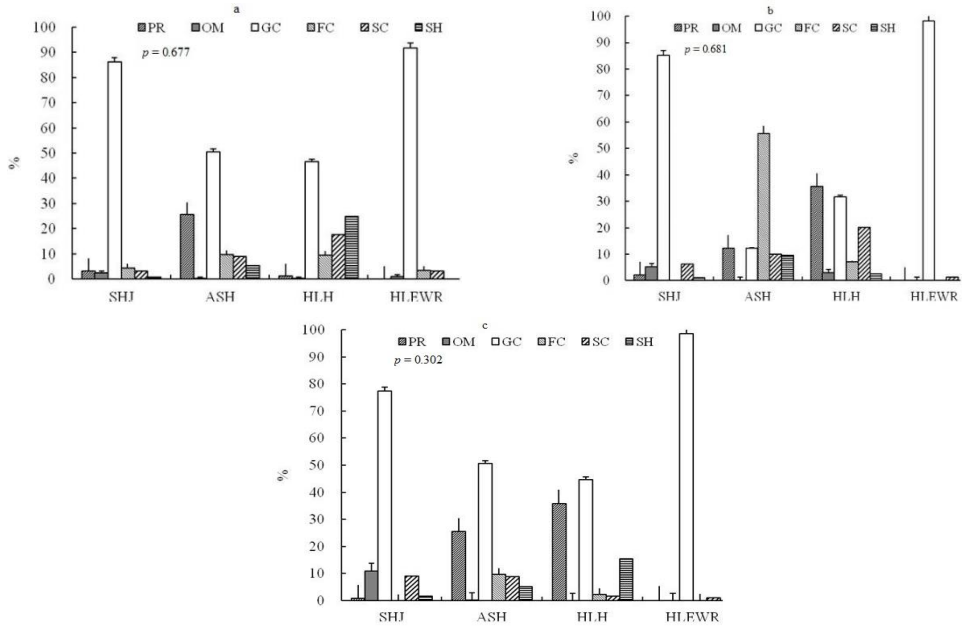

Figure 3. *Percentages of macroinvertebrate FFGs in spring (a), summer (b) and autumn (c), SH = shredders, SC = scrapers, FC = filtering-collectors, GC = gathering-collectors, PR = predators, SHJ = Songhua River along Harbin, ASH = Ashihe River upstream, HLE = Hu-lan river downstream, HLEWR = Hu-lan estuary wetland reserve*

Relationships between physicochemical variables and benthic macroinvertebrates

Figure 4 shows the CCA ordinations during the three seasons. During the spring period, the first two axes respectively explained 18.90 and 36.60% of benthic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1177311788

macroinvertebrate variances, with eigenvalues of 0.964 and 0.907. Biotic data as *Chironomus pallidivittatue*, *C. okinawanus*, *C. plumosus, Limnodrilus hoffmeisteri*, *Branchiura sowerbyi*, *Ephemera shengmi* and *Polypylis hemisphaerula* exhibited high positive relationships with water temperature ($r = 0.93$) and COD_{Mn} ($r = 0.94$) at sites 1, 2, 3, 21, 23, 25, 26, 27, 28, 29 and 30 on the first axe. CCA indicated that *Nippotipula* spp., *Ameletus* spp., *Iron* spp., *Heptagenia* spp., *Ephemera sachalinensis*, *Serratella* spp., *Ephemerella fusongensis*, *Leptophlebia* spp., *Paraleptophlebia* spp., *Corixa substriata*, *Hesperocorixa distanti*, *Gyraulus convexiuculus*, *Galba truncatula*, *Galba pervia*, *Radix auricularia*, *Valvata piscinalis*, *Stenopsyche marmorata*, *Hydropsyche nakaharai*, *Hydropsyche* spp., *Polycentropus* spp. and *Alloperla sapporoensis* were positively correlated with TN and DO at sites 5, 7, 8, 10 and 11 on the second axis (*Fig. 4a,b*).

In summer season, the first two axes explained 55.40% of total variances, with eigenvalues of 0.915 and 0.958, respectively. There were positive significant correlations of *Tipulidae* spp., *Cryptochironomus defectus*, *Stictochironomus maculipennis*, *Chironomus okinawanus*, *Pentaneurella katterjokki*, *Glyptotendipes pallens*, *Ephemera shengmi*, *Unio douglasiae*, *Viviparus chui*, *Limnodrilus helveticus*, *Teneridrilus mastix*, *Limnodrilus hoffmeisteri* with electronic conductivity ($r = 0.78$), depth ($r = 0.69$), water temperature ($r = 0.94$), TN ($r = 0.71$), NO_3^--N ($r = 0.87$) and pH ($r = 0.76$) at sites 1, 2, 3, 20, 24, 25, 26, 27, 28, 29, and 30 on the first axis. While *Tabanus* spp., *Nippotipula* spp., *Cricotopus sylvestris*, *Eukiefferiella gracei*, *Ameletus* spp., *Iron* spp., *Heptagenia* spp., *Baetis* spp., *Ephemerella* spp., *Nais* spp., *Limnodrilus claparedeianus*, *Alloperla sapporoensis*, *Alloperla nikkoensis*, *Alloperla* spp., *Haploperla* spp., *Stenophylax ondakesis*, *Stenophylax koizumii* and *Astenophylax grammicus* were associated with DO and TP at sites 5, 6, 7, 8, 9 and 10 on the second axis (*Fig. 4c,d*).

During autumn, the first two CCA axes respectively explained 20.60 and 41.00% of total variances, with eigenvalues of 0.958 and 0.954. Axis 1 showed positive correlations of water temperature, TP, TN, depth, NH_3-N, electronic conductivity, COD_{Mn} and NH_3-N on *Unio douglasiae*, *Polypylis hemisphaerula*, *Viviparus chui*, *Galba pervia*, *Radix swinhoei*, *Cipangopaludina chinensis*, *Limnodrilus helveticus*, *Limnodrilus hoffmeisteri*, *Branchiura sowerbyi*, *Tubifex tubifex*, *Nais communis*, *Dero* spp. While the second axis revealed that pH and DO were the most important variables to impact the distribution of *Tabanus* spp., *Nippotipula* spp., *Holorusia* spp., *Procladius choreus*, *Stictochironomus akizukii*, *Ameletus* spp., *Iron* spp., *Heptagenia* spp., *Baetis* spp., *Baetis* spp., *Ephemera sachalinensis*, *Serratella* spp., *Ephemerella* spp., *Ephemerella fusongensis*, *Leptophlebia* spp., *Paraleptophlebia* spp., *Ephemera nigroptera*, *Corixa substriata*, *Hesperocorixa distanti*, *Sphaerium lacustre*, *Gyraulus convexiuculus*, *Radix auricularia, Radix ovata*, *Valvata piscinalis*, *Protohermes grandis*, *Parastenopsyche* spp., *Stenopsyche marmorata*, *Goera ramosa*, *Goera japonica*, *Goera kyotonis*, *Stenophylax ondakesis*, *Stenophylax koizumii*, *Astenophylax grammicus*, *Glyphotaelius admorsus*, *Hydropsyche nakaharai*, *Hydropsyche* spp., *Oecetis morii*, *Ganonema* spp. and *Polycentropus* spp at sites 4, 5, 6, 7, 8, 9, 10, 11 and 12 (*Fig. 4e,f*).

Understanding the relative importance of environmental conditions is critical for understanding how to preserve generate benefits to aquatic macroinvertebrate communities (Wilkins et al., 2015). Our modeling demonstrated that benthic macroinvertebrate species richness values were strongly associated with physical and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1177311788

chemical conditions in the Hu-lan Estuary Natural Wetland Reserve and its surrounding waters. Environmental parameters as measured were very influential on macroinvertebrate diversity in freshwater habitats of this reserve. Moreover, several studies have demonstrated that differences in physical and chemical characteristics are detected anytime and with strong influence on aquatic community composition (Bertaso et al., 2015). Habitat quality was second important factor, implying that macroinvertebrate diversity also benefited from improved environmental conditions (Wilkins et al., 2015). Palmer et al. (1997), and Harper et al. (1998) argued that habitat heterogeneity can promote biotic recovery and biodiversity in aquatic environment and is often a goal of environment restoration.

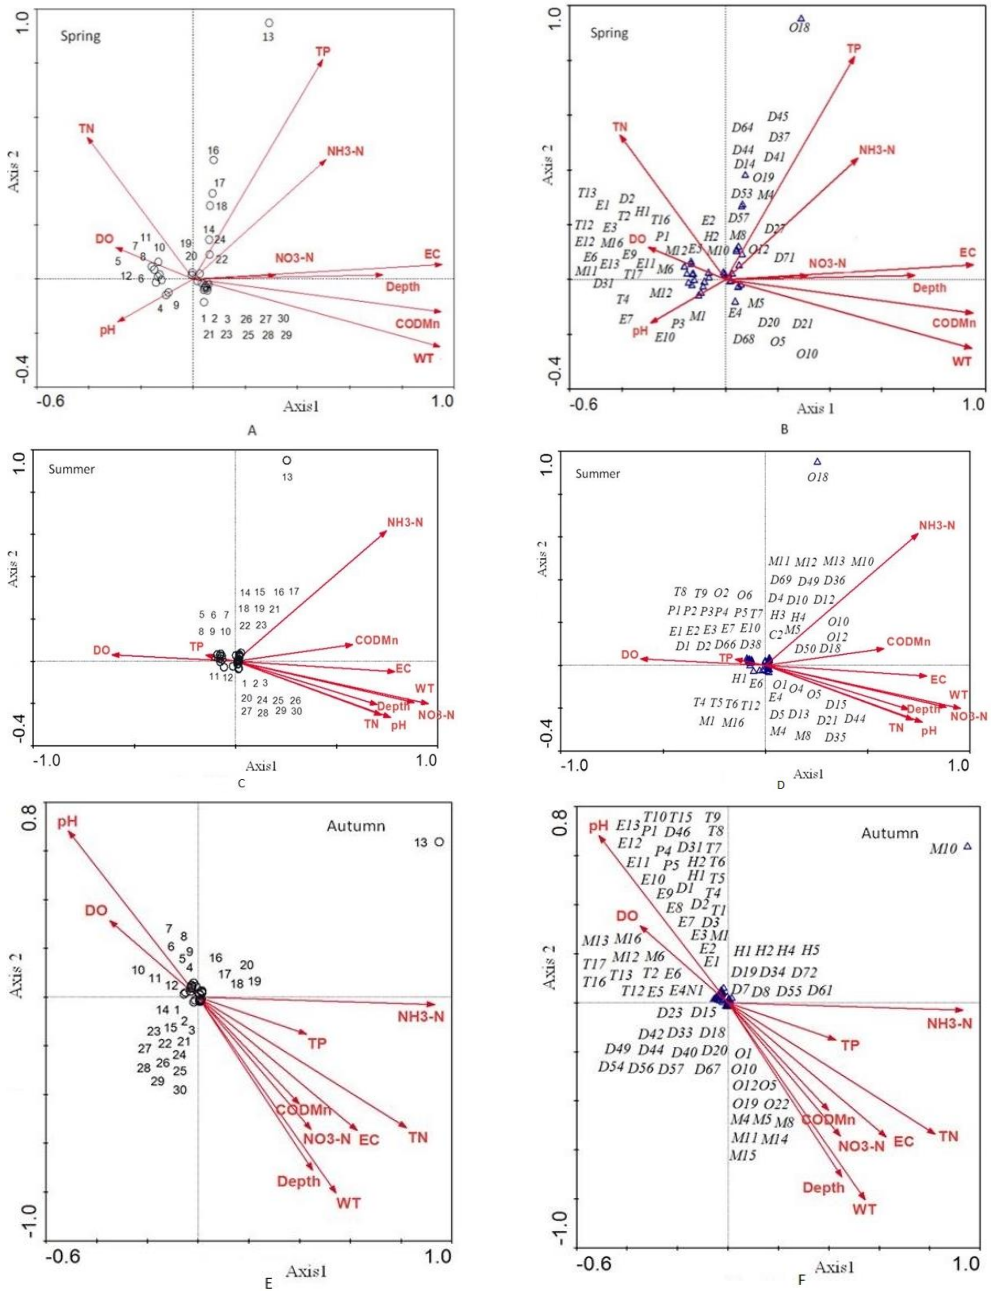

Figure 4. *CCA plots relating the benthic macroinvertebrates associated with physicochemical variables in spring (A, B), summer (C, D) and autumn (E, F)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1177311788

In our study, we recorded pollution-sensitive taxa, including Ephemeroptera, Plecoptera, Trichoptera and Odonata (EPTO) and benthic communities characterized by pollution-tolerant taxa, such as Diptera, Heterostropha, Hygrophila and Tubificida. Luo et al. (2017) also collected sensitive species (e.g., EPT taxa) and less diverse communities with dominance of tolerant species (e.g., Tubificids, Chironomids, and Physids) in the Liangjiang New Area. Although some taxa (e.g. EPTO) are sensitive to aquatic environment conditions (Barbour et al., 1992), many species in these orders are of conservation interest (Wilkins et al., 2015).

Conclusion

Our findings demonstrated the positive of benthic macroinvertebrate community compositions with environmental parameters. We found that Gathering-collectors were the most dominant benthic macroinvertebrate FFG assemblages, and recorded more sensitive and tolerant species in the Hu-lan Estuary Natural Wetland Reserve and its surrounding waters. In order to reach the conservation status assessment of species, we suggest that local faunas should be inventoried and described (many species remain unknown). Tolerance values for macroinvertebrates should be determined. More research teams using benthic macroinvertebrates to assess water quality should operate in this reserve. Wetland conservation efforts, such as planting aquatic vegetation in a watershed, can also help to improve water quality and restore natural flow regimes, and then may structure macroinvertebrate populations.

(Received 22nd Apr 2019; accepted 4th Jul 2019)

Abstract. Maize is a major food, feed and fodder crop, grown extensively all over the world. Genetic engineering has a unique role in crop improvement. Serine-Threonine-Kinase1 (*ZmSTK1*) is a gene-based enzyme, which due to its biochemical action in maize pollen grains, lowers the survival capability and affects pollination. Out of different methods of genes transfer into the genome of the target cell, Agrobacterium-mediated gene transformation is an easy and convenient method in which required gene is insert into the Agrobacterium, which after multiplication carry foreign genes into the host cell's genome. In this research, a simple and easy *Agrobacterium tumefaciens*-mediated method used to establish the genetic transformation system of *zmstk1* into maize germinating embryo as receptor system. Transgenic plants obtained successfully through this method and the complicated culture process not needed. The expression of *zmstk1* in the tissue was determined by observing the histochemical localization of *zmstk1* in order to elucidate the expression of *zmstk1* in mature tassel or pollen.
Keywords: *agrobacterium tumefaciens, gene editing, gene mutation, pollen viability, transgenetic maize*

Introduction

Maize is a major crop found all over the world and used extensively for food, feed and fodder. Because of its consumption at large scale, some high yielding varieties have to be selected to meet the requirement. Naturally, dominant and vigorous varieties also play an important role in production of healthy and disease free food but for high production of maize, some controlled experiments on cellular and molecular level are required. Public and government affiliated institutions of agriculture research are investigating reasons related to adjustment of maize plant for biotic and environmental stresses. Transfer of genes of cold regions maize varieties to increase production and to improve quality, breeders focus on the improvement of new varieties by using these techniques. One of the major hurdles in functional use of this technique to temperate varieties of maize is the selection of germplasm responsible for its renaissance in tissue culture and inoculation by Agrobacterium (Souza et al., 2017). There are many ways to enhance the ability of an organism to produce the required yield of product such as natural hybridization, cellular metabolism enhancement, quantitative trait loci, molecular and genetic recombination and gene transformation into the cell. For different

DOI: http://dx.doi.org/10.15666/aeer/1705_1178911802

purposes, different methods and ways are used. One of the best and advanced research in genetic and molecular experiments is to transfer a specific target gene into the vegetative cells of plants. For this purpose, some experiments held in Shenyang Agricultural University Shenyang, Liaoning, China.

Agrobacterium-mediated transformation is a fast and more accurate method for gene transfer with high frequency and time saving approaches (Que et al., 2014). This method is more extensively adapted now days by both civil and private institutions, however, capability of transformation varies highly from lab to lab for the same plant genotype. Here, advanced Agrobacterium-mediated transformation technique in maize by using a simple form of binary vectors exemplified. This method uses undeveloped embryos as fundamental explants and the bar gene as a selectable marker together with bialaphos as a selective agent in maize (Shrawat and Good, 2011), rice (Hei and Komari, 2008) and in switchgrass (Xi et al., 2009). Development based on genetic transfer varies, in which gene can be inserted into plants more effectively which depend on the species or variety, or the genetic marker being used (Binka et al., 2012). In recent times, a CRISPR/Cas9 toolkit used for multiplex genomic editing in different host plants based on the pGreen and in pCambia backbone (Xing et al., 2014). Genetic changes in plants which effect pollen development can be easily observed by the unusual isolation of markers linked to it (Vasal et al., 2006) and in plants where the genetic changes are due to transposons that present a phenotype are by the abnormal isolation of responsible transposon itself (Lalanne et al., 2004; Boavida et al., 2009).

Serine threonine kinase1 (STK1) and serine threonine kinase2 (STK2) are closely related to paralogous genes of maize predicted to encode serine/threonine protein kinases. Those pollens, which have mutations of *ZmSTK1* or *ZmSTK2*, can compete poorly with wild pollens, indicating to an abnormality in germination or growth of pollen tube. Both genes show their expression only in pollens but not in most of other parts of plants. In medium of germination, *ZmSTK1* and *ZmSTK2* fluorescent fusion proteins are located in the cell membrane of the somatic cell of plant. RNA-sequencing experiments indicated 534 genes, which expressed differentially in *zmstk1* mutant pollens as compared to wild type. Gene ontology molecular functional analysis revealed many differently expressed genes with supposed ribosome initiation and elongation functions, signifying that *zmstk1* may show effect on function of ribosomes. Of these two mutant forms, *zmstk1* may show a more imperative role in pollen development as compared to *zmstk2*, as mutations of *zmstk2* have a smaller transmission effect in pollen development. However, *zmstk2* acts as a booster of *zmstk1* expression because the combination of double mutation shows that pollens are too weak to survive until fertilization as compared to wild and single mutants. Therefore, it is analyzed that the *ZmSTK* paralogs play an important role in pollen development (Huang et al., 2017).

New requirements need to develop some techniques for low copy transfer of genes into the target cell by *A. tumefaciens* (Sivamani et al., 2015*)*. In these experiments, *ZmSTK1* gene transferred into the cells of maize embryo during its initial growth time. For transformation of gene there are different ways used in the bio-scientific field, out of these methods Agrobacterium-mediated method of transformation was found as an easy and best way to transform the target gene into the maize embryo cells (Yadava et al., 2017). In this experiment, *Agrobacterium tumefaciens* used as a vector for multiplication to carry the gene *ZmSTK1* into the target embryo cells and insert the gene into the genome of maize cells.

Materials and methods

Plant material

Wild-type McC and mutant *zmstk1* provided by Dr. Dooner, Rutgers University, USA. The *pMD18-T-pSTK1* recombinant plasmid and the *pCAMBIA1301* plasmid provided by the laboratory from the College of Bioscience and Biotechnology in Shenyang Agricultural University, China.

Instruments and equipment

Test thermostat incubator, PCR machine, refrigerated centrifuge, electrophoresis tank, gel electrophoresis, autoclave, water bath, gel imager, horizontal electrophoresis tank, DC power supply, shaker, 50 ml centrifuge tube, tweezers, scalpel, and 2.0 ml centrifuge tubes.

Major reagents

To make 1% Rifampicin, 0.1 g rifampicin dissolved in 10 ml methanol, sterilized after filtration and stored at -20 °C. To make 5% kanamycin, 1.0 g kanamycin dissolved in 20 ml distilled water, filtered, sterilized and preserved at -20 °C. To make 50 g/l ampicillin, 2 g ampicillin dissolved in 40 ml distilled water, sterilized after filtration and stored at -20 °C. For Acetosyringone solution, dimethyl sulfoxide dissolved in acetosyringone, 200 mmol/l solution was prepared, diluted with distilled water to make 100 mmol/l, filtered and stored at -20 °C. In addition, for 5% sodium hypochlorite solution, 50 ml of pure sodium hypochlorite dissolved in sufficient amount of distilled water, raised the volume to 1 L and stored at room temperature. 70% ethanol was prepared by adding 70 ml of pure ethanol, with the sufficient amount of distilled water and raised the volume 0.1 L. To make YEB medium, 10 g tryptone, yeast 10 g extract and 0.5 g $MgSO_4$.$7H_2O$ mixed with distilled water to raise the volume 1000 ml and stored at pH 7.2. LB medium prepared by dissolving 10 g tryptone, 5 g yeast extract, 10 g NaCl in distilled water, raised the volume to 1 L, and stored at pH 7.0. For sodium phosphate buffer (100 mmol/l, pH 7.0), Solution A (6.55 g NaH_2PO_4 .$2H_2O$ dissolved in 50 ml of distilled water) and Solution B (1.83 g Na_2HPO_4 .$12H_2O$ dissolved in 50 ml of distilled water) mixed and volume raised to 200 ml at pH 7.0. X-Gluc prepared using (5-bromo-4chloro-3 indolylglucuronide) and mother liquor (0.5 mg/ml). 0.025 g of X-Gluc dissolved in 1 ml of N-N-dimethyl amide (DMF) and stored at -20 °C. For X-Gluc base solution (10 mmol/l), 0.1 g of $K_3Fe(CN)_6$ potassium ferricyanide (1 mmol/l) and 0.13 g of $K_4Fe(CN)_6$ were mixed in 200 ml of sodium phosphate buffer, followed by the addition of 300 ul 0.1% Triton X-100, 1.12 g Na_2EDTA Potassium ferricyanide (1 mmol/l) and completely dissolved to make 250 ml.

Construction of maize ZmSTK1 expression vector

First competent cells of *E. coli*were prepared by making LB medium, which used to flatten to activate Escherichia coli DH5a single colonies, stored overnight at 37 °C. Then pre-activated single colony was selected, inoculated in 5 ml LB liquid medium and culture was shacked for 12 h at 37 °C. After that 500 µl bacteria inoculated to absorb in 50 ml LB liquid medium, shacked it at 37 °C and bacterial suspension placed in the already cooled 1.5 ml centrifuge tube and ice bathed for 15 min. The cooled suspension centrifuged for 1 min at 4 °C at 8000 rpm. Supernatant discarded after

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1178911802

removing the net residue of the culture medium and preserved in ice bath. Then suspended bacteria in a pre-cooled $CaCl_2$ solution (0.1 mol/l) at 4 °C and centrifuged for 1 min at 8000 rpm. Then 0.1 mol/l suspension of bacteria centrifuged for 1 min at 8000 rpm at 4 °C and supernatant removed by using 0.1 mol/l $CaCl_2$ solution. Supernatant discarded, net residual culture medium removed and 2 ml pre-cooled $CaCl_2$ solution (0.1 mol/l) added for bacterial suspension. After that, 80% of the volume of glycerol added, mixed, and stored at -80 °C in refrigerator for further use.

Double digestion reaction

The recombinant plasmids *pMD18-T-pSTK1* and *pCAMBIA1301* plasmids digested with restriction endonuclease *HindIII* and *NcoI*. *Table 1* shows the reaction system.

Table 1. *Composition of system used for digestion*

System composition	Consumption
pMD18-T-p*STK1*	15 uL
Hind Ⅲ	1 uL
NcoI	1 uL
10*buffer (Enzyme digestion buffer)	2 uL
Double distilled H_2O	1 uL
Total	20 uL

Recycled digested product

The enzyme digested with the kit and the digested product of *pMD18-T-pSTK1* digested about 1000 bp and named *HindIII-pSTK1-NcoI* and *pCAMBIA1301*. The large fragment digested product named *HindIII-pCAMBIA1301-NcoI*.

Binding with the expression vector

HindIII-pSTK1-NcoI ligated with the vector *HindIII-pCAMBIA1301-NcoI*, and the binding system incubated at 14 °C for 14 h under the conditions of *Table 2*.

Table 2. *Components of enzymatic systems*

System composition	Consumption
T4 DNA Ligase	2.0 uL
T4 Ligase buffer solution	2.0 uL
Hind Ⅲ- pCAMBIA1301-*NcoI*	4.0 uL
Hind Ⅲ-p*STK1-NcoI*	12 uL
Total	20 uL

Conversion

Thawed E. coli competent cells to complete melting drew 100 μl into a new sterile centrifuge tube and immediately placed in ice. Then 5-μl ligase enzyme added, mixed and placed in ice for 30 min followed by putting it in a hot water bath at 42 °C for 90 s and quickly placed in ice for 5 min. Then 1-l LB liquid medium added, mixed and shacked at 37 °C for 1.5 h and centrifuged for 1 min at 8000 rpm, discarded the centrifugal supernatant and added 100 μl LB liquid medium. The bacterial liquid

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1178911802

coated on LB solid medium containing 50 g/l of ampicillin and the surface placed up to the bacterial solution, completely absorbed by the culture medium and cultured at 37 °C for 16 to 24 h. Then a single colony picked and used PCR kit to mention the plasmid. After a double enzyme digestion, electrophoresis detection of recombinant plasmid used and digestion products tested in the positive plasmid named *pCAMBIA1301-pSTK1-GUS*saved in refrigerator at -80 °C.

Preparation of agrobacterium competent cells

Agrobacterium tumefaciens EHA105 cultured on YEB solid medium containing 1% rifampicin and cultured at 28 °C for 48 h. Activated single colony selected, inoculated with 1 ml liquid medium containing 1% rifampicin YEB and shacked at 28 °C overnight. 250 µl of the bacterial solution was taken and incubated in 25 ml of YEB liquid medium containing 1% rifampicin and shook at 28 °C until OD600 = 0.5. Next, took the bacterial suspension, ice bathed for 15 min and centrifuged in a high speed centrifugal machine for 10 min at 5000 rpm and supernatant was discarded. 5 ml 0.15 mol/l NaCl suspension of bacteria was prepared, ice bathed for 15 min and centrifuged at 5000 rpm for 10 min. Then 2 ml 0.1 mol/l pre-cooled $CaCl_2$ solution was prepared with cell suspension, 80% glycerol added and refrigerated at -80 °C.

Transformation of agrobacterium competent cells

Thawing agrobacterium competent cells

Ten ul of *pCAMBIA1301-pSTK1-GUS* added into 100 ul competent cells, mixed and ice bathed for 30 min. Next, placed in liquid nitrogen for 5 min and immediately transferred it to a 37 °C water bath for 5 min. Then 1 ml of YEB added, shook for 5 h at 28 °C, centrifuged at 220 rpm and supernatant removed. 200-µl YEB liquid medium of bacterial suspension added centrifuged at 5000 rpm for 2 min and supernatant removed. YEB solid medium containing 1% rifampicin and 5% kanamycin added and cultured at 28 °C for 48 h. Finally, a single colony picked and PCR used to identify the positive results.

Genetic transformation of maize germination embryos

Strain activation

After preparation, YEB solid medium (1-l YEB medium + 7 g agar powder) placed in a high-pressure sterilization chamber of a steam sterilizer. Petri dishes, gun, gun head, a sealing film, an inoculation ring and other tools were also placed in ultraviolet radiation chamber for sterilization and then in autoclave chamber. Bacterial culture taken out of the refrigerator for 30 min for defrosting. When the medium temperature was moderate, 1% rifampicin and 5% kanamycin added in the ultraclean working medium and poured on a flat plate. When the medium solidified, the inoculation ring burned to red with alcohol lamps, and the front of the rod fixed about 7 cm. The outer ring heated for 10 s, and inoculated ring completely cooled. The positive colonies stained with rings, and the culture medium divided into three zones. After the completion of the inoculation, the inoculation ring placed on the alcohol lamp for burning and cooled. After inoculation on the edge of the line, the area crossed again to make two areas. At the end, the third area also inoculated in the same method as it inoculated into other areas. The inoculation completed after burning the inoculation

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1178911802

ring. After cooling, the metal ring removed and the petri dishes closed with sealing film. Next, placed the petri dish in the incubator in a dark chamber at 28 °Cfor 48 h.

Preparation of bacteria

A single colony of *Agrobacterium tumefaciens* EHA105 containing *pCAMBIA1301-pSTK1* recombinant expression plasmid transferred on the plate with a sterilized gun tip. Seeded in YEB liquid medium containing 1% rifampicin (7.5 µl) and 5% kanamycin (1.5 µl) in a centrifuge tube (size: 2.0 ml) of 1.5 ml, shacked overnight on a 200 rpm speed in a constant temperature shaker at 28 °C and found positive results as shown in *Tables 3* and *4*. Bacterial solution transferred into the 50 ml centrifuge tube, 25 ml of YEB liquid medium, 1% rifampicin 125 µl and 5% kanamycin, 25 µl of mixture added and culture shacked well at a constant temperature. The determined OD value was in the range of 0.4-1.2. The material saved at 4 °C for further use.

Seed sterilization

Healthy seeds selected with no damage, soaked into 70% ethanol for sterilization for 30 s; seeds transferred to 5% sodium hypochlorite for disinfection for 45 min and rinsed the seeds 5 to 7 times with sterile water. Finally, seeds packed into a sterilized jar (200 tablets), sterilized water added and shaken with the help of a shaker at 90 rpm and soaked overnight. The next day, tubes centrifuged at 4000 rpm for 10 min, supernatant removed and precipitate transferred to the sterile jar. Fresh 1% rifampicin 125 µl, 5% kanamycin 20 ml, YEB liquid medium 25 µl, 15% 5 µl of acetosyringone and agar added as transformation and growth medium. Tip of the sterilized blade used to scrape the embryo growth point and placed in the jar. Labeled flasks placed in a thermostatic shaker and incubated at 28 °C and 90 rpm for 12 h. After those 12 h, the seeds transferred into the nutrient rich soil containing vermiculite and perlite and cultured for T° plant stage. Then set different gradients of OD value to 0.4, 0.6, 0.8, 1.0 and 1.2 and acetyl acetone (AS) with concentration gradient of 50 mmol/l, 100 mmol/l, 150 mmol/l, 200 mmol/l and the conversion rate of maize plants was calculated.

DNA extraction and identification of plant genetic transformation

When the plant reached the three-leaf stage, 1-2 cm of blade was cut and put into the centrifuge tube containing 200 µl of NaOH 0.25 mol/l and the tube was centrifuged for 30 s at 100 °C constant temperature. 200 ul of 0.25 mol/l HCl and 100 ul of 0.5 mol/l of Tris-HCl (pH 8.0, NP-40 0.25%) added to the centrifuge tube. The tube again incubated in boiling water for 2 min. About 2 mm² of the leaves was picked up after few steps treatment of acid and alkali and this sample used as a template for PCR amplification. The PCR amplification reaction conditions shown in *Table 5* and the reaction system components shown in *Table 6*.

Table 5. *PCR amplification reaction conditions*

Gel electrophoresis machine used to separate different sized DNA fragments. For the preparation of 10* TBE buffer, 108 g Tris, 7.44 g Na_2EDTA .$2H_2O$ and 55 g of boric acid was taken in a beaker and 800 ml distilled water was added to the beaker stirred to fully dissolved, volume was raised to 1 L with addition of distilled water and stored at room temperature. 0.5* TBE buffer was prepared by mixing 25 ml 10* TBE and 475 ml distilled water and stored at room temperature. 5 mg/ml ethidium bromide(EB)aqueous solution was prepared and agarose gel plates were prepared by mixing 0.2 g agarose and 20 ml 0.5* TBE in a conical flask by flushing liquid in it. After mixing, the flask placed in the microwave for heating for 1 min to dissolve fully and then cooled to 60 °C to add EB drop by drop. After shaking the sample, the combs were fixed, the solution was poured into the sealed gel tank (thickness 3-5 mm) and air bubbles between the comb teeth discharged. Combs taken out after cooling and glue solidification, then gel plate placed into a horizontal electrophoresis tank containing 0.5* TBE buffer until the plane thickness of submerged glue became 2 mm. Further, ten to fifteen µl marker sample added in marked gel hole and input of 180 voltage, 100 mA current to the gel electrophoresis tank provided and samples were run in the gel. Power turned off; gel bands removed from the electrophoresis tank and placed in the gel imager to check the imaging results. To perform GUS

staining of transgenic plants the configured X-Gluc mother liquor and X-Gluc base solution completely mixed to a volume of 300 ml. T° genetically modified transgenic plants and wild-type plants immature and mature roots, young leaves, mature leaves, immature anthers and mature anthers placed in fixed solution of 90% acetone for 15 min. Rinsed with buffer three times, put into the GUS staining solution, vacuumed and placed in the incubator at 37 °C in the dark overnight. Next day, samples rinsed three times with 70% alcohol for decolorization, observed under the microscope, pictures taken and differences analyzed.

Results

The construction of expression vector

The digestion of recombinant plasmid *pMD18-T-pSTK1* and plasmid *pCAMBIA1301* done by Hind III and NcoI restriction enzymes. The digested *Hind III-pSTK1-NcoI* promoter and *Hind III pCAMBIA1301-NcoI* connected with *CaMV35S* promoter instead of *pCAMBIA1301* in the vector. The recombinant plasmid expressing *pCAMBIA1301-pSTK1* transferred into *Escherichia coli* competent cells. After successful transformation, plasmids extracted and transferred into the susceptible state of *Agrobacterium tumefaciens*. The screening of samples performed and selected colonies used for PCR. The results are shown in *Figure 1,* Lane 3, Lane 4 and Lane 5 in 1000 bp band.

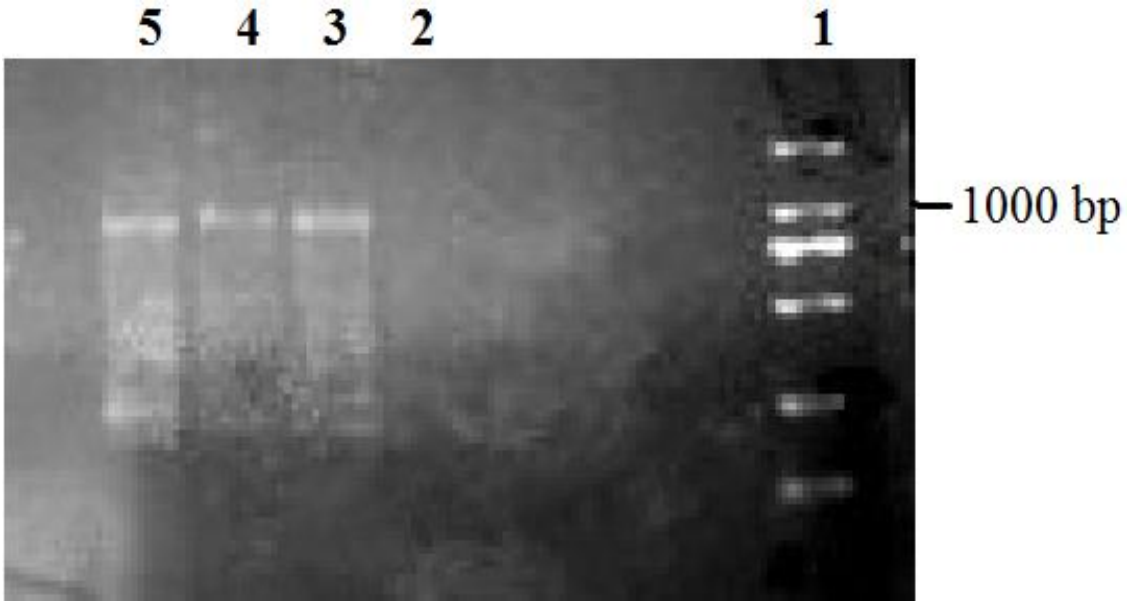

Figure 1. *PCR detection of pCAMBIA1301-pSTK1-GUS. (Note: Lane 1 is 2000 marker; Lane 2 is control carrier pCAMBIA1301; Lane 3-5 are the product to be tested)*

Identification of active colonies

Active colonies identified by their activities in PCR amplification and detection through agarose gel electrophoresis. The detection results are shown in *Figure 2,* Lane 2 and Lane 3 in about 750 bp.

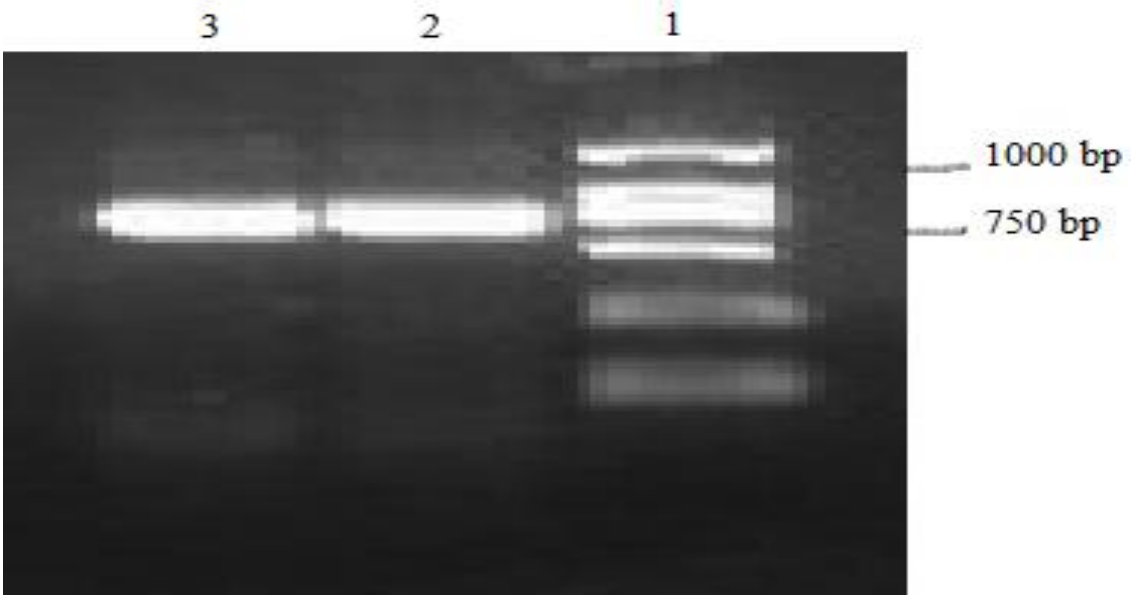

Figure 2. *Detection of bacterial liquid PCR. (Note: Lane 1 is 2000 marker; Lane 2, 3 are colonies to be tested)*

Optimization of transformation conditions

Acetosyringone AS can induce the activation of virulent gene in *Agrobacterium tumefaciens*, and promote the integration of foreign genes. The addition of AS can improve the conversion rate. The maize seeds were treated with different concentrations (OD value were 0.4, 0.6, 0.8, 1 and 1.2) of the bacteria by adding 0.1 mmol/l acetosyringone (AS) and cultivated at constant temperature of 28 °C. The results showed that different concentrations of bacteria had little effect on seed germination (around 20%) but affected the seed conversion rate. When the concentration of bacteria was up to 0.8 OD and acetosyringone concentration was 0.1 mol/l, the transformation rate was maximum.

Regeneration of germinating embryo by genetic transformation

The inoculated corn seeds cultured in nutrient rich soil containing vermiculite and perlite and 150 grains were sown in each pot (15 × 10) as shown in *Figure 3*.

Total 4000 seeds (200 per plot) incubated into germinating embryos and 807 seeds germinated after Incubation. Only three plants successfully transformed as shown in *Figure 4*. The *pstk-1* transgenic plants of T° generation obtained by Agrobacterium-mediated method. The results showed that when OD value was at 0.8 and concentration of AS was 100 mmol/l, the transformation rate was the best. The germination rate was 20.2%, and the conversion rate was 0.075%.

Transgenic plant testing

After DNA extraction, PCR amplification and detection from the transgenic plants results showed that there were bands in the samples and detected at around 750 bp. The PCR results showed that three seeds out of 4000 seeds successfully transformed (*Fig. 5*).

GUS staining of regenerated plants

In GUS staining of non-transgenic plants and *PSTK1-GUS* plants parts such as immature roots, immature leaves and immature anthers, mature root, mature leaves and mature anthers and mature pollen performed. The results showed that all parts of the non-transgenic plants showed no GUS signal. *PSTK1-GUS* transgenic plant immature roots, mature roots, immature leaves, mature leaves and immature anthers also showed no GUS signal but the mature anthers and mature pollens showed GUS signal in the form of dark spots as shown in *Figure 6*.

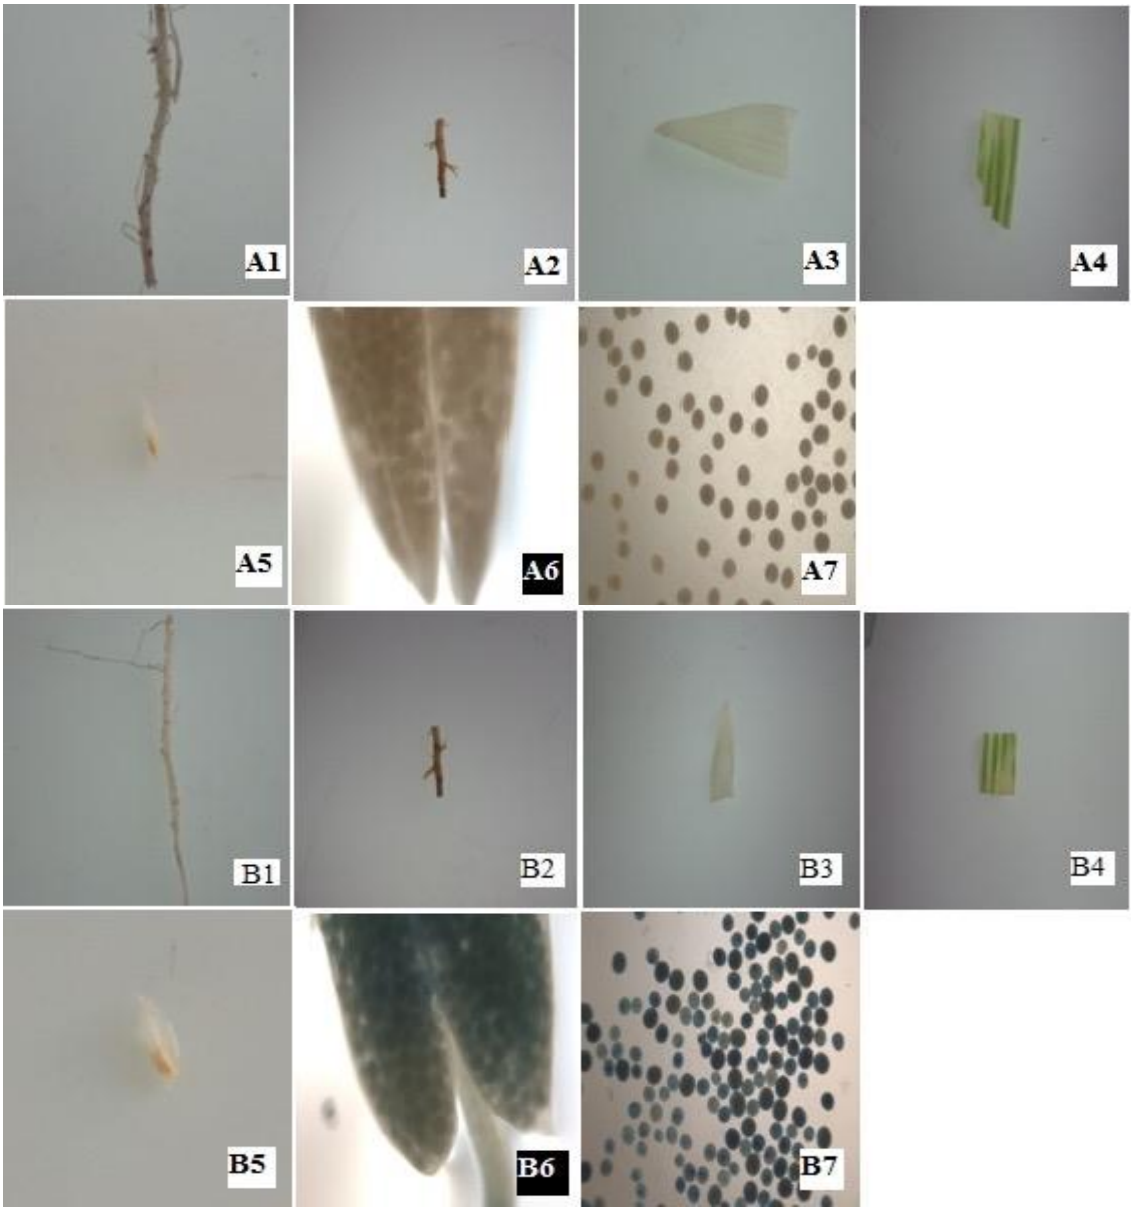

Figure 6. *GUS staining for the non-transgenic and PSTK1-GUS plant parts. (Note: A1-A7 are non-transgenic plants; B1-B7 are PSTK1-GUS plants; A1 and B1 are radicles; A2 and B2 are mature roots; A3 and B3 are immature leaves; A4 and B4 are mature leaves; A5 and B5 are immature anther; A6 and B6 are mature anther; A7 and B7 are mature pollen)*

Discussion

Genetic transformation is an effective way to increase crop yield and improve quality. With the progress of technology, the method of transgenic maize is continuously improved. In maize, there is a variety of transformation methods, such as electroporation, pollen tube pathway, gene gun, polyethylene glycol, and Agrobacterium-mediated transformation. The receptor of electroporation and polyethylene glycol (PEG) is through protoplast, which is very strict to the preparation and operation of receptor, so it cannot be widely used. The complete pollen tube transformation process is done by natural pollination, without tedious preparation work, breeding required time is short and used directly. Sometimes growing season and flowering stage can affect it. It is also affected by environmental conditions such as temperature, wind, light, rain and more. The bombardment carried out by using the tiny metal particles containing DNA to target the receptor, and DNA injected into the recipient cells by a bilayer lipid membrane. Without host restriction, biolistic method transforms into a variety of plants and improves the plant transformation rate. Moreover, receptor-mediated no-gene type restrictions can be applied to different species and different varieties. It can applied to different organelles with high degree of controllability. However, because the bombardment is random and the conversion rate is relatively low, so multiple copies of the gene are inserted in genome during rearrangement. Prone to a variety of ways, the homologous sequence can be RNA-RNA, DNA-DNA, or DNA-RNA with each other, causing transcription or posttranscriptional level gene silencing. According to various methods, Agrobacterium-mediated transformation has the advantages of relatively stable inheritance, simple operation and high conversion rate. This transformation experiment using *Agrobacterium tumefaciens*-mediated transformation of maize germinating embryo was time saving, strong repeatability and no need of the corn growing season constraints. It also does not depend on tissue culture can also be done without the process of tissue culture transformation. The receptor of this study, and the concentration conditions of bacteria and AS optimized was also corn-germinating embryo.

After acid and leaf treatment, PCR amplification used to screen the positive plants, which was simple and effective. This method does not need to extract the detected leaf DNA according to traditional procedure, shortened the testing time, only needs leaf area of not more than 2 mm. At the same time, in this method, plant leaf injury is relatively low and the cost is decreased. Therefore, this method has the advantages of less time consumption and high detection efficiency.

GUS detection method is fast, simple and stable. The GUS gene is beta-D-glucuronidase (Gus) gene, X-Gluc can be hydrolyzed into blue material and staining of tissues showed blue spots with GUS activity (visible), so gene expression of GUS detected in specific tissues at exogenous gene site. This is not reported in other gene transfer method. In this study, the *PSTK1-GUS* gene of T° transgenic plants only had GUS signal in mature anthers and mature pollens, which showed that *stk1* promoter only had transcriptional activity in mature pollen. However, for T° transgenic plants, it is not possible to determine whether the inserted fragments are integrated successfully into the genomic DNA or not and further experiments are needed to verify them.

DOI: http://dx.doi.org/10.15666/aeer/1705_1178911802

Conclusion

The results suggested that the transformation rate to obtain transgenic plants was very low. The GUS staining of non-transgenic and transgenic *PSTK1-GUS* plants showed no GUS signal. However, mature anthers and pollens showed GUS signal in the form of dark spots, which indicated *ZmSTK1* only influences during pollen development and germination. Agrobacterium-mediated gene transformation method is advance and easy for genetic researchers to solve the mysteries behind gene mutation and function at a specific stage.

(Received 23rd Apr 2019; accepted 16th Jul 2019)

Abstract. Guava is susceptible to various phytopathogenic fungi that could be associated with canker diseases. In Pakistan, farmer's economy is heavily affected by this devastating disease. One of the several strategies to managing it is to develop canker disease resistant guava varieties. For the complete understanding of the associated pathogen and its detailed characterization are required. In this study, Neopestalotiopsis spp accessions of Fungal Molecular Biology Culture Collection UAF (FMB-CC-UAF) isolated from canker affected guava plants were investigated to find genetic diversity among them based on ISSR markers. Eleven (11) ISSR primers were used to analyze eight (8) Neopestalotiopsis accessions. Genetic variation among these fungal accessions were estimated using unweighted pair group method with arithmetic mean (UPGMA) based genetic diversity analysis and Nei's genetic diversity. Among them FMB-Guv-JF2 and FMB-Guv-JF7 showed 13.01% genetic difference to each other. However, the maximum genetic distance was estimated to be 82.32% between FMB-Guv-B2A and FMB-Guv-B1. Generated dendrogram revealed the grouping of investigated fungal accessions into distinct clusters with considerable genetic diversity. It is also supported by principal coordinate analysis (PCoA) which showed dispersed pattern of these fungal accessions indicating diverse genetic base.
Keywords: *fruit crop, plant pathogen, biodiversity, characterization*

Introduction

Guava (Psidium guajava L.) originating from tropical America belongs to the genus Psidium, family Myrtaceae. Its cultivars vary in size and vigor but it's usually a small tree or shrub having 3 to 10 m height with shallow root system, (Malo and Campbell, 1994; Yadava, 1996; Gutiérrez et al., 2008). Guava is now cultivated in many tropical and subtropical countries worldwide. Guava has potential to grow in a variety of soils having different textures, wide pH range (usually 4.4-9.4), drainage, even in poor soil and can tolerate dry and humid climatic conditions (Keith et al., 2006). Guava fruits have spherical to pear shape with penetrating aroma. The fruit is a great source of nutrition having vitamin A, C, B complex, iron, calcium, and phosphorus (Pachanawan et al., 2008). Pakistan ranks fourth among guava producers in the world after India, China and Thailand. In Pakistan guava is at third position in terms of area while at fourth position in terms of production (Pervaiz et al., 2008). In Pakistan guava is cultivated on 665 thousand ha with yield 31.79 t/ha (FAO, 2011), annual production is reduced from 509 to 495 thousand tons during 2015-2016 (Pakistan Bureau of Statistics, 2016). Actual yield is less than potential yields as (10-12 t/ha) (Ul-Haq et al., 2013).

Worldwide growth and production of Guava is stressed by different biotic and abiotic factors. Among the biotic factors diseases are the major production constraint of Guava. So far, 177 pathogens found to be associated with different plant parts of guava. Out of these 167 are fungal pathogens. In Pakistan twenty-one fungal pathogens have been reported so far, which to infect guava plant (Abbas et al., 2016). Twenty-one (21) fungi have been reported to infect guava plants in Pakistan *Phytopthora parasitica*, *Capnodium* sp., *Glomerella cingulate*, *Alternaria alternate*, *Alternaria tenuissima*, *Cladosporium*, *Curvularia* sp., *Fusarium solani*, *Fusarium solani* f. f. sp. Psidii, *Fusarium oxysporum*, *Fusarium oxysporum* f. f. sp. Psidi, *Penicillium* sp. on tree bark in Pattoki and Sharqpur, *Pestalotiopsis brevista*, *Phoma psidii*, *Diplodia psidii*, *Stagnopsis psidii*, *Pestalotia psidii*, *Lasiodiplodia undulate*, *Botryodiplodia theobromae*, *Polyporus* sp. Among the important fungal destructive diseases of Guava in Pakistan, Anthracnose, Wilt, Dieback/decline, fruit canker and scab are of great importance.

While conducting to document the data regarding disease incidence and severity of Guava Anthracnose, dieback and fruit canker and sampling for to detect the association of fungal pathogens with the disease affected plants, the research team of "Fungal Molecular Biology Laboratory" Department of Plant pathology, University of agriculture Faisalabad, Pakistan has identified different isolates as Neopestalotiopsis associated with guava plants. However, evolution results in continuous changes to genetic background of phytopathogens, which ultimately brings new races from them elite cultivars have become susceptible (Malathi et al., 2010). Therefore, unequivocal characterization of newly emerged pathogens is crucial for disease control (Saksena et al., 2013). ISSR marker based genetic analysis for determining and assessing the genetic variation among fungal isolates has become more reliable and efficient approach. Therefore, in this study, genetic diversity among Neopestalotiopsis species accessions of Fungal Molecular Biology Laboratory Culture Collection University of agriculture Faisalabad, Pakistan (FMB-CC-UAF), collected from canker affected guava plants were investigated using ISSR markers.

Materials and methods

Fungal accessions

Eight accessions of Neopestalotiopsis species (*Table 1*) isolated from canker infected branches, leaves and fruits of guava plants were used in this study. These fungal isolates were collected from different regions of Pakistan. Pure culture of each isolate were made by single spore technique and were maintained on Potato Dextrose Agar (PDA) medium. However, the list of potential pathogens associated to guava canker disease is given in the *Table 2*.

Table 2. *Fungal pathogen(s) associated with Psidium guajava*

Sr. No.	Pathogen	Symptom(s)	Reference	Country	Disease
1	Fusarium solani f. f. sp. Psidii	Chlorosis, wilting of branches and twigs, browning of internal tissues	Bokhari et al., 2008 and Gupta et al., 2010,	Pakistan, India	Wilt, decline
2	Fusarium oxysporum f. sp. Psidii	Infected seedlings wilt and die at seedling stage, Older plants show vein clearing, leaf epinasty, yellowing of lower leaves, stunting and defoliation. In case of severe decline quick wilting of leaves giving out burning appearance	Prasad et al., 1952; Pandey and Dwivedi, 1985; Ansar et al., 1994 and Lim and Manicom, 2003	India, Australia, Pakistan	Wilt, decline
3	Phytophthora parasitica	Reported to be associated with guava	Safdar et al., 2015	Pakistan	----------
4	Curvularia lunata	Reported to be associated with guava	Safdar et al., 2015	Pakistan	----------
5	Glomerella cingulate/ Colletotrichum gloeosporioide/	Twigs began to die back, twig blight, formation of brown which turns silvery grey on lateral stages, wither tip, bark splitting and roots began to rot at basal region	Ansar et al., 1994; Tandon and Agarwal, 1954; Lim and Manicom, 2003 and ul haq et al., 2013	All guava growing regions	Wilt, dieback and Decline
6	Pestalotiopsis psidii/ Pestalotia psidii	Symptoms appeared as small necrotic spots of blackish gray and brittle usually appeared on leaf apices. Formation of brown spots and corky lesions on fruit epidermis with elevated margin	Lim and Manicom, 2003; Misra and Prakash, 1986 and Rahman et al., 2003	Australia, India. Burma, Malaysia, Venezuela, Zambia. Bangladesh	Fruit canker and scab
7	Gloeosporium psidii/ Colletotrichum gloeosporioides	Numerous small, water soaked and shallow lesions are produced on ripened fruits, later on these lesions become enlarged and dispersed and fuse with each other to form larger spots which are irregular in shape	Srivastava and Tandon, 1969a	India	Anthracnose or Fruit rot
8	Botryodiplodia theobromae	Infection starts as brown discoloration that usually begins at the stem end and moves downwards in irregular way	Srivastava and Tandon, 1969b	India	Soft watery rot
9	Aspergillus awamori, A. wentii and A .niger	Formation of small sized, round water soaked spots, rotted portion ooze that gives out fermented smell, fruit shrinks and reduction in fruit size occur and blackish mass cover the whole fruit surface	(Gupta et al., 1979 and Lal et al., 1980	India	Aspergillus soft rot
10	Pestalotia psidii/ Pestalotiopsis psidii	Dark brown to grey colored spots appeared on leaf margins or tips. On the upper surface of leaves fruiting pustules may also develops	Bilgrami and Purohit 1971	India	Leaf spot
11	Puccnia psidii	Formation of rust pustules on leaves, shoots, flower and fruits	Misra, 2004	Brazil	Guava rust
12	Rhizopus stolonifer	On infected fruits develop oily and water soaked lesions that are slightly sunken with distinct lesion margins	Ooka, 1980	Hawaii	Rhizopus fruit rot
13	Mucor haemalis	Development of water soaked lesions on infected portion, yellow and fuzzy mass of the fungus may cover the whole fruit surface and finally rotted fruits give off yeast like smell	Kunimoto et al., 1977	India	Mucor fruit rot
13	Rhizoctonia solani	Water soaked discoloration of infected seeds as well as seedlings during pre-emergence stage. During post emergence upper leaves develops yellow to brown color, move downward and cause rotting. Finally, seedlings hands down and eventually die	Gupta, 1978	India	Damping off of seedlings/ seedling blight
14	Curvularia siddiquii	Leaves develop dark brown spots that are restricted to leaf tips and margins at initial stage that covers the whole leaf and eventually defoliate	Srivastava, 1963.	India	Leaf spot
15	Phytophthora parasitica/ Phytophthora citricola/ Phytophthora anicotianae	Infected portion develops greyish brown, water soaked lesions with a greyish black centre, internal fruit surface becomes soft that emits unpleasant smell	Mitra 1929; Gupta et al., 1978 and Ko et al.,1982		Phytophthora fruit rot

Sr. No.	Pathogen	Symptom(s)	Reference	Country	Disease
16	Alternaria tenuissima	Reported to be associated with guava	Abbas et al., 2016	Pakistan	----------
17	B. theobromae	Yellowing of leaves, wilting and complete defoliation, infected trees bears no fruits or few fruits, fruits may become dry and wrinkled	Safdar et al., 2015	Pakistan	Guava decline
18	Phoma psidii	Small circular spots having dark brown center with reddish margin. In advance stage of the disease these spots enlarge and coalesce causing necrotic patches and blighted appearance	Sridhar and Ullasa, 1978	India	Leaf blight
19	Phomopsis destructum	Formation of small lesions of dark brown color and increase to 2 cm diameter. Infected tissues become soft and entire fruit becomes rotted within few days	Rao et al., 1976	India	Phomopsis rot

Genomic DNA isolation

Genomic DNA of these studied fungal accessions was extracted from the mycelia grown on PDA media. Mycelium was ground in liquid nitrogen to turn into fine powder. The fine powder of each sample was treated by CTAB method with some modifications, for genomic DNA isolation. The quality and quantity of extracted DNA was analyzed using agarose gel electrophoresis and spectrophotometer (8000 Spectrophotometer, Thermoscientific.) respectively. Purified DNA of each sample was stored at 4°C for further analysis.

PCR analysis

PCR analysis was performed in 96 well Veriti^{TM} thermalcycler (Applied Biosystem). For genetic analysis of Neopestalotiopsis spp accessions, eleven (11) ISSR primers (*Table 3*) were used. PCR for ISSR was carried out in 25 µl reaction tubes containing primers, dNTPs, 10X *Taq* PCR buffer, Taq polymerase and genomic DNA. PCR products were separated on 2% high resolution agarose (ACTGene), visualized under Gel documentation System (BioRad) and photographs were saved.

Table 3. *List of ISSR primers and statistical data obtained by ISSR primers among Neopestalotiopsis spp accessions*

Data analysis

DNA bands were counted from DNA banding profiles of each ISSR primer and scored as, "1" for presence and "0" for absence. The data were analyzed using different software packages such as; PAST v.3.16 for dendrogram based on unweighted pair group method with arithmetic mean (UPGMA) algorithm, PopGen32 v. 1.32 for similarity matrix, DARwin6 v. 6.0 software for Principal Coordinate analysis (PCoA), Power marker v. 3.25 for computing polymorphic information content (PIC).

Results

DNA markers are used to assess genetic variability among different individuals. This study was carried out with eight different neopestalotiopsis spp accessions to detect genetic variation among them. PCR amplification using eleven (11) ISSR primers yielded total 41 scorable loci of which 7 were monomorphic loci (*Table 2*). The number of scorable loci varied from 2 (ISSR19) to 6 (ISSR807). However, maximum number of alleles or bands (30) was obtained from primer ISSR807, while only 10 bands or alleles were produced by ISSR860. Of these 11 (eleven) ISSR markers, six primers (ISSR823, ISSR857, ISSR860, ISSR4, ISSR12, ISSR15) showed 100% polymorphism. The highest value of polymorphic information content (PIC) was 1.7021 of primer ISSR823, whereas the lowest value 0.1948 was from primer ISSR19 with average PIC value per primer was 0.996445.

The dendrogram clearly indicated the two clusters, of which cluster I comprising of four fungal accession, FMB-Guv-B3, FMB-Guv-MB, FMB-Guv-C4 and FMB-Guv-B1. However, cluster II was possessing four accessions viz., FMB-Guv-JF2, FMB-Guv-JF7, FMB-Guv-L2A and FMB-Guv-B2A (*Fig. 1*). This dendrogram showed that these all accessions are diverse and distinct to each other. The fungal accession FMB-Guv-B2A was shown to be highly diverse to FMB-Guv-B1 by scoring the 0.8232 that revealed they are 82.32% dissimilar followed by FMB-Guv-C4 to whom FMB-Guv-B2A is 76.91% dissimilar (*Table 4*). While fungal accessions FMB-Guv-JF2 and FMB-Guv-JF7 are closely related as compared to others with similarity co-efficient 0.1301, which showed, they have 13.01% dissimilarity, so they are more close to each other. Principal Co-ordinate analysis (PCoA) showed comparable results that were obtained in UPGMA based dendrogram (*Fig. 2*) and indicating considerable genetic variability among Neopestalotiopsis spp accessions. Principal coordinate analysis (PCoA) also indicated dispersed pattern of these fungal accessions demonstrating diverse genetic base.

Discussion

Studies at the genomic level are necessary and crucial to understand population genetics and genetic diversity and relationships among individual. There is no report for molecular marker assisted characterization of species of Neopestalotiopsis genus. Therefore, in this study, we have attempted the characterization of different isolates of Neopestalotiopsis spp collected from canker affected guava plants using ISSR molecular marker. Fungal Molecular Biology Culture Collection, University of Agriculture Faisalabad Pakistan, has accessioned these Neopestalotiopsis spp isolates. For identification of polymorphism in terms of genetic diversity among these studied fungal isolates, ISSR markers were used to assess intrapopulation genetic variation in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1180311811

Neopestalotiopsis spp accessions collected from different region of Pakistan. The inherent genetic variation in this study on Neopestalotiopsis spp isolates revealed their genetic distinctness unambiguously. Dendrogram based on UPGMA, Nei's original measures and principal Coordinate analysis (PCoA) showed that they all are genetically diverse. These markers yielded percent polymorphism ranged from 50% to 100%, which is in accordance to the findings of Patel et al. (2018). In this study average polymorphic information content (PIC) values was 0.996445 that indicating the discriminating power and potential of these selected ISSR primers to determine genetic diversity among these fungal accessions. This finding is also similar to the findings of Ijaz et al. (2018 and 2019) and Patel et al. (2018).

Conclusions

This research study was based on the investigation of neopestalotiopsis species collected from canker affected guava tree. By considering these fungal isolates belonging to neopestalotiopsis species, to be an associated pathogen of canker disease in guava. We determined their genetic diversity. The genetic diversity analysis revealed that these subjects are of diverse in their genetic background, though, FMB-Guv-JF2 and FMB-Guv-JF7 showed close relatedness to each other. These results suggested that FMB-Guv-JF2 and FMB-Guv-JF7 could be as monophyletic group in phylogenetic hierarchy. However, remaining isolates were shown as genetically diverse background. The maximum genetic diversity was observed between FMB-Guv-B2A and FMB-Guv-B1 neopestalotiopsis species fungal accessions. Further experimentation to undertaking their molecular taxonomy would be an imperative step to resolve the species boundaries of theses studied isolates.

(Received 23rd Apr 2019; accepted 11th Jul 2019)

Abstract. UV-B radiation has diverse biological effects on plants. The tolerance of *rcd1-1* mutant to UV-B radiation was studied in the present research. Leaves of the wild type under UV-B exhibited chlorosis, curling, and necrotic lesions, but these phenomena were not observed in the *rcd1-1* mutant. The *rcd1-1* mutant accumulated less H_2O_2 and O_2^- under UV-B radiation, and had higher activity of anti-oxidative enzymes. UV-B radiation led to accumulation of UV-B absorbing compounds as flavonoids, and anthocyanins. The *rcd1-1* mutant under UV-B radiation had higher maximum quantum efficiency of primary photochemistry and exhibited less of a decrease of effective quantum yield of photochemical energy conversion in PS II and photochemical quenching of variable chlorophyll fluorescence yield. The *rcd1-1* mutant also showed higher non-photochemical quenching, indicating that it could dissipate excess energy. The *psbA* gene were more highly expressed in the *rcd1-1* mutant, while *ANAC013* and *UNE10* genes were negatively regulated. This may explain why the mutant had a higher photosynthetic capability under UV-B radiation. It can be confirmed that the tolerant *Arabidopsis rcd1-1* mutant under UV-B radiation exhibits higher photosynthetic activity and less oxidative damage than the wild type.
Keywords: *rcd1-1 mutant, UV-B, flavonoids, anthocyanins, gene expression*

Abbreviations: Chl *a* + *b*: chlorophyll *a* and chlorophyll *b*; Fm: maximal fluorescence of a dark-adapted sample; Fo: initial fluorescence of a dark-adapted sample; Fm': maximal fluorescence of an illuminated sample; Fs: minimal fluorescence of an illuminated sample; PSI: photosystem I; PSII: photosystem II; UV-A: ultraviolet-A radiation (315–400 nm); UV-B: ultraviolet-B radiation (280–315 nm); UV-C: ultraviolet-C radiation (wavelength < 280 nm)

Introduction

Ultraviolet radiation from sunlight is divided into three spectral regions: UV-A, UV-B and UV-C. In a natural environment, plants are exposed to 10–100 times more UV-A (315–400 nm) photons than they are to UV-B (280–315 nm) photons (Verdaguer et al., 2017). UV-B radiation has received most attention because it is strongly absorbed by ozone. UV-C, with wavelength shorter than 280 nm, does not reach ground. The decrease of the ozone layer led to a significant increase in UV-B radiation from 1970 till about 1995 and shifts in the spectral UV-composition reaching the Earth surface at mid- and high latitudes. Until now little is known about the mechanism by which the *rcd1-1* mutant tolerates UV-B radiation. In the present research, we explore the UV-B resistance of the *rcd1-1* mutant by morphological and physiological properties, and gene expression. The results may explain why the mutant is tolerant to UV-B, which could enrich our understanding of the regulation mechanism of UV-B response.

Review of literature

Plants are inevitably exposed to UV-B, as they need sunlight. High doses of UV-B radiation can cause stress and damage in plant, including DNA, protein and plasma membrane damage, production and accumulation of reactive oxygen species, cell cycle arrest, chlorophyll degradation, photosynthesis inhibition, and affect various cell processes (Ulm and Jenkins, 2015; Biever and Gardner, 2016). However, UV-B not only has adverse effects on plants, but also can activate the repair mechanism in vivo, especially for plants with insufficient or no UV-B in facility culture. UV-B regulates gene expression related to physiological processes such as metabolism, morphogenesis, photosynthesis and pest resistance (Jenkins, 2014). It also regulates leaf development, regulates clock rhythm, improves plant heat tolerance, cold tolerance, drought resistance and delays flowering time (Yin and Ulm, 2017; Dotto et al., 2018).

Exposure of plants to UV-B induces photomorphogenetic as well as physiological and genetic changes, mostly injurious but sometimes beneficial. Enhanced UV-B in solar radiation could potentially induce DNA damage and radical oxygen species (ROS) production in living cells (He and Häder, 2002; Zlatev et al., 2012). On the other hand, plants have evolved a wide range of protective and repair mechanisms against UV-B stress, such as the formation of surface wax, polyamines and specific alkaloids, flavonoid biosynthesis, DNA repair and changes in metabolism (Ulm and Nagy, 2005; Fujibe et al., 2004; Frohnmeyer and Staiger, 2003). Enhanced UV-B radiation to may also result in lower photosynthesis and leads to a decrease in crop yields. Therefore, understanding how plants protect themselves against UV-B radiation is of utmost importance for agricultural production.

In recent years the model plant *Arabidopsis thaliana* has gained the much attention in research on the effects of UV, because many research tools (such as genetic, molecular biology and bioinformatics tools) could be applied to it. The intervals of *rcd1-1* on BACs F3C3 and F27G20 containing seven open reading frames were determined by genetic mapping. Six of them matched the published genome sequence of *Arabidopsis*. At1g32230 gene has a typical C-T to ethyl methylsulfonate mutation in the antisense chain, which results in G-A transition at the GT splicing site of the third exon-intron connection. RT-PCR showed that the splicing of RCD1 intron in wild type Col-0 was consistent with the predicted structure of At1g32230 and the published full-length cDNAs of CEO1 and RIKEN. In *rcd1-1*, two transcriptional types were identified by RT-PCR amplification and sequence analysis. The 2.7-kb transcript represents mRNA, in which the next (GT) in intron III downstream of the mutant shear acceptor site is used for splicing of intron III. The misspliced *rcd1-1* mRNA was only 11 bp longer than that of wild type. In *rcd1-1*, the expression level of the shorter 1.4-kb transcript was approximately the same as that of the 2.7-kb transcript. In the 1.4-kb transcript, intron splicing occurs from the 5' end of exon IV into exon III, so exon III is completely missing. Both misspliced *rcd1-1* transcript types lead to frame loss and premature termination of codons. In wild col-0, RCD1 was expressed in stem, leaf, bud and young flower, while siliques and root transcription were lower in old flower. In *rcd1-1*, compared with wild type, gene expression increased slightly, and also in old flowers and roots compared with Col-0. In siliques of *rcd1-1*, only the shorter transcripts existed at lower abundance (Ahlfors et al., 2004).

Radical-induced cell death1 (RCD1) protein is an important regulator of stress and hormonal and developmental responses in *Arabidopsis thaliana* (Jaspers et al., 2009). CEO1, also called RCD1, is a protein from *Arabidopsis thaliana* that protects yeast against oxidative damage (Belles-Boix et al., 2000; Ahlfors et al., 2004; He et al., 2012). It contains two conserved globular protein domains: the WWE domain and a poly (ADP-ribose) polymerase (PARP)-like ADP-ribose transferase catalytic domain, the former mediated by specific protein-protein interaction (Jaspers et al., 2010). When the RCD1 protein is expressed in yeast, the yeast is protected from oxidative damage induced by *tert*–butylhydroperoxide, peroxide and diamide (Belles-Boix et al., 2000). The results from gene chip research indicate that a large number of abiotic stress related genes have reduced expression in the *Arabidopsis rcd1-1* mutant (Ahlfors et al., 2004).

Thus RCD1 may be an important regulator of the oxidative stress response, and may also be involved in other abiotic stress responses in plants (Kragelund et al., 2012). This is suggested by a number of key findings. The *Arabidopsis rcd1-1* mutant has proved to be sensitive to ozone and apoplastic superoxide (Fujibe et al., 2004; Moldau et al., 2011). Forward genetic screens for ozone sensitivity and paraquat tolerance led to the isolation of *Arabidopsis rcd1-1* and *rcd1-2* mutants (Jaspers et al., 2009; Fujibe et al., 2004; Overmyer et al., 2000). The *rcd1-2* mutant is tolerant than the wild type (Fujibe et al., 2004), as is the *rcd1-1* allele (Jaspers et al., 2010; Jiang et al., 2009). The *rcd1-2* mutant is resistant to methyl viologen, and sensitive to UV-B. The *rcd1-1* mutant is sensitive to ozone and tolerant to short-term UV-B radiation. In addition, the *rcd1-1* mutant has lower sensitivity to abscisic acid, ethylene and methyl jasmonate than the wild type. Exogenous methyl ester of jasmonic acid (MeJA) inhibits the spread of cell death in *rcd1-1* mutant (Overmyer et al., 2000). By using the gene microarray technology, the expression of a large number of abiotic stress related genes were reduced in the *rcd1-1* mutant (Ahlfors et al., 2004). The *rcd1-2* mutant was resistant to a short period of UV-B radiation and exhibited higher activity of SOD and *APX* gene expression level than the wild type (Fujibe et al., 2004).

Materials and methods

Plant materials, growth conditions and UV treatment

Wild type and mutant *Arabidopsis thaliana* used in this study were all of the ecotype Columbia-0 (Col-0) background. Seeds were vernalizated at 4 °C for 3 d before sowing (Jiang et al., 2009). Seeds were surface sterilized and sown on Murashige and Skoog medium (Murashige and Skoog, 1962) containing 3% sucrose for germination and grew for 14 days under appropriate light conditions at 22 °C. White light was provided by cool white fluorescent lamps (Philips TLD30W/865 tubes, 80 W m^{-2}). Conditions for UV-B irradiation were the same as described by Jiang (Jiang et al., 2009). Radiation (hereafter referred to as UV-B) from the UV-B tubes (Philips PLS9W/01, 1.8 W m^{-2}) was filtered through cellulose acetate film (95 μm; Kunststoff-Folien-Vertrieb GmbH, Hamburg, Germany), which transmitted both UV-A and UV-B, but blocked UV-C. Radiation for control plants (hereinafter referred to as UV-A) was filtered through Mylar film, which removed both UV-B and UV-C. The spectral irradiance from the UV lamps was determined with an iHR550 spectroradiometer (HoribaJobinYvon, Japan). The spectral irradiance was weighted with the generalized plant response action spectrum, normalized to unity at 300 nm to obtain UV-B.

Root length and dry biomass

The seeds of *Arabidopsis thaliana* were planted on MS solid medium after vernalization at low temperature and surface disinfection. The culture dishes were placed vertically. The germination and seedling growth of Arabidopsis thaliana seeds were observed 2, 4, 6, 8, 10 and 12 days after sowing, and the root growth of seedlings was measured by Image J software.

Arabidopsis thaliana seedlings were harvested 14 days after sowing. The adherent MS solid medium was washed with EDTA-Na_2 and deionized water. The fresh weight was measured. Then the fresh weight was put into 65 °C oven until the constant weight, and then the dry weight was measured.

Measurement of cell membrane permeability

The membrane permeability of the wild type and *Arabidopsis rcd1* mutant was evaluated by Evans blue staining and conductivity measurement. Evans blue staining was conducted as described with some improvement. Briefly, samples were evacuated for 5 min and then infiltrated for 20 min with 0.1% Evans blue solution. The process was repeated three times, and each repetition is the average of 10 values. The samples were then boiled for 5-10 min in a mixture of 95% ethanol and lactophenol (2:1) and stored in 5% ethanol for observation. Electrical conductivity measurements were carried out with a conductivity meter (FE330, Mettler-Toledo). The first value (R1) was obtained after the clean leaves and roots were immersed in deionized water for 2 h at room temperature. After immersion for 20 min in boiling water the samples were cooled to room temperature and then measured for a second value (R2). The relative electrical conductivities were determined according to (R1/R2) × 100%.

Location of O_2^- in the leaves, location and concentration of H_2O_2 in the leaves

Generation of O_2^- in *Arabidopsis* leaves in response to UV treatment was detected by the Nitro Blue Tetrazolium (NBT) technique (Uy et al., 2011). *Arabidopsis* leaves were bathed in 0.1 mg mL^{-1} NBT solution and, following evacuation by pumping for 10 min infiltrated under dark conditions until translucent, and then placed at room temperature for 2 h. They were then boiled in 90% ethanol until the chlorophyll was completely removed. At last, the leaves were scanned and observed by Mahalingam et al. (2006). To determine H_2O_2 in the leaves, they were infiltrated as before, but with 0.3 mg mL^{-1} 2-amino benzidine (DAB) solution after UV-B treatment. They were placed in the dark for 8 h, followed by light for 2 h and then harvested and boiled in 90% ethanol until the chlorophyll was completely removed. Finally, the leaves were scanned and observed by Ma et al. (2012). H_2O_2 analysis was assayed as described by Cheeseman (2006).

Measurements of SOD, CAT and POD activity

Frozen plant leaves (1 g) were homogenized in 50 mM sodium phosphate buffer (pH 7.0) containing 0.1 mM EDTA, 0.1%(m/v) phenylmethylsulfonyl fluoride, 1% (m/v) polyvinylpyrrolidone, 0.1% (v/v) TritonX-100 and 50 mM ascorbic acid. The extract was centrifuged at 12,000 × g for 15 min and the supernatant was used for enzymatic assays. In this study, the superoxide dismutase (SOD) activity was measured by the xanthine oxidase method with SOD Activity Assay Kit (Jiancheng Bioengineering Institute, Nanjing, China). Catalase (CAT) and polyphenol oxidase (POD) activities

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1181311833

were measured as described by Ma et al. (2012). For SOD, the enzyme quantity that inhibits the self-oxidation rate of the reaction solution by 50% per ml under certain conditions is defined as 1 enzyme activity unit (U). For CAT, a decrease of 0.1 in A240 per minute was defined as 1 enzyme activity unit (U). For POD, a decrease of 0.01 in A470 per minute was defined as 1 enzyme activity unit (U).

Pigment, anthocyanin, flavonoid and malondialdehyde (MDA) measurements

Total chlorophyll (Chl *a* + *b)* content in plant leaves was measured by the method of Arnon (1949). The absorbance of the extract was recorded at 663 nm and 645 nm. The concentrations of chlorophyll *a*, chlorophyll *b* and total chlorophyll were calculated using the following equation:

$$\text{Chl } a = 0.0127\ \text{A663} - 0.00269\ \text{A645}$$
$$\text{Chl } b = 0.0229\ \text{A645} - 0.00468\ \text{A663}$$
$$\text{total Chl } a+b = 0.0202\ \text{A645} + 0.00802\ \text{A663}$$

Anthocyanin content was determined as described by Noh and Spalding (1998). For flavonoid measurement, 14-day old seedlings were frozen in liquid nitrogen, flavonoids were extracted and quantified as described by Kucera et al. (2003). MDA was measured with Malondialdehyde (MDA) Assay Kit (Jiancheng Bioengineering Institute, Nanjing, China) according to the manufacturer's instruction.

Photochemical activity measurements

Photochemical efficiency was evaluated from the chlorophyll *a* fluorescence of photosystem II, using a modulated fluorometer (Heinz Walz GmbH, Effeltrich, Germany) including optimal quantum yield (Fv/Fm), effective quantum yield (ΦPSII) and non-photochemical quenching (NPQ). Optimal quantum yield was defined as (Fm-Fo)/Fm, where Fm represents maximal and Fo initial fluorescence of a dark-adapted sample. Effective quantum yield is defined as (Fm'-Fs)/Fm', where Fm' represents the maximal and Fs minimal fluorescence of an illuminated sample (Sedej and Gaberščik, 2008). NPQ-values were determined according to the Stern-Volmer equation:

$$\text{NPQ} = (\text{Fm} - \text{Fm}')/\text{Fm}'$$

RNA extraction and quantitative real-time PCR

Total RNA was extracted from seedlings by using E.Z.N.A. Plant RNA Kit (Omega, USA) according to its protocol, then digested with DNAse I (Promega, USA) to eliminate genomic DNA contamination. First-strand cDNAs were synthesized from using PrimeScript 1st strand cDNA synthesis kit (Takara Biotechnology, China) according to the manufacturer's instructions.

The quantitative PCR (q-PCR) assays were performed with the ABI PRISM 7500 Real-time PCR system (Applied Biosystems, USA) using Power SYBR Green Master Mix (Applied Biosystems, USA) following the recommended conditions (50 °C for 2 min, then 95 °C for 10 min, followed by 40 cycles of 95 °C for 15 s and 60 °C for 1 min). Sepcific Primer 5.0 software was used to design the primers for the experiment (*Table 1*).

DOI: http://dx.doi.org/10.15666/aeer/1705_1181311833

Table 1. *The nucleotide sequences of the primers used in qPCR*

No.	Gene	Primer (5'→3')
X16077.1	*18S rRNA*	F: CGTCCCTGCCCTTTGTACAC R: CGAACACTTCACCGGATCATT
NM_103021.3	*ANAC013*	F: AGGGAAGGATAGAGTCATTCATTGT R: AGTCCGTTCGCCATTAGGTG
X79898.1	*psbA*	F: GGTGCCATTATTCCTACTTCTGC R: GTTCATAAGGACCGCCGTTGT
NM_116222.3	*UNE10*	F: TTCCATCATCGCTCCTCCAG R: GTACGACCATCGCTACATGACC

The dissociation curve was used to check for the presence of a unique PCR product and the amplification curves was analyzed to estimate the primer pair efficiencies with the LinReg software (Czechowski et al., 2005). The average efficiency of all reactions on a plate (which was always > 1.95) was used in calculations. All reactions were carried out in three technical replicates. To normalize the qPCR data, a reference gene (18sRNA) was used for detecting gene expression in the wild type and the *rcd1-1* mutant (Jiang et al., 2009).

Statistical analysis

The GraphPad Prism 8 was used for statistical analysis and drawing. For comparing results of different treatments, Variance analysis is followed by a post-hoc test in order to determine pairwise differences. Differences were considered significant for $P < 0.05$.

Results

The rcd1-1 mutant is not sensitive to UV-B radiation

After growing for 8 days in white light condition, the *rcd1-1* mutant was significantly smaller than the wild type. The *rcd1-1* mutant had slower root growth (*Fig. 1a*) and accumulated less biomass (*Fig. 1b*). Also root growth was significantly inhibited (*Fig. 1c*). The ANOVA table for the data of *Figure 1c* (Two-way ANOVA, Sidak's multiple comparisons test) was displayed in *Table A1* in the *Appendix*. Under UV-B radiation, the wild type leaves showed chlorosis, curl, and necrotic lesions. However the *rcd1-1* mutant showed less changes under UV-B radiation (*Fig. 1d*).

The rcd1-1 mutant showed less cell membrane damage after UV-B exposure

Membrane permeability (Evans Blue Stain) correlated positively with duration of UV-B irradiation, and the stain of the wild type was deeper than that of the *rcd1-1* mutant (*Fig. 2a*). The electrical conductivity of the cell membrane exhibited a highly significant increase after UV-B radiation compared to the control. Although the electrical conductivity of the wild type was significantly less than that of the *rcd1-1* mutant before UV-B irradiation, it had a rising trend with increasing irradiation time, and was largest after UV-B irradiation for 6 h (*Fig. 2b*). The ANOVA table for the data of *Figure 2b* (Two-way ANOVA, Tukey's multiple comparisons test) was displayed in *Table A2*. These results indicated that the cell membrane damage of the wild type was more serious than that of the *rcd1-1* mutant after UV-B exposure.

The rcd1-1 mutant showed less content of MDA, O_2^- and H_2O_2 after UV-B exposure

To further investigate the effects of enhanced UV-B radiation on *Arabidopsis*, malondialdehyde (MDA), H_2O_2 and O_2^- productions were analyzed. The level of MDA production was significantly higher in the wild type than that in *rcd1-1* mutant after exposure for 8 h (*Fig. 3a*). The ANOVA table for the data of *Figure 3a* (Two-way ANOVA, Tukey's multiple comparisons test) was displayed in *Table A3a*. Similarly, enhanced UV-B radiation elevated H_2O_2 production considerably in the leaves after exposure for 8 h (*Fig. 3c*). The ANOVA table for the data of *Figure 3c* (Two-way ANOVA, Tukey's multiple comparisons test) was displayed in *Table A3b*. This was also shown by the DAB staining test (*Fig. 3d*). The NBT staining test showed that there was a positive correlation between accumulation of O_2^- in leaves and UV-B exposure time (*Fig. 3b*). More specifically, there was little blue precipitate in the leaves of the wild type and *rcd1-1* mutant before UV treatment and both had nearly the same light color. However, more and more blue precipitate appeared along with increasing duration of UV-B exposure, indicating that O_2^- in leaves increased. The blue precipitate in *rcd1-1* mutant leaves was less than that in the wild type at any testing time point in the whole UV-B radiation treatment process, indicating that the accumulation of O_2^- in the wild type was higher than that in *rcd1-1* mutant after UV-B radiation. In the control group (UV-A radiation treatment) the accumulation of O_2^- in the leaves was also stimulated, but the accumulation was significantly lower than for UV-B radiation. These results suggest that the damage caused by the short-term enhanced UV-B radiation to the *rcd1-1* mutant was less than that to the wild type.

Effects of antioxidant enzymatic activity of the leaves in the rcd1-1 mutant after UV-B exposure

The superoxide dismutase (SOD), peroxidase (POD) and CAT activities were assayed to investigate the effects of enhanced UV-B radiation on the antioxidative system. The SOD activity of the wild type exposed to UV-B radiation showed a slightly increasing trend, while the *rcd1-1* mutant maintained a rapid upward trend except for a decline at 4 h. The SOD activities of both genotypes were elevated after UV-B radiation for 8 h, which significantly increased from 1146 U to 1187 U in the wild type, while from 1152 U to 1299 U in *rcd1-1* mutant (*Fig. 4a*). The ANOVA table for the data of *Figure 4a* (Two-way ANOVA, Tukey's multiple comparisons test) was displayed in *Table A4a*.

The POD activity had a similar trend with the SOD activity, which showed an overall upward trend in leaves of the two genotypes with increasing duration of UV-B radiation. The difference between them was that the POD activity of *rcd1-1* mutant had always showed upward trend, while the wild type reached the highest value at the point of 6 h exposure and reduced a little at 8h. Although the POD activities of the two genotypes were almost identical under normal conditions, which increased up to 60.4% in the *rcd1-1* mutant and 41.0% in the wild type after UV-B radiation for 8 h. However, the POD enzyme activities of the two control groups treated with UV-A only increased slightly (*Fig. 4b*). The ANOVA table for the data of *Figure 4b* (Two-way ANOVA, Tukey's multiple comparisons test) was displayed in *Table A4b*.

The CAT activities differed between *rcd1-1* mutant and the wild type. The CAT activity of *rcd1-1* mutant ascended immediately under both UV-A and UV-B radiation. However, the CAT activity of the wild type fluctuated within a narrow range and finally

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1181311833

declined (*Fig. 4c*). The ANOVA table for the data of *Figure 4c* (Two-way ANOVA, Tukey's multiple comparisons test) was displayed in *Table A4c*. In general, the CAT activity of *rcd1-1* mutant had far higher levels than that of the wild type after UV-B radiation.

Flavonoid and anthocyanin content after UV-B exposure

As ultraviolet absorbing compounds in *Arabidopsis*, flavonoid and anthocyanin could be effectively induced when the leaves were exposed to UV-B radiation. UV exposure resulted in the accumulation of flavonoids and anthocyanin both in *rcd1-1* mutant and the wild type, but in the *rcd1-1* mutant the contents were significantly higher than in the wild type (*Fig. 5*). The ANOVA table for the data of *Figure 5b* (Two-way ANOVA, Tukey's multiple comparisons test) was displayed in *Table A5*.

The chlorophyll content and chlorophyll fluorescence of leaves in rcd1-1 mutant after UV-B exposure

One of the important kinds of damage of UV-B radiation to plants is the inhibition of chlorophyll synthesis. Phenotypic analysis found that the loss of green colour under UV-B radiation of the *rcd1-1* mutant was lower than that of the wild type (*Fig. 6a*). The ANOVA table for the data of *Figure 6a* (Two-way ANOVA, Tukey's multiple comparisons test) was displayed in *Table A6a*. The changes of chlorophyll content in the *rcd1-1* mutant and the wild type were measured. The downward trend of total chlorophyll in both genotypes after UV-B radiation is displayed in *Figure 6c*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1181311833

More specifically, the total chlorophyll content in both genotypes declined rapidly over the first two hours of exposure. After that, the chlorophyll content in the wild type continued to decline, while the *rcd1-1* mutant recovered transiently and chlorophyll content fell again after 8 h. After irradiation for 8 h, the total chlorophyll content in the wild type decreased by 21% while in the *rcd1-1* mutant it significantly decreased only by 15%; the total chlorophyll content of the UV-irradiated *rcd1-1* mutant was 12% higher than that of the wild type. The control group of UV-A treatment suffered only a slight decline of chlorophyll, irrespective of genotype. The trend for chlorophyll *a* was similar to that for total chlorophyll. The degradation rate of chlorophyll *a* in the wild type was significantly higher than that in *rcd1-1* mutant after UV-B radiation (*Fig. 6b*). The ANOVA table for the data of *Figure 6b* (Two-way ANOVA, Tukey's multiple comparisons test) was displayed in *Table A6b*. However, there were no differences of the degradation rate of chlorophyll *b* in the wild type and the *rcd1-1* mutant after UV-B radiation (*Fig. 6c*). The ANOVA table for the data of *Figure 6c* (Two-way ANOVA, Tukey's multiple comparisons test) was displayed in *Table A6c*.

To study the effects of enhanced UV-B radiation on photosynthesis, the chlorophyll fluorescence parameters (Fv/Fm, ϕPSII, qP and NPQ) were determined. Fluorescence values were converted to colour by chlorophyll fluorescence imager (*Fig. 7*).

The effects of enhanced UV-B radiation on the maximal efficiency of PSII photochemistry in the wild type and the *rcd1-1* mutant were reflected in the value of Fv/Fm (*Fig. 8a*). The ANOVA table for the data of *Figure 8a* (Two-way ANOVA, Tukey's multiple comparisons test) was displayed in *Table A7a*. After UV-A radiation, Fv/Fm of the wild type and *rcd1-1* mutant exhibited a slight decline -14.7% and 5% respectively. The value of Fv/Fm showed a sharp decrease from 0.79 to 0.22 (72% decrease) in the wild type under UV-B radiation, but only from 0.80 to 0.59 (26% decrease) in the *rcd1-1* mutant. The results showed that *rcd1-1* was more resistant to UV-B radiation than the wild type with respect to PSII integrity.

The quantum yield (ϕPSII) of the PSII electron transport was used to detrmine the PSII photochemical efficiency (*Fig. 8b*). The ANOVA table for the data of *Figure 8b* (Two-way ANOVA, Tukey's multiple comparisons test) was displayed in *Table A7b*. ϕPSII showed declining trends in both genotypes, but with less decline in *rcd1-1*, and none in the first two hours. Finally, ϕPSII decreased from 0.425 to 0.340 in the *rcd1-1* mutant, and from 0.420 to 0.286 in the wild type.

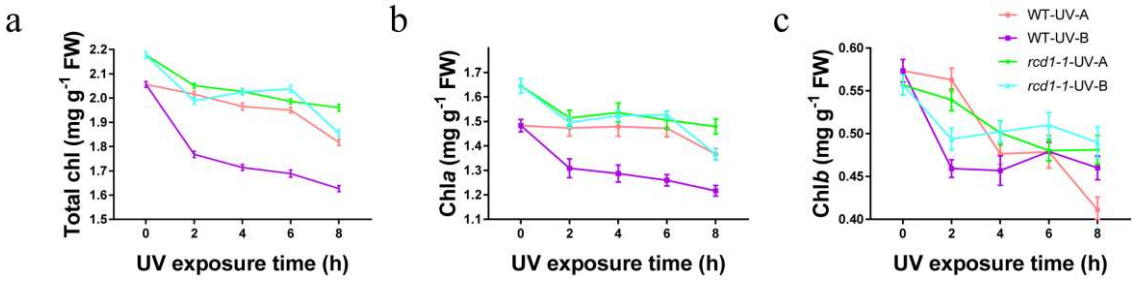

Figure 6. *Effects of enhanced UV-B radiation on chlorophyll content. After UV treatment, about 0.2 g leaves were harvested, ground in 80% (v/v) acetone solution, stored at -20 °C overnight, centrifuged and then measured OD value by spectrophotometer. Total chlorophyll content (**a**), the chl a content (**b**) and the chl b content (**c**) in the wild-type and rcd1-1 mutant were measured. Data are expressed as mean values ± standard errors from three replicates and error bars represent standard errors*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1181311833

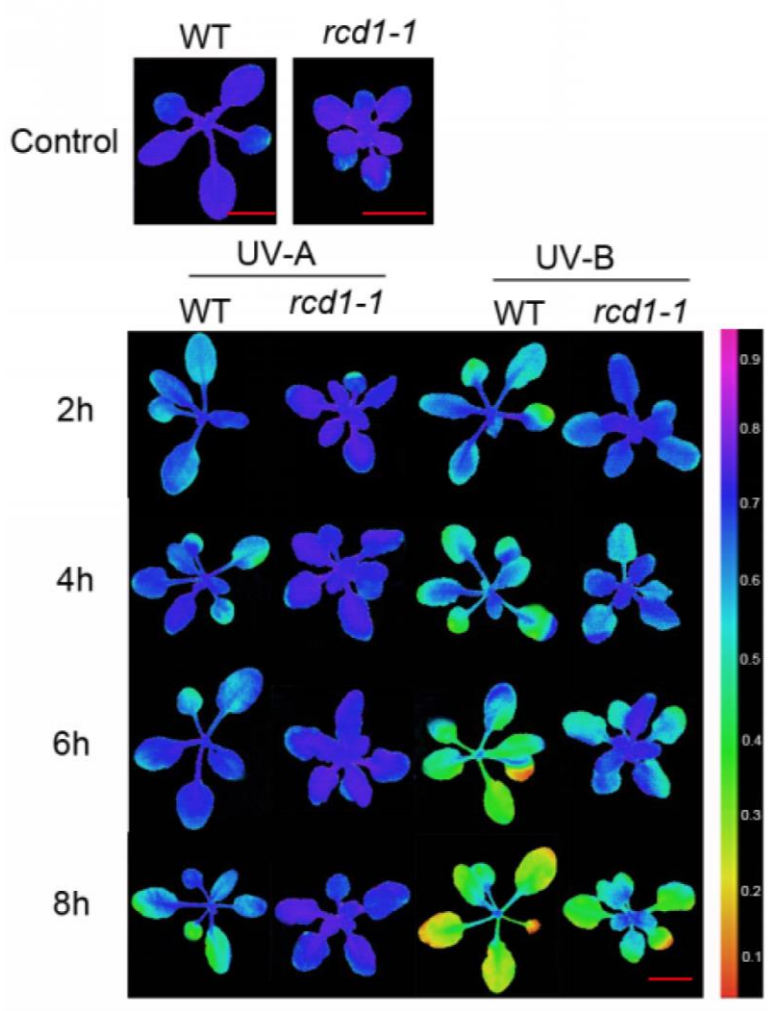

Figure 7. *Changes in fluorescence images of Fv/Fm in the wild type and rcd1-1 mutant leaves: 0 (black) to 1.0 (purple) in chlorophyll fluorescence was represented by color from black to purple. Three-week-old wild type and rcd1-1 mutants were exposed to 0.4 W m^{-2} UV for different hours and measured with Imaging-PAMM-series instrument. The bar value is 10 mm*

UV-B stress changed chlorophyll fluorescence. qP of both the wild type and *rcd1-1* mutant declined with increasing time of UV-A and UV-B exposure (*Fig. 8c*). The ANOVA table for the data of *Figure 8c* (Two-way ANOVA, Tukey's multiple comparisons test) was displayed in *Table A7c*. At the beginning of UV radiation, the qP of the wild type fell by 14.5% while that of the *rcd1-1* mutant dropped by 8%. Finally, after UV-B radiation for 8 h, the qP value of the wild type decreased by 22.6%, while that of the *rcd1-1* mutant had significantly decreased by 15%. Under normal growth condition, the non-photochemical quenching (NPQ) values of the wild type and *rcd1-1* mutant were almost the same, but at the beginning of UV-B exposure the value of NPQ of both genotypes increased slightly (*Fig. 8d*), indicating that the function of the *Arabidopsis* heat dissipation had been enhanced during this period. The ANOVA table for the data of *Figure 8d* (Two-way ANOVA, Tukey's multiple comparisons test) was displayed in *Table A7d*. After UV-B radiation for 4 h, the heat dissipation of the wild type began to decline while that of the *rcd1-1* mutant continued to rise. When plants were exposed to UV-B radiation for 6 h, the heat dissipation of the wild type was only

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1181311833

67.4% of that of *rcd1-1* mutant. Finally, the NPQ value decreased from 0.288 to 0.140 for the wild type, while it decreased from 0.298 to 0.193 for the *rcd1-1* mutant. The results suggested that the longer UV-B exposure impaired the PS II reaction center activity.

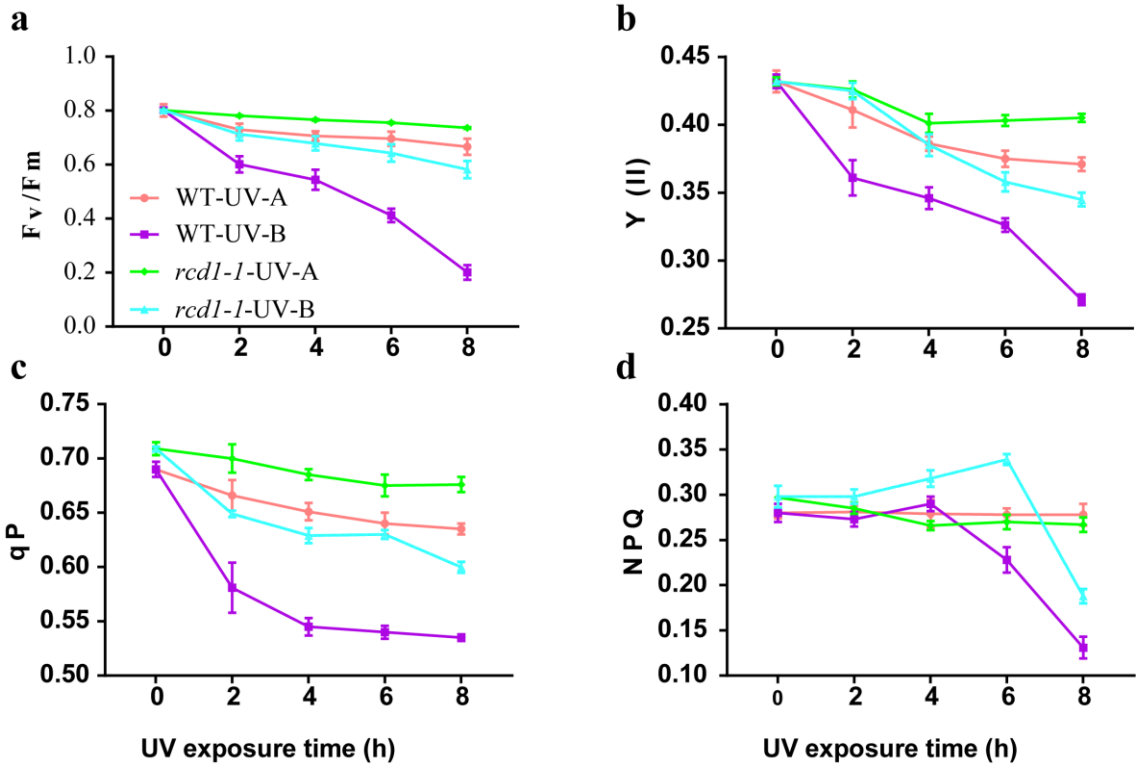

Figure 8. *Effects of enhanced UV-B radiation photosynthetic system II. After UV treatment, the maximal efficiency of PSII photochemistry (Fv/Fm) (**a**), the actual PS II efficiency (ϕPSII) (**b**), qP (**c**) and NPQ (**d**) of the wild type and rcd1-1 mutant were measured with Imaging-PAMM-series instrument. Data are expressed as mean values ± standard errors from three replicates and error bars represent standard errors*

Expression profile of psbA, ANAC013 and UNE10 gene in rcd1-1 mutant after UV-B exposure

Recent progress in the genetics of *Aribodopsis* has revealed that gene expression was regulated by UV-B radiation. In the present study, UV-B modulated the expression of *psbA*, *ANAC013* and *UNE10* genes at transcription level. The expression of the *psbA* gene of the photosystem II showed no consistent difference between plants of different genotypes after 6 h of UV-A treatment. The expression of *psbA* gene in *rcd1-1* mutant was higher than that in the wild type under UV-B radiation (*Fig. 9*). Although the expression of *ANAC013* gene in the two genotypes was significantly elevated both under UV-A and UV-B treatments, it was more highly expressed under UV-B treatment. On the other hand, the *ANAC013* gene was more highly expressed in the *rcd1-1* mutant than in the wild type under the same UV treatment (*Fig. 9*). The expression of the *UNE10* gene in the wild type increased under both UV-A and UV-B treatments, but most under UV-A treatment. In contrast, the expression of the *UNE10* gene in the *rcd1-1* mutant decreased under both UV-A and UV-B treatments (*Fig. 9*).

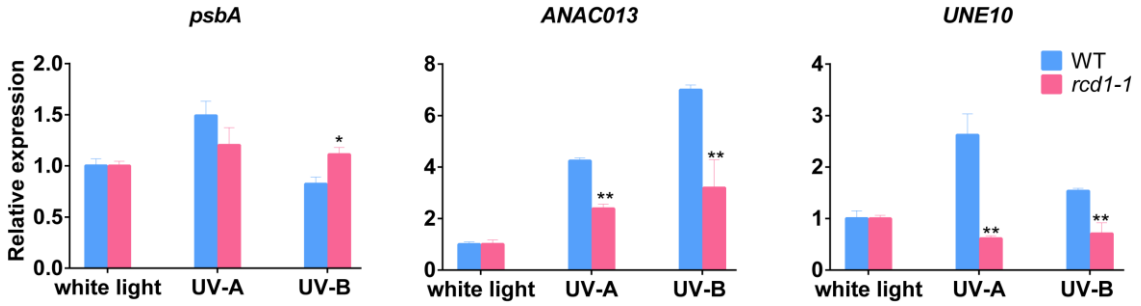

Figure 9. *UV-B-induced expression changes of light response related genes. After supplementary UV-B treatment or control UV-A treatment for 6 h, leaves of Arabidopsis wild type and rcd1-1 mutant were harvested. Relative expression of psbA, ANAC013 and UNE10 genes in the wild type and rcd1-1 mutant detected by real-time PCR. All the data shown are means ± SEM of three independent replications. Data are expressed as mean values ± standard errors from three replicates and error bars represent standard errors. The symbol '*' indicates statistically differences P < 0.05 and the symbol '**'indicates statistically differences P < 0.01 (Two-way ANOVA, Tukey's multiple comparisons test)*

Discussion

It has been reported that *rcd1-1* mutant is sensitive to ozone fumigation and apoplastic superoxide, but tolerant to methylviologen. However, the mechanisms of *rcd1-1* mutant responses to UV-B have remained to be elucidated. In the present research, we studied the effects of UV-B radiation on morphology, cellular membrane permeability, oxidative stress, antioxidant enzymatic activity, photosynthetic and sunscreen pigments, photosynthesis and photosynthetic genes expression of *Arabidopsis*. The *rcd1-1* mutant appears to be more resistant to UV-B radiation than the wild type, and the mechanism for this can now be understood.

Under ordinary growth condition, the wild type grew faster and had more biomass compared with *rcd1-1* mutant (*Fig. 1a-c*); but after UV-B radiation, the wild type exhibited chlorosis, curl, and necrotic lesions (*Fig. 1d*), while the growth of the mutant was much less affected. This was consistent with the result of changes in the chlorophyll content of leaves after UV-B radiation. Compared with the wild type, *rcd1-1* mutant showed a smaller decline in chlorophyll content when exposed to UV-B radiation (*Fig. 6*). UV-B radiation can affect the pigment concentrations in *Arabidopsis* cells by inducing photodegradation of light-absorbing pigments (Prasad and Zeeshan, 2004), resulting in loss of photosynthetic capacity. The present investigation showed that UV-B radiation significantly decreased chlorophyll *a* and *b* contents of both genotypes, but they decreased more in the wild type.

These findings prompted us to further test whether the *rcd1-1* mutant was more tolerant to UV-B radiation. The *rcd1-1* mutant suffered less serious leaf necrosis than the wild type after UV-B treatment. To further understand the extent of damage of UV-B radiation to cell membranes, the electrolyte leakage of leaves was considered, which is a classic assessment index to estimate the effects of UV-B on plasma membranes. The electrical conductivity of *rcd1-1* mutant was lower than that of the wild type after UV-B treatment. Because the higher the electrical conductivity, the more serious the injury to cell membranes; the cell membranes of *rcd1-1* mutant were less damaged than the wild type, which verified the result of Shi et al. (2005) using Evans blue staining.

DOI: http://dx.doi.org/10.15666/aeer/1705_1181311833

Previous studies have shown that UV-B radiation induces the production of cellular reactive oxygen species (ROS), leading to oxidative stress, which in turn damages the photosynthetic apparatus (Liebel et al., 2012; Yannarelli et al., 2006). ROS accumulation induced membrane lipid peroxidation, assayed as malondialdehyde (MDA). In this present study, ROS level of the two genotypes increased in short-term enhanced UV-B treatment, revealing that UV-B radiation did induce oxidative stress. The *rcd1-1* mutant exhibited lower H_2O_2 and O_2^- accumulation levels and higher MDA level than the wild type after UV-B treatment, indicating it suffered from less oxidative stress under UV-B radiation. This might provide an explanation as to why *rcd1-1* mutant has smaller cell membrane damage than the wild type. On the other hand, antioxidant enzymes play a significant part in reactive oxygen scavenging and antioxidant defense systems. The present study showed that *rcd1-1* mutant exhibited higher activities of SOD, POD and CAT than the wild type after UV-B treatment, which explained the oxidative stress results above.

UV-B absorbing compounds, flavonoids and anthocyanin in *Arabidopsis* leaves have an important protective function reducing the transmittance of UV photons through leaf tissue (Yao and Liu, 2006). Anthocyanin production is the predominant mechanism of protection of the young plant. In the present study, *rcd1-1* mutant accumulated more flavonoids and anthocyanin than the wild type, which was similar to *rcd1-2* mutant that also accumulated more sunscreen pigments than the wild type (Ahlfors et al., 2004; Overmyer et al., 2000; Morales et al., 2015). These were evidences that *rcd1-1* mutant was more tolerant to UV-B radiation than the wild type.

Studies with artificial UV-B sources have shown that UV-B radiation may strongly affected PSII, whereas PSI appeared to be relatively insensitive (Sedej and Gaberščik, 2008). If the light energy absorbed by the plant is in excess what is needed for photosynthes, it may lead to a reduction in the potential efficiency of PSII. In the present study, *rcd1-1* mutant exhibited higher maximum quantum efficiency of primary photochemistry (Fv/Fm) than the wild type after UV-B radiation. Meanwhile, the mutant exhibited more slowly decreasing rates of effective quantum yield of photochemical energy conversion in PS II (ϕPSII) and photochemical quenching of variable chlorophyll fluorescence yield (qP). Interestingly, the *rcd1-1* mutant showed higher non-photochemical quenching (NPQ) than the wild type, so the possibility that the *rcd1-1* could release exceeded energy from UV-B by means of this process cannot be excluded. These results show that the *rcd1-1* mutant had a higher photosynthetic capability after UV-B radiation than the wild type.

RCD1 protects plant cells from running into reactive oxygen species (ROS)-triggered cell programs, including cell death, activation of pathogen-responsive genes (PR genes) and extra-plastidic antioxidant enzymes, which could support the induction of the chloroplast antioxidant system (Hiltscher et al., 2014). That the *rcd1-1* mutant exhibited higher photosynthetic capability than the wild type can be explained from the following three aspects. First, the *rcd1-1* mutant accumulated less ROS than the wild type after UV-B radiation, so its photosynthetic apparatus suffered less injury. It is known that excessive O_2^- and H_2O_2 may result in damage of PSII through their effects on the composition and structure of the light harvesting complex which lead to a disturbance in the chloroplast structure. Second, chlorophyll contents in *rcd1-1* mutant dropped less than that of the wild type after UV-B radiation. Third, the *rcd1-1* mutant had higher value of NPQ, which could release excess energy from UV-B by the process of releasing more heat than the wild type.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

The two important targets of UV-B radiation in the plant are the genome and the photosynthetic machinery (Fujibe et al., 2004). One of the earliest effects of UV-B irradiation is the change of gene expression. In the present study, we have investigated changes in expression of genes of *psbA*, *ANAC013* and *UNE10*, which play important parts in photosynthesis, to further investigate the molecular mechanisms of *Arabidopsis* underlying UV-B radiation (Jaspers et al., 2009).

RCD1 is an important regulator of stress and hormonal and developmental responses in *Arabidopsis*, which might negatively regulate a wide range of stress-related down-stream genes (Jaspers et al., 2009; Fujibe et al., 2004). Previous research revealed that *RCD1* interacts with a large number of transcription factors belonging to several protein families, such as AP2/ERF, NAC and basic helix–loop–helix (bHLH) (Jaspers et al., 2009). *ANAC013* and *UNE10* belong to NAC family and basic helix–loop–helix family respectively. These results in the present research showed that *ANAC013* and *UNE10* genes are expressed to a lower extent in the mutant, which proved that *RCD1* gene negatively regulate a wide range of stress-related down-stream genes. The RCD1 functions mainly include ozone sensitivity, paraquat and UV-B tolerance and the ability to interact with different transcription factors (TFs) which could responsible for the unique functions of RCD1 (Jaspers et al., 2009). Several RCD1-interacting TFs (PIF5, PIF7, COL9, COL10 and STO) were known to play a part in light responses (Indorf et al., 2007; Castillon et al., 2007). This suggested that *RCD1* could be involved in signal transduction (Jaspers et al., 2009). *ANAC013* is regulated mainly at transcriptional level under UV-B and partly independent of *COP1*, *UVR8* and *HY5* (Jiang et al., 2012; Safrany et al., 2008). Moreover, it is also modulated by the plant hormone ABA and different abiotic stress. *UNE10* is one of light response genes and similar to *PIF7*, including MYB and BHLH domain, which play an important role in the signal path of the UV-B (Paila et al., 2008). RCD1 interacts in vivo and suppresses the activity of the transcription factors ANAC013 and ANAC017, which mediate a ROS-related retrograde signal originating from mitochondrial complex III (Shapiguzov et al., 2019). Inactivation of RCD1 leads to increased expression of mitochondrial dysfunction stimulon (MDS) genes regulated by ANAC013 and ANAC017.

The *psbA* gene is located in the chloroplast genome and encodes for the D1 protein, a core component of Photosystem II. The results in the present study revealed that the *psbA* gene of photosynthetic system II was expressed to a greater degree in *rcd1-1* mutant than the wild type, which meant photosystem II suffered less damage under UV-B. The result was in accordance with the phenomenon that the photosynthetic capability of the mutant was higher than that of the wild type. Therefore, the *RCD1* gene could be an important genetic resource to improve plant function against UV-B radiation, which may be an interested topic to provide an incentive for further scientific contributions in the near future.

Conclusion

The present research revealed that RCD-1 is sensitive to UV-B radiation in *Arabidopsis.* The *rcd1-1* mutant is more resistant to UV-B probably because of higher flavonoids and anthocyanins in the mutants. *RCD-1* gene may negatively regulate the expression of *ANAC013* and *UNE10*. More work is needed to explore the molecular mechanism of *RCD1*-mediated response to UV-B regulation.

Abstract. The paper presents a new method to evaluate the impact of Xiongan's construction on the collaborative development of Jing-Jin-Ji (JJJ) Urban Agglomeration under different development strategies. Firstly, the SD model of each urban node of JJJ Urban Agglomeration is constructed by using parallel calibration system, and it is applied to simulate the development trend of target system. Then, the paper sets up a fractal model base on gravitational theorem which takes population, GDP and full carbon emissions as main factors to be evaluated with the Low Carbon Economic Linkage Strength. The evaluation results show that: (1) Xiongan as a radiation center can significantly promote the collaborative development of urban agglomeration; (2) On the basis of the existing trend, improving the low-carbon level of Xiongan alone has no significant effect on the low-carbon development, while the effect is significant when Beijing, Tianjin and Xiongan low-carbon levels are improved at the same time; (3) There will be a delay in the transmission of low-carbon economic development capacity from high to low gradient, but this delay does not affect the radiation effect of high gradient cities on low gradient cities, nor does it affect the coordinated development of urban agglomerations.
Keywords: *low-carbon economic strategy, fractal dimension, JJJ Urban Agglomeration, scenario analysis*

Introduction

The Nineteenth Congress of the Communist Party of China pointed out that the main contradiction in the current Chinese society is the contradiction between the people's pursuit of a better life and the insufficient balance of development (Pan et al., 2009). The contradiction of imbalanced development is particularly prominent in Jing-Jin-Ji (JJJ) Urban Agglomeration.

The JJJ Urban Agglomeration includes Beijing, Tianjin, Xiongan New District, Shijiazhuang, Tangshan, Baoding, Langfang, Handan, Zhangjiakou, Chengde, Qinhuangdao, Cangzhou, Xingtai and Hengshui. The total area of the JJJ Urban Agglomeration is 216,000 km^2. It is dominated by plain landforms and belongs to temperate monsoon climate and semi-humid area. As one of China's important economic growth pole, the JJJ Urban Agglomeration is confronted with challenges to achieve sustainable development. The main challenge is facing two significant gradient differences (Li et al., 2013). One is the social-economic gradient, the other is the resource-environment gradient. Beijing and Tianjin show the high gradient of social economy, while the node cities in Hebei show the high gradient of resources and environment. These two kinds of gradient differences make JJJ Urban Agglomeration become the most acute contradiction area in China.

DOI: http://dx.doi.org/10.15666/aeer/1705_1183511849

In this context, JJJ Urban Agglomeration is expected to become a model of urban agglomeration collaborative development and play a leading role in China's low-carbon development. As a newly rising radiation center of JJJ Urban Agglomeration, Xiongan has attracted much attention at home and aboard, which includes the influence of Xiongan's geographical location and different development modes on JJJ Urban Agglomeration.

The study of urban agglomeration has a long history, including both micro-scale and macro-scale research. The research involves in exploring the driving forces for the development of urban agglomerations with different focusing modes by comparing the frontiers of total factor productivity among urban agglomeration (Jia et al., 2018), sharing, matching, and learning mechanisms within urban agglomeration (Duranton et al., 2003), the dynamic mechanism of the growth of cities and urban agglomerations (Cao et al., 2012; White et al., 1994), urban location and boundary delimitation (Tannier et al., 2011), and political policies and their impact on the development of urban agglomerations (Jefferson et al., 2013). Fractal is the most commonly used method in urban agglomerations' research. Factual theory and method have been applied to analyze morphological boundaries of urban agglomerations and characterize boundary shapes (Tannier et al., 2013), and discovery the difference between planned patterns and less planned ones in morphological features of urban agglomerations (Frankhauser, 1998).

With the increasingly prominent environmental problems, it has become a worldwide concern for economists, as is witnessed by many theories and methods which aims at driving the economy towards a sustainable economy (Camagni et al., 1998). The research on urban agglomerations are gradually expanding from the economic system to environmental-economic complex system, such as the heat island effect of high-density urban agglomerations (Zhou et al., 2018), the driving force of low-carbon development (Kang et al., 2018), the evaluation of sustainable development level of urban agglomerations with multiple resource and environmental indicators (Yu et al., 2010).

Different environments co-exist in a city including the natural, the economic production and the social activation. Each of them generates positive and negative externalities for the city, since each of them represents `use advantages' and `use costs' for a city. For social activation, these externalities are manifested in energy consumption and food consumption (biomass resource consumption) and waste discharge in the daily life of clothing, food, shelter and transportation. For economic production, these externalities are finally measured in terms of resource and energy input, positive output (GDP) and negative output (waste emissions). While all the supply of natural resources and degradation of environmental pollutants are related to urban land area. Therefore city's quality of life and environmental concerns undermine all advantages associated with agglomeration economies.

SD model is a useful tool to analyze and forecast urban or city environmental economic system, which is widely used in the system simulation of homogeneous regions and the systematic analysis (Wu et al., 2018), as well as the study of expansion to the periphery of the target city (Rich et al., 2016; Yu et al., 2018). In the research of scenario analysis and strategy selection, the socio-economic plan of the target system is always one of the most important bases for scenario design, especially in carbon emission reduction (Du et al., 2018) and effective utilization of natural resources (Zhang et al., 2008). However, due to the differences of natural conditions and development patterns in heterogeneous regions, the study of urban agglomerations

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1183511849

focusing on these regions is very rare at present. Furthermore, there is another bottleneck problem, that is, how to normalize multiple resources and environmental factors in SD model.

There is no doubt that the dynamics of cities can be best captured by looking at them as complex systems governed by freedom, interacting on different space and time scales in a non-linear fashion (Albeverio et al., 2008). The evolution of cities often depends on the interaction of internal factors (such as decision-making of institutions and individuals) and external factors (radiation between cities and social progress). Therefore, the combination of SD model based on urban metabolic analysis and input-output flow can better solve the obvious heterogeneity in urban agglomeration system simulation and improve the integrity evaluation of urban agglomeration (Elliot et al., 2018).

In addition, the research on low carbon is developing rapidly from the initial concern of carbon emissions accounting of energy consumption to potential carbon environmental capacity of waste emissions and biomass resources consumption. The potential carbon environmental capacity occupancy of waste emissions involves both production (Tan et al., 2018) and living areas (Sun et al., 2018). While the potential carbon environmental capacity occupancy of biomass resources mainly involves living areas, whose theoretical basis is that the more land resources occupied by human demand for food, the less land resources used for the growth of high carbon-fixing vegetation (Timothy et al., 2018). The above research lays a foundation for the proposal of carbon accounting and the solution of the problem of resource and environment normalization in SD model.

Based on the analysis of system dynamics, this paper applies fractal theory and method to analyze the influence of Xiongan New District on the coordinated development of JJJ Urban Agglomeration from the perspective of low-carbon economic analysis, aiming to analyze the Xiongan New District to the promotion of low-carbon development of JJJ urban agglomeration. And this research provides a scientific basis for relevant departments to make decisions.

Materials and methods

Each node city in JJJ Urban Agglomeration has distinct heterogeneity. There are not only huge economic gradients, but also huge resource and environment gradients. In order to objectively evaluate the role of Xiongan in the low-carbon coordinated development of JJJ Urban Agglomeration and the impact of different strategies on the role, this paper proposed an integrated method which combined the system dynamics with the fractal analysis. The proposed method integrated progress and the paper following structure as: (1) analyzing JJJ Urban Agglomeration' system and identifying the Key Factors (KFs) that affect the low-carbon development; (2) setting up the framework of full carbon emission calculation cored in KFs; (3) establishing a SD model of social-economic-environmental complex system for each city in JJJ Urban Agglomeration to predict the development tendency cored in KFs; (4) based on the gravity theory, setting up the fractal model of low-carbon economic linkages strength of urban agglomerations cored in KFs; (5) designing different low-carbon scenario strategies according to system development trend prediction and relevant plan and evaluating the efficiency of JJJ collaborative development under different low carbon economy strategies around Xiongan.

The material of this paper comes from multi-source data of each node in JJJ Urban Agglomeration, including data of social and economic development, data of resource consumption and data of pollution emission.

System analysis and KFs identification

Analysis of heterogeneity of JJJ

Land is the carrier of human activities in production and life, and the carrying capacity of natural resources and environment are closely related to urban land area. Thus in this paper, the heterogeneity of JJJ Urban Agglomeration is explored based on the analysis of the density of GDP, the density of population, the intensity of biological resources consumption, the energy consumption intensity, and the intensity of pollutant emission. The degrees of various indicators above are shown in *Figure 1*.

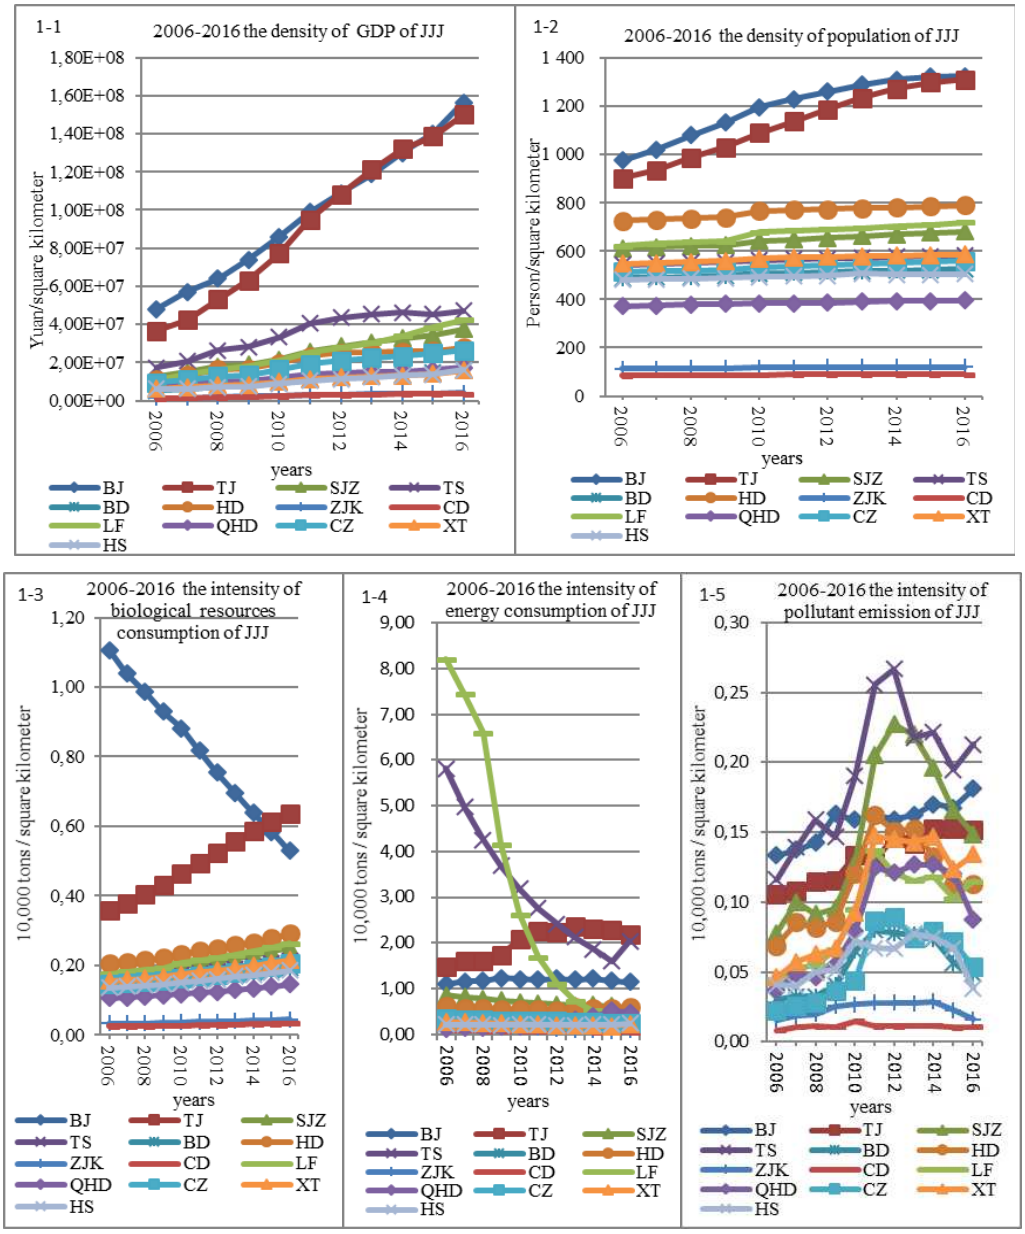

Figure 1. *The level or intensity of social economy and resource environment of JJJ*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1183511849

It can be seen from *Figure 1-1* that Beijing and Tianjin are in a high gradient from the perspective of GDP density, while the other node cities of JJJ Urban Agglomeration are in low gradient, and there is a significant gradient difference in Beijing and Tianjin.

It can be seen from *Figure 1-2* that Beijing and Tianjin are still in a high gradient in terms of population density, while Langfang, Shijiazhuang, Xingtai, Baoding, Tangshan, Zhangzhou, Hengshui and Qinhuangdao are in the middle gradient group, and meanwhile Zhangjiakou and Chengde are at a low level. The gradient difference between the above high, medium and low gradients is also very obvious.

It can be seen from *Figure 1-3* that Beijing and Tianjin are high gradient from the perspective of biological resources consumption intensity (corresponding to the biomass resources output per unit area), while Shijiazhuang, Tangshan, Baoding, Handan, Langfang, Qinhuangdao, Cangzhou, Xingtai and Hengshui are in the middle gradient group, and meanwhile Zhangjiakou and Chengde are at a low level. Among them, there is a huge gradient difference between high gradient and middle gradient.

It can be seen from *Figure 1-4* that Langfang gradually decreases from a high gradient to a low gradient in terms of energy consumption intensity, while Tangshan gradually reduced from the second highest gradient to the same level in Beijing. From the distribution of gradient after 2012, Tianjin is always in the high gradient, followed by Tangshan and Beijing. The above three cities together constitute a high gradient of energy consumption, while the rest has much less gradient of energy consumption.

It can be seen from *Figure 1-5* that Tangshan is always at the highest gradient in terms of pollutant emission, while Shijiazhuang has a large fluctuation, ranging from middle gradient to high gradient. And in recent years, Shijiazhuang has a drop trend. Beijing and Tianjin are relatively stable. At the same time, Cangzhou, Hengshui and Baoding are in the middle-low gradient, while Chengde and Zhangjiakou are in low gradient.

As can be seen from the above analysis, the conclusions can be drawn that the heterogeneity of social economic, resource and environmental of the cities and towns of the JJJ Urban Agglomeration are extremely clear. Therefore, system development predictions and kinetic models for such urban agglomerations need to be built under the same input and output dynamics framework.

Identifying the KFs of JJJ based on urban metabolism

The main input of the urban system is all kinds of resources that can be provided by nature (including water environmental capacity, atmospheric environmental capacity, carbon storage capacity generated by forest resources, and various types of energy, etc.), and some of these resources are consumed through human economic activities. It is converted into products and waste, and the other part is consumed or converted into waste through human production activities. With the increase of waste discharge, the demand for environmental capacity increases accordingly. In order to control waste emissions within naturally available environmental capacity, it is necessary to treat waste generated during human production and life to reduce its emissions. Meanwhile, the process also consumes resources and energy, resulting in a carbon footprint. Therefore, waste emissions should be included in the potential carbon environmental capacity account. In addition, the biomass resources consumed in human life are rising, and the land available for growing high carbonaceous plants is declining. Therefore, biomass resource consumption should be included in the potential carbon environmental capacity occupancy account. The products formed during the production process

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1183511849

(measured in terms of GDP) enter the next circulation area, or as an input enter the next activity, which is either consumed in the activity or a new product is formed. Then, they go to the next activity or become a waste into the environment. The analysis of the metabolic process of the above cities shows that human consumption of biomass resources and waste emissions (including CO_2 and other emissions in the process of energy consumption, wastewater emissions and solid waste emissions) are integrated into the carbon emission accounting system, which can fully reflect the impact of urban production and living processes on the environment.

Therefore, the KFs affecting the low-carbon economy can be identified as follows: population, GDP, waste, energy and biomass resources. Of course, the population as one of the KFs is a subsystem, which is determined by the density of urban employment, the proportion of the population receiving higher education, the natural growth rate and the urbanization rate. GDP, one of the KFs, can also constitute a subsystem, which is composed of per capita GDP, economic density and per capita investment in fixed assets. Waste gas, wastewater and solid waste can form a waste discharge subsystem, which produces the amount of behavior, the amount of treatment (or treatment rate), and the impact of social and economic activities related to it. Energy consumption will also lead to the corresponding carbon emissions. As this part of the emissions is relatively large and has been the concern for a long time, it also becomes a subsystem. The consumption of biomass resources corresponds to the land occupation. The more biomass resources consumed by human life, the more land occupied for the production of these biomass resources, and the less land used for carbon sequestration (planting high carbon sequestration plants). Therefore, the consumption of biomass resources is also a KF. Accordingly, urban greening plays a role of beautifying life and absorbing carbon, so it is also one of the KFs.

Construction the calculation framework of "full carbon emission"

The "full carbon emission" account is set up cored in KFs based on the energy analysis theory and the energy conversion law (Zhang et al., 2015). The account consists of two sub-accounts, which are direct carbon emissions caused by energy consumption and potential carbon consumption caused by waste carbon emissions as well as biomass resources. Different types of substances are normalized by converting into CO_2 emissions to characterize the impact of the emissions on the green low-carbon development of urban agglomerations. Considering the contribution of different sub-items to direct and potential emissions account as well as the availability of data, the two sub-accounts are divided into several sub-sub accounts as shown in *Figure 2*.

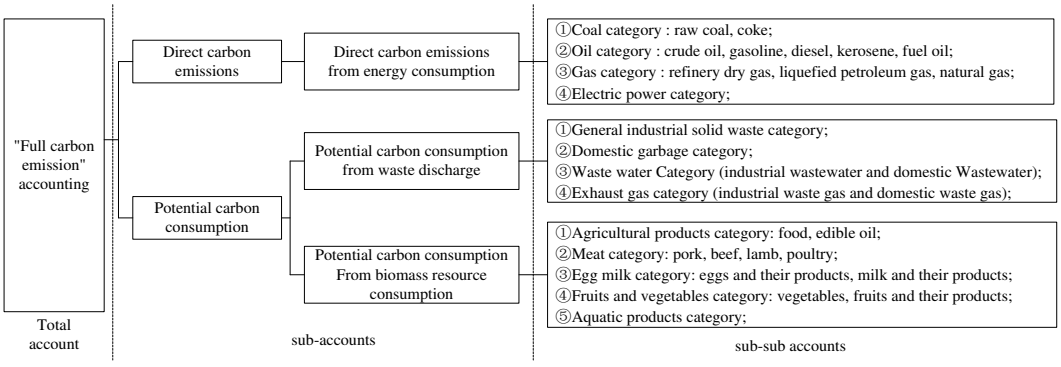

Figure 2. *The framework of the full carbon accounting account*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1183511849

According to *Figure 2,* the "full carbon emission" accounting is performed. Among them, the traditional energy consumption carbon emission conversion coefficient method (Wang et al., 2018) is applied in the calculation of the direct CO_2 emission caused by energy consumption, while the potential CO_2 emissions caused by waste discharge and biomass resource consumption are converted by emergy value conversion and its corresponding with CO_2 emissions. The specific formula is as follows:

$$T_{CO_2} = T_{CO_{2e}} + T_{CO_{2w}} + T_{CO_{2b}} = \sum_{k=1}^{11} CO_{2ek} + \sum_{n=1}^{4} CO_{2wn} + \sum_{m=1}^{11} CO_{2bm}$$
$$= \sum_{k=1}^{11} (V_k \cdot \lambda_k) + \sum_{n=1}^{4} \frac{P_n \cdot \alpha_n \cdot \beta_n}{\gamma} \cdot \frac{0.8856}{3600000} + \sum_{m=1}^{11} \frac{U_m \cdot \alpha_m \cdot \beta_m}{\gamma} \cdot \frac{0.8856}{3600000} \quad \text{(Eq.1)}$$

where: T_{CO_2} is the full CO_2 emission of a certain city (full carbon emission); $T_{CO_{2e}}$ is direct carbon emissions caused by energy consumption; $T_{CO_{2w}}$ is potential carbon consumption caused by waste discharge; $T_{CO_{2b}}$ is potential carbon consumption caused by biomass resource consumption; *k* is different categories of energy consumption for direct carbon emissions (such as raw coal, coke, crude oil, gasoline, diesel, kerosene, fuel oil, refinery dry gas, liquefied petroleum gas, natural gas and electricity); CO_{2ek} is the direct CO_2 emissions consumed in category *k*; *n* is different categories of waste emissions (such as industrial solid waste, domestic garbage, industrial wastewater, domestic wastewater, industrial waste gas and domestic waste gas) which will causing potential CO_2 emissions; CO_{2wn} is potential CO_2 emissions from category *n* waste; *b* is biomass resource consumption which will causes potential CO_2 emissions; CO_{2bm} is the potential CO_2 emissions caused by the *m* type biomass resources consumption; V_k is the raw data of the *k* type energy consumption; λ_k is the CO_2 emission factor of the *k* energy consumption; P_n is the raw data of the *n* type waste discharge; α_n is the *n* type emergy conversion factor of waste; β_n is emergy conversion rate of the *n* type of waste; U_m is the raw data of the *m* type biomass resource; α_m is the emergy conversion coefficient of the *m* type biomass resource, and β_m is the emergy conversion rate of the *m* type biomass resources; γ is the emergy conversion rate of electric energy (1.05×105 sej/J), 1 kWh = 3600000 J, and the power supply per kilowatt hour is 0.8856 kg CO_2 (Odum et al., 1955).

Construction of SD model

The SD model of JJJ Urban Agglomeration economic environmental complex system account is set up cored in KFs. The relationships of the factors in the target system are shown in *Figure 3*.

Variables representing flows of information and initials, arising as results of system activities and producing the related consequences are named as level variables which described as ▭ in the flow diagram, while the rate variables are described as ⧖. Auxiliary variable means the detailed steps by which information associated with current levels are transformed into rates to bring about future changes. In addition, the symbol ☁ represents the sinks or sources.

In *Figure 3,* there are four main level variables: total population of the city, annual GDP output, total energy consumption, total water use (because JJJ Urban Agglomeration is located in water scarce areas, so the indicator is selected). In addition, there is an important system output variable-total carbon emission. All the four main

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1183511849

level variables and the one important output variable is described as ▭. The other variables follow the expression principle of system dynamics flow chart.

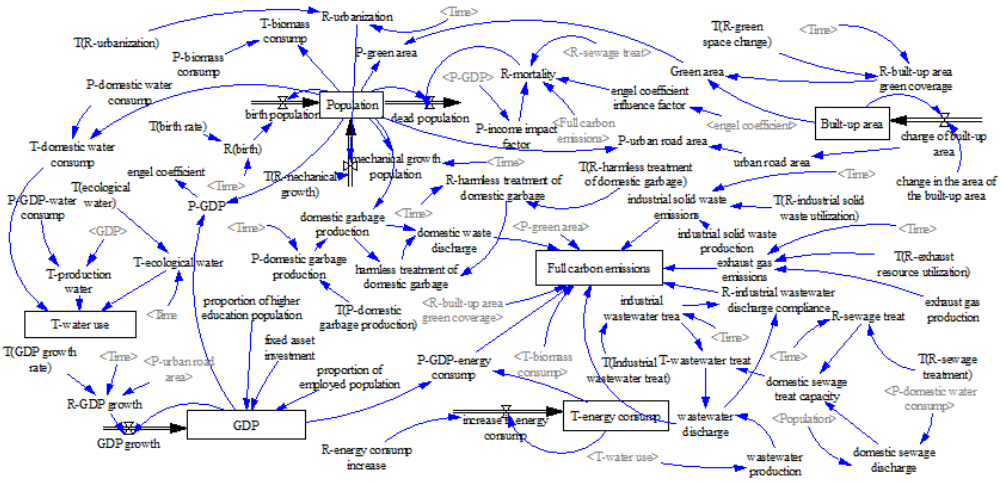

Figure 3. *the flow chart of JJJ Urban Agglomeration*

The SD model takes certain steps along the time axis in the simulation process. At the end of each step, the system variables denoting the state of the system are updated to represent the consequences resulting from the previous simulation step (Zhang et al., 2008). Initial conditions are needed in the first time step. According *Figure 3* and the above principle, we can compile the system dynamics equations of each node city of JJJ Urban Agglomeration one by one based on collecting, collating and analyzing the historical data of the system.

After SD model construction, it is necessary to identify whether the model can be in line with the real situations by the validity test and sensitivity analysis. Accordingly, parameters and relevance can be modified and confirmed until the SD model has good robustness and can reflect the real system in different scenarios.

Construction low-carbon economic linkages strength model

Based on the gravitational model, this paper combines the traditional economic linkages strength model with the "full carbon emission" model to construct the low-carbon economic linkages strength model as follows:

$$R_{ij} = \frac{\sqrt[3]{\frac{P_i}{T_{CO_{2i}}} \cdot \frac{G_i}{T_{CO_{2i}}} \cdot \frac{S_i}{T_{CO_{2i}}}}}{D_{ij}} \cdot \frac{\sqrt[3]{\frac{P_j}{T_{CO_{2j}}} \cdot \frac{G_j}{T_{CO_{2j}}} \cdot \frac{S_j}{T_{CO_{2j}}}}}{D_{ij}} \cdot M_1 \cdot M_2 \cdot M_3 \quad \text{(Eq.2)}$$

where: i and j are the central city and the irradiated city and R_{ij} is the low-carbon economic linkages strength of the central city i accepted by the radiated city j; P_i and P_j are the population size of the i and j cities respectively; G_i and G_j are the regional gross domestic product (GDP) of cities i and j respectively; S_i and S_j are the road areas of cities i and j respectively; $T_{CO_{2i}}$ and $T_{CO_{2j}}$ are cities of i and j annual CO_2 emissions respectively; D_{ij} is the distance between cities i and j; M_1 is the human resources adjustment coefficient,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1183511849

which is affected by factors such as the proportion of urban employment density, the proportion of people receiving higher education (the proportion of the number of undergraduates who are over 6 years old in the permanent population of the city), the influence of natural growth rate and urbanization level; M_2 is the economic resource adjustment coefficient, which is affected by factors such as per capita GDP, economic density and per capita fixed assets investment; M_3 is the natural resource adjustment coefficient, which is affected by factors such as the population per square kilometer, per capita domestic water consumption and urban per capita green area.

According to the principle of pressure superposition, the strength of economic connection from a single source centered on a single city is calculated, and the source superposition formula is used to superpose the low-carbon economic linkages strength of two-source (two central cities) or three-source (three central cities). The formula is as follows:

$$R_j = 10 \cdot \lg(10^{\wedge 0.1 R_{i_1 j}} + 10^{\wedge 0.1 R_{i_2 j}} + 10^{\wedge 0.1 R_{i_3 j}}) \quad \text{(Eq.3)}$$

where: R_j is the low-carbon economic linkages strength of the radiated city j after accepting the superposition of two or three sources of radiation; $R_{i_1 j}$, $R_{i_2 j}$ and $R_{i_3 j}$ are different central cities i_1, i_2 and i_3 radiate the low-carbon economic linkages strength radiation of the same radiated city j ($R_{i_3 j}$ is not included when the two sources are superimposed).

After calculation of the low-carbon economic linkages strength, the distribution of social economic resources and environment in urban agglomerations can be judged by fractal dimension. The fractal dimension can be calculated as:

$$K \propto R_{(\mathrm{K})}^{-D} \quad \text{(Eq.4)}$$

where: K is the number of cities in the region; R is the intensity of low-carbon economic linkages strength between cities; D is the fractal dimension. Take the logarithm of the two sides of *Equation 3,* we can get:

$$\ln R_{(k)} = A - \frac{1}{D} \ln k \quad \text{(Eq.5)}$$

where: k is the number of cities (counties) low-carbon economic connection gravity ranking sequences, and A is an equal constant.

The basic criteria for judging rationality are as follows:

When $D = 1$, the urban agglomeration is a constrained order-scale distribution, which means that the radiation received by cities in urban agglomerations from central cities is an absolute average, not a gradient circle. It is impossible to form a high-to-low order transmission and radiation of the internal energy of the urban agglomeration (low-carbon economic linkages strength) and the radiation efficiency is not optimal.

When $D > 1$, the central city in the urban agglomeration has lost the advantage of high gradient, which is not conducive to its overall development of the urban agglomeration.

When $D < 1$, there is a difference in the distribution of economic linkages strength. From the above analysis, the best fractal dimension is $D < 1$.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1183511849

Li et al. (1992) used the golden section principle and the Fibonacci sequence to derive a judgment that can be used as a reasonable distribution of the network system. That is the golden section 0.618 as the reasonable fractal dimension judgment point. According this judgment, when $D = 0.618$, the urban agglomeration is in the optimal connection gravity of the urban agglomeration.

Results

Data sources

The data of the scenarios analysis are derived from the 2007-2018 China Statistical Yearbook and the statistical yearbooks of relevant cities, the China Energy Statistical Yearbook and the relevant cities' energy statistics yearbooks and the China Environmental Statistics Yearbook. Meanwhile, some of the data are derived from the iFind. The data in this paper covers the economic development status, social development status, environmental quality and resource utilization of cities in the study.

Scenarios design

In this paper, five scenarios are carried out to analyze the strength and dimension of urban low-carbon economic linkages for analyzing the efficiency of JJJ collaborative development under different low carbon economy strategies around Xiongan. And the scenarios designed of this paper is based on the following basic hypothesis: (1) The development of JJJ Urban Agglomeration follows the relevant national and local planning, which does not cover areas and relevant indicators follow the current development trend (based on the prediction of SD model); (2) In the current scenario, Xiongan has the same economic density, population density and carbon emissions intensity as Beijing.

The five scenarios are designed as follows:

Scenario 1: "Beijing-Tianjin" dual source radiation under inertial scenarios. This paper selects the data from 2006 to 2017 as the historical data of the JJJ Urban Agglomeration. Based on the JJJ Urban Agglomeration eco-economic development system dynamics model (Wang et al., 2013), it predicts the carbon emissions and related indicators of cities in the JJJ Urban Agglomeration from 2018 to 2030.

Scenario 2: "Beijing-Tianjin-Xiongan" three-source radiation under inertia scenario. The operational data is the same as scenario 1, except that Xiongan is listed as a radiation source.

Scenario 3: Xiongan achieves carbon peaks ahead of schedule in 2018, and after reaching the peak, carbon emissions are reduced by 0.5% per year on the basis of scenario 1. Meanwhile the development trends and carbon emissions of other cities remain unchanged.

Scenario 4: On the basis of Scenario 3, Beijing and Tianjin are also used as radiation sources, and the development trend remains unchanged. The amount of carbon emissions is reduced by 0.5% per year on the basis of Scenario 1, and other cities remain unchanged.

Scenario 5: Based on Scenario 4, the development trend of other cities remains unchanged, and carbon emissions are reduced by 0.5% per year on the basis of Scenario 1.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1183511849

Results analysis

Based on the above five scenarios, this part applied *Equation 1* to calculate the total carbon emissions, *Equation 2* to calculate the low-carbon economic linkages strength of single-center sources, *Equation 3* to superpose the low-carbon economic linkages strength of multi-center sources, and *Equations 4* and *5* to calculate the fractal dimension value. The calculation results are shown in *Figure 4*.

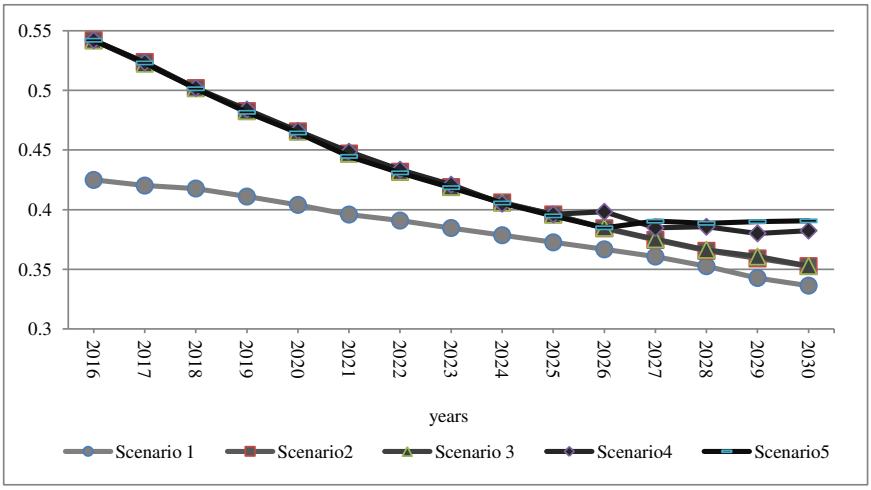

Figure 4. *2016-2030 JJJ Urban Agglomeration low-carbon economic linkages strength fractal dimension*

Building Xiongan as a radiation center of JJJ multi-center urban agglomeration can significantly promote the collaborative development of urban agglomeration

It can be seen from *Figure 4* that from 2016 to 2030, the fractal dimension of the low-carbon economic linkages strength of Scenario 2 is generally higher than the fractal dimension of Scenario 1, which indicates that "Beijing-Tianjin-Xiongan" as the radiation center is better than the "Beijing-Tianjin" dual source as the radiation center.

Synchronized upgrading of multicenter source level can better promote the development of JJJ Urban Agglomeration

From 2016 to 2025, the low-carbon economic linkages strength fractal dimension from Scenario 3 to Scenario 5 is basically equal. By 2026, there will be a divergence except for individual years, the fractal dimension of scenario 4 and scenario 5 increased steadily, while the fractal dimension of scenario 3 decreased steadily. The above comparison results show that improving the low-carbon level of Xiongan alone could not influence on the low-carbon development of JJJ Urban Agglomeration, while the effect is significant when Beijing, Tianjin and Xiongan low-carbon level is improved at the same time.

The delay of radiation from high-gradient to low-gradient will not affect the low-carbon coordinated development of JJJ Urban Agglomeration

There will be a delay in the transmission of low-carbon economic development capacity from high to low gradient. *Figure 4* shows that from 2016 to 2028, the fractal

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1183511849

dimension values of scenario 4 and scenario 5 were basically same. Until 2029, scenario 4 and scenario 5 developed differently. The fractal dimension of scenario 5 began to be higher than scenario 4. The above comparison shows that the delay of low-carbon development capability radiation will not affect the radiation effect of high gradient cities (central source cities) on low gradient cities, nor does it affect the coordinated development of urban agglomerations.

Discussion and conclusions

Discussion

There two points needed to be discussed:

(1) Based on the systematic analysis of the city, this paper studies the effect of Xiongan on the coordinated development of JJJ Urban Agglomeration under different scenarios from the perspective of low-carbon economy. In this paper, the source superposition method is used to measure the low-carbon economic linkages between cities in urban agglomeration under the dual-source and triple-source scenarios. This method is more realistic in describing the radiation situation of the central city to the surrounding cities in space. It has universality and generalization, and can be applied to different urban agglomerations. The difference from this paper is that you need to adjust the source superposition formula according to the number of radiation sources in urban agglomerations.

(2) In order to analyze the radiation effects of low-carbon economy under different carbon emission conditions, five schemes are established according to different total carbon emissions. Since scenario 1 and scenario 2 have the same total carbon emissions, we only choose scenarios 2, 3, 4 and 5 for analysis. The full carbon emissions of JJJ Urban Agglomeration under scenarios 2, 3, 4 and 5 are shown in *Table 1*.

Table 1. *Full carbon emissions of JJJ Urban Agglomeration under different scenarios*

Years	Scenario 2	Scenario 3	Scenario 4	Scenario 5
2016	17.5603	17.5603	17.5426	17.5426
2017	16.4905	16.4887	16.4562	16.4081
2018	16.4260	16.4241	16.3912	16.3438
2018	16.4795	16.4738	16.4400	16.3931
2020	16.6840	16.6735	16.6389	16.5920
2021	16.8278	16.8260	16.7914	16.7437
2022	17.0700	17.0683	17.0335	16.9847
2023	17.4918	17.4901	17.4548	17.4043
2024	17.9335	17.9319	17.8963	17.8438
2025	18.5864	18.5848	18.5485	18.4935
2026	19.0421	19.0406	19.0051	18.9469
2027	19.6471	19.6456	19.6110	19.5489
2028	20.4149	20.4135	20.3798	20.3129
2029	21.0656	21.0642	21.0317	20.9602
2030	22.1694	22.1681	22.1369	22.0586

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1183511849

As can be seen from *Table 1*, Scenario 5 has the strongest carbon reduction compared with Scenario 4, but the increase of fractal dimension is not obvious. On the contrary, scenario 4 has less carbon reduction than scenario 5, but its fractal dimension has been greatly improved. The greater the carbon reduction is, the higher the cost to be borne. Therefore, scenario 5 is much higher than scenario 4 in terms of carbon emission reduction costs, but the radiation effect has not been greatly improved. In summary, there is the most obvious carbon reduction effect in Scenario 4. So if the central cities reduce carbon in advance and grasp the key points of urban agglomeration development, they can achieve better results with less investment, which also validates conclusion 3.

Conclusions

The above fractal dimension analysis of of JJJ Urban Agglomeration show:

(1) As one radiation center of JJJ Urban Agglomeration, Xiongan can significantly promote the collaborative development of the area;

(2) For the development of the whole area, the effect of improving the low-carbon level of Xiongan alone is much less than improving the low-carbon level of Beijing, Tianjin and Xiongan at the same time;

(3) The delay which comes from the transmission from high to low gradient will not affect the radiation on the coordinated development of urban agglomerations.

In the process of low-carbon development and construction of JJJ Urban Agglomeration, it is necessary to pay attention to Xiongan's construction as a high-gradient radiation center, and improve the low-carbon level of all radiation centers in the urban agglomeration at the same time. In the near future, the low-carbon coordinated development of JJJ Urban Agglomeration will be realized at the lowest possible cost.

Abstract. Environmental risk assessment is an important part of environmental management research. However, due to uncertainties in the environmental risk system, assessment results may be partially incomplete. This study takes the leakage accident of liquid ammonia as a typical case. By combining the method of Morris parameter sensitivity analysis with the Latin Hypercube Sampling, the probability sampling analysis is conducted on a group of parameters that have the greatest impact on the output of the accident consequence calculation model, as well as a set of radius values for lethal range caused by toxic gas and its probability distribution function are obtained. based on the probability distribution, the author took advantage of the GIS tool to conduct a comprehensive analysis, thereby calculating the indexes that characterize the status of regional environmental risk. The research ideas proposed in this paper have effectively improved the rationality of the selection of the parameters in the uncertainty analysis. Furthermore, the assessment results based on the uncertainty analysis can cover all possible accident scenarios, which not only comprehensively reflects the risk status of emergency environmental accidents, but also provides more scientific and reliable information for environmental management.
Keywords: *ammonia leakage accident, Latin Hypercube Sampling, Morris sensitivity analysis, individual risk, social risk*

Introduction

Potential hazardous chemical accidents pose serious threat to surrounding area. With the enhancement of public awareness of environmental protection, people realize that it is necessary to establish a scientific methodology system of "environmental risk assessment" for potential accident areas, so that environmental disasters can be effectively prevented (Shao et al., 2013; Hahn et al., 2010). In a broad sense, environmental risk assessment refers to the process of management and decision-making based on the assessment of possible losses to the hazards (including natural disasters) caused or triggered by various social economic activity to human health, social economy, and ecosystem and so on. In a narrow sense, environmental risk assessment usually refers to the probability estimation to the impact degree of toxic and harmful substances (including chemicals and radioactive substances) on human health and ecosystem, and puts forward plans and countermeasures for reducing environmental risk (Lu et al., 1999; Hansen et al., 2016; Chen et al., 2012; Tang et al., 2016).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1185111867

In the process of environmental risk assessment, the inaccuracy of data, randomness of risk and subjectivity of researchers will lead to a certain degree of bias in the assessment results, which is the uncertainty in environmental risk assessment (Xing et al., 2006; Xu et al., 2009; García-Díaz et al., 2012). The current studies show that the existence of uncertainty makes it impossible to obtain the best estimation of the consequences in a given environmental accident, or the results obtained from analysis are not necessarily the best results. However, the existence of uncertainty does not mean that the risk assessment cannot be carried out; on the contrary, the analysis of uncertainty is an indispensable part of environmental risk system. The uncertainty reflects the integrity of risk information to some extent. There are complex causes of the uncertainty in environmental risk assessment, only by effective screening and classifying, can the corresponding treatment methods be founded out. According to one of the widely recognized classification standard, the uncertainty in environmental risk assessment can be divided into three categories: parameter uncertainty, model uncertainty and the integrity uncertainty (Abrahamsson, 2002). Among them, parameter uncertainty refers to the randomness of the valuing of the parameter; or if the specific value cannot be determined under the given conditions, then the probability distribution interval can be represented. Parameter uncertainty is the main reason for researchers' cognitive bias towards risk results. How to deal with this uncertainty correctly is becoming a hot topic in this research field, and the analysis method based on probabilistic statistics theory is a common research method at present.

The core idea of probabilistic analysis method is to assume that uncertainties are originated from randomness, and by using the probability distribution of one or more variables in the risk system, the uncertainty and variability of the results can be quantified (Maxwell et al., 1999; Abdo et al., 2017). Xu et al. constructed a conceptual model for the evaluation of pollution site exposure process, proposed to characterize the uncertainty of site pollution parameters with probability distribution function, and used Monte Carlo method to assess the contribution of parameter uncertainty to the uncertainty of exposure concentration, thus the probability distribution function of pollutant concentration at exposure points can be established (Xu et al., 2014). As for soil pollution, Labieniec et al. use probability distribution function to describe the uncertainty when estimating the exposure risk of people on the contaminated land. They assessed the uncertainty of carcinogenic risk in contaminated soil due to the uncertainty of geographical characteristics, material destination and migration process (Labieniec et al., 2007).

Through the interpretation of previous research literature, it can be found that it can directly express the transfer process of "Parameter→Model→Result" by using probabilistic analysis method to deal with the problem of parameter uncertainty (Abrahamsson, 2002; Betrie et al., 2015); but it is noteworthy that the environmental models currently used to realize the quantitative description of pollutant migration is becoming more and more complex, this kind of models often need a lot of input parameters. When using the probability analysis method to carry out the uncertainty analysis, the researchers usually adopt the empirical method and subjective to determine which parameters needed to be involved in probabilistic sampling analysis, and do not consider the contribution of the parameters to the overall uncertainty of the model's output, which would affect the accuracy of the uncertainty analysis results. The flaw of this approach to some extent limit the application and development of uncertainty analysis technology used in environmental risk assessment. So in this paper, we tries to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1185111867

introduce sensitivity analysis method to objectively screen out the parameters that have high contribution to the uncertainty of the model calculation result, on this basis, the probability sampling method is used to evaluate the influence of parameter uncertainty on the result of risk assessment so as to provide environmental risk management more scientific and reliable technical support.

Methods

In order to design a complete environmental risk assessment scheme based on parameter uncertainty analysis, taking the leakage accident of liquid ammonia as a case, the research work in this paper will be carried out in three steps: (1) parameter sensitivity analysis; (2) uncertainty analysis; (3) risk characterization. As shown in *Figure 1,* firstly, the parameters with statistical characteristic in the accident consequence model are identified, and the parameters' sensitivity analysis are carried out by Morris method so as to screen out a group of parameters that contributed significantly to the uncertainty of the model output; then, these selected parameters are sampled by Latin Hypercube Sampling (LHS) method, the sample data are inputted into the model to simulate, then the probability distribution result of the lethal range values of toxic gas is obtained. Finally, based on the results of uncertainty analysis and the geographic data within the study area, the risk assessment result can be obtained after excuting the spatial analysis in the GIS software.

Sensitivity analysis of model parameters

Accident consequence model and uncertainty parameters identification

There are many mathematical-physical models that can be used for calculating the harmful effect of hazardous chemical accident, among which, The Process Hazard Analysis Software Tool (PHAST) developed by Det Norske Veritas (DNV) is a very effective software package for quantitative calculation of chemical accident consequence. This software package can simulate the effect degree and spread range of gas leakage, fire and explosion by inputting parameters related at the scene of the accident. The Unified Dispersion Model (UDM) integrated in the PHAST can simulate the diffusion process of gaseous substances. And this model is very complex, which is established on the basis of many classic models including BM model, P-G model (Hanna et al., 2008). PHAST provides the interface with "batch mode", through the Matlab's control program, the repetitive execution of the calculation process can be realized, which provides possibility for subsequent sensitivity analysis and uncertainty analysis (Pandya et al., 2012).

The input parameters of UDM model involve various aspects such as leakage source status, leakage mode, diffusion field parameters and meteorological conditions. By referring to the study of Pandy et al., the parameters with uncertainty in UDM model are identified, the statistical characteristics (probability distribution type and value scope) of these parameters are shown in *Table l,* among which, the parameters' statistical characteristics of leakage source status and leakage mode can be got according to the assumption on the basis of on-site investigation data; the meteorological parameters can be gained based on the statistical analysis to the meteorological data from 2007~2017 of study area, the diffusion field parameter is derived from the expert experience after the users applied PHAST.

Table 1. *Statistical characteristics of parameters in PHAST*

Parameter name	Meaning/unit	Distribution form
T_{st}	Storage temperature/K	Triangular(263.15, 283.15, 273.15)
P_{st}	Storage pressure/Pa	Uniform(0.473e06,0.49e06)
L_h	Liquid height/m	Uniform(12.75, 17.25)
T_a	Atmospheric temperature/K	Normal(251, 10.5)
P_a	Atmospheric pressure/Pa	Uniform(0.99e05, 1.035e05)
H_a	Relative atmospheric humidity/-	Normal (68, 10)
u_a	Wind speed/$m \cdot s^{-1}$	Normal(3.4, 1.3)
D_O	Release orifice diameter/m	Triangular(0.16, 0.18, 0.20)
Z_R	Release height above ground/m	Uniform(1, 20)
Z_0	Surface roughness length/m	Uniform(0.5, 1.5)
S_{flux}	Solar radiation flux/$W \cdot m^{-2}$	Triangular(0, 1000, 500)
α_1	Jet entrainment parameter	Normal(0.17, 0.0085)
α_2	Cross-wind entrainment parameter	Normal(0.35, 0.0175)
C_E	Cross-wind spreading parameter	Normal（1.15, 0.0575）
e_{pas}	Near-field passive entrainment parameter	Normal(1, 0.05)
C_{Da}	Drag coefficient of plume in air	Exponential(69.2)
γ	Dense cloud side entrainment parameter	Exponential(34.6)
Ent_{poo}	Pool vaporisation entrainment parameter	Normal(1.5, 0.075)
r_u^{pas}	Max cloud/ambient velocity parameter	Normal(0.1, 0.005)

Morris sensitivity analysis method

Sensitivity analysis is used to assess the effect caused by model input parameter on the output result (Xu et al., 2004; King et al., 2013). The qualitative global sensitivity analysis is also called factor screening sensitivity analysis, whose purpose is to gain the rank of each input parameter sensitivity degree in the model through lower computational cost, so that some inessential parameters can be ruled out and the subsequent uncertainty analysis calculation load can be reduced. Morris method was proposed in 1991 by Max D. Morris, which can effectively identify and sort the importance of model parameters. The main idea is to assume that the "Elementary Effect"(EE), which measures the sensitivity of the parameter, is subject to a certain distribution form, and then the global parameter sensitivity can be determined by measuring the mean value and standard deviation value of the distribution (Morris, 1991).

The model contains k parameters and assumes that the variation range of these parameters is [0,1]. Morris sampling method is used to randomly generate a set of initial parameter vectors $X = (x_1, x_2, \ldots, x_k)$, where the value of x_i is randomly selected from $\{0, 1/p\text{-}1, 2/p\text{-}1, \ldots 1\text{-}\Delta\}$, p is the number of sampling points, Δ is the pre-set variable quantity, then the value of Δ is $\Delta = 1/p\text{-}1$, then the ith parameter's calculation equation of EE are as follows:

$$EE_{1i} = \frac{Y(x_1, \cdots, x_i + \Delta, \cdots, x_k) - Y(X)}{\Delta} \quad \text{(Eq.1)}$$

where Y(X) is the model output corresponding to the initial parameter vector, $Y(x_1, \ldots, x_{i-1}, x_i + \Delta, \ldots, x_k)$ is the model output corresponding to the variable quantity Δ formed by the ith parameter of the initial parameter vector. For the remaining k-1 parameters, repeat the above operation, and calculate the elementary effects of the remaining k-1 parameters respectively and randomly generate n initial vectors. Repeat the above process, then the n EE of k parameters can be represented as EE_{ij}, where j = 1, 2,…, n, i = 1, 2,…, k. The mean value and standard deviation of the EE of each parameter can be expressed as:

$$\mu_i = \sum_{j=1}^{n} EE_{ij} / n \quad \text{(Eq.2)}$$

$$\sigma_i = \sqrt{\sum_{j=1}^{n} (EE_{ij} - \mu_i)^2 / n} \quad \text{(Eq.3)}$$

The screening of parameters

The mean value and standard deviation of each parameter can be calculated by Morris method, if the parameter xi corresponds greater mean value μ, then this means it would cause larger influence on the model output value; the larger the value of variance element is, then the larger the interaction is between this parameter and other parameters when affecting the output of the model, or namely, the influence of this parameter to the output of the model is non-linear. Taking these two indexs into

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1185111867

consideration, m parameters involved in the subsequent sampling analysis of uncertainty can be screened out.

Uncertainty analysis

In order to realize the quantitative recognition of the uncertainty of parameters, that is, to describe the risk system by exact numerical value extracted from the conceptual uncertain risk system, the currently most widely used Monte Carlo method can be adopted (Milazzo et al., 2015), which is a kind of calculation method by random sampling statistics to estimate the probability distribution function. Due to Monte Carlo sampling may "collapse" in some sample points and lead to low sampling efficiency, so if the ideal sampling effect wants to be achieved, it requires a large number of sampling test, because of the complexity of the calculation model integrated in PHAST, this process can often take long time with huge calculation resources.

Latin hypercube sampling

On the basis of Monte Carlo method, Latin Hypercube Sampling (LHS) introduces the idea of multi-dimensional stratified sampling (Hoshino et al., 2000; Wu et al., 2015), that is, n samples are extracted from m-dimensional vector space. The steps are as follows: each dimension is divided into n intervals that do not overlap each other so that each interval has the same probability; a sample point is randomly selected from each interval in each dimension; then randomly select points from the previous step from each dimension and form them into vectors. As a more efficient sampling method, LHS has greater advantages in both sampling efficiency and running time (due to less number of iterations). Therefore, in this study, LHS is selected as the tool for uncertainty analysis of model parameters. The detailed implementation process in this study is as follows:

l) According to the results of sensitivity analysis (parameters screening), confirm m uncertain input parameters needed considering and their probability distributions.

2) According to the required sample size n, divide the value range of each input parameter X_i (i = 1, 2, … , m) into n sub-ranges.

3) Randomly select one value in each sub-range from each parameter, in this way, n samples of this input parameter can be obtained. N samples of m input parameters are randomly combined to form an n × m matrix, where j (j = 1, 2..., n) row represents the input parameters value required for the jth simulation. By substituting the input parameter value matrix into the model, n output results can be obtained.

Conversion to lethal radius

The PHAST simulation result represents the concentration distribution of diffused toxic gas, while the environmental risk assessment focuses on the impact of toxic substances leakage on human health; Therefore, the concentration result needs to be transformed into the human health effect with the help of the "Toxic dose--Response" reference criteria to get the data needed for environmental risk assessment. In this study, the risk result is shown as the magnitude of risk receptor deaths toll caused by the exposure to the risk area. The minimum lethal dose in the toxicity criteria is selected as the threshold to demarcate the radius of lethal area (hereinafter referred to as "lethal radius"), and the toxic gas diffused range is divided into the lethal area and the non-lethal area. The lethal radius is determined by the short-term exposure guidelines-Acute

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1185111867

Exposure Guideline Levels (AEGL) developed by National Advisory Committee (NAC) of U.S.

Statistical analysis of LHS result

After n times of repeated simulation, and the conversion of the simulation results through AEGL criterion, n lethal radius values can be obtained. By statistical analysis to the simulation results, the Probability Distribution Function (PDF) and Complementary Cumulative Distribution Function (CCDF) can be obtained, which are important bases of risk characterization.

Risk characterization

Risk characterization is a process to obtain the final quantitative risk assessment results through spatial analysis in geographic information system, it takes the analysis result of LHS analysis as the base and comprehensively takes into account the factors not involved in LHS analysis, including wind direction probability, accident occurrence probability and population distribution, etc. At present, the regional environmental risk assessment is mainly based on the geographical information system to realize the refined segmentation of the study areas so as to endow the environmental risk with geospatial attributes (Wu et al., 2006; Di Domenico et al., 2014). For the convenience of calculation, the target study area is gridded in the geographic information system platform, and the grid layer of environmental risk source, environmental risk receptor and LHS analysis results included in the risk system is established. According to all types of risk factors, every grid is given an value assignment, so the individual risk and social risk can be calculated respectively with the grid as the calculation unit.

Individual risk

It refers to the probability of death (or a specific level of injury) to an unprotected risk receptor in a specific location of the risk area for a relatively longer time. Individual risk is usually expressed as the risk contour line, and its calculation method is to calculate the individual risk in each grid center generated by each risk source in the study area. Overlay analysis would be done in the individual risk of each risk source, then the total individual risk value in a single grid can be obtained. The calculation process is shown in *Equation 4*.

$$IR_{(x,y)} = \sum_{i=1}^{M} f_i \times p_i^W \times p_i^L \times v_i \quad \text{(Eq.4)}$$

where (x, y) represents the coordinate of each grid center, f_i is the probability of an accident occurring in the risk source i, p_i^W is the probability of wind direction that would locate at (x, y), p_i^L is the LHS analysis result of the ith risk source that would locate at (x, y), v_i is the individual death probability caused by accident happening at (x, y), M is the number of risk sources in this area.

Social risk

Social risk is on the basis of individual risk to consider the regional population density, and its practical significance is to calculate the probability of a potential

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1185111867

accident causing more than or equal to a specified number of deaths. The social risk is usually represented by F-N curve, N stands for death toll in the abscissa, the ordinate is the probability F of occurring N or more death toll. The calculation method is shown in *Equation 5,* and the calculation result is expressed in the form of F-N curve (Hou et al., 2016; Trbojevic et al., 2000).

$$F = \sum_{y=1}^{S} \sum_{x=1}^{T} IR_{(x,y)} \qquad N_d \geq N \tag{Eq.5}$$

where S is the row number of grid in the study area, T is the column number of grid, and Nd is the death toll. From the equation, it can be seen that CCDF is need to be used in the calculation process of social risk.

Results and discussion

Study area

Wuhu is an important city and shipping hub in the middle reach of Yangtze River. The warehouse storage of Sinopec is built in Tianmenshan Street, Jinghu district along the Yangtze River. Various hazardous substances such as chemical raw materials and intermediate products make this place become a high potential hazard-formative risk source; and its adjacent area is the urban densely-populated district, so this kind of adverse condition will increase the risk degree of accidental chemical disaster. This study takes the leakage accident of liquid ammonia storage tank in this warehouse as an example to carry out the environmental risk assessment. The spatial layout of the study area is shown in *Figure* 2.

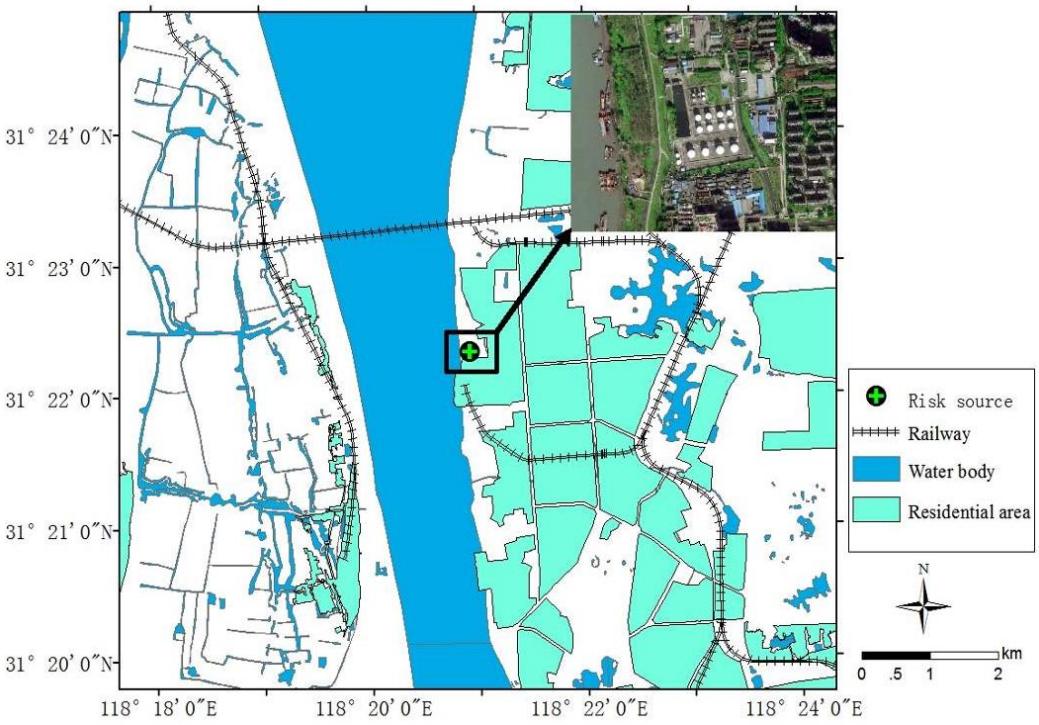

Figure 2. *Spatial layout of study area*

DOI: http://dx.doi.org/10.15666/aeer/1705_1185111867

Parameters sensitivity analysis

Ammonia is widely used in industry. It is usually stored in the liquid phase in pressurized vessel. After its emission, a two-phase flow occurs forming an ammonia cloud composed of vapor and very fine droplets that do not fall to the ground. The droplets evaporate quickly, cooling the air. It results a cold mixture of air and ammonia, denser than the ambient air, even though pure gaseous ammonia is lighter than air at ambient temperature (vapor density of 0.73 at 288.15 K). For NH_3 releases, all the dispersion phases normally occur. Based on the analysis of historical data on leakage accident of liquid ammonia, in research work performed by this paper, the leakage mode is set as "continuous leakage", atmospheric stability class is set as D, with the duration time of 1 h, and the leakage angle is set as horizontal orientation.

According to the principle of Morris method, the sampling of the parameters involved in *Table 1* was carried out in 15 orbits and 8 sampling levels, in this way, 120 groups of samples were generated, which were inputted into the PHAST for calculation, and then the ground level ammonia concentration values at 100 m, 800 m and 3000 m downwind distance under each group of parameter conditions were respectively calculated, based on which the sensitivity index μ and σ for each parameter are calculated. In order to facilitate the comparison of each parameter's influence degree to ouput result, the scatter diagram shown in *Figure 3a, b* and *c* were drawn after taking the normalized values and absolute values of μ and σ.

According to the results shown in the scatter diagram, although the sensitivity index of each parameter varies with the downwind distance, on the whole, the parameters which have the highest sensibility are D_O (release orifice diameter) and Z_R (release height above ground). But for the parameters α_1 and α_2, the μ value is higher in the near-field diffusion. This indicates that the effect of jet velocity on ammonia diffusion is higher than wind speed in near-field, while the effect is gradually weakened in far-field diffusion. It can also be seen from the scatter diagram that the μ value of the parameter is large and the corresponding σ value is large generally, this indicates when a parameter has a greater influence on the output of the model, it tends to interact more with other parameters. Here, the μ values of the parameters corresponding to the three kinds of downwind distances are averaged and ranked. The result is shown in *Figure 3d.* It can be seen that the sensitivity of parameters D_O, Z_R, u_a, α_1, α_2, Z_0, P_a, T_a have order of magnitudes difference with the remaining parameters in *Table 1*. Therefore, they can be considered as parameters that have a greater influence on the output of the model, while other parameters have a very limited influence on the output of the model. Based on this, these 8 parameters are selected to participate in the subsequent uncertainty analysis.

LHS analysis

LHS is performed on the 8 selected parameters. By referring to the research of Kong et al.(Kong et al., 2011), the sampling times of LHS were set to 1000, and the obtained 1000 groups of parameters value are inputtted into PHAST for simulation, 1,000 simulation results and the PDF of the lethal radius of leakage gas are obtained, CCDF of the lethal radius is also obtained. The detailed results are shown in *Figure 4.*

As the probability distribution results shown in *Figure 4,* the lethal radius of liquid ammonia leakage ranges considerably within 100 m~3500 m under the combined action of 8 independent uncertainty variables in the risk system, among them, the lethal radius around 1300 m owns greater probability than the ends of this distribution range, which can differ an orders of magnitude. From the analysis results of LHS, two conclusions can be drawn: Firstly, the environmental risk nearly about 1.3 km distant from the leakage source is relatively high, and the environmental risk beyond 1.3 km decreases with the increase of distance. Here, the magnitude of environmental risk is only a relative concept based on the LHS results, and the magnitude and acceptability of environmental risk should be evaluated by further introducing other elements in the risk system. Secondly, from the perspective of the lethal concentration distribution, the previously risk assessment research for a single and specific accident scenario is not scientific and reliable enough and would provide incomplete and even wrong information to the researchers.

Risk characterization

In order to balance the contradiction between the resolution requirement and computational efficiency of risk characterization, the grid scale is set as 50 m × 50 m in study case considering the actual situation of the study area. The grid partition is carried out in ArcGIS 10.1 to creat the LHS analysis results layer and wind direction probability layer within the study area. The results are shown in *Figure 5*. The population density of the study area is as shown in the *Figure 6*. As the grid is used as the calculation unit for environmental risk analysis, all layer files are saved as raster format.

Individual risk

According to the statistical analysis of the liquid-ammonia leakage accident involving more than one fatality in China over the past 20 years, the occurrence probability f in *Equation 4* is about 1.61×10^{-3}. The CCDF of the lethal radius obtained from the probability sampling analysis is used as the data source of the LHS result layer in ArcGIS. The wind direction probability is obtained through the statistical analysis of historical meteorological data from 2007~2017 in the study area. Since the toxicity criteria used is lethal concentration, so *v* is set to 1. On the basis of the discrete results in each grid, the contour lines of individual risk at different levels in the study region can be depicted through grid calculation and extraction analysis in ArcGIS.

After obtaining the assessment results of individual risk, appropriate measure standard should be selected to evaluate the acceptability of risk, which would be used as the basis of environmental risk decision (Meng et al., 2014; Liu et al., 2012). For individual risk, what are now widely recognized standard is As Low As Reasonable Practicable (ALARP) guidelines, set by Health and Safety Executive (HSE) of UK, which also have two kinds of thresholds for individual risk: acceptable risk and negligible risk. This study refers to the HSE standards, also considering the actual construction situation of Chinese hazardous chemical facilities and the socioeconomic performance of assessment object, the threshold of negligible risk level is determined as 10^{-6}/year, the threshold of acceptable risk level is 10^{-4}/year. *Figure 7* shows the individual risk contour lines of these two kinds of thresholds in case study.

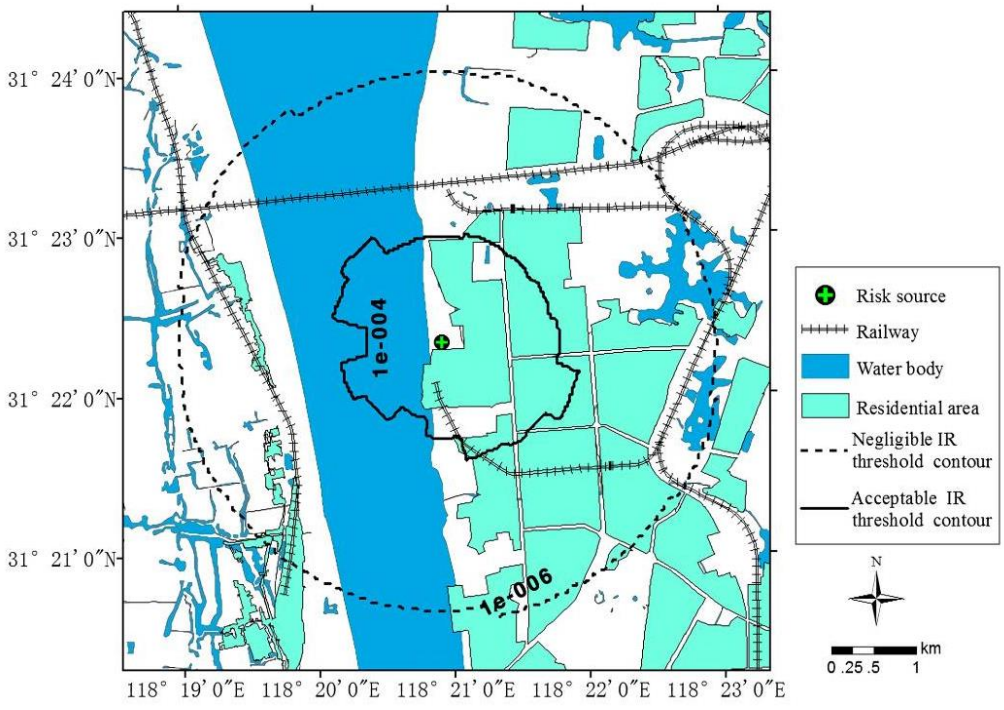

Figure 7. *Individual risk assessment result of case study*

Social risk

Social risk is by taking the analysis results of individual risk as the base to calculate the number of risk receptors within the range of individual risk field so as to obtain the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1185111867

integrated risk assessment conclusion, and it also follows ALARP criterion. By referring to the measure standard of social risk acceptability in UK and the Netherlands and considering the relatively serious loss of toxic gas leakage accident consequence, the line slope of social risk assessment standard selected in this study is n = -2, namely, the risk assessment personnel holds averse attitude; the acceptable line for feature points is determined as (l, 10^{-2}) linear and the negligible line for feature points is determined as (l, 10^{-4}) linear.

The population data of study area is as shown in the *Figure 6,* hereby, the risk receptor number of each lethal radius can be calculated in ArcGIS, and so the death toll and the corresponding probability can be got. Then according to the calculation results of social risk equation, F-N curve can be depicted and the probability of death toll (≥N) can be obtained. The details can be seen in the *Figure 8*.

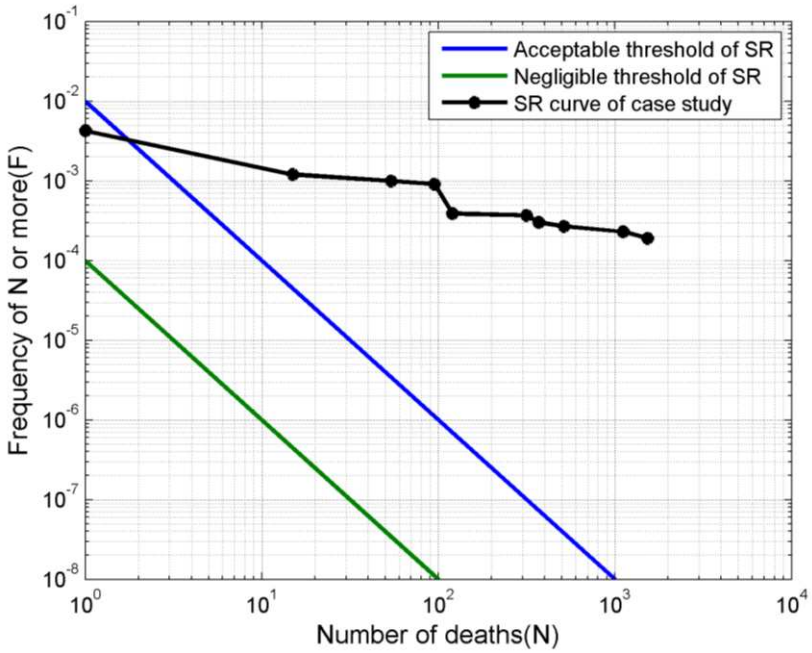

Figure 8. *Social risk assessment result of case study*

Discussion of environmental risk assessment results

According to the description of above two sections, the acceptability threshold values of individual risk and social risk are all determined, and based on which we can make some analysis about the environmental risk assessment result.

It can be seen from the individual risk contour line that some residential areas are not in the acceptable range. Through on-site investigation, there are schools and other sensitive public places in the non-ALARP area. Once an accident happens, this part of the population is vulnerable with poor self-rescue ability. According to the principle of ALARP, the relevant departments should take compulsory measures to design and plan this non-ALARP area to reduce the risk level. For people in ALARP area, the government need to further calculate the economic reasonableness before deciding whether to take further measures to reduce the individual risk value in ALARP area.

The F-N curve of case study is mostly above the acceptable level, so the social risk is not acceptable. The highly concentrated residential area near the chemical hazardous

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1185111867

source is the main reason for this status, namely the unreasonable land use patterns generates higher social risk. This study result also demonstrated a direct relationship between social risk and regional population distribution.

Conclusions

1) Through the results of parameter sensitivity analysis, it can be found that different input parameters in PHAST would generate different effects on the output results, and some even have magnitude-class differences. The method based on sensitivity sequencing can avoid the subjectivity and blindness of parameter selection in uncertainty analysis. The variability presented of LHS analysis results in this study, in fact, is the expression of the uncertainty of environmental risk system in the reality. Probability sampling method can effectively deal with the uncertainty problems contained in the environmental risk system. The all possible random events can be simulated and finally the probability distribution of the simulation results can be obtained, which become the basis of all potential accident scenarios simulation and more all-sided environmental risk assessment.

2) Based on the uncertainty analysis, individual risk and social risk are used to assess the regional environmental risk level, and the results show that these two kinds of assessment indexes are able to scientifically quantify the environmental risk level as well as visually show the risk level in ArcGIS platform, which contributes to the understanding of the risk decision-makers and provides a reference of risk management for the environmental department. The research results of the liquid ammonia leakage accident show that the individual risk and social risk in the study area are on the high side, which exceed the acceptable threshold. Therefore, corresponding risk management measures should be taken by the chemical enterprise and government to reduce the risk level.

3) It is a common issue concerned by the government and public about the environmental hazard source how to have safe and reasonable layout plan and decide the regional development scale according to the regional environmental risk tolerance in the urban area. In this study, regional environment risk state was evaluated from the aspect of short-term toxic harm for the personnel. Moreover, planning and adjustment suggestions were proposed to the residential area. The follow-up research work can also be in consideration of the long-term impact resulted by environmental accident to soil, water and air. With the combination of uncertainty analysis method proposed in this paper, synthetic judgment was conducted to the environmental risk tolerance for the peripheral zone of environmental hazard source.

Abstract. the middle reach of Yellow River is a production area for main grain crops in China and is also an emerging industrial cluster. this study adopts meteorological data from 1951 to 2014 provided by 73 national ordinary stations in the study area, combines Kendall-tau non-parametric test method, Sen's slope estimation method and Savitzky-Golay smoothing filtering method based on sub-regions divided by fuzzy clustering method and analyzes the variation trend of extreme temperature indexes. The results show that: (1) in the middle reach of Yellow River, the variation trend of extreme temperature events is basically similar, but the intensity is different, and the spatial distribution is inconsistent. (2) On time scale, an upward trend has been found in extreme temperature events in the past 60 years. (3) On spatial scale, the change rate of multiple indexes in the arid sub-region is greater than that of those in the humid sub-region; the proportion of meteorological stations with significant index changes in the arid region is higher than that in the humid sub-region. Some indexes have different trends in small areas, which may be caused by local microclimates in urban heat islands and hilly areas, but further analysis and verification is also required.

Introduction

More than half a century in the past, scholars at home and abroad have conducted a lot of research work on extreme climate events in different regions of the world and have achieved research results of different depths. In early 2014, *Science* published 7 papers in a row to discuss the "the Challenge of Climate Science" and elaborate on some core issues of current climate and hydrology sciences, including the issue of "regional climate and extreme events". The paper believed that an important trend of warming research is to reflect global warming in the research on regional climate and extreme events, but the research needs to be further developed, where great difficulties also exist (Wang et al., 2014a; Horton et al., 2015). At present, domestic and international researches focus mainly on the observational facts of extreme climate. The fifth assessment report of the UN Intergovernmental Panel on Climate Change (IPCC) has summed up the observations and research findings of extreme temperature and precipitation events in full length. Many studies show that extreme precipitation events

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1186911885

are very sensitive to the global climate change, and minor changes in the climate may cause greater changes in the frequency and intensity of extreme weather events (Alexander, 2016; Diffenbaugh et al., 2017; Mooshammer et al., 2017; Grotjahn et al., 2016; Ma et al., 2015).

The middle reach of Yellow River is located in the confluence of the Loess Plateau, Ordos Plateau and Inner Mongolia Plateau; where plains, deserts, mountains, platforms, lakes and wetlands are intertwined, topography and landform are complex, terrain changes greatly and the structure of the underlying surface is complex. The area is a major producing area of main gain crops and industrial crops in China and is also an emerging industrial cluster. Extreme temperature events may have an impact on industrial and agricultural production and urban development in the area (Nie et al., 2015). In recent years, researchers have conducted a research on temporal and spatial variation characteristics, variation trends and cases of formation of extreme temperature events in mainland China (Zhou et al., 2010), northern and southern China (Zhai et al., 2003; Tang et al., 2014), certain watersheds (Wang et al., 2013) and certain provinces (Shen et al., 2012; Chen et al., 2012, 2011; Zhang et al., 2014; Li et al., 2015; Wang et al., 2016, 2012), respectively. However, the research on extreme temperature events in the middle reach of Yellow River is still insufficient so far.

Based on previous researches, this study adopts the daily temperature data of 73 meteorological stations and uses the internationally used extreme temperature event indexes to conduct an in-depth research on the temporal and spatial changes in extreme temperature events in the middle reach of Yellow River, reveal the change characteristics and trends, hoping to provide a reference for water circulation, water resource management, ecological vulnerability assessment and hydrogeological hazard warning and other researches in the area under extreme climate conditions.

Data and methodology

Data

This study adopts the temperature data from 1951 to 2014 of 73 national ordinary stations in the middle reach of Yellow River provided by China Meteorological Data Network (http://data.cma.cn/, China Surface Dataset Daily Value Dataset V3.0). The meteorological data selected has passed quality control, including inspection of climate threshold value or allowable value); inspection of extreme value of station; internal consistency inspection of set value, daily average and daily extremum; temporal and spatial consistency inspection and other measures. In addition, the distribution of meteorological stations is shown in *Figure 1*.

Research method

Definition and calculation of extreme temperature indexes

The definition of extreme temperature indexes in this research is based on the "climate change detection and indexes" determined by CCI, WCRP, CLIVAR and ETCCDMI. These indexes and their calculation methods have been widely used in the world, and the research results also reflect that these indexes are characterized by good regional adaptability, low noise, low extremity and strong significance (Li et al., 2012; Zhao et al., 2015). There are 29 indexes in this series, including temperature and precipitation. This paper selects 18 temperature indexes to analyze the extreme

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1186911885

temperature events in the middle reach of Yellow River, and specific indexes and definitions are shown in *Table 1*. The indexes are calculated using RClimDex1.1 software. In the process of calculation, quality inspection and control are conducted on the said meteorological data including outliers and error values. Meanwhile, this paper also adopts new international climate change benchmarks (Zhang et al., 2014).

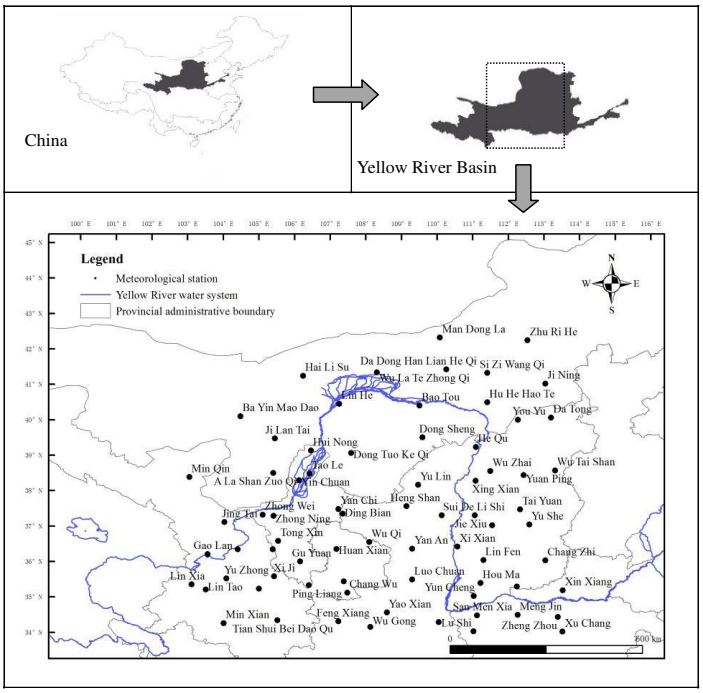

Figure 1. *Meteorological stations in the middle reach of Yellow River*

Table 1. *Definitions of extreme temperature indexes*

Abbreviation of index	Definition	Unit
DTR	Difference between daily maximum temperature and daily minimum temperature	°C
TMAXmean	Average value of annual/monthly/daily maximum temperature	°C
TMINmean	Average value of annual/monthly/daily minimum temperature	°C
TNn	Minimum value of annual/monthly/daily minimum temperature	°C
TNx	Maximum value of annual/monthly/daily minimum temperature	°C
TXn	Minimum value of annual/monthly/daily maximum temperature	°C
TXx	Maximum value of annual/monthly/daily maximum temperature	°C
FD0	Number of days in a year whose minimum temperature is below 0 °C	d
ID0	Number of days in a year whose maximum temperature is below 0 °C	d
SU25	Number of days whose daily maximum temperature is above 25 °C	d
TN10p	Number of days whose daily minimum temperature is below 10% tantile	d
TN90p	Number of days whose daily minimum temperature is above 90% tantile	d
TR20	Number of days in a year whose daily minimum temperature is above 20 °C	d
TX10p	Number of days whose daily maximum temperature is below 10% tantile	d
TX90p	Number of days whose daily maximum temperature is above 90% tantile	d
WSDI	Number of days whose maximum temperature is 90% tantile for 6 days in a row	d
CSDI	Number of days whose minimum temperature is 10% tantile for 6 days in a row	d
GSL	Time span during which the temperature is above or below 5 °C for 6 days in a row	d

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1186911885

Fuzzy clustering analysis

Clustering analysis is a multivariate statistical analysis method, which classifies individuals based on their several characteristics, so that individuals of the same category have a higher homogeneity while individuals of different categories have a higher heterogeneity. When it comes to dealing with actual classification problems, varying degrees of fuzziness is always seen because the boundaries of individual categories are not always clear and exact. When clustering involves fuzzy boundaries between individuals, a fuzzy clustering analysis method is usually used, which is established on fuzzy mathematics. Fuzzy C-Means (FCM for short) was proposed by Bezkek in 1981. The impact of different number of categories c on classification results is highly significant. To evaluate the classification effect under different c values in a scientific way, the predecessors have done a lot of research work and defined a number of evaluation indexes (see *Eqs. 1–4*) to guide the specific classification process. Assuming that different c values are determined according to those indexes (*Eqs. 1–4*), the smaller c value shall prevail if different c values have similar classification effect (Qi et al., 2015).

Partition coefficient (PC):

$$PC(c) = \frac{1}{N}\sum_{i=1}^{c}\sum_{j=1}^{N} u_{ij} \quad \text{(Eq.1)}$$

Classification entropy (CE):

$$CE(c) = \frac{1}{N}\sum_{i=1}^{c}\sum_{j=1}^{N} u_{ij} \log(u_{ij}) \quad \text{(Eq.2)}$$

Partition index (SC):

$$SC(c) = \sum_{i=1}^{c} \frac{\sum_{k=1}^{N}(u_{ij})^{m}\left\|x_j - v_i\right\|^2}{N_i\sum_{k=1}^{c}\left\|v_k - v_i\right\|^2} \quad \text{(Eq.3)}$$

Separation index (S):

$$S(c) = \frac{\sum_{i=1}^{c}\sum_{k=1}^{N}(u_{ij})^{2}\left\|x_j - v_i\right\|^2}{N\min_{ij}\left\|v_k - v_i\right\|^2} \quad \text{(Eq.4)}$$

Analysis method of variation trend of extreme temperature indexes

Meteorological data belongs to time series. For the trend analysis of time series, a linear regression method is usually used, but such method directly calculates the slope based on the actual data value, which is greatly affected by the abnormal value. Sen's slope estimation algorithm has strong anti-noise performance, but it cannot be used to make a significant judgment of sequence trend. The Kendall-tau non-parametric test

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1186911885

method does not require the sample to follow a certain distribution, allows the existence of missing values and can achieve significant judgments, but it cannot be used to obtain the slope of the sequence (ZHAI et al., 2003). Therefore, Kendall-tau non-parametric test method and Sen's slope estimation method are combined in this paper to make full use of their respective advantages, so that they can better serve the analysis of changes in extreme temperature indexes.

Savitzky-Golay smoothing filtering method

To more clearly extract and demonstrate the variation trend of extreme temperature indexes, the Savitzky-Golay smoothing filtering method is used in this paper. The method was proposed by Savitzky and Golay in 1964, which is a filtering method based on local polynomial least squares fitting in the time domain, whose prominent advantage is that it can ensure that signal shape and width remains unchanged at the time of simple and rapid filtering of noise (Cai et al., 2011;). In addition, the Savitzky-Golay smoothing filter in this study uses 7 points 2 times as the polynomial parameter.

Results and analysis

FCM-based climate division

To facilitate the analysis of the overall situation of the extreme temperature indexes in the middle reach of Yellow River on time scale, it is required to summarize 73 meteorological stations as specific climate regions. As mentioned before, the middle reach of Yellow River is located in the confluence of three major plateaus, where the terrain is complex as well as the structure of the underlying surface. It is obviously inappropriate to directly average 73 meteorological stations above and generalize the entire the middle reach of Yellow River as one region. Therefore, proper zoning is required. There are actually a lot of methods for climate zoning, the fuzzy clustering method (FCM) is used in this paper.

Combined with the natural conditions of the geographical location of the research area, latitude and longitude, altitude, average temperature and maximum and minimum temperature of the meteorological stations are regarded as characteristic values to perform clustering analysis on 73 meteorological stations in the middle reach of Yellow River. The number of divisions is preliminarily estimated to be $c = 2$ or $c = 3$. By selecting different c values, FCM can obtain corresponding membership matrix. According to the relationship reflected in the matrix, the classification results shall be plotted when $c = 2$ or $c = 3$ (see *Fig. 2*). On this basis, the most reasonable number of divisions shall be analyzed in combination with 7 different indexes listed in *Table 3*. In addition, it can be seen from *Figure 2* that more stations are not classified in the middle reach of Yellow River when $c = 3$; while the classification shows good results when $c = 2$.

To more intuitively express the FCM climate divisions in the middle reach of Yellow River, the classification results are represented in a map (see *Fig. 3*). It can be clearly observed that 73 stations are classified into 2 different climate divisions along the line of "Yuanping—Xing County—Suide—Yan'an—Pingliang—Tianshui", and the line is very close to China's 400 mm equivalent precipitation line and "HuHuanYong Line", which also fully indicates that it is reliable and reasonable to apply the fuzzy clustering algorithm to climate division in this paper. By referring to the significance of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1186911885

400 mm equivalent precipitation line, this paper defines 2 different climate divisions in the middle reach of Yellow River obtained by FCM clustering analysis as "arid and semi-arid sub-region" and "humid and semi-humid sub-region", respectively. For the purpose of conciseness, they are referred to as "arid sub-region" and "humid sub-region", respectively.

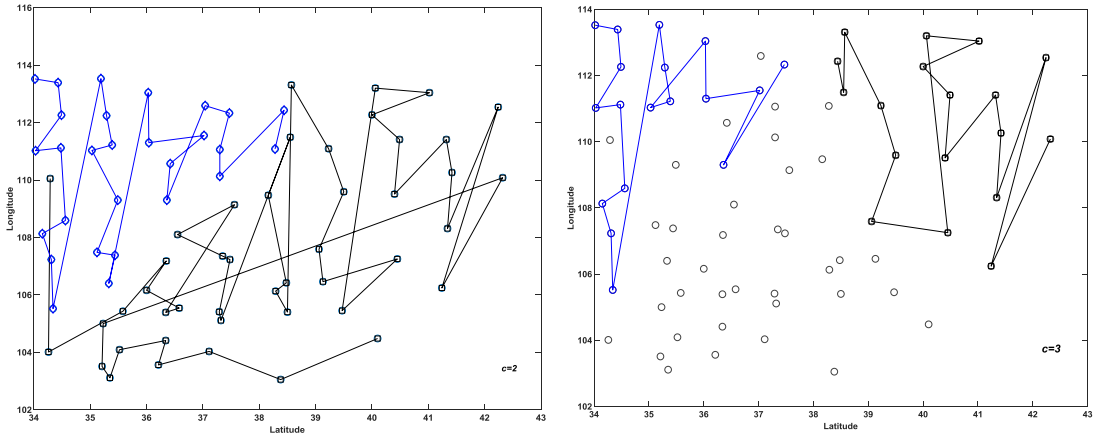

Figure 2. *FCM analysis of meteorological stations*

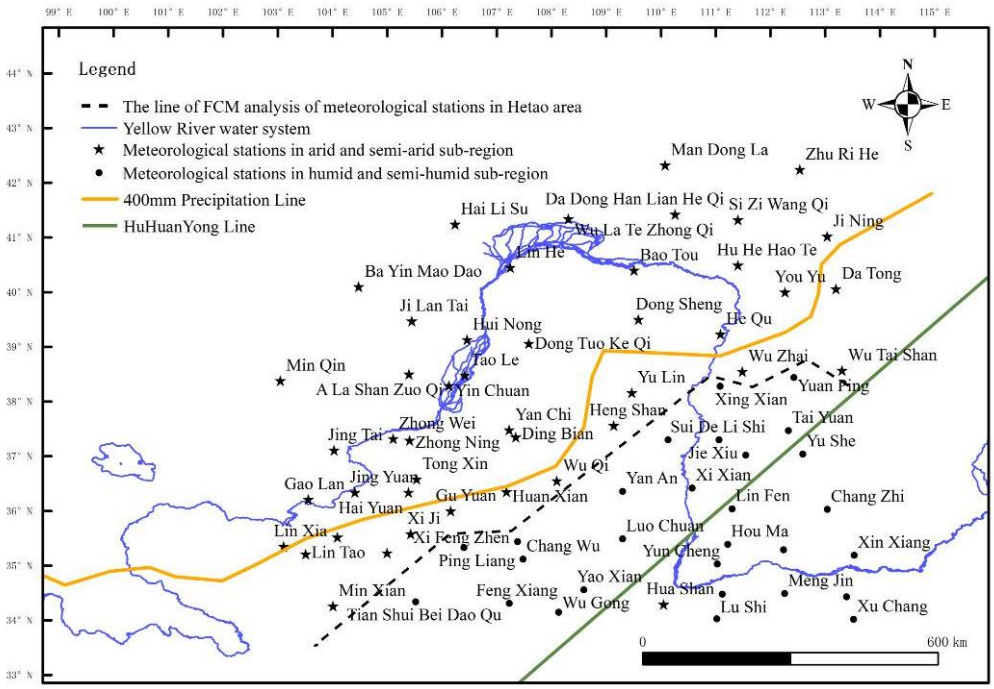

Figure 3. *FCM analysis results of meteorological stations in the middle reach of Yellow River*

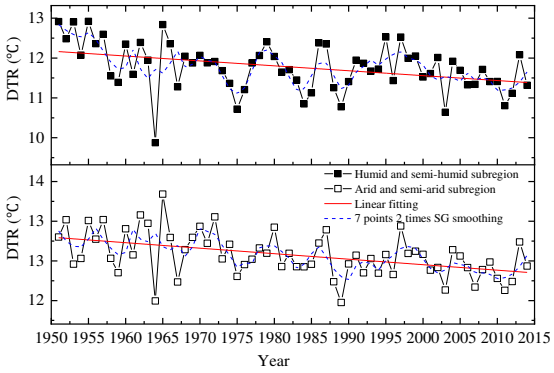
Temporal and spatial variation of extreme temperature indexes

Variation of DTR, TMAXmean, TMINmean, TNn, TNx, TXn and TXx indexes

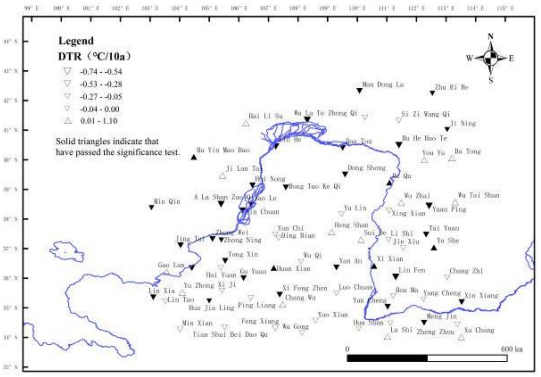
In the past 60 years, the daily temperature range (DTR) has dropped significantly, while the average maximum temperature TMAXmean and average minimum

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1186911885

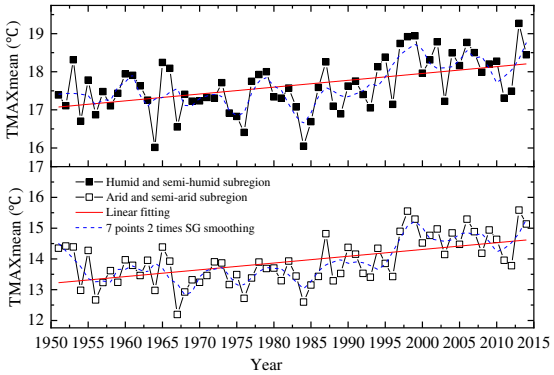
temperature TMINmean have increased significantly, and shown an obvious stage (see *Fig. 4a, c* and *e*). DTR continued to decline around 1951-2000, TMAXmean and TMINmean continued to rise, but the variation trend of indexes began to slow down after 2000. These three indexes had the same rate of change in the arid and humid sub-regions, reaching 0.1 °C/10a, 0.2 °C/10a, and 0.3 °C/10a, respectively (see *Table 3*). The rate of increase of average minimum temperature is higher than that of average maximum temperature, which is the primary reason for the significant decrease in daily temperature range. Viewed from spatial distribution, DTR shows a significant downward trend in most meteorological stations, and the average maximum temperature and average minimum temperature show an obvious upward trend in the entire the middle reach of Yellow River (see *Fig. 4b*, *d* and *f*).



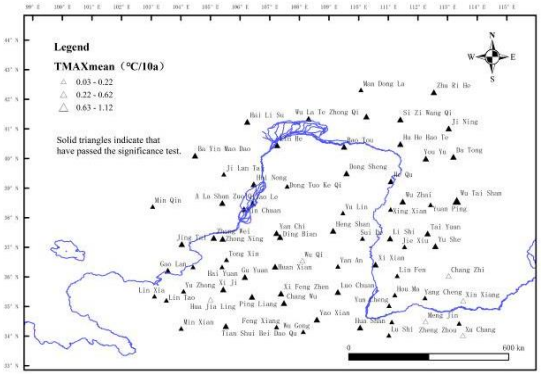
(a) Interannual variation of DTR index



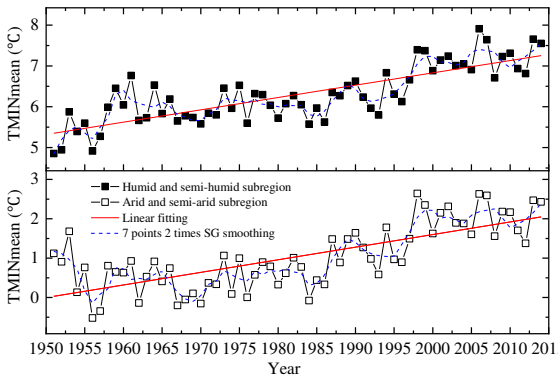
(b) Space variation of DTR index



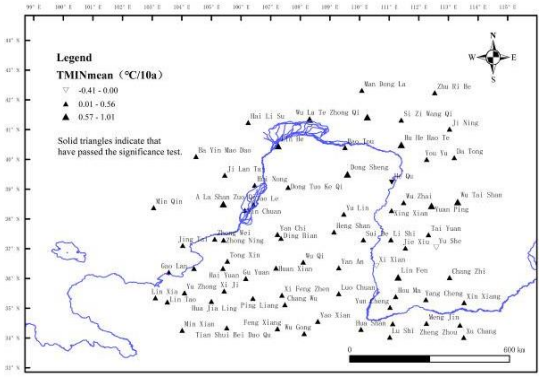
(c) Interannual variation of TMAXmean index



(d) Space variation of TMAXmean index



(e) Interannual variation of TMINmean index



(f) Space variation of TMINmean index

Figure 4. *Temporal and spatial variation of DTR, TMAXmean and TMINmean indexes*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1186911885

It can be seen from *Table 2* that the maximum values (including the extremely high value TNx of minimum temperature and extremely high value TXx of daily maximum temperature) and minimum values (including extremely low value TNn of daily minimum temperature and extremely low value TXn of daily maximum temperature) of extreme temperature show an upward trend. The minimum values have a higher rate of rise and TNx reaches the highest rate of rise in humid sub-region, that is, 0.6 °C/10a. However, the rate of rise of TXx is 0.1 °C/10a only, making it fail to pass the confidence level test.

Table 2. *Variation trend (1) of extreme temperature indexes from 1951 to 2014*

Index name	Arid sub-region	Humid sub-region
	Rate of change (°C/10a)	Rate of change (°C/10a)
DTR	-0.1**	-0.1**
TMAXmean	0.2**	0.2**
TMINmean	0.3**	0.3**
TNn	0.4**	0.6**
TNx	0.3**	0.1**
TXn	0.3*	0.4**
TXx	0.2*	0.1 n.s.

**It passed the 99% confidence level test. *It passed the 95% confidence level test. n.s. means that the variation trend is not significant

On time scale, it can be observed from 7 points 2 times SG smoothing line that TNn index tends to be upward on the whole except the decrease from 1951 to 1955 (see *Fig. 5a*); TNx index has risen significantly since 1951 and reached a peak in 1960, then went down around 1983 (more significant in humid sub-region) and showed a significant upward trend after 1983 (see *Fig. 5c*); TXn index decreased from 1951 to 1957, and then rose wavelike and showed a moderate upward trend after 2000 (see *Fig. 5e*). TXx index rose significantly around the period of 1951-1973, showed a moderate upward trend around the period of 1973-1989, then rose significantly from 1990 to 2000 and then regained a moderate upward trend after 2000 (see *Fig. 5g*).

From the perspective of spatial distribution, TNn and TNx indexes showed an upward trend in most regions, with a significant upward trend in northeastern Gansu, Ningxia, Linhe, Baotou and Hohhot, Inner Mongolia and Shanxi (see *Fig. 5b* and *d*). TXn index showed a significant upward trend in the entire the middle reach of Yellow River with a larger range (see *Fig. 5f*). TXx index rose significantly in some areas such as northeastern Gansu, Inner Mongolia Bayinmaodao, Hohhot, Yuncheng, Shanxi and other areas, with a small range (see *Fig. 5h*).

As mentioned above, average maximum temperature and minimum temperature in the middle reach of Yellow River show a significant upward trend, the rate of rise of minimum is higher than that of maximum and daily temperature range shows a significant downward trend. Seeing from Interannual variation, TNx, TNx, TXn and TXx indexes in this area tends to be upward on the whole, but they are in stages: showed a downward trend around the period of 1951-1955, rapidly rose from 1956 to 2000 and slowed down after 2000. In addition to TNN index, the rate of change of other three indexes in the arid sub-region is higher than that in the humid sub-region.

Figure 5. *Temporal and spatial variation of TNn, TNx, TXn and TXn indexes*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1186911885

It is worth noting that the variation trend of 7 indexes analyzed above slowed down around 2000, which may be related to the slowdown of global warming. In addition, the timing of the slowdown analyzed in this paper is basically consistent with relevant research conclusions (Wang et al., 2014b, c, 2005; Chen et al., 2014).

Variation of FD0, ID0, SU25, TN10p, TX10p, TR20, TN90p and TX90p indexes

From time scale, the index FD0 number of frost days in the past 60 years and the index ID0 number of frozen days show a highly significant downward trend, of which the downward rate in humid sub-region is higher than that in arid sub-region. The downward rate of FD0 and ID0 indexes in humid sub-region is -3.3d/10a and -1.9d/10a, respectively; while that in arid sub-region is -2.6d/10a and -1.5d/10a, respectively (see *Fig. 6a* and *c* and *Table 4*). It is also noted that the index number of frozen days in arid sub-region showed an upward trend while a downward trend in humid sub-region from 1951 to 1963. The index SU25 number of days in summer shows a significant upward trend, and the rate of change in arid sub-region and humid sub-region reaches up to 2.5d/10a and 1.3d/10a, respectively, which indicates that the number of days in arid sub-region whose daily maximum temperature is above 25 °C increases significantly, and the number of days in summer from a climate sense is on the rise (see *Fig. 6e*).

On spatial scale, the index FD0 number of frost days has been reduced by a large margin, the rate of change varied from -10.47 to 0 d/10a and 90% of stations have passed the significance test. The index FD0 showed a slightly upward trend in only two stations, Yushe and Xixian, which may be individual abnormal stations, which cannot negate the overall upward variation trend of FD0 index in the middle reach of Yellow River. The index ID0 number of frozen days has also been reduced by a large margin, that is, -9.62~0d/10a, and 78% of stations have passed the significance test (see *Fig. 6b* and *d*). The index SU25 number of days in summer at all meteorological stations showed an upward trend, of which 67% of stations showed a significant trend, mainly centralized in arid sub-region; while those stations without significant trend are centralized in humid sub-region. The analysis combined with *Table 3* indicates that the upward trend of the index SU25 in humid sub-region is smaller (see *Fig. 6f*).

Table 3. *Variation trend (2) of extreme temperature indexes from 1951 to 2014*

Index name	Arid sub-region	Humid sub-region
	Rate of change (d/10a)	Rate of change (d/10a)
FD0	-2.6**	-3.3**
ID0	-1.5*	-1.9**
SU25	2.5**	1.3*
TN10p	-2.2**	-2.0**
TX10p	-1.0**	-0.8**
TN90p	1.4**	1.4**
TR20	0.8**	1.2**
TX90p	0.9**	0.6*

**It passed the 99% confidence level test. *It passed the 95% confidence level test. n.s. means that the variation trend is not significant

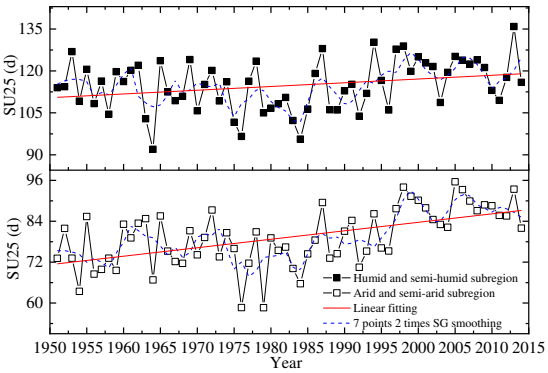
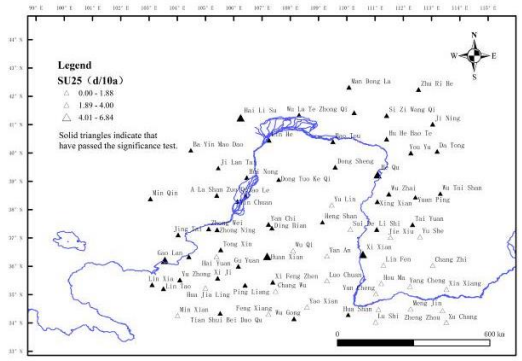
(d) Space variation of ID0 index



(e) Interannual variation of SU25 index



(f) Space variation of SU25 index

Figure 6. *Temporal and spatial variation of FD0, ID0 and SU25 indexes*

On time scale, number of days with cold night TN10P and number of days with cold day TX10P showed a significant wavelike downward trend, and the rate in arid sub-region is higher than that in humid sub-region (see *Fig. 7a* and *c*). Number of days with warm night TN90P, number of days with hot night TR20 and number of days with warm day TX90P showed a significant upward trend, and corresponding indexes in both arid and humid sub-regions have basically the same rate of change, but that is more significant in arid sub-region than humid sub-region, and the three indexes above have passed 99% confidence test. From 7 points 2 times SG smoothing curve, it can be seen that TN90P, TR20 and TX90P indexes tend to rise in stages: The 3 indexes showed a extremely gentle upward trend from 1951 to 1985, but later showed a sharp upward trend (see *Fig. 7e*, *g*, *i* and *Table 3*).

(i) Interannual variation of TX90P index (j) Space variation of TX90P index

Figure 7. *Temporal and spatial variation of TN10p, TX10p, TR20, TN90p and TX90p indexes*

On spatial scale, TN10P and TX10P indexes decreased significantly, reaching -6.43 - 0 d/10a and -1.44 - 0 d/10a, respectively, and the proportion of stations passing the significance test reached 96% and 89%, respectively. It shows that the number of days with cold night and number of days with cold day in the entire the middle reach of Yellow River has the consistent downward trend on spatial scale, but the variation is still more significant in arid sub-region than humid sub-region (see *Fig. 7b* and *d*). TN90P index showed a significant upward trend, 95% of the stations passed the significance test and only two stations in Hequ and Yushe showed a downward trend. TX90P index showed a significant upward trend in most areas of the middle reach of Yellow River, and the proportion of significant stations reached up to 74%, mainly centralized in arid sub-region; Zhengzhou, Xinxiang, Mengjin and Xuchang in humid sub-region showed a downward trend. The space variation is inconsistent in the index TR20 number of days with hot night, and a significant upward trend has been found in northeastern Gansu, north-central part of Ningia, most parts of northern Shaanxi, Linhe, Baotou and Hohhot, Inner Mongolia, most parts of Shanxi and Zhengzhou, Henan. However, a downward trend can also be found in southeastern Gansu, southern Ningxia, Huashan in central Shaanxi, Siziwangqi and Jining, Inner Mongolia (see *Fig. 7f*, *h* and *g*).

Variation of WSDI, CSDI and GSL indexes

Observed from time scale, the index of hot persistence WSDI increased significantly in arid sub-region with an increase rate of 0.7d/10a, but the wavelike upward variation trend was not significant in humid sub-region (not passed the significance test). The index of cold persistence CSDI showed a downward trend, and the downward rate was similar in both arid and humid sub-regions, that is, -2.0d/10a and -1.9d/10a, respectively, which indicates from different angles that the warming is significant in the middle reach of Yellow River. The index GSL crop growth period showed a significant upward trend on the whole, and the rate of rise in humid sub-region is much higher than that in arid sub-region, which is 2.6d/10a (see *Fig. 8a*, *c*, *e* and *Table 4*).

Observed from spatial scale, WSDI index showed an overall upward trend, and 53% of the stations passed the significance test. However, WSDI index showed a downward trend in Minxian County and Huajialing, Gansu, Guyuan and Haiyuan,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1186911885

Ningxia, Zhengzhou, Xinxiang and Xuchang, Henan, which may be caused by local microclimate and other factors, but the specific reasons need to be further studied (see *Fig. 8b*). CSDI index showed a consistent downward trend on the whole in space, but the downward rate varied from 09.74 to 0d/10a, and 71% of the stations passed the significance test (see *Fig. 8d*). GSL index showed a consistent upward trend on the whole in space, but the rate varied from 0.1 to 14.04d/10a, and 78% of the stations passed the significance test. In addition, Yushe is the only station where showed a downward trend, which was not significant (see *Fig. 8f*).

Table 4. *Variation trend (3) of extreme temperature indexes from 1951 to 2014*

Index name	Arid sub-region	Humid sub-region

Conclusion

This study analyzes the spatial-temporal scale of 18 extreme temperature indexes in the middle reach of Yellow River from 1951 to 2014, and draws the following conclusions:

(1) The middle reach of Yellow River is located in the transitional zone of arid and semi-arid and humid and semi-humid climate in China. The arid and semi-arid sub-region (located in the upper reaches of the Yellow River) and humid and semi-humid sub-region (located in the middle and lower reaches of the Yellow River) in the middle reach of Yellow River have basically similar variation trend in terms of extreme temperature events, but the intensity is different and spatial distribution is inconsistent.

(2) On time scale, it is found through the analysis of 18 extreme temperature indexes that the extreme temperature events have shown an upward trend in the past 60 years. On spatial scale, the distributional difference of each index is significant. The variation rate of multiple indexes in arid sub-region is greater than that in humid sub-region. The proportion of meteorological stations with significant variation of each index in arid sub-region is higher than that in humid sub-region. In addition, some indexes such as DTR, TNx, TNx, TXx, WSDI and TX90p has a different variation trend from the entire the middle reach of Yellow River in individual small areas, which may be caused by local microclimates in urban heat islands and hilly areas, but further analysis and verification is also required.

(3) The variation trend of indexes such as DTR, TMAXmean, TMINmean, TNn, TNx, TXx and TXx began to slow down around 2000, which may be related to the slowdown of global warming (hiatus phenomenon). The time of slowdown analyzed in this paper is basically consistent with the conclusions of relevant researches. Regarding the impact of the slowdown of global warming on extreme temperature events, the changes in extreme temperature events around the slowdown of global warming may also be further studies.

Compared with the research results of the approximate region (Zhou et al., 2011; Ma et al., 2003; Li et al., 2010; Ren et al., 2014), this study believes that the extreme temperature events in the middle reaches of the Yellow River are on the rise. This may be the product of global climate change in recent decades. Therefore, changes in extreme temperature events may have many adverse effects on the development of the

DOI: http://dx.doi.org/10.15666/aeer/1705_1186911885

region, and appropriate measures should be considered to protect future ecological and agricultural sustainability, as well as human security.

Abstract. In order to study the water resources of Weihe and to maintain its ecological environment, remote sensing technology is used to study the local water resources (monitoring water quality and quantity). Weihe is not only the political and cultural center of Shaanxi Province, but also an economically active zone. It has become an important part of hydrology and water resources work in Shaanxi Province to keep abreast of the relevant situation of Weihe waters at any time, and also a prerequisite for maintaining the ecological environment of Weihe. Remote sensing technology is a high-resolution tool for obtaining target information, information transmission and comprehensive utilization of information. Especially for the dynamic subject of hydrology and water resources, the depth of Weihe waters is obtained by remote sensing technology, and the pollutant concentration data are obtained according to the characteristics of pollutants. Therefore, remote sensing technology is used to monitor the water quantity and water quality of Weihe waters and to obtain effective information on Weihe waters, which provides a basis for other studies of Weihe waters, and also has a certain supporting role in the management of relevant institutions, and ultimately realizes the sustainable ecological environment of Weihe.
Keywords: *economically active zone, information transmission, the pollutant concentration data, water quantity, the sustainable ecological environment*

Introduction

With the rapid development of social economy, environmental problems are becoming more and more serious. One of the most closely related problems is water resources (Cheng et al., 2018). People's daily life cannot do without water resources. Therefore, water quality and water quantity have become the focus of national attention. By means of administration, law and advanced science and technology, the State coordinates the relationship between social and economic development and water resources, and effectively controls pollutants entering the water body in order to maintain the balanced development of the water body and meet various needs (Xu et al., 2018). As the largest tributary of the Yellow River flowing through Shaanxi Province, Weihe needs to bear the vast majority of living and production sewage in Shaanxi Province. With the rapid economic development in Shaanxi Province and the growing urban population, it seriously threatens the ecological environment of the Weihe waters, greatly affecting the agricultural production of the surrounding farmland and the daily life of the surrounding residents, as well as the lives of the downstream residents. It poses a certain threat. Shaanxi government has issued a series of planning and renovation schemes to control the water environment of Weihe (Triegel and Guo, 1994; Mohammady et al., 2018). It can dynamically monitor the water volume and pollutant concentration of Weihe in an all-round way, so that the water volume can be guaranteed

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1188711899

to a certain extent and the pollutants in the water can be kept within a certain range, so as to realize the self-purification of the water area.

