Chinese herbs have been used as traditional medicine immune booster for human being for thousands of years in China (Yin et al., 2009; Shahrajabian et al., 2018). More than 3 million tons of herb medicines were produced in China, and their medicinal parts were consumed in traditional Chinese medicine (TCM) clinic (Soleymani and Shahrajabian, 2012, 2018; Zhang et al., 2016; Ogbaji et al., 2018). In traditional Chinese medicine, some herbals have been used for anti-aging since ancient times (Liu et al., 2017). *Astragalus membranaceus* as one of the most important Qi tonifying adaptogenic herbs in traditional Chinese medicine has a long history of medicinal use (Yang et al., 2010; Zhong et al., 2012; Liu et al., 2017). In traditional Chinese medicine, which laid a lot of emphasis on Qi (vital energy) and Yin-Yang balance (negative and positive equilibrium). Chinese herbs have used as traditional medicine immune booster for human being for thousands of years in China and many parts of Asia (Shahrajabian

et al., 2019a, b, c, 2020; Sun et al., 2020). The goal of this review is survey on some important ancient and modern pharmaceutical sciences of astragalus.

Materials and methods

All relevant papers in the English language of researchers from different countries were collected. The keywords of astragalus, traditional Chinese medicine, traditional Asian medicine, modern pharmaceutical science, health benefits and western medicine were searched in Google Scholar, Scopus, Research Gate and PubMed.

Results and discussion

Astragalus in traditional Chinese medicine and other parts of the world

Astragalus is considered as benefiting Qi and helping to pass water (Li et al., 2011). It has been used as therapy for Wei Zheng, a term for skeletal muscle fatigue and wasting (Zhou and Mei, 2014). The dried root of *A. membranaceus*, first documented in Shennong Bencao Jing (Shennong's Classic of Materia Medica, 200-300 AD), is one of the most popular health promoting herbal medicines commonly used in China for more than 2000 years. In modern Chinese medicine, it is used in Fu zheng therapy as an immune stimulant (Ionkova et al., 1997). Also known as Huang Qi (Chinese), Milk-Vetch (English), Hwanggi (Korean), and Ogi (Japanese) (Chou et al., 2007; Li et al., 2019). It is sold in dietary supplements in tea or capsule form in the USA, and in the tea, beverages, soup, and trail mix (gorp) in Asia (Song et al., 2008; Zhang et al., 2011). Chinese milk vetch (*Astragalus sinicus* L.) is also a traditional leguminous green manure which plays an important role in maintaining paddy soil fertility and in the popularizing of the double-rice farming system in southern China; it is ploughed into soil at full blooming stage and serves as an alternative to chemical nitrogen fertilizer in the region (Zhu et al., 2012). *Astragalus membranaceus* was originally described in the Shennong's Classic of Meteria medica, the earliest complete Pharmacopoeia of China written from Warring States Period to Han Dynasty (Hei et al., 2005; Auyeung et al., 2016). It is valued for its ability to strengthen the primary energy of the body which we know as the immune system, as well as the metabolic, respiratory and eliminative functions (Liu et al., 2017). This fact is being increasingly substantiated by pharmacological studies showing that it can increase telomerase activity, and has antioxidant, anti-inflammatory, immuneregulatory, anticancer, antitumor, antioxidant, hypolipidemic, antihyperglycemic, hepatoprotective, expectorant, immunomodulatory activity, and diuretic effects (Anon, 2003; Ma et al., 2011; Zhao et al., 2011). *Astragalus membranaceus* (Fisch.) Bunge. has been widely used an anti-osteoporosis herb is traditional Chinese medicine for many years (Du et al., 2004; Wong et al., 2007; Xi et al., 2008; Jiao et al., 2014). In Traditional Chinese Medicine, *Astragalus membranaceus* is a major component in a prescription to treat chronic phlegmatic disorders and general gastrointestinal disturbances including stomach ulcer, chronic diarrhea and intestinal inflammation (Kim et al., 2008; Yang et al., 2014). Other researchers have reported the values of Astraglaus s roots in traditional Chinese medicine with the function of strengthening exterior and promoting health for thousands of years (Ma et al., 2017; Zhao et al., 2011). Traditional Chinese herbs are generally applied in the form of multi-herb formulas in medical treatments and as dietary supplements (Takagi and Ishii, 1967; Li et al., 2011). Lu et al. (2013) reported that *Radix Astragali* is the root