Remote sensing technology is a comprehensive detection technology, which has been widely used in agriculture, address, meteorology, ocean, hydrology, environmental protection and military investigation. Especially in hydrology and water resources work, the use of remote sensing technology provides an important technology for the study of hydrology and water resources (Vikesland, 2018). With the continuous development of science and technology, the application of remote sensing technology in hydrology and water resources is becoming more and more extensive. It not only can accurately provide people with relevant data, and to a large extent, save human and time costs, improve work efficiency, and provide technical support for the related work of hydrology and water resources (Cavalagli et al., 2018). At the same time, because it is not affected by geographical location, and the bad weather and environment have less interference on remote sensing technology, remote sensing technology can achieve all-weather and all-round information collection, saving the time and cost of manual monitoring.

In this form, how to use remote sensing technology to monitor water quality in an all-round and dynamic way has become an important part of local government's environmental protection and water resources protection (Mace et al., 2018). As an important water source for crop growth in Guanzhong Plain, it is necessary to monitor the water quantity and water quality of Weihe to ensure that farmers' production and life are not affected, to ensure the sustainable development of Weihe, and to achieve ecological green and sustainable development.

Therefore, remote sensing technology is used to monitor the water quantity and quality of Weihe waters (Wang et al., 2018). It can acquire and process the water quantity and quality data at a relatively fast speed and in a relatively short period, which is conducive to the acquisition of water resources-related data, thus ensuring the water quantity and improving the water quality, providing a basis for other aspects of Weihe waters research (Liu et al., 2018). It also has certain reference significance in monitoring and improving the situation of water quantity and quality of related rivers, as well as the management of relevant departments and water conservancy construction in Shaanxi Province.

Literature review

With the rapid development of the world economy, environmental pollution has become a key issue of global ecological development. Water resources are the source of human survival, and production and life are inseparable from water. The total amount of water resources per capita in China accounts for only one quarter of the world's per capita water volume, and is considered to be one of the countries lacking water resources. How to control water volume and control rivers has also become the key contents that scholars discuss. Jiang pointed out in his paper that with the increasing water demand, serious shortages of surface water and groundwater appeared in Northwest China and North China (Maggiori et al., 2017). Cai et al. found that over-exploitation of water resources led to land subsidence and ecosystem degradation in many places through the study of water resources in recent years (Nogueira et al., 2017). Jin Shuquan pointed out in the study that the water quality of the Yellow River, Huaihe and Liaohe has been affected to varying degrees in recent years. Among the 47

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1188711899

key cities studied, the water quality standard rate of less than 80% is up to 30% (Kussul et al., 2017).

Shi Xiaoliang, Zhou Zhenghui and Wang Xinshuang retrieved soil water content by using multi-dimensional geospatial data and long time series remote sensing images. Combined with relevant data, a groundwater monitoring model was constructed. The increasing trend of groundwater burial data in more than ten years was verified by an example, and its distribution characteristics were obtained (Zhu et al., 2017). Wang Jie and Wang Liang elaborated the basic principles and advantages of remote sensing technology, and monitored water resources. In the case of combining professional manual survey with remote sensing technology monitoring, they selected better data to ensure the effectiveness of technology and the correctness of results (Jucker et al., 2017).

Ma Qie and Hu Kun, through the comprehensive discussion on the application of remote sensing technology in hydrology and water resources, found a tool for the efficient utilization of water resources for the study of hydrology and water resources in China, and laid a foundation for their development and research (Lu et al., 2017). Fu Guobin and Liu Changming elaborated in detail the monitoring model of water area, precipitation, evaporation, soil moisture and the application and progress of remote sensing technology in the actual dynamic monitoring process from two aspects, and put forward the method of combining remote sensing technology with geographic information system (Gu et al., 2017).

Methods

Remote sensing technology

Remote sensing technology is a comprehensive earth observation science and technology. It uses sensors to receive electromagnetic wave characteristics of target objects or non-target objects, and through information transmission, storage, correction and identification of target objects, ultimately realizes the timing, positioning, quantitative and qualitative research of target objects. Remote sensing was first applied in the field of aviation, and then with the development of aerial photography technology, it gradually developed into a more practical space exploration technology (Mohanty et al., 2017).

The realization of remote sensing technology requires the participation and cooperation of many disciplines as well as a set of precise technical equipment. Therefore, the implementation of remote sensing is a relatively complex system engineering, which mainly consists of four parts (*Fig. 1*).

The information source refers to the object that needs to be detected. Because any target has the characteristics of absorbing, reflecting, transmitting and radiating electromagnetic waves, when the target encounters electromagnetic waves, they will form specific electromagnetic waves of the target. Information acquisition refers to the process of receiving and recording specific electromagnetic waves of objects by using a series of technical equipment, mainly relying on remote sensing platform and sensor equipment. Information processing mainly uses optical instruments and computer equipment to correct, analyze and interpret the information charts, words and data acquired by remote sensing, so that users can get the error of original information, and get the effective information needed by extracting the impact characteristics of the target object through sorting out and summarizing. Finally, it comes to information

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1188711899

application. People use remote sensing technology in different fields and purposes, and they get different information. The information data obtained are mainly for the convenience of users in the inquiry, statistics and analysis of relevant content in the research field.

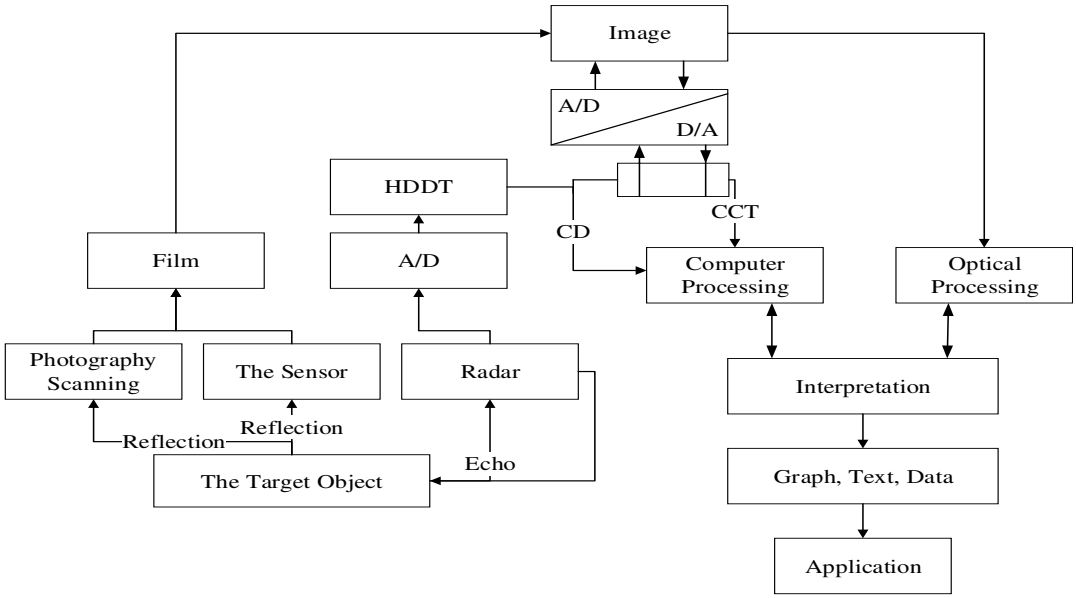

Figure 1. *Composition map of remote sensing system*

The reason why remote sensing technology can be widely used in different fields is that it is different from other technical means. There are three main aspects: firstly, the detection range is wide, the data acquisition speed is fast, and the cycle is short. It can observe the object in a relatively short period of time in a wide range, so as to obtain valuable data, which broadens people's horizons, enables people to study things from the whole, and provides valuable resources for later exploration of the rule of things (Audebert et al., 2018). Secondly, remote sensing technology can dynamically monitor the change of the object and obtain the periodic change of the object in order to predict the weather, disasters and environmental conditions. Thirdly, the data acquired by remote sensing technology is more comprehensive. It can centrally reflect the shape of objective things in each time period, truly reflect the characteristics of various things, and reflect the relevance of many things, as well as the situation for a period of time, which is conducive to the analysis of the causes of certain factors in each time period.

In hydrology and water resources work, remote sensing technology can be used to detect and remote sensing precipitation, evaporation, runoff, groundwater and sediment. When using remote sensing technology to measure precipitation, precipitation is usually indirectly judged by measuring cloud top brightness and cloud top temperature. When measuring evaporation, water evaporation and plant transpiration can be calculated by combining hydrological model. The remote sensing is used to monitor water quality mainly through the spectral analysis of water quality to classify the water quality indicators, and empirical model is used to combine the spectral characteristics of water quality and specific parameters of water body, to obtain relevant data and to provide effective data for the next step. Empirical model method requires effective combination of specific parameters of water quality and spectral characteristics of water body.

DOI: http://dx.doi.org/10.15666/aeer/1705_1188711899

$$Y = A + BX \quad \text{or} \quad Y = AB^X \qquad \text{(Eq.1)}$$

Represents the measured value of remote sensing, Y represents the water quality parameters of objects to be estimated (ElMekawy et al., 2018), and A and B are the undetermined coefficients (*Eq. 1*).

Overview of Weihe

Weihe is the largest tributary of the Yellow River basin, with the largest amount of water. It originated from Niaoshu mountain, Weiyuan County, Dingxi City, Gansu Province. It flows into Shaanxi after Tianshui, Gansu Province, and finally into Tongguan County. The main stream of the Weihe runs 502.4 km in Shaanxi Province, with an area of 671,000 km^2 and an average runoff of 5.38 billion m^3. With the acceleration of industrialization and the continuous development of economy and society, environmental problems are becoming more and more serious, especially water pollution. Weihe is regarded as the life river of Shaanxi in Guanzhong area of Shaanxi Province. Therefore, the water quality of Weihe is closely related to the social and economic development of the area. Moreover, on the one hand, the extreme shortage of water resources in Weihe is due to the decrease of water entering Shaanxi Province year by year (Cassidy et al., 2018); on the other hand, the rapid development of economy, the continuous expansion of cities and the rapid expansion of population make the water consumption for production and living increase sharply. Most of the areas along Weihe are the production areas of crops. Irrigation water demand is large and groundwater has to be collected. This also leads to the decrease of the flow of the river recharged by groundwater, and the decrease of groundwater level also needs to be supplemented by the water in the river. This repeated impact makes the lives of people around the groundwater as a source of living water threatened. The distribution of residential areas and factories along Weihe is relatively concentrated. The demand of sewage discharged from production and living and agricultural production for Weihe water is increasing year by year. The view of Weihe Basin (*Fig. 2)* and the main cities flowed by the Weihe Basin (*Fig. 3*) are shown.

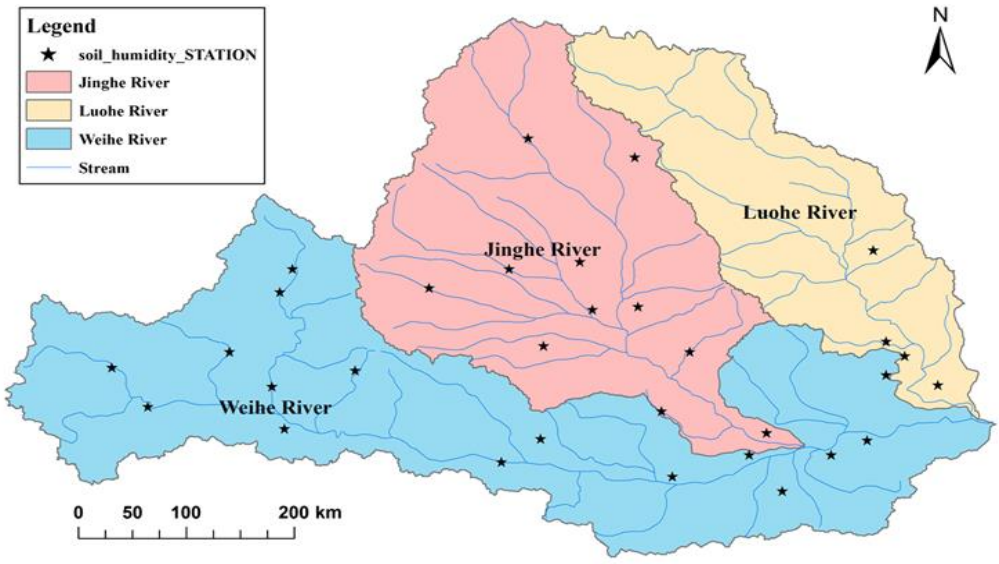

Figure 2. *View of Weihe Basin*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1188711899

Figure 3. *Major cities in the Weihe Basin*

The relevant government departments have also formulated a series of treatment programs, and relevant enterprises have formulated sewage treatment measures, but the concentration of pollutants in river water is still high, so that river water cannot rely on its own purification capacity to maintain ecological balance. Therefore, in view of the problem of water pollution in Weihe, it is very important to quickly establish an effective method to detect the water quality of Weihe.

When monitoring water quantity, a zero-dimensional water quality model is adopted, and a river section is assumed to be a fully mixed reactor. When the sewage with Q_0 and C_0 inflow enters the reactor, due to stirring, the pollutants can be completely uniformly distributed in the tank (Chen et al., 2018). Thus, the equilibrium equation between water quality (*Eq. 2*) and flow rate (*Eq. 3*) is established when the water quality and flow rate are not stable.

$$\frac{dV_c}{dt} = \left(Q_0 c - Q_1 c\right) + \sum S^{'}\left(c,t\right) \quad \text{(Eq.2)}$$

$$\frac{dV}{dt} = Q_0 - Q_1 + q \quad \text{(Eq.3)}$$

When V is constant (*Eq. 4*):

$$\frac{dc}{dv} = \frac{Q_0}{V} c_0 - \frac{Q_1}{V} c + \sum S\left(c,t\right) \quad \text{(Eq.4)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1188711899

C is the concentration of pollutants in the tank (unit: ML-3); Q_1 is the flow rate at the time of outflow (unit: L3T-1); V is the volume of water in the tank (unit: L3); $\sum S(c,t)$ is the flow rate of source and leakage in the tank (unit: ML-3T-1); and q is the flow rate of element leakage (unit: L3T-1). As a result, there is:

$$c = \frac{1}{\left(1+\frac{Vk}{Q_1}\right)}\left(\frac{Q_0}{Q_1}\right)c_0 + \frac{1}{\left(1+\frac{Vk}{Q_1}\right)}\left(\frac{q}{Q_1}\right)c^* \quad \text{(Eq.5)}$$

c* denotes the inflow of source and drain terms, and k is the reaction rate coefficient of pollutant attenuation (*Eq. 5*).

The precipitation and evaporation of water flow are related to the balance of water flow. Therefore, it is required to control the water flow in a certain river section and keep the balance in a period of time.

$$\frac{\partial A}{\partial t} + \frac{\partial Q}{\partial x} = q \quad \text{(Eq.6)}$$

A represents the river bed area, Q is the discharge, q is the input discharge, t represents the time, and X represents the length of the river section.

Water quality monitoring is mainly to detect the types of pollutants, concentrations and changes of various pollutants in different monitoring points, so as to judge the water quality. The testing items mainly include two kinds of indicators reflecting water quality and toxic and harmful substances. The items that must be determined in water quality indexes are water temperature, suspended matter, total hardness, pH value, conductivity, dissolved oxygen, chemical oxygen consumption, ammonia nitrogen, nitrite nitrogen, nitrate nitrogen, volatile phenol, cyanide, arsenic, mercury, hexavalent chromium, lead, cadmium, petroleum, etc. (Liu et al., 2018). They can be used for sulphide, fluoride, chloride, organochlorine pesticides, organophosphorus pesticides, total chromium, copper, zinc, intestinal flora, uranium, radium and so on. The concentration of COD and NH-N_3 is studied only.

Sampling points should be determined according to water depth (*Table 1*), sampling time and sampling frequency (*Table 2*).

Results and discussion

The water quality and quantity of Xi'an, Baoji, Xianyang and Weinan along Weihe are studied. The data of these four regions are collected. The number of sewage outlets in each city (*Fig. 4*) and the data of pollutant concentration in 2007 (*Table 3*) are shown.

Table 1. *Determining sampling points according to water depth*

Water depth	Number	Position
Smaller than 5 m	1	0.3-0.5 m under the water
5-10 m	2	0.3-0.5 m under the water, and 0.5 m above the bottom
10-50 m	3	Half water depth, 0.3-0.5 m under the water, about 0.5 m above the river bottom
Larger than 50 m	Increase sampling points as appropriate

DOI: http://dx.doi.org/10.15666/aeer/1705_1188711899

Table 2. *Sampling time and frequency*

Objects	Sampling time and frequency
Main stream of larger river system and small and medium rivers	Sampling is not less than 6 times in a year, in rich, dry and peaceful seasons, usually twice in each period
Running through urban industrial zones, polluted rivers, browsing waters, drinking water sources, etc.	Samples are taken at least 12 times a year and at least once a month
Understand changes in water quality in a day or a few days	Sample in 24 h or in 3 days at different equal parts of time. In case of special circumstances, the number of sampling times will be increased
Background section	Sampling once a year

Table 3. *Concentration of pollutants in the sewage outlet of Weihe, Guanzhong City*

Town	Chemical oxygen demand (COD) (unit: 10,000 tons/year)	NH-N3 (unit: 10,000 tons/year)	Subtotal (unit: 10,000 tons/year)
Xi'an	9.3515	0.8319	4.4676
Baoji	1.993	0.2048	0.9396
Xianyang	2.896	0.217	1.0299
Yangling	0.018	0.009	0.0798
Weinan	2.5203	0.1735	1.0282

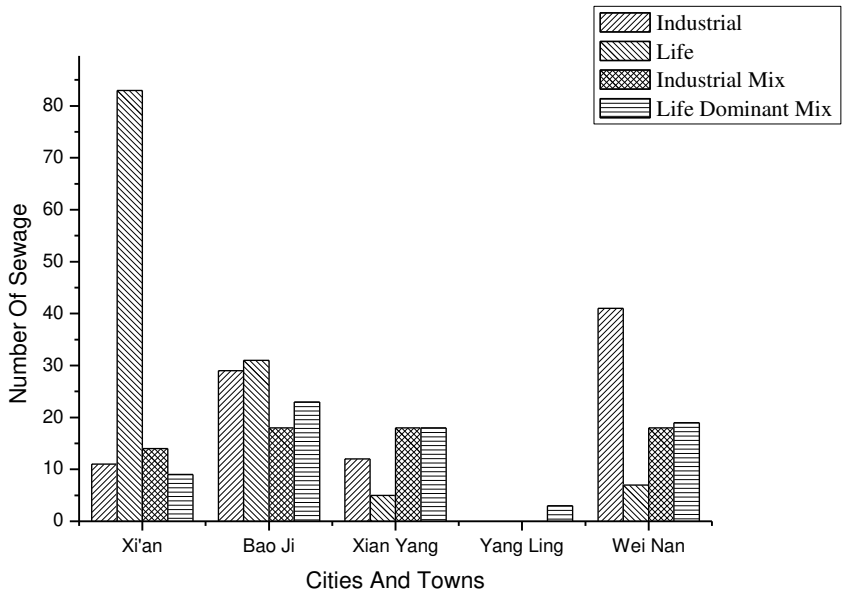

Figure 4. *Number of urban sewage outlets in the middle section of Weihe*

According to the data obtained by remote sensing technology, the discharge of wastewater is 79344 million tons per year, of which COD is 153.351 thousand tons per year and NH-N_3 is 135.68 thousand tons per year. The discharge of urban wastewater is 75.422 thousand tons per year, of which COD is 167.766 thousand tons per year and NH-N_3 is 143.62 thousand tons per year. The monitoring data (*Fig. 5*) are shown below.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1188711899

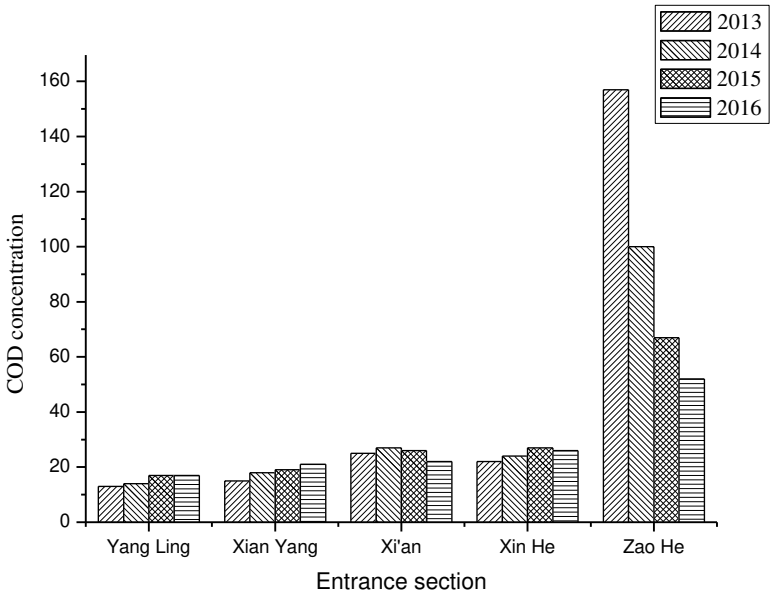

Figure 5. *Monitoring data of COD concentration (mg/L) in different sections from 2013 to 2016*

The annual total runoff variation map measured at Weinan Station is shown in (*Fig. 6*) and the relationship between precipitation and surface water resources in Weihe Basin (*Fig. 7*) are shown below.

The water balance relationship between snowfall and evaporation is calculated by water balance model, and water balance map of Weihe Basin (*Fig. 8*) is obtained.

The natural reasons for the change of water quantity in the Weihe are mainly caused by precipitation and man-made factors. There will be more precipitation in Yangling, Baoji and Weinan, less water in Xi'an and Xianyang, and higher vegetation coverage in Yangling. Therefore, the precipitation and annual runoff are less. This is because the increase of vegetation coverage increases evapotranspiration in the region. Additionally, the amount of water is affected to a certain extent, and the amount of water is reduced.

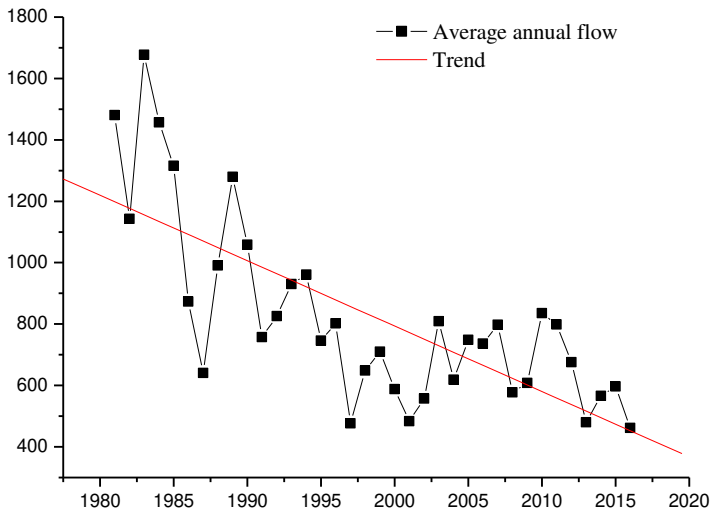

Figure 6. *Annual runoff variation map of Weinan Station from 1980 to 2017*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1188711899

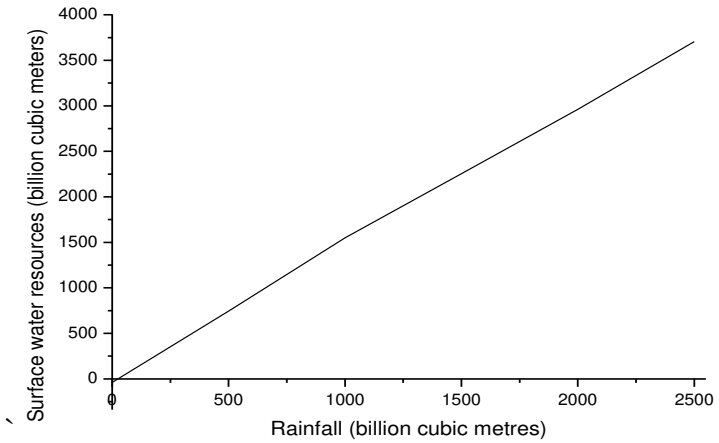

Figure 7. *The relation map between rainfall and surface water resources in Weihe Basin*

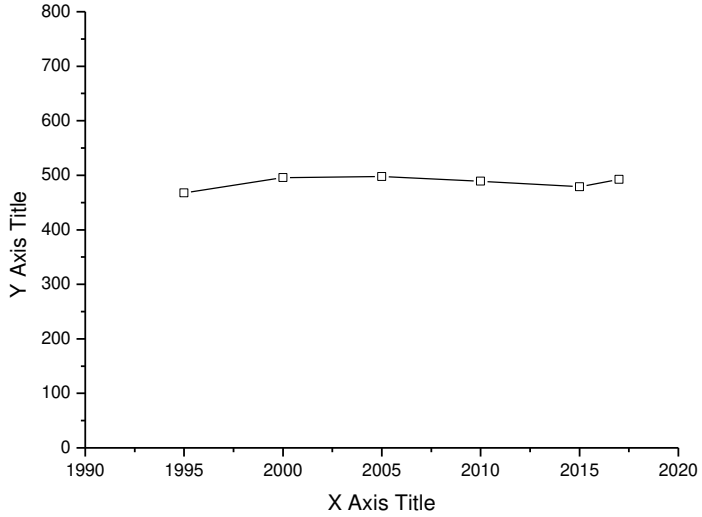

Figure 8. *Water balance map of Weihe Basin*

Moreover, because of the uneven distribution of precipitation in Weihe Basin, its tributaries are unevenly distributed and may even dry up. According to statistics, the actual runoff in the 1970s, 1980s and 1990s was 2.378 billion m^3, 2.333 billion m^3 and 2.231 billion m^3, respectively. Compared with the actual runoff, it increased by 17.0 mm, 16. 3 mm and 15.3 mm, respectively.

Using remote sensing technology to monitor precipitation can greatly improve the accuracy of monitoring, that is, to predict precipitation through cloud top brightness and cloud top temperature, which provides a reliable basis for hydrological departments to predict. The evaporation is monitored by physical methods, and the layered model is used to distinguish soil conditions, while the evaporation is measured. At present, there are also computer models for evapotranspiration, which realize the calculation of evapotranspiration and evapotranspiration on non-uniform ground. For the river runoff, it is monitored by remote sensing technology, which combines this part of data with hydrometeorological station data to survey the river runoff, and calculates the relevant data through hydrological model, which is transformed into effective information, and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1188711899

then estimates the precipitation, evaporation and groundwater, finally obtains the relevant results of the river runoff. Because of this, the water volume of Weihe has been kept within a certain range in recent years, the surrounding agriculture also has a sufficient amount of irrigation water, and people's living water has been guaranteed, maintaining the sustainable development of Weihe Basin.

It can be seen that with the expansion of cities, people's living and industrial water consumption increases, while sewage discharge increases accordingly, but it is found that the discharge of COD and NH-N_3 decreases. On the one hand, it is because natural water has a certain self-purification capacity. When pollutants enter the water body, their pollutant concentration does not exceed the maximum bearing capacity of the water body. Through a series of biological and physical factors to purify the water, the concentration of pollutants in the water is reduced. On the other hand, related units of hydrology and water resources pay more attention to the water pollution and effectively treat the sewage. Using remote sensing technology to obtain relevant data, the sewage treatment rate is constantly improving.

At present, the application of remote sensing technology in hydrology and water resources is mostly qualitative research. Taking Weihe as an example, this paper studies its water quantity and water quality, lays a foundation for the protection of ecological environment in Weihe Basin, and provides ideas and methods for the study of soil water content along Weihe. However, due to the current use of remote sensing technology to obtain information, the process of interpreting information is more complex and consumes. Because of its high cost and large demand for professionals, remote sensing technology has not yet brought its energy efficiency into full play, which also has a certain guiding significance for enterprises and universities to cultivate talents.

Conclusion

Traditional hydrology and water resources research work is inefficient and has poor quality. The discovery of remote sensing technology provides technical support for hydrology and water resources related work, and largely solves the problem of low efficiency and poor quality of research work. As the "mother river" and "life river" in Shaanxi, Weihe affects the production of crops and people's lives. Therefore, the water quantity and quality of Weihe are closely related to the lives of the people around it. It is also closely related to the environment and ecology of Weihe and its coastal areas. It requires the relevant government departments to devote more energy to the governance of Weihe. Therefore, when using remote sensing technology to study the hydrology and water resources of Weihe Basin, the monitoring and remote sensing of precipitation, evaporation, runoff, COD and ammonia nitrogen (NH-N_3) in water quality are mainly applied, so as to obtain the relevant data of Weihe waters, which is conducive to improving the work efficiency of managers and maintaining the ecological environment of Weihe waters. It provides a technical branch for controlling the water quality and quantity of Weihe waters later. It also provides ideas for the water quality and quantity of other basins in Shaanxi Province, and provides a theoretical basis for relevant units to control water source problems.

Limited by the conditions, this paper inevitably produces errors in data monitoring. It is hoped that the impact of other factors on the accuracy of monitoring data can be reduced and more accurate data can be obtained in the future research process.

Abstract. Stormwater management is the core of sponge city construction whose essence is to solve the urban water problem by means of seepage, storage, purification, utilization and drainage. From the environmental geology point of view, this paper mainly consider the geological properties of sponge capacity in the construction of sponge city. Based on a large number of in-situ water infiltration tests and boreholes, two indexes that sponge infiltration and sponge storage are put forward to study and analyze the maximum depth of rainfall infiltration and the infiltration velocity of surface soil under the original sponge geological conditions. These two indexes can directly and effectively represent and summarize the environmental geological suitability in the construction of sponge cities. Moreover, these two indexes are easy to understand, have a strong universality, and easy to promote. Finally, taking Xinxiang city in central China as an example, the environmental geological suitability of Xinxiang sponge city construction is evaluated.
Keywords: *rainfall-runoff; sponge infiltration capacity; sponge storage capacity; stability evaluation*

Introduction

Based on China's national conditions, China is experiencing and will continue to experience a period of rapid urbanization. Urbanization promotes the modernization of the country and the rapid development of the economy. At the same time, the immaturity of the development of urbanization also bring a series of "urban diseases" (Burns, 2012; Carter, 2007; Che, 2015), such as urban water logging, water shortage, water pollution and water ecological degradation. Due to the fact that urban water problem is very complex and still in its infancy, many standards such as construction principle, development mode and index system of sponge city have not been perfected (Wang et al., 2017; Zhang et al., 2016; Yu et al., 2015; Wu et al., 2016; Qiu, 2015; Hu et al., 2015; Hu et al., 2015a, b; Wang et al., 2015; Song et al., 2007), and are still in the process of exploration.

In the 1970s, the United States was the earliest to adopt rainwater flood detention and control measures for urban water problems. However, this measure not only failed to solve the problem of rainwater flood, but also destroyed the urban water ecological balance and polluted the urban water environment due to human engineering activities. By the early 1990s, Maryland (US EPA, 2000a) was the first to propose the concept of "Low Impact Development" (LID). The main connotation is: in the process of land development, the rainfall runoff is controlled by the site to reduce the runoff and rainwater pollution load (Benedict, 2000; US EPA, 2012b). The concept was quickly accepted and developed by Australia, New Zealand and some European countries

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1190111910

(2015) by whom natural and harmonious new urban planning concepts such as "Water-Sensitive Urban Planning" (Hoyer et al., 2011) and "Sustainable Drainage System" (D'Arcy et al., 2000; CIRIA, 2015) were put forward on the basis of LID. Relevant German institutions classified (Ministerium fuer Umwelt, 2001) the runoff water quality of different catchments based on different geographical factors, environmental conditions, geological conditions, etc. (Council, 2008; Dong, 2011; Wanielista, 1993), used GIS technology to plan and design the rainwater treatment plan, combined the water quality conditions and disposal purposes of each city, and decided the final disposal facility (Geiger, 2001; Gantner, 2003). North American scholars (Ji, 2014) proposed the study of rainwater micro-management based on the existing natural system, retaining important hydrological characteristics and functions, adopting the favorable conditions and constraints of rainwater management at the basin scale so as to mitigate the damage to the hydrological ecological environment and restore the regional hydroecological environment as much as possible. The "Optimal Management Practices for Rainwater" research conducted by Sweden and Denmark (Martin, 2011; Revit, 2003) combines hydrological characteristics, landscape design, environmental control, and management systems to comprehensively manage rainwater and flood control. This model is widely accepted because of its low processing cost and good processing effect. It can also be practiced in small and medium-sized cities in China as one of the directions to explore the current stage of urban rainwater management in China.

Different from the traditional "fast-draining" rainwater model, many experts and scholars in China have made new explanations on the nature of sponge cities and put forward new construction concepts (Che et al., 2002). Among the local laws and regulations, Beijing, Nanning and other cities require that new construction, reconstruction and expansion projects in various regions have guiding design patterns and engineering requirements for rainwater utilization in the construction of sponge cities, and formulate many measures for urban rainwater resource utilization (Wang et al., 2017).

The essence of the sponge city construction is to solve the problem of urban water. It is not only the rationality and validity of the measures of seepage, station, storage, purification and drainage should be considered, but also the physical properties of the sponge bearing body (rock and soil), as well as the danger of storing rainwater (including environmental geological problems) should be taken into account. The core content is closely related to environmental geology and hydrology. At present, domestic and foreign scholars still have different opinions on the construction model, essential connotation and viewpoins of the sponge city. They mostly study the "engineering measures" of the construction methods and technical modes (Du, 1996; Taylor, 2005; Wang, 1999), and overlooked the geological properties of the sponge capacity in the construction of sponge cities. They do not consider the overall evaluation of the environmental geological suitability of the construction area or planning area of sponge cities. Moreover, because of the lack of funds, most studies only stay in the theoretical research stage (Keller, 1999; Lloyd, 2002; Eslami, 1995), and have not been put into practice.

Therefore, in order to evaluate the suitability of sponge city construction, we should mainly consider the underground environmental bearing capacity and evaluate the original sponge environmental geological suitability from the geological point of view. This evaluation can effectively save the construction cost of sponge city and minimize

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1190111910

the workload of sponge city, and have a definite object in view to achieve the goal of spongy city construction.

Materials and methods

The environmental geological suitability evaluation of sponge city construction is the premise of sponge city construction. The sponge capacity of geological body in sponge city construction directly affects the difficulty and complexity of city planning, scheme design and site construction. From the point of view of hydrogeology and environment geology, this paper mainly consider the bearing capacity of underground environment (Knödel, 2007; Argent, 2008; Rooijen, 2010). Based on a large number of in-situ water infiltration tests and boreholes, two indexes that sponge infiltration and sponge storage are put forward to study and analyze the maximum depth of rainfall infiltration and the infiltration velocity of surface soil under the original sponge geological conditions. These two indexes can directly and effectively represent and summarize the environmental geological suitability in the construction of sponge cities. They are easy to get and understand, have strong universality and are easy to popularize. Completing the evaluation of environmental geology suitability in sponge city construction can reduce the difficulty and workload of urban planning investigation, design and construction, and provide ideas and reference for urban agglomeration sponge city construction planning and design.

Sponge infiltration capacity

Sponge infiltration refers to the capacity of urban "sponge body" to infiltrate rainfall (rainfall infiltration coefficient): Assuming under an ideal condition (an atmospheric pressure, a hydraulic gradient of one, only vertical infiltration is considered) and during the whole rainfall infiltration process (*Figs. 1* and *2*), the water seepage speed during the complete infiltration process of different soil layers is V_i:

$$V_i = \frac{Q}{t_i} \quad \text{(Eq.1)}$$

V_i: Water seepage velocity in different soil layers; t_i: Complete infiltration time in different soil layers.

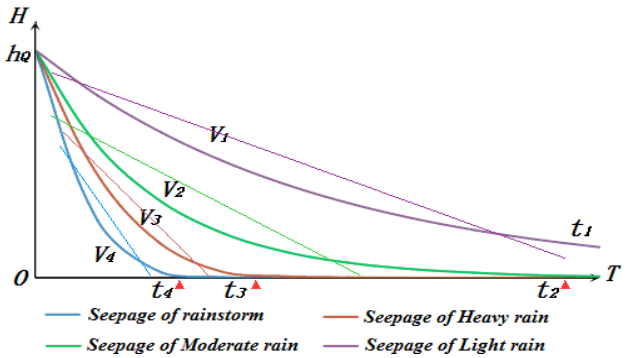

Figure 1. *Rainfall infiltration curves in different soil formations*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1190111910

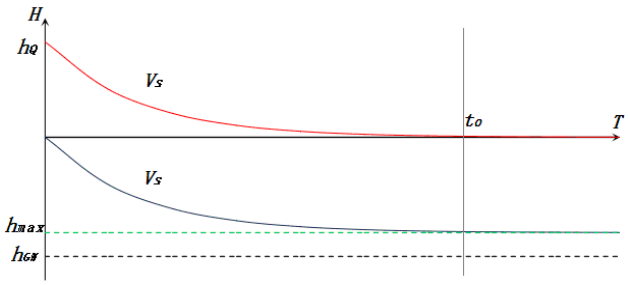

Figure 2. *Schematic diagram of rainfall infiltration curve. (A: The area of the region; Q: Maximum rainfall in 30 years; V_s: Rainwater infiltration rate; h_{max}: Maximum infiltration depth of rainfall; h_{GW}: Depth of groundwater; t_0: The time required for total infiltration of rainfall; n: Weighted effective porosity in penetration depth; h_Q: The height of the rainfall within the area)*

Sponge storage capacity

In the construction of the sponge city, the capacity of the sponge storage refers to the ability of the city "sponge body" to store rainwater (the size of aquifer storage space) and to solve urban water problems effectively (with the water supply capacity of phreatic layer).

Assuming an ideal state (an atmospheric pressure, a hydraulic gradient of 1, considering only vertical infiltration), the time required for complete rainfall infiltration is t_0, and the maximum depth of infiltration is $h_{\max}$:

$$h_{\max} = \frac{Q}{A \square n} \qquad \text{(Eq.2)}$$

Due to equal water permeability, the seepage on the ground is equal to the seepage in the aeration zone.

The sponge capacity P should be defined as: $P = \frac{h_{GW}}{h_{\max}}$

When $P > 1$, $h_{GW} > h_Q$. This indicates that the geological environment (the thickness of the aerated zone) can fully withstand the maximum rainfall Q in 30 years. It means that the city "sponge body" has sufficient rainfall storage capacity and water release capacity;

When $P=1$, $h_{GW} = h_Q$. This indicates that the geological environment just can withstand rainfall Q, and this is a critical state. To construct the sponge city, it is necessary to maintain the natural geological environment or take slight measures;

When $P < 1$, $h_{GW} < h_Q$. This indicates that geological environment cannot withstand rainfall Q. It means that the city "sponge body" has enough rainfall storage capacity and water release capacity.

Case study

Study area

Xinxiang City is located in the north of Henan Province, China. It belongs to the North China Plate. It is located in the Yellow River and Haihe River Basins. The terrain

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1190111910

is high in the north and low in the south. The northern part is mainly the Taihang Mountain and hilly land. The south is the alluvial fan plain of the Yellow River. The plains occupy 78% of the total land area of the city. The annual average precipitation is 573.4 mm, of which precipitation is the most from June to September, accounting for 72% of the annual precipitation, and the annual evaporation is 1748.4 mm. Xinxiang City has three national-level development zones and two provincial-level development zones, which are in a period of rapid urbanization and development.

A total of 123 sets of drilling points and 163 Investigation points information were obtained from the ground survey. The groundwater level in dry season and indoor seepage test data in the study area were collected, and 50 sets of field in-situ water seepage tests were carried out. The location distribution is presented in *Figure 3*.

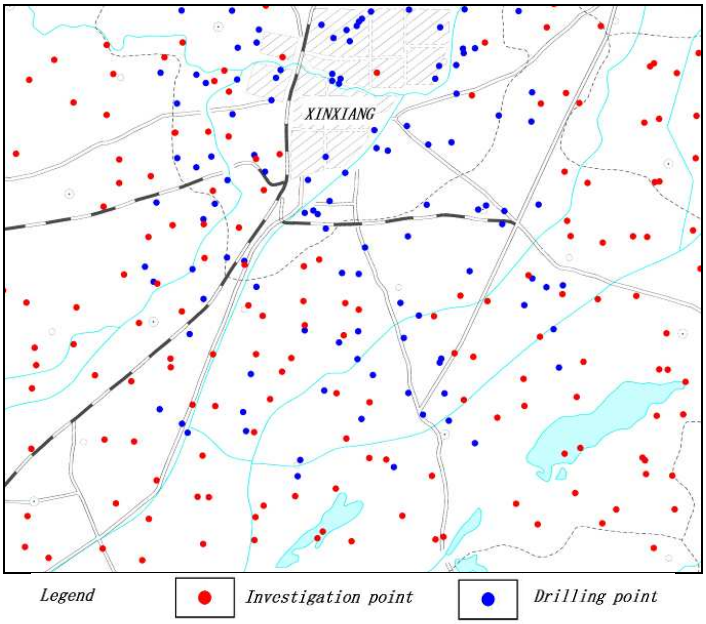

Figure 3. *Distribution of research points*

Results and discussion

Though a large number of field water seepage tests, a table (*Table 1*) of infiltration test results and their correspondent rainfall levels was obtained (*Fig. 4*).

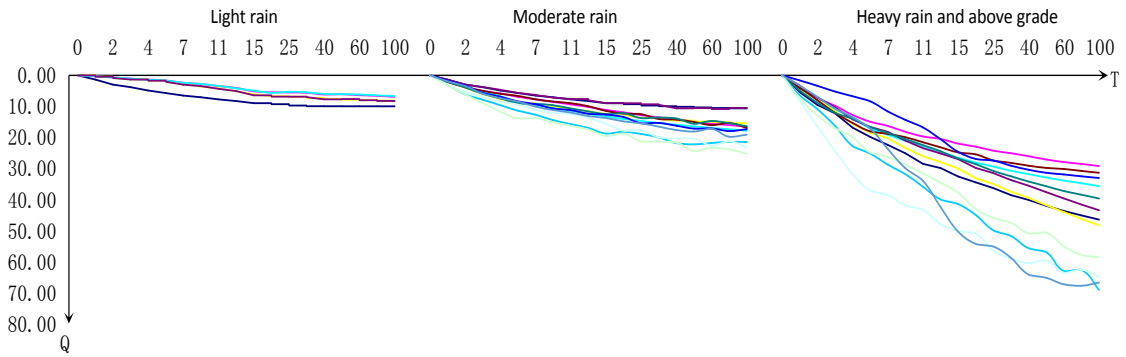

Figure 4. *Infiltration curves corresponding to different rainfall levels*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1190111910

The critical value of the corresponding seepage velocity is determined by the rainfall level in *Table 1*.

Table 1. *Infiltration test results and their correspondent rainfall levels (rainfall does not produce runoff)*

Name of soil	Water seepage speed mm/d	Permeability coefficient cm/s^{-1}	Absorptive rainfall intensity	Rainfall level description (mm/d)	
Clay	4.12	< $1.2*10^{-6}$	Light rain	Light rain	0.1–9.9
Powder sticky	5.18	1.2×10^{-6}-$6.0*10^{-5}$	Light rain	Light rain	0.1–9.9
Floury soil	6.61	$6.0*10^{-5}$-$6.0*10^{-4}$	Light rain	Light rain	0.1–9.9
Loess	6.73	$3.0*10^{-4}$-$6.0*10^{-4}$	Light rain	Light rain	0.1–9.9
Silt	18.36	$6.0*10^{-4}$-$1.2*10^{-3}$	Moderate rain	Moderate rain	10–24.9
Fine sand	22.75–31.76	$1.2*10^{-3}$-$6.0*10^{-3}$	Heavy rain	Heavy rain	25–49.9
Medium sand	57.86–81.32	$6.0*10^{-3}$-$2.4*10^{-2}$	Rainstorm	Rainstorm	50–99.9
Coarse sand	87.46–125.23	$2.4*10^{-2}$-$6.0*10^{-2}$	Downpour	Downpour	100–249.9
Gravel	289.26–342.32	$6.0*10^{-2}$-$1.8*10^{-1}$	Heavy downpour	Heavy downpour	> 250

When $V < 6.0*10^{-4}$, the surface soil layer can only accept the precipitation of light rain;

When $6.0*10^{-4} < V < 1.2*10^{-3}$, the surface soil layer can only accept moderate rainfall;

When $1.2*10^{-3} < V < 6.0*10^{-3}$, the surface soil layer can accept heavy rain;

When $6.0*10^{-3} < V$, the surface water can accept the precipitation above the level of the heavy rain;

Based on the measured data and experimental results, the sponge seepage capacity and the P results of sponge storage capacity of Xinxiang sponge city is divided:

Figure 5 shows that the evaluation of sponge seepage capacity is poor in the study area, only 3% of the area infiltration rate reaches the level of heavy rain in the region, rainwater can directly infiltrate the surface aerated zone to recharge the shallow aquifer in rainy season. Rainwater does not generate rainfall-runoff, causing surface water. This area can be directly used for the water seepage construction of sponge cities. About 26.5% of the area with medium-rainfall infiltration capacity is distributed in the southwest and central part of the region. Rainfall can not fully infiltrate the surface aerated zone to recharge the shallow aquifer in rainy season. Surface runoff and surface water will be formed. In the initial stage of the construction of sponge city, it is necessary to carry out the water seepage construction of sponge city after the improvement of the sponge seepage capacity by paving with water permeability or adding engineering facilities such as grass planting ditch and vegetation buffer zone. 70% of the area only reaches the level of light rain, poor infiltration capacity, when rainwater conditions will form a large number of rainfall-runoff and lead to surface water. The intervention of artificial conditions and high cost of engineering construction, it is not appropriate to directly or selectively carry out the water seepage construction of sponge cities.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1190111910

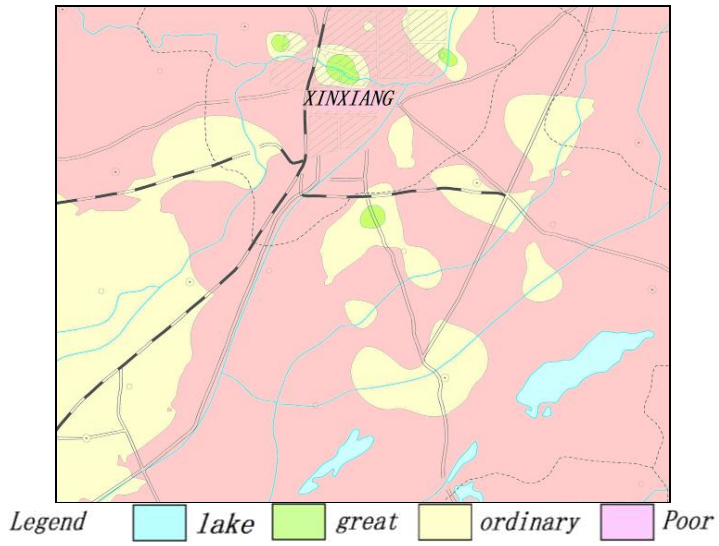

Figure 5. *The V results of sponge seepage capacity in Xinxiang sponge City*

Figure 6 shows that the evaluation of sponge storage capacity is preferably in the study area, 62% of the area can meet the annual rainfall. In rainy season, the water storage capacity of the surface aerated zone is enough to withstand rainfall infiltration and will not produce surface water. This area can be directly used for water storage construction of sponge city. In rainy season, 35.5% of the surface aerated zone in the region is in the critical range of water storage capacity, and some low-lying areas may produce surface water. In the early stage of the construction of sponge city, slope drainage should be carried out, or additional engineering facilities such as reservoirs and artificial lakes should be installed to improve the water storage capacity of sponge city. 2.5% of the area in the region has poor water storage capacity, can not withstand rainfall when rainwater conditions lead to surface water, and the intervention of artificial conditions and high cost of Engineering construction, it is not appropriate to directly or selectively carry out the water storage construction of sponge cities.

Conclusions and future work

The environmental geological suitability evaluation of sponge city construction is the premise of sponge city construction. The sponge capacity of geological body in sponge city construction directly affects the difficulty and complexity of city planning, scheme design and site construction. From the point of view of hydrogeology and environment geology, this paper mainly consider the geological properties of sponge capacity in the construction of sponge city. Based on a large number of in-situ water infiltration tests and boreholes, two indexes that sponge infiltration and sponge storage are put forward to study and analyze the maximum depth of rainfall infiltration and the infiltration velocity of surface soil under the original sponge geological conditions. These two indexes can directly and effectively represent and summarize the environmental geological suitability in the construction of sponge cities. They are easy to get and understand, have strong universality and are easy to popularize. Completing the evaluation of environmental geology suitability in sponge city construction can reduce the difficulty and workload of urban planning investigation, design and construction, and provide ideas and reference for urban agglomeration sponge city construction planning and design.

According to the sponge seepage ability and the sponge water storage ability, the environmental geological suitability of Xinxiang sponge city was evaluated by two indexes. The sponge seepage ability in the study area was obviously superior to the sponge seepage ability, which was consistent with the field investigation results. In addition, some suggestions on the construction of sponge cities are given for the regions with insufficient infiltration and storage capacity to digest the maximum rainfall.

In this paper, the ideal state hypothesis is made in the environmental suitability index of sponge city construction, and the sponge purification capacity is also an important link in the construction of sponge city. Which are insufficient and slightly rough. Besides the sponge seepage and the sponge water storage capacity should be considered simultaneously, which should be the direction and focus of further research.

Abstract. In this study, the bacterial isolate HI6 was recovered from the ice of the Hopar (Bualtar) glacier, Karakoram Mountain Range, Pakistan. Isolate HI6 was identified as *Serratia marcescens* through microscopic and molecular analysis (16S rRNA sequencing). *Serratia marcescens* HI6 was analyzed for different physiological characteristics including temperature, pH and culture media. *Serratia marcescens* HI6 showed best growth at 25°C, on LB medium and pH 7. In addition, the Fatty acid methyl ester (FAME) was extracted and subjected to Fourier Transform infrared (FTIR) and Gas chromatography/mass spectroscopy (GC/MS) analysis. FTIR and GC/MS analysis has revealed that cell membrane of *Serratia marcescens* HI6 contains various types of fatty acids (FA). *i*–C16:1 (35.3% out of total cell membrane fatty acids) was found most predominantly followed by *i*–C15:1 (18.5%) and *n*-C16 (13.2%). Moreover, branched fatty acids (62%) including monounsaturated fatty acids (MUFA) (e.g. *i*–C15:1 and *i*–C16:1) and saturated fatty acids (SFA) were the dominant types of fatty acids in the cell membrane. A polyunsaturated fatty acid (PUFA), C18:2(*cis*–9) (known as linoleic acid) was also detected among analyzed fatty acids.
Keywords: *16S rRNA, Fatty acid methyl ester, Fourier Transform infrared, Gas chromatography / mass spectroscopy*

Introduction

Genus *Serratia* belonging to family Enterobacteriaceae and species of genus *Serratia* share very close genotypic and phenotypic characteristics with each other (Grimont and Grimont, 2006; Karkey et al., 2018). A bacterium with ability to produce red pigments was first observed on polenta by Bizio (1823), which was later identified and named as *Serratia marcescens* (Martinec and Kocur, 1961a). Williams and Qadri (1980) have observed many strains of *Serratia marcescens* that were producing a non-diffusible red pigment prodigiosin. The prodigiosin (red colour pigment) produced by these strains appeared akin to a blood stain with quite devastating consequences on various human consumable items such as consecrated wafers, bread, and polenta (Grimont and Grimont, 2006). In this perspective, many researchers had linked the genus *Serratia*'s history, hundreds of years back (Harrison, 1924; Gaughran, 1969; Reid, 1982). Although, prodigiosin or prodigiosin–like pigments or various types of pigments with red colour, have also been observed

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1191111924

produced by some bacterial species other than *Serratia* (Williams and Qadri, 1980), thus characteristics of microbes concerning these prominent phenomena can only be deduced.

Serratia marcescens, an Enterobacteriaceae family member, is a Gram–negative rod that inhabits soil and water (Szewzyk et al., 1993; Sandner-Miranda et al., 2018; Yeung et al., 2018). It is a saprophytic bacterium, and has been identified in food, notably in starchy variants which offer a marvelous growth environment. Previously it was known as *Chromobacterium prodigiosum* (Wheat et al., 1951; Sleigh, 1983; Ghaith et al., 2018), Bizio proposed the name *Serratia marcescens* in 1823, which was later used by Gaughran, in 1969. Some environmental isolates were reported to produce characteristic red pigment prodigiosin, and formerly it was confused with fresh blood (Gaughran, 1969). It is an omnipresent bacterium and widely found in natural habitats such as soil, honeybee gut, water, air, plants and animals (Grimont and Grimont, 1984; Raymann et al., 2017; Dhar–Purkayastha et al., 2018; Yeung et al., 2018). The biosynthesis of prodigiosin is an important attribute of *Serratia marcescens* (Grimont and Grimont, 1984). Over past few years, it has been known as main causative agent of hospital acquired infections (Mahlen, 2011; Montagnani et al., 2015).

Membrane lipid homeostasis has been shown to play a significant role in bacterial physiology. *Escherichia coli* was used as a study model bacterium for research in lipid biosynthesis for ages (Parsons and Rock, 2013). Biosynthesis of unsaturated fatty acids is a key factor in bacterial membrane homeostasis (Zhang and Rock, 2008). Combination of fatty acids with different melting points was integrated into phospholipids. Bacteria cope with low temperature by increasing the degree of unsaturation of fatty acids incorporated in phospholipids, which leads to high membrane fluidity (Parsons and Rock, 2013). In addition, in order to maintain membrane fluidity at lower temperatures, bacteria integrate fatty acids with lower melting points into lipid bilayer with decrease of outer temperatures that help bacteria to keep balance the order-disorder transition of temperature of the membranes (Suutari and Laakso, 1994; Annous et al., 1997; Bajerski et al., 2017). It is evident from previous studies that high temperature leads to high membrane rigidity, which can be handle by decrease in degree of unsaturation of fatty acids (Ganzert et al., 2011; Bakermans et al., 2012; Bajerski and Wagner, 2013).

A variety of mechanisms are used by bacteria to sustain membrane integrity to cope with temperature changes (Parsons and Rock, 2013). In previous studies, *Serratia marcescens* has been well documented for occurrence of fatty acids in its general cell structure but not specifically in the cell membrane (Bishop and Still, 1963; Bergan et al., 1983). Bermingham et al. (1971) has reported stimulation of growth and production of pigments at temperatures higher than normal by long–chain unsaturated fatty acids in *Serratia marcescens*. The current research work was aimed to study and characterize cell membrane fatty acid profile of psychrotolerant bacterial isolate from Hopar glacier also known as Bualtar glacier in Pakistan.

Materials and Methods

Selection of the isolate HI6

Isolate HI6 (Hopar ice) (selected for this study) was previously isolated from glacial ice, Hopar glacier (36°12'54.77 N, 74°46'9.49 E) using Luria Bertani (LB) agar (*Table 1*) and incubated at 15ºC. After initial isolation, the isolate HI6 was preserved in 30% glycerol using Luria Bertani broth (LB) (*Table 1*) as culture medium and stored at –20°C for future use.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1191111924

Morphology of the isolate HI6

The colony morphology of the isolate HI6 was observed and recorded in terms of shape, production of pigments, size, opacity, margin, elevation and texture. Gram staining of the isolate HI6 was done following the protocol described by Beveridge (2001) and microscopic features were recorded using Laxco™ LMC–3000 Series Bright field Compound Microscope System.

Molecular identification of the isolate HI6

DNA extraction, PCR amplification

The DNA of the isolate HI6 was extracted using the protocol described by Zhou et al. (1996). The extracted DNA was amplified using the thermocycler (T100^{TM} Thermal cycler, Bio–Rad Laboratories, Inc.). The universal bacterial primers 27F (5′-AGAGTTTGATCMTGGCTCAG3–′) and 1492R (5'-GGTTACCTTGTTACGACTT–3') were used for amplification purposes. Cycling conditions was used as initial denaturation at 94ºC for 1 min following by 30 cycles at 94ºC for 1 min, 55ºC for 1 min and 72ºC followed by final elongation at 72ºC for 7 min. Finally, 2% agarose gel electrophoresis was performed to confirm PCR amplification.

Sequencing and phylogenetic analysis

Sequencing (16S rRNA) of amplified PCR product of the isolate HI6 was done by Macrogen Inc. Seoul, Korea. Trimming and filtering of obtained sequences was done using BioEdit (v7.0.5). The trimmed sequences was used to find the homologous bacterial strain by searching in the National Centre for Biotechnology Information (NCBI) (Thompson et al., 1994). Tamura–Nei model (Tamura and Nei, 1993) was used to construct the evolutionary history of the isolate HI6. MEGA 6.0 software was used to construct phylogenetic tree at the bootstrap value of 1000.

Characterization of physiological parameters of the isolate HI6

Effect of different pH, media and temperature on growth of the isolate HI6 was evaluated in this study. Four different temperature, 5, 15, 25 and 35°C, five different media, Minimal salt medium (MSM), Luria Bertani (LB), Nutrient broth (NB), Peptone–yeast–meat extracts (PYM) and Artificial salt media (ASM) as well as five different pH, 3, 5, 7, 9 and 11 were selected for this experiment. Nutrient broth was used as culture medium for all temperature and pH experiments, whereas, 15°C as incubation temperature was used for pH research work. 7 days old culture of the isolate

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1191111924

HI6 was inoculated in 250 mL Erlenmeyer flask containing 100 mL of broth medium and incubated in shaking incubator with 120 rpm for 7 days. To check the growth, optical density (600 nm) of the isolate HI6 was recorded after every 24 hrs via spectrophotometer (Shimadzu). In addition, two-way ANOVA was applied to find the statistical significant of this experiment.

Cell membrane fatty acids analysis

Fatty acids methyl ester preparation (FAME)

The isolate HI6 was grown in LB broth and incubated at 15°C for seven days. About 100 mg culture of the isolate HI6 was taken in 20 mL glass vial and subjected to FAME extraction. Added 2 mL of 5% methanolic HCl to glass vial containing bacterial culture and heated at 70°C for 2 hours. After heating, glass vial was placed at room temperature for 30 minutes to cool down. In next step, distilled water (1 mL) was added and then vortexed well. For extraction of FAME, 1 mL of hexane was poured and vigorously vortexed for about 10 minutes. After formation of two layers in glass tube, upper layer was transferred to new 2 mL clean glass vail and stored under nitrogen at –20°C.

Fourier Transform infrared (FTIR) spectroscopy

The extracted FAME extracted from the isolate HI6 was analysed through by FTIR spectrophotometer (Bruker Tensor 27, equipped with ZnSe ATR) along with the standard obtained through (The Vitamin Company USA). The spectra of FAME from the isolate HI6 were evaluated and recorded by keeping the range in between 4000-600 cm^{-1}. About 35 µL (in triplicate) of extracted FAME was placed on the FTIR spectrophotometer tray and recorded infrared spectrum of sample. The software Opus 65 was used to compare spectrum of extracted FAME with the spectrum of known compounds present in library.

Gas chromatography/mass spectroscopy (GC/MS) analysis

FAMEs analysis was done via GC (Agilent 7890A GC) linked to MS (Agilent 5975C MSD) and controlled by a HP Compaq computer using ChemStation software by following protocol described by Abd El Razak et al. (2014). Helium used as a carrier gas (flow rate of 1 ml/min, initial pressure of 50 kPa, split at 10 ml/min). Moreover, an auto–sampler (HP7683B) was used for injecting about 1 µL of sample in hexane. In addition, FAMEs separation was carried with column (30 m× 0.25 mm) (An Agilent–fused silica capillary column) coated with 0.25 µm dimethyl poly–siloxane (HP–5). The temperature of GC was set initially from 30 to 130°C at 5°C/min then to 300°C at 20°C/min and final temperature held for 5 min. FAME Mix (C4–C24) (Sigma–Aldrich) was used to identify the resultant peaks by comparing mass spectra and R_t (retention time).

Results

Morphology and molecular identification

The isolate HI6 produced red pigment, with round, smooth, convex (3–6 mm in diameter) colonies (*Fig. 1*). Microscopic analysis showed the isolate HI6 as Gram negative short rod (0.7–2.3 µm in length and 0.3–0.8 µm in diameter).

DOI: http://dx.doi.org/10.15666/aeer/1705_1191111924

Based on 16S rRNA sequencing, the bacterial isolate HI6 was identified as *Serratia marcescens* [GenBank accession number MG641443]. In addition, the isolate HI6 showed 100% similarity with *Serratia marcescens* after searching in National Centre for Biotechnology Information database. Phylogenetic analysis on basis of partial 16S gene sequence, clearly shows that *Serratia marcescens* HI6 grouped within clusters of closely related species of *Serratia marcescens* in phylogenetic tree (*Fig. 2*).

Bootstrap values (1000 replicates) for node values from 50% are indicated. The species belonging to genus Pseudomonas were used as an outgroup*

Physiological characteristics

Serratia marcescens HI6 responded differently to various physiological parameters. In this experiment, it has been found that *Serratia marcescens* HI6 grow optimally at 25°C and pH 7 in LB broth (*Table 2*). The *Serratia marcescens* HI6 showed decline in its growth after 120 hrs of initial incubation in about all physiological parameters. It seemed that it has entered in exponential growth phase after 48 hrs of its starting incubation. *Serratia marcescens* HI6 was unable to show any growth at pH 3 and 45°C.

DOI: http://dx.doi.org/10.15666/aeer/1705_1191111924

The LB broth was reported as best growth medium followed by PYM, ASW, MSM and NA. In addition, optimum growth was at pH 7 followed by pH 9, 11 and 5. Moreover, best growth was observed at 25°C followed by 35, 15 and 5°C. Based on these results, *Serratia marcescens* HI6 had the capabilities to grow at wide range of extreme physiological parameters.

Fourier Transform infrared (FTIR) analysis

Results of FTIR analysis revealed different functional groups present in the FAME extracted from *Serratia marcescens* HI6 (*Fig. 3*). The spectrum of the analysed FAME was compared with already online available databases as well as with standard and found that typical functional groups that are exist in fatty acids (FA) (such as saturated FA, monounsaturated FA and polyunsaturated FA), have also been presented in analysed FAME. For example, peak value 2812–3012 cm^{-1} region (which represent =C–H stretching vibration bond), 1710–1766 cm^{-1} (associated with C=O carbonyl bond) and multiple C=C double bond at 1400–1600 cm^{-1}, have clearly indicated that *Serratia marcescens* HI6 had various types of saturated FA, monounsaturated FA and polyunsaturated FA in its cell membrane (*Fig. 3*).

Gas chromatography/mass spectroscopy (GC/MS) analysis

The results of GC/MS has revealed that most copious types of fatty acids were branched fatty acids followed by monounsaturated fatty acids, n–chain saturated fatty acids, hydroxyl fatty acids and polyunsaturated fatty acids (*Fig. 4a,b*) (*Table 3*). In addition, *i*–C16:1 was found most abundant type of fatty acid followed by *i*–C15:1, n-C18:2(*cis*–9), n–C16, *ai*–C17:0, 3–OH–C14:0, n–C12, n–C14, *i*–C17:0, n–C18, n-C18:1(*trans*–9), C18:2(*cis*–9), n–C15 and n–C17 (*Table 3*).

DOI: http://dx.doi.org/10.15666/aeer/1705_1191111924

Moreover, *Serratia marcescens* HI6 was able to produce only one type of polyunsaturated fatty acids, n–C18:2(*cis*–9) (also known as linoleic acid). Overall, branched fatty acids (62%) and *i*–C16:1 (35.2% out of total membrane fatty acids) were the main types of fatty acids produced by *Serratia marcescens* HI6 predominantly.

Discussion

This study was aimed to characterize physiological parameters and analyzed cell membrane fatty acids of the bacterium isolate *Serratia marcescens* HI6. In our knowledge, we are reporting for the first time *Serratia marcescens* from any glacial environment of Pakistan. Although in one study, it has been studied for laccase production isolated from glacial site in Indian Himalayan Region (IHR) (Kaira et al., 2015). *Serratia marcescens* has been known for its abilities to infect insects and spoils various types of food (Flyg and Xanthopoulos, 1983; Abdour, 2003; Bahar and Demirbag, 2007). In addition, its association with promotion of plant growth by combating with plant pathogens has also been observed (Kloepper et al., 1993). Moreover, *Serratia marcescens* has been found to fertile soils by producing phosphatases and unfriendly substances for plant pathogens (de Queiroz and de Melo, 2006; Tripura et al., 2007). Likewise, Pares (1964) has observed in soil that *Serratia marcescens* had role in the nutrient recycling by solubilizing organic iron and dissolving gold and copper. In another research, Janota–Bassalik (1963) has reported mineralization role of psychrotolerant *Serratia marcescens* accompanying by low–moor peat.

The genus *Serratia* is usually found widely in water, plants, mammals and hospitalized human patients (Grimont and Grimont, 2006) but studies about its presence and activities in both Polar and Non–polar cold regions are very rare. The primary habitat for genus *Serratia* is water as plenty of species belonged to *Serratia* has been reported from water (Grimont and Grimont, 2006). Gavini et al. (1979) has isolated *Serratia fonticola* well waters and springs. In another study conducted by Grimont and Grimont (2006), a total of 150 bacterial species belonged to genus *Serratia* including *Serratia marcescens* were reported from river water. In addition, Groscop and Brent (1964) has observed toxicity of non–diffusible red pigment prodigiosin to protozoa, produced by genus *Serratia*, which perhaps a promising factor important for its survival

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1191111924

in water and soil habitats. Based on such research, Grimont and Grimont (2006) has concluded that *Serratia* sp. with pigmentation abilities are existed in non–polluted rather than from polluted water.

Tolerance of *Serratia marcescens* HI6 to different extreme temperature, pH and media was assessed. *Serratia marcescens* HI6 was able to grow on temperature between 5–35°C (25°C optimum growth temp), pH between 5–11 (7 optimum growth pH) as well as on various media including ASW, LB, MSM, NB and PYM (LB optimum growth medium). Recently, Kaira et al. (2015) has reported similar findings for *Serratia marcescens* isolated from glacial site in Indian Himalayan Region (IHR). They observed psychrotolerant *Serratia marcescens* to show optimum growth at 25°C. Many other researchers have also used various temperature (5–37°C) for the growth of *Serratia marcescens* and they have found that it had the abilities to grow over a wide range of temperature (Bishop and Still, 1963; Selvakumar et al., 2008). In our knowledge, none of study has been carried out relating to tolerance of *Serratia marcescens* to extreme pH and various media.

In the present study, the fatty acids present in the cell membrane of *Serratia marcescens* HI6 were assessed using Fourier Transform Infrared (FTIR) spectroscopy. FTIR has the efficiency to recognize major parts of biological material (nucleic acids, proteins, lipids and carbohydrates) in any solution (Forfang et al., 2017). Basically, specific absorbance frequencies of FTIR are central to detect fatty acids (Forfang et al., 2017). In our study, the bands between 1710–1766 cm^{-1} were observed after analysis of extracted FAMEs by FTIR indicating the presence of C=O that associated with fatty acids. According to Dean et al. (2010), presence of the band at 1740 cm^{-1} indicated existence of C=O of ester groups, principally from FA. Moreover, Shurvell (2002) and Maquelin et al. (2002) has described the bands obtained from lipids after Fourier Transform Infrared spectroscopy analysis in detail. According to them, the lipid content present in any sample can easily detected by getting peaks associated to C-O–C stretching in esters (1070–1250 cm^{-1}), CH_2 bending (1460 cm^{-1}), C=O stretching in esters (1745 cm^{-1}), C–H stretching vibrations (=C–H stretch at 3010 cm^{-1}). The FTIR has been used by several researcher to identify the lipids and fatty acids content in many microbes such as *Chlamydomonas reinhardti*, *Scenedesmus subspicatus*, *Mucor plumbeus*, *Mucor hiemalis*, *Mucor circinelloides*, *Mortierella alpine* (Dean et al., 2010; Shapaval et al., 2014; Forfang et al., 2017).

Furthermore, the fatty acids profile of cell membrane of the isolate *Serratia marcescens* HI6 was properly studied using Gas chromatography/mass spectroscopy (GC/MS) in the current study. Findings of this analysis showed that C16:1 was present abundantly in cell membrane of *Serratia marcescens* HI6. None of such study has been carried out in past. Although Bergan et al. (1983) and Bishop and Still (1963) have analyzed the whole cell fatty acids of *Serratia marcescens*, whereas, current study is focused on cell membrane fatty acids of *Serratia marcescens*, so it is very challenging to exactly compare and discuss current study (cell membrane fatty acids analysis) with previous studies (whole cell fatty acids analysis) of *Serratia marcescens* because whole cell fatty acids could significantly differ in type and function from fatty acids present in cell membrane. As distribution of various types of fatty acids in cell membrane play significant role in bacterial adaptability in cold habitats, therefore, present research work specifically focused on it rather than to study whole cell fatty acids. However, current study has generally been discussed with other related bacterial strains of *Serratia marcescens* (Jantzen et al., 1974a, b, 1975). Our

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1191111924

results has supported by research work of many other researchers that observed foremost amount of C16:0, C16:1 and C18:1 in some strains of *Serratia marcescens* (Kates et al., 1964; Kates and Hagen, 1964). Although the contribution of the two last-mentioned fatty acids may also be small from the same strain Kates and Hagen (1964) has reported that amount of C16:1 and C18:1 varied depending upon culture conditions of growth of *Serratia marcescens*. It has been observed by many researcher that gram negative bacterial species possessed higher quantities of C16:0, C16:1 and C18:1 than gram positive bacteria in their cell membranes (Jantzen et al., 1974a,b, 1975; Zhao et al., 2011). Moreover, Bergan et al. (1983) has observed that family Enterobacteriaceae had high amount of C16:0 than C16:1 in their cells and has also reported in few *Acinetobacter* strains (Jantzen et al., 1975).

Likewise, the branched fatty acids were witnessed predominately in cell membrane the isolate *Serratia marcescens* HI6. The branched *iso* and *anteiso* pattern was observed in both saturated fatty acids and monounsaturated fatty acids in the current results. The incorporation of *iso* and *anteiso* branches in the fatty acids chains of cell membrane, is perhaps a strategy to cope with devastating effects of low temperature by maintaining the fluidity of cell membrane (Bajerski et al., 2013, 2017). In few studies, it has been shown that *anteiso* branches pattern of fatty acids of cell membranes in psychrotolerant bacterial species (such as *Chryseobacterium frigidum* and *Chryseobacterium haifense*) reduced the melting temperature of the plasma membrane increasing motion capability and made it possible to freely move molecules across the cell membrane (Hantsis-Zacharov and Halpern, 2007; Kim et al., 2016).

Conclusion

In conclusion, the bacterium isolate HI6 was identified as *Serratia marcescens* after 16S rRNA sequencing. The bacterium isolate *Serratia marcescens* HI6 showed a good potential to grow over a wide range of extreme physiological conditions. Results of FTIR and GC/MS has showed that the isolate HI6 had the ability to produce and accumulate various types of fatty acids in its cell membrane but predominantly *i*–C16:1 and other branched chain fatty acids. This study is important because it gives a clear idea about Fatty acids distribution in the cell membrane of *Serratia marcescens* and their possible role in adaptation in glacial habitats. In addition, this study would be helpful to understand the maintenance of cell membrane fluidity in glacial environments by *Serratia marcescens*. Finally, the bacterium isolate *Serratia marcescens*–HI6 would be used as source of polyunsaturated fatty acids (e.g. linoleic acid) as alternative to the conventional plant sources of PUFA, thus would be helpful to prevent deforestation.

Conflict of interests. The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interests.

Author contributions. All authors have made an equal contributions to the research work and writing of this manuscript.

(Received 23rd Apr 2019; accepted 11th Jul 2019)

Abstract. The objective of research was to assess the selected mineral components (phosphorus, calcium and magnesium) in the tubers of edible potato. Field research was carried out in the years 2015-2017 with an application of biostimulators in individual farms in the town of Międzyrzec Podlaski (51°59' N and 22°47' E), Poland. The experiment was led by means of a split-plot method. The impact of two factors was tested. The first order factor were the three varieties of edible potato: Honorata, Jelly, Tajfun, while of the second order - four variants of applying biostimulators: Kelpak SL, Titanit, GreenOk, BrunatneBio Złoto and a control variant (potato plants sprayed with distilled water). Potato plants were treated with biostimulators three times (beginning of flowering, full flowering and after plant flowering). Within the presented research the applied biostimulators increased the content of selected mineral components in the tubers of tested varieties. Tubers of plants treated with BrunatneBio Złoto preparation were characterized by the largest content of phosphorus, calcium and magnesium in comparison to the plants from control object. The content of microelements in the tubers varied significantly depending on the genotype of the variety. The greatest concentration of phosphorus was noted in the tubers of Tajfun variety, while in case of magnesium - Honorata variety. Large amount of rainfall in 2017 contributed to the occurrence of an increase of the content of phosphorus, calcium and magnesium in potato tubers. Average content of phosphorus amount to, on average: 3.4 $g \cdot kg^{-1}$, calcium 0.73 $g \cdot kg^{-1}$, and magnesium 1.36 $g \cdot kg^{-1}$.
Keywords: *variant, variety, phosphorus, calcium, magnesium*

Introduction

The nutritional value of potatoes (*Solanum tuberosum* L.), apart from carbohydrates, protein and vitamins, is determined by the content of mineral components (Leszczyński, 2012; Wójcik –Stopczyńska et al., 2012). The following are of particular importance: phosphorus, calcium, magnesium – having alkali-forming actions, their presence in food neutralizes the acidifying meat, fish and cereal product properties (Tajner-Czopek, 2006). These elements perform mainly the building and physiological functions in a plant, further to deciding about its dietetic values (Leszczyński, 2012; Wierzbicka,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1192511933

2012). Phosphorus is the key component of compounds which are decisive for the energetic processes. It forms part of specific proteins and participates in the metabolism of carbohydrates. Within the national research the content of phosphorus in potato tubers was shaped at the level of 1.8-3.9 $g \cdot kg^{-1}$ (Zarzecka and Mystkowska, 2004; Wierzbicka, 2012; Zarzecka et al., 2015; Wierzbowska et al., 2016), and in the foreign research it was usually greater and amounted to 2.2-4.9 $g \cdot kg^{-1}$ (Elfaki and Abbsher, 2010; Jarvan and Edesi, 2009; Mahamud et al., 2015). Calcium is considered as an element that conditions the correct growth and development of plants. The content of calcium in tubers, within the national research, was within the limits of 0.30-0.69 $g \cdot kg^{-1}$ (Kołodziejczyk and Szmigiel, 2005; Wierzbicka and Trawczyński, 2011; Wierzbicka, 2012; Zarzecka et al., 2015), and in the foreign ones 0.2-1.4 $g \cdot kg^{-1}$ (Ekin, 2011; Mahamud et al., 2015). Magnesium is a crucial component of potato tubers. Its presence in a plant is determined by the basic processes of metabolism and energy conversion. Magnesium not only participates in approx. 300 enzymatic reactions, but it also constitute an active centre for the chlorophyll molecule. The content of magnesium in dry mass of potato tubers in research carried out by Zarzecka et al. (2006), Wierzbicka and Trawczyński (2011), Wierzbicka (2012) amounted to 0.8-1.3 $g \cdot kg^{-1}$, and in foreign researches it reached the level of 3.3 $g \cdot kg^{-1}$ (Muhamud et al., 2015). Consumption of 200 g of potatoes covers between 10-14% for phosphorus, 8-17% for magnesium.

Environmental and genetic factors have an impact on the concentration of the mineral components in potato tubers (Horvat et al., 2014; Wierzbowska et al., 2015a, b). The chemical content may change in terms of agrotechnical factors, including biostimulators. Many authors indicated a beneficial impact of biostimulators on the chemical content of potato tubers (Bienia et al., 2018; Trawczyński, 2014; Wierzbowska et al., 2016). Applying biostimulators allows correcting the bad state of nutrition of plants (Fageriai et al., 2009; Fernandez et al., 2013; Singh et al., 2013). The most crucial function performed by biostimulators is the supplementation of a deficiency of components in the period of vegetation, caused by various factors, such as intense plant development, drought, agrotechnical errors. Thus, the objective of research was to specify the impact of the selected biostimulators on the content of phosphorus, calcium and magnesium of three varieties of edible potato.

Materials and methods

The experimental site

Potato tubers from the field experiment realized in the years 2015–2017 on an individual farm within the village of Międyrzec Podlaski, Lubelskie voivodeship (51°59' N and 22°47' E), Poland constituted research material (*Fig. 1*). The experiment was conducted in three repetitions with the use of split-plot method, on soil regarded as a rye complex, very good, class IVa. In individual years of research, soils differed in the content of organic matter and available macro-elements. In 2015 and 2016, the soil was characterized by slightly acidic reaction, and in the last year of research, alkaline. The content of organic matter ranged from 15.0 to 18.7 $g \cdot kg^{-1}$. The content of available phosphorus (P) was from high to very high, potassium (K) from medium to very high, and magnesium (Mg) was high. The first factor was three moderately early varieties of edible potato: Honorata, Jelly and Tajfun, and the second one, four types of biostimulators used in three dates (beginning of flowering, fully flowering and after flowering of plants):

1. Control variant – without the use of biostimulators spraying with distilled water
2. Biostimulator Kelpak®SL (active substance - *Ecklonia maxima* algae extract), containing plant hormones: auxin - 11 $mg \cdot l^{-1}$ and cytokinin – 0.031 $mg \cdot l^{-1}$, at a dose of 0.20 $l \cdot ha^{-1}$
3. Biostimulator Tytanit® (active substance – titanium) at a dose of 0.20 $l \cdot ha^{-1}$
4. Biostimulator GreenOk® (active substance – humus substances 20 $g \cdot l^{-1}$) at a dose of 0.20 $l \cdot ha^{-1}$
5. Biostimulator BrunatneBio Złoto (active substances – plant hormones: auxin – 0.06 $mg \cdot l^{-1}$ and cytokinin - 12 $mg \cdot l^{-1}$) at a dose of 0.20 $l \cdot ha^{-1}$

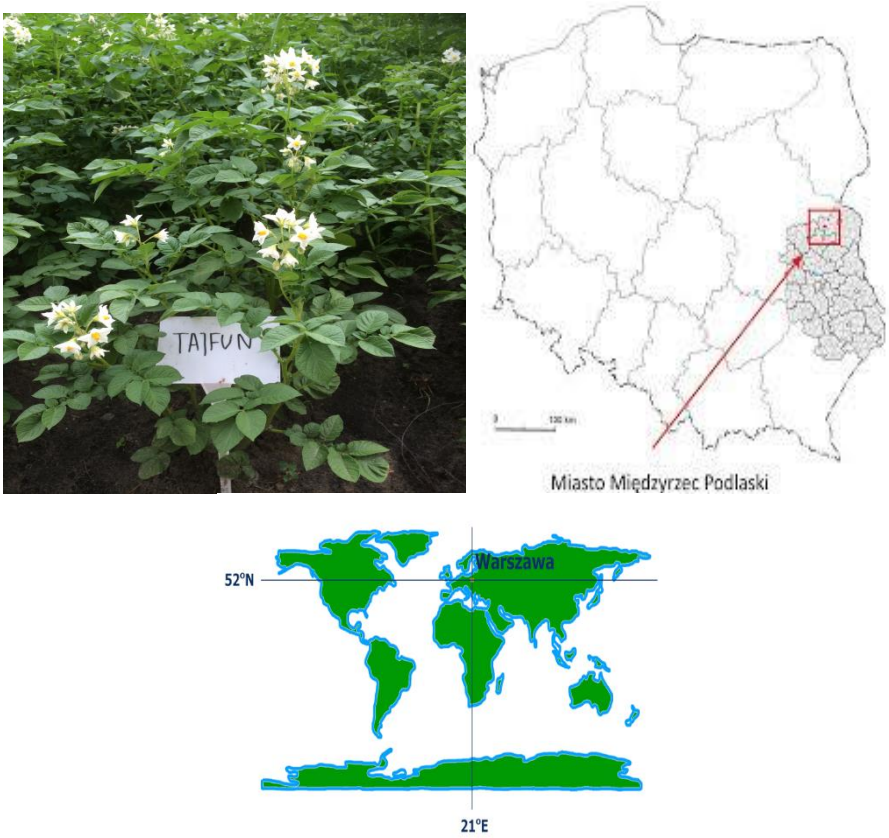

Figure 1. *Location of the experiment*

The forecrop for potato in particular years of research was winter wheat. After harvesting the forecrop, a team of post-harvest crops was made. In autumn, each year preceding planting, organic fertilization in the form of manure in the amount of 25.0 $t \cdot ha^{-1}$ and mineral fertilization with phosphorus-potassium in the amount of P – 44.0 (100 $P_2O_5 \cdot 0.44$) $kg \cdot ha^{-1}$ (lubofos for potatoes 7%) and K – 124.5 (150 $K_2O \cdot 0.83$) $kg \cdot ha^{-1}$ (lubofos for potatoes 25%) was applied. These fertilizers were plowed pre-season plowing. Nitrogen fertilizers were applied in the spring in an amount of N 100 kg/ha (nitro-chalk 27%) and mixed with the soil using a cultivator. Potatoes were planted manually under the marker at a spacing of 67.5 x 37 cm, in the third decade of April (2015, 2016, 2017). Each plot with an area of 15 m^2 accounted for five ridges. Cultivation and care treatments were carried out in accordance with the requirements of

DOI: http://dx.doi.org/10.15666/aeer/1705_1192511933

correct. During the growing season, the potato plantation was protected with the following incidences: Actara 25 WG (thiametoksam) at the rate of 0.08 kg·ha^{-1} and Caliypso 480 SC (thiacloprid) at the rate of 0.1 l·ha^{-1}, and fungicides: Copper Max New 50 WP at the rate of 2.0 kg·ha^{-1} and Dithane Neo Tec 75 WG the rate of 2.0 kg·ha^{-1}. Samples of potato tubers (50 tubers) were taken from each of the plots during harvest in the first decade of September and stored at 10-12 °C, for 8-10 days. Chemical analyses were performed using dry material from 10 representative tubers in three replications.

Chemical analysis methods

Weight of about 0.2-0.3 g of sample was transferred to vessel and HNO_3 and HCL was added, 3:1 respectively. The vessels were placed in the rotor and loaded to the microwave.

Mineralized samples were transferred to the 50 ml flasks through filtering paper and diluted with ultra-pure water.

Samples were examined with SpectroBlue ICP OES spectrometer at the Regional Research Center for Environment, Agricultural and Innovative Technologies, Pope John II State School of Higher Education in Biała Podlaska. Analytical curves were built by diluting Bernd Kraft Der Standard Spectro Genesis ICAL Solutions and VHG SM68-1-500 Element Multi Standard 1 in 5% HNO_3. Operating parameters for ICP OES instrument: coolant flow: 12 l/min; auxiliary flow: 0.90 l/min; nebulizer flow: 0.78 l/min.; pump speed: 30 Rpm; number of measurements: 3.

Meteorological conditions

Meteorological conditions in the years of potato vegetation have been presented in *Table 1* by means of the sum of rainfall and average air temperatures. Vegetation season of 2015 turned out to be the average air temperature of 15.2 °C, higher by 0.2 °C from the average long-term and rainfall at the level of 295.1 mm. The highest average temperature of air was noted in 2016 and amounted to 15.8 °C, was higher from the average long-term one by 0.8 °C, whilst that year was characterized by the lowest volume of rainfall – 200.9 mm, lower by 134.5 mm from the long-term sum. The highest number of rainfall was noted in the vegetation season of 2017–325.4 mm and the lowest air temperature –14.6 °C (*Table 1*).

Results and discussion

Both genetic and environmental factors have an impact on the concentration of mineral elements in tubers. Many authors indicated that the volume of macro-elements in tubers depended on the particular variety (Wierzbicka and Trawczyński, 2011; Żołnowski, 2013; Muhamud et al., 2015; Wierzbowska et al., 2014, 2016).

The conducted research revealed that the genetic factor had a significant impact on the content of phosphorus in potato tubers (*Table 2*). The variety which contained the greatest volume of this component was Tajfun variety, followed by Jelly and Honorata varieties. The impact of different properties on the content of phosphorus are underlined by Wierzbowska et al. (2016), Żołnowski (2013). All the applied biostimulators in the presented studies increased the content of phosphorus in the tubers of the tested varieties. The largest average content of phosphorus was obtained after applying BrunatneBio Złoto biostimulator. The experiment conducted by Wierzbowska et al.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1192511933

(2016) might be the confirmation of the obtained results, whereby the authors noted an increase of concentration of phosphorus after spraying the plants with Asahi SL, whilst other growth regulators (Bio-Algeen S90, Kelpak SL) did not change the content of phosphorus. Farouk (2015) reported an increase in the content of phosphorus in the tubers after applying biostimulators from the seaweed and potassium humus with respect of the control tubers. Biostimulators (Trifender WP, Asahi SL, Kepak SL, Bio-Algeen S90) used in the experiences of Głosek-Sobieraj et al. (2019) did not alter the content of phosphorus. The factor which also significantly modified the content of the analysed element were the hydrothermal conditions appearing in the years of researches. High content of phosphorus was noted in the tubers gathered in 2017, whereby the total rainfall volume was, respectively by 124 and 30 mm higher than in the years 2016 and 2015 (*Table 1*).

Phosphorus decides about the processing value of potatoes; its content in tubers amounts to an average of 57 mg·100 g^{-1}. Phosphorus is a mineral that occurs in the greatest concentration in human organisms. Upon the recommended standard of 700 mg

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1192511933

phosphorus per day, 100 g of potato covers the daily demand of a person for this element in 8% (Wierzbicka, 2012).

Another important element *Solanum tuberosum* is calcium, considered as the element which conditions the correct growth and development of an organism and, along with the collagen, it constitute the key building material of the skeletal system (Zarzecka et al., 2015). In an adult human organism, 99% of calcium occurs in the skeletal system (Friedrich et al., 2002; Miles and Buchman, 2009; Wierzbicka, 2012). The greatest average content of calcium was noted in Tajfun and Honorata varieties, which were in these terms homogeneous, while Jelly variety contained significantly less calcium (*Table 3*). The applied in the experiment biostimulators increased the content of calcium in the tubers, while the greatest value of calcium was obtained upon the use of BrunatneBio Złoto biostimulator. High content of calcium was indicated in the tubers gathered in 2017 in which the sum of rainfall was higher than in 2016 and 2015 (*Table 1*). The applied biostimulators reacted to the meteorological conditions in the years of researches causing a significant increase of the content of calcium in 2017, which was characterised by a beneficial distribution of temperatures and rainfall during vegetation period for potatoes (*Table 3*). All three varieties reacted in a specific manner to the thermal and humidity conditions in place in the years of cultivation, as per the indicated interaction variety x years (*Table 4*). Wierzbowska e al. (2016) within the presented research, having analysed the impact of Asahi Sl, Bio-Algen S90 and Kelpak SL biostimulators, they indicated that the content of calcium in tubers was significantly modified solely by the Asahi Sl biostimulator.

DOI: http://dx.doi.org/10.15666/aeer/1705_1192511933

magnesium, while Jelly the smallest. Biostimulators caused an increase in the concentration of magnesium with regards to the tubers gathered from the control object. The most mineral components were contained in the tubers after application of BrunatneBio Złoto biostimulator, which allows believing that BrunatneBio Złoto is an agent which acts in a stimulating manner on the gathering of phosphorus, calcium and magnesium. In light of the presented research one must note that the content of magnesium in the tubers depends on the hydrothermal conditions. The largest content of this element was present in the tubers gathered in 2017 (*Table 5*) which was characterized by excessive rainfall in comparison to the average long-term sum and was the coldest in comparison to the other vegetation periods.

Conclusions

The content of phosphorus, calcium and magnesium in potato tubers was substantially diversified by the variety genotype. The largest concentration of phosphorus and calcium was noted in the tubers of Tajfun variety, while magnesium in the tubers of Honorata variety. Tubers of plants treated with BrunatneBio Złoto preparation were characterized by the greatest content of the selected mineral components. Meteorological conditions, especially large volume of rainfall in 2017, contributed to an increase of tested macro-elements (phosphorus, calcium and magnesium) in potato tubers of three edible potato varieties.

(Received 24th Apr 2019; accepted 12th Jul 2019)

Abstract. To characterize the ultraphytoplankton community structure and understand its succession and its relationship with environmental factors, High Performance Liquid Chromatography (HPLC-CHEMTAX) was used to analyze the photosynthetic pigment concentration and the algae composition. Algal phyla composition and their abundance were determined based on the presence of pigments, and environmental parameters were synchronously tested in the Three Gorges Reservoir in China. High-performance liquid chromatography (HPLC) analysis showed that there were eight characteristic photosynthetic pigments in the Three Gorges reservoir area: alloxanthin, chlorophyll b, chlorophyll a, fucoxanthin, lutein, neoxanthin, violaxanthin, and zeaxanthin. Among them, fucoxanthin, allophycocyanin, zeaxanthin, and chlorophyll b were the most important photosynthetic pigments in the Three Gorges reservoir area. There were significant differences in the time scale of the eight photosynthetic pigments ($P < 0.05$), but no significant difference in the seven phyla ($P > 0.05$). The calculation of the matrix factorization program chemical taxonomy (CHEMTAX) showed that the ultraphytoplankton community was composed of 7 phyla: *Euglenophytes*, *Chrysophytes*, *Cyanophytes, Cryptophytes*, *Chlorophytes*, *Diatoms*, and *Dinoflagellates*. Redundancy analysis (RDA) revealed that the key environmental factors that affected the structure of the ultraphytoplankton community were light intensity, total phosphorus, and water temperature. The results provided a basis and data support for the biodiversity of phytoplankton in the Three Gorges Reservoir and its relationship with environmental factors and environmental monitoring.
Keywords: *photosynthetic pigment, HPLC, CHEMTAX, total biomass, environmental factor*

Introduction

Ultraphytoplankton include all picoplankton (0.2~2 μm) and 2~5 μm microplankton (< 20 μm) (Ning, 1997). Ultraphytoplankton are light-dependent self-sustaining creatures that consist of prokaryotes and eukaryotes (Sieburth et al., 1978). Ultraphytoplankton are an important source of gross primary productivity and are distributed around the world, some in extreme conditions, such as high temperatures in tropical and subtropical regions, the frigid Antarctic, as well as oceans and lakes under a variety of nutrient conditions. Currently, the prokaryotes cyanobacteria, such as Synechococcus and Prochlorococcus, are a familiar subject in marine

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1193511952

ultraphytoplankton research (Coclet et al., 2017; Chen et al., 2011; Glove et al., 1988), while there are very few studies in fresh water.

As the world's largest deep-water reservoir, the Three Gorges Reservoir of China has huge economic benefits in terms of flood control, shipping and power generation. However, after the damming of the Yangtze River, it underwent tremendous changes in the hydrological situation and water environment (Huang and Li, 2006). The hydrodynamic characteristics of some reservoirs and tributaries have changed significantly. The velocity of the water flow has been markedly slowed, and the flow rate of many tributaries (A river that flows into another river (or other body of water) rather than directly into the sea.) is less than 0.05 $m \cdot s^{-1}$, which is due to the influence of reservoir hydrodynamics and the backwater effect (Deng and Gong, 2007; Li et al., 2007). The decrease in the flow rate causes the vertical flow of the target area to decrease and the residence time of the water to increase significantly, resulting in the sedimentation of suspended matter in the water (Zheng et al., 2008). Under the appropriate temperature, wind speed, light, and biological factors, such as the impact of phytoplankton, the changing conditions will cause the algae to undergo explosive growth into a "bloom" (Kong and Gao, 2005) and thus have a negative impact on the reservoir ecosystem.

Regarding phytoplankton in the Three Gorges Reservoir, there are many reports on microplankton and picoplankton (Pan et al., 2016; Liu et al.,2012; Zhou et al., 2009), but research data for ultraphytoplankton is lacking. The key and prerequisite for studying ultraphytoplankton are to classify them.

The classical phytoplankton taxonomy mainly uses microscopic observation and flow cytometry. The use of electron microscopy and optical microscopy for traditional morphological observation is the basis on which we can also use the cell count plate for sample identification of the count (Wasilowska et al., 2015). This traditional method is indispensable in phytoplankton classification and identification, but it is extremely difficult to classify phytoplankton with minimal particle sizes (e.g., ultraphytoplankton). Although flow cytometry techniques can accurately and efficiently count microscopic phytoplankton that are difficult to observe, it is a challenge to distinguish the phyla of phytoplankton in the sample (Bonato et al., 2016). On the other hand, if there are aggregates and debris in the sample cells, the resulting fluorescence interference will directly affect the test results. Compared with these methods, chemical classification has the advantages of being fast and accurate, with a high-throughput (Li et al., 2013).

Chlorophyll a plays an important role in photosynthesis and is considered a biomarker of phytoplankton in the world (Alvarez-Fernandez and Riegman, 2014). Scientists (Jeffrey, 1974; Hallegraeff, 1981) have recognized the taxonomic significance of different photosynthetic pigments and their composition in phytoplankton. The distribution of different pigments in algae is distinct and exists only in phytoplankton communities (Wright et al., 1991). Therefore, it is feasible and scientific to determine the characteristic photosynthetic pigments of phytoplankton in order to establish phytoplankton groups. Chromatographic techniques, especially reverse-phase high-performance liquid chromatography (RP-HPLC) technology, can be used in analyzing algae pigment content and composition changes, combined with the characteristic photosynthetic pigment and chlorophyll a initial ratio data, through the matrix factorization program CHEMTAX. In addition, the abundance and composition of the phytoplankton population can also be determined using

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1193511952

CHEMTAX. The chemical classifications based on HPLC-CHEMTAX pigment analysis can accurately analyze the phytoplankton community structure and abundance composition, and it is not limited by the phytoplankton grain size. The study of biomass change, taxa composition, and community structure succession of the ultraphytoplankton are significant in modern science. Although this method has been widely used in the study of marine phytoplankton composition and abundance (Madhu et al., 2014; Agirbas et al., 2015), it has not been frequently used in fresh water. To explore the dynamics of the ultraphytoplankton community structure in the Three Gorges Reservoir, our group applied this technique, which can quickly and accurately describe the community structure of the ultraphytoplankton (Li, 2014; Liu et al., 2017).

This study used HPLC-CHEMTAX technology aimed at specific pigments of the ultraphytoplankton to analyze the succession of the ultraphytoplankton community structure and its response to environmental factors in the Three Gorges Reservoir. Specifically, the main objectives of this study were as follows: (i) to discover the spatial and temporal distribution of the total biomass of the ultraphytoplankton in the Three Gorges Reservoir; (ii) to determine the concentration of photosynthetic pigments using HPLC to discover the algae community composition and to determine the dominant algal populations in different spatiotemporal and spatial conditions; and (iii) to illustrate the relationship between community structure and environmental factors of ultraphytoplankton by redundancy analysis. Therefore, this study provided Three Gorges Reservoir plant biodiversity research and eco-environmental management with baseline and basic data.

Methods

Sampling point setting

The Three Gorges Reservoir is an artificial channel lake formed after the completion of the Three Gorges Hydropower Station, which is located at east longitude 107°20'-111°02', north latitude 30°31'-30°20', through the provinces of Chongqing and Hubei in China. It covers 19 counties and cities in the Chongqing and Hubei Provinces, with a total area of 54,000 km^2. Based on the topographic features of the Three Gorges Reservoir, the degree of eutrophication, the status of the bloom, the level of nutrients, the hydrodynamic characteristics, and related literature research, the sampling points were determined as follows: we had a total of 26 sample sites, including 9 major tributaries of Chongqing, namely, the Tangxihe (TXH), Pengxihe (Xiaojiang, XJ), and Modaoxi (MDX) in Yunyang County, the Zhuxihe (ZXH), Caotanghe (CTH), and Meixihe (MXH) in Fengjie County, the Quma Town of Xiaojiang (QM) and KaiCoungty of Xiaojiang (KX) in Kai County, and Daninghe (DNH) in Wushan County and 6 tributaries in the Hubei reservoir area, including Shennong Creek (SN01-SN03) and Mianzhuxia (MZX) in Badong county, Xiangxihe (XX01-XX08) in Xiangxi County, and Yuanshuihe (YSH), Qingganhe (QGH), and Tong zhuanghe (TZH) in Zigui County, as well as the main stream of the Yangtze River (CJ01, CJ05). See *Figure 1* for details.

Figure 1. *Distribution of sampling sites in the Three Gorges Reservoir during 2014*

Monitoring frequency and sampling method

We chose two-month sampling, and the sampling time was from February to December of 2014. A total of 154 samples were collected from 26 stations each time (of which the stations XX08 in June and August were in dry season). Sampling on the 15th-17th of each month, and there were three replicates per site. A 1.5-L water sample was collected using a 5-L organic glass water sampler and was placed in a plastic bottle. Black plastic bags were then used to wrap the plastic bottles, and the samples were returned to the experimental station after the start of filtration. The water samples were passed through a 10-μm sieve, a 5-μm Millipore nuclear membrane, and a 0.7-μm GF/F (Whatman), successively. The sample films containing the ultraphytoplankton were prepared, wrapped with tin foil to avoid light exposure, and kept in liquid nitrogen.

Determination of characteristic photosynthetic pigment contents by HPLC

The sample processing method was as follows: the sample film was cut into 5 mm × 1 cm of debris and placed in a 2-mL Eppendorf tube. After adding 1 mL N,N-dimethylformamide (DMF) for pigment extraction and mixing, the extract was placed in the refrigerator at -20 °C for 40 min. The sample was then centrifuged for 5 min at a rotational speed of 4000 r/min, filtered with a 0.22-M filter membrane, and mixed with 1 M ammonium acetate solution with a volume of 1:1 for Infinity 1260 Series HPLC (Agilent, USA) analysis. The chromatographic separation was carried out on a C8 column (Zorbax Eclipse xdb-C8 4.6 × 150 m, 3.5 um, Agilent, USA) and a 36-min elution procedure.

According to a method in the literature (Li et al., 2015), the external standard method was used to carry out the quantitative analysis, the gradient elution program and the quantitative calculation formula reference (Hu et al., 2011). The identified photosynthetic pigments are as follows: alloxanthin (Allo), chlorophyll *b* (Chl-*b*), chlorophyll *a* (Chl-*a*), fucoxanthin (Fuco), lutein (Lute), neoxanthin (Neox), peridinin (Peri), violaxanthin (Viol), and zeaxanthin (Zeax). Combined with the single factor analysis of variance function in the statistical analysis software SPSS 17.0, the significance was analyzed.

DOI: http://dx.doi.org/10.15666/aeer/1705_1193511952

The community structure of the ultraphytoplankton

The data obtained in the field on the initial ratios of photosynthetic pigments and their concentrations were entered in the matrix of the CHEMTAX software to calculate the characteristics of the ultraphytoplankton community structure in the Three Gorges Reservoir. ANOVA was performed using SPSS 17.0 (Statistical Product and Service Solutions) software, and the significance of functional analysis was analyzed.

Analysis of environmental factors

The environmental and physical indicators of the study included 10 physical and chemical indicators for outdoor measurement, consisting of pH, water temperature (WT), air temperature (AT), transparency (SD), conductivity (SPC), Illumination-water (Illum-W), Illumination-air (Illum-A), Turbidity (Turbidity), and dissolved oxygen (DO), and 7 indoor measurements of water chemistry, consisting of total phosphorus (TP), total nitrogen (TN), ammonium salt ($N\text{-}NH_4^+$), phosphate ($P\text{-}PO_4^{3-}$), nitrate ($N\text{-}NO_3^-$), and chemical oxygen demand (COD). The physical and chemical indicators for outdoor measurement were mainly measured by YSI (dissolved oxygen meter), transparency disk, and photometer. The analysis and test methods of the indoor measurements of water chemistry mainly adhered to the "Surface Water Environmental Quality Standard - GB3838-2002".

Redundancy analysis of the relationship between environmental factors and community structure

If the results of the Monte Carlo test and environmental variables screened showed significant difference ($P < 0.05$), the relationship between environmental factors and the community structure of the ultraphytoplankton could be explained by the RDA analysis module. Ordination plots were made by CANOCO for Windows 4.5 software.

Results

Total biomass of the ultraphytoplankton

It is universally acknowledged that chlorophyll a content indicates the total biomass of the ultraphytoplankton. Therefore, the temporal and spatial distribution of the total biomass of the ultraphytoplankton was identified by analyzing the changes in the content of Chl-*a* at 26 sampling sites (*Fig. 2*).

The concentration range of Chl-a in the Three Gorges Reservoir area was 6.39-18,781.96 μg/m^3, In April, June, and August, the total biomass of the ultraphytoplankton was higher, with the highest value being 18,781.96 μg/m^3 (August; ZXH). In October and December, the total biomass was lower, and the lowest value appeared at the ZXH station in October. The Chl-a concentration of the ultraphytoplankton ranged from 6.39 to 12,704.99 μg/m^3 in the Hubei reservoir area. In April and June, the concentration of Chl-a was the highest, with the highest value at the XX07 station in April. The concentration of Chl-a was lower in October and December, with the lowest value at the ZXH station in October. The concentration range of Chl-a in the Chongqing reservoir area was 28.97-18,781.96 μg/m^3. The Chl-a concentration was higher in August, indicating that the total biomass was the largest, with the highest value at the ZXH site. Lower values were found in December, with the lowest value at the MXH site. Overall, the total biomass of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1193511952

ultraphytoplankton in the Hubei reservoir area was slightly higher than that in Chongqing reservoir area.

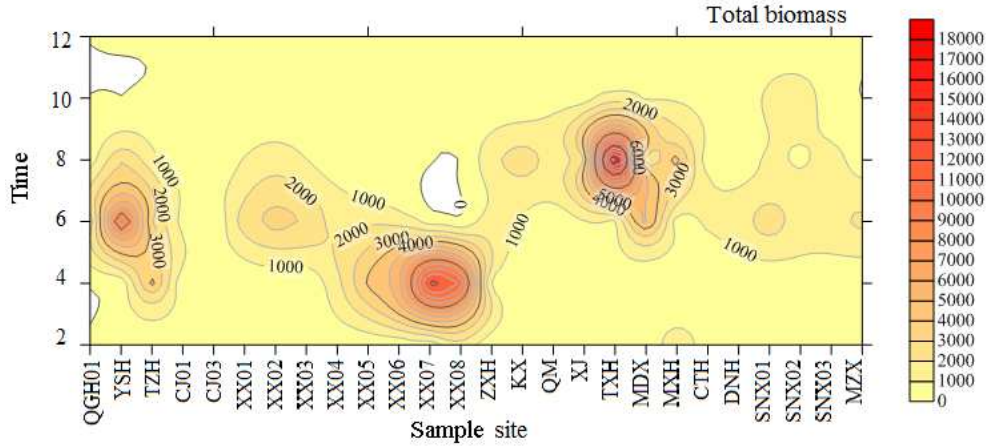

Figure 2. *Temporal and spatial changes of the total biomass*

By using the method of one-way ANOVA, the spatial and temporal differences are analyzed. The results showed that there was significant difference between June and December ($P < 0.05$), and there was no significant difference between the other months ($P > 0.05$). There was also no significant difference in total biomass with space ($P > 0.05$). Therefore, the total biomass is greatly influenced by time of year.

Types of photosynthetic pigments of the ultraphytoplankton

Based on HPLC technology, the photosynthetic pigment composition and content of the ultraphytoplankton in 26 stations in the main stream and tributaries of the Three Gorges reservoir area in 2014 were monitored, and their temporal, spatial, and distribution patterns were analyzed. The results showed that 8 special pigments of the ultraphytoplankton were detected in the Three Gorges Reservoir, including Fuco, Viol, Allo, Lute, Neox, Zeax, Chl-b and Chl-a. Among the target characteristic photosynthetic pigments, Allo, Zeax, Fuco, and Chl-b were the main photosynthetic pigments found in the ultraphytoplankton in the waters of the reservoir area. The total biomass of the ultraphytoplankton, indicated by the content of the Chl-a, has been discussed in the total biomass. The temporal and spatial distribution of the other seven photosynthetic pigments is as follows.

The temporal and spatial distribution of fucoxanthin is shown in *Figure 3A*. In April, the concentration of Fuco was higher, with an average of 534.07 μg/m^3. The highest concentration was 3,621.85 μg/m^3 at the XX08 site. In October and December, the concentration of Fuco was lower, with an average concentration of 13.69 μg/m^3, and the lowest concentration was 3.39 μg/m^3 at the QGH site. The Fuco concentration in the Hubei reservoir area was higher than that in the Chongqing reservoir area.

The temporal and spatial distribution of neoxanthin is shown in *Figure 3B*. In June, the concentration of Neox was higher, with an average of 25.38 μg/m^3 and a maximum of 158.63 μg/m^3 at ZXH. In December, the concentration of Neox was lower, with an average of 0.25 μg/m^3 and a minimum of 0.12 mg/m^3 at CJ03, while the Neox concentration in the Chongqing reservoir area was slightly higher than that of the Hubei reservoir area.

DOI: http://dx.doi.org/10.15666/aeer/1705_1193511952

The spatial and temporal distribution of violaxanthin is shown in *Figure 3C*. In June, the concentration of Viol was higher, with an average of 45.8 μg/m^3, and the highest concentration was 198.32 μg/m^3 at YSH. The concentration of Viol in December was lower, with an average of 0.41 μg/m^3, and the lowest value was 0.13 μg/m^3 at CJ01. Its distribution in space showed an obvious difference, while the Viol concentration in the Hubei reservoir area was higher overall than that of the Chongqing reservoir area.

The temporal and spatial distribution of alloxanthin is shown in *Figure 3D*. In April (average: 254.79 μg/m^3) and June (average: 259.64 μg/m^3), the Allo concentration was higher, with a maximum of 2,295.64 μg/m^3 (April; XX07). In December, the Allo concentration was lower, with an average of 10.44 μg/m^3 and a minimum of 0.75 μg/m^3 at the CJ03 site. The concentration of the Chongqing reservoir area was higher than that of the Hubei reservoir area.

The temporal and spatial distribution of lutein is shown in *Figure 3E*. In June, the Lute concentration was higher, with an average of 122.86 μg/m^3, and the highest value appeared at the KX site (851.37 μg/m^3). In December, the concentration of Lute was lower; its average was 1.34 μg/m^3, and the minimum value was 0.46 μg/m^3 at the CJ03 site. The concentration of Lute in the Chongqing reservoir area was higher than that in the Hubei reservoir area.

The temporal and spatial distribution of zeaxanthin is shown in *Figure 3F*. In August, the Zeax concentration was higher, with an average of 482.80 μg/m^3, and the highest value appeared at the ZXH site (5,214.18 μg/m^3). In December, the concentration of Zeax was lower; its average value was 1.98 μg/m^3, and the minimum value of 0.42 μg/m^3 was at the CJ03 site. The concentration of Zeax in the Chongqing reservoir area was significantly higher than that in the Hubei reservoir area.

The temporal and spatial distribution of chlorophyll b was shown in *Figure 3G.* In June, the Chl-*b* had the highest concentration, and its average was 1,927.22 μg/m^3. In December, the Chl-b had the lowest concentration, with an average of 2.05 μg/m^3. In February, the concentration of the Chl-b at sites XX08 and KX was 0 μg/m^3, and the concentration of the Chl-b in the Hubei reservoir area was higher than that in the Chongqing reservoir area.

Except for the Chl-*a*, the other seven characteristic photosynthetic pigments were analysed by a variance homogeneity test and single factor analysis of variance. The results showed that the contents of the photosynthetic pigments including Fuco, Neox, Viol, Allo, Zeax, Lute and Chl-b were significantly different ($P < 0.05$) with time, but there was no significant difference ($P > 0.05$) in the spatial variation.

The community structure rules of the ultraphytoplankton

The community structure rules of the ultraphytoplankton were shown in *Figure 4*, and the significant taxa of the ultraphytoplankton were *Diatoms, Euglenophytes*, *Cryptophytes* and *Chrysophytes* in different samples for the whole year. In February (*Fig. 4A*), the dominant populations were *Diatoms, Cryptophytes* and *Euglenophytes*. The sharp increase in the number of the *Diatom* phyla appeared at the XX08, TXH, MXH, and SNX01 sites; the sharp increase in the number of the *Cryptophyta* phyla appeared at the TZH, CJ01, XX05, KX, MDX and DNH sites. The rest of the site group structures showed more uniform changes. In April (*Fig. 4B*), *Cryptophytes* and *Diatoms* were the principal phyla from sites QGH to XX04, and the *Diatoms* were the dominant population at sites XX05 and XX06; the major phyla were replaced by *Cryptophytes* from sites XX07 to MZX. In June (*Fig. 4C*), the primary phyla was *Cyanobacteria,*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1193511952

Euglenophytes and *Diatoms*, and the rest samples did not have excessive changes of community structure. In August (*Fig. 4D*), the number of the *Euglenophytes* was higher than *Cryptophytes*. The community structure of each samples' change was obvious, and the major phyla were changed from *Cryptophytes* to *Euglenophytes*. Among them, the proportion of the *Diatoms* at the YSH site increased sharply, and the proportion of the *Cryptophytes* at the QM site increased sharply, while the proportion of the *Diatoms* at the MZX site decreased drastically. In October (*Fig. 4E*), the *Euglenophytes* accounted for 85% of the taxa at all samples except YSH. In December (*Fig. 4F*), *Euglenophytes* was the superior taxa, and the rest of the algae abundance was equal. However, *Cycanobacteria* were the significant taxa at ZXH, and *Chrysophytes* were the dominant taxa at MXH.

DOI: http://dx.doi.org/10.15666/aeer/1705_1193511952

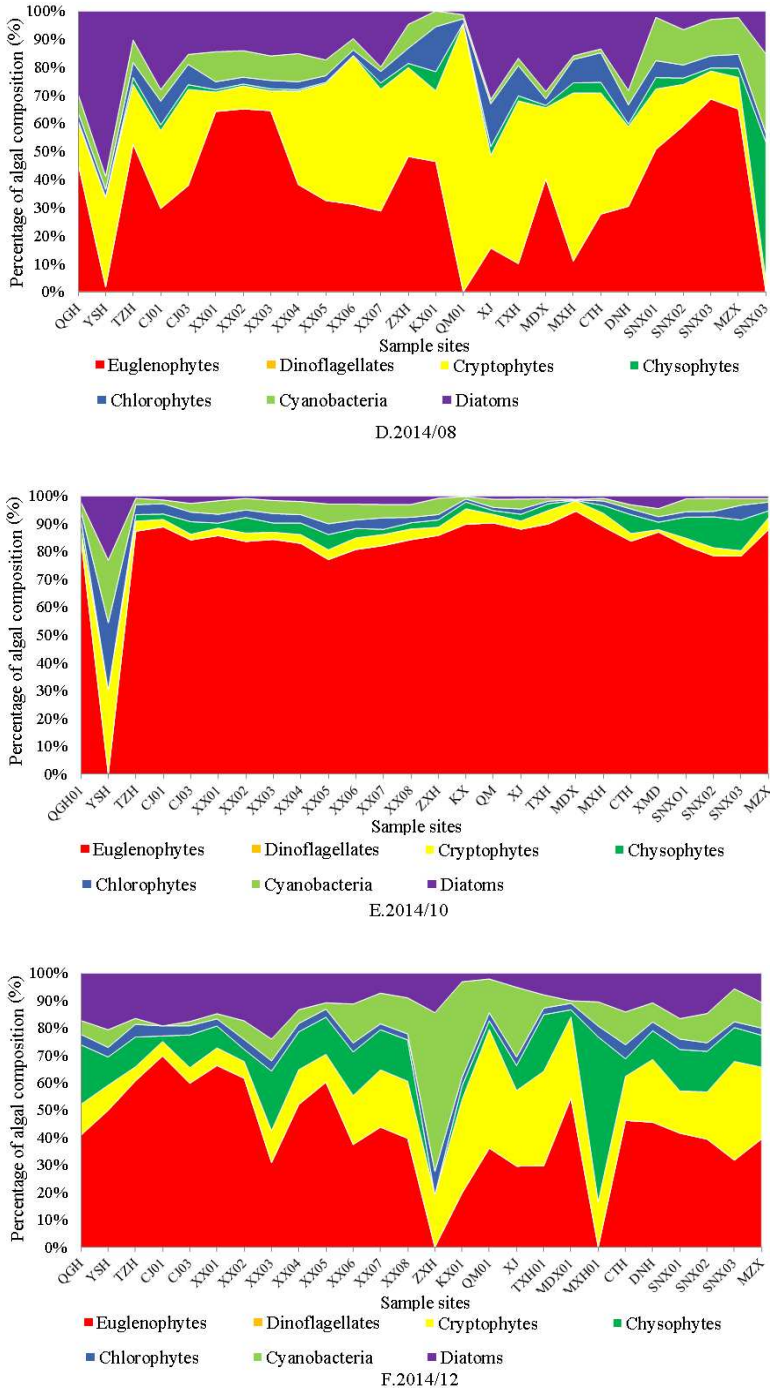

Figure 4. *Temporal and spatial variations of the ultraphytoplankton community structure*

The relationships of time and station were analysed by using the single factor variance of the ultraphytoplankton community structure of the Three Gorges Reservoir. The results showed that the community structure changes over time had significant differences ($P < 0.05$), and there was no significant difference in space ($P > 0.05$). Therefore, community structure was more influenced by the time. The investigation of time change was essential to the change of community structure.

Environmental responses of ultraphytoplankton

The relationships between the ultraphytoplankton community structure and environmental factors were investigated in the Three Gorges Project. The relevance was significantly different in the ultraphytoplankton community structure and environmental factors in February, April, June, and August ($P < 0.05$) rather than October ($P > 0.05$).

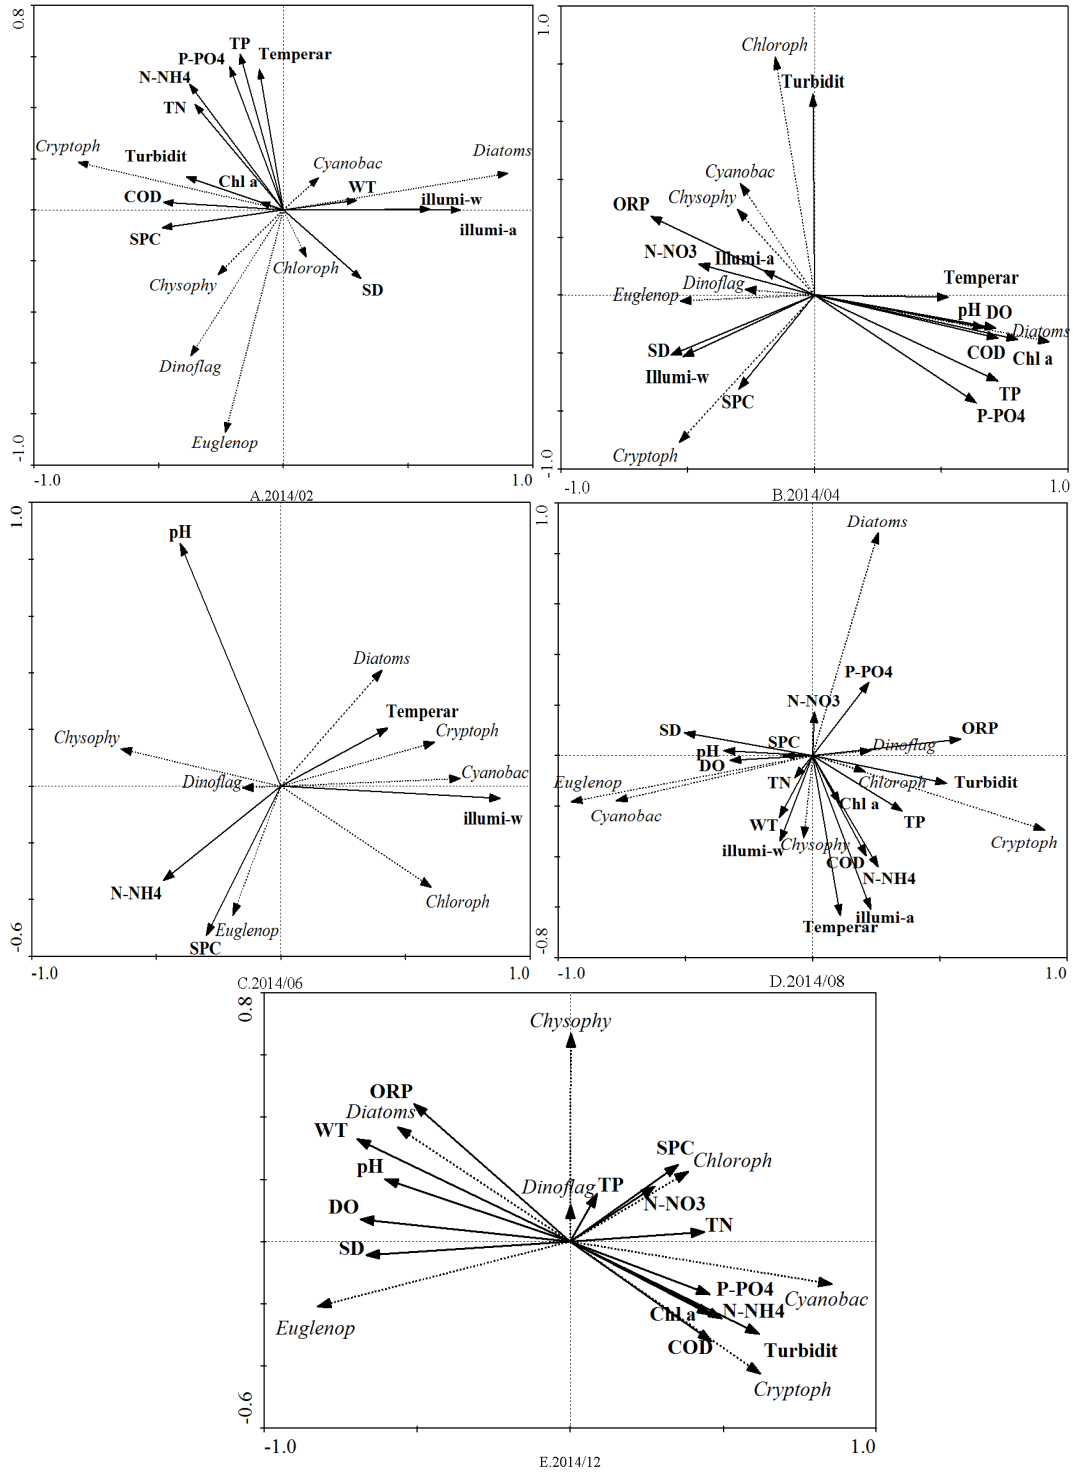

Figure 5. *RDA analysis of the relationship between environmental factors and the ultraphytoplankton phyla assemblages obtained by RDA*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1193511952

In February (*Fig. 5A*), the superior taxa of algae were *Diatoms* and *Cryptophytes*. Relevance analysis between the ultraphytoplankton community structure and environmental factors indicated that WT and illumination were the most important limiting environmental factor. The environmental factors had a significant negative correlation with *Cryptophytes*, and algal abundance had a significant positive correlation with *Diatoms*. In April (*Fig. 5B*), the principal phyla of algae were *Diatoms* and *Cryptophytes*. TP was the all-important limiting environmental factor. In June (*Fig. 5C*), the primary phyla of algae were *Cyanobacteria* and *Chysophytes*, and relevance analysis between the ultraphytoplankton community structure and environmental factors indicated that pH and Iillumi-w were the most vital limiting environmental factor. In August (*Fig 5D*), the superior taxa of algae were the *Euglenophytes* and *Cryptophytes*. Relevance analysis between the ultraphytoplankton community structure and environmental factors indicated that DO and SPC were the most essential limiting environmental factor. In October, pre-screening and Monte Carlo tests found that it was unsuited to RDA analysis ($P > 0.5$). In December (*Fig. 5E*), the primary phyla of algae was *Euglenophytes*. RDA analysis showed that SD and DO were the most considerable environmental factor.

Discussion

Studies have shown that there is a positive correlation between the biomass of phytoplankton and the content of the Chl-a (Alvarez-Fernandez and Riegman, 2014). In this study, the Chl-*a* of the ultraphytoplankton was used to represent the biomass, and the Chl-*a* concentration of the ultraphytoplankton (< 5 μm) ranged from 6.39 μg/m^3 to 18,781.96 μg/m^3. It had also been found in earlier research (Silva et al., 2009) that the contribution rate of the ultraphytoplankton of total phytoplankton was 0.2-99.7%. Instead, the contribution rate of the ultraphytoplankton in fresh water was in the low. In keeping with the distribution of the Chl-*a* in the Three Gorges, the biomass of the ultraphytoplankton in April, June, and August were higher than other months, and it reached the maximum in August. Therefore, August probably developed into the outbreak period of the ultraphytoplankton. Liu et al. (2017) have found that the total chlorophyll a content of ultraphytoplankton was higher in the Xiangxi River Basin of the Three Gorges Reservoir in April and August, which is consistent with the results of this study. The research, which was put forth by Xiang Yingchun in 2014, had shown that, during 2011 and 2014 at the ZXH site, every month showed eutrophication. In conclusion, monitoring the change of the ultraphytoplankton biomass could be used to assess environmental status.

Studies (Wright, 1991; Li et al., 2013) have shown that the characteristic pigments only presented in a group of specific phytoplankton, and the distribution in different groups were different, reversed-phase high-performance liquid chromatography was used to analyse the pigment composition of algae, and then a certain mathematical method was used to calculate the ratios of characteristic pigments to the Chl-a, by which the specific phytoplankton contribution to the total biomass could be indicated, and the abundance and composition of a population could be determined. By using high-performance liquid chromatography to detect target waters, eight characteristic photosynthetic pigments were detected, including Fuco, Allo, Viol, Zeax, Neox, Lute, Chl-*b,* and Chl-*a*. After analysis, we found that Fuco, Zeax, Allo, and Chl-*b* were the most important characteristic photosynthetic pigments of the ultraphytoplankton in the Three Gorges Reservoir in 2014,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1193511952

it had also been found in earlier research (Chen et al., 2003) that the most important characteristic photosynthetic pigments of the ultraphytoplankton in marine were Fuco, Allo and Chl-b, however, Zeax and Lute were hardly found. The temporal and spatial differences in photosynthetic pigments indicated that the temporal and spatial distribution of the ultraphytoplankton populations (Li, 2014), which said that it was more important to correspond to the community of *Cryptophytes*, *Diatoms*, *Euglenophytes*, *Chrysophytes* and other algae populations in the Three Gorges the ultraphytoplankton during 2014. However, the ultraphytoplankton in the marine are mostly *Chlorophytes*, *Synechococcus*, and *Cyanobacteria* (Li, 1995; Chen et al., 2003).

By using HPLC-CHEMTAX technical analysis, we showed that the changes of the ultraphytoplankton community structure in time and space were different. The dominant populations throughout the whole year were *Euglenophytes*, *Diatoms*, *Cryptophytes*, and *Chrysophytes*. *Chlorophytes*, *Cyanophytes*, and *Dinoflagellates* appeared in lower proportions. This is consistent with the results of Li (2014) and Liu et al. (2017). It shows that Euglenophytes, Diatoms, Cryptophytes and Chrysophytes are the dominant species of Ultraphytoplankton in the Three Gorges Reservoir. Special attention should be paid to February, April and June, as in these three months, dominant populations accounted for a large proportion, more than 50%, easily leading to the outbreak of the ultraphytoplankton blooms. Therefore, a deeper observation and positioning investigation of these months could provide powerful data support for the Three Gorges Reservoir water environment improvement to change the ecological environment in the future. Previous reports (Huang and Huang, 2002) showed that *Cryptophytes* were the dominant phyla in water with high organic matter content and nutrient abundance. Similar phenomena were observed in the Three Gorges Reservoir area throughout the study period, and *Cryptophytes* were widely distributed in February, April, and August. Generally speaking, *Diatoms* prefer to live in an environment with high concentration of nitrates (Liu et al., 2012). According to the annual nutrient level, there was no significant difference in time, except for October, which may be the main reason for the lowest proportion of *Diatoms* in October. In 2014, the *Euglenophytes* occupied a dominant position, especially in the fall, present as high as 80%. Most of them live in a fresh water rich in organic matter, which was an indicator of water pollution. The results showed that it is highly likely that ultraphytoplankton *Euglenophytes* blooms will occur in October.

The succession of phytoplankton is influenced by environmental factors. Based on earlier research about lakes and reservoirs, it was reported that in a poor nutrition system, TP < 0.01 mg/L and TN < 0.2 mg/L, and in a rich nutrition system, TN > 0.5 mg/L and TP > 0.02 mg/L (Peng et al., 2013). The minimum contents of TN and TP were 1.58 and 0.02 mg/L, respectively, in 2014, which showed that the Three Gorges Reservoir area water environments all were of a rich nutrition system. The study of the typical tributaries upstream of the Three Gorges Reservoir area and streamwise nutritional status analysis made by Zhang et al.(2010), showed that the content of TN ranged from 0.58 to 1.67 mg/L, while the content of TP ranged from 0.005 to 0.133 mg/L, the rich nutrition system was not changed. In contrast, the content of TN and TP in the Three Gorges branches and mainstream were significantly higher.

In this research, the relationship between the ultraphytoplankton community structure and environmental factors was not significant ($P > 0.05$) in October, showing that the ultraphytoplankton community structure was weak and affected by environmental factors in this month. The relationships between the ultraphytoplankton community structure and environmental factors were significant ($P < 0.05$) in the other

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1193511952

five months. The analysis of RDA showed that the most important environmental factors impacting the ultraphytoplankton community structure included illumination (including illumination in air and underwater illumination), TP, and temperature (including air-temperature and water-temperature). These results were the same as another survey (Gonçalvesaraujo et al., 2012), which studied environmental factors influencing algae. Research (Alam et al., 2016) reported that the main limiting factors of phytoplankton growth were nutrients in the water. In these nutrients, TP was the most effective limiting factor to affect the growth of phytoplankton in fresh water, and because of its shape and concentration, can affect the metabolism process of phytoplankton cells. Studies (Sunda and Huntsma, 1997; Siegel et al., 2002) have shown that the correlation between the content of the Chl-*a*, algal cell density, and illumination, and the correlation between illumination and photosynthesis; the results confirmed that illumination was one of the controlling factors of algae growth. The reason was that sufficient illumination was the first condition of phytoplankton growth. The population structure, growth of phytoplankton, and succession of phytoplankton were directly determined by competition, adaptation, light resistance and light of the water environment. The study found that temperature was the most basic condition to control phytoplankton growth and those different groups of phytoplankton have different requirements of temperature (Zhang et al., 2010). In short, this paper discussed the relationships between the ultraphytoplankton distribution and environmental factors in the Three Gorges Reservoir and we should pay more attention to the effects of illumination, temperature and total phosphorus.

Conclusions

By using HPLC-CHEMTAX technical analysis, 8 types of characteristic photosynthetic pigments and 7 divisions of algae phyla of the Three Gorges Reservoir were quickly detected in 2014. The main types of the ultraphytoplankton in the reservoir were *Euglenophytes*, *Chrysophytes*, *Cryptophytes*, and *Cyanophytes*. During the study period, the Three Gorges Reservoir is a eutrophic water body, and the biomass of the ultraphytoplankton in the Hubei reservoir area was higher than that in the Chongqing Reservoir area. The characteristics of the structure and succession of the ultraphytoplankton community were mainly influenced by illumination, total phosphorus, and temperature. The results provided the basic data for the study of phytoplankton biodiversity and ecological environmental monitoring of the Three Gorges Reservoir.

Abstract. This experiment used molecular marker technology to analyse high sugar genes, clone the target bands and the Random amplified polymorphic DNA (RAPD) molecular markers were converted into Sequence characterized amplified regions (SCAR) molecular markers, and additionally 120 RAPD primers were used to analyse female 3228B (sweet sorghum), paternal 3201B (ordinary sorghum) and their hybrids F_5. The results showed that 95 of 120 pairs amplified products, 25 of them did not amplify products, so the amplification rate reached 79%. The recombination rate of S512 and high sugar genes was 7% in F5 populations. S512 amplified polymorphic bands were recovered, cloned and sequenced, its band length was 441bp. According to the sequence, we transferred the RAPD to SCAR molecular markers and designed SCAR primer. We got the same amplification results with the RAPD in specific amplification progress of sweet sorghum F5 populations, thus the RAPD transfered to SCAR successfully, we called this $SCAR_{S512-441}$.
Keywords: *Random amplified polymorphic DNA (RAPD), Sequence characterized amplified regions (SCAR), amplification, molecular marker, coseparation analysis*

Introduction

Sweet sorghum (*Sorghum bicolour* (L.) Moench) is a variation of common sorghum (Vermerris, 2011), it has a strong resistance, high sugar content, high photosynthesis rates, high productivity, is one of the most important energy plants in the world (Wang et al., 2013; Lu et al., 2013). Sweet sorghum can applied in animal feed and brew as an energy plant, and produce syrup, making sugar. Research shows that the brix of sweet sorghum stems have high heritability, showing great effects on breeding variety (Zhang et al., 2011). We take Liao Tian 6 as a benchmark, the sugar brix of Liao Tian 6 is 18, the sugar brix higher than 18 are regarded as high sugar content. Studies show sugar brix traits of culms of sweet sorghum, is controlled by two major gnes add polygenes (Lu et al., 2012). And sugar contents characters were not a single gene, but have unbalanced multigenes besides a major gene (Wang et al., 2010). As biological research gradually entered the molecular level, molecular marker are more widely used, including germplasm resource research and breeding (Yang et al., 2016). Base on the application of DNA sequence polymorphism, Molecular Marker can mainly divided into three categories: (1) Includes restriction fragment length polymorphism marker and chromosome in situ hybridization marker with molecular hybridization at core. (2) Includes amplified fragment length polymorphism marker and sequence point marker with PCR reaction at core. (3) New molecular marking technique, includes single nucleotide polymorphism marker and expressed sequence tag. It has more advantages which sequence characterization amplified region marker based on RAPD of new molecular technology (Wu et al., 2016). It can overcome the shortcomings of high false

negative and lacks of repetition that translate the specificity band generated by RAPD marker into SCAR marker (Luo et al., 2013; Wang et al., 2016).

At present, SCAR is used a lot in breeding. In resistance gene marker research, anoectochilus roxburghii polymorphic RAPD marker have been developed based on 20 anoectochilus roxburghii germplasm resource, and transforming specific band into SCAR marker, identify its specificity. Use SCAR marker gene to identify the resistance effect of Soybean anthracnose resistance gene (Gu et al., 2011). Transfer RAPD marker which closely-linked with aphid resistance gene to SCAR marker, and make SCAR determinations to F_3 and some resistant varieties (Li et al., 2003), specific bands of F_3 resistant individual obtained. This experiment aimed to make a RAPD molecular marker analysis to experimental populations, find a RAPD primer related to sweet sorghum's high sugar gene, and give target band cloning and sequencing, then translated into stable SCAR marker, reduce the complexity of field farming, establish the theoretical foundation for choosing fine sweet sorghum variety (Tan et al., 2013; Li et al., 2016).

Materials and Methods

Plant material

Sweet sorghum 3228B (as the female parent in this study) and common grain sorghum 3201B (as the male parent) were supplied by Liaoning Academy of Agricultural Sciences. We created F_5 plants from the cross of 3228B ×3201B, and get total of 100 lines. We get the first leave under the fag leaf of the F_5 plants as plant materials. These sorghums have the same genetic background, and the marker which identify the sugar content.

Experiment methods

DNA extraction of seedling stage

Methods apply modified cetyltrimethylammonium bromide (CTAB) (Li et al., 2009; Lan et al., 2015) to extract DNA of male parent, female parent and F_5 plants.

DNA determination

① Concentration measurement: absorbance of the diluted DNA were measured in different detecting waves which are 230nm, 260nm and 280nm.

② Electrophoresis detection: 0.7% Agarose gel's preparation in ready: point sample, electrophoresis.

Build near isogenic pool

We use Bulked Segregation Analysis (BSA) (Yao et al., 2010) to analyze high sugar population and low sugar population. High sugar bulk: Take 1 μl of DNA of 62 varieties of high sugar content sorghum. Low sugar bulk: Take 1 μl of DNA of 38 varieties of low sugar content sorghum.

Build RAPD-PCR reaction system and condition

25 μl reaction system: which established by 25 mmol/L MgCl2 2.0 μl, 10 × Buffer 2.0 μl, 10 mmol/L dNTPs 1.5 μl, 10 μmol/μl primer 1.0 μl, 5 U/μl Taq enzyme 2.5 μl,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1195311962

DNA template (100 ng) 2 μl, and add ddwater to 25 μl. Reaction conditions: 94ºC Initial denaturation 5 min → (94ºC denature 20 s → 50ºC Primer annealing 30 s → 72ºC Primer extension 70 s) 35 cycles → 72ºC extension 10 min → 4ºC storage.

Build SCAR-PCR reaction system

Reaction system: which established by 10 × Buffer 2.5 μ, 10 mmol/L dNTPs 1.0 μl, 25 mmol/L MgCl2 2.5 μL, 5 U/μl Taq enzyme 0.25 μL, 10 μmol/μL S512F 0.5 μl, 10 μmol/μL S512R 0.5 μl, DNA template 1.0 μl (100 ng), and add ddwater to 25 μl. Reaction conditions: 96ºC Initial denaturation 5min → (94ºC denature 1 min → 50ºC Primer annealing 50 s → 72ºC Primer extension 1 min) 35 cycles → 72ºC extension 10 min → 4ºC storage.

Detection of PCR reaction products

① 1.4%Agarose gel's preparation.
② Electrophoresis of PCR product.

Recovery of target band

We sterilize the needle and cut a few times at the polymorphism bands, then put the needle into RAPD-PCR reaction system, repeat this procedure several times and recovery the amplified different bands.

Co-segregated Analysis

Recombination rate (r) = Commutative number/ (High sugar population number + Low sugar population number) ×100% (Wang, 2004).

Genetic distances (cM) = [1/4*ln(1+2r)/(1-2r)]*100.

Marker map (Figure 1)

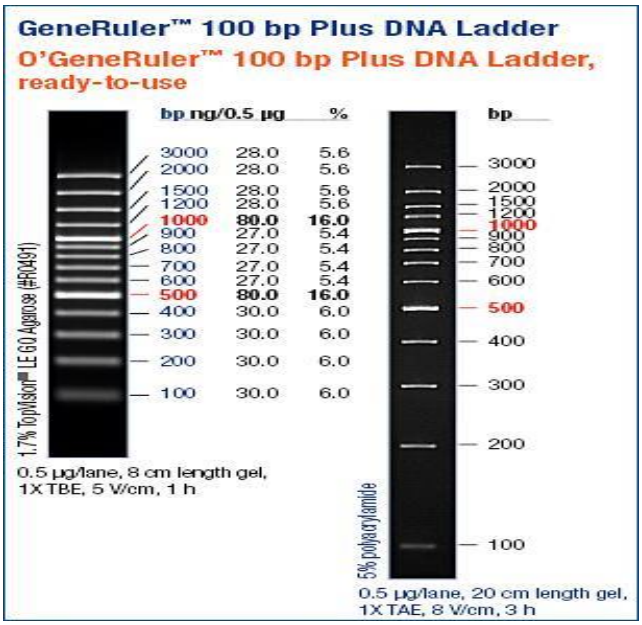

Figure 1. *100bp ladder marker*

Results and Analysis

Purity analysis of DNA

The electrophoretic pattern as shown in *Fig. 2* is total DNA extracted by improved CTAB method. As seen in *Fig. 2*, these bands are clear and without degrade. Purity and concentration of the DNA which was measured with ultraviolet spectrophotometer show that $OD_{260}/OD_{230} \geq 2.0$, $OD_{260}/OD_{280} \geq 1.7$-1.8, further explain, extracted DNA under these conditions can be used in subsequent RAPD- PCR experiment analysis.

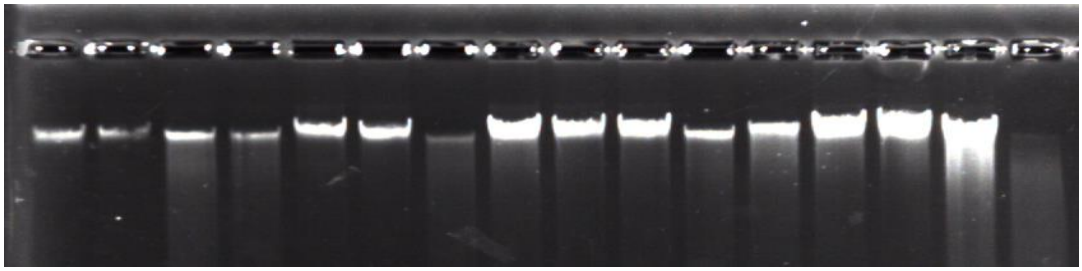

Figure 2. *DNA electrophoresis gel results. Female parent (1) Male parent (2) High sugar individual (3-9) Low sugar individual (10-16)*

RAPD-PCR analysis of sweet sorghum high sugar gene

In this study, with a random selected 120 RAPD primer, the RAPD molecular markers were used to analyze the Sweet sorghum (as the female parent in this study), common grain sorghum (as the male parent), high sugar gene bulk and low sugar gene bulk. The results show that the amplification rate is 79%, 95 primers were amplified bands and 25 primers can not ampliy bands. Most of the primers can amplify more than 6 bands, primer S504 amplify the largest bands, but with low quality images. There was no obvious difference among high sugar gene bulk, low sugar gene bulk and the parents. Primer S506 ampliy 7 bands which are the clearest, and there are also with no obvious difference among high sugar gene bulk, low sugar gene bulk and the parents. Primers S507 have differences between parents and high sugar gene bulk or low sugar gene bulk. Primer S509 amplify the least bands and the bands haven't differences. The amplification results see in *Fig. 3*.

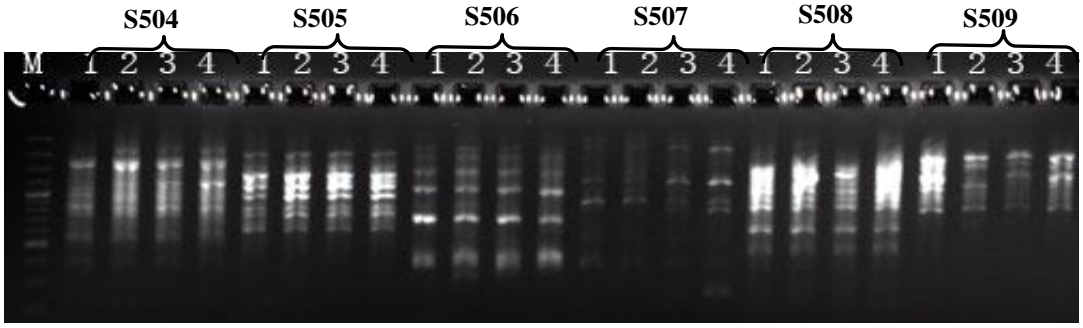

Figure 3. *The PCR-RAPD amplification results of primer S504, S505, S506, S507, S508, S509. Female parent (1) Male parent (2) High sugar gene pool (3) Low sugar gene pool (4) Marker (M)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

Amplification result of primer S510-S513 showed that bands are amplified by 4 primers. The bands amplified by primer S510 showed high polymorphisms between female parent (1) and male parent (2) and have high definition, but there is no polymorphism between high sugar gene bulk (3) and low sugar gene bulk (4) Only one band amplified by primer S511 and unclear. The bands amplified by primer S513 are clear but there are no polymorphism different bands among parents, high sugar gene bulk and low sugar gene bulk. The bands amplified by primer S512 is clearest, and have different bands between the female parent (sweet sorghum) and high sugar gene bulk, but there are haven't different bands between the male parent (common grain sorghum) and low sugar gene bulk, this different bands located at 450bp (*Fig. 4*), Therefore, our study will continue PCR detection and cosegregation analysis of the primer S512 which is the clearest.

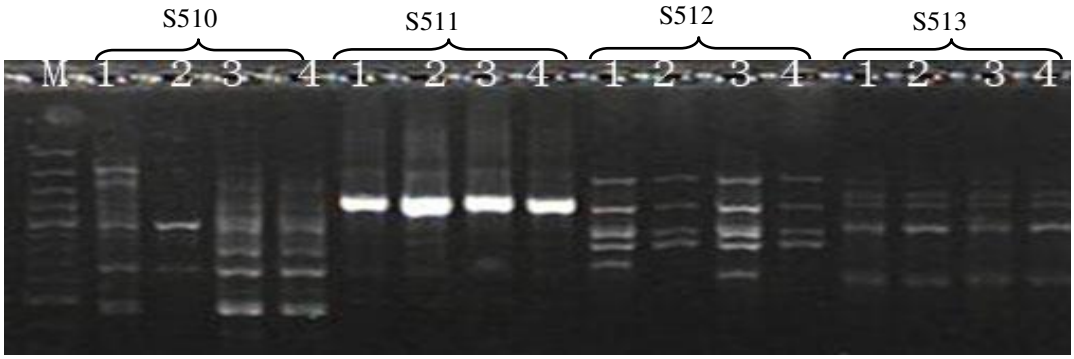

Figure 4. *Amplification results of primer S510, S511, S512, S513. Female parent (1) Male parent (2) High sugar gene pool (3) Low sugar gene pool (4) Marker (M)*

RAPD polymorphism's cosegregation analysis of high sugar gene of sweet sorghum

RAPD-PCR amplification results of the primer S512 in individual

By comparing the individual plant amplification results of parents, high sugar group and low sugar group, we reach that the bands amplified between female parent (sweet sorghum) and high sugar individual by primer S512 are more than the bands between male (common grain sorghum) and low sugar individual (*Fig. 5*).

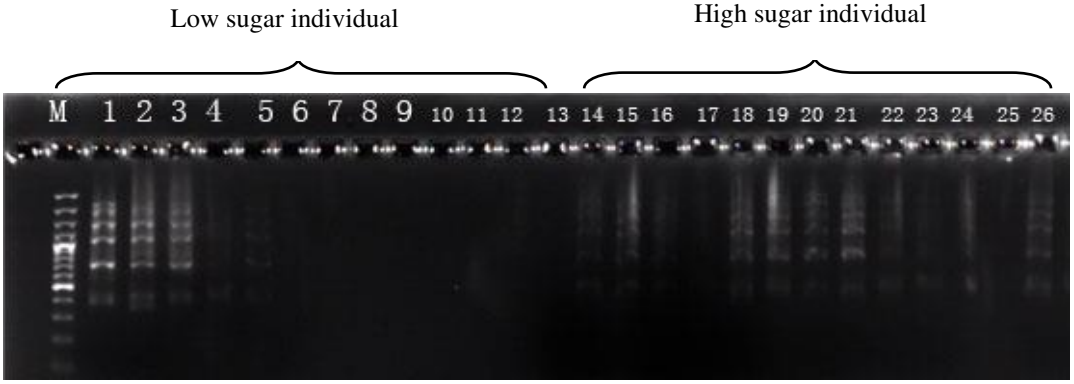

Figure 5. *The single plant amplification results of primer S512. Low sugar individual (1-13), High sugar individual (14-26), Marker (M)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1195311962

Recombination rates analysis

To observe the amplification results of high sugar individual and low sugar individual by primer S512, we get 58 individuals were amplified polymorphism bands and 4 individuals not be amplified in high sugar bulk, and 3 individuals amplified polymorphism, 35 individuals not be amplified, the recombination rate is 7% (*Table 1*). Recover the amplified fragment in the end.

Table 1. *Co-segregation of the S512-441 amplified polymorphic fragment in F_5*

F_5	**Total plants tested**	**Polymorphic fragment**		**Percentage of recombination %**
		Present	Absent	
High sugar	62	58	4	7%
Low sugar	38	3	35	

Recover and clone sequencing of polymmorphism marker

Recover target bands

Recover the difference bands amplified by primer S512, the results of recovery showed that the bands is the same as the target band, both are 450bp (*Figure 6*).

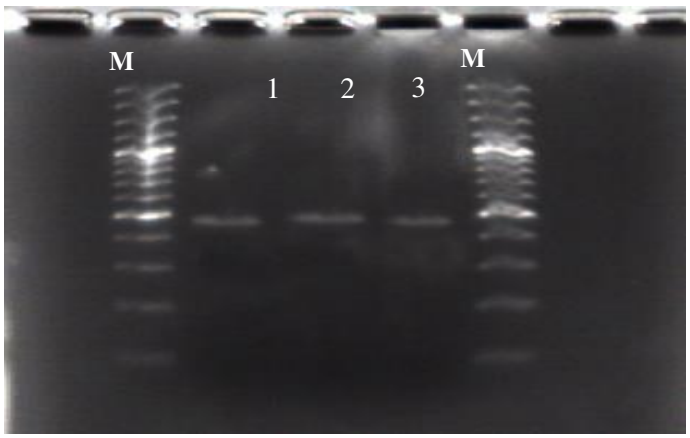

Figure 6. *Recovered fragment of primer S512 (1-3)*

Cloning and sequencing

Cloning and sequencing were given to the recovery difference bands, and results showed the fragment is 441bp.

Transform RAPD molecular marker to SCAR marker

RAPD primer design

Basic sequence and primer design principles of specific primer S512, adding G+C base pairs and designed as follows specific primers sequence ends while avoiding hairpin.

DOI: http://dx.doi.org/10.15666/aeer/1705_1195311962

SCAR-PCR response analysis

Above designed specific primer S512 were used to amplify the parents and two sets of individuals in SCAR-PCR. Results show that SCAR marker the same as RAPD marker of high sugar gene's chain reaction of sweet sorghum F_5. Both female parent (sweet sorghum) and high sugar individuals are amplify a specific band at 450bp (*Fig. 8*), but male parent (common grain sorghum) and low sugar individuals haven't this specific band. It shows that SCAR marker is easy to distinguish and has strong specificity, so we can transform RAPD marker to stable SCAR marker successfully, named this marker $SCAR_{S512\text{-}441}$ depending on the sequence results.

Conclusion

In this experiment, 120 RAPD primers selected at random, the RAPD techniques were used for molecular marker of experimental population to find the RAPD primer related to high sugar gene of sweet sorghum. In recent years, there are great achievements in fruit varieties identification, hybrid identification and mutant detection, construction of molecular genetic maps, gene map, gene diversity and pedigree analysis

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1195311962

through RAPD technology (Li et al., 2018). Because of RAPD marker's poor stability and repeatability, it's difficult to use in crop genetic breeding and assistant selection. We clone and sequence target band, to get good stability and high reproduction SCAR marker. The primer used by SCAR marker is longer than RAPD marker and the primer sequence completely complement with template DNA. To get good stability and high reproduction results, we should better amplify in rigorous conditions (Xiong et al., 2010).

Random selecting 120 RAPD primers, analyzing sweet sorghum (female parent), common grain sorghum (male parent), high sugar gene bulk and low sugar gene bulk by the RAPD marker. The result showed that 95 primers could produce bands, 25 primers could not produce bands, amplification rate is 79%. Because of the bands amplified by primer S512 is the clearest, we observe the results of high sugar individual and low sugar individual amplified by primer S512. In high sugar population, 58 plants amplified polymorphic bands, 4 plants haven't amplified, but in low sugar population, 3 plants amplified polymorphic bands, 35 plants haven't amplified, amplification rate is 7%, genetic distances is 7.5CM. Recovering polymorphic bands of PCR production amplified by specific primer S512 and cloning and sequencing. SCAR specific primers were designed.

S512F: 5'-ACAGGTGCGTACATCGAATG-3'.

S512R: 5'-TTACAGGTGCGTTAATTGCC-3'.

Transfer RAPD marker to SCAR marker, named $SCAR_{S512\text{-}441}$. Be compared with $SCAR_{S336\text{-}1119}$, it is a new SCAR marker which fragment length is shorter, and optimize the SCAR marker's reaction system.

Discussion

We can see that it is low efficiency that transfer RAPD marker to SCAR marker. The cause may be: (1) When designing primers, often contain corresponding 10 base RAPD primer. Because of the original polymorphism can be detected. Even as the increases of amplification's stability and success rate, the transformation of RAPD primers was still affected. (2) Transform specific fragment of RAPD to SCAR attention must be paid to primer design length and PCR reaction condition (for instance, when the anneal temperature is constant, the anneal time and extend time should not be too long). (3) Take many factors into consideration, for instance, base sequencing of sequence's head and tail is instability, annealing temperature of specific transform RAPD to SCAR marker primer, the design of primer in SCAR transformation is closer to the medium of sequence, instead of start at both ends of sequence. However, in practical operations, because of these factors, in alone or in combination, the transformation efficiency of transform RAPD marker to SCAR is reduced. These errors should be minimized (Kula, 2012; Li et al., 2014; Liu et al., 2016).

Using identified high sugar population and low sugar population to test SCAR marker closely linked sweet sorghum's high sugar gene. It has great significance to apply it in practice, and use this marker in high sugar gene variety test.

This experiment optimized optimal reaction system and reaction conditions of RAPD molecular markers and optimal reaction system of SCAR marker, recovery polymorphic bands of PCR product amplified by specific primer S512, and cloning and sequencing. Polymorphic bands linked to sorghum F_5 high sugar gene length of 441bp. The RAPD

marker were converted into SCAR marker, which named $SCAR_{S512\text{-}441}$. Hope to find out more SCAR marker to identify sorghum with high sugar content in the future.

Acknowledgements. The research was partly supported by key project of Liaoning Province Department of Education (2019) and Major incubating project of Shenyang Normal University.

Abstract. Rural settlements are not only the main form of Chinese farmer residence, but also a space for rural production, living as well as other comprehensive functions, being an important part of rural land use. The impact of rural settlement changes on soil and water conservation is studied as it is of great significance for soil and water conservation. Based on the satellites of Xinbin County in 1992, 2001 and 2010, this study analyzes the distribution characteristics of rural settlements by using ArcGIS software spatial analysis function and landscape index method. At the same time, SPSS software is used to analyze the correlation between soil erosion and the size of rural settlements. The results show that soil erosion is positively correlated with rural settlement size and population density. The rural residential areas in Xinbin County are severely fragmented with scattered layout. Soil erosion shows a decreasing trend while increasing in distance from settlements. The bigger the scale, the more serious the erosion.
Keywords: *soil erosion, landscape index, rural habitat, ecological protection, China*

Introduction

Rural settlements are the most significant form of human settlement (Zhou et al., 2013). It has a footprint that interacts with the surrounding social economy, the natural environment and the people. Its layout, form and scale have undergone several major changes (Xi et al., 2018; Yang et al., 2016; Yang, 2015). Although Chinese urbanization level has been greatly improved (Chaolin et al., 2017), the agricultural population quantity is still large. In the future, rural settlement lands will still be an important part of Chinese rural-urban construction land use. Meanwhile, it is still the main form of living for rural populations. There is no overall planning for the layout of rural settlements in most parts of China. Besides, the lack of effective supervision and management of the land result in the spatial layout dispersal (Chen, 2017; Guo et al., 2012). The rural residents have always chosen their settlements spontaneously. Due to the limitations of traditional culture and the natural environment and in order to facilitate the production of farming, the distribution of rural settlements is very fragmented in the mountain areas. This form of layout not only makes it more difficult for farmers to travel, but also negatively affects the natural ecological environment of the mountainous areas, especially the water conservation function in there. The Liaodong mountainous area refers to the mountainous and hilly areas

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1196311977

of 32 counties in the eastern part of Liaoning province, China, including the counties of Benxi, Fushun, Anshan, Tieling and Dandong. As the main water source conservation area and green barrier area in the Liaohe Plain, the Liaodong mountainous area provides 83% of the province's water supply. The mountainous areas of eastern Liaoning should not only meet the current needs of people for production and life, but also offer ecological security and water resources for the future economic development of Liaoning Province. The third remote sensing survey of soil erosion in Liaoning Province shows that the soil erosion area in the mountainous areas of eastern Liaoning was 1626.27 km^2, accounting for 25.2% of the total area, 35% of the total area of soil erosion in the province. This indicates that there are still potential threats to the water conservation function in the mountainous areas of eastern Liaoning. As one of the important water conservation areas, the areas of eastern Liaoning, Xinbin County where its residents are active is the source of the Hunhe River and belongs to the mountainous area (Ma et al., 2014; Ying, 2017). Therefore, both the protection of water conservation functions by increasing natural vegetation and the adverse effects of human activities on water conservation caused by the layout of rural settlements should be considered. This paper analyzes the distribution features, landscape pattern and soil erosion characteristics of rural settlements in Xinbin County (Christensen et al., 2016; Remmel et al., 2017). From a unique perspective, the influence of the evolution of rural settlement landscape pattern on water conservation function is explored. Based on the discussion of the soil erosion status and the spatial characteristics of residential distribution in the three time periods of Xinbin County, this paper researches the distribution features of residential areas affecting soil erosion, and discusses the coupling relationship between rural residential area distribution and water and soil erosion. Through this study, it provides a scientific basis for optimizing the layout of rural residential areas in ecological protection areas and promoting regional water resources protection.

Methodology and data

Research method

Using four methods – the fusion classification, supervised classification, partition classification and visual interpretation, the SPOT and Landsat data are extracted by ENVI4.5 and ArcGIS software (Maguire, 2015; Ju et al., 2016; Ke, 2016).

Based on the land use data of Xinbin County, the superposition analysis is carried out with the support of ArcGIS software. The landscape index are selected at the plaque level (Rodríguez-Loinaz et al., 2015; Chen et al., 2018), including number of plaques (NP), total plaque area (TA), area-weighted average plaque fractal dimension (AWMPFD), plaque density (PD), average plaque area (MPS) and dispersion (RC). Then, Fragstats 3.3 software is used to calculate the landscape index. Finally, SPSS software is used to analyze the correlation between soil erosion and rural settlement size, the structure of the rural settlements and population density (Green et al., 2016; Cronk, 2017).

Data source and processing

Data source

The research data is derived from the data of Landsat5TM in 1992, 2001 and 2010 of Xinbin County with a resolution of 30 m × 30 m, socio-economic data, the map of the status quo of 110,000 land use and the 1:10,000 topographic map. Among them, remote sensing data mainly uses 3 and 4 bands of data (Ying, 2017).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1196311977

Data processing

First, the 3-band and 4-band images are imported into ENVI4.5 software. Second, the Vectors option in the Overlay menu is selected to overlay the boundaries of the study area onto the image. Finally, the ROI Tool in the Region of Interest in the Tools menu and the Subset Data are selected via ROIs option in File in its dialog box, and the Background Value is set to 0, then is saved in a new folder. The other two data are processed in the same way. Next, normalized difference vegetation index (NDVI) and vegetation coverage (VFC) are calculated.

Before calculating NDVI (Gandhi et al., 2015), images of band 3 and band 4 need to be compressed into a layer. The specific operation process is open the 3 and 4 band image in ENVI 4.5 software and Layer Stacking is selected in Basic Tools. Then the dialog box of Layer Stacking Parameters appears. The Import Files button is clicked to output the 3 and 4 band image images, and then they are named. When the results are output, they should be saved in a fixed folder.

Next NDVI is calculated. The specific process is: import the image map of the compressed surface reflectivity into ENVI4.5 software, select band math in the Basic Tools drop-down menu. Input formula (*Eq. 1*), assign 4 channels of surface reflectivity to NIR, assign 3 channels of surface reflectivity to R, then name the output and save the result.

Using NDVI values, vegetation coverage is calculated by *Equation 2*.

$$NDVI = \frac{NIR - R}{NIR + R} \quad \text{(Eq.1)}$$

$$VFC = (NDVI - NDVI_{\min}) / (NDVI_{\max} - NDVI_{\min}) \quad \text{(Eq.2)}$$

Making slope maps and soil erosion maps

The DEM data is obtained from the spatial analysis tool of ArcGIS software to obtain the slope map (Allen, 2016).

According to the soil erosion index *Table 1*, the soil erosion map is obtained using the decision tree in ENVI software (Segatori, 2017). The map is shown in *Figures 1, 2* and *3*.

Table 1. *Ministry of Water Resources soil erosion indicators*

Vegetation coverage (%)	Slope					
	< 5°	5°~8°	8°~15°	15°~25°	25°~35°	> 35°
> 75	Microdegree	Microdegree	Microdegree	Microdegree	Microdegree	Microdegree
60-75	Microdegree	Light erosion	Light erosion	Light erosion	Middle degree	Middle degree
45-60	Microdegree	Light erosion	Light erosion	Middle degree	Middle degree	Serious erosion
30-45	Microdegree	Light erosion	Middle degree	Middle degree	Serious erosion	Very intensive
< 30	Microdegree	Middle degree	Middle degree	Serious erosion	Very intensive	Severe erosion

Rural settlement data processing

Combined with the overlay module in ArcGIS software, the rural settlement attribute data is superimposed with the elevation and slope related attribute data to calculate the spatial distribution characteristics of the rural settlement (Murasingh et al., 2018; Conrad et al., 2015). The number of rural settlements is measured using statistical data, combined with field surveys. The field research is mainly carried out on-site verification of the population data in the form of a symposium in 2013 to correct the statistical data. According to the density of rural settlements, the distance and mutual influence between rural settlements are considered. Then, the analysis of rural settlements is buffered. A buffer at a distance of 1000 m is created. The rural settlements in each buffer form a composite map that is considered to be the same rural settlement unit.

The composite rural settlement unit is spatially superimposed with four different distances of soil erosion. The four ranges are less than 1000 m, 1000 to 2000 m, 2000 to 3000 m, and 3000 m or more. The erosion of the four distance segments will be obtained. The soil erosion map of three years and four distances is shown in *Figures 4*, *5* and *6*.

Results and analysis

Analysis on the quantity structure of rural settlements in Xinbin County

According to the analysis, at the end of 2010, Xinbin County had a total rural population of 219,805, with a total rural settlement of 6705.7 hm^2 and a per construction land area of 305 m^2/person, exceeding the 150 m^2/person specified in China's "Village and Town Planning Standards" (GB50188-93). In other words, the intensive land consolidation in Xinbin County is not enough, which means there is great potential for consolidation. The largest rural settlement area is Yongling town with 939.88 hm^2, followed by Xinbin town of 732.88 hm^2. While the smallest is Xiangshuihezi Township, which is 207.32 hm^2. The township with the largest per capita area is Muqi town with 431.3 m^2/person. The smallest is Wangqingmen Town with only 227.32 m^2/person. The largest population is Yongling Town, with 27,854 people. The least one is Hongsheng Town, with 7464 people. The rural settlement appears as a single entity on the map, not contiguous. The map is severely fragmented, and it is in a dilapidated state with a scattered layout.

Analysis of spatial distribution landscape index of rural settlement

According to *Table 2*, it can be seen that the number of plaques in Yongling Town is the highest, that is, 473, indicating a high degree of fragmentation. The least is Xiangshuihezi Township, which is 97, showing that its rural settlement is relatively complete. The total area of plaque in Yongling Town is 940 hm^2 while the smallest is Xiangshuihezi Township, which is 207 hm^2. The average plaque area in Nanzamu Town is the largest, which is 3.07 hm^2/per, representing that the average land use size of rural settlements is large. The average plaque area of Muqi Town is the smallest, 1.97 hm^2/per, indicating that the average land use size is small. In terms of plaque density, Muqi Town is the largest one, with 0.51 number/hm^2, which indicates that the degree of fragmentation in Muqi Town is higher. The density of plaques in Nanzamu Town and Xiajiahe Town is the smallest, 0.33 number/hm^2, showing that Nanzamu Town and Xiajiahe Town are relatively complete. Beisiping Township has the largest dispersion, which is 3.98. That implies that the distribution of rural settlements in there is scattered. Yongling Town has the smallest dispersion, suggesting that the rural

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1196311977

settlements in there are densely distributed. The main reason is affected by the self-sufficient economy in rural areas. In order to obtain the food needed for subsistence, farmers must have a certain amount of cultivated land. Especially in the mountainous areas of eastern Liaoning, the cultivated land resources are scarce. For the facility of farming, the scattered distribution of rural residential areas is an inevitable form. Townships with small rural settlements include Yongling Town, Xinbin Town and Nanzamu Town, which are located at the bottom of the main river and its tributaries. These places are low-lying and flat places. To a certain extent, the dispersion of rural settlements is a reflection of the impact of human activity intensity on landscape structure. Usually, if the average plaque area of the artificial landscape is small, the number of plaques will be less. Therefore, the greater the degree of separation is done, the plaque is dispersed. The separation between the natural landscape and the semi-natural landscape is small, mainly because the distance between the same plaques is short or concentrated.

Table 2. *Landscape index table of rural settlements land in towns and villages of Xinbin County*

Administrative unit	Coordinate	NP (number)	TA (hm^2)	MPS (hm^2/per)	PD (number/hm^2)	RC	AWMPFD
Beisiping town	125°10′E, 41°47′N	109	236	2.17	0.46	3.98	1.1369

Related studies have shown that the rural settlements as artificial plaques have greater stability and small fractal dimension, and the formed plaques are not prone to change. This leads to an increase in the heterogeneity of the natural plaque landscape around it. The fractal dimension is larger than the artificial plaque, and the landscape tends to be unstable. The area-weighted average patch fractal dimension represents the complexity of the margin of land-use plaque at a certain research scale, generally between 1 and 2. The closer the value is to 1, the stronger the self-similarity of the plaque. The smaller the ratio of the length to the axis, the more regular the shape of the plaque, and the shape of the plaque is close to a circle or a square. This shows that the greater the degree of human interference. Because plaques formed by human interference are generally more regular in shape, similar plaque shapes are prone to occur. The larger the value of the area-weighted average patch fractal dimension, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1196311977

larger the ratio of the length to the short axis. At the same time, the more complex the shape of the plaque, the narrower the geometry of the plaque and the less interference it receives (Cheng, 2016; Yang et al., 2018). The weighted average patch fractal dimension of rural settlement areas in Xinbin County is below 1.16, which is close to 1. This is because the rural settlement plaque belongs to the artificial landscape plaque, the plaque shape is relatively regular, close to the square, and the stability is strong. Xinbin Town has the smallest area-weighted average patch fractal dimension of 1.1034. The largest in Hongmiaozi Township is 1.1419. The values of rural towns and villages are all below 1.5, indicating that these rural township settlements are not in a random state similar to Brownian motion but in a steady state.

Analysis of spatial distribution landscape index of rural settlement

This paper selects soil erosion to reflect the water conservation status of the study area.

Analysis of current situation of soil erosion in Xinbin County

It can be seen from *Table 3* that at present, the farmland erosion is the most serious with the total erosion area of 37,768.73 hm^2. The severe erosion is 472.75 hm^2, accounting for 1.25% of the farmland. The proportion of middle degree erosion in farmland is 49.33%. The least eroded is the unutilized land. This means that measures must be taken to control soil erosion. If the treatment effect on soil erosion is good, such a large proportion of eroded land will decrease. It will convert into light erosion land. From the perspective of the total erosion area, the woodland is second behind the farmland, with an area of 3457.33 hm^2. This is because Xinbin county has a relatively large coverage of forest land. The excessive base and the artificial interference in the woodland have caused the erosion area. Being located in the mountainous area, protecting the water and soil means protecting the forest land in Xinbin county.

Table 3. *Soil erosion status statistics within 1000 m in rural settlements in 2010*

	Farmland (hm^2)	**Woodland (hm^2)**	**Grassland (hm^2)**	**Garden land (hm^2)**	**Unutilized land (hm^2)**
Light erosion	3148	15152	340.42	213.11	10.64
Middle degree	18634.05	13129	786.51	262.49	15.12
Serious erosion	12232.64	4853.6	415.2	96.84	8.35
Very intensive	3281.29	1263.4	100.75	25.67	1.76
Severe erosion	472.75	175.33	17	4.73	0

Relationship between soil erosion and rural settlement distance

From *Table 4*, soil erosion was the most severe in 2001 during the three periods, with an erosion rate of 57%. The soil erosion in 2010 was the lightest with an erosion rate of 39.87%. Ranking in the middle place, the soil erosion rate in 1992 is 55.34%. From the point of view of the buffer zone of 1000 m, it was also the most severe erosion in 2001, with an erosion of 39.06%. The rate in 1992 was similar to that in 2001. Compared with 2010, the soil erosion in these two periods was more serious. Because the rural settlement in these two periods had a low degree of concentration and a more dispersed distribution. At the same time, the degree of land use was also low, making erosion

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1196311977

more serious. Afterwards, with the improvement of living conditions and the guidance of policies such as the revitalization of the Chinese government, the concentration of rural settlement increased, the average plaque area grew, and the intensity of human activities rose, but the density of plaques became larger. The degree of utilization has been improved, and soil erosion has been alleviated to some extent, therefore, the soil erosion rate is lower in 2010 than that of the other two years.

Table 4. *Statistical table of soil erosion at different distances in three time periods*

Years	Distance/m			
	< 1000	**1000-2000**	**2000-3000**	**> 3000**
Erosion rate in 1992	38.49%	12.44%	2.20%	2.21%
Erosion rate in 2001	39.06%	12.81%	2.39%	2.74%
Erosion rate in 2010	21.26%	16.59%	1.79%	0.23%

The soil erosion in the three time periods is gradually decreasing as the distance from the rural settlement increases. This shows that the distribution of rural settlements has a certain impact on soil erosion. Taking 2010 as an example, the erosion rate is 21.26% within 1000 m, and the erosion rate is 16.59% from 1000 to 2 000 m. Because human activities are dependent on land. The closer the rural settlement is, the greater the intensity of human activity, thereby, the erosion is more serious.

Relationship between erosion intensity and rural settlements structure

Table 5 shows the landscape index under different erosion intensities, that is, the different structure of rural settlements under different erosion intensities. Based on the data in *Table 5*, the grey correlation analysis of erosion intensity and the rural settlement structure was carried out by using spss16.0 software, and *Table 6* was obtained. It can be seen from *Table 6* that there is a correlation between soil erosion intensity and the rural settlement structure. The degree of correlation is AWMPFD > PD > NP > RC. From the positive effects of correlation degree, the correlation between AWMPFD, MPS, NP, RC and the soil erosion intensity are positive. In other words, the larger the above indicators, the greater the soil erosion intensity. The larger the value of NP and RC means that the activity range of farmers in the area is large, so the intensity of soil erosion will be severe. The more extensive the farmers use the land, the stronger the interference, and the more regular the shape of the rural settlements, the greater the erosion intensity. From the negative effects of correlation degree, the PD has a negative correlation with soil erosion intensity. The larger it is, the smaller the soil erosion intensity. As the PD value increases, the number of settlements per unit area increases, and the intensive use of land means that the soil erosion intensity may be lower.

Relationship between soil erosion and population density

Arcgis9.3 is applied to compound the map spots of Xinbin county into 33 composite map spots. Through this operation, *Table 7* is obtained. Three of these different patches are eliminated. Correlation and regression analysis use spss16.0. Through this operation, *Table 8* is obtained. *Table 8* shows when the confidence (unilateral) is 0.01, the correlation between population density and erosion area is significant and positively correlated. Because human activities, such as farming and cutting, have aggravated the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1196311977

loss of water and soil, making the erosion area larger. In the protection of water and soil, human influence must be considered.

It can be seen from *Table 9* that there is no relationship between soil erosion intensity and population density. And among the 30 plots, almost every plot has the largest area of middle degree erosion intensity.

Relationship between soil erosion and the size of rural settlements

In the same way, the spss16.0 software is used to analyze the correlation between soil erosion and the size of rural settlements. The results show that soil erosion is highly correlated with the size of rural settlements and is positively correlated. This means that the greater the size of the rural settlement, the more serious the erosion. Therefore, rural settlements should be determined to a reasonable scale to prevent soil erosion. Spss16.0 is applied to analyze the correlation between rural settlement size and erosion grade (severe erosion as a percentage of erosion area). The results show that the erosion intensity is not related to the size of the settlement. This suggests that the larger the rural settlement, the more serious the erosion, but the erosion intensity is not necessarily severe.

Discussion

In terms of the features of the rural settlement itself, the rural settlement area gradually decreases with the elevated altitude. Among them, the rural settlement with the elevation of 121-345 m is the largest, accounting for 50.33% of the total area of rural settlements. There are no rural settlements above 734 m. The land use and spatial distribution of rural settlements are influenced by both natural and human factors. Generally, mountainous and hilly areas are significantly affected by natural geographical factors (altitude, slope, aspect, etc.) (Li-Bang et al., 2018; Guo et al., 2012). From the statistics of the rural settlement area at different altitudes within the entire rural settlement, it can be seen that with the rise of altitude, the scale of rural settlements is getting smaller and smaller. The population density is small, and the spatial distribution of rural settlements is random (Yang et al., 2016). According to the results of the slope analysis, the rural settlements in Xinbin county are mainly distributed on the flat land of 0°-5° and hilly-sloppy lands of 8°-15°. Its rural settlement area accounts for 21.25% and 28.55% of the total rural settlement area of the county. Ren (2017) also pointed out in one of his articles. The spatial distribution of rural settlements showed some spatial orientation to low altitude and to low slope, and were significantly close to rivers and towns; thus formed a special pattern of “dense on the plains, and sparse in the mountainous region” (Ren, 2017). However, in the Xinbin county, there are still a large number of peasants living in areas with slopes greater than 15°, which increases the difficulty of ecological management. For such rural settlements, ecological migration should be considered.

From the perspective of landscape pattern analysis (Wenzhi, 2016), Xinbin county, located in the mountainous area of Liaodong, is affected by various natural and social factors, especially the long-term self-sufficient lifestyle and topographical factors that result in insufficient per capita arable land (Zhou et al., 2013). The situation of rural residential areas in the county include the following aspects: the average plaque area of the landscape features is small; the number of plaques is large; the per capita land area exceeds the standard; the average phenotypic fractal dimension is small, and most townships are small in scale. This reveals that the plaque has a certain stability and dispersion. It is the scattered landscape pattern of rural settlements and the stability of the county as artificial landscape patches, which makes the area of human disturbance to the surrounding natural ecological environment expand continuously, and the fragmentation of natural landscape patches is bound to intensify. This leads to an increase in soil erosion and destruction of the ecological environment in a small area.

In addition, when the confidence level is 0.01, the soil erosion in the study area is significantly correlated with the size and population density of the rural, and it is a positive correlation. The erosion intensity is not related to the size of the settlement. This shows that the larger the rural settlement, the more serious the erosion, but the erosion intensity is not necessarily severe, and human activities will increase the erosion area. Therefore, the distribution of rural settlements must reach a reasonable scale to maximize economic and ecological benefits. At the same time, the study found that soil erosion showed a decreasing trend with increasing distance (Gan et al., 2014), because human activities need to rely on the land. In the place closer to the rural settlement, the greater the intensity of human activity, the more serious the erosion. From the perspective of rural settlement structure, erosion intensity is positively correlated with NP, RC and AWMPFD. This shows that the more dispersed the rural settlements, the more extensive the use, the more human disturbance, the stronger the erosion intensity.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1196311977

On the contrary, PD is negatively correlated with soil erosion intensity, which indicates that the more the rural settlements gather, the higher the utilization degree, the lower the erosion intensity. Therefore, it is necessary to consider improving and strengthening the spatial agglomeration of rural settlements, thereby reducing the intensity of soil erosion.

The spatial distribution characteristics of rural settlements reflect the relationship between human production, life and its surrounding environment under different productivity levels. The landscape pattern of rural settlements and its dynamic changes affect many environmental factors, such as water and soil conservation, topography and so on. How to change the landscape pattern and spatial distribution of the current rural settlements in Xinbin county and even the entire Liaodong mountainous area, so that its ecological environment protection is in the most reasonable state? One of the most effective ways is to study the landscape pattern of rural settlements and its distribution characteristics, namely ecological migration.

Conclusion

Rural settlements are places where people live and move in mountainous areas. The denser the distribution of settlements, the greater the intensity of people's activities. The rational distribution of rural settlements will contribute to soil and water conservation in the region. Otherwise, it will aggravate soil erosion. At present, the layout of rural settlements in China is relatively poor. The analysis of the rational distribution of rural settlements does not consider the impact of the distribution of rural settlements on soil erosion. This paper takes Xinbin county, Liaoning province, China as an example, using remote sensing technology, ArcGIS and Fragstats 3.3 softwares. Based on the remote sensing satellite and land use status map, the landscape pattern of residential area distribution and soil erosion status in three time periods are analyzed. Via the correlation analysis method, the relationship between the distribution characteristics of rural settlements and soil erosion is quantitatively analyzed. The following is the main conclusion.

(1) In general, the proportion of rural settlement land use in Xinbin county is relatively small. The MPS of rural residential patches is small, the degree of land use is not high, the degree of separation is high, and the distribution of settlements is scattered and chaotic, mostly distributed along rivers and traffic roads.

(2) In three periods, soil erosion was the most serious in 2001, with an erosion rate of 57%; in 2010, soil erosion was the least, with an erosion rate of 39.87%. The intermediate soil erosion rate in 1992 was 55.34%.

(3) Soil erosion is positively correlated with population density and the size of rural settlements. However, the intensity of erosion is not related to the size of the settlement. Soil erosion shows a decreasing trend with increasing distance. From the perspective of rural settlement structure, erosion intensity is positively correlated with NP, RC and AWMPFD. On the contrary, PD is negatively correlated with soil erosion intensity.

Acknowledgments. The study is supported by the Fund Project of Shaanxi Key Laboratory of Land Consolidation (2019-ZD05).

Abstract. Hydrogen and oxygen stable isotopes are natural tracers and have played an important role in the investigation of hydrological processes. In this paper, year-round precipitation samples were collected and measured in Chengdu, a subtropical monsoon climate region, to compare the stable isotope characteristics in precipitation and their influencing factors between dry and wet seasons. The results showed that the seasonal variation of δD and $\delta^{18}O$ in precipitation was significant, and the isotopic values in precipitation in dry season were more enriched than those in wet season. The slope and intercept of local meteoric water line (LMWL) in Chengdu were lower than those in the southeast monsoon region of China but higher than those in north China, indicating the combined influence of ocean-source and inland water vapor. The slope of LMWL in dry season was obviously lower than that in wet season, revealing more intense sub-cloud secondary evaporation. The effect of temperature and precipitation was not significant in both seasons. Meteorological variables had greater influence on precipitation isotopes in wet season. D-excess had greater fluctuation during the dry season, reflecting more complex water vapor sources, which resulted in the influence of meteorological factors being masked.

Introduction

As an important part of natural material circulation, water circulation is the link connecting biosphere, atmosphere and hydrosphere. In the study of modern water cycle, hydrogen and oxygen stable isotopes in water bodies can provide a lot of information which is difficult to obtain by traditional hydrological methods due to its sensitive response to climate and environmental changes (Goller et al., 2005; Xie et al., 2011; Wang et al., 2017; Cai et al., 2017; Badaluta et al., 2019). Atmospheric precipitation is an important process of water circulation and a recharge source for rivers, lakes and groundwater. The stable isotopes in precipitation are affected by meteorological conditions, regional geographical position and weather patterns, and usually have a certain spatio-temporal variation law. Therefore, understanding the characteristics of stable isotopes in precipitation can help to understand the processes of water cycle and their feedback mechanism (Celle-Jeanton et al., 2004; Zhang et al., 2005; He et al., 2006). In 1961, the International Atomic Energy Agency (IAEA) and the World Meteorological Organization (WMO) collaborated to establish the Global Network of Isotopes in Precipitation (GNIP) to measure stable isotope data in global precipitation, and more than 800 monitoring sites have been established around the world. Since the 1960s, a large number of studies have been carried out around the world to reveal the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1197911993

variation characteristics of stable isotopes in precipitation of different climate types. For example, Guan et al. (2013) sampled and tested the event and intra-event samples of precipitation, and revealed the influence of synoptic weather system and water vapor source on precipitation isotopes in Flinders, an Australian Mediterranean climate region; Balagizi et al. (2018) reported the isotope values in Virunga, an African tropical climate region with strong evaporation, and suggested that the vapor from soil-plant evapotranspiration and that from lake surface evaporation are main causes of the depleted and enriched isotope compositions during wet and dry periods, respectively; a systematic study of stable isotopes was carried out on Crimean Peninsula, a region with different climate types, and temperature were proved to be the major factor correlated with the isotope values (Dublyansky et al., 2018).

Monsoon climate is widely distributed in the world. In the monsoon climate zone, monsoon is an important carrier of water vapor transport, and controls the spatial distribution and seasonal variation of precipitation. The change of the monsoon's onset time and intensity makes the amount and temporal distribution of precipitation in the monsoon region very uncertain, leading to the frequent occurrence of droughts and floods, which has a great impact on human production and life. Therefore, understanding the law of monsoon activities is of great significance to social and economic development. In recent years, many researchers have revealed the influence of monsoon on local meteorological conditions and water vapor source of precipitation by analyzing the stable isotope composition in precipitation in different monsoon regions around the world. For example, Pang et al. (2006) found that Lijiang is mainly controlled by large-scale India Depression System on the weather scale in summer by analysing the $\delta^{18}O$ data in summer daily precipitation. Srivastava et al. (2015) implemented the early detection of the onset of monsoon by measuring the hydrogen and oxygen isotope compositions in atmospheric water vapor and precipitation in Ahmedabad, India. Peng et al. (2016) found that seasonal wind flow is the main factor affecting Yilan area in northeast Taiwan by analyzing the stable isotope compositions of precipitation and river water, and semi-quantitatively estimated the contribution ratio of air masses from different sources to river water volume. Xia et al. (2019) analyzed the monthly accuracy data of 15 stations provided by GNIP, and obtained the relationship between monsoon flow in Asian tropical monsoon region and isotopic composition in precipitation in different seasons. Qu et al. (2018) compared the isotopic characteristics and meteoric water lines of plum and typhoon rain, two typical precipitation types in monsoon region, and determined the relationship between isotopic composition and transport path and water vapor source.

Chengdu is located in southwest China and belongs to subtropical monsoon climate zone. During the wet season, the East Asian monsoon and the Indian monsoon meet here, bringing water vapor from the western Pacific and Indian Ocean; during the dry season, this area is controlled by the northwest monsoon from the high latitude inland. Due to the influence of the complex monsoon system, the stable isotope ratios in precipitation are significantly different between dry and wet seasons. Wu (2009) obtained the LMWL of Chengdu by analyzing precipitation isotope data of monthly accuracy from 1986 to 1998 provided by GNIP, and preliminarily analyzed the influence of precipitation, temperature and water vapor pressure on isotope compositions. However, the isotope data from GNIP is extremely limited, and those of monthly accuracy cannot reflect the variation characteristics of stable isotopes in precipitation at the weather scale. There is a lack of research on stable isotope in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1197911993

precipitation in this region. In this study, we collected and measured the stable isotope samples in precipitation during the dry and wet seasons in Chengdu in 2018, recorded local meteorological parameters, and discussed the effects of environmental factors and water vapor sources on the precipitation isotopes during the two seasons. The results of this paper will help to understand the atmospheric circulation and transport processes of water vapor in the southwest subtropical monsoon region of China, and provide isotopic evidence for studying the hydrological cycle mechanism in this region.

Material and methods

Study area

Chengdu, one of the largest cities in southwest China, located in the west of Sichuan Basin and the middle reaches of Minjiang River, is bounded by Longquan Mountain in the east and Qionglai Mountains in the west. Its altitude range is 398~4906 m. Chengdu has a subtropical humid monsoon climate with mild climate, distinct seasons and abundant rain. The long-term distribution characteristics of average monthly precipitation and temperature from Chengdu City Data Site of China Weather Network (www.weather.com.cn) are shown in *Fig. 1(a)*.

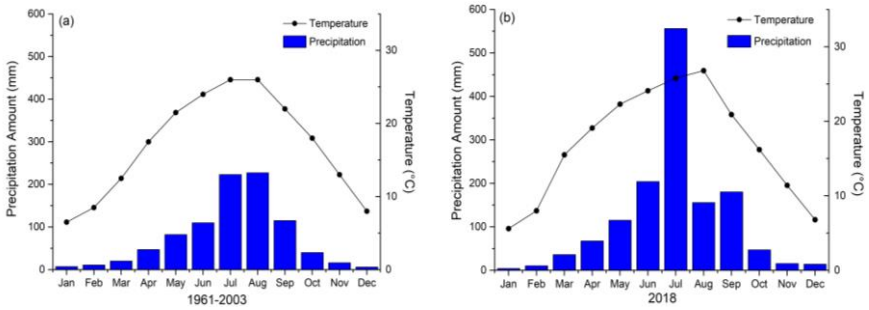

Figure 1. *Monthly precipitation and average temperature in Chengdu in 2018*

The highest and lowest monthly average temperature occurred in August and January, and the largest and smallest monthly precipitation occurred in July and January, respectively. According to the monitoring data provided by Chengdu Public Meteorological Service Website (http://pcc.scqx.gov.cn/sc_cd/fwcp/qhpj/), the average monthly temperature and precipitation in Chengdu in 2018 are shown in *Fig. 1(b)*. In 2018, although the variation trends of temperature and precipitation amount correspond to the multi-year average in Chengdu, the total annual precipitation shows a distinct high value of 1407 mm, which can be attributed to the extremely large precipitation amount in July. The cumulative precipitation from June to September was 1096.9 mm, accounting for 77.96% of the total, and that in other months was 310.1 mm, accounting for 22.04% of the total. According to the temporal distribution of precipitation, June to September was divided into wet season and other months into dry season in Chengdu.

Sample collection and analysis

The sampling point for precipitation was located at the platform test site of the College of Water Resources and Hydropower, Sichuan University (104.08 °E, 30.63 °N, 553 m). This point is far away from local pollution sources and there are no tall

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1197911993

buildings or trees blocking around. The geographical location of the sampling points is shown in *Fig. 2*. According to the IAEA/GNIP precipitation sampling guide, a simple water collecting device was set up: a plastic cylinder with a diameter of 50 mm and a height of 75 mm was fixed on the ground, with a PE plastic film covered above for collecting water; a 500 mm rain collecting bottle was placed in the cylinder, which connected with a funnel with a diameter of 15 mm and a table tennis ball was placed in the funnel to prevent evaporation. After a precipitation event, the rainwater was collected into a 20 mL plastic bottle, and then placed in a refrigerator for cold storage. The meteorological data (i.e. temperature, precipitation amount and relative humidity) during the precipitation were recorded according to the real-time measurements from Tiaosanta weather station, which is about 1 km away from the sampling site. The samples were collected and analyzed in an event precision, and multiple rainfalls occurring in one day were recorded as independent events respectively. The starting and ending times of an individual event are determined based on whether the rainfall intensity is greater than 0.1 mm/h. A total of 113 precipitation samples were collected in 2018, including 59 for wet season precipitation and 54 for dry season precipitation.

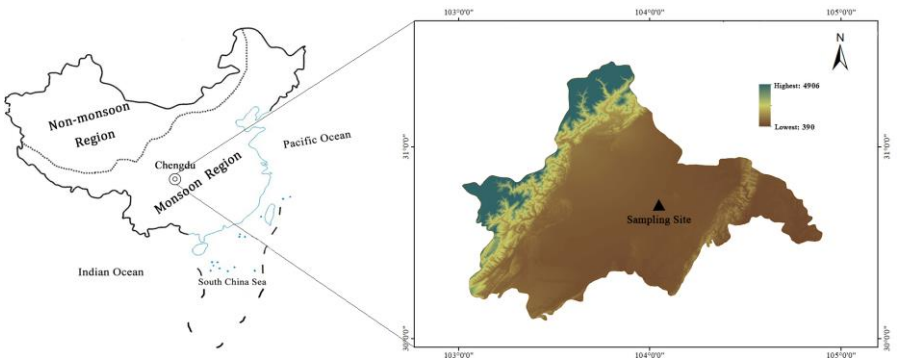

Figure 2. *Location of the study area and sampling site*

The samples were analyzed in College of Water Resources and Hydropower, Sichuan University, using the Triple-Liquid Water Isotope Analyzer produced by Los Gatos Research (LGR). The LGR analyzer uses spectrometry to measure stable isotope content in water and the measurement principle is OFF-AXIS Integrated Cavity Output Spectroscope (OA-ICOS). With the cooperation of a full-automatic sampler, the analyzer measures the samples automatically and continuously according to a computer program. Precipitation samples were filtered using 0.45 μm filter membranes before measurement. Each sample was measured for six times and the first two measurements were rejected for their larger deviation from the actual value. Reference standard samples based on VSOMW-2 and SLAP-2 were measured at an interval of three precipitation samples to diagnose whether abnormalities occur during the measurement. The measurement results are expressed as per mil (‰) deviation from Vienna Standard Mean Ocean Water (VSMOW). The formula is shown in *Eq. 1*:

$$\delta^{18}O(\delta D) = \frac{R_{sample} - R_{standard}}{R_{standard}} \times 1000 \qquad \text{(Eq.1)}$$

For δD and $\delta^{18}O$, the instrumental errors are: δD < 0.3‰, $\delta^{18}O$ < 0.08‰.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1197911993

Statistical approaches

Linear equations were established to evaluate the relationships between δD and $\delta^{18}O$ and between meteorological parameters and isotope composition by the method of least square regression. The correlation coefficients and test of significance were analyzed by Pearson's method and two-tailed t tests, respectively. A sinusoidal periodic function was employed to fit the seasonal variation of isotopes. The statistical analysis in this study was conducted by Origin 9.0 and IBM SPSS Statistics 24.

Results and discussion

Characteristics and seasonal variations of δD and $\delta^{18}O$ in precipitation

δD and $\delta^{18}O$ showed obvious seasonal changes in precipitation events in Chengdu. In order to describe these changes, a trigonometric function fitting was employed in *Fig. 3*. The value of δD changed from -119.38 to 22.10, with an arithmetic average of -43.65 and a precipitation weighted average of -50.52. The value of $\delta^{18}O$ changed from -15.84 to 2.68, with an arithmetic average of -6.60 and a precipitation weighted average of -9.01. Wu (2009) reported the average of multi-year isotope values in Chengdu, which is -5.6‰ in $\delta^{18}O$ and -40.7‰ in δD, respectively.

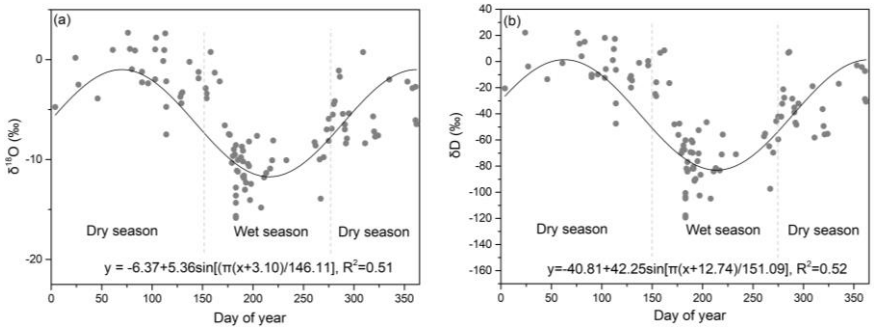

Figure 3. *Seasonal variation of $\delta^{18}O$ and δD in precipitation in 2018*

The average values of both isotopes during our study period are lower than those given by Wu (2009), which may be due to the depletion of heavy isotopes in air masses caused by the heavy summer precipitation in both Chengdu and other areas along the transport path. The maximum and minimum values of δD occurred in January and July, respectively, and those of $\delta^{18}O$ occurred in March and July, respectively. δD and $\delta^{18}O$ showed similar trends and periods of change, while δD showed greater amplitude, indicating that both isotopes in precipitation were affected by the same factors, but δD responded more strongly to environmental changes. Isotopes are enriched in the dry season and depleted in the wet season, which is similar to those in other areas of East Asia affected by subtropical monsoon climate, such as Wuhan, Bangkok and Guangzhou (He et al., 2006; Xie et al., 2011; Deng et al., 2016), but contrast to those in inland areas in the mid-high latitudes (Chen et al., 2017), indicating that the isotopic composition of precipitation in this area is closely related to the characteristics of atmospheric circulation and water vapor sources. Chengdu is located in southwest China, far away from the coastline and its distance from the Indian Ocean is similar to that from the Pacific Ocean. Influenced by different atmospheric circulation systems

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1197911993

and multiple monsoons, the water vapor sources in this region are complex. During the wet season, Chengdu is jointly affected by Pacific High Pressure and Indian Ocean Low Pressure, and air masses with high humidity in this region came from the surface of the Pacific Ocean and Indian Ocean controlled by southeast and southwest monsoon. Due to frequent precipitation and evaporation caused by high temperature during long-distance transportation, isotopes in water vapor were strongly fractionated and D and ^{18}O in precipitation were depleted. During the dry season, Chengdu is affected by Mongolia High Pressure and Aleutian Low Pressure, and the northerly winds control the area. Air masses with low humidity and temperature originated from inland areas in the middle and high latitudes. During the transportation process, the temperature was lower, the precipitation along the transport path was less, and the "rainout effect" experienced by air masses was weaker, making D and ^{18}O in precipitation more enriched. $\delta^{18}O$ and δD of more events deviated from the fitting line to a large extent in wet season, which may be due to the greater variations of temperature and precipitation, which have a greater impact on isotope fractionation during the rainfall processes.

Local meteoric water line (LMWL) during wet and dry seasons

The linear relationship between δD and $\delta^{18}O$ in precipitation is named as meteoric water line. Craig (1961) first proposed the equation of global meteoric water line (GMWL) by investigating and analyzing the stable isotope compositions of different water bodies around the world: $\delta D = 8\delta^{18}O + 10$; Zheng et al. (1983) reported the Chinese meteoric water line (CMWL) based on stable isotope measurements of precipitation in different regions of China: $\delta D = 7.9\delta^{18}O + 8.2$. The linear relationship between δD and $\delta^{18}O$ in precipitation in Chengdu was obtained by least squares method (*Fig. 4a*). The regression equation is given with *Eq. 2*:

$$\delta D = 7.61\delta^{18}O + 6.58 (R^2 = 0.98) \quad \text{(Eq.2)}$$

The slope and intercept of meteoric water lines are affected by the water vapor sources, transport patterns, condensing temperature and the sub-cloud processes, and can be used to reflect the information of regional geography, meteorological conditions and water vapor source. Compared with GMWL and CMWL, the slope and intercept of the LMWL in Chengdu were small, indicating that the precipitation in Chengdu was affected by both the ocean-source and continental air masses on annual scale. Compared with other areas in China, the slope and intercept of LMWL in Chengdu were lower than those in the southeast coastal areas, such as Guangzhou, Changsha and Fuzhou (Xie et al., 2011; Yao et al., 2018; Xu et al., 2019), but higher than those in northern temperate climate regions, such as Lanzhou, Fengxiang, Ningwu and Beijing (Zhai et al., 2013; Chen et al., 2015; Zhao et al., 2018), indicating that the contribution of marine water vapor in the annual precipitation in Chengdu is lower than that in the southeast coast but higher than that in the northern region.

The LMWLs based on precipitation events during the wet and dry seasons is shown in *Fig. 4b*. It can be observed that the LMWLs in wet and the dry seasons differed greatly, which reflected the differences in characteristics of isotope fractionation in the two seasons, which is mainly caused by atmospheric circulation patterns, water vapor sources and evaporation. In previous studies, the seasonal changes of LMWLs of different monsoon regions have been proved variable. The LMWLs of islands and coastal regions which are dominated by the oceanic water vapor all year round show

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1197911993

slight variation between wet and dry seasons and plot closely to GMWL (Xia et al., 2019). The slope and intercept of LMWLs in monsoon marginal regions vary greatly seasonally, with high values in wet season and low values in dry (Zhao et al., 2018). In our study area, the slope and intercept of LMWL in wet season were close to those of GMWL and LMWL of low-latitude islands and coastal areas, indicating the dominance of oceanic air masses during this period, and precipitation was less affected by non-equilibrium fractionation. The slope and intercept of LMWL in dry season were significantly lower than those in wet season, but was close to those in mid-high latitudes, for example, Fengxiang in North China (Zhao et al., 2018), indicating that the region was controlled by inland dry air masses and significantly affected by sub-cloud secondary evaporation. Under dry conditions, non-equilibrium fractionation happens when raindrops fall in unsaturated atmosphere, leading to preferential fractionation of D into atmosphere, relative enrichment of ^{18}O, and fractionation ratio of D to ^{18}O to be lower than 8:1, which explains the lower slope and intercept of regression line.

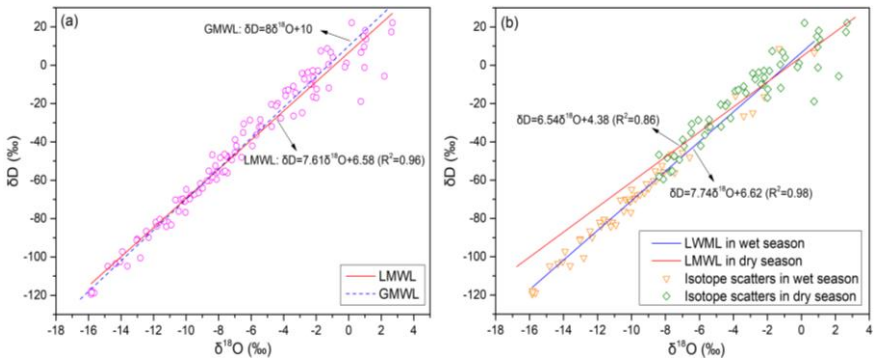

Figure 4. *Year-round and seasonal correlation between $\delta^{18}O$ and δD in precipitation*

Relationship between isotope compositions in precipitation and climatic factors

Precipitation effect

Precipitation effect is an inverse correlation between precipitation stable isotopes and precipitation amount, which is generally significant in tropical and subtropical regions (Dansgaard, 1964). Regression analysis on the $\delta^{18}O$–precipitation amount (P) relationship was performed in dry and wet seasons and the whole year in Chengdu using the least square method. Person's Method and two-tailed tests were used to reflect the degree of correlation and to perform significance test, respectively. The results are shown in *Fig. 5.* On the annual scale, $\delta^{18}O$–P showed a significant negative correlation with a correlation coefficient (r) of -0.42 and passed the significance test of 0.01 confidence level. Compared with other regions in China's monsoon zone, the absolute value of r of Chengdu is lower than that of tropical regions, such as Hong Kong (-0.70, 2015-2016), similar to that of subtropical regions, such as Guangzhou (-0.36, 2007-2009) and Chongqing (-0.40, 2010-2015), and higher than that of temperate regions, such as Fengxiang (0.024, 2016-2017) and Ningwu (-0.05, 2016-2017) (Xie et al., 2011; Zhao et al., 2018; Zhou and Li, 2018; Xia et al., 2019). The geographical difference of r, which is strong in low latitudes and weak in middle and high latitudes, is the same as the results of Araguas-Araguas et al. (1998) in Southeast Asia. This suggested that the influence of precipitation amount on isotopic composition of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1197911993

precipitation decreases with the increase of latitude. On the seasonal scale, the $\delta^{18}O$–P correlations of the precipitation in both seasons failed the significance test of 0.05 confidence level and the r values for dry and wet season were -0.11 and -0.26. It is probably due to the complicated formation mechanism of stable isotopes in monsoon precipitation. The meteorological conditions at the source areas of water vapor determine the initial composition of the isotope, the "rainout effect" that isotopes in water vapor experience along the transport path and the recycled water vapor lead to changes in the isotopic composition. In monsoon climate regions, the sources and transport processes of water vapor are unstable and changeable due to the interaction of different monsoon systems, resulting in differences in stable isotopes in cloud when precipitation happens. Compared with the seasonal r values (-0.44 and -0.22 for dry and wet seasons, respectively) of Changsha at the same latitude, the absolute value of r of $\delta^{18}O$-P relationship in wet season is relatively close between the two regions, while that of Chengdu is significantly lower in dry season (Wu et al., 2015). This may be due to the different division of dry and wet season between the two studies. In the study of Wu et al. (2015), the months of May and October, which is the transition periods between summer and winter monsoon with the most complicated water vapor sources, was not included either in dry or wet season. However, the two months were included in dry season in our study. The alternation and transformation of multiple monsoons resulted in the difference of isotope composition in clouds and subsequently in raindrops, which covered up the influence of precipitation amount.

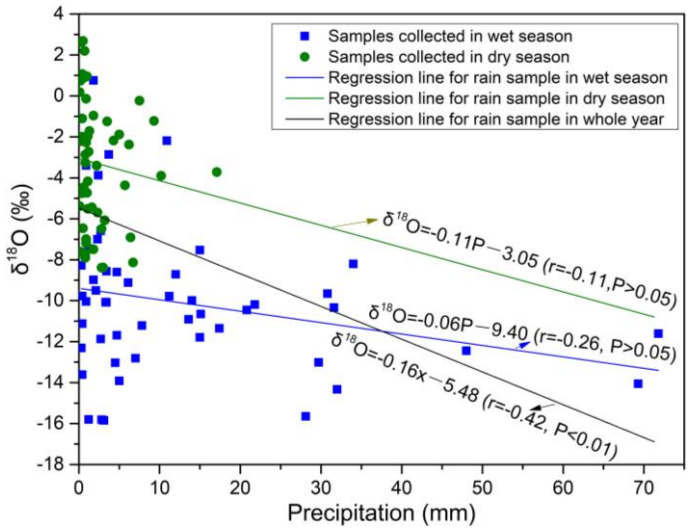

Figure 5. *Linear relationship between $\delta^{18}O$ and precipitation amount in both seasons and the whole year*

According to *Fig. 5*, precipitation intensity is closely related to the variation range of isotopes. The isotopic composition of small-scale precipitation with an amount less than 10 in both seasons had a large variation range, but events with precipitation amount greater than 10 mm all showed low isotopic composition, especially for those occurred in wet season. To determine the influence degree of precipitation intensity on isotope composition, the precipitation data set in this study was divided into two groups (from 0 to 10 mm and from 11 to 70 mm) to examine the $\delta^{18}O$–P correlation separately. The results are shown in *Table 1*. Most precipitation events (88/113) during the study period

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1197911993

happened with an intensity of less than 10 mm and those with a relatively strong intensity of 10-70 mm were monitored mainly in wet season. The correlation between $\delta^{18}O$ and P (10-70 mm) in the dry season is not obtained because of the scarce sample data. When the precipitation events with strong intensity are taken into consideration individually, the absolute values of r of regression equations increase for both wet season (0.45 vs. 0.26) and whole year (0.49 vs. 0.42). While the absolute values of r of the correlation between $\delta^{18}O$ and P (0-10 mm) are lower in seasonal and annual scale. This could be attributed to the influence of atmospheric circulation and external environment. For the one hand, most precipitation events with strong intensity happened in June and July, when the water vapor sourced from ocean area and travelled along a relative fixed path. The isotopes in the cloud layer were relatively stable when the rainfall happened. Reversely, the isotopes in the cloud layer were variable in dry season for the mixing of water vapor from different sources and transportation paths. For the other hand, the influence of isotope fractionation caused by sub-cloud evaporation, is more significant for small-scale precipitation than large one, which enhanced the variability in isotope composition.

Table 1. *Relationship between $\delta^{18}O$ and precipitation events with different intensity (from 0 to 10 mm and from 11 to 70 mm)*

Period	Precipitation intensity	Number of samples	$\delta^{18}O$–P regression equation
Whole year	<10 mm	88	$\delta^{18}O = -0.49P - 4.57$ ($r = -0.23$, $P > 0.05$)
	10-70 mm	25	$\delta^{18}O = -0.09P - 7.67$ ($r = -0.49$, $P < 0.01$)
Dry season	<10 mm	52	$\delta^{18}O = -0.19P - 2.91$ ($r = -0.13$, $P > 0.05$)
	10-70 mm	2	/
Wet season	<10 mm	36	$\delta^{18}O = -0.30P - 8.89$ ($r = -0.15$, $P > 0.05$)
	10-70 mm	23	$\delta^{18}O = -0.07P - 8.67$ ($r = -0.45$, $P < 0.01$)

Temperature effect

According to the Rayleigh fractionation model, the condensation temperature of water vapor is related to the fractionation coefficient of the isotopes. Dansgaard (1964) defined the positive correlation between precipitation isotopes and temperature as temperature effect. The correlation between $\delta^{18}O$–Temperature (T) in Chengdu was shown in *Fig. 6*. On the annual scale, there was a significant negative correlation between $\delta^{18}O$ in precipitation and temperature in Chengdu, showing a "reverse temperature effect", which is inconsistent with the effect of temperature on isotope fractionation in physics. On the seasonal scale, there was no significant correlation between $\delta^{18}O$ and temperature in either dry season or wet season. In previous studies, monthly accuracy data provided by GNIP presented that most (33/38) stations in Southeast Asia controlled by Pacific and Indian Ocean monsoon showed negative correlation or weak positive correlation ($r^2 \leq 0.24$) between $\delta^{18}O$ and temperature (Araguas-Araguas et al., 1998); the negative correlation between $\delta^{18}O$ and temperature has also been widely observed in studies carried out in the monsoon regions of southern China, for example, in Chongqing ($r = -0.52$) and Changsha ($r = -0.38$), which is consistent with the results of this study (Wu et al., 2015; Zhou and Li, 2018). Recent studies in different regions of China show that the correlation between temperature and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1197911993

$\delta^{18}O$ gradually strengthens from monsoon marginal area to inland area (with r value increasing from 0.16 to 0.83), indicating that the influence of temperature on isotope values enhances with the increase of latitude and decrease of monsoon intensity (Wang et al., 2019). These results indicate that the effect of temperature on the isotopic composition is closely related with monsoon activities and was masked by other effects.

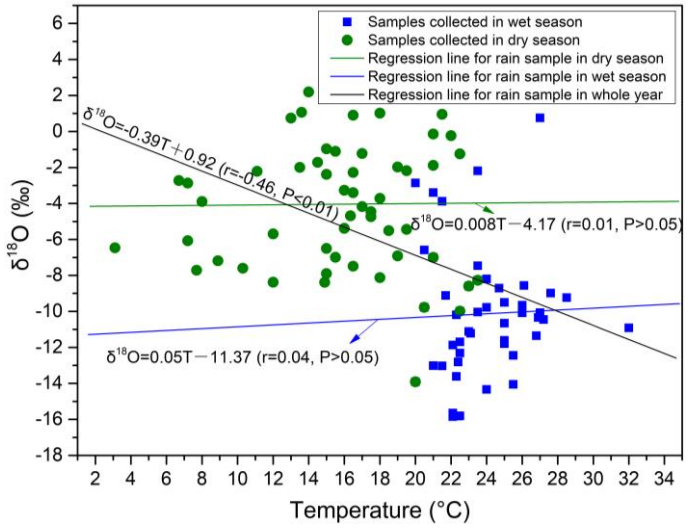

Figure 6. *Linear relationship between $\delta^{18}O$ and temperature in both seasons and the whole year*

Effect of local surface relative humidity

Previous studies have shown that local surface relative humidity (RH) determines the intensity of non-equilibrium isotope fractionation as it is related to evaporation conditions during the falling processes of raindrops, and is considered to be an important factor affecting the isotopic composition of precipitation (Zhang et al., 2007; Crawford et al., 2017). Correlation analysis was performed to determine the relationship between RH and precipitation $\delta^{18}O$ on annual and seasonal scales (*Fig. 7*).

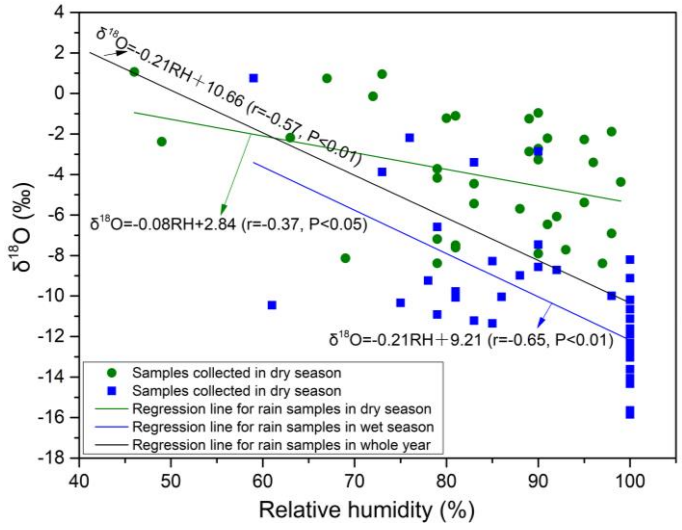

Figure 7. *Correlation between $\delta^{18}O$ and local surface relative humidity before rainfall in both seasons and the whole year*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1197911993

Considering the effect of continuous precipitation on atmospheric saturation, the relative humidity in the atmosphere at the beginning of precipitation was selected. A significant negative correlation between $\delta^{18}O$ and RH was observed on both annual and seasonal scales, indicating that evaporation conditions played an important role in the stable isotope composition in precipitation. Under unsaturated atmospheric conditions, the secondary evaporation of raindrops enriches heavy isotopes in the remaining water droplets during the process of falling from cloud to the ground due to the different kinetic energy of molecules in phase transformation. The enrichment degree of heavy isotopes is related to the unsaturated degree of the atmosphere. In the season when precipitation is scarce, the low relative humidity and strong sub-cloud evaporation increase the effect of non-equilibrium fractionation, resulting in an increase in $\delta^{18}O$ value. When heavy or continuous precipitation occurs, the atmosphere approaches saturation and the effect of sub-cloud evaporation is weakened, leading to relatively depleted value of $\delta^{18}O$. The absolute values of slope and correlation coefficient of $\delta^{18}O$–RH regression in wet season were significantly higher than those in dry season, which may be due to the higher temperature in wet season accelerating the evaporation of raindrops during the sub-cloud processes, thus causing stronger non-equilibrium isotopic fractionation.

Comprehensive effects of local climatic variables

Understanding the relationship between meteorological factors and isotopes is the key to reflect climate change using the isotope method. When only the effect of a single factor on $\delta^{18}O$ was considered, there is no expected significant correlation, which is not enough to explain the isotope changes in precipitation. Compared with unary linear regression, multiple linear regression can better reflect the common influence of multiple meteorological factors on stable isotopes in precipitation, which can be used to explore more complex relationships. Therefore, a multiple linear regression model containing temperature (T), precipitation (P), and relative humidity (RH) was established. Regression equations for the whole year, dry season and rainy season are shown in *Eq. 3*, *Eq. 4* and *Eq. 5*, respectively.

$$\delta^{18}O = 0.26T - 0.05P - 0.18RH + 14.16 (R^2 = 0.477, P < 0.001) \quad \text{(Eq.3)}$$

$$\delta^{18}O = 0.43T - 0.01P - 0.23RH + 21.01 (R^2 = 0.506, P < 0.001) \quad \text{(Eq.4)}$$

$$\delta^{18}O = 0.21T - 0.14P - 0.08RH + 0.51 (R^2 = 0.164, P < 0.05) \quad \text{(Eq.5)}$$

Compared with the correlation equation of $\delta^{18}O$–T, $\delta^{18}O$–P and $\delta^{18}O$–RH, the correlation equation considering multiple variables showed higher R^2 values on both annual and seasonal scales, indicating that different meteorological parameters have mutual influences due to their different relationships with precipitation isotopes. During the wet season, about 50.6% of the $\delta^{18}O$ changes can be explained by local meteorological factors, while in the dry season, the proportion dropped to 16.4%, indicating that the influence of local meteorological factors on isotopes was more masked by other variables in dry season than in rainy season.

Influence of moisture sources on stable isotopes in precipitation

In order to describe the difference in imbalance degree of D and ^{18}O fractionation during two-phase conversion process, Dansgaard (1964) proposed the concept of d-excess: $d = \delta D - 8\delta^{18}O$. In the regional water cycle, d-excess mainly depends on the meteorological conditions of the water vapor source, which is negatively correlated with surface humidity, and positively correlated with temperature. Therefore, d-excess can be used to indicate changes in the source of water vapor. The statistical information and temporal distribution of d-excess in Chengdu's precipitation in 2018 were shown in *Table 2* and *Fig. 8*, respectively.

Table 2. *Comparison of d-excess in precipitation events during dry and wet seasons*

Season	Maximum/‰	Minimum/‰	Range/‰	Average/‰	Standard deviation/‰
Dry	21.13	-24.85	45.97	9.16	9.48
Wet	19.09	-1.95	21.04	9.17	4.34

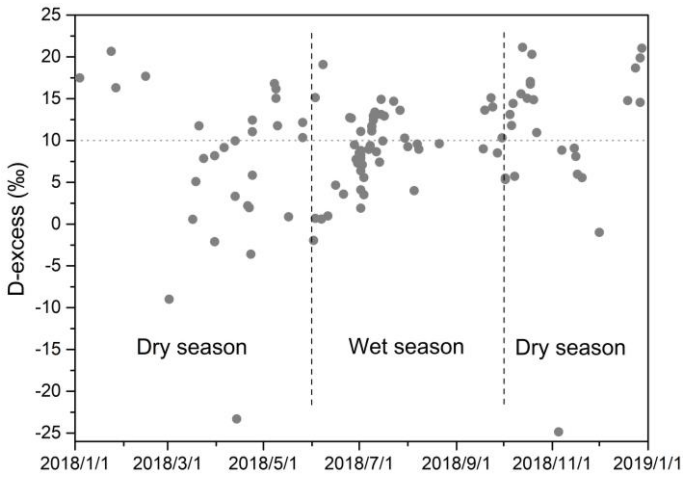

Figure 8. *Temporal variation of d-excess in precipitation in 2018*

Although the d-excess has similar average values in precipitation in dry and wet seasons, it shows a larger variation range and standard deviation in dry season. During the rainy season, the d-excess scatters fluctuate around the global average of 10, indicating that the meteorological conditions of the water vapor source are relatively stable. During the dry season, the scatters of d-excess fluctuate greatly with time, indicating that the source of water vapor in the precipitation is variable. Changes in d-excess can be explained by monsoon activities. During the wet season, the southwest monsoon from the Indian Ocean and the Bay of Bengal, and the southeast monsoon from the South China Sea and the western Pacific controlled the region alternately. Water vapor of precipitation originated from tropical and subtropical oceans, and the weather conditions of the source were relatively close to the transportation path of air masses, so that the temporal variation of d-excess was slight. During the dry season, there were significant temporal differences in monsoon activities. From January to May, the monsoon controlling Chengdu had gradually transitioned from mid-high latitude inland monsoon to mid-low latitude ocean monsoon; from October to December, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1197911993

inland monsoon controlled this area once again as oceanic monsoon subsided gradually. The complicated atmospheric circulation pattern and the contribution of recycled water vapor along the transport path, which is non-negligible under dry conditions, made the water vapor source in the dry season vary greatly in time, explaining the large fluctuation of the d value.

The complexity differences in the source of water vapor (which is related to the initial isotope content in water vapor) and the transport path (which is related to the cumulative precipitation of air masses before reaching the site) can also explain the significant differences in the correlation between $\delta^{18}O$ and meteorological factors in dry and wet season. During the wet season, the temporal variation of the initial isotopic composition in ocean-source water vapor was small, and the uncertainty of transport distance and path was small, which caused smaller difference of isotopic composition in water vapor when the air masses reached Chengdu. During the dry season, Water vapor from different sources and variable transportation paths made the isotopic composition of water vapor over Chengdu significantly different, thus masking the influence of local meteorological conditions on the isotopic composition.

Conclusion

In this paper, a comparison of the stable isotope characteristics during dry and wet seasons in a subtropical monsoon climate region was carried out based on the year-round measured data. The results showed that the stable isotopes in precipitation presented obvious seasonal changes, more negative in wet season and less negative (or positive) in dry season. The LMWL of Chengdu lied between the southeast coast and the northern inland region of China, indicating that Chengdu is affected by both ocean and inland water vapor. The slope of LMWL in dry season was lower than that in rainy season, which indicated that the precipitation in dry season was affected by more intense sub-cloud secondary evaporation. The influence of local meteorological factors on isotopes was analyzed by simple and multiple regressions. The temperature effect and precipitation effect were not significant in both seasons, reflecting the masking effect of other factors. The relative humidity showed a negative correlation with the isotopes during dry and wet seasons, and the correlation difference reflected the strength of sub-cloud secondary evaporation. In a multiple regression that considered the combined influence of multi-factors, the correlation coefficient showed an improvement. The changes in water vapor source under the influence of monsoon reflected by d-excess explained the correlation between meteorological factors and isotopic composition in dry and wet seasons. Compared with the rainy season, more complicated water vapor sources and transport paths in the dry season made the impact of local meteorological variables on isotopes be masked to a greater extent.

Abstract. Small forest patches (SFPs) are considered as one of the most important landscape elements, enriching the monotonous agricultural areas. Various studies focus on the ecological role of SFPs, however none provides a comprehensive characteristics of the reasons for their occurrence in post-glacial areas. The location of SFPs within field areas is not incidental, and the occurrence is mainly determined by physiographic factors which prevent or hinder the use of such areas for agriculture. To a large extent, the distribution of SFPs is determined by the origin of the given area which, in the case of Europe and North America, is related to ice sheets and their effects over millennia. Therefore, the aim of the present paper was the assessment of the reasons for the occurrence of SFPs within intensely cultivated agricultural post-glacial areas in Western Pomerania of Poland. It was found that the occurrence of SFPs is related to natural abiotic factors, the most important being gradient of a slope, presence of sandy soils and wetlands. Additionally, the significance of these factors, size of SFPs and their spatial characteristics to a large degree are determined by geomorphological variability of the area.
Keywords: *agricultural landscapes, small remnant habitats, landscape management, forest fragmentations, post-glacial areas*

Introduction

Small-scale landscape elements, such as small forest patches (SFPs), copses, avenues and scattered trees, constitute significant elements enriching the agricultural areas (Gibbons et al., 2008; van Zanten et al., 2016; Solon et al., 2017). Given the increasing intensification of agricultural activity leading to, among others, depletion of the natural environment heterogeneity, the importance of such elements is increasing (Myga-Piatek, 2010). Small forest patches provide, among other things, habitats for various plant and animal species displaced from anthropogenically transformed habitats (Graae, 2000; Lindgren, 2017; Michel et al., 2007; Yahner, 1986; Wuczyński, 2016; Gamrat and Gałczyńska, 2014; Farah et al., 2017; Stanton et al., 2018). Due to their location between larger forest complexes, SFPs act as stepping stone habitats which, similarly to ecological corridors, facilitate connection between landscapes (Jongman, 2002; Burger and Burger, 2005; Estreguil et al., 2013). Small forest patches and mid-field tree stands are considered to be not only an important element of agricultural landscape protection, but also to have a positive effect on biological as well as microclimatic conditions of the surrounding cultivated fields (Zajączkowski, 2005). They also play an important role in both the sequestration and storage of carbon (Brown and Fisher, 2009).

It is believed that intensively used agricultural landscape has a relatively low landscape aesthetic quality (Hermes et al., 2018), that is why numerous authors stress

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1199512011

the aesthetic and recreation value of SFPs (Arriaza et al., 2004; De Groot, 2006; Van Berkel and Verburg, 2014). In addition, SFPs often provide inspiration and complement cultural heritage (Power, 2010; Schaich et al., 2010; Myga-Piątek, 2012).

The ecological aspect of SFPs was analysed in numerous areas (Baudry et al., 2000; Ryszkowski et al., 2003; Decocq et al., 2016; Varela et al., 2018), however the reasons behind their occurrence within the prevalent agricultural landscape have not yet been fully established. Unarguably, their mid-field location is not incidental and is determined by physiographic factors which prevent or hinder the use of such areas for agriculture. To a large extent, distribution of SFPs is determined by the origin of the given area which, in the case of Europe and North America, is related to ice sheet and its effect over millennia (*Fig. 1*). Additionally, it is conditioned by anthropogenic impact, including economic considerations (Benoit et al., 2012), form of ownership (Crow et al., 1999), development of technology (Vejre and Brandt, 2004; Romanova, 2015), as well as political reasons (Bell et al., 2009).

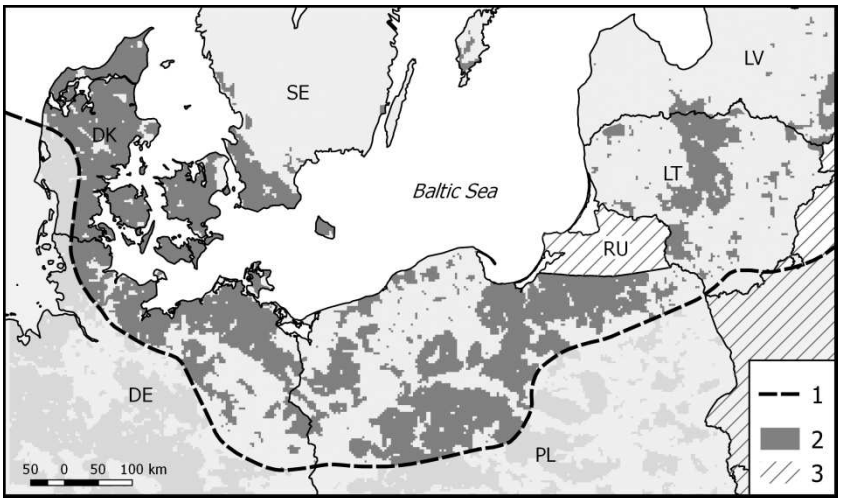

Figure 1. *Predominant agricultural landscape in the area of the last glacial period (based on Corine Land Cover 2000). 1 – limit of Weichselian glaciations, 2 – agricultural landscape, 3 – outside data coverage*

Within the area of intensively used agricultural landscape, the morphological features resulting from glacier retreat (terminal moraines, kames, eskers, dead-ice depression, tunnel valleys) determine the occurrence of small landscape elements including patches of sandy soils, non-runoff depressions (Pieńkowski, 2008) and steep slopes (Najwer et al., 2016). Post-glacial agricultural landscape is additionally diversified by the presence of linear forms, usually not related to physiography, e.g. roadside alleys and hedges (Lenschow, 2005). Given the increasing intensification of agricultural actions, all these forms are in danger of disappearing (Agger and Brandt, 1988; Pieńkowski et al., 2010; Kühne, 2018). It is estimated that in the 2009-2015 period alone, there was a decline in farmland area important to biodiversity in Germany of nearly 13% which, consequently, brought a reduction in the number of trees, hedges, copses and ditches (Agriculture Report, 2017).

Paradoxically, a continuous increase in tree stands has been observed in Europe since the 1960s (European Environment Agency, 2017). An increase in the forest area is also observed in post-glacial areas in Poland (Zając et al., 2014; Pieńkowski, 2015), and the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1199512011

increase rate depends on the region (Żarska et al., 2016; Ciesielska and Ciesielski, 2017). However, global increase in forested area is mainly connected with expansion and consolidation of larger patches in the areas of soils of poor quality and does not apply to intensively cultivated areas, where the number of small and isolated forest patches is decreasing (Brown and Fisher, 2009).

The observed landscape simplification leads to reduction in ecosystem services on which agriculture depends. It is assumed that designing agricultural landscapes requires determination of the desired ecosystem services, evaluation of current landscape structure and implementation of targeted modifications (Landis, 2017). It seems reasonable to argue that determination of physiographical diversity of agricultural landscapes and identifying spatial elements determining the presence and distribution of potential biotopes characteristic for SFPs would be beneficial.

For all the reasons outlined above, the aim of the present paper was an attempt to distinguish these elements with respect to small forest patches. The authors believe that such identification and determination of spatial distribution can provide a significant criterion to be adopted in agricultural landscape planning.

Characteristics of the study area

The studied area of Western Pomerania is situated at 52° 51'N and 54° 06'N to 14° 31'E and 16° 17'E and covers the fragments of three macro-regions in Poland: South Pomeranian Lakeland, West Pomeranian Lakeland and the Szczecin Coastal Region. Land relief of these areas is the result of Scandinavian ice sheet in the Pleistocene glaciation. Therefore, predominant are sedimentary rocks of glacial (loam, sandy loam) and fluvial origin (sand). The effect of marine environment on the climate of this area is significant, as the mean air temperature in winter drops to just below 0 °C, whereas the mean annual air temperature amounts to 8.5 °C and is only slightly higher than the average for Poland. Mean annual precipitation sum amounts to 600-650 mm and precipitation occurring in the summer months is prevalent.

The current landscape was formed primarily in the last 16 thousand years, when in the vicinity of retreating glacier, a complex of post-glacial forms began to form as a result of ice sheet and meltwaters activity. Following the climatic change, the developing natural vegetation was preserved only partially, and the existing forest complexes in Western Pomerania are not of primary forest nature. Nevertheless, forest vegetation was found in great majority of areas of Pomerania. Only wetlands, inundated by floods and coastal quicksand were not covered by forest vegetation. With agricultural development and expansion of settlements, the area of cultivated lands increased, which was coupled with a decrease and fragmentation of the forest area. Changes with respect to intensity of land use were mainly determined by the type of soil. The largest forest complexes remained on sandy terrace plains, outwash plains and terminal moraines, whereas in morainic uplands agricultural use was, and still is, predominant (Pieńkowski and Podlasiński, 2002). At present, forest coverage of this area is 36.5% with pine tree being dominant in forests and Pomeranian beech forests in more fertile habitats. Agricultural use of land reaches 36.7% with cereals (mainly wheat) as the prevent crop followed by rapeseed, corn and sugar beet.

The six study sites (*Fig. 2*) were characterised by predominance of agricultural landscape and the largest number of SFPs areas, as compared with other locations. Selected characteristics of testing sites are presented in *Table 1*. Morainic upland is the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1199512011

prevalent area, similarly to the whole region of Pomerania, particularly in the area of post-glacial agricultural landscape, where soils developed from loamy sands and clays.

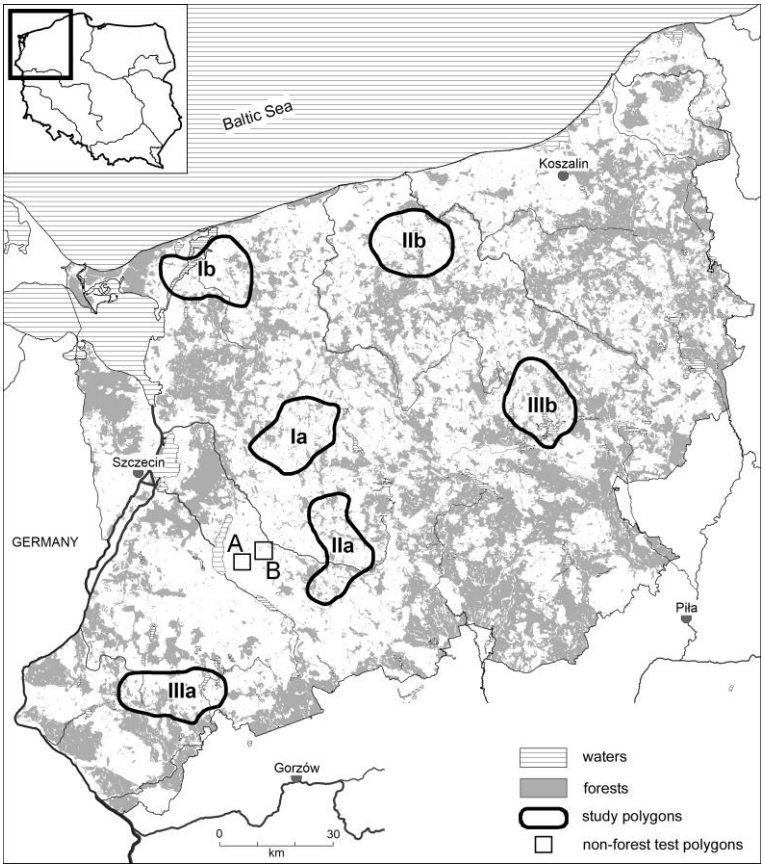

Figure 2. *Study sites in the selected area of Western Pomerania*

Table 1. *Selected properties of study polygons*

Number of polygons	Area [km^2]	Coordinates of polygon centroids		Range of height [m]	Woodiness [%]
Ia	301.1	15° 12’ 15”E	53° 35’45”N	44.0–116.7	16.7
Ib	301.1	14° 46’10”E	53° 56’ 02”N	0.0–31.8	15.0
IIa	301.2	15° 22’ 45”E	53° 18’ 00”N	27.0–103.0	23.1
IIb	301.1	15° 35’ 45”E	54° 01’ 40”N	3.1–85.0	18.2
IIIa	301.0	14° 46’10”E	52° 55’ 50”N	51.0–111.5	21.8
IIIb	301.0	16° 08’ 30”E	53° 39’ 10”N	8.0–221.6	25.4
A	9.0	15° 01’30”E	53° 15’ 20”N	26.7–38.0	0.0
B	9.0	15° 04’ 50”E	53° 16’ 05”N	21.0–42.9	1.1

The distinct nature of relief of the six selected study sites is to a large extent connected with diverse hypsometry. In the regions with high share of terminal moraines, there is a higher ratio of areas with surface inclination of more than 5%. The regions dominated by bottom moraines are characterised by areas of smaller inclination (*Table 2*). Among the analysed study sites, the greatest variability in terms of relief was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1199512011

identified in site IIIb where areas of inclination of 5-10% covered 27.9% of the whole area. This was due to the presence of numerous terminal moraine hills in this region. The smallest terrain variability was identified in sites Ia and Ib where flat upland moraine is predominant. It is worth mentioning that all selected study sites were located outside large outwash plain patches which, due to poor quality of soil, are generally covered by forest vegetation.

Additionally, two study sites of an area of 900 ha and characterised by a total lack of forest vegetation were identified. In these areas, the method of identification developed in the present paper with the aim of facilitating determination of the potential of a given area for establishing SFPs was used. The area marked in *Figure 2* as A covers marginal plain, whereas site B flat upland area.

Table 2. *Percentage of average slope in research areas*

Materials and methods

Areas with the largest number of SFPs within the landscape dominated by agricultural lands were defined by VMapL2 using the analysis assessing the distribution of patches centroids. Hot Spot Analysis module of CrimeStat software was used for this purpose (Smith and Bruce, 2008).

To identify the reasons for occurrence of SFPs, layers of VMapL2 were used in MapInfo software, showing the forest cover from the period 2002-2010, orthophotomaps (from 2010) and digital elevation model (DEM). For the purpose of soil conditions analysis, soil-agricultural maps in the scale 1:5000 were used.

For the assessment of the factor determining the presence of SFPs in a given area, a database was compiled. Single database record included an identifier of a given patch and fields proving characteristics: area [ha], centroid coordinates and the dominant factor determining the existence of a patch (W – land wetness, S – soil, H – hypsometry, O – other) identified by cartographic materials and field observations.

The selected landscape metrics were identified using *Fragstats 4.2* software (McGarigal et al., 2012) and the following was calculated:

- AREA_MN – mean area of patches [ha]
- CIRCLE_MN – metrics of the shape of patches showing their complexity; irrespective of the size of patches
- NNS – nearest neighbour distance – mean distance to the closest neighbouring patch [m]
- NNI – nearest neighbour index showing cluster distribution of centroids.

Results and discussion

Variable factors determining the existence of small forest patches

In many places in Europe, forest landscapes consist of patches of different quality, age, size and isolation, embedded in agricultural matrix (Decocq et al., 2016). Numerous authors called attention to the close link between the geomorphological conditions and agricultural or forest use of land (Iverson, 1988; Hietel et al., 2004; Wulf et al., 2010). However, the studies conducted so far concerned relatively large areas and did not include the reasons behind the occurrence of small forest patches. As opposed to large forest complexes, the presence of small forest patches is determined by abiotic components of relatively small sizes and, consequently, is more prone to transformation due to natural and anthropogenic factors. Particularly in northern Europe, numerous units established by ice sheets are characterised by small size. These are, among others, wet depressions, sandy soil enclaves and slopes of small size – the number, size and distribution of which are frequently connected with land relief. As opposed to flat outwash areas where large forest areas are predominant, morainic areas are dominated by agricultural matrix where the effect of abiotic factors on landscape structure, including distribution of SPFs and spatial patterns of fragmentation, is most evident.

The present paper presents the quantitative and qualitative analysis of these factors on a representative sample of 1237 small forest patches. The analysis of topographic and soil-agricultural maps, aerial photography, digital elevation model and field observations allowed to identify factors determining the existence of SFPs within agricultural land. It was found that the occurrence of SFPs was related to the presence of a series of mutually-interacting natural conditions which were grouped in categories (*Fig. 3*) including factors resulting from:

- Existence of poor soils (S) – of little use for agriculture,
- Area hypsometry (H) – large inclination limiting the agricultural use,
- Excessive land wetness (W) – unfavourable conditions for agricultural use of land.

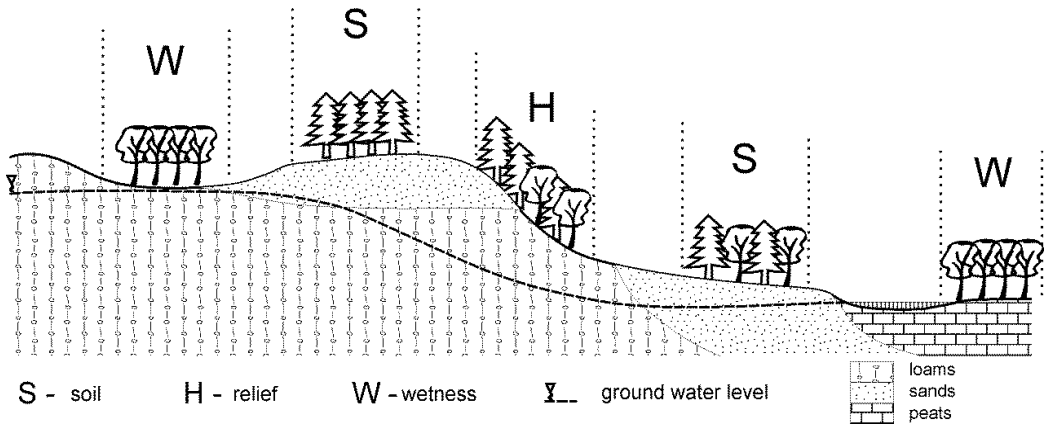

Figure 3. *Diagram illustrating the main abiotic factors determining the existence of SFPs*

In this paper, the category of "other" (O) was distinguished to group mainly the anthropogenic objects including: manor parks, recreational areas, reclaimed areas or discontinued excavation sites. There were no objects not related to the aforementioned factors, which clearly indicates the fact that, apart from the objects classified as "other",

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1199512011

the occurrence of SFPs in agricultural landscape is closely related to physiographic conditions preventing the agricultural use of a given area. Due to the fact that the patches were isolated from larger forest complexes and located on arable land, there were no other reasons for their existence – as defined by other authors (Erickson et al., 2002; Najwer et al., 2016) such as: area near existing woods, rocky ground and seasonally flooded area.

The selection of soil factor (S) referred to patches located in areas of undifferentiated hypsometry with soils unfit for agricultural use located on a flat area. However, in the case of forest patches located on the area with clear inclination and, at the same time, poor soil conditions, the determining factor was found to be hypsometry (H). Small forest patches located in wetland areas (most often hydrogenic soils) were classified as belonging to a group of objects related to land wetness factor (W). In only few cases (mainly larger objects), where the individual fragments of patches were determined by different conditions, the factor which affected the existence of the predominant area of a given patch was considered to be the dominant factor. Examples of SFPs with the analysis of reasons for their occurrence is presented in *Figure 4*.

Figure 4. *Forest patches in the predominantly agricultural landscape. The reasons for their occurrence: H – relief, W – wetness, S – soil, O – other*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1199512011

Variability of the involvement of particular factors affecting the occurrence of SFPs most of all resulted from geomorphological conditions dominating the given area (*Figs. 5* and *6*). In undulating upland area (III), the patches occurring due to high land inclination were predominant. There were, among others, terminal moraine and kame hills of large inclination – more than 25% in both study sites. In the undulating upland area, the presence of SFPs was also attributed to the occurrence of numerous lakes of steep slopes. In the area IIIb, the patches related to a large altitude gradient constituted more than 50% of all recorded objects. However, in flat upland (I) and undulating upland (II) areas, the most common cause of SFPs occurrence was land wetness, often connected with the existence of bog. In the study site Ia, numerous bogs were located in Pomeranian marginal-stream valley, and in the study site Ib – the region of waterlogged subglacial valleys. Within the area of study site IIa, the patches were grouped in the area of the Ina River wide valley, whereas in study site IIb a large share of patches related to land wetness also resulted from the presence of two large bogged subglacial valleys nowadays used as riverbeds. On the slopes of valleys, a relatively large number of patches conditioned by land relief was also identified.

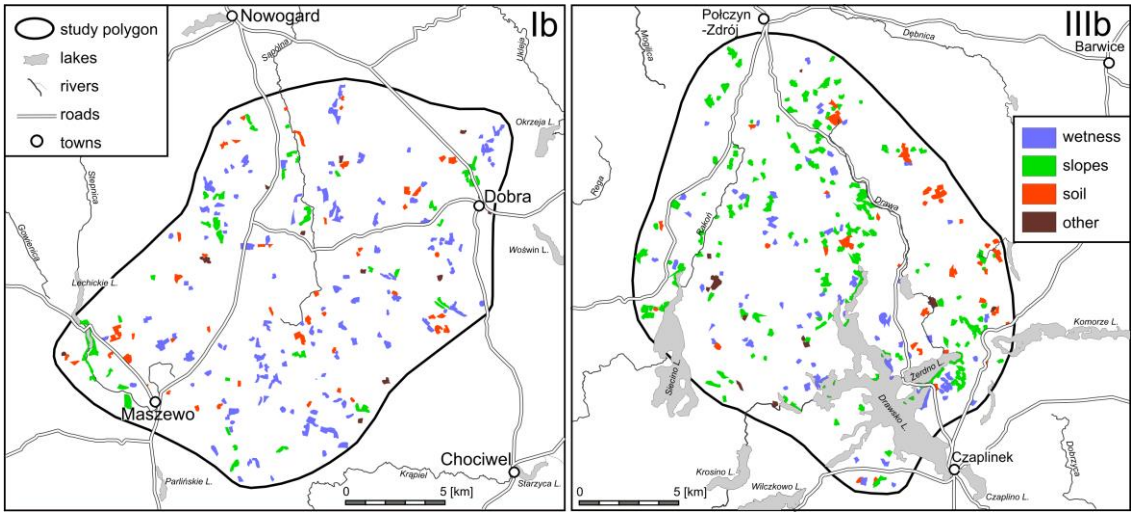

Figure 5. *Variability of the factors determining the occurrence of SFPs in the young glacial area of flat (Ib) and hummocky (IIIb) upland*

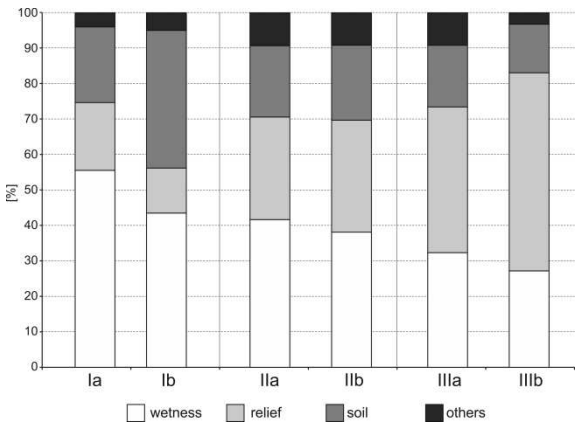

Figure 6. *Share of particular elements determining the occurrence of SFPs in the area of study sites*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_11995120111

Relatively high share of SFPs, occurrence of which was related to patches of soils of poor quality (38%), was found in study site Ia which, in turn, is attributed to the presence of high soil cover mosaicity manifested, among others, by the existence of small compartments of sandy soils.

The selection of the aforementioned factors allowed determination of the areas in terms of potential occurrence of SFPs in agricultural landscape. For this purpose, cartographic materials listed in the Materials and Methods section were used. In identification of the areas three factors were taken into consideration: altitude gradient of more than 15% which hinders agricultural use of the land (Prus and Budz, 2015), soils of sand granulation and wetlands.

Two study sites were identified in the intensively used agricultural area, characterised by a total lack of forests and SFPs (A and B in *Figs. 2* and *7*). These study sites are located in Pyrzyckie ice-dammed basin area which was used for agriculture as early as in the Neolithic period (Pospieszny, 2014). This ice-dammed basin constitutes the largest area of open landscape (Plit and Myga-Piątek, 2014). Both study sites are of different origin – study site A includes ice-dam level IV, study site B covers a fragment of flat morainic upland.

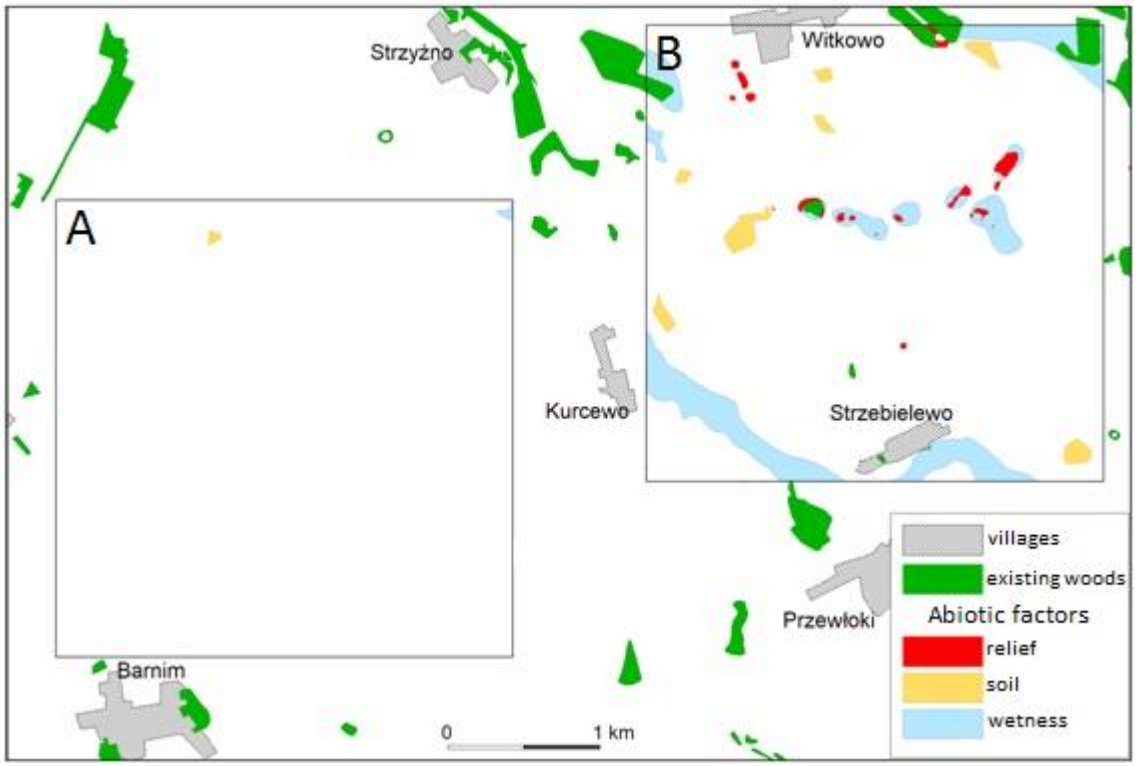

Figure 7. *Variability of the potential of two selected areas of Pyrzyckie ice-dammed basin for constituting possible location of SFPs*

From the perspective of factors conditioning the presence of SFPs, as adopted in this paper, the potential of both study sites for introducing SFPs to landscape is divergent. The analysis of cartographic materials clearly indicates that the first identified study site (A), with the exception of a small compartment of soils of poor quality, does not provide the conditions for the development of tree cover even in the smallest fragments.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1199512011

This is due to homogenous flat area of soils of high quality and optimal moisture conditions. In turn, the other study site (B) is located on flat moraine upland with natural conditions of soil moisture, poor quality of soils and hypsometry which may be taken into consideration in possible establishing of SFPs for the purpose of enriching the agricultural landscape.

Selected spatial characteristics of SFPs

The ecological processes and species richness of agricultural landscape is affected by, among others, the size of SFPs, their shape and distribution against one another (Magura et al., 2001; Moser et al., 2002; Decocq et al., 2016). In the case of the smallest patches, the effect of the shape was found to be slight, however, in the case of larger objects, the complexity of the shape shows a significant effect on biodiversity (Heegaard et al., 2007).

The selected spatial characteristics of patches are presented in *Table 3*. It is difficult to attribute the variability between the study sites to a single dominant landform. However, the analysis of size distribution of patches on individual study sites shows a certain relationships. In all analysed study sites, similarly to post-glacial areas in North America (Host and White, 2003), there was a strong representation of lower size classes. Regardless of the origin, in all study sites there was a dominance of small patches of an area below 5 ha. The smallest (< 2.5 ha) occurred most often on hummocky uplands (*Fig. 8*), which can be attributed to frequent occurrence of small enclaves with different habitat conditions such as waterlogged land depressions, steep slopes and small patches of soils of poor quality. In undulating moraine area, and particularly in the area of flat moraine, larger patches (2.5–5.0) connected with relatively larger zones of depression and steep slopes were predominant.

In the study sites located on flat and undulating uplands, the highest mean size of the patches was found for the objects the origin of which was connected with the hypsometric factor (*Table 4*). These patches were characterised by the highest value of development index (Circle MN). This was mainly due to the presence of larger forest patches located in the area of longitudinal slopes surrounding the lakes and river valleys. In this group of patches, the highest mean values of Circle_MN index was found for SFPs in the study site Ia (0.67). In the hummocky upland area, the patches occurrence of which was related to hypsometry, showed relatively smaller size despite the most frequent occurrence. This can be connected with a small degree of radial relief of these areas and, consequently, relatively small and compact slope area of significant inclination.

Table 3. *Selected metrics of SFPs within the study sites area*

Dominated landform	Study area	Amount	Average area [ha]	NNS* [km]	NNI**

In all of the six analysed study sites, the patches categorised as "other" were characterised by the most compact size (circle-like). The values of Circle_MN index determined for the study sites Ia and IIb was only 0.46.

The mean distance to the nearest neighbour (NNS) was predominantly dependent on the number of patches in a given group. Accordingly, the smallest distance between the patches was found for the group of the most frequently occurring objects related to hypsometry in the study site IIIb (624.7 m). The greatest distance was found with respect to anthropogenic objects in the same study site (3924.5 m).

The values of the NNI index showing cluster nature of the analysed patches, ranged from 0.72 (IIa; factor S) to 1.57 (Ia, factor: O). Grouping of patches was found mainly for the patches occurrence of which was due to land wetness. The greatest dispersion of patches was found for the category of "other". This can be explained by their anthropogenic origin, not related to physiographical variability of the given area.

Conclusion

Until recently, agricultural landscape management constituted a compromise between "environment" and "development". However, recently more attention is paid to ecological and social benefits of actions undertaken as a part of landscape management (de Groot et al., 2010). Many currently developed agri-environmental programmes entail an increase in the amount and quality of forests within such areas. Still, information enabling the development of practical guidelines regarding the optimum spatial design is relatively scarce (Fuentes-Montemayor et al., 2012). Developing appropriate guidelines and implementing informed landscape policy is hindered by the fact that agricultural landscape in Europe alone is characterised by great variability due to, among others, climate, habitat as well as agricultural management (Van Zanten et al., 2014). Particularly the post-glacial areas are characterised by major differences concerning the forms determining the current fragmentation of forest area (Najwer et al., 2016). Therefore, all actions related to achieving optimum visual and spatial structure of landscapes should be implemented individually for such areas and take into consideration their physiographical features. This also concerns the practice of enriching the monotonous agricultural areas with small landscape elements, including small forest patches. Knowledge on abiotic elements which constitute, or may constitute, potential habitats for small forest patches is limited. There is a lack of information concerning the spatial patterns of fragmentation (patch isolation, size and edge), and on practical use of such patterns in implementation of agri-environmental programmes as well as price estimation of ecosystem services (Valdés et al., 2015). Good knowledge of spatial characteristics of particular abiotic elements, which could potentially form habitats for SFPs on diverse geomorphological units, may also be beneficial in the analysis of landscape transformation trends due to climate change, transformation of economic conditions and technological progress.

Within the analysed post-glacial area, the abiotic elements determining the presence of SFPs are mainly: gradient of slopes, occurrence of patches of sandy soils and land wetness. However, the share of these elements in particular land forms is different. On flat and rolling morainic uplands, the most frequent reason behind the occurrence of SFPs is land wetness, whereas on undulating morainic uplands the patches related to land slopes are predominant. It could be assumed that on flat upland moraine in particular, the forecasted climatic change (Erwin, 2009; Samaniego et al., 2018) could

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1199512011

be a decisive factor in excessive drying of small non-runoff depressions and facilitate transformation of these previously forested areas for agricultural use. The fact that the size of the SFPs occurring on that area is relatively small can only expedite this process. In turn, global warming and the resulting lowering of groundwater level (Taylor et al., 2013) most likely will not have a significant effect on the number of SFPs on hummocky upland, as on these areas the presence of SFPs is mostly connected with land relief. Regardless of geomorphological unit, excessive drying of patches of poor soil may lead to their exclusion from agricultural use and, as a result, spontaneous forestation and occurrence of shrubs – the fact already reported in some areas in Poland (Śmigielski et al., 2017).

Meeting the increasing demand for agricultural lands without disturbing the biological diversity is indeed a challenge for the 21st century in lowland agricultural landscapes (Decocq et al., 2016). Therefore, knowledge on the elements determining the occurrence of SFPs may also prove useful in identifying the optimum locations for the establishing of new forest patches in a view of minimisation of resulting economic costs. Increasing availability of a given area's resources resulting from, among others, the INSPIRE Directive, allows faster selecting of such habitats especially, as was identified in the present paper, due to the fact that that the post-glacial landscape of Western Pomerania offers a big potential for creation of such habitats. The authors believe that the obtained results may be useful in planning the design of agricultural landscapes for sustainable and resilient biodiversity. Information on the post-glacial areas potential for establishing small landscape elements and the analysis of spatial conditions should be considered as one of the key criteria in decision making process regarding enriching the monotonous agricultural landscape.

(Received 25th Apr 2019; accepted 2nd Jul 2019)

Abstract. The post-harvest application of *Trichoderma harzianum* proved to be effective in the control of blue mold and brown rot on apple. The possibilities of separately application of harpin protein (hp) and *Lactobacillus acidophilus*'s fermentation product (Lafp) and boscalid+pyraclostrobin fungicide were evaluated to the shelf-life of apples. TRIC8 and the plant activators applied to the fruits one hour before pathogens inoculations. The apples were inoculated with a micropipette via the artificially created wounds with the pathogens *P. expansum* and *M. fructigena* with suspensions of 1×10^6 conidia/mL^{-1}. After one hour the pathogens inoculations, the fungicide was sprayed onto the fruits at recommended dosage. The apples were stored at (22±2°C) for ten days. TRIC8 was reduced lesion diameter of *P. expansum* and *M. fructigena* by 69.73% and 97.13% respectively. Significant results on brown rot was provided by the application of Lafp (100%) but not had same success on blue mold (29.59%). Hp was provided to reduction of lesion diameter on blue mold and brown rot at 29.76% and 41.65%, respectively. The fungicide demonstrated 37.22% and 100% control of blue mold and brown rot on the apples in the shelf-life study, respectively.
Keywords: *apple, biological control, blue mold, brown rot, harpin protein, Lactobacillus acidophilus, post-harvest*

Introduction

Apple (*Malus domestica*) is an economically important crop in Turkey. According to 2017 data, there were produced 3.032164 tons of apple in the field of 175.357 ha in Turkey (FAOSTAT, 2017). The rate of loss of fresh fruits and vegetables after harvest is 25% in developed countries; however, it can increase to 50% in developing countries (Salunkhe and Kadam, 1998). Fruits and vegetable continue to physiological events such as respiration, sweating, and ethylene production after the harvest. In storage as well, fruits that continue physiological activities like respiration, transpiration, and so on, are exposed to activities of fungal pathogens present in the environment, as well as to biochemical and physical changes. Pathogen fungi cause postharvest disease are usually passive pathogens that can only entrance into wounds on fruit. The fruit are susceptible to the decay caused by several pathogenic fungi including *Penicillium* sp., *Geotrichum* sp., *Rhizopus* sp., *Phytophthora* sp., *Monilinia sp.* and *Botrytis* sp. (Barad, 2016; Benli, 2003; Errampalli et al.,2004; 2005; Fiori et al., 2008; Chávez et al., 2014).

DOI: http://dx.doi.org/10.15666/aeer/1705_1201312022

More than 90 fungal pathogen species have been reported as causal agents in apple decay during storage (Jones and Aldwinckle, 1990).

To control blue mold disease caused by *P. expansum*, is the most common wound pathogen during harvest, transport and storage. So, store should be cleaned, ventilated, disinfected before the fruits are stored, and excessive humidity should be avoided (Ozgonen and Kilic, 2013). Little is known about to mechanism used to decay of caused by *P. expansum* on apple. The secretion of pectolytic enzymes have an important role on pathogenicity. On the other hand patulin known as secondary toxic metabolite that produce by blue mold (Morales et al., 2010; Barad et al., 2016; Snini et al., 2016). *M. fructigena* is a common species of *Monilinia* found on apples and pears in Europe, and is commonly referred to as "apple brown rot" (Jones and Aldwinckle, 1990; Leeuwen et al., 2002). Of pome fruits, apple and pear are sensitive to brown rot disease caused by *M. fructigena,* and of stone fruits, plum is sensitive to brown rot disease (Byrde and Willets, 1977). *M. fructigena* has been reported to infect in more than 40 hosts. These include apples, pears, quince, apricots, peaches, plums and cherries (Sagasta, 1977). Post-harvest disease control is achieved by the use of synthetic fungicides such as sodium *ortho*-phenylphenate, imazalil or thiabendazole (Penrose et al., 1989; Yildiz et al., 2005). Use of the fungicides provides satisfactory control against mold infection. But fungicidal residues can have harmful effect on people and environment. The global trend appear to reduced use of fungicides on produce and demand for reducing disease loss in the harvested commodities (Sharma et al., 2009). So, development of alternative control possibilities has become very important because of the need to reduce the use of fungicides, their residues, concerns about human health and environmental pollution, and development of fungicide-resistant strains for pathogenic fungi (Capdeville et al., 2002; Calvo et al., 2017). Nowadays the researches on using biocontrol agents and alternative chemicals and hot-water treatments on postharvest diseases have been increasing (Falconi and Mendgen, 1994; Janisiewicz et al., 1994; Hong et al., 1998; Ippolito, 1998; Benli, 2003; Li and Yu, 2000; Karabulut et al., 2002; Capdeville et al., 2002, 2003; Irina et al., 2006; Wang et al., 2008; Fiori et al., 2008; Manso and Nunes, 2011; Amiri and Bompeix, 2011; Haıssam et al., 2011; Mari et al., 2012; Zhao et al., 2012; Li et al., 2015; Yaseen et al., 2015; Zhu et al., 2016; Kabelitz et al., 2018). Some antagonistic yeasts such as *Candida sake* Satio & Ota, *C. oleaphila* Montrocher, *C. saitona* Nakase & Sutuki, were used to controlling decay of apple and pear caused by *B. cinerea* Pers.: Fries and *P. expansum* Link. (Sharma et al., 2009). Bacteria as antagonist biological control agents such as *Bacillus amyloliquefaciens* BUZ-14 and *Aureobasidium pullulans* and *Pseudomonas fluorescens* have been used against blue mold in apples (Vinas et al., 1998; Ippolito et al., 2000; Mari et al., 2012; Calvo et al., 2017; Wang et al., 2018).

The aim of the study the control possibilities of blue mold disease caused by *P. expansum* and brown rot caused by *M. fructigena*, with *T. harzianum* (TRIC8), harpin protein (hp), *Lactobacillus acidophilus*'s fermentation product (Lafp), and with boscalid+pyraclostrobin was evaluated to extend the self life of the apples.

Materials and methods

Fruit

Granny Smith apple cultivars not treated with pesticides were harvested in Tekirdag Viticulture Research Institute orchards, Turkey. Healthy fruits were selected without

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1201312022

physical injuries. The apples were surface disinfected with 70% ethanol and rinsed in sterile distilled water (SDW), dried at room temperature (24 °C).

Pathogens and antagonist isolates

In the study, *P. expansum* was isolated from decayed apples and other pathogen isolate *M. fructigena* (MON14) and biological control antagonist isolate *T. harizanum* (TRIC8, Accession number: MH351669) were provided by Prof. Dr. Nuray Ozer, Tekirdag Namik Kemal University, Agricultural Faculty, Department of Plant Protection.

Postharvest treatments of apples

P. expansum isolate and *T. harzianum* TRIC8 antagonist isolate were grown on potato dextrose agar (PDA) and incubated at 24 °C for 7 days. Petri dishes containing vegetable juice agar (V8 agar) was inoculated with *M. fructigena* isolate (MON14) and incubated at 24 °C for 10 days. The concentration of the *P. expansum* and *M. fructigena* were adjusted to 1×10^6 conidia/mL^{-1} with the aid of a thoma slide. Artificial wounds were performed using sterile needle to make 2 mm deep and 2 mm wide wounds (two wounds for each the apple) along the fruit equatorial areas. Spore suspension of *T. harzianum* (TRIC8) was counted with a thoma slide and adjusted to concentration 1×10^8 conidia/mL^{-1}. Firstly, each wound on apple was inoculated with 20 µL drop of 1×10^8 conidia/mL^{-1} of TRIC8 and left for incubation at room temperature (22 ± 2 °C) for one hour. After one hour, the apples treated with TRIC8 were inoculated with a micropipette into the wounded points with 20 µL drop of 1×10^6 conidia/mL^{-1} of the pathogens.

1% Harpin protein (Hp) (WDG formulation, Eden Bioscience Co.; Messenger Gold, 12 g/100 l water) (Wang et al., 2008). *Lactobacillus acidophilus'*s fermentation product (Lafp) (Alltech Crop Science; ISR 2000; 100 ml/da) (Boyraz et al., 2006). Hp and Lafp plant activators were dissolved in SDW and then sprayed with commercial dosage to fruits one hour before pathogens inoculations.

However, to compare the results of chemical reactions with *T. harzianum* and plant activators, the test fungicide 25.2% boscalid + 12.8% pyraclostrobin (Basf®, Bellis WG; 50 g/100 l water) was applied with the commercial dose by spraying one hour after the inoculation of the pathogens. To maintain humidity environment, two wet papers were placed in each plastic box was wrapped in an unsealed 0.05 mm polyethylene bag. The development of the diseases were determined by measuring the lesion diameters of decay on apples inoculated with 10^6 spores mL^{-1} pathogens inoculum and incubated for 10 days at 24 °C (22 ± 2 °C). Mean lesion diameter was calculated at the end of the study. Non-inoculated with the pathogens: 20 µl drop Sterile Distilled Water (SDW) was used only for each wound on apple in our study as negative control. Each treatment was independently performed two times with five replicate fruit; in each experiment twenty fruit per treatments were included.

We used to the effectiveness of the applications was calculated using Abbott's formula (Abbott, 1925; *Eq 1*):

$$\% \text{ effectiveness} = [(Ic - It) / Ic] \times 100 \qquad \text{(Eq 1.)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1201312022

Where: Ic is the disease diameter of the untreated control (+), It is the disease diameter of the treatment.

Statistical analysis

At the end of the storage period, the severity of the diseases was determined by the mean lesion diameter in millimetre on the rotted apples. Statistical significance was judged at level $P \leq 0.05$. When the analysis was statistically significant, the Duncan multiple comparison test was used for means separation. SPSS (Statistical Package for Social Sciences, Inc., 2001, Model 11.0 Chicago) was used analysis program.

Results

The results of this study demonstrated that post-harvest applications of the TRIC8 significantly controlled blue mold caused by *P. expansum* on apple at the rate of 69.73%. This effect was found to be significant at $P \leq 0.05$ level. While the mean lesion diameter of *P. expansum* growth of untreated apples was 5.90 cm, the apples treated with TRIC8 had 1.79 cm, at 10^{th} day. The mean lesion diameters of the hp and Lafp treated apples were 4.14 cm and 4.16 cm, respectively, with both plant activators being equally effective (□29.00%) in reducing decay. The control of blue mold by boscalid+pyraclostrobin indicates that is not highly effective (37.22%) against the sporulation of *P. expansum* in the self-life condition (*Table 1*; *Fig. 1*).

Table 1. *Effects of treatments on lesion development of P. expansum on apple fruits*

Treatments	Lesion diameter (cm)	Effect (%)
Inoculated control	5.90 a	0.00 c
T. harzianum TRIC8	1.79 c	69.73 a
hp	4.14 b	29.76 b
Lafp	4.16 b	29.59 b
B+p (fungicide)	3.56 b	37.22 b

Means of treatment within the same column followed by different letters are significantly (P≤0.05) different according to Duncan's multiple range test.

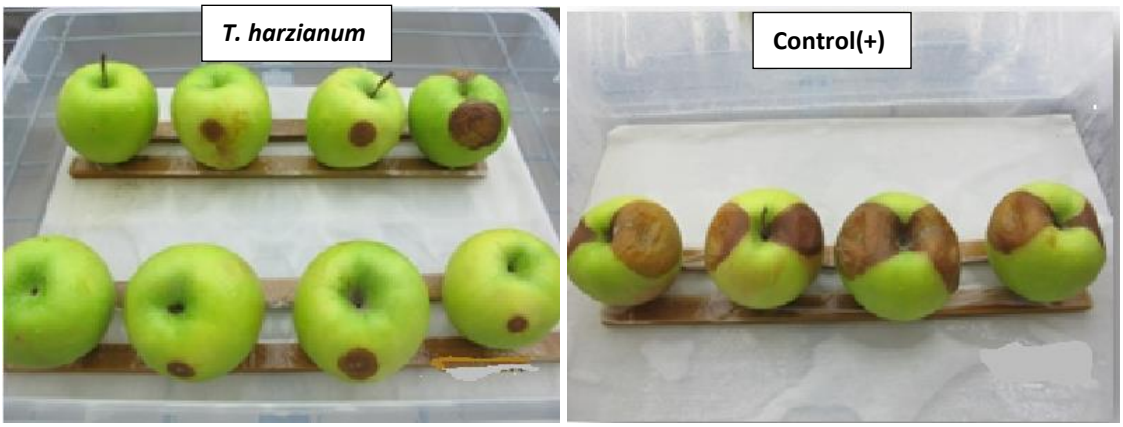

Figure 1. *Biocontrol activity of T. harzianum TRIC8 in inhibiting blue mold caused by P. expansum on apples*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1201312022

The results show that TRIC8 is also effective on the mean lesion diameter of *M. fructigena* on apple. While the mean lesion diameter of *M. fructigena* growth of untreated apples was 7.50 cm, the apples treated with TRIC8 had 0.21 cm, at 10th day. The effect of TRIC8 treatment on brown rot was calculated as 97.13%. This value was significantly as statistically (P≤0.05). The mean lesion diameters of the hp and Lafp treated apples were 4.23 cm and 0.00 cm, respectively. Lafp treatment had a significantly greater effect (100%) in reducing decay than hp (41.65%) treatment (*Table 2*) (*Fig. 2*) (*P ≤ 0.05*).

Table 2. *Effects of treatments on lesion development of M. fructigena on apple fruits*

Treatments	Lesion diameter (cm)	Effect (%)
Inoculated control	7.50 a	0.00 c
T. harzianum TRIC8	0.21 b	97.13 a
hp	4.23 b	41.65 b
Lafp	0.00 c	100.00 a
B+p (fungicide)	0.00 c	100.00 a

Means of *M. fructigena* lesions diameter within each column followed by different at (P≤0.05) according to Duncan's multiple range test.

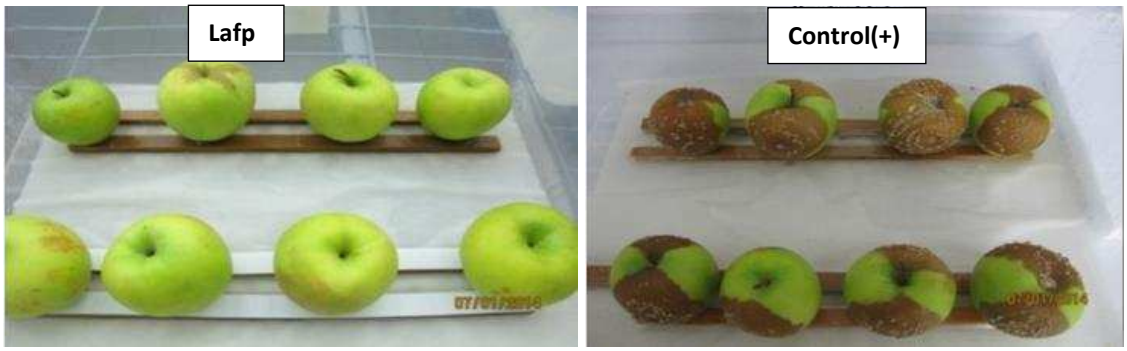

Figure 2. *Plant activator of Lafp in inhibiting brown rot caused by M. fructigena on apples*

Significant differences (P≤0.05) were obtained in *M. fructigena* lesion diameters on wounded the apples when treated with the B+p compared to the treatment with only inoculated *M. fructigena* on the apple (*Table 2*).

Discussion

T. harzianum TRIC8 treatment had a significantly greater effect in reducing decay caused by *M. fructigena* than either decay caused by *P. expansum*. The effectiveness of TRIC8 against both blue mold and brown rot of apple were significantly statistically (P≤0.05). TRIC8 isolate of *T. harzianum* proved its antagonistic potential in controlled reducing blue mold and brown rot on Grany Smith apple cultivars. When the apple treated with TRIC8, demonstrated postharvest pathogens of fruit has the ability to be efficient at 1×10^{8} conidia/mL^{-1} concentration. In apples, Batta (2004) observed low effect (48.8%) of formulated *T. harzianum* against the blue mold on apple is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1201312022

significantly attributed to the antagonistic effect of *T. harzianum* but not to because of the formulation ingredients.

Preliminary studies show that different active ingredients with fungicide; such as benomyl, captan, carbendazim, iprodione, mancozeb, myclobutanil, procymidone, thiram, thiophanate methyl, triforin, vinclozolin, and prochloraz etc., were effective to control of *P. expansum* during preharvest and postharvest. Since noticed of thiabendazole resistant blue mold in apple packing houses, study for alternative chemical control strategies have increased greatly (Eckert and Ogawa, 1988; Biyk et al., 1994; Li and Yu, 2000; Moreira and Mio, 2007; Feliziani et al., 2012).

Boscalid + pyraclostrobin active ingredients with fungicide against *M. fructigena* on apples that is only applied postharvest. Also, brown rot was reduced by 100% in apple fruit postharvest with this fungicide in this study. The same fungicide was able to mycelial growth of *P. expansum* on apple. But, this fungicide was effective when applied 7 or 14 days before harvest and reduced blue mold incidence by 41 to 70% (Xiao and Boal, 2009).

Harpin protein and *L. acidophilus* fermentation product elicitors of systemic acquired resistance in the host tissue that could indirectly help to protect apples from pathogens. The effect of application of harpin protein on the apples was less effective against blue mold and brown rot in this study. Capdeville et al. used to Hp in pre and postharvest treatments of apples induced resistance to *P. expansum* on apple. When they inoculated with the concentration 1×10^4 conidia/mL^{-1} *P. expansum* on apple in hp treatment a few days (4-8 days) before harvest was even more effective than the presented study (Capdeville et al., 2002, 2003).

Lafp had successfully controlled the brown rot caused by *M. fructigena* on apple in the present study. Similarly, the control of blue mold and grey mold on apple with Acibenzolar-S- methyl was reported before (Spadaro et al., 2004). β -aminobutyric-acid (BABA) on the activation of resistance responses in apple was investigated by Quaglia et al. (2017). Conversely, BABA resistance was not effective in the control of blue mold on apple such as Lafp.

Successful results similar to our study were obtained concerning the prevention of disease with *Trichoderma* spp. against *M. fructicola* on peaches and plums in the study of Hong et al. (1998) and with *Trichoderma polysporum* against *M. fructigena* on apples. The antagonist fungus *T. polysporum*, which was isolated from the apple leaves, was found to inhibit *B. cinerea* at 93%, *M. fructigena* at 80%, and *P. expansum* at 87% in postharvest apples (Falconi and Mendgen, 1994).

Aureobasidium pullulans, *Candida infirmominiatus*, *C. laurentii*, *Rhodotourula spp*, *M. pulcherrima*, and *Pichia angust*, from the yeasts isolated from the surface of the fruit, leaves and flowers, were found to be successful to prevent the disease, preharvest and postharvest in addition to *T. harzanium* that we applied in the biological control of post-harvest brown rot (Falconi and Mendgen, 1994; Chand and Spots, 1995; Hong et al., 1998; Irina et al., 2006; Fiori et al., 2008). As for our study, a similar effect was achieved (~70%) as the biological control agent *T. harzianum* successfully controlled *P. expansum* (Falconi and Mendgen, 1994). When the lesions were measured for the different postharvest fruits (pear, grape and kiwi) that were treated with the *T. harzianum* emulsion was found to support our research results (Batta, 2006).

In the biological control of *P. expansum* in the postharvest apples, different *Trichoderma* spp. (*T. atrovide*), apart from *T. harzianum*, also were found to have successful decay inhibition ranged of 35-50% while *Pseudomonas syringae* isolates and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1201312022

P. agglomorates were found to be 100% and 81% effective, respectively. This may be attributed to the different action mechanisms of antagonist bacteria (Nunes et al., 2002; Quaglia et al., 2010).

Yeast-based and bacteria antagonist isolates isolated from the fruit surface of apples, leaves, flowers and soils such as *Sporobolomyces roseus, Aureobasidium pullulans*, *Metschnikowia andauensis*, *Candida sake*, *Cryptococcus in firomo-miniatus*, *C. laurentii*, *Hanseniaspora uvarum*, *Rhodotourula spp.* and *Bacillus amyloliquefaciens* BUZ-14 have also been successfully applied to the postharvest biologic control of *P. expansum* (Janisiewicz et al., 1994; Leibinger et al., 1997; Ippolito et al., 2000; Nunes et al., 2002; Karabulut et al., 2002; Turkekul, 2003; Spadaro et al., 2004; Manso and Nunes, 2011; Calvo et al., 2017).

There was no study to treatment of the apples with Lafp against *P. expansum* postharvest. However, 14 days and 21 days before the harvest, Lafp plant activator was applied to oranges, followed by the inoculation of *P. digitatum* (1×10^6 conidia/mL^{-1}). The reported 50% success rate as a result of the application of plant activator to the fruit 21 days before pathogen application was more effective than our work. In this study as well, in stimulating durability against disease, it is inferred that the time period after the application of the plant activator should be long (Bower, 2007).

The effective results obtained in this research will contribute to the expansion of the usage areas of plant activators that do not harm human health and the environment. It is thought that promising results can be obtained for different pathogens with different combinations of applications of Lafp and *T. harzianum*, which have been successfully used individually.

Conclusion

Biological control with antagonist fungi have been a promising alternative, with lower environmental effect, either alone or as part of integrated pest management to reduce synthetic fungicide usage in postharvest diseases of fruit and vegetables for many years. The present results indicate that *T. harzianum* (TRIC8) has potential as a biocontrol agent for the control of postharvest decay of apple caused by *P. expansum* and *M. fructigena*. TRIC8 treatment was used to control of *M. fructigena* more effective than *P. expansum* on apple and could become an alternative to fungicide in postharvest decay control of brown rot on apple, but registration and development investigations to acquire a commercial product are needed.

Abstract. An ethnobotanical (EB) research was conducted on the wild plants of Watala National Park (WNP) and allied villages of Barnala, District Bhimber, Azad Jammu and Kashmir (AJK), Pakistan. EB data have been collected by questionnaire method employing structured and semi-structured interviews. A total of 79 interviewees (47 male, 32 female) having age 25-65 years were included in the EB study. 92 plant species of 37 families were studied and the obtained data were compiled in an inventory form consisting of ethnomedicinal (EM) use, parts used, mode of application and EB use. For validation of EM data of plants different microstatistical tools like frequency of citation (FC), relative frequencies of citation (RFC), use value (UV), fidelity level (FL) and informant consensus factor (ICF) were used. Direct matrix ranking (DMR) and priority ranking (PR) were applied on EB data for quantitative analysis to find multiple use forms of plant(s) and calculate biotic threats for the plants. Study results depicted that FC ranged 59 to 11, RFC was 0.75 to 0.14 and UV was between 0.82 and 0.15. Leaves were the most frequently used (31%) part of plants and powder form (25%) was the most commonly used form. The highest FL was found for *Senegalia modesta* species (100%) and diseases such as fever, flu, headache, bronchitis and cough ranked first (0.94) in ICF analysis. DMR results showed that *Senegalia modesta* was the first regarding multifarious use. Fuel wood cutting and fire burning were top two threats for the flora of the area. Due to anthropogenic pressure and climatic dynamics plants of the area are under severe threats and there is urgent need to conserve the flora of WNP, District Bhimber for future generations and to introduce sustainable applications.

Keywords: *traditional ethnobotanical knowledge, informant consensus factor, relative frequency, folklore therapeutics, green drugs, conservation status*

Introduction

Plants have been used by man for his sustenance on the planet. Wild plants had been part and parcel of daily needs of people inhabiting different rural parts of the world. Plants provide fundamental necessities of daily life because rural communities are primarily dependent on wild plant resources for fulfilling the needs of their life (Ishtiaq and Khan, 2008).

Ethnobotany (EB) is discipline of botany in which we study the native people's relationship with indigenous flora of the area and it encompasses the biocultural diversity of plants and human sociological paradigms (Harshberger, 1895; Ishtiaq et al., 2016). It was demonstrated that ethnobotany and ecology are interlinked with each other and this

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1202312055

intermingling of two or more disciplines give ecoethnobotany (EEB) discipline which give significant importance of plants in the life of indigenous communities and ecosystem sustainability (Jones, 1941; Ford, 1978; Ajaib et al., 2014a). EB is the study of direct interaction between human beings and the flora through their coinciding biodiversity and civilization/cultural diversity in the form of index of biocultural diversity (IBCD) which describes this interdependence (Pie, 1995; Ahmad et al., 2008; Ishtiaq et al., 2013a). Plants perform variety of keystone roles in our daily life such as plants provide food, fodder, medicines, shelter, cosmetics, shadow, hedging and fencing, dyes, fuel and aesthetics in the form of ornamental taxa. They have a great role in environmental functions such as stabilizing soil, recycling of nutrients, photosynthesis, protecting water drainage areas and help to restraint rainfall through the process of transpiration (Mehmood et al., 2012; Naseem et al., 2018). Plants are also involved in the manufacturing of different phytochemicals also called secondary metabolites which are potential sources of disease treatment through drug discovery and development process (Ajaib et al., 2014b).

Pakistan has rich and abundant plant resources and nearly more than 6000 plants have been reported, particularly more than 2000 species are known as medicinal plants (MPs) being used in the cure of many diseases by local communities of the country (Ali et al., 2001; Umair et al., 2017; Sher et al., 2016). The plants have been playing pivotal role in coping the basic needs of rural communities in various parts of Pakistan and AJK (Ishtiaq et al., 2013b). The indigenous people of mountainous and remote areas of AJK had been dependent primarily on local plants for obtaining needs of life such as food, fodder, shelter and ethnomedicines. The information about plants regarding their role as EMs and other EB necessities is very helpful to ecologists, pharmacologists, taxonomists, watershed and wild life managers. These are documented to conserve the civilization norms and folklore traditions of various ethnic groups and areas and describe how plants are inevitable in the prosperity of indigenous communities of the area (Ishtiaq et al., 2012, 2013a; Ajaib et al., 2014b; Chassagne et al., 2016).

Azad Jammu and Kashmir (AJK) is a territory that connects Pakistan with China and India. Kashmir has a historical background and it was an independent empire in the 18th century but later on during 1940s decade when India and Pakistan emerged on the map of world, this state was tetra-furcated into four sections; one of those is called as AJK (Ishtiaq et al., 2013b). Azad Jammu and Kashmir state has ten districts and Bhimber is one of these and it is located at the southern side connecting District Gujrat of Pakistan and Districts Rajori and Jammu of the Indian part of Kashmir. The study area of Watala National Park (WNP) and allied villages is located in Tehsil Barnala of District Bhimber, AJK. Collectively Districts Mirpur and Bhimber make one division of AJK and it consists of 2526 km^2 area (*Fig. 1*). District Bhimber has plain area with some high mountains in Tehsil Samahni only and its area is 1516 km^2. The population of District Bhimber is 0.343 million with a growth rate of 2.6% and house hold size of 6.7 (Ishtiaq et al., 2016).

The climate of the study area is warm and temperate with an average annual temperature of 23.5 °C. The average rainfall is 752 mm in a year. June is the warmest month of the year, temperature fluctuates with range 40-48.2 °C. January is the coldest month of the year, with an average temperature of 12.1 °C. November is the driest month, with 5 mm of rainfall. In July, the precipitation reaches its peak, with an average of 222 mm (Mehmood et al., 2012; Ishtiaq et al., 2016). Study area (Watala) is located in the North-East of Azad Jammu and Kashmir along 32° 54 (32.9023°) N and 74° 17 (74.2962°) E at an average elevation of 444 m above sea level (GPS Garmin Nuvi) (Nadeem et al., 2014; Ishtiaq et al., 2016).

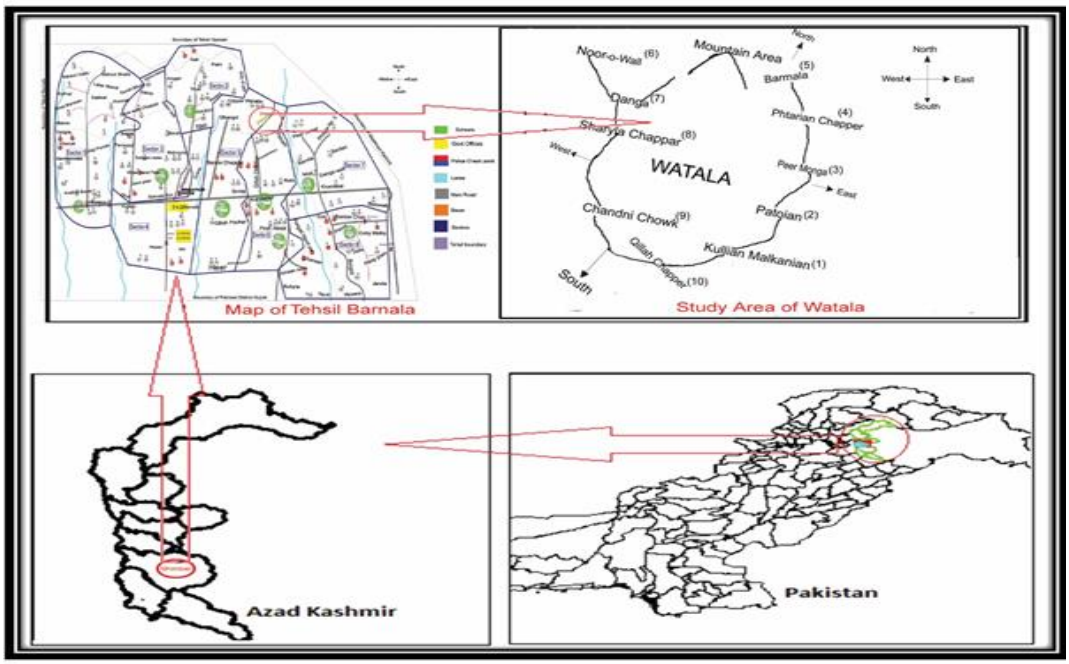

Figure 1. *Map showing location of study area, Watala, District Bhimber within Tehsil Barnala, Azad Kashmir and Pakistan*

WNP area has different ethnic groups residing such as Gojars, Jat, Rajpoot, Jaraal, Syed, Mirza, Kashmiri, Chibs and Awans (Ishtiaq et al., 2007a). In the area key languages spoken are Punjabi, Kashmiri, Saariki, Gojari, and Parhayee and each has different linguistic dialects that fluctuates from one village to other due to mixing of various cultures by bonds of marriages or by migration of people due to Indian firing, long drought spell, or any other cause (Ishtiaq et al., 2013b, 2016).

On many parts of Pakistan commendable work have been reported on EB studies by different workers describing that EB research is very important in drug discovery and development (Shinwari and Khan, 2000; Ishtiaq et al., 2007b). Albeit many sporadic research works are reported on EB studies of different areas of AJK (Qamar, 1996; Amjad et al., 2017; Dar et al., 2018; Ajaib et al., 2015; Ishtiaq et al., 2012, 2013b) but hitherto nothing is published on Watala National Park (WNP) and allied villages of District Bhimber, AJK. This is a first time an attempt to describe the ethnobotanical research on WNP using quantitative analysis by applying various microstatistical indices such as CF, RCF, FL, ICF and UVs. The IBCD, DMR and PR tools were used for determining biotic threat levels on the various plant species of WNP and then recommendations were made for the conservation of these taxa for their sustainable ecosystem services. The pivotal objectives of the research study were to: (i) study the plant biodiversity of the Watala National Park (WNP) and its allied area by preparing check list of plant flora; (ii) investigate and explore ethnobotanical potential of plants of the WNP in the life of rural communities by documenting multiple purpose uses; (iii) traditional folklore therapeutic recipes of medicinal plants (MPs) that may serve drug discovery research in the future; (iv) to document the cultural heritage of the indigenous communities of the WNP area and to calculate the conservation of various plants with recommendations for their protection and conservation for the future.

Materials and methods

An ethnobotanical (EB) study was conducted during years 2015 and 2016 in Watala National Park (WNP) and allied villages of District Bhimber to collect the plant specimens for experimental analysis. During four seasons of the year, several planned and random field trips were conducted in the study area to collect EB information and data were recorded in triplicate manner for each parameter. The EB data were collected through use of Visual appraisal assessment (VAA) and rapid rural appraisal (RRA) methods (Okuthe et al., 2003; Ishtiaq et al., 2007b). In VAT, observations were made in wild areas and in the community houses and market visits and all of important information were instantly documented in a notebook. In RAA method, questionnaire method following Ishtiaq et al. (2013a, 2016) was used. In the process, structured and semi-structured interview patterns were used and data were collected from field visits and from local market surveys including botanic drug sellers (dealers), timber dealers, fuel wood sellers, local hakims and farmers in the research. The data collected from the local people included: botanical name, vernacular name, local name, folklore uses, therapeutic recipes, plants' part used, occurrence in area, characters involved in the collection, trade marketing, mode of usage and other related information like: disease name cured. According to economic values and drug potential, plants of WNP were further categorized into medicinal plants (MPs), food, fruits, fodder, vegetable, thatching, hedging, shelter, ornamental and fuel wood etc. based on the gathered data through interviewing questionnaire from botanic drug sellers, timber dealers, fuel wood sellers, local hakims and farmers. In this research analysis, preference was given to local elder people and hakims, who were the actual consumers and had a lot of indigenous traditional and cultural information about the plants and local ethnic groups with ritual paradigms (Ishtiaq et al., 2016). The collected data compiled in documentary form and it was compared with published and online papers for authenticity and verification.

Data collection and identification of plants

The plant specimens were collected from the area (WNP) for identification and extraction of EB data from villagers by showing them the plant specimens and asking them to answer the questions asked through different interview formats. The collected plants were dried, pressed, mounted properly on herbarium sheets and voucher numbers were assigned to each taxon according to protocol of Alexiades (1996), Cook (1995) and Ishtiaq et al. (2013b). All of these plant taxa were submitted for further reference in the Herbarium (MUH-), Department of Botany, Mirpur University of Science and Technology (MUST), Bhimber Campus. The plants were identified mainly with the help of Flora of Pakistan (www.eflora.com) following printed Flora book (Nasir and Ali, 1970-1989; Ali and Qaiser, 1993-2015), whereas the International Plant Name Index (IPNI) (www.ipni.org) was also used to obtain authentic botanical names.

Quantitative ethnobotanical data analysis

For the corroboration and to analyze the homogeneity of the collected ethnobotanical data, various quantitative indices were used. The collected EB data were formulated in form of a matrix (MS excel worksheet) and summarized as per protocol of Cook (1995) and Ishtiaq et al. (2013b). The obtained data were compared with previous research work published on the same area or on different areas of AJK but with same topic by

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1202312055

using online searching for authentication and reliability. Due to stringent peer review procedure only authentic information were kept for the meta-analysis of the study. The applicability, reliability and authenticity of ethnobotanical research work was rechecked and supported by calculating frequency of citation (FC), use value (UV), relative frequency of citation (RFC), fidelity level (FL), informant consensus factor (ICF), data matrix ranking (DMR) and priority ranking (PR) microstatistical tools following protocols of Ishtiaq et al. (2007b) and Fisseha et al. (2009).

Relative frequency of citation (RFC)

The index of relative frequency of citation (RFC) was determined by using the following formula (Vijayakumar et al., 2015).

$$RFC = FC / N \quad \text{(Eq.1)}$$

where FC is the number of informants reporting use of a particular species and N is the total number of informants.

Use value index (UV)

The use value was calculated by using the following formula (Vijayakumar et al., 2015).

$$UV = \sum Ui / N \quad \text{(Eq.2)}$$

where Ui is the number of uses mentioned by each informant for a given species and N is the total number of informants.

Fidelity level (FL)

The fidelity level (FL), the percentage of informants claiming the use of a certain plant for the same major purpose was calculated for the most frequently reported usages or ailments as:

$$FL(\%) = \frac{Np}{N} \times 100 \quad \text{(Eq.3)}$$

where Np is the number of informants that claim a use of a plant species used for a particular purpose/disease and N is the number of informants that use the plants as a botanic/medicine to fill/treat any given demand/disease (Alexiades, 1996).

Informant consensus factor (ICF)

Informant consensus factor (ICF) was calculated for each category of aliments to identify the agreements of the informants on the reported medicures for the group of ICF was calculated as follows: number of use citations in each category (nur) minus the number of species used (nt), divided by the number of use citations in each category minus one (Heinrich et al., 1998).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1202312055

$$ICF = \frac{nur - nt}{nur - 1} \quad \text{(Eq.4)}$$

Data matrix ranking (DMR)

Data matrix ranking (DMR) describes the multiple usages of one plant for various purposes by the indigenous community and the data is presented in tabular form with % age index of each use-form aliments (Fisseha et al., 2009; Ishtiaq et al., 2013a).

Priority ranking (PR)

Priority ranking (PR) method was used for indicating the preference of the local people about the potential use of each plant in certain use and it describes the biotic pressure on the plants of the area and it assist to calculate the conservation status of various species in the study area (Ishtiaq et al., 2007a, 2013b).

Results

The Ethnobotanical research work is very important because it provides basic information on plant biodiversity, cultural diversity and traditional ethnomedicinal knowledge (TEK) of an area. The current research work was conducted in the rural area of Tehsil Barnala mainly focused on Watala National Park (WNP) and its allied village areas of Tehsil Barnala, District Bhimber Azad Jammu and Kashmir, Pakistan.

The area of WNP is very rich for biocultural diversity as it has a historic background. King of Dogra empire "Mahraja Hari Singh's" maternal grandparents belonged to this territory of WNP. The princess visited this region during his regime. There is a garden of mangoes in this region that is named as "Princess' Garden" locally called "Raani ka Baagh" which was established by the King in desire of the Princess (Baheem, 1890).

In this research work various parameters were studied which included the following steps: (i) social and geographical characteristics of the sample and study sites, shown in *Table 1*, (ii) Family-wise contribution and ethnomedicinal flora, (iii) plant collection, identification and preservation and (iv) documentation of floristic composition of the plants of the area.

Inhabitants of WNP and allied area (10 villages) were interviewed with the above said methodology for documentation of folklore therapeutics and ethnobotanical knowledge of the plants of the area (*Fig. 1*). The interviewees were of both gender with age range of 25-to-65 years and if age groups were made on the basis of 10 years age differences, then it was found that age group "56-65 years" was more knowledgeable due to their keen interest in local plants uses and their personal experience of life (*Table 1*). Less ethnobotanical knowledge was exhibited by age group "16-25 years" due to their preference for use of western medicines. However, the 56-65 years and 60 < years age group showed high level of traditional knowledge which is a good sign of traditional knowledge consistency in the area. The graphical age difference of respondents is shown in (*Fig. 2*).

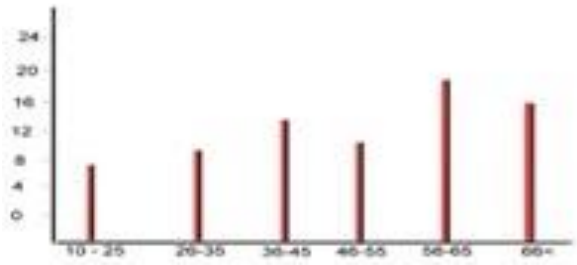

Figure 2. *Graphical age difference of respondents of ethnobotanical study of Watala National Park of AJK, Pakistan*

Family-wise contribution and ethnobotanical flora of Watala National Park and allied areas

For the documentation of ethnobotanical knowledge of the plants of Watala National Park (WNP) different plants were collected from the selected villages and WNP area according to protocol of Ishtiaq et al. (2007b). The collected plants were pressed, dried and mounted on herbarium sheets for preservation in the herbarium of the Department of Botany, Mirpur University of Science and Technology Bhimber AJK. Each collected plant specimen was assigned a herbarium voucher number with prefix: MUH-. The collected plants were herbaria numbers initiating from MUH-3031 to MUH-3122 (*Table 3*). The collected plants were verified and identified mainly with the help of Flora of Pakistan library booklets and online data (www.eflora.com) following Nasir and Ali (1970-1989) and Ali and Qaiser (1993-2015) whereas the International Plant Name Index (IPNI) (www.ipni.org) was also used to obtain correct botanical names, if not found in the herbarium or eflora website. Distribution of medicinal plant (MPs) species according to their family is presented in tabular form and it was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1202312055

found that Poaceae was the first having 15 species (16.31%), followed by Amaranthaceae with 08 species (8.69%) and Malvaceae ranked at third with 6 taxa (6.52%) as described in *Table 2* and in *Figure 3* in graphical format.

Table 2. *Percentage distribution of medicinal plants according to their family from Watala National Park of AJK*

Sr. no.	Family name	No. of spp.	Percentage contribution	Sr. no.	Family name	No. of spp.	Percentage contribution
1-	Acanthaceae	3	3.26%	20-	Flacourtiaceae	2	2.17%

Documentation of wild plant species

Ethnobotanical data of the wild plants of the WNP of AJK were documented containing voucher numbers, botanical names, vernacular name, family name, plant part used, field collection period, exact gathering sites, traditional medicinal uses and other use forms (*Table 3*). In the investigated area, 92 plant species belonging to 83 genera and 37 families were recorded. Among them, Poaceae ranked first having 15 species (16.31%), Amaranthaceae was second having 8 species (8.69%) whereas Malvaceae showed the third highest number having 6 species (6.52%), respectively. Asteraceae, Convalvulaceae, Mimoaceae and Papilionaceae each having 4 species (4.35%) while Acanthaceae, Capparidaceae, Euphorbiaceae, Lamiaceae, Moraceae and Solanaceae each has 3 species (3.26%). Apocynaceae, Cucurbitaceae, Flacourtiaceae, Tiliaceae and Rhamnaceae each has 2 species (2.17%). Anacardiaceae, Asparagaceae, Boraginaceae, Brassicaceae, Cactaceae, Cannabaceae, Celastraceae Cleomaceae, Combretaceae, Commenlinaceae, Cyperaceae, Martyniaceae, Meliaceae, Nyctaginaceae, Oxalidaceae, Potamogetanaceae, Primulaceae, Sapindaceae and Verbenaceae each has 1 species only (1.08%). A pie-chart of medicinal plant species according to their contribution to each family is shown in (*Fig. 3*). Most of the plant species in the area identified as having an ethnomedicinal value were herbaceous (55%), followed by trees (20%), grasses (12%),

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1202312055

shrubs (10%) and climbers (3%) (*Fig. 4*). These results reflect the high altitude of the study area where the herbaceous flora is dominant with fewer grasses and trees.

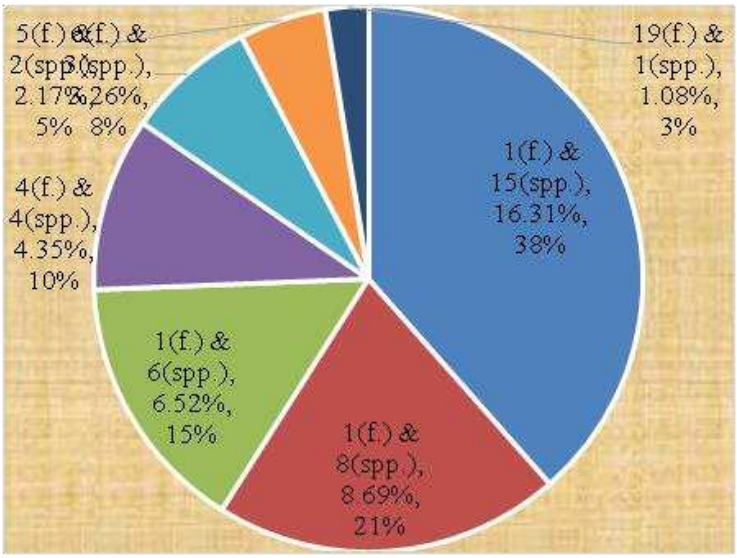

Figure 3. *A pie-chart of medicinal plant species according to their contribution to their family (f: no. of families & spp.: no. of species)*

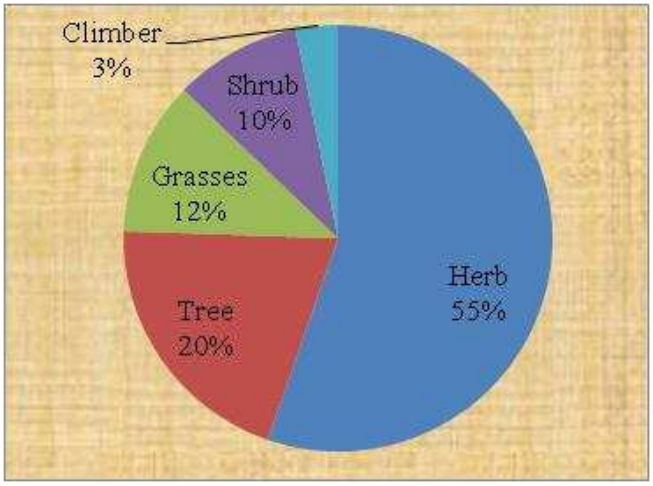

Figure 4. *Life form of plants used in ethnobotanical study of Watala National Park of AJK, Pakistan*

Plant part(s) used

Different plant parts are used in different ways in herbal medicines depending upon the knowledge of indigenous communities and accessibility of those plants to local inhabitants. In the present study, leaves (L = 31%) were the most commonly used plant part in the herbal therapeutic preparations followed by whole plant (WP = 21%), root (R = 10%), fruit & seed (FS = 8.8%), wood (W = 7%), bark (B = 6%), stem (S = 5%), flowers (F = 3%) and legume (Lg = 1%) as shown in *Figure 5*. Ethnobotanical and medicinal uses of plants were also recorded and presented in *Table 3*.

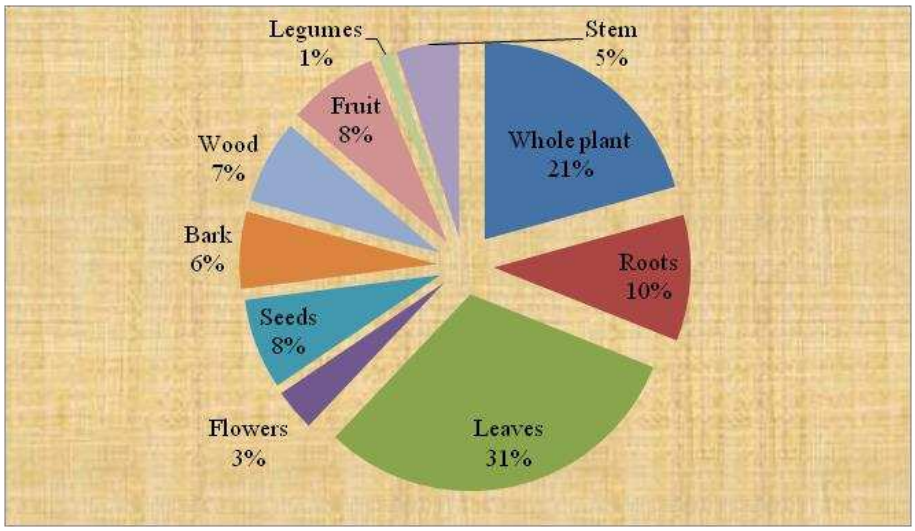

Figure 5. *Plant parts used in herbal recipes in terms of% age from Watala National Park of District Bhimber, AJK*

Method of preparation of folklore therapeutics and mode of administration

Plants are very important source of food and medicines because plants contain many primary and secondary metabolites and the latter ones make them potential sources of medicinal use. Different parts of plants of various types and variable quantity of phytochemicals are used. The different plant parts were mostly used in herbal preparations in various modes such as decoction (22 spp.), extract (18 spp.), wet paste (17 spp.), dry & powder (17 spp.), fuel (16 spp.), juice (11 spp.), palatable (9 spp.), vegetable (8 spp.), poultice (5 spp.) and gum (4 spp.). During the research various methods of folklore tonics' preparation were documented by interviewing the indigenous inhabitants of WNP and allied villages. Common form and mode of herbal therapeutics formation and its administration form were as: food/fodder (direct WP used) with the highest value (25%), and decoction, paste, juice, powder, extract, tea and gum as the least used form (6%) (*Fig. 6*).

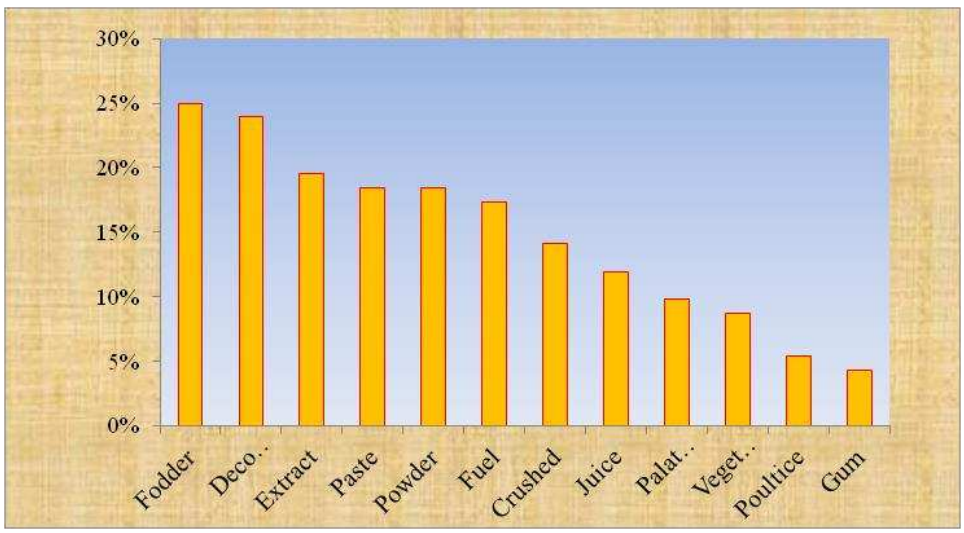

Figure 6. *Common methods of preparation of folklore therapeutics and their mode of administration*

Table 3. *Traditional ethnomedicinal and ethnobotanical uses of wild plants recorded from study area Watala National Park of District Bhimber of AJK*

Sr#	Family, botanical name & voucher no.	Habit	Common name	Used parts	Gathering period	Gathering area(s)	Traditional medicinal uses	Ethnobotanical uses	FC	RFC	UV
(1) Acanthaceae											
1-	*Dicliptera bupleuroides* Nees MUH-3031	Herb	Kalu	Whole plant	Spring	Waste-land	The poultice is used for scabies. The host insect from this plant is collected to make powder, which is very effective to cure pneumonia and hypertension	It is used as fuel in dried form.	48	0.61	0.63
2-	*Justicia adhatoda* L. MUH-3032	Herb	Bhaker	Leaves and almost whole plant	Spring	Waste-land	Half kg of fresh leaves is extracted with 500ml water, used against diabetes and in blood purification. Leaves and flowers are taken, dried under shade, crushed to acquire powder, 50gm of this powder is mixed in 15ml of honey and used to treatment of chest infection. Decoction of leaves is used for skin infection. The stem and leaves are useful for fever and hypertension	It is used for thatching, fuel ,hedging, shadow for other micro-plants, and used as fodder	No	0.66	0.68
3-	*Peristrophe paniculata* (Forssk.) Brummitt MUH-3033	Herb	Kaluu / Kali-Buti	Whole plant	Spring	Bushy-vegetation	The host insect from this plant is collected to make powder, which is very effective to cure pneumonia and hypertension	It is used as fodder, fuel.	19	0.24	0.31
(2) Amaranthaceae											
4-	*Achyranthes aspera* L. MUH-3034	Herb	Puth-Kanda	Whole plant	Spring	Bushy-vegetation	The paste acquired from the root has been used to cure snake bite. Decoction is diuretic. Seeds and leaves are given in prolepses in cattle. Seed powder is also used in treatment of strong abdominal pain. Shade dried whole plant powder is mixed with honey is effective for pneumonia	It is eaten as fodder, also used as fuel in dried form.	46	0.58	0.52
5-	*Aerva sanguinolenta* (L.) Blume MUH-3035	Herb	Booti	Branches	Spring	Bushy-vegetation	A decoction of immature branches is used to cure haematuria and irregular or painful menstruation	It is used as fodder and bioremediator	11	0.14	0.22
6-	*Alternanthera pungens* Kunth MUH-3036	Herb	Kanda-Buti	Leaves and Roots	Spring	Beside pedestrian passes	Roots and leaves paste is beneficial for liver disorder. Roots are used for eye tumor as well as its decoction for cough and pulmonary disorder. Leaves and roots are diuretic and used in blood purification	It is used for fuel in dried form.	18	0.23	0.16

DOI: http://dx.doi.org/10.15666/aeer/1705_1202312055

7-	*Amaranthus graecizans* L. MUH-3037	Herb	Hardar-Chalei	Whole plant	Spring	Bushy-vegetation	The whole climber plant shade dried and ground to form powder is used for cardiac diseases, diabetes and aphrodisiac. Leaves are crushed with sugar and occupied along with black tea for treating constipation and gastrointestinal problems. Poultice of leaf is prepared along with mustard oil for the cure of abscesses	It is used as vegetable and source of fodder.	12	0.15	0.51
8-	*Amaranthus viridis* L. MUH-3038	Herb	Ganar	Whole plant	Spring	Bushy-vegetation	The leaves are used on snake bite and scorpion sting. Root is used to restraint menstruation. It is also used as vegetable (saag)	It is used as vegetable and fodder	43	0.54	0.24
9-	*Celosia argentea* L. MUH-3039	Herb	Gutta-Buti	Whole plant	Spring	Fertile-valley	About 20ml of root extract is used to check undue menstruation. It is used as fodder for cattle	It is used as fodder for cattle	12	0.15	0.23
10-	*Digera muricata* (L.) Mart. MUH-3040	Herb	Tandola / Dawurra	Whole plant	Spring	Waste-land	Extract of the whole plant juice is used as laxative. Leaves are used as vegetable. The tender tips extract is also used for kidney stones	It is used as bioremediator and fodder and vegetable	29	0.36	0.15
11-	*Pupalia lappacea* (L.) Juss. MUH-3041	Herb	Jojera	Whole plant	Spring	Bushy-vegetation	10-12gm of fresh leaf paste mixed with 50-60ml of *Sesamum indicum* oil, mixture is used for bone fracture	It is used as vegetable and chick feed	57	0.72	0.54
(3) Anacardiaceae											
12-	*Lannea coromandelica* (Houtt.) Merr. MUH-3042	Tree	Gandela	Whole plant	Summer	Forest	The gum acquired from the stem is used in confectionery. The bark powder is used as a flavoring. The plant is grown as a hedge as well as a fence	It is used as Fuel wood, shelter and fodder	32	0.41	0.51
(4) Apocynaceae											
13-	*Carissa opaca* Stapf ex Haines. MUH-3043	Tree	Grunda	Whole plant	Spring	Mountain-forest	1kg decoction of fresh roots is used for asthma, jaundice and kidney pain. 30g dried root is crushed to form powder and used in the cure of animal wounds. Milky juice extracted from ripen fruit is effectively used to cure iron deficiency, liver disorders and blood deficiencies. Leaves are used as fodder for goats and sheep. Stem and root are used as fuel especially in local ovens	It is used as fodder, fuel wood, hedging and fencing, fruit	44	0.55	0.36
14-	*Telosma cordata* (Burm. f.) Merr. MUH-3044	Herb	Pakalana	Roots and flowers	Spring	Waste-land	The plump roots are used to make a sweetmeat. The flowers are used in the treatment of conjunctivitis	It is used as fodder and dry fuel	51	0.65	0.72
(5) Asclepiadaceae											

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1202312055

15-	*Calotropis procera* (Aiton) Dryand. MUH-3045	Shrub	Desi-aak	Whole plant	Summer	Barren-land	Whole plant extract is used for dog bite. Commonly latex is used for ring worm and skin diseases. The milky juice is toxic	Its toxic material, kills goats if eaten too much	41	0.52	0.23
(6) Asparagaceae											
16-	*Asparagus gracilis* Browicz MUH-3046	Herb	-	Whole plant	Spring	Bushy-vegetation	The plant is used for its anti-oxidant and anti-urease activity	Fodder for animals	23	0.29	0.41
(7) Asteraceae											
17-	*Artemisia scoparia* Waldst. & Kitam. MUH-3047	Herb	Chahuu	Leaves	Spring	Waste-land	Leaves are used as tonic and anthelmintic	It is used as fodder for goats, dry fuel	41	0.52	0.72
18-	*Bidens biternata* (Lour.) Merr. & Sherff MUH-3048	Herb	-	Leaves and seeds	Summer	Waste- land	Leaf juice is used to treat eye and ear infections. The scoured leaves are applied to skin infections as haemostatic on wounds, and enfolded around the umbilical cord of babies. The seeds are used as an anthelmintic in animals	It is used as fodder and bioremediator	12	0.15	0.55
19-	*Tridax procumbens* (L.) L MUH-3049	Herb	Coat button	Whole plant	Spring	Waste-land	The leaves are used in the treatment of bronchial catarrh, dysentery and diarrhea. The leaves paste is applied to reduce swelling of haemorrhoids and to stop bleeding. Smoke produced by burning of the plant is used to repel mosquitoes	It is used as dry fuel, and fodder.	35	0.44	0.65
20-	*Xanthium strumarium* L. MUH-3050	Herb	Motta-Jojera	Whole plant	Spring	Bushy-vegetation	120ml decoction is prepared from 60mg of dried root of this plant and used in diabetes. Leaves decoction is used for long malarial fever	It is used as fuel	59	0.75	0.52
(8) Boraginaceae											
21-	*Ehretia laevis* Roxb. MUH-3051	Tree	Cham-road	Stem and bark	Summer	Forest	Stem bark powder is used internally to check blood dysentery for three days	Fire wood, shelter, fodder	56	0.71	0.29
(9) Brassicaceae											
22-	*Coronopus didymus* (L.) Sm. MUH-3052	Herb	Thandi-Buti	Whole plant	Spring	Fertile-valley	The plant is used as fumigant to repulse the insects. The plant brings feelings of coolness in the body	It is used as bioindicator	24	0.31	0.52
(10) Cactaceae											
23-	*Opuntia monacantha* (Wild.) Haw. MUH-3053	Shrub	Tarapar-thor	Whole plant	Summer	Barren-land	It is used as hedge plant for fencing the fields	It is used as raticide	23	0.29	0.15
(11) Cannabaceae											

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1202312055

24-	*Cannabis sativa* L. MUH-3054	Herb	Bhaang	Whole plant	Summer	Beside pedestrain passes	The fruit and leaves are used as soporiferous commonly called "Charas". Decoction of seeds is given to cattle for increasing milk. Leaves are also used for constipation, stomach diseases, aphrodisiac and muscle contraction. It is also used for stopping menses and whooping cough. Seeds are used to stop releasing sperms	It is used for fuel, thatching material used in mud-houses	31	0.39	0.44
(12) Capparidaceae											
25-	*Capparis sepiaria* L. MUH-3055	Shrub	Daddur	Whole plant	Spring	Forest	The fruit is used to make powder and effectively used to cure anemia, liver disorder and aphrodisiac. The leaves are used as fodder for goats. Wood is useful as fuel wood	It is used as fuel plant, fodder as well	23	0.29	0.71
26-	*Cleome gynandra* L. MUH-3056	Herb	Talwar-Buti	Leaves	Spring	Hedgerows	Leaf juice is used as an ear-ache drop by drop. Half tea-spoon of leaf juice is used daily for cold. 10g of leaves crushed with the same amount of pepper and garlic extract is used daily for fertility to women after completion of menstrual period	It is used as fodder plant	15	0.18	0.31
27-	*Crateva adansonii* DC. MUH-3057	Tree	Barna	Whole plant	Summer	Barren-land	It is suitable in disorders of urinary organs, urinary tract infections, pain and burning micturition, renal and vesicle calculi.	Fuel wood, shelter and cattle shades	25	0.32	0.29
(13) Celastraceae											
28-	*Maytenus royleana* (Wall. ex M.A. Lawson.) Cufd. MUH-3058	Shrub	Pataki	Whole plant	Summer	Forest	Root extract is abortificent. Leaves are palatable. Whole dry plant is used as fuel wood especially in local ovens	It is used as fodder, hedging plant	31	0.39	0.39
(14) Combretaceae											
29-	*Anogeissus latifolia* (Roxb. ex DC.) Wall.ex Bedd. MUH-3059	Tree	Qaam	Stem bark	Summer	Mountain-forest	Stem bark is crushed and soaked in water over night, 2 spoons of the filtered extract is given twice a day to cure whooping cough	It is used as fuel tree, shelter and fodder	19	0.24	0.18
(15) Commenlinaceae											
30-	*Commelina benghalensis* L. MUH-3060	Herb	Churra	Whole plant	Spring	Shady-land	Leaves are used as vegetable (saag). Plant is used as fodder for cattle. Leaves are laxative	It is used as fodder and vegetable	15	0.18	0.29
(16) Convalvulaceae											

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

Relative frequency of citation and use values

The RFC shows the local importance of every species with reference to the informants who cited uses of these plant species (Vitalini et al., 2012). In our work, RFC ranges from 0.75 to 0.14 (*Table 3*). *Senegalia modesta, Grewia optiva, Pupalia lappacea, Xanthium strumarium, Ehretia laevis, Sida cordifolia, Azadirachta indica, Boerhavia procumbens, Ziziphus jujuba* and *Butea monosperma* were the most cited ethnomedicinal plant species. These species are native to the area and have been known to local cultures over a long time period. Thus their specific properties for curing different diseases have become popularized and well-established among the indigenous people.

The use value (UV) is a measure of the types of uses attributed to a particular plant species. In the present study Datura inoxia, Dalbergia sissoo, Tephrosia purpurea, Abutilon bidentatum, Ricinus communis, Cuscuta reflexa, Calotropis procera and Digera muricata had UV values of 0.75, 0.73, 0.67, 0.59, 0.49, 0.32, 0.23 and 0.15, respectively. As the values for the UV and RFC are dynamic and change with location and with the knowledge of the people, so the values of UV and RFC may vary from area to area and even within the area.

Determination of fidelity level (FL)

The plants are used for treatment in different forms by local inhabitants of WNP of District Bhimber, AJK. This fidelity level analysis describes how the people of local area use a particular plant for the cure of specific disease and it also depicts their trust and belief on the specific plant used for cure that ailment. The analysis showed that highest FL values with first rank were *Grewia optiva* and *Senegalia modesta* (100% each) while *Justicia adhatoda* was at number two with 93% FL value and least *Maytenus royleana* with 23% weightage of worthiness in community popularity index (*Table 4*).

Determination of informant consensus factor (ICF) for ethnobotanical study of Watala National Park of AJK

The informant consensus factor (ICF) is a very important tool being used in ethnobotanical analysis and it describes how frequently a herb is used for cure to a particular disease. It indicates that how much community is unanimously agree to use different number of plant species for cure of particular disease or group of specific ailments. In this study, the highest values were obtained for jaundice, spleen and liver disorders (0.93); and kidney and urinary disorder (0.93). The ratio of cardio vascular diseases with reference of ICF was 0.50 (*Table 5*) and it is the least common disease prevailing in the area. These ICF calculations predictive of herbal therapeutics are used in the culture of indigenous communities.

Direct matrix ranking (DMR)

The data matrix ranking is an important microstatistical tool that describes what frequency of utilization is in an invariable form of a particular species for species purpose in daily life of man. This indirectly measures usage pressure on one species that is being exploited for different purposes by human beings. According to the informants' preview and key information *Senegalia modesta* has the highest DMR values and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1202312055

ranked at first while two taxa of genus *Ficus* named: *Ficus palmata* and *Ficus religious* were at number two. While plant *Butea monosperma* was third at 6th rank as shown in *Table 6*. This DMR table depicts that there are several severe biotic threats due to anthropogenic interference on plants life.

Table 4. *Fidelity level (FL) values of plants of Watala National Park and allied area, District Bhimber, AJK*

Species and family	Vernacular name	Family	Ethnomedicinal uses	Fidelity level (FL)
Grewia optiva J. R. Drumm. Ex Burret	Dhaman	Tiliaceae	Aphrodisiac, antihypertension	100%
Senegalia modesta (Wall.) P. J. Hurter	Phulai	Mimosaceae	Tonic, anti-inflammatory	100%
Justicia adhatoda L.	Baikar	Acanthaceae	Chest infection, hypertension	93%
Alternanthera pungens Kunth Bot.8	Kand booti	Amaranthaceae	Haematuria and menstrual disorders	82%

Priority ranking (PR)

The priority ranking (PR) analysis was also determined from the primary data collected from indigenous communities of WNP and allied villages of Barnala AJK. In order to explore the biotic pressure on plants of the study areas PR was calculated in tabular form and destructive threats were categorized in terms of six ranks: 6 < 5 < 4 < 3 < 2 < 1; number 6 represents the most destructive value, as shown in *Table 7*. This determines how respondents of interviewees of the area declare that which parameter is the most dangerous for the flora or specific plant. The PR analysis depicts that fuel wood cutting of plants is a major threat for the flora of the area, followed by fire burnings (that may be accidental or deliberate fires). As village people mostly depend on wood or its products for making shelter or cattle sheds so this is third number key factor of plants degradation or loss from the environment. Among the studied eight threatening factors hedging and fencing cause the least impact on the loss of plant biodiversity of the area.

Table 7. *Priority ranking (PR) of factors perceived as threats to plant biodiversity based on their level of destructive effects in the study area (destructive threat order is: 6 < 5 < 4 < 3 < 2 < 1; 6 is the most destructive value)*

Threat Factors	Respondents (R1-R6)						Total	Percentage	.m
	R1	R2	R3	R4	R5	R6			
Fuel source	6	3	6	4	6	6	31	15.57	1st
Construction of houses	5	3	4	4	2	3	21	11.05	8th

Discussion

The plants are very important for the life of all human but their significance is increased many times for rural communities of any area because they depend solely on their natural habitat (plants) while coping their basic needs of life. In this research analysis, plants of the Watala National Park (WNP) and allied villages were surveyed and documented in the form of checklist. The key aim was to explore their traditional ethnomedicinal uses and describe their main ethnobotanical applications in daily life of that area. As indigenous communities of WNP and allied villages are the real owner of flora of that area, so their interviews were conducted using semi-structured and structured format in the form of questionnaires. WNP is an area which is declared as national park by the government and it is located in Tehsil Barnala of District Bhimber AJK, Pakistan. The area under study comprised of WNP area and allied ten villages and out of these "Chandni chowk" and "Danga" villages have high altitude 472 and 465 m.a.s.l., respectively. There is low literacy rate in these remote areas as compared to main stream city of Barnala and Bhimber District. The low education is due to remote areas and low income resources with less approach to good educational institutes (Mehmood et al., 2012). It is also compatible with work past ethnobotanists that modern generations and people living in urban areas have almost no knowledge about medicinal properties of plants (Alcorn, 1984; Altieri et al., 1987). This emphasis that the work conducted on EMs and EB of WNP and allied areas is of paramount significance to conserve the traditional ethnomedicinal knowledge on the plants of the area before it is diminished completely from this area.

In the EB investigation data on medicinal and folklore uses of plants of the Watala National Park (WNP) and allied villages was surveyed and 92 plant species were recorded in ethnomedicinal (EMs) and ethnobotanical (EB) perspectives. The analysis showed that people of age group "56-65 years" had the highest level of EB and EMs knowledge about the local flora of the area (*Fig. 2*). This is in coincidence with previous report of Ishtiaq et al. (2013a) that mostly old people have more EMs knowledge and traditional rituals are preferably followed by them. It was concluded that people of the study area primarily depend on the local vegetation to cope many of their daily needs. Generally inhabitants of the area cut trees/and other plants not only to make shelters and other household items but also sell them as timber and fuel wood for domestic and commercial purposes to earn livelihood and source of revenue; similar findings have been reported in past researchers that rural people of many other countries are also dependent on indigenous plant resources for their needs of life (Mcdichen and Mehl (1990).

Ethnobotany is an important and recent approach to study natural resource management by local people involvement. The EB study gives provision for the protection of traditional and cultural knowledge and rights of native people as intellectual property rights. This research on EB analysis of any area cascades significance on how plants and indigenous people of an area are mutually interconnected and dependent on each other in terms of ecosystem sustainability format. In the past some sporadic work has been conducted on other parts of AJK (Ajaib et al., 2014a) and very little is known on District Bhimber flora, particularly no research project is conducted on EB analysis of WNP and allied villages.

Very little work has been undertaken by legal professionals, environmentalists, NGOs or even human rights groups to secure Intellectual Property Rights for native people, as expressed by Martin (1995) and here WNP and allied villages are very

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1202312055

neonate and nothing is found in printed or online literature. The present study area WNP and allied villages is an ecologically important area of District Bhimber, AJK but no attention previously had been given for the documentation and conservation of indigenous knowledge of the area.

Most of the native plants now exist only in graveyards and local people had a lot more information about these plants than the introduced plants. Similar results were also recorded by Meza and Vilagram (1991) in Chile on the level of knowledge of native flora, which was always greater for native flora than introduced species. The local inhabitants, having a little knowledge about the species and proper time of collections, from the poorest link in the trade of medicinal plants as reported by Ajaib et al. (2016) during ethnobotanical studies of wild plants of Tehsil Jatlan Azad Jammu and Kashmir. In WNP and allied areas the highest number of plants recorded for EMs and EB studies belonged to families Poaceae, Amaranthaceae and Malvaceae (*Table 2*) and the cause of this might be that taxa of these families have short life spell and can be grown out soon after monsoon rainfall and secondly the tree line is becoming scarce due to cutting and fire burnings (Ishtiaq et al., 2013a). Other taxa of families were also present in the form of herbs (55%), shrubs (10%), climbers and trees (20%) with variable population occurrence in different villages but their community structures have not well established (*Figs. 3* and *4*), which might be underneath cause of sandy stone soil with few rainfall and deep water table in the area (Ishtiaq et al., 2016).

The present study revealed that the local people used some plant species for more than one purpose as tribal totally depended on the vegetation of the area for a variety of their needs. Some of the important multiple-usage plants included *Senegalia modesta* (Wall.) P. J. Hurter, *Albizia lebbeck* (L.) Benth, *Carissa opaca* Stapf ex Haines, *Capparis sepiaria* L, *Dalbergia sissoo* DC, *Dodonaea viscosa* (L.) Jacq, *Flacourtia indica* (Burm. f.) Merr, *Ficus palmata* Forssk, *Ficus religiosa* L, *Heteropogon contortus* (L.) P. Beauv. Ex Roem. & Schult, *Maytenus royleana* (Wall. ex M. A. Lawson.) Cufd., *Oxalis corniculata* L, *Grewia optiva* J. R. Drumm. Ex Burret, *Saccharum spontaneum* L, *Urena lobata* L, *Vachellia nilotica* (L.) P. J. Hurter & Mabb, *Ziziphus jujuba* Mill. Multiple-usage species provided fruits, vegetables, fuel wood, medicines and other requirements to the local population. This is being described in *Table 4* that many plants are being utilized in admixture to cure one or more disease (s) and fidelity level (FL) also proves it (Ishtiaq et al., 2007b). The plant *Senegalia modesta* (Wall.) P. J. Hurter, has the highest FL (100%), followed by *Justicia adhatoda* L. with 93% FL value. *Flacourtia indica* (Burm. f.) Merr. had an FL value of 62%. It is also believed by indigenous rural communities of the area that plants originated drugs “green drugs” are pure and with least or without toxic effects and this coincides with the doctrine of previous researchers (Ishtiaq et al., 2006b, 2007a). The VAA procedure described that ICF analysis of the data culminated that as people of the area living in rural areas and with hard working life style, so they suffer from the least cardiovascular disorders (ICF: 0.50) while common problems in the area were only minor seasonal diseases like fever, flu, headache, bronchitis, cough having the highest ICF (100%), followed by jaundice, spleen and liver disorders (0.93 5) as shown in *Table 5*. Open life pattern and mosquito and high temperature with heat stroke waves may be the cause of this. Other cause of the liver and spleen disorders may be the use of open spring waters or ponds without proper hygienic measures (Erasto et al., 2005; Ishtiaq et al., 2006a, 2007a, 2010b).

One could assess the pressure on the flora of the area by the process of direct matric ranking (DMR) and the results depicted that many plants have been used in multifarious

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1202312055

forms to cope the needs of life. In this study it was found that *Senegalia modesta* and *Ficus palmata* were being used for different purposes of life by indigenous people and hence in DMR analysis these were at first two positons, respectively (*Table 6*). This describes how the biotic pressure is present on flora of the area and same type of investigations had been recorded that multiple-propose uses creates conservation threats for trees and other plants (Medicken and Mehl, 1990). This all give potential picture of anthropogenic pressure on the local plants of the area and it thrills towards the loss of plants gradually and may be categorized as threatened, endangered or rare taxa, as it was also demonstrated by Ishtiaq et al. (2006b, 2007b) in their previous articles on other areas of AJK.

The research work on WNP and allied areas depicted that as local communities are dwelling in rural area, mostly illiterate with low income resources, so they have to solely depend on wild resources (plants and animals) utilization for livelihood. The priority ranking (PR) statistics is being used as to measure the highly threatening factors for the indigenous plants. The local people use plants for fuel wood, construction, food, fodder, shelter making for livestock, agricultural land preparation by clearing the wild flora of the area. It was found that using plants as fuel is the first threat followed by the fire burning at second (*Table 7*). The hedging and fencing is the least pressure generating factor being at number 7^{th} in analyzed factors. All these factors are keystone threats for the local plants of the area and similar information on threats for plant biodiversity of different areas of AJK and other countries as well (Ahmed and Siraj; 1996; Ishtiaq et al., 2007b). In the analysis it was found that the most threatened species was *Butea monosperma* with highest threatening frequency (29.5%) being used in many needs by local people. Other commonly under threat plants are *Dalbergia sissoo* (19.5%), *Senegalia modesta* (11.25%), *Grewia optiva* (10.25%), *Ziziphus jujuba* (9.25%) as data shown in *Table 8*. These MPs and other taxa are being ruthlessly and unsustainably used by the local communities of the WNP and allied areas for domestic and commercial means that is the main cause of debilitation of plant biodiversity occurrence in the area, ultimately leading towards threatening zone (Mehmood et al., 2012; Ahmed and Siraj, 1996). This all proves that the current scenario should not be ignored and planned biodiversity conservation activities may be introduced and implemented in collaboration with NGOs and Department of Forest with direct participation of the indigenous communities. Main plinth of the problem is unawareness cutting, timber mafia and ignition of fires and it should be tackled by application of incessant methodologies in cooperation with public and private joint venture programs.

Table 8. *Frequency (%) of threatened species in Watala National Park and Allied areas of District Bhimber AJK*

Species name	Frequency (%)
Butea monosperma	29.5
Dalbergia sissoo	19.5
Senegalia modesta	11.25
Grewia optiva	10.25
Ziziphus jujuba	9.25
Azadirachta indica	8.5
Calotropis procera	7.75
Ricinus communis	2.25
Datura inoxia	1.75

Conclusion and future recommendations

The research work of WNP is of paramount significance as this area is first time explored for ethnomedicinal (EMs) and ethnobotanical (EB) analysis and it has provided the detailed list of all plants of the area in checklist form. It also describes how local people of the area fulfil their daily life needs from indigenous plants and their traditional culture was also recorded in document form. Rural people of the area depend on tree species for shelter, fuel, households, fodder, shadow and food purposes. *Butea monosperma, Grewia optiva, Carica opaca, Dalbergia sissoo, Bauhenia variegata, Senegalia modesta*, *Acacia nilotica* and *Mangifera indica* are key species being used in multiple uses. *Dalbergia sissoo, Butea monosperma* and *Mangifera indica* are under severe threat due to microbial attack and anthropogenic activities. There is dare need to protect and devise *ex-situ* and *in-situ* conservation methods in order to keep the ecosystem of WNP in a sustainable form to cope with the primary needs of village communities, whose whole life depends on the biodiversity of the area. Many plants of the area have good medicinal potential and further ethnopharmacological research should be carried out for novel drug discovery and subsequent drug development and "green drugs" are better than allopathic medicines. It is inevitable to mention that participation and cooperation of indigenous communities is very paramount devoid of that all efforts will be futile and fruitless.

Acknowledgements. This research work is part of the first author's doctoral thesis work who (Ms Mehwish Maqbool) is highly obliged to Chairperson and Lab staff of the Department of Botany, Mirpur University of Science and Technology (MUST) Bhimber Campus Azad Jammu and Kashmir, Pakistan for their kind assistance in the Ph.D. research work conducted in field and lab. The first author is highly indebted to her supervisor Dr Muhammad Ajaib for his all-time coaching and gracious guidance in the completion of this part of her doctoral thesis.

Abstract. This research was conducted to examine the effects of gibberellic acid (GA3), which was treated to wheat (*Triticum durum* Desf) seeds before germination, on their germination and the seedling growth under saline conditions. Durum wheat Güney Yıldızı variety, four different GA3 (0 (control), 100, 200 and 300 ppm), and four different salt (0 (control), 50 mM, 100 mM and 200 mM NaCl) concentrations were used in the research. Germination power, germination ratio (%), germination index, mean germination time, sensitivity index (%), radicula length (cm), plumula length (cm), radicula fresh weight (mg), radicula dry weight (mg), plumula fresh weight (mg), and plumula dry weight (mg) were examined. The results indicated that the increasing doses of salt prevented germination and growth parameters of wheat (*Triticum durum Desf*) seeds. It was observed that the doses of GA3 (Gibberellic acid), which were increased gradually before the doses of salt (NaCl), affected germination and growth positively and significantly. The best results of germination characteristics of wheat seed were obtained from the combination of 300 ppm Gibberellic acid + 0 mM (control) salt.
Keywords: *wheat, gibberellic acid (GA3), germination, salt stress, salt doses*

Introduction

There are many important factors that restrict the efficiency of agricultural production in the world and in Turkey. The first step to eliminate these factors is planting and germinating the seed under suitable conditions (Yıldız et al., 2007). Many vegetative and environmental factors such as seed coat, age, dormancy, temperature, humidity, and light play a role in providing these conditions (Hartmann et al., 1990; De Villiers et al., 1994; Khan and Ungar, 1997). Plants are the most sensitive to environmental factors during germination, emergence, and early seedling periods. All of these environmental factors are called stress factors. The effects of these factors on plants often emerge either one by one or together. Because of that, they are examined as either abiotic or biotic factors based on their sources (Anonymous, 2015). One of the abiotic stress factors that were discussed in this study is salinity (Yılmaz et al., 2011). Salinity is observed in a great portion of the lands on which irrigated farming is practiced especially thanks to the development of irrigation practices. Approximately one third (950 million ha) of the agricultural lands in the world are estimated to suffer from high salinity (Hasegawa et al., 1986; Özkaldı et al., 2004; Taghipour and Salehi, 2008). In Turkey, the salinity problem exists in about 1.5-2 million hectares of the agricultural lands. Wheat is the most grown product in the regions where irrigated agriculture has been started with the GAP project. Especially the majority of durum wheat production is met from this region. Therefore, increasing salinity and alkalinity

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1205712071

problems in wheat agriculture must be solved. Seen particularly in the regions where wheat is cultivated, the use of poor drainage and faulty irrigation systems is the most important reason. Alkalinity and salinity problems have emerged in our soils as a result of this faulty practice. Salinity that occurs in soil affects transpiration, respiration, and water intake negatively, and also causes root and stem growth to retard. In consequence, hormonal imbalance, transpiration disorder, and inadequate water and nitrate intake occur (Leopold and Willing, 1984; Dölarslan and Gül, 2012). Another problem is that the toxic effects that occur because of Na and Cl ions existing in saline soils cause the loss of ionic equilibrium (Siegel et al., 1980; Flowers and Yeo, 1981; İnal et al., 1995).

For this purpose, these harmful effects on the plants should be detected by conducting research on various plants (Gupta and Srivastava, 1989; Pessarkli et al., 1991; Van Hoorn, 1991). In determining salt resistance, the seeds of the varieties are kept in saline conditions and the effects of these conditions on germination criteria are taken into consideration (Begum et al., 1992). In similar studies, it was stated that plants were the most sensitive during their early germination and seedling periods in terms of salt resistance (Shannon, 1984). Also, the threshold of tolerance to salt in each plant varies by periods (Shannon, 1985). Suitable varieties and practices that will minimize yield losses arising from salinity problem, which restricts productivity in plant cultivation, are needed (Şenay et al., 2005). Salt resistance varies much among the plant species. The most sensitive periods in detecting the salt resistance of species are the germination and the early seedling periods (Van Hoorn et al., 2001). Various research studies that will enable a homogeneous emergence by expediting germination under soil conditions are conducted (Duman and Eşiyok, 1998). For this purpose, different methods such as stratification, hydropriming, acid etching, and hormopriming with growth and development regulators and hormones are applied and these methods are called priming treatments (Ercişli et al., 1999; Yıldız et al., 2017). Among these, hormones and especially GA3 (Gibberellic acid) have been used extensively. Salinity is considered to be one of the environmental stresses that reduce the growth and efficiency of most glycophytic plants worldwide. Induces both osmotic and ionic stresses leading to deterioration of many physiological and biochemical processes including salinity, water relations, ionic homeostasis, gas exchange and mineral nutrition (Parida and Das, 2005) Gibberellins are involved in the stimulation of enzymes involved in seed germination. Gibberellic acid (GA3) is one of the hormones proposed to control primary dormancy by inducing germination. Cavusoglu et al. (2007) reported that GA3 was the most effective salt stress reducing agent among plant growth regulators used in the research.

The aim of this study was to reduce the negative effects of salt in saline soils by treating GA3 (Gibberellic acid) on durum wheat seeds (Zheng et al., 2009; Kayış, 2014).

Materials and methods

In order to evaluate the effect of seed priming on the germination and seedlings' growth traits of Triticum durum Desf. under different salinity stress levels, a factorial experiment was conducted in completely randomized design (CRD) with four replications, at the laboratory of Seed Science and Techonology in the Department of Field Crops, Faculty of Agriculture, Van Yuzuncu Yil University, Turkey in 2019. In the research, Güney Yıldızı variety of durum wheat (*Triticum durum* Desf.) was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1205712071

provided from GAP Agricultural Research Institute. Wheat is the most grown product in the regions where irrigated agriculture has been started with the GAP project. Especially the majority of durum wheat production is met from this region. Therefore, increasing salinity and alkalinity problems in wheat agriculture must be solved. The Güney Yıldızı durum wheat cultivar developed by the Diyarbakır Agricultural Research Institute is a high yield genotype grown in large quantities in the region. The yield of other varieties in saline soils is low compared to this variety. For this reason, Güney Yıldızı variety was preferred in the study.

Four different GA3 (0, 100, 200, and 300 ppm) and four different salt concentrations (0, 50, 100, and 200 mM NaCl) were used in the research. Wheat seeds were surface-sterilized for 5 min using 2.5% (v/v) sodium hypochlorite, were washed with pure water 7 times, and were left for drying in a sterile container (Azizi et al., 2011). In the experiment, durum wheat seeds were kept under dark conditions at 20 ± 1 °C in three different doses of GA3 (100, 200, and 300 ppm) and distilled water (H_2O) for 24 h until the humidity of the seeds became 12-13%. After the waiting period, the seeds were drained; two folds of blotting papers were placed; and the seeds were placed into 9-cm-diameter sterile petris, putting 20 seeds in each petri. Then, 5 ml from the prepared NaCl solutions at different doses (50, 100, 200, and 300 mM) and pure water were applied to meet the water demand of the seeds in the petri that was used for control. After these applications, the seeds in the petris were placed into incubators under 20 ± 1 °C temperature for germination and emergence test. The initial tests of the seeds were identified according to ISTA (1996) rules. For the tests applied during germination, the seeds were placed between the two-fold blotting papers, 4 × 20 seeds (*Photo 1*) were used for the tests and the tests lasted for 14 days (ISTA, 1996).

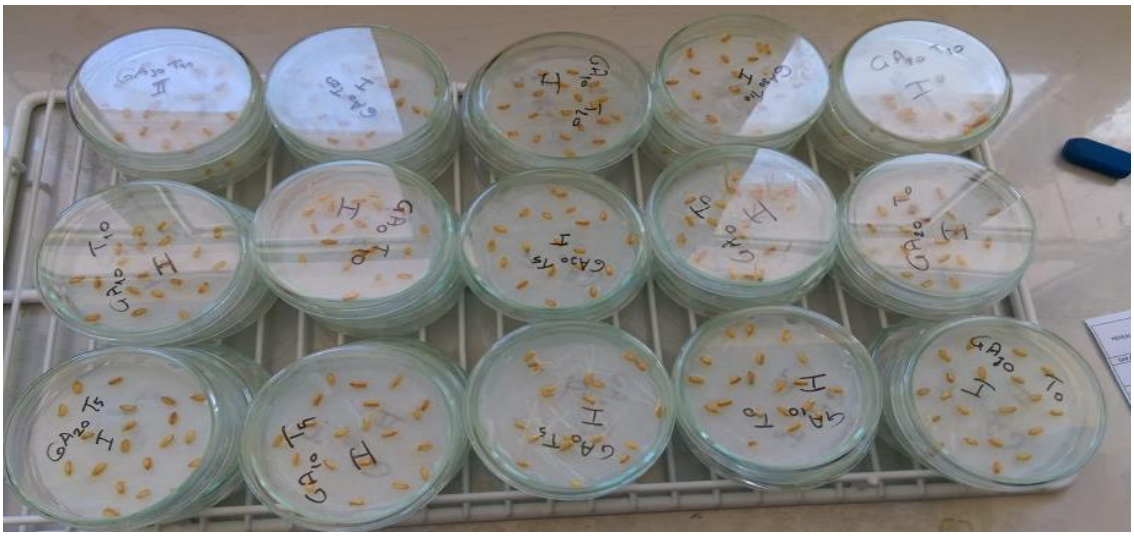

Photo 1. *Seeds in petri dishes*

In this study: germination power, germination ratio (%), germination index, mean germination time, sensitivity index (%), radicula length (cm), plumula length (cm), radicula fresh weight (mg), radicula dry weight (mg), plumula fresh weight (mg), and plumula dry weight (mg) were examined.

Accordingly: root and shoot dry masses were weighed germination rate, germination power, germination index, mean germination time and sensitivity index were calculated

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1205712071

with the following formulas. It was considered that number of germinated seeds on 7th day as "germination rate" and number of germinated seeds on 14th day as "germination power".

Germination rate (GR) was calculated using *Equation 1* (Akıncı and Calıskan, 2010).

$$GR = \text{Total seeds germinated after day 14} / \text{Total number of planted seeds} \quad \text{(Eq.1)}$$

Germination index (GI) was calculated using *Equation 2* (Wang et al., 2004).

$$GI = \Sigma(Gi / Tt) \quad \text{(Eq.2)}$$

GI: Germination index; Gi: i days germinated seed rate; Tt: count day.

Mean germination time (MGT) was calculated using *Equation 3* (Ellis and Roberts, 1980).

$$MGT = \Sigma(fx) / \Sigma f \quad \text{(Eq.3)}$$

f: Number of seeds germinated x: germination day.

Sensitivity index (SI) was calculated using *Equation 4* (Foolad and Lin, 1997).

$$SI = \text{MGT in the salt application} / \text{MGT in the control application} \quad \text{(Eq.4)}$$

Statistical analyses of the obtained data were done using COSTAT (version 6.3) software, and multiple comparison tests of the data were performed according to the Duncan test (Duzgunes et al., 1987).

Results

According to the results obtained from the research, the effect of salt (NaCl) stress on germination characteristics of GA3 pretreated wheat (Triticum durum Desf) seed was found to be statistically significant. In addition, salt doses × GA3 interactions were found to be significant in all parameters ($P < 0.01$) (*Tables 1* and *2*).

According to the results, the highest germination power and ratio (93.89% and 39.33%, respectively) were obtained from 0 mM and NaCl application; and the lowest values (61.65% and 11.78, respectively) were obtained from the 200 mM salt (NaCl) concentration (*Table 1; Figs. 1* and *2*). The effects of gibberellic acid on germination power and ratio were also found to be significant; and the highest germination power and ratio were obtained from the 200 ppm GA3 application with 81.39% and 32.59%. But it is determined that not found significant differences as statistically between 200 and 300 ppm GA3 applications. The lowest values observed as (75.05% and 14.01%) from 0 ppm (control) applications. But it is in the same Duncan groups with 300 ppm GA3 dose application. The salt × GA3 interactions over the wheat seeds were also found to be significant, and the highest germination power and ratio were obtained from the 300 ppm GA3 concentration (98.00%, 58.33%) of the control application (0 mM). But, there are not different statistically among all GA3 applications for germination power whereas the lowest germination power (56.33%) was detected in the 100 ppm GA3 application of the 200 mM salt concentration.

*The difference between the means was evaluated at $P < 0.05$ and $P < 0.01$ level with the Duncan multiple comparison method

The results showed that the difference between salt, GA3, and their interaction regarding the mean germination time was significant ($P < 0.01$) (*Table 1*). The lowest mean germination time (2.70 days) was obtained from the control application (0 mM) of the salt concentration and the longest time (4.78 days) was obtained from the 200 mM application (*Fig. 3*). Also, the effect of gibberellic acid on the mean germination time was significant, and the shortest time was obtained from the 300 ppm application (2.66 days), and the longest time (4.51 days) was obtained from the control application at 0 ppm dose. In terms of salt × GA3 interactions, the shortest time (0.92 days) was obtained from the control application (0 ppm, 0 mM), and the longest time was obtained from the 200 mM salt concentration with the 0 ppm GA3 dose (6.33 days).

DOI: http://dx.doi.org/10.15666/aeer/1705_1205712071

When the germination index (%) values of the wheat seeds were examined, it was observed that the difference between salt, GA3, and their interactions was significant (*Table 1; Fig. 4*). The highest germination index between the salt doses was obtained from the 0 mM control with 11.96%, and the lowest index value was obtained from the 200 mM concentration (4.65%). Regarding the germination index values of the gibberellic acid doses, the highest index value was obtained from the 300 ppm dose (10.41%), and the lowest value was obtained from the control. The highest value of the germination index of the wheat seeds obtained from the salt × GA3 interaction was in 0 mM and 0 ppm GA3 with 13.41%. There is not difference statistically among 100 and 200 ppm GA3 in the 0 and 50 mM of salt applications. The lowest value (3.97%) was obtained from the 200 mM salt and 300 ppm GA3 applications.

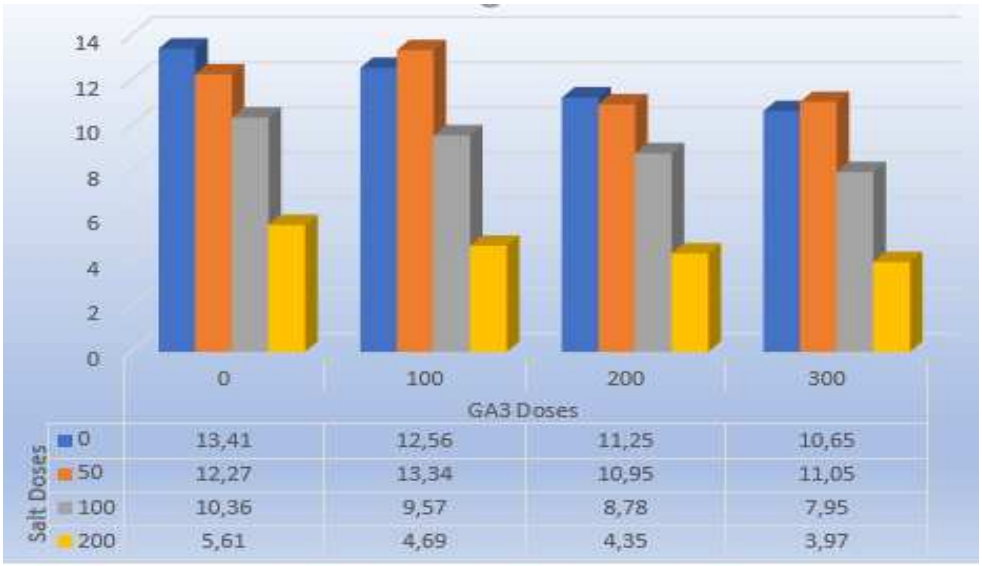

Figure 4. *The impact of salt × GA3 interactions on the germination index (%)*

According to the obtained results, the applications and their interactions were found to be significant regarding the sensitivity index values of the wheat seeds (*Table 1, Fig. 5*). It was observed that increasing salt concentrations decreased the sensitivity index values. The highest sensitivity index value was observed in the 100 nm application (0.84%). But, it is in the same Duncan group with 200 mM salt application. The lowest sensitivity index value was obtained from the control application (0.46%) it is in the same Duncan group with 50 mM salt application. The highest sensitivity index values of the wheat seeds to the gibberellic acid doses were obtained from the 200 ppm concentration (1.23%), and the lowest value was obtained from the 0 ppm concentration (0.31%). The highest sensitivity index in the salt × GA3 interaction was found to be 1.46% (100 mM salt × 300 ppm GA3), and the lowest was found to be 0.28% (0 Mm NaCl × 100 ppm GA3).

Radicula length values were found to be significant in the wheat seeds in terms of the applications and their interactions (*Table 2; Fig. 6*). The lowest radicula length was found to be 1.50 cm in the 200 mM salt concentration, and the highest radicula length (4.5 cm) was obtained from the 50 mM NaCl application In the gibberellic acid applications, the longest root was obtained from the 300 ppm dose (5.54 cm), and the lowest value (1.21 cm) was obtained from the 100 ppm dose. In the salt × GA3

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1205712071

interaction, the highest radicula length was 5.64 cm (0 mM × 300 ppm GA3). It is in same Duncan with 0 mM NaCl and 300 ppm GA3. The lowest radicula length was found to be 0.19 cm (50 mM ×100 ppm).

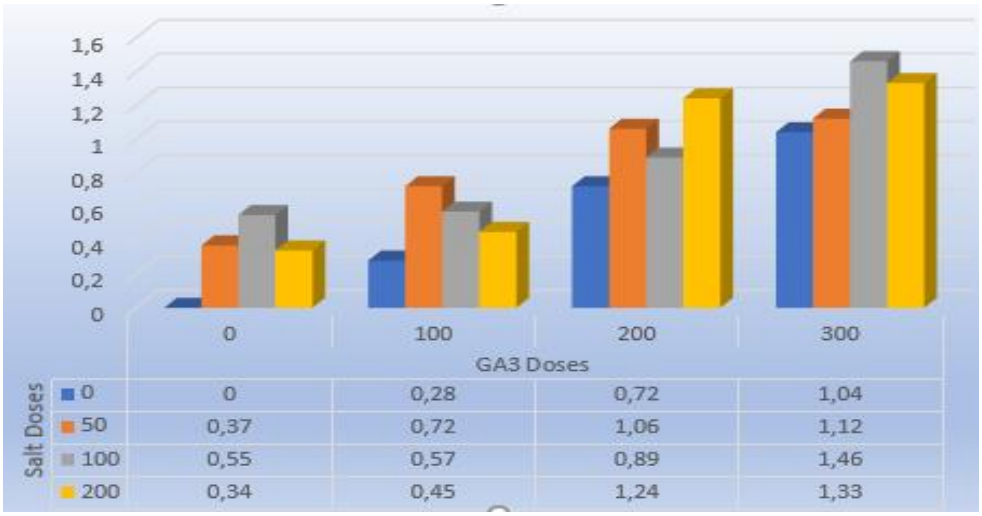

Figure 5. *The impact of salt × GA3 interactions on the sensitivity index (%)*

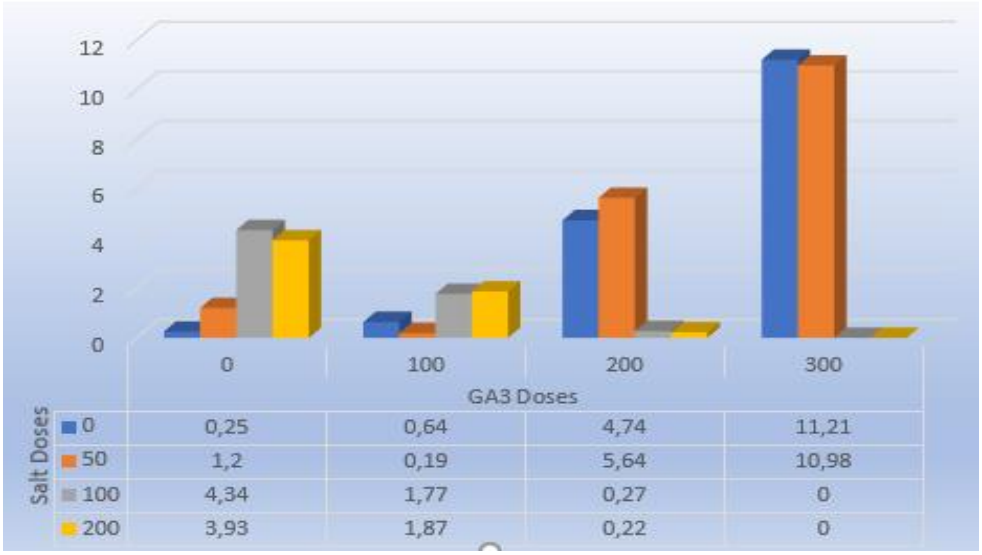

Figure 6. *The impact of salt × GA3 interactions on the radicula lenght (cm)*

According to the results, the effects of the applications on plumula length were found to be significant (*Table 2; Fig. 7*). Depending on the salt concentrations, the highest plumula length (7.29 cm) was observed in the 50 Mm NaCL dose. It is in the same with control. The shortest stem length was observed to be 2.91 cm (T_{200}). Despite this suppressive characteristic of salt, it was observed that the gibberellic acid doses increased the plumula length. The highest stem length (6.20 cm) was obtained from the GA100 dose, and the lowest was 4.86 cm (GA_0). In the salt × GA3 interaction, the highest plumula length (11.50 cm) was obtained from the $T_{50} \times GA_{100}$ application, and the lowest value was observed to be 1.50 cm ($T_{100} \times GA_{300}$).

The results obtained from the applications on radicula fresh and dry weights were found to be statistically significant (*Table 2; Figs. 8* and *9*). The highest radicula fresh and dry weights were observed in the 0 mM (NaCl) application with 36.3 and 3.44 mg, respectively. The lowest values (10.9, 1.40 mg) were obtained from the 200 mM salt (NaCl) concentration. The effects of Gibberellic acid on the radicula fresh and dry weights were significant, and the highest radicula fresh and dry weights were obtained from the 300 ppm application (25.1 and 2.46 mg). The lowest values (21.9 and 2.31) were detected in the 0 ppm dose. The salt × GA3 interactions on the wheat seeds were found to be statistically significant. The highest radicula fresh and dry weights were obtained from the T_0 (0 mM) and 300 ppm GA3 concentration (42.5 and 4.13 mg), and the lowest radicula fresh weights (9.8 mg) was obtained from 200 mM NaCl and 0 ppm GA3 doses. The lowest radicula dry weights (0.98 mg) were detected in the 300 ppm GA3 application of the 200 mM salt concentration.

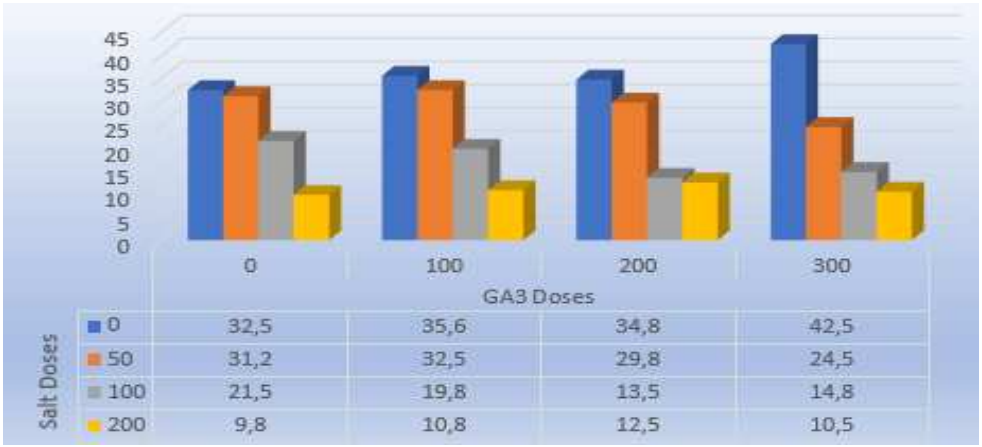

Figure 8. *The impact of salt × GA3 interactions on the radicula fresh weights (mg)*

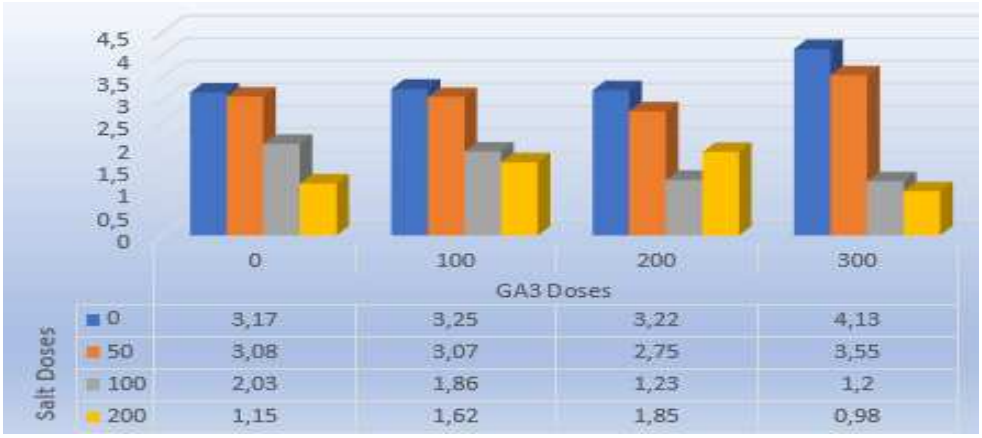

Figure 9. *The impact of salt × GA3 interactions on the radicula dry weights (mg)*

The difference between the plumula fresh and dry weights in the applications was found to be statistically significant according to the results (*Table 2; Figs. 10* and *11*). Considering the results, the results between the plumula fresh and dry weights had parallels regarding the applications. The highest plumula fresh and dry weights were

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1205712071

found to be 213.5 and 20.5 mg, respectively, in the 0 mM (NaCl) application, and the lowest values (71.9 and 7.1 mg) were obtained from the 200 mM salt (NaCl) concentration. The effects of Gibberellic acid on the plumula fresh and dry weights are significant, and the highest fresh and dry weights (149.8 and 15.8 mg) were obtained from the 300 ppm application. The lowest values (144.3) were detected in the 200 ppm GA3 doses. The lowest plumula dry weight (13.8 mg) was recorded in the 100 ppm GA3. The salt × GA3 interactions on the wheat seeds were also found to be statistically significant. The highest plumula fresh and dry weights (240.5 and 25.6 mg) were obtained from the T_0 (0 mM) and 300 ppm GA3 concentration, and the lowest plumula fresh weight values (65.4) was detected in the 200 ppm GA3 concentration of the 200 mM salt concentration. The lowest plumula dry weight (6.0 mg) was detected in the 300 ppm GA3 concentration of the 200 mM salt concentration

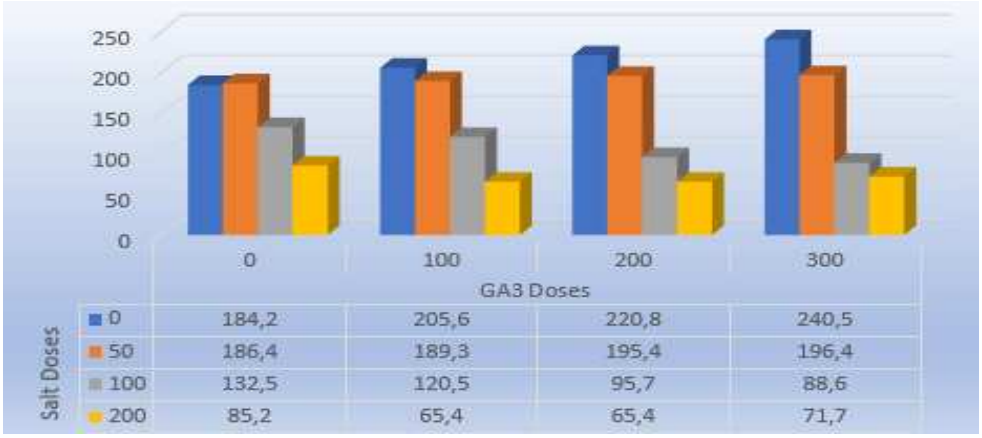

Figure 10. *The impact of salt × GA3 interactions on the plumula fresh weights (mg)*

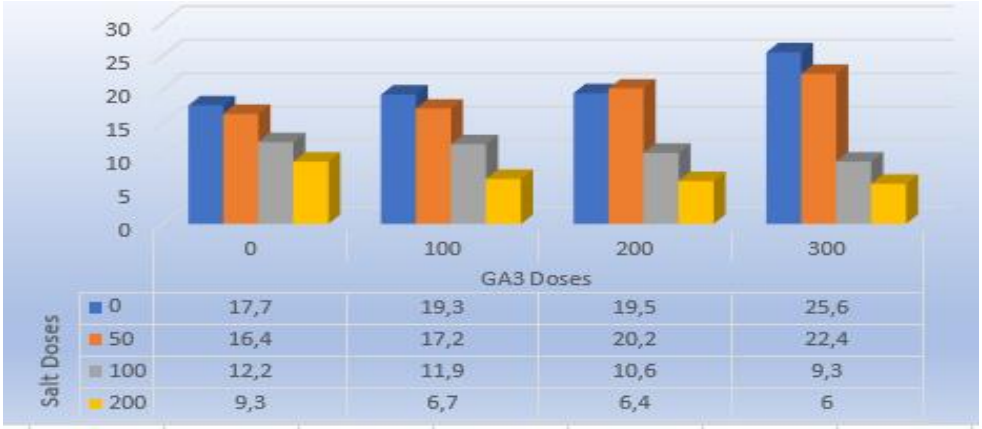

Figure 11. *The impact of salt × GA3 interactions on the radicula dry weights (mg)*

Discussion

The results indicated that the GA3 applications caused the germination power and the germination ratio to increase. However, in the similar studies, it was stated that the increasing salt concentrations had negative and important effects on these ratios (Sharma et al., 2004; Khan et al., 2005; Kızılgeci et al., 2010).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1205712071

According to the results, growth and development of the wheat seeds were prevented due to the salinity concentration, which increased gradually. Many researchers had revealed this effect before (Öztürk et al., 1994; Gulzar and Khan, 2002; Yıldız et al., 2017).

When the GA3 pretreatments on the wheat seeds are examined, mean germination days decreased in parallel with the increasing doses, and it was observed in similar studies that this time lengthened together with the increasing doses in salt concentrations (Öztürk et al., 1994; Ghoulam and Fores, 2001; Gulzar and Khan, 2002; Çavuşoğlu et al., 2007).

In their studies, Yuonesi and Moradi (2015) stated that the gibberellic acid applications had positive and significant effects on germination index despite the increasing salt doses.

It was observed that the gibberellic acid pretreatments were useful regarding the sensitivity index values as in the other parameters (Yuonesi and Moradi, 2015).

As significant decreases in the water intake capabilities occur in the plants that are under salt stress, root and shoot lengths decrease (Kızılgeçi and Yıldırım, 2014). While radicula length is important from this point of view, it should be considered as a selection criterion in salt resistance improvement. According to the results, radicula length decreased depending on the increasing salt concentration (Atak et al., 2006; Saboora and Kriarostami, 2006).

The highest stem length (6.20 cm) was obtained from the GA100 dose, and the lowest was 4.86 cm (GA_0). In the salt × GA3 interaction, the highest plumula length (11.50 cm) was obtained from the $T_{50} \times GA_{100}$ application, and the lowest value was observed to be 1.50 cm ($T_{100} \times GA_{300}$). Sadat Noori and McNeilly (2011) found similar results.

It was observed that increasing salt concentrations reduced the radicula fresh and dry weights (Kızılgeçi and Yıldırım, 2014).

According to the results obtained in our research, it was observed that the GA3 applications increased radicula fresh and dry weights relatively. In a study they conducted with local bread wheat varieties, Shahzad et al. (2012) detected that radicula fresh and dry weights decreased. It was stated that this parameter could be used in improvement works.

It was observed that increasing salt concentrations reduced the plumula fresh and dry weights (Kızılgeçi and Yıldırım, 2014).

In similar studies, it was stated that increasing salt concentrations reduced plumula fresh and dry weights in plants (Muhammad and Hussain, 2012; Akbari et al., 2007).

Conclusion

According to the results, germination and growth of wheat seeds were prevented depending on the gradually increasing salinity concentration. Many researchers had revealed this effect before. It prevents water intake especially in high salt concentrations, and based on this, it causes the enzymes to not to be able to activate and in consequence leads to retardation in germination and growth. In this study, this negative and important effect of salt on the germination parameters was reduced as a result of GA3 applications and successful results were obtained. When the results were evaluated in terms of all the parameters, the best results were obtained from the 300 ppm GA3 applications in 0 mM salt concentration. In conclusion, it was observed that

GA3 (Gibberellic acid) pretreatments lessened the effect of salt (NaCl) stress on germination in wheat seeds. In the world and in our country, as well as fallow fields, soil salinity and alkalics are an important problem. It will be possible to bring these areas to agriculture and increase agricultural production only through these and similar studies.

Abstract. Arbuscular mycorrhizal fungi (AMF) play potentially essential roles in maintaining the diversity and functioning of plant communities in Eurasian steppe representing one of the most important terrestrial ecosystems. However, it remains unclear about the symbiotic relationship between AM fungal communities and the dominant grass species in the steppe ecosystem. We thus examined the species diversity and community composition of AM fungi colonizing three dominant plant species (*Leymus chinensis*, *Stipa grandis* and *Cleistogenes squarrosa*), using field sampling and molecular analyses, in Xilinguole steppe, Inner Mongolia. Our results showed all three plants were well colonized by AM fungi, and 51 operational taxonomic units (OTUs) belonging to six genera with members of *Glomus* dominating in the roots of all the three plants species. By comparison, we found that *L. chinensis* had the most diverse AM fungi within the roots. OTU richness of AM fungi was higher in the roots of *S. grandis* than in the roots of *C. squarrosa* and *L. chinensis*. However, the community composition of AM fungi in three host plant species showed no significant difference. Based on these findings, we concluded that the dominant plant species held diverse AM fungal taxa in their roots, while the host preference did not significantly drive the differences in AM fungal community composition within their roots and resulted in low host specificity. Findings of this study would broaden the concept of host specificity and its implications on plant succession in the largest grassland ecosystem of China.

Keywords: *arbuscular mycorrhizal fungi, diversity, community composition, host specificity, symbiosis*

Introduction

Arbuscular mycorrhizal (AM) symbiosis formed between higher plant roots and the fungi belonging to the phylum *Glomeromycota* is one of the most common mutualistic associations in terrestrial ecosystems (Desai et al., 2016; Stürmer, 2012). In grasslands, the vast majority of plant species are AMF hosts (Bonfante and Genre, 2010; Eom et al., 2000; Harrier, 2001). In these symbiotic associations, plants provide carbon to the fungi to complete their life cycle (Zhang et al., 2016b). In return, AMF benefits their hosts in various ways including enhanced nutrient acquisition and improved protection against biotic and abiotic stresses (Latef et al., 2016; Huang et al., 2017; Chen et al., 2017). Therefore, AM symbionts could play potentially

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1207312089

important roles in plant growth, community diversity and ecosystem stability (Torrecillas et al., 2012).

The host plant strongly influences the AMF diversity and community composition inside the roots (Pivato et al., 2007; López-García et al., 2014; Zheng et al., 2016). However, owing to the wide range of preference for host plants (Krüger et al., 2012), the AMF normally show low host specificity (Lee et al., 2013), and most of the previous studies found that AMF had no host specificity (Clapp et al., 1995; Santos et al., 2006; Smith and Read, 2008). For example, Su et al. (2011) studied the AMF community composition in five plant species of Inner Mongolia and found 18 AMF species belonging to five genera and concluded that most of the AMF had no host specificity, but few species showed a certain degree of the host preference. However, some findings showed that AMF community composition is host-dependent (Lugo and Cabello, 2002; del Mar Alguacil et al., 2018). Bentivenga and Hetric (1992) found host plant had a significant effect on AM fungal sporulation in tallgrass prairie grasses. Li et al. (2010) explored three plant species of hot and arid ecosystem of southwest China and found different AM fungal community composition. Several studies have documented that selectivity between AMF and host plants may be the cause of presence or absence of host specificity (Bever, 2002; Helgason et al., 2002; Zhang et al., 2010). Moreover, Yang et al. (2012) hypothesized that discerning pressure from host plant at different levels (functional groups and taxonomic order) may be a driver for the distribution of AMF. However, the detailed explanation still needs several studies. The previous suppositions are mainly based on morphological investigations and a little molecular work is involved. Therefore, considering the contrasting opinions regarding AMF host specificity and insufficient investigations, further studies are needed to deepen the understanding about the role of AMF in typical steppe. This would broaden the concept of host specificity and its implications on plant succession in the largest grassland ecosystem of China because the low host specificity favours underground communication and nutrient transfer pathways via mycorrhizal networks.

The typical steppe in Inner Mongolia covers more than 20% of total grassland area in China (Xu et al., 2014), and AMF holds a significant value in the success of plant species in the steppe. In this study, we analyzed and compared the diversity and community composition of AMF colonizing the roots of three dominant perennial plant species; *Leymus chinensis* (*L. chinensis*), *Stipa grandis* (*S. grandis*), and *Cleistogenes squarrosa* (*C. squarrosa*). These three plant species are considered long-lived dominant grass species of the typical steppe, Xilinguole (Vandenkoornhuyse et al., 2003). The sheepgrass (*L. chinensis*) is a perennial forage plant and of great significance for grassland productivity and ecosystem (He et al., 2017). While, *S. grandis* is known as needlegrass also has significant nutritional value for the cattle and sheep in this region of Inner Mongolia (Su et al., 2010). The *Cleistogene squarrosa* is the most abundant C_4 perennial bunchgrass species of this region and the importance of *Cleistogene* has been recognized for the development of sustainable grassland system (Liang et al., 2002). Concerning the ecological and economic importance of these three plant species, our goal was to identify the differences in diversity and community composition of AMF in three plant species belonging to the same family (Poaceae) to determine the host specificity. These findings can do a great deal towards a comprehensive understanding of AM fungi associations with roots of perennial plant species and host specificity.

Materials and methods

Study site

The study was carried out in the Inner Mongolia Grassland Ecosystem Research Station (43°38′55.9″N, 116°09′06.3″E), Inner Mongolia Autonomous of China (*Fig. 1*). This grassland system has semiarid climatic conditions with a short plant growing period ranging from May to September. The average annual precipitation is 343 mm, and the mean annual temperature is 0.3 °C with average monthly temperature ranging from -21.6 °C (January) to 19.0 °C (July). The main soil type in this site is chestnut soil with relatively homogenous physical and chemical properties (Li et al., 2015; Ren et al., 2016).

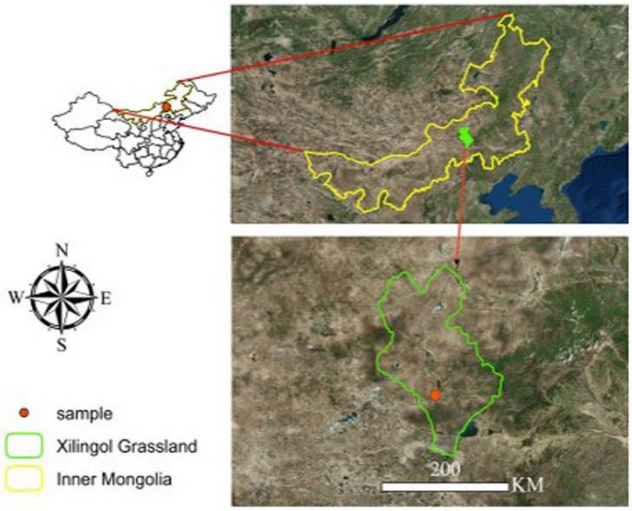

Figure 1. *The geographic location of the sampling site. The green line is the boundary of grassland and red dot is the location of sample plot. The map was created with ArcGIS 10.2*

Field sampling

The sampling was performed on June 24, 2014, and we randomly selected seven sampling points with a distance of 100 m from each other in a 1 × 1 km area as replicates. So, we collected 21 total plant samples and seven samples per species. To diminish the influence of soil type and geographic factors for each point, we selected closely adjacent *L. chinensis, S. grandis, and C. squarrosa* species for each sampling point. Corresponding, we obtained the roots and the rhizosphere soil of each plant using the soil drill. All the samples were preserved in zip lock bags and stored at 4 °C.

AMF structure and colonization

AMF colonization or root length colonization is an indicator of fungal growth within plant roots. In this study, the roots of the collected plants were washed carefully with tap water and cut into segments of 1 cm length. For each sample, approximately 100 root segments were randomly chosen and cleared in 10% KOH at 90 °C and stained with 0.05% Trypan blue, and then examined the percentage of AMF colonization using the magnified intersection method at 200× magnification (Nikon-E100) (Mcgonigle et al., 1990).

DNA extraction and sequencing

In our study, the AM fungi within the roots of *L. chinensis, S. grandis,* and *C. squarrosa* was identified through PCR amplified 18S-rRNA gene fragments with AMF-specific primers, as partial sequences of small subunit (SSU) genes appeared to be more informative than ITS genes for AM fungi (Redecker et al., 2006). For each sample, the total DNA was extracted from 80 randomly obtained fine roots using MoBio Power Soil®DNA Isolation kits (QIAGEN, Valencia, CA, USA). 18S rRNA gene was amplified using a nested PCR protocol. Based on the previous study (Krüger et al., 2009), the chosen primers were AML1/AML2 because they have better coverage and specificity than NS31/AM1, which have been extensively used in recent years (Helgason et al., 1999; Simon et al., 1992). A 10-fold dilution of the DNA was first amplified using the general eukaryotic primers NS1/NS4 (White et al., 1990). In the second phase of nested PCR, the product was amplified using AML1/AML2, and the PCR product was visualized on 1% agarose gel. The expected 800 bp bands were cut out and purified using an AxyPrep DNA Gel Extraction Kit (Axygen, Union City, CA, USA). The purified product was sequenced using the Sanger platform to confirm the presence of AM fungi before proceeding further. Purified DNA was cloned into the pGEM-T Easy vector (Promega, Madison, WI, USA) and then transformed into *E. coli* DH-5α (Tiangen, Beijing, China). The resulting DNA sequences were aggregated using BioEdit to perform the subsequent analysis.

Sequence analysis

We compared our clone DNA sequences with the GenBank database on the NCBI website (http://www.ncbi.nlm.nih.gov/). The closest match was selected to identify the sequences, and only those recognized as *Glomeromycota* were included for further taxonomic analysis.

All the selected AM fungal sequences were gathered from the previous steps, then we conducted standard operational taxonomic units (OTUs) analysis using the Mothur software (Schloss et al., 2009). The sequences with not less than 97% matched, were grouped into OTU (Helgason et al., 1998). After finishing clustering, we selected one sequence in each OTU as the representative sequence and aligned them together with their closest matched identified AM fungal sequences from the NCBI database; then Mega 6.06 program (Kumar et al., 2007) was utilized to align the sequences. Furthermore, in Mega, Kimura2-parameter model was computed to perform neighbor-joining phylogenetic analysis with 1000 bootstrap replicates to calculate the support value of the tree with *Mortierella polycephala* (ID: X89436) and *Endogone pisiformis* (ID: X58724) as outgroups to root the tree (Tamura et al., 2007; Öpik et al., 2003). To further quantify and compare the fungal community diversity, the Shannon-Wiener index was computed with vegan package (Oksanen et al., 2007) in R (Team, 2013) based on the identified OTUs. The Shannon diversity index was calculated according to the following equation:

$$D = \sum_{i=1}^{s} p_i \times \ln p_i$$

where S is the total number of species in the sample and p_i is the relative abundance of certain AM fungus species of the sample (Shannon and Weaver, 1949).

DOI: http://dx.doi.org/10.15666/aeer/1705_1207312089

Nucleotide sequence accession numbers

A total of 51 representative sequences of the clones detected were submitted to NCBI (National Center for Biotechnology Information) GenBank (http://www.ncbi.nlm.nih.gov) with the accession number LS997508-LS997558.

Statistical analysis

The SPSS statistical software was used to compare the AMF colonization rate, species richness, and Shannon diversity indexes among the three species. The data were analyzed using one-way Analysis of Variance method (ANOVA) and significant differences between the different plant species in ANOVA were compared based on Tukey's HSD post-hoc test at $P \leq 0.05$. To gain further insight into the potential relationship between AM fungal communities and their host plant species, NMDS (nonmetric multidimensional scaling) was conducted using PAST (Paleontological Statistics) version 3.21.

Results

AMF colonization

The results showed that all the plant species were well colonized by AMF. *S. grandis* showed an average of 92% colonization, whereas *C. squarrosa* and *L. chinensis* showed average colonization rates of 87% and 90%, respectively (*Fig. 2*). One-way analysis of variance (ANOVA) indicated that there were no significant differences as shown by Tukey's HSD test ($F = (2,18) = 0.054$) in the AMF colonization among the three dominant species.

DOI: http://dx.doi.org/10.15666/aeer/1705_1207312089

phylotypes or sequences types classified into six genera including *Rhizophagus*, *Glomus*, *Diversispora*, *Claroideoglomus*, *Paraglomus,* and *Ambispora* (*Fig. 3*). Of all these AM fungal phylotypes, 19 belonged to *Rhizophagus* (*Rhizophagus* 01-19), 24 to *Glomus* (*Glomus* 01-24), one from each *Diversispora* (*Diversispora* 01) and *Claroideoglomus* (*Claroideoglomus* 01), four from *Paraglomus* (*Paraglomus* 01-04), and *Ambispora* (*Ambispora* 01-02) group contains two phylotypes.

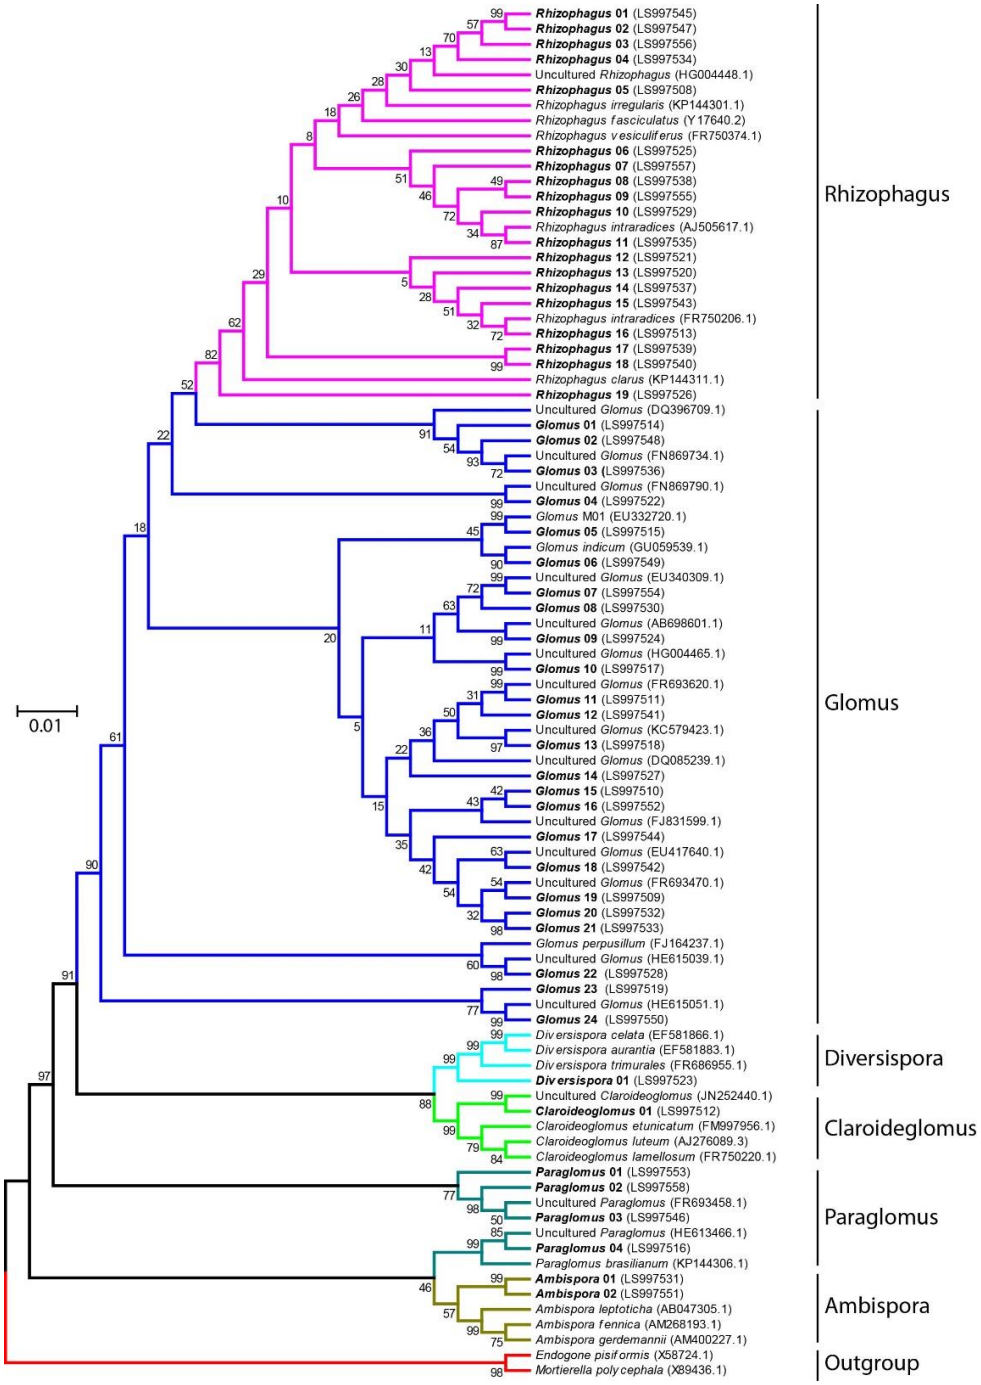

Figure 3. *Phylogenetic tree. The neighbor-joining phylogenetic tree was constructed based on 18S rDNA sequences of the 51 OTUs (bold), and the reference sequences were downloaded from NCBI (their corresponding numbers are shown in the parentheses). The bootstrap values by 1000 replications were calculated. The scale bar represents the sequence divergence at 1%*

In terms of OTUs, *Rhizophagus*-05 and *Glomus*-15 were the most abundant in all three species, with a relative abundance of 27% and 11% respectively, whereas *Glomus*-19 was found only in *S. grandis* and *C. squarrosa* and had a relative abundance of 13% (*Table 1*).

AMF diversity inside roots

The most dominant genera were *Glomus* and *Rhizophagus*, accounting for 50% and 39% of the total clones, respectively, whereas, the *Ambispora* and *Diversispora* were the least frequent genera, making up only 0.6% and 1% of the total clones, respectively (*Fig. 4*). At the genus level, all six AM fungal genera were found *in L. chinensis* whereas only four and three genera were found in *S. grandis* and *C. squarrosa*, respectively (*Fig. 4*).

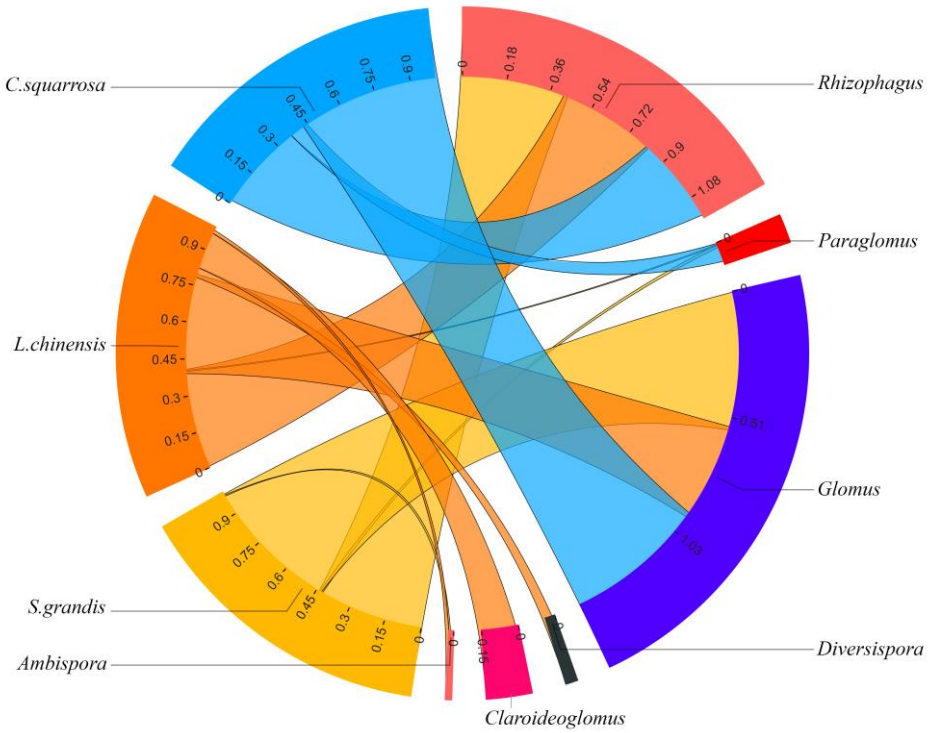

Figure 4. *Chord diagram showing the relative abundance of AMF. The relative abundance of AMF genera detected in the roots of the three plant species*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1207312089

Likewise, the detected OTUs (identified genus) were not evenly distributed among the three plant species. Among the 587 sequence types classified as AM fungi, 167 were from *S. grandis*, 220 were from *C. squarrosa*, and 200 were from *L. chinensis;* however, regarding the OTUs identified data (*Table 1*), *S. grandis* appeared to possess the most AMF phylotypes, i.e., 32, whereas, *C. squarrosa* and *L. chinensis* possessed 20 and 25 AMF phylotypes, respectively.

Concerning species richness, *S. grandis* also showed the higher richness of the AMF OTUs, followed by *C. squarrosa* and *L. chinensis* (*Fig. 5*). Analysis of variance showed that there were statistically significant differences found in species richness ($p < 0.05$). Therefore, we concluded that *S. grandis* had significantly more diversified AM fungal phylotypes than *L. Chinensis* and *C. squarrosa*. Notably, some OTUs were observed for limited hosts. *Rhizophagus* 06, 07, 08, and 18, *Glomus* 02, 03, 06, 08, 17, 21, and 22, *Paraglomus* 01 and 03 were found in *S. grandis*, *Rhizophagus* 03, 11, 15, and 17, *Glomus* 12, 16, 18, 20, and *Paraglomus* 04 were observed in *C. squarrosa,* and in *L. chinensis*, *Rhizophagus* 01, 02, 09, *Glomus* 07, 24, *Diversispora* 01, *Claroideoglomus* 01, *Paraglomus* 02, and *Ambispora* 02 were found (*Table 1*).

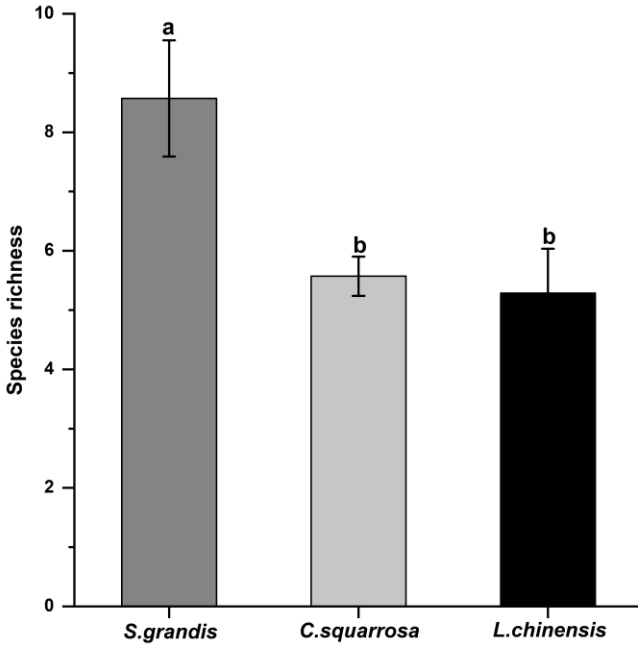

Figure 5. *AMF richness. AMF richness in three different plant species. The analysis of variance revealed that S. grandis deviated significantly from the other two plant species and showed more species richness. Data are means ± SE. Identical letters denote non-significant differences, whereas different letters indicate significant differences, as shown by Tukey's HSD test at P < 0.05*

Furthermore, the Shannon-Wiener index used to indicate species diversity in a community. As our results showed, *S. grandis*, *C. squarrosa* and *L. chinensis* exhibited an average value of Shannon diversity index 1.62, 1.30, and 1.08 respectively, and non-significant differences were found ($p = 0.17$) (*Fig. 6*).

The number of OTUs specific to their host plant was 13 for *S. grandis* and 9 for both *C. squarrosa* and *L. chinensis* (*Fig. 7*). The OTUs data set thus demonstrated the

DOI: http://dx.doi.org/10.15666/aeer/1705_1207312089

uniqueness of AMF-plant combinations of dominant plant species found in Xilinguole steppe regions.

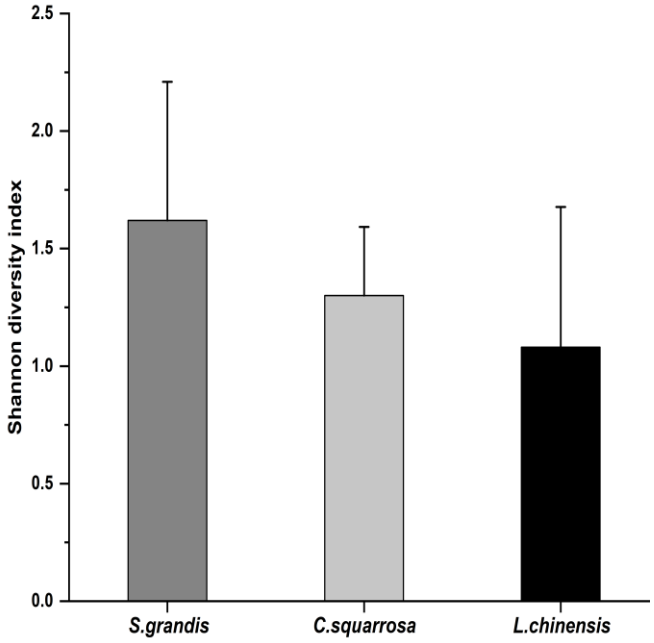

Figure 6. *Shannon-Wiener index. The Shannon's diversity index (mean ± SE), and the analysis of variance revealed a non-significant difference in S. grandis, C. squarrosa, and L. chinensis*

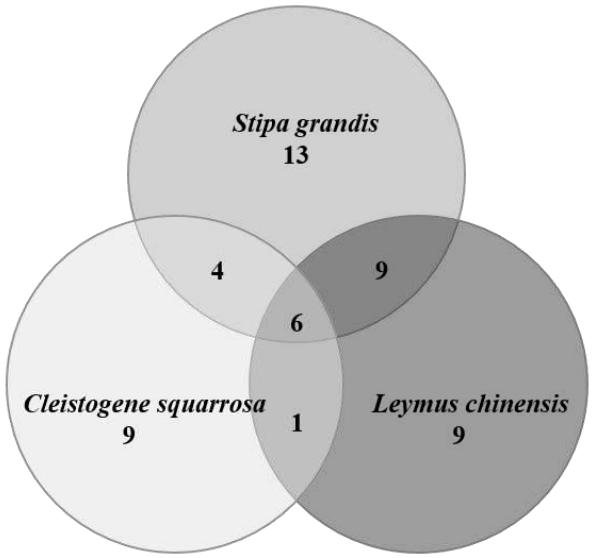

Figure 7. *Venn diagram showing the number of shared and unique OTUs among the host plants*

Moreover, the NMDS analysis indicated that the AMF community components living with one plant species did not tightly group according to their host plant species (*Fig. 8*). It implies that at both the genus and OTU levels, AMF showed a host preference character to a certain extent; however, the host plant species may not be solely the determinant for shaping the overall AM fungal community within roots.

Discussion

AMF colonization

In this study, AM fungal colonization in different plant species was high (85%) at the beginning of the growing season, which is in line with the distinct colonization rates studied previously among different co-occurring plants (Li et al., 2010; Lugo et al., 2003; Su et al., 2011). However, the rate of colonization was non-significant among the threes species, which is consistent with Su et al. (2011). Studies on AM fungal colonization in Inner Mongolia, tallgrass prairie grasses and six locations on the European coast showed similar results in early growth seasons, and AMF colonization was the highest in this period (Bentivenga and Hetrick, 1992; Rodríguez-Echeverría et al., 2008; Su et al., 2011). This is because during the early growing season, the plants grow fast with high metabolic activity and high level of nutrient exchange between host plants and fungi, leading to a higher percentage of AM colonization (Baslam et al., 2011; Bentivenga and Hetrick, 1992; Muthukumar and Udaiyan, 2002; Wang et al., 2015; Su et al., 2011). The structures of AMF, including vesicles and arbuscules are essential sites for nutrient storage and their exchange between the host plants and fungi (Müller et al., 2017; Berruti et al., 2016). Moreover, genus *Glomus* was found to be the most abundant, suggesting that the AMF species belonging to this genus can produce more hyphal segments and spores that can colonize onto plant roots extensively (Zhao et al., 2017). Consistent with this, all three plant species, in our study, were dominated by *Glomus* showing the highest percentage of AMF colonization.

AM fungal diversity and community composition

We found that the number of sequence types/OTUs detected were 51, inferring the rich AMF diversity in this typical steppe. The species richness of AMF in the roots of *S. grandis*, *C. squarrosa,* and *L. chinensis* was 32, 20, and 25, respectively. Moreover, the diversity indexes also indicated the high diversity in all three plant species, especially in *S. grandis*. These findings are supported by the previous studies showing that the plant species in the field conditions held higher AMF diversity in their roots (Öpik et al., 2006; Torrecillas et al., 2012), and perennial plant species of semiarid region hosted the higher AM fungal diversity in their roots (Alguacil et al., 2012). Moreover, the AM fungal community in the current research exhibited that 50% of the total OTUs were contributed from the genus *Glomus*, suggesting it as the most abundant and wide spread genus among the three plant species. These results supported the previous reports that widely distributed AMF had higher abundance in the local environment but with low host specificity (Husband et al., 2002; Öpik et al., 2006; Wirsel, 2004). Moreover, it is also documented that AMF diversity increases with the increase in plant diversity (Alguacil et al., 2011; Torrecillas et al., 2012) because different plant species dominate the typical steppe of Inner Mongolia during the growing season (Su et al., 2011). This explanation is in agreement with our results that *S. grandis* showed a greater extent of AM fungal diversity when compared to *L. chinensis* and *C. squarrosa*, as *S. grandis* also held the highest AMF colonization, which may be attributed to the colonization of more diversified AMF taxa. Alguacil et al. (2011) also concluded that the non-metric multidimensional scaling plot revealed that AM fungal communities of all three plants overlapped, suggesting low host specificity of AMF for these species. This might be because all the species belong to the same family *poaceae*. This is also in line with previous finding stating the absence of host specificity in *poaceae* (Torrecillas et al., 2012). Another explanation could be that the composition of host plant does not effectively influence AM fungal communities. There are also some environmental factors that have substantial effects on the community composition of AMF such as soil properties including structure (Lekberg et al., 2007), fertility (Egerton-Warburton et al., 2007; del Mar Alguacil et al., 2010), moisture content (Wolfe et al., 2007), disturbance (Rodríguez-Echeverría and Freitas, 2006), and climatic factors including temperature and precipitation (Treseder, 2013). Widespread study in Tibetan alpine steppe stated that different plants at the same site had no significant difference in AMF community composition in their rhizosphere soil (Zhang et al., 2016a). In most cases, the AMF community associated with the respective host is not so unique, and there is the probability that a subset of that AMF community is also connected with many other host plants, and it has been reported that a limited number of fungal species associated with globally 90% of plant families, resulting in lower host specificity of AMF (Natasha Teutsch and Hawkes, 2010). In contrast, there are also mounting evidences indicating that co-occurring plant species held apparently distinct AM fungal communities within their roots, including plants in tropical forests (Husband et al., 2002), permanent grasslands (Vandenkoornhuyse et al., 2003), oak-woodlands (Douhan et al., 2005), semiarid coastal dunes (Martínez-García and Pugnaire, 2011), high mountainous meadows (Sýkorová et al., 2007), and farmland (Paul et al., 2013).

Despite the overall community composition similarity, in terms of genus and OTUs, some AMF were still found to be specific to their host plants in our study (*Table 1*). Likely, Lugo and Cabello (2012) found that some AMF species were limited to *B. subarista* and *P. stuckertii*, whereas the *Glomus* species was only associated with *P.*

DOI: http://dx.doi.org/10.15666/aeer/1705_1207312089

stuckertii. Thus, the effects of host plant on AM fungal community composition are still controversial and needs further research to disentangle the reality.

Conclusion

In summary, the overall higher rate of mycorrhizal colonization in the roots of three dominant species of Xilinguole typical grassland reflects the strong association and mutual relationship of plant-AMF. Moreover, there were significant differences in species richness of AMF among the three perennial plant species. However, there were no significant differences in community composition of AMF; some genera exposed a little host preference, wherein *Glomus* was the most dominant in reflecting the actual community composition. These findings can be of vital importance in studying the success of plant species in their ecosystems based on the integrity of their symbiotic relationships with AMF.

(Received 27th Apr 2019; accepted 11th Jul 2019)

Abstract. Plants regulate leaf transpiration rate and water potential by changing the number of stomata and their rate of opening and closing. Stomata act as turgor-operated valves for gas exchange and water evaporation based on environmental needs. During stomatal development, various transcription factors and related genes are involved in the reception or transduction of environmental factors and hormones. Recent studies have led to significant advances in our understanding of intercellular signaling, the underlying pathways, and the polarity of the asymmetric division that controls stomatal development. The endogenous and exogenous factors that regulate these elements have also been identified. However, the mechanism of stomatal formation and development is highly complex and several morphogenesis-related questions are still unresolved. In this review, the molecular basis of stomatal development, including transcription factors, functional genes, and regulatory pathways, is described in detail. The connection between stomatal development and environmental factors such as CO_2, light, temperature and air humidity is discussed. In addition, the influences of plant hormones on stomatal development are sketched out in the review. We also highlight critical questions requiring future research and form a detailed list involving in gene functions and trait changes in mutants.
Keywords: *stomata, molecular mechanism, epidermal patterning factors, bHLH transcription factors, leucine-rich repeat receptor-like proteins*

Introduction

Stomata are apertures typically observed on plant outer leaf layers; they maintain the optimal balance between CO_2 uptake and water loss as a way to adapt environmental conditions in plants (Ni, 2012). In primary leaves of Arabidopsis, stomatal formation involves three types of cells: meristemoid mother cells (MMCs), guard mother cells (GMCs), and meristemoids (Behzadi et al., 2014). A protodermal cell develops into a stoma via three rounds of unequal cell divisions. First, the epidermal cell differentiates into a MMC through a series of unknown steps. The MMC then undergoes an asymmetric division to produce a small meristemoid cell and a stomatal-lineage ground cell (SLGC). The GMC develops into two GCs that flank a central pore to constitute a stoma (Bergmann and Sack, 2007). In addition, a SLGC can form satellite meristemoids (SMs) by spacing asymmetric division, with the SMs gradually differentiating into stomata. Most stomata are formed from SMs in this fashion. In addition to their balancing function, stomata play a significant role in water, carbon, and nutrient cycles.

Thorough investigation of stomatal regulation is therefore essential for understanding plant physiological responses to the environment and their physical functions (Von et al., 2002).

The traditional model explains stomatal development and distribution in terms of cell developmental lineages, cell–cell interactions, and long-distance signaling. In monocotyledons, stomata are arranged in chains parallel to leaf veins (Geisler et al., 2000). In Arabidopsis and other dicotyledons, however, stomatal distribution on the leaf surface is irregular and individual stomata are spaced from one another (Serna and Fenoll, 2000). Although in-depth examinations would be beneficial to understand gas exchange and to reduce moisture loss, such investigations can be very difficult because of this stomatal variation and the complex relationship between stomatal development and the environment.

Many studies have recently shown that stomatal development is a tightly controlled process. The various transcription factors, secreted protein, protease and some regulatory pathways have been shown to play an important role. While several environmental and hormonal factors are known to affect stomatal development, very little is known about the molecular mechanism for these changes. In this review, we describe stomatal distribution patterns and formation, signaling pathways, and genes related to stomatal development accordingly, and discuss directions for future research. We also form a detailed list involved in genes function and trait changes in mutants (*Table 1*).

Table 1. *Genes with mutations known to affect stomatal development in plant*

Basic signal transduction and molecular regulation

Various transcription factors and other proteins involved in stomatal development have been studied along with their related genes. The encoded proteins include a family of epidermal patterning factors (EPFs), subtilisin-type proteinases (stomatal distribution and density 1 [SDD1]), leucine-rich repeat receptor-like proteins (TOO MANY MOUTHS [TMM]), basic helix-loop-helix (bHLH) transcription factors, and MAPK phosphatases (Geisler et al., 2000; Von et al., 2002; Hara et al., 2009; Jakobson et al., 2016). These studies, to some extent, have expounded the mechanisms of stomatal formation and development.

Role of EPF

EPF genes encode a protein family of cysteine-rich peptides that include 11 member ligands in Arabidopsis. The EPF family peptides are classified into four subgroups based on their amino acid sequences. Some proteins have been identified as involved in stomatal development, such as epidermal patterning factor 1 (EPF1), epidermal patterning factor 2 (EPF2), STOMAGEN/EPFL9, and CHAL etc. (Hara et al., 2009; Abrash and Bergmann, 2010; Sugano et al., 2010).

EPF1 and EPF2

EPF1 and EPF2 affect the formation of stomatal precursors through distinct yet overlapping functions. Asymmetric cell division and the formation of stomatal clusters or pairs is controlled by EPF1, which is produced in meristemoids, GMCs, and GCs. Mature leaves lacking *EPF1* consequently show an increase in the number of stomata and frequent stomatal pairing. EPF2 inhibits meristemoid formation and promotes the formation of pavement cells. The *epf2* mutant increases stomatal densities and leads to the formation of small, arrested stomatal lineage cells. In contrast, ectopic expression of *EPF2* suppresses entry divisions, which leads to an epidermis composed only of pavement cells. The double mutant *epf1*/*epf2* displays additive effects, causing greatly increased stomatal densities, stomatal pairing, and arrested cells (Hara et al., 2009; Hunt

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1209112109

and Gray, 2009). Over-expression of either *EPF1* or *EPF2* has been found to suppress stomatal formation, but has revealed that they act on different developmental processes. EPF1 enforces the one-cell spacing rule, whereas EPF2 inhibits the population of cells from acquiring the stomatal lineage fate. *EPF2* can partly substitute for *EPF1* in function, but *EPF2* cannot be replaced by *EPF1*. In addition, *EPF2* expression requires the bHLH transcription factor SPEECHLESS (*SPCH*) and a MAPK (YODA [*YDA*]), suggesting that EPF2 is mediated by the MAPK cascade (Hara et al., 2009). EPF1 and its primary receptor ERECTA-LIKE1 (ERL1) target MUTE as a bHLH protein that controls the transition from meristemoids to GMCs and specifies the proliferation-to-differentiation switch within the stomatal cell lineages, while MUTE directly induces ERL1 (Du et al., 2018).

Although the function of *EPF1* and *EPF2* has been studied deeply in many aspects. Compared with EPF1, however, the function of EPF2 still remains some unknown domains that need to study further in the future. For example, how do the EPF2 peptide and ERECTA receptor affect the downstream signaling components? What proteases activate EPF2?

STOMAGEN/EPFL9

STOMAGEN/EPFL9 is an EPF known to positively influence stomatal development (Von et al., 2002). Over-expression of *EPFL9* shows increased stomatal density and clustering, while loss of *EPFL9* function leads to reduced stomatal density with no clustering. *EPFL9* acts independently of *EPF* to regulate stomatal density and control stomatal clustering, while acts independently of *SDD* to control both stomatal density and clustering (Hunt et al., 2010). In another study, it was showed that STOMAGEN controls stomatal development by binding with the TMM receptor protein to compete with EPF1 and EPF2. Genetic analysis has revealed that TMM is epistatic to STOMAGEN, which suggests that stomatal development is mediated by competitive binding of positive and negative regulators to the same receptor. Loss of *STOMAGEN* function results in fewer stomata. Conversely, *STOMAGEN* over-expression increases stomatal cluster formation and stomatal density (Hunt and Gray, 2009).

Even though the placement of stomata relative to one another has been demonstrated to be controlled by intercellular signaling via several EPFs, the extracellular proteases that function in EPFs pathways still remain unknown (Lee et al., 2015). Environmental signals that regulate the stomatal development via the extracellular propeptides EPFs or the protease SDD1 have still not been certified. Fortunately, the mechanism underlying the interaction of β-carbonic anhydrase and CO_2 RESPONSE SECRETED PROTEASE (CRSP) that influences the action of EPF2 in the CO_2 signaling pathway for stomatal development has been recently uncovered (Engineer et al., 2014). The elucidation of the detailed functions of EPFs other than EPF2 and their impacts on extracellular proteases and environmental signaling during stomatal development obviously requires further investigation.

CHAL

Similar to EPF1 and EPF2, CHAL inhibits stomatal formation. *CHAL* was studied during a screening designed to detect suppressors of *tmm* mutant, and only presented a phenotype in the presence of the *tmm* mutation. Although excess stomata were observed on leaf surfaces of *tmm* mutants, stomata were completely absent from stems.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1209112109

Interestingly, stomata reappeared on stems when *CHAL* was knocked out in the *tmm* mutant. Over-expression of *CHAL* requires ERECTA family (ERf) to suppress stomatal development. These differing results indicate that TMM may play a buffering role in the ERf receptor system, preventing EPF1 and EPF2 from disturbing the formation of normal epidermal patterns by absorbing excess CHAL (Abrash and Bergmann, 2010).

Role of TMM

TMM, a LRR-RLP receptor protein, negatively regulates stomatal density and placement. STOMAGEN positively regulates stomatal development, while EPF1 and EPF2 negatively regulate stomatal development by interacting with TMM as ligands. Loss of *TMM* function fails to orient and suppress asymmetric divisions of cells adjacent stomata or their precursors; in addition, loss-of-function mutants undergo a reduced number of divisions, resulting in the premature conversion of meristemoids into GMCs (Geisler et al., 2000). TMM plays an important role in cell-cell communication and perceives information regarding transient contiguous cell confirmation and location (Bergmann and Sack, 2007). The secretory peptides encoded by EPFs are expressed in meristemoids, with their activity dependent on the function of TMM and ERf members. ERfs and TMM work cooperatively to inhibit stomatal production. EPFs require TMM or ERfs to certify their over-expression phenotypes, which indicates the importance of these three proteins in EPf perception (Horst et al., 2015; de Marcos et al., 2016).

Role of SDD

SDD1 is a negative regulator of stomatal development, which encodes a subtilisin-like serine protease. SDD1 affects both protoderm and neighboring cell fates. During the development of neighboring cells, the shift from pavement cells to SM precursors may be controlled by a SDD1-dependent reaction signal in meristemoids/GMCs. Whether the meristemoid/GMC response causes the neighboring cell shift or instead triggers or extends *SDD1* expression is unclear (Von et al., 2002). Loss of SDD1 function leads to properly spaced but denser stomata. In one investigation, a 1.5-fold increase in stomatal density and index were reported in two *sdd1-1* mutants of Arabidopsis (Bergmann and Sack, 2007). *SDD1* overexpression causes a two- to four-fold decrease in stomatal density but does not considerably alter leaf and epidermal cell sizes (Von et al., 2002).

Role of bHLH transcription factors

In plants, bHLH transcription factors constitute an evolutionarily ancient group known to specify cellular identity. Some homologous bHLH proteins play important roles in the determination of the fate of successive stomatal precursor cells. For example, SPCH, MUTE, and FAMA act to activate cellular transition about stomatal development, share 88% structural homology and 39% sequence homology. Despite their similarities, they can not functionally replace each other during stomatal development because of the specific features of each protein (Ohashi-Ito and Bergmann, 2006).

SPCH

The *SPCH* gene is the key factor in the process of protodermal cell division into MMCs. *SPCH* involves in a basic pathway that initiates asymmetric division in the stomatal lineage (MacAlister et al., 2007; Vatén et al., 2018). The *spch* mutant fails to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1209112109

produce interlocking pavement cells and promote stomatal lineages, while over-expression of *SPCH* raises the number of cells in the stomatal pathway. In addition, SPCH can prolong meristemoid identity, as loss of SPCH function leads to that meristemoids divide significantly fewer times. SPCH is also a target of brassinosteroid (Br) and MAPK signaling, and is an integration point for environmental information that allows for appropriate patterning and optimization of stomatal density under changing conditions (Ohashi-Ito and Bergmann, 2006).

MUTE

MUTE is a bHLH protein that controls the transition from meristemoids to GMCs, which promotes the differentiation of meristemoids into stomata (Pillitteri et al., 2007; Mahoney et al., 2016). The *mute* mutant fails to form stomata, but has no effect on meristemoid formation. Over-expression of *MUTE* has been shown to shift all epidermal cells toward stomata. The promoter of *MUTE* is not active in meristemoids, but is specifically activated in late-stage meristemoids. It was suggested that *MUTE* promoters binding with one finger regulatory elements is important for regulation (Mahoney et al., 2016). Because it is difficult to predicate the number of meristemoid divisions, how meristemoids regulate the timing of *MUTE* expression and the end of meristemoid division is unclear.

FAMA

FAMA, which controls GC fate, is expressed during the symmetric division that produces the two young GCs, but not in mature stomata (Ohashi-Ito and Bergmann, 2006). This protein likely acts as a transcriptional activator to regulate the transition from GMCs to GCs during symmetric division. Loss of FAMA function results in lack of mature stomata, while it develops clusters of GMCs or incipient GCs. Over-expression of *FAMA* converts non-stomatal cells to GCs in *fama* mutant plants (Ohashi-Ito and Bergmann, 2006). Matos et al. (2014) found that FAMA must bind to another protein, RETINOBLASTOMA-RELATED (RBR), to control the GMC to GC transition. These two proteins cause a permanent transition from stem cells to GCs. When the partnership between FAMA and RBR is broken, reversion of the GCs into stem cells can be observed.

SCRM and SCRM2

SCRM and SCRM2 are two additional bHLH proteins, which promote cellular transitions during stomatal development. Both of these proteins share high sequence homology and encode bHLH-type leucine zipper nucleoproteins. SCRM and SCRM2, which exist in cells of all stages, are similar in expression and function (Kanaoka et al., 2008). A *scrm* single mutant displays phenotypes similar to the *fama* mutant, while the *scrm-scrm2* double mutant produces occasional *spch*-like columns. It was showed that SCRM and SCRM2 interact with SPCH, MUTE, and FAMA. Map-based cloning has shown that SCRM is one of the key regulatory factors during cold stress, indicating that the ability of plants to adapt to environmental conditions may be related to developmental factors (Serna and Fenoll, 2000). Both environmental and developmental factors regulate stomatal development, which implicates SCRM as a participant in the integration of environmental signals directly into the stomatal differentiation pathway (Lee et al., 2017).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1209112109

Taken together, these three bHLH family members-SPCH, MUTE, and FAMA-control formation, amplification, division, and final differentiation in stomatal development (*Fig. 1*). Remarkably, the SPCH protein can be phosphorylated by MPK3 and MPK6, whereas no such phosphorylation has been reported for MUTE and FAMA. SPCH generates stem cells and triggers their asymmetric division, while MUTE controls the meristemoid-to-GMC transition. SPCH, MUTE, and FAMA form obligate heterodimers with ICE1/SCRM and SCRM2, but not among themselves. These genes non-redundantly and positively regulate the stomatal development. However, interaction with RBR is inadequate to define the feature of FAMA and indicate a version of FAMA that behaves like MUTE or SPCH (Davies and Bergmann, 2014). It is necessary to study the larger interacted complexes that contribute to stomatal lineage by further work on protein interactions. It is also needed to identify what kind motifs are involved in these protein interactions.

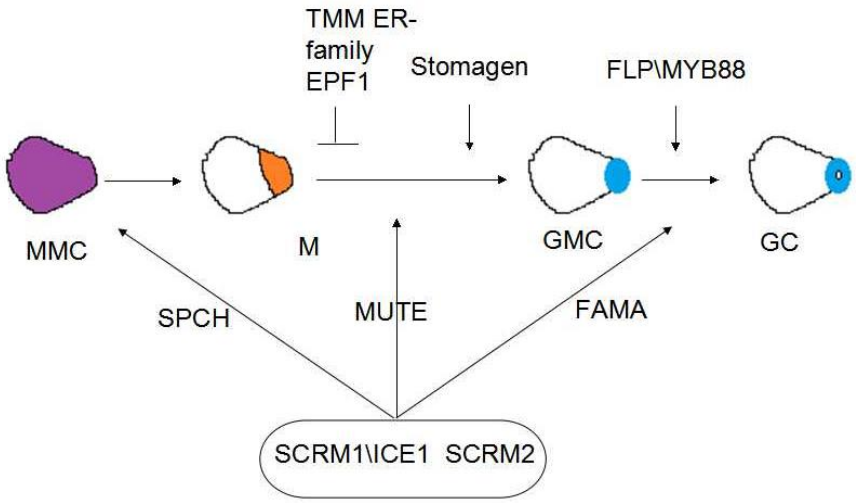

Figure 1. *Model of the differentiation steps regulated by sequential actions of bHLH transcription factors and related genes. MMC: meristeoid mother cell (purple), M: meristemoid (orange), GMC: guard mother cell (blue), GC: guard cell (blue with circle)*

Role of MAPK cascades

The MAPK signaling pathway controls cell fate and division during stomatal development. MAPK cascades are organized into a core module comprising three protein kinases: a MAPK, a MITOGEN-ACTIVATED PROTEIN (MAP) kinase kinase (MKK), and a MAP kinase kinase kinase (MAPKKK). YDA, a MAPKKK in the MAPK cascade, negatively regulates stomatal development. The associated signaling pathway consists of YDA, MKK4/5/7/9, and MPK3/6/9. The YDA-MKK4/5-MPK3/6 complex negatively regulates processes involved in the formation of GMCs from MMCs and of GCs from GMCs. YDA-MKK7/9, in contrast, positively controls these processes (Lampard et al., 2009). Loss of *AtYDA* function generates a clear increase in the production of leaf stomata in Arabidopsis, whereas expression of constitutively active mutants of *AtYDA* causes repressed stomatal formation in leaf epidermis. Furthermore, epidermal cells of *yda* mutant cotyledons display excessive entry divisions, thereby failing to prevent division of neighboring cells that connect two stomatal lineage cells. Asymmetry of cell fates is also compromised in *yda* mutants.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1209112109

Over-expression of *YDA* leads to a significant decrease in stomatal density and the rate of water loss (Bergmann and Sack, 2007). *ABA-INSENSITIVE PROTEIN KINASE1 (AIK1)* gene encodes MAPKKK20 and positively regulates ABA-induced stomatal closure. The stomatal closing in *aik1* mutants was less sensitive to ABA than that in wild-type plants. In addition, the *aik1* mutants exhibit slightly greater stomatal density and significantly increased stomatal index. It was revealed that MKK4 and MKK5 could interact with AIK1 in vivo (Li et al., 2017). As another MAPK cascade**,** MPK12 regulates the stomatal aperture. Loss of MPK12 function results in the stomatal CO_2-insensitivity phenotypes and the higher degree of stomatal opening. It was showed that MPK12 interact with the protein kinase HIGH LEAF TEMPERATURE 1 (HT1) to inhibit the activity of HT1. Because of the higher degree of stomatal opening, the instantaneous water use efficiency is lower in *mpk12* mutants, suggesting that MPK12 is a important regulator of stomatal conductance (Jakobson et al., 2016).

The influence of environmental factors

Role of CO_2 concentration

In the plant epidermis, the adjustable stomatal pores formed by GCs allow CO_2 to enter for photosynthesis and water from transpiration to escape to the atmosphere. Plants accommodate to a continuous rise in atmospheric CO_2 concentration by adjusting stomatal density and closing stomata (Hu et al., 2015; Engineer et al., 2016). Gray et al. (2000) have identified a gene, designated as *HIC* (for high carbon dioxide), that is related to the signal transduction pathway responsible for regulating stomatal numbers at elevated CO_2 (eCO_2). *HIC* encodes a protein similar to 3-ketoacyl coenzyme A synthase, which is expressed specifically in GCs. Loss of *HIC* function results in an increase in stomatal density for reacting to a doubling of CO_2. *HIC* is the first gene to be identified that affects plant developmental responses to global changes in atmospheric composition. β-carbonic anhydrase (βCA) is a CO_2-binding protein that functions early in the CO_2 signaling pathway for stomatal development. Two βCAs, CA1 and CA4, were identified that function in the CO_2 response. Double mutants (*ca1 ca4*) result in an inversion in response to eCO_2 by increasing stomatal development (Hu et al., 2010). Over-expression of *CA4* and *CA1* could refresh CO_2-induced stomatal responses in double mutants. The *ca4* mutant shows a slightly altered sensitivity to the CO_2 stimulus (Hu et al., 2015; Engineer et al., 2016).

A novel CO_2-induced extracellular protease, CRSP, has been identified as a mediator of CO_2 regulation of stomatal development during atmospheric CO_2 elevation. Interaction of CA1, CA4, and CRSP degrades the pro-peptide EPF2, repressing stomatal development. However, EPF2 is vital to CO_2 regulation of stomatal development (Engineer et al., 2014). Future research should focus on if feedback modulation results in CO_2 regulation of EPF2 and CRSP transcripts and what are the transcriptional regulators regulating the eCO_2 response. SLOW ANION CHANNEL-ASSOCIATED 1 (SLAC1) is an S-type anion channel protein, which plays a important role in stomatal closure in response to eCO_2. Loss of *AtSLAC1* function dramatically represses stomatal closure induced by CO_2 (Vahisalu et al., 2008; Hedrich and Geiger, 2017).

Stomatal opening is promoted by the activation of H^+-ATPases (AHA1) in the guard cell plasma membrane, and eCO_2 concentration inhibits proton efflux by plasma membrane AHA1 (Hashimoto-Sugimoto et al., 2013). The *PATROL1* gene encodes a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1209112109

protein with a MUN domain, which is involved in the membrane trafficking of neurotransmitter release. Loss of *PATROL1* function results in the impaired stomatal opening in response to low CO_2 concentration, disturbing the normal plasma membrane targeting of H^+-ATPases (Engineer et al., 2016).

HT1 is a protein kinase and an essential regulator of stomatal CO_2 responses. Loss of HT1 function results in constitutively stomata opening and repressed stomatal CO_2 responses (Jakobson et al., 2016). The open stomata 1 (OST1) protein kinase is involved in CO_2- and ABA-induced stomatal closing (details in ABA section). It was suggested that HT1 phosphorylates the OST1 protein kinase, which inactivates OST1 (Mustilli et al., 2002; Tian et al., 2015). BIG/CIS1 is a calossin-like protein, which regulates CO_2-induced stomatal closure (He et al., 2018). Loss of BIG/CIS1 function fails to show reductions in stomatal density and index, but displays inhibition of stomatal opening with eCO_2 concentration. It was showed that BIG/CIS1 is only demanded in eCO_2-induced stomatal closure, suggesting the signaling pathways of CO_2-mediated promotion of stomatal closure are distinguishable with inhibition of opening (He et al., 2018). Because BIG/CIS1 is associated with auxin transport, further research should focus on if disruptions to auxin signaling underlie the BIG/CIS1 stomatal mutant phenotype. These studies could help researchers to choose plant germplasm for adapting to CO_2 levels.

Role of light

Light intensity affects stomatal density and the stomatal index, which play an important role in cell fate decisions in the epidermis (Casson et al., 2009). CONSTITUTIVE PHOTOMORPHOGENIC 1 (COP1), a E3 ubiquitin-protein ligase, is a repressor of light-controlled stomatal development (Liu et al., 2008). A current study showed that COP1 degrades ICE through ubiquitination pathways in leaf abaxial epidermal cells. Loss of *COP1* function results in the ICE proteins accumulate in the nuclei of leaf abaxial epidermal cells. Interestingly, light impairs the COP1-mediated degradation of the ICE to induce stomatal development, which upregulates EPF2 activity at the transcriptional level, thereby conferring proper stomatal spacing and distribution. Thus, it is likely that the COP1-ICE-EPF2 signaling module integrates light signals into developmental programs that regulate stomatal development (Lee and Park, 2017). ANGUSTIFOLIA3 (AN3) is a positive regulator of stomatal development, which interacts with the *COP1* promoter to regulate light-induced stomatal development. Loss of *AN3* function results in decreased stomatal index, whereas overexpression of *AN3* leads to clusters of stomata (Meng et al., 2018). These suggest that the AN3–COP1–E3 pathway regulates stomatal development with the integration of light signaling. COP10 is another dominant component of stomatal-lineage divisions, which represses stomatal fate and adjusts the initiation frequency and extension of stomatal lineages. Loss of *COP10* function results in the production of stomatal clusters. COP10 regulates genetically in parallel with SDD1 and does not affect epidermal cell differentiation (Delgado et al., 2012). Phytochrome B (phyB) plays an important role in red light-induced stomatal development. Loss of *phyB* function prevents this increased production of stomata under high intensity red light. phyB can also promote the expression of *FAMA* and *TMM* genes in young leaves (Casson et al., 2009). Consequently, phyB has a significant role in the mediation of epidermal cell division and stomatal development. PHYTOCHROME-INTERACTING FACTOR 4 (PIF4), a bHLH transcription factor, can be transported to the nucleus upon binding to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1209112109

phyB. PIF4 may also regulate stomatal development with SPCH, MUTE, and FAMA. Mutations of *PIF4* display a similar defect as in the absence of *phyB* (Casson et al., 2009).

Plasma membrane H^+-ATPase regulates blue light-induced stomatal opening. It is activated via a signaling mediator BLUE LIGHT SIGNALING1 (BLUS1) and blue light-receptor phototropins (phot1 and phot2). BLUS1 and phosphatase act as positive mediators between the H+-ATPase and the phots during stomatal opening. BLUE LIGHT-DEPENDENT H^+-ATPASE PHOSPHORYLATION (BHP) is a novel signaling regulator in blue light-induced stomatal opening interacting with BLUS1, which is owned by the MAPKKK family. Loss of *BHP* function results in impaired stomatal opening in response to blue light (Hayashi et al., 2017). The phots are light-induced receptor kinases, which mediate stomatal opening and phototropism. the *phot1 phot2* double mutant fails to show the blue light-induced stomatal opening and the H^+-ATPase activation, but *phot1* and *phot2* single mutants retain these responses (Doi et al., 2004). A recent study displayed that BLUS1 kinase is phosphorylated by phot1 and phot2, which acts as a common substrate in stomatal opening through the activation of the plasma membrane H^+-ATPase via phosphatase (Takemiya and Shimazaki, 2016).

The light-induced stomatal opening is also inhibited by Rho-type (ROP) GTPase 2 (ROP2). ROP-interactive Cdc42- and Rac-interactive binding motif-containing protein 7 (RIC7) interacts ROP2 and mediates downstream processes. Loss of *RIC7* function activates light-induced stomatal opening, while overexpression of *RIC7* represses light-induced stomatal opening. RIC7 interacts also with Exocyst subunit Exo70 family protein B1 (Exo70B1), a positive regulator of stomatal opening, to optimize the extent of stomatal opening by inhibiting the function of Exo70B1. The mutant *exo70b1* and double mutant *ric7/exo70b1* both display inhibited light-induced stomatal opening (Hong et al., 2016). ENHANCED RESPONSE TO ABA 1 (ERA1) encodes the farnesyl transferase β subunit, which dominates stomatal closure in plants. Loss of *ERA1* function results in more closed stomata phenotype. Further studies indicated that *era1* mutants shows impaired blue light-induced stomatal opening, which suggested a potential function for ERA1 farnesylation in blue light-induced stomatal opening (Jalakas et al., 2017). In addition, Photosystem II Subunit S (PsbS), a integral membrane protein, affects a chloroplastderived signal for light-induced stomatal opening. Over-expression of *PsbS* results in impaired light-induced stomatal opening and a 25% reduction in water loss per CO_2 assimilated under field conditions (Głowacka et al., 2018).

Synergy effects of light and CO_2

The stomatal opening is mediated by light and low concentrations of CO_2 with synergy effects. CONVERGENCE OF BLUE LIGHT AND CO2 1/2 (CBC1/CBC2) are protein kinases related to blue light, which redundantly promote stomatal opening in response to both blue light and low concentrations of CO_2. It was suggested that CBCs positively mediate stomatal aperture by integrating signals from blue light and low CO_2 (Hiyama et al., 2017). In contrast to blue light-induced stomatal opening, the viewpoints about red light-induced stomatal opening are controversial. Some studies showed that red light-induced stomatal opening may be resulted in a low intercellular concentration of CO_2 brought about by mesophyll photosynthesis (Horrer et al., 2016) However, other investigators suggested that such a reduction in the intercellular concentration of CO_2 of leaves was insufficient to lead to stomatal opening. Hiyama et al. (2017) speculated that

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1209112109

the reduced intercellular concentration of CO_2 might result in stomatal opening by inhibiting the S-type channels through CBCs, but such a response did not display in the *cbc* mutants. Further study is needed to elucidate the role of CBCs in red light-induced stomatal opening.

Temperature and air humidity

Temperature affects stomatal development in a complex manner. Temperature increases often leads to somatal opening, whereas heat stress often promptly mediates stomatal closure to decrease transpirational water loss in some plant species (Lahr et al., 2015). Increased temperature restrains the expression of SPCH that acts as the major mediator of stomatal lineage initiation (Vatén et al., 2018). PIF4 is also a core component of high-temperature signaling, which accumulates in the stomatal precursors and combines with the promoter of SPCH in increased temperature. In addition, PIF4 represses also SPCH activation and stomatal production. This study proposed a model where warm-temperature-activated PIF4 binds and represses SPCH expression to restrict stomatal production at increased temperatures (Lau et al., 2018). The CO_2-induced variations of stomatal closure associates with heat stress tolerance. The eCO_2 moderates the negative effects of heat stress, which is accompanied by greater amounts of *RESPIRATORY BURST OXIDASE 1* (*RBOH1*) transcripts and decreased stomatal aperture. Loss of *RBOH1* function results in the impaired eCO_2-induced stomatal closure and the compromised eCO_2-enhanced water use efficiency as well as the heat tolerance (Zhang et al., 2018).

Stomatal movement is influenced by relative air humidity (RH) with ABA content. High elevated air movement (MOV) reduced length and aperture of stomata in plants developed at high RH and increased stomatal sensitivity to ABA (Carvalho et al., 2015). In this process, *CYP707A1,* a ABA catabolism gene, plays a prominent role for influencing stomata development and ABA content. Over-expression of *CYP707A1* during dark in high RH reduced the ABA content in the guard cells and prevented stomatal closure, whereas loss of CYP707A1 gene function resulted in reduced stomatal aperture (Arve et al., 2015; Jalakas et al., 2018). Compared with the influence of CO_2 and light on stomatal development, the molecular mechanisms underlying the action of temperature and air humidity on stomatal development should be further and deeper to study.

The influence of plant hormones

Some hormones, such as Abscisic acid (ABA), jasmonate (MeJA), Brassinosteroids (BRs), Strigolactones (SLs), Salicylic acid (SA) etc. have a strong correlation with stomatal development. With the mechanism of stomatal development being studied in the past decade, many researches have opened the door to understand the function of plant hormone in stomatal development.

Role of ABA

ABA is well known to mediate the opening and closing of stomata in response to changes in water balance. ABA levels are low in the Arabidopsis *aba2* mutant, with the mutant displaying high stomatal density. ABA INSENSITIVE 1 and ABA INSENSITIVE 2 (ABI1 and ABI2) are protein phosphatase 2C proteins, which regulate

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1209112109

ABA-mediated stomatal closure interacting with protein kinases OST1 (Tanaka et al., 2013). The pathway for ABA-mediated stomatal closure is related to perception of ABA that results in the activation of guard cell anion channels by OST1. Loss of *OST1* function results in insensitivity to ABA-mediated stomatal closure and opening, which indicates that OST1 is a positive regulator in ABA signaling (Mustilli et al., 2002; Acharya et al., 2013). OST1 needs normal ABI1 function for its ABA-dependent activation and interacts directly with ABI1 protein (Park et al., 2009). In addition, ABA-induced stomatal closing are abolished in *abi1* and *abi2* mutants (Pei et al., 1997). Although ABA interacts with different functional proteins, transcription factors, kinases, and various environmental factors, the molecular mechanisms about these interaction are massively complex and are not entirely clear.

Role of MeJA

The exogenous MeJA can reduce the stomatal index and stomata density on the cotyledons of Arabidopsis. Coronatine (COR) is perceived via a receptor complex formed by CORONATINEINSENSITIVE 1 (COI1) and JASMONATE ZIM DOMAIN (JAZ) proteins, which promotes entry of bacteria into the plant apoplast by facilitating stomata opening (Yan et al., 2009). COR and jasmonate isoleucine (JA-Ile) co-receptor JAZ2 modulates stomatal aperture by the signaling module COI1-JAZ2-MYC2,3,4-ANAC19,55,72 during bacterial invasion. The jaz2 mutant shows partially repressed pathogen-induced stomatal closing, which is more sensitive to Pseudomonas. The JAZ2 binds to the MYC transcription factors directly mediate the expression of ANAC19,55,72 to control stomata aperture (Gimenez-Ibanez et al., 2017). In addition, the MYC transcription factors negatively modulate jasmonate-inhibited stomatal development and act upstream of the SPCH and FAMA to regulate stomatal development. The stomatal development of the *myc2 myc3 myc4* triple mutant is insensitive to MeJA treatment (Han et al., 2018).

Role of BRs

BRs are steroid hormone that promotes stomatal closure in an ABA-independent manner (Kim et al., 2012). BRASSINOSTEROID INSENSITIVE2(BIN2), a important regulator in BR signaling, encode a glycogen synthase kinase 3 (GSK3)-like kinase (He et al., 2002). BRs negatively modulate stomatal development by repressing BIN2 kinase-induced inhibition of YDA. BIN2 phosphorylates and inactivates the YDA, which inhibits stomata formation. Overexpression of *BIN2* displays a similar stomatal overproduction phenotype as *bsu* mutants. Besides, BRs have been directly involved in stimulating stomatal development in hypocotyls through BIN2 phosphorylation and inactivation of SPCH, which acts downstream of the MAPKs and stimulates cell division and stomatal development. BRASSINOSTEROID-INSENSITIVE 1 (BRI1) kinase binding with BR recruits BRI1-ASSOCIATED RECEPTOR KINASE 1 (BAK1) to produce a receptor complex on plasma membranes (Shang et al., 2016). Transphosphorylation between BRI1 and BAK1 further enlarges BRI1 and BAK1 kinase activities, which results in inactivation of BIN2 by the upstream phosphatase BRI SUPPRESSOR1(BSU1) under high BR levels (Zhu et al., 2013). Loss of *BSU1* function results in massive stomata formation, which needs BIN2 activity (Kim et al., 2012). Loss of *BAK1* function results in insensitivity of ABA-mediated stomatal closure and inhibition of OST1 expression and ROS production. It was further indicated that

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1209112109

BAK1 interacts with OST1 near the plasma membrane, which increases sensitivity in response to ABA. In addition, ABI1 interacts with BAK1 and impairs the interaction of BAK1 and OST1 (Shang et al., 2016).

Role of SLs

SLs play a vital role in regulating stomatal closure in an ABA-independent mechanism. SLs promotes a significant increase in H_2O_2 and NO contents, which is needed for stomatal closure. Disruption of MORE AXILLARY GROWTH 2 (MAX2), DWARF14 (D14), and SLAC1 represses SL-induced stomatal closure. Loss of MAX2 function leads to increased stomatal conductance and more widely opening stomata (Piisilä et al., 2015). The *slac1* mutant shows compromised SL-mediated stomatal closure, showing that SLAC1 is necessary for SL-mediated stomatal closure. Although SL-induced stomatal closure requires H_2O_2, NO, and SLAC1, the detailed molecular mechanism by if SLs regulate the stomatal response remains unknown. It will be required to study whether H_2O_2-activated Ca^{2+} channels are also needed for SL-induced stomatal closure (Lv et al., 2018).

Role of SA

SA regulates ROS production in guard cells through peroxidase-catalyzed reaction, leading to stomatal closure. AtSIZ1 is a small ubiquitin-like modifier (SUMO) E3 ligase, which negatively mediates stomatal apertures via the SA-triggered ROS accumulation. Loss of AtSIZ1 function leads to the accumulation of endogenous SA, which enhances the production of ROS mediated by salicylhydroxamic acid (SHAM)-sensitive peroxidases and impairs stomatal aperture (Miura et al., 2013). In addition, plants growing in the ethylene precursor 1-aminocyclopropane-1-carboxylic acid display increased stomatal density. Stomatal division and development is enhanced in cucumber hypocotyls after brief treatment with ethylene. Furthermore, auxin and gibberellin modulate stomatal aperture opening and closing (Saibo et al., 2003). Compared with other molecular regulatory pathways, the molecular mechanisms underlying the action of ABA and other hormones on stomatal development have not been clearly established.

Future directions

Stomata enable plants to regulate the entry of CO_2 assimilated in photosynthesis and adjust evaporation of water. Although some underlying mechanisms and genes related to stomatal development have been studied, many complex questions related to stomatal morphogenesis and division are still largely unanswered. Future research should involve bioinformatics mining of published gene data, information analysis of transcriptomic and proteomic for deeply studying stomatal development and guard cell responses to environmental factors. In addition, very little is known about the underlying molecular basis for the changes of hormonal factors such as ABA, ethylene, auxin, and gibberellin. The mechanism and regulatory pathway controlling variation in stomatal development in response to environmental signals such as photoreceptors, temperature, and humidity is uncertain. Other problems include determining the genes and pathways involved in stomatal development, ascertaining whether the molecular mechanism of stomatal development differs between monocotyledons and dicotyledons, and understanding how

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1209112109

intercellular signaling is superimposed and orients the intrinsic polarity. Finally, how environmental signals modulate stomatal development needs to be elucidated. Many questions thus remain to be addressed. In a word, the genetic network for the regulation of stomatal development is too complex and tightly impacted by both intrinsic and external signals. The exact molecular mechanisms underlying the interactions among the various impact factors and environmental signals during stomatal development deserve further investigation.

Acknowledgments. We express our gratitude to the anonymous reviewers for helpful comments to improve the manuscript. This work was supported by the National Key R&D Program of China (Grant No. 2018YFD0300305-01) and the Open Projects Program of the Key Laboratory of Ministry of Agriculture and Ministry of Education of the People's Republic of China.

Abstract. In this study, greenhouse gas emitted during the construction stages of three residential buildings with land areas of 204 m^2, 150 m^2 and 120 m^2 in Moradabad city (8.866790 °N, 78.755921 °E) in northern India have been estimated and analyzed. Post design, the construction of a residential building involves five stages viz. design, production of building materials, mobilization of materials, building construction, and disposal of construction waste. Mathematical equations have been developed to calculate the greenhouse gas emissions in all the five stages as well as to estimate the aggregate emissions. Emissions from human-related activities like on-site cooking and water consumption have been included. The results indicate that the production of building materials is responsible for 74% of the total emissions. Steel, concrete, bricks, and cement are consumed in a large volume during the construction and have an environmental impact. Average Greenhouse Gas emissions of the three residential buildings were estimated to be about 0.784 tCO_2e/m^2. Selecting the alternative building materials with low greenhouse gas emissions and incorporating a major renewable energy source are foremost priorities for future construction projects.
Keywords: *construction stages, building materials, human activities, environment, global warming potential, carbon footprint*

Abbreviations: Greenhouse Gas: GHG, Gross Domestic Product: GDP, Global Warming Potential: GWP, Carbon Foot Print: CFP, Liquefied Petroleum Gas: LPG

Introduction

Energy systems are essential for human activities and play a crucial part in the economic growth of the nation. On the other hand, they have ecological implications, including the release of greenhouse gases (GHG) into the atmosphere resulting in the degradation of the environment. The growth of energy systems is difficult to forecast as they are governed by several dynamic factors like population growth, technological development, and socio-economic factors. In the year 2012, the worldwide CO_2 emissions due to energy use touched a remarkable high level of 31.6 Gt (Hong et al., 2015), stagnated in 2014 (32.2 Gt), in spite of about 3% economic growth of the world. It was the first of such observations in the last four decades in which stagnation in emissions was not related to the economic slowdown (International Energy Agency, 2015).

The economic development of the countries is mainly related to the development of infrastructure for which construction activities are key consumers of resources and energy. Therefore, for a sustainable society, it becomes important to engross the construction industries (Asif et al., 2007). The building construction has an effect on numerous secondary commercial activities due to the consumption of a wide range of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1211112126

materials, manufactured in diversified small and big industries (Suzuki et al., 1995). Typical building construction requires about 40% of the gravel-stone-sand, 25% wood and, 16% water per annum globally (Arena et al., 2003). The Statics times (2015), reported that the construction industry occupied 8.09% of Gross Domestic Product (GDP) in 2014 with its production amounting to 928,418 crore Indian rupees. According to Nation Master Statistic (2013), more than 33% of the global emissions and the energy consumption were due to the building construction industry in developing as well as the developed nations. This resulted in the diminution of non-renewable energy assets, obliteration of landscapes, leading to the generation of environmental issues, linked indirectly or directly to the community working in this sector. The total embodied energy involved in building construction is proportionate to the quantity of the building material consumed during the different stages of construction and to the embodied energy of materials (Dimoudi et al., 2008). Therefore, it is imperative to consider the impact on the environment and aim to mitigate the effects of building construction on it.

Reducing GHG emissions from construction industries may fetch numerous advantages to society as well as the economy. The construction, maintenance, and renovation activities contribute between 10–40% of the GDP of countries', and about 10% of employment (UNEP, 2009). The meticulous design of the buildings and proper planning of the construction activities may help in the mitigation of GHG and, at the same time, can rouse the new job opportunities in India and other developing countries. It can also help in social development by providing improved accommodations, clean water and, energy to the community. Top management and policymakers should grab the business prospects due to the environmental crisis, to take a lead in sustainable development. To adopt any mitigation policy, it is, therefore significant to estimate the GHG emissions caused due to different construction stages in developing countries such as India.

GHG emissions

The GHG such as carbon dioxide, ozone, methane, water vapor, and nitrous oxide have a tendency to captivate and release radiations in the thermal infrared range, causing the greenhouse effect, which is a primary reason for global warming.

Due to human activities, the CO_2 level in the atmosphere has increased to 400 ppm compared to 280 ppm in 1750, a rise of 40% (Blasing et al., 2014). The main reasons for the increase in anthropogenic carbon emissions are due to the use of fuels namely; oil, gas, coal, wood, etc. and rapid deforestation.

It is projected that with the current rate of increase in carbon emissions, the atmospheric temperature can rise more than historic limits within 30 years. The rise in the temperature of the earth's atmosphere will not only result in rising sea level, but it will cause severe threats to the ecological balance and survival of biodiversity across the globe (Mora et al., 2013).

Indirect and direct emissions

The present work includes both indirect and direct GHG emissions, as well as the emissions during building construction. The construction activities may not directly consume large quantum of energy but their indirect energy footprint is huge due to the consumption of materials processed through high energy-intensive processing. A few examples of high-energy intensive materials used in the construction industry are steel, bricks, aluminum, cement, glass, etc. In this study, the direct emissions during

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1211112126

construction stages refer to those due to the direct energy use at the site and the indirect emissions are due to the energy footprint and hence add to the carbon emissions of the materials used in building construction. It is expected that this study shall give a comprehensive understanding of emissions from building construction stages in northern India and help in determining the solution for the mitigation of carbon emissions in a phased manner.

Review of literature

In recent decades, varieties of studies have been carried out to analyze the carbon and energy footprints of building and construction activities. The studies carried out are different in scope and methodology. The building life cycle activities were also analyzed. Some related research findings are discussed in this section.

Onat et al. (2014) addressed the rapidly growing emission tendency in the residential buildings in the United States in an attempt to minimize the emissions. The authors concluded that promoting the construction of green buildings is insufficient to curb the emissions unless the existing buildings are retrofitted. Therefore, it becomes necessary to implement a strict green building policy, which should include the new as well as old buildings. Chou and Yeh (2015) proposed a method to augment the CO_2 emissions and their implications on the environment while assessing the life cycle of the buildings. This methodology may be useful in the valuation of major environmental risks for the life cycle of buildings and the selection of a suitable method for construction. Lin et al. (2015) studied the emissions in residential and commercial buildings in China and evaluated the energy-related economic factors. The results indicate that emissions related to energy during building construction are growing briskly and are expected to shoot further in China's eastern regions, particularly in South Asia due to significant migration of people to the urban areas from rural regions.

Akten and Akyol (2018), in their study on Izmir province in Turkey, suggested that the ecological footprint of many countries has exceeded their biocapacity. The human activities and their consumption habits have resulted in an ecological deficit, and the problem is increasing with every passing day.

Doğan (2018) in his detailed study on Eurasian regions and Turkey over a period of 13 years emphasized the connection between global warming and CO_2 concentration. He found that awareness among the population plays a major role in the success of the mitigation policies.

Yang et al. (2018) observed CO_2 concentration around China and raised questions on assumptions of uniform CO_2 level in the atmospheres.

Zheng et al. (2018) in a study on urbanization in China, recommended different policies for reducing carbon emissions for different levels of urbanization.

Marsono et al. (2015) proposed a methodology to reduce the effect of CO_2 emission for buildings as well as to improve their structural stability by encouraging the Malaysian construction industry to increase the use of wood in their building schemes. This methodology can help decision-makers to select the most flexible scheme for Malaysian housing. Lai (2015) conducted a study to explore the carbon footprints (CFP) of three typical hotels in Hong-Kong and found that electricity consumption was the main source of carbon emission. Sharma et al. (2012) assessed a three-story building in the northern region of India. They concluded that the reinforced cement concrete (RCC) framework and steel are the biggest contributors in GHG emissions. Devi and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1211112126

Palaniappan (2014) presented a life cycle analysis of energy in a residential apartment located in the southern region of India. The effect of the service life of the building and monthly electricity consumption on the energy used in construction was predicted using sensitivity analysis. Wang et al. (2015) calculated the carbon emissions from the highway construction activities namely road construction, bridge construction and making the tunnels as 5229, 35547, and 42302 $kgCO_{2e}$/m respectively. They suggested a simple mathematical model to assess the CO_2 emissions from road construction activities. A similar model to assess the emissions from the building construction will be very useful.

Li et al. (2019) assessed the GHG emission in China in different phases of building construction. Their work was focused on the CO_{2e} of building materials procured from urban, national, and global markets. Ceramics and basic construction material were obtained from the urban market, paints and chemicals were obtained from the national market, and metals and petroleum were the materials, which were derived from global sales. The contribution of urban, national, and global materials was estimated to be 68.78%, 24.41%, and 6.8% respectively.

In a study on a Norwegian office building, Moschetti et al. (2019) explored the pathways towards zero-emission buildings. To achieve their objective, they emphasized on alternative design solutions and use of solar energy and building materials with low global warming potential (GWP). The use of solar energy reduced emissions by 30%.

Buildings and construction activities are responsible for the diminution of natural resources and impact the environment and so, this sector has attracted the environmentalists for assessment of emissions and attempts to suggest methods for controlling the impact on environment and depletion of natural resources. Hossain and Thomas (2019) studied the adopted resource recovery principle to reduce waste, increase the efficiency of waste disposal and resource-efficient constructions. They suggested a few sustainable strategies for waste treatments. Some of these strategies included recycling and recovery of secondary materials like timber waste, mortar, etc.

In a study on the building life-cycle carbon emissions in China (Can et al., 2019) reported that the production of building material is a major contributor to the emissions, followed by the construction activities. The study also suggested that the variables such as GDP, income, urbanization, price and overall economy directly affect the emissions by influencing the surge in the construction industry. The effective methods to curb the emissions from building and construction activities may be focused on implementing cleaner technology during the production stages of construction materials and the building design.

Wong et al. (2019) in a study in Australia suggested that the estimation of the embodied emission due to stages of building construction shall be made a mandatory practice. The construction industry has misnomer about carbon accounting and sees it as a threat to increase its cost and efficiency. The regulations of the government to promote designs of low CFP buildings and construction activities may have an immediate positive impact on carbon emissions.

From the literature review it may be extracted that though the effect of building construction materials on the environment and CO_2 emissions have been investigated and analyzed in different regions for different sizes and utilities of the buildings, it is apparent that construction-related human activities like on-site cooking, water consumption has been ignored in the published research. Without the incorporation of human activities, the assessment and GHG emissions from the construction activities

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1211112126

and their analysis is incomplete. Human activities should be given special consideration by the researchers as they affect the GHG emission during the construction phase. Apart from the earlier research work, the present work includes the carbon emissions due to various human actions based on comprehensive process data and the case studies selected in India. The previous research has given limited attention to the buildings of the size and classification identified for the present analysis. The size and carpet areas of the buildings identified for the study are those, which are expected to develop the most in near future and so, with about one-sixth of the world population and being a fast developing country, the study made in the present manuscript is a relevant one.

Materials and methods

Methodologies

Scope of study

The study encompasses the GHG emissions during the stages of construction including several construction activities in the residential buildings, identified and closely studied from the start of construction to its completion. The inherited associated emissions from the materials, GHG emissions from the fuel burned to transport the building materials to the construction site and to transport the construction waste, emissions due to human activities, direct emissions due to electric power consumption at the site and, emissions due to the processing of water and sewage are included in the study.

System boundaries

System boundaries demonstrate the activities included in the analysis. Several aspects influence the GHG emissions of residential buildings during the construction stages. It is relevant to analyze the system boundaries to make certain that the contribution of all significant factors to the CFP is incorporated. A schematic representation of the system boundaries adopted in the present study is given in *Figure 1*.

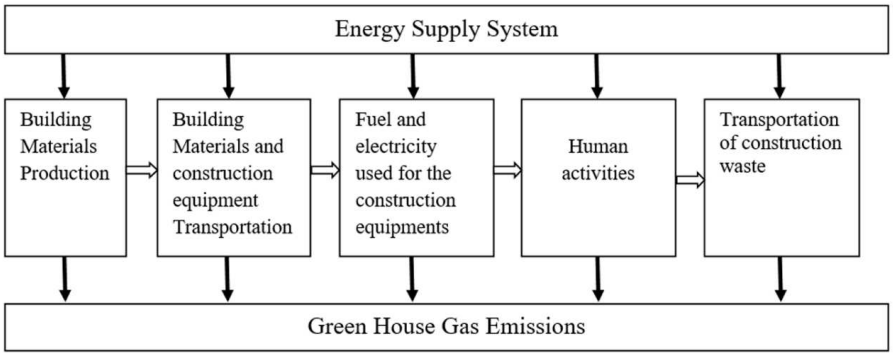

Figure 1. *The system boundary of GHG emissions in the construction of residential houses*

Quantification of GHG emissions

Greenhouse gases emissions from the production of building materials

The GHG emissions due to the consumption of the building materials can be estimated by *Equation 1*. The units of GHG emissions are tons of Carbon dioxide equivalent (tCO_{2e}).

$$GHG_1=\sum_{i=1}^{m} M_{1i} \times F_{1i} /1000 \quad \text{(Eq.1)}$$

where GHG_1 is the total GHG emissions due to the consumption of all building materials; m is the number of materials considered; M_{1i} is the quantity (tones) of the i^{th} material, and F_{1i} is emission factor of the i^{th} material in tCO_{2e}/kg.