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1337113382

of *Astragalus membranaceus* Bunge, and as a famous traditional Chinese medicine (TCM), it has been used to improve muscle wasting-related disorders for a long history. They have also introduced Astragalus polysaccharide (APS) as an important bioactive and a therapeutic agent in the management of muscle wasting. *Astragalus trojanus* Stev. is an endemic plant mostly found in eastern and central Anatolia (1300-3500 m), central Aegean region and slopes of Toros mountain (1300-2300 m) in Turkey (Nartop et al., 2015). This genus is widely distributed throughout the temperate and arid regions of the world, and is principally located in Asia (1500 species), North American (500 species) and South American (150 species), and Europe (120 species), but also on mountains in Africa, However, the centre of origin and biodiversity of Astragalus plants is Eurasia, especially the mountainous parts of South-Western and South-Central Asia (Lysiuk and Darmohray, 2016). Iran alone, being the richest centre of Astragalus habitation, shelters more than 850 species, 527 of which are endemic in the flora of Iran (Ranjbar and Karamian, 2002; Aslanipour et al., 2017; Ghasemian-Yadegari et al., 2017). Aslanipour et al. (2017) stated that the crude drugs prepared from Astragalus roots are used for treating some illnesses such as leukemia, respiratory infections and diabetes in Iranian folk medicine. In South Eastern Turkey (Anatolia district), the aqueous extract of the roots of different *Astragalus spp*. are traditionally used against leukemia and for its wound-healing properties (Yesilada et al., 2005; Nalbantosy et al., 2012; Napolitano et al., 2013). In the district of Anatolia, located in South Eastern Turkey, an aqueous extract of the roots of Astragalus is traditionally used against leukemia and for its wound healing properties (Bedir et al., 2001). *Astragalus corniculatus* Bieb. (Fabaceae) is distributed in Southeastern Romania, South Ukraine and Moldova (Tutin et al., 1972). *Astragalus Tragacantha L.* (Fabaceae) is a western Mediterranean perennial cushion-like plant species well-adapted to drought that grows even in the trace metal and metalloid polluted soils (Salducci et al., 2019). It has been reported that Astragalus is an adaptogen and is usually used in combination with other herbs, such as, ginseng, Echinacea, and glossy privet. Astragalus is primarily used in American medicine to potentiate the function of the immune system and in cardiovascular disease. In traditional Chinese medicine, it is used for influenza and the common cold (McKenna et al., 2002). Nishiyama et al. (1995) reported that in traditional oriental medicine, it is conventional to combine different herbs in order to achieve a variety of treatment purposes simultaneously, or to enhance a single effect without causing severe side effects. Erect milkvetch (*Astragalus adsurgens* Pall.), also as a palatable forage, are also widely used in returning farmland to grassland, it has an important role in restoring the degraded ecosystems and could be an effective and applicable to improve soil nutrients and prevent further soil degradation and erosion, because it grows rapidly, and was characterized by barren-tolerance, wide adaptability and strong resistance (Wang and Wang, 2013).

Bioactive phytochemicals, medicinal uses and potential health benefits of Astragalus in traditional and modern medicine industry

Constituents of the dried roots of *Astragalus spp*. *Radix Astragali* provide significant protection against heart, brain, kidney, intestine, liver and lung injury in various models of oxidative stress-related disease (Hong et al., 1992; Shahzad et al., 2016). Zhang et al. (2007) stated that Astragalus is an important traditional Chinese medicine (TCM), and now widely used an immune modulator, especially to support immune health for various chronic degenerative diseases. Recently, *Astragalus radix* was proved efficacious to be an adjunctive therapy medicine for cancers (Wang et al., 2003). In the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1337113382

Bulgarian traditional medicine, *Astragalus glycyphyllos* is used an antihypertensive, diuretic and anti-inflammatory remedy (Nikolov, 2006). Major classes of compounds of Astragalus species (*Table 1*) are polysaccharides, saponins and isoflavonoids, alkaloid, choline, betaine, folic acid, organic acid, various amino acids, mucoitin, gum, cellulose and fourteen trace elements, including selenium, zinc, and iron, which are essential micronutrients for man and animals (Bedir et al., 2000; Block and Mead, 2003; Yin et al., 2006; Lu et al., 2016). Astragalus genera are the richest source of cycloartanes, the unique triterpenoids with a characteristics 9,19-cyclopropane (Nartop et al., 2015). According to the systematic review by a Chinese scientists on the chemical constituents of the plants (*genus Astragalus* L.) more than 140 cycloartane-type triterpene glycosides, 60 flavonoids and 18 different polysaccharides have been identified so far (Li et al., 2014). Under high soil moisture and wet conditions, Astragalus is susceptible to root rot caused by fungi, which is the main constraint to cultivation. Land must be well drained for Astragalus. Loose soil and raised beds can be used to control soil moisture (Shannon et al., 2014). The chemical structures and chain conformations of polysaccharides play a vital role in their biological activities; however, polysaccharides belong to a structurally diverse class of macromolecules (Jin et al., 2014). Cycloastragenol (CA) is the main aglycon of many cycloartane-type glycosides which only found in Astragalus genus, extends T cell proliferation by increasing telomerase activity which helps the delay the onset of cellular aging (Valenzuela et al., 2009). Astragalus root also contains a series of cycloartane triterpene glycosides, including astragalosides I-VIII, acetylastragaloside, isoastragaloside I and III, astramembrannin II, cycloastragenol, cyclosieversigenis, soyasaponin I, soyasapogenol B, and lupeol (Ko and Chik, 2009). Among these, *Astragalus membranaceus* has a high content of astragaloside IV, which is commonly used as a qualitative marker.