The GHG emission factor of building materials considered in the present analysis is given in *Table 1*.

Table 1. *Building materials used in the construction of residential houses. (Data source: Kilbert, 2007; Shams et al., 2011)*

S.N.	Material	Unit	Emission factor ($kgCO_2e$/unit)	Consumption		
				Case A (204 m^2)	Case B (150 m^2)	Case C (120 m^2)

Emissions from the transportation of construction equipment and materials

GHG emissions from fuel combustion during the transportation of construction equipment and materials and (in tCO_{2e}) are calculated by *Equation 2*.

$$GHG_2 = \sum_{i=1}^{n} M_{2i} * (D_{il} * f_2 + D_{is} * f_3)/1000 \quad \text{(Eq.2)}$$

Where n represents the number of building materials and construction equipment transported to the construction site. M_{2i} is the amount of the i^{th} building material or weight of construction equipment in tones. D_{il} is the transportation distance of the i^{th} material or equipment by land (km). D_{is} is the transportation distance of i^{th} material or equipment by sea (km). f_1 and f_2 are emission factors for land and sea transportation, respectively (Yan et al., 2010). The transportation distances of different materials and equipment are obtained from Google maps.

Emissions from the construction equipment due to the consumption of fuel and electricity

Scientific research has discovered that the fuel consumed by the construction equipment viz. dozer, concrete mixture, channel, and angle type tower hoist, etc. results in the emission of different quantities of N_2O and CH_4, categorized as off-road construction (Eggleston et al., 2006). GHG emission from fuels consumptions of the construction equipment can be calculated (in tCO_{2e}) by *Equation 3*.

$$(GHG)_3 = \sum_{k=1}^{n_3} FC_k \times f_{3k} / 1000 \quad \text{(Eq.3)}$$

Where GHG_3 is the total GHG emission from fuel consumptions by different construction equipment; n_3 is the types of fuels (number) used by different construction equipment viz. diesel, LPG, gasoline, etc., FC_k is the quantity (liters) of the k^{th} fuel used by the construction equipment; F_{3k} is the emission factor of the k^{th} fuel ($kgCO_2$ e/L).

The emission factor of the k^{th} fuel is calculated by *Equation 4*.

$$F_{3k} = F_{CO2} + F_{CH4} \text{ x } GWP_{CH4} + F_{N2O} \text{ x } GWP_{N2O} \quad \text{(Eq.4)}$$

Where F_{CO2}, F_{CH4}, and F_{N2O} is the emission factor of CO_2, CH_4, and N_2O, respectively for fuel 'k'. GWP_{CH4} and GWP_{N2O} are the global warming potentials of CH_4 and N_2O, respectively. In India, the on-site construction equipment is either run on diesel or by electricity, so the emission factor and GWP of diesel are given in *Table 2* (Yan et al., 2010).

Table 2. *Emission factor and GWP of diesel fuel*

Gases	Emission factor ($kgCO_2e/kg$)	GWP
CO_2	2.6140	1
CH_4	0.0239	21
N_2O	0.0074	310

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1211112126

GHG Emissions from electrical energy use for construction equipment like; vibratory plate compactor, sand screening machine, etc., can be calculated by *Equation 5*.

$$GHG_4 = E * f_5 / 1000 \quad \text{(Eq.5)}$$

Where GHG_4 is the total emission of GHG (tCO_{2e}) due to the electricity consumed by the construction equipment, E is the amount of electric power consumed by the construction equipment during the construction period in kWh. The electricity was supplied by the state electricity board. f_5 is the emission factor for electricity in India. Its default value is 0.93 kg/kWh. *Table 3* shows the emission factor of electricity in India from 2008 to 2012 (tCO_{2e}/MWh) (User Guide Version 8.0, 2013).

Table 3. *The emission factor of electricity in India from 2008 to 2012*

Grid	2012	2011	2010	2009	2008
Southern grid	0.91	0.84	0.85	0.9	0.85
North Eastern grid	0.94	0.91	0.9	0.84	0.8
Pan India	0.93	0.9	0.88	0.85	0.81

GHG emissions from human activities

GHG emissions from human activities include electricity use for processing fresh water and sewage and, consumption of liquefied petroleum gas (LPG) for on-site cooking. Following equations are used to calculate the GHG emissions by these two human activities.

$$GHG_6 = W_W * f_6 / 1000 \quad \text{(Eq.6)}$$

$$GHG_7 = W_G * f_7 / 1000 \quad \text{(Eq.7)}$$

Where GHG_6 represent the emissions (tCO_{2e}) due to the consumption of electric power for processing the fresh and sewage water. W_W is the quantity of the water used (m^3), f_6 is the emission factor of electricity used in handing out fresh and sewage water ($kgCO_{2e}/m^3$). GHG_7 is the GHG emission due to LPG used for on-site cooking (tCO_{2e}), W_G is the quantity of LPG used (m^3) and, f_7 is the emission factor for LPG ($kgCO_{2e}/m^3$).

Emissions from the transportation of construction waste

The emissions from combustion of fuel consumed by vehicles used for disposal of construction waste can be estimated by *Equation 8*.

$$GHG_8 = W_S * D*f_8 / 1000 \quad \text{(Eq.8)}$$

Where W_S is the amount of construction waste (tones), D is the distance traveled by disposal vehicles for transporting the waste to dumpsite (km), and f_8 is the emission factor of the fuel (diesel) used in transportation vehicles ($kgCO_{2e}$/ton-km). The emission factor for diesel is 3.17 $kgCO_{2e}$/kg (Hong et al., 2015).

DOI: http://dx.doi.org/10.15666/aeer/1705_1211112126

Estimation of total emissions

The aggregate emissions during different construction phases of the residential buildings can be calculated by *Equation 9*.

$$GHG_{Total} = \sum_{k=1}^{8} CHG\,\kappa \quad \text{(Eq.9)}$$

Case studies of residential buildings

The present research work has been carried out on real construction projects: three residential houses located in Moradabad district of Uttar Pradesh, India. The land areas are 120 m^2, 150 $m^{2,}$ and 204 m^2. *Figure 2* represents the layout and floor plan of the residential houses. The residential buildings under study represent typical middle-class society with independent houses or floors, common in non-metropolitan cities in India like Moradabad.

The description of three residential houses is presented in *Table 4* and the materials used for construction are presented in *Table 1*. The materials include those used in foundation, civil structure, finishing, landscape architecture, and engineering materials.

Figure 2. *Floor plan of the three residential buildings with area and GPS coordinates (given in brackets); (a) 204 m^2 (28.865838°N, 78.753071°E); (b) 150 m^2 (28.866891°N, 78.750128°E) and; (c) 120 m^2 (28.869725°N, 78.752629°E)*

Table 4. *Description of three residential houses under study*

Building	Land area m^2	Number of floors	Covered area (ground floor)	Covered area (first floor)	Construction period	Height of ceiling	Structure	Concrete strength
Case A	204	02	144.5	110.5	25 months and 12 days	3.35 m	Reinforced concrete	22 MPa
Case B	150	02	108.2	82.8	22 months and 15 days	3.35 m	Reinforced concrete	22 MPa
Case C	120	02	86.4	66.4	21 months and 22 days	3.35 m	Reinforced concrete	22 MPa

Results and discussion

The GHG emissions during the construction of each house have been calculated using *Equations 1–8* by substituting the value of appropriate emission factor and the average emission percent due to the factors included in the study is represented in *Figure 3*.

From *Figure 3* we can see that the production of building materials account for 74% of the aggregate GHG emissions, 12% of the aggregate emissions are from transportation of building material and construction equipment, 10% from fuel and electricity used for construction equipment, 2% from human activities, and 2% are from transportation of construction waste. It is observed that besides the massive emission contribution of the productions of building material and their transportation, human activities also contribute 2% of overall emissions during the construction of the residential building. This requires adequate attention of the researchers. The average GHG emission of the three residential buildings was estimated to be around 0.784 tCO_{2e}/m^2.

Figure 4 indicates GHG emissions from primary building materials. It can be seen that GHG emissions from steel, cement, bricks, and concrete mixture were 0.54 tCO_{2e}/m^2 for residential buildings and account for about 68.87% of the total emissions.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1211112126

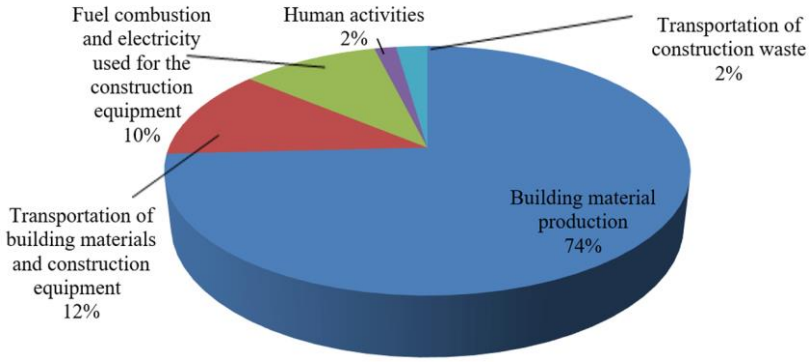

Figure 3. *Distribution of average of the aggregate GHG emissions, in three houses*

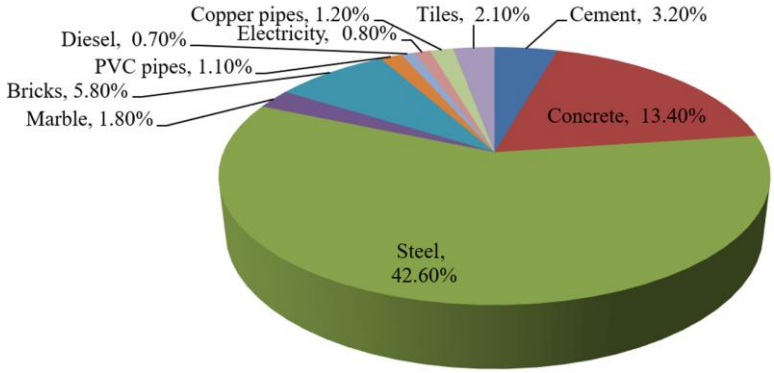

Figure 4. *GHG emissions of primary building materials*

The GHG emissions from steel and cement, the most important construction materials, was approximately 0.349 tCO_{2e}/m^2 and 0.025 tCO_{2e}/m^2 respectively. Other materials like PVC pipes, copper pipes, tiles, marble, diesel, aluminum, plywood, mosaic, etc. have a relatively small contribution.

The consumption of electricity, water and fuel (diesel) in the three residential building are given in *Table 5* month wise. The blank column indicates no consumption due to the completion of construction of the building. The GHG emissions due to the consumption of electricity, water and fuel during the construction stages were estimated from this data.

In the Moradabad district of northern India, nearly 3000 residential houses were constructed in the year 2012-13, with a covered area of approximately 390,000 m^2 (discussion with the town planner, 2013), at this pace of construction of new residential buildings, it is estimated that total GHG emissions may be about 305,760 tCO_{2e} annually.

In order to reduce the emissions due to the construction activities, the recycled building materials along with the environmentally friendly construction practices are recommended to minimize the harm to the environment. Prefabricated building materials and components should be preferred to recover the environmental losses due to GHG emissions. Published research shows that adoption of prefabrication technology during the construction stage add appreciably in the sustainable development of the construction sector (Hong et al., 2015; Aye et al., 2012; Mao et al., 2013; Pons et al.,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1211112126

2011). The comparative values of GHG emissions estimated using *Equations 1–9* are given in *Table 6*. Based on the analysis of results, the major contributors to GHG emissions have been selected. The consumption of materials is directly related to the emissions and the covered area.

Comparative and critical discussion

Based on the study and in correlation with the published research on GHG emissions in different parts of the world, it is deduced that the building construction activities need restructuring to consider the impact of the construction activities and building materials on the environment. It is recommended that the management, contractors, labor and, other stakeholders ought to refer the following guidelines to lower the GHG emissions during the construction stage of buildings.

1. Choose construction sites having low ecological and agricultural significance without any interference with biodiversity.
2. Every construction project should set goals to minimize GHG emissions and watch the performance. GHG emissions should be an important consideration in the design process.
3. Include materials that are more competent and less harmful to the environment.
4. Incorporate features like green roofs and walls and use local species in plantation and landscaping.
5. Saving energy at every stage of the construction process should be a top priority.
6. Poor management and tardy design modifications are the main contributors to waste. Therefore, avoid late modifications to design and intend all work from the commencement of the construction process in order to minimize waste.
7. Strike down over-ordering and facilitate the recycling of waste. Prefer way outs that produce a lesser amount of waste and design material goods that can be dismantled and reused.
8. Make use of materials that can be recycled. Use minimum packing to shield the product. Prefer reuses and avoid landfill.
9. Put the target to minimize water consumption and evaluate progress throughout the construction phase. Use machines and equipment that save water, inspire everyone to detect and report water leaks, and fix them at the earliest possible.
10. Proper project management with time-activity scheduling, deriving benefits from weather and climate, minimize curing and encourage use to solar energy and daylight.

Conclusions

Three residential buildings were identified in Moradabad region of northern India and their construction stages were carefully monitored over a period of two years from 2010-11 to 2012-13 until the buildings were completed. The authors 1, 3 and 4, owned the three buildings, identified as the research subject and so the research and results are 100% authentic and established. The consumption of the construction material, fuel and, electric power was maintained on a day-to-day basis. The equations used to estimate the GHG emissions at a different stage of construction and the aggregate emissions under the framework of the study were developed by the authors. The main deductions from the study highlight that the emissions from building material production account for 74% of the aggregate emissions. Among the construction materials steel, bricks, cement and, concrete together account for about 66% of the aggregate emissions. On-site human activities during the construction phases, which is yet to be published in the research domain, also contribute to the GHG emissions. The deductions of this study are beneficial for the sustainable design and construction management of the residential

DOI: http://dx.doi.org/10.15666/aeer/1705_1211112126

buildings in India and may be used as a reference for developing the strategy and policy to minimize GHG emissions in the building construction industry in any part of the world. The authors are presently working on the life cycle assessment of GHG emissions of the residential buildings taken as research subjects in this study. A life cycle approach is aimed to be developed to investigate the GHG consequences of orthodox as well as low energy forms of residential building construction in India. The authors also aim at extending their work in estimating the life cycle carbon emissions of the residential buildings and further extending the scope of the study to the Kingdom of Saudi Arabia.

Acknowledgments. Authors thankfully acknowledge the funding and support provided by Scientific Research Deanship, King Khalid University, Abha-Asir, Kingdom of Saudi Arabia, with project grant number G.R.P-260-39 to complete the research work.

(Received 28th Apr 2019; accepted 12th Jul 2019)

Abstract. This paper aims to study the effects of lead concentration in irrigation water on the yield and growth traits of rice under soil zeolite stress, with the addition of lead accumulation in rice plants, which were tested in a micro zone at the Experimental Base of Water Conservancy in Shenyang Agricultural University of Liaoning Province, China, through the application of different amounts of zeolite (0, 2500, 5000kg·ha^{-1}) and different lead concentrations (0, 0.25, 0.2, 0.15 mg·L^{-1}) in irrigation water. It was concluded that the lead contents in paddy root, stem, leaf and rice significantly varied with different exogenous lead concentrations. With the increase of the concentration, the lead contents in each part were significantly increased. More importantly, the effect on aboveground material weight was greater than that on underground material weight. The water contents of rice were increased with the decrease in the protein content, and starch content was decreased under zeolite stress. When the concentration of lead increased, the effect was more pronounced. Comprehensive test with various factors indicated that the incorporation of zeolite in soil for rice cultivation with lead-contaminated water irrigation or lead contaminated soil could restrain the movement of lead ions into the rice.
Keywords: *zeolite, lead, quality of rice, enrichment ability, interaction*

Introduction

In recent years, the use of one of China's shortage resources-agricultural irrigation water-has seen an increasing trend concerning industries and urban environments due to the acceleration of industrialization and urbanization, and the rapid development of technology, economy, civilization and people's quality of life. Therefore, the condition of agricultural water is getting worse. To make matters worse, irrigation with contaminated water is becoming one of the major methods to deal with the deficiency of water. In such cases, researches about the effects of recycling water irrigation on the yield and quality of agricultural products attract more attention recently (Galvis et al., 2018; Becerra, 2015). Lead is one of the most toxic elements among all known metal contaminations causing fertility deterioration, reproductive organ tumors, decreased immunity as well as physical anomalies (Zhao et al., 2015) of various organisms including humans. The increased lead level in children's body would damage the brain and nervous system, destroying cerebral cortical cells, which results in mental decline and impaired attention (Zhang et al., 2014). The Pb^{2+} in contaminated water will enter soil, get absorbed by root system and accumulate in plants. Once the concentration of Pb^{2+} exceeds a certain level, plants will be poisoned, and eventually Pb^{2+} will enter human bodies through the food chain to damage our health (Chen et al., 2018; Abrahams, 2002; Luo, 2012). It was revealed that lead would accumulate in rice plants to inhibit their growth, and to degrade their yield and quality (Ashraf et al., 2015; Chen et al., 2010). In China, paddy rice is one of the staple food crops for food supply (Khush, 2013; Huang, 2011). Therefore, it is of key

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1212712137

importance to study how to reduce the absorption and accumulation of lead in paddy rice.

In recent years, many scholars have been focusing on heavy metal contaminated soil treatment with soil conditioner, such as commonly used lime, phosphate, compost, blast furnace slag, molysite, silicate, and zeolite (Gray, 2006; Theodoratos, 2002; Qian, 2009). As a common adsorbent, zeolite can not only improve soil condition, but also purify waste water by removing of heavy metal (Merrikhpour et al., 2013; Shi et al., 2009). Zeolite has porous aluminosilicate mineral, its unique three-dimensional space frame structure makes it have a huge specific surface area, ion has a great adsorption capacity and adsorption exchange capacity, is considered as an economic and efficient heavy metal pollution remediation material, the lead in wastewater has adsorption effect. In addition, some scholars believe that the passivation of zeolite is due to the strong adsorption of heavy metal through its silicon oxygen and aluminum oxygen tetrahedron structure. Zeolite has a certain passivation effect on heavy metal lead in soil, which can effectively inhibit the migration and ecological effectiveness of soil lead (Zhou et al., 2014a). Natural zeolite, as an inorganic soil conditioner, has been widely used to improve the growth and yield of upland crops due to its high cation exchange capacity and intensive affinity for nutrients and water (Malekian et al., 2011; Aghaalikhani et al., 2012; Hazrati, 2017). On top of that, zeolite can also passivate lead in soil to inhibit lead migration and ecological availability in soil (Altaf et al., 2019). Several studies have been conducted for joint use of various soil conditioners (Zhou et al., 2014b, 2017; Wu al., 2016; Yang et al., 2016) for lead-contaminated soil. However, most of these studies are performed in pot experiments with only a few in regional experiments. At the same time, most studies focused on the influence of composite conditioners on soil contamination or improvement of wastewater through zeolite, while researches on rice yield, lead concentration and growth traits of paddy plant affected by zeolite and lead-containing water were rare. Therefore, this paper aims to analyze effects of exogenous lead on the yield of rice under soil zeolite stress, lead accumulation in rice plant, and growth traits through paddy rice planting in small regions to provide a reference for finding ways to reduce lead contamination in paddy rice.

Materials and methods

Material for experiment

This study used a local, mid-late season rice (Oryza sativa L.) cultivar, Shennong 9816, bred by the Rice Research Institute of Shenyang Agricultural University and characterized by high yield, good quality, and strong disease resistance, with brown earth soil for the base. All physicochemical indices are as follows: pH value 7.41; organic substance contents 20.48 $g \cdot kg^{-1}$; total nitrogen contents 1.3 $g \cdot kg^{-1}$, rapidly available phosphorus 20.69 $mg \cdot kg^{-1}$; rapidly available potassium 50.11 $mg \cdot kg^{-1}$. Applied regular fertilizers are as follows: potassium sulfate 100 $kg \cdot ha^{-1}$; carbamide 300 $kg \cdot ha^{-1}$; monocalcium phosphate 200 $kg \cdot ha^{-1}$. The irrigation water is from the comprehensive experiment base of College of Water Resource. As verified through inspection, the irrigation water met potable water standards, with lead concentrations $< 0.06\ \mu g \cdot L^{-1}$.

Methods

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1212712137

The experiment was carried out in non-weighing lysimeters at the College of Water Resource of Shenyang Agricultural University of Liaoning Province, China (42°08′57″ N, 120°30′45″ E, 47 m altitude), during one rice-growing seasons (May to October in 2018). The study area has a temperate continental monsoon climate with 7.5 °C average annual air temperature. Average annual rainfall is 672.9 mm, with the main rainy season from June to September. The regional area for experiment (3.5 m long × 1.2m wide × 0.3m deep) were constructed from concrete blocks and sealed with waterproof paint to prevent seepage between plots. In order to prevent irrigation water in the micro zone from being diluted by rain and thus affecting the test results, transparent awnings were set up, covered by rainy days, and all opened on sunny days, and the planting rate between rice plants was 20 × 25 cm. The experiment has two factors (lead and zeolite) with four levels of lead concentration and three zeolite application rates. There were nine treatment methods as shown in *Table 1*. Each treatment was repeated 3 times. Zeolite was applied all at once during soil harrowing before fertilization and transplantation of paddy plant. During the growth delaying period, all of the nine treatment the areas were irrigated with water from the experiment base, and since seedling establishment period, the areas were irrigated with water of different lead concentrations. The CK area was irrigated with clean water.

Table 1. *Factors and levels of the experiment*

Treatment	**CK**	**I**	**III**	**IV**	**V**
W_0/kg·ha^{-1}	0	2 500	2 500	2 500	2 500
Pb/mg·L^{-1}	0	0	0.15	0.2	0.25
Treatment	**CK**	**II**	**VI**	**VII**	**VIII**
W_0/kg·ha^{-1}	0	5 000	5 000	5 000	5 000
Pb/mg·L^{-1}	0	0	0.15	0.2	0.25

The sampling procedure consisted of randomly taking 5 plants for each treatment during the maturity period of the paddy rice. A soil auger was used to obtain 0.5-1 kg of soil at a depth of 0-20 cm. The roots were carefully rinsed from the soil with a hydropneumatic device and detached from their nodal bases. For the growth traits measurements, the height of the sample plants, the tiller number and the biomass of the substances above ground and below ground were all taken. The samples were then treated as follows. The soil samples were dried naturally in the shade, ground and screened with a 100 mesh screen. The plants were oven-dried, crushed with a plant pulverizer, ground into powder via a mortar, and screened with a 100 mesh screen.

Using a GB5009.12-2017 A pressure dissolution vessel was used to treat samples via the digestion method, and an atomic absorption spectrophotometer (HITACHI Z-2000) (*Fig. 1*) was used to determine the lead content via the flame method. The FOSS (*Fig. 2*) was utilized to determine rice qualities, such as water content, protein, and amylase.

Data processing

The analysis software SPSS19.0 was used for one-way ANOVA. Notable comparison of data was made by using Duncan inspecting method ($P < 0.05$). Software Design-Expert 8.0 was used to calculate the optimum point.

Results and analysis

Lead accumulation in soil and paddy plant under soil zeolite stress

Table 2 shows the lead contents of the root, stem, leaf and rice unit masses at treatment I was 1.27, 0.87, 0.96 and 0.91 times that of the CK group respectively. The Pb content per unit mass of soil increases from treatment III to treatment V, however, no obvious difference was observed. The maximum value of Pb content in soil at treatment V was 2.06 times that of treatment I ($P < 0.05$). The Pb content per unit mass of root first rose and then dropped, and difference among various treatment methods was obvious. The maximum value of Pb content in roots at treatment IV was 2.13 times that of treatment I ($P < 0.05$). The values of Pb content per unit mass of stems, leaves and rice increases, and values of treatment V were 146%, 159% and 146% ($P < 0.05$) that of treatment I, respectively. The Pb content per unit mass of roots, stems, leaves and rice under treatment II were 1.48, 0.84, 0.81 and 0.81 times that of CK group. The Pb content per unit mass of soil increased from treatment VI to treatment VIII, but the difference seemed to be non-significant. The maximum value of Pb content in soil at treatment VIII was 1.83 times that of treatment II ($P < 0.05$). The Pb content per unit mass of roots first rose and then dropped, and the difference among various treatment was significant. The maximum value of Pb content in roots at treatment VII was 1.93 times that of treatment II ($P < 0.05$). The values of Pb content per unit mass of stem, leaf and rice increased and the values of treatment VIII were 142%, 169% and 139%

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1212712137

that of treatment II ($P < 0.05$). With 0.15 $mg \cdot L^{-1}$ extraneous lead concentration, the Pb content per unit mass of roots under 5000 $kg \cdot ha^{-1}$ zeolite application is 18.39% higher than that of 2500 $kg \cdot ha^{-1}$ zeolite application, while the Pb content per unit mass of stem, leaf and rice was lower by 18.10%, 24% and 10.84% respectively. Treated with 0.20 $mg \cdot L^{-1}$ extraneous lead concentration, the Pb content per unit mass of roots increased by 5.01%, while the Pb content per unit mass of stem, leaf and rice declined by 14.63%, 13.27% and 11.70% respectively. Treated with 0.25 $mg \cdot L^{-1}$ extraneous lead concentration, the Pb content per unit mass of roots rose by 2.38%, while the Pb content per unit mass of stem, leaf and rice declined by 5.29%, 9.77% and 15.87%, respectively.

Table 2. *Effects of exogenous Pb on Pb contents of rice seedlings under zeolite stress ($mg \cdot kg^{-1}$)*

Different lowercase indicates significant differences ($P < 0.05$) among treatments

Effects of exogenous Pb on biomass of rice seedlings

The biomass of rice at maturation period is given in *Table 3*. *Table 3* shows the biomass of root, shoot and whole plant in treatment I was higher than that of the CK group by 45.08%, 8.58% and 11.48% respectively. The biomass of root, shoot and whole plant in treatment III was 0.71, 1.16 and 1.10 times that of treatment I. According to the coefficients, the biomass of each part of the plants first rose and then dropped with the increase of exogenous Pb concentration. The biomass of root in treatment IV was 8.65% less than that of treatment I, while the biomass of shoot and whole plant in treatment IV was more than that of treatment I by 4.22% and 4.08%, but all values were still higher than CK group. The difference between treatment IV and treatment V was significant. In addition, the height of rice was positively correlated with the dry weight of the whole plant with a correlation coefficient of 0.359 ($P < 0.05$).

The biomass of root, shoot and whole plant in treatment II was higher than that of the CK group by 63.04%, 2.47% and 14.01% respectively. The biomass of root, shoot and whole plant in treatment VI was 0.93, 1.27 and 1.17 times that of treatment II. According to the coefficients, the biomass of each parts of the plant first rose and then dropped with the increase of exogenous Pb concentration. The biomass of root and whole plant in treatment VII was less than that of treatment II by 34.85% and 5.34% respectively, while the biomass of shoot in under treatment VII was 5.59% more than that of treatment II, but the values were still higher than that of the CK group. There was an obvious difference between treatment VII and VIII. There was positive correlation between the tiller number and dry weight of whole plant with the correlation coefficient at 0.491 ($P < 0.05$). At an extraneous lead concentration of 0.15 $kg \cdot L^{-1}$, the

The coefficient = total biological yield in all treatments/total biological yield in CK group

Zeolite was applied to paddy soil irrigated with lead wastewater. The effects of different zeolite application rates on rice yield are shown in *Table 4*. *Table 4* shows when the application amount of zeolite was 2500 kg·ha^{-1}, the 0 kg·ha^{-1} group without zeolite was used as the control group. The irrigation with different concentrations of lead water increased the yield of clean water by 5.9%, while the other treatments decreased by 3.77%, 8.7% and 17.6%, respectively. When the amount of zeolite was 5000 kg·ha^{-1}, the rice yield showed an upward trend compared with that of 0 kg·ha^{-1}. The rice yield was 8.84%, 11.20%, 16.84% and 8.50% higher than that of the control group under different concentrations of lead-containing water irrigation, and the difference reached a significant level ($p < 0.05$).

Table 4. *Effects of different lead concentrations of irrigation water and different amount of zeolite application on rice yield (g·area^{-1})*

Concentration of irrigation water/mg·L^{-1}	Application amount of zeolite/kg·ha^{-1}		
	0	2500	5000
CK	2058.84 + 105.09ab	2180.88 + 50.64a	2240.88 + 50.64d
0.25	2010.48 + 121.08ab	1655.08 + 44.62a	2235.56 + 50.99b
0.2	2396.04 + 339.83a	2187.84 + 24.9a	2799.68 + 59.51a
0.15	2273.48 + 12.143b	2113.16 + 53.15b	2467.92 + 48.52c

The coefficient = total biological yield in all treatments/total biological yield in CK group

When the concentration of lead water was 0.15, the production of 0 kg·ha^{-1} increased by 10.43%, that of 2500 kg·ha^{-1} increased by 0.1%, and that of 5000 kg·ha^{-1} increased by 10.13% with the addition of different zeolite. When the lead concentration was 0.2 mg·L^{-1}, the 0 kg·ha^{-1} yield increased by 16.38% with different zeolite addition. The yield of 5000 kg·ha^{-1} increased by 24.94% and 14.08% respectively. When the concentration of lead water is 0.25 mg·L^{-1}, the 0 kg·ha^{-1} yield decreases by 2.35% with different zeolite addition. The yield of 5000 kg·ha^{-1} decreased by 0.24% and 24.11% respectively.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1212712137

The results showed that when the amount of zeolite in soil was 2500 $kg \cdot ha^{-1}$, it had an inhibitory effect on rice yield, while when the amount of zeolite was increased to 5000 $kg \cdot ha^{-1}$, it had an promoting effect on rice yield, and in irrigation water with different lead concentrations, the effect of zeolite on rice yield was different, and it played an promoting role in CK.

Effects of different treatment on nutritional quality of rice

The water content in rice irrigated by lead water fluctuated under soil zeolite stress. *Table 5* shows the water contents of rice at treatment I were higher than that of the CK group. The water contents of rice from treatment III to treatment V were obviously higher than that of treatment I, which indicated that the effect of exogenous Pb on water content were not significant under soil zeolite stress. In this experiment, the protein content in rice irrigated by lead water fluctuated under soil zeolite stress. When irrigated with water of the same lead concentration, the protein content of rice treated with treatment VI-VIII was lower than that of treatment III-V, but higher than the CK group irrigated by clean water. It indicated that exogenous Pb under soil zeolite stress had negative effects on the protein content in rice at different extents. The amylase content in rice fluctuated in a non-significant range. The rice under treatment VIII had the lowest amylon content at 15.6%, which was lower than the CK group by 6.02%. Therefore, the effect seemed significant ($P < 0.05$). The water and amylase contents of rice in different treatment satisfied the green rice standard (water content $\leq$ 15.5%, amylase content = 13.0% $\sim$ 20.0%).

Table 6 shows the regression equation is based on effect of interaction of zeolite and lead on protein content in rice. It is shown that the effect of interaction of zeolite and lead on protein content in rice is significant, especially the effect of A^2B and AB^2 on the results is quite influential based on the F values, which represents the concentration of zeolite and lead. The effect of lead concentration on protein content is stronger than zeolite amount.

The taste of rice mainly depends on amylase, protein water contents as well as fatty acid value. The taste is in inversely proportional to the amylase and protein contents but proportional to water content. Calculated using software Design-Expert 8.0, the optimum combination is as follows: zeolite 5000 $kg \cdot ha^{-1}$, lead concentration in water 0.19 $mg \cdot L^{-1}$. Under such optimum condition, the predicted protein content is 6.96%, water content is 11.07% and amylase content is 16.29%, which all meet the green rice standard.

Table 5. *The notability analysis after different treatments*

Discussion

Over the recent years, several heavy metal pollution accidents have occurred, threatening lives and health. Much research on heavy metal pollution has been carried out, with some progress achieved. It has been discovered that biochar itself has a high pH value, thus the addition of 5% biochar in soil can enhance its pH value. With the addition of biochar, the effectiveness of Pb and Cd can be reduced, and the state conversion of Pb and Cd can thus be stabilized. The addition of biochar can also improve the physical and chemical properties of soil affected by combined pollution. Moreover, it can effectively adsorb heavy metal ions, therefore promoting the adsorption of Pb and Cd in soil and reducing the biological effectiveness of Pb and Cd (Gao et al., 2016). Under certain conditions, heavy metals in the adsorption and precipitation states were able to be exchanged between soil solutions, thus reducing the pH value and promoting the release of heavy metals in the adsorption state into the soil. In such cases, the absorption of heavy metals by plants will increase. In the current study, the application of zeolite in paddy plant soil irrigated with water of different lead concentrations was demonstrated to inhibit the migration of Pb to paddy plants, thus improving the quality of paddy plants. The effect of the zeolite application in soil on pH values is worth further research.

Several studies have reported that zeolite mixed with urea increased rice grain yields in flooded paddy fields (Kavoosi, 2007; Gevrek et al., 2009; Sepaskhah and Barzegar, 2010), the results are consistent with the experimental results. However, Research on the effect of lead on the growth of toona ciliata indicated that the total biomass of the whole toona ciliata plant decreases significantly with the increase of the Pb stress gradient, while the biomass of the plant organs (withered leaves, leafstalk) increased with the increase of the Pb stress gradient. This differs from the results of the effects on paddy rice biomass in this study. The soil condition was also an important factor found to affect the growth of toona ciliata and Pb absorption and accumulation. With the same Pb stress gradient, alkaline purple calcium soil had an impact on the Pb effectiveness, and was able to reduce the toxic effect of Pb on toona ciliate (Hu et al., 2012). The study demonstrated that when exogenous Pb entered the soil, the original forms of Pb in the soil clearly changed, revealing that exogenous Pb is maintained in a dynamic conversion process. The application of soil conditioner reduced the content of Pb in an effective state and inhibited the migration of Pb in the soil-plant system. It benefited safe production of plants (Chen et al., 2008). The study of Zhao et al. (2012) suggested that a single treatment with low concentrations of Cd and Pb can promote the growth of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1212712137

pilea cadierei, but inhibit its growth when the concentration exceeds a certain level. Under a combined treatment with various concentrations, the inhibiting effect on the growth of pilea cadierei was strengthened with the increase of metal concentrations. The Cd and Pb absorbing capacities of the leaf, stalk and root of pilea cadierei demonstrated strong significant positive correlations, with the accumulation in the root being the most influential. Under a combined treatment, the heavy metal accumulation in each part of the plant rose. Total migration of Cd and Pb in the above ground part of pilea cadierei was large. In particular, under Cd-Pb combined treatment, the total migration of Pb in the above ground part was much more than that under a single treatment with the same concentration of Pb. Therefore when the soil is polluted by heavy metals, ornamental plants can be planted to absorb the heavy metal, thus promoting ecological restoration.

Conclusions

(1) *Table 2* shows that most of the lead remains in soil and rice roots, and only a small amount migrates to aboveground plants. The unit content of lead in each part of the paddy plant was affected on different levels. The application of zeolite can reduce above ground plant absorption of Pb, inhibit the migration of Pb into rice and optimize the quality of rice. The effect of zeolite application in soil on pH value is worth further studying.

(2) *Tables 3* and *4* show that shows that for lead water irrigation under soil zeolite stress, the paddy rice plant height, and the above, below ground dry weight and yield all increased significantly. The effect of zeolite was influenced by Pb concentration in the irrigation water. Higher Pb concentrations resulted in a higher inhibition effect.

(3) *Table 5* shows that the water content in rice increased and the protein content decreased with the increase of zeolite addition. Thus, the application of zeolite has a negative effect on protein content. The starch content decreased with the increase of zeolite addition. Under different treatments, both water content and amylose content in the rice satisfy the green rice standard (water content $\leq$ 15.5%; amylose content 13.0-20.0%).

Abstract. A novel nitrogen-doped fluorescent carbon dots was successfully prepared via a simple one-step hydrothermal method using the medicinal plant *Pinellia ternata* as an environment-friendly carbon-containing precursor for the first time and ethylenediamine as nitrogen source. The diameter, morphology, ultimate composition and optical performance of the prepared *Pinellia ternata* nitrogen-doped carbon quantum dots (N-CQDs) were characterized by a series of analytical characterization techniques. The photostability was also investigated through the conditions of ionic strength, pH, and storage time. The obtained results showed that the particle size distribution of *Pinellia ternata*-based N-CQDs was uniform with the fluorescence quantum yield as high as 21.3%, and it also exhibited good excitation dependence and excellent light stability. Based on the fluorescence quenching mechanism of fluorescent inner filter effect, it has high sensitivity, selectivity and anti-interference ability for chromium (VI). Under optimal working conditions, the nanoprobe showed a good and sensitive linear response (R^2 = 0.9955) toward chromium (VI) within the concentration range of 0~200 μM with a low detection limit of 15 nM. This method has been successfully applied to the detection of chromium (VI) in environmental water samples, providing a new idea for the development of green natural compound carbon materials.

Keywords: *N-CQDs, fluorescence quecnching mechanism, fluorescent nanoprobe, Cr(VI), environmental samples*

Introduction

Chromium is a steel-gray metal. There is no free state chromium in nature. Chromium (II) is a strong reductant, which is extremely unstable and can be rapidly oxidized to chromium (III) (Abdolmohammad-Zadeh and Sadeghi, 2012; Barrera-Díaz et al., 2012). Therefore, it mainly exists in two forms: chromium (III) and chromium (VI). In addition, as one of the most important micronutrient elements in human body, chromium is an important blood sugar regulator and also one of the components of proteolytic enzymes (Bauer et al., 2013; Broadhurst et al., 2006; Sedman et al., 2006). It plays an important role in the metabolism of glucose and lipid and protein synthesis. The toxicity of chromium was related to its valence (Cosata and Klein, 2006; Gagneten and Imhof, 2009). As a component of glucose tolerance factor, activator of some metabolic enzymes and stabilizer of nucleic acid (Ahmad et al., 2011; Costa, 1997; Kim et al., 2015), chromium (III) could promote insulin to play a role, maintain normal glucose metabolism, promote the production of cholesterol and fatty acids and promote hematopoietic function (Vallejos et al., 2012). Chromium (III) deficiency in human

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1213912153

body could cause diabetes, coronary atherosclerosis and cardiovascular diseases. The toxicity of chromium (VI) was about 100 times higher than that of chromium (III) (Wang et al., 2017). It was also one of the most susceptible metals to allergy. It was second only to nickel, and more easily absorbed and accumulated by human body, causing a series of pathological changes, such as chromium rhinopathy, and even inducing cancer (Ma et al., 2018; Kong et al., 2017; Yuhua et al., 2018). The International Agency for Research on Cancer (IARC) had rated chromium (VI) as a class I carcinogen (Ohira et al., 2015). Therefore, the monitoring of chromium (VI) had attracted the attention of environmental health workers.

Fluorescent carbon quantum dots (CQDs) had been widely used in various research fields due to their advantages of simple preparation, good chemical stability, easy functionalization, good biocompatibility, low toxicity and special optical properties (Wang and Zhou, 2014; Zhang et al., 2014; Zheng et al., 2015; Carrasco et al., 2016). In recent years, many carbon materials had been used to prepare fluorescent carbon quantum dots (Baker and Baker, 2010; Li et al., 2018; Huang et al., 2015). The synthesis of nitrogen-doped carbon quantum dots with excellent optical properties using green natural carbohydrates as precursors had become one of the most popular research topics (Gong et al., 2017; Wang et al., 2018; Gao et al, 2018).

Pinellia ternata is a kind of nourishing medicinal plant. Its raw materials were cheap and easy to obtain. It could be produced on a large scale. Its main bioactive substances included coumarin, alkaloids, amino acids and polysaccharides. *Pinellia ternata* was rich in carbon, nitrogen and oxygen elements. It was one of the ideal carbon materials for preparing carbon quantum dots (Teixeira da Silva et al., 2017; Ng et al., 2012; Zheng et al., 2015).

In this paper, *Pinellia ternata*-based nitrogen-doped fluorescent carbon quantum dots (*Pinellia ternata* N-CQDs) with blue fluorescence were prepared by a simple hydrothermal method using *Pinellia ternata* as precursor and ethylenediamine. The fluorescence quantum yield of *Pinellia ternata*-based N-CQDs was about 21.3%, which had excellent excitation wavelength dependence and optical stability. Based on the fluorescence quenching mechanism (Gunnlaugsson et al., 2005; Alizadeh et al., 2016; Algar and Krull, 2008; Zhang et al., 2017; Wang et al., 2010), a novel fluorescent probe had been developed for the sensitivity and selectivity detection of chromium (VI). This method could be successfully applied to the rapid detection of environmental water and soil samples, as well as subsequent research.

Experiment

Materials and apparatus

Pinellia ternata was purchased from local flower market (Anhui, China); ethylenediamine (EDA) was purchased from Shanghai Aladdin Biochemical Technology Co., Ltd. (Shanghai, China); citric acid, sodium hydrogen phosphate (Na_2HPO_4) and sodium hydroxide (NaOH) were purchased from Tianjin Zhiyuan Chemical Reagent Co., Ltd. (Tianjin, China). Metal salts mainly include $AlCl_3$, $K_2Cr_2O_7$, $MgCl_2$, $ZnCl_2$, $CuCl_2$, $CdCl_2$, $PbCl_2$, $CrCl_3$, $CoCl_2$, $SnCl_2$, $FeCl_3$ and $FeCl_2$. All solutions were prepared from ultrapure water (18.2 MΩ.cm, 25 °C) of Milli-Q system.

G9800A fluorescence spectrophotometer (Agilent Technologies, USA) was used to determine fluorescence spectrum and its intensity; UV-2600 UV-Visible

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1213912153

spectrophotometer (Shimadzu, Japan) was used to determine the UV-Visible spectrum; Tecnai G2 F30s-Twin high resolution field emission transmission electron microscopy (FEI, Netherlands) was used to detect particle size and morphology characteristics of nitrogen doped fluorescent quantum dots; TENSOR 27 Fourier transform infrared spectrometer (FT-IR, Bruker, Germany) was used to determine the infrared spectrum and the structure of materials; D8-advance X-ray powder diffractometer (XRD, Bruker, Germany) was used to determine the crystal morphology; Thermo Scientific k-alpha X-ray photoelectron spectrometer (Thermo Fisher Scientific Inc. U.S.A.) was used to analyze the proportion of its elements and chemical oxidation state; Z-2000 atomic absorption spectrometer (Hitachi, Japan) was used for the determination of metal ionization; XH-B vortex instrument (Shanghai Hannuo Instrument Co., Ltd., China) was used for vortex blending; 80-2 high-speed centrifuge (Shanghai Surgical Instrument Factory, China) was used for centrifugal filtration; TOP wave microwave digestion device was equipped with PM 60 microwave digestion tank (Jena, Germany) for soil sample digestion; and BPZ-6003 vacuum drying chamber (Shanghai Yiheng Scientific Instrument Co., Ltd., China) was used for vacuum drying.

Preparation of Pinellia ternata-based N-CQDs

Pinellia ternata-based N-CQDs were prepared by hydrothermal method according to the reported method. The stems of *Pinellia ternata* were dried naturally at room temperature and ground into fine powder. The powder prepared by weighing 2.0 g was evenly dispersed in 90 mL of hot water at 60 °C. Ethanol (10 mL) and EDA (1 mL) were added to mixture evenly at constant temperature. The powder was transferred to a PTFE lined autoclave (200 mL) and heated at 180 °C for 9 h. After cooling down to room temperature naturally, the bright yellow aqueous solution was centrifuged at 10000 rpm for 15 min to remove large particles of sediment. The sediment was purified by 0.22 μm membrane filtration. The N-CQDs was stored in a refrigerator at 4 °C and diluted with deionized water to the required concentration. The synthetic reaction diagram of *Pinellia ternata* N-CQDs is shown in *Figure 1*.

Figure 1. *The reaction scheme of the synthesis of the Pinellia ternata-based N-CQDs*

Fluorescence quenching test of chromium (VI)

In 10.0 mL glass centrifuge tube, 30 mL water-soluble *Pinellia ternata*-based N-CQDs solution, 2 mL pH 7.0 citric acid-disodium hydrogen phosphate buffer solution and different concentration of Cr^{6+} were added in turn, and then diluted to 4.0 mL with deionized water. At room temperature, the full eddy mixing reaction lasts for 10 min. The slit width of excitation and emission on the fluorophotometer is 5 nm, the excitation wavelength is lambda ex = 356 nm, and the emission wavelength is lambda em = 444 nm. In order to evaluate the influence of coexisting ions on the fluorescence

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1213912153

intensity of N-CQDs and to evaluate the selectivity of Cr^{6+}, other metal ions (including Zn^{2+}, Cu^{2+}, Al^{3+}, Mg^{2+}, Cd^{2+}, Pb^{2+}, Cr^{3+}, Sn^{2+}, Co^{2+}, Hg^{2+}, Fe^{3+} and Fe^{2+}) were detected under the same procedure.

Pretreatment of environmental water and soil samples

In this study, three different water samples (tap water, lake water and waste water) were selected for analysis and detection. All water samples were filtered by simple centrifugal filtration to remove solid particles and suspended solids, then filtered by 0.22 μm membrane, and stored in a 4 °C refrigerator for storage. In this study, three different soil samples (parking lot, highway) were selected for analysis and detection. Soil samples of 1.0 g were weighed and added with 1 mL nitric acid and 3 mL hydrochloric acid. They were placed in a microwave digestion tank of polytetrafluoroethylene (PTFE). Microwave digestion was carried out at 140 °C for 15 min, then cooled to room temperature. The digestion was diluted to 50 mL and stored in a refrigerator at 4 °C.

Results and discussion

Characterization of Pinellia ternata-based N-CQDs

In order to further study the nanostructure characteristics of *Pinellia ternata*-based N-CQDs, the morphology and particle size of *Pinellia ternata*-based N-CQDs were characterized by transmission electron microscopy (TEM). As shown in *Figure 2,* the *Pinellia ternata*-based N-CQDs were uniformly dispersed without agglomeration and were spherical carbon nanoparticles. In addition, the particle size distribution of biomass-based N-CQDs is narrow, mainly between 5 and 6 nm, and the average particle size is about 5.2 nm.

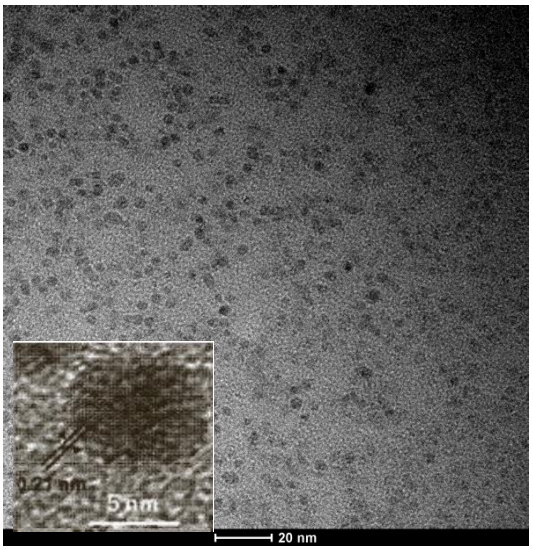

Figure 2. *The TEM image of the synthesized N-CQDs*

The composition and surface chemical structure of *Pinellia ternata*-based N-CQDs were determined by Fourier transform infrared spectroscopy (FT-IR) and X-ray electron

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1213912153

spectroscopy (XPS). *Figure 3* is the infrared spectra of N-CQDs. The broad and strong absorption peaks at 3442 cm^{-1} are attributed to the stretching vibration absorption peaks of O-H and N-H; the peak at 1637 cm^{-1} is attributed to the stretching vibration absorption peak of O = C-NH; the absorption peaks at 1467 cm^{-1} are attributed to the stretching vibration peak of COOH; and the absorption peaks at 1119 cm^{-1} and 1078 cm^{-1} are attributed to the C-N bend. Bending vibration peak and C-O stretching vibration peak. The results show that the *Pinellia ternata* N-CQDs have abundant hydrophilic functional groups, such as hydroxyl, carboxyl and carbonyl groups, which have good water solubility and broad application prospects.

The elements of *Pinellia ternata*-based N-CQDs were characterized by XPS, as shown in *Figure 4*. XPS elemental analysis is consistent with FT-IR results, which proves that the functional groups containing oxygen and nitrogen, such as hydroxyl, carboxyl, amino groups, etc.

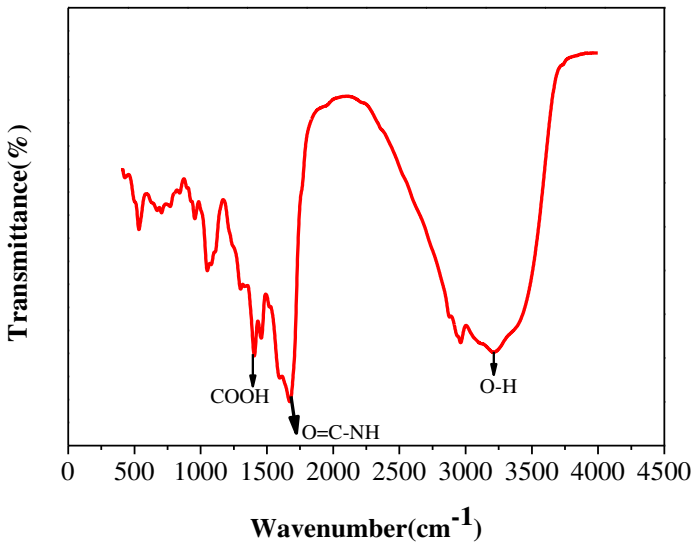

Figure 3. *The FT-IR spectrum of the Pinellia ternata-based N-CQDs*

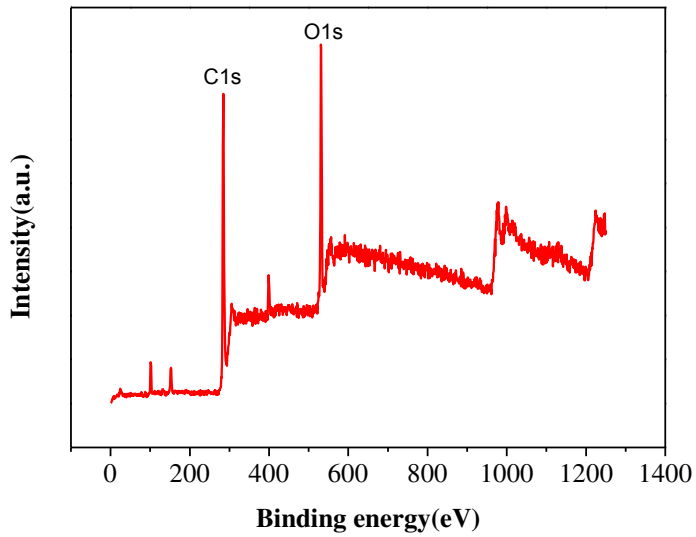

Figure 4. *The XPS spectra of the synthesized N-CQDs*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

Optical properties of Pinellia ternata-based N-CQDs

The optical properties of *Pinellia ternata*-based N-CQDs were characterized by UV-Vis absorption spectra and fluorescence emission spectra. In addition, the illustrations in *Figure 5A* show that *Pinellia ternata*-based N-CQDs are golden in natural light (left) and bright blue fluorescence in 365 nm ultraviolet light (right). Benefiting from its narrow size distribution, *Pinellia ternata*-based N-CQDs exhibit relatively symmetrical fluorescence spectra, as shown in *Figure 5B*. Under 356 nm excitation light, the maximum emission wavelength is 444 nm. The principle of fluorescence depends mainly on the bandgap transition formed by conjugated pion electrons and the surface defects of fluorescent carbon quantum dots. *Figure 5C* is the fluorescence emission spectra of *Pinellia ternata*-based N-CQDs at different excitation wavelengths, showing good excitation wavelength-dependent fluorescence behavior. The results shown that nitrogen doping can adjust the intrinsic electronic and surface properties of CQDs, enhance their effective surface defects and internal carbon core structure, and thus significantly improve their optical properties.

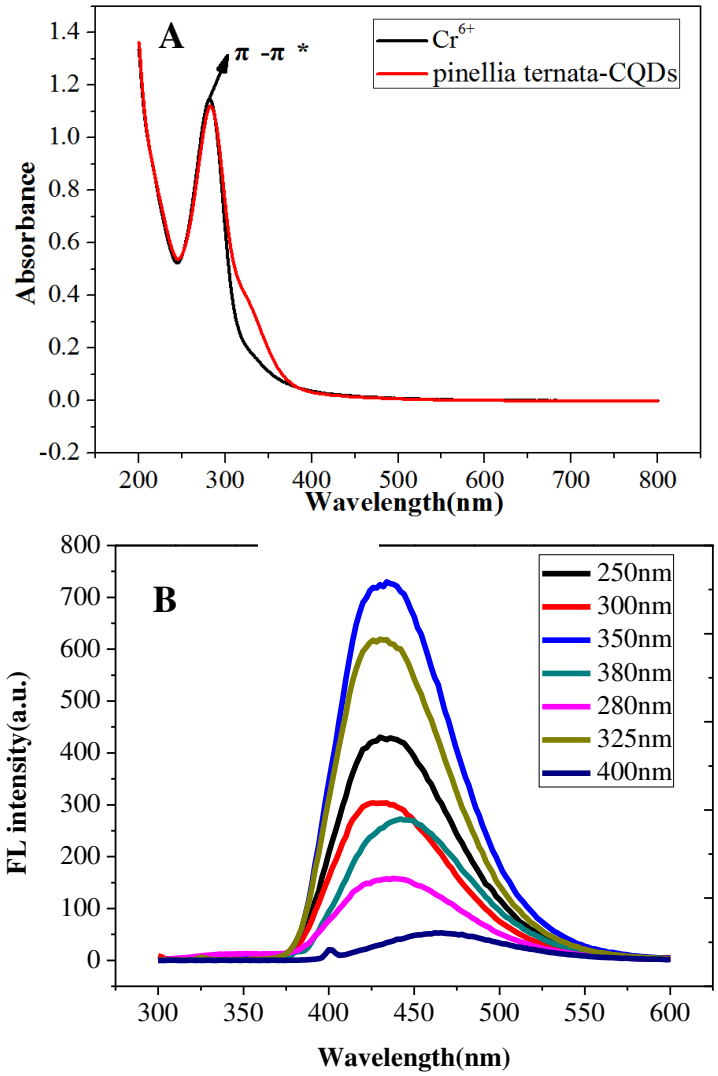

Figure 5. *UV absorption spectra of the Pinellia ternata-based N-CQDs and Cr^{6+}(A); fluorescence excitation and emission spectra of the Pinellia ternata-based N-CQDs (B)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

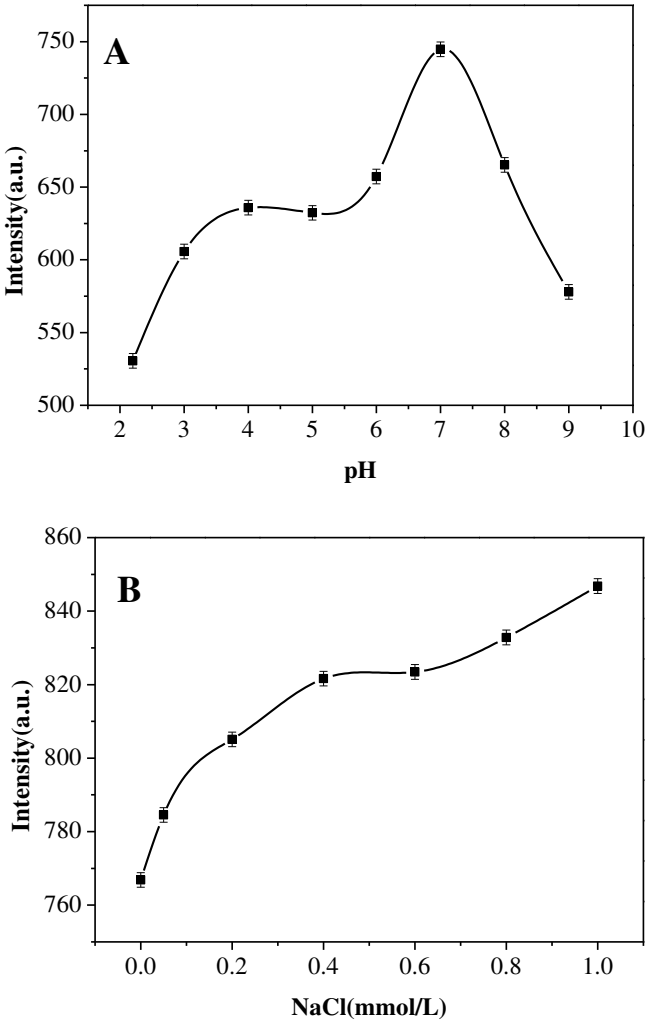
Photostability of Pinellia ternata-based N-CQDs

In order to explore the anti-interference ability of *Pinellia ternata*-based N-CQDs to the external environment, the light stability test was carried out, and the conditions of ion strength, pH and storage time were investigated. As shown in *Figure 6A*, when the pH value of citric acid-disodium hydrogen phosphate buffer changes from 2.2 to 8.0, its fluorescence intensity does not change obviously under acidic and neutral conditions of pH 2.2-7.0, but decreases sharply under alkaline conditions of pH 8.0, which indicates that the probe can be used as a fluorescent nanoprobe in acidic medium. *Figure 6B* investigated the effect of ion strength on the fluorescence intensity of *Pinellia ternata*-based N-CQDs. As can be seen from the figure, the fluorescence intensity only fluctuates slightly with the increasing concentration of NaCl solution, and there is no obvious change. Therefore, *Pinellia ternata*-based N-CQDs still have strong stability in high ionic strength environment. As shown in *Figure 6C* and D, *Pinellia ternata*-based N-CQDs with the same concentration were stored in refrigerator at room temperature for 3 h or even 4 °C for 3 months under the same experimental conditions. The fluorescence intensity of *Pinellia ternata*-based N-CQDs remained basically unchanged and stable, and no floating or sediment could be seen in its aqueous solution by naked eyes. The above experimental results show that the *Pinellia ternata*-based N-CQDs have excellent optical stability.



http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1213912153

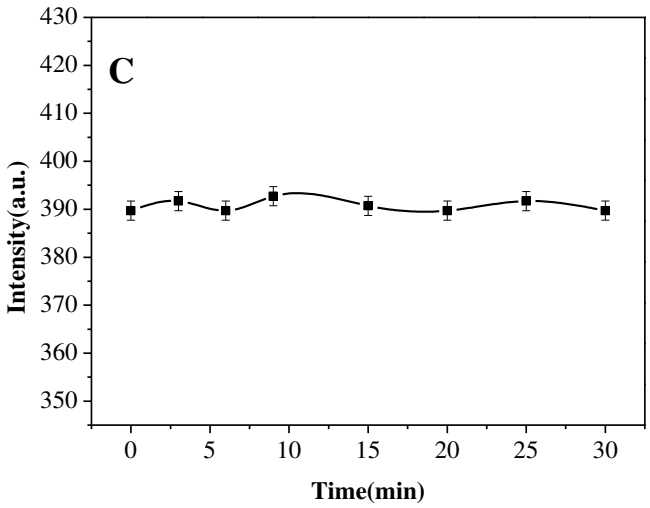


Figure 6. *Effects of various conditions on the fluorescence intensity of the Pinellia ternata-based N-CQDs: (A) pH; (B) NaCl concentrations; (C) storage time*

Selective investigation test

In order to investigate the selectivity of *Pinellia ternata*-based N-CQD fluorescence intensity to different metal ions, 12 metal ions with the same concentration of Al^{3+}, Mg^{2+}, Zn^{2+}, Cu^{2+}, Cr^{6+}, Cr^{3+}, Cd^{2+}, Co^{2+}, Sn^{2+}, Ag^{+}, Pb^{2+}, Fe^{3+}, Fe^{2+}, were investigated. As shown in *Figure 7*, only Cr^{6+} can effectively quench the fluorescence intensity of *Pinellia ternata*-based N-CQDs, while the introduction of other metal ions does not cause significant changes in the fluorescence intensity of *Pinellia ternata*-based N-CQDs. This indicates that *Pinellia ternata*-based N-CQDs have high selectivity to Cr (VI) and can be used as nanoprobe for fluorescence quenching detection of Cr (VI). In addition to Cr^{6+}, other metal ions will coexist with the actual samples. Therefore, this study further investigated the ion interference problem in the detection of Cr^{6+} through competitive experiments, that is, in the presence of other metal ions, the detection of Cr^{6+} was carried out. As shown in *Figure 7*, the experimental results show that the presence of interfering ions has little effect on the detection of Cr^{6+}. In particular, the potential interference ion Cr^{3+}, although causing a slight reduction in the fluorescence intensity of the detection of Cr^{6+}, has a negligible effect, and can be used to distinguish between Cr^{3+} and Cr^{6+}, which is a characteristic that some fluorescent nanoprobes for the detection of Cr^{6+} do not possess. In conclusion, *Pinellia ternata*-based N-CQDs have good selectivity and anti-interference ability as a fluorescent nanoprobe for detection of Cr(VI).

Optimization of experimental conditions

The fluorescence quenching mechanism can be used for rapid detection of Cr (VI). In order to obtain the best fluorescence response signal, some key experimental factors such as solution pH and reaction time were further investigated and optimized. Firstly, the fluorescence intensity of *Pinellia ternata*-based N-CQDs was studied in different pH ranges (2.0-12.0). It can be seen from *Figure 8A* that the fluorescence quenching efficiency is the highest when the pH value is 7.0. The influence of pH value on the quenching process may be related to the form and distribution of acid-base equilibrium

DOI: http://dx.doi.org/10.15666/aeer/1705_1213912153

groups on *Pinellia ternata* N-CQDs surface and Cr (VI) in solution (Vaz et al., 2017). Cr(VI) exhibits a pH-dependent dynamic equilibrium in aqueous solution: $2CrO_4^{2-} + 2H^+ \rightleftharpoons Cr_2O_7^{2-} + 2H_2O$. Cr(VI) mainly exists in the form of chromium (CrO_4^{2-}) and dichromate ($Cr_2O_7^{2-}$). Although it has the same charge number, it has higher molar volume, so it has lower electron density and lower effective interaction with *Pinellia ternata*-based N-CQDs. Its fluorescence quenching efficiency is lower than that of chromite (CrO_4^{2-}). In acidic medium, Cr (VI) mainly exists in the form of dichromate ($Cr_2O_7^{2-}$), so its fluorescence quenching efficiency is low, and gradually increases with the increase of pH.

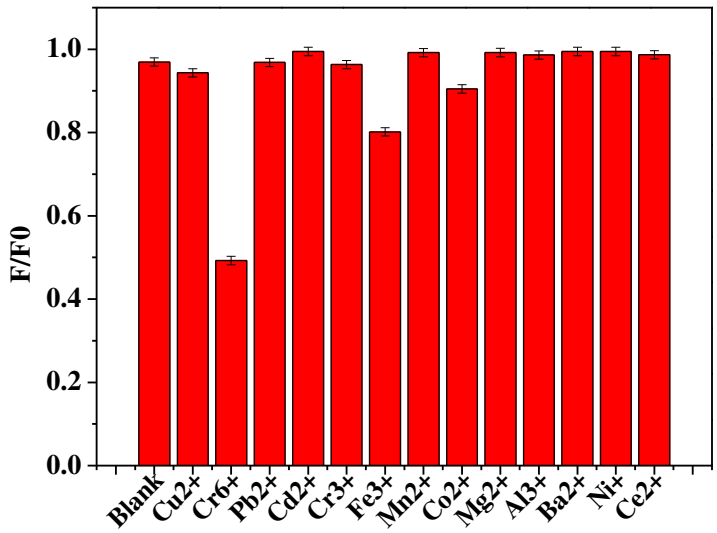

Figure 7. *Evaluation of method selectivity against possible interferents*

In addition, in alkaline medium, the oxygen-containing functional groups on *Pinellia ternata*-based N-CQDs are mainly in the form of chromate (CrO_4^{2-}), which is easy to dephosphorize and increase the negative charge on the surface. The interaction between Cr (VI) and negatively charged chromite (CrO_4^{2-}) is weakened due to electrostatic repulsion, which shows that the fluorescence quenching efficiency begins to decrease gradually. Therefore, pH 7.0 is defined as the optimum determination condition.

In order to determine the quenching response time of Cr^{6+} to *Pinellia ternata* N-CQDs, the reaction time was also discussed in this study. *Figure 8B* shows the fluorescence intensity of *Pinellia ternata* N-CQDs with time after adding Cr^{6+}. The fluorescence intensity of *Pinellia ternata*-based N-CQDs decreases sharply in 0-2 min, and reaches the lowest fluorescence intensity in 2 min. Later, the fluorescence intensity of *Pinellia ternata*-based N-CQDs decreases slightly but tends to stabilize gradually with the extension of time. Therefore, the optimal fluorescence quenching response time is 2 min.

Study on methodological performance

Under the optimum experimental conditions, the relationship between the fluorescence quenching intensity of *Pinellia ternata* N-CQDs and the concentration of Cr^{6+} was studied, and a quantitative analysis method for the fluorescence quenching of Cr^{6+} was established. As shown in *Figure 9A,* the fluorescence intensity of N-CQDs

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1213912153

decreases gradually with the increase of the concentration of Cr^{6+} and changes regularly, which further proves the feasibility and application prospects of N-CQDs as a fluorescent probe for the detection of Cr^{6+}. As shown in *Figure 9B,* the fluorescence quenching efficiency (F0/F) has a good linear relationship with the concentration of Cr^{6+} in the range of 0-200 μM. The linear equation is F0/F = 1.0218 + 0.1156 C (Cr^{6+}), R^2 = 0.9955, and the detection limit is 15 nM (S/N = 3).

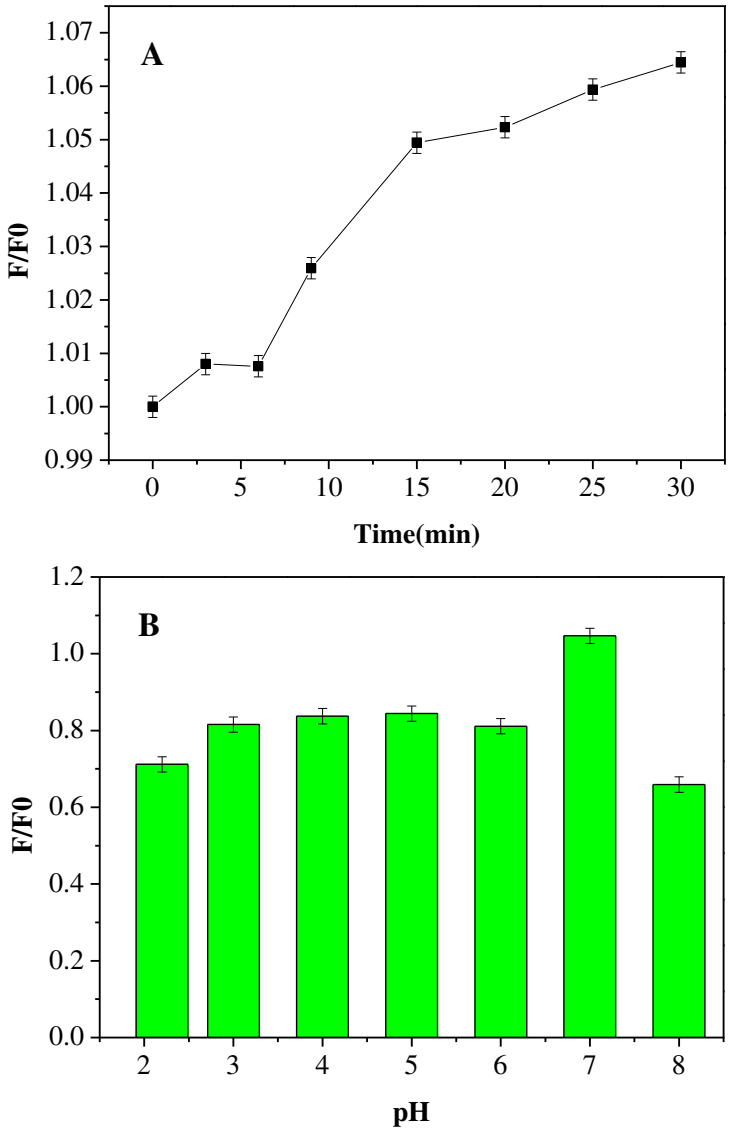

Figure 8. *Effect of reaction time (A) and pH (B) on the fluorescence intensity of the Pinellia ternata-based N-CQDs*

Analysis of fluorescence quenching mechanism

The fluorescence quenching mechanism of *Pinellia ternata*-based N-CQDs for detecting chromium (VI) is similar to that of polyacrylamide-based N-CQDs for detecting Hg^{2+}. It is caused by the synergistic effect of fluorescent inner filter effect (IFE) and electron transfer. As shown in *Figure 10,* at pH 7.0, the ultraviolet-visible absorption spectra of Cr (VI) show two absorption peaks at 272 and 371 nm,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1213912153

respectively, while *Pinellia ternata*-based N-CQDs have ultraviolet absorption peaks at 337 nm, and the maximum excitation and emission wavelengths are 356 and 444 nm, respectively. It is obvious that the absorption spectra of Cr (VI) overlap with the excitation and absorption spectra of *Pinellia ternata*-based N-CQDs. Therefore, Cr (VI) partially shields the excitation spectra of *Pinellia ternata*-based N-CQDs and partially absorbs the light emitted by *Pinellia ternata*-based N-CQDs, resulting in the fluorescence endofiltration effect between *Pinellia ternata*-based N-CQDs and Cr^{6+}, resulting in the quenching of the fluorescence of *Pinellia ternata*-based N-CQDs. In addition, Cr^{6+} has strong electron acceptance and affinity, and it is easy to capture electrons. When the excited state molecule of *Pinellia ternata*-based N-CQDs collides with Cr^{6+}, the nitrogen and oxygen functional groups on its surface can combine with Cr^{6+} to form complexes, which lead to electron transfer and non-radiative transition, leading to fluorescence quenching.

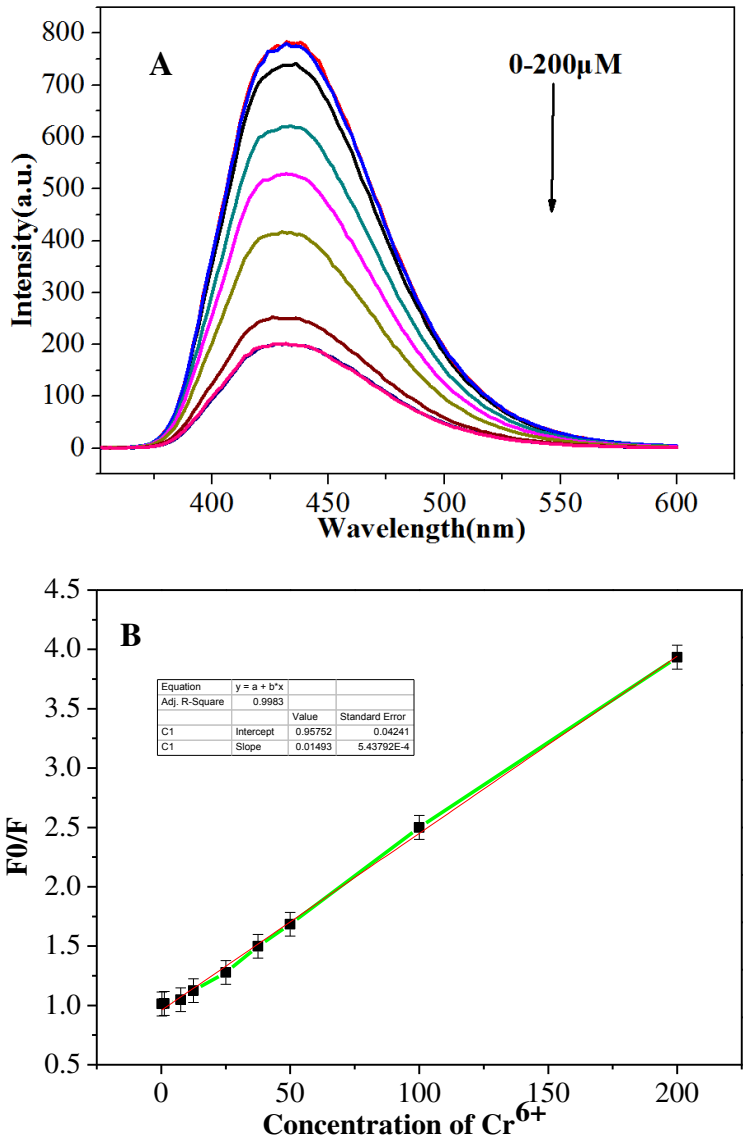

Figure 9. *The fluorescence response of the Pinellia ternata-based N-CQDs upon the addition of different concentrations of Cr^{6+}(A) and a linear correlation of F0/F values versus the concentration of Cr^{6+} over the range from 0 to 200 μM (B)*

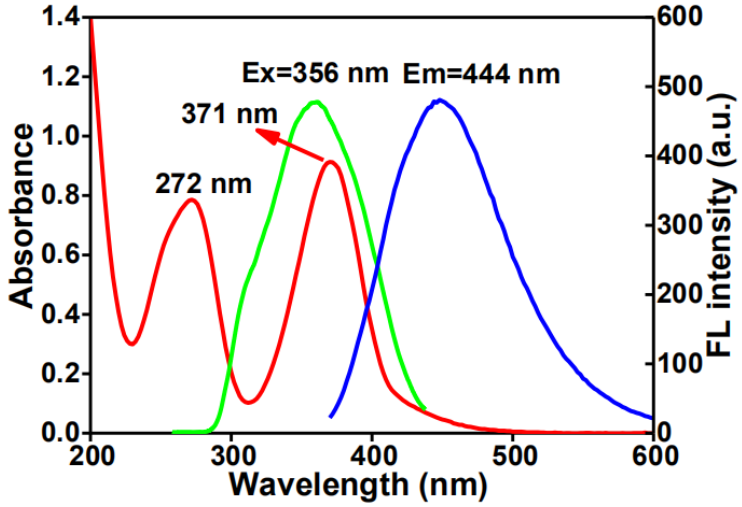

Figure 10. *UV-Vis absorption spectra of Cr (VI) and fluorescence excitation/emission spectra of the Pinellia ternata-based N-CQDs*

Detection of actual samples

In order to verify the practicability of this method, the content of Cr^{6+} in different water samples was investigated. As shown in *Table 1,* the recoveries of water samples were 94.2-102.5% and RSD was less than 5.8%. In order to evaluate the accuracy of this method, FAAS method was used to detect the content of Cr in water samples with the same concentration. The results show that in *Table 1,* the results of the two methods are very close, so, this method can be used for the rapid analysis and detection of Cr^{6+} in environmental water samples, and can be effectively applied to further research.

Table 1. *Analytical results of Cr (VI) in the water samples (n = 3)*

Samples	Spiked (μM)	Found (μM)	Recovery (%)	RSD (%, n = 3)	FAAS Found (μM)

Conclusion

In this study, for the first time, *Pinellia ternata* was used as a carbon precursor and ethylenediamine as a nitrogen source. Nitrogen-doped fluorescent carbon quantum dots with excellent optical properties and fluorescent quantum yield of 21.3% were prepared

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1213912153

by a simple one-step hydrothermal method. The morphology, particle size, crystalline form, chemical element composition and optical properties were characterized by TEM, FT-IR, XPS, UV-Vis and FS. The results show that *Pinellia ternata* N-CQDs have uniform size distribution, rich oxygen and nitrogen functional groups on their surface, and show good excitation wavelength dependence and tunability. Based on the quenching mechanism of fluorescence internal filter effect, Cr^{6+} has high sensitivity, selectivity and anti-interference ability. It can be used as a fluorescent nanoprobe for the analysis and detection of Cr^{6+} in complex environmental samples. The method has good linear relationship, fast reaction, simple operation, high sensitivity, high selectivity and low detection limit. It provides a new idea for developing carbon quantum dot fluorescent nanoprobe for detecting Cr^{6+} and has broad application prospects.

Abstract. Molecular genetic information on mollusk species is being increasingly considered for identification and taxonomic status. In this study, we examined the potential of shell material of freshwater mussels from four different locations in Turkey for DNA sequence analysis. A total number of 212 specimens including empty shells were sampled from a river and three lakes. Mitochondrial DNA was extracted from ground shell material with isolation kits and tissue material was also used for reference. Even though the majority of empty shells did not produce high-quality material, DNA extraction from fresh shells had similar results with tissue material. Mitochondrial 28S rDNA partial sequences were analyzed using the neighbour-joining method for genetic divergence. Phylogenetic analysis revealed two well-differentiated clades of *Anodonta cygnea* and *Unio crassus*. The results clearly indicated that 28S rRNA sequences obtained from shell material are informative enough to reveal major clades, haplotypes and phylogenetic relationship between four populations. These findings support that quite fresh shell material from freshwater mussels can be a convenient DNA source for molecular studies.
Keywords: *Unionidae, phylogeny, shell DNA, bivalve diversity, 28S rDNA*

Introduction

Freshwater mussels as prehistoric bivalve inhabitants of inland waters are represented on all continents except Antarctica. They are classified into six families, about 180 genera and 800 species (Bogan, 2008). Bivalves are remarkable aquatic organisms with heavy impact on ecosystems through filtration, bio-accumulation, energy transfer, being host for other organisms and their role in food web. Such factors as pollution, loss of host fishes and the introduction of non-native species are causing changes in diversity and population structure (Lopez-Lima et al., 2017). Freshwater mussels are globally in decline and are among the most endangered aquatic species (Strayer, 2008). Lopez-Lima et al. (2017) recorded 224 (44%) of the 511 freshwater mussel species as Near Threatened or Threatened in the 2015 *IUCN Red List of Threatened Species*. Despite having highly important ecosystem roles, gaps exist on biology and population structure of freshwater bivalves still standing as the primary obstacle to management and conservation.

Recently, European freshwater mussels have also been gaining increasing attention and 16 species have been recognized in Unionida Margaritiferidae: 2 and Unionidae: 14 (Lopez-Lima et al., 2017). The current taxonomy of freshwater mussels is based on morphological characteristics and studies on genetic diversity are very scarce. Due to variable characteristics as size and shell shape which are affected by the current velocity, substratum and environment, freshwater mussels exhibit high phenotypic plasticity (Baker et al., 2004).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1215512163

Population size, distribution and species data are primary requirements for successful conservation management so the taxonomic status of the order Unionida is to be resolved and DNA sequence would serve valuable data for systematic updates.

Mantle clipping is the widespread method for tissue sampling from mollusks in genetic studies but non-invasive sampling methods are needed for endangered species and in case of lacking live specimens. Henley et al. (2006) described integumental swabbing as a noninvasive method for cell collection from freshwater mussels. A more recent study presented a method for DNA extraction from empty apple snail shells (Andree and Lopez, 2013).

To avoid the phenomenon phenotypic plasticity and facilitate genetic analysis through small shell fragments from live or empty shells, we examined genetic diversity in four populations of freshwater mussels using 28S rDNA sequences. Here we present a successful method and first genetic data on Turkish populations of freshwater mussels.

Materials and Methods

Live specimens and empty freshwater mussel shells

Freshwater mussels and empty shells were collected from Gölmarmara/Manisa (lake), Manavgat/Antalya (dam lake downstream), Küçük Akgöl/Adapazarı (lake), Karasu/Sinop (river) in Turkey (*Table 1*) with the permission of the Ministry of Agriculture and Forestry (*Figure 1a*). While empty shells were placed in plastic bags, tissue samples were taken from live specimens into ethanol 70% and transferred to the laboratory in cooler boxes. Samples were stored at -20°C until analysis.

Table 1. *Sampling locations*

Location	Waterbody	Coordinates	Number of specimens
Karasu	Stream	41.56162"N – 35.04827"E	150
Küçük Akgöl	Lake	40.52365"N – 30.25582"E	40
Gölmarmara	Lake	38.35449"N – 27.59487"E	4
Manavgat	Dam Lake	36.52434"N – 31.31211"E	11

DNA preparation, PCR and sequencing

Total DNA was extracted using EurX GeneMATRIX Tissue & Bacterial DNA Purification Kit (Poland) according to the manufacturer protocol with minor modifications. Samples from each shell were removed with an 8 mmØ ceramic cutting hand drill and crushed into fine powder in a mortar. To avoid contamination, cutting edges were changed with new between samples. Sample material was placed into the 2 ml tube and 350 µl Lyse T buffer added and the precipitate was suspended. Tissue samples were cut into small pieces and buffered. 2 µl RNaseA and 20 µl Proteinase K were added and vortexed. Samples were incubated at 56°C during 3 h after adding 350 µl buffer, the samples were incubated for 10 min at 70°C. Pure ethanol of 350 µl was added and the tubes were centrifuged for 1 min at 12 000g. The supernatant was transferred into DNA binding spin-column and centrifuged repeatedly. After placing the column in the collection tube 500 µl washing buffers were added and centrifuged. Elution buffer was added in new tubes and incubated at room temperature. DNA products were stored at 4°C. The recovered DNA was checked with Thermo Scientific Nanodrop 2000 (USA) for integrity.

Figure 1b. *Shells from collection sites. (a)Karasu, (b)Akgöl, (c) Gölmarmara and (d) Manavgat*

A universal primer set (Justine et al., 2002) was employed for mitochondrial 28S rDNA gene amplification (*Table 2*).

Table 2. *Primer set used for 28S rDNA amplification*

Primer	Direction	Primer Sequence	Reference
C1	Forward	5′-ACCCGCTGAATTTAAGCAT-3′	Justin et al., 2002
C2	Reverse	5′-CTCTCTYTYCAAAGTTCTTTTC-3′	

Each PCR reaction mixture contained 1.5 µl DNA template (880 ng/µl), 1 µl DNA FIREPol® DNA Polymerase (5 U/µl), 10 µl 10X Buffer, 1 µl dNTP (20 mM), 6 µl 25 mM $MgCl_2$ (1.5 nM) and 10 pmol/µl of each primer (0.15 µM), completed with ddH_2O to a total volume of 100 µl. The thermal cycler profile was as one cycle initial denaturation step at 95°C for 5 min, 35 cycles of denaturation at 95°C for 45 sec, annealing at 57°C for 45 sec, elongation at 72°C for 1 min and a final extension step at 72°C for 5 min. The amplified DNA fragments were controlled with agarose gel electrophoresis and purified using ExoSAP-IT™ PCR Product Cleanup Reagent"

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1215512163

(ThermoFisher Scientific, USA). PCR amplified DNA fragments were sequenced with automated 3500xL Genetic Analyzer (Applied Biosystems).

The sequences were aligned with Sequencer v5.4.6 and consensus alignments for each sampling location were deposited to GenBank under accession numbers MK530498, MK530499, MK530500, MK530501.

The number of polymorphic sites, DNA polymorphism, conserved regions, haplotype number, haplotype diversity and Tajima's D statistics were performed with DnaSP v.5.0 (Librado and Rozas, 2009).

Phylogenetic analysis for the 28S rDNA sequence set was performed using the software MEGA X (Kumar et al., 2018). The tree was produced with the Neighbor-Joining (NJ) method using the Kimura 2-parameter model for genetic distance estimation (Kimura, 1980). Percentage of replicate trees in the bootstrap test (1000 replicates) indicated alongside the branch nodes (Felsenstein, 1985).

Results

DNA extraction from all three types of material was affordable. *Figure 2* demonstrates the gel electrophoresis screenshot for mitochondrial DNA from mantle clipping, fresh shell and old empty shell material. Even though mitochondrial DNA can be isolated from all samples, sequencing performance was not the same. While 97% of tissue and 70% of fresh shell samples were sequenced succesfully, only 10% of the PCR products from old empty shells served quality sequences (*Table 3*).

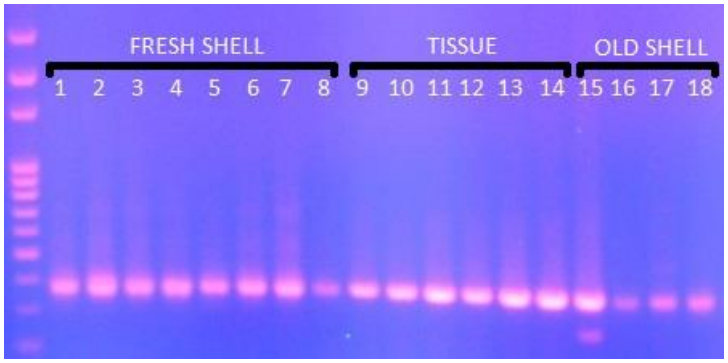

Figure 2. *Gel electrophoresis of mantle tissue, fresh shell and old shell samples*

Table 3. *Number of successfully sequenced specimens from different DNA sources*

Location	Tissue		Fresh Shell Material		Old Empty Shell Material	
	Template DNA (n)	Sequenced (n)	Template DNA (n)	Sequenced (n)	Template DNA (n)	Sequenced (n)

DOI: http://dx.doi.org/10.15666/aeer/1705_1215512163

in NJ tree construction. Nucleotide compositions of consensus sequences are given in *Table 4*.

For all data set, 136 variable sites exist in 339 bg sequence (5.04%). *Table 5* shows conserved, variable and parsimony informative sites, identical, transitional and transversional pair frequencies and transition/transversion ratio (R). The data set has 82 polymorphic and 52 parsimony informative sites and transitional/transversional pair ratio of 0.8 (R).

Table 4. *Nucleotide composition*

Location	T (U)	C	A	G	G+C	A+T
Karasu	20.4	24.3	26.7	28.5	52.9	47.1
Küçük Akgöl	20.1	24.7	25.6	29.6	54.3	45.7
Gölmarmara	19.6	25.2	25.8	29.5	54.7	45.3
Manavgat	20.4	24.5	24.8	30.3	54.8	45.2
Avg.	20.1	24.7	25.7	29.5	54.1	45.9

Table 5. *Nucleotide pair frequency*

Conserved sites	199/339
Variable sites	136/339
Parsimony informative sites	52/339
Singleton sites	83/339
Identical pairs ii	259
Transitional pairs si	10
Transversional pairs sv	13
R si/sv	0.8

The sequence data set represented 16 haplotypes. While haplotype H9 existed in six samples (2 from Golmarmara and 4 from Akgol), haplotype H10 was found in three samples (1 from Golmarmara, 1 from Akgol and 1 from Manavgat). Other 14 haplotypes were found for each sample from all locations. Mean haplotype diversity (Hd), nucleotide diversity (π), Tajima's D test results are given in *Table 6*. Haplotype diversity changed between 0.714 and 1.000 min/max from Akgöl and Manavgat. Average Hd and π were calculated as 0.0881 and 0.062 respectively. Test of neutrality on allele frequency distribution with Tajima's D indices resulted negative for all four populations and was not statistically significant ($p>0.05$).

Table 6. *Genetic diversity and neutrality results (Hd: Haplotype diversity, π: nucleotide diversity)*

Location	n	h	Hd	π	Tajima's D
Karasu	10	9	0.977	0.065	-0.419
Küçük Akgöl	7	4	0.714	0.117	-1.543
Gölmarmara	4	3	0.833	0.006	-0.780
Manavgat	4	4	1.000	0.059	-0.635

Nucleotide substitution rates were calculated with maximum likelihood method using Tamura 3-parameter model (*Table 7*). The nucleotide frequencies are A=23.13%, T/U=23.13%, C=26.87%, and G=26.87%.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1215512163

The divergence between four populations ranged between 0.019 and 0.045 with an average value of 0.031 (3.1%) indicating a correlation between divergence and location. While the highest diversity was found between Karasu and Manavgat populations (4.5%), the populations from Gölmarmara and Akgöl were the genetically closest ones (1.9%) (*Table 8*). The high distance value of Karasu samples is due to the species difference. The Karasu population is clearly located on a separate branch in the phylogenetic tree given in *Figure 3*.

Table 7. *Nucleotide substitution matrix*

	A	T	C	G
A	-	6.77	7.86	**11.15**
T	6.77	-	**11.15**	7.86
C	6.77	**9.60**	-	7.86
G	**9.60**	6.77	7.86	-

Each entry is the probability of substitution (*r*) from one base (row) to another base (column). Rates of different transitional substitutions are shown in **bold** and those of transversional substitutions are shown in *italics*

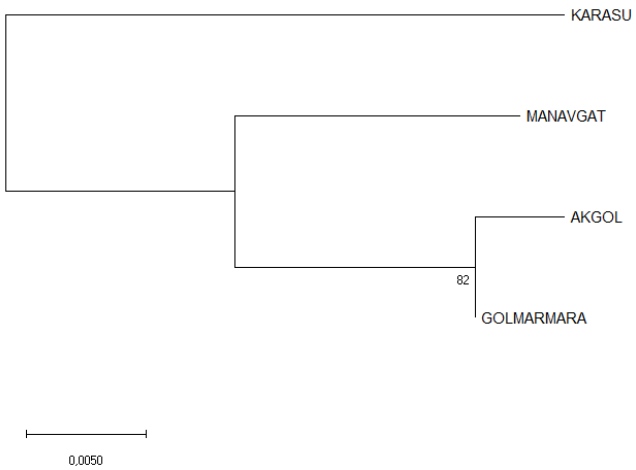

Figure 3. *Phylogenetic relationships among four taxa inferred from 28S rDNA sequences. The evolutionary history was inferred using the Neighbor-Joining method (Saitou and Nei, 1987). The percentage of replicate trees in which the associated taxa clustered together in the bootstrap test (1000 replicates) are shown next to the branches (Felsenstein, 1985). The evolutionary distances were computed using the Kimura 2-parameter method (Kimura, 1980). Evolutionary analyses were conducted in MEGA X (Kumar et al., 2018)*

Figure 3 shows the evolutionary relationship between the four populations. The tree was obtained by Neighbor-Joining method (Saitou and Nei, 1987) in MEGA X (Kumar

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1215512163

et al., 2018). The optimal tree with the sum of branch length was 0,058775. Genetic distances between four populations were estimated by Kimura 2-parameter method (Kimura, 1980). The percentage of replicate trees in which the associated taxa clustered together in the bootstrap test (1000 replicates) are shown next to the branches (Felsenstein, 1985). The analysis involved 4 nucleotide sequences. All ambiguous positions were removed for each sequence pair. There were a total of 339 positions in the final dataset.

Discussion

This is the first study investigating the genetic diversity of freshwater bivalvia through shell DNA analysis. The results clearly indicated that 28S rRNA sequences obtained from shell material are informative to reveal major clades, haplotypes and phylogenetic relationship between four populations. These findings support that quite fresh shell material from freshwater mussels is to be a convenient DNA source for molecular-based studies. Degradation of shells due to the exposure time to environmental components, basically the water, is the primary limiting factor for shell DNA.

G+C ratio (average 54.1%) represented in *Table 4* indicates heterogeneity between four populations. The high number of variable sites supports that the 339 bp 28S rRNA sequence from the shell is a successful molecular marker for freshwater mussels. Transitional/Transversional pair rate R (si/sv) found 0.8 while substitution rate R which is calculated using Kimura-2 parameter was 0.7. These close rates also support the reliability of data analysis.

Consensus sequence analyses supported two well-differentiated clades of unionid species swan mussel *Anodonta cygnea* from Manavgat, Akgol and Golmarmara Lakes and thick shelled river mussel *Unio crassus* from Karasu River. Genetic distance between populations found between 0.003 and 0.045 (*Table 8*) with an average of 0.030. Akgol and Golmarmara populations have exhibited the lowest genetic distance while Karasu River samples have a constant high distance value which is compatable with species difference.

According to Gürlek et al. (2014) Modell has defined four main groups of freshwater mussels of Anatolia according to geographic distribution containing Unio, Anodonta, Potomida, Leguminaia, Gabillotia, Pseudodontopsis, Sinanodonta species. There are only a few more studies on freshwater mollusks of Turkey which all used the morphological description of species. This study is being the first as using shell DNA for genetic classification of freshwater bivalvia from Turkey. Due to the difference between sampling locations, there is a lack of chance to conclude data from the literature. Only Şahin (2013) defined bivalvia specimens from Karasu as *Unio pictorum* through morphological identification methods but our findings indicated a different taxonomy of specimens from the same locality as *Unio crassus* according mtDNA sequence.

The phylogenetic tree of 28S rRNA sequences clearly revealed the genetic difference between four populations (*Figure 3*). Karasu samples were located on a separate branch. Akgol and Golmarmara populations stand close with a result of the hypotheses of geographic isolation.

Ricciardi and Rasmussen (1999) have reported the rapid extinction of freswater species in Nort America and made an extinction rate estimation for freshwater mussels

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1215512163

about two fold than the avarage of freshwater species. Lopes-Lima et al. (2017) have underlined the lack of data on freshwater mussels especially in south-eastern European countries and the importance of more studies for effective management measures.

While thick shelled river mussel *Unio crassus* is classified as "globally endangered" on IUCN Red List (Lopes-Lima et al., 2014), the swan mussel *Anodonta cygnea* is referred as "near threatened" by Killeen and Aldridge (2011). Also, it is noted that the population trend of *Unio crassus* is unknown for the Mediterranean basis so referred to DD (Data Deficient) by Vavrova (2011). Since the taxonomy of freshwater bivalve is still ambiguous and species distribution and population sizes are unclear, molecular studies can serve valuable information for conservation management plans.

Conclusion

The need for effective conservation and management strategies for freshwater ecosystems which are under intense pressure, especially human activities, requires wider monitoring using standardized protocols and methods. But there are gaps on population structures, distribution and taxonomic data for many species as well as freshwater mussels. On country basis, large scale taxonomic studies which are supported with molecular data will help filling these gaps. International cooperation is strongly suggested for database and management projects.

Overall this study suggests shell DNA as a reliable source of divergence data on freshwater bivalve species against the problematic systematic relationships and phenotypic plasticity. Partial sequences of 28S rDNA derived from four populations provide the first genetic data in Turkey with this study.

Future researches are needed for large scale data collection on freshwater bivalves by using non-invasive standardized methods.

Abstract. Organic carbon (OC) fluxes in the Ulleung Basin (UB) sediments, East/Japan Sea (E/JS) were investigated through geochemical analyses and sediment chamber experiment. The UB sediment has high organic carbon contents of over 2% and the mean C/N molar ratio is 7.09, therefore suggesting that the organic matter deposited in the UB is predominantly of marine origin. Apparent sedimentation rates (ASR) calculated from excess ^{210}Pb activity distribution, ranged between 0.036-0.047 cm year^{-1}. The mass accumulation rates (MAR) calculated from porosity, grain density (GD) and ASR, ranged between 131-184 g m^{-2} year^{-1}. Input fluxes of OC (IF) and burial fluxes of OC (BF) varied between 7.89-11.08 and 2.02-3.10 gC m^{-2} year^{-1}, respectively. Regenerated fluxes of OC (RF) estimated with oxygen consumption rate, varied between 6.22-6.59 gC m^{-2} year^{-1}. However, the RF calculated by subtracting BF from IF, varied between 5.87-7.98 gC m^{-2} year^{-1}. The proportions of the IF, RF, and BF to the primary production (177.1 gC m^{-2} year^{-1}) in the UB were about 5.4%, 3.9%, and 1.5%, respectively. These proportions were over 5 times higher than the average of world open ocean. Based on these results, the UB appears to play an important role in the deposition and removal of organic carbon in the E/JS.
Keywords: *particulate organic carbon (POC), input flux of organic carbon (IF), regenerated flux of organic carbon (RF), burial flux of organic carbon (BF), Ulleung Basin (UB)*

Introduction

The amount of organic matter in marine sediments reflect the supply and preservation of organic materials from marine and terrestrial sources (Tissot et al., 1980; Summerhayes, 1981). The export and preservation of organic matter from the surface waters, where they are produced, down to the basin floor determines the role of basins as a potential carbon sink. The export fluxes of particulate organic carbon (POC) play an important role in the transfer of carbon between the atmosphere and the ocean (Savoye et al., 2006; Waples et al., 2006). In the open ocean, the main source of particles is biological production. Organic particles are produced from carbon fixation through photosynthesis and uptake of nutrients. Most of the POC is recycled in the surface water by decomposition into dissolved organic carbon and remineralization into inorganic carbon. Only a small fraction of POC is exported from the euphotic layer and subsequently either recycled in the deep waters or reaching the sediments. The POC

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1216512179

export out of the surface layer is the most important process for the transport of atmospheric CO_2 to the deep ocean (Trull et al., 2011).

Export of organic material from the euphotic zones into deeper oceanic zones occurs in different ways. Particulate materials as biogenic materials, detrital materials and fecal pellets are transported by gravitational settling and lateral transport. Whereas the dissolved organic matter export largely depends on the extent of downward diffusion and mixing. Generally, most of this particle flux is affected by early diagenesis during settling: concentration decreases significantly with increasing water depth preferentially due to biogenically mediated organic matter degradation and dissolution processes (Suess, 1980). So, only a small fraction, which is not reintroduced back into the oceanic water column and the euphotic zone, reaches marine sediments.

Marine sediments acting as important sinks for organic matter are known from, for example, upwelling areas, shelf mud depocentres and marginal sea basins (Leipe et al., 2011). Organic carbon (OC) in marine sediments represents a major component of the global carbon cycle (Seiter et al., 2004). OC cycles in deep basin sediments are of interest for assessment of the long-term removal of CO_2 from surface waters and the regeneration of nutrients from the sediments (Eimeis et al., 2000). A key step in this cycle is represented by the reminelalization of organic matter at the sediment-water interface, via a number of oxidative processes.

The E/JS is a semi-enclosed marginal sea between continental Asia and the Japanese archipelago, connected to open ocean through straits 12–140 m in depth (Chough et al., 2000). The E/JS is considered as a miniature ocean, since it has typical characteristics of open oceans, such as a deep ventilation system, subpolar and subtropical gyres, and a western boundary current (Masuda, 2000). The E/JS has three deep basins (Ulleung Basin, Yamato Basin, and Japan Basin). The UB, located in the southwestern part of the E/JS, is surrounded by continental slopes of the Korean Peninsula, the southwestern part of Japan's main island of Honshu, and Ulleung and Dok island (*Fig. 1*). The northern and western margins of the basin are steep (> 10°), whereas the southern and eastern margins have smooth slopes (1~2°) and a broad continental shelf (Park et al., 2005). The basin floor lies at depths of 2000~2300 m, with the boundary between the continental slope and the UB approximately 2000 m in depth. Recent sediments appear to be primarily hemipelagic (Chough and Brag, 1987), no major rivers drain into the basin along the coast of the Korean Peninsula (Ikehara et al., 1994; Hong et al., 2008).

This study focused on OC cycle at the sediment-water interface and ultimately removal of OC in the UB sediments. The E/JS is a small local sea, but it is similar to the characteristics of the ocean. It is therefore the most suitable model for studying the carbon sinking to the deep ocean floor. The main purpose of this paper is to present a carbon storage and removal mechanisms of deep UB sediments, and to understand role of deep basin sediment for the removal of CO_2 from the E/JS surface water. This result is crucial for future carbon cycle and deep ocean ecosystem modelling.

Materials and methods

Sediment sampling and analyses

Sediment samples were collected using a box corer at sites on the deep basin (D2, D3, and D4) in April 2006 and August 2007. Sediment samples for geochemical analysis were collected from the box core using acrylic core samplers (8 cm i.d.) that were then immediately sealed with polyethylene stoppers (*Fig. 2*). The core samples

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1216512179

were transferred to the laboratory onboard the research vessel, where the sediment was sectioned at intervals of 1 or 2 cm and transferred to acid-cleaned polyethylene bottles that were sealed with caps. The sediment samples for measuring organic carbon content, total nitrogen content, $CaCO_3$ content, opal content, sediment density, water content, and ^{210}Pb activity were stored at 4°C.

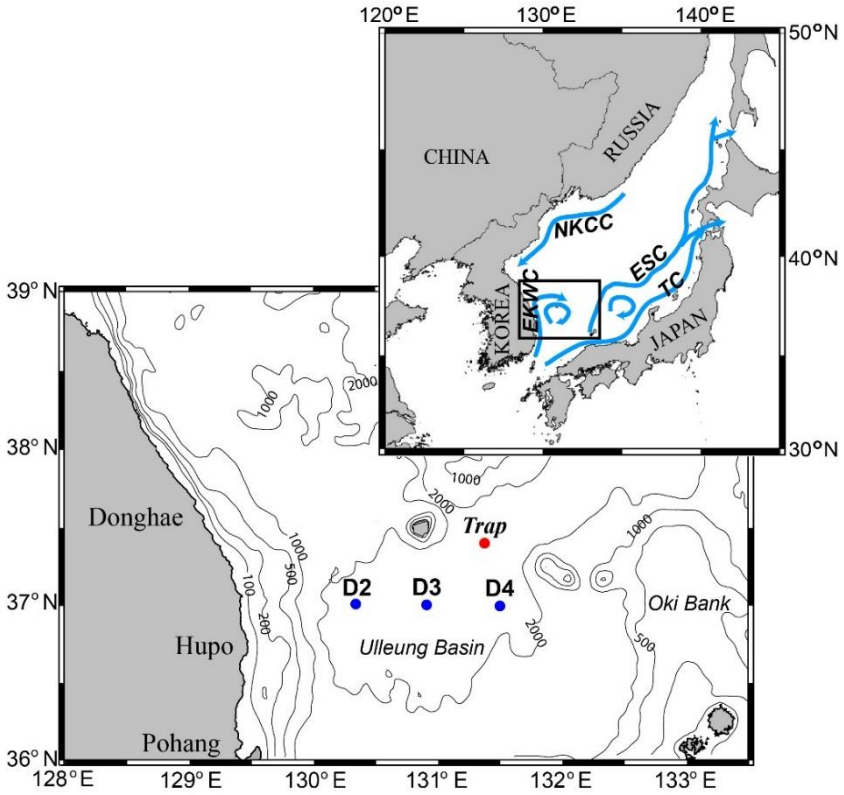

Figure 1. *Study area and sampling sites in the Ulleung Basin, East/Japan Sea. Trap is sediment trap mooring site (KORDI, 2003)*

The organic carbon content was determined by comparing the total carbon measured by a Carlo Erba NA 1500 nitrogen–carbon–sulfur (NCS) analyzer to the inorganic carbon content measured by a Coulometrics inorganic carbon analyzer. Dried samples were combusted at 900ºC in an oxygen atmosphere in the NCS analyzer. The resulting products were chromatographically separated and quantified to obtain the total carbon and total nitrogen contents.

Calculation of the sedimentation rate and sediment mass accumulation rate (MAR)

Dried sediment samples taken from various depths were used to determine the sediment density and porosity. Density was measured by a Micromeritics AccuPyc 1330 density analyzer, and porosity was calculated from water content. A portion of the dried samples were ground and spiked with a known quantity of ^{208}Po to determine the accuracy of the analyses. These samples were leached and brought to dryness three times in the presence of concentrated HNO_3 and 6N HCl. Dilute HCl was then added to the sample, and the solution was separated from the residual solids by centrifugation. For each sample, the dissolved polonium isotopes were plated onto a silver planchet.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1216512179

The ^{210}Pb activity was determined by measuring the alpha activity of its granddaughter, ^{210}Po, using a silicon-surface-barrier detector coupled to a multi-channel analyzer. All measurements were conducted at the Korea Basic Science Institute.

Aparent sedimentation rates (ASR) were estimated based on the ^{210}Pb profiles. The exact relation is *Equation 1*.

$$S = -\lambda/b \qquad \text{(Eq.1)}$$

where ***S*** is the sedimentation rate (cm year^{-1}), λ is the decay constant of ^{210}Pb (0.0311 year^{-1}), and b is the slope of the curve. The calculation of sedimentation rates assumes that the excess ^{210}Pb flux and sedimentation are constant over time. Sedimentation rates calculated from profiles of excess ^{210}Pb activity often overestimate actual accumulation rates because the gradual decrease in mixing efficiency with increasing depth results in a depth profile indicating exponential decay (Niggemann et al., 2007), which can be falsely interpreted as undisturbed sediment accumulation.

The sediment mass accumulation rate (MAR) was calculated by following *Equation 2*.

$$\text{MAR (g m}^{-2}\text{ year}^{-1}\text{)} = (1-\varphi) \times \text{GD (g cm}^{-3}\text{)} \times \text{ASR (cm year}^{-1}\text{)} \times 10^4 \qquad \text{(Eq.2)}$$

where φ is porosity, and GD is sediment grain density. The porosity was calculated from the water content. At all stations, water contents decreased rapidly within the top 10-15 cm and were relatively constant below it. We used an average of porosities below 15 cm at each station for the MAR calculation. An average of GD below 15 cm was also used for the MAR calculation.

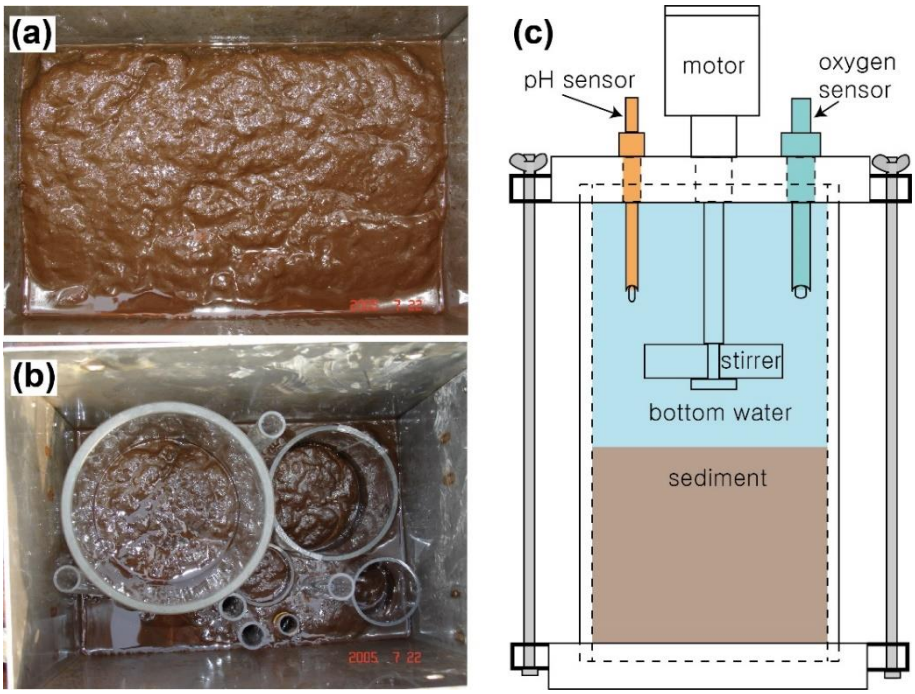

Figure 2. *Photographs of (a) sediment sampling using a box corer and (b) subsampling for geochemical analyses and sediment incubation chamber experiment. A schematic diagram of (c) sediment incubation chamber (Lee et al., 2019)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1216512179

Sediment incubation for calculation of oxygen consumption rate (OCR)

Bottom water taken from the Rosette-sampler was carefully added on top of the sediment at each stations where sediment sampling was performed using the box corer (*Fig. 2*). The water column height overlying the 30 cm sediment core was 18 cm, corresponding to a water volume of approximately 2 L. Immediately after adding bottom water, acryl cover was put on acryl core liner without trapping any air. The core was incubated together with the overlying water at approximately *in-situ* temperature (0.4°C) in a darkened, refrigerator for benthic exchange measurement of oxygen. A stirring speed in the overlying water of approximately 9 rpm was obtained by using a Poly Ethylene stirring bar attached to a Poly Ethylene rod 10 cm above the sediment surface during incubation time of 1-2 days (*Fig. 2*). The sediment incubation was performed until the oxygen was completely depleted or the reduction in oxygen became steady. At the beginning and end of the incubation, overlying water was collected, and the DO concentration was adjusted via Winkler titration. The oxygen consumption rate (OCR) was estimated by reference to the changes in the concentrations measured by the respective sensors in the chamber (Lee et al., 2019), and calculated using the *Equation 3*.

$$F = dC/dt \times V/A \quad \text{(Eq.3)}$$

where F is the net flux of substance via the water-sediment boundary layer (mmol m^{-2} day^{-1}), dC/dt is the slope of the changes in the concentration of oxygen over time (mmol L^{-1} d^{-1}), V is the chamber volume (L), and A is the area of the chamber's horizontal plane (m^2).

Surface chlorophyll-a concentration

The monthly surface chlorophyll-a concentration (mg/m^3) were used MODerate resolution Imaging Spectroradiometer (MODIS)-aqua level 3 data (4x4 km spatial resolution and Standard Mapped Image (SMI) projection) and obtained from NASA Ocean Biologoy Processing Group (http://oceancolor.gsfc.nasa.gov/). The chlorophyll-a concentration data on August, 2007 covered the study area was resampled from the level 3 data.

Results

Surface sediment characteristics

Figure 3 shows contents of the total organic carbon (TOC), total nitrogen (TN), calcium carbonate ($CaCO_3$) and biogenic opal (Si) in the UB sediment. TOC contents in the surface sediments were over 2.6% except station D3. TOC contents profiles showed dramatically decreasing from 2.6 to 1.7% in the uppermost 5 cm, and slightly decline below it. TN content profiles displayed same profiles of organic carbon contents at all stations. At surface sediments, TN contents varied from 0.25% to 0.4%. At all stations, calcium carbonate contents were under 1% at whole depth. The Si contents ranged from 10% to 16% at stations D2 and D4 (*Fig. 3*).

TOC contents are positively correlated with TN values at the UB sediments, with mean TOC/TN (C/N) molar ratio of 7.09, which is almost same as the Redfield ratio (6.63), indicating that the organic matter deposited in the UB is predominantly of

marine origin. Biogenic opal/TOC (Si/C) ratio ranged from 4.8 to 9.9, with a mean Si/C ratio is 7.2 (*Fig. 4*). The mean Si/C ratio of station D2 is 7.6, and station D4 is 6.7.

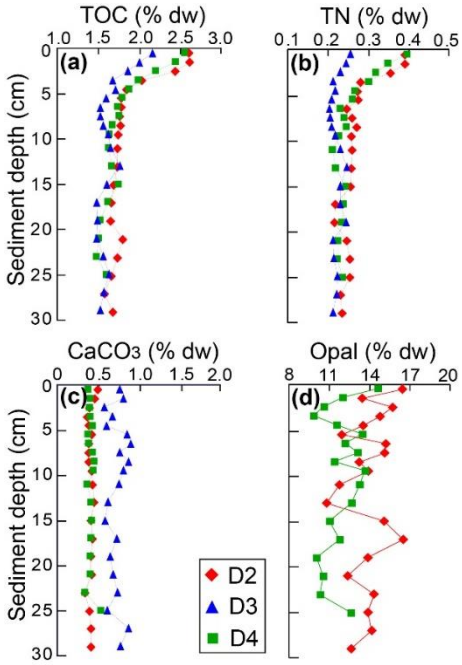

Figure 3. *Depth profiles of (a) total organic carbon (TOC), (b) total nitrogen (TN), (c) calcium carbonate ($CaCO_3$) and (d) biogenic opal in the Ulleung Basin sediment. In site D3, the biogenic opal content could not be analyzed*

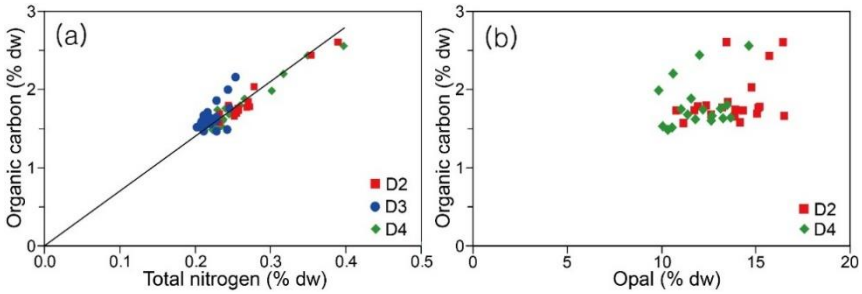

Figure 4. *Organic carbon versus (a) total nitrogen contents and (b) biogenic opal contents at the Ulleung Basin sediment. The C/N ratio was calculated from the slope of the best-fit regression line*

Sedimentation rate

Sedimentation rates were calculated primarily from excess ^{210}Pb distribution, with the common assumption that fluxes of sediment and the associated excess ^{210}Pb activity are reasonably constant on decadal to centennial timescales in the UB. The apparent sedimentation rates (ASR) varied between 0.036-0.047 cm year^{-1} (*Fig. 5*). The sediment mass accumulation rate (MAR) was calculated by porosity, sediment grain density (GD), and ASR in UB sediments. The porosity varied from 0.85 to 0.86, and the GD varied from 2.61 to 2.63 g cm^{-3} (*Table 1*). The calculated MARs ranging from 131 to 184 g m^{-2} year^{-1}, was relatively higher at the station D3 than at the station D4.

Organic carbon fluxes in the sediment

Time-series sediment trap was deployed at 2,100 m water depth in the UB from December 1998 to January 2000 (KORDI, 2003), which reported that OC content was approximately 6%. Input flux of organic carbon (IF) was calculated from the MAR and OC content at 2,100 m water depth. The calculated IFs varied from 7.89 to 11.08 gC m^{-2} $year^{-1}$. Burial flux of organic carbon (BF) was calculated from the MAR and the averaged OC content below the sediment depth 15 cm where it was not changed considerably (*Fig. 3*). The calculated BFs varied between 2.02-3.10 gC m^{-2} $year^{-1}$ (*Table 1*).

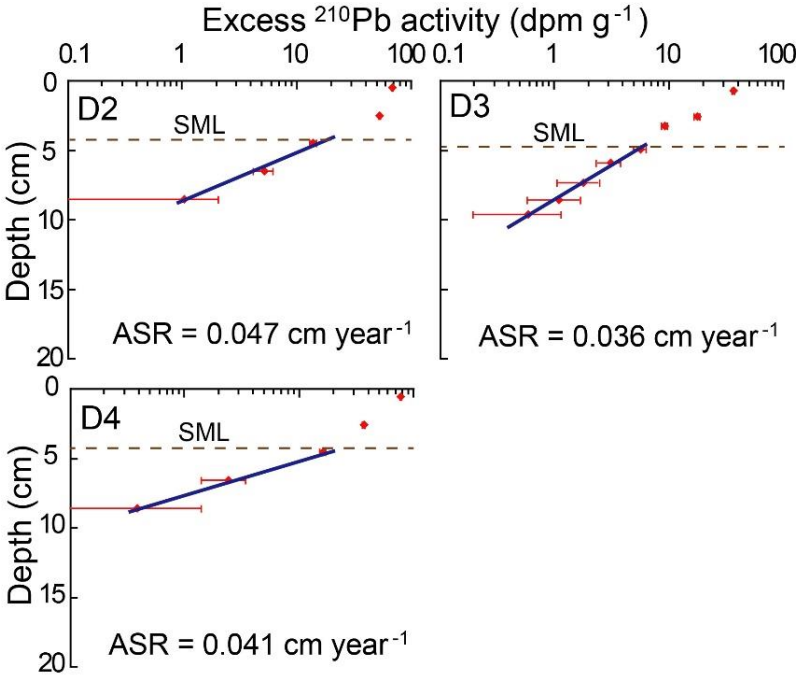

Figure 5. *Depth profiles of excess ^{210}Pb activities (error bars denote standard deviations) at site D2, D3 and D4 in Ulleung Basin sediment. The dotted lines indicate the surface mixed layer (SML)*

Table 1. *Water depth (m), Porosity(φ), grain density (GD), apparent sedimentation rate (ASR), mass accumulation rate (MAR), Input flux of organic carbon (IF), regenerated flux of organic carbon (RF), and burial flux of organic carbon (BF) in the Ulleung Basin sediment*

Site	Water Depth (m)	φ	GD (g cm^{-3})	ASR (cm $year^{-1}$)	MAR (g m^{-2} $year^{-1}$)	IF	RF	BF

[a] Regenerated flux of organic carbon calculated by subtracting burial flux from input flux

In sediments underlying well-oxygenated bottom waters, oxygen is the most important electron accepter for organic matter decomposition. The sedimentary oxygen consumption rate (OCR) is a good first-order indicator of organic matter oxidation rates in many locations. Concentrations of oxygen in the overlying water decreased linearly

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1216512179

with time over the entire period of the sediment incubations in this study (*Fig. 6*). A linear decrease was to be expected since oxygen concentration did not decrease by more than 5-10% of the almost initial bottom water values. At the stations D2 and D3 in April 2006, sedimentary OCRs were 1.85 and 2.05 mmol m^{-2} day^{-1}, respectively. At the stations D2 and D4 in August 2007, the measured sediment OCRs were 1.87 and 1.85 mmol m^{-2} day^{-1}, respectively (*Fig. 6*).

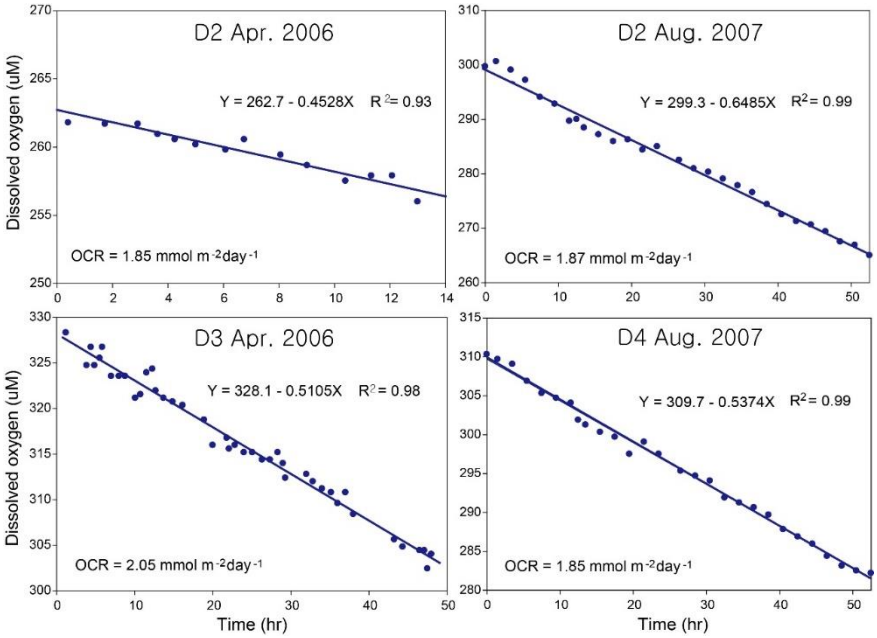

Figure 6. *Time-series of dissolved oxygen concentration in overlying water of chamber experiment at sites D2 and D3 in basin sediment in April 2006, at sites D2 and D4 in August 2007. The solid lines indicate the result of linear regression at considerable oxygen reduced section*

Regenerated flux of organic carbon (RF) was calculated from the sedimentary OCR, since oxygen most likely is the predominant electron acceptors in the mineralization process of sediment, and the oxygen is used in the reduction of the reduced species. In deep sediment, 90% of oxygen is consumed in the mineralization of organic matter and the rest is consumed in the reduction of the reduced species. So, the oxygen consumption and mineralization of organic matter coincides with nearly. In general, 138 moles of oxygen needed to oxidize 106 moles of organic carbon undergoing mineralization. At the stations D2 and D3 in April 2006, the RFs calculated with the OCR were 6.22-6.90 gC m^{-2} $year^{-1}$, respectively. At the stations D2 and D4, the RFs were 6.29-6.22 gC m^{-2} $year^{-1}$ in August 2007, respectively (*Table 1*).

Discussion

Sedimentary organic carbon

At the UB, the high organic contents (> 2.5%) are rarely found in the deep sea sediments, except for the Black Sea with a large river discharge (Cociasu et al., 1996; Reschke et al., 2002) and the Chilean upwelling areas with high primary productivity

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1216512179

(Schubert et al., 2000; Böning et al., 2005). The UB sediments are less influenced by river discharge since no major rivers drain into the sea along the east coast of Korea (Ikehara et al., 1994).

In the UB, OC flux estimated by the Honjo-type time-series sediment trap was 8.8 gC m^{-2} $year^{-1}$ at the 1020 m water depth from December 1998 to January 2001 (KORDI, 2003), which is about 3 times higher than that in the Bering Sea (Takahashi et al., 2000) and comparable with that in the Chilean upwelling area (Hebbeln et al., 2000). Therefore, the high OC contents in the UB appear to be resulted from the high export production in this area. Besides the high export production, the high OC contents in the UB may be due to the less dilution effect by calcium carbonate (Lee et al., 2008). Chen et al. (1995) suggested that carbonate saturation depths for aragonite and calcite in the E/JS were 300 and 1300 m, respectively. Thus, calcium carbonate contents in the UB sediments were less than 1% (*Fig. 3*), which caused the high OC contents in the UB.

The OC and TN values were used to calculate the C/N molar ratios, which were used to identify whether sedimentary organic matter had originated from algal or land–plant sources. The average C/N molar ratio is 7.09 (*Fig. 4*). Algae have C/N molar ratios between 4 and 10, whereas vascular land plants have ratios of 20 or greater (Jasper and Gagosian, 1990; Meyers, 1994; Prahl et al., 1994). The average Si/C ratios are 7.6 and 6.7 in sites D2 and D4, respectively (*Fig. 4*). The typical stoichiometric proportion of OC to biogenic opal in diatoms with adequate light and nutrients is approximate 7 (Haskell et al., 2013), this suggests that the deposited organic matter in the UB sediment was predominantly of diatoms.

In the UB sediment, more than 80% of deposited organic matter is composed of marine origin biogenic matter, which are dominated by silicate diatoms (Niggemann et al., 2007). In the surface ocean, they sink with POC and ballast minerals, such as siliceous opal and $CaCO_3$ at the same time (Amstrong et al., 2001; Honda and Watanabe, 2010). A $CaCO_3$ is mostly dissolved at a 1,300 m or shallower water depth, but POC and opal settle down on the deeper sea bed. Therefore, at over 2,100 m water depth, the $CaCO_3$ was slightly dissolved and did not significantly affect POC flux. However, the POC sink with high content of biogenic opal, leading to higher POC flux, which may have increased the OC content in the UB sediment.

Fluxes of organic carbon in the sediment

The ASR tends to decrease with increasing water depth, which is consistent with the previous result found by Hong et al. (1997) in the UB. In addition, the sedimentation rates of this study are very similar to those measured by Hong et al. (1997), 0.04-0.17 cm $year^{-1}$, in the same study area. Miralles et al. (2005) proposed an inverse linear relationship between the ASR and water depth in the northwestern Mediterranean margin sediments; ASR (cm $year^{-1}$) = $0.155 - 4.978 \times 10^{-5} \times$ water depth (m). This relation holds strongly in this study area, with only 10 % deviation between the measured values and the expected values from the above relationship.

The high BF values (over 2 gC m^{-2} $year^{-1}$) have rarely been found in the deep sea sediments (deeper than 2000 m), except for the Black Sea deep basin and intense upwelling areas. The BFs obtained from the deep basin of the Black Sea are similar to, or 2–3 times higher than those in the UB (Hay, 1998). In the Peruvian and Namibian upwelling areas, the IF is about an order of magnitude higher than in the UB (Calvert and Price, 1983; Böning et al., 2004). Although MAR estimated in the northern Gulf of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1216512179

Mexico is similar to that in the UB, the IF is much lower due to low organic carbon contents (Yeager et al., 2004).

Since oxygen respiration is the principal mineralization process in the sediment of the UB (Lee et al., 2008), a respiratory quotient of 0.77, which is consistent with the Redfiled stoichiometry for the oxidation of organic matter. But Accornero et al. (2003) presented that a respiratory quotient of 0.85 was assumed to convert sediment oxygen consumption into organic carbon remineralization in the sediment of the Gulf of Lions. In the conversion of oxygen consumption into mineralization rates, we assumed that oxygen was consumed by re-oxidation of reduced components within the sediment chamber. This process was found to significantly affect OC oxidation in other continental margin sediments (Canfiel et al., 1993). Previous studies have demonstrated that in sediments of the UB, oxygen and other processes such as Mn-oxide and Fe-oxide reduction, sulfate reduction does play a considerable role in the OC oxidation (Lee et al., 2008; Choi et al., 2009). In the UB, near the sediment-water interface is anoxic condition due to oxygen penetration depth is a few millimeters, and stimulate the heterotrophic activity. Consequently, converted RF by OCR is lower than calculated RF by subtracting BF from IF (*Table 1*).

Organic carbon cycle in the Ulleung Basin

In the UB, Hahm and Kim (2001) estimated the export flux of OC (EF, 64 gC m^{-2} $year^{-1}$) using tritium and helium isotopes and Kim et al. (2011) determined an annual average EF (59 ± 3 gC m^{-2} $year^{-1}$) using $^{238}U/^{234}Th$ disequilibrium. Based on Kim et al. (2011) seasonal average EFs were 216.0, 102.2, 55.2 and 84.2 mgC m^{-2} day^{-1} in spring, summer, autumn and winter, respectively. In spring, the EF was higher than other seasons. This value was attributed to the highest value of the phytoplankton biomass, and the primary production was higher than in summer and autumn. In summer, the EF was moderate value. In autumn, the value was about four times lower than spring. This lower EF value was attributed to the lower primary production in autumn. In winter, however, despite of high primary production, the EF was relatively very low.

Berger et al. (1989) suggested the proportions of OC export flux to primary production in the world open ocean and coastal ocean. The world open ocean and coastal ocean EF/PP ratios are 0.10 and 0.25, respectively. The annual average primary production in the UB was about 177.1 gC m^{-2} $year^{-1}$ (Kim et al., 2011), the EF/PP ratios are 0.36, 0.07 and 0.29 at station D2, D3 and D4, respectively (*Table 2*), average EF/PP ratio is 0.299 (Kim et al., 2011). Satellite-derived primary production ranged between 161-222 gC m^{-2} $year^{-1}$ in the E/JS and the UB is much higher than the Japan basin (Yamada et al., 2005). The EF in the UB was 2 times higher than the world open oceans.

The exported POC from the UB surface ocean is one of the largest sinks of atmospheric carbon dioxide. For example, *Figure 7* showed the satellite-derived chlorophyll-a concentration image in August, 2007. Increasing chlorophyll-a concentration was covered in the study area compared to around area. Hyun et al. (2009) proposed that phytoplankton and bacterioplankton production is enhanced by coastal upwelling and anticyclonic eddy (i.e. Ulleung warm eddy) in the UB. Omand et al. (2015) proposed that a submesoscale eddy-driven flux of POC is unresolved in global carbon cycle models but can contribute as much as half of the total springtime export of POC from the highly productive oceans. Yoo and Park (2009) suggested that the southwest region in the E/JS is highly productive due to southerly wind-driven

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1216512179

coastal upwelling from spring to fall. Various studies noted that East Korea Warm Current (EKWC) is important factor, which the production in the coastal region transported into the UB by anticyclonic Ulleung Warm Eddy (Isoda and Saitoh, 1993; Michell et al., 2005; Hyun et al., 2009). Time-series sediment trap was deployed at 2100 m water depth in the UB from December 1998 to January 2000 in order to estimate an annual flux of particulate matter (KORDI, 2003), which was 122 g m^{-2} $year^{-1}$, less than the MAR (161 g m^{-2} $year^{-1}$) estimated at site D4. The location of sediment trap deployment was apart about 50 km from site D4 (*Fig. 1*). The site D4 located in eddy region, so export production at D4 is higher than that of sediment trap mooring site.

Table 2. *POC Export flux (EF), Input flux (IF), regenerated flux (RF), and burial flux (BF) of organic carbon/primary production (PP) ratios in the Ulleung Basin. The average primary production in the Ulleung Basin was about 177.1 gC m^{-2} $year^{-1}$ (Kim et al., 2011). Open ocean and Coastal ocean are the average proportions of organic carbon flux to primary production in the world open ocean and coastal ocean (Berger et al., 1989)*

Site	EF / PP ratio	IF / PP ratio	RF / PP ratio	BF / PP ratio
D2	0.328	0.062	0.045	0.017
D3	0.062	0.044	0.033	0.012
D4	0.254	0.055	0.040	0.015
Ave. UB	0.211	0.054	0.039	0.015
Open ocean	0.100	0.010	0.009	0.001
Coastal ocean	0.250	0.066	0.058	0.008

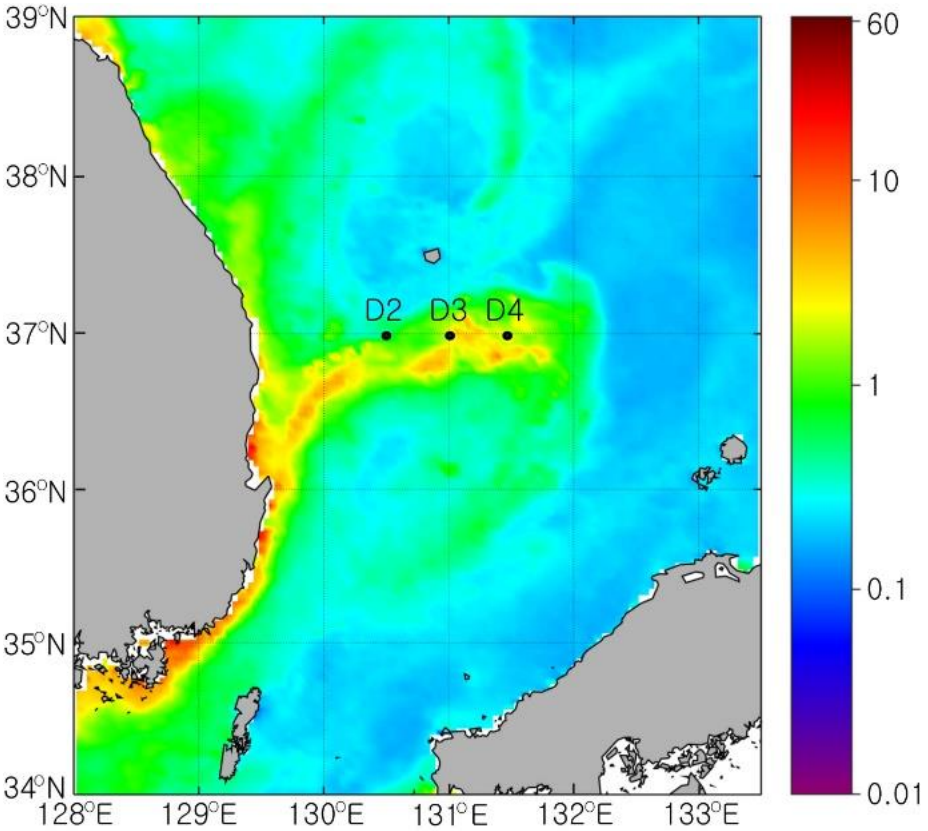

Figure 7. *Monthly mean of surface chlorophyll-a concentration derived from MODIS-aqua in the Ulleung Basin in August, 2007*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1216512179

Berger et al. (1989) suggested the proportions of IF, RF, and BF to primary production in the world open ocean and coastal ocean. In the world open ocean and coastal ocean benthic boundary layer, IF/PP ratios are about 0.010 and 0.066, respectively. In the UB deep benthic boundary layer, IF/PP ratio is 0.054 (*Table 2*). In the UB, the POC input to the benthic boundary layer is 5 times higher than in the world open ocean. In the world open ocean, coastal ocean, and UB sediments, RF/PP ratios are about 0.009, 0.058, and 0.039, respectively. The BF/PP ratios are 0.001, 0.008, and 0.015 in the open ocean, coastal ocean and UB, respectively (*Table 2*). Over 1% of primary production is buried on the UB sediment. It is a very rare case in the world coastal ocean and open ocean. Although a large value of IF in the coastal ocean sediment does not contribute significantly to carbon removal. In the coastal area, about 90% of OC deposited in sediments is remineralized, and returned to the water mass with CO_2. In the UB sediment, however, only approximately 80% of the deposited OC is remineralized and approximately 20% is buried. It is important that the UB play a significant role in deep ocean carbon storage.

Conclusion

The UB sediment of E/JS are characterized by high OC contents and high IF of OC. High OC contents (over 2.5%) and high IFs in the deep basin sediments have rarely been found, except for the Black Sea deep basin and intense upwelling areas. The high OC content appeared to result from high export production at surface water in UB. A mean organic matter C/N molar ratio is 7.09, indicating that the organic matter is predominantly of marine origin. The ASRs calculated by activities of excess ^{210}Pb were ranged between 0.036-0.047 cm year^{-1}. The MARs calculated from the ASR and GD, ranged between 131-184 g m^{-2} year^{-1} and agree well with mass flux determined by the previous time-series sediment trap result (122 g m^{-2} year^{-1}). The IF and BF estimated by the MAR were ranged between 7.89-11.08 gC m^{-2} year^{-1}, 2.02-3.10 gC m^{-2} year^{-1}, respectively. The RF estimated by OCR were ranged 6.22-6.59 gC m^{-2} year^{-1}, but RF calculated by subtracting BF from IF were ranged between 5.87-7.98 gC m^{-2} year^{-1}. The average IF/PP, RF/PP and BF/PP ratios of UB sediments were 0.054, 0.039, and 0.015, respectively.

In the UB, high proportion exported to the deep ocean with organic carbon produced by the primary production, high efficiency deposited to the deep boundary layer, high efficiency buried in the sediment. The UB might play an integral role in the deposition and removal of organic carbon. The area of E/JS is only 0.3% of the world ocean, however, may play a fundamental role in the global carbon cycle. These results show promise in terms of carbon cycle in the regions with high production input. The combined data on the in-situ and remote-sensing data clearly reproduce the understanding of the spatial and temporal pattern than is possible by using hydrographic cruise data. This approach is particularly important for interpreting deep waters in the regional and/or global scales.

Acknowledgements. The authors thank the captain, officers and crew of the *R/V Eardo* who were most helpful in all our shipboard operations. We also thank to Dr. Jeong Hee Han of Korea Basic Science Institute, Republic of Korea for ^{210}Pb measurements. Abstract. Pigmentation is closely associated with various behaviors, and it is also an important feature that influences the popularity and price of ornamental fish. However, the molecular mechanism that regulates the pigmentation of fish is barely understood. There are two clearly different pigmentation phenotypes, i.e. light and dark phenotypes, in the same natural population of *Leptobotia taeniops*. Type and distribution of chromatophores is the cellular basis of the pigmentation. To analyze the composition of chromatophores in the light and dark phenotypes of *L. taeniops* and the correlation of the pigmentation to the expressions of pigment synthesis genes, we studied the pigment cell types and distribution in the skin of *L. taeniops* by microscope, and analyzed the expressions of genes that regulate melanin production using real-time qRT-PCR. Our results showed that the amount of melanophores in the skin was the major factor that caused the pigment deviation of *L. taeniops* living in the same habitat. The expressions of *TYR*, *Tyrp1*, and *Dct* genes were significantly higher in the skin of the dark phenotype than those in the light phenotype. This result implied that the amount of melanophores was influenced by the expression of these genes in the skin of *L. taeniops*.
Keywords: *chromatophores, ecological adaptation, fish skin, melanin-related gene, pigment cell, real-time fluorescent quantitative PCR*

Introduction

Pigmentation of fish is associated with various behaviors, such as warning, courtship, and hiding (Blakeslee et al., 2009; Culumber, 2013; Jiang et al., 2019). Additionally, in some species of fish, such as *Poecilia reticulate*, bright flashy colors may show a parasite infection (Houde and Torio, 1992) and the pigmentation has also been associated with immunocompetence in *Betta splendens* (Clotfelter et al., 2007). In ornamental fish market, pigmentation is an important feature that influences the popularity and price of ornamental fish. However, although cellular basis and development pattern of pigmentation of some fish species, such as *Betta splendens*, has been studied (Khoo et al., 2014; Carey et al., 2015), the molecular mechanism that regulates the pigmentation of fish is still rarely studied.

Leptobotia taeniops is a small freshwater fish living in Yangtze River basin (Hunan Fisheries Science Institute, 1980; Ding, 1994; Ni and Wu, 2006; Fang et al., 2011). There are two obviously different pigment phenotypes, i.e. light and dark phenotypes, in the same natural population of *L. taeniops* (Jiang et al., 2019), and the difference is not influenced by heredity (Meng, 2011).

Type and distribution of chromatophores is cellular basis of the pigmentation (Khoo et al., 2014). It has been well documented that teleost fish have various chromatophore types, such as melanophores, xanthophores, erythrophores, iridophores, cyanophores, and leucophores (Jeon et al., 1993). Since the light phenotype of *L. taeniops* is of a near golden color and the dark one is yellowish-brown, and there are black stripes and splashes on their body (Jiang et al., 2019), melanophores and xanthophores were maybe the major chromatophores that influence the pigmentation of *L. taeniops*. In addition, melanin is the chromogenic substance in melanophores and tyrosinase plays an important role in synthesis of melanin (Lamoreux et al., 2001), and in our previous study, we have proved that the expression of tyrosinase gene in skin significantly higher in the light phenotype of *L. taeniops* than those in the dark phenotypes (Jiang et al., 2019). However, although it is important to elucidate the molecular mechanism that regulates the pigmentation of *L. taeniops* to adapt their external environment and protect wild *L. taeniops*, how the expression of tyrosinase gene in skin influences the pigmentation of *L. taeniops* and whether it associates with other genes is still unknown.

To analyze the composition of chromatophores in the light and dark phenotypes of *L. taeniops* and the correlation of the pigmentation to the expressions of pigment synthesis genes, we studied the pigment cell types and distribution by microscope, and analyzed the expressions of genes that regulate melanin production using real-time quantitative reverse transcription PCR (qRT-PCR). The results would provide important reference to elucidate the molecular mechanism that regulates the pigmentation of *L. taeniops* to adapt their external environment.

Materials and methods

Sample collection

The fish samples were collected from Yueyang Section (113.2051 N, 29.5140 E) of the Yangtze River during July to September, 2017, and transported to the Aquaculture Laboratory of Hunan Agricultural University to temporary culture in a circulating water system at 25 ± 1 °C. Healthy light and dark phenotype samples (6 specimens of each phenotype) were anaesthetized using MS-222, photographed, and measured body lengths and body weights. Subsequently, they were dissected and their sex was identified through sex gland. The skins at both sides of the dorsal fin base were collected using anatomical tools for microscopic examination of chromatophores and total RNA extraction.

Microscopic examination of chromatophores in skin of L. taeniops

The skins for microscopic examination of chromatophores were washed using phosphate buffer and made temporary slides. The temporary slides were examined and photographed using an Olympus BX53 microscope (Olympus, Japan). Amount of chromatophores in randomly selected 100 × 100 μm square regions of the photographs was counted and each phenotype was examined 10 times.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1218112189

Another 1 × 1 cm of skins were fixed 24 h using 4% paraformaldehyde tissue stationary fluid and paraffin sections of the skins were prepared and hematoxylin and eosin (HE) staining was conducted according to previous reports (Huang et al., 2018; Li et al., 2019). Then the skin tissue slices were examined and photographed using an Olympus BX53 microscope (Olympus, Japan).

Total RNA extraction and qRT-PCR

Total RNA was extracted from 50–80 mg of each skin sample using E.Z.N.A total RNA kit I (OMEGA, China) according to the manufacturer's introduction. The first stand of cDNA was synthetized using a RevertAid first strand cDNA synthesis kit (Fermentas, USA) with Oligo(dT)$_{18}$ primer according to the manufacturer's introduction (Jiang et al., 2019). Fluorescent quantitative PCR primers were designed using primer 6.0 software according to tyrosinase (*TYR*), tyrosinase-related protein 1 (*Tyrp1*), dopachrome tautomerase (*Dct*), Microphthalmia-associated transcription factor (*Mitfa*), Sox10 and melanocortin 1 receptor (*MC1R*) gene sequences of Cyprinidae fish in GenBank database (*Table 1*). β-Actin gene was used as endogenous reference (Jiang et al., 2019).

β-Actin	β-Actin-R	CTCGAAGTCAAGGGCAACAT	Internal control primer	Jiang et al., 2019

To calculate the amplification efficiencies (*E%*) and the correlation coefficients (R^2) of the primers, the cDNA was gradiently diluted to 5, 25, 125, and 625 times and the E% and R^2 of the primers were calculated by qRT-PCR. The qRT-PCR was conducted as our previous description (Ni et al., 2018; Jiang et al., 2019). Three technical repetitions of each sample were set to exclude technical error. The results were collected and analyzed using CFX manager software 3.1. Relative expressions of the genes were calculated by the comparative Ct ($2^{-\Delta\Delta Ct}$) method (Spivak et al., 2012).

Data analysis

Each parameter result is presented as means ± standard deviation (SD). Independent *t*-test was used to compare the significance of difference between the light and dark

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1218112189

phenotypes. p-values < 0.05 were considered statistically significant. The statistical analyses and plotting were conducted using R 3.5.1 (R Core Team, 2017).

Results and discussion

Amount of melanophores caused pigment deviation of L. taeniops

Type and distribution of chromatophores is cellular basis of the pigmentation. Specific combinations of chromatophores in skin of *Betta splendens* formed the pigmentation patterns of the dark blue, ultra-maine, turquoise-bronze, and golden strains (Khoo et al., 2014). There were two major chromatophores, i.e. melanophores and xanthophores in the skin of *L. taeniops* (*Fig. 1*). There was no significant difference of the xanthophore amounts in the skin between light and dark phenotypes (Independent *t*-test, $t = 0.893$, $p = 0.384$). However, the melanophore amounts were significantly increased in dark phenotype skin than those in light phenotype skin (Independent *t*-test, $t = 10.622$, $p < 0.001$; *Fig. 1*). The result showed that the pigment deviation between light and dark phenotypes of *L. taeniops* mainly caused by the difference of melanophore amount.

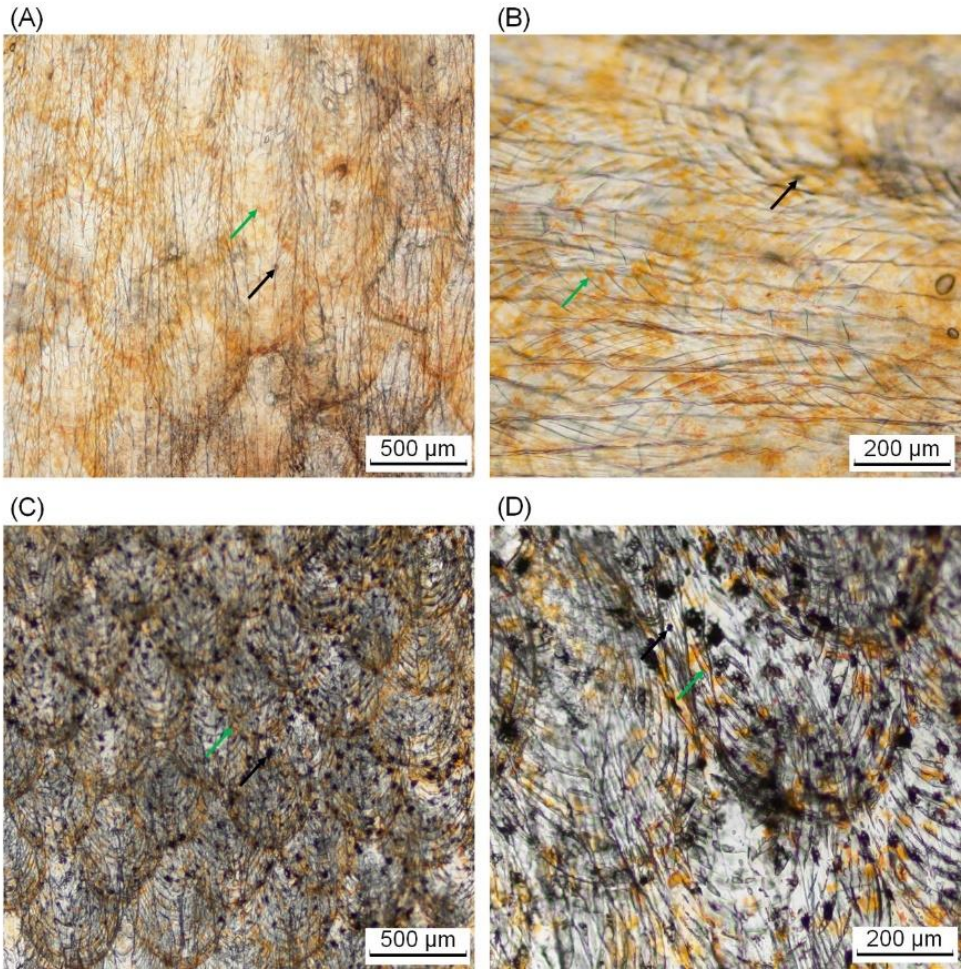

Figure 1. *Microscopic profiles of skin temporary slides showed pigment cells of Leptobotia taeniops. A and B: light phenotype of L. taeniops; C and D: dark phenotype of L. taeniops. The black arrows indicate the melanophores, and the green arrows indicate the xanthophores*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1218112189

The tissue structure of *L. taeniops* skin was analogous to other fish, including epidermis (EP; Approximately 50-100 μm), dermis (D; Approximately 130-200 μm), and subcutaneous layer (SL). The epidermis did not keratinization and covered by multilayer epithelial cells. The epithelial cells were flat and arranged closely. Under the epithelial cells, glandular layer occupied the majority of the epidermis. It was composed by goblet-cell (GC), club cell (CC), and epithelial cell (EC). The malpighian layer was close to the basement membrane. The dermis was constituted by dense connective tissue and was rich in fiber. The dermis was divided into the loose layer (SS) and the compact layer (SC) according to the fiber arrangement. The loose layer occupied a large part of the dermis, and the fibers in the loose layer arranged loosely. The fibers in the compact layer arranged closely. The subcutaneous layer located below the dermis, and contained a large number of fat cells, vessels and nerves (*Fig. 2*). The pigment cells of *L. taeniops* mainly distributed in the dermis, and a small amount of the pigment cells distributed in the epidermis. The pigment cells were stained into deep color by HE staining as the cells contain pigment granule. Shapes of the pigment cells were diversiform, and were mainly long strip and asteroid. A large number of pigment cells distributed in the loose layer and their distribution was not continuously and evenly (*Fig. 2*). This result implied that the pigment cells were not even-distributed in the skin of *L. taeniops*, in accordance with the results of the skin temporary slides.

The dermis of light *L. taeniops* was thicker than those of dark phylotype, while the epidermis and subcutaneous layer of light *L. taeniops* was thinner. The epithelial cells in the skin of light *L. taeniops* were more than those of dark phylotype (*Fig. 2*). These results implied that although the amount of melanophores caused the pigment deviation of *L. taeniops*, there was a deeply histological basis that influenced the amount of melanophores. This may be influenced by expression of the pigment genes.

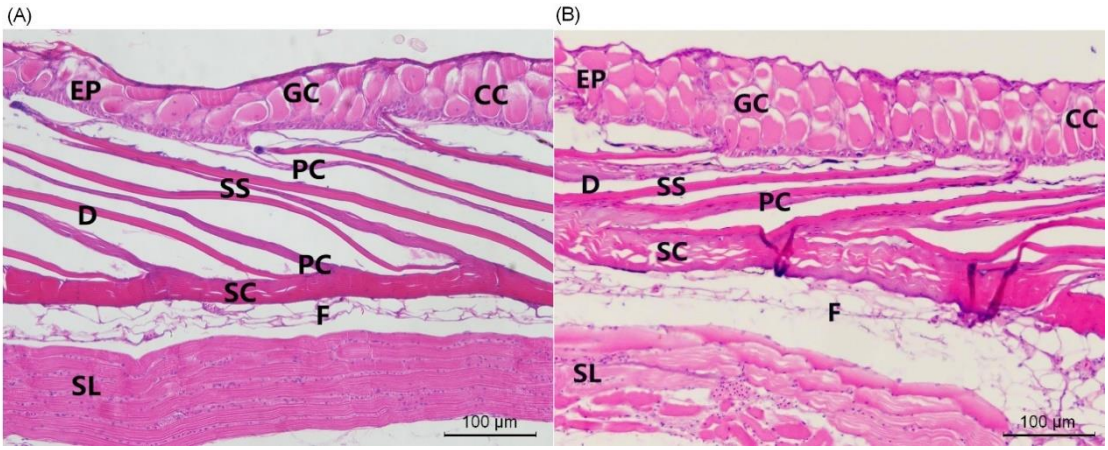

Figure 2. *Microscopic profiles of the skin paraffin sections with H-E dyeing of Leptobotia taeniops. A: Light phenotype; B: dark phenotype. EP, epidermis; D, dermis; SL, subcutaneous layer; SS, loose layer; SC, compact layer; GC, goblet cells; CC, club cell, EP, epithelial cells; PC, pigment cells; F, fat cells*

TYR, Tyrp1, and Dct genes were higher expressed in light than in dark L. taeniops

The first step of melanin production involves *TYR* which catalyzes the transformation of tyrosine to dopaquinone and then dopachrome in the eumelanin pathway. Then, *Dct*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1218112189

catalyzes the transformation of dopachrome to dihydroxyindole carboxylic acid (DHICA) and *Tyrp1* catalyzes the oxidation of DHICA and finally biosynthesis of eumelanin (*Fig. 3*; Murisier and Beermann, 2006). In addition, *MC1R* protein shows high affinity for α-melanocyte-stimulating hormone (α-MSH) and bingding of α-MSH to *MC1R* activated adenylate cyclase and increased cyclic adenosine monophosphate production, thus activating a variety of intracellular pathways which promote a switch in melanin synthesis from pheomelanin to eumelanin (Sturm et al., 1998). *Mitf* is critically involved in melanin synthesis, which enhances transcription of the genes encoding major enzymes in the melanin synthesis pathway, including *TYR*, *Tyrp1*, *Tyrp2*, and *Dct* (Yasumoto et al., 1994, 1997; Udono et al., 2000; Saito et al., 2003). Sox10 regulates the development of neural crest-derived melanocytes and the early development of the prospective neural crest (Aoki et al., 2003; Honoré et al., 2003). Therefore, we analyzed the expression of these genes in the skin of the light and dark *L. taeniaps*. The *E%* of TYR, Tyrp1, Dct, Mitfa, Sox10, and MC1R primers were 104.8%, 101.8%, 102.6%, 103.8%, 101.4%, and 95.5%, respectively; and the R^2 were 0.991, 0.998, 0.997, 0.997, 0.994, and 0.987, respectively. All of them were achieved the technical requirements of qRT-PCR that 90% < *E%* < 105% and $R^2 > 0.98$. The results showed that these primers could be used to quantify the expressions of these genes in the skins of *L. taeniops* with different pigmentation.

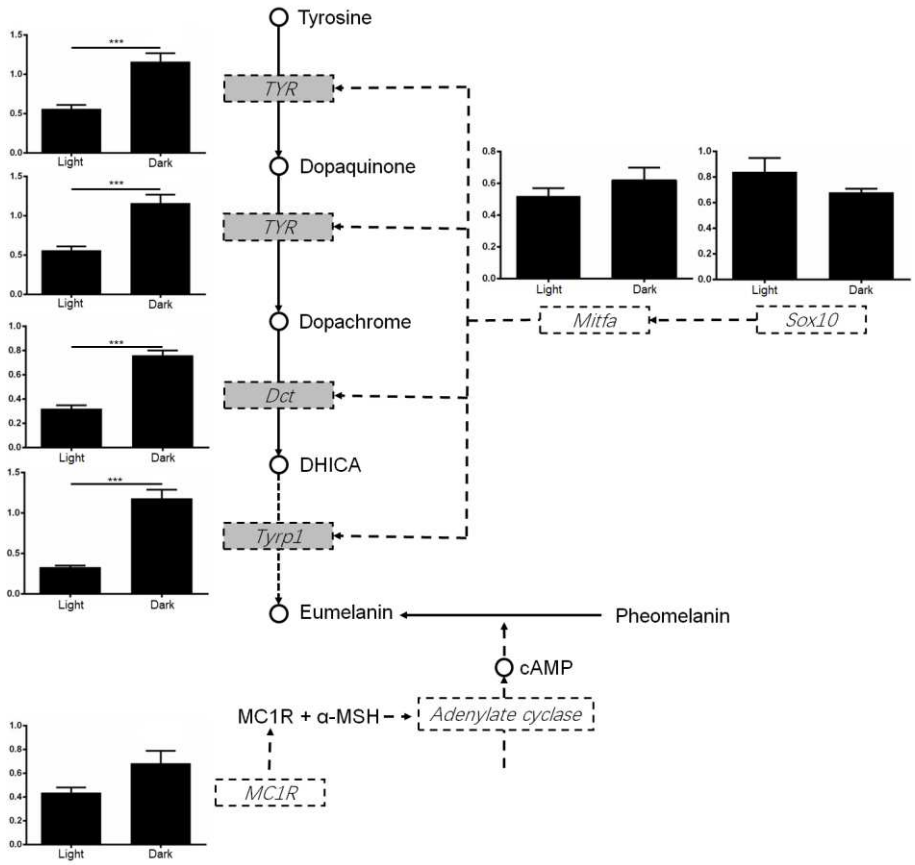

Figure 3. *Regulatory pathway of eumelanin biosynthesis in the skin tissue of Leptobotia taeniaps. TYR, tyrosinase; Tyrp1, tyrosinase-related protein 1; Dct, dopachrome tautomerase; MC1R, melanocortin 1 receptor; α-MSH, α-melanocyte-stimulating hormone; cAMP, cyclic adenosine monophosphate; Mitfa, microphthalmia-associated transcription factor. *p < 0.05; **p < 0.01; **p < 0.001*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1218112189

Although only six specimens of each phenotype were analyzed through qRT-PCR, qRT-PCR experiments with small sample size had been reported in previous reports, and their results were also considered reliable (Varkonyi-Gasic et al., 2007; Vieth et al., 2007). In the present study, the expressions of *TYR* (Independent *t*-test, $t = 4.966$, $p < 0.001$), *Tyrp1* (Independent *t*-test, $t = 7.603$, $p < 0.001$), and *Dct* (Independent *t*-test, $t = 8.800$, $p < 0.001$) genes in the skin of the dark phenotype were significantly higher than those in the light phenotype, while the expressions of Mitfa (Independent *t*-test, $t = 1.060$, $p = 0.314$), Sox10 (Independent *t*-test, $t = 1.403$, $p = 0.191$), and *MC1R* (Independent *t*-test, $t = 1.986$, $p = 0.075$) were not detected significant difference (*Fig. 3*). These results showed that the eumelanin biosynthesis was the major reason that caused the pigment deviation of *L. taeniops*. However, the expressions of the upstream regulation factors, i.e. *Mitfa*, *Sox10*, and *MC1R*, were not significantly different. This result implied that there was probably another undiscovered way to regulate the expression of *TYR*, *Dct*, and *Tyrp1* genes and the eumelanin biosynthesis.

Sox10 is a major regulator of neural crest formation (Honoré et al., 2003) and it is reported that regulates the development of neural crest-derived melanocytes in *Xenopus* (Aoki et al., 2003). In addition, MITF expression is maintained in about 90% of melanomas and a genomic amplification of MITF has been frequently observed in metastatic melanomas (Beuret et al., 2011). However, our results showed that both *Sox10* and *Mitfa* genes were not significantly upregulated in the skin of *L. taeniops*. These results implied that the developments of neural crest melanocytes and skin melanocytes were through different pathways, and pigmentation was probably not a direct factor that causes melanomas. In addition, our results also implied that through regulating *TYR* pathway, but not *Sox10* pathway, probably changed the production of melanophores and produced novel ornamental fish species.

Conclusion

In summary, amount of melanophores in the skin was the major factor that caused the pigment deviation of *L. taeniops* living in the same habitat. The amount of melanophores was influenced by the expression of *TYR*, *Tyrp1*, and *Dct* genes in the skin of *L. taeniops*. The expressions of these genes were significantly higher in the skin of the dark phenotype than those in the light phenotype. However, what and how external factors regulate the expression of these genes still need to be further studied in future.

(Received 1st May 2019; accepted 11th Jul 2019)

Abstract. The objective of this study was to explore the effect of transient changes of Pilot-Scale Anaerobic-Anoxic-Oxic Process (A2O). The effects of transient changes in Tibet, China of water temperature on water quality indicators such as chemical oxygen demand (COD), the total phosphorous (TP), total nitrogen (TN) and ammoniacal nitrogen (NH_4^+-N), as well as microorganism and mixed liquor suspended solids were analyzed. The A2O system had a hydraulic retention time of 21 h, a mixture of the reflux ratio of the mixed liquor of 200%, a reflux ratio of the sludge of 100%, a temperature fluctuation range of 8-25 °C, and a water sampling interval of 3 h. The results showed that the optimal removal rates of different water quality indicators were different. The removal of COD, TN and NH_4^+-N mainly occurred in anaerobic tank and TP mainly in anaerobic tank and oxic tank. There was no obvious relationship between microorganism density and indicator organisms in anoxic tank, oxic tank and anaerobic tank. The concentrations of COD, TP, TN and NH_4^+-N in the effluents did not meet the first grade A standards, and the mixed liquid suspended solids did not show a significant growth trend with increasing temperature.
Keywords: *nitrogen and phosphorus removal, dissolved oxygen, microorganism, A2O, Tibet*

Introduction

Currently, the Anaerobic-Anoxic-Oxic (A2O) process, improved from the traditional activated-sludge process, has become the most popular sewage treatment method in Tibet, China (Chen et al., 2018). The sewage temperature in Tibet has obvious inter-annual and diurnal changes, the daily temperature difference can reach about 10 ℃, and the inter-annual temperature difference can reach about 15 ℃, which is mainly caused by drastic change of environmental temperature and centralized of water consumption time. Frequent change of water temperature could influence microbial growth and community structure, and adsorption performance and sedimentation performance of activated sludge, which ultimately leads to large fluctuations in wastewater treatment efficiency.

It is widely agreed that the effect of A2O is influenced by the unique environment factors of the plateau, namely, water temperature and atmospheric pressure. At present, according to the on-site measurement, the lowest temperature of sewage in Linzhi City is -1 ℃, the highest is 14 °C (Zong et al., 2018). According to the comprehensive analysis of the survey, the reason for the sewage temperature of -1 °C in Linzhi City is mainly due to the following two reasons: firstly, the sewage pipeline in Linzhi City is too long, and the sewage flow is too small, resulting to a large heat loss in the sewage flow; secondly, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1219112202

groundwater level is too high, and some groundwater seeps into the sewage pipeline, causing its average temperature to be too low (Zong, 2017).

Our previous study has shown that the traditional activated-sludge process cannot satisfactorily remove nitrogen and phosphorus from domestic sewage in Tibet (Zong, 2017). Temperature is a main influencing factor of sewage treatment efficiency (Ai et al., 2018). In the process of the phosphorus removal of sludge denitrification, the release and absorption rates of phosphorus are changed under excessively high or low temperatures, and the proportion of denitrifying phosphorus accumulating organisms in the activated sludge is greatly affected by temperature variation (Zhang et al., 2016). In addition, the nitrification capacity of the sewage treatment system is obviously weakened when the water temperature falls below 15 °C, and even lost totally when the temperature drops below 4 °C (He et al., 2010; Li et al., 2013). Thus, the nitrogen removal is severely inhibited under a low temperature (Li et al., 2014).

As for the A2O process, the nitrification/denitrification is weakened at a low temperature and a high sludge load. In this case, nitrite nitrogen will accumulate in the system, and denitrifying phosphorus removal will happen in the anoxic tank. The phosphorus removal efficiency of the system could decline due to the sludge bulking induced by non-filamentous bacteria (Li et al., 2014), and the lack of small molecular carbons required for phosphorus release by phosphorus-concentrating bacteria (as the hydrolysis of macromolecular organic matter is suppressed under a low temperature) (Shen et al., 2017).

The atmospheric pressure has a direct bearing on the oxygen partial pressure, and the oxygen partial pressure controls the dissolved oxygen (DO) in water. When partial oxygen pressures was below 40 kPa, the removal efficiencies of chemical oxygen demand (COD), and ammoniacal nitrogen (NH_4^+-N) increased with the increase of DO, meanwhile, nitrification was the main control process in simultaneous nitrification and denitrification (SND). However, partial oxygen pressures above 40 kPa did not affect their removal efficiencies, and denitrification became the main control process in SND (Xing et al., 2013). The nitrification can be enhanced by extending the aeration time, while the denitrification can be stimulated by prolonged exposure to anaerobic conditions (Yoo and Lee, 2015). Under low aeration, the nitrogen and phosphorus removal were greatly hindered in the A2O system (Li et al., 2013). The DO could affect the conversion of polyhydroxy alkyl ester and glycogen (Chen et al., 2014), as well as the activity of desulfurase and polyphosphatase, and affect phosphorus removal subsequently. The total number and activity of ammonia oxidizing bacteria are respectively determined by the hydraulic retention time (HRT) of solids and the DO concentration (Limpiyakorn et al., 2005).

Transient and non-steady state of domestic sewage is relatively common, and the temperature of sewage varies significantly during a day in Tibet. The present study used A2O system as a typical sewage treatment process to investigate the removal rates of nitrogen and phosphorus in daily responding to water temperature change, analyze the characteristics of the microbes in anaerobic tank, anoxic tank and oxic tank, and explore the mechanisms of nitrogen and phosphorus removal and microbial transient response under plateau environmental factors.

Materials and methods

Description of the anaerobic-anoxic-oxic process system and wastewater

A pilot-scale A2O sewage treatment device was designed and fabricated with plexiglass in Tibet, China. With an effective volume of 210 L, the device consists of 8 segments: the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1219112202

first 2 are anaerobic tanks with an effective volume of 35 L, the middle 2 are anoxic tanks with an effective volume of 58 L, and the last 4 are oxic tanks with an effective volume of 117 L. Besides, the effective volume of the sedimentation tank is 210 L. In both anaerobic and anoxic sections, each tank has a 50 rpm stirring device at the bottom; in each oxic tank, there is an aerator for oxygen supply. Inflow, return sludge and nitrifying liquid are controlled by a peristaltic pump. To maintain a constant temperature, the water temperature was regulated by a constant temperature circulator. In each tank, a sampling hole was opened on the tank wall. Before the experiment, the activated sludge was cured for 32 d. The temperature, MLSS, and volume percent of MLSS after settling for 30 min (SV30) were set to 22.5 °C, 4,787 mg/L and 35%, respectively.

The urban domestic sewage in Linzhi was directly adopted for our experiments. The main water quality indices of the sewage are given in *Table 1*.

Table 1. *Quality indicators of sewage*

Potential of hydrogen	Dissolved oxygen (mg/L)	Temperature (°C)	Chemical oxygen demand (mg/L)	Total nitrogen (mg/L)	Total phosphorous (mg/L)	Ammoniacal nitrogen (mg/L)
6.20~8.70	1.87~4.68	8.05~23.10	217.17~526.36	23.12~112.51	2.59~7.28	12.09~45.15

Operation of the anaerobic-anoxic-oxic process

The operation of the A2O device was studied under transient change of water temperature, in order to disclose the law of removal rates under different water temperatures. The control plans for the three parameters are specified below. On water temperature control, the inlet water flow was designed as 10.0 ± 0.1 L/s, HRT as 21.0 ± 0.2 h (the HRT ratio between anaerobic tank, anoxic tank and oxic tank = 35:58:117), DO as 3.0~4.0 mg/L, the reflux ratio of the mixed liquor $R_i = 200\%$, and the reflux ratio of the sludge R = 100%. Both the mixed liquor and the sludge were continuously refluxed. Temperature fluctuation range is set to 8~25 °C. The temperature was controlled with an error of or less than 0.1 °C. The experiment was replicated three times. Water quality sampling interval was 3 h (*Fig. 1*).

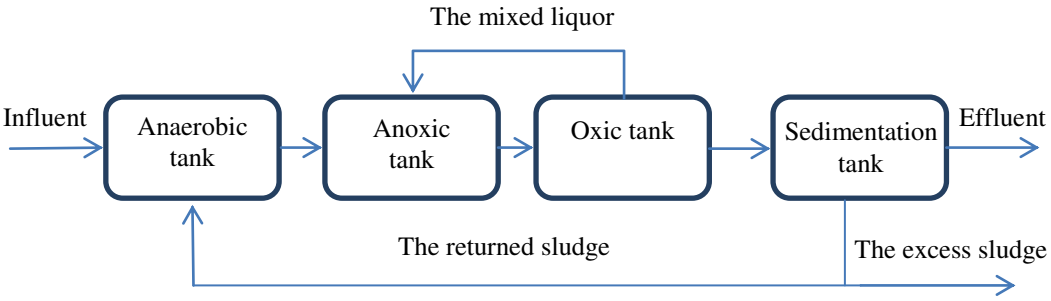

Figure 1. *Schematic of anaerobic-anoxic-oxic process*

Analytical methods

The measurement methods of the test indicators are selected according to the existing standards (State Environmental Protection Administration of China, 2002).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1219112202

Statistical analysis

All data were initially verified for normality using the Shapiro-Wilk method. The differences between different treatments were evaluated by one-way analysis of variance in SPSS, followed by Tukey's test. All differences were considered significant at $p < 0.05$. All these statistical analyses were performed using the SPSS statistical package (ver. 22.0, SPSS Company, Chicago, IL, USA).

Results

Removal rate at temperature transients

Figures 2–5 provide the removal rates of COD, TP, TN and NH_4^+-N in anaerobic, anoxic and Oxic tanks at different temperatures.

As shown in *Figure 2,* the COD removal effect in the anaerobic tank maintains a good removal efficiency under the temperature from 8 °C to 25 °C. The removal efficiency of individual temperatures is low, and the average removal rate is 67.18%, which is lower than 75.69% (Huang et al., 2017); COD is mainly removed in the anaerobic tank with a maximum removal rate of 89.09% and a minimum removal rate of 34.11% corresponding to the temperature of 18.2 °C and 22.3 °C, respectively. The COD removal effect in the anoxic tank is generally acceptable, and the COD removal rate in the anoxic tank is only increased by 4.44%, which is lower than 12.72% (Huang et al., 2017), which increases the maximum value by 15.91% and the minimum value of -8.13% corresponding temperature are 22.3 °C and 15.1 °C, respectively; the maximum removal rate of 87.48% and the minimum value of 50.02% corresponding temperatures are 18.2 °C and 22.3 °C. The COD in the oxic tank can be removed as a whole due to the removal of the anaerobic tank and anoxic tank, but the average value of the relative anoxic removal rate is 10.07%, which is larger than 5.98% (Huang et al., 2017), the removal rate increases by a maximum of 27.69% and the minimum value of -0.90%, the corresponding temperatures are 8.98 °C and 18.2 °C; the average COD removal rate is 81.69%, and the maximum value of 91.15% and the minimum value of 70.06% corresponding temperature are 8.45 °C and 17.50 °C. The above trend is also consistent with the low temperature and room temperature COD treatment effects, but the effect is poor (Li et al., 2012); according to the COD removal rate effect, the test temperature is 18.2 °C, the removal rate can reach 92.19%, the measured COD effluent can reach the first grade A standards (GB18918-2002), but other temperatures are difficult to reach this standard.

As shown in *Figure 3,* the TP removal effect in the anaerobic tank changes obviously between 3.54% and 83.41% at the temperature of 8~25 °C. The removal efficiency of individual temperatures is low, and the average removal rate is 30.15%, which is lower than 69% (Bao et al., 2012). The highest TP removal rate of 63.58% and the lowest value of 5.56% corresponding temperatures are 12.00 °C and 22.40 °C, respectively. The anoxic tank contributes very little to the TP removal rate which is only increased by only 2.50%, which was lower than 56.00% (Zhou et al., 2013), which increased the maximum value by 20.19% and the minimum value by -13.86% corresponding to temperatures of 14.70 °C and 8.05 °C, respectively; the maximum removal rate of 71.95% and the minimum value of 6.06% corresponding temperatures are12.00 °C and 22.4 °C. The TP in the oxic tank is not obvious due to the poor removal rate of the anaerobic tank and anoxic tank, but the average value of the relative anoxic removal

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1219112202

rate is 11.90%. Considering the dilution of the anaerobic section, the effect of removing TP is more significant, but the overall TP removal rate is still low (Zhou et al., 2013), the removal rate increases by 46.93% and the minimum value by -3.50%, and the corresponding temperatures are 8.49 °C and 22.3 °C, respectively; The average removal rate was 44.55%, and the maximum values of 83.41% and the minimum value of 3.54% corresponding to the temperature of 12.00 °C and 22.40 °C, respectively. When the test temperature is 12.00 °C, the removal rate of TP can reach 83.41%, and the sedimentation tank effluent regarding the TP can reach the grade 1 B standard (GB18918-2002), but TP removal rate can not reach this standard at the other temperatures. Overall, the removal rate of TP has two critical points of 9.54 °C and 14.70 °C.

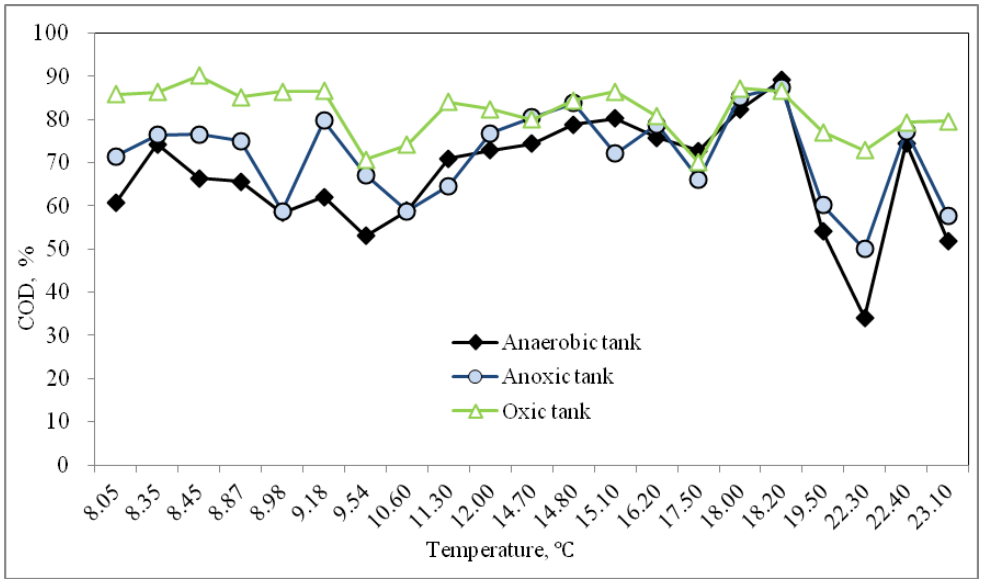

Figure 2. *Removal rate of chemical oxygen demand at different temperatures*

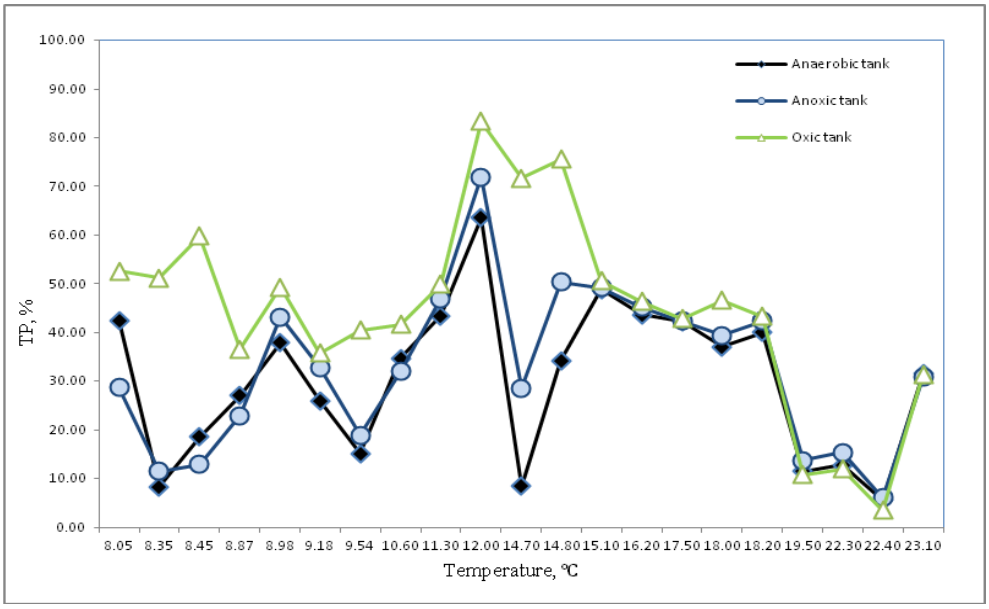

Figure 3. *Removal rates of total phosphorous at different temperatures*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1219112202

As shown in *Figure 4,* the TN removal rates in the anaerobic tank changes obviously between 1.34% and 95.37% when the temperature changed from 8 °C to 25 °C. The removal rate of TN is higher than other studies (Zhou et al., 2013). The average removal rate is 51.56%, which is higher than the result obtained by Zhou et al. (2013). The anoxic tank contributes very little to the TN removal rate which is only increased by 5.53%. The values corresponding to the value of 93.20% and the minimum of 20.23% corresponding to the temperatures were 9.18 °C and 8.35 °C. The TN in the oxic tank is not obvious due to the poor removal rate of the anaerobic tank and anoxic tank, but the average value of the relative anoxic removal rate is 4.53%, and the removal rate increases by 48.22% and -27.22%. The corresponding temperatures are 22.40 °C and 19.50 °C respectively; the average TN removal rate is 61.62%, and the maximum values of 95.37% and the minimum values of 23.16% correspond temperatures are 9.54 °C and 16.2 °C, respectively. According to the TN removal rate, the better temperature is 9.54 °C, and the removal rate can reach 95.37%, which is better than 80% (Wang et al., 2011). However, the dissolved oxygen value is as high as 3.70 mg/L, which is much higher than 1.20 ± 0.2 mg/L (Liu et al., 2011). Other temperatures are difficult to reach the Grade 1 B standard (GB18918-2002). Overall, the removal rate of TN has two critical points of 10.60 °C and 16.20 °C, and it is possible that 10.60 °C and 16.20 °C are the extreme temperatures of certain low temperature denitrifying microorganisms and these require additional attention in future research.

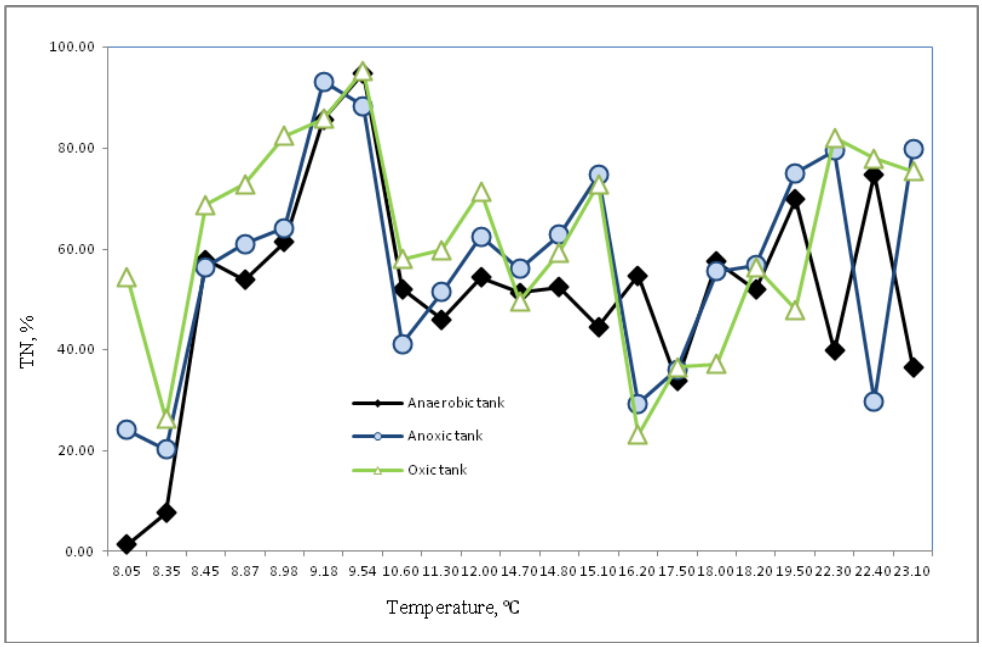

Figure 4. *Removal rates of total nitrogen at different temperatures*

As shown in *Figure 5,* the removal rate of NH_4^+-N in the anaerobic tank changes obviously between 9.36% and 97.23% under the fluctuation of temperature between 8 °C and 25 °C, the removal rate of NH_4^+-N changes obviously. The average removal rate is 61.46%, which is lower than 67.0% (Sohsalam and Sirianuntapiboon, 2008); the highest NH_4^+-N removal rate of 95.87% and the lowest value of 6.16% correspond temperatures are 22.30 °C and 8.35 °C, respectively. The anoxic tank contributes very little to the NH_4^+-N removal rate which is only increased by 4.04%, which is lower than

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1219112202

16.12% (Sahariah et al., 2015), which increases the maximum value by 85.65% and the minimum value of -1.38% corresponding to the temperatures of 9.18 °C and 8.05 °C, respectively; the maximum removal rate of 95.08% and the minimum value of 9.36% corresponding temperatures are 95.02 °C and 8.05 °C. The NH_4^+-N in the oxic tank is not obvious due to the poor removal rate of anaerobic tank and anoxic tank, but the average value of the relative anoxic removal rate is 11.29%, which is larger than 11% (Peng et al., 2005), the removal rate increases the maximum value 57.14% and the minimum value of -2.50%, the corresponding temperatures were 8.05 °C and 17.50 °C, respectively; the average removal rate of NH_4^+-N was 77.42%, and the maximum value of 98.12% and the minimum value of 34.83% corresponding temperatures are 22.30 °C and 8.35 °C, respectively. According to the removal rate of NH_4^+-N, the better temperature is 22.30 °C, the removal rate can reach 98.12%, and the measured NH_4^+-N effluent in the sedimentation tank can reach the first grade A standards (GB18918-2002), and the initial concentration is low so other temperatures can also reach this standard. In general, the two critical temperatures of 10.60 °C and 17.50 °C divide the curve into three parts. 8.05~9.54 °C is the first part, which is a significant increase in the NH_4^+-N removal rate. 10.60~17.50 °C is the second part, which is not obvious for the NH_4^+-N removal rate. 17.50~23.10 °C is the third part, which is a significant change in the TP removal rate. And it is possible that 10.60 °C and 17.50 °C are the extreme temperatures of certain low temperature denitrifying microorganisms.

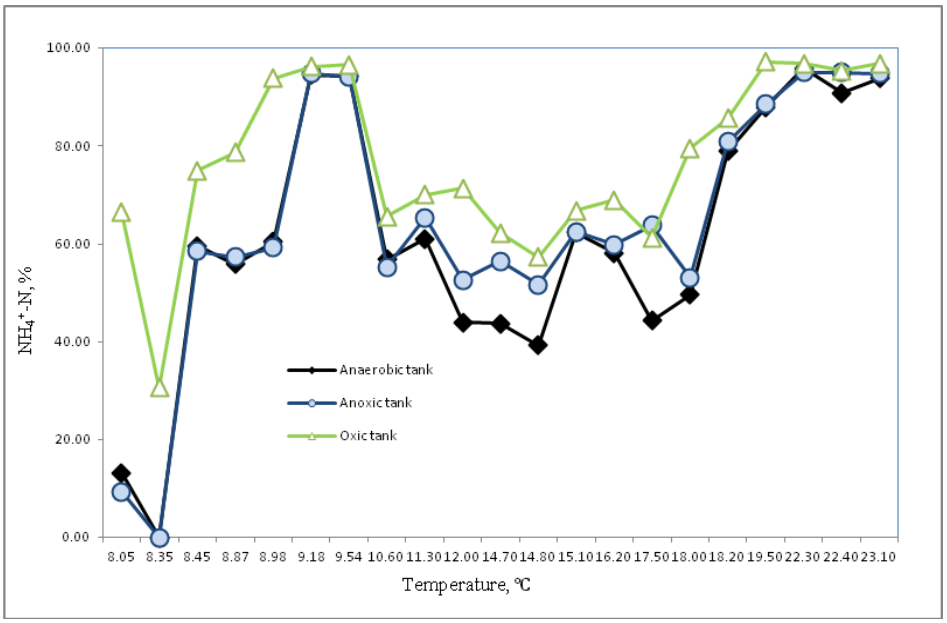

Figure 5. *Removal rates of ammoniacal nitrogen at different temperatures*

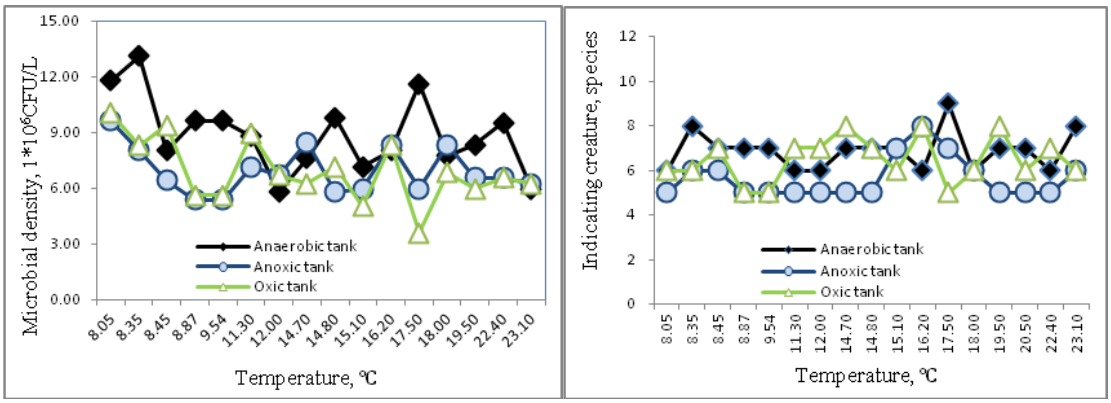
Microorganisms

The response of microorganisms in anaerobic tank, anoxic tank and oxic tank under temperature fluctuation of 8–25 °C is shown in *Figure 6.*

It can be seen from *Figure 6a* that the microbial density of anaerobic tanks generally shows a process of gradually decreasing from the high level and then increasing. The microbial density of the anoxic tank and oxic tank is flatter. The experiment showed that the microbial density in each tank was from 8 °C to 12 °C and 12 °C to 23.1 °C.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1219112202

The microbial density of 8~12 °C showed a downward trend, which may be related to the higher temperature of sludge culture and domestication. The trend appeared in density; the microbial density of each tank showed a oscillating upward trend at 12 °C to 23.1 °C. Overall, the microbial density of anaerobic tanks was higher than that of anoxic tank and oxic tank. There was no significant difference in microbial density between anoxic tank and oxic tank, but the experimental microbial density was lower than 10^8 CFU/L (Yang, 2017).



a **b**

Figure 6. *Microbial response at different temperatures*

It can be seen from *Figure 6b* that the relative changes of indicating creature are not significant in the three reaction cells, and the anaerbic tank and oxic tank indicate that the indicating creature are significantly better than the anoxic tank. Microscopic observations showed that the indicated microorganisms in each tank were pointed caterpillars, bell worms and trichinella, and the number of pointed caterpillars and bell worms decreased gradually while the trichinella showed an increasing trend. It has also been observed that Surticae has an increasing trend, which may be related to DO, and DO is greater than the minimum limit of 2.5 mg/L (Bernot and Wilson, 2012).

Mixed liquid suspended solids and volume percent after settling for 30 min

It can be seen from *Figure 7* that MLSS shows a certain increasing trend with increasing temperature in the range of 8.05 °C to 11.3 °C. In the range of 11.3 °C to 23.1 °C, MLSS shows a certain downward trend with increasing temperature; MLSS is less than 3,000 mg/L (Whang and Lim, 2008). SV30 shows a slow downward trend with increasing temperature.

Discussion

The removal contributions of anaerobic tank, anoxic tank, oxic tank and secondary sedimentation tank at the average removal rate of COD, TN, NH_4^+-N and TP are shown in *Figure 8*.

In addition to TP, the removal of COD, TN, and NH_4^+-N mainly occurs in anaerobic tank, while TP mainly occurs in anaerobic tank and oxic tank. The COD removal effect in each tank is consistent with the microbial density in the corresponding tank; the TP removal effect in each tank is consistent with the change trend of MLSS, and the two

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1219112202

also exhibit a certain positive correlation, which is related to MLSS was key factors, which had a significant impact on Anaerobic phosphorus release and anoxic phosphorus uptake in the biological phosphorous removal process. Wang et al. (2007) are more consistent; TN and NH_4^+-N removal effects have a more consistent trend.

Conclusion

Under the unique plateau environmental factors, the effects of temperature transients on COD, TP, TN, NH_4^+-N removal rate and microbial response were studied using a pilot-scale A2O process. The transient temperature changes show that the optimal removal rate of each water quality index is different. The COD removal rate maintains a good removal efficiency and the removal rate of TN, TP and NH_4^+-N in the anaerobic tank changes obviously under the temperature from 8 °C to 25 °C. The removal of COD, TN and NH_4^+-N mainly occurs in anaerobic tanks while TP mainly occurs in anaerobic and oxic tanks, anaerobic There is no obvious response relationship between microorganisms and indicator organisms in the tank, anoxic tank and oxic tank. The COD, TP, TN, NH_4^+-N in the effluent do not meet the Grade A standard, and the MLSS follows the increased temperature. The increase has not shown a significant growth trend. There are two distinct critical temperatures of 10.60 °C and 16.20 °C to the NH_4^+-N removal rate, of 10.60 °C and 17.50 °C to the TN removal rate and of 9.54 °C and 14.70 °C to the TP removal rate, and it is possible that two distinct critical temperatures are the extreme temperatures of certain low temperature denitrifying microorganisms. The above problems may be related to the long-term response time of temperature transient changes under high altitude environmental factors, and the corresponding mechanism needs to be studied later.

Abstract. The *Rickettsia*, secondary symbiotic bacteria prevalent in arthropods, has been gradually recognized to play a significant role in the biology of their hosts in the past 20 years. A few previous studies have reported the occurrence of *Rickettsia* in several aphid species, located in the secondary bacteriocyte, sheath cell, or aphid hemolymph extracellularly. In this study, we found that *Rickettsia* symbiont infected camellia aphid, *Aphis aurantii*, with a relatively high infection rate (22%). Moreover, based on the next-generation sequencing of 16S rRNA genes, the relative abundance of *Rickettsia* from an *A. aurantii* sample could even reach 59.1%, which exceeded that of *Buchnera*, the primary endosymbiont of aphids. By using transmission electron microscopy, we also observed dense populations of rod-shaped *Rickettsia* symbionts in midgut epithelial cells of *A. aurantii*. Our study is the first to confirm that the *Rickettsia* can invade into midgut epithelial cells of *A. aurantii*, offering new insights into the location and possible infection route of *Rickettsia* in aphids.
Keywords: *bacteria, arthropods, Next Generation Sequencing, electron microscopy, endosymbiont*

Introduction

Aphids (Hemiptera, Aphididea) are considered notorious agricultural pests that cause severely damage to host plants via sucking on the phloem sap and transmitting phytopathogenic viruses (Eastop, 1977; Huang and Qiao, 2014; Skaljac, 2016). Due to the lack of various essential amino acid in the plant phloem sap, primary/obligate symbionts play an important role in providing essential nutrition to complete the diet of sap-feeding insects (Brumin et al., 2012; Hansen and Moran, 2013). For aphids, *Buchnera aphidicola* supplying nutrients as a primary endosymbiont has been reported in numerous studies (Baumann et al., 1995; Shigenobu et al., 2000; Wilson et al., 2010). Besides primary symbionts, insect secondary/facultative symbionts have generally been considered not necessary for host development and reproduction in the past. However, increasing evidence shows that multiple facultative symbionts might have significant influence on aphid fitness (Oliver et al., 2010), including *Hamiltonella defensa* for protection against parasitoids and predators (Schmid et al., 2012; Costopoulos et al., 2014), *Regiella insecticola* for protection against entomopathogen (ŁUkasik et al., 2013), *Wolbachia* for possible nutritional function (Augustinos et al., 2011). Furthermore, the endosymbiont *Serratia* symbiotica seems to undergo an evolutionary scenario from facultative stage to obligate stage, and establish a co-obligate endosymbiotic consortium with *B. aphidicola* in *Cinara cedri* (Lamelas et al., 2011) and *Cinara tujafilina* (Manzano-Marín and Latorre, 2014).

The *Rickettsia* are intracellular symbionts of eukaryotes and ubiquitous in arthropods (Weinert et al., 2009; Merhej and Raoult, 2011), some of which are best known as

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1220312212

human and animal pathogens vectored by blood-sucking arthropods, being responsible for epidemic typhus, murine typhus or spotted fever (Raoult and Roux, 1997; Sakurai et al., 2005). *Rickettsia* bacteria are thought to be maternally (Weinert et al., 2009) and also plant-mediated horizontally transmitted (Caspi-Fluger et al., 2011). In general, *Rickettsia* bacteria are facultative symbionts in most arthropods, with influences on host fitness such as fitness benefits, female bias and sensitivity to insecticides in whitefly (Kontsedalov et al., 2008; Himler et al., 2011), male killing in ladybird beetle (Von Der Schulenburg et al., 2001), and thelytokous parthenogenesis induction in a parasitoid wasp (Hagimori et al., 2006). However, considering such wide occurrence in arthropods, more distinct and specific functions of *Rickettsia* symbionts await to be discovered in the vast majority of hosts.

For aphids, some studies have shown that *Rickettsia* can live in secondary bacteriocytes, sheath cells (Fukatsu et al., 2000; Skaljac, 2016), as well as in the hemolymph of hosts with extracellular stage (Tsuchida et al., 2005). A recent study using 454 pyrosequencing of 16S rRNA genes indicated the presence of *Rickettsia* in insect guts of 19 taxonomic orders (Yun et al., 2014). It seems to indicate that *Rickettsia* might be distributed more widely across the digestive system of insect taxa than previously thought. However, further studies are needed to investigate the real location of *Rickettsia* in insect digestive system, for example, free living in the gut or within the midgut epithelial cells. The camellia aphid *Aphis Aurantii* is a common pest species in the subtropical and tropical regions. In our study, we found that *Rickettsia* existed in wild *A. Aurantii* populations feeding on the plant *Loropetalum chinense*. We further investigate three questions: 1) whether the *Rickettsia* is common in *A. aurantii* populations; 2) how much can the relative abundance of *Rickettsia* in the symbiotic microbiome of *A. aurantii*; 3) whether the gut cells of *A. aurantii* contain *Rickettsia* symbiont.

Materials and Methods

The samples of *A. aurantii* were collected from seven different localities distributed in Yunnan, Guangxi, Fujian and Zhejiang provinces of southern China (*Fig. 1*). All samples were collected from different locations and plant individuals, making sure these samples were from different clones. All samples were directly preserved in 95%-ethanol in the wild and frozen at −80°C for further experiment in laboratory. For eliminating possible surface contaminants, all 27 individuals from 19 different clones were washed thrice in 70% ethanol, and then rinsed in sterile deionized water. DNA was isolated with DNeasy Blood & Tissue Kit (QIAGEN) as following the manufacturer manual. The specific primer pair (Ric16SF1: 5'-TGGCTGTCGTCAGCTCGT-3' and 5'-Ric16SR1: TCCACGTCACCGTCTTGC-3') (Sakurai et al., 2005) was used to detect and classify the *Rickettsia* infection. All PCRs were carried out in a 50 μl volume with 4 μl DNA template (2-20 ng/μl), 5 μl 10×Buffer, 2.5 mM dNTP mixture, 10 pmol of each primer and 1 unit of ExTaq DNA polymerase (TaKaRa Bio Inc., Otsu, Japan). The PCR conditions were an initial step of 3 min at 95°C followed by 30 cycles of 30 s at 94°C, 30 s at 52°C and 1 min at 72°C followed in turn by final extension of 10 min at 72°C. PCR products were visualized on 1% agarose. To assure the accuracy of results, sterile deionized water was used as a negative control and some positive products (Individual ID: 17, 22 and 23) were sequenced (*Table 1*).

DOI: http://dx.doi.org/10.15666/aeer/1705_1220312212

To investigate relative abundance of *Rickettsia* in the symbiotic microbiome of *A. aurantii*, three aphid clones (HCX25 from *Mangifera indica*, HCX30 and HCX31 from *L. chinense*) were selected for NGS of bacterial 16S rRNA genes. Ten individuals of each clone followed the above steps of DNA extraction. The primer set (338F: 5'-ACTCCTACGGGAGGCAGCA-3' and 806R: 5'-GGACTACHVGGGTWT CTAAT-3') (Srinivasan et al., 2012) was used to amplify the V3 and V4 region of the bacterial 16S rRNA genes with 95°C for 5 min (1 cycle), 95°C for 30 s, 50°C for 30 s, 72°C for 40 s (25 cycles), followed by 72°C for 7 min. The PCR products was purified using a GeneJET Gel Extraction Kit (Thermo Fisher Scientific, Waltham, MA, United States). Finally, paired-end sequencing of the 16S rRNA was conducted on Illumina HiSeq 2500 with 2×250bp reads (Illumina, Inc., SanDiego, CA, United States) at Biomarker Bioinformatics Technology, Co., Ltd. (Beijing, China).

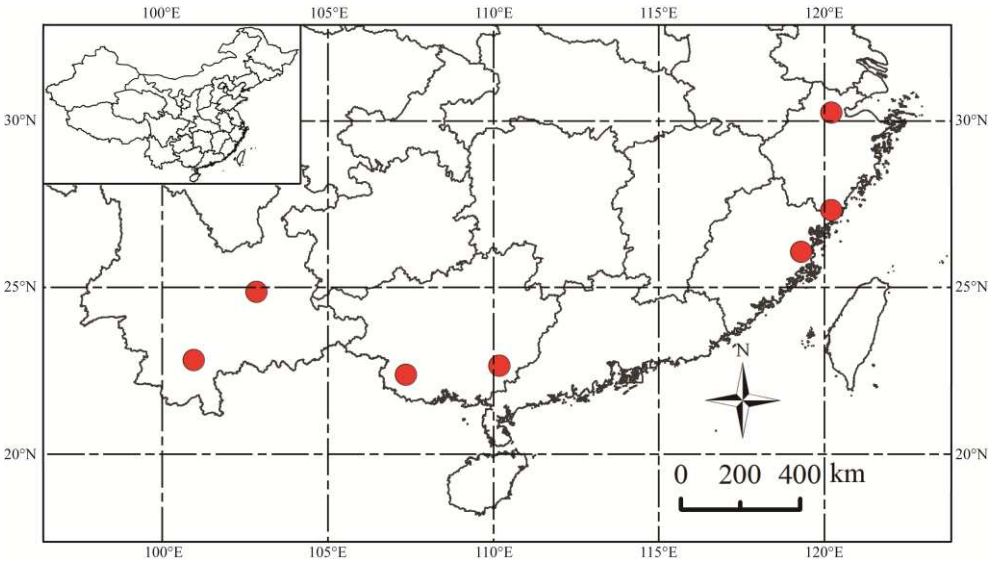

Figure 1. *Overview of geographic distribution of Aphis Aurantii clones collected in this study. Collection sites are labeled with red circle*

The paired-end reads were merged using FLASH v1.2.11 (Magoč and Salzberg, 2011), sequences were further quality trimmed using Trimmomatic v0.33 (Bolger et al., 2014), ensuring >20 quality scores on a sliding window of 50 bp. The chimera sequences were identified and removed using the UCHIME algorithm (Edgar et al., 2011). Sequences with ≥ 97% similarity were clustered into the same operational taxonomic units (OTUs) using UCLUST v10.0 (Edgar, 2010). All OTUs were identified with the RDP classifier (Version 2.2) (Wang et al., 2007) to obtain taxonomic information. The raw sequences have been submitted to the NCBI Sequence Read Archive (accession number SRR8668504, SRR8668505 and SRR8668506).

The 16S sequence of *Rickettsia* from HCX31 was extracted from the NGS sequences of bacterial 16S rRNA genes. The 16S sequences of other *Rickettsia* species was selected and download from GenBank. The data was aligned using MAFFT v 7.409 (Katoh and Standley, 2013), and some sequences not in the same regions were removed using BioEdit 7.0.5 (Hall, 1999). *Orientia tsutsugamushi* (AF062074.1) was chosen as outgroup. Finally, maximum likelihood (ML) tree was conducted using IQTree v1.5.4 and the HKY+F+I model with 1000 ultrafast bootstraps (Nguyen et al., 2014).

The aphid guts of HCX31 individuals were dissected in 1×PBS using fine forceps. The dissected guts were prefixed in 2.5% glutaraldehyde at room temperature for 2h, and postfixed in 1% osmium tetroxide at room temperature for 60 min. After dehydration through an ethanol series and acetone, the guts were embedded through an SPURR embedding medium series. Ultrathin sections were made on an ultramicrotome (EM UC7; Leica), stained with uranyl acetate and lead citrate, and observed under an H-7650 Hitachi transmission electron microscopy at 80KV.

All Clones were collected from *Loropetalum chinense* except for C20 (HCX25) from *Mangifera indica*. NGS=NGS of bacterial 16S rRNA genes; SD=Specific detection using specific primers for *Rickettsia*. + represents using this method. +R represents a fragment of 300 bp obtained from specific primers, indicating the present of *Rickettsia* species

Results

The *Fig. 2* showed the rapid identification result of *Rickettsia* symbiont using the specific primers. A fragment of 300 bp was observed in 6 of 27 individuals. The result suggested a *Rickettsia* occurrence rate of 22.2% in our study. A total of 19 *Rickettsia* species with 403 bp length were selected to construct a ML phylogenetic tree. In the phylogenetic tree (*Fig. 3*), *Rickettsia* were classified into three major clades with high support values: one including *Rickettsia* from leeches, arthropods and our sample; a second clade including *Rickettsia* endosymbiont from *Bemisia tabaci* and some vertebrate pathogen *Rickettsia* such as *R. typhi* and *R. japonica*; a third clade containing sequences obtained from environmental samples.

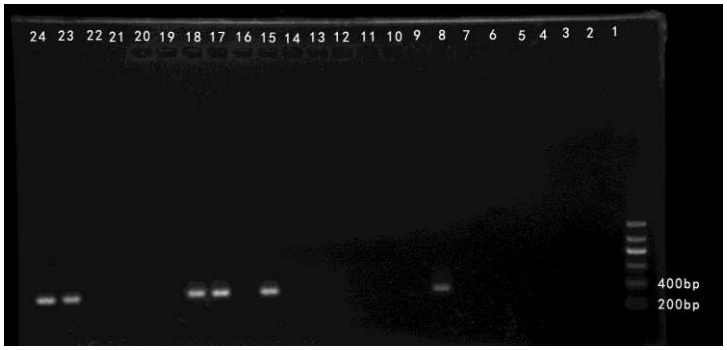

Figure 2. *Specific detection of Rickettsia sp. with primers Ric16SF1 and Ric16SR1 in 19 clones and 27 individuals of A. aurantii. Lanes 1-24: 1-24 individuals, Marker: marker F (200bp 400bp 700bp 1000bp 1500bp 2000bp). The remaining three are not shown due to observation in a small gel, and negative control does not show a fragment of 300 bp. The products in lanes 15, 17 and 23 have been sequenced and submitted to GenBank (Table 1)*

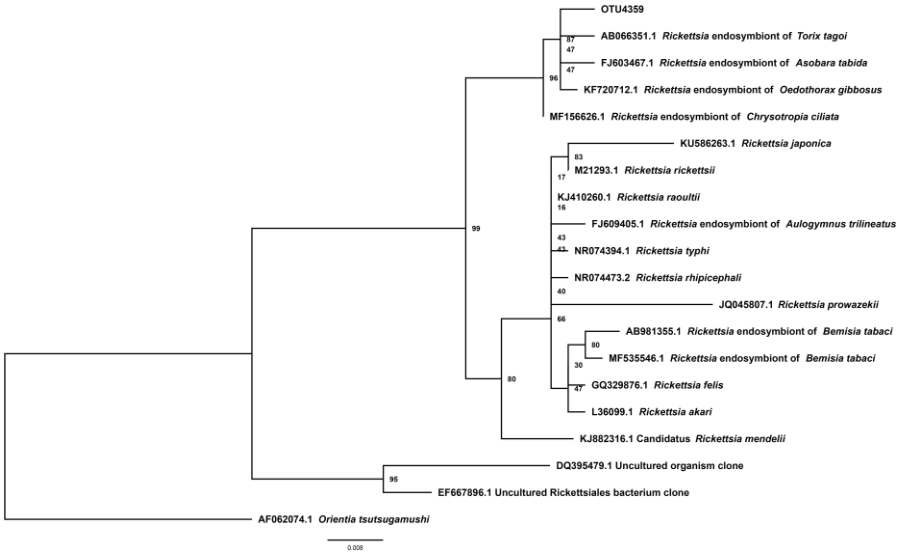

Figure 3. *ML phylogenic tree of Rickettsia based on 16S rDNA sequences. OUT4359 is the sequence from our sample HCX 31. The node values represent the bootstrap values*

The NGS of bacterial 16S rRNA gene yielded 47,579, 54,211 and 54,337 effective tags from HCX25, HCX30 and HCX31, respectively. The average length of effective tags was about 420bp. The OTUs number of the rarefaction curves had very slow growth with the increase of sequencing depth, indicating that the majority of bacterial OTUs had been observed (*Fig. 4A*). A total of 42 OTUs were obtained at 97% sequence-similarity level (31 OTUs for HCX25; 34 OTUs for HCX30 and 34 OUTs for HCX31) (*Fig. 4B*). The top 10 genera based on relative abundance in three samples were illustrated in *Fig. 4C*. For HCX25 and HCX30, the genus of dominant bacteria was *Buchnera*, the primary endosymbiont of aphids, accounting for 98.3% and 98.8%, respectively. For HCX31, the dominant bacteria were *Rickettsia* with 59.1% relative abundance, followed by *Buchnera* with 39.2%. Electron microscopic observation of the gut of HCX31 with dense populations of rod-shaped bacteria in the gut cells (*Fig. 5*). The *Rickettsia* cells ranged from 0.35-0.5 μm in width to 0.5-1 μm in length.

Discussion

Although all 27 individuals in our study were collected from *L. chinense*, the *Rickettsia* occurrence rate was similar with 17% of Guidolin and Cônsoli (2018) in *Aphis aurantii*. Cautiously, some bacteria occur at low proportion within a host, making limits of detection of specific primers due to low bacterial DNA concentration. The *Rickettsia* occurrence rate of 22.2% might be underestimated. Like other pathogens, some evidence have shown that the plant can be a media and provide a place for horizontal transmission of *Rickettsia* (Perlman et al., 2006; Caspi-Fluger et al., 2011). This may explain the phylogenetically similar symbionts occur in unrelated phytophagous insect species (Caspi-Fluger et al., 2011). The *Rickettsia* sequence from our sample is clustered together with *Rickettsia* from other arthropods in ML tree. *Rickettsia* are popular in many arthropod groups also including some other sap-feeders, but it is rare in aphids (Oliver et al., 2010). All records only include *Acyrthosiphon pisum* (Chen et al., 1996; Sakurai et al., 2005; Sepúlveda et al., 2017), *Amphorophora rubi* (Haynes et al., 2003), *Aphis citricidus* (Guidolin and Cônsoli, 2017, 2018). Haynes et al. (2003) also reported that the *Rickettsia* was very rarely detected in just 1% and 2% occurrence rates in natural populations of *Am. rubi* and *Ac. pisum*, respectively. A relatively high infection rate (22%) of *A. aurantii* was reported in our study, showing a significant difference compared to *Am. rubi* and *Ac. pisum*. Interestingly, the range of host plants of *A. aurantii* is also wider with 104 plant families compared to three families of *Am. rubi* and 23 families of *Ac. Pisum* (host plant information from http://www.aphidsonwor ldsplants.info), which is concordant with the comparative result of *Rickettsia* infection rates among the three aphid species. Guidolin and Cônsoli (2018) also consider that the polyphagous species may tend to more frequently infected with secondary symbionts than the oligophagous one.

Little is known about the influences of *Rickettsia* on their aphid hosts. A few studies show that *Rickettsia* symbionts can enhance aphid host's resistance to natural enemies (ŁUkasik et al., 2013) and cause reductions in body weight and fecundity in the pea aphid (Chen et al., 2000). The invasive order of the most *Rickettsia* is considered from the gut to the haemocoel and then to the salivary glands (Perlman et al., 2006). Brumin et al. (2012) investigated the subcellular localization of *Rickettsia* endosymbiont in the whitefly, showing that *Rickettsia* infected the digestive salivary and had the possible digestive purposes. For aphids, several previous works of *Rickettsia* location only have shown the distribution of *Rickettsia* endosymbiont in secondary bacteriocytes, sheath cells and hemolymph (Fukatsu et al., 2000; Tsuchida et al., 2005; Skaljac, 2016) with the exception of the gut.

Conclusion

Our research confirms the *Rickettsia* location in gut cells, providing a necessary supplement to reveal a complete and clear *Rickettsia* localization in aphids, contributing to understanding its evolution and function in the future research. To understand *Rickettsia* evolution and pathogenesis, more works such as a comprehensive analysis of the entire genome need be done. Meanwhile, it will be interesting to test whether wider host plant range increases the infection possibility of *Rickettsia* in other aphids in the future.

Abstract. Considering the two unique factors of the plateau environment (i.e. water temperature and oxygen partial pressure), this paper explores the nitrogen and phosphorous removal of pilot-scale anaerobic-anoxic-aerobic (A2O) process. The experimental results show that none of the total phosphorous (TP), total nitrogen (TN) or NH_4^+-N of the outlet water satisfied the Chinese national standard GB18918-2002, while COD only fulfilled the standard requirements under a few working parameters. The optimal values of the four working parameters were determined as: the optimal HRT=26.25 h, the optimal DO=3.0 mg/L, the optimal temperature=15°C. All these optimal values deviated greatly from the existing studies. The microbial densities corresponded poorly to the three working parameters, and were smaller than those under non-plateau environment; the number of indicator microorganisms had good correspondence with the optimal values of our experimental parameters.
Keywords: *anaerobic-anoxic-aerobic (A2O) process, water temperature, hydraulic retention time (HRT), dissolved oxygen (DO), nitrogen and phosphorous removal*

Introduction

The anaerobic-anoxic-aerobic (A2O) process, improved from the traditional activated-sludge process, has become the most popular sewage treatment method in Tibet (Chen et al., 2018), China. It is widely agreed that the effect of A2O is influenced by the unique environment factors of the plateau, namely, water temperature and pressure.

With a mean elevation of more than 4,000 m, Tibet can be categorized as a typical plateau region with low temperature. Taking Linzhi for instance, the domestic sewage falls in the range of 4°C and 14°C (Zong et al., 2018), which is a typical low-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1221312226

temperature sewage. The water temperature in other parts of Tibet is theoretically below this range, because Linzhi is a city with below-average elevation in Tibet.

According to Lewis-Whitman's two-film theory (Ruiz-Urbieta et al., 1975), the maximal concentration of oxygen that can be dissolved in liquid medium decreases with the pressure. The atmospheric pressure is only 67.24 kPa in Linzhi. The elevation and atmospheric pressure of other cities in Tibet are listed in *Table 1* below.

Table 1. *Elevation, pressure of Tibet in China*

	Lhasa	**Changdu**	**Shigatse**	**Linzhi**	**Shannan**	**Naqu**	**Ali**
Elevation (m)	3658.0	3306.0	3836.0	3000.0	3551.7	4507.0	4278.0
The local pressure (kPa)	59.87	63.81	57.88	67.24	61.06	50.36	52.93
Oxygen partial pressure (kPa)	12.54	13.37	12.13	14.09	12.79	10.55	11.09
Oxygen levels (%)	59.87	63.81	57.88	67.24	61.06	50.36	52.93

Note: Standard Oxygen levels are 100%

Temperature is a main influencing factor of sewage treatment (Ai et al., 2014; Abourabia and Abdel Moneim, 2019). Its influence mainly exists in the following aspects: On the phosphorus removal of sludge denitrification, the release and absorption rates of phosphorus are changed under excessively high or low temperatures, and the proportion of denitrifying phosphorus accumulating organisms (DPAOs) in the activated sludge is greatly affected by temperature variation (Zhang et al., 2016; Wu, 2017); the nitrification capacity of the sewage treatment system is obviously weakened when the water temperature falls below 15°C, and basically disappears when the temperature drops below 4°C (He et al., 2010; Li et al., 2013). Thus, the nitrogen removal is severely inhibited under a low temperature (Li et al., 2014).

In view of the above, this paper explores the mechanism of nitrogen and phosphorus removal of A2O system, as a typical sewage treatment process. Starting from the microbial variation law, the author discussed the influence of water temperature, dissolved oxygen concentration, hydraulic retention time (HRT) and other factors on nitrogen and phosphorus removal, analyzed the operation features of A2O system at high elevations, and investigated the microbial features in the anaerobic section, anoxic section and aerobic section. The research discloses the mechanism of nitrogen and phosphorus removal in the reactor, shedding light on how plateau environmental factors affect the mechanism of nitrogen and phosphorus removal. Moreover, our research results lay a theoretical basis for the biological sewage treatment system in the plateau environment.

Materials and methods

Description of the A2O system and wastewater

As mentioned above, our experiment aims to disclose the law of removal rates under different water temperatures, HRTs and dissolved oxygens (DOs). For this purpose, the process flow of our experiment was designed as the following chart.

A pilot-scale A2O sewage treatment device was designed and fabricated with plexiglass. With an effective volume of 210 L, the device consists of 8 segments: the first 2 are anaerobic tanks, the middle 2 are anoxic tanks, and the last 4 are aerobic tanks.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1221312226

The volume ratio of the anaerobic, anoxic and aerobic sections is 1:1:2. Besides, the effective volume of the sedimentation tank is 26.25 L. In both anaerobic and anoxic sections, each tank has a 50 rpm stirring device at the bottom; in each aerobic tank, there is an aerator for oxygen supply. Inflow, return sludge and nitrifying liquid are controlled by a peristaltic pump. To maintain a constant temperature, the water temperature was regulated by a constant temperature circulator. In each tank, a sampling hole was opened on the tank wall. Before the experiment, the activated sludge was cured for 32 d. The temperature, mixed liquor suspended solids (MLSS), and volume percent of MLSS after settling for 30 min (SV_{30}) were set to 22.5ºC, 4,787 mg/L and 35%, respectively. The number of parallel samples per point is three, and the average of three samples is taken when the accuracy requirement is met, otherwise resampling is considered (*Figure 1*).

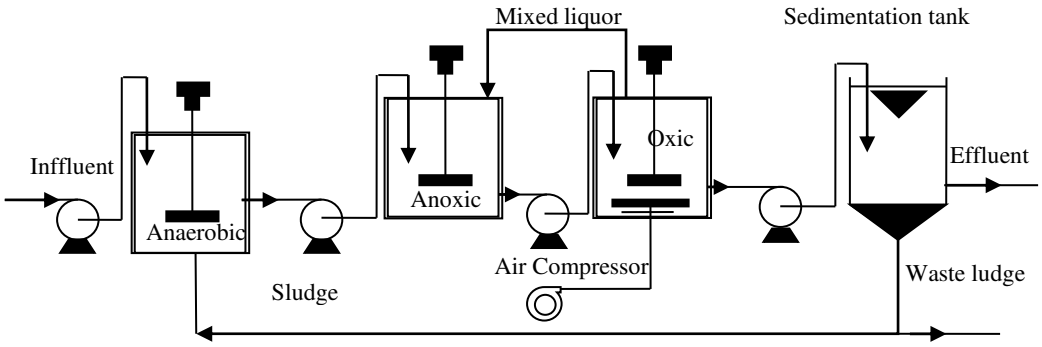

Figure 1. *Schematic of anaerobic-anoxic-aerobic (A2O) process*

The urban domestic sewage in Linzhi was directly adopted for our experiments. The main water quality indices of the sewage are given in the table below (*Table 2*).

Table 2. *Quality indicators of sewage*

pH	DO (mg/L)	Temperature (°C)	COD (mg/L)	TN (mg/L)	TP (mg/L)	NH_4^+-N (mg/L)
6.99~8.41	1.12~5.08	8.98~29.10	149.48~526.36	36.51~147.08	3.96~11.56	30.81～54.16

Operation of the A2O device

The operation of the A2O device was studied under three working parameters, i.e. water temperature, hydraulic retention time (HRT) and DO, in order to disclose the law of removal rates under different water temperatures, HRTs and DOs. The control plans for the three parameters are specified below.

On water temperature control, the inlet water flow was designed as 10.0±0.1 L/s, HRT as 21.0±0.2 h (the HRT ratio between anaerobic tank, anoxic tank and aerobic tank=1: 1: 2), DO as 2.0±0.1 mg/L, the reflux ratio of the mixed liquor Ri=200%, and the reflux ratio of the sludge R=100%. Both the mixed liquor and the sludge were continuously refluxed. The temperature was changed by an electric heater between five levels: 10, 15, 20, 25 and 30°C. The water samples were collected 72 h after the temperature reached the design temperature. The temperature was controlled with an error of or less than 0.1°C.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1221312226

On HRT control, the inlet water temperature was designed as 20±0.1°C, the HRT ratio between anaerobic tank, anoxic tank and aerobic tank as 1: 1: 2, DO as 2.0±0.1 mg/L, the reflux ratio of the mixed liquor Ri=200%, and the reflux ratio of the sludge R=100%. Both the mixed liquor and the sludge were continuously refluxed. HRT was adjusted by changing the inlet water flow between five levels: 4, 8, 12, 16 and 20 L/s. HRTs corresponding to the five levels were respectively 52.5, 26.26, 17.5, 13.125 and 10.5 h. The water samples were collected 72 h after the change of the inlet water flow. The flow was controlled with an error of or less than ±0.1 L/s.

On DO control, the inlet water temperature was designed as 20±0.1°C, the inlet water flow as 10.0±0.1 L/s, HRT as 21.0±0.2 h (HRT ratio between anaerobic tank, anoxic tank and aerobic tank=1:1:2), the reflux ratio of the mixed liquor Ri=200%, and the reflux ratio of the sludge R=100%. Both the mixed liquor and the sludge were continuously refluxed. DO was altered between 10 levels (1, 2, 2.5, 2.8, 3, 3.2, 3.5, 4, 4.5 and 5 mg/L) by changing the amount of blast aeration. The water samples were collected 72 h after DO reached the design level. DO was controlled with an error of or less than ±0.1 mg/L.

Analytical methods

According to the working standards, the experimental indices were respectively measured by the following methods: COD was determined by the potassium dichromate method, the TN by the ion chromatography, TP by potassium persulfate oxidation, MLSS by the gravimetric method, the SV30 by the standard method, DO by membrane electrode method, pH by the portable pH meter, NH_4^+-N by the Nessler's reagent photometry, the water temperature by water thermometer, the inlet water flow by float flowmeter, and the microorganisms by biochemical microscope counting.

Results

Sewage treatment at different HRTs

Table 3 displays the operation parameters like DO, MLSS, pH and temperature at different HRTs.

Table 3. *Process Parameter at different hydraulic retention times (HRTs)*

Designed Flow (L/h)	4	8	12	16	20
HRTs (h)	52.50	26.25	17.50	13.13	10.50
DO (mg/L)	3.16	2.30	1.64	1.98	2.04
pH	8.10	8.00	8.27	8.40	8.41
MLSS (mg/L)	964	996	1084	930	920
SV_{30} (%)	10	10	10	10	10
Temperature (°C)	21.4	20.0	19.5	20.7	20.6

Effect on removal rates

Figure 2 provides the removal rates of COD, TP, TN and NH_4^+-N in anaerobic, anoxic and aerobic tanks at different HRTs.

As shown in *Figure 2(a)*, the COD removal rate ranged between 69.65% and 93.98% under the five HRTs; in descending order of the COD removal rate, the inlet water flows were ranked as 8, 12, 16, 4 and 20 L/h, and HRTs as 26.25, 17.50, 13.13, 52.50 and 10.50 h; the optimal HRT was much greater than 7~14 h; the highest COD removal rate was observed at the design inlet water flow of 8 L/h; the removal effect was obvious in anaerobic and aerobic sections, but the removal rate was not significantly enhanced in the anoxic section.

As shown in *Figure 2(b)*, the TP removal rates fell in the range of 4.53%~64.56% under the five HRTs; in descending order of TP removal rate, the inlet water flows were ranked as 8, 12, 20, 16 and 4 L/h, and HRTs as 26.25, 17.50, 10.50, 13.13 and 52.50 h; the optimal HRT was much greater than 7~14 h; the highest TP removal rate was observed at the design inlet water flow of 8 L/h; the removal effect was obvious in anaerobic and aerobic sections, but the removal rate was not significantly enhanced in the anoxic section.

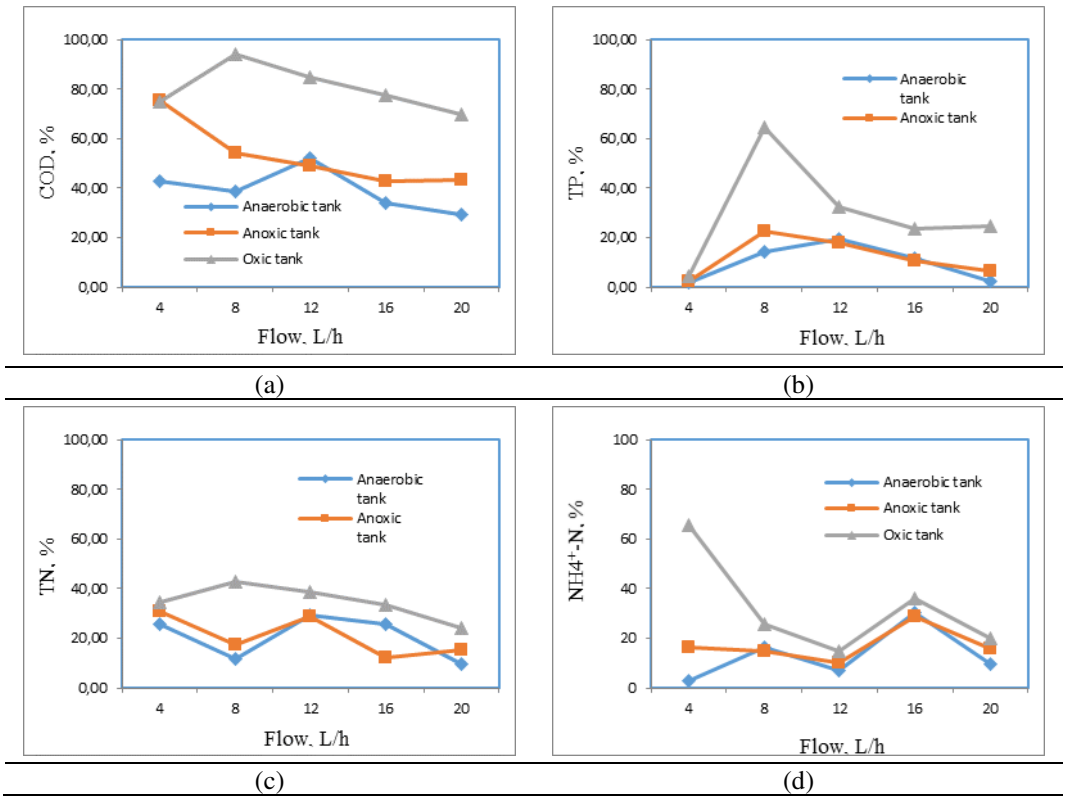

Figure 2. *Removal rate at different hydraulic retention times (HRTs)*

As shown in *Figure 2(c)*, the TN removal rates shifted from 23.92% to 42.85% under the five HRTs; in descending order of the TN removal rate, the inlet water flows were ranked as 8, 12, 4, 16 and 20 L/h, and HRTs as 26.25, 17.50, 52.50, 13.13 and 10.50 h; the optimal HRT was much greater than 7~14 h; the highest TN removal rate was observed at the design inlet water flow of 8 L/h; the removal effect was obvious in anaerobic and aerobic sections, but the removal rate was not significantly enhanced in the anoxic section.

DOI: http://dx.doi.org/10.15666/aeer/1705_1221312226

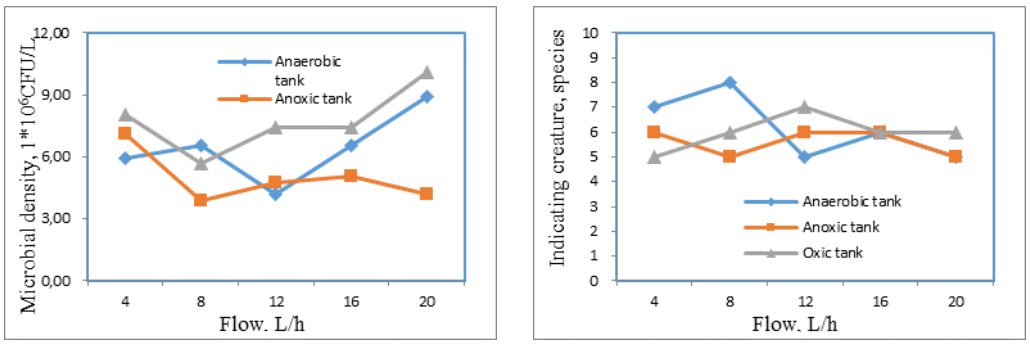
As shown in *Figure 2(d)*, the NH_4^+-N removal rates changed within 14.92% and 65.47%; in descending order of the NH_4^+-N removal rate, the inlet water flows were ranked as 4, 16, 8, 20, 12 L/h, and the HRTs as 52.50, 13.13, 26.25, 10.50 and 17.50 h; the optimal HRT was much greater than 7-14 h; the highest NH_4^+-N removal rate was observed at the design inlet water flow of 4 L/h; the removal effect was obvious in the aerobic sections, but the removal rate was not significantly enhanced in the anaerobic or anoxic section.

To sum up, the optimal HRT was 26.25 h among the five designed HRTs; HRT increased more significantly in the plateau environment than other regions.

Microbial response

The microbial density and indicator microorganisms under the above five HRTs are shown in *Figure 3*.

It can be seen from *Figure 3(a)* that, under the five HRTs, the different levels of inlet water flows could be ranked as 20, 16, 8, 4 and 12 L/h in descending order of the number of microorganisms in the anaerobic section, 4, 16, 12, 20 and 8 L/h in the anoxic section, and 20, 4, 12, 16 and 8 L/h in the aerobic section. Since the microbial effect is correlated with microbial density, microbial residence time, and inlet/outlet water quality, it is not reasonable to evaluate the microbial response with the bulk density of the microorganisms.



(a) (b)

Figure 3. *Microbial response at different hydraulic retention times (HRTs)*

It can be seen from *Figure 3(b)* that, under the five HRTs, the different levels of inlet water flows could be ranked as 8, 4, 16, 12 and 20 L/h in descending order of the diversity of indicator microorganisms in the anaerobic section, 16, 4, 12, 8 and 20 L/h in the anoxic section, and 12, 8, 16, 20 and 4 L/h in the aerobic section. The indicator microorganisms reached the peak diversity at 8 L/h. The most populous microorganisms include vorticella, trochilia, rotifera and oxytricha.

The microbial analysis show that the microbial density is not directly correlated with the optimal HRT, because the treatment effect depends on retention time and inlet/outlet water quality, in addition to microbial density; moreover, the indictor microorganism analysis confirmed that the indicator microorganisms reached the peak diversity at 8 L/h and the most populous microorganisms were vorticella, trochilia, rotifera and oxytricha.

Effect on removal rates

Figure 4 gives the removal rates of COD, TP, TN and NH_4^+-N in anaerobic, anoxic and aerobic tanks at different DOs.

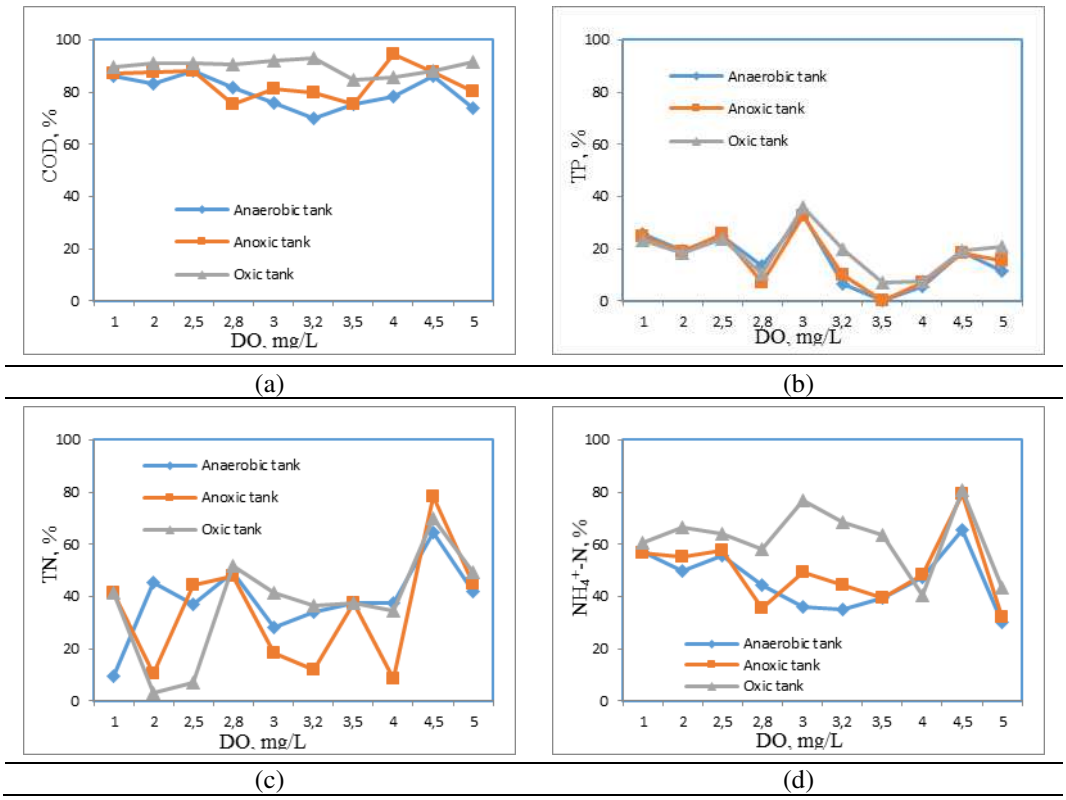

Figure 4. *Removal rate at different dissolved oxygens (DOs)*

As shown in *Figure 4(a)*, the COD removal rate ranged between 84.59% and 92.84% under the ten DOs; in descending order of the COD removal rate, the DOs were ranked as 3.2, 3.0, 5.0, 2.5, 2.0, 2.8, 1.0, 4.5, 4.0 and 3.5 mg/L; the optimal DO was far higher

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1221312226

than 2.0 mg/L, but the COD differed slightly between the working parameters; the COD removal rate peaked at the design DO of 3.2 mg/L; the removal effect was obvious in anaerobic section, but the removal rate was not significantly enhanced in the anoxic or aerobic section.

As shown in *Figure 4(b)*, the TP removal rate fluctuated between 7.27% and 35.84% under the ten DOs; in descending order of the TP removal rate, the DOs were ranked as 3, 2, 1, 5, 3.2, 4.5, 2, 2.8, 4 and 3.5 mg/L; the optimal DO was far higher than 2.0 mg/L; the highest TP removal rate appeared at the design DO of 3 mg/L; the removal effect was obvious in anaerobic section, but the removal rate was not increased in the anoxic or aerobic section.

As shown in *Figure 4(c)*, the TN removal rate fell between 7.27% and 35.84% under the ten DOs; in descending order of the TN removal rate, the DOs were ranked as 3, 2, 1, 5, 3.2, 4.5, 2, 2.8, 4 and 3.5 mg/L; the optimal DO was much higher than 2.0 mg/L; the highest TN removal rate appeared at the design DO of 3 mg/L; the removal effect was obvious in aerobic section, but the removal rate was not increased significantly in the anoxic or anaerobic section.

As shown in *Figure 4(d)*, the NH_4^+-N removal rate changed between 80.76% and 40.35% under the ten DOs; in descending order of the NH_4^+-N removal rate, the DOs were ranked as 4.5, 3.0, 3.2, 2.0, 2.5, 3.5, 1.0, 2.8, 5.0 and 4.0 mg/L; the optimal DO was much higher than 2.0 mg/L; the NH_4^+-N removal rate reached the maximum at the design DO of 4.5 mg/L; the removal effect was obvious in aerobic section, but the removal rate was not increased significantly in the anoxic or anaerobic section.

In summary, the optimal DO was 3 mg/L among the ten designed DOs; the DO in the plateau environment was much greater than that in the other regions; however, the removal rates of TP, TN and NH_4^+-N were not high under plateau environmental factors; in particular, only about 35% of TP were removed.

Microbial response

The microbial density and indicator microorganisms under the above seven DOs are displayed in *Figure 5*.

It can be seen from *Figure 5(a)* that the seven DOs could be ranked as 2.8, 4.5, 2.5, 5, 2, 3.2 and 1 mg/L in descending order of the number of microorganisms in the anaerobic section, 2.5, 5.0, 2.8, 3.2, 2, 4.5 and 1 mg/L in the anoxic section, and 2.5, 2.8, 5.0, 3.2, 4.5, 2 and 1 mg/L in the aerobic section. Since the microbial effect is correlated with microbial density, microbial residence time, and inlet/outlet water quality, it is not reasonable to evaluate the microbial response with the bulk density of the microorganisms.

It can be seen from *Figure 5(b)* that the seven DOs could be ranked as 2.8, 4.5, 1, 2, 2.5, 5 and 3.2 mg/L in descending order of the diversity of indicator microorganisms in the anaerobic section, 1, 5, 2.5, 3.2, 4.5, 2.8 and 2 mg/L in the anoxic section, and 5, 2, 2.5, 3.2, 1, 2.8 and 4.5 mg/L in the aerobic section. The indicator microorganisms reached the peak diversity at 5 mg/L, when the most populous microorganisms were vorticella and rotifera. Meanwhile, the most populous microorganisms became vorticella, rotifera and trochilia at the DO of 3 mg/L.

The microbial analysis show that the microbial density is not directly correlated with the optimal DO, because the treatment effect depends on retention time and inlet/outlet water quality, in addition to microbial density; moreover, the indictor microorganism

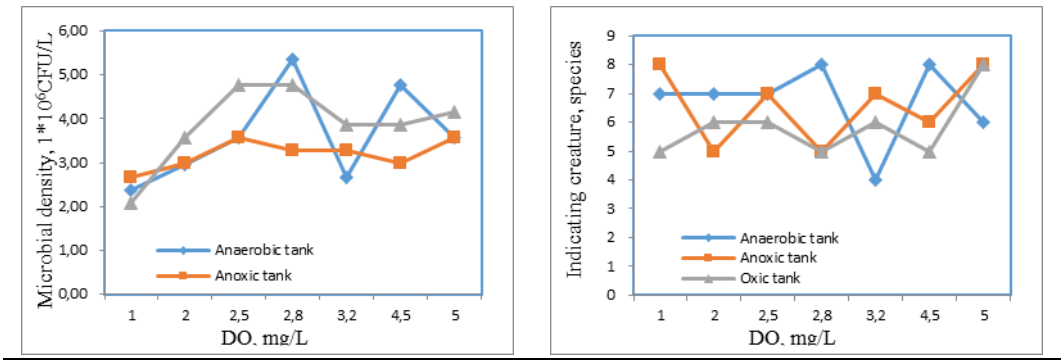
DOI: http://dx.doi.org/10.15666/aeer/1705_1221312226

analysis confirmed that the indicator microorganisms reached the peak diversity at 5mg/L, when the most populous microorganisms were vorticella and rotifera.

Sewage treatment at different water temperatures

Table 5 lists the operation parameters like DO, MLSS, pH and HRT at different water temperatures.



(a) (b)

Figure 5. *Microbial response at different dissolved oxygens (DOs)*

Table 5. *Process parameter at different temperatures*

Designed Temperature(°C)	10	15	20	25	30
HRT(h)	26.25	26.25	26.25	26.25	26.25
DO(mg/L)	1.80	1.87	1.76	1.80	1.63
pH	7.52	7.69	7.58	7.52	8.18
MLSS(mg/L)	1137	2132	1889	1137	983
SV30(%)	15	17	15	15	13
Temperature(°C)	8.98	14.8	17.5	22.4	29.1

Effect on removal rates

Figure 6 shows the removal rates of COD, TP, TN and NH_4^+-N in anaerobic, anoxic and aerobic tanks at different water temperatures.

As shown in *Figure 6(a)*, the COD removal rate ranged between 70.06% and 84.33% under the five water temperatures; in descending order of the COD removal rate, the water temperatures were ranked as 15, 30, 25, 10 and 20°C; the optimal water temperature was obviously 15°C, as the COD removal rate reached the peak value under this temperature; the removal effect was obvious in anaerobic section, but the removal rate was not significantly enhanced in the anoxic or aerobic section.

As shown in *Figure 6(b)*, the TP removal rate fluctuated between 3.54% and 75.55% under the five water temperatures; in descending order of the TP removal rate, the water temperatures were ranked as 15, 20, 30, 10 and 25°C; the optimal water temperature was obviously 15°C, as the TP removal rate was the highest under this temperature; the removal effects were obvious in anaerobic and aerobic sections, but the removal rate was not significantly enhanced in the anoxic section.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1221312226

As shown in *Figure 6(c)*, the TN removal rate fell between 36.60% and 77.98% under the ten DOs; in descending order of the TN removal rate, the water temperatures were ranked as 10, 25, 15, 30 and 20°C; the optimal water temperatures were 10 and 25°C, as the peak TN removal rate was measured under the two temperatures; the removal effects were obvious in anaerobic and aerobic sections, but the removal rate was not significantly enhanced in the anoxic section.

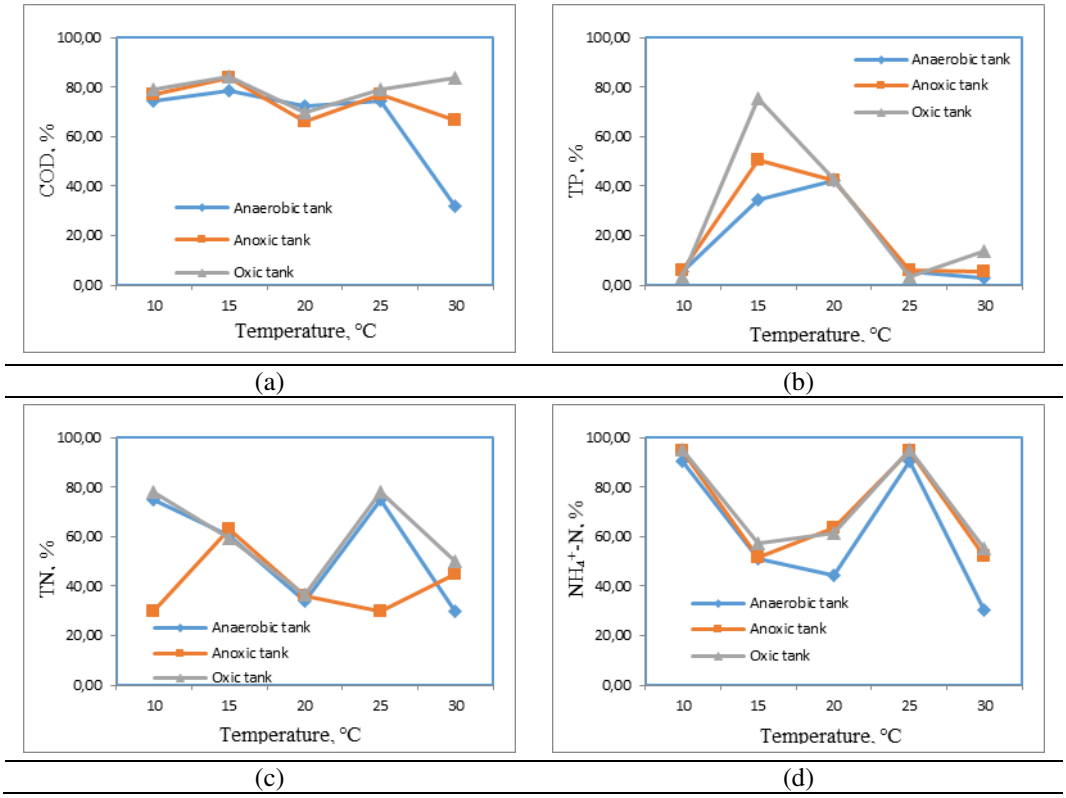


Figure 6. *Removal rate at different temperatures*

As shown in *Figure 6(d)*, the NH_4^+-N removal rate changed between 55.44% and 95.44% under the five water temperatures; in descending order of the NH_4^+-N removal rate, the water temperatures were ranked as 10, 25, 20, 15 and 30°C; the optimal temperatures were 10 and 25°C, as the peak NH_4^+-N removal rate was obtained under these two temperatures; the removal effect was obvious in anaerobic section, but the removal rate was not significantly enhanced in the anoxic or aerobic section.

Overall, the optimal water temperature was 15°C among the five designed water temperatures; the optimal temperature in the plateau environment was lower than that in the other regions.

Microbial response

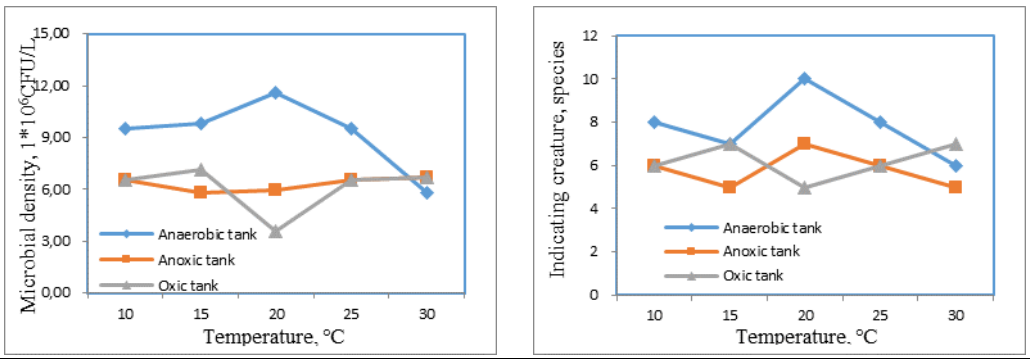
The microbial density and indicator microorganisms under the above five water temperatures are displayed in *Figure 7*.

It can be seen from *Figure 7(a)* that the five water temperatures could be ranked as 20, 15, 10, 25 and 30°C in descending order of the number of microorganisms in the anaerobic section, 30, 25, 10, 20 and 15°C in the anoxic section, and 15, 30, 25, 10 and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1221312226

20°C in the aerobic section. Since the microbial effect is correlated with microbial density, microbial residence time, and inlet/outlet water quality, it is not reasonable to evaluate the microbial response with the bulk density of the microorganisms.

It can be seen from *Figure 7(b)* that the five water temperatures could be ranked as 20, 10, 25, 15 and 30°C in descending order of the diversity of indicator microorganisms in the anaerobic section, 20, 10, 25, 15 and 30°C in the anoxic section, and 15, 30, 10, 25 and 20°C in the aerobic section. The indicator microorganisms reached the peak diversity at the water temperature of 20°C, when the most populous microorganisms were vorticella, trochilia and oxytricha. Meanwhile, the most populous microorganisms were also vorticella, trotifera and trochilia at the water temperature of 15°C.



(a) (b)

Figure 7. *Microbial response at different temperatures*

The microbial analysis show that the microbial density is not directly correlated with the optimal water temperature, because the treatment effect depends on retention time and inlet/outlet water quality, in addition to microbial density; moreover, the indictor microorganism analysis found that the indicator microorganisms reached the peak diversity at 15°C, when the most populous microorganisms were vorticella, rotifera and oxytricha; furthermore, it should be noted that the diversity did not increase with the water temperature (Tian et al., 2013).

Discussion

Discussion of HRTs

Some of the recent studies on the optimal HRT are as follows. Wang et al. (2014) suggested that the optimal HRT was 8~12 h for the processing of high-load sewage by A2O and electro-coagulation. Ye et al. (2018) put the optimal HRT to 6 h for the removal of organic matters and nutrients from urban sewage with dual-A2O (D-A2O).

In our experiment, the optimal HRT is determined as 26.25 h based on the removal rates and microorganism response. This conclusion differs greatly from the results of the previous studies. The difference may be attributed to the environmental factor of low water temperature. The microbial density in low-temperature water body treated by the A2O is generally considered as 10^8CFU/L (Yang, 2017). In our experiment, however, the microbial density was merely 10^6CFU/L under the plateau environmental factors.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1221312226

Discussion of DO

Large numbers of DOs come to the anoxic unit through International recirculation flow and destroyed the hypoxic environment, affecting the nitrogen removal (Li et al., 2012). With respect to total nitrogen removal, nitritation–denitritation at low DO levels of 0.3–0.5 mg/L was essentially equal to the complete nitrification– denitrification at DO levels of 1.5-2.5 mg/L with the addition of external carbon sources (Zeng et al., 2010). Under the conditions of 11 h HRT, 1.0-2.0 mg/L DO concentration, 200% mixture reflux proportion, 80% sludge reflux proportion and 20d sludge age, the effluent concentration can achieve the first order A standard of Discharge Standard of Pollutants for Municipal Wastewater Treatment Plant (Zhang et al., 2011). Controlling to DO at 0.8-1.5 mg/L, the treatment efficiency of full-scale Biolak/A^2O process was near optimal with the total nitrogen efficiency of 69.45% (Ju et al., 2013). DO levels in the range of 0.5 to 3.5 mg/L in the aeration basin did not have significant impact on effluent ortho-P concentration in a completely mixed basin within the EBPR process (Gu et al., 2006). In our experiment, the optimal DO is determined as 3.0 mg/L based on the removal rates and microorganism response. This conclusion deviates greatly from the results of the previous studies. A possible cause for the deviation lies in the unique environmental factors of the plateau.

Discussion of temperature

The temperature and functions of A2O process were closely related (Zhao et al., 2010). Under the condition of average temperature of 14.2°C and carbon-to-nitrogen radio of 4.81, enhanced nitrogen and phosphorus removal was achieved (Wang, 2010). The changes of temperature could affect the community structure and the Shannon diversity index of nitrifying bacteria (Tao et al., 2009). In our experiment, the optimal water temperature was determined as 15°C based on the removal rates and microorganism response. This conclusion was very inconsistent with the results of the previous studies, which may be ascribed to the unique properties of microorganisms at low temperatures on the plateau. Because Nitrification rates at high altitude aquatic ecosystems are scarce (Hayden and Beman, 2014; Molina et al., 2018).

Conclusions

Under the unique environmental factors of plateau, this paper designs a pilot-scale A2O device to explore the effects of DO, HRT and water temperature on the removal rates of COD, TP, TN and NH_4^+-N, and the law of microbial response to these working parameters. The results show that none of the TP, TN or NH_4^+-N of the outlet water satisfied the Chinese national standard GB18918-2002, while the COD only fulfilled the standard requirements under a few working parameters. The optimal values of the four working parameters were determined as: the optimal HRT=26.25 h, the optimal DO=3.0 mg/L, the optimal temperature=15°C. All these optimal values deviated greatly from the existing studies. The microbial densities corresponded poorly to the three working parameters, and differed significantly from those under normal conditions; the number of indicator microorganisms was basically consistent with the optimal values of our experimental parameters. In addition, the SV30 (Xu et al., 2013) and NLSS (Zhang et al., 2018) were both low in our experiment.

(Received 3rd May 2019; accepted 11th Jul 2019)

Abstract. Based on the daily rainfall data of 19 meteorological stations in Guizhou Province from 1968 to 2017 and combining the characteristic of hydrogeology in Guizhou Province, this study revised the Dry-Wet Abrupt Alternation Index (DWAAI) and analyzed the spatial and temporal evolution characteristics of drought-flood abrupt alternation in Guizhou Province in recent 50 years. The results show that: 1. the revised DWAAI index has good applicability in Guizhou Province; 2) The time of drought-flood abrupt alternation is mainly distributed from April to October. In terms of the interannual variation, the station proportion and intensity show an increasing trend, and the increasing trend was significant in station proportion. The intensity of drought-flood abrupt alternation in autumn shows a decreasing trend, and the station proportion and intensity increase in other seasons, in which the intensity of the drought-flood abrupt alternation in spring and summer and the station proportion of the drought-flood abrupt alternation in summer increase significantly. (3) The frequency of the drought-flood abrupt alternation in Guizhou Province decreased from east to west as a whole. It is easy to occur in spring in the south, in summer in the middle and the north with the largest area, and in autumn in the east. With the increase of the years, the scope of prone areas has been expanding. The results are of great significance for disaster prediction and early warning and drought and flood control in this area.
Keywords: *drought and flood, revised index, trend analysis, spatial analysis*

Introduction

Guizhou is a province with frequent natural disasters, mainly including flood and drought disasters, low-temperature freezing, wind and hail, landslide and debris flow, among which the occurrence frequency of flood and drought disasters is higher, with the larger disaster area, which mostly appear as flower arrangement, so it is easy to form drought-flood abrupt alternation events and pose a serious threat to the local social and economic development. The drought-flood abrupt alternation refers to the meteorological and hydrological events such as floods when there is no precipitation or little precipitation in the early stage and the drought has occurred, and then high-intensity precipitation occurs in a short period of time (Huang, 2015). The drought-flood abrupt alternation usually coincides with the growth period of autumn harvest and summer harvest crops, encounters the abrupt alteration of drought and flood disasters in a short period, the influence and loss of the region is multiplied, and climate change leads to the increase of extreme hydrological events, which increases the risk of drought-flood abrupt alternation to a large extent. Many scholars in China and abroad studied flood and drought disasters from the aspects of forming factors (Djebou et al., 2014), physical processes (Langousis and Kaleris, 2014; Goswami et al., 2018) and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1222712244

evolution rules (Grinsted et al., 2014; Andrea et al., 2018), but most of them focused on relatively independent elements such as "flood" and "drought" (Zhou et al., 2013; Han et al., 2014; Liu et al., 2014; Rajsekhar et al., 2015) or uses drought-flood abrupt alternation as a fixed element. With the intensification of climate change, especially the frequent and wide occurrence of drought and flood events in China, the study of "flood" and "drought" coupling has entered into a development period in China. Many scholars used conventional meteorological dry and wet indicators such as continuous rain-free days (Cheng et al., 2012), precipitation anomaly (Shen et al., 2012) and SPI (Wu et al., 2006a,b) to study the drought-flood abrupt alternation, with good results in macroscopic law recognition and characteristic analysis, but failing to completely describe the process and intensity of the drought-flood abrupt alternation. For better quantify, Wu et al. (2006b) compared the differences in precipitation between May-June and July-August, and defined a Long-cycle Drought-Flood Abrupt Alternation Index (LDFAI); Zhang et al. (2012) referred to LDFAI, and defined the Runoff Drought-Flood Abrupt Alternation Index (RDFAI); Shan et al. (2018) improved the problem of large time scale of LDFAI index and constructed the Dry-Wet Abrupt Alteration Index (DWAAI), which not only reflects the difference of drought and flood in the former and later stages, but also reflects the degree of urgency from drought to flood, that's, it can comprehensively reflect the "abrupt" and "alternation" of the drought-to-flood.

Based on DWAAI and combining with the characteristics of hydrology, meteorology, soil and geology in Guizhou Province, this study revised the degree of drought and flood in the former and later stages of the index. Based on the calculated results, the temporal and spatial evolution characteristics and regularities of drought-flood abrupt alternation events in Guizhou Province are analyzed by using climatic tendency rate, Mann-Kendall method and Inverse Distance Weighting (IDW). The purpose of the study is to monitor and warn drought-flood abrupt alternation disasters, formulate comprehensive response plans for the sudden disasters of drought-flood abrupt alternation, reduce disaster losses, and provide scientific support for agricultural production safety in this region.

Materials and methods

Overview of the research area

Guizhou Province belongs to the Yangtze River Basin and the Pearl River Basin, and its geographical position is between 103°36′E-109°35′E and 24°37′N-29°13′N. The territory is high in the west and low in the east, sloping northward, eastward and southward from the middle, with an average elevation of about 1,000 m above sea level and over 1,600-2,800 m above sea level in the west. The river network of the whole province is dense, the river slope is steep, the landform is complex and diverse, mainly with mountainous and hilly areas, and the karst landform is widely distributed, accounting for about 73% of the total area of the province. Guizhou Province belongs to the sub-tropical temperate and humid monsoon climate region. The basic meteorological data of 19 meteorological stations in the province over the past 50 years have been collated and counted,and the annual average temperature is about 15 ℃ and rain and heat are in the same season, with the annual rainfall of 1,179 mm but the uneven spatial and temporal distribution, descending from southeast to northwest. The annual rainfall from May to October accounts for 75% of the total.

Data sources

The data of this study are obtained from the National Meteorological Information Center of China Meteorological Administration (http://data.cma.cn), using daily rainfall data of 19 basic meteorological stations in Guizhou Province from 1968 to 2017 to sort and make up the difference in the quality of the original data. See *Figure 1* for spatial distribution of meteorological stations.

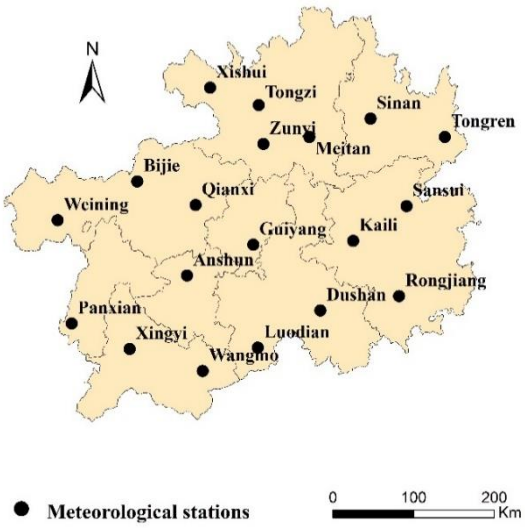

Figure 1. *Distribution of meteorological stations in Guizhou province*

Indicators and methods

Revised DWAAI index

(1) DWAAI index

The DWAAI index calculation model is derived from the LDFAI defined by Wu et al (2006b). The LDFAI index was improved by Shan et al. (2018) to construct the DWAAI index, with equation as follows:

$$DWAAI_i = \left[K + \left(SPA_{la\,i} - SPA_{ea\,i}\right) \times \left(\left|SPA_{ea\,i}\right| + \left|SPA_{la\,i}\right|\right)\right] \times a^{-\left|SPA_{ea\,i} + SPA_{la\,i}\right|} \quad \text{(Eq.1)}$$

$$K = \sum_{i=1}^{n} \left(\frac{SAPI_i - SAPI_0}{i} \right) \quad \text{(Eq.2)}$$

In *Equation (1)*, $SPA_{ea\,i}$ and $SPA_{la\,i}$ represent the anomalies of normalized precipitation in the early and late periods (Maheras et al., 1999); in *Equation (2)*, $SAPI_i$ and $SAPI_0$ represent the value of the Standard Antecedent Precipitation Index (SAPI) in the *i*-th day and the antecedent last day of the flood period, which is calculated with the standardization of Antecedent Precipitation Index (API); n represents days in flood period; *a* represents weight coefficient, with the value range of $1<a\leq1.4$ as recommended by Literature (Shan et al., 2018), and $a=1.1$ according to the actual situation of Guizhou and the comparison and rationality analysis of various calculation results.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1222712244

(2) DWAAI index revision

In the drought-flood abrupt alternation events, the formation of drought in the early stage and drought-flood abrupt alternation in the late stage are two different stages, with different mechanisms. The formation of drought is the result of drought accumulation in the early stage, and the influence of daily precipitation on drought in the early stage decreases exponentially with the increase of drought date (Lu, 2009); floods caused by late heavy rainfall have short-term characteristics, and there is no attenuation and accumulation process. Therefore, this study revise $SPA_{ea\,i}$ and $SPA_{la\,i}$ as follows:

$$SPA_{ea\,i} = \sum_{j=0}^{m} k^j SPA_{i-j} \quad (i \geq 45 and\, i, j \in N) \tag{Eq.3}$$

$$SPA_{la\,i} = \frac{1}{n} \sum_{j=1}^{n} SPA_{i+j} \quad (i \geq 1 and\, i, j \in N) \tag{Eq.4}$$

In *Equation (3)*, m represents the number of drought days, and the influence of the 44th day in the early stage on the drought is less than 1‰, so m takes 44 herein; k represents the attenuation index; Lu (2009) recommends k as 0.9 in the study of the Mississippi Valley. But Guizhou Province is of mainly karst landform, mountainous and hilly, the soil thickness is thin and the groundwater layer is deep, so the attenuation degree is larger. Combined with the actual parameter optimization, k=0. 87 is selected in this study. In *Equation (4)*, n represents the days of flood period, because of the short-term nature of flood and flood, the excessively large value of n will cause "drought and flood neutralization". Combined with the meteorological characteristics of Guizhou Province and the actual calculation results, n=5 in this study. According to the calculation results and the actual situation of Guizhou, the classification of drought-flood abrupt alternation grade based on DWAAI index is shown in *Table 1*.

Table 1. *Grade division of drought-flood abrupt alternation*

Grade	None	Light	Moderate	Heavy
Value range of DWAAI	(0,12.0)	[12.0,18.0)	[18.0,25.0)	[25.0,∞)

Research methods

Referring to the regional drought assessment index constructed by Huang et al. (2010), this study uses frequency, station proportion and intensity of drought-flood abrupt alternation to reflect the spatial and temporal characteristics of drought-flood abrupt alternation events in Guizhou Province, among which station proportion reflects the range of drought-flood abrupt alternation events with equation as follows:

$$P = \frac{m}{M} \times 100\% \tag{Eq.5}$$

In *Equation (5)*, P represents station proportion; m represents the number of the meteorological stations which occurred drought-flood abrupt alternation event in study

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1222712244

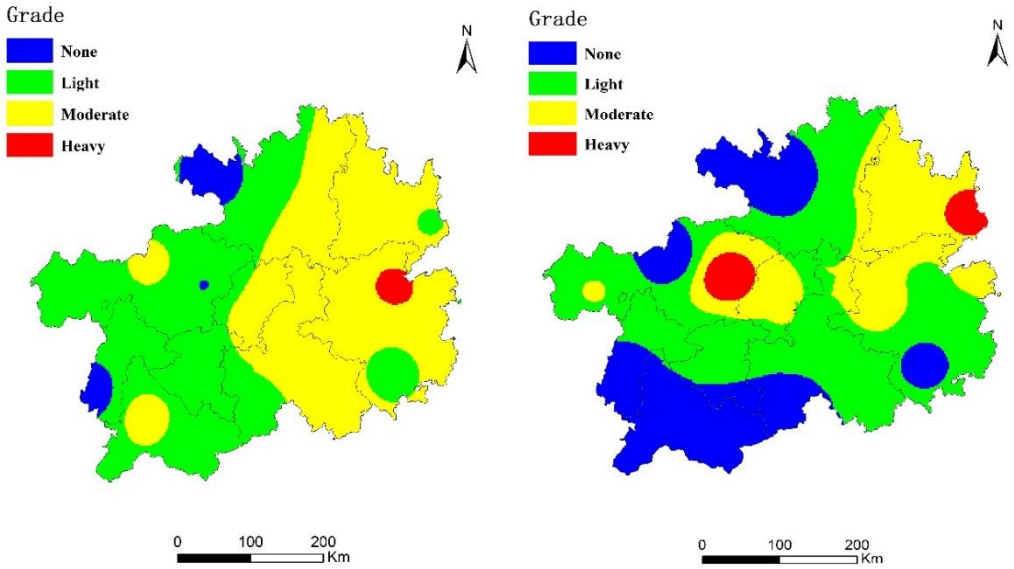
area; M represents the number of all the meteorological stations in study area. It indicates the scope of drought-flood abrupt alternation in a certain region.

The climate tendency rate and Mann-Kendall method are used to analyze the trend. The climate tendency rate is linear tendency rate. The least square method is used to fit the unitary regression equation of the long-time element sequence, which is expressed as 10 times of the regression coefficient. Mann-Kendall method is used to test the significance of the trend. ArcGIS Inverse Distance Weighting (IDW) method is used to analyze spatial evolution characteristics.

Results

Verification of indicator applicability

At present, the research on the drought-flood abrupt alternation in China is mainly concentrated in the middle and lower reaches of the Yangtze River and the Huaihe River Basin while the characteristics and types of rainfall, drought and flood in Guizhou Province are different from those in the above areas. Therefore, this study takes the typical drought and flood abrupt alternation events in 2011 and 2012 as examples to verify the applicability of the revised DWAAI index in Guizhou Province. According to the calculation results, the spatial distribution of drought-flood abrupt alternation events in Guizhou Province in 2011 and 2012 is shown in *Figure 2*.



(a) 2011 (b) 2012

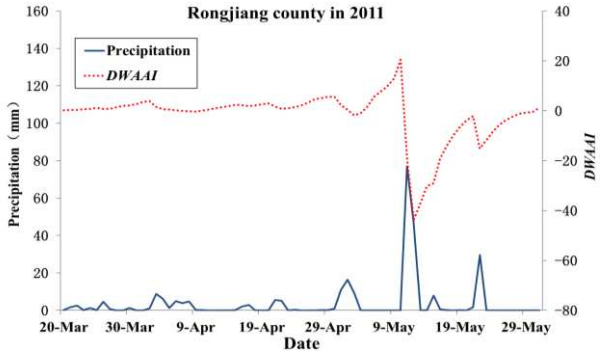
Figure 2. *Spatial distribution of drought-flood abrupt alternation events in 2011 and 2012 in Guizhou province*

According to the actual situation, in the middle and upper part of June 2011, there was a strong precipitation process in the northern-central Jiangxi, the central Hunan and the eastern Guizhou. Although the drought was alleviated, the drought-flood abrupt alternation occurred in some areas of the three provinces. In late May 2012, due to uneven distribution of rainfall, serious drought-flood abrupt alternation occurred in

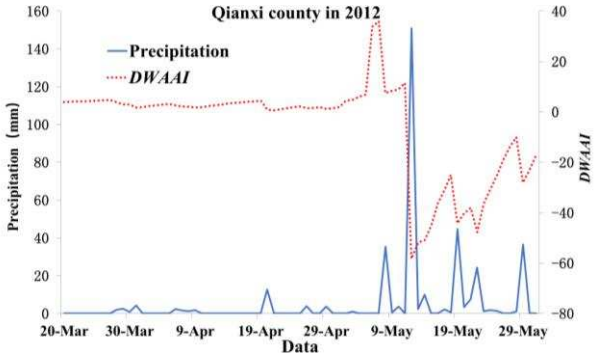
http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1222712244

Yanhe County and Dejiang County of Tongren City and Qianxi County of Bijie City. As can be seen from *Figure 2a*, in 2011, except for a few areas such as the west of Zunyi City and the southwest of Liupanshui City, most regions of Guizhou Province experienced drought-flood abrupt alternation in different degrees, with the most serious in the east. As can be seen from *Figure 2b*, in 2012, except for the southern and northwest regions of Guizhou Province, the drought-flood abrupt alternation occurred in different degrees in other regions, and the high-intensity regions are consistent with the historical reality.

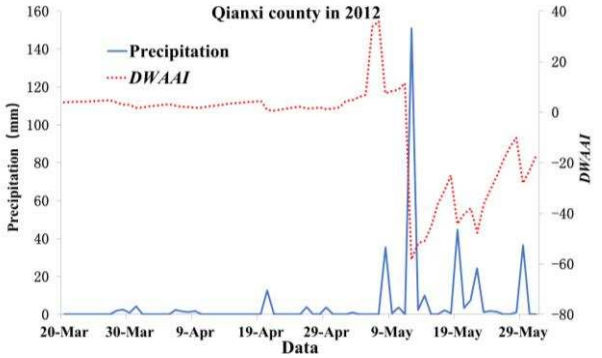
Combining with the actual situation of the drought-flood abrupt alternation in Guizhou Province from 2011 to 2012, this paper selected data of the rainfall process and the corresponding DWAAI indices before and after the occurrence of drought-flood abrupt alternation happened in Rongjiang County in 2011, and in Qianxi County and Tongren City in 2012, as shown in *Figure 3*.



(a) Rongjiang county in 2011



(b) Qianxi county in 2012



(c) Tongren city in 2012

Figure 3. *The process of typical drought-flood abrupt alternation events in 2011 and 2012 in Guizhou province*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1222712244

From *Figure 3a* we can see that, in the Rongjiang County, the accumulated precipitation in 45 days before May 10th 2011 was 87.5mm, and the accumulated precipitation in 5 days after May 10th was 132.2 mm, wherein the single-day precipitation on May 11th was 77 mm, and the DWAAI of May 10th was 20.5, which had reached an extremum, so the May 10th had been determined as the date of the drought-flood abrupt alternation occurrence, with a degree of moderate; moreover, from *Figure 3b* we can see that, in the Qianxi County, the accumulated precipitation in 45 days before May 7th 2011 was 35.3 mm, and the accumulated precipitation in 5 days after May 7th was 190.5 mm, although the single-day precipitation reached 150.9 mm on May 12th, the DWAAI extreme value 35.9 appeared on May 7th with a degree of severe, this is because the single-day precipitation on May 8th was 35.4 mm, which can better reflect the "abrupt" degree of the change of drought and flood since that day, therefore, the May 7th had been determined as the date of the drought-flood abrupt alternation occurrence, and after a certain period of flood season, the drought-flood abrupt alternation had produce serious impact in mid- and late-May; similarly, as can be seen from *Figure 3c*, Tongren City had determined the May 8th as the date of the drought and flood abrupt alternation occurrence, but its DWAAI was 15.4, indicating it was a slight degree drought-flood abrupt alternation. This is because the accumulated precipitation in the previous period reached 204.9mm, indicating from the perspective of the "alternation" of the drought-flood that the degree of drought-flood abrupt alternation is not as severe as the Qianxi County, which further proves the applicability and rationality of the indices. Therefore, the applicability of the revised DWAAI in Guizhou Province has been verified.

Characteristics of temporal evolution

Distribution characteristics within a year

As can be seen from *Figure 4*, the time of drought-flood abrupt alternation in Guizhou Province is mainly distributed from April to October, and the cumulative drought-flood abrupt alternations account for 93.51% of the total; from July to September, it's relatively concentrated with 75 times, 59 times and 67 times respectively, accounting for 19.48%, 15.32% and 17.40% of the total number of events, respectively.

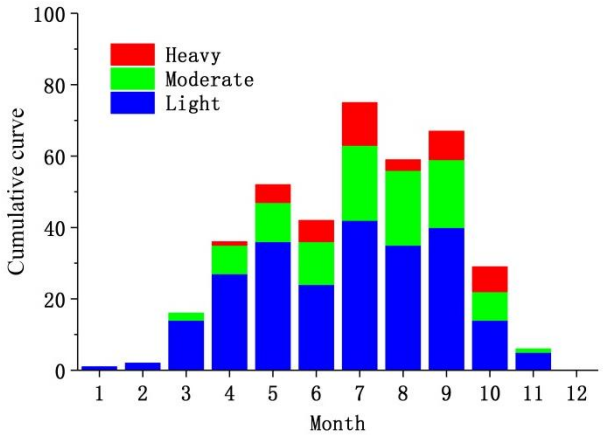


Figure 4. *Annual distribution of drought-flood abrupt alternation events over 1968-2017 in Guizhou province*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1222712244

From December to February of the following year, the drought-flood abrupt alternation rarely occurred; from the point of view of the cases of moderate and above drought-flood abrupt alternation, it mainly occurs from July to September, 33 times, 24 times and 27 times, accounting for 8.57%, 6.23% and 7.01% of the total times respectively, which is basically consistent with the research results by Chen et al. (2015) and Lu (2010) on the characteristics of drought, rainstorm and flood in Guizhou Province, respectively. The drought-prone type is summer drought and spring drought in Guizhou Province, and the rainfall is concentrated in May-October in the whole province, so the period from the end of spring to early autumn is the period of drought-flood abrupt alternation, which is consistent with the *Figure 4*, further proving the applicability of the DWAAI index in Guizhou Province.

Interannual variation

(1) Station proportion. As can be seen from *Figure 5* ,the station proportion of drought-flood abrupt alternation in Guizhou province fluctuates from 10.53% to 78.95% in recent 50 years with greater interannual difference. In 2015 and 1986, there were partially regional drought-flood abrupt alternations for 5 years; in 2013 and 2007, there were partially regional drought-flood abrupt alternations for 14 years; in 2016-2017 and 2014, there were regional drought-flood abrupt alternations for 21 years; in 2011-2012 and 2002, there were regional drought-flood abrupt alternations for 10 years; before 2000, there were mainly partially regional and regional drought-flood abrupt alternation; after 2000, the regional drought-flood abrupt alternation occurred frequently, and the years with the highest station proportion were all after 2000, i.e., 2002 and 2011, respectively (78.95% of station proportion), which shows that the occurrence range of drought-flood abrupt alternation in recent 20 years is expanding.

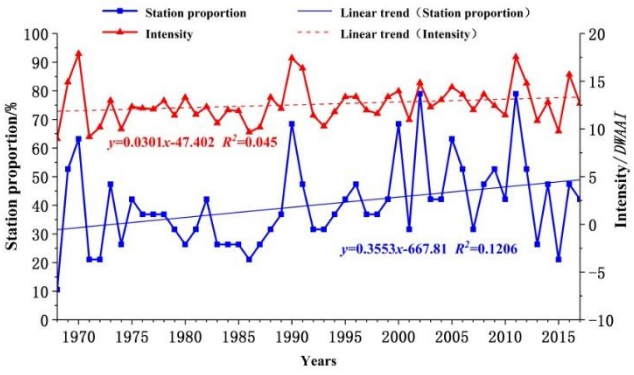

Figure 5. *Variation characteristics of station proportion and intensity of drought-flood abrupt alternation over 1968-2017 in Guizhou province*

(2) Intensity. As can be seen from *Figure 5*, the intensity of drought-flood abrupt alternation in Guizhou Province in recent 50 years fluctuated from 8.96 to 17.88, and the average intensity of drought-flood abrupt alternation is 12.59, which shows that the drought-flood abrupt alternation in Guizhou Province is mainly mild, and the intensity of drought-flood abrupt alternation is higher than 12.00 for 29 years, during which in 1970, 2011 and 1990, the intensity is higher than 17.00, that's, 17.88, 17.55 and 17.43, respectively. They are the three years with the highest intensity of drought-flood abrupt alternation over the past 50 years.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1222712244

From the change trend of station proportion and intensity (*Table 2*), the climate tendency rate is consistent with the result of Mann-Kendall method. The station proportion and intensity have increased in Guizhou Province in recent 50 years, and the increasing trend of station proportion is significant, which shows that with the increase of time, the intensity and range of drought-flood abrupt alternation in Guizhou Province increased.

Table 2. *Trend detection results of station proportion and intensity of drought-flood abrupt alternation over 1968-2017 in Guizhou province*

	Linear tendency rate/10a-1	**Mann-Kendall test**	
		Z	**β**
Station proportion/%	3.55*	2.06*	0.39
Intensity	0.3	1.4	0.04

Note: Z is Statistics of Mann-Kendall test; β is Sen's slope, means trend of annual average; * means significant trend when α=0.05; the same below

Characteristics of seasonal drought-flood abrupt alternation over the years

(1) Spring (March-May). As can be seen from *Figure 6a*, the station proportion of drought-flood abrupt alternation in spring in Guizhou Province in the past 50 years ranged from 0.00% to 42.11%, averaging 10.84%; only in 1973 occurred the regional drought-flood abrupt alternation, with the station proportion of 42.11%. In 1969, 1977, 1999 and 2006, there were partially regional drought-flood abrupt alternations or non-obvious drought-flood abrupt alternation for 4 years, while there were regional drought-flood abrupt alternations for the other 45 years, and large-scale drought-flood abrupt alternation occurred frequently from 1994 to 2007 in spring. The interannual intensity of drought-flood abrupt alternation in spring varies from 0.00 to 16.80, averaging 10.91; the intensity of drought-flood abrupt alternation in spring exceeded 12.00 for 15 years, of which it occurred after 2000 for 7 years and occurred for 4 years in recent 10 years, that's, 2009, 2011-2012 and 2016, respectively.

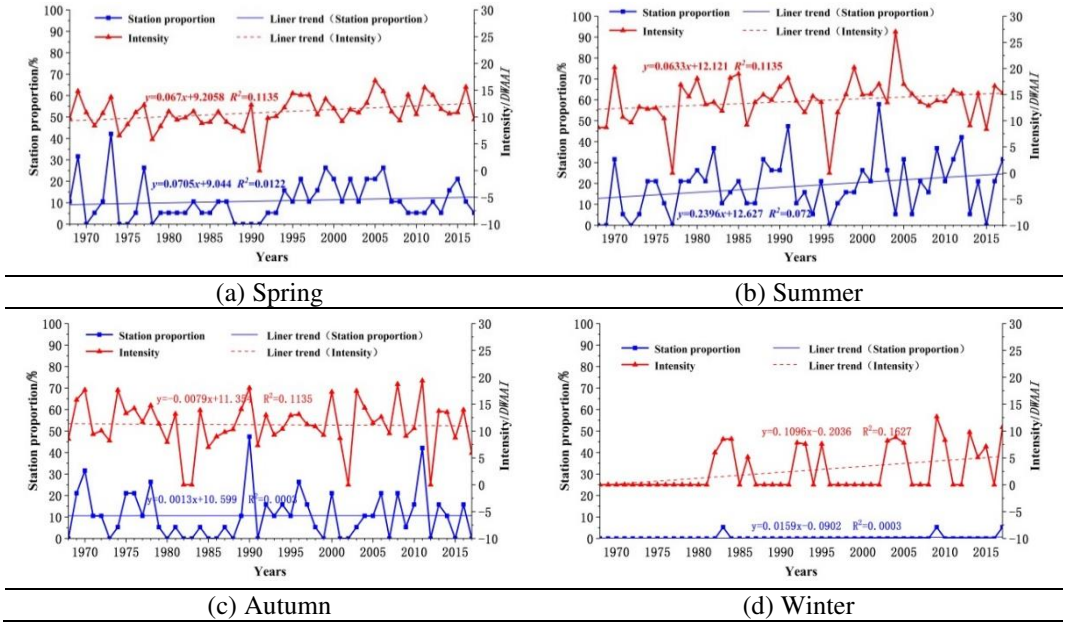
(2) Summer (June-August). As can be seen from *Figure 6b*, the station proportion of drought-flood abrupt alternation in summer in Guizhou Province over the past 50 years is between 0.00% ~ 57.89% (average 18.74%), which is generally higher, indicating that the occurrence range of drought-flood abrupt alternation in summer is large in Guizhou Province. The years with the highest station proportion in summer is 2002, and the station proportion is 57.89%, which is regional drought-flood abrupt alternation. In 1982, 1991, 2009 and 2012, there were regional drought-flood abrupt alternation for 4 years. In 2011 and 2005, there were partially regional drought-flood abrupt alternation for 10 years, and in 2016 and 2014, there were regional drought-flood abrupt alternation for 23 years. The interannual intensity of drought-flood abrupt alternation in spring varies from 0.00 to 27.02, averaging 13.74; the intensity of drought-flood abrupt alternation exceeded 12.00 for 37 years, of which it reached 27.02 in 2004, which is generally at a severe level, and it is the year with the strongest intensity of drought-flood abrupt alternation.

(3) Autumn (September-November). As can be seen from *Figure 6c*, the station proportion of drought-flood abrupt alternation in autumn for 50 years is between 0.00% and 47.37%, averaging 10.63%; in 1990 and 2011, there were regional drought-flood abrupt alternation in autumn for 2 years; in 1970, 1978 and 1996, there were partially

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1222712244

regional drought-flood abrupt alternation in autumn for 3 years; in 1969 and 1975-1976, there were regional drought-flood abrupt alternation in autumn for 21 years, among which it occurred after 2000 for 9 years and after 2010 for 4 years.

The interannual intensity of drought-flood abrupt alternation in autumn varies from 0.00 to 19.36, averaging 11.15; the intensity of drought-flood abrupt alternation in autumn exceeded 12.00 for 22 years, of which it reached 19.36 in 2011, which is generally at a moderate level, and it is the year with the strongest intensity of drought-flood abrupt alternation in autumn.



(a) Spring (b) Summer

(c) Autumn (d) Winter

Figure 6. *The seasonal variation characteristics of station proportion and intensity of drought-flood abrupt alternation over 1968-2017 in Guizhou province*

(4) Winter ((December-February). According to the calculation results, there were only three drought-flood abrupt alternation in winter in Guizhou Province in the past 50 years, which were in 1983, 2009 and 2017, and all of them were mild events. From Figure 6d, we cannot find the change rules from the station proportion. The interannual intensity of drought-flood abrupt alternation in winter ranges from 0.00 to 12.66, averaging 2.59. Therefore, there is no obvious drought-flood abrupt alternation in winter in Guizhou Province.

According to the station proportion and intensity variation trend of drought-flood abrupt alternation in different seasons (*Table 3*), the climatic tendency rate is basically consistent with the result of Mann-Kendall method. In spring, the station proportion of drought-flood abrupt alternation in spring tends to increase slightly, and the intensity tends to increase significantly. The station proportion and intensity of drought-flood abrupt alternation increase significantly in summer. The intensity of drought-flood abrupt alternation in autumn tends to slightly decrease. The station proportion linear tendency rate isn't consistent with the result of the Mann-Kendall test statistic Z, but the absolute values of them are both lower, so there is no obvious change trend in station proportion in autumn; the station proportion and intensity of drought-flood abrupt alternation in winter increased, but not significantly.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1222712244

Characteristics of spatial evolution

Spatial distribution characteristics of occurrence frequency

As can be seen from *Figure 7*, the frequency of drought-flood abrupt alternation in Guizhou Province from 1968 to 2017 is obviously different, decreasing from east to west as a whole. The prone areas of drought-flood abrupt alternation are mainly concentrated in central and southern Tongren and southeastern, central and eastern Guizhou, with a frequency of 50.85% ~ 68.00%, once every 1-2 year; the frequency in the western part of Bijie is low, ranging from 24.01% to 33.90%.

Table 3. *Trend detection results of station proportion and intensity of drought-flood abrupt alternation on different seasons over 1968-2017 in Guizhou province*

Season		Linear tendency rate/10a-1	Mann-Kendall test	
			Z	β
Spring	Station proportion/%	0.71	1.35	0
	Intensity	0.67*	2.11*	0.06
Summer	Station proportion/%	2.4*	2.87*	0.25
	Intensity	0.63*	1.97*	0.07
Autumn	Station proportion/%	0.01	-0.02	0
	Intensity	-0.08	-0.09	-0.01
Winter	Station proportion/%	0.16	0.4	0
	Intensity	1.1	1.74	0

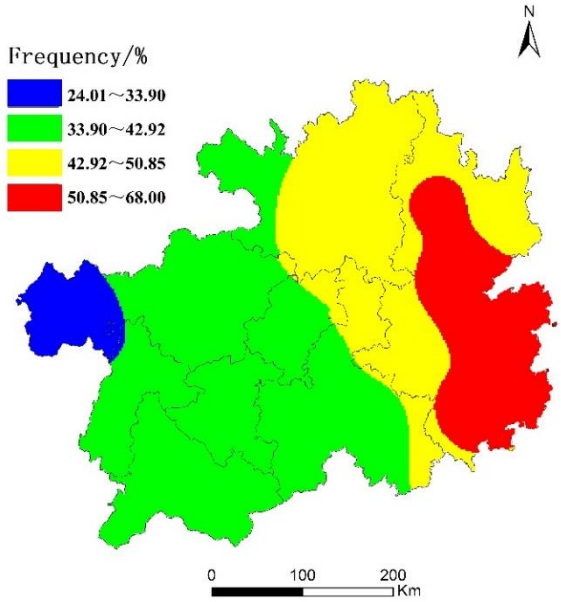


Figure 7. *Spatial distribution of drought-flood abrupt alternation frequency over 1968-2017 in Guizhou province*

Characteristics of seasonal spatial variation

In accordance with the calculation result, the frequency of drought-flood abrupt alternation in different seasons is calculated by four zones including once every more than 10 years (0 ~ 10%), once every 7 ~ 10 years (10% ~ 15%), once every 5 ~ 7 years

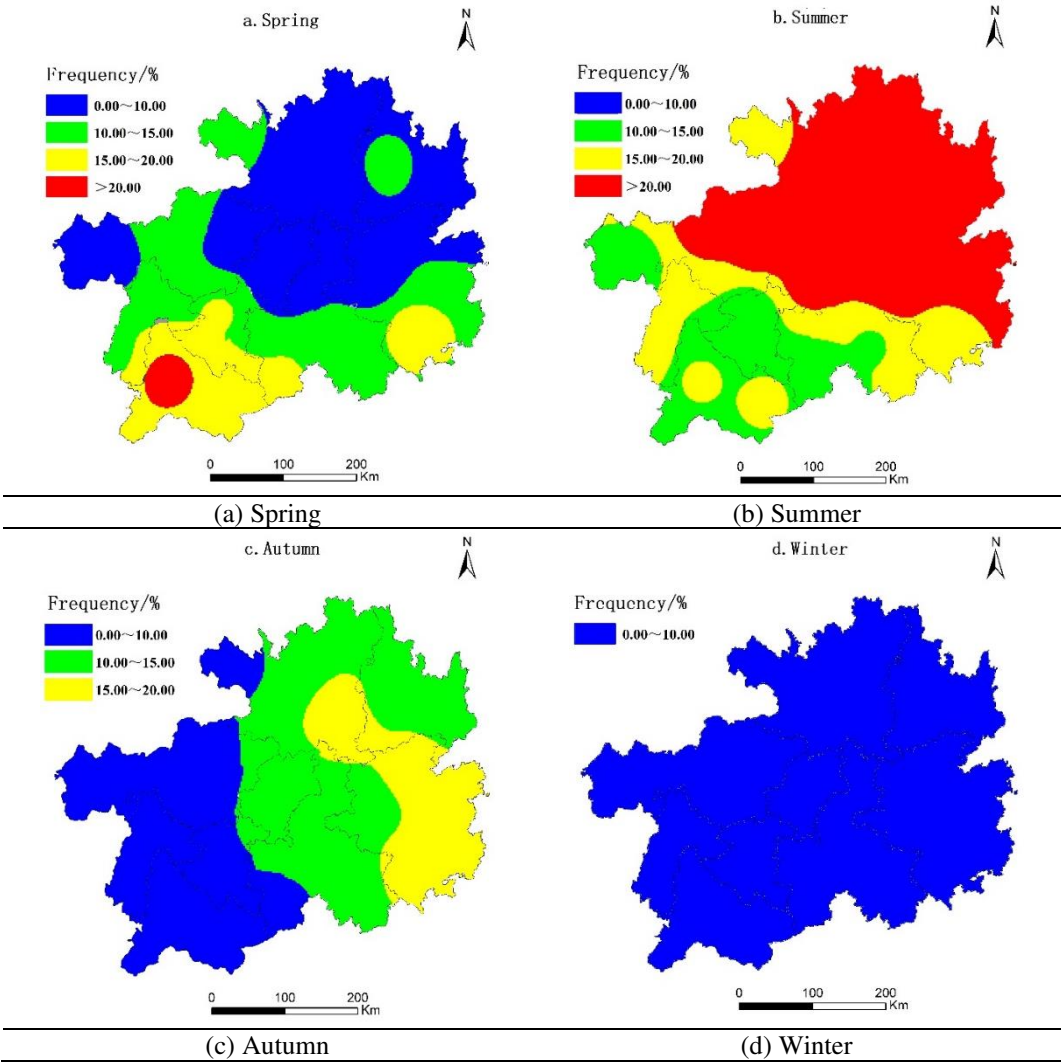
http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1222712244

(15% ~ 20%) and once every less than 5 years (> 20%), with the spatial distribution shown in Figure 7 and the area proportion of different zones shown in *Table 4*. The area proportion of each frequency and the product of the frequency are used to express the severity index of the zone with drought-flood abrupt alternation.

Table 4. *The area proportion of each frequency on different seasons over 1968-2017 in Guizhou province (%)*

Frequency / Season	0~10%	10%~15%	15%~20%	>20%	Severity index
Spring	48.43	31.97	17.47	2.13	9.90
Summer	3.53	21.25	21.44	53.78	17.34
Autumn	38.79	41.65	19.56	0.00	10.57
Winter	100.00	0.00	0.00	0.00	5.00

As can be seen from *Figure 8*, the spatial distribution of the frequency of drought-flood abrupt alternation varies greatly in different seasons.



(a) Spring (b) Summer

(c) Autumn (d) Winter

Figure 8. *Spatial distribution of drought-flood abrupt alternation frequency on different seasons over 1968-2017 in Guizhou province*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1222712244

The frequency of drought-flood abrupt alternation in spring is higher in the south than in the north, and the prone area is mainly in the southwest of Guizhou, of which the frequency in Xingyi City is more than 20%, that's, once every less than 5 years; the frequency in most of the central and northern regions and the western part of Bijie is less than 10% (*Figure 8a*). Summer is the opposite to spring, with the overall decline from north to south, the prone areas with the frequency of more than 20% run throughout most of the north-central region, and only in the southwest of Guizhou, the frequency is less than 10% (*Figure 8b*). In autumn, the frequency of drought-flood abrupt alternation decreases from east to west, and the southeast of Guizhou, the southwest of Tongren and the southeast of Zunyi are relatively vulnerable to drought-flood abrupt alternation, with the frequency of 15% ~ 20%, that's, the frequency in most areas of northwest and southwest Guizhou is less than 10% (*Figure 8c*). Fewer drought-flood abrupt alternation occurs in winter, without obvious characteristics of the spatial distribution, and the frequency is below 10% in the whole province (*Figure 8d*).

From *Table 4*, it can be seen that the frequency of drought-flood abrupt alternation in more than 80% areas of the province in spring and autumn is less than 15%; the frequency of drought-flood abrupt alternation in summer is over 50% in more than 50% of the whole province, and only 3.53% of the area have the frequency of lower than 10%. In winter, there are less drought-flood abrupt alternation events. In terms of severity, drought-flood abrupt alternation is the severest in summer, with the order from high to low as summer, autumn, spring and winter.

Characteristics of interdecadal spatial change

In order to describe the characteristics of interdecadal change conveniently, every 10 years has been counted as one decade since 1968. In accordance with the calculation result, the frequency of drought-flood abrupt alternation in different decades is calculated by four zones including once every 5 years (0 ~ 20%), once every 3 ~ 5 years (20% ~ 33.33%), once every 2 ~ 3 years (33.33% ~ 50%) and once every 1~2 years (> 50%), with the spatial distribution shown in *Figure 8*, and the area ratios of different zones shown in *Table 5*.

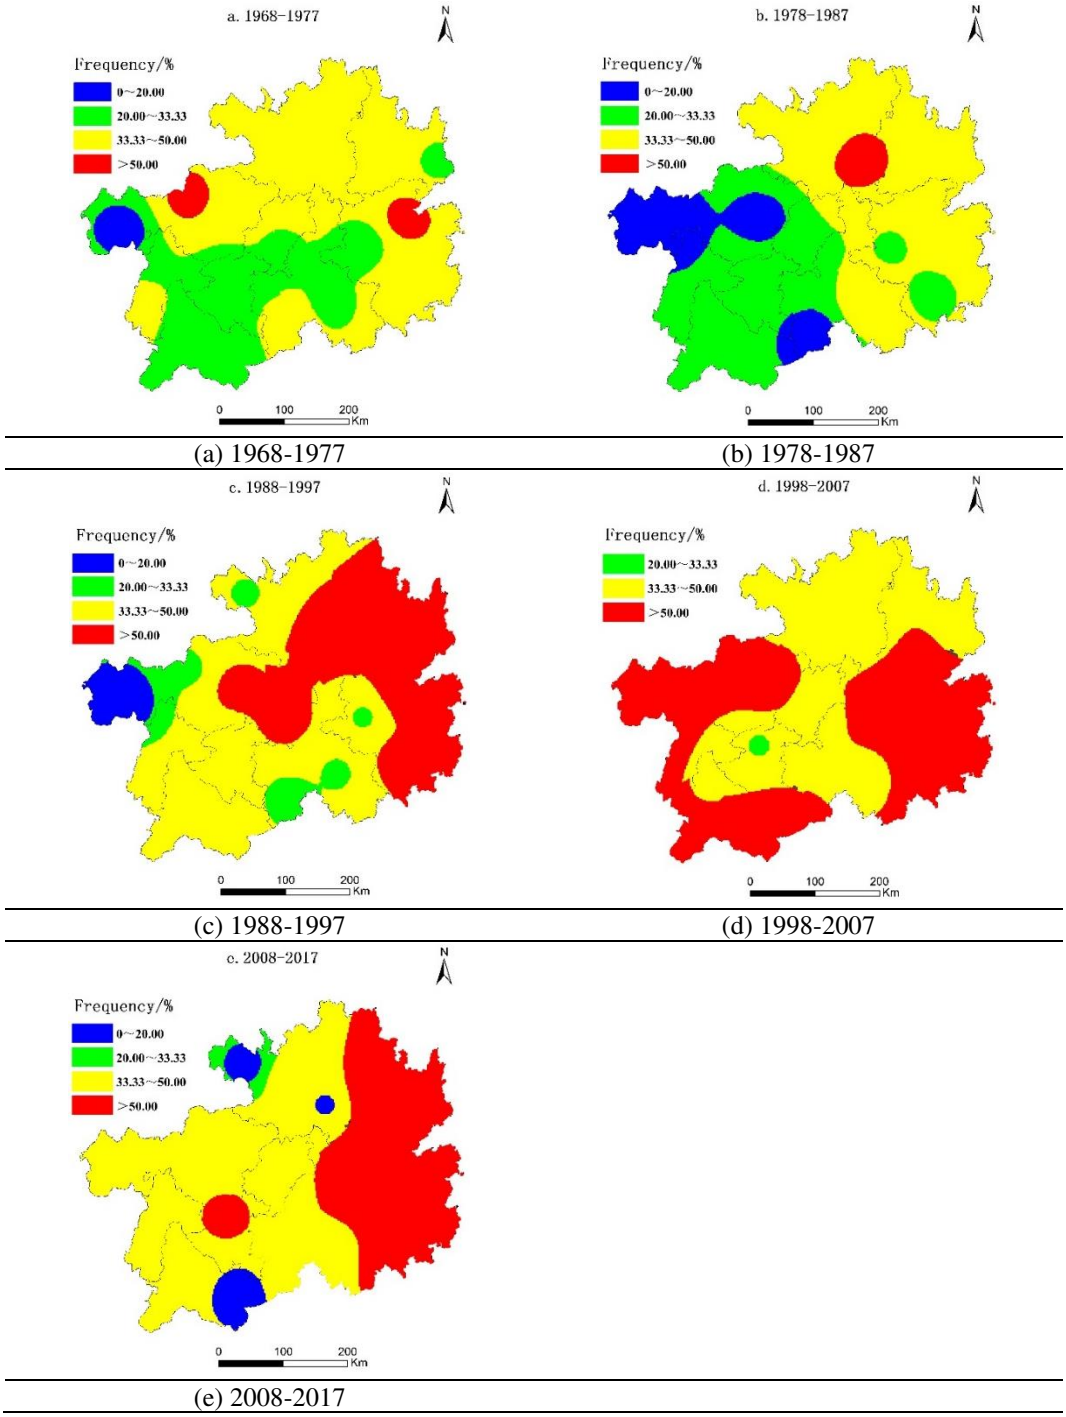
Table 5. *The area proportion of each frequency in different decades in Guizhou province(%)*

Frequency / Decade	0~20%	20%~33.33%	33.33%~50%	>50%	Severity index
1968-1977	2.39	33.78	60.37	3.46	36.13
1978-1987	13.79	35.48	47.79	2.94	32.22
1988-1997	4.31	8.16	49.05	38.48	42.29
1998-2007	0.00	0.45	48.62	50.94	45.84
2008-2017	1.38	5.14	58.45	35.02	43.38

As can be seen from *Figure 9*, except for 1998-2007, the spatial distribution of drought-flood abrupt alternation in each decade basically declines from east to west. With the increase of the decades, the scope of prone areas has been expanding. From 1968 to 1987, the frequency is higher than 50%, i.e. once every 1-2 years, the drought-flood abrupt alternation is sporadically distributed in southeast Quizhou, Bijie, Zunyi and Tongren (*Figures 9a,b*). From 1988 to 1997, the scope of prone areas has been extended to Guiyang, Zunyi, Tongren and southeast Quizhou (*Figure 9c*). From 1998 to 2007, except for some areas in Anshun, the drought-flood abrupt alternation occurred

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1222712244

once every 1 ~ 3 years in the whole province, among which, the scope of the prone areas once every 1 ~ 2 years was further expanded to the northwest, southwest and southeast Guizhou (*Figure 9d*). From 2008 to 2017, except for some areas in Zunyi and southwest Guizhou, the drought-flood abrupt alternation occurred once every 1-3 years in the whole province, and the range of prone areas was slightly reduced compared with that in 1998-2007. However, the overall distribution range is still relatively large (*Figure 9e*).



(a) 1968-1977 (b) 1978-1987

(c) 1988-1997 (d) 1998-2007

(e) 2008-2017

Figure 9. *Spatial distribution of drought-flood abrupt alternation frequency in different decades in Guizhou province*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1222712244

As can be seen from *Table 5*, from 1988 to 1997, the area of the prone areas with drought-flood abrupt alternation once every 1-2 years increases sharply. In 1998-2007, more than 50% of the area of the province suffered from drought-flood abrupt alternation once every 1-2 years. In recent 10 years, the area of prone areas has decreased, and the frequency is 33% ~ 50%, that's, the area with drought-flood abrupt alternation once every 2 ~ 3 years is relatively stable. The frequency of drought-flood abrupt alternation is 20% ~ 33.33%, that's, the area with drought-flood abrupt alternation once every 3 ~ 5 years decreased significantly. In terms of severity, from 1998 to 2007, the drought-flood abrupt alternation is the severest, followed by it from 2008 to 2017 and it is the lowest from 1978 to 1987.

Discussion

Chen et al. (2015) studied the temporal and spatial variation characteristics of drought in Guizhou Province. Lu (2010) carried out research in the climate characteristics of rainstorms and floods in Guizhou Province, and concluded that spring and summer are the high incidence periods of drought in Guizhou Province, the spring drought tends to occur in the western region of Guizhou, and the summer drought tends to occur in the northeastern region of Guizhou, from late-December to early-February, there is no rainstorm in the whole province, from mid-November to mid-March, there is no heavy rainstorm, and the extraordinary rainstorm concentrates from late-May to mid-September, which is consistent with the spatial and temporal characteristics of drought-flood abrupt alternation in the search results of this paper. Compared with 1998-2007, although the range in the recent 10 years is slightly reduced, high-intensity drought and flood abrupt alternation occurs more frequently, such as in 2011~2012, 2014 and 2016, and the resulted social and economic losses are much higher than in the past, which indicates that the drought -flood abrupt alternation has a tendency of becoming more intense. Therefore, it's of important practical significance to study the evolution law of drought and flood abrupt alternation, monitor it and alarm early warnings.

The drought in earlier period is the premise of the formation of drought-flood abrupt alternation, and the extreme precipitation event is a necessary condition for drought and flood abrupt alternation. Raksekhar et al. (2015), Liu et al. (2014) assessed or analyzed the drought characteristics of the study area by establishing or improving drought indicators. Goswami et al. (2018), Andrea et al. (2018) studied the formation factors of extreme precipitation. Compared with the above research results, the DWAAI can couple "droughts" and "floods", and describe the entire process of drought-flood abrupt alternation events completely, which has laid a foundation for exploring the formation mechanism of drought-flood abrupt alternation events.

The food crops and economic crops in Guizhou are mainly harvested in the autumn, and the crucial growth period of most crops coincides with the period of the occurrence of drought-flood abrupt alternation, therefore, the drought-flood abrupt alternation has a great impact on agricultural production. And the influencing mechanism of drought-flood abrupt alternation on crops is quite complicated, generally speaking, both droughts and floods would affect the growth and development of crops and thus leading to production reduction. In addition, if drought-d flood abrupt alternation occurs, it would produce superposed losses; but for some dryland crops, a certain-degree drought during the rooting period can effectively increase the root length and thus enhancing the drought tolerance; if the drought is relieved or there is a slight flood, there may be a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1222712244

certain "compensation" effect (Gao et al., 2017). Therefore, it is necessary to combine specific physiological indicators of crops and the soil moisture conditions to carry out more in-depth experimental research on the crops' response mechanism to the abrupt alternation of droughts and floods.

Conclusions

(1) The revised DWAAI index has the advantages of high accuracy, comprehensive reflection, reasonable calculation results and good agreement with the real situation, so it has a good applicability in Guizhou Province.

(2) Temporally, the drought-flood abrupt alternation mainly occurs from April to October in Guizhou Province. In terms of interannual variation, the station proportion and intensity have the trend of increasing year by year, and the increasing trend of station proportion is significant. In terms of seasonal characteristic, except autumn, the station proportion and intensity all have an increasing trend, among which the intensity of drought-flood abrupt alternation in spring and summer and the station proportion of drought-flood abrupt alternation in summer increase obviously, the intensity of drought-flood abrupt alternation in autumn has a decreasing trend and the trend of station proportion is not obvious.

(3) Spatially, the frequency of drought-flood abrupt alternation in Guizhou Province is decreasing from east to west, varying greatly in different seasons, i.e., in the southern region in spring, in the middle and north in summer with the largest area of the prone areas, and in the eastern region in autumn. Along with the increase of the decades, the scope of the areas where drought and waterlogging change rapidly is expanding, among which the drought-flood abrupt alternation is the severest from 1998 to 2007.

(4) The spatial and temporal characteristics of drought-flood abrupt alternation events could be discussed by improving the index. In the future research, on the one hand, we can try to combine atmospheric circulation and other factors to study the formation mechanism of the drought-flood abrupt alternation events, so as to better predict and give warning; on the other hand, we can use modeling, experimentation and other approaches to study the influencing mechanism of drought-flood abrupt alternation on certain crops, such as rice, corn or wheat, so as to develop scientific countermeasures for disaster prevention and alleviation.

(Received 3rd May 2019; accepted 11th Jul 2019)

Abstract. Green finance is a financial activity for supporting environmental improvement, for tackling climate change and for conserving and efficiently utilizing resources, which is also a requirement for sustainable economic development. Existing researches on the green finance policies and policy systems are still in their infancy, which are predominantly qualitative analyses, while empirical studies concerning the green finance policies are scarce. This paper combs the development course of China's green finance, and then evaluates the effectiveness of carbon emissions trading pilot programs through robust regression. The results reveal that China's total carbon emissions are still on the rise, though the emission intensity is declining by years. The carbon emission intensity is lower in the pilot areas with relatively developed economy, where the carbon emissions trading pilot programs are obviously effective in reducing the carbon emissions. Referring to the control variables, the increase of foreign direct investment (FDI) and technology progress (TE) both reduce the intensity of carbon emissions, while the increase of per capita GDP will lead to the deterioration of the environment; Environmental support effort (ENVI) has not yet played a role in slowing down environmental pollution. Thus, China's current green finance policy system should strengthen the reform of policy guarantee and market operation, which has certain reference value for further improving the policy system and promoting the development of green finance.
Keywords: *green finance, robust regression, CO_2 emission intensity, dynamic panel regression, environmental support effort*

Introduction

Green finance, as the product of a combination of financial theory with economic practice, redefines the management policies and business processes of financial industry from the perspectives of environmental protection and sustainable development. While assisting in the economic transition, it can also realize the sustainable development of finance itself. Therefore, green finance is also known as "environmental financing", "sustainable finance", "ecological finance" or "carbon finance". Although the theoretical community has differing descriptions of its meaning, the basic connotation is always how the financial institutions carry out financial activities around improving environment and tackling climate change.

With the rapid and extensive growth of China's economy since the reform and opening up, ecological environment is increasingly deteriorating, which has become a major bottleneck restricting sustainable economic development. Finance, as the core of modern economy, plays an important role in resource allocation. Green finance can shift investment from the energy-intensive and high-polluting industries to the green and environmental, which is a powerful guarantee for promoting sustainable economic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1224512258

development and industrial restructuring. However, green finance is an emerging financial industry. Although it is featured with positive externalities, it is difficult to clarify property rights and bring benefits to it, which hinders the development of green finance. Therefore, studying the healthy development of green finance is not only an urgent task, but also a requirement for the sustainable development of China's economy.

Literature review

In recent years, green finance has been studied by many scholars at home and abroad mainly from the following two aspects: One is the connotation of green finance; and the other is the empirical analysis on green finance evaluation. Regarding research on the connotation of green finance, Salazar (1998) argued that green finance is a financial innovation that seeks economic development along the path of environmental protection, with purposes of seeking economic development alongside environmental protection and achieving a balance between economy and environment. In Cowan's (1999) opinion, green finance is a discipline that studies the relationship between environment and financing. According to Labatt and White (2002), green finance is a market-based financial instrument that aims to improve environmental quality and transfer environmental risks. Scholtens (2006) focused on analyzing the transmission mechanism between finance and sustainable development, who pinpointed that the green finance can address resource and environmental issues via the optimal combination of financial instruments. There are also a number of scholars who have done similar researches (Vyas, 2015; Wang and Zhi, 2016; Raberto et al., 2018; Volz, 2018).

Meanwhile, the empirical analyses on green finance evaluation concentrate mainly on three aspects. Firstly is the impact of green finance on financial institutions. Many scholars believe that the financial institutions should implement green financial strategies because by doing so, they can better attain the corporate risk management objectives and make strategic decisions that are conducive to the long-term corporate development, which is an objective requirement for the sustainable development of financial industry (Chami, 2002). There is also an argument that the financial institutions' implementation of green finance policies does not pose significant influence on their profits or risks (Gelema et al., 2011). Thus, clearly, the theoretical community has failed to reach a consensus as to the impact of green finance on the financial institutions. Secondly is the empirical analysis concerning green finance and green financial products. Brennan and Schwartz (1985) initiated the inclusion of environmental factors in the financial instrument pricing, who took into account the natural consumption cost in the corporate options pricing method. On this basis, Cortazar et al. (1998) extended the calculation method of the above model to propose a real options model for optimal timing of corporate investment in environmental technologies based on the corporate operating costs and environmental protection policies. Climent and Soriano (2011) have also done relevant research. Thirdly is the evaluation of green finance and environmental risks. By establishing index systems measuring the relationship between bank channels and green performance, Street and Monaghan (2001) and Cleene and Wood (2004) evaluated the green performance level of banks during operation. There are also a number of scholars who have done similar researches (Hoti and Mcaleer, 2004; Thomas, 2010; Zeng, 2014; Liu et al., 2018).

The above literatures offer substantial implications. In this study, green finance is defined as financial activities that support environmental improvement, tackle climate

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1224512258

change, and conserve and efficiently utilize resources. It channels funds into projects like environmental protection, energy conservation, clean energy, green transportation and green buildings through tools and policies such as credits, bonds, funds, insurance and carbon finance. Despite respective emphases of the above literatures, the research on the effect of China's green finance policies is still in its infancy, which needs to be deepened urgently.

Development history of China's green finance

The development course of China's green finance can be divided roughly into three stages:

(1) Years 2005-2008: The emerging stage of green finance

At the national policy level, energy conservation, emission reduction and environmental protection received increasing attention during this period. The *Eleventh Five-Year Plan* (2006-2010) put forward clear quantitative targets for the energy conservation and emission reduction. In this stage, green credit policies began to be formulated and issued in succession, such as the *Opinions on Implementing Environmental Protection Policies and Regulations for Preventing Credit Risks* (2007) and the *Green Credit Guidelines* (2008), which mark the sprouting of green finance in China.

(2) Years 2009-2014: The initial developing stage of green finance

During this period, the national green policies kept stepping up. Firstly, the Chinese government made international commitments on greenhouse gas emission control target. Secondly, the energy-saving and emission-reducing policies were launched continuously. Thirdly, ecological civilization was emphasized and the "strictest ever environmental law", i.e. the *Environmental Protection Law* (2014), was introduced.

In this stage, the green credit policy system began to be established, developed and improved gradually. Policies like the *International Experiences in Promoting Green Credit: Equator Principles and IFC's Performance Standards and Guidelines* (2010), the *China Green Credit Development Report 2010* (2011), the *Green Credit Guidelines* (2012), the *Opinions on Green Credit Practice* (2013), the *Green Credit Statistics System* (2013) and the *Key Evaluation Indices for the Implementation of Green Credit* (2014) were introduced. As a result, China formed a rather complete green credit policy system that centered on the *Green Credit Guidelines* with the green credit statistics system and evaluation mechanism as the two major cornerstones.

(3) Year 2015–present: The scale development stage of green finance

The main features of this stage are as follows: Firstly, the green development and ecological civilization policies have been introduced intensively. In 2015, the top-level design scheme for ecological civilization, i.e. *The Overall Plan for the Reform of Ecological Civilization System*, was launched. Subsequently, numerous environmental related policies, regulations, regimens and plans were introduced in succession, including the *Action Plan for Water Pollution Prevention and Control*, the *Action Plan for Air Pollution Prevention and Control*, the *Atmospheric Pollution Prevention and Control Law of The People's Republic of China*, and the *Action Plan for Soil Pollution Prevention and Control*. Secondly, the green finance system has begun to be established.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1224512258

In 2015, the People's Bank of China issued the *Energy Efficiency Credit Guidelines*, the *Green Financial Bonds Announcement* and the *Green Bond Support Project Catalogue*, which mark the opening of China's green bond market. The *Guiding Opinions on Building a Green Finance System* released in 2016 marks the establishment of China's top-level green finance framework system, thus making China the first nation in the world to set up a rather complete green finance policy system.

After more than a decade's accumulation, China's achievements in the green finance field have drawn worldwide attention. Countries around the world are increasingly understanding China's concept, listening to China's wisdom, appreciating China's programs, and taking China's development opportunities as their own. The development of China's green finance is characterized by giving equal consideration to the domestic and international green development, and actively leading green development at the international level while continuously progressing the reform of domestic green development towards the deep water zones.

This paper uses empirical method to analyze the impact of China's green finance policies on environmental pollution. The significance could be explained by two points. First of all, it analyzes the formation process of the green finance policy system in China so as to deepen understanding about green finance policy system and combine with green finance industry development course to observe limitations of the policy. Secondly, based on the analysis on green finance policy and literature, the paper begins with "carbon emission permit trading policy" and adopts robust regression method to test policy implementation effects, therefore objectively assessing the advantages and disadvantages of the policy and exploring the validity of this policy in explaining green finance policy. Finally, by reference to empirical analysis, the paper proposes two pertinent countermeasures so as to provide new thought for the further research on green finance and economic sustainable development in China.

Materials and methods

Emerged in China, the green finance originated from the *Notice on the Use of Credit Policies for Promoting Environmental Efforts* promulgated by the China Environmental Protection Administration and the *Notice on Issues Concerning the Implementation of Credit Policies and Strengthening of Environmental Efforts* issued by The People's Bank of China in 1995. Restricted by the economic development level and public ideology at the time, the green finance did not receive enough attention when it was initially introduced. It was not until China's official launch of green credit-related policy in 2007 that the green finance gained further development.

Materials

China's overall ecological environment has been improved positively as its green finance policy matures and functions. During the 13th Five-Year Plan period, China is expected to totally reverse the deterioration of ecological environment. From a macro perspective, the allocation of financial resources is optimized by establishing a green finance system, whose influence is then propagated to the real economy, thus transforming the extensive growth towards a green, comprehensive and intensive direction. From 2007 to 2017, the funds for pollutants discharge reduction increased by years in the national public fiscal expenditure (including central and local governments)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1224512258

(see *Figure 1*), which reached 561.733 billion yuan in 2017, suggesting the Chinese government's determination to govern environment.

From a micro perspective, policies on green credit, green bonds and environmental insurance were introduced intensively from 2015 to 2018. The increasingly perfect policy system has promoted the rapid development of related industries effectively while laying a solid foundation for the establishment of a sound green finance system. The green credit supply and green bond issuance in China are increasing by years. *Table 1* presents the status of China's green bond issuance from October 2016 to October 2018. As can be seen, the issuing scale of green bonds has been maintained at higher levels since 2016.

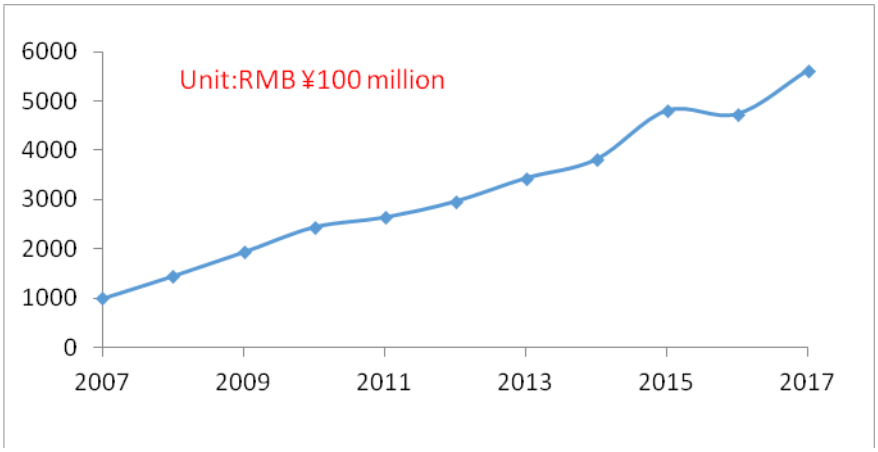

Figure 1. *General public budget fiscal expenditure for pollutants discharge reduction. Data Source: China Statistical Yearbook 2008-2018*

Table 1. *Issuance of green bonds (excluding asset-backed securities) from 2016 to October 2018*

	2016	**2017**	**January-October 2018**
issue number	29	68	65
issuing scale (billion)	1985.3	1908.75	1252.89

In *Figure 2*, the amount of green debt financing instruments managed by Shanghai Clearing House is displayed, which was up to 34.48 billion yuan in December 2018. From the figure, it is also clear that the amount of China's green debt financing has been increasing continuously.

Concerning insurance, China's environmental insurance is primarily the environmental pollution liability insurance, which is also known as the green insurance. In 2014, about 5,000 companies signed for the environmental pollution liability insurance. In 2015, the number of insurance sign-ups was 14,000, with a signing premium of 280 million yuan, offering risk protection of 24.421 billion yuan. In 2016, the premium income from the environmental pollution liability insurance was nearly 300 million yuan, offering risk protection of over 26 billion yuan. In 2017, the environmental pollution liability insurance provided risk protection of 30.6 billion yuan to more than 16,000 companies.

Methods

The *Notice on Launching Pilot Programs of Carbon Emissions Trading* issued in 2011 has initiated the exploration of issues pursuant to carbon emissions trading in China. As an important supplement to China's green finance system, the *Notice* will have a profound impact on the future of China's green finance industry. In 2013, carbon markets were launched and started trading in seven pilot provinces and municipalities (Beijing, Tianjin, Chongqing, Shanghai, Hubei, Guangdong and Shenzhen). As of now, the trading volume has reached 270 million tons of carbon dioxide, and the transaction amount exceeded 800 million euros, hence making China the world's largest carbon emissions trading market. This paper employs the robust regression technique to empirically analyze the effectiveness of implementing the carbon emissions permit policies.

Econometric model

(1) Traditional Econometric Model

The following dynamic panel regression model is finalized based on the research of green finance in the classic literatures combined with the theoretical analysis of green finance policies herein:

$$CO_{2_{it}} = \beta_1 + \beta_1 D_{it} + \sum \alpha X_{it} + \varepsilon_{it} \quad \text{(Eq.1)}$$

where, CO_2 denotes the intensity of carbon dioxide emissions; D is the dummy variable (D= 0 indicates that the green finance policy is not implemented in the non-pilot or pilot areas, while D= 1 indicates that the green financial policy is implemented in the pilot areas); X is the control variable (including foreign direct investment, technological progress, economic development level and environmental support effort); and i, t represent the region and year, respectively.

Most regressions are based on the ordinary least square (OLS) method at present. However, when many outliers are present in the data, the traditional least squares-based regression is no longer applicable. Robust regression, on the other hand, is a method in statistical robust estimation, whose main idea is to modify the objective function in the classical least squares regression that is highly sensitive to outlier values. Since the data

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1224512258

in this paper involves 30 provinces of China, there are huge interprovincial differences, so it seems more reasonable to estimate the above model via robust regression.

Common robust regression methods include least median square (LMS) method, M estimation method, etc. This paper adopts M estimation method.

(2) Robust regression algorithm based on M estimation

In case of any abnormal value in sample data, the residual estimated by OLS is often not in normal distribution, but biased tail instead. Considering residual quadratic sum, the role of abnormal value significantly increases, which leads to poorer estimation accuracy. Robust regression method mainly aims to improve the drawback of OLS in its great susceptibility to abnormal value. The basic thought is to minimize residual function $\rho(e_i)$, and derive each regression coefficient. The chosen residual function $\rho(e_i)$ does not endow all sample data with similar impact factor like how OLS chooses residual quadratic sum. On the contrary, it givens different weights according to the size of residual and therefore weakens the impact of abnormal value on regression result.

Common robust regression method is the M estimation method proposed by Huber in 1964. *Eq.2* presents its fundamental principle

$$Y_i = \beta_0 + \beta_1 X_{i1} + \cdots + \beta_p X_{ip} + e_i = X_i'\beta + e_i \ \ (\mathrm{i} = 1,2,\ldots,\mathrm{n}) \tag{Eq.2}$$

where, in β_0, β_1, ..., β_p are regression coefficients and e_1, e_2, ..., e_n are independent identically distributed with $\mathrm{E}[e_i] = 0$.

The M estimation method is exactly to seek β so as to reach the minimum of *Eq.3*.

$$\sum_{i=1}^{n} \rho(e_i) = \sum_{i=1}^{n} \rho(Y_i - X_i'\beta) \tag{Eq.3}$$

For reducing the role of abnormal value in Y_1, Y_2, ..., Y_n, it is necessary to take a function of growth rate of $\rho(x)$ slower than that of x^2, and meet the following conditions.

- $\rho(x)$continuity, $-\infty < x < +\infty$;
- $\rho(0)$=0, $\rho(x) = \rho(-x)$, and $\rho(x) \geq \rho(y)$ under the condition of $|x| \geq |y|$;
- $\lim_{x\to+\infty} \rho(x)x^{-2} = 0$.

Obviously, when $\rho(e_i) = e_i^2$, M estimation is OLS. Consequently, M estimation can be considered as the extension of OLS estimation as shown in *Eq.4*.

$$\rho'(x) = \psi(x) \tag{Eq.4}$$

If the target function solves the partial derivative of parameter β and set its value as 0, then *Eq.5* about parameter k+1 formula will be obtained.

$$\sum_{i=1}^{n} \psi(Y_i - X_i'\beta)X_i' = 0 \tag{Eq.5}$$

For ensuring the validity of above formula, $\rho(x)$meets the conditions as below: p(x) is defined as the non-negative convex function on （-∞，+∞）. $\rho'(x) = \psi(x)$ is valid under all conditions, in which $\lim_{|x|\to\infty} \rho(x) = \infty$.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1224512258

Therefore, M estimation property is greatly related to chosen function $\rho(x)$. In measuring β, the choice of initial value is very important. Throughout scale quivariance, *Eq.6* may be simplified as *Eq.6*.

$$\sum_{i=1}^{n} W_i X_i' e_i = 0 \quad \text{(Eq.6)}$$

Eq.6 is a weighted least square (WLS) problem, of which the weight depends on the size of residual e_i, the residual reversely depends on regression coefficient β, and regression coefficient reversely depends on estimated weight W_i. In this case, it is necessary to adopt the iteration method to solve the formula. Moreover, in this process, the key is to choose proper objective function $\rho(x)$ and weight function $W(x)$ so as to decrease residual abnormal value weight, increase the weight of sample data with minor residua, weaken the influence of abnormal value on regression analysis and reinforce regression formula robustness.

(3) Variable setting

According to *Eq.1* and economic principle, the paper chooses the following variables.

Carbon intensity (CO_2): Carbon dioxide emissions are calculated based on the carbon emission coefficient of energies. Considering the GDP variance among provinces, the variable is measured by CO_2 emissions/GDP.

Foreign direct investment (FDI): Measured by RMB-denominated FDI/GDP, FDI brings promotion of the green and energy-saving technologies, which thus may contribute to reducing the carbon intensity.

Technological progress (TE): Technological progress can improve the energy efficiency of industrial enterprises to lower the carbon intensity. The variable is herein measured by the volume of invention patent applications that best reflects the technological level.

Economic development level (Pgdp): It is measured by the natural logarithm of GDP per capita. The higher the level of economic development, the more it contributes to the increase in environmental investments, thus lowering the intensity of industrial pollution.

Environmental support effort (ENVI): It is measured by the regional investment in governing industrial pollution/GDP. The government's efforts to strengthen the environmental protection promote the use of environmental technologies by companies, and prompt the shift of highly polluting companies to areas with weak environmental regulations.

Results

Descriptive statistics for every variable

Considering the availability and consistency of data, this paper selects the panel data of 30 provincial-level regions (excluding Tibet) from 2000 to 2016. The raw data comes from *China Statistical Yearbook*, *China Environmental Statistics Yearbook*, *China Science and Technology Statistical Yearbook*, as well as the statistical yearbooks of various provinces. *Table 2* lists the descriptive statistics for each variable.

Three carbon emissions trading pilots and three non-pilot provinces are selected to explore the variation trends of CO_2 emissions and CO_2 intensity since 2000. In *Table 3*,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1224512258

relevant minimums and minimums are listed. The numbers in brackets indicate the years in which the values appear.

It can be seen from the above table that the minimum CO_2 emissions occur in 2000 for all provinces, while the maximums all appear in 2013 and beyond, showing an upward trend of emissions. Regarding the CO_2 intensity, all minimums appear in 2016, while all maximums occur in 2000, so the emission intensity is declining by years.

Table 2. *Descriptive statistics for every variable*

	Mean	**Min**	**Max.**	**s.d.**
CO_2 (Kg/10000 yuan)	3.580	0.752	14.27	2.212
FDI (10000 yuan)	3752484	9930	22573222	4388323
TE	36146	124	512429	71974
Pgdp (Yuan / person)	29432	2759	118198	22861
ENVI (Yuan/10000 yuan GDP)	17.476	0.684	99.185	14.08

Table 3. *Trends of CO_2 emissions and CO_2 emission intensity in some provinces*

	Beijin		Shanghai		Guangdong	
	emissions	intensity	emissions	intensity	emissions	intensity
Min	11489 (2000)	0.752 (2016)	15247 (2000)	1.152 (2016)	26194 (2000)	1.071 (2016)
Max.	19900 (2012)	3.634 (2000)	32473 (2016)	3.196 (2000)	86615 (2016)	2.439 (2000)
	Jiangsu		Sanxi		Heibei	
	emissions	intensity	emissions	intensity	emissions	intensity
Min	23878 (2000)	1.113 (2016)	18673 (2000)	4.122 (2016)	31040 (2000)	2.576 (2016)
Max.	86097 (2016)	2.792 (2000)	55070 (2014)	11.139 (2000)	86420 (2013)	6.175 (2000)

Note: Parentheses are the year.The unit of emission is ton, and intensity is ton/billion yuan

Analysis of empirical results

In this paper, robust regression is performed using *formula (1)* with the control variables FDI, TE, Pgdp and ENVI. The results are shown in *Table 4*.

Table 4. *Regression models results*

Variable	**Coefficient**	**Z-Statistic**	**Prob.**
D	-0.750841	-2.299761	0.0215
Pgdp	1.05811	17.63547	0.0000
FDI	-0.001119	-3.888342	0.0001
TE	-0.851207	-14.1518	0.0000
ENVI	0.066388	13.32519	0.0000

After analyzing the significance (Prob.) and coefficient of the control variables in the empirical model, we find that:

The p values of explanatory variables are all less than 0.05, indicating their significance in the present experiment.

The coefficient of green finance policy(dummy variable D) is negative, suggesting that the green finance policies are helpful for lowering the carbon intensity. This implies that there should be a transmission mechanism whereby the green finance policies promote the development of green finance and the green finance development reduces the carbon intensity.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1224512258

Concerning control variables, the coefficients of FDI and TE are negative, suggesting that the promotion of green and energy-saving technologies brought by FDI and the technological advancement in China have led to an improved energy efficiency of industrial enterprises, both of which have lowered carbon intensity. The coefficient of per capita GDP (Pgdp) is positive, indicating that the environmental pollution in China has become increasingly serious with the growth of per capita income. So far, there has been no inflection point on the environmental Kuznets curve in China. The coefficient of environmental support effort (ENVI) is also positive, but very small, which is 0.066, indicating that China's investment in environmental governance has not yet abated the environmental pollution.

Discussion

Foreign green finance practice and experience

Comparing with western developed countries, China has obtained great progress in green finance. But the large gap should not be overlooked. Firstly, foreign green finance starts early. German government had already established the world's first environment policy bank as early as 1974. Later on, large foreign banks represented by Citibank took the lead to formulate and implement a full set of environment assessment standards and mechanisms in 2002, namely the "equator principle". Secondly, green finance products in foreign developed countries are in wide variety and scope, including both fundamental products like green credit and green bond but also derivatives like carbon fund. However, the green finance system in China is rather unsound, and related laws and regulations are imperfect. This may be evidenced by inadequate incentive mechanism, untimely environmental protection information disclosure, insufficient internal impetus of companies, poor innovation of green finance products, and many other internal problems. In consequence, the practice and development experience of foreign green finance provide great reference for the construction and development of green finance in China.

As to the green finance policy practice of foreign developed countries, it should be noted that these countries do not have identical policy and system, but they all combine a series of international standards of international banks like the "equator principle" with domestic reality, and formulate proper green finance implementation tenets and policies. *Table 5* shows the comparison of foreign green finance policy in developed countries.

As shown in *Table 5*, America primarily implements green finance policies by large banks, while Germany and Japan rely on large banks and policy banks. From the perspective of policy, these policies are all based on the equator principle. From the perspective of core system, Germany implement green finance policy by interest subsidy policy. From the perspective of advantages, German government take part in the implementation of green finance policy and offer pertinent guarantee.

Countermeasures to green finance development in China

Based on the above analysis, the following suggestions are put forward for the sustainable development of China's green finance:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1224512258

(1) Establishment of a green finance policy guarantee mechanism

The policy guarantee mechanism refers mainly to the institutional construction and policy design by relevant governmental departments. Firstly, the green finance system must be improved by establishing a systematic finance system from the aspects of basic legal system, business standard system, business implementation system and supervision system of green finance. Secondly, the fiscal and taxation support system needs to be improved. According to estimations, the funds required for green development in China account for more than 15% of China's fiscal revenue. Apparently, fiscal funds cannot afford all the demands for green development. In such a context, innovations should be made by "transforming subsides into equity investment, into financing guarantee, into risk compensation, into special incentives and by relieving taxes". By doing so, the fiscal funds are used for stimulating the supply of market-oriented green finance instead of being directly used for green finance supply, thereby ensuring the efficiency and fairness of fiscal fund utilization by market means. Thirdly, the information communication mechanism should be set up. Green finance is not only an issue of eco-environmental protection, but also a financial reform issue involving multiple governmental and market sectors such as the environmental protection departments, the fiscal and taxation departments, the financial regulatory departments, financial institutions and intermediary service agencies. To promote the information communication between various departments, a sound cross-functional coordination mechanism must be established, and a bridge should be built between the government and the market.

(2) Improvement of the market operation mechanism

To play the role of green finance in supporting green industries, we must start from two aspects. On the one hand, the green finance organizational system needs to be improved. First of all, it is necessary to expand the participants of green finance market, and encourage the further greening of existing banks to adjust business operations in accordance with the *Equator Principles*. Meanwhile, the enthusiasm of non-bank financial institutions such as securities, insurance and fund companies should be fully mobilized for participating in the green finance business. Secondly, it is necessary to set up professional green development banks by the national, provincial and municipal governments after learning from international experience. Finally, it is necessary to foster green finance intermediary service agencies, encourage the existing intermediary services to actively participate in green financial operations, and accelerate the cultivation and development of professional intermediaries like the green credit rating agencies, green financial product certification institutions, green asset assessment firms, green financial information consulting services and environmental risk assessment agencies, so as to provide technical support for financing of green projects.

On the other hand, green financial products and instruments need to be innovated. First of all, it is necessary to promote the green credit innovation, such as innovating the mode of mortgage guarantee, tapping the intrinsic values of emission permits, energy efficiency improvement and other intangible assets, and developing innovative tools like emission permit mortgage loans, patent pledge loans and contract energy management financing. Secondly, it is necessary to promote the green insurance business, and comprehensively popularize the compulsory liability insurance system for environmental pollution. Meanwhile, developing other innovative types of green

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1224512258

insurance is also necessary, such as green auto insurance and green construction insurance, so as to reflect the support for green industries through insurance mechanism. Thirdly, it is necessary to develop a green capital market dominated by green stocks, bonds and funds to form a green financial market structure with diversified participants and financial products. Finally, carbon finance should be developed vigorously. At the end of 2017, the construction of national carbon emissions trading market formally began. Expected to be formally completed in 2020, the market will effectively slow down the growth of China's carbon emissions and bring a new impetus to the sustainable development of China's economy.

DOI: http://dx.doi.org/10.15666/aeer/1705_1224512258

Conclusions

In this paper, the history and status quo of China's green finance development are combed first. On this basis, robust regression is employed to evaluate the effectiveness of the "carbon emissions trading pilot policies". The following conclusions are drawn:

China's green finance has undergone three stages of development. With the establishment of the top-level green finance framework system in 2016, China has become the first nation in the world to set up a relatively complete green finance policy system. At the macro level, China's support for environmental protection has been strengthened, and the funds used for emission reduction are growing by years in the public fiscal expenditure. At the micro level, the green credit, green bonds and environmental insurance have shown year-over-year growth.

According to the results of empirical analysis, the CO_2 emissions in various regions of China are on the rise, but the emission intensity is declining, suggesting China's certain achievements in the environmental governance. All the pilot provinces and cities that have adopted the carbon emissions permit policy are economically developed regions of China. They exhibit lower carbon intensity on average as compared to the non-pilot areas, and the green finance pilot policy is effective in significantly reducing carbon emissions. Similarly, the increases in foreign direct investment and technological progress have both contributed to lowering the carbon intensity, while the elevated level of economic development has aggravated the environmental pollution. These conclusions have an explanatory role in answering the issues faced by China's green finance policies. On this basis, we put forward two suggestions: establishing a green finance policy guarantee mechanism and improving the market operation mechanism.

Based on robust regression model, the paper analyzes and assesses the validity of "carbon emission permit trading experimental unit policy". Though some periodical results have been reached, some problems still deserve further research. The first one is data accessibility. As the paper does not collect any data about the application of green credit in specific projects, it does not show the preference of green finance policy to specific industries in China. The second one is about the choice of independent variable in regression analysis model. Because of data accessibility, the paper expresses it with some alternative variables. This lowers the persuasiveness of conclusion. Targeted at these problems, future studies should compare the green finance practice in other countries and make long-term tracking of related statistics in Chinese green finance business to raise useful policy suggestions in favor of the development of green finance in China.

(Received 3rd May 2019; accepted 11th Jul 2019)

Abstract. Climate change causes drought and rainstorm, two extreme hydrological events, to occur interlock, and in a short period of time the rapid transformation of drought and flood disasters, resulting in more difficult rescue and relief, agricultural losses more serious. In order to study the characteristics of drought and flood in tobacco growing period in Xingren County. By defining the Long-cycle Drought-Flood Abrupt Alternation Index (LDFAI) and Short-cycle Drought-Flood Abrupt Alternation Index (SDFAI), the moving average method and precipitation anomaly are used. For the daily precipitation data during the tobacco growth period (5~8 months) from 1961 to 2012 in Xingren County, A comprehensive analysis of the (LDFAI SDFAI) change trends and monthly precipitation changes during the growth period of tobacco. The characteristics of rapid change of drought and flood in tobacco growing period were identified. The results showed that: the LDFAI in the tobacco growth period are mainly from drought to flood. In the future, there will be an increasing trend from flood to drought, and the strength is reduced; The trend of SDFAI is: increase-decrease-decrease; there is an increasing trend from drought to flood events in May-June; June-July is a period of drought-flood abrupt alternation, and the intensity is higher. In July-August, the flood to drought event has a decreasing trend and the intensity is reduced. During the tobacco maturity period, Monthly average precipitation is higher, the precipitation fluctuates greatly, Extremely prone to Drought-Flood Abrupt Alternation. The research results can provide theoretical basis for the formulation of countermeasures for disaster prevention and mitigation in Xingren County in China.

Keywords: *climate change, drought-flood abrupt alternation, moving average method, precipitation anomaly method, tobacco growth period, Xingren County*

Introduction

The Fifth Assessment Report of the Intergovernmental Panel on Climate Change (IPCC, 2013) points out that global warming has become an indisputable fact. Affected by climate change, extreme hydrological events present with the special complex phenomenon of flood and drought. Xingren County experienced the worst drought in 100 years in 2010. It lasted from August of the previous year to April. It lasted for 9 months and the soil moisture was extremely poor, which seriously affected tobacco seedlings and transplanting. The drought-flood abrupt alternation is a meteorological and hydrological event in which there is no rainfall or less rainfall in the early period, followed by high intensity rainfall and flood disaster in the short term, with the superimposed losses of drought and flood disasters in the region (Huang, 2015). Climate change causes two extreme hydrological events, drought and floods, which occur alternately and change rapidly in a short period of time to form a drought-flood disaster, which makes it more difficult to rescue and causes more serious losses on

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1225912269

social economy and the people's production and life. It has a significant and far-reaching impact on agricultural production and food security, water resources security, and ecological environment security (Niu et al., 2013). In 2010, drought and drought caused a loss of 50,000 tons of Xingren Tobacco and an economic loss of 60 million yuanRMB.

At present, foreign scholars mainly focus on the extreme hydrological events. Vogel (1978) studied the climate causes of abnormal precipitation in St. Louis; Ting et al. (1997) studied the variation of summer precipitation in the United States and its relationship with the Pacific SST. Domestic studies mainly focus on the causes for the change between drought and flood (Li et al., 2014), the analysis of the law on the drought-flood abrupt alternation (Shen et al., 2012; Sun et al., 2012) and the impact of the drought-flood abrupt alternation on rice and peanut yield in the Yangtze River Basin (Yuan et al., 2008; Zhou et al., 2012). However, there are few reports on the drought-flood abrupt alternation in a short time scale and the disaster caused by the drought-flood abrupt alternation in tobacco growth period. Drought seriously affects the growth and development of flue-cured tobacco and the accumulation of dry matter. Excessive soil moisture is not conducive to tobacco growth and reduces the biomass of tobacco plants. In fact, Xingren County is one of the main tobacco growth areas in China, and also one of the prone areas to drought and flood disasters. Drought and flood disasters mainly occur in May to August, which has a greater impact on tobacco planting.

In view of this, according to the daily precipitation data from May to August at the meteorological station in Xingren County from 1961 to 2012, this study uses the precipitation anomaly percentage, the long-period drought-flood abrupt alternation index and the short-period drought-flood abrupt alternation index to systematically analyze the evolution characteristics of drought-flood abrupt alternation time in the tobacco growth period in this area, so as to provide reference for tobacco cultivation, flood control and drought relief.

Xingren County is located in QianXiNa buyi and miao minority autonomous prefecture is located in east longitude 104°54' - 105°34', north latitude 25°16' to 25°47' in Guizhou, China, *Figure 1*.

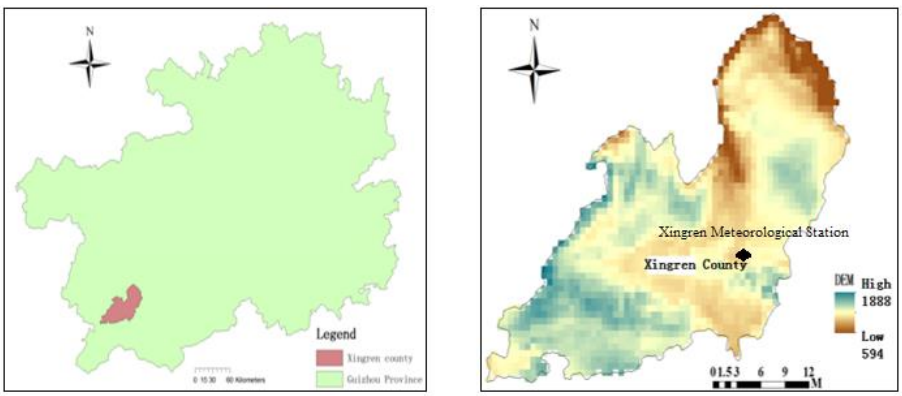

Figure 1. *Overview of the research area*

It is a low-latitude plateau temperate and humid monsoon climate region in mid-subtropical zone. There is no severe cold in winter and no intense heat in summer. The frost-free period is longer, the rain and heat is in the same season, the annual average

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1225912269

temperature is 15.2ºC, the annual rainfall is 1,315.3 mm, and the annual accumulated temperature of 10.0 ℃ is 4,588.0 ℃. Superior light, heat, water and other climatic conditions make the county a suitable flue-cured tobacco growth areas. However, drought, hail, flood and other disasters seriously affect the yield and quality of flue-cured tobacco (Xiao and Cui, 2014).

Materials and methods

Data source

The data used in the analysis of drought-flood abrupt alternation events are the daily precipitation data of Xingren National Reference Meteorological Station from 1961 to 2012, which are provided by the National Meteorological Information Center in China. Xingren National Reference Meteorological Station is located in east longitude 105°11', north latitude 25°26'.

Research method

Precipitation anomaly percentage (Pa)

The precipitation anomaly percentage reflects the deviation degree of precipitation from the average state at a certain period of time, and its calculation formula is as follows (Guizhou Provincial Bureau of quality and Technology Supervision, 2015).

$$Pa = \frac{P - \overline{P}}{\overline{P}} \times 100\% \quad \text{(Eq.1)}$$

where, P precipitation for a certain period of time, *mm*; $\overline{P}$ annual mean precipitation at a certain period of time, *mm*.

For the classification of drought and flood grades, refer to the monthly scale classification standard in DB52/T1030-2015 *Drought Standard of Guizhou Province*, as shown in *Table 1*.

Table 1. *Classification of drought and flood grades by precipitation anomaly percentage (unit: %)*

Type of drought	Pa	Type of flood	Pa
Extraordinary	Pa≤-95	Light	40≤Pa<60
Severe	-95<Pa≤-80	Moderate	60≤Pa<80
Moderate	-80<Pa≤-60	Severe	80≤Pa<95
Light	-60<Pa≤-40	Extraordinary	95≤Pa
Normal	-40<Pa<40		

Long-period drought-flood abrupt alternation index in tobacco growth period

The time scale of drought-flood change is defined as two months, that's, drought in May-June and flood in July-August, which is called drought-flood, and vice versa. There is no standard definition for the drought-flood abrupt alternation index. This paper refers to the definition of the drought-flood abrupt alternation index proposed by Wu et al. (2006) on the Yangtze River Basin, and adjusts the weight coefficient.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1225912269

a) Standardization of precipitation

$$R = \frac{P_i - \overline{P}}{\sqrt{\frac{1}{N}\sum_{i=1}^{N}(P_i - \overline{P})^2}} \quad \text{(Eq.2)}$$

where R- standardized precipitation; P_i- original value of precipitation, *mm; i=1, 2, 3, ..., N*; $\overline{P}$- Average precipitation, *mm; N*- The total number of samples.

b) *LDFAI*

$$LDFAI = (R_{78} - R_{56}) \times (|R_{56}| + |R_{78}|) \times 2^{-|R_{56}+R_{78}|} \quad \text{(Eq.3)}$$

where, R_{78}- Standardized precipitation from July to August; R_{56}- Standardized precipitation from May to June; R_{78}-R_{56}- The intensity of drought-flood abrupt alternation; $|R_j|+|R_i|$- Intensity term of drought-flood abrupt alternation; $2^{-|R_{56}+R_{78}|}$ is weight coefficient, which functions to increase the weight of drought-flood abrupt alternation events and reduce the weight of all-drought or total-flood event. The criteria for judging the drought-flood abrupt alternation are as follows: if *LDFAI* is great than 1, it's drought-flood event; if *LDFAI* is less than 1, it's the flood-drought event; if *LDFAI* is in the middle, it's normal; the absolute value of *LDFAI* reflects the intensity of the drought-flood abrupt alternation, the greater the absolute value is, the more serious the drought and flood rapid change event is (Shan et al., 2015).

Short-term drought-flood abrupt alternation index during the tobacco growth period

The calculation method of SDFAI is basically the same as that of LDFAI, with the formula is (Wu et al., 2006)

$$SDFAI = (R_j - R_i) \times (|R_i| + |R_j|) \times 3.2^{-|R_i+R_j|} \quad \text{(Eq.4)}$$

where R_j- Standardized precipitation in the *j*-th month; R_i- Standardized precipitation in the *i*-th month; R_j-R_i- The intensity of drought-flood abrupt alternation; $|R_j|+|R_i|$- The intensity item of drought-flood abrupt alternation; $3.2^{-|R_i+R_j|}$- Weight coefficient; j=i+1(i=5, 6, 7).

Non-uniformity of precipitation distribution

The non-uniformity of precipitation distribution is studied and analyzed by using the non-uniformity and coefficient of rainfall distribution. The formula is as follows:

$$C_V = \frac{\sigma}{\overline{P}} \quad \text{(Eq.5)}$$

$$\sigma = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(P_i - \overline{P})^2} \quad \text{(Eq.6)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1225912269

where σ- Mean square error; $\overline{P}$- Average precipitation over the same period of years, *mm*; P_i- Rainfall in the *i*-th year, *mm*.

Results and analysis

Trend of long-term drought-flood abrupt alternation

Characteristics of typical long-term drought-flood abrupt alternation

According to the precipitation sequence during the tobacco growth period in Xingren County, the Pa value and LDFAI value from May to June and from July to August from 1961 to 2012 are calculated by the *Eq.1* to *Eq.3*. *Table 2* lists the years with the highest (lowest) LDFAI values from 1961 to 2012 and its Pa value from May to June and from July to August by the *Eq.1* to *Eq.3*.

Table 2. *Six highest (lowest) LDFAI values and its Pa value from 1961 to 2012*

Year	Highest (LDFAI)			Year	Lower (LDFAI)		
	LDFAI	May-June Pa/%	July-August Pa/%		LDFAI	May-June Pa/%	July-August Pa/%
1999	9.73	-40.84	67.40	1978	-3.14	43.92	-26.46
1986	8.12	-37.24	68.54	1972	-3.04	18.96	-59.52
1988	3.33	-46.93	27.60	1966	-1.94	21.76	-22.59
1970	3.00	-39.41	25.99	1974	-1.80	24.40	-20.17
2004	2.92	-39.07	25.51	1962	-1.54	16.05	-21.63
1961	1.96	-42.05	16.25	1994	-1.39	15.33	-20.52

It can be seen that in the years with higher *LDFAI*, the precipitation in from May to June is less (35%), and drought event occurs, and the precipitation from July to August is more (15%), and flood event occurs, so the drought-to-flood event is formed. From May to June in 1999, the precipitation generally decreased by 40.84%, belonging to light drought event, but from July to August in 1999, the precipitation generally increased by 67.40%, and moderate flood occurs, with *LDFAI* as high as 9.73, belonging to typical drought-flood event. In the years with lower *LDFAI*, the precipitation from May to June is more (15%), which belongs to flood event, and from July to August, the precipitation is less (20%), which leads to the drought event, so the flood-to-drought event occurs. The precipitation from May to June in 1978 is more (43.92%) and the light flood occurs; the precipitation from July to August is less (26.46%) and the drought occurs, with the *LDFAI* of -3.14, belonging to typical flood-to-drought event. Therefore, *LDFAI* can reflect the phenomenon of drought-flood abrupt alternation to a certain extent.

Interannual trend of long-term drought-flood abrupt alternation

Figure 2 depicts that interannual change of LDFAI from 1961 to 2012. It can be seen from the figure that most of LDFAIs are positive, indicating that the long-term drought-flood abrupt alternation in Xingren County is mainly drought-to-flood. LDFAI fluctuated more frequently from the end of 1960s to the end of 1970s, which indicates that there are more drought-flood abrupt alternations from the end of 1960s to the end of 1970s. LDFAI appeared two anomalously large in the early 1980s and the end of 1990s,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1225912269

mainly due to two high intensity drought-to-flood events. According to the 3a moving average curve and 5a moving average curve, the occurrence frequency and intensity of the long-term drought-flood abrupt alternation events are decreasing.

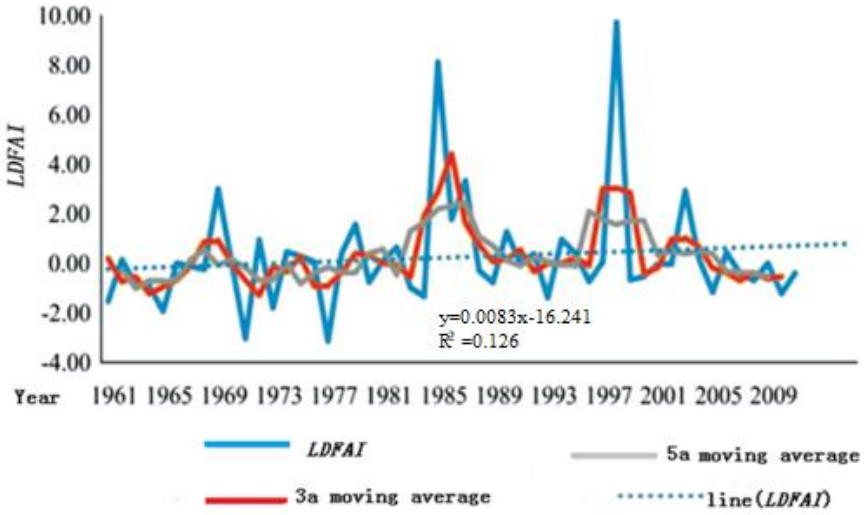

Figure 2. *Trend of the long-term drought-flood abrupt alternation in the tobacco growth period in Xingren County*

Trend of the short-term drought-flood abrupt alternation

Characteristics of typical short-term drought-flood abrupt alternation

According to the precipitation sequence during the tobacco growth period in Xingren County, the short-period drought-flood abrupt alternation index in the tobacco growth period from 1961 to 2012 is calculated by the *Eq.4* to *Eq.6*. *Tables 3, 4 and 5* show *SDFAI* and its *Pa* values of the typical drought-flood abrupt alternation years from 1961 to 2012.

Table 3. *SDFAI and characteristics of drought-flood from May to June in Xingren County*

Year	May Pa/%	June Pa/%	SDFAI	Type
1979	-42.51	55.95	3.66	Light drought to light flood
1980	43.12	-46.29	-4.10	Light flood to light drought
1991	-74.88	41.74	3.86	Moderate drought to light flood
2007	-51.48	60.33	5.26	Light drought to light flood
2008	132.14	-45.31	-1.96	Extraordinary flood to light drought
2011	-73.16	49.36	5.72	Moderate drought to light flood

Table 4. *SDFAI and characteristics of drought-flood from June to July in Xingren County*

Year	June Pa/%	July Pa/%	SDFAI	Type
1965	58.94	-39.84	-4.75	Light flood to light drought
1970	-51.57	74.17	6.40	Light drought to moderate flood
1980	-46.29	44.61	1.80	Light drought to light flood
1999	-68.08	86.77	8.44	Moderate drought to serious flood
2004	-43.70	51.29	2.49	Light drought to light flood
2011	49.36	-63.01	-5.97	Light flood to moderate drought

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1225912269

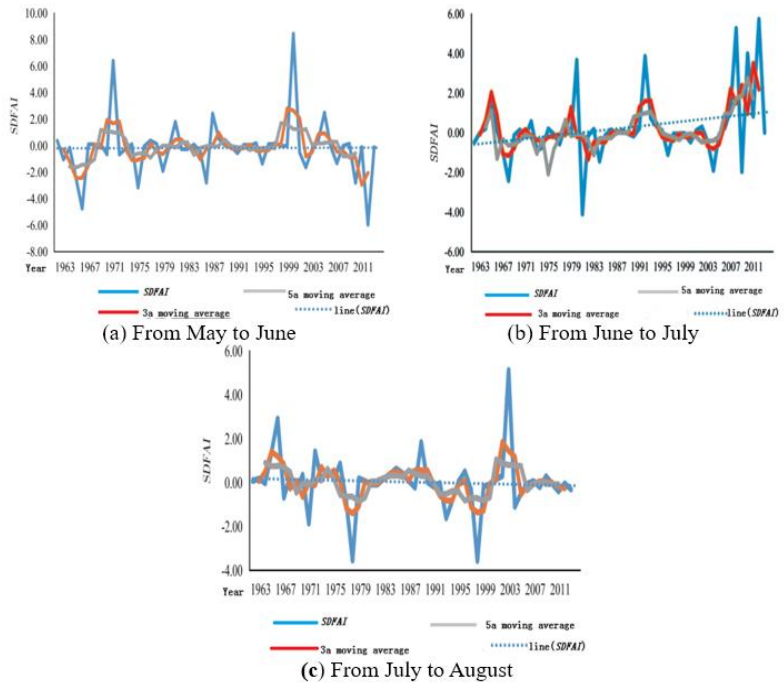
Table 5. *SDFAI and characteristics of drought-flood from July to August in Xingren County*

Year	July Pa/%	August Pa/%	SDFAI	Type
1965	-39.84	50.18	2.92	Light drought to light flood
1977	80.18	-48.13	-3.54	Serious flood to light drought
1988	-40.97	110.08	1.84	Light drought to extraordinary flood
1997	69.66	-46.07	-3.57	Moderate flood to light drought
2002	-54.83	65.70	5.12	Light drought to moderate flood

The comparison shows that SDFAI is mainly positive from May to June, mainly from light and moderate drought to light flood, with the only event from extraordinary flood to light drought in 2008. SDFAI is higher from May to June, which indicates that the intensity of drought-flood abrupt alternation events is higher in this period and the period when drought-flood abrupt alternation events are prone to occur. From July to August, SDFAI is low, which indicates that the intensity of drought-flood abrupt alternation events is decreased and the number of drought-flood abrupt alternation events is decreased. From May to June of 1980, the light flood to light drought occurred, but from June to July of 1980, the light drought to light flood occurred again, the drought and flood occurred frequently in a year, and it is the tobacco flourishing period (Qiu et al., 2013), so we should guard against the adverse effects brought by the drought-flood abrupt alternation.

Interannual trend of short-term drought-flood abrupt alternation

Figure 3 depicts the interannual change of SDFAI from 1961 to 2012. Through the analysis, we can conclude that the short-term drought-flood abrupt alternation has the following characteristics in the tobacco growth period.



(a) From May to June (b) From June to July

(c) From July to August

Figure 3. *Trend of the short-term drought-flood abrupt alternation in the tobacco growth period in Xingren County*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1225912269

a) From May to June mainly occurs the drought-to-flood; SDFAI oscillated frequently and violently after the 21st century. The drought-to-flood events with higher intensity mainly occurred after the 21st century, the flood-to-drought events with higher intensity mainly occurred before 1980s, and only two drought-to-flood events with higher intensity occurred after 1980s. From 3a moving average curve, 5a moving average curve and SDFAI trend curve, it can be seen that the drought-to-flood events have an increasing trend, which is obvious.

b) From June to July mainly occurs the flood-to-drought; SDFAI oscillated frequently from the beginning of 1960s to the beginning of 1980s. The drought-to-flood events with higher intensity mainly occurred after 1990s, and only one drought-to-flood event with higher intensity occurred in 1960s. From 3a moving average curve, 5a moving average curve and SDFAI trend curve, it can be seen that the flood-to-drought events have a slight increasing trend.

c) From July to August mainly occurs the flood-to-drought; SDFAI oscillated frequently from the beginning of 1960s to the beginning of 1980s. The drought-to-flood events with higher intensity mainly occurred after 1990s and only one drought-to-flood event with higher intensity occurred in 2002 after entering the 21st century, without any drought-to-flood event event afterwards. From 3a moving average curve, 5a moving average curve and SDFAI trend curve, it can be seen that the flood-to-drought events have a slight increasing trend.

Changes of monthly precipitation during tobacco growth period

The maximum, minimum, average and non-uniform coefficient of monthly precipitation distribution during the tobacco growth period from 1961 to 2012 in Xingren County are analyzed. The calculation results are shown in *Table 6*.

Table 6. *Statistics on monthly precipitation characteristic amount of 52a tobacco growth period in Xingren County*

Month	Maximum precipitation		Minimum precipitation		Monthly average precipitation in tobacco growth period	$C_{V,M}$	Annual extreme ratio of monthly rainfall
	Year	Precipitation (mm)	Year	Precipitation (mm)			
5	2008	390.9	2011	45.2	168.39	0.42	8.65
6	2006	480.4	1961	81.4	274.44	0.37	5.90
7	1987	474.3	1972	57.1	239.54	0.46	8.31
8	1988	418.4	2011	26.2	199.16	0.46	15.97

As can be seen from *Table 6*, the precipitation in Xingren County increased firstly and then decreased during tobacco growth period, among which the maximum precipitation, the minimum precipitation and the maximum of monthly average precipitation are all in June, indicating that the precipitation in June is more and June is prone to flood disasters; the annual extreme value ratio of monthly precipitation is also smaller in June, and the value of $C_{V,M}$ is also smaller in June,, indicating that the monthly precipitation fluctuation is small. The value of $C_{V,M}$ is larger in August and the annual extreme value ratio of monthly precipitation is the largest in August, which indicates that precipitation fluctuates greatly in this period and drought-flood abrupt alternation events are easy to occur.

Discussion

The growth period of spring tobacco in the field is from May to August, including root elongation period (30-35 d), flourishing period (30 d) and mature period (60-65 d) (Tang, 2011). In the growth period of spring tobacco in the field, the precipitation is suitable in the range of 400 ~ 520 mm, the monthly average water requirement is about 100 mm at the elongation period, about 200 mm at the flourishing period is and about 100 mm at maturity period (Ran et al., 2010). In May, which is the elongation period, the monthly rainfall could meet the needs of tobacco growth, moderate water shortage could promote root development, and excessive water would lead to root necrosis. Due to the increasing trend of short-term drought-to-flood events, irrigation and drainage work should be done well to ensure the survival rate of tobacco seedlings. In June, when tobacco is flourishing, the monthly average rainfall can meet the demand of tobacco growth, and with small fluctuation of rainfall, drought and flood events are not easy to occur, but the drought-flood abrupt alternation events with high intensity are easy to occur in this stage, so the precautions are required. July to August is the maturity period of tobacco, the precipitation fluctuates greatly, and the monthly average rainfall is relatively large. The excessive rainfall may cause the tobacco leaves to be too thin to modulate, low nicotine content and the insipid aroma. The mature tobacco leaves should be picked in time according to the forecast situation of the meteorological department, with the efforts made in the drainage of tobacco fields to ensure the quality of tobacco leaves.

Mechanism of the drought-flood abrupt alternation

Xingren County belongs to the typical monsoon climate fragile area, and the monsoon change causes the uneven annual precipitation distribution. What's more, the local is of the karst landform, and with strong water permeability and poor water retention, so it's extremely easy to suffer from the drought. In addition, the abnormal atmospheric circulation over the Qinghai-Xizang Plateau results in the formation of cold and high-pressure air masses in the plateau, which block the warm and humid air flow from the Indian Ocean and the Bay of Bengal. However, it's not easy for the cold air from the north to reach the area and it's difficult for the cold and warm air flows to intersect to form precipitation. The water vapor producing strong precipitation mainly comes from the South China Sea and the Bay of Bengal in the northern Indian Ocean (Sun et al., 2017). In summer, the southwest monsoon intensifies, and the transported water vapor increases. When cold air intrudes, the cold and warm air flows converge, resulting in relatively strong precipitation, resulting in drought-flood abrupt alternation. Another factor that produces strong precipitation in a short period of time is that the topographic relief within the territory is large, and the topography is high in the west and low in the east; blocked by the topography, during the day, the foot of the mountain, receives less solar radiation, air heating is not as fast as the top of the mountain, leading to heat air on the mountain top, floating in the sky; the air at the foot of the mountain, is cold and the atmosphere is relatively stable. At night, the temperature at the top of the mountain drops faster than that at the foot of the mountain, and the air sinks after cooling, raising the warm and humid air at the foot of the mountain. As the air rises, the water vapor cools down continuously, resulting in heavy rainfall and a sharp drought-to-flood.

DOI: http://dx.doi.org/10.15666/aeer/1705_1225912269

Conclusions

The main conclusions are as follows:

(a) During the tobacco growth period in Xingren County, the long-term drought-flood abrupt alternation is dominant, and the frequency of the l long-term drought-flood abrupt alternation events generally decreases. In the 21st century, the trend of flood-to-drought events increases and the intensity decreases.

(b) The evolution trend of short-term drought-to-flood events during the tobacco growth period in Xingren County is as follows: increase-decrease-decrease; and the increasing trend is obvious, which is identical with the change trend of short-term drought-to-flood events. From May to June, the drought-to-flood increases; from June to July, it's easy to suffer from the drought-to-flood rapid change, with the relatively high intensity, and then at the transition period of tobacco from flourishing to maturing period, excessive or insufficient water should be prevented from to avoid the decline in tobacco yield and quality; from July to August, the flood-to-drought has a increasing trend, with the increasing intensity, and it's the tobacco maturity period, it's necessary to prevent tobacco quality from deteriorating due to the drought-flood abrupt alternation.

(c) In the tobacco flourishing period, the monthly average precipitation is the most and the fluctuation of precipitation is the least, so the flood disaster is very easy to happen. In the tobacco maturity period, the monthly average precipitation is more and precipitation fluctuation is greater, so it's extremely prone to drought-flood abrupt alternation and we should take precautions.

(Received 3rd May 2019; accepted 11th Jul 2019)

Abstract. Drought-flood abrupt alternation disaster caused by climate change results in greater difficulty in disaster relief and more serious agricultural losses. In order to identify the characteristics of drought-flood abrupt alternation in the tobacco growth period and effectively prevent and reduce the drought-flood abrupt alternation disaster, the daily precipitation data in the tobacco growth period from 1951 to 2017 in Guiyang City are used and the data of soil moisture content in the Xiuwen country Irrigation Test Base of Guizhou Irrigation Test Center are adopted. By defining continuous days without available precipitation and the cumulative available precipitation during the flood period, the characteristics of drought-flood abrupt alternation in Guiyang are comprehensively analyzed. The results are as follows: (1) it can be verified by soil moisture content data that the law of drought-flood abrupt alternation in tobacco growth period can be accurately described based on continuous days without available precipitation and the cumulative available precipitation during the flood period. (2) In the tobacco growth period, there are two or more times of drought-flood abrupt alternation with low intensity. (3) In tobacco root extension period, there is no drought-flood abrupt alternation; during the flourishing growing period of tobacco, drought-flood abrupt alternation with low intensity prevails, and the intensity and frequency of drought-flood abrupt alternation increase; in tobacco mature period, the intensity of drought-flood abrupt alternation fluctuates greatly, and the intensity and frequency of drought-flood abrupt alternation increase. The research results can provide theoretical basis for the formulation of tobacco disaster prevention and mitigation countermeasures in Guiyang China.
Keywords: *climate change, drought-flood abrupt alternation disaster, continuous days without available precipitation, accumulative available precipitation during flood period, tobacco, Guiyang City*

Introduction

The IPCC's fifth assessment report points out that the global warming has been no longer in question (IPCC, 2013). Extreme climate events such as torrential rain, flood, high temperature and drought caused by climate change frequently occur in the world, which has attracted wide attention of scholars both at home and abroad (Mesmoudi et al., 2017; Nocera et al., 2017; Scafetta et al., 2017; Bello and Mamman, 2018; Kong, 2018; Magrini et al., 2018; Zhao et al., 2018; Uttam et al., 2018; Dittus et al., 2018).

Tobacco is an important economic crop in Guiyang. Guiyang has a long history of flue-cured tobacco planting, and the quality of tobacco leaves is better. In 2017, the city planted 13,700 hectares of flue-cured tobacco, and acquired 16,700 tons of flue-cured tobacco, with 36. 72% of fine tobacco and 96. 70% of medium tobacco. Tobacco industry is the dominant traditional industry in Guiyang and plays an important role in local economic construction. However, due to the influence of special karst landform and the continuous occurrence of Nino phenomenon (ElNino) in recent years, the spatial

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1227112286

and temporal distribution of precipitation in Guiyang tobacco area is uneven, drought and flood disasters occur frequently, which seriously threatens the output and quality of tobacco in Guiyang. Therefore, it is necessary to study the characteristics of drought-flood abrupt alternation in Guiyang tobacco area so as to provide scientific basis for disaster prevention and reduction.

Drought-flood abrupt alternation refers to the meteorological and hydrological events in which there is no precipitation or little precipitation in the early period and the drought has occurred, and then high-intensity precipitation and flood occurs in a short period (Huang, 2015). Many scholars in China have made in-depth study on drought-flood abrupt alternation from different points of view. Wu et al. (2006) first define a summer long-cycle drought-flood abrupt alteration index (LDFAI). On the basis of this, most of the scholars study the space-time evolvement law of drought-flood abrupt alternation in different areas (Shan et al., 2015; He et al., 2016; Liu et al., 2017; Peng et al., 2018). If LDFAI is used to study the law of drought-flood abrupt alternation in tobacco growth period, this only considers the difference of drought and flood in the early and late period and the time scale is too large. The drought-flood abrupt alternation degree can be evaluated only after the end of the whole growing period of tobacco, which is unable to meet the needs of real-time monitoring and early warning assessment. Based on LDFAI, the dry-wet abrupt alteration index (DWAAI) is constructed, which can well reflect the abrupt alternation degree. According to the theory, there is only one time of drought-flood abrupt alteration in a year, and the date of abrupt alteration is the day when the value of DWAAI is the highest. In fact, the tobacco growth period is also the season of frequent occurrence of drought and flood in Guiyang. Thus, DWAAI can't be used to study the evolvement law of drought-flood abrupt alternation in tobacco growth period because there may be two or more times of drought-flood abrupt alteration.

The analysis of drought in continuous days without precipitation from the point of view of daily precipitation can make drought monitoring and assessment more precise on time scale (Jiang et al., 2009; Wang et al., 2014; Gu, 2014; Shan et al., 2015), the application is more mature, and is determined as local standard in Gansu and Guizhou (Gansu provincial bureau of quality and technical supervision, 2011; Guizhou provincial bureau of quality and technology supervision, 2015). However, the index of continuous days without available precipitation is considered only in the sense of meteorology. In fact, precipitation can be used by crops only if it reaches a certain level, so the effectiveness of precipitation should be considered. Huang et al. (2014) improve continuous days without available precipitation, considering that the continuous days without available precipitation can integrate both precipitation and precipitation days, and indirectly reflect the income and expenditure of farmland precipitation and profit and loss of soil moisture. Flood disaster of crops is not only directly affected by excessive and concentrated precipitation, but also closely related to soil texture, light conditions, crop species and their developmental stages (Huo and Wang, 2009). Yang et al. (2017) put forward the concept of "equivalent precipitation" that represents the cumulative effect of precipitation in the early period and current process on flood. Based on this, the grade index of spring corn flood is constructed. In consideration of the cumulative effect of precipitation on flood process, Fan (2018) constructs the catastrophic index of oilseed rape flood process by taking the effective cumulative precipitation and the number of rainy days as the cause of flood disaster.

DOI: http://dx.doi.org/10.15666/aeer/1705_1227112286

During the study of drought period of drought-flood abrupt alteration, continuous days without available precipitation are used as the drought index of tobacco in order to analyze the drought characteristics of tobacco in different growing periods from the daily dynamic perspective. The formation process of tobacco flood can be objectively and quantitatively characterized by the classification of flood grades by accumulative available precipitation in flood period. Based on this, this study explores the evolvement law of drought-flood abrupt alteration in tobacco growth period, which can provide scientific and technical support for timely and accurate evaluation of the impact of drought-flood abrupt alteration on tobacco growth and realize flood control, drought resistance, high and stable yield and evaluation of disaster reduction benefits of water conservancy projects.

Materials and methods

Data sources

The data are the daily precipitation data of Guiyang National Standard Meteorological Station from 1951 to 2017 provided by the National Meteorological Information Center, and soil moisture content data the No. 2 test pit of Xiuwen country Irrigation Test Base of Guizhou Irrigation Test Center in 2015 and 2016 in China.

Overview of the study area

Guiyang City, located in the east of Yunnan-Guizhou Plateau and the central part of Guizhou Province, is an important central city in southwest China in *Figure 1*.

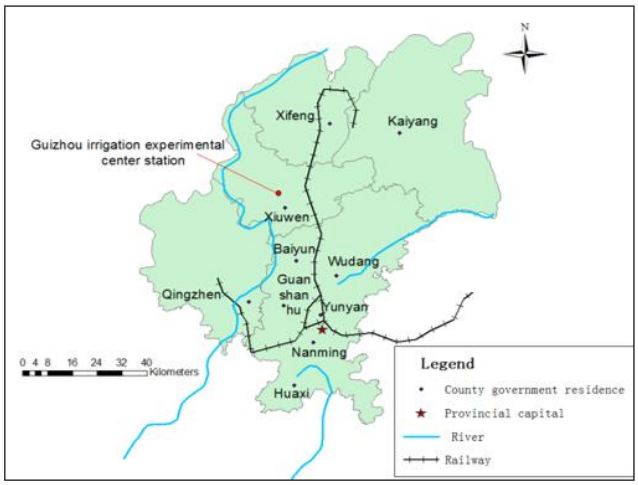

Figure 1. *Overview of the study area*

Guiyang city has a total area of 8,034 square kilometers and an area for tobacco cultivation, planted 13,700 hectares of flue-cured tobacco. With the altitude of around 1,100 m, it is located in the Federl circulation cell and is controlled by the westerlies all the year round. It belongs to the subtropical humid and mild climate with the annual average total precipitation of about 1,130 mm. The precipitation distribution is uneven. Rainwater is abundant in summer, accounting for about 70% of the annual precipitation, so that it is easy for drought-flood abrupt alteration to occur.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1227112286

Calculation of accumulative available precipitation

Available precipitation refers to the part of total precipitation that can be preserved in the root layer of crops to meet the needs of crop evapotranspiration, excluding surface runoff and the part that leaks below the water-absorbing layer of crop roots. The main factors affecting available precipitation are precipitation intensity, soil texture and structure, topography and flatness, soil water content before precipitation, crop species and growing period (Guo et al., 2012). Available precipitation calculation formula for a certain precipitation (Xu, 2009) is:

$$P_{e\mathrm{i}} = \alpha_i P_i \quad \text{(Eq.1)}$$

where, P_i is total precipitation of i^{th} time of precipitation, *mm*; a_i is the available utilization coefficient. Considering the factors such as large terrain slope, barren land and unique karst landform in Guiyang, the values of a_i are as follows, by combination of the available utilization coefficient of precipitation studied by the scholars (Dastane, 1974; Liu et al., 2009): when $P_i \leq 5$ mm, $a_i=0$; when 5 mm$\leq P_i \leq$50 mm, $a_i=0.85$; when $P_i>50$ mm, $a_i=0.85$.

The accumulative available precipitation during the flood period P_E is equal to the sum of the multiple time of available precipitation during the flood period, and the calculation formula is as follows:

$$P_E = \sum_{i=1}^{n} P_{ei} \quad \text{(Eq.2)}$$

In general, tobacco has certain flood tolerance. Considering the different flood tolerance of tobacco in different growing periods and the different critical values of precipitation in effective process of different growing periods, this study classifies the flood standards of tobacco in different growing periods (Tang, 2011), in *Table 1*.

Table 1. *Classification of tobacco flood grade based on accumulative available precipitation*

Tobacco growth period	**Process effective precipitation critical value P_k (mm)**	**Grading**			
		Light flood	**Moderate flood**	**Severe flood**	**Extreme flood**
Root extension stage	25	≤40	40~55	55~70	>85
Grow prosperous stage	35	≤50	50~75	75~100	>125
pre-mature stage	25	≤45	40~65	65~85	>105
mature late stage	20	≤40	40~55	55~70	>85

Continuous days without available precipitation

Continuous days without available precipitation refer to the duration days when the precipitation is less than the available precipitation critical value in the crop growing season. This index combines the precipitation and the precipitation days, but the daily water requirement of the crops is basically close under the non-precipitation

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1227112286

meteorological conditions. Therefore, the index can indirectly reflect the income and expenditure of farmland precipitation and profit and loss of soil moisture. Combined with the law and actual situation of tobacco water demand in Guiyang (Cai et al., 2005; Cheng, 2006; Gao, 2006), the formula for calculating continuous days without available precipitation is as follows (Huang et al., 2014):

$$Dnp = \sum_{j=1}^{m} a \cdot Dnp_j \quad \text{(Eq.3)}$$

where, *Dnp* is number of continuous days without available precipitation, *d*; *a* is the adjustment coefficient of tobacco in different growing periods and the specific value is shown in *Table 2*. The calculation formula of Dnp_j is as follows:

$$Dnp_j = \begin{cases} 1 & P_{ei} \le P_0 \\ 0 & P_{ei} > P_0 \text{ and } P_n \le P_k \text{ or } P_{ei} > P_k \end{cases} \quad \text{(Eq.4)}$$

where, P_{ei} is the daily available precipitation, mm; P_0 is the critical value of daily available precipitation, mm; P_0 is 5 mm during the critical water demand period (flourishing growing period) of tobacco, and is 3 mm in the rest periods. P_n and P_k is the process accumulative precipitation, of which P_n refers to the accumulation of available precipitation process that can alleviate drought and reach the root layer of crops to be used by crops, mm; P_k is the critical value of available precipitation, mm. The meaning of *Eq. 4* is:

1) When $P_{ei} \le P_0$, that is, the daily precipitation is below the critical value of daily available precipitation, drought occurs or continues, and days without available precipitation are calculated, that is $Dnp_j=1$;

2) When $P_{ei} > P_0$ and $P_n < P_k$, that is, the daily precipitation forms available precipitation, but the process available precipitation is still insufficient to end the drought, the drought is interrupted but not alleviated and the drought continues after the precipitation process ends, and the drought days don't accumulate, $Dnp_j=0$;

3) When $P_{ei} \ge P_0$, that is, the accumulative precipitation of one effective precipitation process is greater than the critical value of the effective process precipitation, excessive precipitation will be lost in the form of surface runoff, and the drought will continue after the precipitation process ends, and the drought days don't accumulate, $Dnp_j=0$;

Application of Dnp to evaluate multiple drought processes in tobacco growth period

The tobacco growth period is in the season of frequent drought in Guiyang City, and sometimes there are two or more times of drought, so it is necessary to evaluate the accumulative process of drought in the whole growing period of tobacco. Perfect the *Eq. 3* (Huang et al., 2014):

$$Dnp = \sum_{i=1}^{n} a \times (\sum_{j=1}^{m} Dnp_{ji} - D_{pj}) \quad \text{(Eq.5)}$$

where, *Dnp* is the accumulative continuous days without available precipitation during *n* times of drought processes in the whole growing period of tobacco; Dnp_j is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1227112286

continuous days without available precipitation in a single drought process, and the meaning is the same as *Eq. 4*; *n* is the time of drought in the whole growing period of tobacco; *m* is the number of day of j^{th} drought. The meaning and value of *a* are the same as *Eq. 3*; *Dpj* is the equivalent days of available precipitation in the process of relieving drought to reduce the drought in the later period of j^{th} drought in tobacco growth period; *j* is the time of drought. The calculation formula of *Dpj* is as follows:

$$Dpj = P_{nj} / 2P_0 \quad \text{(Eq.6)}$$

where, P_{nj} is accumulative available precipitation in the course of a drought mitigation when $P_n \geq P_k$, mm, the calculation process of P_{nj} is the same as *Eq. 2*. The result of the calculation of *Dpj* is taken as an integer. The meaning of P_0 is the same as *Eq. 4*. According to the previous calculation result of crop water demand (Tang, 2011), the daily water demand of tobacco ET_c is close to the critical value P_0 of available precipitation and can be approximately equal. Therefore, the meaning of the *Equations (5)-(6)* is that the drought can compensate for the drought in the later period of available precipitation. In the process of interrupting the drought, if the precipitation is excessive in a single day, the excessive precipitation will be lost in the form of surface runoff, and the drought can't be relieved.

According to previous research result of available precipitation and the characteristics of tobacco water demand in Guizhou (Tang, 2011), the specific P_k vales be included in the *Table 1*. The values of P_0, P_k and *a* are subdivided and adjust according to the tobacco growth period. P_0 is 4 mm in the root extension period and the pre-mature period, 5 mm in the flourishing growing period, and 3 mm in the pre-mature period. Please refer to the table for the specific values of P_k. *a* is 1.1 in the root extension stage and the post-mature period, 1.3 and 1.2 in the flourishing growing period and the pre-mature period respectively. The days without available precipitation in a single drought process is calculated according to *Eq. 3* and *Eq. 4*. When the continuous days without available precipitation reaches above 10*d*, it is determined as a drought process, and the specific classification is shown in *Table 2*.

Table 2. *Criteria for tobacco drought grades based on continuous days without available precipitation*

Drought grade	Normal	Light drought	Moderate drought	Severe drought	Extreme drought
continuous days without available precipitation	≤10	10~20	20~30	30~45	>45

According to the local agricultural production experience in Guizhou, the tobacco transplanting period is in the first ten-day period of May. Assuming that the transplanting is completed on May 10 and the soil moisture is sufficient, and the drought start date is counted from May 11; if the start day is rainy, the first rain-free day after the end of the precipitation process is taken as the drought start date; if the start day is a rain-free day, this day is the start day of the drought.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

Results and analysis

Analysis on the evolvement law of drought-flood abrupt alternation during the tobacco growth period

In accordance with the daily precipitation data in Guiyang from May to August of 1951, the daily available precipitation P_{ei} is calculated by the *Eq. 1*, and the accumulative available precipitation in different periods is calculated by the *Eq. 2*. *Eqs. 3-6* are used to calculate continuous days without available precipitation to study evolvement process of drought-flood abrupt alternation during the tobacco growth period.

Figure 2 describes the evolvement law of drought-flood abrupt alternation during the tobacco growth period. In a short period of two weeks after tobacco transplanting, the accumulative available precipitation reaches more than 90 mm. At this time, it is tobacco root extension period when the daily average water demand is 3 mm, so serious flood disaster occurs at this period.

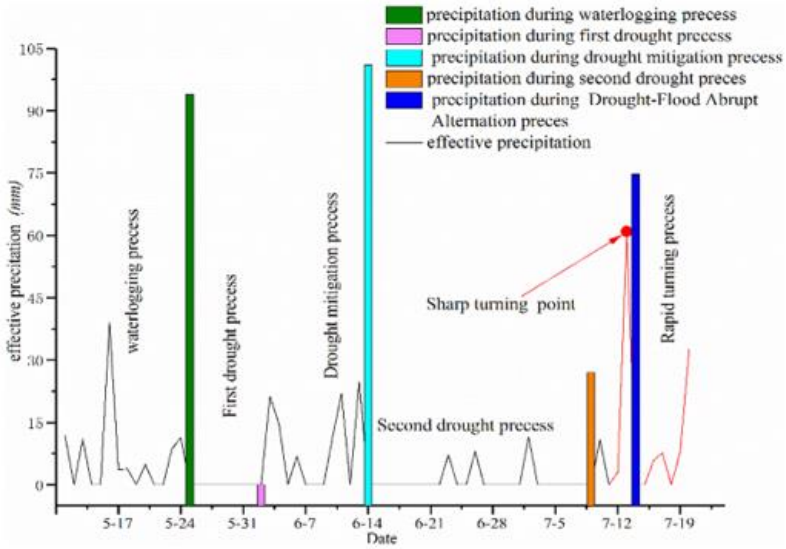

Figure 2. *Evolvement process of drought-flood abrupt alternation during the tobacco growth period*

During the next week, there is no available precipitation and belongs to light drought. In the following two weeks, the total available precipitation is as high as 100 mm. Because there is a light drought process in the early period, this precipitation can alleviate the drought in the early period. At this time, the tobacco is in the flourishing growing period and the daily average water demand is large, so there is no flood disaster. From June 14 to July 10, the accumulative available precipitation is less than 30 mm while it is the critical period of tobacco water demand and the daily average water demand is more than 5 mm. The water shortage will seriously affect the output and quality of tobacco. The *Dnp* value is calculated to be 28 days, belonging to moderate drought. From July 10 to July 13, in a short period of 3 days, the accumulative available precipitation is more than 70 mm, and drought-flood abrupt alternation occurs. The intensity turns from moderate drought to moderate flood, and the point of drought-flood abrupt alternation is on July 13.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1227112286

In order to verify the feasibility of the research method, the soil moisture content and precipitation data of No. 2 test pit of Xiuwen Irrigation Test Base of Guizhou Irrigation Test Center from May 1 to August 31, 2016 are selected in this study. The variation law between precipitation and soil moisture content is studied and described in detail in *Figure 3*.

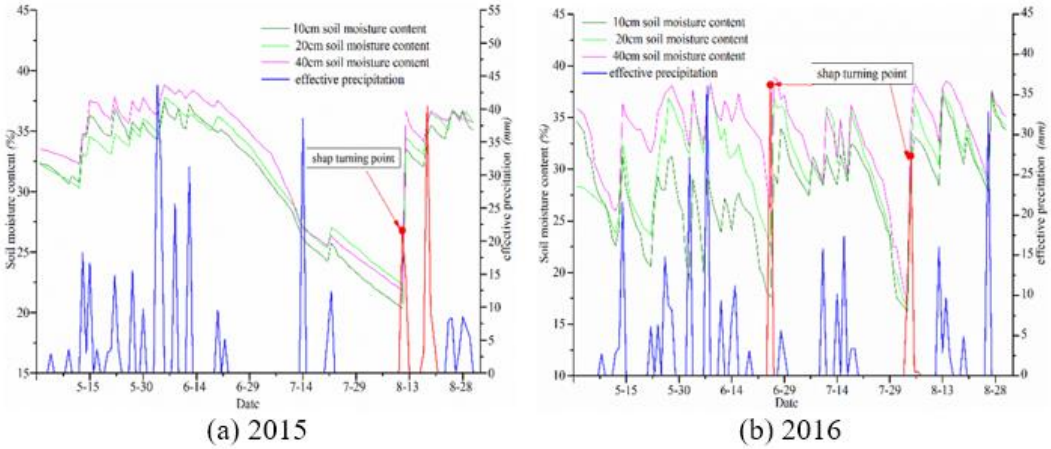

Figure 3. *Variation Law between Precipitation and Soil Moisture in the Irrigation Experimental Station of Xiuwen County in 2015 and 2016*

Li et al. (2007) hold that during the whole growing period of flue-cured tobacco, the soil moisture should be maintained at 60%-68%, 78.5%-81%, 76%-78% of the field water holding capacity during the root extension period, flourishing growth period and mature period, respectively, which is most beneficial to the growth and development of flue-cured tobacco. It can be seen from *Figure 3a* that during the root extension period of tobacco in 2015, 5 times of available precipitation are more than 10 mm and soil moisture content is more than 80% of the field water holding capacity. Han et al. (1992) hold that too high soil moisture is unfavorable for root development during the root extension period of tobacco and that total absorption area and active absorption area of root all decrease, so tobacco is subjected to flood stress at this period. In the flourishing growth period of tobacco, 3 times of available precipitation exceed 20 mm and the soil moisture content is more than 80% of the field water holding capacity. The soil moisture content at this time is beneficial to the growth and development of tobacco and the formation of output and quality because the flourishing growth period is critical for tobacco water demand. In the pre-mature period, there is a precipitation of more than 35 mm. Guiyang City belongs to typical karst landform, the surface water leakage is serious, and the temperature is high, the evaporation is vigorous, so the drought has not been alleviated. In a short week from August 13 to August 17, the total available precipitation is nearly 70 mm and the soil moisture content increases from 50% to 80% of the field water holding capacity. Drought-flood abrupt alternation occurs, and the point of drought-flood abrupt alternation occurs on August 13. According to the calculation, in the drought period of this year, continuous days without available precipitation are as long as 52 days, which belongs to Extraordinary drought. The accumulative available precipitation in the drought period is only 48 mm, which belongs to the transition from Extraordinary drought to moderate flood. Therefore, it is feasible to identify the drought-flood abrupt alternation in tobacco growth period based

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1227112286

on continuous days without available precipitation and accumulative available precipitation during flood period.

In the tobacco growth period, Guizhou is prone to have droughts and floods, therefore, there may be more than two drought-flood abrupt alternations. According to *Figure 3b*, it can be found that two drought-flood abrupt alternations occurred in 2016, and the abrupt turning point of drought and flood occurred on June 26 and August 2, respectively. The first drought-flood abrupt alternation occurred in the flourishing growing period of tobacco, the number oconsecutive non-effective precipitation days reached 32 days, belonging to heavy drought, the accumulative effective precipitation reached 45 mm in flood period, belonging to middle flood, with the intensity of abrupt alternation from heavy drought to moderate flood. However, it can be seen from the figure that before and after June 26, the soil moisture content rises from 40% to 90% of the field water holding capacity, which is a severe drought-flood abrupt alternation. There is some error in the intensity discrimination, but it can accurately judge the occurrence time of the drought-flood abrupt alternation. The second drought-flood abrupt alternation occurred in the late stage of tobacco maturity, with 35 consecutive days of non-effective precipitation during the drought period, belonging to heavy drought, and the accumulative effective precipitation in the flood period reached 35 mm, belonging to light flood, with the intensity of abrupt alteration from heavy drought to light flood. Before and after August 2, the soil moisture content increased from 40% to 90% of field capacity, belonging to the severe drought-flood abrupt alternation. In the drought period, the number of the continuous non-effective precipitation days in the first drought-flood abrupt alternation is almost the same as the cumulative effective precipitation in the flood period. Therefore, in the whole tobacco growth period, it is possible to have many drought-flood abrupt alternations, but the intensity of drought-flood abrupt alternation will not be too high.

Characteristics of drought-flood abrupt alternation in typical years

The number of days of non-effective precipitation and the accumulative effective precipitation in the flood period during the whole growing period of tobacco in Guiyang from 1951 to 2017 are counted and screened year by year, with the specific screening results shown in *Table 3*.

Table 3. *characteristics of Drought-Flood Abrupt Alternation in typical years of tobacco growth in Guiyang*

Year	Continuous days without available precipitation (d)	Cumulative effective precipitation during waterlogging (mm)	Sharp turning degree	Sharp turning point
1957	18	93	Light drought turn Severe flood	June 14th
	16	158	Light drought turn Extreme flood	July 28th
	40	50.49	Severe drought turn Light flood	July 6th
1958	18	43.03	Light drought turn Light flood	August 3rd
	14	82.62	Light drought turn Moderate flood	August 23th
1970	47	228.75	Extreme drought turn Extreme flood	July 11th
1975	72	100.98	Extreme drought turn Severe flood	August 9th
1988	48	171.02	Extreme drought turn Extreme flood	August 22th
1991	51	363.72	Extreme drought turn Extreme flood	July 9th
2010	52	76.58	Extreme drought turn Moderate flood	August 24th
2016	42	54.91	Severe drought turn Light flood	August 4th

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1227112286

It can be seen from *Table 3* that in the years with severe drought, the number of consecutive non-effective precipitation days is more than 45 days, and the number of consecutive non-effective precipitation days in 1972 is as high as 72 days, from May 28 to August 9, when is flourishing growing period and pre-mature period of tobacco, with the accumulative effective precipitation less than 100 mm, which results in extraordinary drought events, and then within the following 3 days, the accumulative effective precipitation is as high as 100 mm, resulting in heavy flood disaster. In 1957, two drought-flood abrupt alternation occurred, and the abrupt alternation was relatively low. Because of the low intensity of drought in the early period and the high level of flood in the later period, we should focus on preventing the adverse effects of flood in the later period. In the 1970s, two high-intensity drought-flood abrupt alternation occurred, and due to the severe drought in the early period, we did not forget the late flood prevention work while doing the early drought relief work. In the 21st century, the drought degree in the drought period is still serious, and the cumulative effective precipitation in the flood period has been reduced, so we should focus on addressing drought in the early period, especially in the flourishing growing period, when there may be summer drought.

The trend of drought-flood abrupt alternation in different growing periods of tobacco

Figure 4 shows the trend of drought-flood abrupt alternation in different growing periods of tobacco. (Since the root extension period of tobacco is dominated by waterlogging, and only 4 times of drought-flood abrupt alternation occur, it will not be described here).

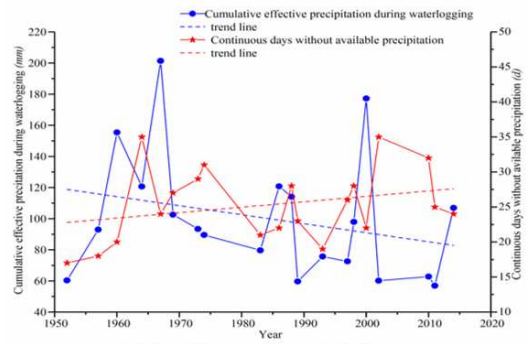
Nearly 20 drought-flood abrupt alternations in different degrees occur during the flourishing growing period of tobacco. The duration of drought varies from 20 to 30 days, which is due to excessive cumulative effective precipitation in the root extension period of tobacco, which compensates for the later drought. The cumulative effective precipitation during the flood period is mostly concentrated in 50~100 mm, and the intensity of abrupt alternation is mostly from moderate drought to moderate flood. As can be seen from the change trend curve, during this growing period, the duration of drought increases significantly, and the cumulative effective precipitation in the flood period shows a significant decreasing trend, indicating that the intensity of abrupt alternation is lightening and the drought is increased in the future, when is the critical period of tobacco water demand. Severe drought would make leaves lose water seriously, and the water in the lower leaves is transferred to the upper leaves excessively, causing the lower leaves to wither and form "dry drying". Therefore, the adverse effects of summer drought on tobacco growing should be prevented emphatically.

There are about 25 drought-flood abrupt alternations with varying degree in the pre-mature period of tobacco. The duration of drought fluctuates greatly, because if the accumulative effective precipitation is too much in the flourishing growing period of tobacco, it can compensate for relieving the drought in the later period, and if the tobacco suffers from summer drought in the flourishing growing period, which may aggravate the drought in the later period. The cumulative effective precipitation in flood period is mostly concentrated in the range of 50~150 mm, and the intensity of abrupt alternation is mostly from heavy drought to heavy flood.

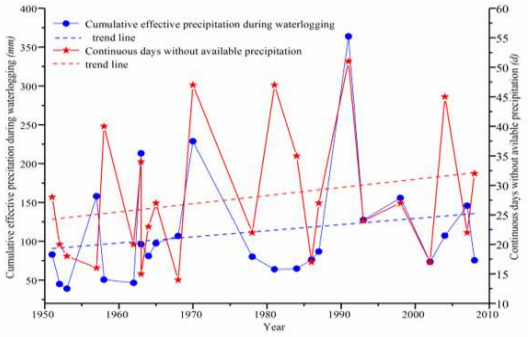
It can be seen from the trend curve that during the growing period of tobacco, the duration of drought has a significant increasing trend, and the cumulative effective precipitation during the flood period has an increasing trend, which indicates an

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1227112286

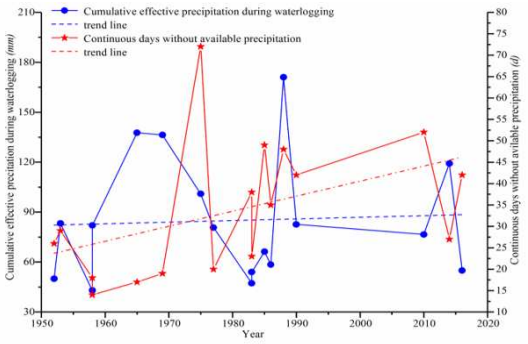
increasing trend in the intensity of abrupt alternation in the future. If the tobacco field waterlogging time is too long, resulting in the root oxygen deficiency, it's easy to form "water drying". Therefore, while doing a good job in drought relief, we should pay attention to preventing the adverse effects caused by the drought-flood abrupt alternation.



(a) Flourishing growing period of tobacco



(b) Pre-mature period of tobacco



(c) Post-mature period of tobacco

Figure 4. *Trend of drought-flood abrupt alternation in different growing periods of tobacco*

In the post-mature period of tobacco, there are 15 drought-flood abrupt alternations in different degrees. Before 1970s, the drought lasted about 20 days in the drought period, and after 1980s, the drought lasted about 40 days in the drought period. The cumulative effective precipitation during the flood period is mostly concentrated in 50~100 mm, and the intensity of abrupt alternation is mostly from heavy drought to moderate flood. According to the changing trend curve, during the growing period, the duration of drought is obviously rising, and the accumulative effective precipitation in flood period is increasing, which indicates that there is an increasing trend in the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1227112286

intensity of drought-flood abrupt alternation in the future, and then there is less water demand for tobacco. If the precipitation is too much, the temperature will decrease, the sunshine will weaken, the accumulation of organic matter in the tobacco leaves will decrease, the air humidity will increase, and diseases and pests will easily occur under high temperature. It is important to prevent the adverse effects of flood on tobacco yield and quality.

Discussion

Guiyang is a typical monsoon climate fragile area, and is extremely prone to drought-flood abrupt alternation because of the monsoon changes, atmospheric circulation anomalies and local unique geographical factors such as geomorphology. The water vapor of heavy rainfall mainly comes from the South China Sea and the Bay of Bengal in the northern Indian Ocean. In the early March-April of the years with drought-flood abrupt alternation, the intensity of the Bay of Bengal monsoon, the East Asian monsoon, the Indian Ocean monsoon and the South China Sea monsoon is all remarkably weak, and the water vapor transport is insufficient, so it is easy to form drought. In summer, the southwest monsoon strengthens and the water vapor transported increases. When the cold air invades, the cold and warm air flow intersects, which is easy to form strong precipitation and cause the drought-flood abrupt alternation. Sun et al. (2017) analyzed the characteristics of atmospheric circulation anomalies, and found that in the early period of the years with drought-flood abrupt alternation, the western Pacific subtropical high is westward strong, the zonal motion of mid-latitude and high-latitude circulation is strong, the upper weaterlies are strong, and the cold air cannot move southward, which is not conducive to precipitation. In the later period, the meridional motion of the mid-latitude and high-latitude circulation is enhanced, the trough beyond the east of Ural Mountains is deepened, the East Asian coastal ridge is strengthened, and the water vapor from southeast and southwest directions is transported to southwest China, resulting in more precipitation in southwest China and the drought-flood abrupt alternation. The terrain in the territory is undulating and blocked by the terrain, the mountain is less exposed to solar radiation in the days, and the air is not as hot as the top of the mountain, causing the air on the top of the mountain to be hot and floating in the sky. The air at the foot of the mountain is cold, and the atmosphere below is relatively stable. In the evening, the temperature at the top of the mountain drops faster than that at the foot of the mountain. The air becomes cooler and then sinks, raising the warm and humid air at the foot of the mountain. The water vapor cools down continuously in the process of air rising, producing heavy rainfall and prone to drought-flood abrupt alternation.

Peng et al. (2018) uses the long and short period drought-flood abrupt alternation index to analyze the characteristics of drought-flood abrupt alternation in Zhengzhou in summer. If this method is used to study the law of drought-flood abrupt alternation in the growing period of tobacco, only the difference of drought and flood in the early and late periods is considered, and the time scale is too large. Only when the whole growing period of tobacco is over, can the degree of drought-flood abrupt alternation be evaluated, which cannot meet the needs of real-time monitoring and early warning evaluation. Chen et al. (2018) used hydrus-1d model to simulate soil moisture movement and study drought-flood abrupt alternation in the growing period of rice. The author thinks that this method not only considers meteorological factors, but also

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1227112286

considers soil moisture condition and water requirement during the crop growing period, with the certain feasibility. However, the continuous non-effective precipitation days and the accumulative effective precipitation during the flood period can indirectly reflect the income and expense of farmland precipitation and loss of soil moisture, and can accurately describe the law of drought-flood abrupt alternation in the growing period of tobacco. The method does not involve complex operations, and does not require a large number of data to simulate, so it can quickly achieve the monitoring and early warning evaluation of drought-flood abrupt alternation during the growing period of tobacco.

Conclusions

(1) In this study, the drought index of tobacco growth period constructed by continuous non-effective precipitation days is used to take into account the dual factors of precipitation and precipitation days, which can indirectly reflect the income and expenditure of farmland precipitation and soil moisture profit and loss. The flood index of different growing periods is constructed by using cumulative effective precipitation in the flood period, and the effects of water requirement, flood tolerance and precipitation process on tobacco growth were comprehensively considered. The precipitation and soil moisture data of Xiuwen County Irrigation Experimental Base in 2015 and 2016 are used to verify that the continuous non-effective precipitation days and cumulative effective precipitation in flood period could accurately describe the evolution of drought-flood abrupt alternation in tobacco growth period. It can realize the real-time monitoring and early warning evaluation of the drought-flood abrupt alternation during the growing period of tobacco in this area, and provide scientific basis for timely and accurate disaster prevention and reduction.

(2) In the tobacco root extension period, waterlogging is the main cause. It is easy to suffer from drought-flood abrupt alternation in flourishing period. Guiyang is located in the Yunnan-Guizhou plateau, where there is a severe drought-flood abrupt alternation in the tobacco growing period. In the later stage of maturation drought, the duration of drought increased obviously, and the intensity of drought-flood abrupt alternation increased rapidly, so the adverse effects of flood stress on the yield and quality of tobacco should be prevented.

(3) In the next step, artificial precipitation simulation test of drought and waterlogging is carried out to further improve the accuracy of the coupling method in this paper.

Abstract. Study on the effects of Pb and Cd stress on the photosynthetic physiological characters of potato. The single-factor randomized block experiments with the potato variety Xishu 1 as the test material. The photosynthetic rate (Pn), stomatal conductance (Gs), transpiration rate (Tr), intercellular CO_2 concentration (Ci) and SPAD value of the potato decreased with the increased concentrations and prolonged treatment. As the concentrations of Pb and Cd continued to increase, most of the photosynthetic physiological indices tended to be stable. But in the treatment with high concentration of Cd, the SPAD value decreases sharply. The potato photosynthetic system has certain tolerance to Pb and Cd, and the effect of Cd on the photosynthesis of potato is greater than that of Pb.
Keywords: *Pb and Cd, potato, photosynthetic, physiological characters, stress*

Introduction

With the progress of the human society and the accelerated industrialization process, environmental pollution has become one of the most prominent ecological problems in the world, including the heavy metal pollution of soil (Wan et al., 2008). Heavy metal pollution has been one of the hotspots in ecological and environmental biology research. So far, there have been a lot of studies on the effects of heavy metals on the biological morphology, their physiological and biochemical effects and the resistance mechanism of plants against heavy metal pollution (Kong et al., 2007; Zhou et al., 2007; Li et al., 2008). The current research mainly focuses on the toxic effects of heavy metals on plants, toxic mechanisms and the resistance mechanisms of plants, but little research involves the photosynthetic physiological characters of plants under heavy metal stress.

At present, 20 million hm^2 of soil has been polluted by heavy metals such as Pb and Cd in China, accounting for about one-fifth of the total cultivated land area (Lee, 2016). Every year, the economic loss caused by heavy metal pollution can be as high as 20 billion RMB (Gu et al., 2003). According to statistics, the land area suffering from heavy metal pollution accounts for 64.8% of the total wastewater irrigation area, including 46.7% mild pollution, 9.7% moderate pollution and 8.4% serious pollution (Chen et al., 2002). At present, the soil in the suburbs of most cities in China has been polluted to varying degrees. In many places, the contents of heavy metals such as Pb and Cd in grains, vegetables, fruits and other foods already exceed the standards and are close to the critical values. According to the survey conducted by the Ministry of Agriculture, among the 320 key polluted areas including suburbs, wastewater irrigation areas and industrial mines in 24 provinces (cities), 606,000 hm^2 of field crops suffer from excessive pollution, accounting for 20% of the total area monitored. In particular, the output and area of agricultural products with excessive heavy metal content account for about 80% of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1228712295

the total output and area of the agricultural products with excessive amount of pollutants. The pollution of Pb, Cd, Hg, Cu and their combinations is the most serious (Hou et al., 2017). Pb and Cd are the elements toxic to the plant growth. A large number of studies have confirmed that Pb can affect the antioxidant enzyme systems of plants (Sun et al., 2009; Cai et al., 2012); that the root tips of Cd-polluted broad bean seedlings turn dark brown and suffer from necrosis (Mo and Li, 1992); and that Cd can inhibit the growth of corn, wheat (Parlak, 2016), cucumber (Chen, 1990) and tomato (Moral et al., 1994), etc., and result in symptoms like leaf chlorosis and yellowing, which all affect the crop yield. In recent years, through research, Wang et al. (2009) found that the chlorophyll content, photosynthetic rate, transpiration rate and other indicators of radish leaves significantly dropped with the increase in the concentration of the Pb and Cd mixed solution (Wang and Shi, 2008); Wang et al. (2009) found that low-concentration Pb and Cd mixed solution has certain promoting effects on various physiological indicators of wheat, and that with the increase of concentration, the synthesis of chlorophyll will be blocked (Wang and Zheng, 2009). This reveals that Pb and Cd have certain impacts on the photosynthesis of plants; however, no research has been reported on the effects of Pb and Cd on the photosynthetic physiological characters of potato.

Potato (*Solanum tuberosum* L.), an annual herb of the Solanaceae family, is an important type of staple food and vegetable (Furrer et al., 2018). Potato is rich in nutrients and has high edible value. The starch in the dry matters' accounts for 75%-80%, which can be easily absorbed by the human body; the protein availability is 71%, which is 21% higher than that of grain, and what is more, it is rich in vitamin C (Li, 2013). In China, potato is an important kind of export goods; and in agricultural production, it is an excellent fore crop for cereal crops, and also an excellent crop for intercropping and replanting. Therefore, developing potato production is of great significance to improving the living standards of the people and promoting the development of light industry, food industry and grain production. With the development of industrialization and urbanization, large amount of Pb and Cd are continuously entering the soil, resulting in more and more serious pollution, which brings great harm to humans, environment and agriculture. So far, heavy metal elements have been accumulated to varying degrees in the soil (Bat, 1997; Fang, 2015; Jing et al., 2018; Pozza and Bishop, 2019), especially in suburban soil. The contents of Pb and Cd in soil have already greatly exceeded the world soil background values. For plant growth, Pb and Cd are non-essential elements, and both of them can adversely affect the chlorophyll synthesis and antioxidant enzymes of plants. When the dose exceeds a certain level, they may seriously affect the physiological metabolism of plants, hinder their growth and even lead to plant deaths (Bai et al., 2012). However, no research has been reported on the effects of Pb and Cd stress on the photosynthetic physiological characters of potato. This experiment explored the relationship between the photosynthetic physiological characters of potato and the heavy metal pollution of soil, so as to reveal the response of the potato photosynthetic system to heavy metal stress, and provide theoretical guidance for potato production.

Materials and Methods

Test materials

The potato variety tested was Xishu No. 1, supplied by Plateau and Subtropical Crop Laboratory, Xichang University.

The height, diameter, volume of pots is 150 g, 35 cm, 1750 cm^3.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1228712295

Experimental design

The experiment was carried out in the phytotron at Xichang University. We arrange the condition of enviroment on normal status which potato can grow healthy. During the experiment, the indoor CO_2 concentration was (450±50) $\mu mol \cdot mol^{-1}$, the light intensity (420±50) $\mu mol \cdot m^{-2} \cdot s^{-1}$, the relative humidity (55±8)%, the daytime temperature (25±2)ºC, the nighttime temperature (15±2)ºC and the illumination 12 h per day. The test soil was collected from the surface soil in the experiment field at Xichang College. The physical and chemical properties were as follows: the pH value was 6.30 (water)/7.71 ($CaCl_2$), the total P content was 441 $mg \cdot kg^{-1}$, the total N content 853 $mg \cdot kg^{-1}$, the total K content 2313 $mg \cdot kg^{-1}$, CEC 11.23 meq/100g, the organic matter content 25.1 $mg \cdot kg^{-1}$, and the contents of the heavy metals Pb and Cd 20 and 0.2 $mg \cdot kg^{-1}$, respectively. The Pb stress treatment levels were respectively 0(CK), 200, 500 and 1000 $mg \cdot kg^{-1}$, and Pb was added in the form of $Pb(CH_3COO)_2$; the Cd stress treatment levels were 0(CK), 20, 50, 100 $mg \cdot kg^{-1}$, and Cd was added in the form of $CdCl_2 \cdot 2.5H_2O$. After being treated, the soil was mixed well and stabilized for two weeks, and then potato seedlings were transplanted. The plants with roughly the same weight and height (about 8-10 cm) were selected and randomly allocated to the soil with different concentrations. For each treatment level, 16 pots were planted, and each pot had one plant. After transplantation, the water was added by the weighing method to maintain the soil moisture at about 60% of the field moisture capacity. After 30 days of heavy metal stress treatment, the photosynthetic physiological indices were determined.

Determination of the photosynthetic physiological indices

The potato leaves (the 3rd and 4th pairs of leaves of the main stem from top down) were measured during the period from 10:00 to 11:30 using the CI-340 portable photosynthetic measure system (CID (Beijing) Ecological Scientific Instrument Co., Ltd.). The indices determined included net photosynthetic rate (Pn), transpiration rate (Tr), stomatal conductance (Gs) and intercellular CO_2 concentration (Ci). At the same time, the SPAD value of the leaves was measured by SPAD-502 (Minota, Japan) chlorophyll meter. For each leaf, the indicators were determined for three times.

Data analysis

The above experiment was repeated 3 times, and the average values were taken as the results. And then statistical analysis and plotting were performed using the software SAS 8.2 and Excel.

Results

Effects of Pb and Cd on the photosynthetic physiological characters of potato

Effects of Pb on the photosynthetic physiological characters of potato

It can be seen from *Fig. 1* that under different concentrations of Pb, the photosynthetic physiological characters of potato showed different variation patterns. Under the action of Pb, the photosynthesis rate of potato decreased with the increase of the Pb concentration, and the treatment groups were significantly different from the control group. When the concentration of Pb was 200 $mg \cdot kg^{-1}$, the net photosynthetic rate decreased the most – by 22.97%, and then the decline gradually slowed down.

When the concentration of Pb was 1000 mg·kg^{-1}, the net photosynthetic rate was 52.55% of that in the control group. After Pb treatment, Tr of the potato leaves decreased with the increase of the Pb concentration, and the results of the treatment groups were significantly different from those of the control group. When the concentration of Pb exceeded 200 mg·kg^{-1}, the decrease of Tr became slower; and when the concentration of Pb was 1000 mg·kg^{-1}, Tr was 74.66% of that in the control group. When the concentration of Pb was 200 mg·kg^{-1}, Gs was not significantly different from that in the control group. With the increase of the Pb concentration, the decrease of Gs became faster. When the concentration of Pb was 1000 mg·kg^{-1}, Gs was 74.67% of that in the control group. With the increase of the Pb concentration, the decrease of Ci gradually slowed down and the content tended to be stable. At the Pb concentration of 500 and 1000 mg·kg^{-1}, Ci was 84.21% and 83.32% of that in the control group, respectively.

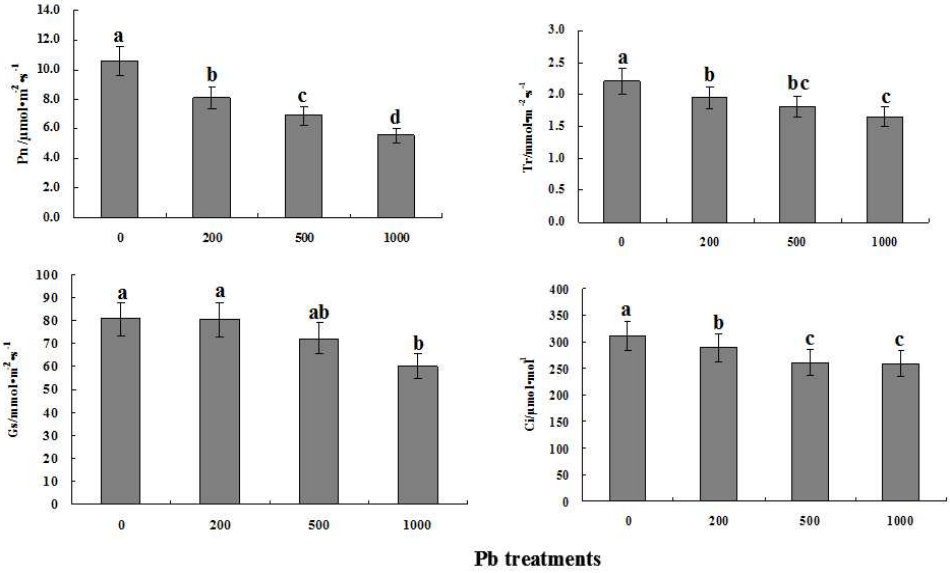

Figure 1. *Effects of Pb on the photosynthetic physiological indices of potato. The data are displayed as mean±SD, n=3. Different letters indicate the significant differences between treatments, P<0.05*

Effects of Cd on the photosynthetic physiological characters of potato

It can be seen from *Fig. 2* that under different concentrations of Cd, the photosynthetic physiological characters of potato showed different variation patterns. Under the action of Cd, the photosynthesis rate of potato decreased with the increase of the Cd concentration. When the concentration of Cd was 20 mg·kg^{-1}, the photosynthetic rate of potato did not differ much from that in the control group; but when the concentration was 50 mg·kg^{-1}, the net photosynthetic rate decreased the most – by 26.75%, and after that, the decline gradually slowed down. When the concentration of Cd was 100 mg·kg^{-1}, the net photosynthetic rate was 50.28% of that in the control group. After Cd treatment, Gs showed a different decline trend from that in the Pb treatment – it decreased more slowly with the increase of the Cd concentration. When the concentration of Cd exceeded 50 mg·kg^{-1}, Gs tended to be stable; and when the concentration of Cd was 1000 mg·kg^{-1}, Gs was 68.04% of that in the control group.

DOI: http://dx.doi.org/10.15666/aeer/1705_1228712295

With the increase of the Cd concentration, Ci first declined and then increased. When the Cd concentration was 50 mg·kg^{-1}, Ci declined the most and was 89.39% of that in the control group. When the Cd concentration was 50 mg·kg^{-1}, Ci started to increase. At the Cd concentration of 100 mg·kg^{-1}, Ci increased to 98.47% of that in the control group.

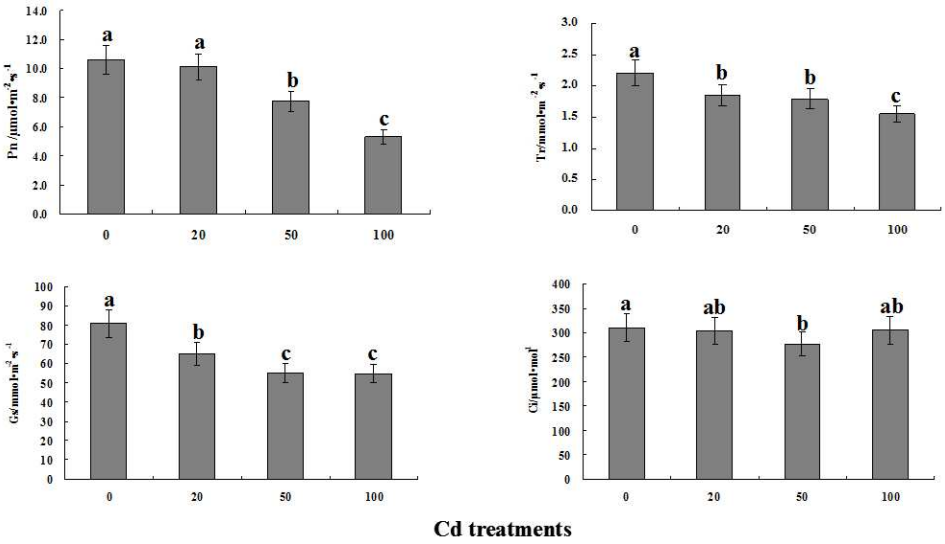

Figure 2. *Effects of Cd on the photosynthetic physiological indices of potato. The data are displayed as mean±SD, n=3. Different letters indicate the significant differences between treatments, P<0.05*

Effects of Pb and Cd on the chlorophyll content of potato

It can be seen from *Fig. 3* that the SPAD value of potato decreased with the increase of Pb and Cd concentrations, and the variation patterns were different. Under the Pb stress, the SPAD value showed a downward trend with the increase of the Pb concentration, and the decrease rate became smaller. When the Pb concentration exceeded 500 mg·kg^{-1}, the SPAD value tended to be stable. Under the Cd stress, the SPAD value decreased with the increase of the Cd concentration, and when the concentration of Cd exceeded 50 mg·kg^{-1}, the decrease of SPAD value became much faster.

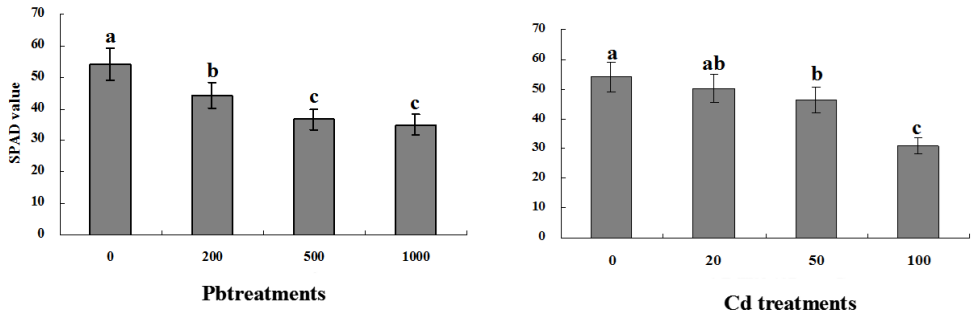

Figure 3. *Effects of Pb and Cd on the photosynthetic physiological indices of potato. The data are displayed as mean±SD, n=3. Different letters indicate the significant differences between treatments, P<0.05*

Discussion

The photosynthesis of plants mainly depends on three physiological processes, namely, the conduction, light and dark reaction of the photosynthetic substrate CO_2. The leaves have strong CO_2 conductivity, and high light and dark reactions are the important foundations for plant leaves to achieve a higher photosynthetic rate (Liu et al., 2007; Yang, 2012). Environmental stress has multiple impacts on the photosynthesis of plants. It not only directly causes damages to the photosynthetic structure, but also affects the photosynthetic electron transport, the photosynthetic phosphorylation and the dark-reaction-related enzyme systems. It is generally believed that the factors causing a decrease of the photosynthetic rate include stomatal limitation and non-stomatal limitation (Jing et al., 2018). The net photosynthetic rate (Pn) of plant leaves is an important indicator to measure the photosynthesis of plants, and its changes can also directly reflect the degree and variations of photosynthesis. Factors affecting Pn mainly include Ci, Gs and Tr. They work synergistically during the plant photosynthesis to promote the photosynthetic reactions. Tr can measure the transpiration intensity and stomatal opening of plant leaves, of which the latter can directly affect the velocity of CO_2 entering the leaves and the intercellular CO_2 concentration, and thus affecting the carbon assimilation (Shabbir et al., 2016).

In recent years, the inhibition of plant photosynthesis by heavy metal has been confirmed by many studies. It is generally believed that the inhibition mechanisms include (Quartacci et al., 2000; Mukhopadhyay et al., 2015): heavy metals can destroy the photosynthetic enzymes in leaves and cause photosynthetic pigments to decrease; heavy metals reduce the chlorophyll content and cause the structural damages of the chloroplast and destruction of the chloroplast membrane. Chlorophyll is the initiator of photosynthesis. Within a certain range, the higher the chlorophyll content, the higher the net photosynthetic rate. After the Pb treatment, the photosynthetic pigments of plants were damaged, especially chlorophyll a. Its content decreased rapidly after the concentration of Pb increased, and the inhibitory effect was even more obvious under high-concentration Pb stress (Wang et al., 2009). The reduction of the chlorophyll content is related to the damage of the enzymes for the synthesis of chlorophyll. Some research proposes that, after being absorbed by plants, heavy metal ions act on the SH part of the peptide chain of the chlorophyll synthase and change its normal configuration to inhibit the activity of the synthase and block the synthesis of chlorophyll (Qiu et al., 2006). In addition, according to some studies, heavy metal ions can make the chloroplast envelope disappear, resulting in irreversible damages of chloroplast (Kutschera, 2015; Soares et al., 2016); under the Pb stress, the chloroplast structure will change significantly (Bashmakov et al., 2017); and under the high-concentration Pb stress, the chloroplast membrane system will collapse and the chloroplast will shrink, resulting in numerous large lipid globules (Zhou et al., 2005). It shows that heavy metal can cause great damages to the function of chloroplast and significantly reduce the chlorophyll content of plant leaves.

Heavy metals inhibit plant photosynthesis by affecting the stomatal opening of leaves, especially cadmium and lead. In this experiment, under the treatment of high-concentration Pb and Cd, the decrease of Pn became significantly faster, Gs significantly decreased, and at the same time Ci increased. According to the study of Farquhar and Sharkey (1982) on the determination of stomatal limitation and non-stomatal limitation, the inhibition of potato photosynthesis by Pb and Cd in this experiment was caused by non-stomatal factors. It was not because the decrease of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1228712295

stomatal conductance resulted in insufficient CO_2 supply, but because the photosynthetic structure was destroyed, which inhibited the activity of the dark reaction enzyme and thus reduced the photosynthetic rate of the plant (Mobin and Khan, 2007; Huang et al., 2018).

Conclusions

This experiment studied the effects of Pb and Cd on the photosynthesis of potato. After the treatment of Pb and Cd within a certain range of concentration, the photosynthetic rate (Pn), stomalal conductance (Gs), transpiration rate (Tr), intercellular CO_2 concentration (Ci) and chlorophyll content (SPAD) of potato were on a downward trend. As the concentrations of Pb and Cd continued to increase, most of the photosynthetic physiological indices tended to be stable, indicating that the potato photosynthetic system has certain resistance to Pb and Cd. Under the high-concentration Cd treatment, the SPAD value decreased sharply, which indicates that the effect of Cd on potato photosynthesis is greater than that of Pb.

(Received 3rd May 2019; accepted 11th Jul 2019)

Abstract. In order to understand the sedimentary age and geotectonic environment characteristics of the Ruyang Group in geological history, this study, with the LA-ICP-MS method, focuses on the study of U-Pb isotope geochronology and geotectonic environment analysis of detrital zircons in the bottom of Xiaogoubei Formation of Ruyang Group in Daimeishan of Henan. Results show that the ages of detrital zircons of Xiaogoubei Formation range from 1720 Ma to 2727 Ma, the youngest detrital zircon age near the harmonic line is 1720 ±65 Ma, the main peak age is 2547 Ma, and the second peak ages include 2178 Ma and 1832 Ma. Therefore, we consider that the lower age limit of Xiaogoubei Formation is ~1720 Ma; the sediment sources of Xiaogoubei Formation mainly come from the geological bodies of the interior of the North China craton in the late Neoarchean, early Paleoproterozoic, middle Paleoproterozoic, late Paleoproterozoic and early Neoproterozoic. At the same time, the detrital zircon age of samples has a good response relationship with the Precambrian geological events in North China Craton, which reveals the then construction environment.

Introduction

There are many opinions on the division of the stratigraphic ages of Xiong'er rift trough: Guan et al. (1980) and Xing et al. (1996) advocated that the Ruyang Group composed of Bingmagou Formation and Beidajian Formation should be classified into the Mesoproterozoic Jixian System and the Luoyu Group composed of the Cuizhuang Formation and the Luoyukou Formation into the New Proterozoic Qingbaikou System. Chen et al. (1999) called the Bingmagou Formation - Luoyukou Formation collectively the "Ruyang Group", unifying into the Mesoproterozoic Jixian System. In order to limit the stratigraphic age, Guan et al. (1980) first obtained glauconite K-Ar dating data in the Sanjiaotang Formation and Cuizhuang Formation, i.e., 1071 Ma-1089 Ma and 1138 Ma-1159 Ma, respectively, which is the basis to classify Luoyu Group into Qingbaikou System; Qiao et al. (1997) obtained the Pb-Pb age of carbonate rocks in Luoyukou Formation as 855 ± 54 Ma; Liu et al. (1999) obtained the Rb-Sr age of clay

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1229712304

minerals as 1125 ± 3 Ma in the Cuizhuang Formation and the Ar-Ar age as 918.8 Ma in the flints of Dongjia Formation. In recent year, Su et al. (2012) has made important progress in this area, studied the zircon U-Pb dating of the "sedimentary tuff" interbedded in the middle part of the Luoyukou Formation near Yangpo Village in Ruzhou, Henan Province, and obtained the high-precision dating date of 1611 ± 8 Ma, which provides accurate age data for Luoyukou Formation and its underlying strata such as Luoyu Group and Ruyang Group in this area. In the same year, Hu et al. (2012) carried out U-Pb dating of LA-ICP-MS zircon in the Maanshan Formation at the bottom of the Wufoshan Group in Songshan area, found the youngest zircon age of two samples is 1732 ± 11 Ma and 1655 ± 22 Ma, respectively and defined the sedimentary age of the Songshan-Jishan Formation area, believing that the sedimentary age of the Foshan Group is later than 1655 Ma; Hu et al. (2014) obtained the youngest detrital zircon age of 1744 ± 22 Ma at the bottom of Yunmeng Mountain, defined the detrital sedimentary age of the rift trough after the volcanic rocks of the Xiong'er Group. All of the researches are of great significance for the stratigraphic comparison and the establishment of chronostratigraphic framework in this area.

In addition, Daimeishan area is a national geological park and AAAAA scenic spot. Its unique natural environment can not be separated from the joint action of tectonic activities, rock types and climate. Among them, tectonic activities are of great significance to its later genesis. Therefore, the analysis of tectonic environment in its geological and historical period is conducive to strengthening the understanding of its modern geographical environment. We can also understand the tectonic background and the characteristics of the surrounding environment and the large paleogeographic pattern in the western part of Henan Province of the North China Craton at that time.

This study involves the U-Pb dating of the LA-ICP-MS detrital zircon of Xiaogoubei Formation of Ruyang Group in Daimei Mountain, Henan Province. Combining the results of previous researches, this study compares the zircon ages of different regions in the southern margin of the North China Craton, and reveals the characteristics of the formation and evolution of the crystalline basement and the Xiong'er rift trough in the southern margin of the North China Craton. It is of great significance to understand the tectonic environment of the study area and restore the characteristics of paleoenvironment.

Materials and methods

Regional geological background

Xiong'er rift trough is mainly distributed in the junction of Henan, Shanxi and Shaanxi provinces in China (*Figure 1a*), particularly in the west of Henan, and the Neoproterozoic strata are mainly composed of neutral+acidic volcanic basement with an extremely thick (7000 m) of Xiong'er Group, upper detrital rock and carbonate sedimentary caprocks. The Neoproterozoic strata are divided into the Xiaoqinling-Luanchuan stratigraphic block (I), the Mianchi-Qushan stratigraphic block (II), and the Songshan-Jishan stratigraphic block (III) according to the lithological combination and sedimentary characteristics of the area *(Figure 1b*).

DOI: http://dx.doi.org/10.15666/aeer/1705_1229712304

Profile and sampling location

The section of this study is located in the area of Daimei Mountain (35°2'1.72"N, 111°57'44.26"E), Xin'an County, Luoyang City, Henan Province (*Figure 1b*). The Xiaogoubei Formation and Yunmenshan Formation are observed and measured in detail in the early stage. Xiaogoubei Formation (73.0 m thick) is not integrated on the metamorphic rocks of Majiahe Formation of Xiong'er Group, mainly composed of gray-grayish white medium-thick layers containing gravel sandstone and purplish red medium-fine feldspar quartz sandstone, with large-scale cross-bedding and lenticular bedding, and parallel bedding, and is of fan-delta deposit. Samples used for zircon dating are taken from the first layer of brown-yellow thick-bedded quartzite-fine medium-grained feldspar quartz sandstone (palimpsest structure can be seen) (*Figure 2*).

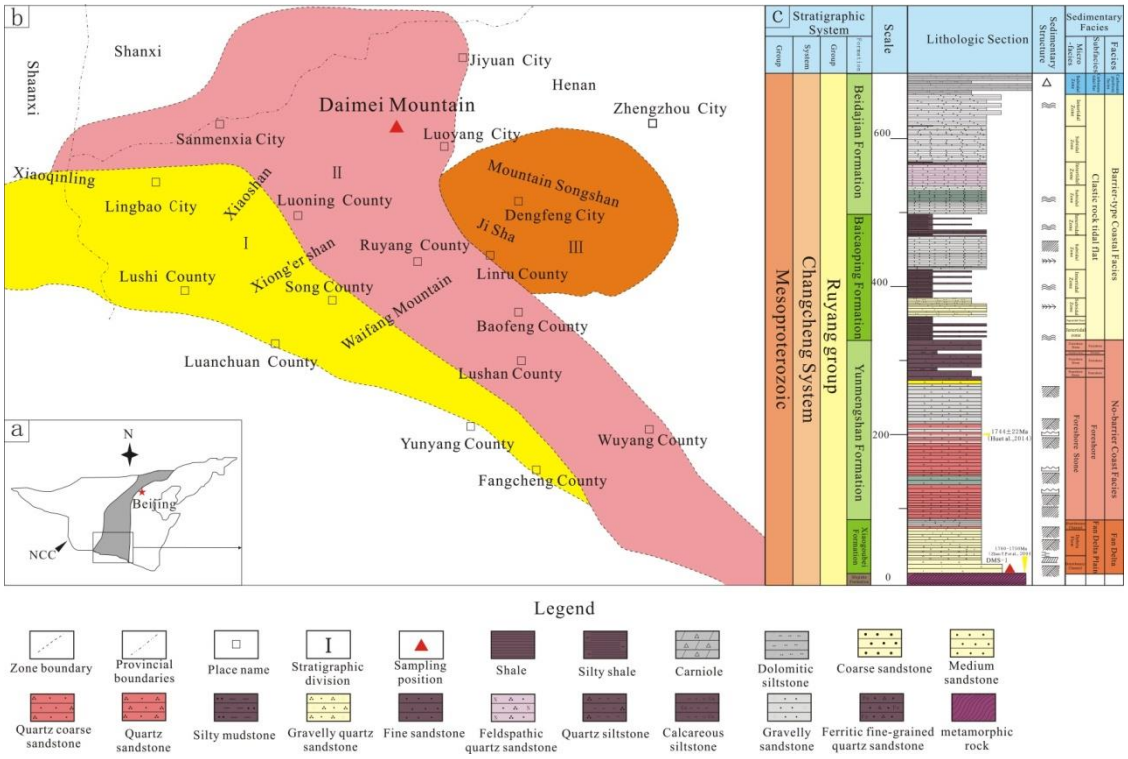

Figure 1. *Geotectonic setting (a), stratigraphic zoning map (b) and sampling location map (c) of the Xiong'er rift trough (as modified by Su et al. (2012))*

Methods of analysis and data processing

Sample crushing and zircon selection are completed by Langfang Keda Rock and Mineral Separation Technology Co., Ltd. By means of flotation and electromagnetic separation, single-grain zircons with different crystal shapes and sizes are selected under binocular lens to ensure their representativeness.

In general, the $^{206}Pb/^{238}U$ age is generally used for younger zircons of less than 1000 Ma, whereas the $^{207}Pb/^{206}Pb$ age, which is more reliable, is generally used for older zircons of greater than 1000 Ma due to lead loss (Black et al., 2003). After the experiment, ICPMSDataCal software (Liu et al., 2009) and Isoplot program (Ludwig, 2003) (Version 3.0) are used to analyze and process the data with the weighted average age calculated and a harmonic graph plotted.

Results

Morphology and Th/U ratio of zircons

Among samples, the size of zircon particles is different and mainly in the shape of equiaxial shape, followed by long column and spindle shape, with the particle diameter between 50-150 μm. The grinding circle is mainly sub-circular and sub-angular with occasional round grains, so it can be seen that the zircons in the samples may come from a distant source region and have been subject to long-time handling and strong abrasion.

The cathodoluminescence image analysis shows that there are obvious differences in the internal characteristics of zircons in the samples, most of the zircons have obvious magmatic growth oscillation zonal structure, and most of the crystal zoning is narrow, indicating that the magmatic rocks are more acidic (*Figure 3*). The core-mantle structure can be seen in individual zircons.

U-Pb age

A total of 86 valid data points are obtained from the Xiaogoubei Formation (sample DMS-1), and the harmonic degree of its surface age is greater than 90 on average. A harmonic graph and a histogram of age distribution are made for the valid data of the samples, and most of the data points are distributed along and near the harmonic line (*Figure 4*). As the average age of zircons measured is more than 1000 Ma, $^{207}Pb/^{206}Pb$ is selected as the age of zircon formation. The zircon age of Xiaogoubei Formation (sample DMS-1) is 1720~2727 Ma, and the youngest detrital zircons near the harmonic line is 1720 ± 60 Ma (measuring point DMS-1-03). The main peak age is 2547 Ma, and the second peak ages are 2178 Ma and 1832 Ma (*Figure 4*).

Discussion

Restriction of harmonic age of the youngest detrital zircons on the age of Xiaogoubei Formation

The youngest age data obtained for the detrital zircons in the sedimentary rocks will provide the largest age for the sediments, provided the samples are not contaminated

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1229712304

and the test system is stable. The minimum harmonic age of detrital zircons from Xiaogoubei Formation studied in this paper is 1720 ± 60 Ma (measuring point DMS-1-03), which represents the largest sedimentary age of Xiaogoubei Formation. The top-boundary age of Ruyang Group-Luoyu Group is limited to 1.6 Ga, and the bottom-boundary age is limited to 1.75 Ga. In combination with the result of dating, it is shown that between 1750 Ma and 1720 Ma, or showing a deposition discontinuity. However, due to the lack of more accurate tuff age data, this conjecture needs to be further verified.

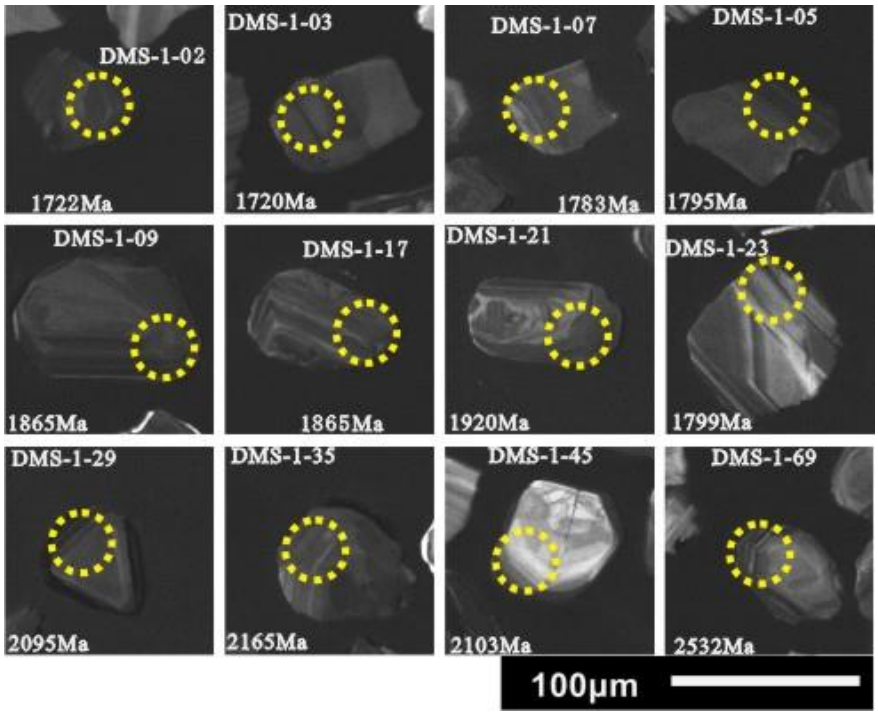

Figure 3. *Xiaogoubei Formation (DMS-1) in Daimei Mountain Area, Henan Province, representative zircon cathodoluminescence (CL) image (beam spot diameter of 24 μm)*

Source analysis of detrital zircons

According to the analysis of zircon age distribution histogram, the age distribution of Xiaogoubei Formation is divided into three groups: 2.75~2.4 Ga (peak value is 2547 Ma), 2.4~2.0 Ga (peak value is 2178 Ma), and 2.0~1.7 Ga (peak value is 1832 Ma), which accounts for 34%, 37% and 29% of the entire zircon age distribution respectively (*Figure 4*). It is considered that the source of Xiaogoubei Formation comes from the geological bodies in late Neoproterozoic, early Palaeoproterozoic, middle Palaeoproterozoic, late Paleoproterozoic and early Neoproterozoic (Wan et al., 2009; Hu et al., 2010; Zhou et al., 2011).

Response of detrital zircons to the precambrian geological events in the North China Craton

Crust growth and caratization events

The peak age of ~2.5 Ga and the age distribution of few ~2.7 Ga are recorded in the detrital zircons of the Xiaogoubei Formation. For a long time, 2.9~2.7 Ga is considered

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1229712304

as a period of large-scale continental crust growth in the North China Craton. The main evidences from the rocks are greenstone belts and TTG gneiss in the western Shandong region and the TTG gneiss from Jiaodong, Hengshan, Fuping, Jidong, Zhongtiao Mountains, Henan and Inner Mongolia. In addition, the peak age of ~2.7 Ga in the Proterozoic sedimentary basins of North China can also be observed, which indicates that the rocks of 2.9~2.7 Ga are common, together with the age records of ~2.7 Ga zircons from the Xiaogoubei Formation and Yunmengshan Formation of Xiong'er rift trough. In the meantime, the gneiss, TTG and granitic gneiss in the craton have the Hf and Nd model age of 2.9~2.7 Ga, and the age of their formation or upwelling from the mantle is considered to be 2.9 to 2.7 Ga, which indicates that the North China Craton has a large-scale continental crust formation during this period (Jahn et al., 2008).

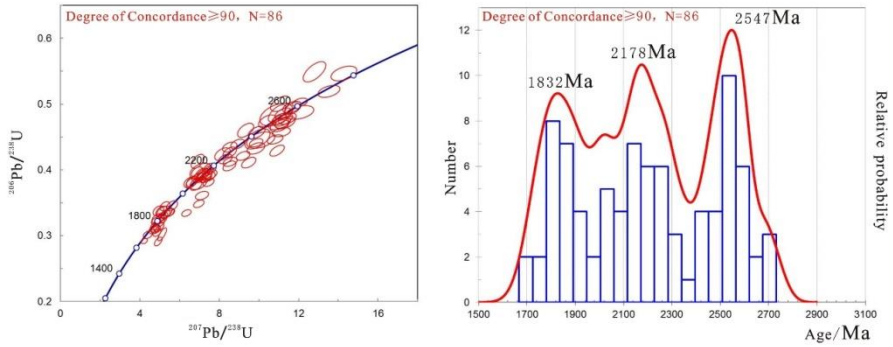

Figure 4. *U-Pb harmonic curve and age distribution histogram of detrital zircons in middle Paleoproterozoic Xiaogoubei Formation (Sample DMS-1) in Daimei Mountain Area, Henan Province*

Paleoproterozoic rift events

The U-Pb age distribution of detrital zircons from Xiaogoubei Formation shows a large amount of age distribution of 2.4~1.95 Ga, with a peak value of ~2.1 Ga. It is reported that during the period of 2.3~2.0 Ga, the North China Craton may have experienced a fracture-tension event of the basement continental block, and three rift belts of Fengzhen, Jiaoliao and Jinyu formed in the northern margin, eastern margin and central regions of North China, thus forming three internal sag basins (or rift belts) in Fengzhen, Jiaoliao and Jin-Henan cratons, which, along with the basic dykes, rift volcanic rocks and A-type granites found at the same time, have extensional properties, which can be proved effectively.

Paleoproterozoic orogenic belt and Mesoproterozoic rift events

In addition, the U-Pb ages of the detrital zircons in the Xiaogoubei Formation are mostly in the range of 1.95 ~ 1.7 Ga, with the peak age of ~1.8 Ga. It is reported that the large-scale metamorphism of the North China Craton at 1.95~1.82 Ga and the intrusion of granite and pegmatite veins related to metamorphism may be related to 1.9~1.8 Ga orogenic activities of three lift belts in Fengzhen, Jiaoliao and Jinyu. The zircons with the age distribution from 1.8 to 1.75 Ga correspond to the development of the Xiong'er rift trough, accompanied by the intrusion of 1.78 Ga basic dykes (Cui et al., 2011). This event also foreshadowed the beginning of the Mesoproterozoic rift and sedimentary events throughout the North China Craton.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1229712304

Conclusions

(1) The lower age limit of Xiaogoubei Formation is 1.72 Ga and the Mesoproterozoic Ruyang Group is dominated by delta-clastic littoral sedimentary environment, which is obviously different from the underlying Xiong'er Group.

(2) Xiaogoubei Formation comes from the geological bodies in late Neoproterozoic, early Palaeoproterozoic, middle Palaeoproterozoic, late Paleoproterozoic and early Neoproterozoic.

(3) The detrital zircon peak age of Xiaogoubei Formation has a good response relationship with the Precambrian geological events in North China Craton: the detrital zircon age of ~2.7 Ga mainly reflects the crustal growth of the craton, the peak age of ~2.5 Ga reflects the evolution of the North China cratonization, the detrital zircon age of 2.4~1.9 Ga mainly reflects the Paleoproterozoic rift event, the detrital zircon age of 1.95~1.8 Ga is mainly related to the orogenic activities of the three rift belts including Fengzhen, Jiaoliao and Shanxi-Henan and the detrital zircon age of 1.8~1.75 Ga mainly reflects the development period of the Xiong'er rift trough, foreshadows the beginning of the Mesoproterozoic rift event in the North China Craton.

(Received 4th May 2019; accepted 16th Jul 2019)

Abstract. The mining activities, one of the most drastic examples of human intervention to nature, have considerably deteriorated the environment. Although being one of the smallest and least populated cities of Turkey, Artvin is notably affected by mining in many ways such as acid rains, water contamination and medical problems. The activities also affect soil properties. The present study aimed to assess the effects of restoration and reclamation of the former smelter factory and determine the changes in some soil properties according to land use/land cover (LULC) and slope aspect. With this purpose, Pearson correlation and two-way ANOVA methods were used. Results showed that while LULC significantly affected ($p < 0.05$) all soil properties except silt content, bulk density, $CaCO_3$ content, C:N ratio, Cd and Zn; slope aspect significantly affected less soil properties such as sand, silt, pH, EC, $CaCO_3$ and Pb. The interaction between factors also significantly affected ($p < 0.05$) soil properties like LULC. According to partial eta squared ($\eta 2$) values, while the most significantly affected soil properties by LULC, slope aspect and their interaction were found to be Cr (0.93), Clay (0.59) and Cr (0.94), respectively; the ones least affected were found to be total nitrogen (0.12), $CaCO_3$ (0.14) and total nitrogen for 63-day (0.18), respectively. Despite the black alder's and black locust's lack of phytoremediation abilities concerning soil heavy metal content except Pb, *Alnus glutinosa* and *Robinia pseudoacacia* may be suggested for the restoration and reclamation of mining soils in terms of phytoremediation beside their advantages such as improving nitrogen mineralization.
Keywords: *copper mining, two-way ANOVA, black alder, black locust, partial eta squared*

Introduction

The human being has been forced to find new resources for energy and row material and to change land use because of increasing population since ancient times. Pollution, deforestation, erosion, drought-desertification and global climate change are only a few negative results of human activities causing the land use and land cover changes (LUCC) (Deng et al., 2013; Mahmood et al., 2010). The mining, one of the human activities, also has some negative impacts on the environment such as hydrologic, biologic, societal, blasting, subsidence, air quality and land surface effects (Allgaier, 1997).

Artvin has recently come into question with LUCC due to the construction of hydropower plants and mining activities. In this scope, there are 72 mineral deposit reserves determined in Artvin province consisting of 44-Cu-Pb-Zn, 1-Fe, 17-Mn, 5-Cu-Mo and 5-Au (TUİK, 2013). Total copper reserve including Artvin province and Murgul is 329.681 tones (DPT, 2001). Murgul mining entity, dated back to Genoese era, operated in between 1907-1914 by Russians, reactivated in 1951 with the copper smelter by General Directorate of Mineral Research and Exploration (MTA). The

DOI: http://dx.doi.org/10.15666/aeer/1705_1230512321

sulphuric acid factory, operated in between 1963-1975 and 1986-199 was also added to the entity to prevent SO2 emission. The SO2 production, emitted from the factory in between 1951-197 was estimated as 795431 tons (Erdin, 1983; Oruc, 2013). Damages to the ecosystems such as soil loss, lesions and color changes especially on the leaves of fruit trees, lower pH and organic matter content in soil and sulphur accumulation in needles around smelter due to SO2 and other emissions from the factory, were reported by some researchers (Erdin, 1983; Hutchinson and Whitby, 1977; Oruc, 2013). The current physical and chemical properties of soils which influence some vital processes such as carbon storage and nitrogen retention are determined by the duration and the type of land use. On the other hand, heavy metal contamination of soil is another environmental problem, which threatens human health beside the environment by affecting the food chain (Liu et al., 2017; Yesilonis et al., 2016). The area around the factory was planted by Artvin Forest Directorate in 1996 with *Robinia pseudoacacia* and *Alnus glutinosa* sp. to remediate the area. In remediation, beside above mentioned species pine, oak, lime, larch, poplar and birch also have been used in the world. The afforestation of these sites after soil amelioration results in good results (Fischer and Fischer, 2006).

Mining activities cause extreme influences on ecosystem and soil properties and it requires more time to restore soil quality. Therefore, assessing the changes in soil properties is important to see the effects of reclamation of mining areas (Shrestha and Lal, 2011). One of the most important factors affecting restoration and quality of soil is LUCC resulted from human-being, which have an effect on the changes in biological properties. Biomass and forest floor affect many features such as microbial biomass, soil nutrients and soil organic matter (Qi et al., 2018) which have a vital role in carbon balance. The amount of carbon sequestrated in soil in global scale has been estimated 3.3 and 4.5 times more than that in atmosphere and biosphere, respectively (Lal, 2004). The soil properties are expected to change by also slope aspect which is one of the topographic features and closely related to local climate (e.g. precipitation, evaporation and solar incident radiation) (Xu et al., 2008) beside LUCC. Therefore, the slope aspect was taken as the main second factor expected to change selected soil properties.

The aim of the present study was to test our hypothesis that assumes afforestation with black alder and black locust compared to grasslands would improve the soil properties, affecting soil quality after the mining (smelter factory).

Materials and methods

Site description

The study area is located between 41°15’53” - 41°16’21” N latitudes and 41°33’21” - 41°34’04” E longitudes (*Fig. 1*). It is found in Murgul district which is composing of two deep valley surrounded by high mountains with steep slopes (Acatay, 1968). The average elevation of the study site is 600 m above sea level. This region is characterized by mountainous topography with steep slopes. The average slope ranges between 40 and 60%. Soil parent material varies widely from sedimentary marl to igneous dacite, rhyodacite, rhyolite (Anonymous, 2002). The soil texture ranges from clay loam, silty clay loam to sandy loam, loam and loamy clay. Humus form includes both moder and mulls. The soil in the district is generally acidic due to high precipitation causing leaching of base cations (Yener, 2013).

DOI: http://dx.doi.org/10.15666/aeer/1705_1230512321

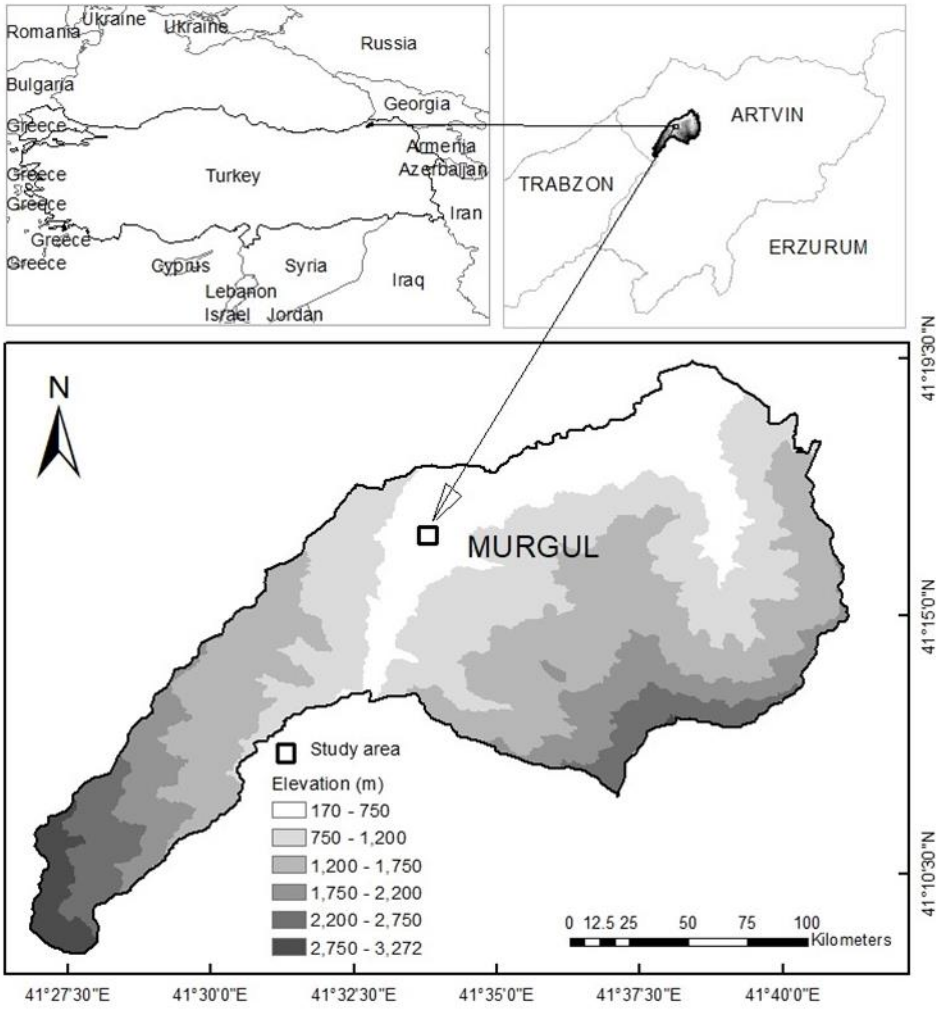

Figure 1. *Location of the study area in Murgul province, northeast Turkey*

The study area shows Eastern Black Sea climate under Black Sea macroclimate type, temperate in winter, warmer in summer and quite rainy in all seasons. According to the extrapolated climate data from the meteorological station closest to the study area, the annual mean temperature and the annual mean precipitation are 11.2 °C and 1213 mm, respectively. Mean annual minimum and maximum temperature are 7.1 °C and 16.6 °C, respectively (DMI, 2005). The growing season in the region is about six months (from May to October). The climate type is AB'1rb'3 (perhumid, mesothermal with no season of water deficiency, close to oceanic climate) according to Thornthwaite (1948).

In the district, along with oriental spruce, beech (*Fagus orientalis*), fir (*Abies nordmanniana)*, Scotch pine (*Pinus sylvestris)* and alder (*Alnus glutinosa)* species are found. Regarding understory vegetation, European mountain ash (*Sorbus aucuparia),* Caucasina laurel *(Prunus officinalis),* black sea holly *(Ilex colchica), common elder (Sambucus nigra),* European blueberry *(Vaccinium myrtillus),* Caucasian honeysuckle *(Lonicera caucasica),* fly honeysuckle *(Lonicera xylosteum),* rock red currant *(Ribes biebersteinii), oriental currant (Ribes orientale),* pontic azalea *(Rhododendron ponticum),* and yellow azalea *(Rhododendron luteum)* species are widely spread on the forest floor (Ansin, 1980).

DOI: http://dx.doi.org/10.15666/aeer/1705_1230512321

Soil sampling and analyses

The sampling was done during the summer season of 2017. 54 sample plots were determined and equally distributed in 2-slope aspects such as north facing slopes (NFS) and south facing slopes (SFS), and 3 land use/land cover (LULC) types including 18-black alder, 18-black locust and 18-grassland with 9-replicate (2 slope aspects × 3 LULC × 9-replicate = 54). Top soil is the most common used part in related to LUCC-soil quality studies because of its susceptibility to LUCC (Gol, 2017). Therefore, 54-top soil (disturbed) and 54-soil-core (undisturbed) samples were collected at 0-20 cm soil depth to determine some soil properties. All soil samples were air-dried and sieved through 2-mm mesh before analyses. All measurements were done with two repetitions. Bulk density (BD) was determined by steel core sampler after soil samples were oven-dried at 105 °C (Blake and Hartge, 1986). Soil skeleton (Stoniness) was determined using undisturbed soil core samples. Soil texture analysis was done using Bouyoucos hydrometer method (Bouyoucos, 1962). Soil acidity (pH) and electrical conductivity (EC) were determined in 1:2.5 and 1:5 soil: distilled water ratio, respectively with glass electrode, and organic carbon (SOC) was determined using Walkley & Black wet digestion method and soil organic matter was calculated by multiplying percent of organic carbon with a factor of 1.724 2001 (Kalra and Maynard 1991). Soil lime content ($CaCO_3$) was determined with Schreiber's Calcimeter (Nelson, 1982). Total nitrogen (TN) was determined following Kjelhdal digestion, distillation, and titration method (Pansu and Gautheyrou, 2007). Carbon-nitrogen ratio (C:N) was determined as the ratio of total carbon to total nitrogen. Potentially mineralisable-N (NO_3^--N plus NH_4^+-N) was determined by microdestillation method following Bremner and Keeney (1965) in the beginning and at the 63rd days of incubation, and the net mineral nitrogen was calculated for 63 days (Ammonium for 63 days: Ammon63; Nitrate for 63 days: Nitrate63; Total N for 63 days: T63) using the difference between beginning and 63rd day (Guleryuz et al., 2007). Heavy metals in soil such as Cadmium (Cd), Chromium (Cr), Cupper (Cu), Lead (Pb) and Zinc (Zn) were determined with ICP-OES following EPA (1996) 3051 procedure.