Table 1. *Astragalus membranaceus main compounds*

Compound	Effect
Flavonoids	Plant metabolites with antioxidant effects; give plants yellow color
Isoflavones	Polyphenolic compounds that are classified as phytoestrogens; formononetin is one of the prominent ones
Lectin	Carbohydrate-binding proteins
Polysaccharides	Carbohydrates whose molecules contain linked monosaccharides; starch, inulin, cellulose
Saponins	Amorphous glycosides of terpenes and steroids that can form emulsions and can foam (soap-like); Astragaloside IV is one the most-studied saponins in Huang Qi

On the basis of traditional Chinese medicine view of cancer, causes are endogenous causes and exogenous causes. Endogenous causes are the seven emotional states (anger, grief, fear, worry, over joy, shock and melancholy) can be seen as the way that stress, worry, over work, and emotional grief can suppress the immune system and allow predispositions for cancer growth to take hold. So, while it can seem simplistic to attribute cancer to normal emotions such as sadness, worry, fear, etc., the TCM view is that when these emotions are excessive, prolonged or unresolved, they can cause disease. The concept of Jing in TCM can be likened to the role of genetics in cancer, which is an important factor indeed. Exogenous causes consists of six exogenous causes for all illness, including cancer, are climatic factors of wind, cold, dampness, dryness,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1337113382

summer heat and fire. And, other miscellaneous causes are environmental causes, dietary causes, and drugs. The TCM concepts of yin/yang balance, the need for calmness of mind, absence of strife, the practice of health promotion through movement, all support modern ideas on the role of psychological, neurological and immunological health in cancer prevention (Shahrajabian et al., 2019d, e, f, g, h). Liu et al. (2011) reported that in many parts of the world, especially in China and Germany, the combined use of herbal treatment and conventional cancer treatment is far more widespread than in America. They have also mentioned that 66.44% of cancer patients in China combined the use of herbal medicine with Western treatment. A prospective, controlled study conducted in Israel (Yaal-Hahoshen et al., 2011) found significant improvement in anemia and neutropenia in breast cancer patients who were given an herbal mixture containing Huang Qi and other Chinese herbs. Rios and Waterman (1997) reported that cycloastragenol (CAG) is a secondary metabolite isolated from Radix Astragali, present in all known *Astragalus spp*., CAG (9,19-cycloanostane-3,6,16,25-tetrol,20,24-epoxy-(3β, 6α,16β,20R,24S); is both a triterpene aglycone and the most common genuine aglycone in the bioactive triterpenoid saponins called astragalosides. *Astragalus polysaccharides* (APS) are one of the main efficacious principles of Radix Astragali (*Astragalus membranaceus*), which is reported to have anti-oxidant, anti-diabetic, anti-hypertensive, and immunomodulatory activities (Wu and Chen, 2004; Wu et al., 2005). It has been noted that the crude polysaccharide extract of A. membranaceus was mainly composed of carbohydrates with small amount of proteins (Cho and Leung, 2007). It has been demonstrated that the main components of the ethylacetate extract of Astragalus were isoflavonids such as calycosin-7-O-β-D-glycoside, formononetin-7-O-β-D-glycodie and (6R, 10R)-9,10-dimethoxypterocarpan-3-O-βD-glycoside, and these glycosides and other their aglycones were proved to exhibit strong antioxidant activity (Zhang et al., 2007). Li et al. (2010) also mentioned that the dried root of Astragalus contains 2'4'-dihydroxy-5,6-dimethoxyisoflavone, kumatakenin, choline, betaine, polysaccharides, saponins, glucuronic acid, sucrose, amino acids, traces of folic acid and astraisoflavanin. So many other scientists also revealed that *Astragalus membranaceus* has a notable functional role in various pharmacopoeias as a herbal immunomodulator and an anti-diabetic drug (Wei et al., 2011; Agyeman et al., 2013). Its roots have been used in many state-approved Chinese Herbal formulas for the treatment of diabetes (Jai et al., 2003; Wei et al., 2011). Some experiments have showed that Astragalus exhibits immunomodulating and immunorestorative effects both in vitro and in vivo (Guo et al., 2005), and have shown preliminary promise against the experimental coccidial infection when used in conjunction with vaccine (Cho and Leung, 2007). Song et al. (2017) reported that Astragalus extract mixture HT042 is a combination of three standardized herbal extracts from *Astragalus membranaceus* root, *Elutherococcus senticosus* stem, and *Phlomis umbrosa* root, and it has been developed to promote height growth in children with short stature. Sun et al. (2012) revealed that *Astragalus membranaceus* is a popular traditional Chinese medicine, commonly used in Chinese herb prescription to treat liver disease, and the extract prepared from the roots of *Astragalus membranaceus* and *Paeonia lactiflora* demonstrated better hepatoprotective activity than the herbs used individually. Ko and Chik (2009) demonstrated that root extract of *Astragalus membranaceus* administrated orally and locally can protect rats against hapten-induced colitis through attenuation of TNF-αand IL-1βand up-regulating of Il-10. Shen et al. (2008) indicated that *Astragalus membranaceus* has a potential role in treating allergic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1337113382

asthma. Zhang et al. (2009) *Astragalus membranaceus* and its effective components are effective in reducing fasting blood glucose and albuminuria levels, in reversing the glomerular hyperfiltration state, and in ameliorating the pathological changes of early diabetic nephropathy in rat models. Ko and Chik (2009) demonstrates that both oral and locally administered *Astragalus membranaceus* possess protective effects against experimental colitis through differential modulation of colonic cytokines. Yang et al. (2013) found that *Astragalus membranaceus* polysaccharide (AMP) has antitumor activity in vivo at least partly via improving immune responses of host organism, and seems to be safe and effective for the use of anti-tumor therapy. Lv et al. (2017) suggest that *Astragalus polysaccharide* (APS) which is a bioactive extract of *Astragalus membranaceus* may represent a natural therapeutic approach for treating inflammatory bowel disease, such as ulcerative colitis. Yan et al. (2010) found that administration of *Astragalus mongholicus* polysaccharides could significantly increase serum and liver antioxidant enzyme activities in mice and decrease peroxidative lipid levels. Jalsrai et al. (2010) found that doses of *Astragalus mongholicus* extract which did not interfere with locomotor activity and situational anxiety appear to be useful in the treatment of convulsive disorders. Kim et al. (2016) highlighted the ability of *Astragalus membranaceus* to facilitate sperm development and semen quality. Tian et al. (2016) reported that Astragalus may be beneficial as an adjuvant therapy in the treatment of type 2 diabetes. Zhou et al. (2018) demonstrated that the extract from *Astragalus membranaceus* with water extraction-ethanol supernatant method inhibit cell growth and induce apoptosis in cultured breast cancer cells. This effect astragalus extract to suppress breast cancer cells growth was associated with its ability to inhibit PI3K/Akt/mTOR activity. Maresca et al. (2017) concluded that the 50% hydroalcoholic extract of Astragali radix is a valuable candidate for the adjuvant treatment of articular disease. Liu et al. (2017) concluded that the appropriate dose of Astragalus depends on several factors, such as the user's age, health status, and several other conditions. They have also found that natural products are not always necessarily safe, and dosages can be important. Sheng et al. (2005) found that one of the most important biological role of saponins is modulating the cellular oxidant antioxidant balance.

Conclusions

Traditional Chinese medicinal materials have been used for thousands of years and are believed to be abundant, safe, and inexpensive. Astragalus has been used in Chinese traditional medicine as an immunity booster for almost 2000 years. The genus Astragalus is a member of the Fabaceae of Legume family and it is native to northern China and Mongolia. It is widely distributed in China, Siberia, and northern Korea. Some actions of *Astragalus membranaceus* are anti-viral, anti-bacterial, immune system enhancing, immune stimulant, anti-infective some viruses, adaptogen, cardio-tonic, diuretic, hypotensive, anti-oxidant, immunomodulator, hypoglycaemic, circulatory stimulant, vasodilator, anti-fatigue, anti-cancer and hepatoprotective. Chemical constituents are polysaccharides, triterpenoid saponins (Astragalosides), flavonoids, choline, phytosterols, volatile oils, amino acids (Asparagine, Gamma-aminobutyric acid, Canavanine), aglycones, coumarins, astrapterocarpan, betaine, calcium, copper, isoflavonoids, rich in potassium and magnesium. Astragalus membranaceus classically prescribed in TCM in combination with other Chinese medicinal herbs as a dried root, powdered or as a decoction, with the combination depending on the desired therapeutic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1337113382