Data analyses

Pearson correlation analysis was performed to determine the significant ($p < 0.005$) relationships among variables. Then, two-way analysis of variance (ANOVA) was used following the general linear model procedure to determine the effects of factors (vegetation cover, slope aspect) and their interaction (vegetation cover*slope aspect) on dependent variables. Tukey HSD test were used to determine differences between vegetation cover groups. To interpret the interaction, six new variables were computed with original cells as a level. Then, one-way ANOVA was run and simple main effects from one-way ANOVA was examined using the contrast results 2005). An anthropogenic index (AI) which indicates antropogenic impacts on selected soil properties with a specific number, using partial eta-squared values from two-way ANOVA, developed by Zhang et al. (2012) was used using the formula below:

$$AI = \frac{1}{n} + \sum_{i=1}^{n} \left(\frac{\eta 2ai}{\eta 2ni + \eta 2ai} \right) \times 100 \qquad \text{(Eq.1)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1230512321

where $\eta 2_{ai}$ and $\eta 2_{ni}$ refer to partial eta-squared values of land use and soil series for a certain soil property, respectively, and n is the number of soil properties. In this study, $n = 19$. Anthropogenic index ranges from 0 to 1: the larger the AI value, the higher the anthropogenic impact. All statistical analyses were performed using SPSS v20.0 (IBM.Corp, 2011).

Results and discussion

Changes in physical soil properties

Soil texture among the land uses ranged from sandy loam to loamy clay. The texture classes were determined as loamy clay (44%), clayey loam (44%) and the remaining (12%) for black locust; loamy clay (50%), clayey loam (28%) and the remaining (22%) for black alder; and sandy loam (39%), loam (33%) and the remaining (28%) for grasslands. Sand content of soil differed significantly ($p < 0.001$) both for vegetation cover and slope aspect (*Fig. 2b; Table 1*). Sand content of soil on NFS (60.3%) was found significantly ($p < 0.001$) higher than that on SFS (52.1%). Sand content of grassland soils (64.9%) was significantly ($p < 0.001$) higher than that of black alder (52.8%) and black locust (51.4%). Mean sand content did not differ significantly ($p = 0.33$) for their interaction (*Table 1*).

Clay content of soils also differed significantly ($p < 0.01$) with vegetation cover, slope aspect and their interaction (*Fig. 2a; Table 1*). Clay content of NF slope soils (17.3%) was found significantly lower than that of SF slope soils (27.1%). Clay content of grassland soils (14.3%) was significantly ($p < 0.001$) lower than that of black alder (26.1%) and black locust (26.3%). Clay content of NF black alder soils (19.1%) was found significantly ($p < 0.001$) lower than that of SF ones (33.5%) and mean clay content of NF black alder soils (19.1%) was found significantly ($p = 0.015$) higher than that of NF grassland soils (12.0%) (*Table 1*). The lower clay and higher sand contents in grasslands, having little or no protective vegetation cover, may be due to the removal of clay by erosion (Miheretu and Yimer, 2018; Tsehaye and Mohammed, 2013; Bewket and Stroosnijder, 2003). Hung et al. (2017) stated that the higher clay content in tree systems (e.g. forests) compared to other land uses may attribute to the protective cover by tree crowns, roots and litter reducing soil erosion. BD in the present study ranged from 1.38 gr/cm3 to 1.84 gr/cm3 and was not significantly affected by any of the factors according to two-way ANOVA ($p > 0.05$) (*Table 1*). BD in forests was found lower than that in other land uses (e.g. grassland) by some other researchers (Assefa et al., 2017; Gol, 2017; Tesfaye et al., 2016; Toohey et al., 2018; Yesilonis et al., 2016). The lower BD in forests as compared to the other land uses can be attributed to higher clay content and loosening of the surface soil with plant root growth (Qi et al., 2018). Vegetation cover, slope aspect and their interaction significantly affected soil stoniness ($p < 0.001$). The stoniness of soil was not differed significantly between NFS and SFS ($p = 0.91$). The stoniness of grassland soil (46.9%) was higher than that of black alder (38.9%) and black locust (35.6%) soils ($p < 0.005$). The interaction between vegetation cover and slope aspect also significantly affected soil stoniness (*Fig. 2c; Table 1*). Soil stoniness of SF grassland (53.8%) was significantly higher than that of black alder (32.2%) and black locust (32.0%) ($p < 0.001$). The slope aspect significantly affected only grassland soil ($p = 0.005$). The soil stoniness of NF grassland (35.8%) was found lower than that of SF grassland (53.8%).

LULC: land-use/land cover, SASP: slope aspect, NFS: north facing slopes, SFS: south facing slopes, BD: bulk density. By slope aspect, values of same LULC follow the various lower-case letters indicate significant difference. By LULC, values of same slope aspect follow the various upper-case letters differ significantly

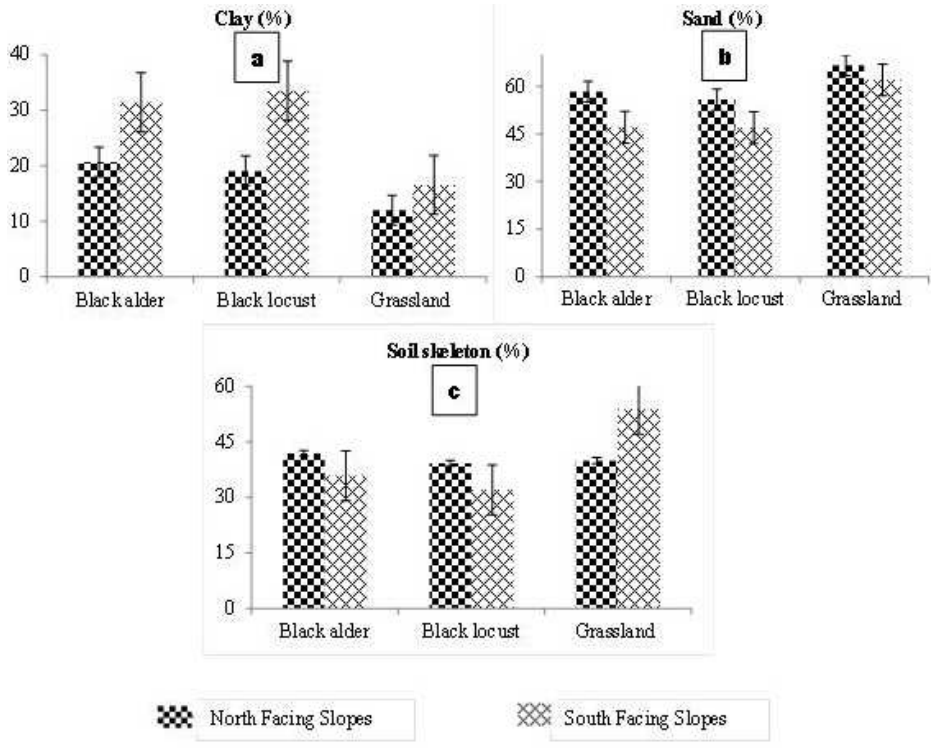

Figure 2. *Physical soil properties significantly affected by LULC and slope aspect*

Changes in chemical soil properties

The pH in the study area ranged from 3.93 (very strongly acidic) to 7.79 (weakly alkaline) according to Hazelton and Murphy (2016). This range is consistent with other

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1230512321

studies (Kuo et al., 1983). pH was significantly affected by vegetation cover ($p < 0.001$), slope aspect ($p = 0.005$) and their interaction ($p < 0.001$) (*Fig. 3a; Table 3*). pH of grassland soils (5.29) was found significantly lower than that of black locust (6.03) and black alder (6.72) soils ($p < 0.001$). As the slope aspect changes from north to south for all vegetation covers, soil pH significantly increased from 5.82 to 6.21 (*Table 3*). The interaction also affected soil pH ($p < 0.001$). While, black locust soil pH was significantly found lower than that of other vegetation cover soils in NFS, grassland soil pH was significantly lower than that of other vegetation cover soils in SFS. The change of land use from forests to grasslands resulted in a decrease in soil pH may be attributed to either removal of basic cations by harvesting/grazing or leaching of them because of sparse vegetation cover 2018). Shrestha and Lal (2011) also reported a significant increase in soil pH after reclamation of soil. Some researchers (Kucuk, 2013; Tufekcioglu and Kucuk, 2004) reported the results unlike ours. Kucuk (2013) for example, reported that soil pH in forests (5.35) was lower than that in grasslands (6.87).

Soil EC in the study area changed between 19.5 and 421 µS/cm which is in the class of non-saline soils meaning salinity effects are mostly negligible according to Hazelton and Murphy (2016). All factors including also interaction significantly affected soil EC ($p < 0.001$) (*Fig.3b; Table 3*). EC significantly decreased in the order of black alder > black locust > grasslands. As the aspect changed from north to south, EC increased from 97.5 to 179.1 µS/cm. According to interaction between two-factors, while the lowest soil EC in north and south aspects was determined in black locust and grasslands respectively as 40.1 and 29.9 µS/cm (*Table 3*). This change may be attributed to the leaching of soil bases and subsequent reduction in soil carbonate (Biro et al., 2013). The correlation between EC and $CaCO_3$ in the study area was significant ($r = 0.71$ and $p < 0.01$) (*Table 2*).

LULC: land-use/land cover, SASP: slope aspect, NFS: north facing slopes, SFS: south facing slopes, OM: organic matter, EC: electrical conductivity, TN: total nitrogen, CN: carbon: nitrogen ratio, Ammon6 Nitrat63 and T63: ammonium, nitrate and total nitrogen mineralization for 63-day. By slope aspect, values of same LULC follow the various lower-case letters indicate significant difference. By LULC, values of same slope aspect follow the various upper-case letters differ significantly

Organic matter classes of soils in the study area ranged from weak (1.69%) in black locust to moderate (2.59%) in grasslands according to 2016). Organic matter content of black alder soils (1.70%) were significantly found lower than that of grassland soils (2.59%)($p = 0.002$) (*Fig. 3c; Table 3*). Similar results were found by some other researchers (Pu et al., 2018; Wei et al., 2011; Yesilonis et al., 2016). The slope aspect alone did not affect soil organic matter ($p = 0.46$). In SFS, soil organic matter content of grasslands (3.13%) was higher than that of black locust (1.51%) and black alder (1.49%) (*Fig. 3c; Table 3*). While soil organic matter content of black alder increased from south (1.49%) to north (2.66%) facing slopes ($p = 0.02$), that of grasslands decreased ($p = 0.037$). The positive effect of north aspect on organic matter content by also found by Qin et al. (2017). Increasing organic matter content in north aspect can be attributed to more organic carbon and more total nitrogen accumulation in the soil because of higher soil water content and less evaporation (Johnson et al., 2011).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1230512321

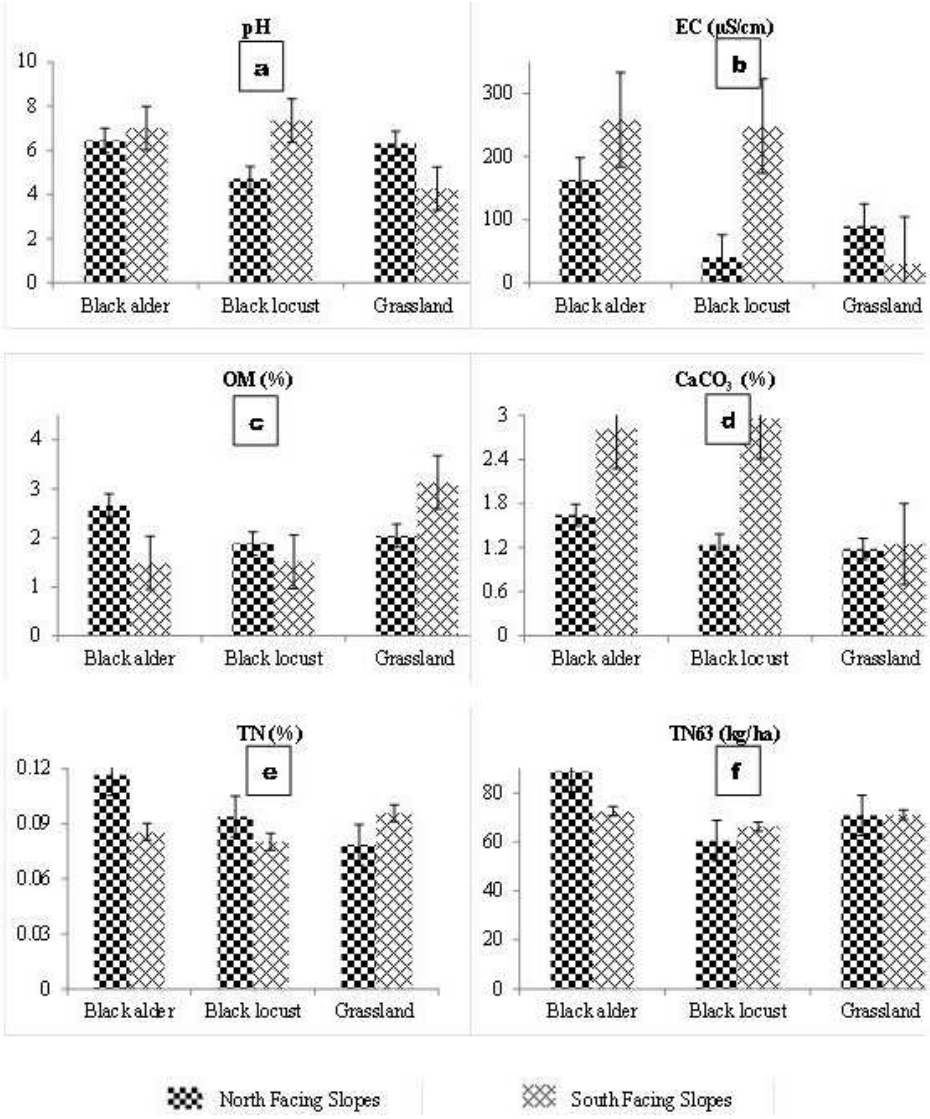

Figure 3. *Chemical soil properties significantly affected by LULC and slope aspect*

On the one hand, $CaCO_3$ content of soils was not significantly affected by vegetation cover ($p = 0.05$) and vegetation cover*slope aspect interaction ($p = 0.164$), on the other hand, the content decreased from south (2.34%) to north (1.35%) without considering vegetation cover effect ($p = 0.008$) (*Fig. 3d; Table 3*).

When not considered the effects of vegetation cover, soil EC in SFS (179.1 µS/cm) was also significantly greater than that in NFS (97.5 µS/cm)($p < 0.001$). Soil EC in grasslands (59.9 µS/cm) was found significantly lower than that in black locust (144.3 µS/cm, $p = 0.01$) and black alder (210.7 µS/cm, $p < 0.001$) without considering slope aspect effect. In SFS, soil EC of grassland (29.9 µS/cm) was found significantly less than that of other vegetation covers ($p < 0.001$). Soil EC of vegetation covers except grasslands increased from NFS to SFS (*Table 3*).

TN of soils was not affected by vegetation covers ($p = 0.05$) and slope aspect ($p = 0.07$) but significantly affected by their interaction. It significantly increased from south (0.085%) to north (0.117%) for only black alder ($p = 0.012$) (*Fig. 3e; Table 3*). That increase may be attributed to improving ecological condition depending on more

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1230512321

moisture in north. Similar results were found by some other researchers (Bangroo et al., 2017; Gol, 2017; Rezaei et al., 2006). Soil TN of north –facing black alder (0.117%) was found significantly greater than that of NF grasslands (0.078%) ($p = 0.001$). This can be attributed to removal of organic matter with grazing and higher level of N-fixation in black alder (Ripley et al., 2010; Wilson et al., 2011). Similar results were reported by some other researchers (Beheshti et al., 2012; Miheretu and Yimer, 2018; Tesfaye et al., 2016; Wilson et al., 2011). Soil C:N ratio was not significantly affected by vegetation cover ($p = 0.05$), slope aspect ($p = 0.46$) and their interaction ($p = 0.87$) (*Table 3*). While Miheretu and Yimer (2018) and Chacon et al. (2009) also found similar results like in the present study. Significant effects of land use on soil C:N ratio also found in some other studies (Assefa et al., 2017; Kucuk, 2013).

Looked at variables regarding 63-day nitrogen mineralization (ammonium, nitrate and total); slope aspect alone had no significant effect on 63-day nitrogen mineralization. Vegetation cover alone had significant effect on 63-day ammonium, nitrate and total nitrogen mineralization. 63-day ammonium mineralization of grassland soils (35.9 kg/ha) was found significantly higher than that of black locust (26.1 kg/ha) and black alder (21.8 kg/ha) ($p < 0.001$). Higher ammonium mineralization in grassland soils can be attributed to lower pH (Xue et al., 2013). The correlation between NH4-N and pH was negative ($p < 0.0$ $r = -0.59$) (*Table 2*). Similar results were found by Wei et al. (2011) in loess plateau of China who reported higher nitrogen mineralization in grassland soils compared to others due to lower bulk density. Nitrate and total nitrogen mineralization in 63-day period of black alder soils (58.8 kg/ha and 80.6 kg/ha) were found significantly higher than that of the other vegetation covers (*Fig. 3f; Table 3*). Higher nitrate mineralization in forest (alder) soils compared to the other land uses can be attributed to that on the one hand, black alder, being one of the N-fixing trees provides resources both easily accessible and abundant for soil microbes and facilitates N mineralization, on the other hand, it contributes to the supply of organic substrates which are easily decomposed and decrease C:N ratio (Cui et al., 2018). The higher nitrate mineralization can also be attributed to positive correlation with pH ($r = 0.4$ $p < 0.01$) (*Table 2*). Similar results were found also by some other researchers (Hart et al., 1997; Tecimen et al., 2013; Uri et al., 2008). Uri et al. (2008), for example, reported higher annual net nitrogen mineralization (99 kg/ha) in the birch stand than that (51 kg/ha) of in grasslands in Estonia. Tecimen et al. (2013) explained the difference with the effect of increasing organic carbon. The 63-day ammonium mineralization of SF grassland soils (40.6 kg/ha) was found significantly higher than that of SF black locust (23.7 kg/ha) and black alder (21.2 kg/ha) soils ($p < 0.001$). Both in NFS and SFS, 63-day nitrate mineralization of black alder soils (66.4 kg/ha and 51.4 kg/ha respectively) was significantly higher than that of grassland soils (39.7 kg/ha and 30.5 kg/ha respectively). 63-day total nitrogen mineralization of NF black locust soils (60.5 kg/ha) was lower than that of black alder soils in the same aspect (88.7 kg/ha).

Changes in heavy metal concentrations

Average Cd and Zn contents of soils in the study area were 0.7 ppm (0 to 6.3 ppm) and 148.5 ppm (72 to 312 ppm), respectively. These values are slightly higher than the average concentrations (0.5 ppm for Cd and 64 ppm for Zn) reported by Kabata-Pendias and Mukherjee (2007). This can be due to the copper mine near the study area. Cd and Zn concentrations among heavy metals did not significantly differed according to vegetation cover, slope aspect and their interaction ($p > 0.05$) (*Table 4*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1230512321

Cr concentration in soil ranged from 5.2 to 29.5 ppm with the average value of 20.2 ppm. This value is consistent with the range of world mean (54 ppm) reported by Kabata-Pendias and Mukherjee (2007). Soil Cr concentration of grasslands (13.8 ppm) was found significantly lower than that of black alder (23.3 ppm) and black locust (24.4 ppm)($p < 0.001$). The soil Cr content of black alder and black locust significantly increased from NFS to SFS unlike grasslands ($p < 0.05$). The soil Cr content of SF grassland (6.7 ppm) was significantly lower than that of black alder (28 ppm) and black locust (26.8 ppm) in the same aspect (*Fig. 4a; Table 4*). Higher Cr contents of forest soil may be related to higher pH ($r = 0.6$ $p < 0.01$) (*Table 2*) (Kabata-Pendias and Mukherjee, 2007).

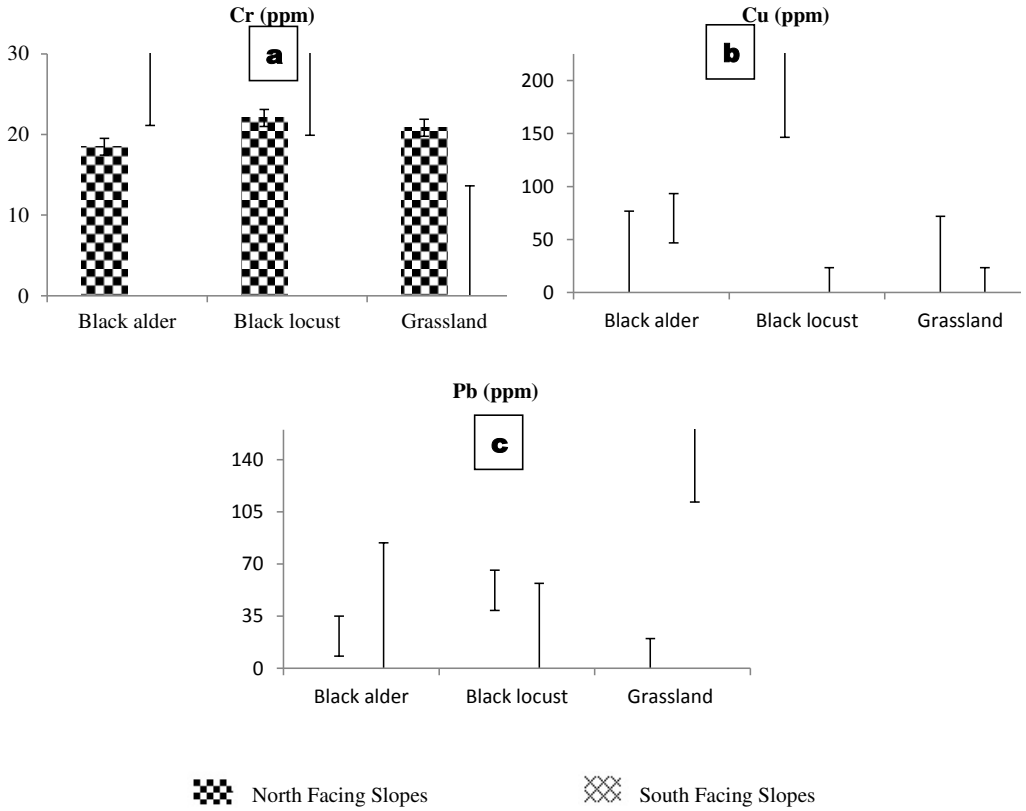

Figure 4. *Heavy metal contents of soils significantly affected by LULC and slope aspect*

Cu content of soils in the study area ranged from 0 to 380 ppm with the average value of 49 ppm. This range is consistent with the range in the world (2 to 250 ppm) reported by Kabata-Pendias and Mukherjee (2007). Soil Cu concentration of black locust (109.1 ppm) was significantly higher than that of grassland (0.001 ppm) ($p = 0.007$). While in north aspects, the lowest and the highest soil Cu concentrations belonged to grasslands (0.001 ppm) and black locust (218.3 ppm), respectively, in south aspects, the lowest and highest soil Cu concentrations belonged to grassland (0.001 ppm) and black alder respectively (70.0 ppm) (*Fig. 4b; Table 4*). Higher Cu contents in forest soils might be related to higher clay contents than that in grassland soils ($r = 0.7$ $p < 0.001$) (*Table 2*). Zheng et al. (2016) also reported positive correlation between Cu and clay contents of soil for coastal soils in China.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1230512321

Pb content of soils in the study area ranged from 0 to 254.2 ppm with the average value of 48 ppm. This value is higher than that in the world (up to 90 ppm) Kabata-Pendias and Mukherjee (2007). Pb concentration was found significantly highest in grassland soils (80.5 ppm) compared to black locust (33.2 ppm) and black alder (31.3 ppm) soils. The Pb concentration significantly increased from north (26.8 ppm) to south (69.9 ppm) ($p = 0.002$). In SFS, grassland soils had significantly higher Pb concentration than others ($p < 0.001$). Grassland soil Pb concentration increased from north (6.5 ppm) to SFS (154.5 ppm) (*Fig. 4c; Table 4*). The lower Pb content in forest soils may be related to higher pH ($r = -0.5$ $p < 0.01$) and higher clay content ($r = 0.7$ $p < 0.001$) (*Table 2*). The lower Pb content in black alder and black locust may be related to phytoremediation (Escobar and Dussan, 2016; Babu et al., 2013; Escobar and Dussan, 2016; Lee et al., 2009). *Alnus acuminata* subsp. acuminata for example, took Pb and Cr up as 135 mg/kg and 71 mg/kg, respectively (Escobar and Dussan, 2016).

Many studies have been performed to determine the effects of copper smelter on heavy metal concentration (Adamo et al., 2002; Dudka et al., 1996; Hutchinson and Whitby, 1977; Kuo et al., 1983). For example, Adamo et al. (2002) found the related heavy metal concentrations of soil near the smelter in Ontario, Canada as 43 3 5 2.7 and 63 ppm for Cu, Pb, Zn, Cd and Cr, respectively. Hutchinson and Whitby (1977) reported heavy metal concentrations in soils for Cu, Pb and Zn near the Sudbury smelting region of Canada as 134 51 and 62 ppm, respectively. Cai et al. (2015) reported the average heavy metal concentrations in soil near Tonglushan copper mine in Hubei, China for Cu, Pb and Cd as 38 120 and 2.59 ppm, respectively. While Cu, Pb, Cd and Cr concentrations in soils determined in the present study was consistent with those in the other studies (Adamo et al., 2002; Dudka et al., 1996; Hutchinson and Whitby, 1977; Kuo et al., 1983), Zn was found higher than the others.

Comparison of main factors' effects with partial eta squared (η2)

The anthropogenic index was computed using *Equation 1*. This index indicates which main factor was more effective on selected soil properties, natural (slope aspect) or anthropogenic (land use/land cover). This index was computed as 0.75 closer to indicates adverse human impact on soil properties.

The partial eta-squared values (η2) were also used to compare the effect size (explained proportion of variance by any factor) of main factors and their interaction on selected soil properties. The related values (η2) were presented in *Tables 4* and *Figure 5*. Regarding soil texture, clay was the most affected texture component by land use, slope aspect and their interaction with η2 values of 0.6 0.59 and 0.1 respectively (*Fig. 5*). pH, EC and OM were the most significantly affected soil chemical properties after Cr by land use, slope aspect and their interaction respectively, were pH with values of 0.6 0.1 0.81; EC with values of 0.5 0.3 0.46 and OM with values of 0.2 0.0 0.31 (*Fig. 5*).

The most significantly affected soil properties by land use and interaction was found Cr with values of 0.93 and 0.94 (*Fig. 5*). The significant interaction effect on soil properties such as pH, OM, TN, Stoniness and heavy metals except Cd was found higher than that of main factors. That means the interaction between main factors strengthen the effect. For example, while effect size of land use and slope aspect on Pb content were 0.29 and 0.27 respectively, the interaction effect was found 0.54 which was about two times higher than that of the other factors (*Table 4*).

LULC: land-use/land cover, SASP: slope aspect. NFS: north facing slopes, SFS: south facing slopes. By slope aspect, values of same LULC follow the various lower-case letters indicate significant difference. By LULC, values of same slope aspect follow the various upper-case letters differ significantly

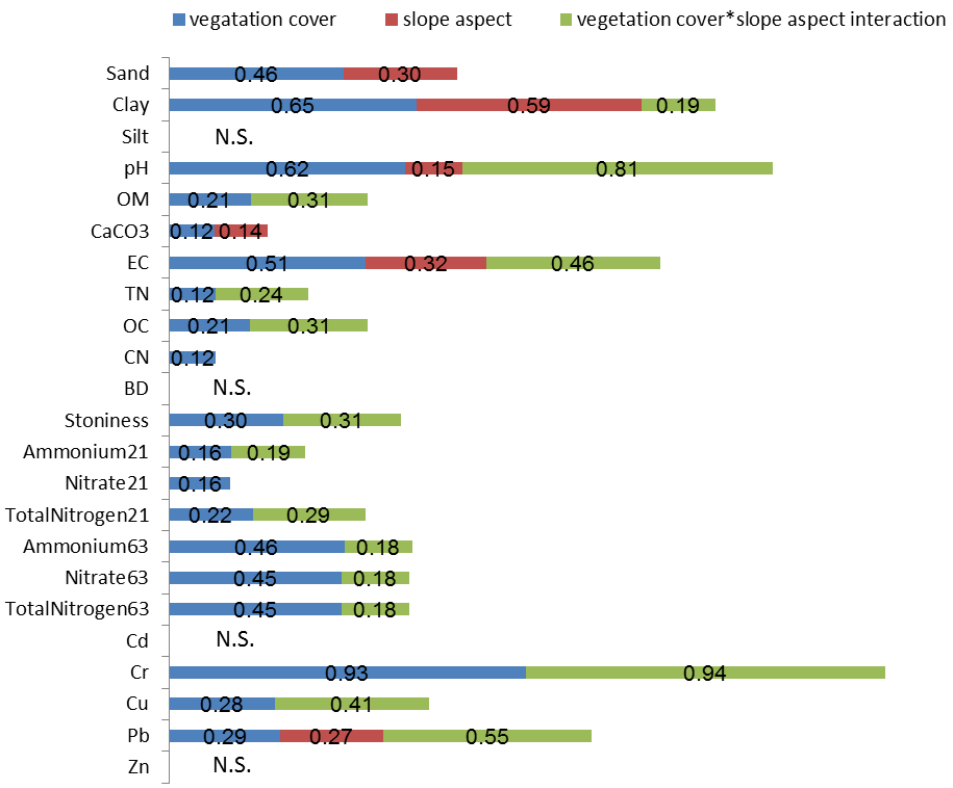

Figure 5. *Effect size (η2) of independent variables on selected soil properties*

Conclusion

The results from the present study showed significant interaction effect beside LULC and slope aspect on selected soil properties. In general, main factors and their interaction improved selected soil properties affecting soil quality. The most affected

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1230512321

soil properties by LULC and slope aspect were Cr content and clay content, respectively. The improving effects of afforestation compared to grasslands was revealed on only clay contents and soil skeleton among physical properties; pH, nitrate and total nitrogen mineralization for 63-day among chemical properties. Our study showed that changes in LULC from grasslands to forest (especially to black alder) promoted soil quality in terms of total nitrogen and NO_3-N, playing a fundamental role in ecological restoration, beside other soil properties. Although decreasing effect (phytoremediation) of black alder and black locust on heavy metals except Pb in soil was not found In the present study, *Alnus glutinosa* and *Robinia pseudoacacia* may be suggested for the restoration/reclamation of mining soils in terms of phytoremediation beside their advantages such as improving nitrogen mineralization. However, further periodical studies are needed to determine the improving effects of afforestation on soil properties after mining. Results from the present study may be generalized to larger areas which are similar to the study area in terms of land-use and vegetation cover

Abstract. Δ[1]-pyrroline-5-carboxylate synthase (P5CS) is a key enzyme in proline biosynthesis. In this study, the nucleotide sequence of sugarcane *P5CS* (*SoP5CS*) gene was obtained from sugarcane. Then the ORF of *SoP5CS* linked with pET-30a vector and the SoP5CS protein was expressed successfully in *E. coli* by the induction of 1.0 mM IPTG at 28 °C for 6 h. The prokaryotic expression protein was expressed as inclusion bodies (IBs). It was purified by Ni- NTA Resin firstly and then refolded, dialyzed and further purified by gel filtration. The monoclonal antibody of SoP5CS was prepared using mice. The expression of *SoP5CS* gene and the corresponding protein and physiological parameters associated with drought resistance were detected in sugarcane leaves under different drought stresses, they worked together to regulate the drought resistance process of sugarcane. This is the first report on the preparation of P5CS monoclonal antibody and the expression of the antibody in sugarcane, which would provide new methods to study the function of SoP5CS response to various abiotic stresses and other aspects.
Keywords: *sugarcane, P5CS gene; proline, monoclonal antibody, physiological index*

Introduction

Proline plays an important role in plant osmotic adjustment processes, and it is a penetration protective agent, protein stabilizer and free-radical scavenger (Kishor et al., 2005). Studies have shown that the accumulation of proline showed a positive correlation with stress adaptation of drought and salt in plants (Kishor et al., 1995). In normal conditions, proline is synthesized mainly by ornithine pathway, whereas it is made directly through the glutamate pathway under stress conditions (Delauney et al., 1993). P5CS is a bifunctional enzyme and catalyzes the first two steps of glutamate pathway (Kishor et al., 1995).

In plants, the activity of P5CS was assayed in duckweed under gradually increasing cadmium stress (Qiao et al., 2015), and in *Arabidopsis thaliana* under salt tolerance (Saibi et al., 2015). More researches concentrated on the *P5CS* gene, which has been

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1232312335

isolated from many plants, such as cowpea (Hu et al., 1992), alfalfa (Ginzberg et al., 1998, barley (Romman et al., 2011), sorghum (Su et al., 2011), Chinese wolfberry (Guan et al., 2014); Nitraria tangutorum (Zheng et al., 2014), mulberry (Zhou et al., 2016), and others. The expression of *P5CS* gene was analyzed by RT-PCR under salt stress (Ortega et al., 2008), Northern blotting under drought (Porcel et al., 2004), salt (Do et al., 2003) stress and qRT-PCR (Jain et al., 2015) under drought stress. And previous research showed that drought stress could induce the changes in gene and protein expression and physiological parameters associated with drought resistance (Kuzuoglu-Ozturk et al., 2012; Dey et al., 2016; Wang et al., 2016; Cao et al., 2017).

Monoclonal antibody is widely employed in the detection and identification of protein in plants by Western blotting and enzyme-linked immunosorbent assay (ELISA). The former is widely used in studying the expression of a protein in different plant tissues (Pereira et al., 2005), under various stresses (Pruvot et al., 1996; Ozturk et al., 2012). Most reports have been focusing on transgenic plants accumulation of a foreign protein resistant to virus (Yu et al., 2011), disease (Maruthasalam et al., 2007), pest (McManus et al., 1999), abiotic stress (Subramanyam et al., 2012) and so on.

To our knowledge, there have not been any reports about P5CS monoclonal antibody in plants. Sugarcane (*Saccharum* L. spp. hybrids) is the most important sugar crop and one of the main agricultural commodities in the world. Guangxi is the largest sugarcane producing areas in China, however, about 80% of the sugarcane is planted in upland areas with shallow tillage layer and no irrigation system, so drought is a main constraint factor for sugarcane production (Li and Yang, 2015). The purpose of this study was to prepare monoclonal antibody of sugarcane P5CS gene to provide a reference for further study on the mechnism of sugarcane resistance to drought stress.

Materials and methods

Sugarcane material and treatments

The sugarcane variety GT 21 was used as plant material, and the single bud cane setts were planted in sand. After the seedlings grew to 3-4 leaves, they were transplanted to plastic pots containing sand and soil with the ratio of 1:2 for culturing. When the seedlings grew to 7-8 leaves, the consistent plants were selected for drought treatment, that is, the plants were subjected to withholding water and the control plants were well-watered. The leaf samples were collected from leaf + 1 (top visible dewlap leaf) at 0, 1, 3, 5 and 7 d, respectively, after drought treatment. There were three replications for each treatment and all the samples were wrapped in aluminum foil, placed in liquid nitrogen and stored at -80 °C.

Experiment reagents

The Trizol reagent and anti β-Actin mouse monoclonal antibody were bought from Beijing ComWin Biotech Co., Ltd. (Beijing, China); *Eco*R I and *Xho* I restriction enzymes and RevertAid First Strand cDNA Synthesis Kit were bought from Thermo Fisher Scientific (Shanghai, China); PMD18-T vector and DNA Ligation Kit were got from TaKaRa Company (Dalian, China). Escherichia coli DH5α and BL21 (DE3) were bought from TransGen Biotech (Beijing, China). Protein A Sefinose™ Kit, Ni-NTA-Sefinose Column, Sefinose™ CL-6B and Non-Interference Protein Assay Kit were products of Sangon Biotech Company (Shanghai, China). pET-30a was kept by the

DOI: http://dx.doi.org/10.15666/aeer/1705_1232312335

laboratory. All other chemicals were obtained from commercial sources and analytical grade.

Isolation of SoP5CS

Total RNA of sugarcane leaves was extracted and tested the concentration and integrity by Implen P 300 NanoPhotometer and 1% agarose gel electrophoresis. The cDNA for gene cloning was synthesized using RevertAid First Strand cDNA Synthesis Kit. Based on the sugarcane *P5CS* gene sequences in GenBank (Accession No. Eu005373), the primers of upstream and downstream for both sides of its largest open reading frame (2148 bp) designed with Primer Premier 5.0 software are 5'-TCAGAATTCATGGCCACCGTGGACCGGACC-3', and 5'-TGTCTCGAGTTG-CAAAGGAAGGTTCTTATG-3', respectively, that *Eco*R I and *Xho* I restrict enzyme sites are underlined. The PCR products were purified and cloned into PMD18-T vector and sequenced on both strands in Beijing Genomics Institute (Shenzhen, China).

Prokaryotic expression, extraction and purification of SoP5CS protein

The pET-30a was used as the prokaryotic expression vector. The plasmids of recombinant strain PMD-SoP5CS and pET-30a were extracted and double digested with *Eco*R I and *Xho* I. Then *SoP5CS* and the vector fragments were ligated and transformed into the *E. coli* BL 21 (DE 3) cells. The recombinant plasmid was detected by PCR and sequenced (The Beijing Genomics Institute, Shenzhen), and verified by double enzymes digestion. The recombinant strain was incubated in liquid LB medium (contained 100 mg/L kanamycin) until the value of OD_{600} reached 0.4–0.6, and the target protein was induced with 1.0 mM IPTG for an additional 6 h. The cell pellets were collected by centrifugation and resuspended in lysis buffer (500 mM NaCl, 50 mM NaH_2PO_4, and 10 mM imidazole, pH 8.0), then lysed by sonication (pulse 5 s, pause 5 s, 20 min) using an ultrasonic processor VCX 750 (Sonics & Materials, Inc.). Then the cell lysate was centrifuged to precipitate the cellular debris and the supernatant was transferred to fresh microcentrifuge tubes for further purification using a Ni-NTA-Sefinose Column. Then the wash fractions were collected and analyzed by SDS-PAGE.

Refolding, dialysis and concentration of SoP5CS protein

The over expressed SoP5CS proteins were refolded under the buffer (PBS, 2 mM DTT, 0.05% SKL, pH 7.4) and centrifuged, then the supernatant was collected and dialyzed for overnight at 4 °C with dialysis tubing cellulose membrane (MW 10,000 Da, Sigma). The proteins were further dialyzed twice with fresh dialysis buffer each time for 3 h. The dialyzed proteins were analyzed by SDS–PAGE to confirm it remained intact and then purified by gel filtration using Sefinose™ CL-6B. Then the protein was concentrated by PEG 20000 and determined using the Non-Interference Protein Assay Kit.

Preparation of monoclonal antibody

Female BALB/c mice were immunized subcutaneously using conventional methods. The immunization was given 3 times with 2 week intervals after the first immunization. And the mice would have an ictus immunisatorius before the cell fusion. The antiserum was collected in 10 days after the last immunization and the SoP5CS antibody titer was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1232312335

determined by indirect ELISA. The mouse whose antiserum exhibited the highest value of the antibody titer was selected for the subsequent fusion. Splenocytes of selected mice were fused with Sp2/0 cells, then the fused cells were suspended and placed into a total of 96 wells cell culture plates under 5% CO_2, 37 °C. Two weeks later, positive hybridomas were selected and subcloned. Supernatants from the positive wells were detected by indirect ELISA and the clones showed high titer and good condition were selected to generate ascites. Antiserum of selected mouse was reacted with different amounts of the purified SoP5CS protein to analyze the quality. For Western blotting, the dilution rate of SoP5CS antibody and goat anti-mouse antibody (Beijing ComWin Biotech Co., Ltd.) was 1:2000. The membrane was placed in FluorChem and HD2 (ProteinSimple) was exposed for 1-10 min for images captured by using electrochemiluminescence (ECL) substrate (PIERCE). Then the monoclonal antibodies were purified by using the protein A column and stored at -80 °C.

Application of monoclonal antibody

After drought treatment, the leaves were sampled to detect the expression of *SoP5CS* gene and its encoded protein. Besides, the physiological parameters, including proline, maleic dialdehyde (MDA) and abscisic acid (ABA) contents, superoxide dismutase (SOD), catalase (CAT) and P5CS activities, relative water content (RWC) and Chlorophyll content (SPAD value) were also measured. Total proteins in sugarcane leaves were extracted with the method of Parrott et al. (2005) and qRT-PCR was used the method described by Niu et al. (2015). RWC of the leaves were calculated with the method of Kautz et al. (2015). SPAD value was measured as the method of Phan et al. (2016). Other physiological parameters (contents of proline, MDA and ABA, and activities of SOD, CAT and P5CS) were measured using ELISA Kit (ColorfulGene Biological Technology Co., Ltd., Wuhan, China).

Statistical analysis

The data were analyzed using the IBM SPSS Statistics 20 software and Excel 2013 (Microsoft). There were three replicates for each experiment, and statistical differences were compared based on the Duncan's test with P values set at 0.05 and 0.01 levels.

Statement on ethical approval

All experimental procedures were conducted in conformity with institutional guidelines for the care and use of laboratory animals in The Animal Experimental Center of Shanghai General Hospital, Shanghai, China, and conformed to the National Institutes of Health Guide for Care and Use of Laboratory Animals.

Results

Construction of prokaryotic expression vector

Bands of about 2150 bp were obtained by RT-PCR (*Fig. 1A*) and they were recovered together and inserted into pMD-18T to get the recombinant plasmid pMD-SoP5CS which showed a fragment of 2148 bp by sequencing. ORF of *SoP5CS* was ligated with pET-30a and the recombinant plasmid pET-SoP5CS was expressed in *E. coli* BL 21 (DE 3) and confirmed by double digested with *Eco*R I and *Xho* I. The result

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1232312335

showed that the prokaryotic expression vector with *SoP5CS* gene pET-SoP5CS had been built successfully (*Fig. 1B*).

Expression, purification, AND concentration of SoP5CS protein

The molecular weight of the fusion SoP5CS protein is ~84 kDa according to the sequences of pET-30a and ORF of *SoP5CS*. SDS-PAGE analysis revealed that the target protein was expressed only in the insoluble inclusion bodies (IBs) (*Fig. 2A*). Then the SoP5CS protein was purified using Ni–NTA Resin (*Fig. 2B*), the final product was refolded and dialyzed. After gel filtration, the pure SoP5CS protein was obtained (*Fig. 2C*). Then the protein was concentrated using PEG 20000 and a expected single band of ~84 kDa protein was observed (*Fig. 2D*). About 15 mg of SoP5CS at the concentration of 1.37 mg/ml was obtained by the protein quantitative kit, and the purity was more than 90%, which meet the requirement of preparing the monoclonal antibody.

Titer and specificity analysis of SoP5CS antibody

After fusion of immunized BALB/c mouse splenocytes and Sp2/0 mouse myeloma cells, cell supernatant was measured by indirect ELISA (OD_{450}). The cell lines with the highest positive value were selected and subcloned. Nine hybridoma cell lines that stably secreted SoP5CS McAb were obtained and they were 1E1, 3D10, 3H10, 5F8, 5E12, 4D6, 4F10, 5C10 and 2F11. The titer of 9 hybridoma cell lines was determined by indirect ELISA method (*Table 1*). Based on the growth state, the cell line of 4F10 was finally selected to collect the supernatant which was purified by Protein A Sefinose™ Kit. The pure supernatant was reacted with different amounts of SoP5CS protein by Western blotting. The expected 84 kDa in different brightness bands were detected with different amount of antigen (*Fig. 3*).

According to the growth state, the cells of 4F10 and 4F10E8 were selected to inject the mice, and the ascites was purified by Protein A Sefinose™ Kit. The concentration of monoclonal antibody was 2.15 mg/ml measured with UV spectrophotometer. The titer

of the purified antibody was more than 64 k analyzed by indirect ELISA method (*Table 2*), which met the requirement of Western blotting detection. Thus, the preparation of SoP5CS monoclonal antibody was successful and it is ready for further research.

Expression of SoP5CS gene and its encoded protein in sugarcane under drought stress

Under drought stress, the expression level of *SoP5CS* increased rapidly, reached the peak at 5 d, which was 11.22-fold higher than that at 0 d, and also maintained at high levels (~5-fold) at 3 and 7 d (*Fig. 4A*). Endogenous SoP5CS proteins from sugarcane leaves under drought stress were detected by Western blotting and β-actin was used as the reference gene. A total of 25 μg protein was loaded in each lane and the results (*Fig. 4B, C*) indicated that the relative expression levels of SoP5CS under drought stress were all higher than that in normal condition (0 d). But the expression level of SoP5CS protein increased slightly that were all below 2-fold while compared to 0 d, and the highest expression was at 7 d (1.99-fold).

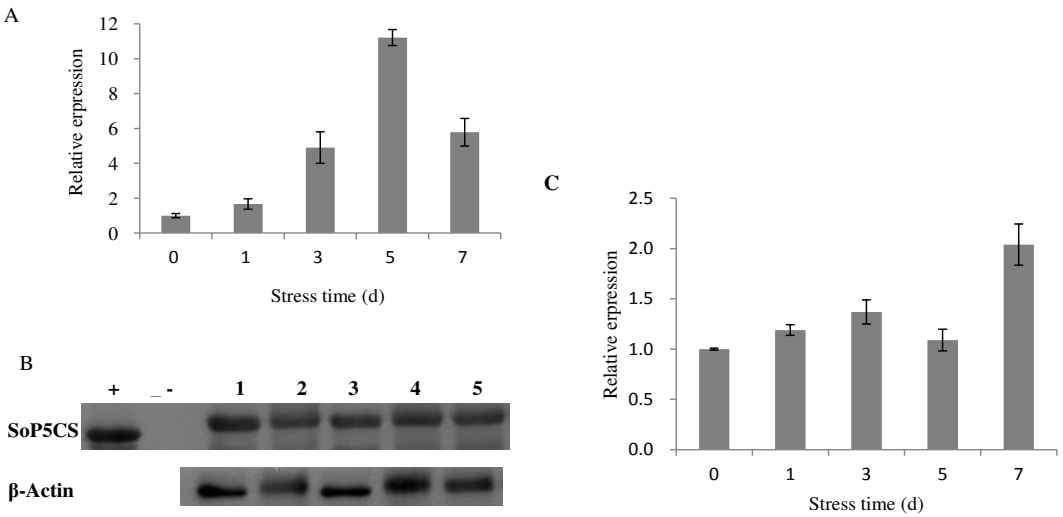

Figure 4. *Relative expression of SoP5CS gene (A) and its encoded protein (B, C) in sugarcane leaves under drought stress. Physiological changes in sugarcane leaves under drought stress

Under drought stress, contents of proline and MDA increased rapidly and reached the peak at 7 d, and those at 1, 3 and 5 d were also significantly higher than those of 0 day (*Fig. 5A, C*). ABA content increased slightly and also reached the peak at 7 d (*Fig. 5B*).

As shown in *Figure 6A,* there was no significant difference in SOD activity between normal condition (0 d) and 1 d, while it was significantly higher at 3, 5 and 7 d. Drought stress treatments showed significantly higher CAT activity than that at 0 d (*Fig. 6B*). P5CS activity showed the trend of increase firstly and then decrease, which reached the peak at 3 d (*Fig. 6C*). Chlorophyll content and RWC decreased slightly firstly and then reduced markedly as the drought stresses were intensified (*Fig. 7*).

Discussion

There have been no literature reports on overexpression and purification of plant P5CS in *E. coli* yet, however, the prokaryotic expression vector of pET-30a has been used in different proteins from other plants (Wan et al., 2010; Zhu et al., 2012; Wang et al., 2015). In this research, the recombinant protein was expressed in *E. coli* as an inclusion body, but it takes long and intricate steps to form soluble proteins and it is difficult for purification (Nahálka et al., 2009). The formation of bacterial IBs is common due to an imbalance between protein deposition and removal (Carrio et al., 1999; Carrio and Villaverde, 2001). The concentration of IPTG, growth temperature and time may influence the expression pattern of recombinant protein (Sorensen and Mortensen, 2005; Montalbán et al., 2006). But in many cases, screening and optimization of these conditions still could not eliminate the formation of IBs (Sahdev et al., 2008; Xue et al., 2011). Although we made efforts to optimize the expression conditions, the recombinant protein still accumulated as IBs. The IBs of SoP5CS were firstly purified by Ni-NTA Resin and about 15 mg purified SoP5CS was obtained from 1 liter of culture broth after refolding, dialysis, gel filtration and concentration. The yield of SoP5CS was not very high compared with other proteins purified from inclusion body (Ruan et al., 2016), but it was enough for further use.

Under drought stress, drought resistance genes could be induced. And previous research showed that the expression of *P5CS* gene was up-regulated under drought stress (Jain et al., 2015; Zhou et al., 2016; Wei et al., 2016), which was consistent with the results of our study. The expression of SoP5CS protein in different drought stresses was also up-regulated but showed lower expression quantity compared to the corresponding gene. In this study, distinct changes in physiological parameters associated with drought resistance were also detected. The increased activities of both SOD and CAT could protect sugarcane cells against reactive oxygen species (ROS). The free proline acts as a multifunctional osmolyte in plants and plays important roles in enhancing osmotic stress tolerance (Krasensky and Jonak, 2012). Higher activity of P5CS could help synthesize more proline that act as an osmoprotectant thus help tolerate drought stress. Endogenous ABA was also increased with the up-regulated of *SoP5CS*, thus *SoP5CS* may be involved in an ABA-dependent stress signaling pathway. Previous studies showed that accumulation of ABA was important for the regulation of *P5CS* expression and proline accumulation level in *Lycium chinense* (Guan et al., 2014). The up-regulated expression of *SoP5CS* gene and the corresponding protein and physiological changes in sugarcane leaves might work together to regulate the drought resistance process of sugarcane.

Conclusion

In this study, SoP5CS monoclonal antibody was prepared and the expression of SoP5CS protein and the corresponding gene and physiological parameters associated with drought resistance were detected in sugarcane leaves under drought stress. The SoP5CS monoclonal antibody obtained in the present study will be useful for further research on plant stress response, defense signaling pathways, and other aspects in plants. In future research, the function of SoP5CS could be identified by over-expression of SoP5CS protein not only in sugarcane but also in other plants. The preparation of SoP5CS monoclonal antibody could provide a new approach in research of the P5CS protein in plants.

(Received 6th May 2019; accepted 16th Jul 2019)

Abstract. This study determined the effect of carrot meal supplementation on productivity and carcass characteristics of Arbor acre broiler chickens aged 22 to 42 days in Limpopo province, South Africa. A total of 200 female Arbor acre broiler chickens were randomly allocated to five treatments with five replicates, each having 8 birds, in a completely randomized design. The supplementation levels were 0 (FA0), 20 (FA20), 50 (FA50), 75 (FA75) or 100 (FA100) g of carrot meal per kg DM feed. The results showed that dietary carrot meal supplementation had no ($P > 0.05$) effect on growth rate, live weight and carcass characteristics of female Arbor acre broiler chickens aged 22 to 42 days. Carrot meal supplementation improved feed intake, feed conversion ratio, metabolisable energy intake and nitrogen retention of Arbor acre broiler chickens aged 22 to 42 days. Dietary feed intake, feed conversion ratio, live weight, metabolisable energy intake and nitrogen retention were optimized at different dietary carrot meal supplementation levels of 52.8, 63.8, 38.0, 42.0 and 44.3 g/kg DM feed, respectively. It is concluded that carrot meal supplementation improved intake, feed conversion ratio, metabolisable energy and nitrogen retention of female Arbor acre broiler chickens aged 22 to 42 days.
Keywords: *metabolisable energy, meat sensory attributes, vitamin C, diets, performance*

Introduction

Poultry production is nutritionally, economically and socially important in Limpopo province and the world as a whole. Chicken production is an important source of income and employment, and it contributes substantially to food security among rural people in Africa (Ng'ambi et al., 2012). Much of the poultry meat comes from broiler chickens. Not only are broiler chickens heavier at an early age but they also have better feed conversion ratio (Havenstein, 2004). High mortality in broiler chickens leads to poor productivity and low income for rural people. Carcasses from broiler chickens have high fat content and, thus, reduced carcass quality and feed efficiency. High fat content meat is also not liked by consumers (Steenfeldt et al., 2007). Excessive fat is one of the main problems faced by the broiler chicken industry, since it does not just reduce carcass quality and feed efficiency but also causes consumer rejection and difficulties in meat processing (Macajova et al., 2003).

There is some evidence that carrot meal supplementation reduces chick mortality and improves carcass characteristics (Steenfeldt et al., 2007). Carrot (*Daucus carota)* is a commonly consumed vegetable species belonging to the family Apiacea, which grows in temperate regions of Europe, Asia and Africa (Hammam, 2014). It contains a lot of active ingredients such as steroids, tannins, flavonoids, and carotene (Jasicka-Misiak et al., 2005; Vasudevan et al., 2006). Aromatic plants such as carrots can increase feed intake, feed conversion ratio, weight gain and can improve the oxidative stability of tissues (Ürüşan and Bölükbaşı, 2017). Carrot meal has been tested for its potential as food in livestock industry

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1233712346

(Rust and Buskirk, 2008; Steenfeldt et al., 2007); however, its prospect in Arbor acre broiler-based diets has not yet been fully exploited. Information generated in this study will help in formulating strategies aimed at improving productivity and carcass characteristics of Arbor acre broiler chickens. Improvement of productivity of broiler chickens may enhance the economic, nutritional and social status of broiler chicken farmers. Therefore, the aim of this study was to determine the effects of supplementing diets with carrot meal on feed intake, digestibility, live weight, growth, feed conversion ratio, mortality and carcass characteristics of Arbor acre broiler chickens.

Materials and methods

Study site and experimental design

This study was conducted as part of the Pahlomoje Poultry Project, Shikwane village in Maruleng Municipality, South Africa. The project site is 64 km north-west of Tzaneen. The chickens were raised on commercial starter mash up to 21 days old before the experiment commenced. Prior to the start of the experiment the chickens were fed a 22% crude protein (CP) diet that would satisfy their nutritional requirements according to NRC (1994). A total of 200 female Arbor acre broiler chickens (Females were used because there were not enough males), weighing 650 ± 4 g per chicken were randomly assigned to five treatments with five replicates, each replicate having 8 Arbor acre female chickens in a completely randomized design. Thus, chickens were raised on 25 floor pens in an environmentally controlled house and temperature maintained at 30 to 33 °C and 23 to 25 °C during the starter and grower phase, respectively. Lighting was provided continuously (*Fig. 1*). The chicks were vaccinated against Newcastle virus disease and infectious bronchitis. A grower diet was offered from day 22-42 days with different carrot supplementation levels (*Table 1*). The nutrient composition of the treatments is presented in *Table 2*. The diets contained similar nutrients but different carrot meal levels ranging from zero to 100 g per kg DM. The carrot meal contained 12% crude protein, 17.1 MJ of gross energy/kg DM, 18% ash, 13.3% neutral detergent fibre (NDF), 8.8% acid detergent fibre (ADF) and 300-700 mg/kg dry matter (DM) of vitamin C. The grower diet was formulated and produced by a commercial feed company, Meadow Feeds, South Africa. Feed and water were offered ad libitum throughout the experiment.

UA_{20}	930	16.9	200	20
UA_{50}	930	16.9	200	50
UA_{75}	930	16.9	200	75
UA_{100}	930	16.9	200	100

Data collection

The initial live weights of the chickens were taken at the beginning of the experiment and weekly weights were taken thereafter using the electronic weighing scale (RADWAG AS 220/C/2). Weekly feed intakes were determined. Daily mean growth rates and feed conversion ratios were calculated. Digestibility was done when the chickens were between 35 and 42 days. Digestibility was conducted in specially designed metabolic cages with separate watering and feeding troughs. Four birds were randomly selected from each replicate and transferred to metabolic cages to measure apparent digestibility. A three-day acclimatization period was allowed prior to a three-day collection period. Droppings voided by each bird were collected daily at 09h00. Care was taken to avoid contamination from feathers, scales, debris and feeds. Dry matter and nitrogen contents of the diets, refusals and faeces were determined. At 42 d of age, 3 chickens per pen were slaughtered according to the rules and regulations of University of Limpopo Animal Research Ethics Committee. After slaughtering, carcass weight of each chicken was measured. Dressing percentage was determined by dividing carcass weight by live weight and then multiplying by 100. Breast, fat pad, thigh, wing, drumstick, gizzard and liver weights were measured using an electronic scale. Breast

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1233712346

meat samples were further analysed for meat sensory attributes. Breast meat was prepared and the skin was left on the meat samples. Nothing was added to the meat samples to add taste. An oven set at 105 °C was allowed to preheat prior to cooking. The meat samples were put in trays and they were covered with aluminium foil to prevent water loss. Thereafter, the trays with meat were put in an oven for approximately 60 min and the meat samples were turned after every 10 min. Samples were cut into small 5 cm cubic pieces and served immediately after cooking to a total of 30 panel composed of students and staff members of the University of Limpopo that were from the Sepedi, Setswana, Tshivenda and Tsitsonga tribes. The panel was shown how to infer and record scores for each parameter. The waiting period between meats samples tastings was 10 min. Distilled water with lemon was given to panel to clean their palate between sub-sample measurements to avoid crossover effects. Breast meat was evaluated for tenderness, juiciness and flavour using a 5-point ranking scale (AMSA, 1995) (*Table 3*).

Table 3. *Evaluation scores used by the sensory panel*

Score	Sensory attributes		
	Tenderness	**Juiciness**	**Flavour**
1	Too tough	Much too dry	Very bad flavor
2	Tough	Dry	Poor flavor
3	Neither tough nor tender	Neither dry nor juicy	Neither bad nor good flavor
4	Tender	Juicy	Good flavor
5	Too tender	Too juicy	Very good flavor

Chemical analysis

Dry matter and nitrogen contents of the diets, refusals, faeces and meat samples were determined as described by AOAC (2008). Neutral and acid detergent fibre contents were analysed by AOAC (2008) methods. The energy of the diets, excreta samples and meat were determined using an adiabatic bomb calorimeter IKA® C5003 Control.

Statistical analysis

Data on feed intake, feed conversion ratio, growth rate, live weight and carcass characteristics of Arbor acre broiler chickens were analyzed using the general linear model procedures of the statistical analysis of variance (SAS, 2008). Where there was a significant difference, the Duncan test for multiple comparisons was used to test the significance of differences between treatment means (SAS, 2008). The dose - responses in feed intake, live weight, growth rate, feed conversion ratio, metabolisable energy, nitrogen retention and carcass characteristics of the chickens were models using the following quadratic equation:

$$Y = a + b_1x + b_2x^2 \quad \text{(Eq.1)}$$

where y = feed intake, digestibility, live weight, growth rate, feed conversion ratio, metabolisable energy, nitrogen retention and carcass characteristics; a = intercept; b_1 and b_2 = coefficients of the quadratic equation; x = dietary carrot meal supplementation level and $-b_1/2b_2 = x$ value for optimum response. The quadratic model was fitted to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1233712346

experimental data by means of the NLIN procedure of SAS (SAS, 2008). The quadratic model was used because it gave the best fit.

The relationships between carrot meal supplementation and optimal responses in meat tenderness, flavour and juiciness were models using a linear regression equation (SAS, 2008) of the form:

$$Y = a + bx \quad \text{(Eq.2)}$$

where Y = optimal tenderness, juiciness and flavour; a = intercept; b = coefficient of the linear equation and x = dietary carrot meal supplementation level.

Results

Results of the effect of carrot meal supplementation on feed intake, growth rate, feed conversion ratio, live weight, metabolisable energy intake and nitrogen retention of female Arbor acre broiler chickens aged 22 to 42 days are presented in *Table 4*. Carrot meal supplementation had no effect ($P > 0.05$) on growth rate of female Arbor acre broiler chickens aged 22 to 42 days. Broiler chickens on a diet supplemented with 50 g of carrot meal per kg DM had higher ($P < 0.05$) feed intakes than those on a diet not supplemented with carrot meal, and those on diets supplemented with 20 or 100 g of carrot meal per kg DM feed. Feed intakes of female Arbor acre broiler chickens aged 22 to 42 days were optimized at dietary carrot meal levels of 52.8 ($r^2 = 0.888$) (*Table 5*).

Carrot meal supplementation improved dietary intake of female Arbor acre broiler chickens aged 22 to 42 days. However, these improvements did not have any impact on growth rates of the chickens. Similarly, improvements in dietary intake, feed conversion ratio, metabolisable energy intake and nitrogen retention did not result in any improvement of live weights of the chickens. Female broiler chickens on a diet supplemented with 50 g of carrot meal per kg DM had higher ($P < 0.05$) live weights than those on diets supplemented with 20 or 100 g of carrot meal per kg DM feed. Broiler chickens on a diet supplemented with 20 g of carrot meal per kg DM feed had higher ($P < 0.05$) live weights than those on a diet supplemented with 100 g of carrot meal per kg DM. Live weights of female Arbor acre broiler chickens aged 22 to 42 days were optimized at dietary carrot meal levels of 63.8 ($r^2 = 0.780$) (*Table 5*). Supplementation with 50 g of carrot meal per kg DM feed improved ($P < 0.05$) feed conversion ratio. Feed conversion ratios of female Arbor acre broiler chickens aged 22 to 42 days were optimized at dietary carrot meal levels of 38.0 ($r^2 = 0.673$) (*Table 5*).

In the present study, dietary intake and feed conversion ratio and live weight of female Arbor acre broiler chickens aged 22 to 42 days were optimized at different dietary carrot meal supplementation levels of 52.8 and 63.8 g/kg DM feed, respectively. Female broiler chickens on a diet supplemented with 20 g of carrot meal per kg DM had higher ($P < 0.05$) metabolisable energy intakes than those on a diet not supplemented with carrot meal and those on diets supplemented with 50, 75 or 100 g of carrot meal per kg DM. Broiler chickens on diets supplemented with 50 or 75 g of carrot meal per kg DM had higher ($P < 0.05$) metabolisable energy intakes than those on a diet not supplemented with carrot meal. Metabolisable energy intakes of female Arbor acre broiler chickens aged 22 to 42 days were optimized at dietary carrot meal levels of 42.0 ($r^2 = 0.385$) g/kg DM (*Table 5*). Female broiler chickens on diets supplemented with 20 or 50 g of carrot meal per kg DM had higher ($P < 0.05$) nitrogen retention values than

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1233712346

those on a diet not supplemented with carrot meal and those on diets supplemented with 75 or 100 g of carrot meal per kg DM. Nitrogen retention of female Arbor acre broiler chickens aged 22 to 42 days were optimized at dietary carrot meal levels of 44.3 ($r^2 = 0.603$) g/kg DM (*Table 5*). Carrot meal supplementation improved dietary metabolisable energy intakes of female Arbor acre broiler chickens aged 22 to 42 days. In the present study, metabolisable energy intake and nitrogen retention of female Arbor acre broiler chickens were optimized at different carrot meal supplementation levels of 42.0 and 44.3 g/kg DM feed, respectively. This means carrot meal levels for optimal metabolisable intake and nitrogen retention intake will depend on the variable of interest.

Table 4. *Effect of carrot meal supplementation on feed intake (g DM/bird/day), growth rate (g/bird/day), feed conversion ratio (FCR) (g DM feed/g live weight gain), live weight (g/bird aged 42 days), metabolisable energy (MJ/kg DM) and nitrogen retention (g/bird/day) of female Arbor acre broiler chickens aged 22 to 42 days*

r^2: regression coefficient. Carrot meal: carrot meal supplementation level for optimal variable

Results of the effect of carrot meal supplementation on carcass characteristics of female Arbor acre broiler chickens aged 42 days are presented in *Table 6*. Carrot meal supplementation had no effect ($P > 0.05$) on carcass, breast, drumstick, thigh, liver, gizzard and fat pad weights of female Arbor acre broiler chickens aged 42 days. Results of the effect of carrot meal supplementation on tenderness, juiciness and flavour of meat of female Arbor acre broiler chickens aged 42 days are presented in *Table 7*. Carrot

DOI: http://dx.doi.org/10.15666/aeer/1705_1233712346

meal supplementation did not improve ($P > 0.05$) meat tenderness and flavour of female Arbor acre broiler chickens aged 42 days. Female broiler chickens supplemented with 20, 50 or 100 g of carrot meal per kg DM feed produced meat with higher ($P < 0.05$) juiciness than those of meat from a diet not supplemented with carrot meal and those on a diet supplemented with 75 g of carrot meal per kg DM. A positive relationship was observed between carrot meal supplementation to the diets of female Arbor acre broiler chickens and meat juiciness ($r^2 = 0.085$). Carrot meal supplementation did not affect tenderness and flavour of female Arbor acre broiler chicken meat. However, carrot meal supplementation improved the juiciness of female Arbor acre broiler chicken meat. Thus, there was a weak but positive relationship between carrot meal supplementation and juiciness of female Arbor acre broiler chicken meat.

Table 6. *Effect of carrot meal supplementation on carcass characteristics (g) of female Arbor acre broiler chickens aged 42 days*

Discussion

In the present study, carrot meal supplementation had no effect on growth rate of female Arbor acre broiler chickens aged 22 to 42 days. Carrot meal supplementation improved dietary intake of female Arbor acre broiler chickens aged 22 to 42 days. However, these improvements did not have any impact on growth rates of the chickens. Similarly, improvements in dietary intake, feed conversion ratio, metabolisable energy intake and nitrogen retention did not result in any improvement of live weights of the chickens. These results are similar to those of Erhan and Bölükbaşı (2017) who found out that supporting the diet with citrus peel oil did not change the weight of the broilers. According to Yu et al. (2005), the obtained results in this study may be attributed to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1233712346

antioxidant and antimicrobial properties of carrot meal. However, the present results are contrary to those of Ürüşanet al. (2018) who observed improvements in live weights of chickens supplemented with carrot meal. Similarly, Abdu et al. (2012) reported improvements in live weights of rabbits with carrot meal supplementation. This might also be because large amounts of easily-fermented components as sugars and soluble non-starch polysaccharides contribute some energy to the chickens Steenfeldts et al. (2007).

Supplementation with 50 g of carrot meal per kg DM feed improved feed conversion ratio. Rizal et al. (2010) reported an improvement in feed conversion ratio of broiler chickens supplemented with carrot meal. Improvements in dietary feed conversion ratio observed in the present study are similar to those observed by Hammershøj et al. (2005) and Hammershøj et al. (2010) reported improvements in feed conversion ratio of laying hens when they were supplemented with carrot meals. However, Khan (2019) reported no improvements in feed conversion ratio of broiler chickens fed carrot pulp. In the present study, dietary intake and feed conversion ratio and live weight of female Arbor acre broiler chickens aged 22 to 42 days were optimized at different dietary carrot meal supplementation levels of 52.8 and 63.8 g/kg DM feed, respectively. This means that carrot meal levels for optimal productivity will depend on the particular variable of interest. This has implications on ration formulation where carrot meal is included.

Carrot meal supplementation improved dietary metabolisable energy intakes of female Arbor acre broiler chickens aged 22 to 42 days. These results are similar to those of Magouze et al. (1998) who observed that carrot meal supplementation in growing rabbits improved their metabolisable energy intakes. However, El-Kerdawy et al. (1992) found that carrot meal supplementation to the diets of growing rabbits decreased their metabolisable energy intakes. Similarly, Steenfeldts et al. (2007) observed a decrease in metabolisable energy intakes of laying hens supplemented with carrot meal. The results of the present study indicate that carrot meal supplementation increased nitrogen retention in female Arbor acre broiler chickens aged 22 to 42 days. Their findings may imply that an alteration of tissues takes place, particularly muscle and fat deposits, which may differ in nutrient digestion (Moran and Bilgili, 1990). However, these results contradict with those of El-Kerdawy et al. (1992), which indicated that carrot meal supplementation to the diets of growing rabbits decreased nitrogen retention. Similarly, Steenfeldts et al. (2007) found that nitrogen retention in laying hens supplemented with carrot meal was increasing. In the present study, metabolisable energy intake and nitrogen retention of female Arbor acre broiler chickens were optimized at different carrot meal supplementation levels of 42.0 and 44.3 g/kg DM feed, respectively. This means carrot meal levels for optimal metabolisable intake and nitrogen retention intake will depend on the variable of interest.

Carrot meal supplementation had no effect on carcass, breast, drumstick, thigh, liver, gizzard and fat pad weights of female Arbor acre broiler chickens aged 42 days. Ürüşanet al. (2018) reported increase in hot carcass weight and carcass yield of broiler chickens feed carrot seed oil authors indicated that increase carcass weights which were observed in many studies, occurred because of the appetizer properties of plant extracts by increasing the gastric digestion liquor. Carrot meal supplementation did not affect tenderness and flavour of female Arbor acre broiler chicken meat. Meat sensory attribute values of tenderness and flavour were similar across the dietary treatments. It is not clear how carrot meal supplementation affect the sensory attributes of broiler chickens and this may require further studies. However, carrot meal supplementation

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1233712346

improved the juiciness of female Arbor acre broiler chicken meat. Thus, there was positive relationship between carrot meal supplementation and juiciness of female Arbor acre broiler chicken meat. No such information was found for either indigenous or broiler chicken breeds. Further research is needed to deepen the knowledge in this area.

Conclusion

Carrot meal supplementation did not have any effect on growth rate, live weight, carcass weight, meat tenderness and flavour of Arbor acre broiler chickens aged 22 to 42 days. However, carrot meal supplementation improved intake, feed conversion ratio, metabolisable energy intake, nitrogen retention and meat juiciness of female Arbor acre broiler chickens aged 22 to 42 days. As a result, carrot meal can be added in the diet of broilers as a beneficial dietary supplement which contains natural antioxidants. Optimal improvements of feed intake, FCR, live weight, metabolisable energy intake and nitrogen retention were achieved at different carrot meal supplementation levels. Thus, carrot meal levels for optimal productivity will depend on the parameter in question. This has a lot of implications in diet formulations where carrot meal is included. Further studies are recommended to repeat and confirm results of this study.

FIRST MOLECULAR CHARACTERIZATION OF THE PARTIAL COAT PROTEIN AND 3'UTR GENES RELATED TO *DASHEEN MOSAIC VIRUS* ON FLAMINGO FLOWERS (*ANTHURIUM* SPECIES) IN THE MEDITERRANEAN COAST OF TURKEY

KOÇ, G.

Subtropical Fruits Research and Experimental Center, Çukurova University, Adana, Turkey (e-mail: gkmnkoc@hotmail.com.tr)

(Received 7th May 2019; accepted 16th Jul 2019)

Abstract. Observations were carried out on *Anthurium sp* growing at Mediterranean region (Adana, Mersin and Antalya provinces) of Turkey in 2015-2017. During the studies virus-like symptoms in plants; systemic chlorotic mosaic and irregular uniformity on leaf and petals were recognized. Eleven of 73 samples showed positive response with the Potyvirus group specific antibodies and their results were also confirmed by RT-PCR. The 327 bp products via using the Potyvirus-specific primers, MJ1 and MJ2 were run in 1.5% agarose gel. Further amplifications were made with the 3'UTR and 3'end of the coat protein of the viral genome. RT-PCR analysis using the primer MJ1 and M4T resulted in an amplification of 719 bp amplicon. Direct sequencing of RT-PCR products and BLAST results have showed that there were two clades between 96-99% among the Mediterranean coast DsMV isolates. The data are available in Genebank with accession Number MK758088/Antalya; MK758087/Yenice). DsMV infection on *Anthurium sp*, was determined serologically and molecularly. To our knowledge, this is the first molecular record describing the occurrence, distribution and genome organisation of DsMV isolates that have been infecting Flamingo flowers at the Mediterranean coast of Turkey. Findings may have shown an evidence about uncontrolled distribution from Northern corner to Southern side.
Keywords: *DsMV, potygroup serology, RT-PCR, molecular agroecology, evolution*

Introduction

Flamingo flowers (Anthurium plants) are native to Central and South America. Anthurium belongs to the Alismatales ordo, Araceae family, *Anthurium* genus. It is known to have over 500 species. It is grown both to be sold as a potted plant and cut flower. The most grown species are *Anthurium crystallinum, Anthurium veitchii, Anthurium magnificum, Anthurium scherzerianum* and *Anthurium andreanum.* Among the species of *Anthurium*, *Anthurium scherzerianum* is the most cultivated species. As a result of various hybridization studies of this species, different colors were produced. Mostly *Anthurium andreanum* species are produced as cut flowers. The Anthurium plant in Turkey is cultivated in the Marmara, Aegean and Mediterranean regions. The nice plant has 8-15 cm diameter flesh-like flower tray, reproductive organ and 40-70 cm length flower on stem. Flamingo flower shows tropical plants' characters. Therefore, they require high levels of humidity, temperature and shading. Due to the climate requirements, it has been cultivated under cover in the Mediterranean, Aegean and Marmara regions of Turkey.

Like in the case of other ornamental plants, many diseases have been reported in its cultivation areas. For example; members of the Tospovirus, Nepovirus, Potyvirus and Cucumovirus species are among the most important viral factors causing damage and loss due to their infections on ornamental plants (Sutic et al., 1999; Daughtrey et al., 1997; Loebenstein et al., 1995). Such as *Cucumber mosaic virus* (CMV), *Dasheen mosaic virus* (DsMV) (Rivas et al., 1997; Miura et al., 2013) and Tomato spotted wilt

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1234712365

virus (TSWV) (Fidan et al., 2016; Norman and Ali, 2012; Chen et al., 2003; Uchida et al., 1999). The species of ornamental plants belongs to family Areceae (Aroid) which are the most important hosts of *Dasheen mosaic virus* (DsMV). DsMV attacks at least 16 genera including Aglaonema, Caladium, Dieffenbachia, Philodendron and Zantedeschia genuses. Colocasia, Xanthosoma, Cyrtosperma species are also prone to infection with the virus (Nelson, 2008).

DsMV, has a narrow range to the plants of Aroid family (Brunt et al., 1996), the DsMV has been transmitted through tainted sap and via non-persistent manner by a couple of aphid species, including *Myzus persicae, Aphis gossypii* and *Aphis craccivora* (Buddenhagen et al., 1970). And also DsMV is not transmitted via seed propagation. The disease fundamentally causes tainted planting material which is the most common symptom. If vegetatively propagated cultivated plants have infection, it results in tainted flowers (Zettler et al., 1970; Van der Meer, 1985).

Investigation on commercial Flamingo flower plants have shown mosaic, chlorotic line indications in the veins of many plant leaves. They hindered the growth of the plant and were found to cause deformities in the nodes with color changes in the blossoms. The pathogen causing the symptoms has characterized as Dasheen mosaic infection (DsMV). The *Philodendron verrucosum* plant is a good lesion host for DsMV (Tooyoma, 1975). The other six Philodendron species tested and have deliberately contaminated with virus infection and showed diverse mosaic effects. Pale colored spots were found in *Anthurium scandens* the leaves of the cv violaceum plant. Further deformation of blossoms as well as the color quality of the knot were observed (Chagas et al., 1993). The DsMV infection results in deterioration of the appearance and nature of the blossoms. The mosaic, deformity and little protuberance indications of *Anthurium sp. cv. river* have been related with the Dasheen mosaic potyvirus and isolated the agent (Chagas et al., 1993).

If physical and molecular properties are focused on The DsMV, it is 750 nm in length and 11-13 nm wide which has flexuous, non-enveloped particles (De Brot and Ordosgoitti, 1974). The viral genome includes a monopartite single-stranded (ss) molecule of positive sense RNA of about 10 kbp, which contains 5ˈ and 3ˈ terminal UTRs flanking an imperative single ORF and the 3ˈ UTR finishing with a poly-A tail (Hull, 1994; Adams et al., 2005; Ha et al., 2008; Cuevas et al., 2012). The ten utilitarian proteins in their solicitation from 5ˈ to 3ˈ are P1 (1st protein), Helper Component-Pro (accomplice fragment protease), P3 (3rd protein), 6K1, CI (barrel molded thought protein), 6K2, VPg (genome-associated), NIa-Pro (genuine protease of minimal nuclear fuse protein - NIa), NIb (broad nuclear consolidation protein) and (CP) coat protein (Colinet et al., 1998; Adams et al., 2005; Cuevas et al., 2012; Hull, 1994).

Essentially, plants that gave signs were subjected to Enzyme Linked Immuno Sorbent Assay (ELISA) testing utilizing DsMV polyclonal antisera and gave a negative outcome. ELISA tests with potyvirus monoclonal antiserum PTY 1, a particular antiserum explicit to the potyviral coat protein region, gave a positive response. ELISA is the most convenient procedure for routine distinguishing proof of DsMV in huge amounts of plant tests with variable contamination titres. Nevertheless, DsMV IgG is in limited facility, and the exceedingly thick concentrate of aroid sap is represented to intrude with ELISA tests (Rodoni and Moran, 1988). Moreover, past examination exhibited that recognizable proof of DsMV by ELISA was clashing obviously due to uneven course of DsMV (Hu et al., 1994). Serological investigation of potyviruses is routinely mismatched, due to immunological cross-reactions among species (Brunt,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1234712365

1992) and biological identification is extremely unbalanced. On the other hand, continuous advances in nucleic acid advances have enabled the improvement of stunning acknowledgment and recognizing proof instruments.

The currently accepted criteria for detecting disease species in the Potyviridae family are based on the collection of genomic information. Moreover, differentiation in host range and host reaction, antigenic properties and the morphology of inclusion bodies can be considered as criteria for limiting (King et al., 2012; Babu et al., 2011). In the same study, the 327-bp part of the coat protein gene area from the contaminated *Colocasia esculenta* plant, which has whitepox symptoms, has researched by Reverse Transcriptase Polymerase Chain reaction (RT-PCR) technique utilizing primers specific to the Potyviruses. DNA sequence investigation and BLAST examination demonstrated a close association with DsMV. Similarly, the presence of Dasheen mosaic infection (DsMV-Sc) has been verified on *Spiranthes cernua* plants that show chlorotic spots and mosaic indications (Guaragna et al., 2006).

The conspicuous confirmation was reliant on the Polymerase Chain Reaction, which was used for Potyvirus (Langeveld et al., 1991). Grisoni et al. (2006) has been used Potyvirus group specific primers for recognizable evidence of Potyvirus tainting Vanilla. Same researchers reported primer pair MJ1 and MJ2, which amplify a short fragment (327 bp centered on coat protein gene) of an extensive part of the potyviruses.

In the Mediterranean Region of Turkey, which has an important place in the production of ornamental plants, the studies of viral diseases started on the demands of the producers of Flamingo flower cultivations as interior and cut flowers. The symptoms; systemic chlorotic mosaic and irregular uniformity on leaf and petals) were considered to be related to Dasheen mosaic virus. As the production areas are usually intertwined with undergrowth vegetable production areas, it has been investigated in terms of viral diseases which are problem in both vegetable and ornamental plants.

Therefore, aims of the studies were to clarify the recognition and recognizable proof of the Potyvirus species tainting Flamingo flower (Anthurium sp.), through sequencing of fractional coat protein gene and the 3'UTR area of the viral genome. Then, the nearness of DsMV in Flamingo flower plants will be recognized by DAS-ELISA and RT-PCR systems. Finally, the CP and 3'UTR of some DsMV isolates will be sequenced in molecular genetic for distinguishing proof. The study may be the broadest research on DsMV in recent years at Turkey.

Materials and methods

Experiments have been set in Antalya, Mersin and Adana cities located at the Mediterranean region of Turkey (*Fig. 1*). Seventy-three samples from symptomatic Flamingo flower plants showing common DsMV symptoms (upward leaf curling, mosaic, yellowing, distortion and flower mosaics) and some asymptomatic leaf samples were used in molecular analyses (*Fig. 2*).

Serological tests

Collected samples were labelled and placed into plastic packs, then were conveyed to the Virology Lab via putting them in ice pail and kept at 4 °C. All samples were used within 24 h.

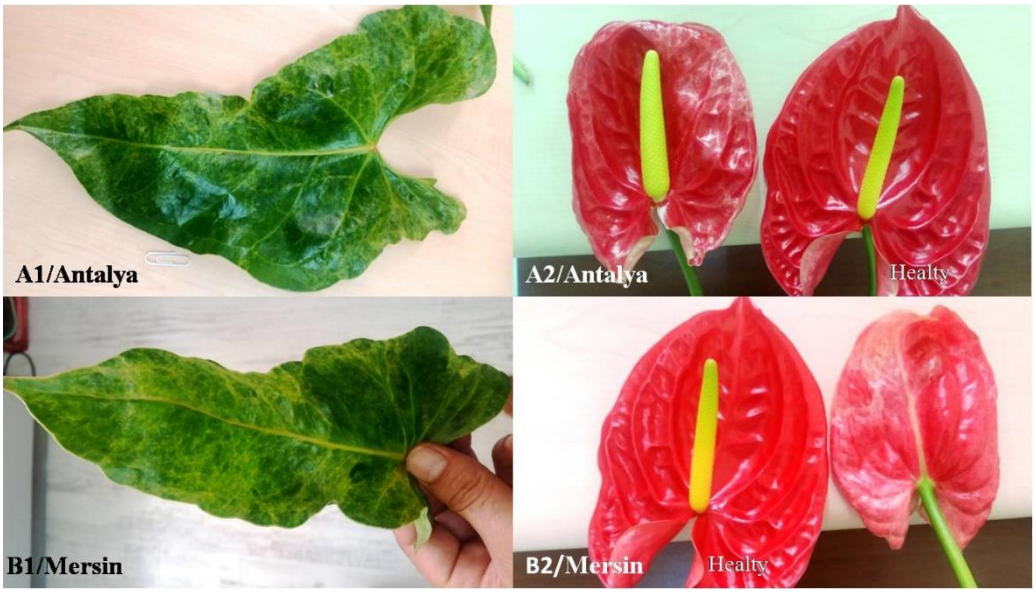

Figure 2. *Athurium plants have showing typical DsMV symptoms (upward leaf curling, mosaic, yellowing, distortion and flower mosaics)*

Enzyme linked immunosorbent assay

For distinguishing evidence infections contaminating Flamingo flower, leaves were attempted through ELISA utilising polyclonal antiserum specific to infections. The ELISA tests contained various virus species which are found in ornamental plants. All

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1234712365

the tested polyclonal antibodies were given in *Table 1*. ELISA antisera one by one received from Agdia U.S. and Bioreba AG, Switzerland. Tests covered location of infections in tainted fresh leaves and conveyed according to Clark and Adams (1977). To each well of ELISA plates (Nunc F96 Maxisorp) 200 µl of IgG diluted in coating buffer (BIOREBA antisera 1: 1000 ratio or Agdia antisera 1: 200 ratio) was added and they were incubated for 4 h at 30 °C. The ELISA plate was washed with wash buffer and left for 3 min, which was repeated 3 times. Samples prepared with extraction buffer were incubated for 16 h at 4 °C by adding 200 µl of positive and negative controls to each well. The ELISA plate was washed again as described in the second step. IgG diluted 1: 1000 (Bioreba) and 1: 200 (Agdia) in conjugated buffer was incubated at 30 °C for 4 h by adding 200 µl to each well and the ELISA plate was washed again as described in the second step. Subsequently, 200 µl of the substrate solution (1 mg/ml paranitrophenylphosphate) was added to each well and allowed to stand at room temperature in the dark for 1 h.

The results were obtained by observing the formation of yellow color in the ELISA reader and measuring the absorbance values at 405 nm wavelength. Samples that gave at least twice the absorbance value of the healthy control value were considered infected or positive. Values close to positive but not definite were considered suspicious.

Nucleic acid based assays

We focus on DsMV in molecular studies because serologically positive results were obtained by *Potyviru*s genus-specific antibodies (Agdia). Moreover, the most obvious disease in Flamingo flower is DsMV and typical symptoms in the collected samples indicate DsMV.

Total RNA isolation and reverse-transcription polymerase chain reaction (RT-PCR)

Total nucleic acid was extracted from contaminated Flamingo flower plants according to Dellaporta et al. (1983) and their RNAs were used in Reverse-Transcriptase Polymerase Chain Reactions (RT-PCR). In the first place the samples were prepared from different tissues of infected Anthuriums such as Leaf, Petal, stamen + pistil, Peduncle or stem due to covering causal disease agent.

RT-PCR detection of CP region by MJ1 and MJ2

Sense MJ1 (5'-ATGGTHTGGTGYATHGARAAYGG-3' and MJ2 (5'-TGCTGCKGCYTTCATYTG-3') designed by Marie-Jeanne et al. (2000) (*Fig. 3*). Grisoni et al. (2006) published a single letter code H: A/C/T\, Y:C/T, R:A/G, K:G/T that amplify a 327 nt fragment in the CP gene of potyviruses of DsMV isolates. The cDNAs were obtained using Thermo Sci. Verso 1-Step RT-PCR Kit pack according to producer's manual. DsMV PCR mix was replicated by program through a cycle of RT at 49 °C for 45 min (m), 94 °C for 2 min; following 38 cycles of 94 °C for 30 s, 50 °C for 55 s., extension 72 °C for 55 s, and a final step of 72 °C for 10 min in a thermal cycler (Babu et al., 2011).

Amplification of partial coat protein gene and 3'UTR; The universal primer sequence M4T, which trigers to the 3'end of the potyviral gene and the reverse primer in combination with the forward primer MJ1 were used. The RT-PCR was performed in a 20 mL volume. Each primers MJ1 and M4T-5'-GTTTTCCCAGTCACGACTTTTTTTTTT-3' are shown in (*Fig. 3*). The RT-PCR mix

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1234712365

was subjected to thermal programme: RT at 48 °C for 45 min, denaturation at 94 °C for 2 min; 38 cycles of 94 °C for 30 s, annealing. at 50 °C for 55 s and extension at 72 °C for 55 s, and last step of 72 °C in 10 at thermal cycler (Babu et al., 2011).

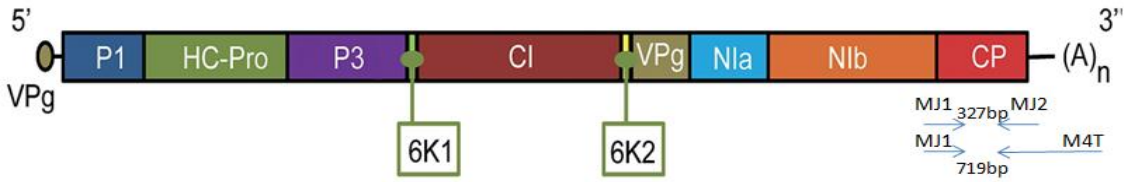

Figure 3. *Schematic representation of Potyvirus genome (Cuevas et al., 2012) and the primers' amplicon ranges for DsMV Mediteranean isolates in this study*

Analysis of RT-PCR products

10 µl of PCR product was utilized within gel loading buffer and dissected on a 1.5% agarose gel containing 0.5 mg/ml of ethidium bromide (Sambrook et al., 2001). 100 bp DNA stepping ladder (thermo) was also used on each gel to compare PCR products' size.

Phylogenetic analysis

The DsMV containing RT PCR products obtained by MJ1 and MT4 primer sequences and dnasp5 program was conducted. Phylogenetic analyses were performed by MEGA 7 software and neighbour joining process, according to conventional analysis. Obtained sequences were compared with strains of DsMV genebank (NCBI, National Center for Biotechnology Information). Sequences from the accessions (accession Number MK758088/Antalya; MK758087/Yenice) were considered. Sequence alignment of the DsM virus isolates and homology between sequences were calculated according to Thompson et al. (1994). A sequence identity matrix of the 3'UTR region and partial CP gene of the DsMV isolates were constructed using the BIOEDIT with worldwide DsMV sequences obtained from the GeneBank.

Results

Type of symptoms on Anthurium sp.

Upward leaves curling, mosaic, yellowing, distortion and mosaic flower associated with Flamingo flower plants were indicating DsMV symptoms (*Fig. 2*). Virus infected leaves in the fields were light yellow and leaf margin areas resembled to distortion (*Fig. 2A1-A2*); There were leaf mosaics reduced in size and shapeless malformated leaves (*Fig. 2A1-A2*). General flower discoloration was observed and petals had mild whitish mosaics on the Flamingo plants (*Fig. 2B1-B2*).

Occurrence of viruses by serology (ELISA)

Immunological assay performed in ELISA serological tests: they were individually repeated at least two times to approve presence of the virus. 11 out of 73 samples have given positive reactions (with 15.06% incidence) with the potyvirus genus group

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1234712365

specific antiserum. The 11 positive samples of Flamingo flowers were collected from 2 provinces, 6 of them were from Antalya and other 5 were from Yenice, Mersin, Turkey (*Fig. 2*).

Further verification tests have applied RT-PCR with total nucleic acids isolated from the samples following ELISA tests. Due to having positive result to Potyvirus group, any positive reaction for other tested virus species and groups, cellar DsMV symptoms and not in laboratory opportunities of DsMV commercial antiserum. As well DsMV is previously reported on many aroid species (Nelson, 2008).

The RT-PCR amplification

For confirming the serology test results, RT-PCR analyses were conducted. DsMV; 327 bp sections as the objective RNA have been put in CP focal areas and DsMV; 719 bp on 3'UTR and coat protein partial genes, are identical for detection experiments. Selected MJ1–MJ2 were published as degenerate primers by different researchers (Chen et al., 2001; Pappu et al., 1993; Langeveld et al., 1991). For the reason of couple of these primers good at for RT-PCR based detection.

Extracted RNAs (327 nt) were chosen symptomologically from two samples, and they yielded expected products (*Fig. 4*) on agarose gel (1.5%) electrophoresis. The RT-PCR results affirmed DsMV in Flamingo plants.

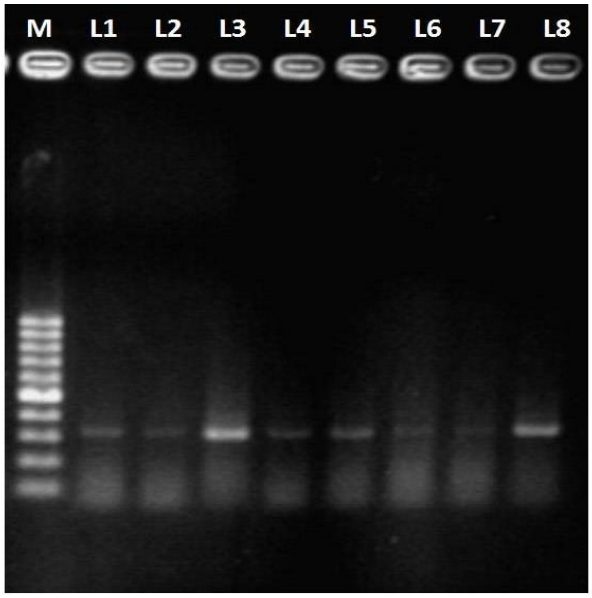

Figure 4. *First lane M DNA ladder; RT-PCR products of 327 bp of DsMV CP on agarose gel (1.5%) (Lane1, A1 Leaf; L2, A2 Petal; L3, A2 stamen + pistil; Lane4, A2 Peduncle or stem; Lane5, B1 Leaf; Lane 6, B2 Petal; Lane 7, B2 stamen + pistil; Lane 8, B2 Peduncle or stem) positive Flamingo flower samples ("A" coded samples from Antalya and "B" coded samples from Yenice/Mersin of Mediterranean Cost in Turkey)*

Additionally, conserved CP central regions resulted bands in RT-PCR analysis using primer pairs combination of MJ1 and M4T. We obtained 719 bp cDNA bands of DsMV located between partial CP and 3'UnTranslated Region verifying discrimination of different isolates in RT-PCR system (*Fig. 5*). The 3'UTR sequences of potyviruses have an opportunity for understanding different isolates (Frenkel et al., 1989; Pappu et al., 1993).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1234712365

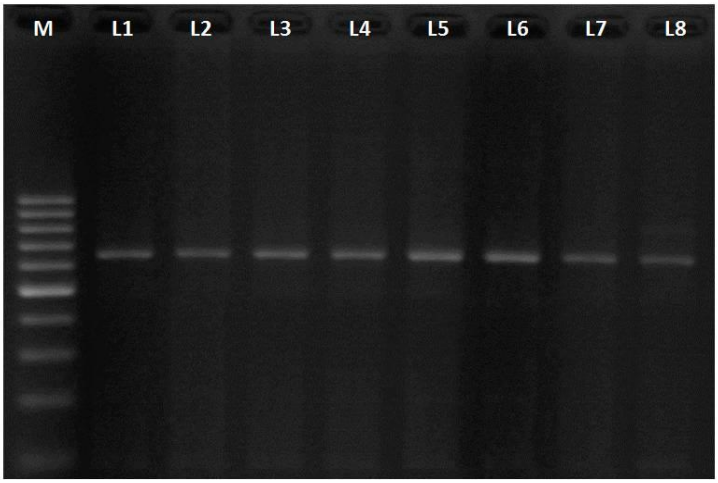

Figure 5. *RT-PCR product of 719 bp of DsMV CP on agarose gel (1.5%); First lane, M DNA ladder; Lane1, A1 Leaf; L2, A2 Petal; L3, A2 stamen + pistil; Lane4, A2 Peduncle or stem; Lane5, B1 Leaf; Lane 6, B2 Petal; Lane 7, B2 stamen + pistil; Lane 8, B2 Peduncle or stem) positive Flamingo flower samples ("A" coded samples from Antalya and "B" coded samples from Yenice/Mersin of Mediterranean Coast in Turkey*

ELISA tests were conducted against 20 viruses where two types of group specific antiserums were used. Positive results were obtained only against Potygroup specific polyclonal antiserums and 327 nt CP core regional primers by RT-PCR (*Fig. 4*) among all viruses infected samples (*Table 1*). In addition to the species specific ELISA tests, *Tospo* group specific antiserums did not give any positive results for all collected samples. RT-PCR resulted 719 nt amplicon that was specific for DsMV. There were additional results found from different plant tissues; leaf; petal; stamen + pistil and peduncle or stem (*Fig. 5*).

Phylogenetic analysis

Phylogenetic analysis was performed by MEGA 7 programming, entire DsMV sequences were distinguished (*Fig. 6*). Two distinct haplotypes which were symptomologically chosen from Anthurium sp plants at Mediterranean region of Turkey were determined from present DsMV isolates by either RT-PCR or sequences. Two different but not so significantly distinct haplotypes have been analyzed in NCBI system and their sequences were submitted to NCBI as new records.

The Flamingo flower samples from Turkey in Genebank have accession numbers MK758088/Antalya and MK758087/Yenice. The accession numbers were first recorded to NCBI system (*Fig. 6*) and they listed with other isolates from worldwide in *Table 2*. The two isolates of DsMV have approximately 99.49% similarity with each other isolate in Turkey. They were replaced in two clades as they were isolated from two Anthurium species. This is may be caused by two production materials imported from different origins. Phylogenetic tree showed that both isolates are related with each other at the Mediterranean region of Turkey. Their sequences were clarified that two Anthurium sp DsMV isolates from the Mediterranean region of Turkey have similar homology with *Xanthosoma* sp Et56 from Ethiopia (Accession Num. MG602233.1) and *Colocosia esculenta* TW from Japan: Utsunomiya (Accession Num. AJ298036.1) isolates.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1234712365

The DsMV from Flamingo flower Antalya, Turkey isolates (accessed as new record to NCBI system with accession number: MK758088) (100%-Turkey) have showed approximately 91.40% similarity with Japan: Utsunomiya (Accession Num.AJ298036.1) isolate and 90.54% Nicaragua NiNG1 (Accession Num.AM910398.1); 87.32%. Tanzania *Xanthosoma* sp. Tz24 (Accession Num.MG602242.1) around the world (*Table 2*; *Fig. 6; Table 3*). The other DsMV isolate, Yenice was reported to NCBI system with accession number: MK758087 (99.49%-Turkey). The DsMV Yenice has approximately 89.54% similarity with *Xanthosoma* sp Et56 from Ethiopia (Accession Num. MG602233.1) isolate and 84.55% New Zealand Taro DsMV1 (Accession Num.AY994104.1); 83.50% French Polynesia *Vanilla tahitensis* FP (WP013, Accession Num. AJ616719.1) (*Table 2*; *Fig. 6; Table 3*, respectively).

The developmental history was derived utilizing the Neighbor-Joining technique. The ideal tree with the aggregate of branch length = 24.38716469 is appeared. The level of recreate trees in which the related taxa bunched together in the bootstrap test (1000 repeats) are appeared at the branches. The tree is attracted to scale, with branch lengths in indistinguishable units from those of the evolutionary distances used to deduce the phylogenetic tree (*Fig. 6*).

Discussion

The sanitary status of Dasheen viruses in Turkey has not been broadly studied. Therefore, in the project, we aimed to determine and identify how to detect the virus and possibly control economically important viruses associated with Flamingo flower.

Typical symptomatic Flamingo flower plants in this study, were tested with ELISA and RT-PCR analyses. 73 samples were collected from Mersin and Antalya provinces in the in Mediterranean region: among which 11 were positive with the potyvirus infection in ELISA and RT-PCR similarly to previous works (Kibar, 2014; Kidanemariam, 2016, 2018)

In our study frame, virus infected leaves in the fields were light yellow and leaf margin areas resembled distortion, leaves having mosaics reduced in size and shapeless, malformated leaves were observed, flowers had discoloration and petal mosaics were also observed on flamingo plants. The same was found in the case of several aroids (Elliott et al., 1997; Lima et al., 2004; Nelson, 2008; Cabrera et al., 2010; Babu and Hegde, 2014). Infrequently, yellow and green patterns occurred over the whole leaf surface, which may have seemed slender with a distorted edge (Kohler et al., 1997).

In a close study, an excessive strain of DsMV caused pale green and yellowish designs on stunted and extremely distorted leaves in French Polynesia (Jackson, 1982). A few of which can be decreased to strap-like structures without flaps. The presence of DsMV in *Anthurium andreanum* (Flamingo blossom) and a few orchid (*Cymbidium spp*.) species was just investigated by means of serological methods. DsMV was verified in two *Anthurium andreanum* leaf samples in Trace location of Turkey (Kibar, 2014). Similarly, Greber and Shaw (1986) diagnosed Dasheen mosaic virus (DsMV) via mechanical inoculation of plant sap and serological tests in wild and cultivated plant species. Also close results, reported by Simone and Zettler (1990) that there are hosts of DsMV in a few different tropical plants besides Araceae family ornamental flora. Viral

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1234712365

agents belonging to the genera Tospovirus, Nepovirus, Potyvirus and Cucumovirus had been among the main viral agents inflicting loss of ornamental plants which were reported (Daughtrey et al., 1997; Loebenstein et al., 1995; Sutic et al., 1999).

The Flamingo flower samples, in Mersin (Yenice) and Antalya, gave positive reactions (with 15.06% incidence) against the potyvirus genus group specific antiserum but there were not any serological reactions against other tested viruses and groups. Likewise, Lima et al. (2004) reported that their collected samples from 20 symptomatic Anthurium flowers were revealed positive results in ELISA. Our results were consistent with the potyvirus specific antiserum in ELISA but negative response obtained with the antiserum for CMV. Only difference between the above study and ours were antisera which we did not have DsMV antiserum.

Valverde et al. (1997) reported DsMV in Dasheen vegetation, which was produced in in vitro environment. DsMV was determined by means of ELISA check in distinctive forms of *Colocasia esculenta* plant in different researches (Hu et al., 1994; Rodrigues et al., 1984; Zettler et al., 1987; De Brot and Ordosgoitti, 1974). Kibar (2014) reported the DsMV serologically by ELISA on Anthurium and Cymbidium flowers. Shukla et al. (1992) referenced a couple of challenges related to serological identification of some potyviruses, which were direct result of characteristic complexities related with the potyvirus coat proteins (Shukla and Ward, 1989a, b; Ward and Shukla, 1991). Shukla et al. (1994) expressed that the complexities came about because of 3 overwhelming inconveniences. Those are especially in the first place variable cross-reactivity of potyvirus antisera; in second placeamazing and conflicting combined pursuing; and in the third place absence of cross-response between certain strains.

ELISA and molecular assays have been used for the detection of DsMV by different papers (Abo El-Nil et al., 1977; Nelson, 2008; Babu and Hegde, 2014), both techniques are sensitive for the detection of viruses but RT-PCR is more reliable with high selectivity to detect such viruses (Randles et al*.,* 1996).

Among molecular analyses of this study, the RT-PCR have been intensified with degenareted primers MJ1–MJ2 and 327 bp target fragments were obtained for the detection of DsMV. Based on many previous results (Chen et al., 2001; Pappu et al., 1993; Langeveld et al., 1991) MJ1–MJ2 were selected which were reported as degenerate for the DsM virus from different aroid isolates. The 327 bp fragments as the target RNA have been amplified for both potygroup and DsMV due to highly conserved CP core central regions. Similarly, Marie-Jeanne et al. (2000) reported a 327 bp fragment in the Coat Protein genes of potyviruses. Since they amplify a short part and gave superior enhancement signals in preliminary experiments of diverse isolates DsMV isolates Marie Jeanne et al. (2000) also concluded similar results with DsMV. 719 bp on coat protein partial genes and 3'UTR, were resulted for specific detection and discriminations.

Likewise, Babu et al. (2011) clarified the 327 bp CP fragments from the infected *Colocasia esculenta* plants via RT-PCR. The processing of unique primers particular to the Potyviruses and cDNA sequence evaluation confirmed for DsMV.

As well Grisoni et al. (2006) applied Potyvirus group specific primers for recognizable proof of Potyvirus contaminating Vanilla plants. The primer pair MJ1 and MJ2 explicitly amplify a brief piece (327 bp) of the middle district of coat protein gene of a big portion of the potyviruses.

In Addition to 327 bp region amplification; primer pairs combination of MJ1 and M4T were studied for 719 bp cDNA bands of DsMV to compare the isolates with

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1234712365

worldwide isolates via ncbi database in project scope. RT-PCR sequences of 719 bp affirmed the diseases for DsMV positive plants from East Mediterranean isolates in ELISA. The amplified PCR 719 bp products were applied for sequencing and phylogenetic tree discrimination. No critical differences was observed among the plant tissues when the RT-PCR was applied. That is identical to the result obtained on exceptional tissues in agarose gel electrophoresis in our study. Frenkel et al. (1989) and Pappu et al. (1993) decided that the 3'UTR sequences of potyviruses were useful for differentiation of strains and species of potyviruses

Edited DsMV sequences from East Mediterranean isolates were compared with strains of gen bank (NCBI). Sequences of The Mediterranean region isolates of Turkey were edited as accession Number MK758088/Antalya and MK758087/Yenice for the first time in Turkey (*Fig. 6*).

The main outcome from analysis of sequence revealed that DsMV Yenice (Mersin) and Antalya isolates were most similar to both in itself and all the other compared geographically originated isolates. In the same way, Babu et al. (2011) compared 3'UTR region of different isolates by universal primers MJ1 and M4T and also they identified DsMV was closely related to DeSLK2 isolate. Finally, same papers reported DsMV as the first report of molecular based detection of the DSMV infecting *Amorphophallus paeoniifolius i*n India. Briefly, it was determined that the 3'UTR sequences of potyviruses had an opportunity that benefited for differentiation of isolates (Frenkel et al., 1989; Pappu et al., 1993).

Similarly, Zavareh et al. (2013) determined the DsMV in Anthurium plant by means of PCR method. Furthermore, it is reported that the Areceae family is a few of the most essential hosts of Dasheen mosaic virus (DsMV) in ornamental plant species Nelson (2008).

In another group of studies, presence of DsMV with molecular techniques was detected by Reyes et al. (2009) in a tropical plant Cocoyam (*Xanthosoma spp*.); Babu et al. (2011) in *Colocasia esculenta*, and Chen and Adams (2001) identified the complete genome sequences of an isolate of Dasheen mosaic virus (DsMV) in *Zantedeschia aethiopica*. Likewise, Maino (2003) concluded the variability within the coat protein-CR of DsMV isolates from French Polynesia, Papua New Guinea, Vietnam Solomon Islands, Samoa, and New Caledonia via amplifying, cloning and sequencing. In comparison with the DsMV sequences at the database, the most variability changed into taken as 21.9%, while the center district of the CP become analysed, while the greatest variability dropped to 6%. Additionally, equivalent guide was demonstrated, most variability become present in the N end.

Li et al. (1998) ordinarily cloned and sequenced the 3' - terminal 3158 nts of the Caladium isolate of (DsMV-Ch). The sequences included the 3' end of the Nia, Nib and CP-coding regions and a 246 nt UTR (with the exception of the poly-A tail) in the long run. The comparisons of DsMV-Ch CP with that of DsMV-LA and DsMV-TEN isolates found a closeness of 84-88% on the nucleotide level, and 92-94% at the amino acid level. When all data considered an arrangement of the amino acid sequencing of the 3 isolates discovered N terminal variability and a close similarity among the DsMV-Ch and DsMV-TEN.

Conclusion

The Mediterranean region of Turkey is a critical agricultural cultivation area for many types of plants grown. Ornamental vegetation has a vital importance inside the production of cultivated crops which contribute substantially to the financial system and have an excessive export capacity.

Decorative plants' leaves and cut flowers are the most common wealth of ornamental plant market in global scale. Productivity and quality losses occur because of adverse outcomes of diseases in decorative flowers that economic importance is increasing day by day. Especially in practice, there is no chemical application to control virus diseases. Consequently, the virus diseases can restrict the production via reducing flower production within the Mediterranean region of Turkey. It should be understood to apply control measures and their epidemiology and molecular origin ought to be known.

Studying the Anthurium sp. as cut flower species in greenhouses (Flamingo plant) becomes important for economical reasons. Viral disease agents have reduced their market value and their aesthetic value for consumers.

Natural distribution and occurrence of Dasheen viruses in the studied area have determined as very limited distribution in Turkey. Our results have already mentioned above sanitary situations in Flamingo flowers growing regions are very vitally important in Turkey. As well as, to prevent the spreading of common plant viruses and DsMV is only possible with the detection of the agent. All of DsMV positive samples in this study have already been eradicated. Therefore, maintaining Turkey's disease free status with the definite destruction of the inoculum sources needs controlled quarantine applications. Probably, DsMV's insect vectors, are actually second main factors, are responsible for the epidemiology by re-infection in the green houses. Insecticide applications are commonly used technique for management strategy against aphids (Knauss et al., 1975; Monge et al., 1987; Valverde et al., 1997). Even it is one of the main threatening elements to the ecology and environment. Resistant cultivars and sanitation should be used for control of the DsMV in practices. Sometimes resistance breaking isolates can be developed in greenhouses (Fidan and Sarı, 2019). Infected plants, presence of vectors and presence of virus have vital effects on the spread of DsMV at infected areas (Çolak Ateş et al., 2018).

Some potyvirus isolates, such as Alfalfa Mosaic Virus (AMV), Zucchini Yellow Mosaic Virus (ZYMV) and Plum Pox Potyvirus (PPV), etc.) are highly infectious and are able to transmit with aphids. They have been studied and molecularly characterised from different hosts both in Turkey and in Cyprus (important for material exchange) (Özer et al., 2012; Fidan et al., 2012; Koç, 2010; Koç and Baloğlu, 2006).

Therefore, molecular epidemiology should be well understood and spread to field or outdoor plants should be prevented. In addition, the presence of broad range vector aphids in the greenhouses and outside, and the lack of biological and more ecologically friendly chemical protection, the risk of infection increases that will allow DsMV to spread more by aphids from cultivated plant crops. It also originates progressively from different weed species and occurs after infection with infected seedlings or inoculum sources if it is not well controlled.

This is the first molecular event report of DsMV in Anthurium sp in the Mediterranean region of Turkey. Our results have shown reliable laboratory molecular methods with immunological ELISA and molecular RT-PCR analyses. Further advanced techniques such as Next Generation Sequencing should be used to confirm our results. Due to the fact that DsMV have been transmitted not only by aphids but also

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1234712365

by infected material and cuttings, certified plant materials, eradication and vector management are powerful strategies to overcome the DsMV disease. Otherwise, the disease transmitted to the open field rotates with vectors in every season and returns as an epidemiological threat of agroecological origin.

This paper additionally indicates that uncontrolled distribution of infected ornamental plants between countries will allow the spread of plant viruses. In the present paper RT- PCR was a standardized method for reliable detection of DsMV. The results have also revealed that all exported plant materials should be distributed with certain quarantine regulations.

The harvest should be made with sterilized cutting equipments by the practitioners. Otherwise, if eradication or sterilization rules are not followed, infection may spread to more plants and areas. Mechanical harvesting might cause more spread of DsMV than vector transmission in time. Moreover, correct decoding of molecular epidemiology codes may open new doors to the fight against DsMV. Deep impacts on the ecological environment can be prevented provided that virus vector relationships are understood correctly. Therefore, more detailed and multidisciplinary studies should be focused. Moreover, these studies should not only be limited to in vivo, but also projects that can be applied in vitro.

Abstract. The main aim of this study was to investigate the responses of agronomic traits, photosynthesis and glutamine synthase (GS) expression in different sugarcane (*Saccharum* L. spp. hybrids) varieties under different nitrogen levels. Sugarcane varieties GT11 (nitrogen inefficient) and GXB9 (nitrogen efficient) were planted at three levels of nitrogen supply, e.g. 0 kg/ha (low nitrogen level, L-N), 150 kg/ha (medium nitrogen level, M-N) and 300 kg/ha (high nitrogen level, H-N) of urea application. The agronomic traits, photosynthesis, and GS activity and expression were determined at different growth stages of sugarcane. The results showed that the plant height, stalk diameter, leaf area, chlorophyll content, net photosynthetic rate, GS activity and GS1 protein expression in GT11 increased with the increase of nitrogen application, while the plant height, stalk diameter, chlorophyll content, net photosynthetic rate, GS activity and GS1 protein expression in GXB9 reached the maximum on medium nitrogen level. The leaf area of GXB9 was always higher than that of GT11 on the same nitrogen level. Under the low and medium nitrogen levels, the activities of GS and expression of GS1 protein were higher in GXB9 than GT11. The transcription expression levels of *scGS1.a* and *scGS1.b* were down-regulated while that of *scGS1.c* up-regulated by the increase of nitrogen application level. In conclusion, the nitrogen inefficient sugarcane variety needs more nitrogen application, but excessive nitrogen application is not good for the nitrogen efficient sugarcane variety.

Keywords: *physiological characteristic, photosynthesis, molecular response, chlorophyll, nitrogen utilization*

Abbreviations: GS: Glutamine synthase; H-N: High nitrogen; L-N: Low nitrogen; M-N: Medium nitrogen

Introduction

Sugarcane is the most important sugar crop and a regenerative energy crop grown worldwide in tropical and subtropical areas, which contributes more than 90% of the total sugar in China (Li and Yang, 2015). Nitrogen is the main nutrition element of crops, it is required for protein synthesis, nucleic acid, phospholipid and many organic substances, and also plays an important role in photosynthesis. Previous studies have indicated that application of nitrogenous fertilizer is considered a significant measure to guarantee the productivity in sugarcane. However, excessive application of nitrogen fertilizer is common in sugarcane commercial production in China, and the application rate of urea is usually 500-700 kg/ha or higher, much higher than the world average. In our previous study, the effects of different nitrogen application levels (150, 300, 600 kg/ha urea) on

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1236712384

key enzymes of nitrogen metabolism and contents of related active substances in different sugarcane varieties were investigated, which indicated that the nitrogen metabolism of sugarcane was significantly enhanced with the increase of nitrogen application amount within a certain range of nitrogen application level (150-300 kg/ha urea) (Zhang et al., 2015). Over application of nitrogen fertilizer not only declines nitrogen use efficiency and increases the cost of sugarcane production, but also results in a series of negative effects such as cane quality degradation and agricultural environmental pollution (Bijay et al., 1995; Li et al., 2016).

Nitrogen assimilation is a vital process controlling plant growth and development. Plants absorb nitrogen in nitrate, ammonium and amino acid forms, and ultimately transform it into ammonium form. Majority of the organic nitrogen in plants is derived from the assimilation of ammonia into the amide position of glutamine by the enzyme GS (Lea and Miflin, 2011). GS is a key enzyme involved in the nitrogen assimilation and metabolism of nitrogen compounds, and is also the first enzyme to transformed inorganic nitrogen into organic nitrogen in plants. GS pathway of ammonia assimilation is of crucial importance for crop growth and productivity. In most plant leaves, GS mainly exists in the form of GS1 and GS2; the expression of GS1 was evidently affected by the concentration and the form of nitrogen, while the expression of GS2 was mainly affected by light (Edwards et al., 1990). For higher plant, GS1 are mainly distributed in the companion cells of leaf vascular tissue phloem. The main functions of GS1 are assimilating ammonia produced by endogenous protein degradation, amino acid catabolism and stored nitrogen source, involving in the transfer of nitrogen source, and reusing finally (Swarbreck et al., 2011). GS1 was generally encoded by 3-5 genes, for Arabidopsis, tobacco and maize, GS1 was encoded by at least five homologous genes (Keegstra and Cline, 1999; Keiki et al., 2004; Li et al., 2006; Lightfoot et al., 1988; Lothier et al., 2011; Tingey et al., 1988), and it was encoded by three genes in rice (May and Soll, 1999). Previous researches indicate that GS1.a mainly participates in nitrogen remobilization during leaf senescence and nitrogen migration under low nitrogen condition, and affects grains' size, number and grouting (Antoine et al., 2006; Bernard et al., 2008; Kusano et al., 2011; Mayumi et al., 2005). GS1.b is mainly responsible for the primary NH_4^+ assimilation in roots, nitrogen remobilization during leaf ageing, assisting in the primary nitrogen assimilation of GS2 (Bernard et al., 2008; Kazuhiro et al., 2013). GS1.c can ease the ammonia poisoning, and also remission nitrogen assimilation in grain growth period (Goodall et al., 2013). Nogueira et al. (2005) have identified and characterized the *GS1* (*scGS1.a*, *scGS1.b* and *scGS1.c*) in sugarcane.

To our knowledge, there is no report about the impact of different nitrogen levels on the *GS1* gene expression in sugarcane. The purpose of this study was to investigate the effects of different nitrogen application rates on plant growth and photosynthesis in different sugarcane varieties, the response of *GS1* in sugarcane to nitrogen levels, and further reveal the role of GS1 in nitrogen metabolism and the related regulation mechanism, to provide a reference for efficient nitrogen utilization and regulation in sugarcane.

Materials and methods

Experimental materials

The experiment was conducted at College of Agriculture, Guangxi University in Nanning, China. The sugarcane variety GT11 (Nitrogen inefficient variety) and GXB9

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1236712384

(nitrogen efficient variety) were used for the experiment (Zhang et al., 2015). The soil used for experiment was red soil with pH 7.32, organic matter 4.23 g/kg, total nitrogen 0.27 g/kg, total phosphorus 0.33 g/kg, total potassium 7.85 g/kg, alkali-hydrolyzable nitrogen 21.55 g/kg, effective phosphorus 8.4 mg/kg, and available potassium 96 mg/kg. Urea (N 46%) was used as the nitrogenous fertilizer.

Plant culture and nitrogenous fertilizer application

Single-budded seedcane sets of the two sugarcane varieties were planted in sands for germination under warm and wet condition on March 3, 2016. After 45 days, the healthy and consistent plants were selected and transplanted into plastic pots of 36.3 × 30 cm (height × diameter) filled with 20 kg soil, and two plants of the same variety were grown in each pot.

Three levels of nitrogen supply were set and applied after transplanting, that is, 0, 150 and 300 kg/ha, or 0, 1.55 and 3.10 g urea per pot were applied at seedling stage (May 15), referred to as the low nitrogen, medium nitrogen and high nitrogen levels, respectively. There was a low nitrogen content (total nitrogen 0.27 g/kg, alkali-hydrolyzable nitrogen 21.55 g/kg) in the soil used in the experiment, which could not be ignored. Therefore, we used the low nitrogen level to represent the actual nitrogen level in the soil even if we gave no nitrogen in the soil. Therefore, the experiment consisted of six treatments (two varieties and three nitrogen levels), and 9 replicates were arranged in a completely randomized block design, so total had 54 pots (*Fig. 1*).

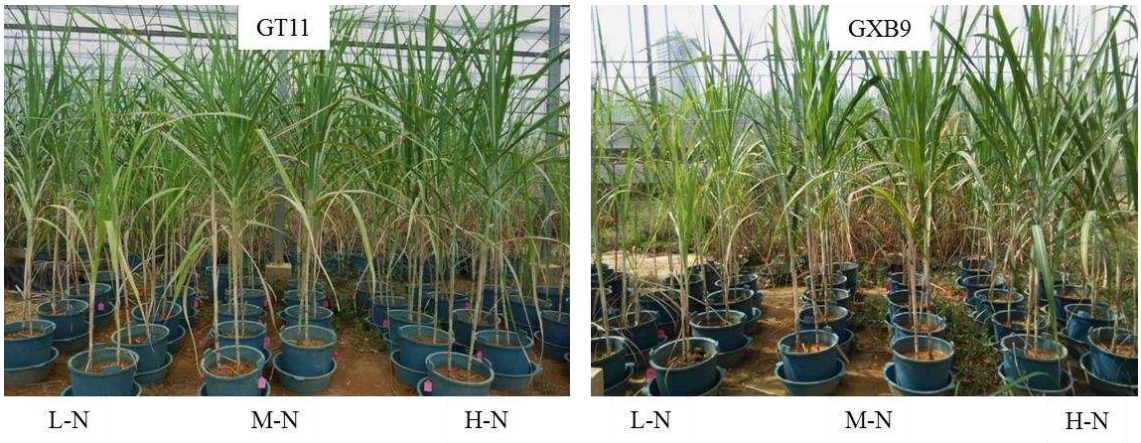

Figure 1. *Growth photos of two sugarcane varieties (GT11 and GXB9) under three nitrogen application levels at sampling day (2016-07-12)*

Sampling and assay

The leaf + 1 (the top visible dewlap leaf) was sampled on June 10, July 12, August 12, and September 15, respectively. Part of the fresh leaf sample was used for determination of GS activity with the method as described by Wei (2005), and the rest was frozen in liquid N_2 and kept at -80°C before use.

Investigation of agronomic traits

Nine plants were chosen randomly for agronomic trait investigation at sampling days after treatment. The plant height and stem diameter were estimated with conventional

methods. Leaf area of leaf + 1 was estimated using CI-203 Handheld Leaf Area Meter (CID Bio-Science, Inc., Camas, USA) and the leaf chlorophyll was estimated by SPAD readings measured with SPAD-502 chlorophyll meter (Konica Minolta, Inc., Tokyo, Japan).

Assay of photosynthetic rate

Net photosynthetic rate was measured using a LC Pro-SD portable photo system unit (Opti-Sciences Inc., Hudson, USA) at a photon irradiance of 1504 μmol m^{-2} s^{-1}. The measurement was conducted at a gas flow rate 200 μmol s^{-1}. Nine plants in each treatment were randomly selected for measurement from 9:00 to 11:00 am in the morning of September 3 when it was sunny.

Quantification of scGS1 gene expression on transcription level

The relative expression of *scGS1.a* (AY835453), *scGS1.b* (AY835454) and *scGS1.c* (AY835455) was quantified at the sampling days (June 10, July 12, August 12, and September 15, respectively) after treatment. The expression of *scGS1* in sugarcane leaf + 1 was performed in randomly selected 9 plants with a Light Cycler® 480II (Roche Applied Science, Basel, Switzerland) using the SYBR Premix Ex TapTM II (TaKaRa, Dalian, China) in accordance with the product manual. The GAPDH gene of sugarcane (accession number EF189713) was used as an internal control to quantify the relative transcript level. Specific primers for those genes were designed using the Primer Premier 5 software based on their cDNA sequences (*Table A1* in the *Appendix*). The relative level of gene expression was calculated using the $2^{-\Delta\Delta Ct}$ formula (Livak and Schmittgen, 2001).

Western blot analysis of scGS1 protein in sugarcane

Total soluble protein was extracted from sugarcane leaf with 100 mM Tris (pH 7. 8, containing 10 mM $MgCl_2$, 100 mM 2-mercatoetanol, 5% Polyvinylpolypyrrolidone) (Nogueira et al., 2005), and quantified using the method of Bradford (1976). For Western blot, denatured proteins were fractionated by SDS-PAGE [12.5% (w/v) polyacrylamide] according to Laemmli (1970) and transferred to nitrocellulose membrane as described by Towbin et al. (1979). Anti-GS1 primary polyclonal antibody was used to detect GS1 protein. Protein–antibody complexes were located using horse reddish peroxidase, and conjugated goat anti-rabbit immunoglobulin G. Pierce® ECL Western Blotting Substrate (Thermo, U.S.A.) was used for development and then observed under FluorChem HD2 (Alpha, Protein Simple, U.S.A.). The GS1 polyclonal antibody (AS08295, Agrisera, Sweden) and secondary antibody (Goat anti-rabbit lgG, HRP conjugated, CoWin Biosciences, Beijing, China) were purchased in a biological reagent company.

Data analysis

All the data were analyzed using Microsoft Excel 2010 and SPSS 21.0. ANOVA test was used to compare the mean values of each treatment. Significant differences between the means of parameters were determined by using the LSD test ($P < 0.05$).

Results

Effects of different nitrogen levels on agronomic traits in different sugarcane varieties

The data in *Table 1* show the growth rate of two sugarcane varieties under medium and high nitrogen levels increased with the course of growth, and the highest growth rate occurred between August and September. In general, the plant height and stem diameter in the variety GT11 increased with the level of nitrogen application. For the variety GXB9, the highest plant height and stem diameter were recorded on medium nitrogen level (*Table 1*). The leaf area of two sugarcane varieties significantly increased with the level of nitrogen application (*Table 1*). Under the same nitrogen level, the leaf area is basically characterized by GXB9 > GT11 (*Fig. A1* in the *Appendix*).

Data are presented as mean ± SE, and data points with different letters are significantly different ($P < 0.05$) between different nitrogen levels from the same sugarcane variety at the same time. L-N, low nitrogen level; M-N, medium nitrogen level; H-N, high nitrogen level

Effect of different nitrogen levels on chlorophyll content in different sugarcane varieties

Overall, the chlorophyll relative content in the variety GT11 is characterized by high nitrogen > medium nitrogen > low nitrogen levels, increased with the levels of nitrogen application. The chlorophyll relative content in the variety GXB9 showed the order of medium nitrogen > high nitrogen > low nitrogen levels (*Table 1*).

Effect of different nitrogen levels on net photosynthetic rate in different sugarcane varieties

At booming stage of sugarcane (September 3), the net photosynthetic rate in the variety GT11 was significantly higher in the high nitrogen treatment than the low

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1236712384

nitrogen treatment. For the variety GXB9, the net photosynthetic rate was significantly higher under medium nitrogen level than low and high nitrogen levels. Under low and medium nitrogen levels, the net photosynthetic rate was higher in the variety GXB9 than the variety GT11, but had no significant difference between them under high nitrogen level (*Fig. 2*).

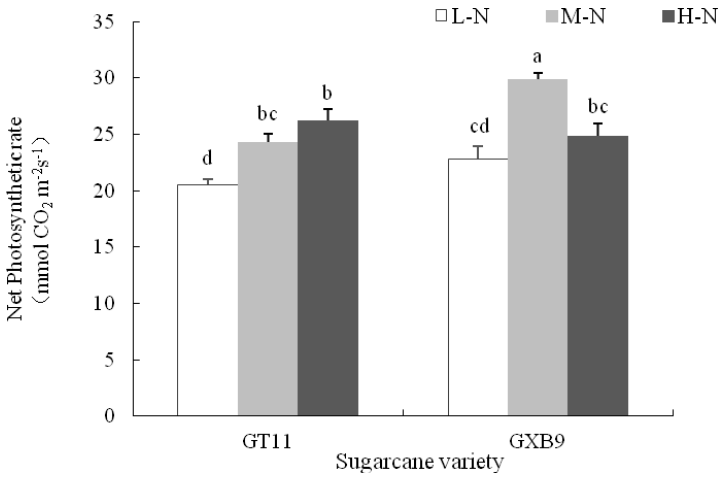

Figure 2. *Photosynthetic rate in leaves of two sugarcane varieties under different nitrogen levels measured on September 15, 2016. Treatments labeled with different small letters represent statistically significant difference at $P < 0.05$. L-N, low nitrogen level; M-N, medium nitrogen level; H-N, high nitrogen level*

Effect of different nitrogen levels on GS activity in different sugarcane varieties

The data in *Figure 3* showed that the GS activity in leaves of the variety GT11 increased with the level of nitrogen application (*Fig. 3A*), and peaked on August 12 in all the treatments except for the high nitrogen treatment in GXB9. The GS activity was significantly higher on high nitrogen level than that on low and medium nitrogen levels. The highest GS activity was recorded in the variety GXB9 under medium nitrogen level on August 12 (*Fig. 3B*). Under low and medium nitrogen levels, the GS activity was always higher in the variety GXB9 than the variety GT11 (*Fig. A2*), and this may be related to the higher biological nitrogen fixation ability and nitrogen efficiency of the variety GXB9.

Effect of different nitrogen levels on scGS1 expression in different sugarcane varieties

From *Figure 4,* we can see that for most treatments, *scGS1.a* expression was higher in August and September than June and July. *scGS1.a* expression tended to decrease with the level of nitrogen application in both sugarcane varieties. Under low nitrogen level, *scGS1.a* expression was higher in GXB9 than GT11 (*Fig. A3A*), while under high nitrogen level, *scGS1.a* expression in GXB9 is lower (*Fig. A3B*).

From *Figure 5,* we can find that in June and July, *scGS1.b* expression tended to decrease with the level of nitrogen application in both two sugarcane varieties except for that in GT11 in August and September when it showed the highest under medium nitrogen level.

The data in *Figure 6* showed that the *scGS1.c* expression tended to increase with the level of nitrogen application from June to September and the growth course from June to August in both sugarcane varieties. For different sugarcane varieties, the *scGS1.c* expression showed the order of GXB9 > GT11 under the same nitrogen level (*Fig. A4*).

Influence of different nitrogen levels on GS1 protein expression in different sugarcane varieties

The GS1 protein expression in the variety GT11 increased with the level of nitrogen application, and that in GXB9 reached the maximum under medium nitrogen level (*Figs. 7* and *8*). The GS1 protein expression is higher in GXB9 than GT11 under low and medium nitrogen levels (*Fig. A5*).

Discussion

Nitrogen is the biggest nutrient element for crop growth and development demand. However, excessive nitrogen fertilizer application will reduce plant nitrogen utilization efficiency and cause serious environmental pollution. Zhou et al. (2006) found that different sugarcane varieties responded differently to different nitrogen levels, and the sugarcane variety RB72-454 with high biological nitrogen fixation ability has better growth potential than others under low nitrogen condition. In this study, the plant height, stem diameter increased with the level of nitrogen application in the nitrogen

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1236712384

inefficient sugarcane variety GT11 while showed the highest at medium nitrogen level in the nitrogen efficient sugarcane variety GXB9 with high biological nitrogen fixation ability, which suggested that the responses of different sugarcane varieties to nitrogen application are varied, and nitrogen efficient sugarcane variety needs less nitrogen fertilizer application.

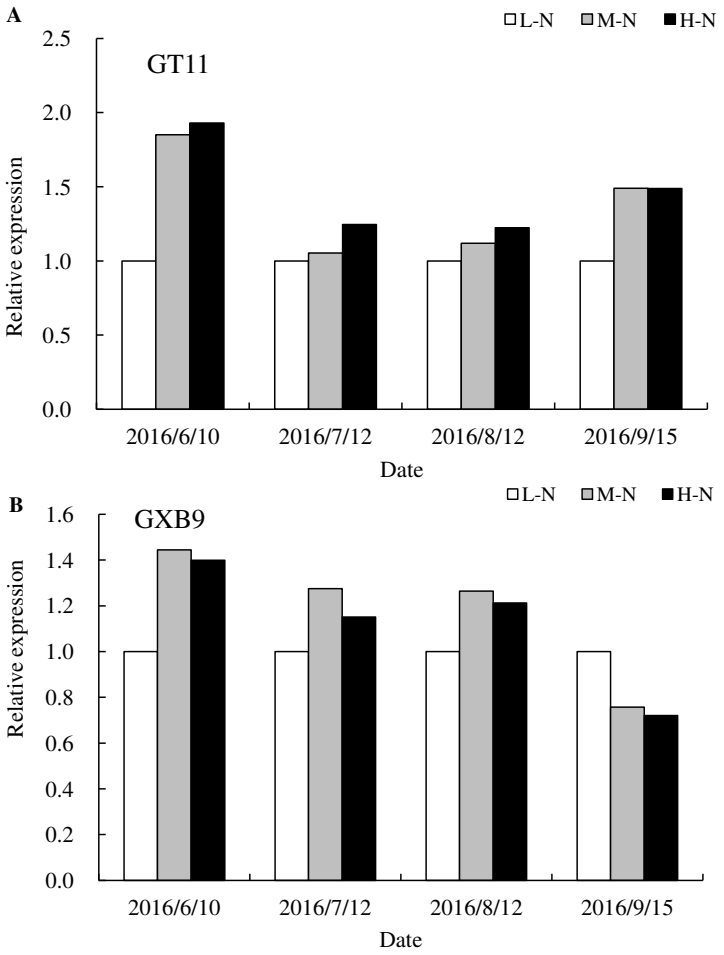

Figure 8. *Effects of different nitrogen levels on the expression of GS1 protein in different sugarcane varieties. L-N, low nitrogen level; M-N, medium nitrogen level; H-N, high nitrogen level*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1236712384

Accumulation distribution rate of nitrogen reached 60 to 80% in leaves, and the proportion of nitrogen in leaves increased with the growth course of sugarcane (Jiang, 2016). Sugarcane leaf segments had contrasting amount of chlorophyll, nitrogen and sugars (Mattiello et al., 2015). Nitrogen fertilizer application can obviously increase the chlorophyll content and leaf area in wheat (Li et al., 2007). In this study we found that sugarcane leaf area significantly increased with the increase of nitrogen application levels. We also found that appropriate nitrogen fertilizer application could increase the content of chlorophyll in leaves, which is consistent with the results reported by Shao et al. (2009).

Wu and Zhao (2010) reported that nitrogen has the best level range for promoting photosynthetic rate. Out of this range, photosynthetic rate decreases. Nitrogen efficient wheat genotypes have strong photosynthetic capacity under low nitrogen condition, but inefficient genotypes need sufficient fertilizer to get higher photosynthetic capacity and higher yield (He et al., 1999). N supply and the sugarcane ability to respond to N influenced photosynthesis (Bassi et al., 2018). In this study we proved that the photosynthetic rate increased with the increase of nitrogen level in the nitrogen inefficient variety GT11, while it showed the highest on the medium nitrogen level in the nitrogen efficient variety GXB9, and significantly higher in the latter than the former.

In this study, the GS activity in all the treatments presented a typical single peak during whole detection duration, and most reached peak on August 12. August belongs to the booming stage, and the plant growth needs large amount of nitrogen. Luo (2007) pointed out that nitrogen can significantly improve GS activity in rice leaf, and the GS activity presented a single peak during whole growth period and reached peak at the heading stage. In this study, the GS activity in the variety GT11 increased with the increase of nitrogen level, while that in the variety GXB9 presented medium nitrogen > low nitrogen > high nitrogen from August to September, which is similar to the result reported by Gui (2007). The variety GXB9 also showed high GS activity under low nitrogen condition, and it always showed significantly higher than the variety GT11, but it seems that high nitrogen has inhibitory effect on the GS activity in the variety GXB9. Nitrogen could induce GS gene expression (Higashi et al., 1998; Ortega et al., 2001). The expression of *GS1-1* in wheat was raised when the nitrogen supply decreased, and high NH_4^+ supply specifically induced *GS1-3* gene expression in barley and sorghum (Caputo et al., 2009; Elomari et al., 2010; Goodall et al., 2013). In the present study, the *scGS1.a* expression decreased with the increase of nitrogen application in the variety GXB9, while the highest under low nitrogen in the variety GT11, which is consistent with the results in wheat reported by Caputo et al. (2009). The relative expression of *scGS1.a* in plant showed the highest level under low nitrogen supply could reduce plant damage due to nitrogen deficiency. Robinson et al. (2007) used NH_4^+ labeled ^{15}N as nitrogen source in a sugarcane hydroponic cultural experiment, and found marked nitrogen transport from xylem to leaves accumulated in the form of glutamic acid and glutamine, forming a marked small nitrogen library. In the present study, the expression of *scGS1.a* was significantly higher in the variety GXB9 than the variety GT11 at the booming stage of sugarcane under the medium and low nitrogen condition, reflecting that the variety GXB9 could have stronger ability for transfer of nitrogen from library to source, which could be related with its low nitrogen resistance characteristics. At the early stage of the sugarcane growth, the expression of *scGS1.b* decreased with the increase of nitrogen application rate while the expression of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1236712384

scGS1.c increased with the increase of nitrogen application rate for both sugarcane varieties. The enzyme scGS1.c can accelerate the assimilation of NH_4^+ and reduce ammonia poisoning. The expression of *scGS1.c* is 15 times higher in the variety GXB9 than the variety GT11 in June, indicating that the NH_4^+ assimilation ability of the variety GXB9 is significantly higher than the variety GT11.

The results in the present study showed that, application of 150 kg/ha urea can keep or significantly increase the GS1 protein expression in the leaves of sugarcane variety GXB9, but more nitrogen fertilizer application rate was needed for the variety GT11. The GS1 protein expression level was higher in the variety GXB9 than the variety GT11, which indicated that the former has stronger low nitrogen endurance than the latter. GS1 protein in sugarcane was commonly encoded by the genes *scGS1.a*, *scGS1.b* and *scGS1.c*. We found that the relative expression ratio of *scGS1.a* : *scGS1.b* : *scGS1.c* on transcription level is approximately 60 : 26 : 0.6, which indicated that *scGS1.a* is the most highly expressed sugarcane *GS1* gene. We also found that the GS1 protein relative expression increased with the increase of nitrogen application in sugarcane. However, there was big difference between transcription expression and enzyme activity due to the influences of various factors. Ortega et al. (2001) reported that there is no GS enzyme activity increase when the GS1 gene transcription increased in alfalfa. GS enzyme in plants is in a dynamic process of biosynthesis and decomposition, and enzyme synthesis is positively correlated with the substrate concentration (Guan et al., 2007). Under low nitrogen condition, lack of GS substrate will cause primary oxidative modification of GS activity sites His residues, followed by protein conformation change or enzyme split, and the process will only be suspended until the GS peptides is hydrolyzed. It is thus clear that lack of substrate prompts enzyme decomposition under insufficient nitrogen condition, and rich substrate helps GS enzyme synthesis and keeps its stability under rich nitrogen conditions. It is also clarified that GS1 transcription level increased but the GS protein expression quantity decreased under low nitrogen condition in the present study.

Conclusion

The nitrogen inefficient sugarcane variety GT11 had the best performance in plant height, stalk diameter, leaf area, SPAD, net photosynthetic rate, GS activity and GS1 protein under high nitrogen levels, while the nitrogen efficient sugarcane variety GXB9 performed the best under medium nitrogen level. Under the low and medium nitrogen levels, the activities of GS and expression of GS1 protein were higher in GXB9 than GT11. The genes *scGS1.a* and *scGS1.b* had higher expression levels in leaves under low nitrogen level while the gene *scGS1.c* increased the relative expression level with the increase of nitrogen application rate. It is suggested that scGS1.a and scGS1.b be more important for nitrogen metabolism, possibly taking part in the nitrogen assimilation in sugarcane under low nitrogen level.

(Received 8th May 2019; accepted 16th Jul 2019)

Abstract. The study is based on establishing soil acidity and fertility of Vertisols after the mineral fertilisers had continuously been applied from 1984 to 2016. The two phosphorus (35 and 70 kg P ha^{-1}), the invariable nitrogen (120 kg N ha^{-1}) and potassium (66.4 kg K ha^{-1}) doses were used in Kragujevac location (central Serbia) for over 33 study years. The impact of fertilisation with mineral fertilisers on soil acidity, organic carbon content, the total N, P and K as well as on P, K forms balance and on some microelements (Fe, Mn, Cu and Zn) availability was studied at soil depths of 0-20 and 20-40 cm. After 33 years, the highest changes were noticed in the surface layer (0-20 cm), with an increase in the acidity level and a decrease in organic carbon content and in the total N. Simultaneously, a higher P and K content and a higher Fe and Mn mobility were established in the same soil layer whereas mineral fertilisers had no significant effect on the changes in chemical properties at 20-40 cm deep soils.
Keywords: *plant production, soil properties, nutrient, acidification, farming sustainability*

Introduction

Constantly used mineral fertilisers in conventional plant production were found to affect numerous soil properties. In this regard, continuously used nitrogen, phosphorus and potassium in mineral form were found to somewhat influence soil physical characteristics (Herencia et al., 2011; Suwara et al., 2016), and to a larger extent the soil chemical and biological properties (Belay et al., 2002; Zhong et al., 2010) as well as the soil enzyme activity (Piotrowska and Wilczewski, 2012; Chen et al., 2018). Soil physical and chemical properties and fungi diversity and abundance were also found to be significantly affected by long-term mineral fertilisation, especially in terms of fungi diversity reduction and soil acidification (Yan et al., 2019).

Soil and water contamination most often bring about soil acidification (Herencia et al., 2007; Undurraga et al., 2009). One of the solutions made to the potential harmful effect of the long-term and one-sided use of fertilisers is considered to be fertilisation management system managing the nutrients put into and taken out of the soil within the crop rotation system (Hirzel et al., 2011). Therefore, a reasonable use of the mineral fertilisers over a longer period of time may keep up or even upgrade the soil quality and its production capacities, too (Belay et al., 2002).

One of the best ways to assess how fertilisation affects fertility and other soil properties is through the long-term experiments (Mitchell et al., 1991). Such experiments may provide useful information about farming systems sustainability,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1238512396

particularly when fertilisers are invariably used and for quite a long time. That is why the current study was aimed at establishing the changes in soil chemical properties caused by these fertilisers on Vetisols in the central Serbia.

Materials and methods

Experimental location

The investigation was performed in a long-term trial field of the Centre of Small Grains, in Kragujevac (44º02´ N and 20º56´ E, altitude: 185 m asl), central Serbia (*Fig. 1*), on Vertisols (IUSS Working Group WRB, 2014). The study location of Kragujevac is approximately 113 km away from Belgrade.

Figure 1. *Study location map (Kragujevac, central Serbia)*

Climatic conditions of the study location

Based on the climatic data outlined in Walter climate-diagram (Walter et al., 1975) (*Fig. 2*), the annual air temperature of Kragujevac location averaged 12.2ºC and the total annual rainfalls averaged 673 mm over the last twenty years (Republic Hydrometeorological Service of Serbia, 1998-2017). July and August were found to be the hottest (22.9ºC and 22.4ºC, respectively) and January and December the coldest months (1.3ºC and 2.3ºC, respectively). On average, May (74 mm) and June (70 mm) were the rainiest and February (42 mm) and January (45 mm) the driest months.

Walter climate-diagram denotes that, on average, humid periods over the year were present from January to June and from September to December whereas dry periods prevailed in July and in August. According to Köppen classification (1936) and based on the previously outlined data, the climate of Kragujevac location could be determined as moderately warm and humid with hot summers and dry winters.

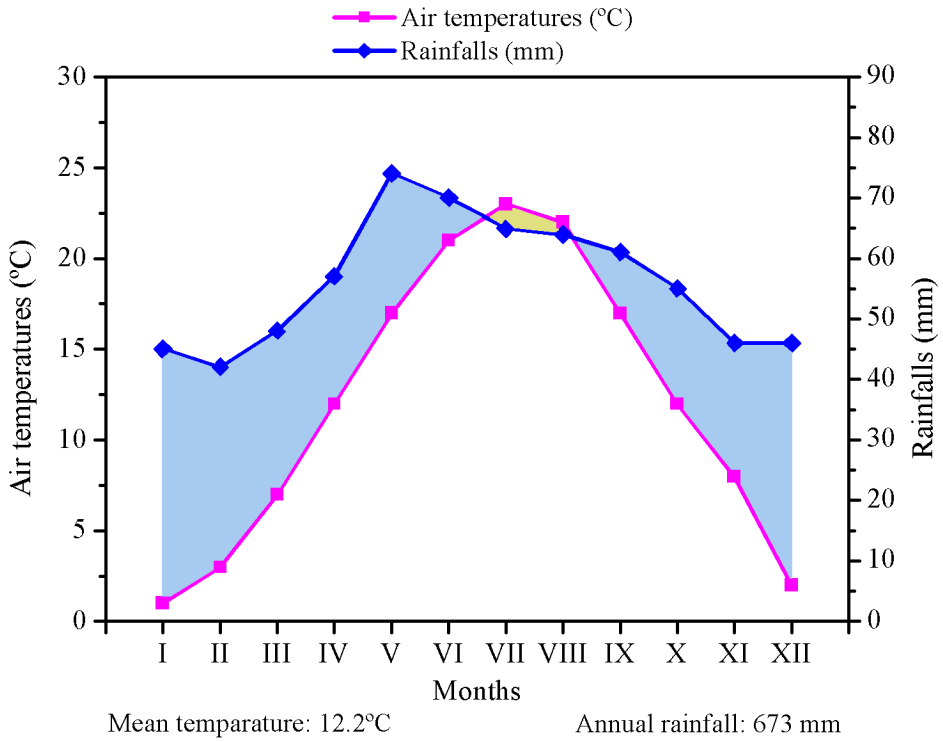

Figure 2. *Walter climate-diagram of research area (1998-2017)*

Agrochemical soil properties

The soil studied is characterised by lessivage process. Prior to the experiment, the soil had an excessive acid reaction, a low phosphorus content, moderate organic carbon (OC) and potassium content (*Table 1*). Soil acidity and the total and available K content were found to increase at 20-40 cm depth whereas OC content, total N and total and available P contents were found to decrease. The available Fe, Mn and Cu contents also decreased whereas Zn one increased.

Table 1. *Agrochemical properties before setting up of the experiment*

Depth cm	pH		Hh cmol kg^{-1}	OC %	Total			Available					
	H_2O	KCl			N	P	K	P	K	Fe	Mn	Cu	Zn
					%	mg kg^{-1}							
0-20	5.90	4.60	13.29	1.56	0.17	977.4	15000	260	186	71	118	2.4	1.7
20-40	5.90	4.47	11.11	0.96	0.11	763.6	15700	190	215	64	110	2.2	2.8

Experimental design

Having started in 1984, the experiment was continuoulsy carried out till 2016 within the two-field crop rotation of the winter wheat (*Triticum aestivum*) and of maize (*Zea mays* L.). Soil cultivation was typical of the existing environmental conditions with standard agronomical measures suiting maize and wheat used and plant remains from the previous vegetation removed.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1238512396

In the course of the experiment, the phosphorus doses were continuously used, the lower dose of 35 kg P ha^{-1} (P1) and the higher one of 70 kg P ha^{-1} (P2). The two P doses were combined with the constant N dose (120 kg N ha^{-1}) in the variants NP1 and NP2 with the constant N (120 kg N ha^{-1}) and K (66.4 kg K ha^{-1}) doses in the variants NP1K and NP2K. Nitrogen and potassium were also used in the same rates in the variant – NK. Fertilisation treatments were compared with the control treatment in which no fertilisers were used (0). Super-phosphate – $Ca(H_2PO_4)_2 \cdot CaSO_4$, urea – $CO(NH_2)_2$ and potassium chloride – KCl were used for fertilisation. Fertilisation technology was standard for each vegetation season, in which the total amounts of super-phosphate and pottasium chloride as well as 1/3 of urea were always applied before sowing. The remaining urea amount was used during vegetation depending on the climatic circumstances so that for wheat, it was used in the period from the end of March to the beginning of April and for maize during the second half of May.

The experiment proceeded according to the random system block design (RSBD) with four replications. Each plot was 15 m^2 in size. The average (composite) soil sample was taken for each treatment and formed from the five sub-samples. In every treatment, firstly at the depth 0-20 cm, the probe (Eijkelkamp) was used to take five individual samples (sub-samples) being mixed together and an average or composite sample was singled out from the total mass. The procedure was repeated for each treatment (0-20 cm) as well as for that of 20-40 cm. Composite samples (24 for 0-20 cm and 24 for 20-40 cm) were chemically analysed after the corresponding treatment. Soil samples were collected in the period from the 10^{th} to the12^{th} October, 2016 after the maize harvest.

Soil laboratory analysis

Soil pH was determined on the pH meter (MA 5730 ISKRA) in 1 : 2.5 suspension with water (AA) and l M KCl (SA). Hydrolytic acidity (Hh) was determined following the method of Kappen while the availability of phosphorus (AP) and potassium (AK) was determined following that of Egner-Riehm with ammonium-lactate (pH = 3.7) used as the extraction means. Upon the extraction, potassium was determined through the atomic absorption spectrometry (AAS) and phosphorus through spectrophotometry UV/Vis S2000 (WPA, England) after the colour had been developed with NH_4MoO_4 and $SnCl_2$. The total phosphorus (TP) was determined through spectrophotometry at the wave length of 400-490 nm after digestion with $HClO_4$ and treatment with ammonium paramolybdate-vanadate reagent (Olsen and Sommers, 1982) and the total potassium (TK) AAS after degrading the sample with mixture HF and H_2SO_4. Further, the content of soil microelements available forms (Fe, Mn, Cu and Zn) was determined through atomic absorption spectrophotometry (AAS) using the apparatus AAS N-1 (Carl Zeiss Jena, Germany). The available Fe (AFe) was determined after being extracted in the solution l M CH_3COONH_4 (pH 7). Determining the available Mn (AMn) content was done using the extraction means of 0.l M H_2SO_4 and that of Cu (ACu) and Zn (AZn) using 0.l M HCl.

Statistical analysis

The data obtained from the parameters were subjected to statistical analysis using the WinSTAT program being the statistics Add-In for Microsoft Excel (Copyright © 2018 Robert K. Fitch). The effects of treatment with fertilisers were tested using ANOVA and the differences between the treatments were registered using t-test for the levels of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1238512396

95 and 99%, whereas the balance of available microelements dependant on the substantial acidity and available P, was tested using the square regression.

Results and discussion

The experiment conducted for 33 years was characterised by monitoring acidifying of both layers tested. AA and SA were found to have significantly increased in the surface layer whereas Hh was found to have had just a mild increase. Thus, AA of 5.90 fell in the control variant after 33 years amounting to 5.57. In addition, SA pH in KCl decreased from 4.60 to 4.18 whereas Hh mildly increased from 13.29 cmol kg^{-1} to 14.10 cmol kg^{-1} for the same period. The process of somewhat milder acidification also prevailed in the 20-40 cm deep layer.

Table 2. *Characteristics of the acidity after 33 years of fertilisation*

Variants	pH		Hh

Lsd 0.01	0.091	0.094	0.238
	20-40 cm		
0	5.60 ± 0.10	4.40 ± 0.11	10.51 ± 1.44
NK	5.63 ± 0.11	4.16 ± 0.11	12.30 ± 0.11
NP1	5.50 ± 0.09	4.30 ± 0.11	10.92 ± 0.10
NP2	5.60 ± 0.09	4.33 ± 0.19	10.53 ± 0.17
NP1K	5.50 ± 0.09	4.23 ± 0.11	11.11 ± 0.11
NP2K	5.90 ± 0.13	4.26 ± 0.13	11.17 ± 0.20
Lsd 0.05	0.0679	0.084	0.408
Lsd 0.01	0.0929	0.116	0.559

In addition to the natural acidification, the long-term and continuous use of mineral fertilisers also favoured additional acidification of the Vertisol in both soil layers (*Table 2*) in that the acidification of the surface layer seemed to be more expressed. This may be accounted for by the fact that it was the zone of fertilisers used and, therefore, of their direct impact on this layer. In the 0-20 cm deep layer, the differences in AA, SA i Hh between the control variant and those with fertilisation appeared to be highly significant ($P \leq 0.01$). However, the highest acidification was established in NK variant, meaning that their long-term use increased acidity more significantly than their combination with phosphorus fertilisers did. Such a trend was expected considering that soil acidification over a long period of nitrogen fertilisation is well-known and already confirmed. However, the long-term and continuous application of the fertilisers, which, beside nitrogen, also contain phosphorus such as MAP, may often result in higher acidification (Belay et al., 2002; Saleque et al., 2004).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1238512396

Therefore, at 20-40 cm depth, the differences in AA between the control and fertilisation treatments were lower, denoting at fertilisation to have a lower impact on this type of acidity in deeper soil layers even after 33 years of being applied. On the other hand, the variations in SA and Hh between fertilisation and control treatments seemed to be more pronounced. Identically with the changes in soil acidity in the surface layer, those in the deeper ones also suggested the highest acidity in NK variant.

When comparing the initial (1984) organic carbon (OC) content and the total nitrogen (TN) one in 2016 in the control variant, study period was not found to be profoundly reflected on their balance. However, more significant changes did happen in the experimental stage with fertilisers applied (*Table 3*). Namely, in all the fertilisation variants, the OC content and TN one were significantly reduced in the surface layer compared to the control variant ($P \leq 0.01$). In contrast to the significant impact of the long-term fertilisation with nitrogen on sustaining and improving OC content (Bundy et al., 2011), the total and nitrate nitrogen (Zhang et al., 2012), then that contained in the fertilisers used over the current research had, however, no positive effect. The content of these two components could be expected to drop with the depth (*Table 4*).

Lsd 0.01	0.107	0.0107	118.57	726.46	5.99	5.58

OC: organic carbon; TN: total nitrogen; TP: total phosphorus; TK: total potassium; AP: available phosphorus; AK: available potassium

When phosphorus and potassium content in Vertisols are concerned with, the fertilisers containing these two elements were reported to directly influence their concentration in relation to the initial level in 1984. So, after 33 years, in all the variants with P fertilisers, the TP and AP content increased with variations in relation to the control and NK treatment was found to be statistically highly significant ($P \leq 0.01$) proportionally to the applied fertilisers rates. The highest changes were noticed in the surface layer while the long-term use of fertilisers strongly favoured the accumulation of the available forms in the zone of their input (Otto and Kilian, 2001; Cakmak et al., 2010).

Such a balance of phosphorus was influenced by both, phosphorus doses used on a year basis (35 and 70 kg ha^{-1}) and by its being incompletely utilised. Thus, in this layer, the same phosphorus rates were found to favour the accumulation of this element considerably more in NP1K and NP2K than in NP1 and NP2 variants. The long-term use of lower P rates with NP1K treatment favoured the increase in AP highly significantly ($P \leq 0.01$) compared with the higher rate used in NP2 treatment. Similar trend was reported for the fertilisers impact on TK and AK.

P content in 20-40 cm deep layer unambiguously suggested its barely slight mobility compared to its input zone (*Table 4*) whereas a much better mobility applied to potassium, with its content in the 20-40 cm layer considerably matching that in the surface layer. Therefore, the potassium introduced through fertilisation over 33 years of the experiment was continuously leached and more or less evenly distributed in the 40 cm layer being analysed.

Fertilisation lasting thirty-three years exhibited its effect on the available microelements forms content *(Table 5)* in that the highest available Fe content was established with NK and the lowest one with NP1 in 0-20 cm and with NP2K in 20-40 cm, respectively. Neither statistically significant differences between the variants with the highest and lowest Fe content were revealed nor those between the other variants, were. Contrary to Fe content, the lowest Zn content was recorded in both studied layers in NK variant in that in 0-20 cm layer the differences between NK and NP2 variants were statistically significant ($P \leq 0.05$) and those between NK and remaining variants

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1238512396

highly statistically significant ($P \leq 0.01$). As for 20-40 cm layer, highly significant differences could be recorded only between NK with the lowest Zn content and NP1K and NP2K in which the highest Zn content was established.

Thus, the lowest Mn content was recorded in NP1 and NP2 variants but with no clearly established effect of the phosphorus rate. On the other hand, Cu content decreased with fertiliser rate increased, with Cu lowest content established in the NP2 and NP2K variants.

The decreasing trend of active Mn and Cu forms with NP1 and NP2 variants in relation to the control and Zn with NK, NP1 and NP2 variants, was observed at the 20-40 cm depth, at which the lower content of all the four microelements analysed in relation to the surface layer, was also observed.

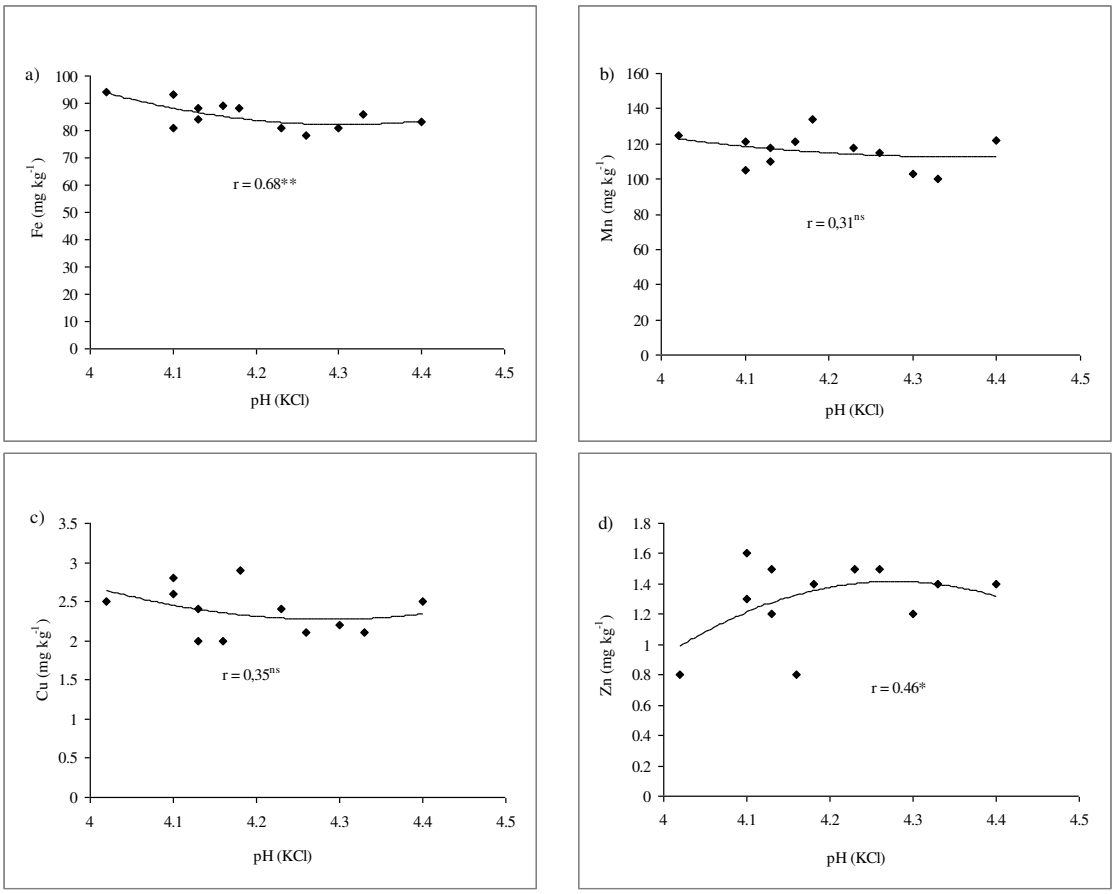

Figure 3. *The ratio between the available microelements forms rates (Fe, Mn, Cu, Zn) and pH (KCl) in the surface layer*

Therefore, the experience about fertilisers impact on the microelements available forms, some of which being Fe, Mn, Cu and Zn content in the soil, seemed to vary but mainly denying that mineral fertilisers had significantly altered their concentration (Rutkowska et al., 2009) and also stressing a more significant long-term use of organic fertilisers compared with the mineral ones (Li et al., 2010; Richards et al., 2011). As supported by Thakur et al. (2011), in addition to the organic, mineral fertilisers, of which particularly the phosphorus ones (Molina et al., 2009), mainly containing heavy metals (As, Cd, Cr) as well as numerous micronutrients, particularly Zn, may also

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1238512396

influence the microelements content. Thus, the input of P fertilisers may result in a higher Zn content, which was evident in NP1K and NP2K variants in both layers studied.

The availability of microelements in the soil may result from numerous factors, of which OC, soil response in the presence of the phosphorus soluble forms, take an important part (Wei et al., 2006; Asadu et al., 2014). Thus, micronutrients and toxic ions, cations availability, increased with the increase in soil acidity (Khabaz-Saberi and Rengel, 2010). When comparing the dependence between SA and Fe, Mn, Cu and Zn content in the surface layer, highly significant correlation between this trait of the studied soil and available Fe in it, could be found (*Fig. 3*). In addition, the correlation with the available Zn content seemed to be significant whereas no interdependence between Mn, Cu and SA was revealed.

Overall, significant correlation existed between the soluble forms of phosphorus and available Mn and Zn whereas it did not between phosphorus and available Fe and Cu content (*Fig. 4*).

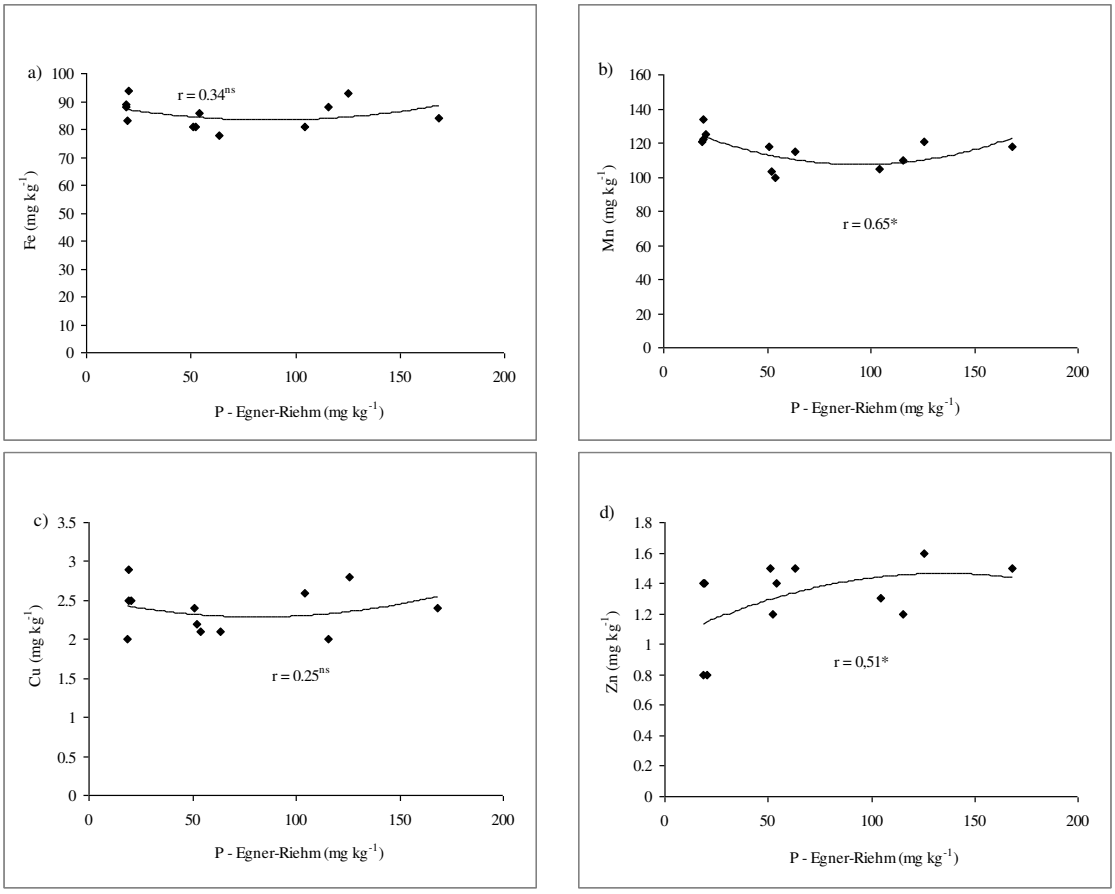

Figure 4. *The ratio between the available microelements forms rates (Fe, Mn, Cu, Zn) and the available P in the surface layer*

Conclusion

Mineral fertilisers, particularly nitrogen and potassium ones used over thirty-three years, were reported to have caused the acidification of Vertisol, reduced organic carbon content and the total nitrogen one in the surface layer. The changes in the same parameters seemed to be less expressed in the 20-40 cm deep layer. Simultaneously, the total and available phosphorus and potassium content increased in all the cases in which the fertilisers containing these two elements were used, being in proportion with their rates used. Due to low mobility, phosphorus remained in the input zone so that even thirty-three years of its continuous use exhibited a limited effect on its content in deeper horisons. To sum up, Fe, Mn, Cu and Zn available forms content was revealed to depend upon a fertiliser type and phosphorus amount introduced. While NK fertilisers exhibited a significant effect on Zn content, the NP and NPK ones had it on Mn and Cu content. Cu was also found to respond mostly to the amount of phosphorus input in that Cu availability forms decreased with increase in the phosphorus used.

Abstract. The aim of this study was to study the effect of meteorology and soil fertility on direct-seeded rice growing period and yield formation. A two year field experiment was conducted with six rice varieties (*Fengliangyou 2 (FYL-2), Fengliangyouxiang-1 (FLYX-1), Liangyou 168 (LY-168), Guofeng-1 (GF-1), Quanyou-801 (QY-801)* and *Japonica Rice-107 (WD-107)*) in Central China during 2017 and 2018. Two soil fertilities (high fertility and low fertility) were texted in present study. The result showed that the difference in temperature and sunshine hours during the growth periods between 2017 and 2018 induced the difference in growing period and grain yield. On the other hand, compared to low soil fertility, high soil fertility significantly increased grain yield of direct seeded rice by promoting panicle number and grain number. The highest yield was recorded in *QY-801* in both years and both soil fertilities, Quanyou-801 might be the most suitable variety for direct-seeded rice planting in Central China.
Keywords: *soil condition, yield, yield component, path analysis, fertilization method*

Introduction

As the main crop in China, rice is the first in terms of planting area and yield, thus, ensuring a stable increase in rice production is the basic condition of Chinese food security (Chen et al., 2016). As far as seedling raising methods are concerned, rice cultivation can be divided into direct seeding cultivation and transplanting cultivation. Compared with traditionally transplanted rice production system, the technology of direct-seed rice has the advantages of labor-saving, rice seedling field-saving, short growth period, high yield and high efficiency, and it is more suitable for large-scale cultivation and plays an important role in the process of agricultural mechanization in China (Pan et al., 2017). Direct-seeded rice is characterized by continuous growth, low tiller node position, rapid growth process, few leaves, rapid population formation and large scale (Hu et al., 2019). Its photosynthetic capacity is high in the early stage, low in the middle and late stages, and its yield formation is characterized by more panicles,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1239712406

smaller panicle type, and lower grain filling and setting level (Wang et al., 2018; Du et al., 2019). Normally, the yield of direct-seeded rice is not only affected by its own genetic conditions and acquired crop management, but also influenced by the environment of paddy field.

Meteorology and soil are the main influencing factors for rice growth and development. Some previous studies showed the influence of climate on rice performance. For example, the study of Mo (2017) found that temperature fluctuations at critical growth stages of rice may cause crop yield loss, shifts in crop growth periods as well as in sowing and harvesting times. Kong (2017) demonstrated high temperature during the grain filling stage not only reduced the fragrant rice yield, but also affected grain quality. Rao (1988) even obtained the correlations between weather parameters and the biomass of rice. As far as soil condition is concerned, there are regional differences in soil conditions in China and the spatial variation is small (Sun et al., 2008). Tang (2009) compares the influence of soil fertility on three major food crops and finds the soil contribution rate to rice production and basic yield. Seyfferth (2014) investigated the effect of arsenic concentrations in soil on major rice-growing regions in Cambodia. Furthermore, there is a significant difference in fertilizer contribution rate, basic soil contribution rate and yield when the same rice genotype grows under different soil conditions (Zou et al., 2015). However, there was no much study about environmental effect on direct-seeded rice performance reported.

Thus, present study was conducted in Hubei province (major rice producing province in Central China) in order to study the effect of different soil fertility and meteorology on direct-seeded rice performance in different rice genotypes.

Materials and methods

Experimental design and crop management

Two years experiment was conducted in Taihu Farm, Jingzhou City during 2017 and 2018 (longitude 30°34'57, dimension 112°04'78). Six rice varieties were used in present study: *Fengliangyou 2 (FYL-2), Fengliangyouxiang-1 (FLYX-1), Liangyou 168 (LY-168), Guofeng-1 (GF-1), Quanyou-801 (QY-801) and Japonica Rice-107 (WD-107)*, which are provided by Jingzhou Fulongxing Seed Industry Co., Ltd. The rice seeds were sowed into experiment fields on June 20, 2017 and 2018. Before sowing, the seeds were soaked in water for 24 h, germinated in manual climatic boxes for another 10 h (33°C), then shade-dried. Pre-germinated seeds of six rice genotypes were hill-seeded with direct-seeded machine into two different fertility soils at a space of 25 × 15 cm while each hill was planted with 3–5 seeds. The soil fertilities were shown in *Table 1*.

The treatments were arranged in randomized complete block design (RCBD) in triplicate with net plot size of 12 m^2. The temperature and sunshine hours during the experiment were shown in *Figure 1*.

Nitrogen fertilizer was applied to the field in the form of urea 1 day before sowing, rice 3 leaf stage and rice booting stage according to the ratio of 6:2:2. The total amount was N 134.60 kg hm^{-2}, and the phosphate fertilizer passed the superphosphate one day before sowing. The form is applied to the field at one time, the total dosage is P_2O_5 79 kg hm^{-2}, and the potassium fertilizer is applied to the field in the form of potassium chloride in the ratio of 7:3, 1 day before sowing and rice booting stage, the total dosage is K_2O 97 kg hm^{-2}. Fertilization management for two years is exactly the same. The

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1239712406

field management refers to the local rice high-yield management requirements, timely drying the fields, and doing pest control and weed control.

Table 1. *The fertility from two soil conditions*

	Total nitrogen (g kg^{-1})	**Total phosphorus** (g kg^{-1})	**Total potassium** (g kg^{-1})	**Available nitrogen** (mg kg^{-1})	**Available phosphorus** (mg kg^{-1})	**Available potassium** (mg kg^{-1})	**Organic matter** (g kg^{-1})	**PH**
Low	1.99	0.99	13.55	87.21	38.43	129.23	17.80	5.56
High	2.78	1.08	14.69	151.63	28.41	209.10	25.86	5.45

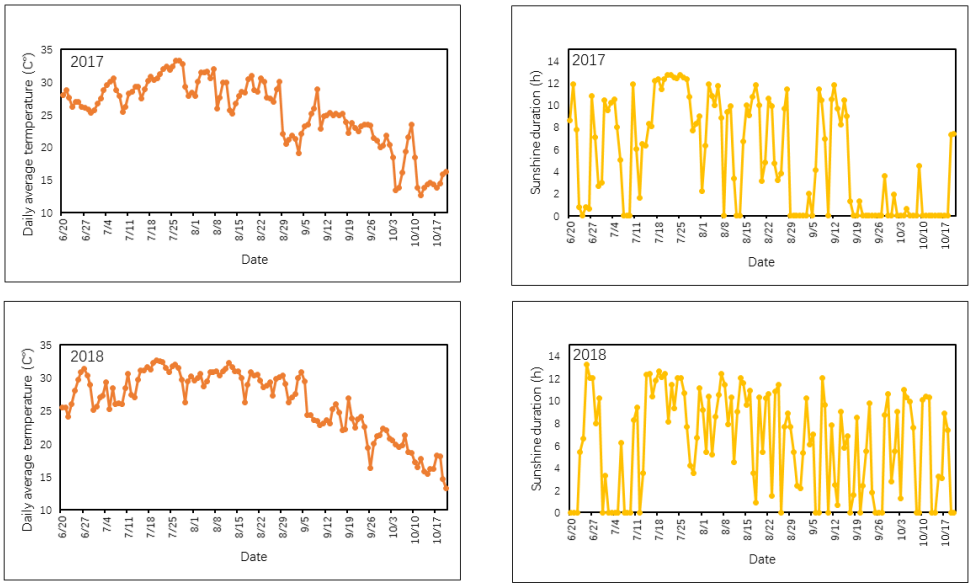

Figure 1. *The air temperature and sunshine duration during the experiment*

Water managements were followed as adopted by local farmers. No standing water was kept in the field from sowing to the three-leaf stage of rice, subsequently, the field was reflooded to about 3 cm water depth until the end of the tillering stage. Then, water was drained for about 7 days to control the production of non-productive tillers. At the following stages, water layer at soil surface was maintenance at 5 cm until grain filling stage. All other agronomic practices i.e., pest and diseases management, and weed control were the same in all treatments by following the guidelines and standards recommended by the province.

Determination of rice yield and growth period

After the direct-seeding, the three-leaf stage, booting stage, heading stage, flowering stage and maturity stage of rice were recorded. At maturity, the rice grains were harvested from ten-unit sampling area (10.00 m^2) in each plot and then threshed by machine. The harvested grains were sundried by a small thresher (150A, Maizhe, Hangzhou, China) and dried (101-0A, Keheng, Shanghai, China), then and weighed to estimate grain yield. Thirty hills of rice from different locations in each plot were sampled for estimating the average effective panicles number per hill. Six hills representative plants were taken for estimation of the yield related traits.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1239712406

Statistical analysis

Data were analyzed by using statistical software by ANOVA (SPSS, 21.0) while differences amongst means were separated by using least significant difference (LSD) test at 5% probability level. Graphical representation was conducted via Sigma Plot 14.0 (Systat Software Inc., California, USA).

Results

Growth period

The growth process of rice was shown in *Table 2*. It could be observed the growth period of all varieties is within 130 days, of which the growth period of 2018 is in the range of 113-125 days, and the whole growth period of *FLY-2* and *WD-107* under low soil fertility was 1 day longer than high fertility. However, there was no remarkable difference between two soil fertility conditions in other rice varieties.

Three-leaf stage (SS-TI): time from seeding to trifoliate; booting stage (SS-PI): time from tillering to booting stage; heading period (PI-HD): time from the end of the booting to the heading; maturity: time from the head to maturity; total growth period: the time from the start of sowing to maturity. The same below

The growth period in 2017 ranged between 115-130 days. The entire growth periods of *GF-1, FLY-2, WD-107* under low soil fertility were 1 more day than the high fertility, whilst there was no significant difference observed between different soil fertility among the other varieties. Moreover, the growth period in 2017 is 2 to 5 days older than 2018. The growth period of *FLY-2* in 2017 is 5 days longer than 2018 while other varieties were 2 to 3 days longer.

Grain yield and its related trails

As shown in *Table 3*, the yield of direct-seeded rice varies among years, soil fertilities and genotype. Compared to low soil fertility, high soil fertility remarkably increased the rice yield by 6.52% - 12.22%. The increment could be explained by the improvement in the panicle number. Compared with low soil fertility, the number of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1239712406

effective panicles increased by 0.56% - 8.51% due to high soil fertility. Moreover, higher grain number per panicles were recorded in high soil fertility than low soil fertility for *LY-168, FLYX-1, QY-801* in both 2017 and 2018. On the other hand, compared to 2017, lower seed-setting rates were recorded in 2018 for *GF-1, LY-168, FLYX-1*.

The same letter indicates that the variety is not significantly different under the LSD (0.05) method at the same place and year, and the same letter is reversed. The total line represents a comparison of differences between different fertility. The same below

Correlation analysis and path analysis

The correlation analysis between yield structure and yield was shown in *Table 4*. For low soil fertility, the effective panicle per had a negative significant correlation with both seed setting rate and grain weight whilst there exited a significant positive correlation between seed setting rate and grain yield. For high soil fertility, there exited a significant negative correlation between grain number and effective panicle whilst the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1239712406

grain yield had a significant positive correlation with both seed setting rate and 1000-grain yield.

The path analysis of yield structure and yield was shown in *Table 5*. The order of the effects of the two fertility on yield is 1000-grain weight > seed setting rate > effective panicle per unit area > number per panicle. The effective panicle number per unit area under low fertility had a high negative impact on yield through yield (-0.0676), with a high positive impact on yield through 1000-grain weight (0.0452), and the effective panicle number per unit area under high fertility through seed set rate (-0.0141) and 1000-grain weight (-0.0380) had a high negative impact on yield. The seed setting rate under two fertility conditions had a high positive impact on yield through 1000-grain weight.

Discussion

Present study investigated the effect of climate and soil fertility on direct-seeded rice yield and growing period. There are many factors which could affect the rice growing period such as climate, variety and cultivation management. Early study revealed a significant influence of water stress on growing period for rainfed lowland rice (Inthavong et al., 2011). Present study showed that the growth period of direct-seeded rice in 2017 was longer 2 to 5 days than 2018, which may attribute to the lower average daily temperature in 2017. This result agreed with the study of Fulu et al. (2013) who demonstrated that the increase in temperature will lead to the advancement of rice phenology and the shortening of growth period. The difference in growth period between varieties was large and it might be related to the difference in rice genotypes. However, there was no remarkable difference between two soil fertilities in rice

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1239712406

growing period and thus the growth period of direct-seeded rice might be mainly affected by climate condition and rice genotypes.

As far as yield formation was concerned, both soil fertility and meteorology had influences on direct-seeded rice yield in present study. The grain yield of GF-1, LY-168 and FLYX-1 in 2018 was significantly lower than 2017 and it could be explained by the decrement in seed-setting rate. Further reason might be related to the higher temperature of the flowering stage in 2017. Previous study already evidenced that heat stress could induce rice spikelet degeneration (Zhang et al., 2017). The study of Tang et al. (2018) also revealed that high temperature during the early grain filling stage could reduce rice yield by affecting the photosynthesis and antioxidant capacity. Furthermore, the study of Xuan et al. (2015) showed that average temperature at the flowering stage is higher than 30°C will reduce the rice seed setting rate. Moreover, we observed that the panicle number of *GF-1, LY-168* and *QY-801* in 2018 was higher than 2017. It might relate to the higher sunshine hour in 2018 during the experiment. This result was consistent with the research of Liu et al. (2013) who demonstrated there was a correlation between sunshine hours and rice productivity. On the other hand, present study showed that soil fertility greatly affected the yield formation of direct-seeded rice. Soil fertility is an important indicator of soil fertility. It is a measure of the ability of soil to provide various nutrients needed for crop growth and it is also the comprehensive expression of various basic properties of soil, the most essential characteristic of soil which is different from parent material and other natural bodies, and the material basis of soil as natural resources and agricultural means of production (Rahman and Parkinson, 2007). Compared with low soil fertility, the grain yield of all rice varieties increased due to high soil fertility and the increment was attributed to the enhancement in grain number and panicle number. It indicated that the rice plant could develop more effective tillers under high fertility conditions. Our result was consistent with early study (Fan et al., 2016) which indicated that higher soil fertility could improve rice yield and its related trail. Our result also agreed with the investigation of Yadivinder et al. (2004) who indicated that there was a correlation between rice yield and soil fertility. Early study also evidenced the benefits of improved soil fertility on irrigated rice performance (Haefele et al., 2000). Furthermore, the study of Huang et al. (2010) showed that A. bisporus residues return could induce positive regulation in soil nutrients, soil enzymatic activities, N use efficiency and crop yields as organic manure in a paddy soil.

Combined with correlation analysis and path analysis, it can be found that the 1000-grain weight is a factor which had the greatest impact on grain yield and is different from previous studies (Mirza et al., 1976) which showed that there was no significant correlation between grain yield and grain weight. The source of the difference was mainly caused by different varieties and cultivation management. Present study showed that soil fertility affected direct seeded rice yield by influencing the panicle number and grain number, however, the path analysis in this study divided two soil condition so that the difference in soil fertility was ignored. Therefore, the constituent factor that had the greatest impact on yield was not the panicle number and grain number. The effective panicle number under low fertility had a high negative impact on yield through the seed setting rate whilst the 1000-grain weight had a high positive impact on yield. Under high fertility, the number of effective panicles had a negative effect on the yield through seed setting rate and 1000-grain weight, which was related to the yield potential of rice. The light energy and the absorbed fertility are limited in the limited growth time of rice so the yield potential is limited (Du et al., 2018). Hence, the yield components are

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1239712406

generally negatively correlated. However, the number of effective panicles per unit area under low fertility didn't reach the highest level in present study, and the yield potential was not fully realized, so the yield could be increased by other yield components. The seed-setting rate had a high positive impact on yield through 1000-grain weight, indicating that the rice has not reached the rice yield potential level in the late growth stage, and rice self-regulation by strengthening individual growth may attribute to insufficient fertility in the later stage (Ren et al., 2017).

Conclusion

Present study showed that the growing period of direct-seed rice was mainly affected by climate and genotypes. The soil fertility, meteorology and genotypes all had impact on yield formation of direct-seeded rice. The soil fertility influenced the grain yield by affecting the panicle number and grain number. was affected by Different soil fertility affected grain yield and related trail significantly. In addition, considered the highest yield was recorded in *QY-801* in both years and both soil fertilities, Quanyou-801 might be the most suitable variety for direct-seeded rice planting in Central China. In order to revealed the mechanism of how meteorology and soil fertility affect the growth and development of rice, more study should be conducted at molecular and physiological level.

Abstract. The present work is an attempt to assess the effect of biostimulants derived from various materials on the yield and selected organic components in Italian rye grass against the background of nitrogen regime. A field experiment was arranged as a randomized subblock design (split-plot) in Poland in August 2013. The following factors were examined: type of biostimulant: Algex, Tytanit, Asahi SL and a control (no biostimulant addition); and nitrogen application rate: 0 (control); 120 and 180 kg ha^{-1}. The results reported here indicate that biostimulants applied in the study contributed to similar yield performance to plants fertilised with a 60 kg ha^{-1} lower nitrogen rate, the highest increase in yield (42.2%) being recorded for Algex-treated grass. An application of biostimulants beneficially affected Italian rye grass yield quality as it was followed by a significant increase in chlorophyll content in leaves as well as protein compounds and soluble carbohydrates in the dry matter of the test grass. The nitrogen rate of 120 and 180 kg ha^{-1} significantly increased Italian rye grass yields, chlorophyll content in plant leaves and protein compounds, the concentration of soluble carbohydrates being significantly lower in the dry matter of test plants.
Keywords: *grass, fertilisation, chlorophyll, protein compounds, soluble carbohydrates*

Introduction

Agriculture intensification has undoubtedly contributed to an increase in the effectiveness and efficiency of crop and animal production. Simultaneously, such farming relying on an application of high rates of mineral fertiliser and plant protection agents negatively influences soil effectiveness (Reguraman et al., 2019), and the quality of the final products. Moreover, it leads to natural environment degradation. In recent years, there has been an increase in the plant growth and frequency development regulator use frequency in crop production, also called biostimulants, in order to counteract intensive fertilisation, nitrogen application in particular. The products contain biologically active substances which affect metabolism and so make it possible to obtain higher plant efficiency (Kocira et al., 2015). On their own, biostimulants are not nutritional products but they increase nutrient uptake from soil (Brown and Saa, 2015). Growth stimulants are of either mineral or organic origins (Kocira et al., 2016) and are produced from algae and seaweed extracts (Algex), microorganisms, phytohormones as well as macro- and microelements (Tytanit, Asahi). An application of these products is safe for the environment (Tuhy et al., 2013) and may partly complement the influence of crop plant production chemicals, including mineral

fertilisation (Murawska et al., 2017). Relevant literature on the subject has demonstrated that individual biostimulants may have a different effect on yield quality and quantity, an increase in nutrient availability for plants, water retention ability, antioxidant content and chlorophyll production in plants (Khan et al., 2009; Sharma et al., 2014; Godlewska and Ciepiela, 2016a). Growth stimulants affect synthesis of natural plant hormones and an increase in their activity. According to research reports (Haider et al., 2012; Renuka et al., 2018), biostimulant application can also reduce abiotic and biotic stress of crop plants. Research has confirmed a positive effect of this type of products on crop plants, but it has also demonstrated that their effect is more dependent on crop plant species and cultivar than biostimulant rate (Sultana et al., 2005). Growth regulators are applied worldwide in vegetable and fruit production as well as cereals, oil seed rape and maize. However, there is still a paucity of reports on the efficiency of these products applied to fodder grasses constituting grassland established on ploughed land. Thus, the authors of the present work attempted to assess the effect of biostimulants derived from various materials on the yielding, chlorophyll content, protein content and simple sugars in *Lolium multiflorum* against the background of nitrogen regime.

Materials and methods

A field experiment was arranged as a randomized subblock design (split-plot) with three replicates at the Siedlce Experimental Unit of the University of Natural Sciences and Humanities in Poland (52.169° N, 22.280° E) in the second decade of August 2013. The plot area was 10 m^2. According to the Polish soil classification system (Systematics of Polish Soils, 2011), the soil used in the experiment was the culture soils with the hortisole type, developed from loamy sand. Based on the analysis performed at the Regional Chemical Station in Wesoła (*Table 1*). The following factors were examined:

- Type of biostimulant: Algex, Tytanit, Asahi SL and a control (no biostimulant addition)
- Nitrogen application rate: 0 (control); 120 and 180 kg· ha^{-1}

Table 1. *The chemical composition of soil*

pH in 1 n KCL	Content of soil				
	Humus (%)	Assimilable components (mg kg^{-1} of soil)			N – total (g kg^{-1} d.m. soil)
		$P_2O_4^-$	K^+	Mg^{2+}	
6.8	3.78	170	114	84	1.3

Algex is an extract of the sea alga *Ascophyllum nodosum* which contains vitamins, amino acids, phytohormones (auxins, cytokinins, gibberellins), polysaccharides, betaine as well as macro- and microelements such as N − 8%, P − 3.6%, K − 7%, B − 0.036%, Zn − 0.025%, Cu − 0.009%, Fe − 0.016%, Mn − 0.036% and Mo − 0.0036%. Algex is manufactured by Rosier, Moustier, Belgium.

Tytanit is produced by INTERMAG Ltd., Olkusz, Poland. Tytanit contains 8.5 g Ti per 1 dm^3 (0.8% m/m) in the form of Ti-ascorbate.

Asahi SL is produced by Arysta Life Science Ltd., Warsaw, Poland. The product contains the following phenolic compounds: sodium p-nitrophenolate − 0.3%, sodium o-nitrophenolate − 0.2% and sodium 5-nitroguaiacolate − 0.1%.

DOI: http://dx.doi.org/10.15666/aeer/1705_1240712418

The sowing rate of *Lolium multiflorum* Lam. cv. Dukat was calculated based on the standards drawn up by IMUZ (the Institute for Land Reclamation and Grassland Farming) (Jankowski et al., 2005). Standard cultivation methods were applied in the experiment and, additionally, plants were fertilised with different biostimulants.

The grass sowing rate was 31 kg ha^{-1} (TWG - thousand-grain weight – 2.8 g, 11071429 kernels per hectare). In 2013, when seeds were sown, neither biostimulants nor nitrogen fertiliser was applied. In October 2013 only one cut was performed at the plant height of 6 cm. Over the study period (2014-2015), the cutting regime consisted of three harvests per year. Ammonium nitrate was applied three times per year. The total nitrogen amount was split into three equal rates which were applied before each cutting. P and K fertilisation was applied to all the plots. Phosphorus was applied once as triple superphosphate at the rate of 40 kg ha^{-1} P_2O_5 in the spring. The amount of potassium (160 kg ha^{-1} K_2O) was split into three equal rates and applied prior to each cutting as 60% potash salt. The biostimulants was sprayed as an aqueous solution. The spraying was performed before each cutting: the first application was three weeks before the first cutting, the second one two weeks after the first harvest and the last one three weeks after the second harvest. Biostimulant rates following each cut were applied as recommended by the manufacturer, that is thinned with water to obtain the volume of 400 dm^3: Algex − 6 dm^3 ha^{-1}, Tytanit − 0.4 dm^3 ha^{-1}, Asahi SL − 0.6 dm^3 ha^{-1}.

Leaf chlorophyll was determined using a Minolta Chlorophyll Meter SPAD-502. It measures the light absorption by leaves at the wavelength of 650 and 940 nm. The quotients of light absorption at the two wavelengths are unitless and are called SPAD values. They reflect the leaf greenness index which corresponds to the total chlorophyll content (Blackmer and Schepers, 1994). Measurements were taken in each plot on 10 randomly selected grass leaves (top leaves) the day before harvest.

During harvest of each cut, green matter from each plot (whole area, that is 10 m^2) was weighed to determine the yield, and 0.5 kg green matter samples of grass were taken to determine the drying-up coefficient and to carry out chemical analyses. The samples were left to dry in a ventilated room. Airy dry matter was weighed (to determine dry matter yield per plot) and was then shredded and ground. The obtained material was subjected to chemical analysis to determine dry matter (by determining moisture content), protein compounds, and soluble carbohydrates. The method of determination was near-infrared spectroscopy (NIRS) using a NIRFlex N-500 spectrometer and ready-to-use INGOT calibration applications.

Statistical analysis was conducted using the program STATISTICA StatSoft, Inc. (2011), STATISTICA (data analysis software system), version 10 (www.statsoft.com). Significance of differences between means was checked using the Tukey test at the significance level of $\alpha \leq 0.05$.

Meteorological conditions during the study period were changeable and precipitation was very unevenly distributed (*Table 2*). The mean air temperature in the 2015 growing season was by 2 degrees lower than the mean across 2006-2015. By contract, unusual precipitation shortages occurred in September 2014, April and August 2015.

Results and discussion

The results of the research demonstrated that all the biostimulants affected Italian rye grass yielding. Regardless of the study years and nitrogen rate (*Table 3*), significantly higher grass biomass yields were determined following an application of biostimulants

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1240712418

compared with control yields of grass dry matter. Algex, Tytanit and Asahi contributed to an increase in biomass yield, respectively by 42.2, 27.3 and 18.8%, on average, compared with control yields. An application of Tytanit and Asahi significantly increased plant dry matter yields compared with control (where no biostimulants had been used). However, in each study year and for all the nitrogen rates biomass yields of plants treated with these biostimulants were significantly lower compared with biomass yields harvested in Algex-treated plots. Many authors have confirmed a positive effect of these biostimulants on yield amount for various crop plants (Nerrisa et al., 2016; Godlewska and Ciepiela, 2016b; Kovacik et al., 2018; Whitted-Haag et al., 2014; Przybysz et al., 2014). However, Lola-Luz et al. (2013) reported different results of their studies. Following an application of *Ascophyllum nodosum* extract, they found no statistical increase in cabbage yield. Thus, it should be noted that the effect of biostimulants may be highly influenced by crop plant species (Michałek et al., 2018) and further investigation of this issue is warranted.

Italian rye grass is a short-lived species as have been demonstrated by results of this research. In the first study year, yields of this grass species were by 49.6% higher compared with the second year, the differences being statistically significant.

Nitrogen regime significantly increased yields of the grass. In both the study years, increasing nitrogen fertiliser rates contributed to a significant increase in Italian rye grass yields compared with control where no nitrogen had been applied. The highest increase in Italian rye grass yield (by 73.9%), compared with control, was recorded in the second study year after the rate of 180 kg N ha^{-1} had been applied.

An increase in nitrogen rate was followed by a significant increase in the dry matter of the grass in the control unit and the biostimulant-treated plots.

Dry matter yields (t ha^{-1}) for individual cuts as affected by nitrogen regime and biostimulant type are shown in *Table 4*. Regardless of the remaining factors, the highest Italian rye grass biomass yields were harvested with the second cut, which may have been associated with meteorological conditions (*Table 2*). The yields differed significantly from those harvested with the first and third cut.

Regardless of nitrogen regime, biostimulants significantly increased Italian rye grass yields. Moreover, compared with control, higher dry matter yields were recorded for Tytanit-treated plants harvested with the first cut in units without nitrogen fertilisation, and Asahi-sprayed grass harvested in plots without nitrogen fertilisation and fertilised with 120 kg N ha^{-1}, the differences being statistically insignificant. It should be mentioned that, following an application of biostimulants, similar yields were produced at a lower (by 60 kg ha^{-1}) nitrogen rate.

Nitrogen fertilisation at the rate of 120 and 180 kg ha^{-1} resulted in a significant increase in Italian rye grass yields harvested with all the cuts compared with the biomass of the non-fertilised control.

Increased nitrogen rates contributed to an increase in the dry matter yield of Italian ryegrass in all the plots treated with the biostimulants and in the control unit although not all the differences were statistically significant.

Chlorophyll content in Italian rye grass leaves harvested with individual cuts as affected by nitrogen regime and biostimulant application is presented in *Table 5*. Regardless of biostimulant use and nitrogen fertilisation, chlorophyll content in the leaves of the test grass fluctuated significantly during the growing season. Chlorophyll content was the lowest in the leaves of grass harvested with the first cut, it being the highest in the leaves of plants harvested with the third cut. Similar results were reported by Ciepiela and Godlewska (2015).

DOI: http://dx.doi.org/10.15666/aeer/1705_1240712418

Regardless of the remaining factors, all the biostimulants applied in the experiment contributed to a significant increase in chlorophyll content in Italian rye grass leaves although their effect was not the same. Tytanit and Asahi significantly increased (by 14.6 and 21.8%, respectively) chlorophyll content in plant leaves compared with control grass which had not been treated with the biostimulants. A positive effect of biostimulants on chlorophyll amount in leaves has been confirmed by Kováčik et al. (2018), Radkowski (2013) who applied Tytanit, as well as by Borowski and Blamowski (2009) and Przybysz et al. (2014) who used Atonik (equivalent of Asahi). An application of Algex was also associated with an increase in chlorophyll content in grass leaves but the increase was barely 6.4% compared with control and it was insignificant. El-Miniawy et al. (2014) applied Algreen and observed an increase in chlorophyll content in strawberry leaves whereas Pacheco et al. (2019), who applied *Ascophyllum nodosum* extract, observed lower chlorophyll contents in *Achilleamille folium* L. leaves.

Analysis of the average chlorophyll content in Italian rye grass leaves revealed that the rate of 120 and 180 kg N ha^{-1} resulted in a significant increase in the amount of this pigment in the test grass leaves. Distribution of chlorophyll content in the leaves of plants harvested with individual cuts indicated that nitrogen regime had no significant effect on the characteristic tested for plants harvested with the first cut.

Increasing nitrogen rates significantly affected chlorophyll content in Italian ryegrass harvested in units treated with Tytanit. In the remaining plots, an increase in nitrogen rate contributed to an increase in chlorophyll content in the grass although the majority of the differences were statistically insignificant.

The concentration of protein compounds in the dry matter of Italian rye grass averaged 106.4 g kg^{-1} DM (*Table 6*) and was influenced by all the experimental factors. Regardless of the nitrogen regime and biostimulant application, the lowest amount of protein compounds was determined in grass harvested with the first cut, and the highest in the third cut, the differences being statistically significant.

Biostimulants tend to increase certain contents, for example protein content or sugars, affecting yield quality (Aydin et al., 2012; Kocira et al., 2017). In the study reported here, the average highest increase in the plant content of protein compounds following an application of Tytanit was 27.5% compared with control. Both Tytanit and Asahi significantly increased protein compounds in the dry matter of Italian rye grass harvested with all the cuts at each nitrogen rate. Also Algex had a positive effect on the amount of protein compounds in the test grass but the effect of an application of the biostimulant was frequently dependent on the cut and nitrogen rate. An application of this biostimulant resulted in a significant increase in protein compounds determined in grass harvested with the first and second cut in plots without nitrogen fertilisation, and with the third cut at all the nitrogen rates. There are research papers published worldwide which have confirmed a positive effect of the above-mentioned biostimulants on protein compounds in crop plants (Haroun et al., 2011; Ciepiela and Godlewska, 2015; Murawska et al., 2017; Hidangmayum and Sharma, 2017).

Nitrogen fertilisation significantly increased protein compounds in Italian rye grass dry matter. Their amount in plants harvested with all the cuts increased as increasing nitrogen rates were applied, the differences being statistically significant. Nitrogen applied at the rate of 120 and 180 kg ha^{-1} contributed to an increase in the dry matter content of protein compounds, the respective increases being 22.1 and 43.1%, compared with plants harvested in plots where no nitrogen had been applied.

Different lower-case letters within the same line indicate significant differences. Different uppercase letters indicate that the values in the column for individual factors (Dose N and Cut) and their interaction differ significantly

An increase in nitrogen rate was followed by a significant increase in protein content in Italian ryegrass grown in units which were either without biostimulant or treated with Algex or Asahi SL.

Soluble carbohydrates in Italian rye grass were affected by cuts, an application of biostimulants and nitrogen regime (*Table 7*). Regardless of the experimental factors, the average concentration of these compounds in dry matter was 123.7 g kg^{-1}. The highest concentration of soluble carbohydrates was determined in the grass of the cut harvested in spring, which may have been due to a substantial utilisation of these compounds because of increased plant respiration at high temperatures (the second and third cut) which makes use of sugars. Similar findings were reported in previous works which examined a biostimulant produced from brown algae applied to *Dactylis glomerata* and *Festulolium braunii* (Ciepiela and Godlewska, 2014).

Regardless of the cuts and nitrogen regime, all the biostimulants applied in the experiment significantly increased soluble carbohydrates in Italian rye grass compared with control plants (by 35.2%, on average). A positive effect of extracts obtained from sea algae on the concentration of soluble carbohydrates in plants has been reported by other authors, too (Zodape et al., 2010; Haroun et al., 2011). However, not all studies have confirmed the above tendencies. Cwalina-Ambroziak and Amarowicz (2012) applied Asahi SL and observed a decline in the sugar content of tomato and red pepper fruit.

Different lower-case letters within the same line indicate significant differences. Different uppercase letters indicate that the values in the column for individual factors (Dose N and Cut) and their interaction differ significantly

Nitrogen applied at the rate of 120 and 180 kg ha^{-1} significantly reduced soluble carbohydrates in Italian rye grass dry matter (by 21.4%, on average), regardless of the remaining experimental factors, compared with control where no nitrogen had been applied, the finding having been reported in earlier works of the authors of this paper.

Increased nitrogen rates were followed by the decline in solouble carbohytrates in the test grass harvested in units treated with different biostimulants although most of the differences were statistically insignificant.

Conclusions

Regardless of biostimulant application and nitrogen regime, Italian rye grass yield quality and quantity differed significantly for individual cuts and in study years. The highest concentration of chlorophyll in Italian rye grass leaves and protein compounds in dry matter were determined in plants harvested with the third cut. Significantly the highest amount of soluble carbohydrates was determined in the dry matter of Italian rye grass harvested with the first cut. The results reported here indicate that biostimulants applied in the study contributed to similar yield performance of plants fertilised with a nitrogen rate which was by 60 kg ha^{-1} lower, the highest increase in yield (by 42.2%) being recorded for Algex-treated grass. This finding indicates that it is possible to reduce nitrogen rates without compromising the yield, which is beneficial for the

DOI: http://dx.doi.org/10.15666/aeer/1705_1240712418

environment. An application of biostimulants beneficially affected Italian rye grass yield quality as it was followed by a significant increase in chlorophyll content in leaves as well as protein compounds and soluble carbohydrates in the dry matter of the test grass. Of the three biostimulants, the best effects were observed for Asahi-treated plants in terms of the concentration of chlorophyll in leaves and soluble carbohydrates, and for Tytanit-treated plants as far as protein compounds were concerned. The nitrogen rate of 120 and 180 kg ha^{-1} significantly increased Italian rye grass yields, chlorophyll content in plant leaves and protein compounds, the concentration of soluble carbohydrates being significantly lower in the dry matter of test plants. Treatment of Italian ryegrass grown for animal feed with the test biostimulants is reasonable because they contribute to an increase in plant dry matter yield, chlorophyll content, protein compounds and soluble carbohydrates at each nitrogen fertilisation level. It should also be stressed that yields harvested in biostimulant-treated units fertilised with 120 kg N ha^{-1} were higher compared with non-treated plots fertilised with 180 kg N ha^{-1}. Of the test biostimulants, Algex was superior in terms of yield-formation properties. The favourable results of the study reported here as well as the fact that the effect of biostimulants is species- or even cultivar-dependent are a stimulus to continue research into an application of biostimulants to other species of meadow plants.

(Received 10th May 2019; accepted 16th Jul 2019)

Abstract. The study was carried out to investigate the effect of broiler breeder age (35 and 50 weeks), storage period (2 and 6 days) and storage type (cooling, 30 °C hot room and partially oil covered in a hot room 30 °C) and their interactions on egg quality traits and hatchability of the Ross-308 broiler breeder eggs. The experiment included the measurements of the egg quality characteristics in the research laboratory. The results obtained from this experiment were summarized as the following: Broiler breeder ages had significant ($p \leq 0.05$) effects on some of the improved quality traits of the eggs such as: egg weight, albumin weight, yolk weight, haugh unit, yolk height, yolk index, hatchability and fertile egg hatchability percentage. Storage periods had significant ($p \leq 0.05$) effects on the egg weight, albumin weight, haugh unit, yolk index, hatchability and fertile egg hatchability percentage. Storage types (conditions) had significant ($p \leq 0.05$) effects on the egg weight, albumin weight, yolk weight, haugh unit, albumin and yolk percentage, albumin height, egg specific gravity and yolk height, yolk diameter, yolk index, hatchability and fertile egg hatchability percentage.
Keywords: *egg quality, storage period, storage type, egg storage, hatchability*

Introduction

Breeder age could be considered as one of the major factors affecting variability in egg characteristics, fertility, hatchability and broiler performance (Elibol et al., 2002; Guibert et al., 2012; Peebles et al., 2001). It is known that young breeders tend to have smaller eggs with higher proportion of albumen to yolk, lower albumen pH and higher shell thickness than eggs from old breeders (Peebles et al., 2000). Breeder age could be also a contributing factor to post- hatch performance of broilers, smaller yolk proportions of eggs from a young flock may be associated with low final body weight of their offspring (Ulmer-Franco et al., 2010). Hulet et al. (2007) reported that broilers from old breeders had higher body weight until 35 d compared to broilers from the young breeders. Generally, breeders kept in production till ages of 60-65 weeks. The main factors directly associated with egg deterioration are temperature and relative humidity, besides manipulation and storage period, however, during egg storage, some components of albumen and yolk may alter and tend to deteriorate egg quality (Feddern et al., 2017).

A storage duration beyond 7 d increases incubation duration (Tona et al., 2003) and has a negative effect on hatchability (Fasenko et al., 2001b; Tona et al., 2004; Yassin et al., 2008) and chick quality (Tona et al., 2003, 2004). The negative effects of prolonged egg storage may be caused by changes in egg characteristics, embryo quality or by both (Reijrink et al., 2008). Poor shell quality was associated with a higher percentage of egg moisture loss during incubation (Peebles et al., 2001) and low hatchability (Narushin and Romanov, 2002). It is suggested that prolonged egg storage may cause embryonic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1241912439

stress, manifesting in increasing embryonic necrotic and apoptotic cell death, decreased embryonic metabolism, and developmental delays; as a result, irreparable damage to the embryo may occur, thus resulting in increased embryonic mortality and decreased chick performance (Christensen et al., 2001; Fasenko, 2007; Hamidu et al., 2010).

Preincubation of hatching eggs before or during storage was reported to reduce the detrimental effects of periods of storage more than 7 d (Fasenko et al., 2001a; Reijrink et al., 2009). The effect of preincubation on hatchability was found to be influenced by the length of egg storage period and the developmental stage of the embryo before (Reijrink et al., 2009) or after (Fasenko et al., 2001a) the heating. According to Santos (2005), ambient temperature and prolonged egg storage negatively influenced the quality of eggs and significantly reduced the Haugh unit. Factors associated with the management and feeding of hens can play a role in internal egg quality, but egg handling and storage practices also had a significant impact on the quality of eggs reaching consumers (Jin et al., 2011).

The aim of this study was to investigate the effects of broiler breeder ages, egg storage periods and egg storage types on egg quality traits and hatching percentage.

Materials and methods

This study was conducted at the laboratory and poultry farm of College of Agricultural Sciences, University of Sulaimani, in Iraq. A total of (4200 eggs) of broiler breeder (Ross-308) were used in this experiment, at 35 and 50 weeks of breeder's age.

The experiment was divided in to two stages, the first stage included storing the eggs for 2 and 6 days in three types of storage conditions including (cooling, hot room 30 °C and partially oil covered in hot room), followed by the second stage which started to measure the egg quality characteristics in the laboratory.

The experimental studied factors were as the following:
Factor one: included two levels of broiler breeder ages (35 and 50) weeks.
Factor two: included two levels of storage periods (2 and 6 days).
Factor three: included three levels of storage type (storing of the eggs in cooling, hot room at 30 °C and partially covered the eggs (blunt side) with oil in the hot room).

Egg test

Two thousand one hundred (2100) eggs were taken from each different breeder ages and 1050 eggs were stored for each 2 and 6 days in the three types of storage condition where 350 eggs selected for each type (storage types were denoted by cooling = C, hot room 30 °C = H and partially oil covered in hot room = O), after storage periods 50 eggs from each group were taken to measure the quality characteristic of the eggs and remain 300 eggs to for measure hatchability percentage.

Egg weight (g)

The eggs were weighed individually using sensitive electric balance type Mettler toledo (max = 101 g and e = 0.1 mg) and recorded in gram (*Fig. 1*).

Albumin weight (g)

After yolk separation from albumin, albumin was weighed by using sensitive electric balance type Mettler Toledo (max = 101 g and e = 0.1 mg) (*Fig. 2*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1241912439

Figure 1. *Sensitive electric balance type Mettler Toledo used to measure egg weight*

Figure 2. *Sensitive electric balance type Mettler Toledo used to measure albumin weight*

Yolk weight (g)

After yolk separation from albumin, yolk was weighed by the same balance (*Fig. 3*).

Shell weight (g)

Shell weight was calculated by the following equation:

$$\text{Egg shell weight} = \text{Egg weight (g)} - \text{Yolk with albumin weight (g)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1241912439

Figure 3. *Sensitive electric balance type Mettler Toledo used to measure yolk weight*

Yolk, albumin and shell percentage

Traits were calculated by the following equations:

$$\text{Yolk } \% = \frac{\text{Yolk weight } (\text{g})}{\text{Egg weight } (\text{g})} \times 100$$

$$\text{Albumin } \% = \frac{\text{Albumin weight } (\text{g})}{\text{Egg weight } (\text{g})} \times 100$$

$$\text{Shell } \% = \frac{\text{Shell weight } (\text{g})}{\text{Egg weight } (\text{g})} \times 100$$

Yolk, albumin ratio

The following equation was used to measure this trait:

$$\text{Yolk, albumin ratio} = \frac{\text{Yolk weight } (\text{g})}{\text{Albumin weight } (\text{g})}$$

Albumin height (mm)

Albumin height was recorded after pouring albumin on the phial-layer by Spherometer (*Fig. 4*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1241912439

Haugh unit (HU)

Haugh unit was calculated depending on the albumin height (mm) and egg weight (g) by the following equation:

$$HU = 100 [\log (H + 7.57 - 1.7 W^{0.37})]$$

H = height of albumin (mm)

W = weight of egg (g)

Figure 4. *Spherometer used for measure albumin height*

Yolk height (mm)

Yolk height was recorded by the Spherometer after pouring yolk in to the Petri-dish (*Fig. 5*).

Yolk diameter (mm)

Yolk diameter was recorded by the same Vernier after pouring yolk in to the Petri-dish (*Fig. 6*).

Yolk index

Yolk index was calculated depending on the yolk height and yolk diameter (mm) by using this equation:

$$\text{Yolk index} = \frac{\text{Yolk height}}{\text{Yolk diameter}}$$

Egg specific gravity

Egg specific gravity was recorded after storing the eggs. Eggs were put-in the 9 of salt solution and egg specific gravity takes the same specific gravity of solution that float it.

DOI: http://dx.doi.org/10.15666/aeer/1705_1241912439

Figure 5. *Spherometer used for measure yolk height*

Figure 6. *Digital Vernier used for measure yolk diameter*

Fertility and hatchability

These traits were calculated by the following equations:

$$\text{Fertility } \% = \frac{\text{No. of fertile egg}}{\text{No. of total settable eggs}} \times 100$$

$$\text{Total egg hatchability } \% = \frac{\text{No. of hatched chicks}}{\text{No. of total egg set}} \times 100$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1241912439

$$\text{Fertile egg hatchability \%} = \frac{\text{No. of hatched chicks}}{\text{No. of fertile eggs}} \times 100$$

Statistical analysis

The present experiment was conducted using Completely Randomized Design (C.R.D) with three factors namely broiler breeder ages, storage periods and storage types to study the effect of these factors on the egg quality and hatchability traits. Statistical analysis was accomplished using (Xlstat-2017 Program for Windows version 19.6). Duncan's multiple range tests were used to determine the significance of differences among treatments means. Level of significance used in all results was ($P \leq 0.05$).

Results

Egg weight (g) and albumin weight (g)

The effects of interactions between broiler breeder ages, storage periods and storage types had significant ($p \leq 0.05$) effect on egg weight (g) (*Table 1*), the highest weight (58.179 g) was recorded by broiler breeder 50 weeks of age with 2 day of storage period and cooling condition of storage type and the lowest weight (46.931 g) was recorded by broiler breeder 35 weeks of age with 6 day of storage period and hot room condition of storage type.

Table 1. *Effect of interactions between breeder ages, storage periods and storage types on egg weight (g) and albumin weight (g) (mean ± SEM)*

Factors			Traits	
			Egg weight (g)	Albumin weight (g)
Breeder ages (week) × Storage periods (day) × Storage types (C, H and O)

Egg specific gravity and yolk height

Also, The effects of interactions between broiler breeder ages, storage periods and storage types had significant ($p \leq 0.05$) effect on egg specific gravity (*Table 6*), the highest value (1.090) was recorded by both broiler breeder 35 and 50 weeks of age with 2 day of storage period and cooling condition of storage type and the lowest (1.070) was recorded by broiler breeder 35 weeks of age with 6 day of storage period and hot room condition of storage type, also, the value (1.070) obtained from breeders 50 weeks of age with 2 and 6 day of storage period and hot room condition of storage type.

The interactions between broiler breeder ages, storage periods and storage types had significant ($p \leq 0.05$) effect on yolk height (mm) (*Table 6*), the highest value of yolk height (19.290 mm) was recorded by broiler breeder 50 weeks of age with 2 day of storage period and cooling condition of storage type and the lowest (16.300 mm) was recorded by broiler breeder 35 weeks of age with 6 day of storage period and hot room condition of storage type.

Table 6. *Effect of interactions between breeder ages, storage periods and storage types on egg specific gravity and yolk height (mm) (Mean ± SEM)*

Factors			Traits

		O	$36.010^{cd} \pm 0.35$	$0.510^{ab} \pm 0.45$

Means values in the same column having different superscripts are significantly different at $P \leq 0.05$. Means values in the same column having the same superscripts are not significantly different at $P \leq 0.05$. C = cooling, H = hot room 30 CO and O = partially oil covered in hot room

Hatchability and fertility percentage

The interactions between broiler breeder ages, storage periods and storage types had a significant ($p \leq 0.05$) effect on value of hatchability (*Table 8*), the highest value (91.00%) of hatchability was recorded by broiler breeder 50 weeks of age with 2 day of storage period and cooling condition of storage type and the lowest value (32.33%) was recorded by broiler breeder 50 weeks of age with 6 day of storage period and hot room condition of storage type. Also, there were no significant ($p \leq 0.05$) effects of interactions between broiler breeder ages, storage periods and storage types on fertility (*Table 8*).

Fertile egg hatchability

The interactions between broiler breeder ages, storage periods and storage types had significant ($p \leq 0.05$) effect on values of fertile egg hatchability percentage (*Table 9*), the highest value (96.26%) of fertile egg hatchability was recorded by broiler breeder 35 weeks of age with 2 day of storage period and cooling condition of storage type and the lowest value (35.14%) was recorded by broiler breeder 50 weeks of age with 6 day of storage period and hot room condition of storage type.

Discussion

The increase of egg weight with advancing age of broiler breeders (older breeders) may be due to increase the parts of egg components (especially yolk and albumin weight) giving more growth and activation of the reproductive system of broiler breeders compared to younger breeders. This can be explained by the associated increase in egg weight with age. Similar results were reported by several investigators with respect to egg weight increase with advancing age of broiler breeders (Javid et al., 2016; Akyurek and Okur, 2009; Yildirim, 2005; Vieira et al., 2005).

Also, the results of the present study indicated that egg weight of fresh egg decreased and egg weight loss increased with prolonged eggs storage period and storage condition. When the storage period is extended the egg weight declines due to loss of moisture from the egg, and the value of egg weight in oil covered was similar to eggs stored in cooling condition, because of the oil covered condition preventing the loss of more moisture from the eggs compared with un covered eggs in the hot room. These results with respect to the effect of storage period on egg weight loss agreed with those of Reijrink et al. (2010) and Gonzalez (2010).

Gualhanone et al. (2011) also, showed that heavier eggs resulted in heavier chicks, as expected, corroborating several authors that reported a positive correlation between egg weight and chick weight, older breeders with heavier eggs produced heavier chicks, irrespective of incubation temperature, chick weight is an important factor in broiler growth, since it was reported that there is a positive and strong correlation between chick weight at hatch and broiler market weight (42 to 45 days of age). Similar results were reported by several investigators with respect to egg weight increase with advancing age of breeders (Yildirim, 2005; Vieira et al., 2005; Zakaria et al., 2009). This severe effect of older breeders may be considered as a method of improving the percentage of high quality chicks obtained from older breeders.

The increase in the albumin egg weight in older breeders may be due to more growth and activation of the reproductive system of females compared to younger breeders (Javid et al., 2016). And albumin weight was decreased with a longer storage period of egg and storage condition, this is caused by water loss or migration from the albumin. These results were in agreement with the suggestions of Yeasmin et al. (2014) and Jin et al. (2011) whom reported that the albumin weight was greatly influenced by the storage temperature condition and storage period of the eggs.

Generally, the present study showed that the interaction between the main factors showed clearly the decreased the egg weight and albumin weight for old broiler breeders (50 weeks), this was may be due to the storage periods and storage condition that caused the loss of moisture from the egg. The present results are very similar to those reported by Reijrink et al. (2010), Gonzalez-Redondo (2010) and Jin et al. (2011).

Yolk weight increasing by progressing the age may be due to more activation of reproductive system of females and liver activity compared to younger breeders; these results were similar to the finding by Javid et al. (2016) that recorded the increase in egg components by old breeders compared with young breeders. And yolk weight increased with a longer storage period of egg and storage condition this was caused by some of water migration from the albumin to the yolk, these finding of the present study were in agreement with chose by several authors (Khan et al., 2014, 2013; Demirel and Kirikci, 2009) who reported positive correlation between increased yolk weight with increased storage periods and condition. The interaction between the main factors showed clearly the increase of yolk weight for old broiler breeders (50 weeks) was caused by activity of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1241912439

reproductive system of females and liver, and for storage periods and conditions, this was may be due to the and migration of moisture from the albumin to the yolk. The results were very similar to the results reported by Javid et al. (2016), Khan et al. (2014, 2013) and Demirel and Kirikci (2009).

According to the present results there were no effects of main factors and their interactions on shell weight, however, numerically shell weight increased with advancing of age in broiler breeders and the other factors (storage periods and storage conditions) had no effect on shell weight. These findings were in line with Yeasmin et al. (2014), Akyurek and Okur (2009) and Silversides and Scott (2001), who reported no effect of storage period and storage temperature on egg shell weight.

Albumin and yolk percentage of eggs were affected significantly by storage conditions and the interaction between broiler breeder ages, storage periods and storage conditions. When decreased albumin ratio already increased yolk ratio, this was because albumin loses more water than yolk, which caused a proportional increase in yolk ratio. The results were similar to the finding of Demirel and Kirikci (2009) and Kırıkçı et al. (2005) whom found the effect of storage period on albumin and yolk percentage.

The cause of affecting of interaction between broiler breeder ages, storage periods and storage type conditions on increasing of shell percentage may be due to decrease of other eggs component ratio during storage period. Shell ratio determined in the present study was similar to the finding of Demirel and Kirikci (2009).

According to the results there were no effects of main factors and their interactions on yolk albumin ratio. However, numerically there was a little difference between the interactions of main factors; this is may be due to the variety and the proportion of the yolk and albumin of eggs during the storage periods and storage conditions. These results were in agreement with those suggested by Suk and Park (2001).

In the present study, there was not effect of broiler breeder ages on albumin height, but there was a significantly effect of interactions between broiler breeder ages with storage temperature condition on albumin height. These results were consistent with the findings of Yeasmin et al. (2014) and Silversides and Scott (2001), who reported the reduction of albumin height was due to the decrease in thick albumen height, because of breakdown of the ovomucin-lysozyme complex during storage periods.

In the present study the storage of eggs clearly reducing of (HU) between young and older breeders. Also, these disparate effects caused by the influence of interaction of age with storage (Tona et al., 2004), these results may be due to increase of egg weight and albumin height of eggs from old broiler breeders compared to young broiler breeders. This result of reduced HU was due to age of broiler breeders or storage periods which were consistent with the reports of Akyurek and Okur (2009), Tona et al. (2004) and Silversides and Scott (2001).

The results showed that Haugh unit values decreased with increased egg storage periods and conditions in the present study, water loss from the egg, or migration of water from the albumen to the yolk or evaporation from the eggs components is the most likely reason of it. These results were consistent with the findings of Monira et al. (2003), who reported that values decreased with storage period. The present results relating to the effect of storage period on Haugh unit were similar with the findings of Grashorn et al. (2016), Alsobayel and Albadry (2011), Nowaczewski et al. (2010), Demirel and Kirikçi (2009) and Tilki and Saatçi (2004), who reported that the Haugh unit significantly decreased with increasing days of storage, due to loss of water from the eggs.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1241912439

There was no significant effect of broiler breeder ages on egg specific gravity, these results were in agreement with Gualhanone et al. (2011) and Akyurek and Okur (2009), who reported that no effect of breeder age on (ESG). On the other hand, specific gravity of eggs declined gradually with the advancing storage period as a resulted in maximum decreases at hot room of storage condition in both covered and non-covered with oil, but the specific gravity of eggs kept at room temperature declined more rapidly than that of cooling temperature condition, this might be due to the size of the air cell with increase of storage period and temperature the size of the air cell increased. These results were in agreement with Yeasmin et al. (2014), Alsobayel and Albadry (2011) and Akyurek and Okur (2009), who observed the size of the air cell increased with different storage temperatures.

In the present study the yolk height values were increased by advancing the age of broiler breeders, this was may be due to the size of yolk in heavy egg (this was clearly observed in continued *Table 1* that the highest egg weight (58.179 g) was recorded by broiler breeder 50 weeks of age with 2 day of storage period and cooling condition of storage type) compared to light egg, but yolk height decreased with increase of storage periods and storage temperature, this was may be due to the decrease of the strength of vitelline membrane that caused loss a little of water from the yolk and finally it caused the change in yolk index value. These results were confirmed with Abdel-Azim and Farahat (2009) and Günlü et al. (2007), who found the change of yolk index value under the effect of changing yolk height value.

The increase in yolk diameter observed in the present study could be due to decrease of the strength of vitelline membrane. When eggs are stored under room temperature for long periods, the strength of vitelline membrane breaks which makes the yolk to spread into the albumin. These results were in agreement with Kirunda and McKee (2000), who reported that vitelline membrane strength decreases during storage and makes the yolk more susceptible to breaking, as a result, water slowly enters into the yolk from the albumen, so this creates a mottled appearance in yolk, and the yolk becomes flattened. The yolk diameter values were higher in room temperature, because at a very high temperature, the amount of water migration from the albumen to the yolk is high, which helped to increase yolk diameter (Yeasmin et al., 2014).

The results of *Table 7* also showed that the yolk index (YI) values were significantly decrease with increased storage periods which was most likely due to water loss from the egg. On the other hands, the yolk index values equation depended on the yolk height and yolk diameter, when the yolk diameter increased with increase storage periods and conditions which resulted in an increase the YI values. These results were similar to those found by Abdel-Azim and Farahat (2009), Günlü et al. (2007), Gupta et al. (2007) and Kuzniacka et al. (2005).

The results in the present study showed that hatchability percentage was significantly affected by ages of broiler breeders, storage periods and storage type conditions. These results may be return to the effect of these factors on the egg quality; changes in the quality of eggs can affect the embryonic development during the incubation period and finally the hatchability results. On the basis of the results obtained, it can be concluded that present results in this study were confirmed by Sebastian et al. (2016), who found the lower levels of hatchability parameters were recorded in Ross 308 broiler breeders over 40th weeks of age. Hatchability was significantly lower in the eggs incubated at high ambient temperature (Gualhanone et al., 2011). Some negative changes in egg quality of all poultry species were reported due to prolonged storage period. For

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1241912439

example, water loss from eggs was related to hatchability (Kozuszek et al., 2009). Also, variations in hatchability may be explained various factors, such as: storage duration, care of hatching eggs, age of breeder, age of broody birds, quality of eggs, seasons, nutrition (Miazi et al., 2012).

The hatchability values recorded by Khan et al. (2013), Mustafa and Al-Sardary (2009), Reijrink et al. (2009), Demirel and Kırıkçı (2009) and Fasenko et al. (2001b) were very close to the results of the present study. Some embryos of eggs stored for a long period could not begin developing instantly after normal incubation temperatures were provided. Khan et al. (2013) found the significant differences in the hatchability of the total of the incubated eggs according to the duration of the storage period before the incubation.

Mustafa and Al-Sardary (2009) finding that the highest hatchability percentage was obtained in the young breeders (33 weeks) compared with old breeders (53 weeks).

Also, Reijrink et al. (2009) noted the detrimental or beneficial effect of pre-storage incubation when storage period was prolonged. Hatchability characteristics were affected by storage period, decreasing with increased storage period, similar results were found by Demirel and Kırıkçı (2009).

According to Fasenko et al. (2001b), the effect of pre-storage incubation on hatchability when storage period is prolonged depends on the developmental stage of the embryo after pre-storage incubation.

According to the present results there were no significant effects of storage periods and storage conditions on the fertility percentage, these results may be due the occurrence of the fertilization of the eggs in the fundamental part of female reproductive system inside the body therefore these factors did not affect on the fertility percentage.

On the other hands, it was shown that the eggs' fertility depends on various factors, such as: age, breed, season, lighting, level of nutrition, time of mating and number of mail with females (Miazi et al., 2012).