effect and the specific TCM diagnosis. Polysaccharides in Astragalus intensify phagocytosis in reticuloendothelial systems, stimulate pituitary-adrenal cortical activity, and restore depleted red blood cell formations in bone marrow. Astragalus uses are in kidneys problems, strengthens the kidneys, incontinence and frequent urination, urinary tract infection, gastric ulcers, decreased appetite, chronic diarrhea, strengthens the spleen, poor digestion, liver problems, viral hepatitis, strengthen the liver, postpartum fever, uterine bleeding, topical adjuvant therapy for chronic viral cervicitis, vaginitis, edema, lupus, rheumatoid arthritis, myasthenia gravis, strengthens and builds bone marrow, excessive sweating, night sweats, slow healing wounds, increasing white blood cell count, leukopenia, ischemic heart disease, angina pectoris, recovery from severe loss of blood, diabetes, anemia, high blood pressure, heart palpitations, congestive heart failure, strengthens the blood, increases interferon production, impaired immunity, chronic viral infections, general debility, increases energy, HIV/AIDS, cancer, myalic encephalomyelitis (chronic fatigue syndrome), improves sleep quality, upper respiratory infection, common cold, chemotherapy, radiation therapy, flu, combats coxsackie B myocarditis, amerlirate side effects of drugs, appropriate herb for weak and elderly. Isoflavonoids, such as calycosin-7-O-β-D-glucoside, ononin, astraisoflavan-7-O-β-D-glucoside, calycosin and formononetin, are principle bioactive compounds found in Radix astragali-based drugs or foods. In summary, Astragalus is an ancient herb for modern medicine which can promote good health and as drugs to treat diseases. Further clinical researches are necessary to uncover various substances and their effects on astragalus which contribute to public health.

(Received 13th Jun 2019; accepted 28th Aug 2019)

Abstract. Prostrate knotweed (*Polygonum aviculare* L.) is a persistent native weed of China. This weed is characterized by high genetic and biological plasticity having a capacity to spread on a landscape scale. The present study planned to investigate the infection of a plant parasitic powdery mildew on *P. aviculare* on a landscape scale in three different locations of Shenyang during 2018. These locations were selected with a control treatment for proper comparison. Different growth parameters were observed and calculated by coefficient of determination (R^2). Maximum temperature (Maxt) ranged 25-30 °C and Minimum temperature (Mint) between 17-20 °C with relative humidity 64-78% played a vital role for the emergence and flourishing of pathogen pressure on the plant. The elevated value of $R^2 = 0.97$ for Mint with *RMSE* (Root Mean Square Error) < 5 recorded excellent prediction followed by $R^2 = 0.82$ with RMSE < 5-10 for Maxt recorded very good model prediction. Highly significant ($P < 0.001$) height of *Polygonum aviculare* was recorded (23.125 ± 0.59) in parasite free plants compared to (20.99 ± 0.96) location-I having Mean ± SD. Both temperature ranges has a significant effect ($P < 0.0001$) with ($F = 5.917$; $P < 0.0001$; $F = 25.721$; $P < 0.0001$) three locations; however, the effect of the locations on plants height (*P. aviculare*) did not differ statistically ($F = 2.102$; $P > 0.05$) between two temperature ranges from 25-30 °C and 17-20 °C. According to our findings, plant parasitic powdery mildew (pathogen strain HMLAC226) affected significantly with growth characteristics of prostrate knotweed.
Keywords: *ecology, landscape, native plant, transect method, Liaoning-Province*

Introduction

Prostrate knotweed (*Polygonum aviculare* L.) is an annual native weed to Europe, introduced in China during 2004 (Coquillat, 1951; Flora, 2004; Ma et al., 2013), initially collected in Canada in 1821 and widespread in the globe (Costea and François, 2005). Its extensive distribution is credited to elevated genetic polymorphism and phenotypic agility (Meerts, 1995) and spread in soyabean, rice, maize, sweet potato, cotton, sugarcane, orchards and other agricultural crops (Tottman and Wilson, 1990). This weed grows in poorly aerated heavy compacted soil with 3.5 pH (You et al., 2005). *P. aviculare* L. belongs to Polygonaceae family grow up to 30.50-91 cm long with tiny elliptic lanceolate

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1338313394

foliage. Its foliage is opposite, lance form to rectangle and 12.50-63.50 mm elongated, silver, papery casing at every nodule, flowers are present in the groups in clusters (Severoglu et al., 2012). Due to its taproot system, the roots of full-grown plants reached up to 70 cm in alluvial soils. However, thick parallel inferior roots were dispersed in the upper segment (15-25 cm) of soil (Costea and François, 2005).