Fertility percentage found in the present study was similar to fertility percentage reported in previous studies of Khan et al. (2014) and Demirel and Kırıkçı (2009), who reported that there was no positive or negative effect of storage period on the fertility value.

According to the results of the present study there were significant effects of main factors and their interactions on hatchability of fertile eggs. Hatchability of fertile eggs also may be influenced by same factors that affected total hatchability such as storage duration, care of hatching eggs, age of broody birds, quality of eggs, seasons and nutrition (Miazi et al., 2012). Also, Mustafa and Al-Sardary (2009) found that the highest hatchability of fertile eggs percentage was obtained in the young breeders (33 weeks) compared with old breeders (53 weeks). In embryos less or further advanced damage caused by prolonged storage period might be irreversible and sometimes might cause embryonic mortality. Similarly, Tona et al. (2001) reported the process of embryo development in Cobb hens at different ages (27-60 weeks) also reported a rapid increase in the total embryonic mortality during incubation of eggs laid by older hens (46-64 weeks of age). Significant differences were found in the hatchability of the fertile eggs according to the duration of the storage period before the incubation conducted by Khan et al. (2013).

Reijrink et al. (2009) found that hatchability of fertile eggs in broiler breeder stored for 3, 5 and 8 d were higher than hatchability of fertile eggs stored for 12 d at 16 °C to 18 °C.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1241912439

Some embryos could not begin developing immediately after normal incubation temperatures if stored for a long period reported by Tona et al. (2001).

In conclusion, some of the quality traits of the eggs were significantly affected by broiler breeder ages, storage periods and storage types such as: egg weight, albumin weight, yolk weight, haugh unit, yolk height, yolk index, hatchability and fertile egg hatchability percentage.

Conclusions

Some of the quality traits of the eggs were significantly affected by broiler breeder ages, storage periods and storage types such as: egg weight, albumin weight, yolk weight, haugh unit, yolk height, yolk index, hatchability and fertile egg hatchability percentage. According to the results of the present study**,** the following points can be recommended: If the purpose of eggs production was for hatching, we recommend purchasing eggs laid by younger breeders than older breeders that is useful for owners of the hatcheries, but if the purpose of eggs production was for table eggs (consumption) we recommend to purchasing the eggs laid by older layers than younger layers that is useful for the commercial sellers and for consumers. Also, the best storage condition for storage (keeping) the eggs was under the cooling condition, but if this condition is not prepared because of disorder or disable of hatcheries machine, disconnect of electric source or prepare the large number of the eggs we recommended storage the eggs under oil covered condition (partially covered by oil) for short period (1-2 days) to prevent the water loss from the eggs.

(Received 10th May 2019; accepted 16th Jul 2019)

Abstract. In this study, the effects of gibberellic acid (GA_3) and brassinosteroid (BRs) applications on the yield and berry quality of Sultani grapes were determined during the 2017-2018 period. 28-homobrassinolide (Hbl) solutions with concentrations 4 ppm (Hbl-4) and 8 ppm (Hbl-8) were spray-applied at veraison. Three GA_3 concentrations were implemented by spraying method. The applications times were as follows; Application 1: 10 ppm, clusters 5-10 cm in length at pre-bloom stage (first week of May), Application 2: 15 ppm at 45-50% flowering (mid-June), and Application 3: 20 ppm with 3-5 mm berry diameter stage. GA_3 and BRs on yield components, some quality characteristics relating to clusters and berries (weight, breadth and length, etc.), color of bunches, total phenol content and antioxidant activity were investigated. Results showed that the effects differed, and they were not consistent on all the variables. Effects of the HBl treatments on yield were not as high as GA_3 but there were some positive improvements. Hbl was found to be influential on increasing cluster breadth. Berries were harder with the hormone applications. Quality characteristics were more influenced by the seasons rather than the hormones. Color and total anthocyanin contents were better with the hormones. Fructose content indicated a significant increase with the Hbl-4 application. 28-homobrassinolide might carry some potentially useful effects on improving yield, not to the extent of GA_3, and also on color along with increasing sweetness during the production of 'Sultani' grapes.
Keywords: *Vitis vinifera, Sultani, berry, hormone, gibberellic acid (GA_3), brassinosteroid*

Introduction

In Turkey, only about 50-60 grape cultivars are economically cultivated despite their vast variety (about 1200). Seedless table grape production constitutes about 37% of all production. Sultani (aka 'Thompson Seedless'), originated from the Aegean region of Turkey, since it is the most valuable raisin and table grape variety in the world. Its berries are green-yellow in color, seedless and small, with ellipsoid shaped berries, and the bunches are very large in size with long cylindrical body with wings on both sides (İşçi and Altındişli, 2015).

Applications of growth regulators such as gibberellins, ethylene or auxin in grape growing aim to improve fruit yield and quality. Especially gibberellic acid is the most effective growth regulator in improving bunch compactness, berry characters as well as yield and quality of berries. Gibberellic acid is mostly commercially used in seedless varieties to increase yield of grapes depending on its concentration and the time of application (İşçi and Gökbayrak, 2015; Reynolds et al., 2016; Ghorbani et al., 2017).

Brassinosteroids promote a dual response of cell division and cell elongation resulting in both enhancement and acceleration of the overall growth of the plants (Bartwal et al., 2013; Ali, 2017; Chai, 2012). They show growth regulatory effects in plants similar to those of endogenous plant hormones, auxins and gibberellins. In carrot, application of 24-epibrassinolide resulted in longer plants with increased vegetation weight (Que et al., 2017). Chai et al. (2013) determined that keeping brassinosteroids

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1244112450

from expression resulted in delayed color development in strawberries. It was shown that the application of brassinosteroid to grape berries evidently enhanced skin coloration and the final sugar level of the flesh, and significantly promoted ripening (Mitchell et al., 1970; Vardhini and Rao, 2002; Symons et al., 2006).

The objective of this study was to determine and compare the effects of gibberellic acid (GA_3) and 28-homobrassinolide applied at different phenological stages on quantity and quality of the 'Sultani' vines.

Materials and methods

Plant material

Vitis vinifera L. 'Sultani', a seedless grape, was grafted on 41B rootstock in 2005. Implementations were carried out at the experimental vineyard located in Bornova, İzmir. The vineyard is on sandy and silt soil 2.0 × 3.0 m spacing. Each vine carried approximately 20 grape clusters. Guyot-trained vines with four canes carrying 11-12 buds were drip irrigated. All viticulture practices were performed according to standard vineyard practices. During winters of 2017 and 2018, Bordeaux mix was applied following pruning, and wettable powder sulphur was used when the summer shoots were 10 cm long. Lateral shoots were accordingly removed in order to facilitate pest management.

Hormone treatments including the control were carried out freshly prepared solutions that contained 0.1% Tween 20 as the surfactant. Control vines were sprayed with distilled water. There were no other manipulations on the clusters. 28-homobrassinolide (Hbl, 0.1%; Repar, MD, USA) solutions with concentrations 4 ppm (Hbl-4) and 8 ppm (Hbl-8) were applied at veraison (last week of July) by spraying with a handgun sprayer at a rate of 10 ml/cluster, and the solution was made sure to cover the entire surface area of the berries in each cluster. Three GA_3 concentrations were implemented by spraying method. The applications times were as following; 1. application: 10 ppm, clusters 5-10 cm in length at pre-bloom stage (first week of May), 2. application: 15 ppm at 45-50% flowering (mid-June), and 3. application: 20 ppm with 3-5 mm berry diameter stage (last week of July).

The weather conditions in the two seasons (2017 and 2018, respectively) were as follows: average monthly temperature in year round was 18.2 °C and 19.2 °C. Mean temperature during the months of vegetation period (April-October) was 24.2 and 24.3 °C. Mean total precipitation was 1.78 mm and 1.65 mm, during which the vegetation period it was recorded as 0.64 and 0.93 mm. Average humidity was 60.6% and 64.3% throughout the seasons. The relative humidity during the vegetation period in 2018 was 4.2% higher compared to that in 2017.

The vines were monitored and harvested when the control vines reached 16°Brix. Yield components (yield per vine and per hectare) were recorded and some quality characteristics relating to clusters and berries (weight, breadth and length, etc.) were determined under lab conditions. Tensile strength of the pedicel (Newton, N) was measured with a penetrometer (Somyftec, France) on 50 berries taken from the clusters. The external berry color was measured at the equatorial area of each side of 50 berries using a colorimeter (CR-300, Minolta Co, Osaka, Japan), average scores were recorded in terms of CIE-L* a* b* values. The colorimeter had an 8 mm diameter viewing area and was calibrated with a white tile (L* = 97.26, a* = + 0.13, b* = + 1.71). From these data, the Color Index of Red Grapes (CIRG) (Carreño et al., 1996) was calculated as:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1244112450

CIRG = (180- h^o)/(C* + L*). Based on this index, the berries were classified into five categories: green-yellow (CIRG < 2); pink (2 < CIRG < 4); red (4 < CIRG < 5); dark red (5 < CIRG < 6); and blue-black (CIRG > 6).

The total soluble solids (°Brix) content in the juice was determined with a digital refractometer (PR-1, Atago, Tokyo, Japan) and expressed as percentage. Titratable acidity was measured by titration with 0.1 N NaOH to pH 8.1, and the results were expressed as g tartaric acid·100 mL-1 fruit juice. Sugar composition of grape (fructose and glucose) was determined with HPLC (Thermo Dionex Ultimate 3000) according Camara et al. (1996) only in year 2017. Total phenol content and extraction for antioxidant activity was measured by Thaiponga et al. (2006).

Statistical analysis

The trial was completely randomized with three replicates in each treatment. Each replicate had four vines. A total of 12 vines was used for each application. The mean data collected relating to different parameters of 'Sultani' grapes were statistically analyzed by Minitab® 16.1.1 statistical software. The differences between the significant means were determined with the Tukey's test ($p \leq 0.05$).

Results and discussion

Yield components of the cultivar were not affected by the treatments (*Table 1*). However, the seasonal variations exhibited significant differences and always in the second year that decreases were observed. The weather data indicated that although mean values of temperature, humidity and precipitation all year round were not quite apart, the values during the vegetation period showed that the second period was hotter, more humid and had more rain. This might have caused the yield to be lower. Interestingly, in the first year of hormone applications, GA_3 had always the highest values, followed by mostly the control group. In second year of the experiment, on the other hand, it was the control group that had the highest cluster and vine yield. One stipulation on this observation could be that hormone treated vines might be more prone to the adverse effects of the weather conditions or that they might exert some negative effects on bud fruitfulness. Vergara et al. (2018) also stated that exogenous applications of brassinosteroids at veraison did not improve yield. Senthilkumar et al. (2018) investigated preharvest application of GA_3 and brassinosteroid together and found that they provided best vine yield and highest cluster weight. Champa et al. (2015) showed that 0.5 ppm brassinosteroid at pea stage and veraison significantly increased bunch weight in 'Flame Seedless'. Baneh et al. (2017) reported positive effects of GA_3 on increasing yield of Iranian seeded grape cultivars. In their study involving application of a GA_3 based growth regulator, Nicolaescu et al. (2015) indicated its promoting activity on cluster productivity in 'Beauty Seedless' cultivar. Reynolds et al. (2016) also reported effects of GA_3 on increasing yield as positive and negative dependent on the cultivars. Ghorbani et al. (2017) stated that effects of 24-epibrassinolide on yield of 'Thompson Seedless'vines were mainly dependent on the time of the applications, such that after bloom it tended to provide the highest yield, but it gave the lowest yield when applied at budbreak.

Cluster characteristics, except for the cluster length, did not change with the hormone applications (*Table 2*). The clusters were wider than they were longer, showing that 28-homobrassinolide was as effective as GA_3. Fresh and dry weight of the rachis were

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1244112450

higher in the first year. Cluster length showed a significant increase in the second year. Although Haubrick and Assmann (2006) stated promoting effect of brassinosteroids on stem elongation, this effect was not observed in this study. This might be due to circumstances of the trial conducted. The increase was seen in all the clusters in the experiment. Champa et al. (2015) stated in their study with double application of brassinosteroid that cluster size significantly increased in 'Flame Seedless'.

The hormone treatments generally caused no significant differences in the characteristics of berries (*Table 3*). Berry breadth, berry weight and tensile strength of the pedicel differed between the seasons, being higher in the first season. Berry firmness was affected by the hormone application. Clear difference was observed between GA_3 and the Hbl-4/control groups. It seems that H8 was also capable of increasing berry firmness as GA_3 did. This might be the result of brassinosteroids, keeping the pectins in the cell walls from solubilization and/or depolymerization which lead to pulp softening (Villareal et al., 2008). Suehiro et al. (2018) reported enlarging effect of GA_3 in 'Shine Muscat' grapes. There are many reports on the effects of GA and CK on berry enlargement throughout the developmental stage (Peppi and Fidelibus, 2008; Zoffoli et al., 2009; Acheampong et al., 2015). In Flame Seedless (Champa et al., 2015) berry weight and berry size showed an increase after brassinosteroid applications at pea stage and veraison. GA_3 treated vines of 'Thompson Seedless' produced heavier berries with greater size compared to the control vines (Koukourikou et al., 2015). 'Skookum Seedless' berries increased their firmness following application of GA_3 (Reynolds et al., 2016).

Quality of the 'Sultani' berries were not affected by the treatment (*Table 4*), but they showed a significant increase in the second season compared to the first season. Soluble solids content between GA_3 and Hbl-4 treatment was comparably high in 2016, and a balance was observed in all the applications in 2017. Total acidity exhibited a slight increase in the second season. Maturity index was under the influence of the hormones. Hbl-4 resulted in the highest index value in both seasons. The others showed a minor decrease in the second season. Our findings were in consistent with those of Vergara et al. (2018) in 'Red Globe' and in contrast with those of Ashgari and Rezaei-Rad (2018) in 'Thompson Seedless". Reynolds et al. (2016) also showed that response of berry quality characteristics was cultivar specific. İşçi and Gökbayrak (2015) indicated no effects of homobrassinolide applied at anthesis on Brix and pH of 'Alphonse Lavallee', but they showed that seasonal effects were clear on total acidity.

Color of the berries were interactively affected by the treatments and the season (*Table 5*). Brightness (L*) was higher and generally the same in the second season. Yellowness (b*) was generally similar between the seasons, except for the Hbl-8 treatment. As was with the brightness, b* was higher in the treated berries compared to the control berries. Redness (a*) stayed at similar levels among the hormone applications, but significantly increased between the seasons. CIRG value (Carreño et al., 1996) of the grapes showed that the 'Sultani' berries fall within the class of green-yellow. It did not change with the applications, but seasonal differences were found significant even though the class they belonged to be the same. In agreement with our findings, Vergara et al. (2018) stated that brassinosteroid analogs applied to Red Globe berries at veraison resulted in better coloration. However, the response here was also dependent on the seasonal effects.

Biochemical aspects of the berries treated with various hormones indicated that hormones resulted with significant contributions to the contents of total anthocyanin and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1244112450

total phenolics (*Table 6*). TAC increased with the hormones. TPC on the other hand responded differently to the type of the hormones. GA_3 treated berries had the highest TPC, but 28-homobrassinolid comparably lowered it. Ma et al. (2012), in agreement, showed that 24-epibrassinolide increased phenolic contents in grapes. Since the responses of TAC and TPC were similar to the treatments, it can be assumed that the phenolics contents in the 'Sultani' berries might be mainly related to anthocyanin accumulation as also stated by (Xi et al., 2013). Fructose content of the berries showed a significant increase with Hbl-4 treatment. Glucose accumulated more with the hormones than the control group. In a similar study Asghari and Rezaei-Rad (2018) indicated that three times applied 24-epibrassinolide made a significant contribution to the total anthocyanin contents of 'Thompson Seedless' table grapes. Vergara et al. (2018) also showed that brassinosteroid analogs improved the anthocyanin content of 'Red Globe' grapes. Application of 0.6 ppm at veraison resulted in highest total phenolics and total anthocyanin contents in 'Thompson Seedless' berries (Ghorbani et al., 2017).

Conclusion

No matter the information gathered from this study and from all previous conducted valuable studies indicate that hormones do not greatly influence fruit growth and quality, understanding the role of plant growth regulators in composing grape quality and improving yield still requires some researches. Despite its relatively new-found place among plant hormones, brassinosteroids do have some promising effects on quality and quantity, obviously depending on its type, concentration and the time of application. Due to their degradation and limited transport, it might be useful to apply at the closest time or phenological stage to the intended outcome and therefore, repeated applications may be more effective. Improvement shown by brassinosteroid applications in berry firmness, color development and anthocyanin increases validate these hormones to be the subject of further research.

Acknowledgment. The author thanks Dr. Bhushan Mandava and Prof. Dr. Zeliha Gökbayrak for kindly providing the 28-homobrassinolide.

Abstract. Root-knot nematode (*Meloidogyne incognita*) has become a serious risk for cucumber globally. Haphazard use of synthetic chemicals poses a serious threat to agricultural crops, eliminating predators and also polluting natural community. Thus these negative effects led towards development of eco-friendly approaches which are safe and effective for *M. incognita* management. The study has been planned to coat seeds with Snef1216 (*Penicillium chrysogenum*) and evaluate its ability to control *M. incognita* in cucumber. It reduced *M. incognita* invasion rate significantly in different inoculums 500J2 (second stage juveniles) 67.09% followed by 1000J2 and 2000J2 plant^{-1} 60.44% and 36.02%, respectively. It inhibited development of nematodes 60.30%, 50.37% and 38.77% at 500, 1000 and 2000J2 plant^{-1} inoculation levels respectively compared to control. Snef1216 reduced significant ($P<0.05$) reproduction rate at 500J2 (69.46%), 1000J2 (62.89%) and 2000J2 (63.62%) of *M. incognita*. It interfered in galls formation and nematodes g^{-1} in root mass. Snef1216 enhanced seed germination (22.09%) with germination index (53.77%) and germination rate (64.49%). Additionally, seed dressing with Snef1216 exhibited additional biomass, reduced invasion of second-stage juveniles and also restrained development of nematode. Our results suggest that Snef1216 can be introduced as a biomass enhancer and potential bio-control agent against *M. incognita* in cucumber.
Keywords: *biological control, seed dressing, invasion, penetration, biological control agents, biomass*

Introduction

Plant parasitic nematodes can easily damage crops not only by direct feeding but also acting as a facilitator for other organisms (Palomares-Rius et al., 2017; Smant et al., 2018). However, damage caused by nematodes is often not easy to differentiate from other agents due to their microscopic size. These are usually soil, roots and leaves inhibiting microorganisms cause an enormous threat to agriculture, manifested in up to 157 billion US$ worth of damage (Youssef et al., 2013).

Root-knot nematodes (RKNs) are common and have an extremely broad host range which includes more than 5500 plant species (Trudgill and Blok, 2001). Among

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1245112464

different genera, *Meloidogyne* is one of the most destructive plant parasitic nematodes (Xiang et al., 2017; Li and Chen, 2017). However, four main species of this genus, i.e. *Meloidogyne incognita*, *Meloidogyne hapla*, *Meloidogyne arenaria* and *Meloidogyne javanica* have been reported to decrease yields, among them *M. incognita* is one of the most widespread species (Dong et al., 2014).

Cucumber (*Cucumis sativus*) is a commonly cultivated plant belonging to the family Cucurbitaceae, is ranked as an important vegetable globally (Sebastian et al., 2010; Mao et al., 2016). However, China has been ranked as number one and accepted as the world's largest producer of cucumber (FAOSTAT, 2018). This is an important vegetable crop cultivated widely throughout the country, especially in North China (Tian et al., 2011; Huang et al., 2014; Huang et al., 2016). The researcher reported that about 50% of vegetables grown in greenhouse infected by root-knot nematodes with annual loss up to 400 million US dollars (Huang et al., 2014) and it is hard for farmer to diagnose its damage due to similarities with nutritional deficiencies such as chlorosis (Zeng et al., 2018).

The infestation of *M. incognita* adversely affects the growth of the plant, yellowing and stunted leaves growth and ultimately the destruction of whole plants due to absorption of important nutrients (Escobar et al., 2015; Li and Chen, 2017). Infected roots showed bushier and shorter length compared with healthy roots (Miyashita et al., 2014). They directly feed upon plants and caused the lesion in it which helps in development of secondary pathogens such as pathogenic bacteria, fungus and viruses which caused secondary infections (Smant et al., 2018). Unfortunately, it is difficult to control it in soil because of its interaction with other pathogens and plant-parasitic nematodes (PPNs), and developing disease complextion (Back et al., 2002; Divon and Fluhr, 2007; Son et al., 2009; Björsell et al., 2017).

Chemical nematicides have been used to control this pest but their continues and indiscriminate use poses adverse effects on soil and environment (Huang et al., 2014). Due to their hazardous effect on human, availability of such pesticides has become limited in local markets such as methyl bromide, ethylene dibromide (EDB) and dibromochloropropane (Oka et al., 2000; Gotlieb et al., 2003; Dong and Zhang, 2006; Nicol et al., 2011; Onkendi et al., 2014). To overcome this problem, eco-friendly and safe approaches for prevention and management of this nematode are needed urgently because root-knot nematodes have high reproduction rates and short generation times (Trudgill and Blok, 2001; Jang et al., 2016). With increasing demands of organic and chemical free crops, there is a dire need to develop strategies for this destructive pathogen (Huang et al., 2014; Kokalis-Burelle, 2015).

Signs of Progress in recent decades regarding biocontrol agents have led to several products. Biological control is usually safe as compared to chemical control. Meanwhile, Fungi belonging to genera *Fusarium*, *Trichoderma*, *Phyllosticta*, *Acremonium, Chaetomium, Paecilomyces,* and *Penicillium* have been known as antagonistic to plant-parasitic nematodes (Kalele et al., 2007; Govinden-Soulange and Levantard, 2008; Sharon et al., 2009; Siddiqui and Akhtar, 2009). Within an integrated and more sustainable management strategy the use of biocontrol agents, like *P. chrysogenum*, seems to be a promising alternative in the future. However, some studies reported the effectiveness of such fungus against *M. incognita* in different crops. The biocontrol effect against different pathogens in the presence of *P. chrysogenum* is reported in a wide range of plants and pathogens providing evidence for the effect of *P. chrysogenum* on nematode infection. Dry mycelium enhanced plant growth and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1245112464

reduced root galls to protect cucumber and tomato plants against *M. javanica* (Gotlieb et al., 2003). *P. chrysogenum* used alone and in the combination of two (*Aspergillus niger*, Plant growth promoting rhizobacteria PGPRS and Arbuscular mycorrhizal fungi) could boost plant growth and reduce reproduction of *M. incognita* in tomato (Siddiqui and Akhtar, 2009). Yao et al. (2014) also reported that *P. chrysogenum* is one of the most important fungi to control *M. incognita* in tomato. Thus, keeping in view the biocontrol potential of Snef1216 (*P. chrysogenum*) against *M. incognita* on different crops, the present study was planned to explore the nematicidal activity of fungus fermentation for control of *M. incognita* by seeds dressing on cucumber seeds and to enhance biomass at Nematology Institute of Northern China, Shenyang Agricultural University, Liaoning, China. The results of the present study should help as a theoretical foundation for the development of marketable and valuable biocontrol agent.

Material and methods

Experimental design

The study has been designed to evaluate the efficacy of Snef1216 (*Penicillium chrysogenum*) against *M. incognita* on cucumber by seed coating with randomized complete block design (RCBD) during 2018. Each treatment have been replicated five time.

Preparation of PDA

200 g of potatoes were boiled in 1 L of distilled water and filtered through cheesecloth on becoming soft. After that, 20 g of glucose and 17 g of agar were added into it and boiled again for 1 minute. Then, 100 ml PDA was poured in 250 ml conical flasks and sealed. PDA containing flask were sterilized into a steam autoclave machine for 30 minutes at 121^{o}C and preserved at room temperature.

Activation of Strain Snef1216 (Penicillium chrysogenum)

P. chrysogenum strain Snef1216 was obtained from the China General Microbiological Culture Collection Center. Jiang et al. (2011) identified it and stored at -80^{o}C at Nematology Institute of Northern China (NINC), Shenyang Agricultural University, China. Before use, a small quantity of strain was added into PDA filled cavities by the help of a sterilized needle and placed into an incubator for 7 days at 25-28^{o}C for the confirmation and purity level and strain activation.

Fermentation preparation

For the preparation of fermentation (nutrition medium) 50 g Sucrose, 8 g $NaNO_3$, 2 g K_2HPO_4, 0.08 g $MgSO_4.7H_2O$, 0.4 g KCl, and 0.003 g $FeSO_4.7H_2O$ were mixed together into 1000 ml distill water and the consequent mixture was boiled for few minutes. Then, 100 ml nutrition medium was poured into 250 ml conical flasks and sterilized into steam autoclave machine for 30 minutes at 121^{o}C. Five fungus cakes were added (1 mm diameter of each) into 100 ml nutrition medium and put on a shaker for 3 days at 28^{o}C and 150 rpm. After that, 100 ml new medium was poured into each flask and were again put on a shaker for 8 days at 28^{o}C and 150 rpm for fermentation development and then stored at 4^{o}C after filtration (Jiang et al., 2011).

DOI: http://dx.doi.org/10.15666/aeer/1705_1245112464

Sterilization of seeds and seeds coating

Seeds were surface sterilized by 1-2 ml 75% ethanol and 0.05% Tween 20. After that 1-2 ml 95% ethanol was added and left for 1 minute then, 1-2 ml absolute ethanol was added and allowed for a few minutes to rinse with sterilized distilled water and air-dried. After that seeds were divided equally into two Petri dishes, half-seeds were coated with Snef1216 (*P. chrysogenum*) and half were taken as a control treatment. Uncoated or control seeds were placed into Petri dish containing double layers of wet filter papers for seed germination. For seeds coating, fermentation of Snef1216 (*P. chrysogenum*) was added and properly mixed for uniform coating on all seeds and left for complete drying, and was placed into Petri dish containing double layers of wet filter papers for seed germination. Germination % (G%), germination index (GI), and germination rate (GR) were calculated by *Eqs.1-3* (Bartlett, 1937; Mukhtar, 2008; Mukhtar et al., 2012).

$$G\% = \frac{N.G.S}{T.N.S} \times 100 \quad \text{(Eq.1)}$$

Whereas, N.G.S. is no. of germinated and T.N.S. is total no. of seeds.

$$GI = \frac{N.G.S.(1)}{D.C.(1)} + \frac{N.G.S.(2)}{D.C.(2)} + \frac{N.G.S.(f)}{D.C.(f)} \quad \text{(Eq.2)}$$

Whereas, N.G.S. (1), N.G.S. (2) and N.G.S. (f) are the numbers of germinated seeds in 1st, 2nd and final counts; D.C. (1), D.C. (2) and D.C. (f) are stand for days to 1st, 2nd and final counts.

$$GR = \frac{a + (a+b) + (a+b+c)(a+b+c+m)}{n(a+b+c+m)} \quad \text{(Eq.3)}$$

Whereas, a, b and c are the number of seedling in the first, second and third counts, m stands for the number of seedling in final count and n is number of counts.

Germinated seedlings were transferred into seedling trays which were filled with sterilized substrate. At four leaves stage plants were transferred into pots (20 cm diameter), those filled with 800-1000 g sterilized sand, soil and substrate (1:1:1).

Nematode Inoculums

The population of root-knot nematode (*M. incognita*) was maintained in tobacco and tomato plants, grown in greenhouse of Nematology Institute of Northern China (NINC), Shenyang Agricultural University, China. Plants were uprooted and roots were washed gently then, cut into 1-2 cm pieces and macerated for 30 seconds in a small amount of water by using the electric blender. Macerate was transferred into the funnel and added 0.05% NaOCl into it. The mixture was manually shaken for 1-2 minutes to separate the eggs from the gelatinous matrix. Then, the suspension was poured through 200 and 500 µm size meshes respectively and washed with tap water to remove NaOCl. Eggs were further purified by centrifugation in 454 g L^{-1} sucrose for 4 minutes at 3000 rpm. The supernatant was poured into 25 µm (500 µm mesh and rinsed several times with

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1245112464

sterilized water. Eggs inoculums were transferred into a funnel and allowed to hatch into second stage juveniles (J2). These (J2) were then allowed to crawl through eight layers of Kim-wipe tissues into sterilized water by using the Baermann funnels method (Baermann, 1917). The J2 in the resulting suspension adjusted at 500J2, 1000J2 and 2000J2/3 ml used as inoculums. These inoculums were injected 2-4 cm deep into rhizosphere with a plastic rod into 3 holes made around the base of the stem (Selim, 2010). The plants were monitored regularly to examine the different stages of the nematodes in the roots at different intervals viz., 7, 14, 21 and 28 dpi (days post inoculation).

Staining of roots

Plants were uprooted; carefully washed the roots under running tap water to remove soil particles and bleached in 10, 20 and 30 ml for young, mature and older roots respectively. Bleaching process was performed in 5.25% NaOCl into 50 ml distilled water for 4 minutes and washed for 45 seconds under running water and soaked into distilled water for 15 minutes. For stain preparation, 1 ml fuchsin acid was added into 30-50 ml distilled water and heated for 1 minute in the microwave. Then these roots were put into the preheated stain and reheated the stain untill boils. Washing was performed under water for color fading. Then, 2-3 drops of 5 mol/L HCl was added into 20-30 ml glycerol heated and placed the roots into it. Roots were examined after cooling under the microscope and observed different stages of RKN (Hussey, 1985).

Growth Index observation and determination

Growth parameters like plant height (cm) by using scale, stem diameter (mm) by using Vernier calipers, root length (cm), root and shoot weight (g) were calculated. Leaf area (LA) was calculated by using *Eq.4* Quarrie and Jones equation (Aldesuquy et al., 2014; Ahmad et al., 2015). Germinated plants were maintained in greenhouse at ambient light at 26-32°C and were irrigated by showering of tap water with the interval of three days. Five plants were selected randomly from each treatment at 28 dpi (Days post inoculation) for evaluating the variation among growth parameters.

$$LA = (Length \times Width) \times 0.75 \quad \text{(Eq.4)}$$

Following treatments were used (T1) control with (2000 J2) RKN (T2); control with (1000 J2) RKN; (T3) control with (500 J2) RKN; (T4) control without inoculation (T5); Coated or treated with (2000 J2) RKN; (T6) Coated or treated with (1000 J2) RKN; (T7) Coated or treated with (500 J2) RKN; (T8) coated or treated without inoculation.

Statistical Analysis

In order to assess the significant effects of all treatments on cucumber, all recorded data were analyzed by one-way Analysis of Variance (ANOVA). Mean difference between treatments were calculated for the significance test through Duncan's multiple range test (P>0.05). All statistical processes were administered by different statistical packages such as IBM-SPSS statistics 25.0 version software and MS Excel. Graphs were constructed through Sigma Plot 10.0 software.

Results

Seed Germination

The effect of fermentation on the seed germination is shown in *Fig. 1A, B and C*. Significant difference among treatments was observed. However, significant results (P<0.05) showed that seeds coated with fermentation broth of Snef1216 (*P. chrysogenum*) were found efficient to enhance 22.09% germination (G%) compared to control. Seed germination index (GI) noticeably demonstrated the potential of Snef1216 (*P. chrysogenum*) which increased to 53.77%. While, germination rate was boosted to 64.49% by pretreated seeds with fermentation as compared to control.

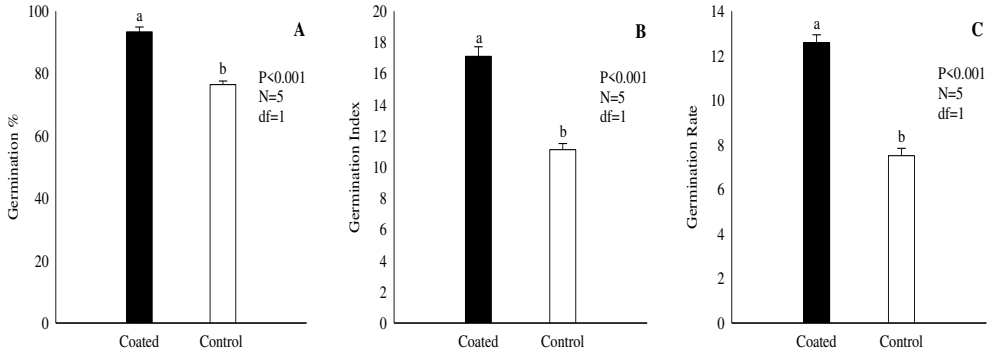

Figure 1. *(A) Germination percentage of cucumber seeds. (B) Germination index of treated and untreated seeds. (C) Effect of coating on germination rate. The error bars illustrated the mean±Standard error. Different letters on bar indicates that values are significantly different according to Duncan's multiple range test at P>0.05*

Growth Parameters

Table 1 and *Fig. 2* demonstrated that all treated seed efficiently promoted plant growth; like maximum plant height, 104.3 cm was observed in T8 followed by T4 and T7 96.8 and 94.9 cm, respectively.

Table 1. *Treatment effect on growth parameters of cucumber plants infected Meloidogyne incognita*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1245112464

Significant (P<0.05) stem diameter was recorded in T8 6.6 mm followed by T7 and T6 6.4 and 6.2 mm, respectively. The leaf area was ranged between 72.5-116.2 cm^2 in T1 and T8. Maximum root length observed was 45.30 cm in T8 compared to a minimum in T1 20.3 cm. Similarly, the highest shoot and root weight was recorded in T8 52.1 and 16.6 g compared to T1 27.8 and 6.3 g. The results revealed that pathogenicity of root-knot nematode (RKN) at different levels of inoculums viz., 500, 1000 and 2000 J2 of *M. incognita* per pot resulted into a significant (P<0.05) decrease in plant growth, however, treated plants showed significant biomass over control.

Figure 2. *Efficacy of coating of Snef 1216 (P. chrysogenum) on the growth of cucumber*

Nematode Infection

The Snef1216 *P. chrysogenum* was tested for its potential control toward *M. incognita* on the cucumber plant. The plants were monitored regularly to examine the different stages of the nematodes in roots at different intervals viz., 7, 14, 21 and 28 dpi (days post inoculums). Data presented in *Figs. 3* and *4*. showed that all the seed treated with Snef1216 efficiently reduced the penetration rate of J2 into cucumber roots at different inoculums levels such as 500J2/plant reduced invasion 67.09% followed by 1000 and 2000J2/plant 60.44 and 36.02%, respectively. It also inhibited the development of nematodes (J3 and J4) like 500J2/plant reduced 60.30% followed by 1000 and 2000J2/plant 50.37 and 38.77%, respectively. Similarly, rate of reproduction was 69.46, 62.89 and 63.62% at the same inoculation level (*Figs. 3* and *4*). At 7 dpi and 28 dpi less nematode population were present. Whereas, at all dpi-s control plants had highest population of nematodes while, seed treated with Snef1216 (*P. chrysogenum*) showed significantly fewer nematodes (*Fig. 5*). It was also observed that fewer females and males were developed in treated plants resulting in the development of few egg masses compared to control. It is obvious from results that the Snef1216 (*P. chrysogenum*) exhibited a drastic reduction in galls and no. of nematodes per gram of root weight as compared with control at different inoculum levels viz., 500, 1000 and 2000J2/per plant (*Fig. 6*).

Discussion

Seed dressing with fungus enhanced germination percentage, germination index, and germination rate. However, seed treatment with non-pathogenic inoculants like fungus showed boosted seed germination rate, seedling vigor and reduced the occurrence of pathogenic infections (Zheng and Shetty, 2000; Bharath et al., 2006; Dubey et al., 2007). Seed treated with *Trichoderma* species enhanced the germination parameters (Oyarbide et al., 2001; Mukhtar, 2008; Asaduzzaman et al., 2010; Mukhtar et al., 2012). Seed treatment with fermentation broth of Snef1216 could be an effective and reasonable way to enhance the germination of cucumber and reduce nematodes invasion in plant roots.

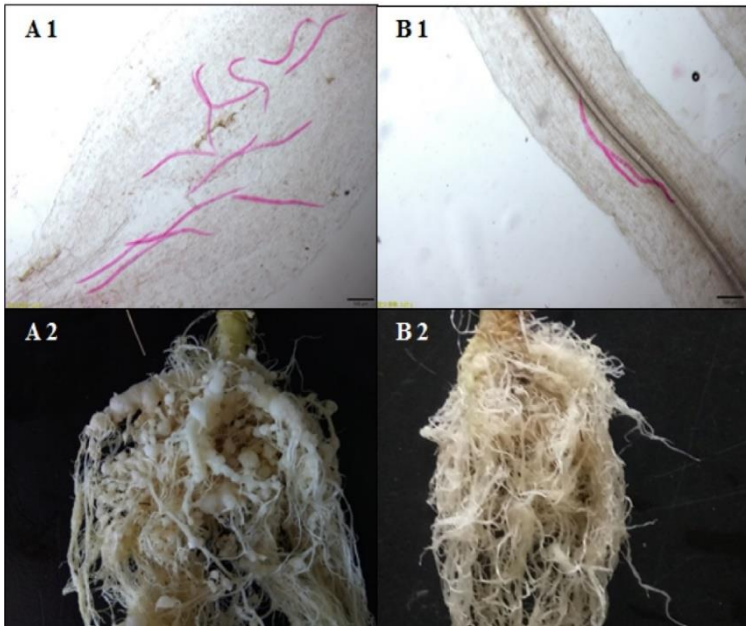

Figure 3. *(A1 and A2) Roots of seeds without coating. (B1 and B2) Roots of seeds coated with Snef 1216 (P. chrysogenum) fermentation*

The results indicated that seed coating resulted in increased biomass with low nematodes attack at different inoculums levels viz., 500, 1000 and 2000 J2/per pot as compared to their controls. Thus, our results are agree with Duggal et al. (2017) who reported that the pathogenic level of root-knot nematode in different inoculums viz., 0, 10, 100, 1000 and 10000 J2/pot resulted into significant reduction in plant growth parameters like plant height, root and shoot weight at or above 1000 J2 inoculums level. It was also reported that plant growth was inversely proportional to inoculums levels, at highest inoculums plant showed less biomass or vice versa. Vos et al. (2012) and Banuelos et al. (2014) supported our findings that *Arbuscular mycorrhizal* fungi improved plant growth and vigor in brinjal, tomato, and ornamental plants. *Syncephalastrum racemosum* efficiently increased plant growth in cucumber (Huang et al., 2014). Siddiqui and Akhtar (2009) described that antagonistic fungi (*P. chrysogenum* and *A. niger*) efficiently enhanced the tomato growth and significantly reduced gall formation. Seed treatment with fungus Snef1216 (*P. chrysogenum*) efficiently promoted the growth parameters compared to control at different levels of inoculums and play a vital role in the promotion of plant growth.

Seed treated with endophytic fungi like *Fusarium*, *Trichoderma*, *Chaetomium*, *Acremonium*, *Paecilomyces*, and *Phyllosticta* potentially control *M. incognita* in cucumber (Siddiqui and Akhtar, 2009; Yan et al., 2011). Seed treatment used as a standard way for the application of *P. chrysogenum* that could concurrently confer resistance to root-knot nematodes in agricultural. Mascarin and Junior (2012) reported

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1245112464

that *T. harzianum* efficiently decrease the population of *M. incognita* in cucumber and enhanced plant growth under greenhouse conditions. *A. niger* had the ability to inhibit the *M. incognita* in tomato (Jang et al., 2016). *Fusarium oxysporum* showed repelling effect towards *M. incognita* in tomato as well as promoted plant growth (Selim, 2010; Terra et al., 2018). Gotlieb et al. (2003) reported that dry mycelium enhanced plant growth and reduced root galls to protect cucumber and tomato against *M. javanica.* Our findings clearly demonstrated that seed treatment with fungus Snef1216 (*P. chrysogenum*) significantly reduced the infection of root-knot nematode and lowered the number of 2nd stage juvenile's invasion in to cucumber roots. The pathogenic level of *M. incognita* in capsicum under greenhouse condition was observed that number of galls, egg masses was increased with increase in levels of inoculum conspicuously at and above 1000 J2 level (Duggal et al., 2017). Our results also revealed that pathogenic level of root-knot nematode was also observed in cucumber that the number of galls and egg masses was increased with increase in inoculums level while, seeds treated with Snef1216 significantly reduced compared to control. It also inhibited the development and rate of reproduction of nematodes in the roots. Cucumber is susceptible and an excellent host for multiplication of *M. incognita* but, seeds treated with Snef1216 significantly reduced the infection of nematodes and galls at a different level of inoculums also enhanced biomass.

Although different biological control approaches have been employed in current agriculture system to control nematodes on crops and vegetables, but seed dressing with strain Snef1216 on cucumber is limited. The outcomes from this study presented that Snef1216 is useful as a seed dressing, in order to decrease nematode infection. These results showed that seed dressing could be an effective alternative and reasonable way to control *M. incognita*.

Conclusion

Based on the finding of the present study, it is concluded that Snef1216 (*P. chrysogenum*) showed plant growth-promoting characters as well as have nematicidal activities with potential biocontrol agents against RKNs on cucumber under greenhouse conditions. It can be considered as a commercial biocontrol agent, however, before recommending this Snef1216 as commercial nematicides further study is needed to evaluate its active component screening and mechanisms of action. However, present findings may provide a theoretical foundation as a biocontrol agent for better control of root-knot nematodes (*M. incognita*).

Abstract. In order to study the seepage characteristics of slopes with weak interlayers under different rainfall levels, the finite element analysis model was established using the Seep/w module in Geostudio2018. The calculation conditions of big rain, heavy rain and rainstorm were carried out. The variation of pore pressure at different monitoring points and monitoring lines was obtained. The results show that under different rainfall levels, the pore pressure of slope surface increases first and then decreases, reaches saturation in the process of rainfall, and decreases gradually after the rainfall, and the pore pressure presents shapes like a backwards S at the elevation of weak interlayers. The wetting front infiltrates the silty clay layer uniformly and a "sudden change" occurs at the elevation of weak interlayers. The rainfall infiltration degree under low intensity and long duration is greater than that of high intensity and low duration. The research results will provide a reference for the understanding of the rainfall infiltration mechanism of the slope with weak interlayers as well as the slope treatment and prevent the catastrophic disasters occurring in slopes.
Keywords: *numerical studies, unsaturated soils, interlayers, pore water pressure, wetting front, geo-studio*

Introduction

Weak interlayers widely exist in the interior of the slope (Long-Qi and Neng-Pan, 2016; Yang et al., 2018), not only controlling its stability (Kulasingam et al., 2004), but also having a great influence on the seepage characteristics (Thompson, 1984; Ming et al., 2011). Meanwhile, Rainfall is the key factor affecting slope safety (Rahardjo et al., 2005). Rainfall causes the rise of the underground water level (Chaplot et al., 2003) and the reduction of shear strength in rock and soil (Fang et al., 2015), thus leading to catastrophic disasters. According to some relevant studies (Lee et al., 2013), rainfall-induced landslides account for 51% of the total number of landslides. Therefore, it is of great significance to study the effects of rainfall on slopes with weak interlayers.

Rainfall-induced landslides are mainly characterized by shallow instability in the early stage and overall slipperiness in the later period (Zhang and Wang, 2012). The influence of rainfall on slope seepage is mainly reflected in the formation of transient saturation zone at the foot of the slope, and then diffuses to its depth (Philip, 1993). Previous studies have focused on the influence of different rainfall types and different soil or rock mechanical properties on the seepage characteristics and slope safety. For example, soil properties such as the anisotropy ratio (Zhang and Lin, 2016), the saturated hydraulic conductivity (Woolhiser et al., 1996), the matric suction (Lim et al., 1996), the cohesive strength (Schultz et al., 1985) and the internal friction angle (Mitchell et al., 1972) all play important roles, and rainfall types such as different peak

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1246512478

rainfalls (Sheng, 2000), different rainfall levels (Tian, 2014) and different return periods (Ng et al., 2001) equally have a great impact. Meanwhile, antecedent rainfall should be considered before starting numerical calculations (Rahimi et al., 2011).

As a weak part in the slope, interlayers have the characteristics of high permeability and low shear resistance, and they are sensitive to rainfall. Experimental study on slopes with a thin soft band layer under rainfall has been conducted by Elkamhawy et al. (2018) to study the seepage characteristics and failure modes, but discussions are not sufficient, theoretical methods were proposed such as the shear strength reduction method (Jie-Qun et al., 2013) and the three-dimensional combined rotational-translational mechanism (Huang et al., 2017) but they are applied under the condition without rainfall. In addition, the seepage stability mechanism of weak interlayer under rainfall condition is still lacking, which needs to be further studied.

Previous studies have mostly focused on the impact of rainfall types on the seepage characteristics of homogeneous slopes or its stability with interlayers. However, few studies have involved systematic analysis of seepage characteristics, which can reveal the mechanism of rainfall infiltration and rock and soil deterioration. So in this paper, numerical model of a slope with weak interlayers was established with Geo-studio and seepage characteristics were quantitatively studied under different rainfall levels. The results of the research will provide a reference for the understanding of rainfall infiltration mechanism of the slopes with weak interlayers as well as the its treatment and prevent the catastrophic disasters occurring in slopes.

Methods and theory

Model and boundary conditions

The simulation model was established according to the geometry presented by Yang et al. (2008), as shown in *Figure 1*. However, Yang et al. (2008) did not give a systematic description of the seepage characteristics. In this paper, the monitoring points and monitoring lines are adopted to illustrate the seepage characteristics not only on the slope surface but also along its elevation, which can give a better understanding. The slope height of the first and second grade is 10 m, and the third one is 8 m high. The slope ratios of all the three stages are 1:1. There are two weak interlayers, which are the ribbon structure layer with a thickness of 2 m (8.2°with horizontal direction). For the correct reflection of rainfall infiltration, the depth of the foundation is set to 22 m. The mesh size is refined to 0.2 m in weak interlayers and 0.4 m in other parts. The whole model is divided into 5,481 nodes and 5,375 elements.

In order to study the seepage characteristics of the slope surface at different locations, four monitoring points on the surface of the slope are taken. They are monitoring point 1 located at (30, 50), monitoring point 2 located at (41.5, 42), monitoring point 3 located at (56.5, 34) and monitoring point 4 located at (66, 22). Four monitoring lines are also taken to investigate the seepage law in the slope at different locations; they are monitoring line 1 located at $x = 30$, monitoring line 2 located at $x = 41.5$, monitoring line 3 located at $x = 56.5$ and monitoring line 4 located at $x = 66$.

To study the rainfall infiltration, the initial condition should be defined. In this paper, the initial seepage field is calculated by the initial infiltration line shown in *Figure 1*. CDEF is the rainfall infiltration boundary, BC, FG and AH are the impervious boundary, AB is the fixed head boundary of 26 m and HG is the 15 m fixed head boundary.

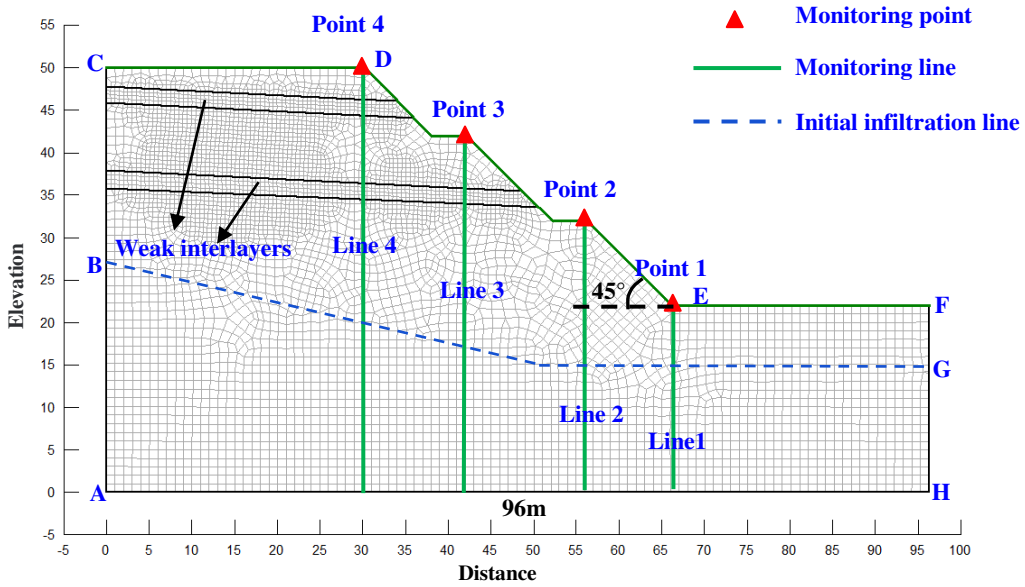

Figure 1. *Slope simulation model*

According to the climate monitoring data of Linchang Highway, three simulation schemes are determined for different rainfall levels: big rain, heavy rain and rainstorm on the basis of the standard of State Meteorological Administration of China. The rainfall intensity is 1.67 mm/h in big rain condition, and the duration is 4 d. The rainfall intensity is 3.33 mm/h in heavy rain condition, and the duration is 2 d, while the rainfall intensity is 6.67 mm/h in rainstorm condition, and the duration is 1 d. The calculation time is set to 5 d in Geo-studio and the specific rainfall conditions are shown in *Table 1*.

Table 1. *Rainfall conditions*

Rainfall level	Rainfall intensity (mm/h)	Rainfall duration time (d)	Rainfall amount (m)
Big rain	1.67	4	0.16
Heavy rain	3.33	2	0.16
Rain storm	6.67	1	0.16

Material properties

The SEEP/W module in Geo-studio is utilized to simulate the rainfall infiltration, and the unsaturated seepage equation can be expressed as (Fredlund and Rahardjo, 1993):

$$\frac{\partial}{\partial x_i}[k_{ij}{}^s k_r(h_c)\frac{\partial h_c}{\partial x_j}+k_{i3}k_r(h_c)]+Q=[C(h_c)+\frac{\theta}{n}S_s]\frac{\partial h_c}{\partial t} \quad \text{(Eq.1)}$$

where x_i, x_j is the position coordinates in i and j direction, $k_{ij}{}^s$ is the saturated permeability tensor, k_r is the relative water permeability, h_c is the pressure head, β is the unsaturated coefficient, S_s is the pondage restored in soil, Q is the input and output of the flux, $C(h_c)$ is the water capacity which is the function of h_c, n is the porosity and t is the time.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1246512478

The water characteristic curves (SWCC) characterizing the variation of volumetric moisture content or permeability coefficient with matric suction, which was proposed by Fredlund and Rahardjo (1993) in 1994, can obtain the closed solution of volume water content under the range of negative pore pressure from 0 to -1×10^6 KPa and is adopted in this paper:

$$\theta_w = C_\phi \frac{\theta_s}{\left\{\ln\left[e + \left(\frac{\phi}{a}\right)^n\right]\right\}^m} \quad \text{(Eq.2)}$$

where θ_w is the volumetric moisture content, C_ϕ is the modified function, θ_s is the saturated volumetric moisture content, ϕ is the negative pore water pressure.

According to the volume water content function of Fredlund (Fredlund and Rahardjo, 1993), SEEP/W module in Geo-studio software sets the corresponding governing equation (Fredlund and Rahardjo, 1993), which can be expressed as:

$$k_w = k_s \frac{\sum_{i=j}^{N} \frac{\theta(e^y) - \theta(\psi)}{e_i^y} \theta(e_i^y)}{\sum_{i=1}^{N} \frac{\theta(e^y) - \theta_s}{e_i^y} \theta^0(e_i^y)} \quad \text{(Eq.3)}$$

where k_w is the permeability coefficient calculated by water content or negative pore water pressure, k_s is the saturated permeability coefficient of slope soil, y represents the dummy variable of the negative pore water pressure algorithm, i is the numerical distance between j and N, j is the minimum negative pore water pressure described by the final function, N is the maximum negative pore water pressure described by the final function and Ψ corresponds to the first j of negative pore water pressure. θ_0 is the initial value of the equation.

The slope soil is composed of silty clay. The physical and mechanical properties of silty clay and interlayers are determined according to the experiment and field investigation. The values of parameters are shown in *Table 2,* and the SWCC curves are shown in *Figure 2.*

Materials	Weight (kN/m^3)	Cohesive strength (KPa)	Internal friction angle	Permeability coefficient (m/d)	Saturated water content
Silty clay	25	31	27	0.0108	0.25
Interlayers	12	16	13	0.88128	0.43

Results

Comparison of pore water pressure variation on the slope surface

The variation of pore pressure at different monitoring points (monitoring point 1, monitoring point 2, monitoring point 3 and monitoring point 4) is shown in *Figure 3*. Under the action of rainfall, the slope surfaces at different positions experienced the process from unsaturated to saturated and then to unsaturated, that is, the pore pressure increases to 0 at first and then decreases, except for monitoring point 3, and the variation of pore pressure caused by different rainfall grades is quite different. For monitoring point 1, monitoring point 2 and monitoring point 4, pore pressure goes through a process of rapidly rising to saturation, continuing and then decreasing under different rainfall levels, and the time when the slope surface reaches saturation is positively proportional to the rainfall level. However, it is worth noting that the big rain, which represents the long period of weak rainfall, has the ability to make the duration of slope surface saturation longer (average 0.5 day for rainstorm, 1 day for heavy rain and 2.4 days for big rain). Although the time of the big rain condition when slope surface reaches saturation is later than other rainfall levels (heavy rain and rainstorm). It means that the effect of a short period of heavy rain on the slope seepage characteristics is less than that of a long period of weak rain. This is because prolonged weak rainfall can make slope infiltration more sufficient, and large amounts of rainwater are prevented from draining away from the slope surface, which is closely related to the infiltration rate of the soil (Jun-Ping et al., 2016), if the rain intensity is larger than the infiltration rate of soil, then rainfall infiltration will be determined by infiltration rate rather than rainfall intensity. Therefore, more attention should be paid to slope safety monitoring and drainage in the case of long-term weak rainfall.

For monitoring point 3, the change of pore pressure is different from other monitoring points, although pore pressure increases during rainfall, the slope surface does not reach the saturated state. This is because monitoring point 3 is located at the top of the secondary slope. Under this condition, rainwater not only infiltrates from monitoring point 3, but also drains to the lower part of the slope. This phenomenon is observed in Elkamhawy's works (Elkamhawy et al., 2018) and is discussed in section 4. Therefore, the increase of pore pressure at monitoring point 3 is significantly smaller than that at other monitoring points.

Comparison of pore water pressure variation in the slope

Variation of pore water pressure of different time under a rainstorm

Variation of pore water pressure of different time under rainstorm is shown in *Figure 4*. Pictures on the left side are the pore pressure distribution of the whole monitoring line, while on the right side are the region where local pore pressure changes

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1246512478

dramatically. The pore pressure distribution on different monitoring lines is also very different, the monitoring line 1 and 2 did not pass through the weak interlayer, while the monitoring line 3 passed through the second weak in

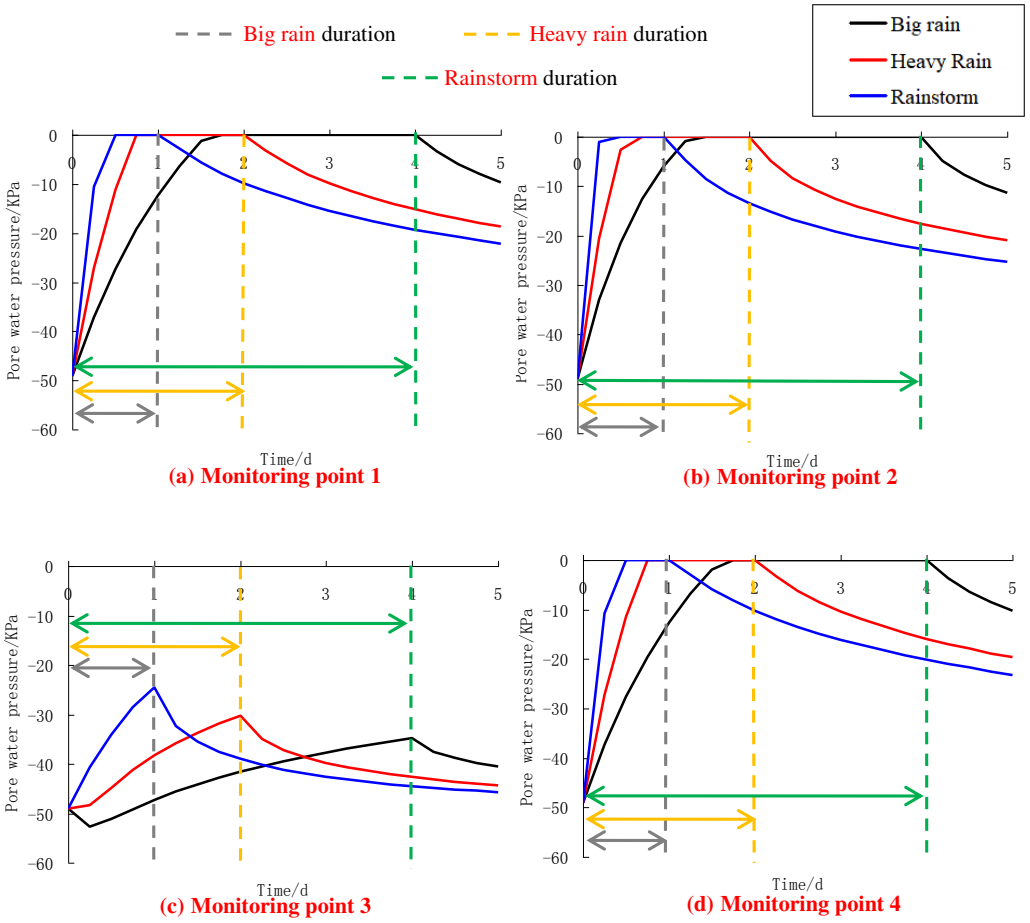

Figure 3. *Pore water pressure of different monitoring points*

terlayer and the monitoring line 4 simultaneously passed through two weak interlayers.

For monitoring line 1, it is not only affected by rainfall infiltration in the process of rainfall, but also by the drainage of upper rainwater because it is located in the lower part of the slope. Therefore, except for the shallow part (elevation 18-22 m), which is greatly affected by rainfall on the surface of the slope, the pore pressure increases linearly with the elevation and remains unchanged during rainfall. Compared with the local enlarged image on the right, the pore pressure on the shallow part rapidly increases to saturation during rainfall, and then gradually develops to the depth. After the rain stops, the pore pressure of the slope surface gradually drops, but the affected area is only limited to the elevation of 18-22 m and has a small impact on the rest.

For monitoring line 2, except the area where the pore pressure in the surface of the slope changes sharply (elevation 28-32 m), the rest of the area first remains unchanged with the elevation (elevation 22-28 m), and then presents a linear increase distribution with the elevation. For the shallow part (figures on the right), the change of pore pressure is similar to that of monitoring line 1.

DOI: http://dx.doi.org/10.15666/aeer/1705_1246512478

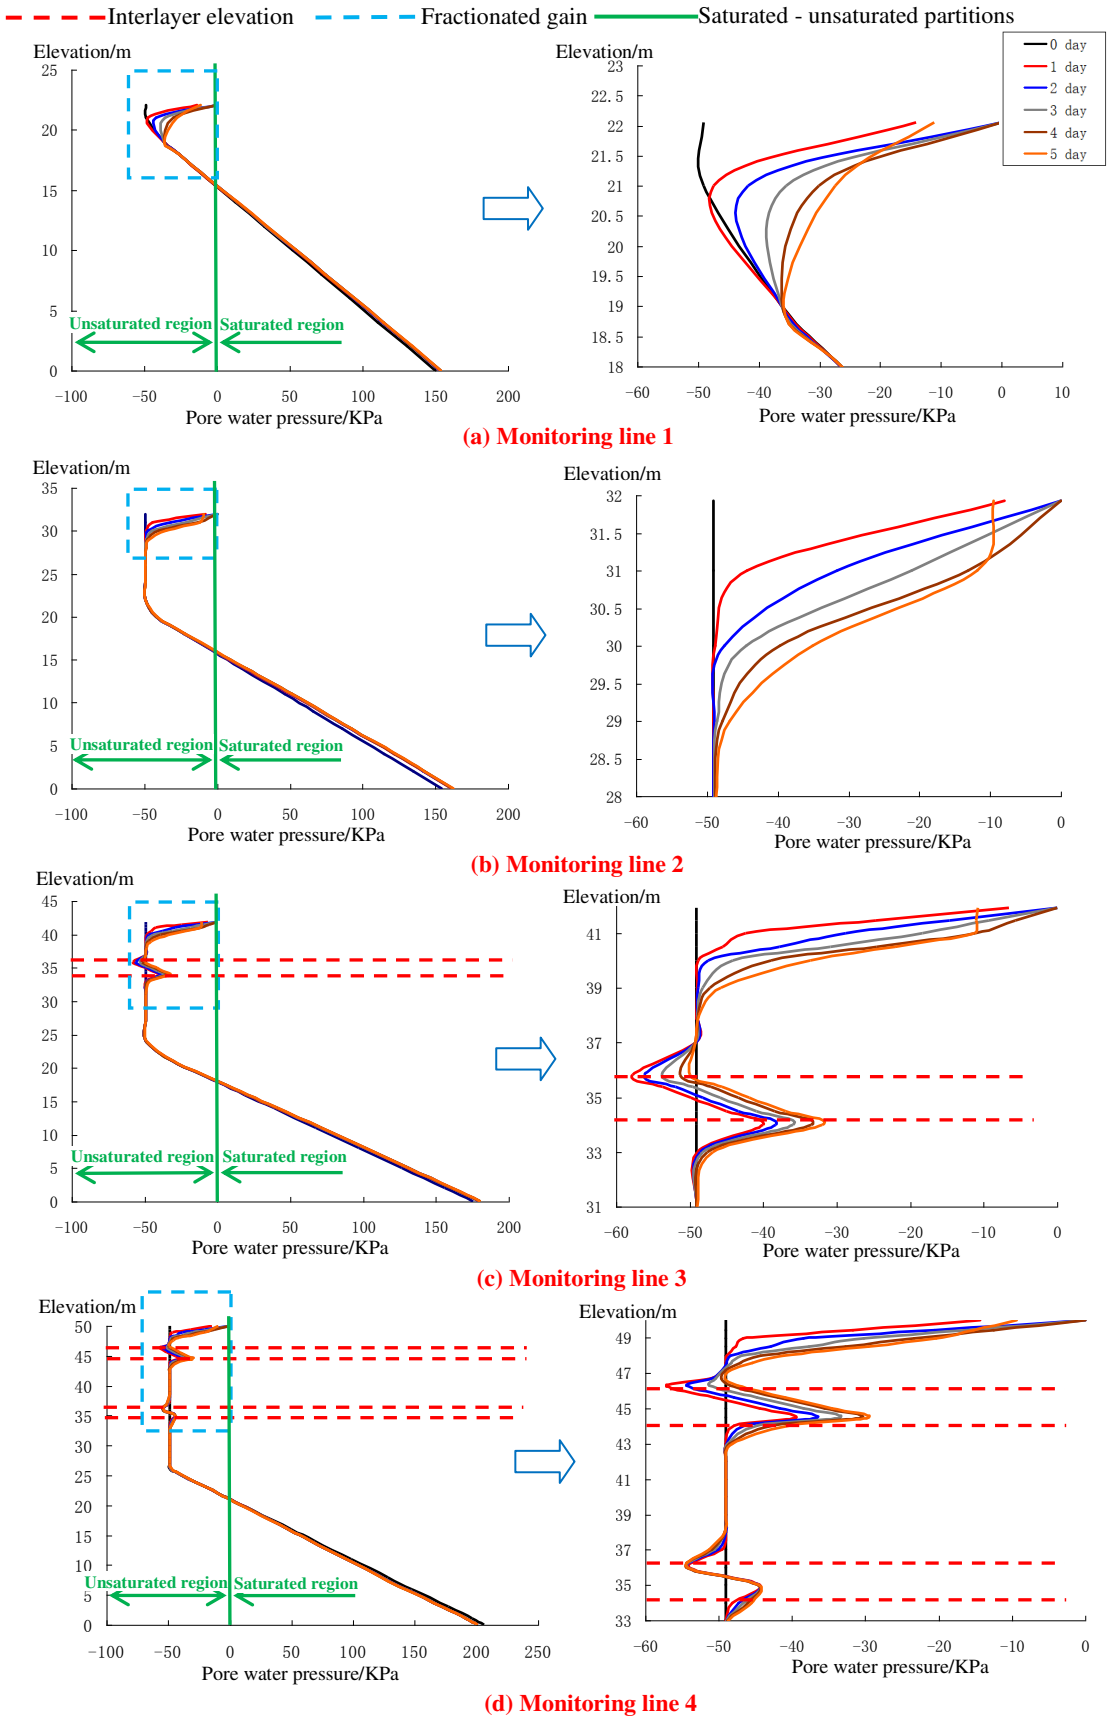

Figure 4. *Variation of pore water pressure of different time under a rainstorm*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1246512478

For monitoring line 3, in addition to the dramatical changes of surface pore pressure, there is also an obvious variation at the elevation of the weak interlayer. The pore pressure at the weak interlayer presents obvious shapes like a backwards S along the elevation, that is, the upper and lower surface pressure of the weak interlayer decreases sharply, while the internal pore pressure of the weak interlayer is large, forming a more obvious drainage effect. This is because the permeability coefficient of the weak interlayer is smaller than that of the silty clay, so this kind of shape is formed, and the variation range of pore pressure in the weak interlayer is also large.

For monitoring line 4, it passes through two weak interlayers, so the pore pressure of the monitoring surface presents two shapes like a backwards S. The first one is consistent with the change rule of monitoring point 3, while the second one is slightly different, mainly reflected in that the overall change range of pore pressure is smaller than that of the upper weak interlayer. Meanwhile, the change range of pore pressure in the weak interlayer at different times is also not so obvious, which is mainly due to the deep distance from the second weak interlayer to the slope surface and the impact of rainwater infiltration is small.

Variation of pore water pressure on the 5th day under different rainfall levels

Variation of pore water pressure on the 5^{th} day under different rainfall levels is shown in *Figure 5*. Pictures on the left side are the pore pressure distribution of the whole monitoring line, while on the right side are the region where local pore pressure changes dramatically. As can be seen from the left side, the change of pore pressure with elevation is consistent with that in *Figure 4,* and the shapes like a backwards S also exist in monitoring 3 and 4. However, when the rain stopped, the surface pore pressure would fall back in different order under different levels of rainfall, as shown on the right side of *Figure 5*. Rainstorm falls the fastest in the shallow part of the slope, followed by big rain, followed by a heavy rain. Meanwhile, the pore pressure at the weak interlayer is also different, and the pore pressure of the rainstorm is close to that of the heavy rain, the pore pressure of big rain is relatively backward. This is also easy to understand, because the low rainfall intensity makes the less water needed to be excreted from the weak interlayer, and the pore pressure of heavy rain whose rainfall intensity in the lowest is correspondingly smaller than other rainfall levels.

Variation of the wetting front

Definition of the wetting front

Rainfall infiltration is a typical unsaturated problem, according to Bodman et al. (1944), for the general rainfall process, the water content of the slope can be divided into four parts: saturation zone, transition zone, conduction area and wetting area. The lowest end of the wetting area is the wetting front, as shown in *Figure 6a.*

The soil moisture content is constantly changing with the continuous rainfall process. Fredlund (Fredlund and Rahardjo, 1993) proposed that when rainfall is applied to the slope surface, the soil surface moisture content increases rapidly from initial water content θ_0 to saturated water content θ_s. And as the rainfall continues, the wet front is continuously advanced to the deep side of the slope, and the water content curve gradually becomes smooth. The variation of soil moisture content over time is shown in *Figure 6b.*

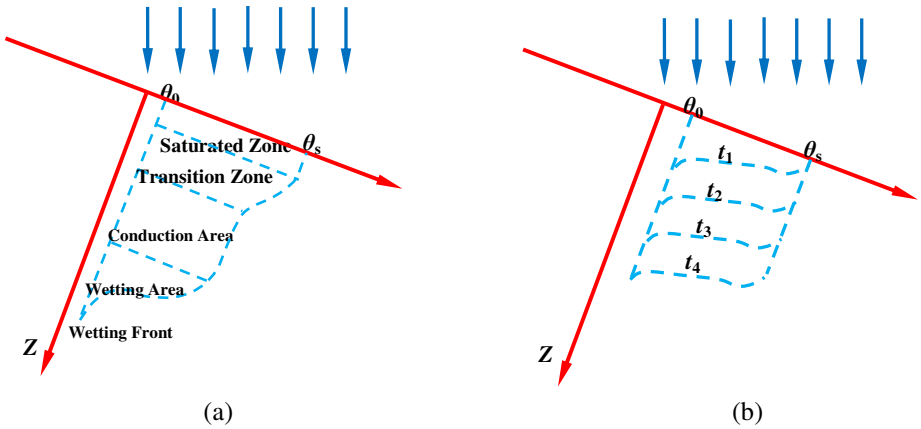

Figure 6. *Wetting front diagram.* ***a*** *and* ***b:*** *Typical water cut profile of water infiltration*

Variation of the wetting front of slope under different rainfall grades

The wetting front changes under different levels of rainfall are shown in *Figure 7*. As can be seen from the graph, the law of the development of wet front under different rainfall grades is almost the same, that is, there is uniform infiltration on the surface of clay slope. However, a sudden change in the weak interlayer occurs because the permeability coefficient in the weak interlayer is larger than that in the silty clay, so that rainfall is easier to infiltrate than other parts of the slope. Under the different rainfall levels, the development of the wetting front of rainstorm is less than that of a heavy rain, and less than that of a big rain, which indicates that rainfall infiltration under the condition of long duration and low rainfall intensity is more abundant than the high rainfall intensity of short duration. This is because, under the same rainfall condition, the high-intensity rainfall cannot completely infiltrate into the slope body, most rainwater is lost on the its surface, while the low-intensity rainfall is just the opposite, and the rainfall can fully infiltrate into the soil mass. Therefore, for the actual slope engineering, it is more likely to lose stability in the case of long duration and low rainfall intensity. At the same time, because of the high permeability of the weak interlayer, the internal pore pressure increases and the soil parameters deteriorate under the condition of rainfall, which makes it easier to form the potential failure surface. Therefore, the reinforcement of weak interlayer is also very important.

Validation and discussion

Elkamhawy et al. (2018) carried out the experimental study on failure mechanism of a slope with weak interlayers triggered by intensive rainfall. Experimental results showed that during the time of rainfall, the infiltrated water flowed out from the slope through the weak interlayer near to the toe causing piping and local failure, then the tensile cracks formed at the top grew and expanded due to sliding of the failed soil blocks along the weak interlayer, which is in accordance with our numerical results. In section 3.1 and 3.2 the pore water pressure in monitoring point 1 and monitoring line 1 have higher values than other parts, which means that rain water is abundant at the foot of the slope. So in order to restrict the growth of positive pore water pressure at the toe, we can apply the method of constructing horizontal and vertical drains to discharge the infiltrated water directly.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1246512478

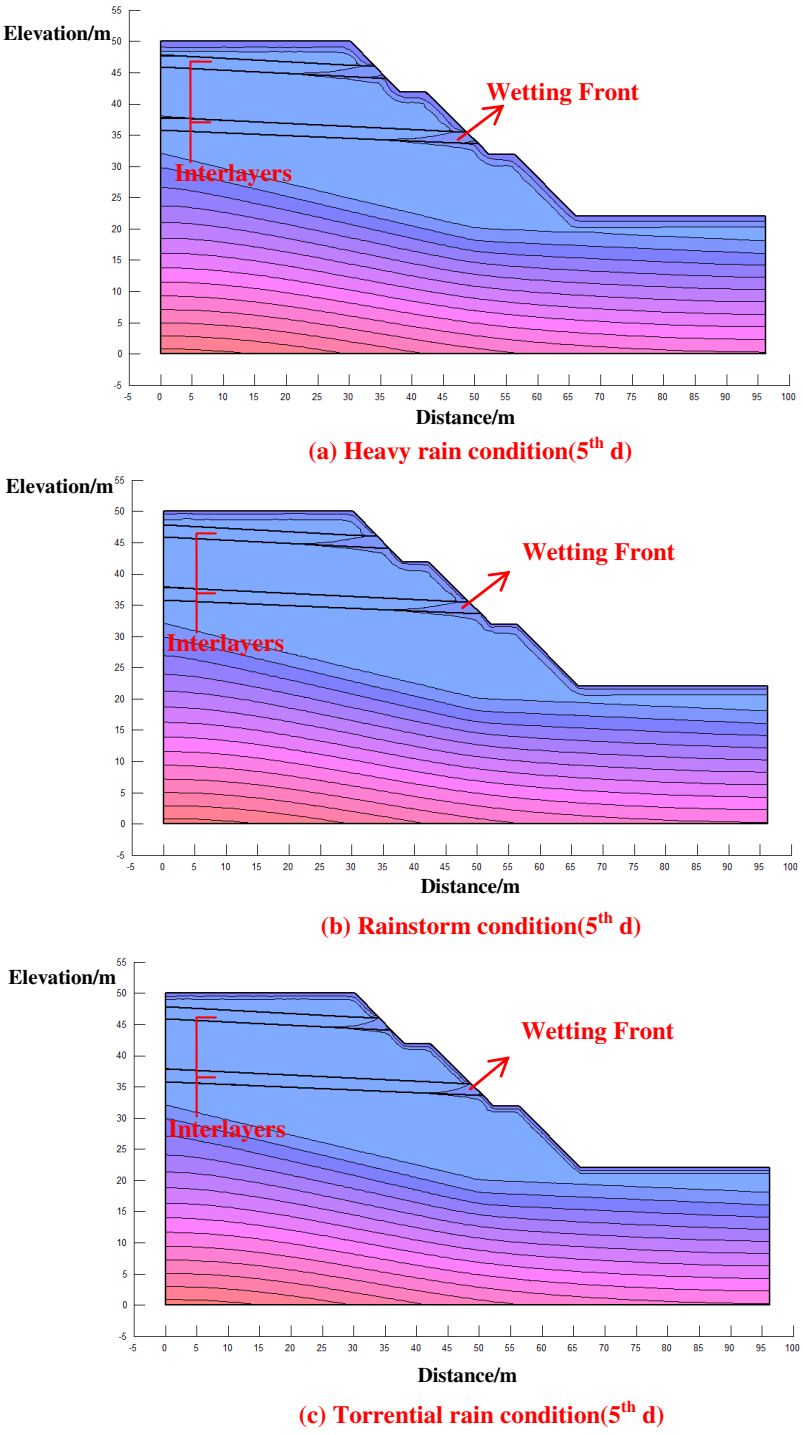

Figure 7. *Variation of the wet front under different rainfall grades*

In addition, the shapes like a backwards S of pore water pressure at the elevation of weak interlayers mean that weak interlayers is a potential leakage passage for rainfall infiltration, and along which the soil block tend to slide, so it is necessary to make proper reinforcement treatments of weak interlayers. For example, we can use soil nailing to link between the wedges prone to slide with the stable soil under the weak interlayers.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1246512478

Moreover, in our simulation, we found that the surface pore water pressure undergoes a longer period of saturation in big rain than heavy rain and rainstorm, which means that the the rainfall with low intensity and long duration has a worse effect on slope than the rainfall with high intensity and short duration, so it is very important to pay more attention to the rainfall with low intensity and long duration and prevent the landslides.

Conclusions

In this paper, the seepage characteristics of the slope with weak interlayers under different rainfall levels are numerically simulated, and the following conclusions can be obtained:

(1) Under different rainfall grades, the surface pressure of the slope at different elevations increases rapidly and reaches saturation at the time of rainfall, and decreases rapidly after the rainfall. Under the same rainfall amount, high rainfall grade makes the time when pore pressure reaches saturation earlier, and the long duration of the rainfall makes the longer duration time when the pore pressure reaches saturation.

(2) Rainfall has a great influence on the pore pressure variation in the surface layer and weak interlayer of the slope, but has limited effect on the other parts. The pore pressure distribution in different positions of the slope is also quite different. The pore pressure of the lower part increased linearly with the elevation, and the pore pressure of the middle and lower parts remains unchanged first and then increases linearly with the elevation. The pore pressure of the upper and middle parts shows shapes like a backwards S along with the elevation at the weak interlayer.

(3) Wetting front uniformly infiltrates in silty clay layer, and “sudden change” appears in weak interlayers. Meanwhile, the development of the wetting front of low intensity and long duration rainfall is larger than that of high-intensity short rainfall.

(4) For the actual slope engineering, it is very important to pay more attention to the rainfall with low intensity and long duration and prevent the landslides.

(5) Although systematic analysis of seepage characteristics are discussed in this paper, what occurs in nature is complex, and different conditions such as the variable thickness and angles of weak interlayers, different rainfall types, duration and different slope geometry should be included in future studies.

(Received 14th May 2019; accepted 20th Aug 2019)

Abstract. To study the response of some narbon vetch varieties to different defoliation intensities on forage, seed yield and their components under rain fed condition. A field experiment was conducted at College of Agricultural Sciences-University of Sulaimani in Iraq country during the winter season of 2017-2018, using split plot design. Three varieties of narbon vetch (ICARDA 2561, ICARDA 2380 and ICARDA 2706) were implemented in the main plots and arranged according to Randomized Complete Block Design and replicated three times, and four defoliation intensities (different height of forage cutting from ground level) Control (not defoliated), Low = 8 cm, Moderate = 6 cm and Severe = 4 cm from ground level) were allotted in subplots. Means comparisons were carried out using the least significant difference test (LSD) at 5% and 1% significant levels. The results of this study indicated that the interaction between ICARDA 2561 and moderate defoliation intensity gave the highest values of fresh forage yield and fresh stem percent, and the interaction between ICARDA 2380 and severe defoliation intensity gave maximum fresh leaf percent, Regarding leaves/stem ratio, maximum ratio showed by interaction between ICARDA 2561 and low defoliation intensity. The interaction between ICARDA 2380 and moderate defoliation intensity awarded the highest values of most traits such as plant height, no. of branches/plant, no. of leaves/plant, leaves weight/plant, leaves dry weight/plant and stem dry weight/plant, Maximum values of these traits biological yield, pods number/m², pod yield, seed number/pod and seed yield reached attained by the interaction between ICARDA 2706 and control treatment, but the interaction between ICARDA 2561 and control treatment gave the highest values of pod length and seeds weight/pod but concerning 100 seeds weight, the highest weight obtained by interaction between ICARDA 2380 and control treatment.

Keywords: *Vicia narbonensis, lines, cutting height, growth, yield, yield components, dry matter percent*

Introduction

The genus Vicia is made up of approximately 190 species worldwide. The genus is primarily found in the Mediterranean and Irano- Turanian regions. However, the genus Vicia is widely distributed in the temperate zone of the northern hemisphere and in extra-tropical South America (Tahereh et al., 2012). Narbon vetch (*Vicia narbonensis* L.*),* which is resistant to cold and drought, is an annual legume species (Açıkgöz, 2001; Fırıncıoğlu et al., 2012). Vetch can be grazed by animals as fresh forage (Haddad, 2006) or can be cut and preserved as hay and silage (Abdullah et al., 2010). Vetches hay can be used as a protein supplement, and their grains serve as energy and protein sources in the rations of ruminants and non-ruminants (Sadeghi et al., 2009).

DOI: http://dx.doi.org/10.15666/aeer/1705_1247912490

The potential of narbon vetch for grain production as livestock feed is greater than other vetch species, and the grain contains tannin and trypsin inhibitors that is directly affecting its efficiency of feed (Berger et al., 2002; Larbi et al., 2010), in general narbon vetch is cultivated for grain production (Buyukburc and Iptas, 2001). The species also has great importance in the system of crop rotation, either as pure stands or in a mixture with cereals for green forage or hay production to provide high-quality of livestock feed (Altınok, 2002; Altınok and Hakyemez, 2002; Iptaş and Karadağ, 2009; Nizam et al., 2011). Furthermore, narbon vetch is used as a valuable green manure plant, because it produce a high amount of green biomass, and its ability to fix large amounts of nitrogen to the soil as a legume (Albayrak et al., 2004a, b; Avcıoğlu et al., 2009; Fırıncıoğlu et al., 2012).

Narbon vetch is a fast-growing crop, with vigorous regrowth ability, and does better under warm temperatures and drier conditions (annual rainfall amount below 350 mm) than faba bean. It is tolerant to cold. When aerial parts damaged by frost may be die, but new shoots regrow when conditions will better in the spring. It can grow in many types of soils from sandy soils to loams provided they are well-drained. The input requirement of narbon vetch has low (fertilizer and pesticides) but does particularly well on alkaline soils and responds positively to P fertilizer (Mebarkia et al., 2013; Sanchez-Vioque et al., 2011). Like many other Vicia species, the culture of *Vicia narbonensis* L. has long been neglected due to the presence of anti-nutritional factors that also cause an undesirable odorand taste in grain and foliage. Once cooked, the anti-nutritional factors removed, and Narbon beans can be eaten and are described as being of high quality (Bryant et al., 2011).

Forage growers cut forages frequently at a height of 3-inches or more. However, recent reports indicate that there may be an advantage to cutting crop closer, leaving an inch or less of stubble height, which was found that annual alfalfa yields were 1.6 tons per acre higher when cutting at 1-inches compared to 5-inches heights (@griculture Online, 1999).

A study from West Virginia reports that alfalfa cut at 1 or 2 inches yielded as much as38% more than alfalfa cut at 4 inches (Belesky and Fedders, 1997). A reduction of a ½ ton of dry matter per inch as cutting height increased from 2 to 6 inches above the ground when combined across three harvests for the year (Wiersma, 2000).

However, there is little information available on the forage yield of narbon vetches grown under climatic conditions of Sulaimani. Therefore, the current study aimed to determine forage and seed yields for three varieties of narbon vetch (*Vicia narbonensis* L.) at different defoliation intensities, and which variety has ability to adapt with our condition and regrowth after defoliation to produce high yield crop.

Materials and methods

A field experiment was conducted at College of Agricultural Engineering Sciences-University of Sulaimani located (Latitude: 35 33’ N, Longitude 45° 27’ E, at altitude of approximately 830 m) during the winter season of 2017-2018, to study the effect of different varieties and defoliation intensities on growth, forage, seed yield and its components of narbon vetch (*Vicia narbonensis* L.) under rainfed condition conducting in split-plot design. Three varieties of narbon vetch (ICARDA 2561, ICARDA 2380 and ICARDA 2706) were implemented in the main plots and arranged according to the randomized complete block design (CRBD) and replicated three times, and four

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1247912490

defoliation intensities (different height of forage cutting from ground level) (Control (not defoliated), Low = 8 cm, Moderate = 6 cm and Severe = 4 cm from ground level) were allotted in subplots for seed traits, but for forage traits treatments were allotted without control (Low = 8 cm, Moderate = 6 cm and Severe = 4 cm from ground level). Each subplot consists of 3 rows, 2 m long with 0.30 m apart between rows.

Sowing was conducted during 12th December 2017 according to the recommended seed rates 120 kg/ha for three varieties and all plots were fertilized with 120 kg P_2O_5/ha as triple superphosphate, which was broadcasting before sowing, and the germination percentage for each used varieties was higher than % 95. All required agricultural practices were used as needed. Forage cutting conducted for all subplots on 4th January 2018 to determine forage yield traits:

Forage yield traits

- Fresh Forage Yield (ton/ha)
- Dry Forage Yield (ton/ha)
- Fresh Leaf%
- Dry Leaf%
- Fresh Stem%
- Dry Stem%
- Dry Matter%
- Leaves/Stem Ratio

In addition, on the same day of cutting we were taken a sample randomly (5 plants of each subplot) to estimate forage yield component traits were:

Growth traits

- Plant height (cm)
- No. of Branches/plant
- No. of leaves/plant
- Leaves weight/plant (g)
- Dry leaves weight/plant (g)
- Stem weight/plant (g)
- Dry Stem weight/plant (g)
- Root weight (g)
- Dry Root weight (g)

When the plants matured physiologically, harvesting was carried out on 4th June 2018 to record seed yield traits from each plot, but the averages of 10 pods were taken from each plot to estimate yield component traits as follows:

Seed yield and its components

- Seed Yield (ton/ha)**,**
- Biological Yield (ton/ha)**,**
- Pods Number/m^2
- Pod yield (ton/ha)
- Average Pod Length (cm)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1247912490

- Average Seeds Number/Pod
- Average Seeds Weight/Pod (g)
- 100 Seeds Weight (g)

The data were statistically analyzed according to the methods of analysis of variance as a general test and combined analysis conducted (AL Mohamad and AL Younis, 2000). Comparison among the means was carried out using the least significant test (L.S.D) at a significant level of 5% and 1% (AL Mohamad and AL Younis, 2000).

Results and discussion

Data in *Table 1* and *Appendix 1* indicated that the effect of varieties on forage yield traits was not significant for most characters but on the other traits such as (fresh forage yield, dry forage yield and fresh leaf percent) were found to be significant, ICARDA 2561 gave maximum value of fresh forage yield (13.356 ton/ha), while ICARDA 2380 recorded minimum value of this trait which was (11.706 ton/ha). But the highest dry forage yield and fresh leaf percent were (1.492 ton/ha and 63.467%) respectively exhibited by V3, in which the lowest values of both traits were (1.302 ton/ha and 60.763%) recorded by ICARDA 2380 and ICARDA 2561 regularly. These differences among varieties may be due to genetic variance and capability of each variety for best production. These results were in agreement with the results of Muhammed (2017).

Table 1. *Effect of varieties on forage yield traits of narbon vetch*

Varieties	Fresh forage yield (ton/ha)	Dry forage yield (ton/ha)	Fresh leaf %	Fresh stem %	Dry leaf %	Dry stem %	Dry matter %	Leaves/stem ratio
ICARDA 2561	13.356	1.393	60.763	39.237	7.450	3.032	10.482	1.337
ICARDA 2380	11.706	1.302	63.358	36.642	7.957	3.167	11.123	1.082
ICARDA 2706	13.130	1.492	63.467	36.867	8.242	3.100	11.342	1.267
LSD ($P \leq 0.05$)	0.923	0.079	2.171	N.S	N.S	N.S	N.S	N.S

N.S: not significant

The results of *Table 2* and *Appendix 1* confirmed that the effect of defoliation intensities on all forage yield traits was significant except these characters' dry forage yield, dry stem percent, and dry matter percent were found to be not significant. Moderate defoliation intensity (6 cm) gave maximum values of fresh forage yield, fresh stem percent and leaves/stem ratio was (13.907 ton/ha, 39.971% and 1.356) respectively, while minimum values of fresh forage yield and fresh stem percent were (12.054 ton/ha and 35.404%) registered by low defoliation intensity (8 cm), but regarding leaves/stem ratio, minimum value was 1.062 obtained by severe defoliation intensity (4 cm).

Concerning both traits (fresh leaf and dry leaf percent), low defoliation intensity (8 cm) gave the best percent (64.929 and 8.283%) respectively, while the lowest percentage of these both traits were (60.029 and 7.606%) recorded by moderate defoliation intensity (6 cm).

In theory, leaving tall stubble and leaves at the base of the plant provides more photosynthetic area and energy for new stem growth following harvest. Prevision results showed that cutting to the soil surface increased forage yield at the first cut by

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1247912490

increasing the weight of individual shoots harvested. This is simply because defoliation closer to the soil surface removed greater part of individual shoots of plants that had been uniformly managed prior to the first harvest. Plants at the first cut in the second-year growing season had stems arising mainly from the crown. This character- is tic of the plant canopy increased individual shoot weight steeply with decreasing cutting height reported by Shen et al. (2013), this result was in agreement with our results.

Table 2. *Effect of defoliation intensities on forage yield traits of narbon vetch*

Defoliation intensities	Fresh forage yield (ton/ha)	Dry forage yield (ton/ha)	Fresh leaf %	Fresh stem %	Dry leaf %	Dry stem %	Dry matter %	Leaves/stem ratio
Low (8 cm)	12.054	1.371	64.929	35.404	8.283	3.086	11.369	1.268
Moderate (6 cm)	13.907	1.483	60.029	39.971	7.606	3.081	10.687	1.356
Severe (4 cm)	12.231	1.334	62.630	37.370	7.760	3.132	10.892	1.062
LSD ($P \leq 0.05$)	0.656	N.S	1.103	1.216	0.401	N.S	N.S	0.166

N.S: not significant

Data represented in *Table 3* and *Appendix 1* showed that the effect of interactions between varieties and defoliation intensities on forage yield traits was significant on some traits such as fresh forage yield, fresh leaf percent, fresh stem percent, and leaves/stem ratio, but on the others was not significant. The interaction between ICARDA 2561 and moderate defoliation intensity (6 cm) gave the highest values of fresh forage yield and fresh stem percent were 15.587 ton/ha and 42.53% respectively, while the lowest yield of fresh forage was 11.291 ton/ha exhibited by interaction between ICARDA 2380 and low defoliation intensity (8 cm), and the lowest percent of fresh stem was 33.49% obtained by interaction between ICARDA 2380 and severe defoliation intensity (4 cm), also this interaction gave maximum fresh leaf percent 66.51%, in which minimum percent of fresh leaf was 57.47% recorded by ICARDA 2380 when treated with moderate defoliation intensity (6 cm). Regarding leaves/stem ratio, a maximum ratio was 1.432 showed by the interaction between ICARDA 2561 and low defoliation intensity (8 cm), in which the interaction between ICARDA 2380 and severe defoliation intensity (4 cm) recorded minimum leaves/stem ratio 0.532.

Table 4 and *Appendix 1* illustrated Effect of varieties on growth traits of narbon vetch, which was found that the effect was significant on plant height, leaves weight/plant, stem weight/plant and root dry weight, but on the other traits was not significant. The highest values of plant height, leaves weight/plant and stem weight/plant were (44.089 cm, 20.413 g, and 20.013 g) exhibited by ICARDA 2380**,** respectively, but maximum value of root dry weight was 0.922 g showed by variety 3, while the lowest values of these traits plant height, leaves weight/plant, stem weight/plant and root dry weight were (34.386 cm, 16.723 g, 12.490 g and 0.634) g recorded by (ICARDA 2706, ICARDA 2561, ICARDA 2561, and ICARDA 2380) respectively.

The differences between varieties in some growth traits may be positively and strongly related to the differences in genetic map and these adaptations to the climate. These results were in agreement with the results reported by (Muhammed, 2017).

Data in *Table 5* and *Appendix 1* confirmed that most growth traits of narbon vetch such as (no. of branches/plant, no. of leaves/plant, leaves weight/plant, leaves dry weight/plant and stem weight/plant) significantly affected by different defoliation intensities, while the other traits (plant height, stem dry weight/plant, root weight and root dry weight) not affected by this factor. Moderate defoliation intensity (6 cm) gave maximum values of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1247912490

(no. of branches/plant, no. of leaves/plant, leaves weight/plant and leaves dry weight/plant) were (2.919, 26.027, 21.941 g and 3.070 g) respectively, on the other hand, maximum stem weight/plant (17.721 g) presented by severe defoliation intensity (4 cm), in which minimum values of these traits (no. of branches/plant, no. of leaves/plant and leaves dry weight/plant) were (2.294, 20.257 and 2.259 g) appeared by severe defoliation intensity (4 cm), but concerning both traits (leaves weight/plant and stem weight/plant), the lowest values showed by low defoliation intensity (8 cm) which was (16.194 and 13.298) g respectively. Previous works confirmed that alfalfa growth in the spring is primarily from crown buds and depends on temperature and available root energy reserves. Shoot growth after the first harvest originates from both crown and auxiliary buds. When the crop is cut very short (1-inch or less) most of the axillary buds are removed and new shoots must come from the crown buds (Wiersma, 2000).

The results were obtained from *Table 6* and *Appendix 2* indicated that the effect of interactions between varieties and defoliation intensities on all growth traits was significant with the exception of the character root weight which was found to be not significant. The interaction between ICARDA 2380 and moderate defoliation intensity (6 cm) awarded the highest values of (plant height, no. of branches/plant, no. of leaves/plant, leaves weight/plant, leaves dry weight/plant and stem dry weight/plant) were (41.59, 3.553, 34.420, 33.537 g, 4.923 g, and 2.830 g) respectively, but the highest amount of stem weight/plant was 25.163 g offered by ICARDA 2380 when interacted with severe defoliation intensity (4 cm), and maximum root dry weight was (1.073 g) obtained by interaction between ICARDA 2706 and severe defoliation intensity (4 cm). while the lowest height of plant was 30.37 cm exhibited by interaction between ICARDA 2706 and low defoliation intensity (8 cm), but the minimum values of (no. of branches/plant, leaves dry weight/plant and stem weight/plant) were (2.107, 1.953 g and 11.067 g) showed by ICARDA 2380 when interacted with low defoliation intensity (8 cm) respectively. Regarding these traits (no. of leaves/plant, leaves weight/plant, stem dry weight/plant and root dry weight), the interaction between ICARDA 2380 and severe defoliation intensity (4 cm) gave minimum values were 17.997, 13.270 g, 1.087 g and 0.570 g, respectively.

Table 6. *Effect of interactions between varieties and defoliation intensities on growth traits of narbon vetch*

N.S: not significant

Data represented in *Table 7* and *Appendix 3* confirmed that the effect of varieties on all seed yield and its components traits was significant with the exception of the characters (pods number/m^2, pods length, and seeds weight/pod) which was found to be not significant. Maximum values of (biological yield, pod yield, average seeds number/pod and seed yield) were (5.082 ton/ha, 2.709 ton/ha, 3.554 and 2.040 ton/ha) respectively recorded by ICARDA 2706, but regarding 100 seeds weight, ICARDA 2380 gave the highest value which was 20.001 g, while ICARDA 2380 gave minimum value of biological yield 3.997 ton/ha, and ICARDA 2561 exhibited the lowest values of (pod yield, seeds number/pod and seed yield) were (2.092 ton/ha, 2.817 and 1.584 ton/ha) respectively, in which minimum weight of 100 seeds was 16.149 g registered by ICARDA 2706. The superiority of ICARDA 2706 in biological, seed yield and some other traits may be due to its adaptation in compare to other variety which

N.S: not significant

All traits of seed yield and its components of narbon vetch were shown in *Table 8* and *Appendix 2* affected significantly by different defoliation intensities. Control (not defoliated) treatment gave the highest values of these traits (biological yield, pods number/m², pods weight/m², pod length, seeds number/pod, seeds weight/pod, 100 seed weight and seed yield) were (15.725 ton/ha, 735.89, 8.0767 ton/ha, 5.936 cm, 4.333, 0.910 g, 22.196 g and 6.201 ton/ha) respectively, in which the lowest values of these previous traits exhibited by severe defoliation intensity (4 cm) were (0.376 ton/ha, 20000, 0.12719 ton/ha, 5.132 cm, 2.323, 0.584 g, 10.378 g and 0.098 ton/ha) respectively. Previously Mitchell et al. (2010), who reported switch grass should not be harvested within below a 10-cm stubble height to ensure carbohydrate translocation to the plant crowns for setting new tiller buds and maintaining stand productivity.

Table 8. *Effect of defoliation intensities on seed yield and its components of narbon vetch*

Defoliation intensities	Biological yield (ton/ha)	Pods number/m²	Pod yield (ton/ha)	Pod length (cm)	Seeds number/pod	Seeds weight/ pod (g)	100 seeds weight (g)	Seed yield (ton/ha)
Control (not defoliated)	15.725	735.89	8.077	5.936	4.333	0.910	22.196	6.201

N.S: not significant

Results of *Table 9* and *Appendix 2* confirmed that the effect of interactions between varieties and defoliation intensities on all seed yield and its component traits of narbon vetch were significant. Maximum values of these traits (biological yield, pods number/m^2, pod yield, seeds number/pod and seed yield) were attained by the interaction between ICARDA 2706 and control (not defoliated) treatment were (17.589 ton/ha, 794.33, 9.031 ton/ha, 4.600 and 6.999) ton/ha respectively, but the interaction between ICARDA 2561 and control (not defoliated) treatment gave the highest values of (pod length and seeds weight per pod) were (6.227 cm and 1.013 g) respectively, but concerning 100 seeds weight, the interaction between ICARDA 2380 and control (not defoliated) treatment gave the highest weight which was 24.820 g, while the minimum values of (biological yield and pod yield) were (0.098 and 0.046) ton/ha exhibited by interaction between ICARDA 2380 with severe defoliation intensity (4 cm), but when ICARDA 2561 interacted with severe (4 cm) defoliation intensity

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1247912490

recorded the lowest values of (pods number/m^2, pod yield, seeds number/pod, 100 seeds weight, and seed yield) were (3.00, 0.008 ton/ha, 1.500, 5.227 g and 0.004 ton/ha) respectively. Regarding the average of pods length, minimum length exhibited by the interaction between ICARDA 2380 and low (8 cm) defoliation intensity which was 3.060 cm, and when ICARDA 2380 interacted with moderate (6 cm) defoliation intensity recorded minimum value of seeds weight/pod was 0.233 g.

Table 9. *Effect of interactions between varieties and defoliation intensities on seed yield and its components of narbon vetch*

N.S: not significant

Conclusions

From the results of this study, we concluded that most traits of growth, forage yield, seed yield and its components of narbon vetch were affected significantly by different varieties, defoliation intensities and their interactions as follow:

- The interaction between variety 1 and moderate defoliation intensity (6 cm) gave the highest values of fresh forage yield and fresh stem percent, and maximum fresh leaf percent exhibited by interaction between variety 2 and severe defoliation intensity (4 cm), but maximum leaves/stem ratio, showed by interaction between variety 1 and low defoliation intensity (8 cm).
- The interaction between variety 2 and moderate defoliation intensity (6 cm) awarded the highest values of plant height, no. of branches/plant, no. of leaves/plant, leaves weight/plant, leaves dry weight/plant and stem dry weight/plant, but the highest amount of stem weight/plant was offered by variety 2 when interacted with severe defoliation intensity (4 cm), and maximum root dry weight was obtained by interaction between variety 3 and severe defoliation intensity (4 cm).
- Maximum values of biological yield, pods number/m^2, pod yield, seeds number/pod, and seed yield were attained by the interaction between variety 3 and control (not defoliated) treatment, but the interaction between variety 1 and control treatment gave the highest values of pod length and seeds weight per

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1247912490

pod, but concerning 100 seeds weight, the highest weight obtained by the interaction between variety 2 and control treatment.

Recommendation

We recommend from this study that there is a forage yield benefit to cutting or defoliation at shorter heights from ground level when the plants are not under stress or low in root carbohydrate levels, medium and high defoliation intensities significantly reduced available forage production. Seed production was adversely affected by defoliation intensity, and further study must be conduct at different locations and conditions to know the performance of these varieties.

(Received 15th May 2019; accepted 16th Jul 2019)

Abstract. The present study aimed to identify of *Rhizobium leguminosarium* from Broad bean nodules, *Azotobacter chrococcum* and *Bacillus megaterium* from the soil in Sulaimani city/Iraq. Cultural characteristics showed that the colonies of bacteria were circular, smooth convex, and white color in *Rhizobium leguminosarium* and *Bacillus megaterium*, while creamy colored for *Azotobacter chrococcum.* The isolated bacteria were motile, rod, and gram-negative in *Rhizobium leguminosarium* and *Azotobacter chrococcum,* and gram-positive in *Bacillus megaterium*. Biochemical tests found that *Rhizobium leguminosarium* was positive for Catalase and negative for Indole Production, Methyl Red, Vogas Proskauer, Citrate Utilization and Gelatinase, *Azotobacter chrococcum* was positive for Catalase and Citrate Utilization, while *Bacillus megaterium* was positive for Catalase, Citrate Utilization and Gelatinase. *Rhizobium leguminosarium* utilized Starch Glucose, Mannitol, Galactose, Raffinose, Trehalose, Mannose and Xylose, but *Azotobacter chrococcum* did not utilize Galactose and xylose, while *Bacillus megaterium* did not utilize Trehalose**.** The molecular method based on the detection of plasmid DNA*, nod*D2 and *nod*D3 in *Rhizobium leguminosarium*, chromosomal DNA, *nif*H2 and *nif*H3 in *Azotobacter chrococcum*, genomic DNA and two random primers in *Bacillus megaterium* on gel electrophoresis have been successfully applied. We conclude that cultural, morphological and biochemical tests used for identification of these isolates was equivalent to the molecular-based method.
Keywords: *biological nitrogen fixation, nod and nif genes, phosphate solubilization, PCR, gel electrophoresis*

Introduction

Rhizobia are soil bacteria able to form nodules and establish a symbiosis with the roots of leguminous plants. During the symbiotic process, rhizobia reduce atmospheric nitrogen into a form directly assimilated by plants (ammonium) (Berrada and Fikri-Benbrahim, 2014). *Azotobacter* is an aerobic and free-living bacterium that can fix atmospheric nitrogen into the soil. Plants are able to utilize the ammonia as a nutrient (Biomate India, 2008). *Bacillus megaterium* is a gram-positive bacteria; it has a very efficient protein secretion system, grow on several different and cheap carbon sources, lack endotoxins, and are nonpathogenic. Proteins produced from and with it are of great industrial importance (Bunk et al., 2010). *B. megaterium* has the ability to solubilize phosphorus in the soil (Patel et al., 2016).

Nitrogen (N) and Phosphorus (P) are mineral nutrients often limiting plant growth because they are required in large amounts in relation to their availability in the soil

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1249112506

(Harpole et al., 2011). Biological Nitrogen Fixation (BNF) is known to be a key to sustain agriculture and to reduce soil fertility decline (Kahindi et al., 2009). (BNF) is an efficient source of fixed N2 that plays an important role in land remediation (Mohammadi et al., 2012). Nitrogen fixation in symbionts and free-living microbes is catalyzed by nitrogenase; an enzyme complex encoded *nif*DK and *nif*H genes. Nitrogenase itself consists of a molybdenum-iron protein (MoFe), subunit I and an iron-containing protein (Fe) subunit II. This biological process between *Rhizobium* strains and their legume partners can happen under low levels of available nitrogen with the help of many different genes such as a *nod, nif, fix*, production of polysaccharides, competition, infection process, and host specificity. *Nod*D is appositive transcription regulator from the Lysr family and present in all *rhizobia* (Shamseldin, 2013). The structural *nif* genes from taxonomically diverse microbes are nearly identical and function in a similar manner to encode nitrogenase (Ruvkin et al., 1980). *Azotobacter spp.* studies on the genetics in this genus should take into consideration their *nif* genes which are responsible for fixing nitrogen (Dashti, 2011; Khider, 2011; Abid, 2013; Mohamed, 2017). The *nif*H gene is the biomarker most widely used to study the ecology and evolution of nitrogen-fixing bacteria (Raymond et al., 2004). Phosphate solubilization ability of microorganisms is associated with the release of low molecular weight organic acids (Puenta *et a*l., 2004). The phosphate solubilization ability of microorganisms is regulated by several genes (Young and Lai, 2008), these genes are induced under phosphate starvation and constitute the Pho regulation (Bagyaraj et al., 2000). *Bacillus megaterium var. phosphaticum* was used to create a bio-preparation called Phosphobucterin with the purpose of enhancing mineral phosphorus solubilization (Sylvia et al., 1999).

The present study was carried out to compare two strategies for the isolation and identification of *Rhizobium leguminosarium* from bean nodules, *Azotobacter chroococcum* and *Bacillus megaterium* from soil depending on classical phenotypic approaches and through molecular methods by detection of *nod*D genes in *R. leguminosarium* and *nif*H genes in *A. chroococcum* and cheek the presence of *B. megaterium* that reported in different researches to do significant role in biological nitrogen fixation and phosphorus solubilization up to date. We used the molecular methods addition to the classical taxonomical process to support and to be sure that the bacteria which identified by the classical taxonomical process are same using molecular methods or not, because often the tests or characteristics of the classical taxonomical process of many bacterial species are similar which in some cases make the identification difficult. So, this classification should be confirmed and supported by molecular examination. This study consider the importance report and the first time identified of these bacteria depending on molecular approach in Bakrajow soil in Sulaimani city, Kurdistan region, Iraq.

Materials and methods

Isolation of bacteria

Rhizobium leguminosarium spp.

Nodulated Broad bean was selected from the organic farm of Bakrajow; the plant washed thoroughly with running tap water, then healthy, unbroken, firm and pink nodules were selected for the isolation. Isolation of *Rhizobium* was done on Yeast Extract Mannitol Agar (YEMA) (Handley et al,. 1998; Castro et al., 2003; Kucuk et al., 2006).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1249112506

The selected nodules were repeatedly washed in sterile water for 3-4 min, then washed with 70% ethyl alcohol, next rewashed with sterile water, after that crushed with a sterile glass rod. The resulting suspension was streaked on YEMA medium and incubated at 28 °C for 2-3 days. The developed colonies were isolated and purified then identified (Agrawal et al., 2012).

Azotobacter chroococcum spp.

Modified Ashby's Medium (MAM) was used as the specific *A. chroococcum* medium (Astafyeva and Shalabayeva, 2016). Two grams of soil samples were added to 500 ml Erlenmeyer flasks containing 100 ml (MAM), then stirred on rotary shaker 180 rpm for 10 min, streaked out on (MAM) and incubated at 28 ± 2 °C for 2-5 days to be checked for purity (Marwa et al., 2010).

Bacillus megaterium

B. megaterium was isolated through suspending 10 g of soil in 100 ml distilled water in a conical flask. Aerobic spore formers pasteurized a diluted soil sample at 80 °C for 10-15 min and serial dilutions were made from soil suspension, then 100 µl of soil suspension at different dilutions powered onto the surface of Sperber's medium which is a selective medium for isolating *B. megaterium*. Incubated at 28-30 °C for 48 h. Developed colonies of *B. megaterium* appearing on the plates were observed (Shiva et al., 2010).

Purification of bacteria

A single colony of each isolated bacteria (48 h old surface film) was streaked on their selective media; the growth was observed depending on the type of bacteria, *R. leguminosarium* and *B. megaterium* after 24-48 h and *A. chroococcum* after 3-7 days at 28 °C of incubation. The well separated and apparently uncontamination colonies appearing on the plates were streaked on agar medium, plating and picking were repeated at least 4-5 times (Ausubel et al., 1987).

Identification of isolated bacteria by cultural and microscopical characteristics

Cultural characteristics for each isolated were achieved on their media including the shape, color and type of the colonies after 24-48 h for *R. leguminosarium* and *B. megaterium*, and after 3-7 days for *A. chroococcum* at 28 °C of incubation, while microscopical tests for each isolated were carried out for fixed smears using gram stain, shape, and motility followed the method described by Mahon and Manuselis (2000).

Identification of isolated bacteria by biochemical tests

The isolated bacteria were characterized biochemically such as Catalase test and Gelatinase test according to Forbes et al. (2002), methyl red, vogas proskauer and Indole production depending on Atlas et al. (1995) and Citrate utilization according to Mahon and Manuselis (2000).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1249112506

Identification of isolated bacteria by carbohydrate fermentation test

Carbohydrate fermentation profiles were conducted in Yeast manitol broth for *R. leguminosarium*, Modified Ashby's broth for *A. chroococcum* and Sperber's broth for B. *megaterium* as carbon sources amended with 0.004% of chlorophenol red and 1% of one of the investigated sugars namely: Starch, Glucose, Mannitol, Galactose, Raffinose, Trehalose, Mannose and Xylose, growth was observed after 5 and even up to 15 days at 28 °C of incubation. Acid and gas production were detected by observing the color change of chlorophenol red from red to yellow (acid) and accumulation of gas in Durham's tube (gas) (Forbes et al., 2002).

Maintenance and storage of bacterial culture

The cultures were maintained for a short time at slant medium, and for a long time without losing their activity in 20% glycerol and stored at - 70 °C (Ausubel et al., 1987).

Identification of bacteria by molecular basis protocol

Extraction of Chromosomal, Genome and Plasmid DNA from bacteria

Plasmid DNA was extracted from pure culture of *R. leguminosarium* using Genet bio, PrmePrep Plasmid DNA isolation kit, and Chromosomal DNA from pure culture of *A. chroococcum* and Genome DNA from pure culture of *B. megaterium* were extracted using the PrestoTM Mini gDNA Bacteria Kit Protocol.

PCR amplification conditions

The conditions of PCR amplification: for *nod*D2 and *nod*D3 were performed according to the modified method of Del Cerro et al. (2015a) at cycling conditions consisted of a single cycle of 95 °C for 10 min, followed by 45 cycles of 95 °C for 2 min, 60 °C for 30 s and 72 °C for 30 s, and a final extension cycle at 72 °C for 6 min., while PCR reactions for *nif*H2 and *nif*H3 were done depending on Setubal et al. (2009), and for random primers 1 and 2 of *B. megaterium* carried out depending on Patil et al. (2013). The forward, reverse and random primers are shown in *Table 1.*

Gel electrophoresis

The PCR products were checked by electrophoresis by dissolve 0.5, 1, 1.5 and 2% (w/v) agarose gel depending on the size of amplified DNA fragments in 100 ml IX TBE buffer by heat in microwave oven for 3 min, then cooled solvent to 45 °C at room temperature, Gels were stained in ethidium bromide and then covered the gel tank by lid and electrophoresis was run at (80 V, 100 V) 10 V/cm. DNA fragments were visualized at 312 nm with a UV-transilluminator Image (Helmut et al., 2004).

Results

Isolation

R. leguminosairum was isolated from Broad bean plant nodules using yeast mannitol agar medium, and colonies observation were done after 2-3 days of incubation at 28 ± 2 °C (*Fig. 1*). The nodules were found positive for the presence of *R. leguminosarium*. *A. chroococcum* was isolated from the soil using Modified Ashby's

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1249112506

medium, and the growth was observed after 3-7 days of incubation at 28 °C (*Fig. 2*). *B. megaterium* was isolated from soil using Sperber's medium, and the colonies were observed on the plates after 48 h of incubation at 28-30 °C (*Fig. 3*). Then the bacteria were characterized morphologically, biochemically and molecularly.

Identification of isolated bacteria by the morphological and biochemical characteristics

To identify the species, the following were determined: the growth, morphological, biochemical properties, and carbohydrate fermentation tests according to Brenner et al. (2005).

Table 2 represents cultural and microscopical characteristics of *R. leguminosarium, A. chroococcum and B. megaterium*. The colonies of all the bacteria were circular in shape and smooth convex in type, but in color, *R. leguminosarium and B. megaterium* were white while *A. chroococcum* was creamy color. The all bacteria were rod in shape and motile, but in gram stain, *R. leguminosarium* and *A. chroococcum* were negative while *B. megaterium* was positive.

Table 2. *The cultural and microscopical tests of the isolated Rhizobium leguminosarium, Azotobacter chroococcum and Bacillus megaterium*

Test	**Bacteria**		
	Rhizobium leguminosarium	***Azotobacter chroococcum***	***Bacillus megaterium***
Colonies

Identification of bacteria by the molecular basis

Moreover based on the molecular method, plasmid DNA and *nod*D genes of *R. leguminosarium*, chromosomal DNA and *nif*H genes of *A. chroococcum*, and genome DNA and random primers of *B. megaterium* were detected.

The chromosomal DNA from *A. chroococcum*, genome DNA from *B. megaterium* and plasmid DNA from *R. leguminosarium* were detected on the agarose gel electrophoresis, the result shows in *Figure 4*, lane 2, 4, 6 respectively.

The PCR was carried out for all tested isolates to check the presence of *nod*D2 and *nod*D3 genes in *R. leguminosarium*, *nif*H2 and *nif*H3 genes in *A. chroococcum*, and to know the presence of the *B. megaterium* in the region using two random primers. Their

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1249112506

banding patterns of DNA on agarose gel electrophoresis were compared with their references' primers. The PCR products for *R. leguminosarium* were: *nod*D2 (100 bp) (*Fig. 5*) and *nod*D3 (150 bp) (*Fig. 6*), for *A. chroococcum* were: *nif*H2 (250 bp) (*Fig. 7*), and *nif*H3 (130 bp) (*Fig. 8*) lanes 2, while these bands did not appear in the negative control (lanes 3) in all figures.

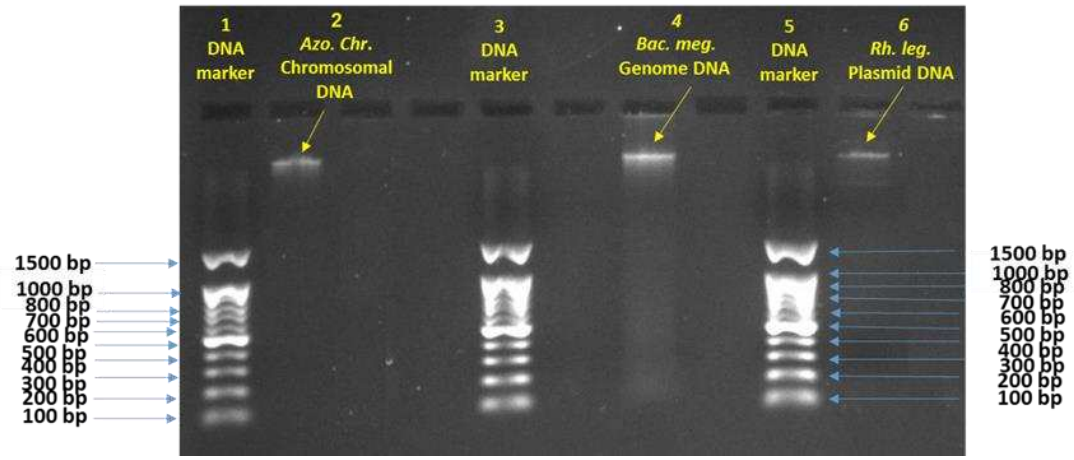

Figure 4. *Agarose gel electrophoresis shows DNA marker lanes (1, 3, and 5), extracted chromosomal DNA from A. chroococcum lane 2, genome DNA from B. megaterium lane 4, and plasmid DNA from R. leguminosarium lane 6*

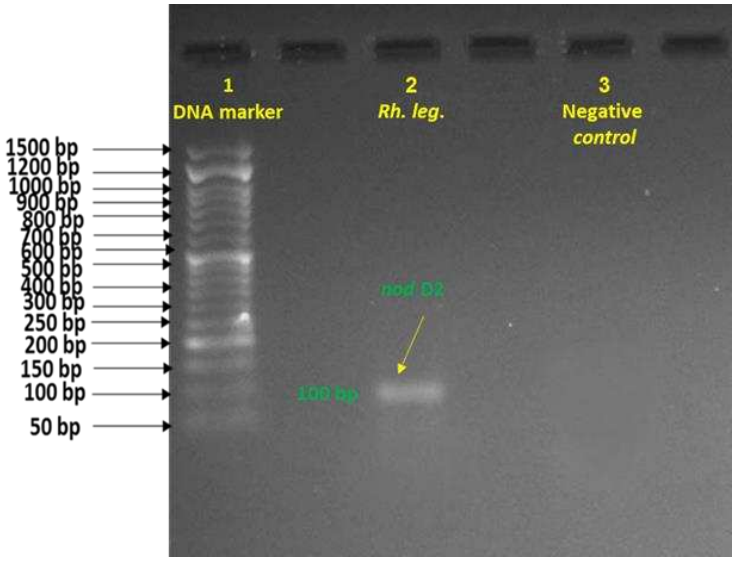

Figure 5. *Agarose gel electrophoresis shows the PCR amplified products of the nodD2 gene (100 bp). Lane 1: DNA marker, lane 2: R. leguminosarium (+ve PCR product), lane 3: negative control (-ve PCR product)*

For *B. megaterium* using random primers (1 and 2) were obtained high amplification rate and reproducible banding pattern which confirmed the existence of *B. megaterium* in the regions (*Fig. 9*) lanes 2 and 3. Therefore, all the bacteria that classified depending on the traditional approach were compared with that of molecular-based methods.

Discussion

This research work aimed to compare two different methods reported in the literature for the isolations of *R. leguminosarium* from Broad bean nodules, *A. chroococcum* and *B. megaterium* bacteria from Bakrajow soil in Sulaimani city, Iraq, in order to prove the presence and identify these bacteria. Different criteria have been presented by several researchers to delimit characteristic which can be used as a key for identification of all studied bacteria, generally included morphological, cultural, biochemical and molecular

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1249112506

characteristics, highlighting the points which may be used as the diagnostic indications. All bacteria were processed through the characteristics using common procedures for isolation and identification of all isolated bacteria using selective media for each bacteria.

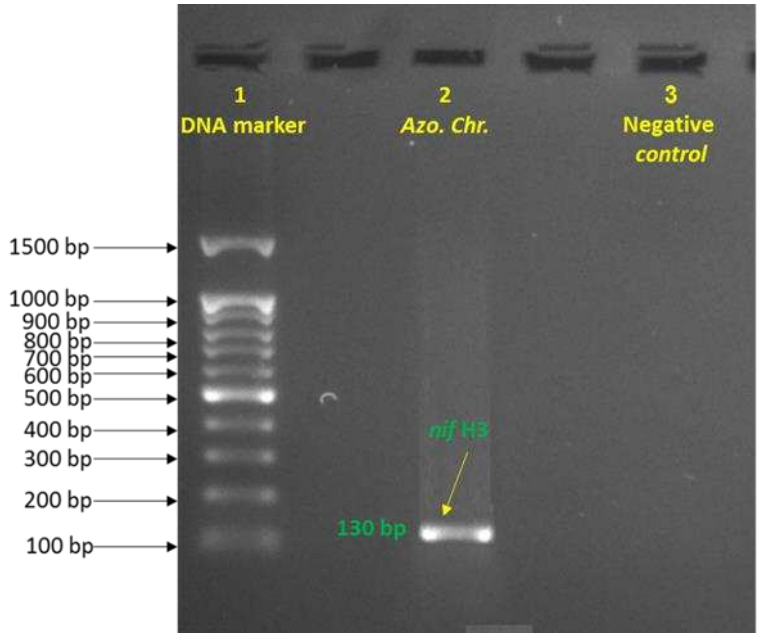

Figure 8. *Agarose gel electrophoresis shows the PCR amplified products of the nifH3 gene (130 bp). Lane 1: DNA marker, lane 2: A. chroococcum (+ve PCR product), lane 3: negative control (-ve PCR product)*

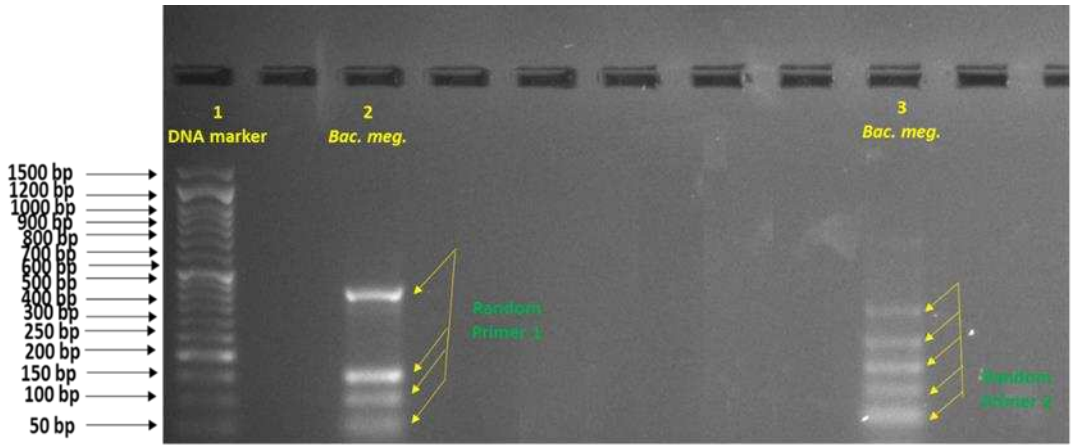

Figure 9. *Agarose gel electrophoresis shows the PCR amplified products of the B. megaterium isolate generated using 10-mer random primers: Lane 1: DNA marker, lanes 2 and 3: random primers 1 and 2 respectively (+ve PCR products)*

The nodules of Broad bean showed presences of *R. leguminosarium* basing on the characteristics, the colony morphology on a selective medium is clearly recognizable (*Fig. 1*), so the isolated bacteria classified as *R. leguminosarium* when the colonies were circular in shape, white color, smooth convex in type, and the bacterium was motile, rod

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1249112506

and gram-negative. The biochemical characterization found positive for Catalase test, and negative for other biochemical tests, when *R. leguminosarium* utilized starch and all other sugars and produced of gas and acid, considered the important observations to classify the isolated bacteria as *R. leguminosarium*, Depending on these characteristics the isolated *Rhizobium* was classified as *R. leguminosarium* according to Brenner et al. (2005). Same results have also reported by other researchers like Shoukry et al. (2013), Datta et al. (2015) and Tesema (2018).

Obviously molecular characterization of the isolated *Rhizobium* identified based on the extraction and purification of plasmid DNA from pure culture of *R. leguminosarium* to detect of *nod*D genes, because nodulation genes (*nod* genes) are located on the plasmid which is also called mega plasmid (Kumari and Sinha, 2011), which have been successfully applied and the banding pattern of plasmid DNA on agarose gel electrophoresis showed in *Figure 4* lane 6. The PCR was carried out for isolated bacteria by using complementary primers in order to amplify and cheek the presence of *nod*D2 and *nod*D3 for isolated *Rhizobium* which identified as *R. leguminosarium* by the traditional approach. The *nod*D2 and *nod*D3 genes were (100 bp) and (150 bp) in *Figures 5* and *6,* lanes 2, respectively. *Nod*D genes act as the family of regulatory (Kidaj and Wielbo, 2010). In legume nitrogen-fixing symbioses, rhizobial *nod* genes are obligatory for initiating infection thread formation and root nodule development (Fujishige et al., 2007). *Nod*D is the core signaling protein, reacting to plant flavonoids then binding to nod boxes, binding sites upstream of *nod* genes, typically *nod*A and/or *nod*B, triggering the expression of a *nod* gene cascade and thus the construction of the Nod Factor (Jones et al., 2007). The *nod* gene is controlled by *nod*D gene. *Nod*D proteins act as a transcriptional activator of inducible nod gene (Kumari and Sinha, 2011). So the importance of *nod*D in nitrogen fixation process gives importance to our choice of these genes (*nod*D2 and *nod*D3) which are located on the plasmid for this study. The common nodulation genes (*nod*DABC) are found in all bacteria that nodulate legumes (Giraud et al., 2007). Also Black et al. (2012) reported that all fourteen species of *Rhizobium* contained *nod*D, *nod*E, *nod*G, *nod*I, *nod*M, *nod*P, *nod*Q, *nod*V, and *nod*W. As well Rossen et al. (1985), Hu et al. (2000) and Zeze et al. (2001) showed and confirmed presence of *nod*D in *R. leguminosarium.*

The soil sample was processed through the colony characteristics, morphology, and biochemical tests, using common procedures for isolation and identification of *A. chroococcum* and *B. megaterium* species in the soil using selective media for each bacteria. The sample showed presences of the two species depending on their characteristics.

The colony morphology of *A. chroococcum* on Modified Ashby's medium clearly appeared (*Fig. 2*), and the medium that used is to be selective enough, so the isolated classified as *A. chroococcum* when the colonies were circular in shape, creamy color, smooth convex in type and the bacterium was motile, rod and gram-negative, in biochemical characterization found positive for Catalase test and Citrate utilization, but negative for other biochemical tests. The important observations that the isolates classified as *A. chroococcum* when utilized different carbon sources such as starch, glucose, mannitol, raffinose, trehalose and mannose. Marwa et al. (2010), Dashti (2011), Khider (2012), Abid (2013) and Mohamed (2017) obtained same results when they isolated different strains of *Azotobacter* from the soil of different regions in Kurdistan-Iraq. The isolated *Azotobacter* was classified as *A. chroococcum* according to Brenner et al. (2005) in Bergey's Manual of Determinative Bacteriology.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1249112506

Indeed molecular characterization of the isolated *Azotobacter* based on the extraction of chromosomal DNA from pure culture of *A. chroococcum* and the banding pattern of the chromosomal DNA on agarose gel electrophoresis showed in *Figure 4* lane 2. Then the *nif*H genes detected on chromosomal DNA of *A. chroococcum*, because *nif* genes in some free-living bacteria are located on the chromosome (Kumari and Sinha, 2011). Using of the complementary primers to well-conserved regions in the bacterial genome, led to amplify the *nif* genes (nitrogenase genes) *nif*H2 and *nif*H3 genes by PCR which identified as *A. chrococcum* by classical approach. The *nif*H2 and *nif*H3 genes were (250 bp) and (130 bp) in *Figures 7* and *8,* lanes 2, respectively. *Nif*H acts as dinitrogenase reductase, obligate electron donor to dinitrogenase during dinitrogenase turnover and is required for FeMo-Co biosynthesis and apodinitrogenase maturation (Shamseldin, 2013). The region of chromosome which contain *nif*K, *nif*D, *nif*M, *nif*A, *nif*N, *nif*B, *nif*Q, *nif*Z, *nif*P, *nif*F, *nif*W, *nif*B, *nif*L, and *nif*Y genes are located between the fragment of chromosome which contains *nif*H2 and *nif*H3 and the fragment contain *nif*V, *nif*S, and *nif*U (Hamilton et al., 2011). Importance of region of *nif*H2 and *nif*H3 genes on chromosome took into consideration to select these genes for this study. Previous studies by Kirshtein et al. (1991), Ueda et al. (1995), Zehr et al. (2003), Aquilantia et al. (2004), Mary Ann and Virginia (2007), Dashti (2011), Hamilton et al. (2011), Khider (2012), Abid (2013) and Mohamed (2017) indicated that N-fixing bacteria were investigated by the diversity of nitrogenase genes in different environments, through amplification of *nif* genes, i.e., *nif*H, *nif*D, *nif*V, *nif*K, *nif*U which encode nitrogenase complex from cultivated organisms.

Sperber's medium was used as a selective medium to identify the *B. megaterium* depending on the colonies (*Fig. 3*) and bacterium morphology, and other characteristics, the isolated classified as *B. megaterium* when the colonies were circular in shape, white color, smooth convex in type and the bacterium was motile, rod and gram-positive. In biochemical characterization found positive for Catalase, Citrate utilization and Gelatinase tests, but negative for Indole Production, Methyl Red and Vogas Proskauer. *B. megaterium* had the ability to utilize all carbon sources except trehalose. Other researchers have also reported same results such as Dunca et al. (2005), Tenzing et al. (2016), Patel et al. (2016) and Environment and Climate Change Canada (2018). So the isolated *Bacillus* was classified and identified as *B. megaterium* according to Brenner et al. (2005) in Bergey's Manual of Systematic Bacteriology.

Molecular characterization of the isolated *B. megaterium* was identified through extraction of the genome DNA from pure culture of *B. megaterium* culture, and the banding pattern of the genome DNA on agarose gel electrophoresis showed in *Figure 4* lane 4. The PCR was carried out for isolated bacteria by using two random primers 1 and 2 to detect and cheek the presence of *B. megaterium* in the region which identified as *B. megaterium* by classical approach. In the results found that the banding patterns were intense, clear and reproducible in *B. megaterium* (*Fig. 9*). Previous studies by Shiva et al. (2010) and Patil et al. (2013) indicated the presence of *B. megaterium* in the different area by these primers.

Conclusion

As the result of the morphological and growth characteristics, physiological and biochemical properties of all isolated bacteria according to Brenner et al. (2005) in Bergey's Manual of Systematic Bacteriology, and based on the molecular methods: the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1249112506

isolated *Rhizobium* was taxonomically classified as *Rhizobium leguminosarium*, isolated *Azotobacter* as *Azotobacter chroococcum* and isolated *Bacillus* as *Bacillus megaterium*, so the results of the classical approaches were parallel with molecular methods. Our recommendation is using molecular method with multiplex PCR for one step identification of each bacteria is faster, more accurate and low cost. Detection of other *nod* and *nif* genes required further work.

Acknowledgments. We wish to thank Dr. Zaid Khalaf Khidhir from Faculty of the Agricultural Sciences University of Sulaimani for his cooperation; we also wish to thank Professor Dr. Nawroz Abdul-razzak Tahir from Faculty of the Agricultural Sciences University of Sulaimani for his helpful in the molecular part.

Abstract. *Dendrocalamopsis beecheyana* var. *pubescens* is native to the southern provinces of China. In this study, the genetic diversity of 17 accessions from 6 populations of Fujian and Guangxi provinces were assessed. Genetic diversity was estimated using ISSR (inter-simple sequence repeat) markers. Sixteen selected primers produced 185 ISSR loci, of which 167 (90.27%) were found to be polymorphic. Dendrogram analyses revealed that the 17 accessions formed six major groups, while the six populations were clustered into three major groups. A high genetic diversity was identified at the species level, with the percentage of polymorphic band (*PPB*), Nei's gene diversity (*He*) and Shannon's information index (*I*) was found to be 90.27%, 0.2497, and 0.3949, respectively. In addition, Nei's differentiation coefficient (*Gst*) was relatively high (0.5399) and a low rate of gene flow (*Nm*) of 0.4261 was observed. The results clearly show that there is a high degree of genetic variation at the species level and a low degree of genetic variation at the population level. Moreover, ISSR molecular markers could be effectively utilized for the characterization of *D. beecheyana* var. *pubescens* accessions and identification of the relationships within populations.
Keywords: *D. beecheyana var. pubescens primers, genetic variation, Fujian, species level*

Introduction

Dendrocalamopsis beecheyana var. pubescens is considered to be an important ornamental bamboo with low cold tolerance, which is widely cultivated in the southern region of Guangdong Province, Hongkong, and Taiwan (Editorial Committee of Chinese Flora of Chinese Academy of Sciences, 1996). In China, this bamboo species is used for the manufacture of construction materials, while the bamboo shoots are used in the traditional Chinese cuisine of Fujian and Guangxi Provinces. In addition, it has been used for soil and water conservation and also to improve the environment in the coastal town of Zhangzhou in Fujian Province (Li et al., 2017). Thus, this bamboo has gained its value for ornamental, ecological, economic, and social purposes and is characterized by its wide adaptability, fast breeding, and highly developed root system (Desai et al., 2015).

To date, genetic diversity analysis of bamboo species has been done with molecular marker variations using PCR amplification (Barkley et al., 2005; Tian et al., 2012; Yang et al., 2012). However, studies on *D. beecheyana* var. *pubescens* have been limited to tissue culture, physiological biochemistry, and cultivation techniques with little information reported on genetic diversity. Considering the rich genetic diversity of bamboo species, its genetic diversity analyses can help to determine the genetic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1250712519

resources of the species, and also the selection and conservation of improved cultivars.

In recent years, a number of molecular marker technologies have been developed and widely applied in genetic diversity and DNA fingerprinting studies including random amplified polymorphic DNA (RAPD) markers, restriction fragment length polymorphism (RFLP) markers, amplified fragment length polymorphism (AFLP) markers, and inter-simple sequence repeat (ISSR) markers (Grover et al., 2016). RAPD has been regarded as an approach that exhibited high efficiency, sensitivity, and specificity, with rapid and simple method to analyze genomic DNA; however, it is incapable of discriminating between heterozygotes and homozygotes (Williams et al., 1990). The RFLP method offers large numbers of markers, but requires larger quantities of DNA from fresh samples (Yang et al., 1996). Similarly, AFLP markers offer high resolution, stability, and efficiency, but the requirement of high-purity DNA and restriction enzyme makes it expensive to use (Vos et al., 1995). ISSR markers provide a simple, rapid, and highly efficient method that is comparatively economical (Zietkiewicz et al., 1994). Moreover, this technique can detect abundant polymorphic fragments without previous knowledge of the position of the target DNA sequences. Furthermore, ISSR method exhibited high reproducibility since it used long primer lengths and high annealing temperatures (Archak et al., 2003). Due to these advantages, ISSR method was selected to study the analysis of genetic diversity among *D. beecheyana var. pubescens* accessions. In the present study, we applied this approach to estimate the genetic diversity within and among the populations of *D. beecheyana* var. *pubescens* collected from different regions in Fujian and Guangxi Provinces. Moreover, due to limited information based on ISSR marker few related report about the genetic diversity was compared with other species, such as mango (Luo et al., 2011), cucumber and apricot (Li et al., 2014), and *Platycodon grandiflorus* (Nie et al., 2014). These analyses provided insights into the germplasm resources and genetic relationships of natural bamboos populations that can help inbreeding improved varieties and for conservation.

Materials and methods

Plant materials

A total of 17 accessions of *D. beecheyana* var. *pubescens* from 6 natural populations of Fujian and Guangxi Province were used in this study. The geographical location of each population was determined using GPS and are listed in *Table 1*. The samples were cultivated at the Chishan state-owned forest farm, Dongshan, Fujian, China. Fresh young leaves were collected for the analyses (*Fig. 1*).

DNA extraction

Total genomic DNA from each accession was extracted using a Biospin Plant Genomic DNA Extraction kit following the manufacturer's instructions. The qualitative and quantitative analysis of DNA was performed on 1% agarose gels using an ultraviolet spectrophotometer (NANODROP 2000c Thermo Fisher, Beijing, China). The extracted DNA was diluted to 25 ng/μL and stored at -20 °C for future use.

Primer selection and ISSR-PCR amplification

In order to select appropriate primers for *D. beecheyana var. pubescens*, 100 ISSR primer sequences (*Supp. Tab* 1) provided by the University of British, Columbia (UBC) (https://www.ubc.ca/) in Canada were screened using an optimized ISSR-PCR system by the Shanghai Sangon Biological Engineering Technology Service Co. Ltd., China.

ISSR-PCR amplifications were performed in a total reaction volume of 20 μL containing 2.5 mM $MgCl_2$, 0.25 mM dNTPs, 1.25 U of Taq DNA polymerase (TaKaRa Biotechnology, Dalian, China), 0.6 μM primer, 10 ng genomic DNA, and 2 μL 10× buffer. The reactions were performed in a TProfessional Thermocycler (Biometra, Gottingen, Germany) with the following conditions: initial denaturation at 94 °C for 5 min; followed by 40 cycles of 45 s at 94 °C, 30 s at annealing temperature (50-60 °C), 90 s at 72 °C; and final extension at 72 °C for 10 min. The PCR products were stored at 4 °C until further use. These PCR products (0.5 μg/mL in 1× TBE buffer (445 mmol/L Tris, 445 mmol/L borate, 10 mmol/L EDTA)) were subjected to electrophoresis on a 1.5% agarose gel at 120 V for approximately 1 h and the gel was later analyzed using Gel Documentation System (Bio-Rad, Hercules, California, USA).

Data analysis

Polymorphic DNA fragments, obtained with reproducible bands, were scored as present (1) or absent (2). The binary data matrix was analyzed using POPGENE32 (Yeh et al., 2000) to obtain the following genetic diversity parameters within and among populations: percentage of polymorphic bands (*PPB*), number of alleles (*Na*), effective number of alleles (*Ne*), Nei's gene diversity (*He*), Shannon's information index (*I*), total genetic diversity (*Ht*), genetic diversity within populations (*Hs*), coefficient of gene differentiation (*Gst*), and gene flow (*Nm*). A cluster analysis was performed using the DATA processing system (DPS) program and a dendrogram was constructed using an unweighted pair-group method with arithmetic averaging (UPGMA).

Results

ISSR polymorphism

The ISSR primer screening yielded 16 primers exhibiting high polymorphism and stability (*Table* 2). These ISSR primers generated 185 amplified fragments with an average of 11.6 bands per primer and 167 bands (90.27%) were polymorphisms. The fragment sizes ranged from 200 to 2200 bp and the number of bands varied from 9 to 15. The highest proportion (100%) of the polymorphic bands was obtained with the primers UBC818, UBC826, UBC842, UBC888, and UBC889, while the lowest proportion (66.67%) was obtained with the primer UBC850. The results of the amplification using the primer UBC856 for all 17 accessions are illustrated in *Figure 2*. This example showed the high genetic diversity present in the 17 accessions.

Genetic diversity

At the species level, *Na, Ne, He, I* and *PPB* were found to be 1.9027, 1.3873, 0.2497, 0.3949 and 90.27%, respectively that were relatively higher than populations (*Table* 3). The accessions from the Western Fujian population exhibited highest values for the genetic diversity parameters, with *Na* = 1.5676, *Ne* = 1.4243, *He* = 0.2315, *I* = 0.3358,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1250712519

and *PPB* = 56.76%. However, genetic diversity in this population was observed to be lower than that at the species level. The lowest level of genetic diversity was found in the Eastern Guangxi population (*Na* = 1.1568, *Ne* = 1.1239, *He* = 0.0673, *I* = 0.0968, *PPB* = 15.68%). At the population level, the values for *Na, Ne, He, I* and *PPB* were found to be in the range of1.1568–1.5676, 1.1239–1.4243, 0.0673–0.2315, 0.0968–0.3358, and 15.68–56.76% respectively. Based on these results, it can be concluded that the highest genetic variations were observed in the Western Fujian population, while the lowest variations were observed in the Eastern Guangxi and Southern Guangxi populations.

Genetic differentiation and relationships

From Nei's genetic diversity, genetic differentiation (*Gst*) was estimated as 0.5399, indicating that 53.99% of the genetic variation was distributed within populations. The level of the gene flow (*Nm*) was found to be 0.4261 individuals per generation within the six populations, thus, demonstrating that there was minimum gene flow between the populations (*Table* 4).

Table 4. *Nei's analysis of genetic variability of the six populations*

	Ht	*Hs*	*Gst*	*Nm*
Mean	0.2912	0.1340	0.5399	0.4261
SD	0.0253	0.0082		

Ht: total genetic diversity; Hs: genetic diversity within populations; Gst: coefficient of gene differentiation; Nm: gene flow

Genetic diversity was assessed using genetic distances (*D*) and genetic similarity coefficients (*GSC*). It was observed that *D* ranged from 0.0564 (between Western Fujian and Central Fujian populations) to 0.4590 (between Southern Fujian and Eastern Guangxi populations) and *GSC* ranged from 0.6319 (between Southern Fujian and Eastern Guangxi populations) to 0.9451 (Western Fujian and Central Fujian populations) (*Table* 5). This analysis showed similar trends in *D* and *GSC* levels. The highest *GSC* (0.9451) and the lowest *D* (0.0564) were found between the Western Fujian and Central Fujian populations, indicating the closest relationship between them. Moreover, the lowest *GSC* (0.6319) and the highest *D* (0.4590) were found between the Southern Fujian and Eastern Guangxi populations, indicating a distant relationship was between these populations.

The UPGMA tree that was constructed based on genetic distance (*D*) demonstrated that the 17 accessions clustered into six groups (*Fig. 3a*). Group A, C, E and F comprised one accession each, FAF, JL, DZ and HZ respectively. However, Group B consisted of eleven accessions, namely, YS, SM, ZL, CTB, QGG, GAF, PG, FPG, PC, XN, and WG. Group D consisted two accessions, WL and CF. An UPGMA tree constructed from the population data generated three clusters (*Fig. 3b*). Cluster I

DOI: http://dx.doi.org/10.15666/aeer/1705_1250712519

included two populations (WF and CF), cluster II contained three populations (EG, SG and NG), and cluster III consisted one population (SF).

Discussion

Polymorphism analysis

In this study, after a preliminary screening of 100 ISSR primers, those primers were selected that showed clear, reproducible, and polymorphic bands. The primers that generated fuzzy bands or failed to generate an amplification product were rejected, including those that showed monomorphic bands due to the formation of dimers in the primers. The 16 selected primers were used for the analysis of the 17 *D. beecheyana* var. *pubescens* accessions. The selected primers produced an average of 11.6 bands, which is lower than that observed in other bamboo species (Desai et al., 2015). The present study confirmed that the selection of competent primers is very important when using ISSR markers (Safaei et al., 2016).

Genetic diversity

Genetic diversity data is an essential component of a breeding program. In the present study, 17 accessions of *D. beecheyana* var. *pubescens* showed higher levels of genetic diversity at the species level compared to the population level. However, the accessions demonstrated relatively high levels of diversity within the six populations. These results are consistent with the data reported in *Jatropha* previously (Arolu et al., 2015). It was observed that the genetic diversity of *D. beecheyana* var. *pubescens* (PPB_s = 90.27%, He_s = 0.2497) at the species level was higher than that of the short-lived perennial species *Blysmus sinocompressus* (PPB_s = 74.76%, He_s = 0.1668) (Hu et al., 2016) and mating breeding system species *Platycodon grandiflorum* (PPB_s = 76.29%, He_s = 0.2326) (Nie et al., 2014). At the population level, the average He_p in *D. beecheyana* var. *pubescens* was 0.1340 (*Table* 3) that was almost similar to that of *Taxus fuana* (0.1165) (Shah et al., 2008) but lower than that of apricot (0.1738) (Liu et al., 2016). Low He_p value is attributed to low genetic diversity. Similarly, the low average value of I_p (0.1941) also indicated a low level of genetic diversity (*Table* 3). High value have been reported in *Portulaca oleracea* (I_p = 0.515) (Alam et al., 2015). Further, the average value for PPB_s was found to be 31.98% that was lower than that of *Platycodon longiflorum* (PPB_s = 55.67%) (Nie et al., 2014). Low genetic diversity within populations has been reported in other plant species, such as *Taxus fuana* (Shah et al., 2008) and *Monimopetalum chinense* (Xie et al., 2005).

Our results indicated that *D. beecheyana* var. *pubescens* showed considerable genetic variation between populations and high genetic diversity within populations. A mixed mating system has been recognized as an important factor to determine the level of genetic diversity in a plant species (Godt et al., 2001). However, other factors can also influence the genetic variation including, the geographic factor that can exhibits significant negative effect on genetic diversity and higher temperatures that can boost the seedling growth and increase genetic diversity. However, *D. beecheyana* var. *pubescens* flowers every 10–120 years in an unpredictable mode. The propagation is mainly dependent on selfing by underground rhizomes. Thus, in the present study, the breeding system was not likely to be a contributor towards genetic diversity.

Two possible explanations can be proposed for the high total genetic diversity within populations. Firstly, since *D. beecheyana* var. *pubescens* lives for many years before flowering, it is highly possible that habitat heterogeneity of the long-lived plants could have contributed to the pattern of genetic diversity in this species (Hu et al., 2016). Secondly, the geographical prevalence of this species might have supported high

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1250712519

genetic diversity compared to a species with restricted distribution (Godt and Hamrick, 1996). The populations of *D. beecheyana* var. *pubescens* examined in this study were narrowly distributed in Fujian and Guangxi Provinces. This restricted distribution might have resulted into low genetic diversity among populations (Ge et al., 2005).

Genetic differentiation and relationships

Various factors such as life history, geographic distribution, and gene flow within populations can influence the genetic structure of plant species (Hilfiker et al., 2004). In this study, we found that the genetic differentiation coefficient among populations of *D. beecheyana* var. *pubescens* (*Gst* = 0.5399) was higher than the average of other long-lived species (*Gst* = 0.19) (Nybom, 2004). This suggested that there was a high level of genetic differentiation in *D. beecheyana* var. *pubescens.* However, genetic variation in *D. beecheyana* var. *pubescens* in the Fujian and Guangxi Provinces was mainly observed at the intra-population level (53.99%) and inter-population level (46.01%). This can be attributed to the geographical location that might have had a significant influence on genetic differentiation leading to the higher genetic diversity at the intra-population level (Yuan et al., 2007). In addition, the complex topography of the region, including remote and isolated mountains, may have hindered the gene flow between populations, thus promoting population differentiation (Wheeler et al., 2011). In the present study, gene flow among *D. beecheyana* var. *pubescens* populations was found to be 0.4261 that indicated limited level of gene flow between populations and thus it could not prevent genetic differentiation at the intra-population level.

Genetic diversity was estimated using genetic distance (*D*) and genetic similarity coefficients (*GSC*), which ranged from 0.0564–0.4590 and 0.6319–0.9451, respectively. This range was consistent with a previous study that reported a range of 0.045455–0.454545 for *D* (Yuan et al., 2014), however, the *GSC* range (0.39–0.95) was lower compared to our study (Noroozisharaf et al., 2015). The *GSC* obtained from our ISSR analysis exhibited a high genetic diversity among *D. beecheyana* var. *pubescens* accessions. Moreover, the 17 accessions were found to form six major groups in the UPGMA dendrogram. The clustering in this dendrogram was not consistent with the geographical distribution, suggesting that there was no obvious correlation between genetic distance and geographic distance of accessions in Fujian and Guangxi Province. However, the 6 populations clustered into three major groups in the UPGMA dendrogram, and in particular, three populations, EG, SG and NG, formed a cluster with high genetic similarities due to the same place of origin. Therefore, based on the findings of this study, it can be concluded that the geographic distribution may have influenced the genetic distance or the genetic relationships of populations and the widespread accessions may have exhibited higher level of genetic diversity than the narrowly distributed ones. The population SF was found to be grouped away from other two groups, thus, supporting the hypothesis that these *D. beecheyana* var. *pubescens* accessions origin from SF were the independent species. Therefore, a high level of genetic variation can be estimated in widespread accessions.

Economical aspects and fiscal policy consideration

D. beecheyana var. *pubescens* as one of the protection forest was introduced to coastal regions of southern and eastern China for soil and water conservation and to improve the environment as well. Since, the southeast coast of China has been suffering

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1250712519

from typhoons, storm surges and other natural disasters throughout the year, it is crucial to strengthen the coastal shelterbelt system to minimize economic losses. Certainly, some capital investments and fiscal policies would be required to conserve the coastal shelterbelt. In this context, this study provided important genetic information for devising the conservation strategies of *D. beecheyana* var. *pubescens.*

One primary objective of conservation is to protect the genetic diversity. Considering the low genetic diversity among populations and high genetic variation within populations of *D. beecheyana* var. *pubescens* in China, the most effective strategy for maintaining genetic variation is to conserve and cultivate as many populations as possible. Moreover, transplanting individuals from other populations would enhance inter-population gene flow and genetic diversity. Thus, the foremost step for all populations in situ must be the prevention of the anthropogenic disturbance. Subsequently, we should make it a priority to cultivate the high genetic diversity of *D. beecheyana* var. *pubescens* in initial period. Since the WF population exhibited the highest level of genetic diversity, it should be preferred for cultivation. Further, the population with high genetic diversity may have the ability to adapt to the environment as compared to the population with low genetic diversity. For *ex situ* conservation, a germplasm bank is required to be established for this species.

Conclusion

In this study, the ISSR markers were found to be viable for detecting the high level of genetic diversity within populations and considerable genetic differentiation among populations. In addition, the polymorphism generated by ISSR markers was very high. Based on the findings of this study, it was observed that rich genetic diversity existed in *D. beecheyana* var. *pubescens.* Besides, the genetic differentiation and relationships obtained in this study may help in understanding and evaluating the conservation in China. The cluster results of 17 materials related to adaptability, resistance, water and soil conservation and growth period, which need to be further studies. It is necessary to strengthen the collection, identification and excavation of the germplasm resources of D. beecheyana var. Pubescens to enrich the genetic diversity of breeding materials.

(Received 16th May 2019; accepted 16th Jul 2019)

Abstract. Aboveground vegetation is an important component of the terrestrial ecosystem carbon storage, with a significant role in maintaining the global carbon cycle and balance. At present, the estimation method of aboveground vegetation carbon storage was concerned by people. Based on the national data of major trees, forest sample plots and major crops, the carbon storage models of 13 species of tree and 9 types of stands were established through regression analysis, and the carbon storage factors of main crops per unit area was calculated, Moreover, the carbon storage of forest in China was estimated. The results of model fitting showed that the fitting determination coefficients (R^2) were all above 0.9. Evaluation indicators of five regression models were selected to conduct model verification. And the verification results showed that the variation range of total relative error (TRE) of tree regression model is -6.03~4.76%, and that of forest classification regression model is -3.24~7.43%. The China forest carbon storage calculated by regression model is 8.999 Pg, considering that forest inventory is carried out based on a certain degree of canopy density, so the error between the results 8.427 Pg of regression model and forest inventory is within the permit range. Therefore, the aboveground vegetation carbon storage models established in this study can be used to estimate the carbon storage of China's main vegetation types.
Keywords: *forest type, tree, crop, carbon storage, regression model*

Introduction

Global climate change is a scientific problem that mankind has to deal with together, particularly climate warming is widely concerned by the scientific community (Canadell et al., 2000; Zeng et al., 2010). The vegetation ecosystem is an important part of the terrestrial ecosystem, the carbon sinks in vegetation ecosystem plays an important role in the global carbon cycle, it is a key factor in the study of global carbon cycle and carbon balance, it also plays an indispensable role in regulating climate change, absorbing greenhouse gases and mitigating the greenhouse effect (Cao and Woodward, 1998; Li et al., 2011). The quality and dynamics of regional forest cover, including afforestation, deforestation and forest protection, are important factors in mitigating climate change in the context of sustainable development (Koh and Ghazoul, 2010; Aryal et al., 2014; Edenhofer et al., 2014). The aboveground vegetation carbon storage, especially annual carbon increment, is a reliable index to measure the ecological function of vegetation, so how to determine the carbon storage of aboveground vegetation with high efficiency is a hot and important issue in scientific research.

Since the 1960s, many scholars have estimated and predicted the carbon storage of different types of forest (Nunery and Keeton, 2010; Popescu, 2007), many people has been well recognized that forest carbon pools are affected by forest management methods (Berbés-Blázquez, 2012), and they believe that it is a more accurate and feasible method to establish the carbon storage model of individual tree and then make scale transformation (Chave et al., 2005; Navar, 2009). Yangliu using Landsat 8, built a variety

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1252112535

of forest accumulation prediction models by the method of machine learning information extraction and realized the measurement of coniferous forest, broad-leaved forest and mingled forest (Yang et al., 2017). Kurz, Heath and Holly K had respectively studied the northern forest, temperate forest and tropical forest and update prominent forest biomass carbon databases to create the Abies fabri Craibt complete set of national-level forest carbon stock estimates (Woodbury et al., 2007; Gibbs et al., 2007). Gilabert had conducted a research which is explored the relationships between crop canopy leaf area index, biomass and normalized differential vegetation index (NDVI) used by the method of remote sensing (Martínez and Gilabert, 2009). Chao Zhang were analyzed the forest carbon storage and their spatial distribution in China's small (2,300 km^2) liuxi river basin a, and determined the different contributors of carbon storage (Zhang et al., 2016). Rengtang Chen and Zhongke Feng established regression equations of each organ for Quercus acutidentata and other 7 tree species based on 1259 standard plots and 836 standard trees, measured and studied the biomass of 8 types of forest stands at Xiaolong Mountain (Cheng et al., 2007). Wensheng Cheng established binary volume models and form factor models of the main tree species in China which are based on the single volume tables of each province, and improved efficiency and reduced the workload of large area scale measurement of standing wood volume (Wensheng et al., 2017). The main method to calculate the carbon storage of forest ecosystem at large scale is based on the forest resource inventory data and there are increasing number of studies have been conducted on the application of forest resource inventory data and remote sensing data to the calculation of carbon storage of forest ecosystem (Zolkos et al., 2017; Jenkins et al., 2003). Although it is of high precision to estimate carbon storage of sample plots using forest resource inventory data, there are still some problems when predicting large scale carbon storage of sample plots, such as it is easy to ignore the sparse forest with less than 20% crown density. Moreover, large-scale forest resource inventory takes a lot of manpower and material resources and lasts for a long time, such as China's latest forest inventory took five years which has seriously affected the timeliness of forest carbon storage research. The calculation of regional scale carbon storage based on remote sensing data also has many defects, such as there is great uncertainty in the calculation of various remote sensing vegetation indexes (Moncada Rojas and Botero, 2013; Trishchenko et al., 2002). On the other hand, NDVI and other vegetation indexes always reflect the status of vegetation productivity, and it is quite different from the carbon storage of vegetation.

This study attempts to establish aboveground vegetation carbon storage measurement models to solve the problem of carbon storage estimation in large scale vegetation ecosystem. This paper aims to establish models with high precision and timeliness and partly relies on sample plot inventory data. This study using the national permanent sample plot data and the binary volume table as basic materials, the study was based on the national fixed sample land data and the measured forest sample land data in various regions of the country, using the SPSS software to regression analysis, and establishing 13 types of trees binary carbon storage models, 9 types of forest stands carbon storage models and staple crops carbon storage models.

Materials and methods

Tree data

The data of forest biomass in this study are derived from the eighth national forest inventory data and the measured data of different forest types in different regions of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1252112535

China (Department of Forest Resources, 2014). Mainly including place names, longitude and latitude, altitude, annual average temperature, annual average rainfall, forest origin, tree species, composition, age, average DBH, average height, forest density, standing stock volume, arbor biomass (trunk, branch, leaf, ground, etc.) (Wang et al., 2001; Zhao and Zhou, 2004; Fang, 2001). In this study, forest biomass was measured by standard plot method. Standard plot is the miniature of the whole stand. Standard plot is only different from the whole stand in area, but not in quality. The data used in this study include dominant tree species, research area, stand origin, age, stand volume and tree biomass. Some of the data are shown in *Table 1*. Based on the analysis of 160 million sets of forest inventory data in China, the inventory data of dominant tree species in various provinces and cities were selected, and the volume of individual tree was calculated. Then the biomass of sample plot was estimated according to dominant tree species in forest sample plot. National forest data are divided into nine categories, such as: coniferous forest, hardwood broad-leaved forest, soft leaf broad-leaved forest, miscellaneous wood forest, coniferous and broad-leaved mixed forest ecosystem, Coniferous mixed forest, Broad-leaved mixed forest, Chinese fir forest, Mongolica forest, and Tthirteen tree species such as: Pinus tabuliformis, Picea asperata Mast, Cryptomeria fortune, Cunninghamia Lanceolata, Quercus, Abies fabri, Pinus yunnanensis, Pinus massoniana, schima superba, Betula, Pinus elliottii, Larix gmelinii, Liquidambar formosana Hance.

Table 1. *Forest biomass data (part of the data)*

Dominant species	Research area	Stand origin	Stand age (a)	Standing stock (m^3/ha)	Biomass (Mg/ha)
Spruce	Ebian County, Sichuan Province	Planted forest	35	337.8	173.08
Spruce	Heishui County, Sichuan Province	Planted forest	32	125.2	107.82
Larix olgensis Henry	Fengcheng City, Liaoning Province	Planted forest	32	357.63	283.61
Larix principis-rupprechtii Mayr	Quangou Nature Reserve in Shanxi Province	Natural forest	35	287	189.99
Larix gmelinii	Shangzhi City, Heilongjiang Province	Planted forest	24	173.58	168.79
Pinus	Tianshui City, Gansu Province	Planted forest	42	92.94	60.7
Pinus	Zhengning County, Gansu Province	Secondary forest	26	89.41	89.44
Platycladus orientalis	Yongshou County, Shaanxi Province	Planted forest	17	18.53	35.43

Crop data

The crop data in this study mainly include rice, wheat, maize, beans, potato, cotton, oil, sugar, tobacco, vegetables, total of ten species. The yield of sown area of crops originated from the National Statistical Yearbook (2014). Through the method of sample plot investigation and experimental analysis, the sample plot of 1 m × 1 m was randomly selected from the selected experimental observation farmland sample plot before the crop was mature, After the collection of plant samples, the samples were put

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1252112535

into a constant temperature oven (100 constant temperature) to bake to constant weight according to different organs. After being taken out, the dry matter weight of each organ was weighed, and the biological quantity of crops was calculated by adding, so as to obtain the economic coefficient of crops.

Model selection

Carbon storage model of forest stand

In order to ensure the application value of the model, this paper uses SPSS software to analyze the correlation of the carbon storage between tree species, and generates the scatter plots. According to the data point distribution, it is found that power function is more consistent with data rules, and combined with the results of previous carbon storage models, the model is obtained by nonlinear regression:

Forest stand carbon storage model:

$$C = aV^b \quad \text{(Eq.1)}$$

C is forest stand carbon storage (Mg), V stands for forest stand volume (m^3), a and b are estimated parameters.

Carbon storage model of tree species

Measuring DBH is usually fast, convenient and accurate, but measuring tree height is time-consuming and laborious. In forest survey, only part of dominant tree height is usually measured, and the missing tree height is often predicted by tree height curve model of different tree species (McRoberts et al., 2013). Therefore, the H index coefficient of tree height in tree species biomass model is set to 1, and the expression of tree species carbon storage model is as follows.

$$C = aD^bH \quad \text{(Eq.2)}$$

C is the carbon storage of single tree species (kg/tree), D is diameter at breast height (DBH) (cm), H is the tree height (m), a and b are estimated parameters.

Carbon storage model of crop

The economic yield and economic coefficient of crop production carbon coefficient are selected as independent variables in the crop carbon storage model. Through the model, the crop vegetation carbon storage per unit area can be calculated.

$$C = C_f * D_w = C_f * Y_w/H_t \quad \text{(Eq.3)}$$

C is Crop carbon storage (unit: t/ha), D_w is crop production, Cf is carbon coefficient, Y_w is economic output, H_t is economic coefficient.

Model evaluation standard

The last and most important step of regression analysis is to verify the model. It is not appropriate to evaluate the predictive ability of the sample calculation model only

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1252112535

by using the fitting or test indicators, the test sample which means that samples not involved in the fitting model also need to be used in fitting or test indicators. Zeng et al. (2011) believed that the applicability test could not reflect the prediction accuracy of the model, and suggested to combine the test sample and modeling sample for modeling in order to make full use of the sample information The statistical indicators of model test and evaluation include the following five items: Coefficients of determination (R2), Standard error of estimated (SEE), Total relative error (TRE), Mean systematic error (MSE) and Mean prediction error (MPE) (Tang et al., 2008), the specific calculation formula was shown in (*Eqs. 4–8*). In the formula: y_i Is the actual observed value; $\hat{y}_i$ is the estimation; $\bar{y}_i$ is the mean of the reference values; n is the number of estimation, and p is number of parameters. R2 and SEE are the most common evaluation indicators which are reflect the goodness of the fit of models. TRE and MSE are the important indexes to reflect the fitting effects which are should be within $\pm 3\%$ or $\pm 5\%$ and it works best when close to zero. MPE is a precision index which reflecting average carbon storage valuation. In addition, the good fitted model should also have the characteristics of parameter stability and residual (symmetric random distribution with 0 as the base).

$$R^2 = 1 - \sum(\hat{y}_i - y_i)^2 / \sum(y_i - \bar{y}_i)^2 \quad \text{(Eq.4)}$$

$$SEE = \sqrt{\sum(y_i - \hat{y}_i)^2 / (n - p)} \quad \text{(Eq.5)}$$

$$TRE = \sum(y_i - \hat{y}_i) / \sum \hat{y}_i \times 100 \quad \text{(Eq.6)}$$

$$MSE = \sum(y_i - \hat{y}_i) / \hat{y}_i / n \times 100 \quad \text{(Eq.7)}$$

$$MPE = t_\alpha (SEE / \bar{y}) / \sqrt{n} \times 100 \quad \text{(Eq.8)}$$

Results

Carbon storage model of stands

Based on the sample data of each forest tree species, Carbon storage model was processed by SPSS 23 software with nonlinear regression analysis method. And the generated carbon storage model of 9 stand types were evaluated by 4 indicators. The results of the indicators evaluation and parameters estimation are shown in *Table 2*.

As shown in *Table 2*, TRE and MPE of carbon storage model in each stand were low, which indicated that the parameters of each model were very accurate. Accurate prediction of model parameters is the basis for the accuracy of model prediction capability. R2 values were over 0.9, which indicated that the fitting precision was perfect. Meanwhile, MSE was also lower, which indicated that the model had a better accuracy in estimating carbon storage. In general, the regression model had an excellent fitting performance on different forest types.

Carbon storage model of individual tree

Through process and analysis, the regression model of carbon storage model of 13 types of tree species in China was established, and the sample data were non-linearly fitted, and the fitting results of the model were calculated by evaluation indexes respectively. The parameter estimation and fitting evaluation are shown in *Table 3*.

11	Pinus elliottii	0.00914	2.104	0.966	12.08	1.98	3.12	7.15
12	Larix gmelinii	0.00897	2.113	0.935	7.75	1.84	5.34	4.58
13	Liquidambar formosana Hance	0.00632	2.292	0.902	34.32	2.58	7.43	8.17

As can be seen from the evaluation results in *Table 3,* the overall fitting degree of the regression model of carbon storage of 9 types of tree species was over 0.9. Among them, only Picea asperata Mast, Quercus, schima superba and Liquidambar formosana Hance trees were slightly less than 0.9. And MPE was an important index in the calculation of carbon storage. It can be seen from the table that the mean square error was controlled within 5%, and the overall influence was small, which was in line with the calculation of carbon storage of major tree species.

Carbon storage model of crop

We collected and sorted out the crop economic output, economic coefficient, carbon absorption and other related factors in the Statistic Yearbook of China, the biomass per hectare and carbon storage per hectare were obtained by regression model analysis. The parameters were shown in *Table 4*. If the aboveground vegetation density stays the same, the calculated parameters can be used to calculate the carbon storage of crops directly by multiplying the planting area of agricultural crops by the carbon storage per unit area.

Table 4. *Coefficient of crop carbon storage*

No.	Crop	Carbon storage per hectare (t/ha)	Absorptivity of carbon (%)	Carbon sink per hectare (t/ha)

Model evaluation and analysis

Model evaluation and analysis of stand carbon storage

We tested the applicability of each aboveground vegetation carbon storage model with data not involved in the model fitting. The evaluation indexes of TRE and MSE were respectively calculated by the regression model of 9 types of forest stand, and the test results were shown in *Table 5*. The range of TRE in the table varied from -4.72% to 2.64%, and MSE variation range was -4.12%~3.25%. The absolute value of the predicted error of all indexes was less than 5%, which meets the requirements of the model method of biomass and the industry standards (Tang et al., 2008). In order to verify the accuracy of the stand carbon storage model, a set of reserved data was used to verify the accuracy of the model. The results of analysis and comparison between the predicted and measured values were shown in *Figure 1*. The above results show that the model can effectively convert forest carbon reserves.

Table 5. *Results of forest carbon storage model test*

Forest stand	TRE (%)	MSE (%)	Forest stand	TRE (%)	MSE (%)
Coniferous forest	-4.72	-3.75	Miscellaneous wood forest	-.346	-2.27
Chinese fir forest	-3.87	-4.12	Coniferous mixed forest	-3.56	-4.08
Mongolica forest	-2.65	-3.42	Broad-leaved mixed forest	2.64	3.25
Hardwood broad-leaved forest	1.96	2.74	Coniferous and broad-leaved mixed forest	1.76	1.87
Soft leaf broad-leaved forest	-2.05	-1.89	-	-	-

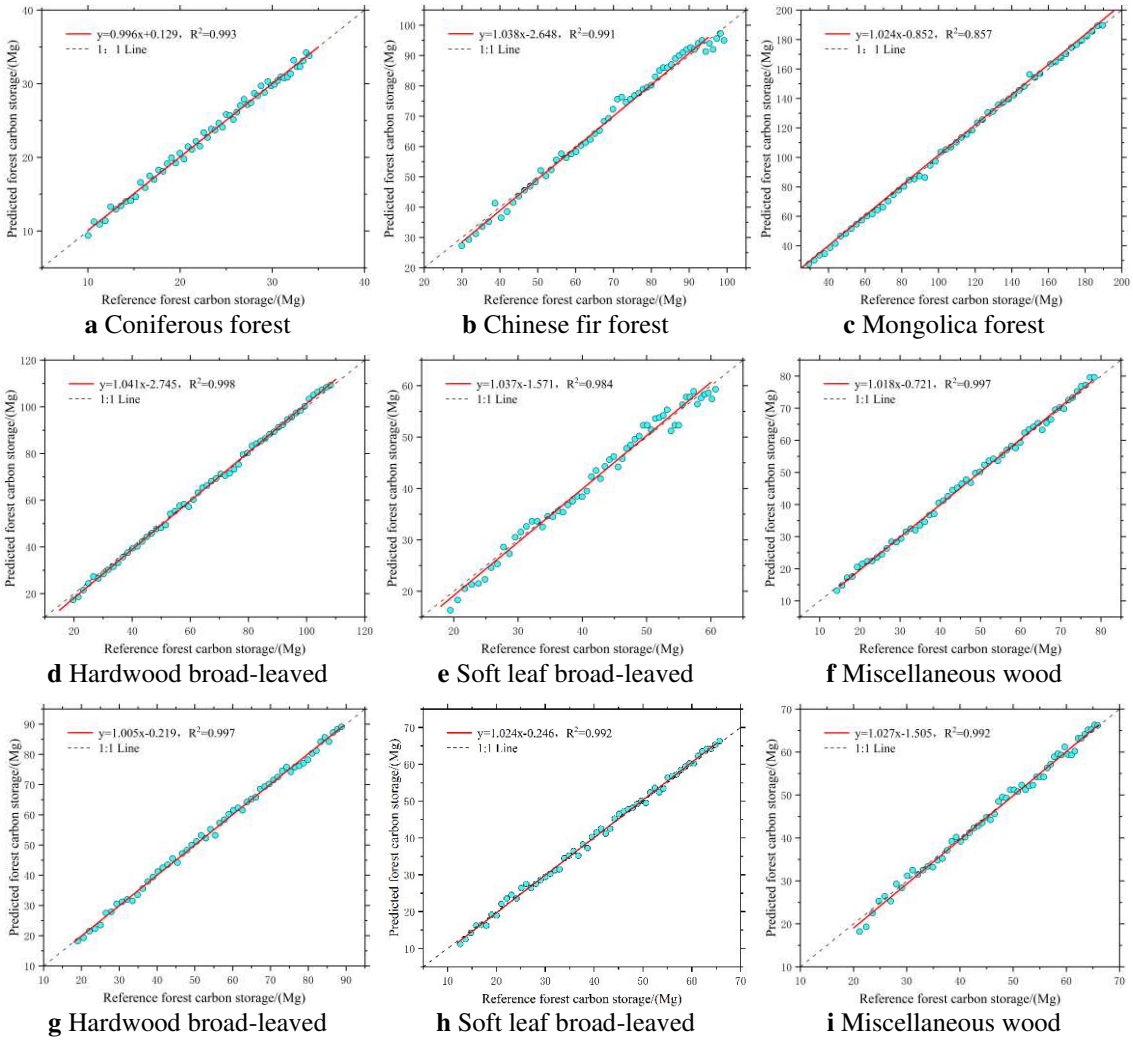

Figure 1. *Reference value and estimation value distribution of forest stand carbon storage*

Model evaluation and analysis of individual tree carbon storage

TRE and MSE were used to test the error of the carbon storage model of 13 species of individual tree. As shown in *Table 6*, experimental investigation showed that the relative TRE of individual tree carbon storage measurements is -6.03%, the relative TRE of hypsometrical measurements is 3.93%, MSE of individual tree carbon storage measurements is -4.72%, and the relative MSE of hypsometrical measurements is 4.37%, all of which are higher than the accuracy required for traditional forestry surveys. In order to verify the accuracy of the tree carbon storage model, a set of reserved data was used to verify the accuracy of the model. The results of analysis and comparison between the predicted and measured values were shown in *Figure 2*. The above results show that the model can effectively convert tree carbon reserves.

Spatial distribution of forest carbon storage in China

In order to quantitatively analyze the spatial distribution characteristics of forest carbon storage in China and verify the accuracy of research model, this paper divides China into six regions (the northeast, the north, the northwest, the southwest, the central

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1252112535

south and the eastern coasts) and separately estimates the regional carbon storage calculated from forest inventory and the results of carbon storage value obtained in this paper.

It can be seen from *Table 7,* the calculated value based on forest resource inventory is basically match the spatial distribution of carbon reserves value obtained by the simulation in this study. The specific distribution is: the largest is southwest and northeast, followed by central south and north, while northwest and east are relatively small, which is basically consistent with previous studies (Zhao et al., 2014). While there still has some differences between simulation results and results obtained from forest resource inventory, the main reason is the carbon reserve calculated based on forest resource inventory has error. Forest resource inventory is based on 20% crown density standard which means that sparse forests with crown density less than 20% and shrubs were not examined. This error cannot be ignored at the national scale. In addition, there might be some errors also in the process of forest resource inventory and carbon storage calculation. The difference between northeast and southwest is the largest, the reason should be these two areas are the main forest areas in China, and the forest area is large and the terrain is complex. However, the simulation method in this paper can take the calculation of carbon reserves of sparse forests and shrubs into account at the same time, the simulation results match the actual carbon reserves distributions.

Discussion

The carbon storage conversion model was established by regression model in this study, problem of estimated the carbon storage of single wood level and stand level of each dominant tree species has been solved successfully, It is a less time consuming, lower cost and less laborious approach. Diameter at breast height was the main explanatory tree variable used to estimate the tree carbon storage components for all species. Several authors have noted that inclusion of total height does not usually lead to a substantial increase in the predictive ability of diameter-based biomass regressions, and they also assume that d is sufficient to yield a reliable tree carbon storage prediction (Johansson, 1999; Porté et al., 2002; Jenkins et al., 2003). However, other authors also found that when h was added as a factor, the fitting effect of the model was significantly improved (Reed and Tomé, 1998; Bartelink, 1996), and the accuracy of carbon storage estimation was improved (Menéndez-Miguélez et al., 2013). In this study, D was a good predictor of carbon storage, but the addition of h as the second variable improved the prediction of several species. Tang et al. compared 5 biomass estimation methods based on forest inventory data (Tang, 2016), four carbon storage assessment methods were compared by Gao et al. (2016). Feldpausch et al. (2012) reported that the mean relative error in biomass estimates when h was included was 50% lower than when h was excluded. There are two sets of carbon storage conversion models, one based on DBH and the other based on DBH and tree height, The model of binary was as, D and H are tree DBH and tree height respectively, a, b and c are parameters of the binary model. In the investigation of forest resources, usually only the average tree height of trees was measured, so the coefficient of the tree height parameter H was one in this study.

The combined variable D^2H is usually used in biomass equations (Chave, 2010), and the accuracy of carbon storage estimation has been found to increase significantly (measured as R^2) when h or D^2H was also included, in addition to H. In fact, tree biomass is closely correlated with D^2H, as shown by Parresol (1999) and Carvalho and Parresol (2003). In the models developed by Parresol (1999), height was a good predictor of stem wood but not of stem bark biomass, whereas Carvalho and Parresol (2003) obtained the best estimates for stem, crown and total tree biomass of Pyrenean oak by including the variable D^2H as the sole independent variable in the equation. Bi et al. (2004) reached a similar conclusion, reporting that D^2H performed better for predicting stem and bark components than diameter alone but not for branch and leaf components. In the present study, D、H yielded the best estimates of all biomass components and AGB for P. leiophylla, J. depeanna and Q. crassifolia. The results reported here suggest that the best equations for biomass estimation for most species are based on D and H.

In the total carbon storage of China's forest vegetation, arbor forest accounts for more than 85%, which is the main part. According to the statistics of dominant tree species, the top 10 tree species in terms of area proportion are oak, birch, larch, Pinus massoniana, poplar, yunnan pine, eucalyptus, spruce and cypress, which accounts for 52.54% of the total area in China. In this paper, according to the proportion of dominant tree species in the area, 13 dominant tree species of trees in China were selected. At the same time, according to the composition of dominant tree species, the national arbor forest was divided into 9 categories. such as: coniferous forest, hardwood broad-leaved forest, soft leaf broad-leaved forest, miscellaneous wood forest, coniferous and broad-leaved mixed forest ecosystem, Coniferous mixed forest, Broad-leaved mixed forest, Chinese fir forest, Mongolica forest. Since the bamboo forest in China only accounts for

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1252112535

1.98% of the national forest area, and the bamboo forest is mainly distributed in several southern provinces of China, the research on bamboo forest is not included in this paper. In future studies, special studies will be conducted on bamboo forest, grassland and shrub.

Conclusions

Based on the general volume table, national forest inventory data and national crop statistic yearbook, this paper proposed a regression modeling method to estimate the carbon storage of large-scale aboveground vegetation in China. The proposed method proved to be capable of reducing field work, evaluating contribution of forests to the global carbon cycle and to support international research on forest carbon and greenhouse gas exchange. According to the results of the modeling, the following conclusions can be drawn.

(1) For Stands and individual trees carbon storage regression model, MSE were within 10% and TRE were within 5%, and it has high fitting precision. Based on the established aboveground vegetation carbon storage model, the regional carbon storage would be directly calculated by using the survey original data. As this method avoids the conversion of tree material volume to biomass, so it has the advantage of high efficiency.

(2) In this study, the carbon storage coefficient of crops can be calculated by directly multiplying the area of crops with the corresponding carbon coefficient, which can be used to estimate carbon storage after UAV detection and the estimation of crop production in a large area.

(3) During the growth and development of aboveground vegetation, the environmental conditions such as water, light, soil characteristics and site conditions have a great influence on the growth and development of trees. Due to the difficulty in collecting and receiving some data, these factors are not considered in this study. Therefore, factors such as rainfall, altitude and site index should be introduced into the model in the future research of carbon storage model.

Abstract. A typical chlorinated hydrocarbon contaminated site was selected as the research object in southern China. First, Gas Chromatography-Mass Spectrometer (GC-MS) was used to analyze the composition and concentration of pollutants in soil and groundwater samples. Then, we investigated the microbial community structure, composition, and abundance by high-throughput sequencing analysis. Principal component analysis and environmental factor correlation analysis were further used to illustrate the functional diversity of microbial communities. Eventually, the results showed that the composition and structure of the microbial community were significantly different due to the various degrees of pollution in the soil and groundwater. In the soil with high pollution degree, the functional diversity of the microbial community was notably different from that of non-polluted or slightly polluted soil. This indicated that soil microbial physiological activities and community functional diversity could be affected by the residual concentration of chlorinated hydrocarbons in contaminated soils. The dominant microbial community in the soil was Penicillium, which had a higher abundance in the soil environment, while the Phylum Firmicutes were more sensitive species. In addition, as stain-resistant bacteria, Brevundimonas, Rhizobium Frank, and Pseudomonas were observed in the groundwater, where Lasiodiplodia was the dominant microbial community, while Fusarium was more sensitive species.
Keywords: *chlorinated hydrocarbon, soil and groundwater microorganism, community structure, species diversity, degradation*

Introduction

Due to the rapid development of urbanization in China, local governments have promoted the strategic transformation of industrial structure and urban layout, revealing problems of abandoned industrial buildings and resources facing relocation. A large number of heavily polluting industrial enterprises have been moved into industrial parks, which were originally in the main urban areas.

Through the long-time production history, a large amount of toxic and harmful substances persist in the soil of site thanks to some heavily polluting enterprises, because of improper operations, leakages, insufficient environmental supervisions and some other reasons, adversely affecting the local ecological environment, the health of

local people as well as land redevelopment and utilization. Organic pollutants have always been the vital monitoring targets in the investigation of contaminated sites. Most of them are generally bio-accumulative, chronically toxic and have a "three-way" (carcinogenic, teratogenic and mutagenic) effect, which have been listed as priority pollutants in the world (Su et al., 2015). At present, the soil and groundwater pollution situation in China is severe. In addition, according to reliable data, most of the contaminated sites contain chlorinated hydrocarbons and aromatic hydrocarbons (Tan et al., 2017). Chlorinated hydrocarbons have been extensively studied for their high toxicity, refractory degradation, and strong accumulation. According to the survey, once chlorinated hydrocarbons enter the groundwater, if they are not effectively repaired, the pollution can last for decades, even hundreds of years (Wang, 2018).

Chlorobenzene and chlorinated alkane are common pollutants in the soil of chemical pollution sites in Jiangsu Province. In addition to chemical detection and analysis methods, biological diagnosis is also an important means to assess the environmental risks associated with organically contaminated soils (Gao, 2014). The community structure and functional diversity of microorganisms have long been regarded as important biological indicators in soil and groundwater environments, and have received extensive attention in recent years. Through laboratory testing of microbial indicators in contaminated sites, the composition, concentration and biological toxicity of pollutants in contaminated sites can be accurately determined, thus providing a detailed and accurate reference for the risk assessment and remediation of contaminated sites. The specific indicators are as follows: (1) in the soil environment, the routine indicators of microorganisms include microbial biomass, microbial community structure, microbial functional diversity, microbial genetic diversity, total soil DNA, total soil RNA, etc.; (2) in the groundwater environment, routine microbiological indicators include, number of coliforms, heat-resistant coliforms, Escherichia coli, and total number of colonies.

Soil and groundwater microbial community diversity is very sensitive to changes in soil chemical properties and can be used as an important biological indicator to measure soil and groundwater quality and to assess the sustainability of soil ecosystems. The site pollution habitat is a special habitat composed of site pollutants-soil-groundwater-microorganisms (Song, 2015). A series of physical and chemical changes, caused by external pollutants, will occur in the soil and groundwater, and profoundly affect the environmental and biological properties of the site. High-throughput sequencing technology can be applied to evaluate the functional diversity of microbial communities in the site (Zhang et al., 2018; Shi et al., 2018; Li et al., 2019), such as comparing different soil types (Luo et al., 2013), different plant species in the same soil (Nie, 2013), and the diverse functions of soil microbial communities in different vegetation rhizosphere (Liang et al., 2018; Qiu et al., 2019). However, studies on the functional diversity of soil and groundwater microbes in chlorinated benzene and chlorinated alkane-contaminated sites using high-throughput sequencing technology have rarely been reported.

We attempted to use high-throughput sequencing technology to analyze the soil and groundwater microbial community functions and diversity of chlorobenzene and chlorinated alkane-contaminated sites, and to study the relationship between soil and groundwater pollution levels and microbial activity. Therefore, the present study was aimed to provide details of the spatial variations of the bacterial communities in surface sediments collected from different locations within the contaminated site.

Materials and methods

Brief introduction of the sampling site

The soil and groundwater samples selected for this study were from a decommissioning industrial contaminated site that was used as a point of production for chemical products. The enterprise was located in Taizhou, Jiangsu province, China, and focused on new material industry, and engaged in chlorine alkali, methane chloride, and fine chemicals production in 1960 to 2017.

Collection and analysis of soil and groundwater samples

The samples were collected from an industrial site of a chemical plant in May 2017. Five-point sampling methods were adopted to collect soil samples, and the hardened parts on the surface were removed. The depth of sampling for soil analysis was at 4 m and 7 m of S1 and S11, respectively. Soils were air-dried in shade and sifted through 10 meshes for analysis. The groundwater table was 0.8 m, and depth of the groundwater monitoring well construction was 9 m. The water-table contour map shows that the direction of groundwater flow is west to east (*Fig. 1*). Groundwater samplings were from Groundwater well No.11, No.1 and No. 6, as shown in *Figure 1*.

Figure 1. *Groundwater flow direction of the contaminated site*

After extraction, centrifugation, activation and purification, the samples were placed in Gas Chromatography-Mass Spectrometer (GC-MS) for analysis with helium as carrier gas. According to the obtained mass spectrogram, the database was searched. The result shows that the main pollutants in the environment are halogenated aliphatic compounds and chlorinated hydrocarbons.

Soil contaminant

There are about 20 kinds of organic contaminants in the soil samples, including entachlorobenzene, hexachlorobenzene, hexachloroethane, hexachlorobutadiene, phenol, phenanthrene, quinone, total petroleum hydrocarbon, dichloromethane, carbon tetrachloride, pentachloroethane,1,2-dichloroethane, 1,1,2-trichloroethane, 1,1,2,2-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1253712549

tetrachloroethane, cis-1,2-dichloroethylene, trichloroethylene, tetrachloroethylene, chlorobenzene, carbon disulfide, chloroform. The contaminant concentration of soil sample at depth 4 m was higher than that of 7 m soil sample, such as chloroform was over 10.5 times.

Compared with the "Site Soil Environmental Risk Assessment Screening Value" (DB11/T 811-2011) (industrial land), there were excessive levels of methylene chloride, carbon tetrachloride and chloroform in the soil. Their values were respectively 4.3 times, 26.6 times, and 207 times the standard.

Groundwater contaminant

About 29 organic substances were detected in groundwater, including hexachloroethane, hexachlorobutadiene, phenol, 2-methylphenol, 3-methylphenol, 4-methylphenol, total petroleum hydrocarbons, 1,2-dichloride Propane, vinyl chloride, 1,1-dichloroethylene, dichloromethane, trans-1,2-dichloroethylene, cis-1,2-dichloroethylene, carbon tetrachloride, 1,2-dichloroethane, trichloroethylene, 1,1,2-trichloroethane, 1,3-dichloropropane, tetrachloroethylene, 1,1,2,2-tetrachloroethane, 1,2,3-trichloropropane, pentachloroethane, toluene, ethylbenzene, m-xylene and o-xylene, o-xylene, carbon disulfide, chloroform. Compared with Regional Screening Level (RSL) Summary Table (TR = 1E-06, HQ = 1) April 2019. In the G3 groundwater sample, no pollutants other than the above organic substances were detected.

High-throughput sequencing analysis of soil and groundwater microorganisms

According to the manufacturer's protocols, Microbial DNA was extracted from soil and groundwater samples using the E.Z.N.A.S. tool DNA Kit (Omega Bio-tek, Norcross, GA, U.S.). The amplification of the V3-V4 region of 16S rDNA and the Internal Transcribed Space (ITS) region of Eukaryotic Ribosomal RNA gene were examined by Polymerase Chain Reaction (PCR). Purified amplicons were pooled in equimolar and paired-end sequenced (2 × 250) on an Illumina platform according to the standard protocols. Then low quality reads with less than 80% bases with quality (Q-value) of 20 or lower and/or over 10% bases unknown (N) were removed from each data set to gain more reliable results. After that, the clean reads of high quality from all soil and groundwater samples were merged together and assembled by using FLASH (v 1.2.11) with a minimum overlap of 10 bp and mismatch error rates of 2%. The resultant high-quality sequences were processed to generate operational taxonomic units (OTUs) by UPARSE pipeline at the 97% sequence similarity threshold. The taxonomic categorification was performed with the RDP classifier based on UNITE Database (Wu et al., 2018) (https://unite.ut.ee/) and SILVA Database (Rosselli et al., 2016) (https://www.arb-silva.de), respectively. Based on the species abundance of each sample in the OUT list, vegan packages are used in the R to calculate 3 types of microbial diversity index (Chao1, Shannon and Coverage), and ggplot2 packages are used in the R to perform the principal component analysis. Chao1 index presents the total number of OUT in the sample; Shannon index shows the degree of α-diversity of species in the microbial community; and Coverage index presents the Database's coverage rate for different sample.

Results

Analysis of bacterial diversity in site soil and groundwater

The contaminant concentration of GW3 sample was high. In particular, the concentration of GW1 sample, of which 1, 2-Dichloropropane, carbon tetrachloride and chloroform reached to 19.5 μg/L, 193 μg/L and 63 μg/L, respectively. The 1, 2-dichloroethane concentration of GW2 was 1.3 μg/L. GW1 served as control.

Through high-throughput sequencing data analysis, a total of 264259 high-quality and valid sequencing results, with an average length of 459, were obtained from soil and groundwater bacteria samples from six groups of contaminated sites. The sequence clustering was divided with 97% consistency to obtain 3,840 OTUs. *Table 1* presented the results of Unique Tags, OUT quantity and Alpha diversity index in the soil and groundwater bacteria samples from six pollution sites. The coverage of sample libraries in each group was higher than 99.5%, and the main distribution was between 99.66% and 99.72%. The gene sequences in the bacterial samples had high detection probability, and the sequencing results could well reflect the real situation of the bacteria community in the contaminated site soil and groundwater.

Table 1. *High-throughput sequencing results of the bacteria in groundwater and soil*

Treatments	OTUs	Unique tags	Chao1	Shannon	Coverage
CK	681	33532	977.39	5.05	0.9971
SD1	994	39555	1216.46	5.69	0.9966
SD2	1109	39657	1318.59	5.19	0.9968
GW1	1279	56658	1578.24	6.30	0.9968
GW2	842	47606	1093.45	5.57	0.9972
GW3	893	47288	1173.23	5.84	0.9971

CK group represented the blank control group for bacteria sequencing; SD1 and SD2 represented the control group with soil depth of 4 m and 7 m respectively; GW1, GW2, and GW3 represented the bacteria control group in groundwater when the contaminant content was low, medium, and high, respectively

Chao1 index is used to predict the total number of OUT (microbial species) in the sample, which reflects the abundance of bacterial population to some extent. The higher the Chao1 index is, the higher the richness of the bacterial community will be. As shown in *Table 1*, the bacterial abundance in soil showed little difference at different depths, i.e. different pollution levels, but there were significant differences in the bacterial abundance in groundwater at different pollution levels ($p < 0.05$). Under the condition of medium pollutant content and high pollutant content, the bacterial abundance in groundwater was significantly reduced ($p < 0.05$), while the bacterial abundance in soil was not different with the influence of soil pollutant concentration. It suggested that the bacteria in groundwater were more sensitive to the change between the pollutant concentration of GW1-GW2, and the bacteria abundance would be greatly changed.

The Shannon index reflects the degree of α-diversity of species in the microbial community, and the higher the value of Shannon index is, the higher the degree of diversity will be. From *Table 1*, it could be seen that different depths, i.e. different pollution degrees, had smaller differences in the diversity of bacteria in soil, but there

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1253712549

were also significant differences in the diversity of bacteria in groundwater with different pollution levels ($p < 0.05$). Under the condition of medium pollutant content, the bacterial diversity in groundwater was significantly reduced ($p < 0.05$), while the bacterial diversity in soil did not change significantly with the influence of soil pollutant concentration. This also indicated that the concentration of pollutants between GW1-GW2 will have a huge impact on the diversity of bacteria. The bacteria in groundwater were more sensitive to the change of pollutant concentration, which was consistent with the change of the abundance of the bacteria community mentioned above.

The results of the change of bacterial community abundance showed that Bacillus can promote the bio-abundance of Bacillus in medium level pollution (see *Fig. 2* for details). In addition, compared with the community abundance of the control group, Comamonadaceae and Methylophilaceae had higher community abundance at this stage, while in the stage of pollution, the community abundance was low and exhibited extreme sensitivity, which could be used as the signature microorganism at this stage. Rhizobium and Pseudomonas were found in highly contaminated soil as two types of high community abundance, and the community abundance was reduced in both pollution-free and low-pollution states. Lysobacter, as a marker of low pollution in groundwater, was low in other pollution levels. Hydrogenophaga and Bacillus could be used as indicators of moderate groundwater pollution, while Brevundimonas could be used as markers of bacteria in highly polluted groundwater. In this way, Brevundimonas, Rhizobium and Pseudomonas might also be pollutant degrading-bacteria.

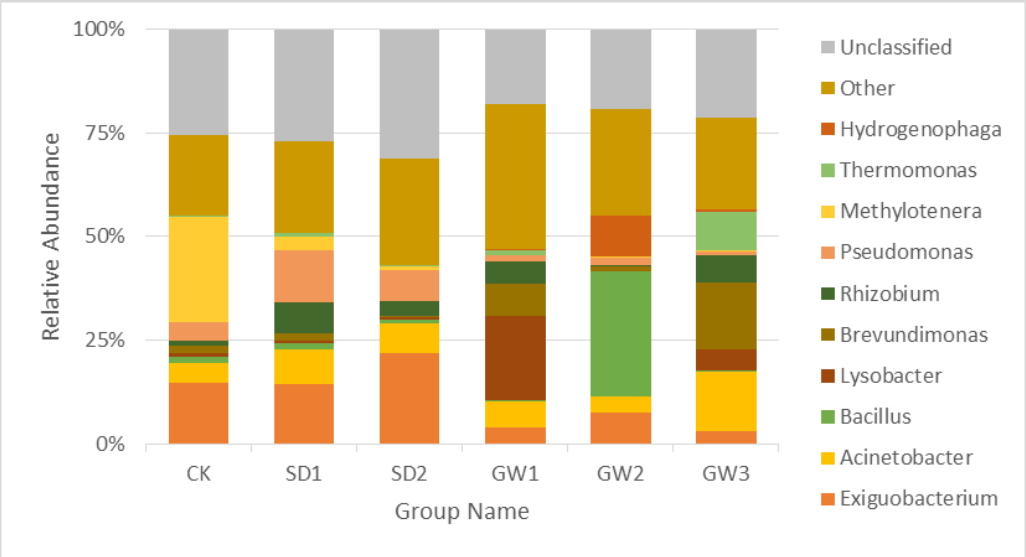

Figure 2. *Bacterial species abundance of soil and groundwater*

Through the primary ingredient analysis by OTU of bacteria in the control group and different environmental media, it could be seen (*Fig. 3*) that the cumulative contribution of bacteria in the first and second components of the six groups was 35.3% and 21.5%, respectively. The results showed that in different pollution levels and environmental media, the medium groundwater environment had the greatest impact on the diversity of communities, while the groundwater with high and low pollution levels did not show

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1253712549

apparent changes in the overall structure. For both soil and control groups, the diversity of their communities was generally similar.

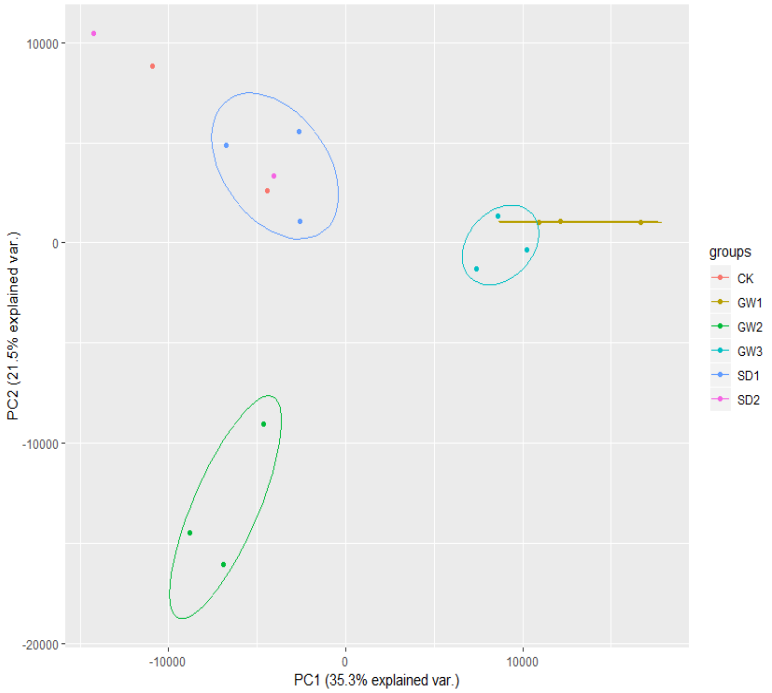

Figure 3. *OTU principal component analysis for the bacteria abundance in the control group and different environmental media*

Bacterial community of groundwater samples was analyzed by analyzing the main components of the group of bacteria OTU in the control group and the groundwater sample group under different pollution conditions. It could be seen (*Fig. 2*) that the accumulative contribution of bacteria in the first and second main components of the four samples was 42.8% and 21.4%, respectively. The control group and the contaminated groundwater sample group were separately clustered and far away, indicating that the pollution would lead to large differences in the diversity of bacteria in the groundwater environment. However, in the groundwater with different pollution levels, the bacteria group with medium pollution level was significantly separated from the bacteria group with high pollution level and the bacteria group with low pollution level in the first principal component. The distance was relatively far, indicating that the groundwater with medium pollution level would produce large and significant differences in the diversity of bacteria. Compared with the bacteria of high pollution level, the bacteria of low pollution level in groundwater were divided in the second principal component and did not coincide in the 95% confidence interval, indicating that the diversity of the bacterial community was also different between high and low pollution levels.

Analysis of fungi diversity in site soil and groundwater

A total of 103254 high quality and valid sequencing results, with an average length of 357, were obtained from soil and groundwater fungi samples in 6 groups by high-throughput sequencing data analysis. The sequence clustering was divided with 97% consistency, and 652 OTUs were obtained. *Table 2* showed the results of Unique Tags,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1253712549

OUT quantity and Alpha diversity index in the soil and groundwater fungi samples of six pollution sites. The sample library coverage of each group was as high as 99.9%, and the main distribution was between 99.95% and 99.97%. The gene sequences in the fungi samples had a high probability of detection, and the sequencing results could well reflect the real situation of the fungi community in the contaminated site soil and groundwater.

Chao1 index is used to predict the total number of OUT (microbial species) in the sample, which reflects the fungi population abundance to a certain extent. The higher the Chao1 index is, the higher the richness of the fungi community will be. It could be seen from *Table 2* that the fungi abundance in soil was not significantly different with different depths, namely different pollution levels, and the fungi abundance in groundwater with different pollution levels was also similar.

Shannon index reflects the degree of diversity of species in the community of fungi, and the higher the value of Shannon index is, the higher the degree of diversity will be. It could be seen from *Table 2* that unless there was a significant difference in the diversity of fungi community in transenvironmental media, the diversity of fungi community was the same in soil and groundwater with different pollution levels. The extent of the contamination has caused a small change in the growth of the fungi population. Therefore, it could be seen that the changes of fungi abundance and diversity in contaminated soil and groundwater environments were not obvious in the large structure level, which further required investigation.

Table 2. *High-throughput sequencing results of the fungi of in groundwater and soil*

Sample name	OTUs	Unique tags	Chao1	Shannon	Coverage
CK	176	17728	204.07	2.69	0.9997
SD1	190	15245	240.89	2.13	0.9996
SD2	201	19651	224.80	3.71	0.9997
GW1	216	14908	258.73	4.08	0.9995
GW2	169	19009	227.81	3.12	0.9997
GW3	199	16713	235.30	3.55	0.9996

CK group represented the blank control group for bacteria sequencing; SD1 and SD2 represented the control group with soil depth of 4 m and 7 m bacteria; GW1, GW2, and GW3 represented the bacteria control group in groundwater when the contaminant content was low, medium, and high, respectively

Through high-throughput sequencing analysis of fungi samples in soil and groundwater, 652 OTUs belonged to 6 phyla, 16 classes, 35 orders, 67 families and 94 genera respectively. Alternaria of Pleosporaceae followed the above community abundance characteristics in groundwater, showing that the community abundance increased with the increase of pollution concentration in the environment. In addition, compared with each group, the community richness of the Penicillium in the highly polluted soil environment was higher, while that of the other environments was lower, which might indicate the characteristic expression of the Penicillium in the soil environmental pollution at this stage. However, Fusarium had a much higher abundance in low-concentration groundwater environment than that under other conditions. The abundance of Gibberella and Cladosporium in a moderately polluted groundwater environment was much higher than that under other conditions. The abundance of Lasiodiplodia in the groundwater environment with a high concentration of pollution

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1253712549

was much higher than that under other conditions (*Fig. 4*). All illustrate that these four strains could be as each phase of the identification of strains of bacteria and sign.

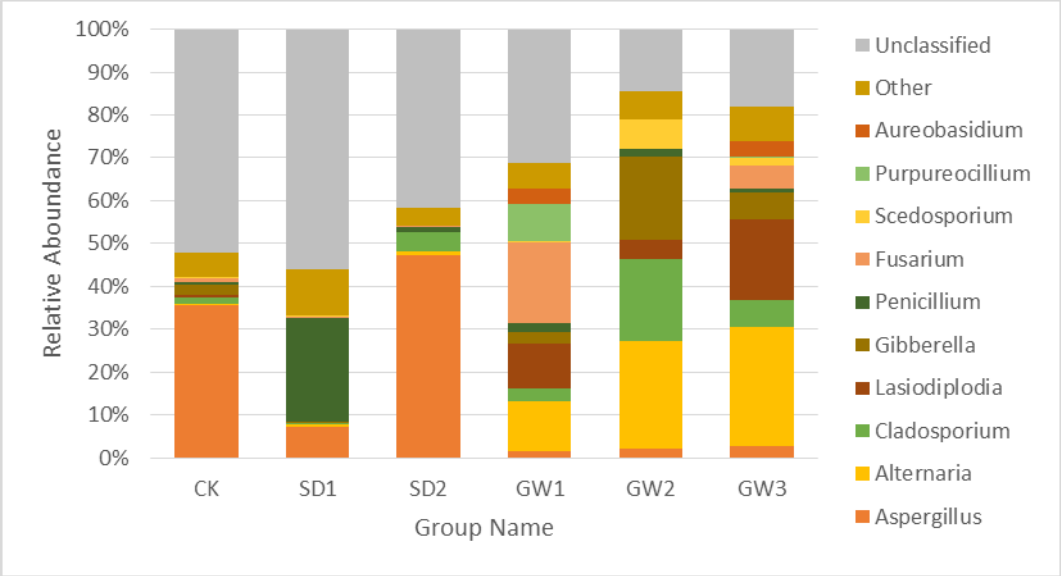

Figure 4. *Fungus abundance of soil and groundwater*

By principal component analysis of the OTU of the fungus in the control group and different environmental media, it could be seen (*Fig. 5*) that the accumulative contributions of fungi in the first and second main components of the six groups were 32.6% and 19.3%, respectively. The separation of the two groups was relatively distant, indicating that the pollutant would lead to the change of community diversity. Compared with the groundwater environment, the shallow soil environment with high pollution had more changes in the first principal component. The community diversity under three kinds of groundwater environment was not much different.

Discussion

Considering the diversity of microbial community structure and function, there is a huge potential value in investigating and assessing the risk of organic contaminated sites such as chlorinated hydrocarbons. In recent years, organizations and researchers at home and abroad have carried out a large number of related experiments and achieved remarkable results. Current experimental studies have found that the structure and functional diversity of microbial communities in contaminated sites are highly correlated with the degree of contamination in contaminated sites. For highly contaminated soil and groundwater environment, the microbial community structure will be destroyed by pollutants, and the diversity of microbial communities will decline significantly compared with natural soil (Goh et al., 1997; Fu, 2018). This study has shown that the composition and structure of the soil and groundwater with different pollution levels were significantly different. And no matter in the soil or the water environment, the higher the concentration of pollutants are, the lower the microbial community abundance is, which was consistent with the results of Fantroussi et al. (1999), Banerjee et al. (1997) and Teng et al. (2004). The site was heavily contaminated

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1253712549

with chlorinated hydrocarbons and the structural and functional diversity of the internal microbial population changed significantly. There are several reasons for this phenomenon. On the one hand, high concentrations of pollutants, such as chlorinated hydrocarbons, benzenes, heavy metals, etc., have poisoned and inhibited the physiological activities of microorganisms in the environment, resulting in changes in the community structure of microorganisms. Most of the sensitive microorganisms gradually died and the reproductive ability declined under the external high pollution environment, while other microorganisms with higher anti-pollution capabilities survived in the soil and groundwater. Eventually, the diversity of microbial in the environment declined. On the other hand, pollutants such as chlorinated hydrocarbons would gradually accumulate in microorganisms and some protozoa over time, which had a chronic toxic effect (Shi et al., 2010). Under the effect of bioaccumulation, the mortality rate of microorganisms and protozoa gradually increased and the reproduction rate gradually decreased, further causing changes in community structure and composition and aggravating the attenuation process of biodiversity.

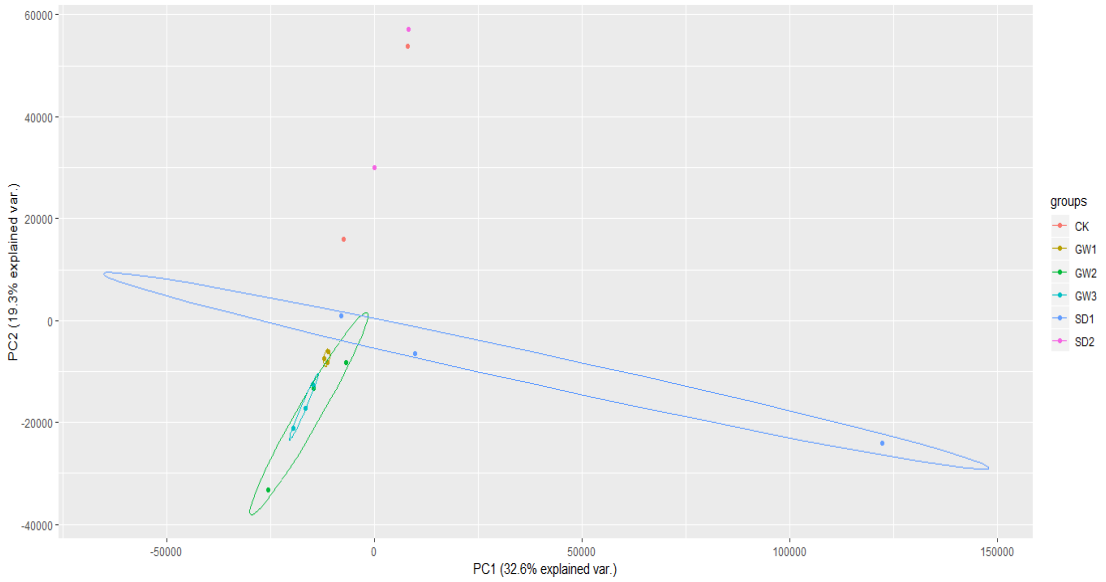

Figure 5. *OTU principal component analysis for the fungus abundance in the control group and different environmental media*

Besides, due to the residual effect of chlorinated hydrocarbon pollutants, there is a huge security threat to the sustainable development of human society and the balance of the natural environment. Through a large number of experimental studies, researchers and environmentalists at home and abroad have discovered that they can use the characteristics of microbial community structure and functional diversity to degrade chlorinated hydrocarbon organic pollution. As early as in the 1990s, Walter Reineke (Fritz et al., 1992) has studied the degradation of Pseudomonas to chlorobenzene and the toxicity of chlorobenzene to Pseudomonas. Shirley F (Nishino et al., 1987) reported that Pseudomonas putida could survive in soil and groundwater contaminated by chlorobenzene for a long time. This might be because that Pseudomonas was highly resistant to chlorobenzene toxicity, and they could use chlorobenzene as a carbon source for their own growth and reproduction, and absorb and degrade it to maintain their own

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1253712549

life activities (Song et al., 2007). In addition, Krausova et al. (2006) also found that a microbial community consisting of Acinetobacter and Pseudomonas can degrade methane in river water to more than 80% within six days. The experiment finds that the main types of anti-pollution bacteria in the groundwater were Brevunmdimonas, Pseudomonas and Rhizobium Frank. They were abundant in groundwater and could effectively degrade chlorinated hydrocarbon pollutants in water, which were consistent with the results of Walter Reineke (Fritz et al., 1992), Shirley F (Nishino et al., 1987), Krausova (2006) and Wright et al. (2017).

The existence of microorganisms is not only positive for remediation and limiting the expansion of pollution, but also the main influencing factor for determining the structure and functional diversity of microbial populations in contaminated sites. Under the original natural environmental conditions, the microbial community structure and functional diversity in soil and groundwater depend on the interaction between various microorganisms and the external environment. With the infiltration of external pollutants, the structure and diversity change. Some sensitive microorganisms tend to be inferior, and the remaining microorganisms with higher tolerance and ability to degrade external pollutants gradually take advantage, even by using pollutants as energy and nutrient sources to enhance the abundance of their communities. Wright et al. (2017) found that in the presence of methylene chloride and trichloroethylene, the relative abundance of Pseudomonas was significantly increased, and different levels of methylene chloride contamination in the site would cause different changes in microbial community structure. Taseli and Gokcay (2005) tested Penicillium's ability to degrade chlorinated compounds, and found it could remove not only the pentachlorophenol, but also the 2-chlorophenol and trichloroacetic acid, which all present great biodegrability. In addition to the bacteria, Fungus also show up their extraordinary ability in degrading chlorinated and polycyclic aromatic hydrocarbons, which even can be enhanced by oxidation (Marco-Urrea et al., 2015). The experimental analysis found that Penicillium was the dominant flora in the soil and had high abundance, while Phylum Firmicutes was a sensitive population, which was greatly affected by chlorinated hydrocarbon pollutants, and the result was consistent with the results of Carvalho M. B. et al. (2009). Additionally, the advantaged Fungi in the environment was Aspergillu, while Fusarium spp. was a more sensitive population.

But there also exist some limitations in this study. Through the high-throughput sequencing technology, we discovered the dominated and sensitive species in the chlorinated hydrocarbon contaminated site, which could provide some insights for assessment and remediation of organochlorine contaminated sites. However, limited by time and energy, more in-depth research is expected to be conducted on the selected species to explore its degradation mechanism and sensitivity threshold. In addition, the collection of samples from multiple regions can bring more general results and avoid the differences in community distribution levels caused by regional differences. In spite of that, this study still has its profound practical significance, and plays a connecting role in the future restoration of organochlorine contaminated sites.

Conclusion

The project analyzed the structural and functional diversity of microbial communities in chlorinated hydrocarbon contaminated sites, and selected microbial flora that could maintain its own advantages in the chlorinated hydrocarbon pollution environment and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1253712549

have certain ability to degrade pollutants, which not only proved the analysis of the microbial indicators of the site can be used to assess the pollution degree and risk of the contaminated site, and provided a scientific and specific theoretical basis for the development and application of in situ bioremediation technology for chlorinated hydrocarbon contaminated sites. While in order to solid the results and make the conclusion taken into practice, further research will be necessary to select and cultivate microbial ability to degrade pollutants.

Abstract. The ecological environment in high-altitude areas are fragile. Improper highway construction or excessive vehicle emission may lead to irreparable damages to the natural environment in such areas. To ensure the sustainable development of the ecological environment in high-altitude areas, it is essential to evaluate the influence of highways construction and operation on the environment in such areas. In this article, using the normalized difference vegetation index (NDVI) to indicate environmental changes in the high-altitude areas road domain. Studying sections from Pengjiazhai Town to DaYagen, DaYagen to Dongxia Town and Dongxia Township to Riyue Tibetan Town along the National Highway G214, with the altitude ranging from 2620~3760 m. Four different machine learning methods including Extreme Learning Machine, Wavelet Neural Network, BP Neural Network and Cubic Smoothing Index are then applied to analyze the NDVI changes in study areas in order to build prediction models. The results of the MAE, WMAE, RMSE and R^2 value of the four different models show that the Wavelet Neural Network model works the best in predicting the NDVI in high-altitude areas. Based on this result, it is suggested that Wavelet Neural Network is more suitable for the intelligent prediction of road vegetation coverage in high-altitude areas.
Keywords: *normalized difference vegetation index (NDVI), prediction models; high-altitude highways, road land vegetation cover, machine learning*

Introduction

Due to the vulnerability and sensitivity of the ecological environment in high-altitude areas, it can be easily destroyed by engineering construction or other human activities compared to normal areas. Moreover, the ecological recovery ability of such areas is relatively weak and the recovery cycle is long. However, during the highways construction and operation process, the surrounding environment will be affected (Tu, 2016). For example, vehicle emission will cause the reduction of the surrounding vegetation coverage, which may further lead to soil degradation. In addition, the related indexes used to characterize the ecological environment of the highway domain are uncertain due to the particularity of the region and the data is usually classified. Therefore, it is essential to explore a certain algorithm that can be used to estimate and predict the environmental influence of highway on the surrounding environment in order to better reveal the environment change in road domain and to keep the sustainable development of the ecological environment in high-altitude areas. About vegetation indexes there are different kinds of vegetation indices that are commonly used, including Normalized Difference Vegetation Index (NDVI), ratio vegetation index, difference vegetation index, vertical vegetation index, environmental vegetation index and so on. Within which the NDVI is the most commonly used index in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1255112571

vegetation research due to its advantages of detecting vegetation growth state, vegetation coverage and eliminating partial radiation errors. It is the best indicator of plant growth state and vegetation spatial distribution density, and can reflect the influence of plant canopy. Therefore, NDVI is selected to characterize the vegetation environment around the highway region in this study.

As for the research methods, five traditional prediction methods were used in previous research including empirical prediction method, trend extrapolation method, regression prediction method (Abutaqiya et al., 2019; Zhu et al., 2019), time series prediction method (Yang and Chen, 2019; Moews et al., 2019; Zhang et al., 2019), and gray prediction (Guo et al., 2019; Lin et al., 2018; Zhao and Zhou, 2018). The above five methods are more inclined to capture the data distribution characteristics through simple mathematical model. For instance, the regression prediction method and the gray theory fit more to the linear distributed data. Such prediction methods can not describe the characteristics of more complex nonlinear distributed data and can not reflect the accurate change of the dataset. On the other hand, with the continuous development of scientific information technology and the application of big data analysis, artificial intelligence prediction methods were used in environment-related research. For example, neural network (Chen, 2018; Leng et al., 2017), fuzzy logic (Xu et al., 2017) and multiple combination prediction methods (Mishra et al., 2015; Feng et al., 2015; Perez and Gramsch, 2016; Sun et al., 2013) were used to predict the concentration of PM2.5. In recent years, different machine learning models are introduced to predict wind, electricity, solar, coal and other resources. Cocchi et al. (2017) applied the time series analysis method, S-ARIMA, S-ARIMAX, extreme learning machine, support vector machine (SVR) and other methods in renewable energy market price bidding. It turned out that the accuracy of Support Vector Machines is superior to other methods. Liu et al. (2018) used wavelet decomposition, empirical mode decomposition and extreme learning machine methods to predict wind speed multi-step. Li et al. (2018) predicted energy consumption based on grey prediction theory and support vector machine that optimize through extreme learning machine. The results showed that the combination of SVR and ELM is more effective than single prediction method. Yi et al. (2019) applied the extreme learning machine to predict the growth of algae in the river. It was concluded that the ELM model had better prediction and generalization performance than the traditional BP neural network and adaptive neuro-fuzzy inference system. Fijani et al. (2019) employed a two-layer analysis method combined with a hybrid model formed by an extreme learning machine to monitor and predict the relevant quality parameters of water in the environment. By using the mixed model analysis, it was found that the results were more accurate than the single model in the prediction of results. Kisi et al. (2018) utilized the new wavelet combination model to establish a reference evaporation prediction model by comparing the wavelet extreme learning machine with the neural network. It was found that wavelet connection models usually had better precision than a single model, while WELM model was more suitable for predicting daily evaporation.

With the economic and infrastructure development in recent years, the demand for highway infrastructure in high-altitude areas is increasing. However, related research methods less attention were paid on the prediction of environmental indicators in highway regions. Considering the vulnerability and sensitivity of the ecological environment in high-altitude areas, it is important to explore the environmental influence of highway construction and operation in such areas. At the same time, it is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1255112571

necessary to discuss which machine learning method can be applied to the road domain NDVI value in high-altitude areas. In addition to, the diversity and uncertainty of the factors affecting the road ecology asks for prediction models with higher ability and accuracy. Considering the characteristics of the discrete-distributed data, ELM, wavelet neural network, BP neural network and cubic smoothing index are considered to predict the NDVI along road domain. There methods are suitable for capturing the nonlinear characteristics and have good global learning ability. In this paper, spatial analysis of the NDVI along National Highway G214 were conducted using GIS. The extreme learning model, wavelet neural network, BP neural network and cubic smoothing index were applied to predict the vegetation index of high-altitude highway roads. This research explored the possibility of using machine learning method in exploring the ecological environmental impact of the road in the high-altitude areas. The results would help improve the sustainable development of the ecological environment in high-altitude areas.

Materials

In order to study and forecast the normalized difference vegetation index of highway in high-altitude region by using machine learning algorithm, G214 highway of Xi'ning City, Qinghai Province of China is selected for research and analysis. In this paper, we apply ArcGIS and ENVI tools to process and analyze the remote sensing image data in the research areas (101°20′~101°57′E; 36°55′~36°65′N). Remote sensing (RS) technology can quickly obtain the regional multi-factor surface information, and through combining the spatial analysis technology of GIS, can quickly get the required information for the target areas. On the satellite selection, the Landsat-8 satellite was chosen. The Landsat-8 satellite was launched on February 11, 2013 and is a follow-on satellite to the Landsat series of US terrestrial satellites. It is equipped with land imager (OLI) and thermal infrared sensor (TIRS). It has important applications in many fields, such as natural resource protection, energy exploration, environmental management, natural disaster monitoring and so on.

The starting point of the research data extraction is G214 Pengjiazhai Town, and the end point is the Riyue Tibetan Township. In order to reflect the particularity of the road environment indicators, the research range is divided into three sections, specifically Pengjiazhai Town~Dayagen; Dayagen~Dongxia Township; Dongxia Township~Riyue Tibetan Township, as shown in *Figure 1*.

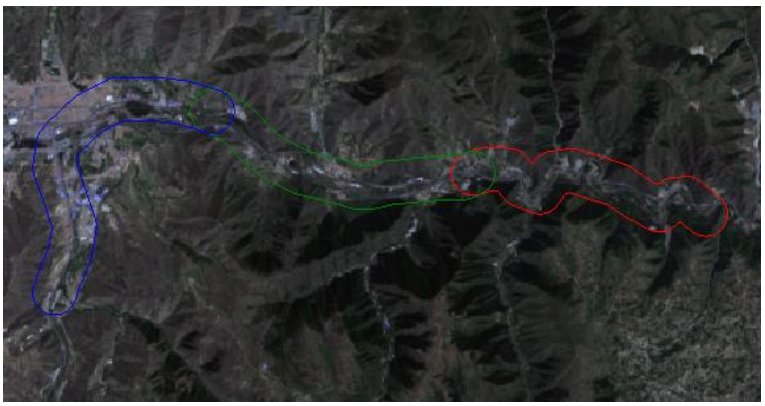

Figure 1. *Three sections of road research domain*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

After the remote sensing image is processed by ArcGIS and ENVI, the image is clipped by ENVI. The main purpose is to eliminate unnecessary research areas. The range of the research road domain is 400 m on each side of the road of the G214 median line. The vector polygon of the study areas uses ArcGIS to analyze the spatial buffer of the road center line data, and the buffer radius is 400 m. Then the image clipping operation of ENVI software is used to obtain the image data of the research areas. The cropped remote sensing image is shown in *Figure 2*.

Figure 2. *The overall research domain obtained by clipping*

As for the research indicator of vegetation index, also known as spectral vegetation index, refers to the multi-spectral data obtained from remote sensing sensors, which are composed of linear and nonlinear combinations of various values that have certain indicative significance to vegetation (Wang, 2015). Because of the strong absorption of blue and red lights radiation by plant leaf tissue, but the strong reflection of near infrared radiation, the near infrared reflection increases with the increase of vegetation. Therefore, the linear or non-linear combination of red band and near infrared band is usually used to characterize the quantity distribution and quality of surface vegetation. This paper studies the vegetation coverage information by extracting NDVI to characterize the ecological environment in the G214 research areas.

As a remote sensing index reflecting the status of land cover vegetation, NDVI is defined as the quotient of the difference between the reflectivity of the near infrared band and the red band. The formula for calculating the difference between the reflectivity of the near infrared band and the red band is as follows:

$$NDVI = \frac{NIR - R}{NIR - R} = \frac{Band5 - Band4}{Band5 + Band4} \quad \text{(Eq.1)}$$

In the formula: Band4 and Band5 are the fourth (red) band luminance value and the fifth (near infrared) band luminance value of Landsat-8 remote sensing satellite OLI image, respectively. The calculation process is accomplished by ENVI remote sensing image processing software, and the NDVI is calculated by reflectivity image.

Specific Landsat-8 remote sensing satellite data selection from 2013~2018, according to the quarterly selection of one to two small cloud cover, small interference factors of Landsat8 remote sensing satellite map to establish a buffer radius of 400 m range of data extraction. The extracted data are shown in *Tables 1–3*.

It can be known from the above tables that normalized difference vegetation index is extracted according to the range of road domain segments, and the results of NDVI extraction are limited to [-1,1], which avoids the inconvenience caused by too large or too small data. The negative value indicates that the surface cover is cloud, water, snow and so on, reflecting the height of visible light; zero means there are rocks or bare soil, Band4 and Band5 are approximately equal; positive value indicates vegetation cover, which increases with the increase of coverage. In general, there is a strong positive correlation between vegetation index and vegetation coverage. The higher the positive value of NDVI, the higher the vegetation coverage rate is, and the better the corresponding ecological background environmental quality is. In this study, taking the remote sensing satellite map of June in the second quarter of 2013 as an example, NDVI data extracted from ArcGIS are used to show the results of the data. Four types of methods

ELM

ELM is a new training algorithm for single hidden layer feed forward networks, (SLFNs) (Huang et al., 2006). Before the training begins, ELM algorithm selects the excitation function of hidden layer, and randomly selects the number of hidden layer nodes in the network, and inputs the weights. Let N different random data sample data are $G=\{(x_1,t_1),(x_2,t_2),\cdots,(x_N,t_N)\}$, $x_i=[x_{i1},x_{i2},\cdots,x_{in}]\in R^n$, $t_i=[t_{i1},t_{i2},\cdots,t_{in}]\in R^m$, $i=1,2,\cdots,N$. Single hidden layer number is L, and the excitation function $g(x)$ that standard SLFNs model just show as:

$$\sum_{i=1}^{L}\beta_i g_i(x_j)=\sum_{i=1}^{L}\beta_i g(a_i\bullet x_j+b_i)=t_j,\ j=1,2,\cdots,\ \mathrm{n} \qquad \text{(Eq.2)}$$

In the formula: $a_i=[a_{i1},a_{i2},\cdots,a_{in}]^T$ is the input weight vector that connects the node of the i hidden layer; b_i is the bias for i hidden layer nodes; $\beta_i=[\beta_{i1},\beta_{i2},\cdots,\beta_m]^T$ is an output weight vector connecting i hidden layer nodes; $a_i\bullet x_j$ represent the inner product of a_i and x_j. $g(x)$ contains L hidden layer nodes. Its standard SLFNs can approach L

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1255112571

training sample data infinitely, and there exists β, a_i and x_j can make it possible to build a formula like this.

Then we can set up the following extreme learning machines:

$$\sum_{i=1}^{L}\beta_i g\left(\alpha_i \bullet x_j + b_i\right) = t_j,\ j = 1,2,\cdots,\ \mathrm{n} \tag{Eq.3}$$

The above formula is transformed to form the following matrix:

$$H\beta = T \tag{Eq.4}$$

H is the hidden layer output matrix of the definite matrix network, Column i representation and input $x_1, x_2, \cdots, x_N$ as the output vector of the associated i hidden layer node, Line j represents the implicit layer output vector associated with the input.

In the formula:

$$H\left(\alpha_1,\alpha_2,\cdots,\alpha_l,b_1,b_2,\cdots,b_L,x_1,x_2,\cdots,x_N\right) = \begin{matrix} g\left(\alpha_1 - x_1 + b_1\right) & g\left(\alpha_2 - x_1 + b_2\right)\cdots g\left(\alpha_L - x_1 + b_L\right) \\ g\left(\alpha_1 - x_2 + b_1\right) & g\left(\alpha_2 - x_2 + b_2\right)\cdots g\left(\alpha_L - x_2 + b_L\right) \\ \vdots & \\ g\left(\alpha_1 \quad x_N + b_1\right) & g\left(\alpha_2 \quad x_2 + b_2\right)\cdots g\left(\alpha_L \quad x_N + b_L\right)_{N\times L} \end{matrix} \quad \beta = \begin{matrix} \beta_1^T \\ \beta_2^T \\ \vdots \\ \beta_L^T{}_{L\times m}; \end{matrix} \quad T = \begin{matrix} t_1^T \\ t_2^T \\ \vdots \\ t_L^T{}_{L\times m} \end{matrix} \tag{Eq.5}$$

Training SLFNs is equivalent to finding out least square solution of β for the $H\beta = T$ just like this: $\beta = \min_{\beta}\left\|T(a_1,\cdots,a_N,b_1,\cdots,b_N)\beta - T\right\|$.