Prostrate knotweed seeds require moist-cold stratification for germination (Batlla et al., 2009). The seeds of this weed lose dormancy in March and April and germinate in a single flush between March and May. Its flowers are hermaphroditic and self pollinated (Meerts et al., 1990). In California, more than 36 insect taxa were documented to feed on the nectar of this weed; however, both above ground and terrestrial insects were attracted on the flowers (Bugg et al., 1987).

Recently many studies that endeavour to work out the fiscal worth of the ecosystem services provided by plant life have paid their attention on both native and deliberately cultured landscapes floral communities (Bolund et al., 1999; Chen et al., 2008; Tyrväinen et al., 2005). Now the ecologists approach to understand that an assessable level of ecological functionality can be accomplished by a sophisticated collection of species (Hobbs et al., 2009; Pickett et al., 2008). At the functional level, natural urban flora can be measured and prolonged in the logic that it is performing an extensive assortment of experimental ecosystem services on subsidiary terra firma with a negligible contribution of continuation possessions (Rink, 2009; Del and Peter, 2010).

Powdery mildews (*Erysiphe polygoni*; Erysiphales family Erysiphaceae) are significant cluster of fungi, capable for causing diseases in natural flora. This pathogen has 873 species with 17 genera (Braun, 2012) attack on 10,000 species of angiosperms in the world (Braun, 2012). The most imperative, key pervasive and easily predictable invasive pathogen of prostrate knotweed (*P. Aviculare*) is powdery mildew (*Erysiphe polygoni*), strain HMLAC226, gene JN621872 through DQ490766 ITS sequence present in Mengyin, Shandong, China (Pintye et al., 2012). The attack symptoms are grayish-white, powdery mat visible on the upper surface of leaves (Abkhoo, 2009). The pathogen reduce photosynthesis, increase respiration, transpiration, and or caused the growth retarded (Severoglu et al., 2012).

The fungal spores shifted through air to the newly introduced host plant and its growth started on epidermal cells of the leaf by means of haustoria (Carlile et al., 2001) and put the haustoria into mesophyll cells of prostrate knotweed (Takamatsu et al., 1998). However, moderate temperature and humidity (%) played a significant role for flourishing and spreading pathogen infection (Koike et al., 2007) that becomes the base of significant loss to the landscape of China.

The article aimed to determine parasitic powdery mildew (pathogen strain HMLAC226) on certain physiological characteristics of prostrate knotweed. These characteristics studied at different temperatures ranges and in various locations of Shenyang using determination coefficient (R^2) and Root Mean Square Error (*RMSE*) under Liaoning Key Laboratory for Biological Invasions and Global Changes, College of Bioscience and Biotechnology, Shenyang Agricultural University, Shenyang China.

Materials and methods

Experimental site

The studied areas northern part in China having the hilly area that edges into South Korea. During survey we selected three locations randomly (location I having latitude

Experimental design

Ecological survey was conducted in three locations of Shenyang by line transect ecological method of sampling in field conditions during 2018. During ecological survey in July, prostrate knotweed leaves infected with powdery mildew (*Erysiphe polygoni*) and its pathogen strain HMLAC226 was selected. The transect line was sixty meter long parallel to the roadside and collected three points twenty meters in one side of the transect (*Fig. 1B*) and data were recorded using quadratic methods (100 × 100 cm). Control point was also selected in these three locations having three replications at each location in same environmental cues. The selected surveyed points were observed during peak season for three weeks and temperature data were recorded on the spot and calculated. However, after collection of the temperature data from three locations, maximum and minimum temperature was calculated. Three whole knotweed plants in each quadratic ring were selected randomly and uprooted keeping in view no any part of the plant was damaged by external or physical injury. A sum total of nine plants collected from three quadratic rings from each sampling point, uprooted along with control plants or pathogen free plants (selected from close observations), taken in the laboratory for measuring its growth parameters and other characteristics. Control plants were the average of disease free plants collected within three locations. The initial pathogen symptoms were present on the leaves just like dusted flour. Powdery mildew usually starts off as circular, powdery white spots, which can appear on leaves, stems of the plant. However, control plants or pathogen free plants were selected from the same environmental conditions near to the infected community of knotweed populations.

Pathogen identification

Powdery mildew-infected leaves of *P. aviculare* from these three locations and examined under microscope under microscope (Olympus DP 80 model) with the magnification of 20 µm and 200 µm. The spore slides were prepared using cedar wood oil (artificial, Shanghai specimen model factory, China) which was pale-yellow to yellow in color. The drops solution of this oil was xylene based with acid value < 60 mg KOH g^{-1} was used and identified the pathogen with the help of available literature (Braun, 1987; Braun and Takamatsu, 2000; Braun et al., 2003) on morphometric characteristics of the pathogen (*Fig. 2*).

Growth parameter measurement

Plant height (cm), root length (cm), number of lateral and main branches was measured; however, all leaves were removed separately from randomly selected nine plants from each sampling point. The leaf area was measured by destructive method (Ahmad et al., 2015; Aldesuquy et al., 2014).

Re-modification of the evolving model

The regression-type relationship carried out for developing the model for treatments and comparison of RMSE with R^2. The regression model was set out to determine the effect of different growth parameters ultimately gave the information about model fitness of how far away the fitted line is from the reference line. The researchers previously exposed that how condensed or scattered the observed points are around the fitted line, which alternatively revealed about the validity and good-fit of the model

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1338313394

(Hossain et al., 2017). For the evaluation of different growth parameters in an experiment with n observations and agreement between predicted and actual values was purposed with root mean square error (RMSE) that was defined by *Equation 1* (Debaeke et al., 1997; Ahmed et al., 2019).

$$RMSE = \sqrt{1/n \times \sum_{j=1}^{n} ((Yield_{mes} - Yield_{sim})^2} \quad \text{(Eq.1)}$$

Where n is the number of observations, $yield_{mes}$ represents actual cumulative percent, $yield_{sim}$ is predicted cumulative percentage (Mayer and Butler, 1993). RMSE gave a magnitude of the characteristic variation between predicted and actual values. The RMSE categorized to assess the precision of the model (Royo et al., 2010) reported that RMSE < 5 means awesome prediction; 5-10, very good prediction; 10-15, good prediction; > 15, inadequate prediction. The lowest RMSE designated the appearance of the model fitness had optimized.

Statistical analyses

The above ecological indices were focused on analysis of variance through invasion condition at different locations with analysis of variance (ANOVA) test. The mean differences between locations growth characters were calculated using Tukey's HSD (Honest Significance Test), post hoc on Fishers's LSD test, these tests were performed using SPSS statistical software (version 13.0; Inc., Chicago, IL, USA) and R (version 3.3.1) package (Nigussie et al., 2017; Rcore, 2016). The geographic coordinates were recorded using GPS navigator and map of the studied locations was designed by ArcGIS version 10.2 software (ArcGis, 2013).

Results

The data recorded highly significant ($P < 0.001$) plant height of *P. aviculare* in uninfected powdery mildew control ($23.125 + 0.59$) compared to (20.99 ± 0.96) location-I, location-II (19.42 ± 0.53) having Mean ± SD. Statistically highly significant ($P < 0.0001$) root length (cm) was recorded in control treatment (21.08 ± 0.40) comparable with location-I (18.87 ± 0.80) recording significant result ($P < 0.01$). Leaf area (cm^2), number of main branches and number of lateral branches differed significantly ($P < 0.01$) in control compared to other but illustrated non-significant ($P > 0.05$) result with rest of locations at Shenyang (*Table 1*). The experiment deliberated that the effectiveness of powdery mildew (*Erysiphe polygoni*) significantly reduced the plant height, root length, leaf area and lateral branches significantly; but do not differ statistically with main branches of the selected prostrate knotweed (*P. aviculare*).

Different growth parameters calculated by co-efficient of determination (R^2). The studied maximum temperature (Maxt) ranged 25-30 °C, minimum temperature (Mint) between 17-20 °C with relative humidity 64-78% was played a significant role for the emergence and flourishing of pathogen pressure on the plant; however, elevated value of $R^2 = 0.97$ for Mint with RMSE < 5 recording awesome model prediction followed by $R^2 = 0.82$ with RMSE < 5-10 for Maxt recording very good model prediction (*Table 2*).