And the Moore-Penrose generalized inverse matrix of the hidden layer output matrix H^+ can be expressed as follows: $H^+\beta = T$.

The solution is used as the weight parameter on the right side of the network. Overcoming the traditional artificial neural network prediction network prediction model some disadvantages such as the training time is long, and it is easy to produce over-fitting. The method mainly includes input layer, hidden layer and output layer, so when we are doing algorithmic calculations, it only needs to determine the number of neurons in the hidden layer to carry out the next operation, which overcomes the difficulty of determining multiple computational parameters and the complicated programming process of the traditional neural network system.

3.2. Wavelet neural network

Wavelet neural network (WNN) is a new type of neural network based on wavelet theory (Nian et al., 2001), which replaces the usual linear or nonlinear excitation function with wavelet basis which can scale and translate. The time-frequency local characteristic of wavelet transform is combined with the self-learning of neural network. Compared with the standard neural network, the structure of wavelet transform is simpler, the convergence is faster, and the blindness is effectively avoided.

In WNN, the number of input layer nodes, hidden layer wavelet elements and output layer nodes are M; J; N; respectively. The expansion coefficient of the j-th wavelet

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1255112571

element in the wavelet layer is a_j, translation coefficient is b_j, The weights of the m neurons in the input layer to the j wavelet elements in the hidden layer are ω_{mj}. The connection weights of the j-th wavelet element to the n-th output neuron is ω_{jn}. Output layer n-th node ideal output value is y_n^*. The wavelet layer uses non-orthogonal Morlet wavelet functions. The classical Tansig function is used in the output layer. WNN is a compact combination of wavelet analysis and BP neural network. Based on the structure of BP neural network, wavelet basis function is used to replace the traditional Sigmoid function as the transfer function of neuron nodes.

The input of the j-th wavelet element of the hidden layer is:

$$r_j = \sum_{m=1}^{M} \omega_{mj} X_m \quad \text{(Eq.6)}$$

The output of the j-th wavelet element is as follows:

$$c_j = \psi_{a_j,b_j}(r_j) = \cos(1.75\frac{r_j - b_j}{a_j}) \bullet \exp(-0.5(\frac{r_j - b_j}{a_j})^2) \quad \text{(Eq.7)}$$

The output layer's n-th node outputs as follows:

$$y_i = 1/(1+\exp(-\sum_{n=1}^{N} \omega_{jn} c_j)) \quad \text{(Eq.8)}$$

The network output error function is:

$$E = \frac{1}{N} \sum_{n=1}^{N} (y_n^* - y_n)^2 \quad \text{(Eq.9)}$$

The training of WNN is mainly aimed at ω_{mj}, a_j, b_j, ω_{jn} to optimized and selected. WNN has the advantage of faster convergence than the forward neural network. Firstly, the basic elements and the whole structure of the WNN are determined according to the wavelet analysis theory, which can avoid the blindness in the design of the structure such as BP neural network. Secondly, WNN has stronger learning ability and higher precision.

BP neural network

BP neural network is a multi-layer feedforward neural network trained according to the error reverse propagation algorithm. It was proposed by scientists led by Rumelhart and Mc Clelland in 1986 (Rumelhart et al., 1986). As one of the widely used prediction models, BP neural network is also called back propagation neural network. Its main model structure is composed of input layer, hidden layer and output layer. The number of hidden layers can be adjusted according to the actual needs. One or more layers can be used to realize all connections between the neurons between the adjacent upper and

DOI: http://dx.doi.org/10.15666/aeer/1705_1255112571

lower layers, but there is no connection between the neurons in each layer. The BP neural network has better description ability for complex nonlinear problems, that is, good nonlinear mapping ability, function approximation ability and fault tolerance.

Cubic smoothing exponential model

Exponential smoothing method is proposed by Brown (2013). Brown thinks that the situation of time series is stable or regular, so the time series can be postponed reasonably. He believes that the recent past situation, to a certain extent, will continue into the future, thus putting a greater weight on the recent data. In the calculation of exponential smoothing method, the key is the value of α, but the value of α is easy to be subject to subjective influence, so how to reasonably determine the value of α is very important. Generally speaking, if the data fluctuates greatly, the value of α should be larger. It can increase the impact of recent data on the prediction results. If the data fluctuates steadily, the α value should be smaller. When the time series fluctuates, but the long-term trend changes little, we can choose a slightly larger α value, which is usually between 0.1~0.4. When the time series fluctuates greatly, the long-term trend changes greatly. In order to make the prediction model more sensitive and keep up with the change of data, it is advisable to choose a larger α value when the trend is obvious and rapid rise or fall, for example, the value can be chosen between 0.6~0.8, so as to make the prediction model more sensitive and able to keep up with the change of the data. The trial algorithm is usually used to determine the α value in the model. First of all, according to the specific time series analysis, referring to the empirical judgment method, to roughly determine the rated value range, and then take different α value for trial calculation, compare the prediction standard error under different α value. The minimum error α of prediction standard is chosen as the reasonable smoothing coefficient of the model. The basic formula for calculating the smoothing index is as follows.

$$Y_{t+1} = X_t + (1-\alpha)Y_t \tag{Eq.10}$$

In the formula, X_t is the actual value of period t, Y_t is the predicted value of phase t; α is an exponential smoothing coefficient.

The formula for calculating the cubic smoothing index is:

$$S_t^{(1)} = \alpha X_t + (1-\alpha)S_{t\ 1}^{(1)} \tag{Eq.11}$$

$$S_t^{(2)} = \alpha S_1^{(1)} + (1-\alpha)S_{t\ 1}^{(2)} \tag{Eq.12}$$

$$S_t^{(3)} = \alpha S_1^{(2)} + (1-\alpha)S_{t\ 1}^{(3)} \tag{Eq.13}$$

$$a_t = 3S_t^{(1)} - 3S_t^{(2)} + 3S_t^{(3)} \tag{Eq.14}$$

$$b_t = \frac{\alpha}{2(1-\alpha)^2}[(6-5\alpha)S_t^{(1)} - 2(5-4\alpha)S_t^{(2)} + (4-3\alpha)S_t^{(3)}] \tag{Eq.15}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1255112571

$$c_t = \frac{\alpha}{2(1-\alpha)^2}(S_t^{(1)} - 2S_t^{(2)} + S_t^{(3)}) \quad \text{(Eq.16)}$$

When the forecast period is T year and the base year is the t year. The prediction model of Y_{T+t} cubic exponential smoothing method is as follows:

$$Y_{t+T} = a_t + b_t T + c_t T^2 \quad \text{(Eq.17)}$$

In the formula $S_t^{(1)}$ is the single exponential smoothing value; $S_t^{(2)}$ is the quadratic exponential smoothing value; $S_t^{(3)}$ is the cubic exponential smoothing values, a_t, b_t, c_t are the smoothing factor. The cubic smoothing index prediction model, it has the advantage of requiring a small amount of data to predict the desired results, and its main theoretical basis is a kind of time developed on the basis of moving average method. The method of inter-sequence analysis and prediction is compatible with the whole average and moving average without abandoning the data of the past.

Optimum architecture of model

(1) ELM model

Considering the output of ELM is influenced by weight and matrix, the prediction results are fluctuating. In order to make the prediction result more accurate, it is necessary to determine the optimal number of hidden layer nodes and neurons. Therefore, the normal mean square error (NMSE) is used as the criterion to select the optimal number of nodes and the number of neurons. When the smaller the value of NMSE, the higher the prediction accuracy of the model. Therefore, the ELM model need to determine number of neurons and input nodes to construct model. By repeated tests the trail number of neurons and the number of input nodes were 5; 10; 15; 20; 25; 30 and 2; 3; 4; 5; 6; 7; 8, respectively. The NMSE values of the output results of each experiment are calculated to compare the parameters, so as to obtain the most suitable number of neurons and input nodes. Its mathematical expression is:

$$NMSE = \frac{\sum_1^N (p_j - \hat{p}_j)^2}{\sum_1^N (p_j - p_j)^2} \quad \text{(Eq.18)}$$

In the formula, the $\hat{p}_j$ represents predictive NDVI value; the p_j represents the actual NDVI value; N for valid number $j = 1,2,\cdots N$.

According to *Table 4,* when the number of neurons is 25 and the number of input nodes is 6, the NMSE value can reach the minimum, which indicates that the prediction precision of ELM model is the best.

(2) WNN model

In the process of WNN training, the number of hidden layers and the number of iterations are mainly constructed. The standard variance is used as the evaluation index

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1255112571

to determine the number of the best hidden layers and the number of iterations, and the predicted value is compared with the actual standard variance. When the error between the two is the smallest, the prediction model is the best. The number of neurons used in this paper by the actual tests chose 5; 10; 15; 20; 25; 30, and the number of iterations is 10; 30; 50; 70; 90 just showing in *Table 5*.

Through the experiments showing in *Table 5*, we can see that when the number of neurons is 10 and the number of iterations is 50, the WNN can achieve the best prediction effect.

(3) BP neural network

In the research process of this paper, when the double hidden layers algorithm model is constructed, the key parameters of the model need to determine the learning rate parameters, the number of training times, and the number of neurons in the double hidden layer. By repeating the test when the test parameters of learning rate parameter is set to 0.005, the precision requirement is set to 0.01, and the training times are 1000 meet the accuracy requirements. According to the characteristics of the neural network, the data type of this study belongs to the single-layer input and output type. Respectively, the input layer and output layer set to 1. In the experiment, when the double hidden layer numbers are set to 50 and 1 shown in *Figure 4,* the MSE value and the variance value shown in *Figure 5* are obtained, which meets the requirements of the test.

(4) Cubic smoothing exponential model

In this paper, after the construction of the cubic smoothing index algorithm, the results of the model can be obtained by determining the smoothing index of α. The extracted data show that the road domain NDVI values are fluctuating and the range of fluctuation is not very large. According to the characteristics of the algorithm, when the data series fluctuates, but the long-term trend changes little, we can choose a slightly larger α value, which is usually between 0.1~0.4. Therefore, the smoothing coefficients α are 0.05, 0.1, 0.15, 0.2, 0.25, 0.3, 0.35, 0.4, 0.45, 0.5, respectively, and the corresponding NMSE values are calculated. The details are shown in *Table 6*.

When the smoothing coefficient α is 0.35, the NMSE is 0.1597723, and the corresponding NMSE is larger when the smoothing coefficient is small or the smoothing coefficient is larger. Therefore, 0.35 is chosen as the best smoothing coefficient of the model.

Application results of model

The optimal prediction models are obtained after the correlation parameters are determined by the above four kinds of prediction models. There are different indicators used to evaluate the prediction effect of the models, the MAE; WMAE; RMSE and R^2 (Goodness of Fit) of the test values and the real values are compared and analyzed to evaluate the prediction effect (Sun et al., 2013; Feng et al., 2015; Li et al., 2018; Yi et al., 2018).

MAE: it is defined as the average error of road domain NDVI prediction, and a smaller MAE value indicates that the prediction is more accurate. Its expression is as follows.

$$MAE = \frac{\sum_{1}^{N} \left| \hat{p}_j - p_j \right|}{N} \quad \text{(Eq.19)}$$

WMAE: it is the average relative error of road domain prediction, and the smaller average relative error represents more accurate prediction. Its expression is shown below.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1255112571

$$WMAE = \frac{\sum_{1}^{N}\left|\hat{p}_j - p_j\right|}{\sum_{1}^{N} p_j} \quad \text{(Eq.20)}$$

RMSE: indicates the fluctuation range between the predicted values and the true values error. The smaller RMSE error indicates that the model is more suitable for this kind of prediction. Its expression is shown below.

$$RMSE = \sqrt{\frac{\sum_{1}^{N}\left|\hat{p}_j - p_j\right|^2}{N}} \quad \text{(Eq.21)}$$

R^2 (Goodness of Fit): it is for the predicted value of road field, it is shown that the predicted values are in good agreement with the actual situation, and the expression is as follows.

$$R^2 = \frac{SSR}{SST} = \frac{\sum_{1}^{N}\left|\hat{p}_j - p_j\right|^2}{\sum_{1}^{N}\left|p_j - p_j\right|} \quad \text{(Eq.22)}$$

Above the formula: $\hat{p}_j$ represents predictive NDVI values; p_j represents the actual NDVI values; p_j represents the average of the actual values, N for valid number $j = 1,2,\cdots N$.

Results

In this paper, the predicted and actual values of four machine learning models, such as ELM, WNN, double hidden layers BP neural network and cubic smoothing index, are programmed by MATLAB software. Using the above-mentioned extracted Pengjiazhai Town~Dayagen, Dayyagen~Dongxia Township, a total of 52 sets of data for machine learning training, another road Dongxia Township~Riyue Tibetan Township a total of 26 sets of data for prediction simulation test of the effect. Through training the output predictive values were outputted and compared with that of the real values, then the MAE; WMAE; RMSE; R^2 are calculated and analyzed respectively. In addition, the analysis compares the prediction effects of the four machine models and which model is more suitable for the prediction of the normalized difference vegetation index at high-altitude.

(1) Analysis of the results of ELM

After determining the optimal numbers of neurons in the ELM and the input nodes, apply the MAE, WMAE, RMSE; R^2 shown above and four indexes are used to describe the prediction effect of it. The comparison and analysis of the actual values and the

(2) Analysis of the result of WNN

After determining the optimal number of neurons and the number of iterations, the WNN uses two sets of data to learn it. At the same time, in order to prevent the data overfitting, the minimum error is set to 10^{-3}. The prediction effect of WNN is compared as shown in *Figure 7,* and the calculation results are shown in *Table 8*.

(3) Analysis of the results of BP neural network

Through the data training in the above process, the BP neural network determines the number of cycles and the hidden layer, and gets the comparison of the prediction effect of it as shown in *Figure 8,* and the concrete value of the calculation result is shown in *Table 9*.

(4) Cubic smoothing index

It is known that the prediction effect can reach the best when the smoothing coefficient $\alpha = 0.35$ of the cubic smoothing index, so the corresponding index between the predicted value and the actual value can be calculated. The prediction effects of it compared as shown in *Figure 9*, and the calculated results are shown in *Table 10*.

α	MAE	WMAE	RMSE	R^2
0.35	0.045676	0.149187191	0.00139507	0.79231912

When evaluating the prediction quality and applicability of machine learning models, the MAE, WMAE, RMSE, and R^2 calculated above are usually employed. MAE and WMAE are utilized as the average error and the average relative error of the predicted value. The smaller the value, the higher the accuracy of the prediction. As the root mean square error of the predicted value, RMSE can reflect the fluctuation range between the predicted value and the actual value, and the smaller the value, the more suitable this kind of machine learning model is for this kind of research. R^2 can reflect the agreement between the predicted value and the real value in the overall effect, and the larger the value, the better fit the prediction of the whole range. The results of the four indexes are shown in *Table 11,* and the comparison between the true values and the predicted values of the four models are shown in *Figure 10*, the concrete values of the prediction results of the four models are shown in *Table 12*.

Discussion

Compared with the other three models, the MAE predicted by the ELM with a single hidden layer is the largest. The comparison from *Table 11* and the line chart shows that the average error of the model is 79.24% higher than that of the WMAE model. It is 36.0% higher than the BP neural network model and 12.11% higher than the cubic smoothing index model. In general, the superiority of ELM has been demonstrate in the previous literatures (Liu et al., 2018; Yi et al., 2018; Fijani et al., 2019) The comparison and analysis show that the average error of WNN is relatively small, which indicates that the accuracy of WNN is better. As for the mean relative error (WMAE) of the WNN, it is 79.24% higher than that of the ELM model, 69.51% higher than BP neural network, and 77.80% higher than cubic smoothing index. Compared with the WNN, the RMSE value of the ELM model and BP neural network model are significantly larger than it. The fluctuation range effect of WNN is 92.21% higher than that of ELM model, 92.78% higher than that of BP neural network, and 90.02% higher than cubic smoothing index. This shows that the fluctuation range between the predicted value and the actual value of the WNN is small, and there is no sudden change of the predicted value compared with the other three models, from the predicted comparison chart of the broken line fully proves it. According to some researches using wavelet transform to predict the results is more accurate (Feng et al., 2015; Kisi et al., 2018). In terms of the fit of the prediction effect, extreme learning machine's R^2 reaches 0.809441907; BP neural network is 0.8728, WNN is 0.844069851; the cubic smoothing index is 0.79231912, and the overall fit effect of the BP neural network is 7.26% higher than that of the ELM model, 3.29% higher than the WNN, and 9.22% higher than the cubic smoothing index. Although overall fit of BP neural network is superior to that of the other three types, the improvement effect is not very obvious, which shows that the four kinds of models all have better prediction results in terms of predicted fit degree.

Conclusions

There is little research on predicting the normalized difference vegetation index (NDVI) of high-altitude highways by using relevant machine learning algorithm, but in the process of highways construction, especially, the highways operation and construction in the ecologically fragile areas at high-altitude will affect the surrounding ecological environment. Therefore, in this paper, four machine learning algorithms of ELM, WNN, BP neural network and cubic smoothing index are introduced to predict the normalized difference vegetation index (NDVI) of high-altitude highways to promote the sustainable development of the ecological fragile areas of the high-altitude environment and road construction.

Through research, it is found that WNN is more complex than ELM and cubic smoothing index in algorithm models, but compared with BP neural network, it is relatively simple and easy, an because of its multiple iterations and the continuous replacement of algorithm weight, the WNN is more complex than the ELM and the cubic smoothing index. Considering the weight effect of the whole data, the prediction precision is high. The prediction time of BP neural network is relatively longer when the condition of double hidden layer is adopted and the number of iterations is larger, so the efficiency of the neural network is greatly reduced. Under the condition of considering the weight of the data, the cubic smoothing index tries to have different smoothing coefficients, but it fails to solve the sudden change which is easy to produce a large value. The ELM as a single hidden layer is relatively simple, and its prediction effect is poor, the precision is not high, and it is easy to produce abrupt values. In the high-altitude areas, the road normalized difference vegetation index is more easily affected by the external factors, and the climate factors at high-altitude are more complex and changeable than in ordinary areas, and the data are characterized by fluctuating variability. Therefore, the model selection requires high precision, not easy to occur mutation, and can pay attention to the global factors and other characteristics. In this paper, compared with the other three models, WNN has higher overall prediction accuracy, closer to the actual value and no large deviation, thus showing a higher prediction level. Therefore, the WNN is more suitable for the prediction of road normalized difference vegetation index (NDVI) in high-altitude areas, which will helpful to the coordinated and sustainable development of ecological environment and highway construction in high-altitude areas. In the future research, we can pay attention to the method of comparison and selection is combined with the analysis and screening of the factors affecting the vegetation and the extent of roads, so as to find out the overall trend of the influence of highway on vegetation cover in road areas.

Data availability. The research data in this paper mainly downloaded the Landsat8 satellite data through the geospatial data cloud http://www.gscloud.cn/, and selected the available satellite data in the region where G214 is located through the geographic condition information, then made use of ENVI and GIS software to extract the data for this research as described in the article. The specific data extracted is shown in *Tables 1–3* in this paper.

Funding. The Project was Supported by Natural Science Basic Research Plan in Shaanxi Province of China (Program No. 2017JQ5122 and No. 2018JQ4009), and the Science and Technology Project of Transportation Department of Qinghai Province (Program No. 2016-03).

Abstract. *Ceratocystis fimbriata* sensu lato species complex is a group of highly diverse cryptic species known to be associated with different diseases in a range of host plants. For the accurate identification of fungal pathogens belonging to this species complex, molecular approaches have been employed in juxtaposition with morphological characterization. Different DNA based methods have become the routine practice of mycologist community throughout the world. Among them, multilocus sequence typing (MLST) approach is gaining popularity. Four fungal taxonomy groups have been established MLST scheme for few fungi, to date. However, in *Ceratocystis fimbriata* species complex, no report on MLST based genotyping is available yet. Therefore, by considering this perspective, we attempted MLST method for genotyping and diversity analysis of this species complex. We investigated ITS and TEF1-α loci, for two multilocus sequence typing scheme. Allelic profile of each locus gave 23 sequence types (STs) and 22 Allele types (ATs). However, the typing efficiency of ITS region was high as compared to TEF1-α. The phylogenetic network parallelograms based on neighbor net algorithm also showed genetic diversity in studied isolates. This relationship study was further supported by generating phylogram, which resolved these isolates in three different clades showing unequivocal phylogenetic diversity and relatedness.

Keywords: *Ceratocystis fimbriata, Dalbergia sissoo, genotyping variation, sequence types (STs), allele types (ATs)*

Introduction

Ceratocystis fimbriata complex represents a group of cryptic species of sever plant pathogen(s) and saprobe(s) as well (Wyk, 2005). *C. fimbriata* complex parasitizes a wide range of plant families from herbaceous to woody plants. The *C. fimbriata* was first time reported in Sweet potato in 1890 (Halsted, 1890). Since 1980, several fungi of species were isolated and identified from a range of host plants from around the globe (Seifert et al., 1993; Wyk et al., 2005). *C. fimbriata* is widely accepted as a complex that comprised of Latin American, North American, Asian and the African clades that include many fungal species (Johnson et al., 2005; Heath et al., 2009). In past few decades, new taxa have been evolved extensively in this complex with special reference to advancement in DNA based identification methods (Fourie et al., 2015). Different *Ceratocystis* species in the *C. fimbriata* sensu lato species complex have been reported to date that are associated with different plant diseases (Harrington, 2000). The fungi of this species complex causes root rot, cankers and vascular wilts and staining in woody hosts (Wingfield et al., 1996; Marin et al., 2003; Al Adawi et al., 2013).

DOI: http://dx.doi.org/10.15666/aeer/1705_1257312582

The pathogens belong to Ceratocystis fimbriata sensu lato species complex are soil borne with fruity odor characteristics. This feature facilitates their dispersal by insects and beetles (Wyk et al., 2005). With wide host rang, this species complex has been recognized as of diverse taxonomic entity. However, with the aid of molecular based studies, different taxa have been recognized and diverged as distinct species from this species complex. It has been documented by DNA based studies that Ceratocystis fimbriata species complex represents diverse and discrete grouping based on geography and host (Harrington, 2000; Baker et al., 2003). Previously, in this complex, species delineation was made based on single gene genealogy of ITS (internal transcribed spacer) region. Nevertheless, multiple gene genealogies and analyzing phylogenetic diversity had been attempted to specify species boundaries.

However, there are diverse molecular tools employing for genotypic diversity analysis. Whereas, multilocus sequence typing (MLST) tool has become more popular scheme for genetic diversity studies. In fungal molecular biology, so far established MLST schemes are for Fusarium species (Westerdijk Fungal Biodiversity Institute), Candida species (Imperial College), Aspergillus (Oxford University), Bipolaris species and Scedosporium apiospermum and S. boydii species (International Society of Human and Animal Mycology, ISHAM). However, in Ceratocystis species complex, MLST scheme has not been established yet. Although this complex is a cryptic species complex and there is a great room of genetic diversity. By considering this perspective, we have attempted two multilocus sequence typing (MLST) method for genotyping and analyzing genetic variation in Ceratocystis species complex. This may be used for further studies based on other loci. Hence, the data generated by MLST scheme could be used for epidemiological studies for which accurate recognition of different species, subspecies and strains are required.

Material and methods

Fungal isolates

We used 23 isolates of *Ceratocystis fimbriata* sensu lato from our collection of fungal isolates associated to dieback affected shisham (*Dalbergia sissoo*) plants. Each isolate was characterized based on its morphocultural characteristics and was labelled as FMB (Fungal Molecular Biology Laboratory-Culture Collection) with a unique identification number as given in *Table 1*.

DNA extraction

Fungal DNA was extracted with GeneJET Genomic DNA Purification Kit (Thermoscientific, USA). The DNA samples were quantified with a NanoDrop 8000 spectrophotometer (Thermofisher). However, DNA quality was checked on agarose gel electrophoresis and stored at -20 °C until further use.

Molecular biology and computational biology

We used two genes, internal transcribed spacer (ITS) and translation elongation factor 1 α (TEF1-α), for polymerase chain reaction (PCR), sequencing and phylogenetic analysis. PCR amplifications of these two genetic regions was carried out in Veriti^{TM} 96 wells thermalcycler (Applied Biosystems) using 25 µl reaction volume with the ITS (White et al., 1990) and TEF1-α (Oliveira et al., 2015; Li et al., 2017) sequence regions

based primer pairs. PCR products were purified using a FavorPrep PCR purification kit (Favorgen Biotech Corporation, Taiwan) and were sequenced in both directions (Eurofins Genomics DNA sequencing services, USA). High quality trimmed sequences were generated using BioEdit software version 7.2.6.1. For getting consensus sequences of sequences obtained using forward and reverse primers DNASTAR Lasergene v. 7.1.0 SeqMan pro (SeqManTMII) software package was used. These generated sequences were compared with the sequences available in NCBI database using BLASTn and were deposited in GenBank under accession numbers, given in the *Table 1*.

Genotyping variation analysis of ITS and TEF1-α genes

Nucleotide sequences of ITS and TEF1-α genes were used for genetic distance analysis. Genotypic variation of each locus was assessed using MLSTest v1.0 software. The allele types (ATs) number, sequence types (STs) number, number of polymorphism, typing efficiency and discrimination power at 95% confidence interval were computed using this software. Neighbor net algorithm was used to perform phylogenetic network of each loci by splitsTree4 V4.14.8 software.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1257312582

Nucleotide sequences of both genes were concatenated using Geneious software v. 4.8.5 in the order as ITS and TEF1-α to generate concatenated dataset file. The best evolutionary model for concatenated dataset was selected from Bayesian Information Criterion (BIC) using MEGA 7.0 software. However, evolutionary model with lowest BIC value was selected to construct a maximum likelihood phylogram. Sequences were aligned with ClustalW for phylogenetic tree construction. A phylogenetic tree of the 23 aligned sequences based on best evolutionary model was obtained for the heuristic search in bootstrap analysis with 1000 replications by applying the Neighbor-Joining method to a matrix of pairwise distances estimated through Maximum Composite Likelihood (MCL) approach using MEGA7 (Molecular Evolutionary Genetics Analysis version 7.0) software.

Results

Twenty-three fungal isolates collected from dieback disease affected tissues of *Dalbergia sissoo* (Shisham) were characterized based on morphological and genomic investigations. These characterizations has set them under the *Ceratocystis* species complex. Molecular characterization was based on the direct sequencing of ITS and TEF1-α regions. The generated sequences of these isolates were subjected to BLASTn tool to search their homology with already available sequences of the type materials in NCBI database (https://blast.ncbi.nlm.nih.gov/Blast.cgi). The sequence similarity using BLASTn showed significant similarity with Ceratocystis species of *Ceratocystis fimbriata* sensu lato complex.

The Genotypic variation profiling of 23 isolates belongs to *Ceratocystis fimbriata* sensu lato complex was generated using MLSTest software. The analysis showed 23 best different sequence types (STs) numbers and 22 allele types (ATs) numbers of both loci (*Table 2*). However, the frequency of each allele types (ATs) numbers in each isolate is given in *Table 3*.

The allelic profile of both genes including number of alleles, discrimination power (95% confidential interval), typing efficacy and number of polymorphisms were calculated, given in the *Table 4*. A diverse genetic relationship was found among the genotyped variants of 23 *Ceratocystis fimbriata* sensu lato after analyzing phylogenetic network of each of the both loci (ITS and TEF1-α) using neighbor net algorithm (*Fig. 1*).

Among 24 calculated models of concatenated dataset, the best evolutionary model of concatenated dataset (ITS and TEF1-α) for maximum likelihood (ML) phylogenetic tree was K2 (Kimura 2-parameter) with BIC (Bayesian Information Criterion) score 2721.116. This model was selected based on the theory that evolutionary models with the lowest BIC values are considered to describe best substitution pattern. The phylogenetic tree (*Fig. 2*) with highest log likelihood (-1145.9648) was drawn to scale, with branch lengths measured in the number of substitutions per site. Codon positions included were 1st + 2nd + 3rd + Noncoding. There were 749 positions in the final dataset.

The evolutionary hierarchy was inferred using ML method based on the K2 model, which categorized these fungal isolates into three discrete clades. The phylogram showed that the clade III was outer group and comprised of FMB-BZ1-SD, FMB-M12-SD, FMB-Thatta-SD, FMB-ST-SD, FMB-GHP2E-SD, FMB-BLCN-01, and FMB-GHP1E-SD with 96% bootstrap support. However, Clade I and Clade II were shown to be evolutionary diverged from Clade III with 96% and 86% bootstrap support respectively (*Fig. 2*).

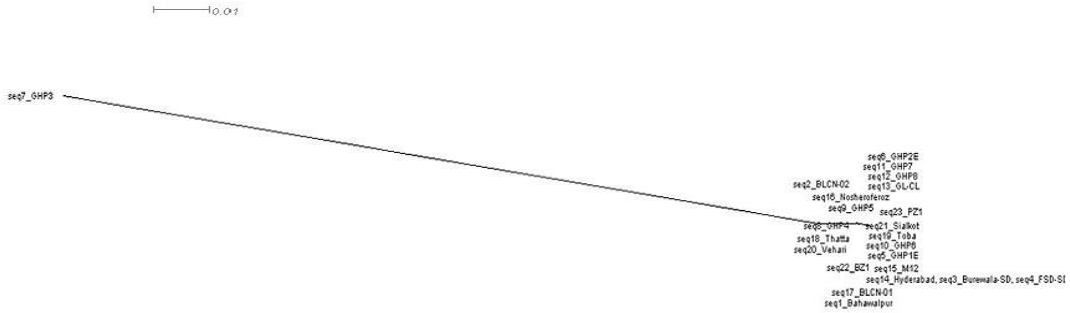
a



b

Figure 1. *Phylogenetic network of two loci, (a) ITS, (b) TEF1- α with neighbor net algorithm by split tree software*

Clade I majorly comprised of fungal isolates from Punjab (a province of Pakistan), as FMB-GHP3-SD, FMB-GHP4-SD, FMB-GHP5-SD, FMB-GHP6-SD, FMB-GHP7-SD, FMB-BWP-SD, and FMB-TTS-SD except FMB-BLCN-02, which was collected from Baluchistan (a province of Pakistan). These fungal isolates made cladding with 96% bootstrap support. However, in clade II fungal isolates from KPK, Sindh and Punjab (provinces of Pakistan) made grouping. In clade II, the isolate FMB-PZ1-SD (KPK) was evolutionary diverged from clade III with 86% bootstrap support. However, fungal isolates of this group, FMB-Nosheroferoz-SD, FMB-Hyderabad-SD (Sindh), FMB-BR-SD, FMB-FSD-SD and FMB-VR-SD (Punjab) were shown to diverged from FMB-PZ1-SD and grouped together in this clade with 67% bootstrap support (*Fig. 2*). Based on the phylogenetic networks of both loci and phylogenetic tree of concatenated dataset, among these 23 studied isolates, 9 isolates (FMB-BLCN-02, FMB-GHP3-SD FMB-GHP7-SD, FMB-PZ1-SD, FMB-FSD-SD, FMB-Nosheroferoz-SD, FMB-BZ1-SD, FMB-M12-SD and FMB-GHP1E-SD) were selected for phylogenetic analyses to delimit the species boundaries of Ceratocystis species associated to dieback disease of Dalbergia sissoo. These selected isolates showed more genotyping variation among all studied isolates by multilocus sequence typing (MLST) approach.

Pertaining to allelic profile for multilocus sequence typing (MLST), typing efficiency of ITS locus was more (0.124) than TEF1-α (0.021). This genotyping supports the phylogram generated through concatenated dataset of both loci. This genotyping results have deduced that, the ITS region has more resolving and typing power than TEF1-α region to species identification and discrimination in case of Ceratocystis species of *Ceratocystis fimbriata* sensu lato complex. This is the first report of using two multilocus sequence typing (MLST) scheme for studying and typing genetic variation in Ceratocystis species complex.

Discussion

There are different approaches that have been employing for genotypic diversity studies. Among of them, multilocus sequence typing (MLST) has become more robust scheme. In the field of fungal molecular biology, MLST scheme Fusarium species, Candida species, Aspergillus, Bipolaris species and Scedosporium apiospermum and S. boydii species have been established by four working groups of Fungal taxonomy. However, in Ceratocystis species complex, MLST scheme has not been established yet. Although this complex is a cryptic species complex and there is a great room of genetic diversity. By considering this perspective, we have attempted two multilocus sequence typing (MLST) method in Ceratocystis species complex.

Table 4. *Allelic profile including number of polymorphism, number of alleles, typing efficiency, discriminatory power of ITS and TEF1- α genes*

Locus	No. of alleles	No. of polymorphisms	Typing efficiency	Discrimination power (95% confidence interval)
ITS	22	177	0.124	0.996(0.985-1)
TEF1- α	22	1049	0.021	0.996(0.985-1)

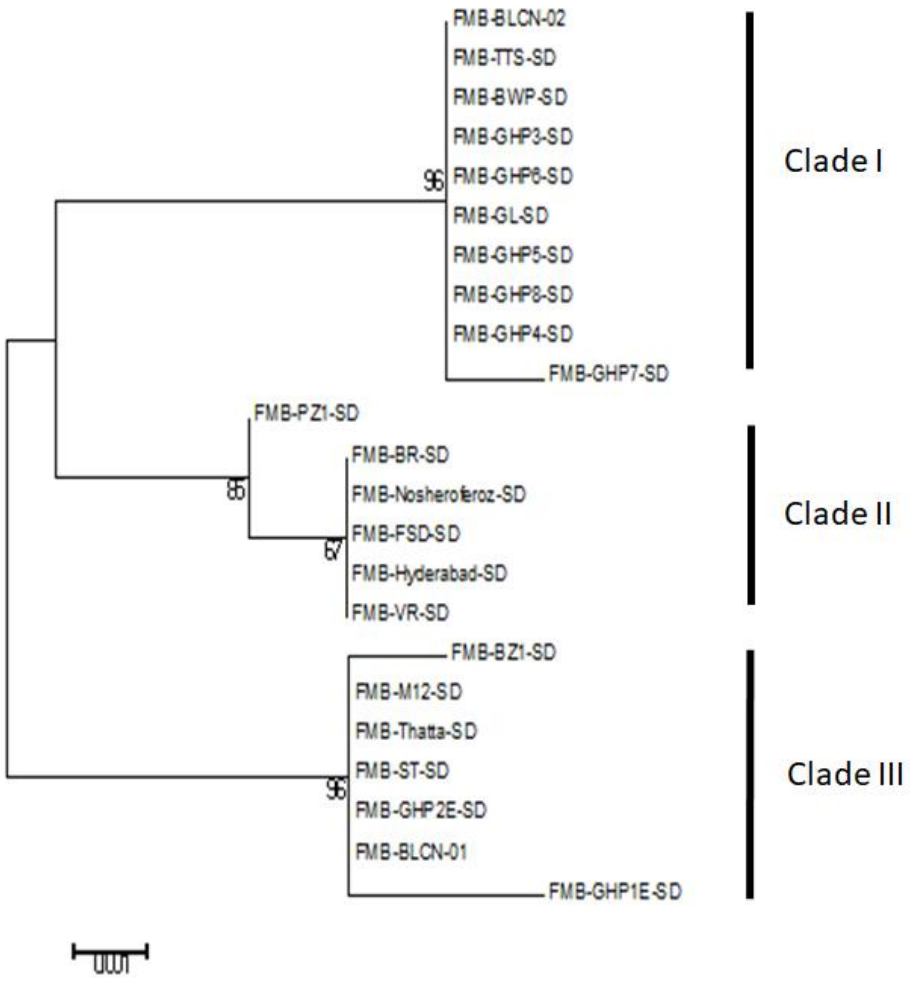

Figure 2. *A maximum likelihood (ML) phylogenetic tree of concatenated dataset of two loci (ITS and TEF1-α) based on evolutionary model K2 (Kimura 2-parameter)*

We have attempted to study the genetic variation and typing analysis among the isolates of Ceratocystis species. We have 23 isolates of this fungus collected from dieback tissues of Dalbergia sissoo. Initially we have used 2 loci, internal transcribed spacer (ITS) and translation elongation factor 1 α (TEF1-α), for MLST based genotyping analysis of *Ceratocystis fimbriata* sensu lato species complex. Successful sequencing of both loci in all isolates was attempted. We identified 23 STs (sequence types) in both loci. The number of polymorphism for each locus was varied which was 177 for ITS and 1049 for TEF1-α.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1257312582

The sequences of 23 isolates of *Ceratocystis fimbriata* sensu lato species complex were analyzed by applying neighbor net algorithm using Splits-Tree software. The graph of ITS region-based sequences generated by Splits-Tree was shown as parallelogram, which implied all could be diverse but characters are shared by a set of species. However, the graph of TEF1-α showed the clustering of species at the one end of graphical string except FMB-GHP3-SD on its other end. The genetic network not shown to be able to describe genetic variation. This phylogenetic network results supported the allelic profiles generated by MLST tool which showed typing efficiency of ITS is more (0.124) as compared to TEF1-α (0.021), however, their discriminatory power was same (0.996). The sequence types (STs) number were 23 in case of both loci, which depicted that each isolates had one ST type. However, the allele types (ATs) number was 22 in both loci. Each isolates has one type of allele except FMB-GL-SD, FMB-BLCN-02 that have same type of allele of TEF1-α. Similarly, in case of ITS loci, each isolate has one type of allele except FMB-Hyderabad-SD, FMB-VR-SD that possess same type of allele.

In nutshell, here we have presented first two multilocus sequence typing (MLST) scheme based relationship analysis among *Ceratocystis fimbriata* sensu lato species complex associated to dieback disease in Dalbergia sissoo in Pakistan to studying and typing genetic variation in Ceratocystis species complex. In future, more loci may be explored for allelic profiling of these fungal isolates. Allele types (ATs) of those loci could be appraised to apprise sequence types (STs) numbers of these fungal isolates in way that is more precise.

Conclusion

Ceratocystis fimbriata sensu lato species complex is a group of cryptic species. Several species have been evolved and identified as discrete taxa. In Ceratocystis fimbriata species complex, no report on MLST based genotyping is available yet. We investigated two loci (ITS and TEF1-α) of 23 fungal isolates from dieback disease affected tissues of Dalbergia sissoo for MLST scheme. In allelic profile, the typing efficiency of ITS region was shown to be high by scoring the value of 0.124 as compared to TEF1-α with 0.021 typing score. This allelic profile result was supported by phylogenetic network parallelograms based on neighbor net algorithm, which showed genetic diversity in studied isolates though some were sharing characters. This relationship study was further supported by generating phylogram of concatenated dataset by applying K2 evolutionary model in maximum likelihood phylogenetic analysis, which resolved phylogenetic diversity and relatedness among these fungal isolates with maximum bootstrap support.

Abstract. Water scarcity on a global scale declines the availability of fresh water for agricultural usage. This situation demands the urgent need of utilizing saline water as an alternative resource for irrigation. Stressful environments characterized by adverse natural conditions such as drought, salinity and heat impact the normal molecular, biochemical and physiological processes in crops. Plant stress responses to adverse environmental conditions are reviewed with emphasis on growth, physiological and electrophysiological mechanisms of plant tolerance. This review may also help in interdisciplinary studies to evaluate the photosynthetic threshold levels for rewatering of plant with diluted saline water. Furthermore, considering the goal of high plant production, the best rewatering time was found when plants undergo threshold levels. Therefore, this review provides a new method for dilution of saline irrigation based on plant physiology, which has a huge practical and theoretical importance for saline irrigation research.
Keyword: *photosynthetic traits, growth properties, plant tolerance, rewatering time, threshold levels*

Introduction

Salinity is a major abiotic constraint curtailing crop growth and yield all over the world. The soil salinity is a widespread global concern caused as a result of abundant seawater intrusion in coastal areas, occurrence of saline groundwater and inadequate irrigation and/or drainage (Souza Filho et al., 2003; Nadeem et al., 2014; Yepes et al., 2018). Salinity induced stress in crop plants is a severe environmental problem in many parts of the world, particularly arid and semi-arid (i.e., dry) regions (Rady et al., 2018). Increasing soil salinity issues in some parts of the arid and semi arid regions is due to the inadequate drainage facilities which obliges the use of poor-quality water for irrigation, which may cause 30% shrink in cultivable land within the next 25 years (Shahbaz and Ashraf, 2013). In the present scenario, the adverse effects of land salinization become evident for the fact that over 30 m ha of irrigated lands are significantly damaged by the salt build up and about 0.5 m ha are reported to be lost from farming annually (Singh, 2018). Salinity poses adverse effects to almost all growth stages and metabolic processes in plants starting from a reduction in seed germination, a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1258312604

disruption of node formation, a retardation of plant development and finally ending up with a reduction in final crop yield (Munns and Tester, 2008). This reduction in crop yield will pose a severe threat to the global food security as the world populace is estimated to reach between 9 and 10 billion in 2050 (Lutz et al., 2017). Therefore, in order to feed the burgeoning world populace, sustainable irrigation practices should be adopted that improve the existing salinised agricultural lands (Flowers and Yeo, 1995; Biswas, 2008; Garcia, 2008).

Water scarcity and salinity are two major constraints which affect the agricultural production all over the world and the adoption of different irrigation regimes is the key requisite to improve water use efficiency in agricultural practices (Nangare et al., 2016; Mosaffa and Sepaskhah, 2018). Therefore, knowledge on the understanding of the physiological responses that define the plants' tolerance to surpass salinity stress is essential. By understanding the mechanism of the plants' stress tolerance, it is possible to develop water efficient irrigation regimes for agricultural activities (Zhang et al., 2011). Water saving agriculture is an effective approach to manage the ever increasing demand for food. Practically, this is achieved by amendments in different technological disciplines such as agronomy, biology and engineering. The engineering approaches include efficient utilization of existing water resources, water desalinization, and usage of brackish water or recycled sewage water for agricultural purposes. Meanwhile, agronomic and plant biology approaches include a wide range of innovative methods such as crop rotation, water conservation, water-fertilizer combination, physiological responses of plants, crop management and vegetative growth (Du et al., 2014, 2015).

In case of water scarcity, diluted saline water becomes the inevitable source for irrigation of plants. However, to ensure the safe use of saline water, effective crop management strategies are required to be developed in order to understand the response of crops to salinity (Bustan et al., 2004; Azeem et al., 2017a). The use of diluted saline water as an alternative resource for fresh water to irrigate the moderately salt tolerant crops will reduce irrigation cost, sustain agricultural productivity and save water resources. Thus, this comprehensive review aims to focus on the effect of rewatering or dilution of salted water on the photosynthetic responses in plants *growing* under saline stress (*Fig. 1*). Furthermore, this review emphasized the restoring abilities of plants from salt stress after re-watering or dilution of salted water.

Physiological response of plants to salt stresses

Photosynthetic characteristics

Salinity stress obstructs the physiological processes of plants (Negrão et al., 2017). It imposes a severe impact on the photosynthetic activity of plants (Sayed, 2003; Ashraf and Shahbaz, 2003; Kao et al., 2006; Munira et al., 2015; Habib et al., 2012; Hu et al., 2009). Photosynthesis is the most essential and complex functional process in all plants and a key factor in the development of plants. The stress induced by salinity impacts the overall capacity of photosynthesis (Ashraf and Harris, 2013). During salinity exposure, plants experience changes in photosynthetic characteristics, including transpiration rate (T_R), relative leaf water content (Lee et al., 2005) and photosynthetic pigments (Tort and Turkyilmaz, 2004; Murillo-Amador et al., 2007; Taffouo et al., 2010; Javed et al., 2017). However, the regulation of photosynthesis is being distressed through stomata limitation, thereby reducing T_R and leaf water potential (Ψ_L) (Azevedo Neto et al., 2004; Azeem et al., 2017b).

DOI: http://dx.doi.org/10.15666/aeer/1705_1258312604

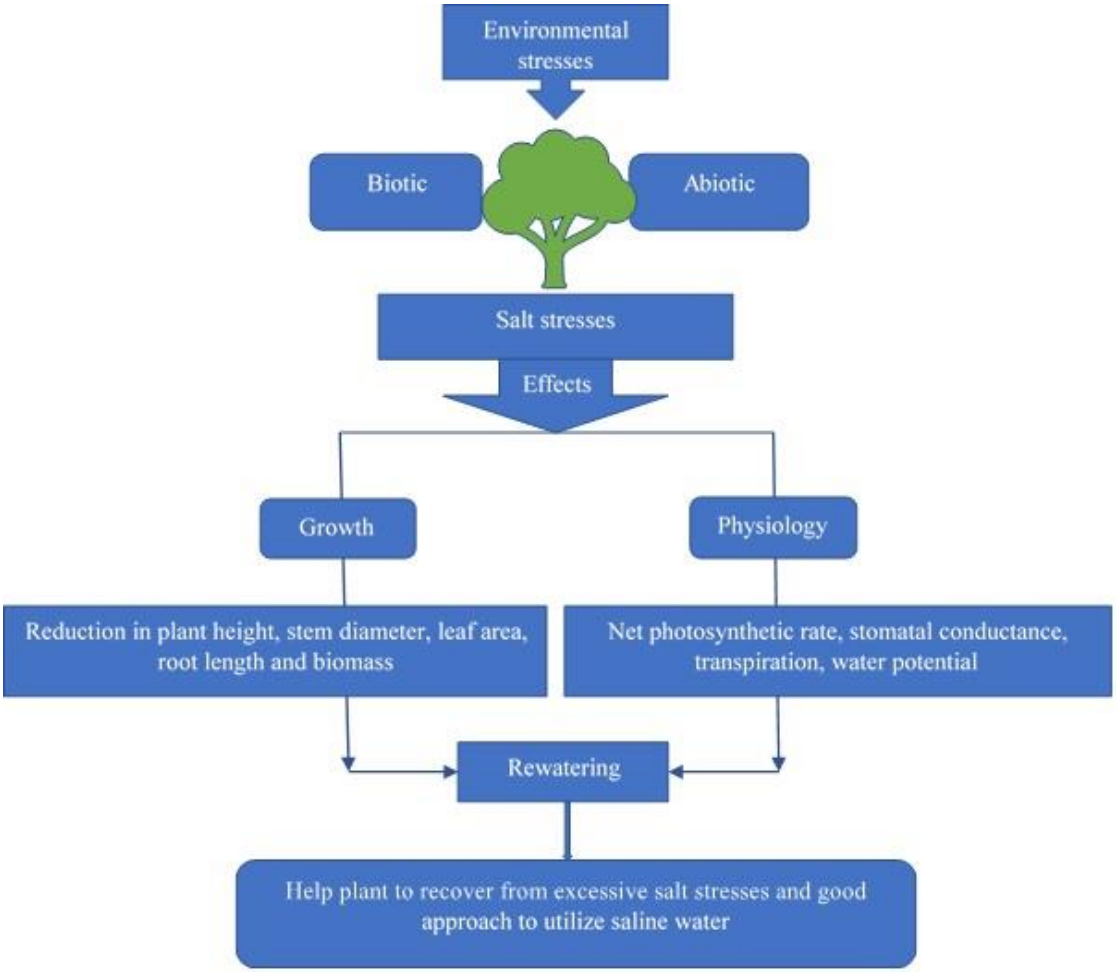

Figure 1. *Graphical representation of salt stress on plant and afterwards rewatering effects*

Stresses in plants inhibit the net photosynthetic rate (P_N) through stomatal opening-closing restrictions (Saibo et al., 2009; Rahnama et al., 2010), particularly in the case of green plants. Salt-stress in the leaves of tomato plants is increased through increased Na^+ concentration (Ullah et al., 2017). Salt stress of > 80 mM of NaCl strongly inhibited the P_N and stomata conductance (S_g). This indicated that the high salt concentration exhibited toxicity in the leaves of tomatoes, which is the main reason of reduction of S_g and P_N under high-stress (> 80 mM of NaCl) (Wang et al., 2011a). Limitation in S_g has been recorded usually at early stages of drought-stress, which in turn increases the water use efficiency (WUE). Stomatal closure has more inhibitory results on transpiration than diffusion of CO_2 into the leaf tissues (Sikuku et al., 2010). Though in comparison, under severe-stress dehydration takes place in mesophyll cells and initiating marked inhibition of necessary photosynthetic metabolic process as well as reduces WUE of plants (Damayanthi et al., 2011; Anjum et al., 2011). Yousif et al. (2010) examined the salt-tolerance difference mechanisms between water spinach (*Ipomoea aquatica* L.) and New Zealand spinach (*Tetragonia tetragonoides*). The P_N, S_g and T_R of both species are reduced with increasing salt-stress, but P_N, S_g and T_R in New Zealand spinach are maintained at 100 mM NaCl than in water spinach. Chartzoulakis et al. (2002a) observed the salt-stress caused by varying concentrations of NaCl (0, 25, 50, 100 and 200 mM) on the growth and photosynthetic traits of six olive

DOI: http://dx.doi.org/10.15666/aeer/1705_1258312604

cultivars (Kalamata, Koroneiki, Mastoidis, Amphissis, Megaritiki and Kothreiki). The P_N and S_g of fully prolonged young leaves of all cultivars were reduced significantly at high concentrations of salinity > 100 mM. In all species, Kalamata showed the higher tolerance to salt stress at 100 mM NaCl, followed by Megaritiki and Kothreiki. Effects of abiotic stresses on plant physiology and their corresponding threshold values are shown in *Table 1*.

Table 1. *Effect of stresses on photosynthetic characteristics and their corresponding threshold values*

P_N is net photosynthetic rate; S_g is stomatal conductance; T_R is transpiration

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1258312604

Stomatal closure is one of the instant responses to water-stress. Generally the atmospheric vapor pressure and leaf turgor pressure can be disturbed because of reduction in stomatal opening in response to drought and salinity stress (Chaves et al., 2009; Javed et al., 2018). Therefore, reduction in P_N under traumatic conditions like drought, temperature, and salinity, is normally due to suppression in the mesophyll cells and stomatal opening-closing limitation (Flexas et al., 2004; Azeem et al., 2017a).

The research by Boughalleb et al. (2016a) on *Astragalus gombiformis Pomel*, found that P_N, S_g, T_R, and internal CO_2 concentration (Ci) was decreased significantly with water-stress duration as compared to that of well watered conditions. A Cerrado's native plant, *Campomanesia adamantinum* (*C. adamantium*) O. Berg, has a potential to exhibit stress tolerant abilities. It is susceptible to grow in an atmosphere of high temperature, dry land and water deficit region. During the experimental period, the photosynthetic factors are evaluated for *C. adamantium.* Seedlings are more stable for plants under control condition, and vast variations are noted in stress subjected plants. At the thirty-first day of water-deficit, S_g and T_R are reduced and P_N approaches to zero as 0.285 lmol m^{-2} s^{-1}. Consequently, WUE also reaches close to zero. Subsequently, the plants are rewatered to recover the photosynthetic metabolic activity (Junglos et al., 2016). Further, the threshold levels of photosynthetic capacity is explained by the extent to which the plants can withstand the stress imposed on the different features of photosynthesis, which can subsequently be used for rewatering of plants to regain the photosynthetic capacity affected by stresses.

Leaf water potential and carbonic anhydrase activity

The leaf water potential (Ψ_L) is termed as the energy status of water in the leaves. The comparative activity of S_g and P_N regulation is directed to water-use efficiency (Vos and Groenwold, 1989) and leaf water potential (Wani et al., 2013). Leaf water potential or leaf water status is a major factor affecting overall behavior and performance of stomata (Ruiz-Sýnchez et al., 1988). Salt-stress inhibits photosynthesis process by lowering Ψ_L (Parida and Das, 2005). Gorai et al. (2010) stated that limited supply of water reduced the dry weight of whole-plant, with a reduction in relative water content and Ψ_L. In certain studies, salt-stressed plants exhibit osmotic regulation due to changes in leaf water status (Kaymakanova and Stoeva, 2008; Gama et al., 2009). Among the different physiological parameters recommended to indicate water-status of vine, Ψ_L has been considered more feasible (Baeza et al., 2007) rather than S_g (Cifre et al., 2005) and temperature of leaf canopy (Bernard et al., 2004). However, there still exists some uncertainity as to which time plant shows the best water status, and what time of the day is optimum for measuring the water potential. (Deloire et al., 2004), used predawn Ψ_L as a standard to assess water-status at different stages of plants development in France. In Portugal, (Lopes, 1998), attained a very close relationship between P_N and predawn Ψ_L under water-stress conditions. Sato et al. (2006) checked the validity of predawn Ψ_L as an indicator for irrigation of wheat in northern Syria. Whereas, Intrigliolo et al. (2004) and Salón et al. (2005) measured Ψ_L during daylight and found that Ψ_L at mid-morning or at noon seem to execute the water-status better than predawn Ψ_L.

Williams and Araujo (2002) described that the measurements of plant water status are associated with plant physiology. According to Xiloyannis et al. (1997), olive plants (*Olea europaea*) adopt different strategies to survive under water-stress conditions as: (i) by lowering their Ψ_L and water content (WC) of leaf tissues, and then use soil water

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1258312604

up to −2.5 MPa; (ii) plants stop shoot's growth but not its P_N activity; (iii) adjustment of osmotic pressure, which is found to show a significant part in maintaining leaf cell activities. Generally, good positive relationships are found between S_g, Ψ_L and growth of plants. The growth of New Zealand spinach (*Tetragonia tetragonoides*) showed a notable reduction in Ψ_L and osmotic potential with increasing salinity. Water spinach showed tolerance and survived up to −1.99 Mpa (Yousif et al., 2010). Plant water status and stem water potential are used as indicators for irrigation scheduling, which requires the description of reference values or threshold values, in order to acheive the optimum irrigation levels. Depending on the response of plants in relationship with Ψ_L and WC, the obtained threshold values are −1.04 and −1.46 MPa, respectively for irrigation of apple varieties i.e., *Mutsu* and *CoxOrange* (De Swaef et al., 2009). Increasing salinity reduces the osmotic potential of the bean plants. This variation is considered as one of the defensive mechanism of plants to tolerate stresses. The values noticed indicate an inverse relationship between osmotic potential and salt stress in bean leaves. The statistical analysis revealed that the decline in osmotic potential is significant with increased NaCl concentration > 120 Mm (Qados, 2011).

A decline in water potential was noticed as a result of reducing relative WC (Kalapos, 1994; Bhatt et al., 2008). Therefore, some plants could convert intracellular HCO_3^- into CO_2 and H_2O by carbonic anhydrase activity (CA) to maintain water content. Carbonic anhydrase activity (CA) is very important in biological functions of plants that include reactions of carboxylation and decarboxylation and it is also takes part in the transporting of inorganic CO_2 to active photosynthetic cells (Henry, 1996). CA is a zinc containing enzyme activity, and is found in all living organisms. CA plays a dynamic role in assisting the transport of CO_2 and protons in intracellular spaces and in the layers of the extracellular space, across cell membranes. It is also involved in several other processes like photosynthesis and respiration. CA catalyzes the rapid inter conversion of HCO_3^- into CO_2 and H_2O. Meanwhile, CA activity is pretentious by deficiency of Zn and also takes part in sustaining the inorganic carbon levels (Tavallali et al., 2009). A reduction in CA activity caused by deficiency of Zn may contribute to the decrease in P_N (Hacisalihoglu et al., 2003).

CA activity helps plants to prevent from losses of water under traumatic environmental conditions (Hu et al., 2011). Kicheva and Lazova (1998) elucidated the reduction of CA activity in wheat seedlings in response to slight osmotic-stress. However, it increased rapidly under severe osmotic-stress conditions. It is noted that wheat cultivars differ in their response to drought stress with different CA activities (Guliyev et al., 2008). CA activities varied with plant species, osmotic-stress levels and stress durations. CA activity is higher in *Pharbitis nil* (*Linn.*) Choisy (*P. Nil*) than *Parthenocissus tricuspidata* (*Sieb. et Zucc.*) (*P. Tricuspidata*) and *Lonicera japonica* Thunb (*L. Japonica*) under drought-stress. CA activity is undetectable in *P. tricuspidata* but for *L. japonica*, CA activity is lower under medium or high stress, than that of the stress under low level. With an increase in drought stress duration, CA activity sharply decreases (Xing and Wu, 2012).

CA plays an important role in a number of physiological processes, such as maintaining acid-base balance, ion exchange, reactions of carboxylation and decarboxylation, and circulation of inorganic carbon between the cells (*Table 2*). CA regulates the photosynthetic mechanism in response to low stomata conductance (Wu and Xing, 2012). Xing and Wu (2015) examined the variations in CA activities with fluctuating nutrient levels for 3-climber species. *P. nil* showed higher CA activity when

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1258312604

compared with the other two species. While, *P. tricuspidata* showed the lowest and nearly undetectable CA activity. CA activity of *P. nil* under 1/2 and 1/4 strength nutrient solutions, is slightly higher than those under 1/16 and 1/32 strength nutrient solution. For *L. japonica*, CA activity is lower under control (full-strength nutrient solution) than those which are concealed under 1/4, 1/8, 1/16 and 1/32 strength nutrient solution. In previous studies, it is found that, by the regulation of CA activity P_N increased in *Orychophragmus violaceus (L.) O. E. Schulz* (*Orychophragmus violaceus*) and it is observed as a shade tolerant crop in comparison of other *Brassicaceae* species (Wu et al., 2007; Wu et al., 2005). Therefore, water status in crop can be maintained by the regulation of CA activity. As a result, carbon and water source are provided for the photosynthesis process by the plant (Hu et al., 2011). Hence, CA activity deeds for the survival of plants under stressed environments (Wu et al., 2011).

This section emphasized on two key factors *viz.,*(1) the water status and water potential of stem and leaves to indicate the threshold values for irrigation or rewatering of plants; (2) the role of CA activity for regulation of photosynthesis against stressful environments.

Table 2. *The role of CA activity during stress condition*

Plant species	Treatment	CA-activity role	Reference
Okra	Salt stress $NaCl + CaCl_2$	In moderate and low salt stress levels CA-activity play a main role to maintain plant water status	Azeem et al., 2017a
Orychophragmus violaceus (L.) O. E. Schulz and *Brassica napus* (*L.*)	Salt stress ($NaCl$, Na_2SO_4, $NaCl + Na_2SO_4$)	The CA-activity in plants showed good regulatory and was initially activated, when the leaves were under slight stress levels. A substantial increase of CA-activity noted under moderate-stress-levels. Due to regulation of CA-activity, photosynthetic activity was increase and showed development of growth parameters	Javed et al., 2018
Broussonetia papyrifera (L.) Vent. and *Morus alba* L.	Salt stress $NaHCO_3$	The stomatal opening and closing affected through variation in leaf-water potential, initiating an imbalance in gaseous exchange, and disturb the photosynthetic activity. To overcome this situation, CA-activity is become activated in leaves and providing partially carbon-water source to plants suffering from shortage of water	Wu and xing, 2012
Pharbitis nil (Linn.) Choisy, *Lonicera japonica* Thunb. and *Parthenocissus tricuspidata (Sieb. et Zucc.)*	Nutrient deficit (1/2,1/4,1/8,1/16,1/32)	CA-activity was increasing with nutrient deficit and activate when plant is going to stress due to nutrient deficit	Xing and Wu, 2015
Brassica napus (*L.*)	Drought stress (poly-ethylene glycol 6000 (i.e. 0, 20, 40 and 80 g L^{-1}))	CA-activity is also activated in drought stress when duration of drought was increasing. CA-activity helps plants during drought stress for H_20 and CO_2 regulation and maintain its growth	Xing et al., 2018

CA activity is carbonic anhydrase activity

Electrophysiological properties of plants

Plants are subjected to several diverse abiotic stresses throughout the growing season in the field (Tester and Bacic, 2005). Toxic effects imposed by salt stress decreased the production of new leaves and inhibited leaf expansion (Mansour and Salama, 2004). In plants, salt tolerance is attributed by structural and functional variations, such as plant growth regulation, Ψ_L and osmotic adjustment. Water deficiency and its stability in plants can be described through its electrophysiological properties, in which, Ψ_L of a plant was reflected by WC, capacitance and leaf air temperature.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1258312604

A miniaturized, nondestructive sensor that employs a microwave micro strip ring resonator is developed for estimation of WC in single grain of wheat (Abraham et al., 2000) detected the amount of applied water/day, soil moisture content and leaf-air temperature based on electrical resistance. Koide (1991) revealed the relationship between Ψ_L with hydraulic resistance and capacitance of a plant. (Turner, 1988) used pressure chamber to calculte Ψ_L. While, Zhang et al. (2015) suggested the rapid measurement of drought resistance in the leaves of *Broussonetia papyrifera* (*B. Papyrifera*) and *Morus alba* (*M. Alba*) based on electrophysiological properties. A significant bonding is detected between physiological capacitance (C_p), WC and Ψ_L. The changes in physiological resistance and C_p, varied the water status in leaves (*Table 3*). Tensity of plant's leaf cell also can describe the status of water in leaf cells of plants, and that reflects the tolerance of plants to stress (Zhang et al., 2015). The outcomes of this review highlight the electrophysiological characteristics as rapid responses of plants to stress resistance. Furthermore, electrophysiological properties can be used to obtain precise information for irrigation and dilution of saline irrigation on the basis of water status in leaves.

Table 3. *Plants responses due to variation in water potential, physiological capacitance and leaf tensity under salt stress and re-watering*

Plant species	Salt treatments	Effect	Re-watering effect	Mechanism	Reference
Okra Abelmoschus esculentus	Salt stress (NaCl + $CaCl_2$)	Salt stress in every level reduces plant water potential and physiological capacitance	Recovery in the moderate and slow salt levels but could not recover in high salt stress	Plant stop to get water from root zone because of osmotic process	Azeem et al., 2017b
Orychophragmus violaceus (L.) O. E. Schulz and *Brassica napus* (L.)	Salt stress (NaCl + Na_2SO_4)	Physiological capacitance and leaf tensity of both species decline with increasing concentration of salts under single salts effect and a mixture of salts	Plant show better recovery during re-watering in single and mixture of salts, but single salts recover well	Due to excess amount of salts, plant leaf tissue loss the ability to hold water	Javed et al., 2017
Brassica napus (L.)	Drought stress poly-ethylene glycol 6000 (i.e. 0, 20, 40 and 80 g L^{-1})	Leaf water potential and physiological capacitance are decreased with increasing drought stress level	Re-water from 40-0 recover better, but 80-40 could not recover because higher drought damage plant leaf cell badly that could not recover during re-watering	During drought stomatal conductance decreased and effect the water regulation and sustainability	Xing et al., 2018

Plant growth features

Salinity is one of the key limiting factors affecting the physiological processes and its impacts may pose severe consequences on the growth of plants (Vilagrosa et al., 2003). The effect of salinity is different for different plant species and for different genotypes because plants exhibit unique tolerance mechanism (Memon et al., 2010; Gama et al., 2007). Salt stress inflicts biological disturbances in plants, causing adverse effects on plant growth, plant quality, and plant yield (Jouyban, 2012; Siddiqui et al., 2008; Qados, 2011). Mostly, species of brassica are considered to possess inbuilt salt tolerant mechanism because of their ability to cope up with salt-stress (Maggio et al., 2005; Hayat et al., 2007). This mechanism might be particularly significant with concerns for survival of salt tolerant plants. Previous studies point out the effects of salt stress on plant growth characteristics (Riccardi et al., 2014; Boughalleb et al., 2016b; Rameshwaran et al., 2016). Some researchers studied the relationship between the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1258312604

reduction in plant length by increasing the concentrations of NaCl (Mustard and Renault, 2006; Jamil et al., 2007; Rui et al., 2009). Certain other studies elucidated the toxic effect of NaCl concentrations on leaf characteristics (Netondo et al., 2004; Chen et al., 2007; Yilmaz and Kina, 2008). The harmful effect of salinity on the number of leaves per plant also increases with increasing concentration of salts. Numerous studies have focused on the effect of varying concentration of salts on fresh and dry weight of plants, either positively or negatively, which is dependent on the nature of salt present (Bayuelo-Jimenez et al., 2002b; Niazi et al., 2005; Turan et al., 2007; Taffouo et al., 2009, 2010).

Drought-salt resistance in plants is explained by structural and functional adaptations, such as osmotic adjustment, Ψ_L, S_g limitations and growth regulation (Zollinger et al., 2007). Plants undergo different changes from the very onset period of salinity stress till maturity periods (Munns, 2002). The variations in the plant development differ with differing time scales after salinization. Quick response of salinity to plants result in dehydration of plant's cells and cell shrinkage, but some hours later on there occurs the regaining of cell volume. But this mechanism affects the cell elongation and division and thereby impacting the plant root growth and leaf size (Läuchli and Grattan, 2007). Understanding these times dependent mechanism of plants in response to salinity, lead to the accomplishment of "two-phase" growth responses to salinity (Munns, 2005).

Salinity exceeding 6 dS/m causes constriction in the length of stem and impacts severe consequences on fruit quality (Carter et al., 2005). Among cultivars, there are even dissimilarities with respect to the tolerance mechanism (Ahmad et al., 2005) and these differences are not parallel with seasonal tolerance, as explained by Nerson and Paris (1984) for melon, Heenan et al. (1988) rice, Bayuelo-Jimenez et al. (2002a) bean and Tajbakhsh et al. (2006) barley. The best growth of *Rhizophora mucronata Lam.* is attained at 50% seawater, and a further rise in salinity beyond this level scales down the growth (Aziz and Khan, 2001). Experimental results demonstrated that in a salt-stress condition, the mangrove *B. parviflora* shows optimal growth performance at 100 mM NaCl, however a further increase in NaCl concentration retards the growth of plant. A concentration of about 500 mM NaCl was found to be lethal to mangrove plants (Parida et al., 2004). The mangrove *Aegiceras corniculatum (L.) Blanco* shows tolerance up to 250 mM NaCl and is found to be dead beyond this concentration (Mishra and Das, 2003). Increased concentration of NaCl results in a significant reduction of root/shoot ratio and leaf growth biomass (Meloni et al., 2001). There is an overall trend found for the increase in the plant's lengths of the *Vicia faba* L. by using the concentrations of NaCl, 60 mM and 120 mM. More precisely, after treatment of 10 days, the increment is negatively correlated, by increasing NaCl concentration from 60 to 120 mM and consequently, 40% death of the plants occurs at initial stage by using highest concentration of 240 mM NaCl (Qados, 2011). Contrary results are recorded as well, such as Dantas et al. (2005) on cowpea (*Vigna unguiculata L.*), and Memon et al. (2010) on *Brassica campestris* L., specified that the usage of low concentrations of NaCl causes an increase in plant's height, whereas high NaCl concentrations affected the growth of plants. Studies on moth bean (*Vigna aconitifolia* L.) (Mathur et al., 2006), radish plant (*Raphanus sativus* L.) (Jamil et al., 2007) and *Vigna mungo* L. (Kapoor and Srivastava, 2010) indicated that increased NaCl concentrations causes a decline in plant's length.

In the light of the different tolerant mechanisms adopted by plants at their specific developmental stages against salinity, this review encompasses the reference levels or point for re-watering, the plants can endure after being exposed to salinity stress.

Effects of rewatering on the physiology of plants

Recovery of physiological parameters by rewatering

Photosynthetic responses to stresses are very complex and these include the chemistry of restrictions, taking place at diverse spots of leaf cell at different time periods in relation to the growth of plants (Boughalleb et al., 2016b). The stress intensity, duration and progression rate influence the plant responses to salinity and water shortage (Nohong and Nompo, 2015). These factors are associated with acclimation responses under drought stress, thereby affecting the photosynthetic rate indirectly. Under the influence of salinity, acclimation responses also include an adjustment in ion-transport such as uptake and extrusion of ions. These reactions are eventually clue to refurbishment of cellular homeostasis, shows survival of plants under stress (Chaves et al., 2009). Moreover, the carbon balance of plants during a period of water-stress and afterward regaining may depend as much on the recovery of P_N (Flexas et al., 2006). Overall, the plant recovers 40 to 60% of maximum photosynthetic rate only after rewatering, when subjected to extreme water-stress, and recovery is continued through the next days, but maximum P_N is not recovered always (Sofo et al., 2004). The strong influence of severe water-stress on P_N and its recovery has been established by Miyashita et al. (2005), in kidney bean and has been recommended by (Gómez-del-Campo et al., 2015), for *Vitis vinifera L.* plants.

Moreover, the recovery phase after stress release (e.g., irrigation or rewatering), becomes a major part of general plant biological responses to water-stress period. Recovery of the photosynthetic capability of plants from severe water-stress, defines the future growth development and survival of plants. Recently, this area is gaining much attention (Ennahli and Earl, 2005; Gallé et al., 2007; Xing et al., 2018; Javed et al., 2018; Azeem et al., 2017a). There is a need for further studies in order to understand the physiological basis and mechanism of recovery from water-stress. A method to assess the restriction of photosynthetic processes during water-stress time scales and then recovery has been suggested by Grassi and Magnani (2005), who recorded the results by dividing the total limitation into 3-parts: stomatal closure, diffusion of mesophyll and carboxylation activity. These outcomes highlight the importance of mesophyll conductance during stress periods and for further research, it suggests an important involvement in the overall plants adaptation to drought-stress. Additional short-term experiments on water stress revealed a reduction of mesophyll conductance (Galmés et al., 2007), indicating a general trend of stress and afterwards exhibits high resistance during rewatering. However, Badger and Price (1994) and Gillon and Yakir (2000) suggested that CA activity helps for regulation of mesophyll conductance during stress and facilitating diffusion of CO_2 at cellular level, and shows recovery (Flexas et al., 2008). *Campomanesia adamantinum O. Berg*, a salt tolerate plant, subjected to water deficit condition and rewatering which is done on day 31 from the onset of suspension of irrigation. The S_g and T_R began to drop from the 23rd day to 31st -day and photosynthetic rate approached to zero as 0.285 lmol m^{-2} s^{-1}. Therefore, WUE and Rubisco carboxylation activity are also reached to zero values. Subsequently, plants are rewatered to regain photosynthetic metabolism (Junglos et al., 2016). According to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1258312604

Yousfi et al. (2016), there had been a small recovery after rewatering in some species of *Medicago laciniata L.* as a result of severe drought stress. During rewatering phase, the plants recovered their photosynthetic metabolism, with consequent increase rate of S_g, T_R and WUE (*Fig. 2*).

A small contribution is found in this aspect of study by Galle et al. (2009) in tobacco (*Nicotiana sylvestris*) and Flexas et al. (2009) for hybrid Richter-110 (*Vitis berlandieri* × *Vitis rupestris*), focusing on reduction of P_N under stress followed by rewatering to persuade recovery. In summary, the present literature strongly supports the important of rewatering and recovery of physiological parameters during rewatering as shown in *Figures 2* and *3*.

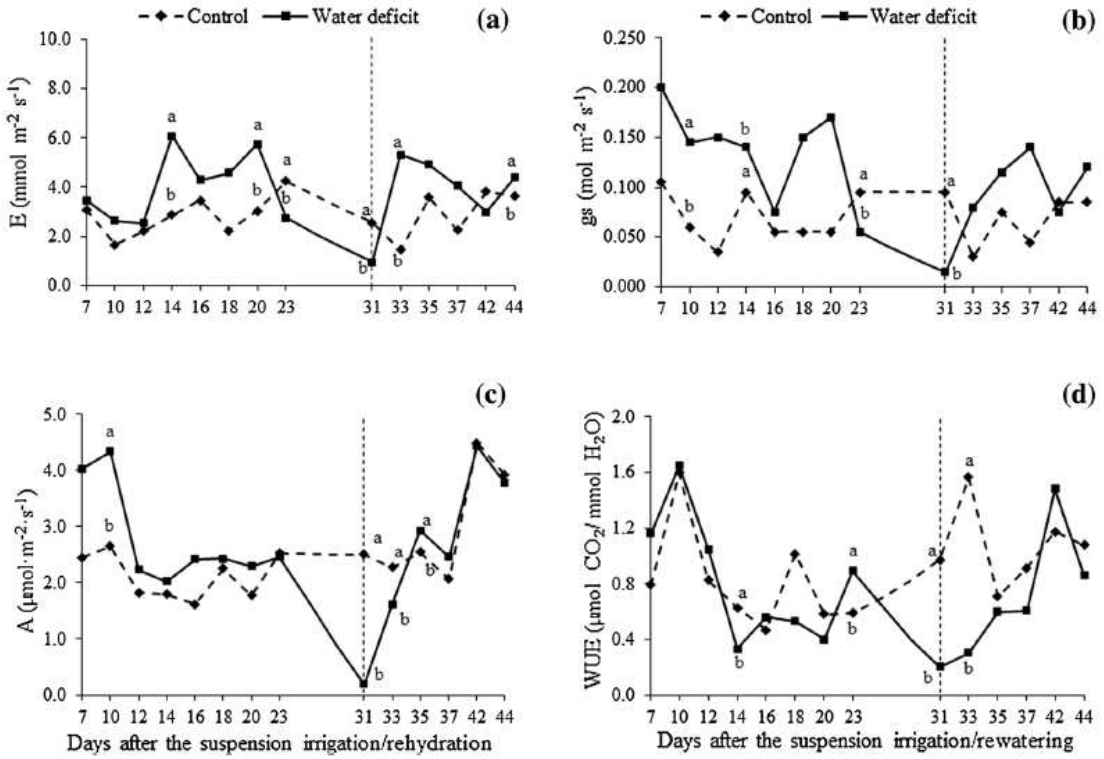

Figure 2. *Transpiration (TR = E) (a), stomatal conductance (Sg = gs) (b), photosynthetic rate (PN = A) (c), and water-use efficiency (WUE) (d) during different intervals when Campomanesia adamantium is grown in well-watered and water deficit condition (Junglos et al., 2016)*

Dilution of salt water

Generally, plants exhibit different physiological responses when subjected to slight, moderate and high salt stress. Many works have been done by researchers to check the response of different crops by using saline water (Turhan et al., 2014; Al-Harbi et al., 2015; Rameshwaran et al., 2016; Zhang et al., 2016; Martinez et al., 2018; de Cássia Alves et al., 2018; El-Mogy et al., 2018; Rodriguez-Ortega et al., 2017). Rewatering facilitates a positive response for plant water status and plant growth development. Over the last few years, many researchers have addressed the reaction of photosynthesis to rewatering after water-stress, which highlights the influence of salt stress and subsequent rewatering with pure water on plants (Hura et al., 2006; Pérez-Pérez et al.,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1258312604

2007; Luo et al., 2008; Gomes et al., 2008). But none of these studies reflect the dilution of salted water or rewatering with saline water. However, by doing so it is possible to utilize the saline water resources for agricultural activities.

Moderately, salt-tolerant crop can be irrigated by diluted saline water, when freshwater resources are limited. Diluted saline water becomes the readily available water for irrigation of plants. The order of dilution or re-watering is that the plants are suffering in high concentration of salts irrigated with moderate concentration of salts. In another sense, at threshold levels, the plant can be re-watered with diluted saline water (Javed et al., 2017). The regime is considered very important in plants to adopt the behavior of salt tolerance under drought stress environment, at which P_N is sustained and recovered throughout the phases of water-stress (Chartzoulakis et al., 2002b). Junglos et al. (2016) rewatered *Campomanesia adamantinum O. Berg* plants when photosynthetic rate approached to zero. Therefore, it is essential for plants to be re-watered with diluted saline water prior to their wilting stages instead of applying direct saline-water to crops.

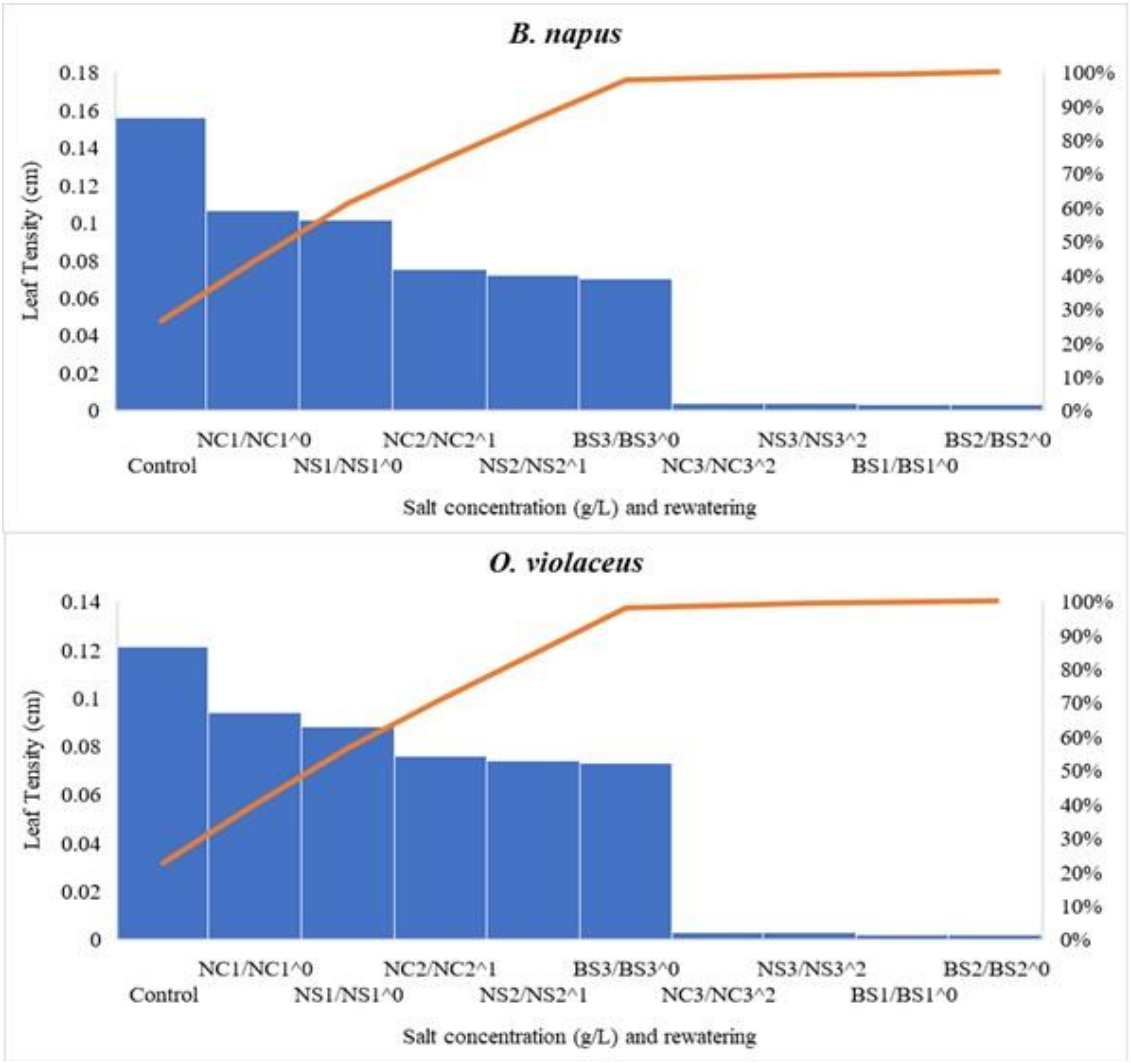

Figure 3. *Effect of salt stress on leaf tensity of Brassica napus and Orychophragmus violaceus under salt stress conditions followed by recovery during re-watering (Javed et al., 2017)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1258312604

This review thus suggested new insights in the agricultural field to design irrigation scheduling by considering the salt tolerant capability of crops as explained well in *Figure 4*.

Afterwards, irrigation water use efficiency can be ascertained through the application of precise irrigation quantity, based on the rewatering point. It would be an affirmative step, if implemented, to increase crop production in salt affected regions. It will aid in maintaining the stability between the irrigation amount and optimum crop water consumption and effective utilization of salt water, thereby reducing the everlasting demand fresh water resources for irrigation purposes.

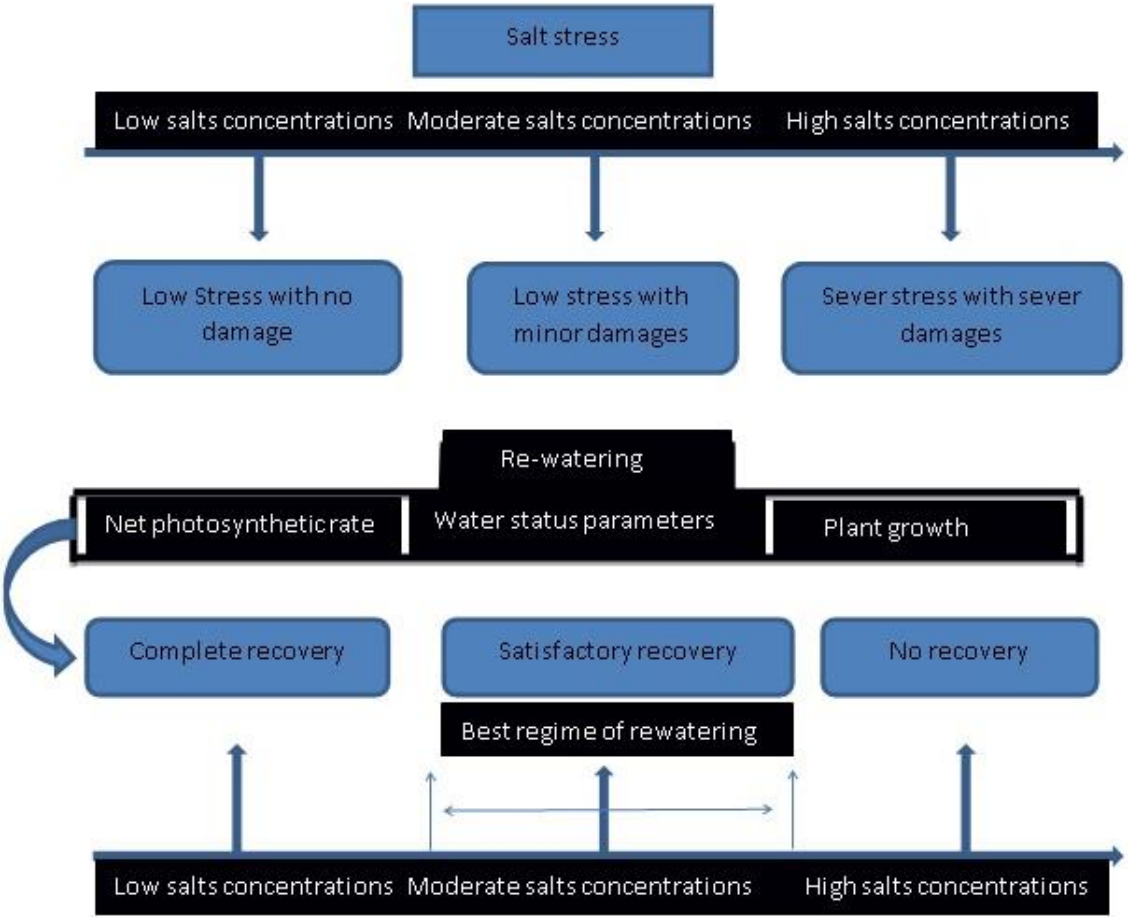

Figure 4. *Irrigation scheduling by considering the salt tolerant capability of crops*

Conclusion

This review briefly described the stress effects with respect to tolerance and physiological performances of plants. The review provides information for precise theoretical and practical irrigation based on physiological and electrophysiological characteristics. Efforts have been made to link the relative tolerance of several plant species to salt stress and subsequent rewatering with regard to toxicity under stress and their recoveries after rewatering. Present facts offer some strategies to counteract salt stress in crops through rewatering. Hence this review affirms the promising future of increasing crop production even under saline conditions. However, the vast majorities of research have focused on stress responses based on irrigation of plants. Plant

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1258312604

response to stresses and then rewatering with saline water is a good approach in the field of saline irrigation and is a boon for regions where fresh water resources are limited. Therefore, the effect of salinity in plant could be reduced by diluting the saline irrigation (re-watering) response to threshold growth and photosynthetic values. Application of dilution of saline irrigation could be helpful to save water resources, maintain crop productivity even in stressful environments and reduces irrigation cost. It is recommended based on findings of this review; short experiment in controlled environment can be done to determine the dilution point for re-watering of different crops before wilting. Afterwards, this information can be utilized for irrigation of open field crops with diluted water.

Abstract. The climate of stratosphere was simulated with a spectral element model under two different vertical level distributions, one had 28 levels with 0.3 hPa at the top of the atmosphere and another 66 levels with 4.5×10^{-6} hPa at the top boundary. Simulation results were validated against ERA-Interim reanalysis dataset from ECMWF (European Center for Medium-Range Weather Forecasts) and the influence of vertical level distributions on the numerical simulation of stratospheric temporal mean state had been analyzed. It is shown that the lift of upper boundary can reduce the temperature error above the height of 100 hPa level significantly. It can also improve the simulation of seasonal variation of zonal mean zonal wind on 50 hPa in the northern high latitudes. In both configurations, cold biases of 10-year averaged zonal mean of temperature are mainly discerned at levels around 75 hPa at low latitudes and levels around 175 hPa at high southern latitudes. The simulated seasonal variation of westerly at 50 hPa in the northern hemisphere with 66-layer model coincides with results of ERA-Interim better.
Keywords: *spectral element, atmospheric model, vertical resolution, numerical modeling, middle atmosphere*

Introduction

With the advancement of observation technique, there have been more observations available in the stratosphere and their reliability has improved greatly as well. People have come to possess more knowledge of variation tendency of the stratospheric climate and have deepened their understanding on the anthropogenic and natural factors that contribute to the climate change. People also have a more comprehensive understanding of the connections in processes of dynamics and radiation thermodynamics between the changes in the stratosphere and that specific to the earth's surface. For example, it has been realized that temperature change in the stratosphere is an important component of the global climate change, and its trend can give evidence for the separation of natural and anthropogenic effects contributing to the climate change (Randel et al., 2009); the vapor in the stratosphere plays an important role in the radiation balance of troposphere (Held and Soden, 2000); the stratosphere can influence the climate of the earth surface as well as its variability through the remote response mechanism between the stratosphere and the troposphere (Baldwin et al., 2007; Mitchell et al., 2013); and so on. The researches on the stratospheric climate are getting more people's attention. Of which, numerical modeling is an important direction.

In atmospheric climate models, two discretization methods, which are finite difference and spectral approximation, are mostly used to solve the partial differential equations numerically. Other methods, such as finite element, finite volume and so on are also used in some models. The advantage of finite difference is that it is simple and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1260512614

intuitive and easy for implementation of parallel computing. But it has the weakness of low accuracy compared to spectral approximation. The advantage of spectral method is that it has high accuracy. But since spectral approximation is carried out on the whole domain of computation, its local errors can disseminate to large area and it is hard to implement parallel computing basing on the idea of region splitting. The finite element method has the merits that it is suitable for seeking solution for domain of complex geometry; it is flexible and also easy for parallel computing. But it cannot give high accuracy solution as the spectral method does. The finite volume method can be used to construct discreet scheme more flexibly than the finite difference method and it share similar merits and weakness with the finite difference method. The spectral element method combines the merits of high accuracy from spectral approximation and flexibility from finite element discretization (Patera, 1984). The basic idea of performing computation with spectral element method is dividing the domain into finite elements and then solving the problem with spectral approximation within each of them. The spectral element method has been used widely in numerical modeling of geophysical fluid dynamics (Founier et al., 2004; Giraldo, 2005; Liu, 2011).

Many climate models used mainly for troposhere study cannot depict the stratosphere well due to their low height of top boundaries. In theses low top models, although reasonable mean climate can be reproduced through introducing damping at their top boundaries, which usually situate at the stratosphere, the simulated variability is small. There have been increasing evidences showing that the variability in the stratosphere has significant influence on the modes of climate variability in the troposphere and the earth surface (Norton, 2003; Charlton et al., 2004; Scaife et al., 2005). Besides, the influence of climate change on the stratospheric circulation is a hot topic in current scientific research, whereas the reactions of stratospheric circulation variation to ozone and earth surface climate are unclear to a large extent (Butchart and Scaife, 2001; Butchart et al., 2006; Abalos et al., 2015; Linz et al., 2017).

Since the paper of Boville (1984), many works on the influence of the middle atmosphere on the properties of the tropospheric simulation have been performed (for example, Boville and Cheng, 1988; Boville and Baumhefner, 1990; Sassi, 2010; Shaw and Perlwitz, 2010). Ruosteenoja (2006) studied the sensitivity of the simulations of tropospheric stationary waves to the height of the model top with a linear model. It is of necessity to study the influence of the height of model top on the simulation of stratosphere as well. In the paper, a model, in which the prognostic variables are discretized with spectral element method in the horizontal and the whole stratosphere is included, will be used to simulate the stratospheric climate under configuration of two different top boundary extensions; and, if a lid in the mesosphere versus one in the lower thermosphere makes any difference to the representation of climate in the stratosphere will be studied. The work will enrich the understanding on the sensitivity of the simulations of stratospheric climate to the height of the model top and contribute to the choice of model resolution for study of stratosphere.

Materials and Methods

The atmospheric general circulation model SEMANS (Spectral Element Model with Atmospheric Near Space resolved) (Liu et al., 2015) is used in the work. It uses a horizontal coordinate on the projection plane of cubed sphere (Ronchi et al., 1996) and a p-σ mixed vertical coordinate (Simmons and Burridge, 1981). The model prognostic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1260512614

variables are discretized with spectral element method in the horizontal and finite difference in the vertical respectively. When spectral element discretization is used, a triangular or quadrilateral basic element (Giraldo, 2005; Liu, 2011) is often adopted. SEMANS adopts a quadrilateral basic element. By using of coordinate on the projection plane of cubed sphere, SEMANS can overcome the difficulty of polar problem which is unavoidable in longitude-latitude grids. Through using of p-$\boldsymbol{\sigma}$ mixed vertical coordinate, the model can treat topography easily and reduces the error from calculation of pressure gradient at high altitude of the atmosphere as well. Schemes used for physical processes are shown in *Table 1*.

Table 1. *Schemes used for physical processes*

Physical process	Scheme used
Deep convection	Zhang and McFarlane (1995)
Shallow convection	Park and Bretherton (2009)
Boundary layer parameterization	Nonlocal diffusion scheme (Holtslag and Boville, 1993)
Near surface constant flux over land	Monin-Obukhov similarity theory
Near surface constant flux over ocean water and sea ice	Bulk formula
Thermal radiation	Ramanathan et al.(1986)
Solar radiation for height below 60 km	δ-Eddington approximation (Briegleb, 1992)
Solar radiation for height above 100 km	Radiation heating rates from TIME-GCM (Thermosphere Ionosphere Mesosphere Electrodynamics General Circulation Model) (Marsh and Roble, 2002)
Solar radiation for height between 60 km and 100 km	Weighted average of TIME-GCM results and output of radiation transfer with δ-Eddington approximation

The low boundary value, initial value and the data for validation of simulation results are all from the ERA-Interim reanalysis datasets (Simmons et al., 2007). In model validation, the reanalysis data from 1997 to 2006 will be used.

Two numerical experiments were designed. In the first one (denoted by EXP1), the model atmosphere was divided into 28 layers and the air pressure of model top is 0.3 hPa (see *Fig. 1a*); in the second one (denoted by EXP2), the model atmosphere was divided into 66 layers and the air pressure of model top is 4.5×10^{-6} hPa (*Fig. 1b*). In both numerical experiments, every projected plane was divided into 81 basic elements (*Fig. 1c*) and the 8^{th} degree Gauss-Legendre-Lobatto interpolation polynomials were used to approximate the solution with spectral method within each basic element (*Fig. 1d*). Since the model atmosphere in EXP2 had extended beyond 100 km in altitude, the radiation transfer scheme in EXP1 was no longer valid for high level atmosphere. In EXP2, radiation heating rates from TIME-GCM (Thermosphere Ionosphere Mesosphere Electrodynamics General Circulation Model) (Marsh and Roble, 2002) were used in model layers above a certain height (approximately 100 km); in model layers below a certain height (approximately 65 km) radiation transfer scheme identical to that of EXP1 were used; in model layers between the two heights, weighted average of TIME-GCM results and radiation transfer results of EXP2 were used (chemical processes were not considered here). The atmospheric state at 0000 UTC 1 January 1997 from the ERA-Interim datasets was used as initial values. For model layers above the height of 1 hPa level, initial values of model variables are identical to those of the highest model layer just below the height of 1 hPa level. The low boundary

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1260512614

conditions (ground surface temperature, sea ice concentration, soil moisture etc) are all multi-year (1997-2006) means with monthly variations included. In each numerical experiment, the model was integrated for 20 years and monthly mean results were saved. If not noted specifically, the results for model output and reanalysis all denote 10 year mean case.

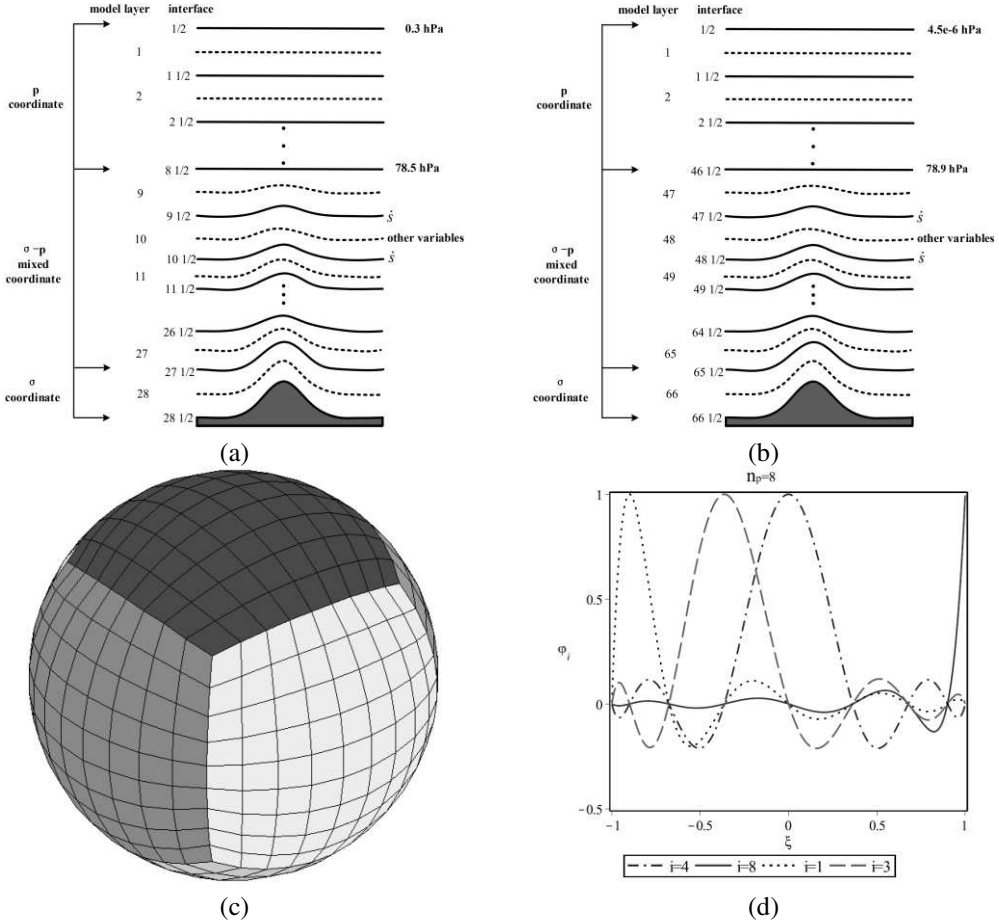

Figure 1. *Discretization of SEMANS. (a) vertical division of model atmosphere in version of 28 layers, (b) vertical division of model atmosphere in version of 66 layers, (c) projected grids on cubed sphere (81 elements in each face), (d) Gauss-Legendre-Lobatto interpolation polynomials in local coordinate from -1 to 1 (with a degree of 8)*

Results

The two numerical experiments all reproduce such features as the 2-wave pattern in the northern hemisphere and the 1-wave pattern in the southern hemisphere of geopotential at 20 hPa. The strength of simulated perturbation in the northern hemisphere is weaker than that of the reanalysis data and the strength of simulated perturbation in the northern hemisphere is close to that of the reanalysis data (see *Fig. 2*). The patterns of geopotential reproduced by both the 28 layer version and the 66 layer version of SEMANS are similar, whereas the values from the 28 layer version are bigger (compare *Fig. 2a* with *2b*). Compared to results from reanalysis dataset, the extent encircled by the 26400 geopotential meter contour is smaller (compare *Fig. 2a* with *2c*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1260512614

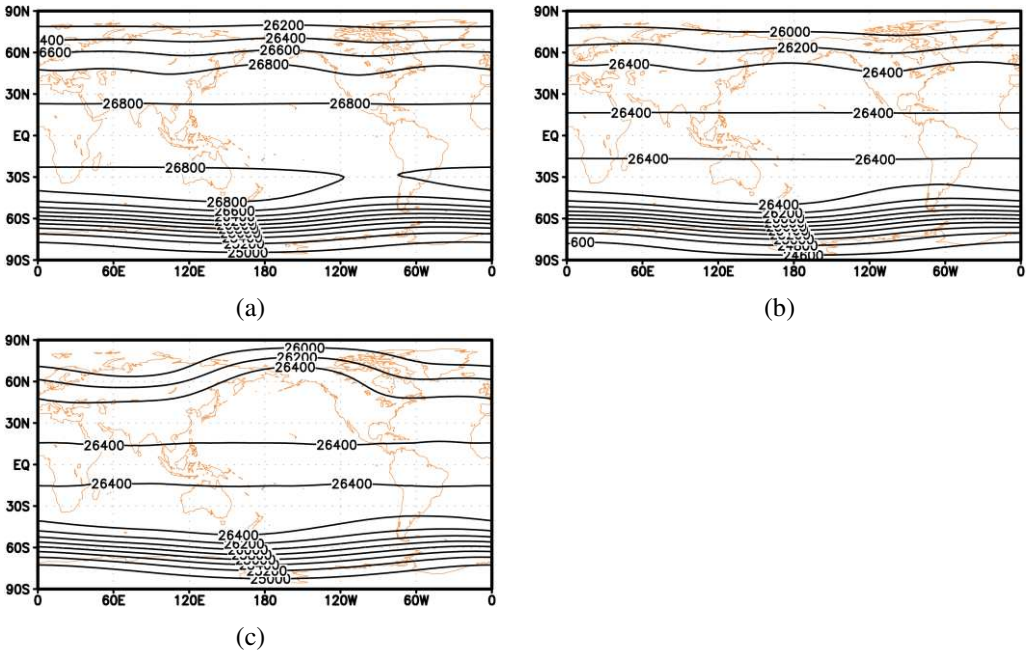

Figure 2. *Distribution of geopotential height at 20hPa (unit:gpm). (a) EXP1, (b) EXP2, (c) ERA-Interim. The horrizontal axis is longitude (°) and the vertical axis is latitude (°) in each panel*

From the 10-year averaged zonal mean temperature difference (*Fig. 3*), it can be seen that, the simulated climate features of temperature are similar from the two different configurations of SEMANS; the cold biases of zonal mean temperature in the low latitudes are mainly confined to the atmospheric levels around 75 hPa; there are cold biases above the height of 20 hPa level in the two polar regions and the biases from the 66-layer configuration are relatively smaller; there are also severe cold biases around the 175 hPa level in the southern high latitudes and the region near 45°N (compare *Fig. 3a* with *3b*).

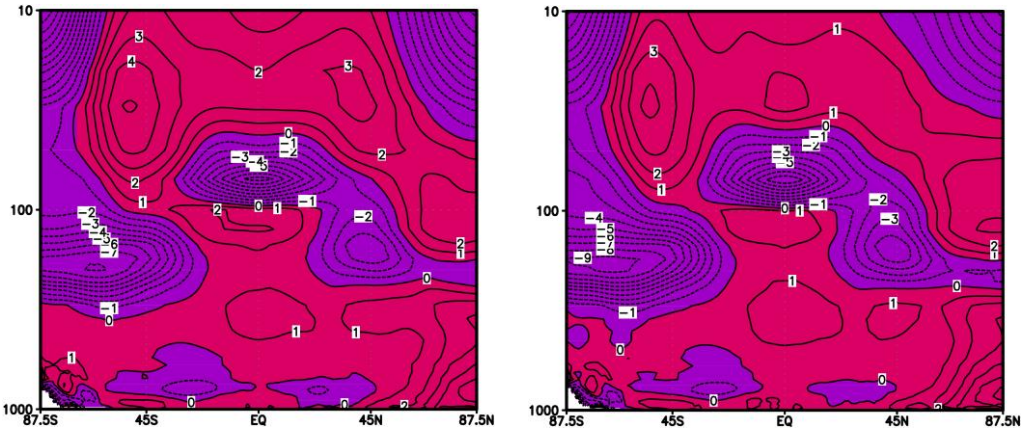

Figure 3. *Difference of zonal mean temperature (unit:K) between model results and ERA-Interim. (a) EXP1 minus ERA-Interim, (b) EXP2 minus ERA-Interim. The horrizontal axis is latitude (°) and the vertical axis is pressure (hPa) in each panel*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1260512614

The divisions of model atmosphere are identical within the troposphere in the two configurations. But due to the influence of differences in the height of model top and divisions of model atmosphere at higher levels, there are also differences in the reproduced temperature of troposphere, which are quite smaller compared to that of stratosphere.

From the differences of regionally averaged temperature between model results and ERA-Interim (*Fig. 4*), it is clear that, the simulated temperature biases varies with height in the same manner for results in EXP1 and its counterpart in EXP2; the globally averaged annual mean temperature from the 66-layer model is colder than that from the 28-layer model (see *Fig. 4a*); in the winter, the simulated temperatures above the height of 100 hPa level in the high latitudes of both hemisphere are warmer in EXP2 (see *Fig. 4b* and *4d*); in the summer, the simulated temperatures above the height of 100 hPa level in the high latitudes of both hemisphere are colder in EXP2 (see *Fig. 4c* and *4e*). It's apparent that the biases of simulated temperature above the height of 100hPa level are smaller in EXP2. In contrast, the biases of simulated regionally averaged temperature in the high latitudes in both the spring and the autumn are smaller (figures not shown).

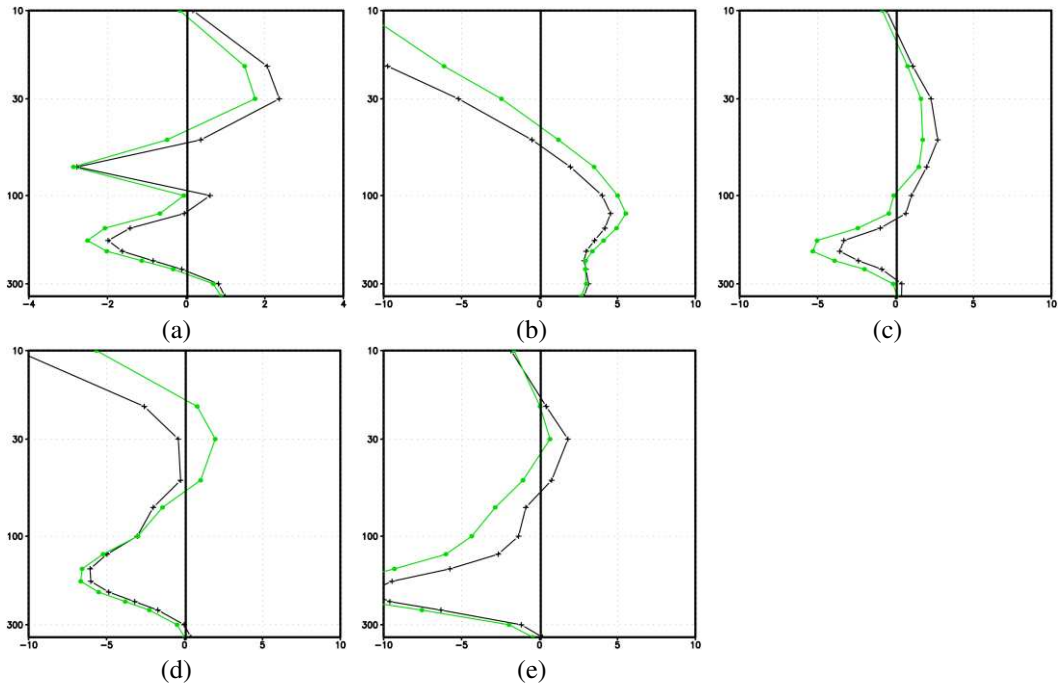

Figure 4. *Differences of regionally averaged temperature between model results and ERA-Interim. Cross and solid dot denote results from EXP1 minus ERA-Interim and EXP2 minus ERA-Interim respectively. (a)annual global average, (b) winter (December, January and February) 60−90°N average, (c) summer (June-August) 60−90°N average, (d) winter (June-August) 60−90°S average, (e) summer (December, January and February) 60−90°S average. The horrizontal axis is temperature difference (K) and the vertical axis is pressure (hPa) in each panel*

In both numerical experiments, the major features of zonal mean zonal wind distribution (such as position of westerly belts, easterly belts and centers of strong wind) at 50 hPa are consistent (see *Fig. 5a* and *5b*). Compared to that of ERA-Interim, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1260512614

simulated seasonal variation of westerly in the northern hemisphere and intensity of westerly wind in the southern hemisphere by the 66-layer model agrees with that of ERA-Interim better (compare *Fig. 5a* with *5b* and *5c*).

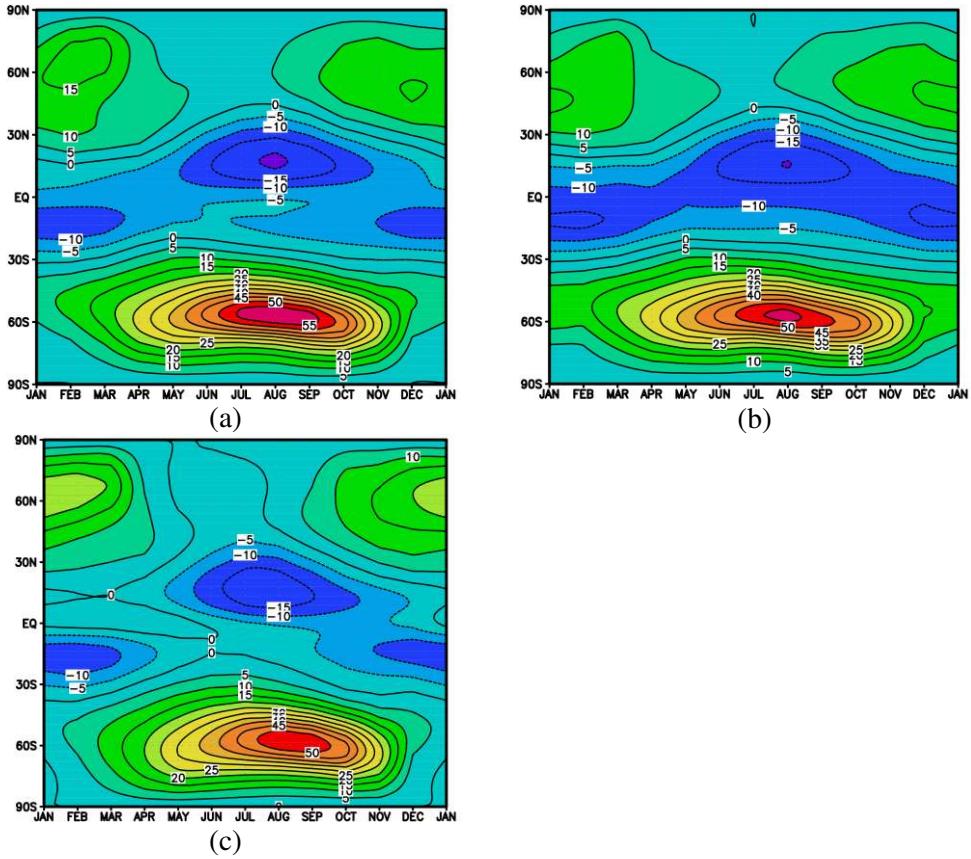

Figure 5. *Distribution of zonal mean zonal wind at 50hPa (unit: m/s). (a) EXP1, (b) EXP2, (c) ERA-Interim. The horrizontal axis is time (month) and the vertical axis is latitude (°) in each panel*

Discussion

In the study, a numerical atmospheric model with two configurations had been used to study the influence of vertical divisions of the model atmosphere on the simulation of stratospheric climate. All the employed schemes of physical processes except solar radiation are identical in the two configurations. There have been work on the effects of upper layer of atmosphere on simulations of stratosphere or troposphere based on results from different models (for example, Sassi et al., 2010). It would be difficult to deduce the reason of specific feature in simulated stratospheric climate from multiple models since there are many factors involved. In contrast, attribution is simple if simulations are from the same model. But work to study the influence of upper atmosphere on the simulation of stratospheric climate under the same dynamical framework are still less.

The analysis in the work was only on the mean climate. This is very limited. Any downward influence of the middle atmosphere on the troposphere is likely to happen during dynamically disturbed times. Thus, the time mean is not a sufficient measure to describe climate influence. More work of comparative analysis, such as the behavior of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1260512614

the model during sudden stratospheric warming, the features of the penetration of stratospheric anomalies in the two models, and so on, should be done in future research.

No chemical process has been included in SEMANS and the radiation process scheme is rather simplified for atmosphere of high altitude (above 65 km). If the chemical processes and more complex radiation process scheme are considered, the simulation results may show new features. So, much further work needs to be done in the future research.

Conclusion

A numerical model named SEMANS had been used to study if a lid in the mesosphere versus one in the lower thermosphere makes any difference to the representation of climate in the stratosphere. It's shown that, there are apparent similarities in the simulation results from the two configurations; the cold biases of zonal mean temperature in the low latitudes are mainly confined to the atmospheric levels around 75 hPa; the globally averaged annual mean temperature from the 66-layer model is colder than that from the 28-layer model; the biases of simulated temperature above the height of 100 hPa level are smaller in results from 66-layer version model; the simulated seasonal variation of westerly in the northern hemisphere and intensity of westerly wind in the southern hemisphere by the 66-layer model agrees with that of ERA-Interim better.

Abstract. The objective of this study was to observe the relationship between levels of family environmental tobacco smoke (ETS) and obstructive sleep apnea hypopnea syndrome (OSAHS). Clinical datr AHI, lower oxygen saturation, longer apnea time, and lower ventilation time ($p < 0.05$). There was a correlation between EST and OSAHS. Compared with non-exposa of 209 patients who visited the respiratory department were retroactively collected. The data entailed gender, age, body mass index (BMI), family environmental smoke exposure, medical history, Epworth sleepiness scale (ESS) score, and polysomnography (PSG) indicators. Two groups of patients were studied: ETS-exposed group and non-ETS-exposed group. Using the apnea hypopnea index (AHI), OSAHS patients were classified as mild ($5 \leq AHI \leq 15$), moderate ($15 < AHI \leq 30$), and severe ($AHI > 30$). There were 148 cases in the OASHS group and 61 cases in the normal group. 56.66% of the OASHA group were ETS-exposed patients, which was significantly higher than that the normal group ETS-exposure of 31.57% . Compared to the OSAHS patients unexposed to ETS, the OSAHS patients with EST exposure had a greater degree of lethargy, greateed, the EST-exposed group was more susceptible to OSAHS, and the longer the time, the more severe the condition.
Keywords: *obstructive sleep apnea hypopnea syndrome, health effects, passive smoking, sleep apnea hypopnea index, ESS questionnaire*

Introduction

Environmental tobacco smoke (EST) exposure has become a worldwide health problem. Currently, there are 1.3 billion smokers worldwide, and a high number of people are exposed to family environmental tobacco smoke (Rando et al. 999; Aviado et al., 1996). Studies have shown that EST impairs the stability of the internal environment and affects normal physiological processes, leading to various chronic diseases. Obstructive sleep apnea hypopnea syndrome (OSAHS) accounts for most of sleep apnea hypopnea syndrome cases, a frequently-occurring disease (Muggli, 2004). In China, OSAHS affects about 4% of adults. The syndrome is characterized by snoring and repeated apnea resulting in sleep fragmentation, morning discomfort, dry mouth, daytime sleepiness, fatigue, dizziness, headache, decreased memory, and inattentiveness. These problems result in reduced work efficiency, increased risk of industrial accidents and traffic accidents, as well as sudden death during sleep (Davidson and Reed, 2018; Theweny, 2015). With improvement in living standards, ageing and incidence of obesity have increased significantly, and the incidence of OSAHS is increasing year by year, thereby posing an important public health problem. Since OSAHS and ETS often occur simultaneously, they may have common oxidative stress and inflammatory pathways, leading to metabolic disorders (Barnes et al., 2006; Elliott et al., 2007; Jenkins and Counts, 1999; Steenland, 1999; Thun et al., 1999). At

DOI: http://dx.doi.org/10.15666/aeer/1705_1261512622

present, local and foreign scholars have studied the etiology and pathogenesis of OSAHS. Studies have suggested that ETS is one of the risk factors for OSAHS, but there are few studies on the relationship between ETS and OSAHS.

In the present study, the relationship between EST and OSAHS was studied by investigating the association between ETS exposure and the severity of OSAHS, so as to provide a theoretical basis for effective prevention and treatment of OSAHS.

Materials and methods

Materials

Setting and samples

The clinical data of 209 patients who visited the Department of Respiratory Medicine were retrospectively collected. The patients were divided into ETS-exposed group and non-ETS-exposed group. The ETS-exposed group was sub-divided into mid-ETS (tobacco smoke in the house but not in the same room as patient), and heavy-ETS (tobacco smoke in the same room as patient). Using the latest American Society of Sleep Medicine Standards (AASM) and AHI, patients with OSAHS were classified as mild ($5 \leq AHI \leq 15$), moderate ($15 < AHI \leq 30$), and severe ($AHI > 30$). The OSAHS classification is shown in *Table 1*.

Table 1. *Grading of OSAHS*

Classification	AHI (time/hour)	$LSaO_2$ (%)
Mild	5-15	85-90
Moderate	> 15-30	80- < 85
Severe	> 30	< 80

Inclusion criteria

Patients older than 18 years, patients who snored while sleeping at night and in daytime, and those with complete clinical data (including BMI, ESS score and PSG monitoring, etc.) were included in the study.

Exclusion criteria

Patients with loss of polysomnography, maxillofacial deformity, severe pneumonia, asthma, pulmonary interstitial disease, and chronic obstructive pulmonary disease were excluded. Moreover, those with severe heart failure, liver failure, renal failure, and neuromuscular diseases were excluded. Patients with central and mixed sleep apnea, and those on prolonged use of sleeping and sedative drugs were considered ineligible.

Methods

Polysomnography

Polysomnography (PSG) is the most important test for diagnosing OSAHS. Through continuous monitoring of night-time breathing, arterial oxygen saturation, electroencephalogram, electrocardiogram, heart rate and other indicators, you can know whether the snorer has apnea, the number of pauses, the time of suspension, the minimum arterial oxygen value at the time of suspension, and The extent of the impact on physical

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1261512622

health is an internationally recognized gold standard for the diagnosis of OSAHS. The polysomnography is the most commonly used sleep monitoring method and is the internationally recognized gold standard for diagnosing OSAHS. According to the results of polysomnography, not only can the diagnosis of OSAHS be made, but also the severity can be judged, and it is convenient to formulate clinical treatment plans and quantitatively evaluate the operation or other treatment effects. Polysomnography is used to measure various physiological signals during sleep. The parameters of the measurement include: (1) Breathing: The airflow monitor can find the length and frequency of sleep apnea syndrome. Stopping breathing for more than 10 s is called a pause. Insufficient breathing usually means that the respiratory airflow drops by more than 50%. (2) Oxygen saturation: A decrease in blood oxygen saturation is a key manifestation of OSAHS patients. (3) Muscle movement: Monitoring of chest movements can help diagnose whether the pause is central or obstructive. Other types of sleep disorders can be manifested as leg movements, jaw closures, and other characteristic sports. (4) Brain waves and eye movements: Sleep can be divided into different stages according to brain waves and eye movements, namely fast phase and slow phase (deep and light sleep). (5) Electrocardiogram (ECG): Some patients with OSAHS may have abnormal heart rhythms. (6) Position of the body: OSAHS is most likely to occur in the supine position, when the base of the tongue falls and it is easy to block the upper respiratory tract. Two of these assessment methods are often cited to summarize sleep monitoring outcomes: (1) Calculate the mean of the hourly breathing disorder by calculating the average of the sum of night-time sleep apnea syndrome and hypopneas, ie, breathing Pause the hypogastric index Apnea Hypopnea Index (AHI). Adult AHI greater than or equal to 5 can be defined as OSAHS. (2) The lowest oxygen saturation in sleep apnea syndrome, although there is no specific indication of sleep apnea syndrome, but less than 85% can determine sleep apnea syndrome. The PSG monitor with US Embla NN7000 (Jain, 2018) multi-lead sleep monitor was used to monitor the subjects for polysomnography ≥ 7 h overnight. At the same time, the subjects were advised to avoid drinking alcohol, coffee, tea, taking sleeping pills, and sedating drugs. The monitored parameters were EEG, ocular electricity, mandibular muscle power, nose and mouth airflow, chest and abdomen exercise, ECG, eye movement, body position, snoring, and fingertip oxygen saturation. The results were analyzed with computer software, and were strictly followed by professional physicians in accordance with the American Sleep Medicine Society. The sleep monitoring indicators selected for reflecting the objective severity of the patient's disease were AHI, minimum oxygen saturation, mean oxygen saturation, longest apnea time, and longest low ventilation time.

Tests and questionnaires

The clinical data of all selected subjects were collected. These were gender, age, height, weight, past medical history (hypertension, diabetes, cardiovascular and cerebrovascular diseases). The ESS score, AHI, minimum oxygen saturation, mean oxygen saturation, longest apnea time, and longest low ventilation time were recorded. The ESS shown in *Table 2* was used for the subjects. The ESS was assessed by a professional under the guidance of a questionnaire containing 8 questions, each with 0-3 points and 4 levels. The maximum score was 24 points. Determination of lethargy ESS score < 5 is normal, 5-9 is mild sleepiness, 10-15 is moderate sleepiness, 16-24 is severe sleepiness. The higher the score, the more severe the daytime sleepiness, and scores greater than 10 points were considered to be excessive daytime sleepiness.

Statistical analysis

Normal distribution data are presented as mean ± standard deviation ($\bar{x} \pm s$). Statistical differences were analyzed with χ^2 test and *t*-test. All statistical analyses were performed using SPSS 23. Differences were assumed statistically significant at $p < 0.05$.

Results

Characteristics of participants

A total of 209 patients were included in the study, out of which 148 patients had OSAHS, comprising 111 males and 37 females. The remaining patients comprised 37 males and 24 females. The population of OSAHS patients with EST exposure formed 56.66%, which was significantly higher than that in the normal group (31.57%), and the OSAHS group had significantly higher BMI ($p < 0.05$). There were no significant differences in age, and in male and female distribution ($p > 0.05$; *Table 3*).

Comparative analysis of OSAHS with EST exposure and the non-ETS-exposed group

There were 87 cases in OSAHS group with EST exposure consisting of 77 males and 10 females. In the non-ETS-exposed OSAHS group, there were 61 subjects made up of 34 males and 27 females. Compared with OSAHS group without exposure to ETS, OSAHS group with EST exposure differed significantly in gender composition ($p = 0.000$), but there were no significant differences in age, BMI and past medical history between the two groups ($p > 0.05$). These results are shown in *Table 4*.

Contrastive analysis of somnolence and PSG of OSAHS within the EST-exposed and non-exposed groups

Compared with non-exposed OSAHS group, OSAHS group exposed to EST had more somnolence, higher AHI, lower oxygen saturation, and longer apnea pause time and hypopnea time ($p < 0.05$; *Table 5*). The exposed group scored higher on the ESS than the non-exposed group, which said there was more drowsiness. The reported SD values are highly overlapping in case longest apnea time in *Table 5,* but statistical processing was reliable.

Comparison of characteristics, ESS scores and PSG in OSAHS with different exposure levels

The groups were divided into ETS-exposed group and the non-ETS-exposed group, and the ETS-exposed subjects were classified into mid-ETS (tobacco smoke in the house but not in the same room as patient) and heavy-ETS (tobacco smoke in the same room as patient). In the ETS-exposed group, 25 OSAHS subjects with mid-ETS exposure, and 62 OSAHS subjects with heavy-ETS exposure were included. There were no significant differences in age and BMI between the two groups. Compared with OSAHS patients with mid-ETS exposure, OSAHS patients with heavy-ETS exposure

Discussion

Obstructive sleep apnea hypopnea syndrome (OSAHS) is a common sleep-disorder in the general population. It is one of the causes of drug resistance, refractory hypertension, and heart failure. If it is not treated effectively for a long time, it results in irreparable damage to multiple organs. The disorder seriously affects the quality of life and longevity of patients. The present study compared the ESS scores and AHI index of OSAHS patients exposed to ETS with those of OSAHS patients who were not exposed to ETS. In addition, the ESS score and PSG data of the OSAHS subjects exposed to mid-ETS were compared with those of OSAHS patients exposed to heavy-ETS. The study was aimed at providing scientific data and basis for adjunct clinical intervention in OSAHS. Long-term exposure to EST reduces the sensitivity of tissues to hypoxia and degrades the capacity to recover from conditions caused by hypoxia. These pathological changes impair the ability of the body to recover automatically from apnea when it occurs (Coggins, 2008; Owili et al., 2018; Van et al., 2018). This will result in a longer apnea and a long-term decline in blood oxygen saturation associated with it. It has been reported that patients with OSAHS exposed to mid-EST experienced longer and lower nocturnal hypoxemia than non-exposed OSAHS patients (Berman et al., 2018). In the treatment of OSAHS patients, doctors should, through joint interventions in multiple disciplines, pay attention to the patient's environmental status, and actively persuade them to improve the environment so as to reduce the occurrence of long-term complications of the disorder (Nachamkin, 2012; Li et al., 2018; Maskarinec et al., 2000). Improving the home environment can be used as an adjunct to conventional therapy for OSAHS.

The sample size used in this study was small. Moreover, retrospective studies may have recall bias. To obtain more reliable data, it is important to use a larger sample size and more representative study locations (Yang et al., 2018; Nurminen and Jaakkola, 2004). It is also important to apply more stringent control conditions in the study of EST and improvement of OSAHS. The relationship between ETS and OSAHS is expected to be further elucidated through animal experiments.

DOI: http://dx.doi.org/10.15666/aeer/1705_1261512622

Conclusion

This study shows that there is a certain correlation between EST and OSAHS. Compared with subjects who were not exposed to ETS, patients exposed to EST are more susceptible to OSAHS, and the longer the exposure time, the more severe the condition. This study found that the BMI of the OSAHS group was significantly higher than that of the non-OSAHS group, which is consistent with the currently well-recognized high incidence of obesity and OSAHS. The study found that the ETS exposed group had higher ESS, higher AHI, lower oxygen saturation, and longer apnea time and hypopnea time. Compared with non-smokers, the current smoking population has longer sleep latency, shorter sleep time, longer I-stage sleep time, and slower slow-wave sleep time. The sleep characteristics of OSAHS patients are prolonged latency, sleep fragmentation, and prolonged stage I sleep. III stage IV sleep reduction. To a certain extent, this also explains the impact of ETS exposure on sleep.

Thus, OSAHS may be mitigated by improving the environment. Families are the main places where tobacco smoke is exposed. Public health policies need to focus on family smoking ban. To publicize and pay attention to the harm of EST, we should actively advocate smoking cessation, strengthen the publicity of the hazards of passive smoking, control the impact of EST on OSAHS, and have great significance in preventing OSAHS.

Abstract. The relationship between land surface temperature (LST) and land use patterns has long been explored to understand the impact of urbanization on the urban heat island effect. This paper reports the geographically weighted regression method. The LST is derived from the radiation transfer model and the urban reflectance is grouped into three types from the linear spectral mixture in Nanjing City, China. The high LST on October 3, 2009 in the central city, suburbs, outer suburbs, and outer suburbs near water were 44, 40, 36, and 33°C, respectively. The LSTs of the central city in spring, summer, and autumn were 1–5°C higher than that of the suburbs. The high absorption coefficient of vegetation, substrate, and dark surfaces with LST were -0.80, 1.05, and -1.64, respectively. The promoting role of impervious surfaces is much higher than the cooling effects of vegetation on LST. Water surfaces have a more obvious effect on adjusting LST. If the landscape diversity index or the fragment index are low, the vegetation cover has a more noticeable negative correlation with LST. The way in which LST relates to land reflectance and to landscape provides a quantitative reference for urban planning of sustainable development in Nanjing.
Keywords: *spectral unmix, heat island, landscape indices, Nanjing, radiative transfer equation*

Introduction

The main feature of the urban heat island effect is that the LST in central urban areas is higher than that in the suburbs (Landsberg, 1831). In the study of the urban heat island pattern, remote sensing data for land surface temperature (LST) inversion were mainly gathered by the National Oceanic and Atmospheric Administration's Advanced Very-High-Resolution Radiometer (AVHRR), Moderate Resolution Imaging Spectroradiometer (MODIS), Landsat Thematic Mapper/Enhanced Thematic Mapper (Landsat TM/ETM), and Advanced Spaceborne Thermal Emission and Reflection Radiometer (ASTER). The urban area is firstly determined using the temperature difference between the urban and rural surface detected by AVHRR (Rao et al., 1972). Heat island intensities from AVHRR data are highest in the day time and in the warm season for towns in North America (Roth et al., 1989). Qin et al. (2001 a,b) proposed a single window algorithm for Landsat TM/ETM and modified the land temperature inversion algorithm for MODIS. ASTER data is optimized using a neural network algorithm (Mao et al., 2008). A split window algorithm is provided for Landsat 8 and the root mean square is determined as 0.93°C (Rozenstein et al., 2014). When the urban reflectance is known, the algorithms are divided into three types; the single-channel method (Coll et al., 2012), the multi-channel method (Atitar and Sobrino, 2009), and the multi-angle method (Sobrino and Jiménez-Muñoz, 2005). When the urban reflectance is not known, the algorithms are again divided into three types, but which differ from the preceding case; the stepwise retrieval method (Sobrino et al., 2008), simultaneous

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1262312638

retrieval (Hulley and Hook, 2011), and simultaneous retrieval with unknown atmospheric information (Wang et al., 2013).

In a related analysis of the spatiotemporal characteristics of LST, the urban heat island magnitude is considered to be inversely correlated with the rural temperature (Streutker, 2002). The intensity of the urban heat island reached a maximum during the summer and a minimum during the winter periods. The overall relationship between urban heat island and population density have been quantitatively explored (Li et al., 2012). The minimum temperature difference formed at the end of the cooling process increases with urban length and while wind speed is on the decline (Lee et al., 2012). The LST has been increasing in recent years, with an increase of LST in both rural and urban areas (Rajasekar and Weng, 2009; Alavipanah et al., 2015; Fu and Weng, 2016a; Haashemi et al., 2016).

By predicting the urban expansion pattern of cities in the Pearl River Delta of China and considering the LST and urban reflectance patterns, the radiation temperature is expected to increase by 13.01 K (Weng, 2001). LST possesses a more negative relation with the unmixed vegetation abundance than with the normalized difference vegetation index (NDVI) across the spatial resolution from 30 m to 960 m (Weng et al., 2004). The NDVI can be easily influenced by leaf area, view angle, and soil background, thus, it is not a suitable indicator for quantitative vegetation research (Small, 2001). The three-end members of substrate, vegetation, and dark surface, can represent more than 95% of the 30 million ETM+ image spectra with misfits of less than 0.04 (Small, 2004, 2005). There is a negative relation between LST and vegetation abundance, and a positive relation between LST and impervious surface. The rates of change of low and high temperatures differ depending on the impervious surface abundance (Small and Lu, 2006). The heat island effect is more noticeable in industrial and commercial areas (Zhang et al., 2012). The LST is expected to increase by 2.63°C by overall regression, and 3.17°C from geographically weighted regression, and additionally, according to an analysis of the accuracy the overall regression underestimates the heat island effect and its risks (Su et al., 2012). High-intensity urban land in Atlanta has the highest mean LST value of 294.9 K with a yearly amplitude of 17.4 K (Fu and Weng, 2016b). Information support systems for urban heat landscape have been proposed to simulate the urban heat island and mitigate these effects (Quattrochi et al., 2000). Landscape indices can also be used to predict the LST. The landscape dominance index and the landscape shape index account for 56% and 6–12% of the variance of the LST, respectively (Chen et al., 2014).

In spite of these significant studies, there are few studies of the regional arithmetical relation between LST and urban reflectance. Using Landsat TM/ETM imagery of Nanjing City, this study aims to illustrate the quantitative relation between LST and urban reflectance Specific objectives of this study are as follows: (1) to derive the LST and analyze its temporal, spatial, and fractal characteristics. (2) to apply linear spectral unmixing to analyze the urban reflectance of vegetation, substrate, and dark areas. (3) to investigate the relation between LST and vegetation, substrate and dark abundance using geographically weighted regression (GWR). This research also investigates the relation between LST and the enhanced vegetation index (EVI) under landscape diversity indices and fragment indices.

Materials and Methods

Study Sites

Nanjing City is in the central region of the Yangtze river downstream at 118°22′-119°14′E, 31°14′–32°37′N in Jiangsu province. The total area of Nanjing City was 6597 km^2, with 1427.81 km^2 of built area in 2018. Nanjing City has a humid subtropical climate. The average, maximum (summer), and minimum (winter) temperatures, are 15.4, 39.7, and -13.1°C, respectively. Rainfall averages 1006 mm per annum. Nanjing's geomorphology is primarily characterized by low mountains and low hillocks, with 3.5% low mountains, 4.3% hilly areas, 53% low hillocks, and 39.2% plains and rivers (Li et al., 2016). The natural vegetation is mixed deciduous forest and broadleaf evergreen forest. Nanjing includes seven districts, Central, Jiangning, Qixia, Pukou, Liuhe, Lishui, and Gaochun districts, respectively (*Fig. 1*).

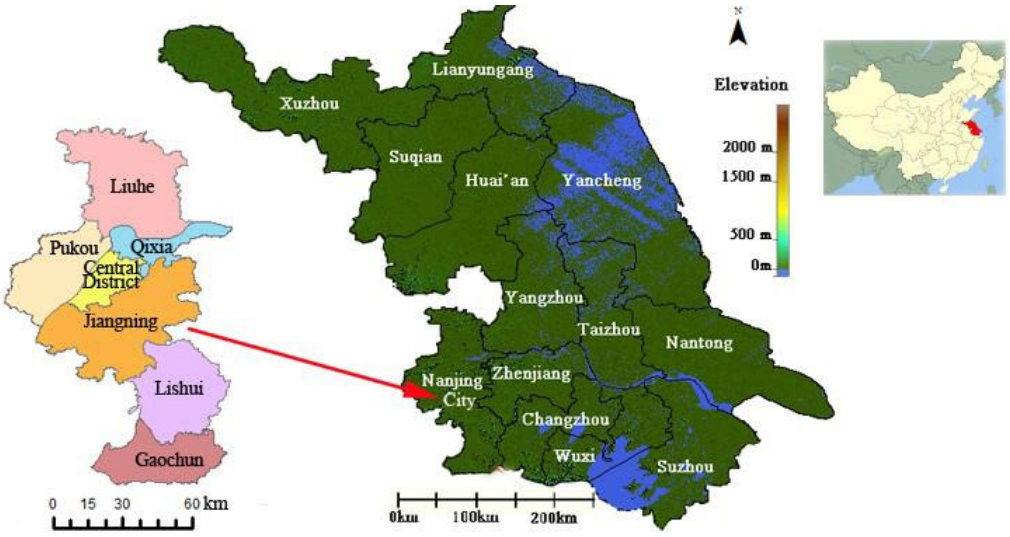

Figure 1. *Nanjing City of China. There are seven districts in Nanjing.*

Nanjing is the Capital of Jiangsu province with nearly 2000 years of history. The GDP of Nanjing was 972.08 billion yuan in 2015, ranking 11th in China. In 2015 Nanjing's industrial infrastructure account for 2.4% in primary industry, 40.3% in secondary industry, and 57.3% in tertiary industry. Nanjing's resident population in 2015 was 8.24 million and the urbanization rate was 81.4%. The reform and open policy of the 1980s produced a rapid urbanization phase and further encroachment on the countryside. The Nanjing Plan of 1991-2010 proposed new towns around the main old city (Jim and Chen, 2003).

Data

The data sets were downloaded from the United States Geological Survey (USGS) website (http://glovis.usgs.gov/ accessed 7th March 2019). 22 Landsat images are used to derive the LSTs in Nanjing (*Table 1*). The Landsat TM image obtained on May 20, 2006 is utilized to derive the landscape diversity indices and fragment indices. The Landsat image obtained on October 3, 2009 is utilized to derive the fractions of substrate, vegetation, and dark surface land cover by linear spectral unmixing.

Methods

Radiative transfer equation

The LST is obtained using the radiative transfer equation from the following expression (Berk et al., 1987; Sobrino et al., 2004).

$$L_{sensor} = (\varepsilon L_\lambda + (1-\varepsilon)L_\downarrow)\tau + L_\uparrow \quad \text{(Eq.1)}$$

where L_{sensor} is the at-sensor radiance above the atmospheric radiance, ε is the urban relectance, τ is the total atmospheric transmissivity between the land surface and the sensor, $L_\downarrow$ and $L_\uparrow$ are the downwelling and upwelling atmospheric radiances, $L_\uparrow$and L_λ

is the blackbody radiance given by Planck's law.

The formula for the actual temperature, T is as follows:

$$T = \frac{K_2}{Ln(K_1/L_\lambda + 1)} \quad \text{(Eq.2)}$$

where K_1 and K_2 are constants. For Landsat TM, K1 = 607.66 and K2 = 1260.56, and for Landsat ETM, K1 = 666.09 and K2 = 1282.71.

$$NDVI = (TM4 - TM3)/(TM4 + TM3) \quad \text{(Eq.3)}$$

where TM4 and TM3 are the near the infrared and red bands, respectively.

$$F_V = [(NDVI - NDVI_S)/(NDVI_V - NDVI_S)] \quad \text{(Eq.4)}$$

$$\varepsilon surface = 0.9625 + 0.0614F_V - 0.046F_V^2 \quad \text{(Eq.5)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1262312638

$$\varepsilon built = 0.9589 + 0.086F_V - 0.0671F_V^2 \quad \text{(Eq.6)}$$

where F_V is the percentage of vegetation cover, and $\varepsilon surface$ and $\varepsilon built$ represent the emissivities corresponding to the natural and urban surfaces, respectively.

Linear spectral mixture model

The linear spectral mixture model assumes that the spectral reflectance of the field of view of a sensor can be expressed as a linear combination of the constituent end members (Small and Lu, 2006).

$$R(\lambda) = f_1E_1(\lambda) + f_2E_2(\lambda) + \cdots + f_nE_n(\lambda) \quad \text{(Eq.7)}$$

where $R(\lambda)$ is the observed reflectance, λ is the wavelength, $E_i(\lambda)$ is the spectrum of the end members, f_i is a coefficient representing the abundance of the corresponding end members.

The linear spectral mixture has two significant problems. One is to determine the number of end members related to surface reflectance. Another one is to determine the reflectance spectrum of end members. Linear spectral mixture models can be standardized by using end members that span the global mixing space. The mean substrate, vegetation, and dark end members can be used to define a global standard mixture model for Landsat spectra (Clement et al., 2009; Small and Milesi, 2013).

Geographically weighted regression

Geographic weighted regression is an extension of the traditional global regression because it allows for local regression rather than global parameter estimation (Fotheringham et al., 2001). The GWR method is also applied to LST and environmental driving factors (Buyantuyev and Wu, 2010; Zhou and Wang, 2011; Schwarz et al., 2012; Du et al., 2016).

The equation for the GWS model is:

$$y_i = \beta_0(u_i, v_i) + \sum_k \beta_k(u_i v_i)\, x_{ik} + \varepsilon_i \quad \text{(Eq.8)}$$

where (u_i, v_i) is the coordinate of the *i*-th point, $\beta_k(u_i v_i)$ is the *k*-th regression parameter of the *i*-th point, and ε_i is the random error of the *i*-th sample.

Data near the *i*-th point will have a more profound effect on $\beta_k(u_i v_i)$ than data further away.

$$\hat{\beta}(u,v) = (X^T W(u,v) X)^{-1} X^T W(u,v) y \quad \text{(Eq.9)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1262312638

where $\hat{\beta}(u,v)$ represents the unbiased estimate of β, $W(u, v)$ is a weight function, which ensures that observation points close to the specific point will have a large weight.

$$W_{ij} = \exp\left(\frac{d_{ij}^2}{b^2}\right) \quad \text{(Eq.10)}$$

where W_{ij} is the weight of observation point *j* related to the point *i*.

If the observation point *j* coincides with point *i*, the weight of point *j* is 1. If the distance between points *j* and *i* is greater than the bandwidth, the weight of point *j* is zero. Thus, the GWR model takes the bandwidth into account.

Landscape indices

The land surface is classified into five types by an un-supervised classification method and checked with Google Earth, including farmland, forest, water areas, construction land and other land. Based on the land classification, landscape diversity and Landscape fragmentation indices are calculated by fragstas.

Results

The Character of Urban Reflectance and LST

The urban reflectance is classified into three types by linear spectral unmixing, including the substrate fraction (*Fig. 2a*), vegetation fraction (*Fig. 2b*), and dark fraction (*Fig. 2c*). The LST is inversed by radiation transfer model in Nanjing City on October 3, 2009.

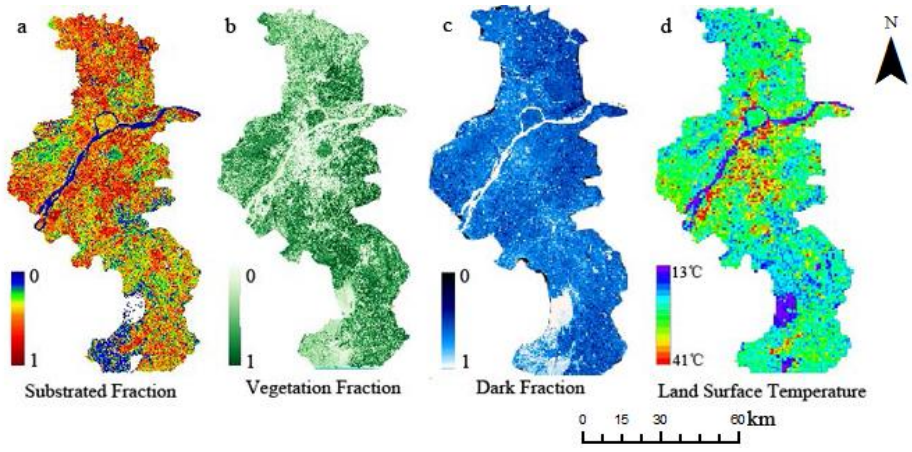

Figure 2. *The urban reflectance and LST in Nanjing City on October 3, 2009. The fraction of impervious surface from 0-100% (Fig.2a). Vegetation fraction (Fig.2b). Water Fraction (Fig.2c). LST (Fig.2d)*

High impervious surface fractions are mainly distributed in the middle and the north part of Nanjing City (*Fig. 2a*). The central city of Nanjing is in the center along the Changjiang river. With urbanization, the impervious surface is gradually extending in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1262312638

the northerly direction. Low vegetation surface fractions are in the center of Nanjing City and some is also observed in the north (*Fig. 2b*). The vegetation in cultivated areas, forest parks, and undeveloped remote areas in the outer suburbs is less disturbed. High water surface fractions are in the middle and in the south, and correspond to the Yangtze river and Gucheng lake, respectively (*Fig. 2c*). Nanjing City with the high LST observed on October 3, 2009 is in the center of Nanjing (*Fig. 2d*). The high temperature area is larger than the area of the high impervious surface fraction. With the rapid progress of urban construction in Nanjing, the city is subject to a large number of anthropogenic heat sources, including fuel combustion, automobile exhaust, and air conditioning, increasing the air temperature. The development of commercial and service industries in Nanjing has resulted in business areas with dense population. These areas are have high densities so the heat is not easy to diffuse.

Characteristics of the spatial dimension of LST

Taking the city of Nanjing as the center, and extending to the north, east, south, and west we make a temperature profile for October 3, 2009 (*Fig. 3*). The LST profile serves to observe the general characteristics of LST and horizontal distribution trends. The section of the profile running from north to central urban (*Fig. 3a*), has a low temperature of approximately 24°C, corresponding to the Yangtze River basin, and the profile continues from central urban to the south (*Fig. 3b*).

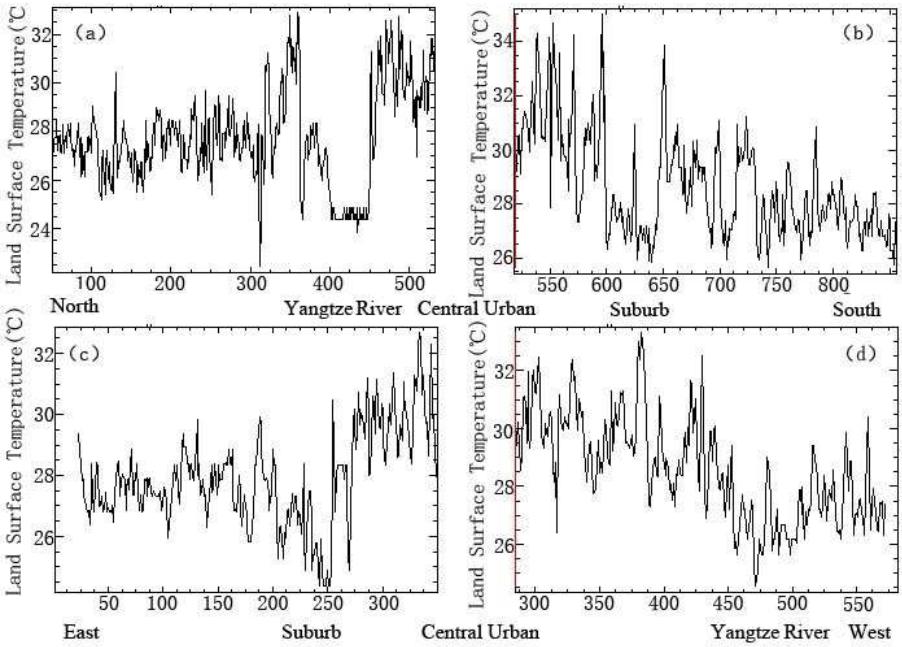

Figure 3. *Spatial sectional view of LST in Nanjing on October 3,2009. From north to Central direction (a). From central to south direction (b). From east to central direction (c). From central to west direction (d)*

The junction of the urban and rural areas has a low temperature because of high vegetation cover. The section of the profile running from east to central urban (*Fig. 3c*) and the corresponding place of low temperature is the junction of urban and rural areas. The section of the profile running from central urban to east (*Fig. 3d*) has a low

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1262312638

temperature of about 26°C. As a result, the temperature in central urban is higher by 8-6°C than that in Yangtze River and urban-rural junction with high vegetation cover.

Characteristics of the temporal dimension of LST

LST time series data from April 17, 2000 to October 14, 2013 is selected in the central city (*Fig. 4a*), the suburbs (*Fig. 4b*), the outer suburbs (*Fig. 4c*), and the outer suburbs near a lake (*Fig. 4d*) of Nanjing City (*Fig. 4e*). The high LST is 44°C in central city, 40°C in suburbs, 36°C in outer suburbs, and 33°C in outer suburbs near water. During the fourteen years of the presented time series data, urban development has expanded to the suburbs and impacted its LST. The land surface of the outer suburbs is less disturbed by humans and the LST is 5°C lower than that in central urban. The LST in the outer suburbs near the lake is lower than that in the outer suburbs, mainly because of the influence of the water surface.

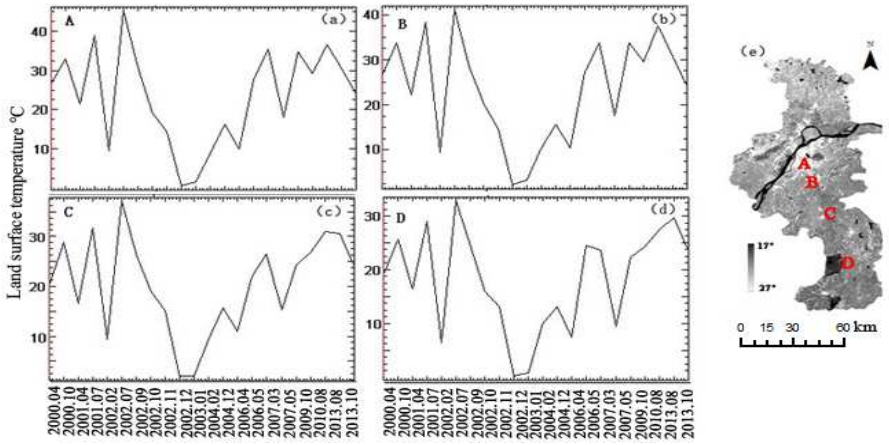

Figure 4. *Time series of LST in Nanjing from Year 2000-2013. Time series curve in central urban (Fig.4a). Time series curve in suburbs (Fig.4b).Time series curve in outer suburbs (Fig.4c). Time series curve in outer suburbs near lake (Fig.4d). Sample position map (Fig.4e)*

Characteristics of the fractal dimension of LST

From 2000 to 2010, the LST of the central city in spring, summer, and autumn was 1-5°C higher than that of the suburbs (Jiangning, Qixia, and Pukou districts) and outer suburbs (Liuhe, Lishui, and Gaochun districts), for example, on July 12, 2002 and May 7, 2007 (*Table 2*).

Table 2. *Zoning LST in Central urban, suburbs (Jiangning District, Qixia District, and Pukou District) and outer suburbs (Liuhe District, Lishui District, and Gaochun District) from 2000 to 2010. (Units: ℃)*

In winter, the LST is less than or close to that of the suburbs and the outer suburbs, such as on December 27, 2002 and February 8, 2004.

Comparing the LST of different years, the intensity of the heat island effect is decreased on May 20, 2006 and October 3, 2009. During the period 2007-2010, the LST difference between central urban and outer suburbs is small because urbanization has led to the expansion of urban space, thus the intensity of the heat island effect is relatively weakened.

Relationship between LST and Land Cover

In the GWR method, local R^2 and standard residuals provide the criteria for judging the degree of fit to observational data. Local R^2, ranges from 0 to 1, and indicates the degree of local regression of the simulation for the observed values. Higher values indicate that the local regression model fits the results well, and lower values less-well. The coefficients represent the relationship between the two variables of LST and vegetation surface, and the related directions. The residual represents the difference between the observed and estimated values. The standard residual is zero.

Fig. 5 shows the correlation between LST and vegetation based on the GWR, in which the LST is the dependent variable and the vegetation abundance is the argument. High local R^2 represents a strong correlation, and mainly occurs in the central area of Nanjing and the suburbs (*Fig. 5a*).

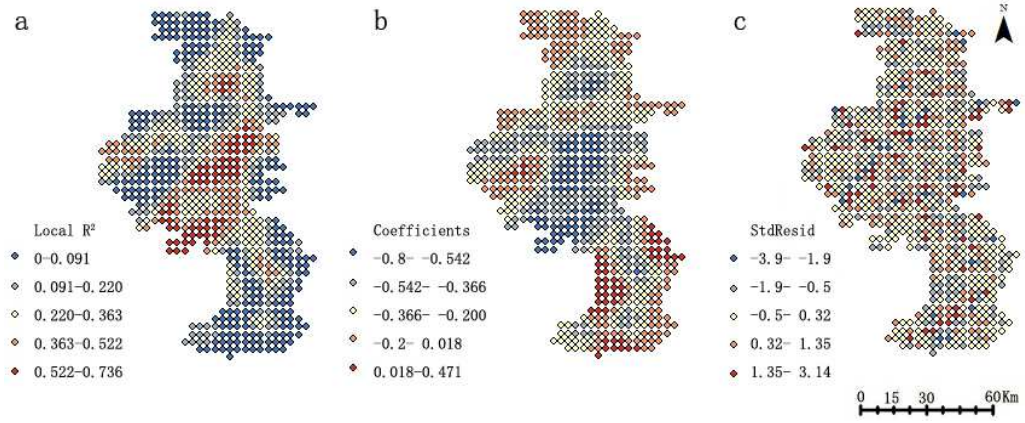

Figure 5. *Correlation between LST and vegetation based on geographically weighted regression model in October 2009 in Nanjing City. Fig.5a is Local R2. Fig.5b is Coefficients. Fig.5c is StdResid*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1262312638

Lower local R^2 represents a relatively weak geographic linear correlation, and mainly occurs in the south and north of Nanjing. Vegetation in the Central district of Nanjing showed a stronger negative correlation with LST and the coefficient ranged from -0.8 to -0.542 (*Fig. 5b*). Vegetation abundance in the outer suburbs displayed a weak negative correlation with the LST. The distance from the central district has a significant impact on the relationship between vegetation and LST. Positive residuals represent a high predictive value and negative residuals a low value (*Fig. 5c*). On the whole, the standard residuals are distributed in an apparently random pattern, and all residual values are lower than four, thus the overall model fit well.

Figure 6 shows the correlation between LST and impervious surface abundance based on GWR. The high R^2 is mainly distributed in the central district and southern suburbs of Nanjing where the LST and impervious surface have a strong correlation (*Fig. 6a*). The coefficient of LST and impervious surfaces are all positive, showing a significant positive correlation (*Fig. 6b*). The coefficients in the urban center range from 0.803 to 1.045. The impervious surface has a significant impact on land surface warming. Absolute values of the majority of standard residuals are lower than 1, indicating that the model fit very well (*Fig. 6c*).

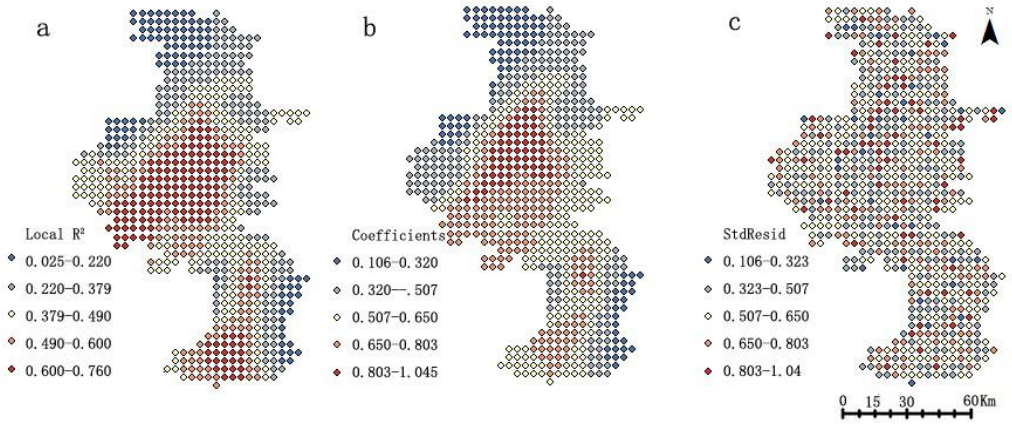

Figure 6. *Correlation between LST and impervious surface based on geographically weighted regression model in October 2009 in Nanjing City. Fig.6a is Local R2. Fig.6b is Coefficients. Fig.6c is StdResid*

Comparing *Fig. 5b* to *Fig. 6b*, the coefficients in the central district for vegetation and impervious surfaces range from -0.800 to -0.542 and from 0.803 to 1.045, respectively. The promoting role of impervious surface is much higher than the cooling effects of vegetation on LST.

Figure 7 shows the correlation between LST and water from GWR, in which the LST is the dependent variable and water abundance is the argument. The high R^2 is mainly distributed in the middle and north of Nanjing in the proximity of the Yangtze River and Gucheng Lake (*Fig. 7a*). The high local R^2 reaches 0.538 indicating that there is a good fit between LST and water. The coefficients in the south and middle of Nanjing are negative valued which signifies a negative correlation between LST and water (*Fig. 7b*). Along the Yangtze River, the coefficients are low (-1.64 to -1.07), thus, the Yangtze River forms a band which impedes heat transfer, and further slows down

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1262312638

the urban heat island effect. The absolute value of the standard residuals is less than four signifying that the model fit well (*Fig. 7c*).

Comparing *Fig. 5b* to *Fig. 7b*, the low coefficients for vegetation and water surface fitting with LST are -0.8 and -1.64, respectively, thus the water surface has a more obvious effect on adjusting the LST than the vegetation.

Relationship between LST and Landscape Indices

Landscape indices can describe the detailed pattern of the land surface. Landscape diversity indices include patch richness density and Shannon's diversity index. Landscape fragmentation indices include number of patches, patch density, division and splitting indices. These indicators are selected to reflect different aspects of landscape features and to verify the accuracy of the indicators (*Table 3*).

The Shannon's diversity index of the central city is 1.1691, and is the smallest of all districts. Diversity indices of the suburbs (Qixia, Pukou, and Jiangning districts) are 1.4072, 1.4287, and 1.4270. Diversity indices of the outer suburbs (Lishui, Liuhe, and Gaochun districts) are 1.4848, 1.4288, and 1.5037.

The division index of the central city is 0.7664, and is the smallest of all districts. Division indices of the suburbs (Qixia, Pukou, and Jiangning districts) are 0.8819, 0.9737, and 0.9777. Division indices of the outer suburbs (Lishui, Liuhe, and Gaochun districts) are 0.9853, 0.9723, and 0.9677.

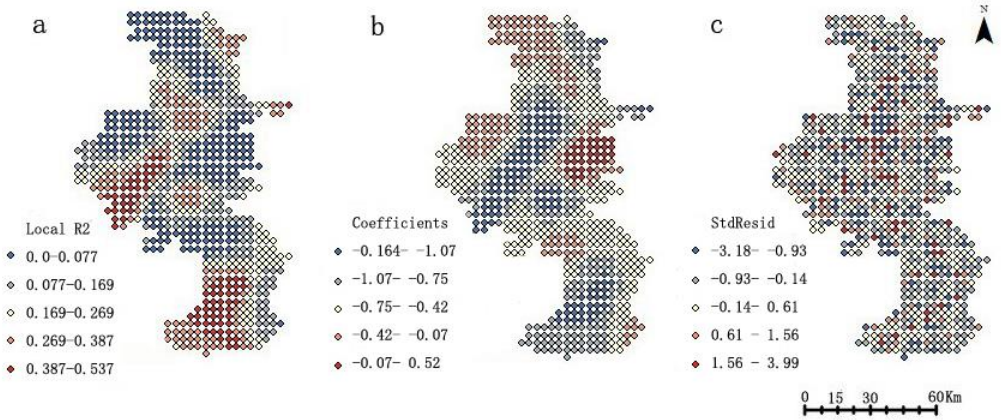

Figure 7. *Correlation between LST and water surface based on geographically weighted regression model in October 2009 in Nanjing City. Fig.7a is Local R2. Fig.7b is Coefficients. Fig.7c is StdResid*

Table 3. *Landscape index in Nanjing zones on May 20, 2006*

District	Landscape indices					
	Number of patches	Patch density	Division index	Splitting index	Patch richness density	Shannon's diversity index
Lishui	99019	92.93	0.9853	68.08	0.0047	1.4848
Liuhe	132821	90.08	0.9723	36.15	0.0034	1.4288
Pukou	80495	88.72	0.9737	37.96	0.0055	1.4287
Qixia	20283	51.79	0.8819	8.46	0.0128	1.4072
Central	18084	50.19	0.7664	4.28	0.0139	1.1691
Jiangning	147583	91.91	0.9777	44.84	0.0031	1.4270
Gaochun	69328	86.29	0.9677	30.95	0.0062	1.5037

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1262312638

The diversity index in the central city is lowest of all, and the LST and EVI display a significant negative correlation. Diversity indices in the suburbs are in the middle value of all. The LST and EVI have a weak negative correlation (*Fig. 8*). Diversity indices in the outer suburbs are the largest of all the sites, and the LST and EVI show substantially no linear correlation.

If the landscape diversity indices are smaller, the LST has a more obvious negative correlation with the vegetation index. Conversely, if the landscape diversity indices are greater, the LST response to the vegetation index is weaker.

Similarly, if landscape fragmentation indices are smaller, the LST has a more obvious negative correlation with the vegetation index. Conversely, if landscape fragmentation indices are greater, the LST response to the vegetation index is weaker.

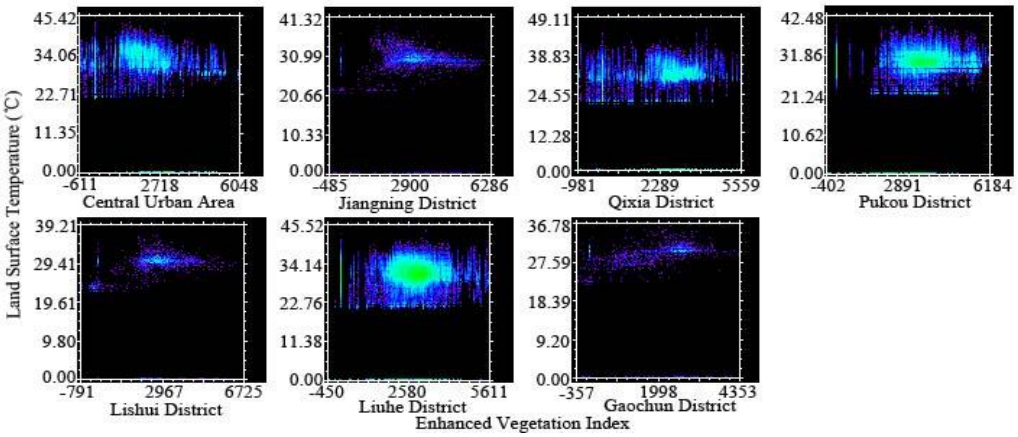

Figure 8. *The relation of LST and enhanced vegetation index (EVI) under different landscape indexes in Nanjing zones. X axis is enhance vegetation index and Y axis is LST*

Conclusions

In the spatial dimension, the high temperature is in the central city, and the low temperature is in the suburbs and the Yangtze River, and there was a 6-8°C temperature difference on October 3, 2009. In the temporal dimensional, the maximum LSTs in the central city, suburbs, outer suburbs and outer suburbs near water are 44, 40, 36, and 33°C, respectively. In the fractal dimension, the LST of the central city in spring, summer, and autumn is 1-5°C higher than that of the suburbs. In winter, the LST of the central city is less than or close to that of the suburbs.

In the quantitative relation between the LST and urban reflectance, vegetation in the Central District of Nanjing showed a stronger negative correlation with LST and the coefficient is -0.8. Impervious surface in the central district of Nanjing displayed an extinctive positive correlation with the LST and the highest coefficient is 1.045. The promoting role of impervious surface is considerably higher than the cooling effects of vegetation on LST. The water surface of Gucheng Lake had a negative correlation with LST and a low coefficient of -1.64. The water surface has a more obvious effect on adjusting the LST.

The landscape diversity indices and fragmentation indices have a negative relationship with both the LST and vegetation index. If the landscape diversity indices are smaller, the LST has a more noticeable negative correlation with the vegetation

DOI: http://dx.doi.org/10.15666/aeer/1705_1262312638

index. Similarly, if the landscape fragmentation indices are smaller, LST has a more obvious negative correlation with the vegetation index.

Discussions

In this research, the GWR model is utilized to explore the scale-dependent and spatial non-stationary relationships between LST and urban reflectance. In the GWR model, the strength of the regression relationships increased significantly, with a mean of 59% of the changes in LST values explained by the predictors, compared with only 43% using the ordinary least squares model (Li et al., 2010). The most important problem for the GWR method is to set the local regression parameters and select a suitable bandwidth, which involves the problem of spatial autocorrelation. Here the local regression parameters are set to be adaptive and not consider the spatial autocorrelation factor. However, spatial autocorrelation is a key issue for future research. The land cover and land surface temperature have the same trend with the published paper (Liu et al., 2016; Wang et al., 2018).

Scaling is another important factor effecting the relationship between landscape patterns and LST. Thirty meters was found to be the optimal resolution in the study of the relationship between urban relectance and LST classes. Ninety meters was found to be the optimal spatial resolution for assessing the landscape-level relationship between land cover and LST patterns (Liu and Weng, 2009). Here the Landsat dataset of 30 meters resolution was selected to derive the LST.

The impact of urbanization on the urban heat island can be mitigated not only by balancing land use patterns, but also by optimizing the spatial landscape (Zhou et al., 2011). Landscape patterns can determine the land function. The same amount of vegetation cover in different landscape patterns will play a different role in slowing LST. The composition metric alone explains about 56% of the landscape mean LST. Whereas, adding a configuration explains approximately another 6–12% (Chen et al., 2014). Here we study the correlation between LST and vegetation index under different landscape index conditions; a focus of research on the quantitative relation between LST and urban landscape pattern.

(Received 13th May 2019; accepted 16th Jul 2019)

Abstract. This study was conducted to determine the residue effects of chicken manure on the yield and yield components of eight onion varieties as second crop after lettuce in field condition. Varieties (14-16, Burgaz, Karbeyazı, Naz, NWG, Perwana, Seyhan, Şampiyon) and also four different doses of chicken manure at the rates of 0, 20, 40, 60 t ha^{-1} with the recommended dose of NPK were used. A non-fertilized parcel was used as control. The experiment was laid out in split plot design and replicated three times. Yield and yield components were investigated. According to the results residual effect of chicken manures and onion varieties as second crop significantly affected the yield and bulb production in the field condition. The application of chicken manure significantly improved yield, bulb weight, bulb height, number of shoot tip, number of dried leaf compared to control. Highest yields (46.31 t ha^{-1}) were obtained in the parcels where the chicken manure was applied at a rate of 60 t ha^{-1}. The onion cultivar Burgaz was more responsive to the chicken manure compared to other onion cultivars. The best yield was shown by the Burgaz cultivar under 60 t ha^{-1} chicken manure treatment, thus this method is the most suitable for onion production.
Keywords: *onion, varieties, organic manure, NPK, yield*

Introduction

Onion (*Allium cepa* L.) is a vegetable that is widely consumed due to its flavoring and health-promoting properties. Onions have many possible health benefits including reducing the risk of obesity, heart disease, and cancer. Onion bulb is a rich source of minerals like phosphorus, calcium, magnesium, iron, manganese and carbohydrates. It also contains protein, Vitamin C, Vitamin B6, and antioxidants (Ware, 2017).

According to the statistics, Turkey's bulb onion production is 2131513 ton in 576918 ha area (Anonymous, 2017).

Healthy life and environmental consciousness are important today. In this case it caused to increase on natural feeding. Using of chemical matter was decreased and natural productions get importance. But soil fertility is important in this case. Organic matter improves soil's physical, chemical, biological properties and is also effect the availability of nutrient. But high level organic material in soils especially in dry conditions may be caused unable effects and also it can be create organo-mineral complex and it reduced the availability of some mineral (Sezen, 1995). Animal fertilizers are major source of organic matter for soil.

Boyhan and Hill (2008) found that fertilizer requirements were higher with organic fertilizer sources compared with conventional fertilizers presumably because nutrients were less available in organic compounds due to slow mineralization rates.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1263912647

Work has been done to predict the availability of plant nutrients from organic sources over time. Whitmore (2007), for example, found that 40% of the total N from composted chicken manure was available in the first year, with the remainder available in subsequent years at a rate of 6 to 12% per year.

Many researchers reported that soil application of chicken manure increased yield and yield criteria of onion (Shaheen et al., 2007; Dina et al., 2010; El-Shatanofy and Manar, 2011; Yoldas et al., 2011; Ali et al., 2018).

Comparisons of conventional and organic farms matched by soil type indicated that organic practices improved soil fertility (Liebig and Doran, 1999). This included a 22% increase in organic matter, 20% more total N, lower bulk density and higher water holding capacity.

Many authors reported that the onion yield and bulb production was significantly affected by onion cultivars (Soleymani and Shahrajabian, 2012; Ali et al., 2018).

The objective of this study was to evaluate the residue effect of chicken manure on yield and yield criteria of onion as second crop in field condition.

Materials and methods

The study was carried out in experimental area of the Ödemiş Vocational School, at the Ege University, in İzmir (38°16'N, 27°59'E) during the 2017 year. The experimental designs were split plot with three replications. Before sowing of lettuce, the chicken manure were applied to soil at the rates of 0 – 20 – 40 – 60 t ha^{-1} and also recommended dose of NPK (150:100:150 kg ha^{-1}). Five different treatments with control and three replications were conducted in 15 plots. Lolla Rossa lettuce variety was sown and harvested at the end of vegetation. After harvesting the lettuce plant, onion varieties was sown in order to determine the residual effect of chicken manure and chemical fertilizer in field conditions. No nutrient addition was made for onion. In this study, during the growth period, weeds were removed by hand hoeing and irrigation was done on a regular basis.

Eight onion varieties called 14-16, Burgaz, Karbeyazı, Naz, NWG, Pewana, Seyhan, Şampiyon were used. *Allium cepa* L. was planted in each plot with 30 cm between rows and 15 cm above the rows. Total plot length is 11.5 m and plot width is 6.2 m.

The composition of chicken manure that residual effect investigated was analyzed according to Kacar (1995) and is presented in *Table 1*.

Table 1. *Some properties of chicken manure*

DOI: http://dx.doi.org/10.15666/aeer/1705_1263912647

Soil samples (0-30 cm) were collected from the individual experimental plots (15 samples) at the beginning of onion vegetation. The soil sample was air dried, ground, and passed through 2 mm sieve for the determination of chemical parameters. pH (Jackson, 1967), total soluble salt (Anonymous, 1951), $CaCO_3$ (Kacar, 1995), organic matter content (Reuterberg and Kremkurs, 1951) were determined in the soil. Total N was also analyzed according to Bremner (1965), the available K^+, was determined after extracting with 1 N NH_4OAc by flame photometer (Atalay et al., 1986) and available P was measured by colorimeter (Olsen et al., 1954).

At the end of the vegetation, the plants were harvested. Average bulb head weight, bulb height, bulb width and flesh thickness, number of storage leaf, number of shoot tip, and number of dried leaf were determined as growth and yield parameters.

Ten randomly selected plants were harvested from each plot (avoiding side effect) to record the data on data set for all characters. Bulb length and diameter refers to the height of the bulb and the average width at the widest point in the middle portion of the mature bulb measured using vernier caliper. Average bulb weight computed by weighing ten bulbs together and calculating the average.

Total bulb yield was computed based on the weight of matured bulbs yield per plot and converted in to hectare base and expressed in tones. Marketable bulb yield was determined after discarding bulbs smaller than 3 cm in diameter, splitted, thick necked, rotten and discolored. Split bulbs percentage was determined by counting the number of split bulbs per plot and expressed in percentage in reference to total number of normal bulbs per plot.

The collected data on various parameters were statistically analyzed. Analysis of variance was computed and LSD was used to compare means. Trial statistical evaluation result of data was done using software package TARIST (Açikgöz et al., 1993).

Results and discussion

Soil properties

The physical and chemical properties of soils before onion sowing are presented in *Tables 2* and *3*. pH, organic matter, lime values in the soil did not show any statistical difference between applications at the beginning of vegetation. On the contrary, the salt, N, P, Na, Fe content of the soil was significantly affected by the applications. The highest values were analyzed in the parcels which the chicken manure was applied as 60 t ha^{-1}.

Before onion sowing, field soil properties are neutral (6.6-7.3), humus (< 1%) and lime (0-2.5) poor. When the productivity status of the soil is investigated, N is moderate (0.05-0.1%); K (< 150 ppm), Ca (715-1430 ppm) poor; rich in P (3.26 ppm); Mg (large 114 ppm) is good; Fe (large 4.5 ppm); Zn (large 1 ppm), Mn (large 1 ppm), Cu (large 0.2 ppm) is determined to be sufficient according to Güneş et al. (2000).

Onion yield and yield characteristics

Residue effect of chicken manure on yield and some quality criteria of onion as second crop after the lettuce production are given in *Table 4*.

In the field condition, the results showed significant differences in yield amongst treatments ($p < 0.01$) (*Table 4*). Highest yields (46.31 t ha^{-1}) were obtained in the parcels which the chicken manure was applied as 60 t ha^{-1}. This application increased yield by 44% compared to the control plots. But there was no statistically significant difference in yield between mineral fertilizer and 60 t ha^{-1} of chicken manure application. Similarly Rumpel (1998), Sharma et al. (2003), Yoldas et al. (2011), Indira and Singh (2014), Zewde et al. (2018) found that animal manure applications increased onion yield. Organic manures activate many species of living organisms which release phytohormones and may stimulate the plant growth and absorption of nutrients (Arisha et al., 2003). Organic manures improved the water holding capacity of soil and provide nutrients for a long duration due to less leaching of nutrients and increase efficiency (Carol et al., 1999). Mahala et al. (2018) reported that the increased yield and yield parameters with poultry manure might be because of rapid availability and utilization of nitrogen for various internal plant processes for carbohydrates production. Later on these carbohydrates may undergo hydrolysis and get converted into reproductive sugars which ultimately helped in increasing yield.

Yield

Similar to the results Velmurugan and Swarnam (2017), explained that rice grain yield were significantly affected by the residual effect of manures and Inorganic fertilizer to okra, different our results, Abdelrezzag (2002) reported that chicken manure tend to reduce onion yield for all levels in comperation with fertilizer and control.

In the study, the highest yield was observed Burgaz variety ($p < 0.01$) (*Table 5*). Highest yield after Burgaz obtained with Şampiyon variety. The differences in yield among varieties can be caused by differences in genetic characteristics of varieties (Khan et al., 2011).

The interaction between onion cultivars and treatment was found statistically significant on yield. Maximum yield was obtained in Burgaz variety with the 60 t ha^{-1} of chicken manure application as 79.87 t ha^{-1}. Hasan et al. (2018) reported similar results in their studies.

Bulb weight

Treatments, variety and the interaction between onion cultivars and treatment affected bulb weight of onion significantly ($p < 0.01$). Highest values (138 g) were obtained in the parcels which the chicken manure was applied as 60 t ha^{-1} in the field (*Table 4*). This application increased weight of onion by 44% compared to the control plots. But there was no statistically significant difference in bulb weight between mineral fertilizer and 60 t ha^{-1} of chicken manure application. Similarly, Yohannes et al. (2013) reported that farmyard manure and nitrogen fertilizer increased bulb weight. Organic fertilizers provide nutrients to the plants by decomposing and increase growth and yield. Manures improved the soil structure, fertile and availability of nutrient to the plant. Better nutrition of the plant; increase the cell division of plant tissues and the rate of photosynthesis. This is reflected in product growth and the bulb weight (Ewais et al., 2010).

Bulb weights of Burgaz variety (195.2 g) were higher than the others onion variety significantly (*Table 5*).

The interaction between onion cultivars and treatment for bulb weight was found statistically significant The highest bulb weights was obtained in Burgaz variety with mineral fertilizer as 268.7 g in the field condition.

**p < 0.01; *p < 0.05; n.s.: not significant

Bulb width

The residual effect of chicken manure and mineral NPK applications on onion bulb width not found significant (*Table 4*). Similarly, Yohannes et al. (2013) and Mekonnen et al. (2017) reported that farmyard manure did not affect bulb length of onion in their work.

The highest bulb width (5.8 cm) was observed Burgaz variety ($p < 0.01$) followed by the bulb width (5.1 cm) in Şampiyon variety (*Table 5*). The interaction between onion cultivars and treatment for bulb width was statistically important. Maximum bulb was obtained in Burgaz variety with the mineral NPK application as 6.60 cm.

The differences in the responses to the applications of onion varieties may be genetic variation and also depending on the adoptability of variety in specific environment (Shah et al., 2012; Ali et al., 2018).

Bulb height

Onion bulb height was significantly ($p < 0.01$) affected by the residual effect of chicken manure and mineral NPK applications (*Table 4*). The highest value (7.2 cm) was determined in mineral NPK application and followed bulb height (6.9 cm) by the application of chicken manure as 20 t ha^{-1}. Similarly, Yohannes et al. (2013) reported that application of FYM at a rate of 45 ton ha^{-1} gave the highest mean bulb diameter (5.99 cm). Consistent with the results Metwally and Bary (1999) suggested that the poultry manure improve the bulb growth by enhancing the soil properties and overcome the leaching of nutrients from the root zone. As different Mekonnen et al. (2017) reported that organic manure did not significantly influence bulb length.

In the study, bulb height of Burgaz variety (7.9 cm) was reported higher than other varieties ($p < 0.01$) (*Table 5*). The interaction between onion cultivars and treatment for bulb height was found non-significant.

Number of storage leaf

According to statistical analyzes, number of storage leaf was not affected from the treatments. But these characteristics have changed significantly in relation to the varieties

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1263912647

(*Tables 4* and *5*). Highest value was obtained in Burgaz variety (7.4 cm) followed Şampiyon variety (6.9) (*Table 5*). However, there was no statistically significant difference between Burgaz and Şampiyon variety. The interaction between onion cultivars and treatment had a significant effect on the number of storage leaf ($p < 0.01$). The number of storage leaf was higher in the application of mineral fertilizer and Burgaz variety.

Number of shoot tip

The results presented in (*Tables 4* and *5*) showed that treatment and onion variety had significantly affected number of shoot tip of onion, where the interaction had also significantly affected. The highest number of shoot tip (1.5) was observed with the application of chicken manure at the rate of 60 t ha^{-1}. While the lowest numbers of shoot tip (1.2) was observed in mineral NPK aplication. Among the onion variety highest number of shoot tip was recorded in variety 14-16 and Perwana.

Maximum number of shoot tip was obtained in 14-16 varieties with the 60 t ha^{-1} of chicken manure application as 20 t ha^{-1}.

Number of dried leaf

Treatments, variety and the interaction between onion cultivars and treatment affected number of dried leaf of onion significantly ($p < 0.01$) (*Tables 4* and *5*). Highest value (3.2) was obtained in the parcels which the chicken manure was applied as 60 t ha^{-1} in the field. Number of dried leaf of Burgaz variety (4.7) were higher than the others onion variety significantly (*Table 5*). The highest number of dried leaf was obtained in Burgaz variety with mineral fertilizer as 6.2.

Conclusion

As a result it was found that residual effect of chicken manures and onion varieties as second crop significantly affected the yield and bulb production in the field condition. Residual of chicken manure increased yield, bulb weight, bulb height, number of dry shell, number of shoots of onion varieties. The highest results were obtained especially with 60 t ha^{-1} of chicken manure application in the field condition. The onion varieties Burgaz gave more response to the organic manure as compare with other onion varieties in yield, bulb weight, bulb height, bulb width, number of storage leaf and number of dried leaf.

The interaction of chicken manure and onion cultivar also affected the yield of onion. The best yield was shown by Burgaz cultivar under 60 t ha^{-1} chicken manure treatment, thus this method is the most suitable for onion production.

In today's world, where healthy life and environmental consciousness is gaining importance, it should be aimed to increase the conscious use of natural organic fertilizers.

(Received 13th May 2019; accepted 16th Jul 2019)

Abstract. The aim of this study was to assess the influence of selected biostimulants (Tytanit, Rooter) and foliar fertilisers (Optysil, Metalosate Potassium, Bolero Bo, ADOB 2.0 Zn IDHA, ADOB B, ADOB 2.0 Mo) on the activity of dehydrogenases, acid and alkaline phosphatases and catalase, and their influence on the level of biological nitrogen fixation based on the nitrogenase activity in soybean cultivation. Between 2016 and 2018 a field experiment was conducted at the Gorzyń Experimental and Educational Station, Poznań University of Life Sciences in Poland. During the three years of the experiment the foliar fertilisers and biostimulants significantly stimulated the catalytic dehydrogenase activity (DHA) and alkaline phosphatase activity (PAL) in all the experimental variants, as compared to the control variant. The analysis of the results of acid phosphatase activity (PAC) during the entire soybean growing period showed that it decreased significantly compared to the control variant when Tytanit, Rooter and Bolero Mo preparations were applied. Additionally, the analysis of catalase activity (CAT) revealed that apart from Tytanit, all the preparations significantly stimulated this enzyme, as compared with the control variant. The field analyses of biological nitrogen fixation showed that the fertilisers and biostimulants significantly stimulated nitrogenase activity under the soybean plantation.
Keywords: *dehydrogenase activity, phosphatase activity, catalase activity, nitrogenase activity, BIF*

Introduction

In recent years agrotechnical treatments with pesticides as well as phosphorus and nitrogen fertilisation have become a threat to all elements of the ecosystems (Nardi et al., 2016). New sustainable, cost-effective and environment-friendly cultivation technologies that ensure high yield and quality of crops are being sought to limit the negative influence of these treatments on the soil environment (Vernieri et al., 2006). The application of environment-friendly practices is dictated by European Union law (EU Directive 2009/128) and recommendations concerning integrated protection/cultivation which have been in effect, in Poland since 2014. Moreover, due to the feed protein deficit in Europe and Poland (Borowska et al., 2016) there is a pressing need to search for opportunities to increase the yield of crops, especially legumes, which are a valuable sources of protein.

DOI: http://dx.doi.org/10.15666/aeer/1705_1264912666

Legumes are becoming increasingly important in sustainable agriculture (Massawe et al., 2016). What speaks in favour of their cultivation is the fact that they improve the physicochemical properties of soil, enrich organic matter content by leaving large amounts of crop residue and reduce the consumption of nitrogen fertilisers. Soybean (*Glycine max* L.) is one of the most important crops in this group. Its seeds contain about 40% of protein with a favourable amino acid composition and 20% of fat, with the predominant share of unsaturated fatty acids. The cultivation of soybean is gaining popularity in Poland as a result of the changing climate and the introduction of new varieties (Gaweł, 2011; Florek et al., 2012; Stagnari et al., 2017).

One of the metabolic features of legumes is their ability to coexist with bacteria that fix atmospheric nitrogen (diazotrophy process) (Poole et al., 2018). As the content of valuable protein in a plant depends on the system formed between the plant and rhizobia, it seems right to look for agents that increase the efficiency of this symbiosis.

Biostimulants, which are defined as materials containing one or more active substances and/or microorganisms, are gaining increasing attention in scientific circles. They increase the uptake of nutrients by plants and tolerance to abiotic and biotic stress and they improve the yield quality (Calvo et al., 2014). Biostimulants can also stimulate the activity of rhizosphere microorganisms and soil enzymes, the production of hormones and increase photosynthesis (Giannattasio et al., 2013).

Intensified cultivation has caused foliar fertilisation to become an indispensable agrotechnical treatment. Among the large number of nutrients that are necessary for the proper growth of plants, some must be supplied in larger quantities, while others – in smaller or even trace amounts. Plants exhibit the highest demand for potassium and nitrogen (more than 200 kg when the yield per 1 ha is calculated), while they need only small amounts of zinc, boron, copper and molybdenum (only a few grams when the yield per 1 ha is calculated). This shows that foliar fertilisation is particularly effective when micronutrients need to be supplied to crops. In some situations, it is also recommended that macroelements such as nitrogen, and magnesium, and less frequently phosphorus, potassium, sulphur and calcium, should be sprayed onto leaves (Szewczuk and Sugier, 2009).

Each of the agrotechnical treatments applied to crops, i.e. fertilisers or biostimulants, may lead to changes in the soil environment. Many studies have shown the diverse effects of these treatments on the populations of selected groups of microorganisms and the level of soil enzymes they secrete (Karaca et al., 2010).

The determination of the biochemical activity of soil based on the activity of soil enzymes is an important tool in helping to assess soil quality. Enzymes are considered to be good and sensitive indicators because they quickly react to changes in the soil caused by natural and anthropogenic factors. Furthermore, they are easy to measure and their activity determines the main microbiological reactions occurring in the cycles of nutrients in the soil (Nannipieri et al., 2002; Karaca et al., 2010). Studies have shown that agrotechnical treatments affect enzymatic activity more than other biochemical parameters (Saviozzi et al., 2001).

The aim of this study was to assess the influence of selected biostimulants (Tytanit, Rooter) and foliar fertilisers (Optysil, Metalosate Potassium, Bolero Bo, ADOB 2.0 Zn IDHA, ADOB B, ADOB 2.0 Mo) on the activity of dehydrogenases, acid and alkaline phosphatases and catalase, and their influence on the level of biological nitrogen fixation based on the nitrogenase activity in soybean cultivation.

Materials and methods

Between 2016 and 2018 a field experiment was conducted at the Gorzyń Experimental and Educational Station, Poznań University of Life Sciences. The GPS coordinates of the experiment at the Gorzyń Station were as follows: N-52.56589, E-015.90556, 65 m AMSL. Each year one-factor experiments were conducted as randomised block design in four replications, with following nine factor levels: 1. control variant –not treated plants; 2. Tytanit; 3. Optysil; 4. Metalosate Potassium; 5. Rooter; 6. Bolero Mo; 7. ADOB Zn IDHA; 8. ADOB B; 9. ADOB 2.0 Mo (*Fig. 1*).

Figure 1. *Experimental culture at the plants' full growth (BBCH 35-40)*

Each fertiliser was applied in a timely manner, according to the manufacturer's recommendations (*Table 1*).

Soybean seeds, Merlin cultivar (SAATBAU) were used in the experiment. When seeds of this cultivar are purchased, they are already encapsulated with rhizobia of the *Bradyrhizobium* genus together with the polymer, which also acts as a preservative and protects the bacteria from sunlight.

The Merlin cultivar can be grown all over Poland. It is characterised by high yield (from 2.4 t ha^{-1} on poor quality soils up to 3.2 t ha^{-1} on good and very good quality soils), high resistance to lodging and high regeneration capacity.

The seeds were sown (25th April 2016, 24th April 2017 and 20th April 2018), on plots with an area of 21 m^2, with a distance between rows of 15 cm, and sowing density was 90 seeds per 1 m^2.

DOI: http://dx.doi.org/10.15666/aeer/1705_1264912666

Table 1. *The terms and doses of biostimulants and fertilisers applied in the experiment*

Biostimulants/foliar fertilisers		Term and dose of biostimulant	Fertiliser characteristics
Biostimulants	Tytanit	I: leaf and shoot development (BBCH 13–29) - 0.3 dm^3 ha^{-1} II: inflorescence development (BBCH 51–59) - 0.3 dm^3 ha^{-1} III: beginning of pod development (BBCH 71) - 0.3 dm^3 ha^{-1}	Liquid, mineral stimulant containing titanium (Ti). It increases the yield volume and development of plants, improves yield quality parameters and increases plants' natural resistance to stress factors. Composition: 8.5 g Ti $(dm^3)^{-1}$
	Rooter	BBCH 13–14 - 1 dm^3 ha^{-1}	Biostimulant – it stimulates the growth of the root system, accelerates regeneration and improves the uptake of soil minerals. Composition: P_2O_5 13.0%; K_2O 5.0%
Foliar fertilisers	Optysil	I: leaf and shoot development (BBCH 15–29) - 0.5 dm^3 ha^{-1} II: inflorescence development (BBCH 51–55) - 0.5 dm^3 ha^{-1} III: beginning of pod development (BBCH 71–73) - 0.5 dm^3 ha^{-1}	Liquid, silicon antistressor stimulating the growth and development of plants, activating their natural immune systems and increasing tolerance to unfavourable cultivation conditions. Composition: 200 g SiO_2 $(dm^3)^{-1}$
	Metalosate Potassium	2-3 treatments every 10-14 days during intensive growth - 3 dm^3 ha^{-1}	Liquid foliar fertiliser containing an easily absorbable form of potassium, which supplements potassium deficit in plants with amino acids. Composition: K_2O 24%
	Bolero Mo	Before florescence - 1.5 dm^3 ha^{-1}	Liquid foliar fertiliser containing boron and molybdenum to supplement the deficit of these elements in plants. Composition: B 8.2%; Mo 0.8%
	ADOB 2.0 Zn IDHA	Before florescence - 1 dm^3 ha^{-1}	Foliar fertiliser containing zinc (Zn) fully chelated by biodegradable chelating agent IDHA. Composition: Zn 100 g kg^{-1} (weight percentage content 10, chelated by IDHA)
	ADOB B	I: before florescence - 2 dm^3 ha^{-1} II: after florescence on pods - 1 dm^3 ha^{-1}	Liquid, highly concentrated foliar fertiliser containing boron that regulates auxin activity and participates in cell division. Composition: N 78 g kg^{-1}; B 150 g kg^{-1}
	ADOB 2.0 Mo	Early stages of development - 0.15 dm^3 ha^{-1}	Liquid, single-component fertiliser which increases the rate and efficiency of use of nitrogen by plants and improves interaction with iron. Composition: Mo 20%

According to the FAO/WRB classification [IUSS Working Group WRB], the soil in the experimental plots is a typical luvisol soil formed from light loamy sands, deposited in a shallow layer on light loam (*Haplic Luvisols*) (*Table 2*). The soil texture was determined by means of sieving the sand fraction from the silt and clay fraction (Van Reeuwijk, 2002).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1264912666

Table 2. *The texture of soil material sampled from a depth of 0-25 cm*

Percentage content of soil fractions %				Texture class
Fraction	Sand 2 – 0.05 mm	Silt 0.05-0.002	Clay < 0.002	
	78	18	4	LS

LS – loamy sand

The agrotechnical treatments were carried out as recommended for the specie tested. The following crop protection products were applied: herbicides: Stomp Aqua 455 CS (2.6 L ha^{-1}) in April and Pantera 040 EC (1.75 L ha^{-1}) in May; Piorun 200 SL (0.2 L ha^{-1}) in June or Fastac 100 EC 0.1 (L ha^{-1}) in August; fungicides: Korazzo 250 SC 1.0 (L ha^{-1}) in June.

Weather conditions

The weather course in the years of the study was presented as mean values of the Sielianinov (Stachowski, 2010) hydrothermal indicator (*Fig. 2*), calculated based on meteorological data registered in the Experimental Station. Interpretation of the indicator: K > 1.5 - excess moisture for plants, K = 1.0-1.5 - optimal humidity, K = 0.5-1.0 - insufficient humidity for plants, K < 0.5 - humidity below required for plants (drought). During the growing seasons in 2016 and 2017 the weather conditions were similar in terms of temperature and rainfall. During the growing season the highest average air temperature was noted in July both in 2016 (19.5 °C) and 2017 (18.9 °C), whereas the lowest temperature was noted in April, i.e. 8.7 °C in 2016 and 7.5 °C in 2017. However, the weather conditions in 2018 were different than in the previous years (*Fig. 1*). The highest average temperature was noted in August (21.2 °C), whereas the lowest was noted in May (12.7 °C). As far as the average monthly temperature from April to September is concerned, 2018 was the warmest – it was 2.9 °C warmer than 2016 and 1.7 °C warmer than 2017. In 2016 there was drought only at the end of the growing season. Likewise, in 2017 there was no rainfall deficit. On the contrary, it was a wet year, especially from June to August. On the other hand, in 2018 rainfall was unevenly distributed and there were droughts which were particularly unfavourable for plants in May, June and August.

Influence of fertilisers on nitrogenase activity (diazotrophy)

Plants representing each experimental variant (5 on average) were selected to measure the diazotrophy level. The analyses were made at the beginning of the flowering period. The nitrogenase activity (diazotrophy) was tested with the acetylene method on a CHROM5 gas chromatograph (Sawicka, 1983). The amount of acetylene reduced to ethylene was measured and expressed as nMC_2H_4 $plant^{-1}$ h^{-1}.

Microbial analyses

Soil samples collected from the arable layer (0-20 cm) were used as the research material for biochemical analyses. Each year they were collected at four terms: 1st term – at the plants' emergence (BBCH 5-10), 2nd term - at the plants' full growth (BBCH 35-40), 3rd term – at the plants' florescence (BBCH 51-59), 4th term – after harvest.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1264912666

Soil samples were taken from five places of each experimental plot, in four replications for each of the nine variants of the experiment. In this way, at each analysis term we received 36 samples of soil, each of 1 kg.

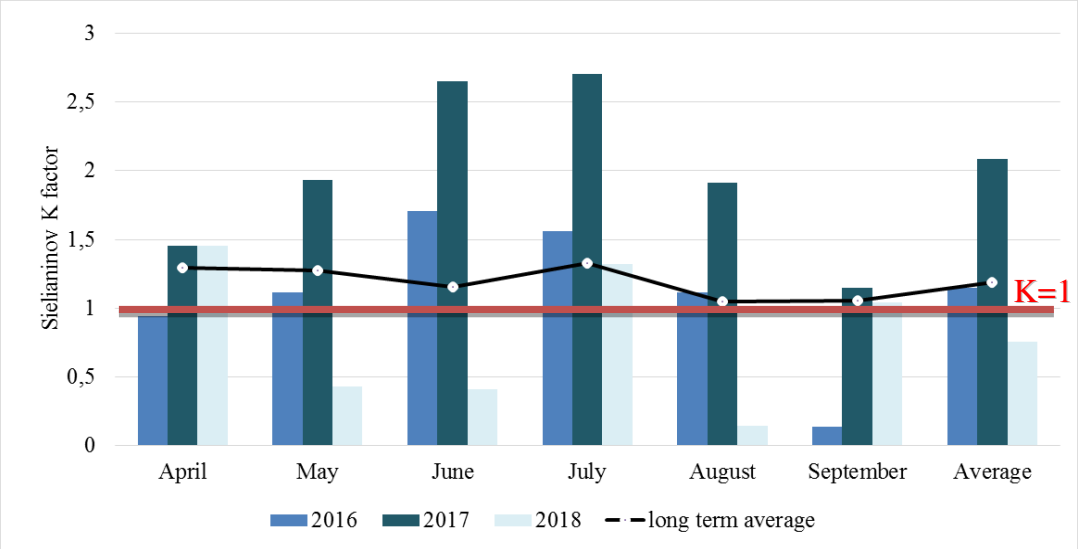

Figure 2. *Climate graph according to Sielianinov characterizing weather conditions in Gorzyń*

Soil enzymatic activity

The analyses of soil enzymatic activity in individual variants were based on the colorimetric method applied to measure dehydrogenase activity (DHA), where 1% triphenyl tetrazolium chloride (TTC) was used as the substrate. The activity was measured after 24-h incubation at a temperature of 30 °C and a wavelength of 485 nm and it was expressed as µmol triphenyl formazane (TPF) 24 h^{-1} g^{-1} dm of soil (Thalmann, 1968).

Additionally, acid phosphomonoesterase activity was measured (EC 3.1.3.2) (PAC) by means of the method developed by Tabatabai and Bremner (1969), where disodium p-nitrophenyl phosphate tetrahydrate was the substrate. The activity was measured after 1-h incubation at 37 °C and a wavelength of 400 nm. The results were converted into µmol (p-nitrophenol) PNP h^{-1} g^{-1} dm of soil.

Catalase activity was measured by means of permanganometry, according to the method developed by Johnsons and Temple (1964), where 0.3% H_2O_2 was the substrate. After 20-min incubation at room temperature (about 20 °C) 0.02 M $KMnO_4$ was titrated to a light pink colour and expressed as µmol H_2O_2 g^{-1} d.m. min^{-1}.

Biological index of fertility

The biological index of fertility (BIF) was calculated using the dehydrogenase activity (DHA) and catalase activity (CAT) in the following formula: (DHA + kCAT)/2, where k was the factor of proportionality and equalled 0.01 (Saviozzi et al., 2004).

Statistical analyses

The dynamics of changes in the soil enzymatic activity were analysed statistically. The results were analysed with two-way ANOVA using Statistica 9.1 software. The

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1264912666

fertilisation method and the term of analysis were the factors differentiating the traits under study. The significance of differences between the pairs of factors was checked with Tukey's test. Principal component analysis (PCA) was used to visualise the multidimensional dependencies between the soil biochemical activity and the types of fertilisation.

Results

The experiment showed the influence of biostimulants and foliar fertilisers on soil enzymatic activity and fertility (BIF) as well as nitrogenase activity under a soybean plantation. The two-way analysis of variance revealed the highly significant effect ($p = 0.001$) of foliar fertilisation/biostimulants and the term of tests on enzymatic activity and the biological index of fertility (BIF) of soil under the soybean plantation (*Table 3*).

Table 3. *F-test statistics and significance levels of two-way analysis of variance for soil bioactivity. Foliar fertilisation/biostimulants and the terms of tests were the factors influencing the traits under study*

Biological fixation of nitrogen under soybean plantation

The field analyses of biological nitrogen fixation showed that the fertilisers and biostimulants significantly stimulated nitrogenase activity under the soybean plantation. The diagram (*Fig. 3*) presents the average nitrogenase activity during the three years of the study. In comparison with the control sample, nitrogenase activity increased in all the experimental variants. The application of the Tytanit and Rooter biostimulants resulted in the highest nitrogenase activity. In comparison with the control plot, nitrogenase activity in these variants increased by 77% and 69%, respectively. Apart from the control sample, the lowest biological nitrogen fixation activity was observed in the Bolero Mo variant.

Analysis of soil biochemical activity

Figure 4 shows the results of the analysis of dehydrogenase activity in the soil under the soybean plantation. During the three years of the experiment the foliar fertilisers and biostimulants significantly stimulated the catalytic dehydrogenase activity in all the experimental variants, as compared with the control variant. The ADOB 2.0 Mo and Bolero Mo foliar fertilisers resulted in the highest dehydrogenase activity. The research

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1264912666

also showed that the highest dehydrogenase activity occurred at the second term of analyses, when the plants were at the phase of full growth (BBCH 35-40).

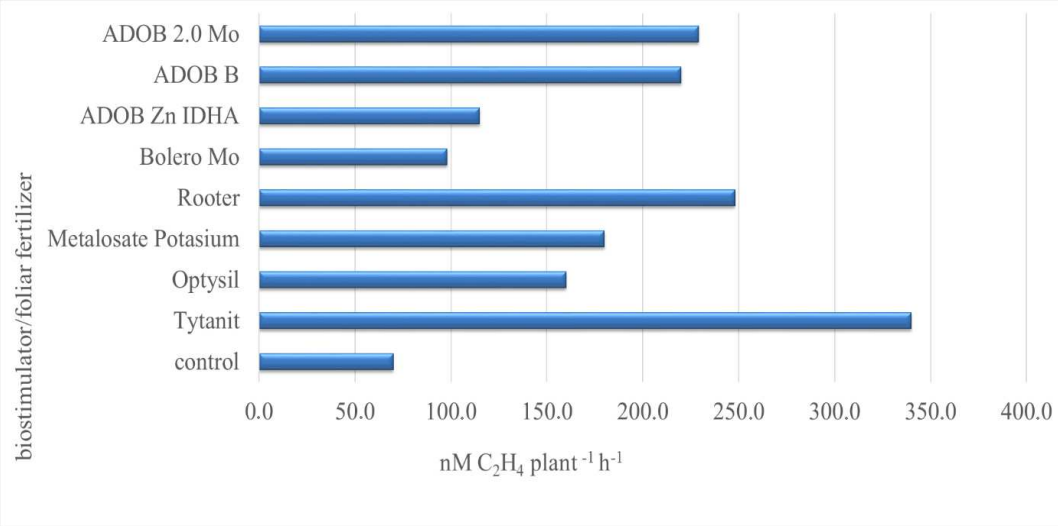

Figure 3. *The influence of the biostimulants and fertilisers on biological nitrogen fixation*

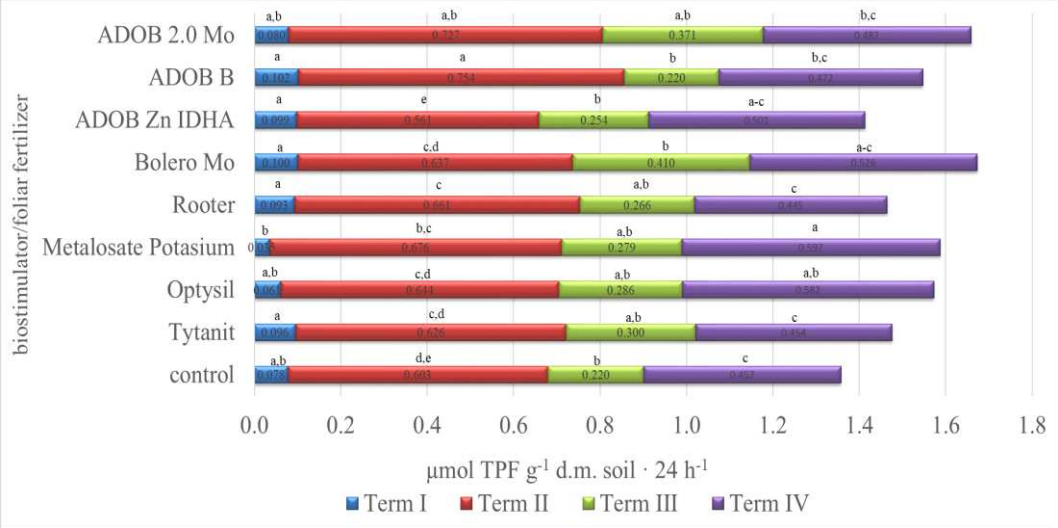

Figure 4. *The influence of biostimulants and fertilisers on dehydrogenase activity. (Note: data are represented as means of five replications. a, b, c, d, e – homogenous groups according to Tuckey's test; different letters denote statistical differences at level α = 0.05; n = 5, in the same term)*

The analysis of the results of acid phosphatase activity (PAC) during the entire soybean growing period showed that in comparison with the control variant it decreased significantly when Tytanit and Rooter biostimulants and Bolero Mo foliar fertiliser were applied (*Fig. 5*). This effect was not observed with the other foliar fertilisers, i.e. Optysil, Metalosate Potassium, ADOB Zn IDHA, ADOB B and ADOB 2.0 Mo. Moreover, at the second term of analyses, i.e. at the stage of full development of the plant just before flowering, acid phosphatase activity in all the experimental variants

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1264912666

was higher than in the control variant. The highest activity was observed after the application of ADOBE 2.0 Mo and Optysil foliar fertilisers (*Fig. 5*).

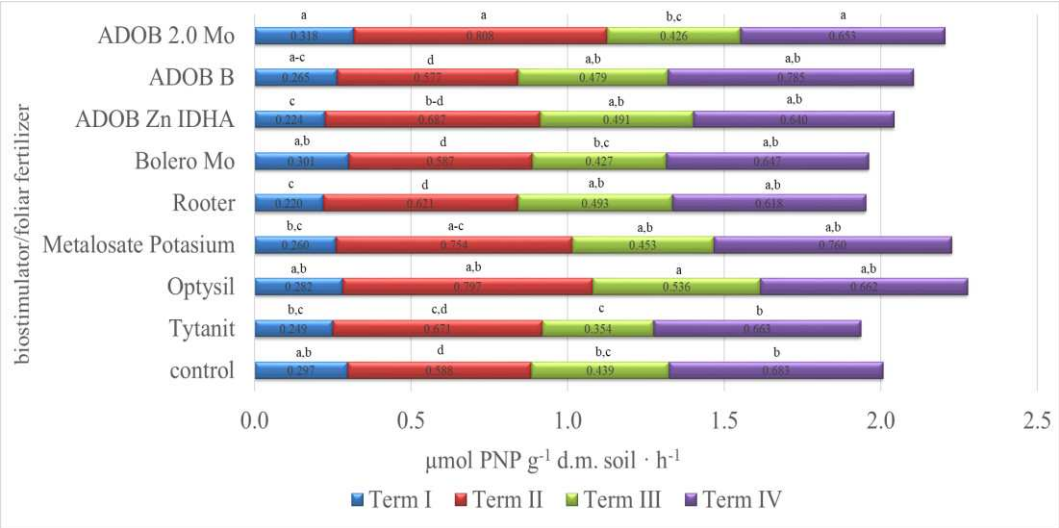

Figure 5. *The influence of the biostimulants and fertilisers on acid phosphatase activity. (Note: data are represented as means of five replications. a, b, c, d, e – homogenous groups according to Tuckey's test; different letters denote statistical differences at level α = 0.05; n = 5, in the same term)*

The analysis showed that in comparison with the control variant the biostimulants and most of the foliar fertilisers used in the research increased alkaline phosphatase activity (PAL) (*Fig. 6*). Metalosate Potassium and Bolero Mo foliar fertilisers stimulated enzyme activity particularly significantly. In comparison with the control variant, the Tytanit and Rooter biostimulants increased PAL activity by 6% and 5%, respectively. Similarly to dehydrogenase activity, alkaline phosphatase activity also increased significantly at the second term of analyses after the application of the fertilisers and biostimulants.

The analysis of catalase activity revealed that apart from Tytanit, all the preparations significantly stimulated this enzyme, as compared with the control variant (*Fig. 7*). The application of the Metalosate Potassium resulted in the highest catalase activity. The research also showed that the enzyme exhibited high activity at the fourth term of analyses, i.e. after the harvest in all experimental variants, where it ranged from 55.9 µmol H_2O_2 g $^{-1}$d.m. min^{-1} after treatment with Tytanit biostimulant to 149.7 µmol H_2O_2 g^{-1} d.m. min^{-1} after the application of Metalosate Potassium.

The biological index of soil fertility (BIF) calculated on the basis of the dehydrogenase and catalase activity was significantly greater after treatment with all the biostimulants and foliar fertilisers (*Fig. 8*). The highest value of the index was noted when Metalosate Potassium foliar fertiliser was applied to the soybean plantation. By contrast, ADOB 2.0 Mo foliar fertiliser resulted in the lowest BIF value. The BIF also had a very high value at the phase of the plants' florescence. It ranged from 2.77 after treatment with ADOB 2.0 Mo fertiliser to 8.34 after the application of Bolero Mo fertiliser. Treatment with ADOB Zn IDHA and ADOB B fertilisers also resulted in high BIF values.

(Note: data are represented as means of five replications. a, b, c, d, e – homogenous groups according to Tuckey's test; different letters denote statistical differences at level α = 0.05; n = 5, in the same term)*

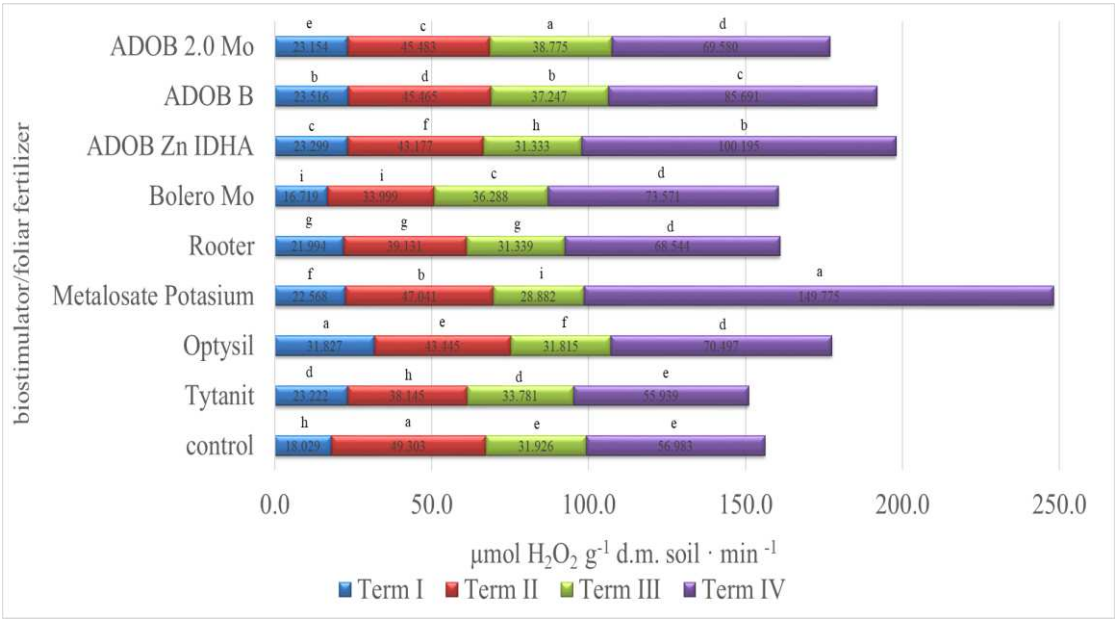

Figure 7. *The influence of the biostimulants and fertilisers on catalase activity. (Note: data are represented as means of five replications. a, b, c, d, e, f, g, h – homogenous groups according to Tuckey's test; different letters denote statistical differences at level α = 0.05; n = 5, in the same term)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1264912666

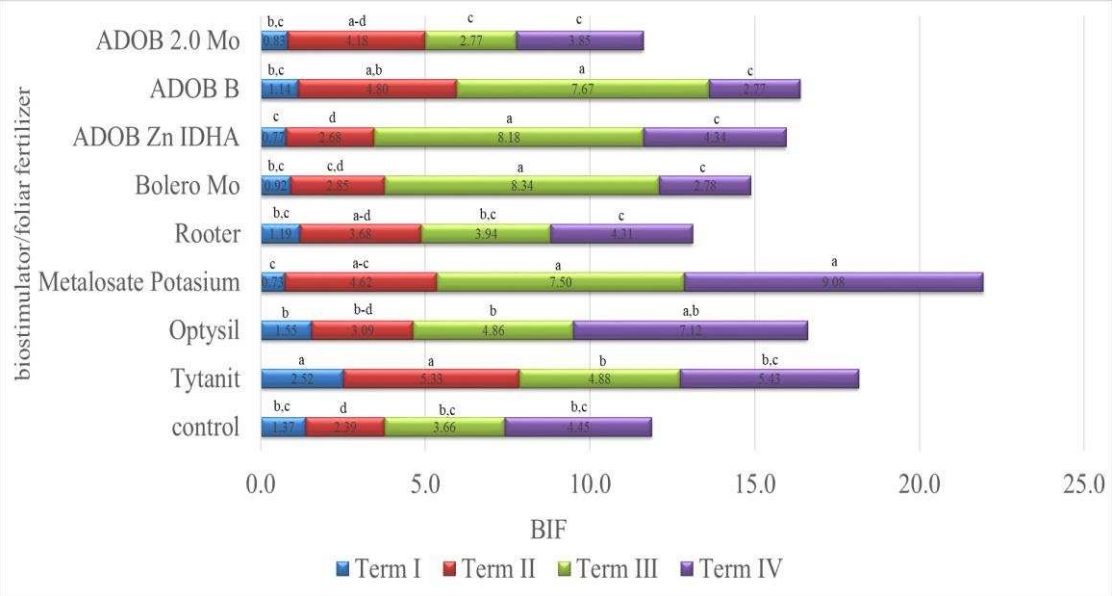

Figure 8. *The influence of the biostimulants and fertilisers on the BIF value. (Note: data are represented as means of five replications. a, b, c, d – homogenous groups according to Tuckey's test; different letters denote statistical differences at level α = 0.05; n = 5, in the same term)*

The influence of the foliar fertilisers and biostimulants applied to the soybean plantation at specific terms was subjected to principal component analysis (PCA) (*Fig. 9*). The first two main components explained more than 77.68% of the total variance. The parameters of soil biochemical activity in 2018 were considerably divergent from those observed in 2016 and 2017, probably as a result of the weather conditions (*Fig. 1*). The growing season in 2018 was the warmest of all the research years. In comparison with the previous years, the average temperature difference amounted to 2.9 °C in August and 1.7 °C in May. In 2016 and 2017 the thermal conditions were very similar so the PCA showed similar dependencies for those two years. In those years, at the phase of the plants' florescence (the 3rd term of analyses) and after the harvest (the 4th term of analyses), the biostimulants and foliar fertilisers significantly influenced alkaline phosphatase activity and the value of the biological index of fertility (BIF). In 2018, the 2nd and 4th terms of analyses influenced the catalytic activity of catalase (CAT) and dehydrogenase (DHA).

Discussion

Biological nitrogen fixation

The biostimulants and foliar fertilisers which increased the biological fixation of nitrogen under the soybean plantation contained the essential macro- or microelements for this process. According to scientific reports, the role of some chemical elements in the process of nitrogen fixation is very important.

Molybdenum, boron, iron, and cobalt are among the micronutrients that significantly affect plants' development and the nitrogen fixation process. Molybdenum and iron are particularly important elements. They are components of nitrogenase – the bacterial enzyme thanks to which the diazotrophy process is possible. Nitrogenase is a protein

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1264912666

composed of two subunits – the larger one containing the FeMo cofactor and the smaller one containing iron only (Symanowicz et al., 2005). The availability of molybdenum is naturally limited in acidic, moist, and poorly buffered soils. According to some reports, when the leaves of leguminous plants are treated with molybdenum in a field, the nitrogen fixation efficiency, the weight of root nodules, and the seed yield increase (Vieira, 1998; Weisany et al., 2013). This effect was also observed in our research when the ADOB 2.0 Mo fertiliser with high molybdenum content was applied. Although plants contain small amounts of boron, this microelement plays an important role in a wide range of physiological processes. It affects the separation of plant tissues and is necessary for the optimal growth of plants. Plants with boron deficit have fewer *Rhizobium* cells and infectious threads (Brown et al., 2002; Weisany et al., 2013). The significantly higher rate of biological nitrogen fixation after the application of the foliar fertiliser with boron (ADOB B - variant 8) could have caused the increase in the content of this parameter.

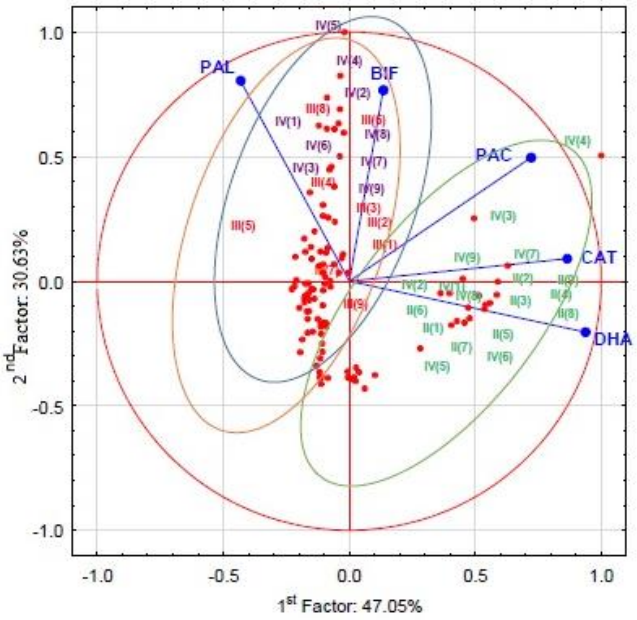

Figure 9. *The dependence between soil enzymatic activity for all variants with fertilisers and biostimulants at the terms of analyses; I - 1st term, II - 2nd term, III - 3rd term, IV - 4th term; (1) control sample – no biostimulants or foliar fertilisers; (2) Tytanit; (3) Optysil; (4) Metalosate Potassium (potassium + amino acids); (5) Rooter; (6) Bolero Mo - liquid suspension boron fertiliser with molybdenum; (7) ADOB Zn IDHA (chelated zinc); (8) ADOB B (high boron content); (9) ADOB 2.0 Mo (high molybdenum content); PAC - acid phosphatase; PAL- alkaline phosphatase; DHA - dehydrogenase; BIF - biological index of fertility*

The role of phosphorus in symbiotic systems has also been the subject of many studies which have confirmed its key importance for the efficiency of atmospheric nitrogen fixation (Bucher, 2007; Bonilla and Bolaños, 2009). The Rooter biostimulant, which contained phosphorus and potassium, had a highly stimulating effect on the nitrogen fixation process. Phosphorus participates in a wide range of molecular and biochemical processes, and some phosphate bonds carry the energy used in cells. The presence of phosphorus in soil affects plants' ability to form root nodules, especially the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1705_1264912666

weight and number of nodules (Abusuwar and Omer, 2011), which translates to the nitrogen fixation level.

When plants are deficient in phosphorus they are usually deficient in nitrogen too. The role of sulphur and potassium is less important for symbiotic systems than that of the abovementioned elements. Nevertheless, potassium ions are very desirable in saline soils because they function as osmolytes. In view of the fact that almost half of the irrigated soils around the world are considered to be saline, the addition of potassium helps to maintain the symbiotic system between bacteria and plants (Zahran, 1999; Bonilla and Bolaños, 2009).

Biochemical activity

Soil enzymes are a group of catalysts that play a permanent and major role in maintaining the ecological properties of the pedosphere, its physicochemical properties, fertility and health (Das and Varma, 2011; Utobo and Tewari, 2015; Niewiadomska et al., 2018b). These include both extracellular enzymes and those that can be found in microorganisms (both in proliferating cells and in sporulating forms). Enzymes are responsible for the course of all chemical reactions in microbial cells, including the synthesis of proteins, nucleic acids or carbohydrates (Błońska, 2011). On the other hand, soil enzymes participate in the decomposition of organic matter released into the soil during plants' growth, the formation and decomposition of humus as well as the release and transfer of mineral substances to plants. Although microbiological and biochemical properties are dynamic, enzymes are a precise and important determinant of soil fertility and they are of even greater significance when it is necessary to determine changes occurring in soil (Burns et al., 2013; Niewiadomska et al., 2018a).

When fertilisers are applied into soil, the enzymatic activity changes significantly. The direction and intensity of the change depends on the type and dose of fertiliser and on the enzyme in question (Selivanovskaya et al., 2006; Napora and Grobelak, 2014). Changes in the activity of soil enzymes reflect environmental disturbances, which influence both the soil and plants (Bielińska and Mocek-Płóciniak, 2012).

Dehydrogenases (DHA) are enzymes belonging to the group of oxidoreductases. They catalyse the oxidation of organic compounds. Active dehydrogenases can only be found inside living cells and their presence indicates the presence of physiologically active microorganisms. They are commonly found in the pedosphere, where they participate in the decomposition of organic compounds. The identification of dehydrogenase activity in soil indicates the intensity of the respiratory metabolism of soil microorganisms, mostly actinobacteria and eubacteria.

The study showed that the biostimulants and foliar fertilisers significantly stimulated dehydrogenase activity. The activity was high during the period of full growth of soybeans, i.e. at BBCH 30-45. It may have been caused by increased secretions from the root system at the time and it resulted in a greater count of microorganisms. Dehydrogenase activity also increased considerably after the harvest, which may have been caused by the fact that organic matter in the form of crop residue entered the soil. Kang et al. (2009) also observed a similar increase in dehydrogenase activity in the spring and autumn. In our study the activity of this enzyme in the spring may also have been stimulated by higher rainfall in June. Brzezińska et al. (2001) and Błońska et al. (2012) reached similar conclusions in their studies, where they proved that the high humidity of the substrate increased dehydrogenase activity. The macro- and microelements applied with the foliar fertilisers and biostimulants were also significant.

Bielińska et al. (2013) noticed that fertilisers containing nitrogen, phosphorus and potassium had a positive influence on the dehydrogenase content in the soil. Swędrzyńska et al. (2013) and Niewiadomska et al. (2018a) made similar observations in their studies on similar biological soil conditioners. According to Bilen et al. (2011) and Kumar et al. (2015), boron increases dehydrogenase activity. Taran et al. (2014) proved that molybdenum stimulated the production of these enzymes by the root nodules of leguminous plants and discussed a possible positive correlation between titanium and soil biochemistry.

The biostimulants used in the experiment (Tytanit and Rooter) had a positive effect on acid phosphatase activity because they reduced its level. Apart from the Bolero Mo, the other foliar fertilisers used in the experiment did not cause this effect. This shows that these biostimulants and the foliar fertiliser positively affected the plants' ability to absorb phosphorus. The acid phosphatase activity in the other experimental variants was higher than in the control variant. It is important to remember that when plants are exposed to phosphorus deficiency they increase the secretion of acid phosphatase through the root system into the soil. These dependencies were confirmed in the studies by Lemanowicz and Koper (2012) and Niewiadomska (2013), who investigated the effect of PRP SOL fertiliser containing phosphorus, potassium, zinc, boron and molybdenum under an alfalfa plantation. The research showed that the fertiliser decreased the catalytic activity of acid phosphatase by activating inaccessible compounds for plants. Bielińska and Mocek-Płóciniak (2009) made similar observations. Lemanowicz and Koper (2010) also observed higher activity of these enzymes in the experimental variant which was not fertilised with phosphorus. Rotaru (2015) found that the deficit of this macroelement stimulated plants' secretion of acid phosphatases.

As far as alkaline phosphatase is concerned, most of the foliar fertilisers significantly increased the activity of this enzyme. It may have been stimulated by increased activity of the soil microorganisms reacting to organic phosphorus compounds released by soybean plants into the soil. Lemanowicz and Koper (2010) proved the correlation between the content of organic forms of phosphorus and the activity of alkaline phosphatases in soil.

With the exception of Tytanit, the other preparations applied in the experiment significantly stimulated catalase activity. As early as 1963, Koter demonstrated higher catalase activity in plants fertilised with boron. Hu and Zhu (2008) observed that fertilisation with silicon increased the activity of catalase and dehydrogenases. Romanowicz and Krzepiłko (2013) indicated that soil oxygenation and temperature significantly affected catalase activity. According to Szymczak et al. (2011), the catalytic activity of this enzyme is a good marker of physiological stresses in plants.

The results of analyses of the catalase and dehydrogenase activity enabled the calculation of the biological index of soil fertility (BIF). The variants with Metalosate potassium and Tytanit preparations had a significant influence on the BIF values, as compared with the control sample. The former preparation resulted in particularly high BIF values in the soil samples collected after the harvest of soybean plants. This effect was caused by the significant influence of these fertilisers on the activity of catalase and dehydrogenases. According to Natywa et al. (2014), mineral fertilisation, which increases the yield of crops, indirectly affects the amount of crop residue and thus increases the biochemical activity of soil after harvest.

Conclusion

When foliar fertilisation is applied, the plant extracts the necessary elements mostly through the leaves, but also through the stem and the entire aerial system. However, it is necessary to remember that this method of 'feeding' cannot replace soil fertilisation. It only quickly provides the necessary ingredients to the plant at difficult phases so as not to slow down its growth. The biostimulants and foliar fertilisers applied in our research stimulated most of the parameters of soil biochemical activity and the process of nitrogen fixation under the soybean plantation. This may have been caused by the fact that the foliar application of nutrients to the plants increased the rate of their penetration and resulted in higher efficiency of their use. Macro- and micronutrients differ in their rate of penetration but foliar fertilisation accelerates this process several times. The disadvantage of foliar fertilisation is the limited amount of the fertiliser that can be provided to plants. Therefore, this method is particularly effective when it is necessary to supply them with the elements that they need in smaller amounts, e.g. iron, boron, and molybdenum. Apart from the increased efficiency of the foliar application of micronutrients, this method is also safer for the environment and for the plant itself. The search for methods that increase the yield and biochemical parameters of the soil environment is an important part of sustainable agriculture policy.

We can observe increasing importance of legumes in sustainable agriculture. The following facts speak in favour of cultivation of this group of plants: they improve the physicochemical properties of soil, enrich the content of organic matter and leave large amounts of crop residues with high content of nitrogen. Soybean (Glycine max L.) is one of the most important crops in this group of plants. Soybean seeds contain about 40% of protein with a favourable amino acid composition and 20% of fat, with the majority of unsaturated fatty acids. Conducting further research in the search for preparations supporting the yielding capacity of soybeans, while not affecting the environment, seems necessary in the realities of modern agriculture.

Acknowledgements. This research was financed by the Ministry of Agriculture and Rural Development of the Republic of Poland in the framework of the Multi-annual Program 'Increasing the use of domestic feed protein for the production of high quality animal products in conditions of balanced development' implemented at the Department of Agronomy of the University of Life Sciences in Poznan.