Table 1. *Effect of different growth parameters of Polygonum aviculare L. at different locations*

Weed	Plant height (cm)	Root length (cm)	Leaf area (cm^2)	Main branches	Lateral branches
Control	23.125 ± 0.59^a	21.08 ± 0.40^a	2.71 ± 0.31^a	7.63 ± 0.74^a	3.38 ± 0.52^a
Location-I	20.99 ± 0.96^b	18.87 ± 0.80^b	2.42 ± 0.14^b	7.00 ± 0.76^a	2.50 ± 0.53^b
Location-II	19.42 ± 0.53^c	16.18 ± 1.00^c	2.32 ± 0.14^b	6.88 ± 0.64^a	2.50 ± 0.53^b
Location-III	19.84 ± 1.00^c	16.26 ± 1.04^c	2.30 ± 0.15^b	7.38 ± 0.52^a	2.63 ± 0.52^b
C. V.	0.57	2.24	0.003	0.016	-0.03
S.E.	0.217	0.336	0.050	0.133	0.104
LSD	$P < 0.001$	$P < 0.001$	$P < 0.01$	$P > 0.05$	$P < 0.05$

C.V. = component variance; the same letter do not differ statistically from each other at 5% significance level ($P > 0.05$); however, means having different letters indicated statistically significant result ($P < 0.05$) or ($P < 0.01$) or ($P < 0.001$), LSD = least significant Difference; (mean ± SD), S. D. = standard deviation, S.E. = standard error

Table 2. *Regression model for growth parameter of Polygonum aviculare L. showing comparison of co-efficient determination (R^2) with RMSE during 2018*

Weed	Regression model	R^2	RMSE
Prostrate knotweed (*P. aviculare L.*)	PH = -0.5769 x H + 21.24	0.50	20.17
	Rl = -1.5488 x R + 22.482	0.42	51.16
	LA = 7.4975 x A + 0.5067	0.35	26.94
	Mb = 0.1875 x M + 6.7083	0.52	1.75
	Lb = 0.0625 x L + 2.4167	0.75	0.11
	Maxt. (°C) = 0.93 x Ma + 26.069	0.82	8.55
	Mint. (°C) = 1.4375 x Mi + 15.547	0.97	4.28

PH = plant height; Rl = root length; LA = leaf area; Mb = number of main branches; Lb = number of lateral branches; Maxt = maximum temperature; Mint = minimum temperature; R^2 = coefficient of determination; RMSE = root mean square error

However, the value of $R^2 = 0.75$ with RMSE = 0.11 described strong model fitting in the experiment. The polynomial relationship for number of main branches also displayed a linear arc pattern which strung with an initial linear stage followed by moderate asymptotic trend at the growth stage by R^2 (0.52) with RMSE (1.75) indicated the good model prediction. The values more than 15 indicated insufficient prediction of the model fitness. Maximum, minimum temperature was effecting significantly ($F = 5.917$; $P < 0.0001$; $F = 25.721$; $P < 0.0001$); however, the interaction between location with height of the *P. aviculare* did not differ statistically ($F = 2.102$; $P > 0.05$) between two temperature ranges from 25-30 °C and 17-20 °C (*Table 3*). The root length of the *P. aviculare* was affected highly significant ($F = 54.41$; $P < 0.0001$) with height and locations showed its plasticity but there interaction (PH x L) to total variance was strongly trait specific recording non-significant result ($F = 3.796$; $P > 0.05$).

The plant height was recorded significant result ($F = 3.796$; $P < 0.05$) with leaf length; however, plant height showed high significant ($F = 7.900$; $P < 0.001$) result with location. The interaction between leaf length and location (Ll × L) with height ($F = 0.579$; $P > 0.05$) did not correlated statistically; however, it was also a trait specific.

Table 3. *Analysis of variance of the interaction of maximum, minimum temperature, with location, plant height, leaf length of P. aviculare on four locations during 2018*

Parameter	Source	d.f.	MS	*F*
Maxt	Location (L)	2	10.778	5.917***
	Plant height (PH)	1	3.828	2.102NS
	L x PH	2	1.514	0.831NS
Mint	L	2	18.111	25.721***
	PH	1	0.193	0.274NS
	L x PH	2	0.399	0.567NS
Rl	PH	1	66.82	54.141***
	L	2	20.18	16.353***
	PH x L	2	1.13	0.912NS
PH	Ll	1	2.483	3.796*
	L	2	5.167	7.900**
	Ll x L	2	0.379	0.579NS

The range of maximum temperature = Maxt. was 25-30 °C and minimum temperature = Mint. was 17-20 °C; location = L; plant height = H; Leaf length = Ll in northeast regions. For each effect, we show the mean square (MS); degree of freedom (DF); F and P value. Significance level is P > 0.05

The fresh leaves infected with powdery mildew scrapped off gently into small pieces. These infected leaves were examined under microscope. In our study, the first symptoms visible as powdery white scraps on the upper portion of foliage further developed to plentiful hyphal development on the upper and lower sides of the leaves (*Fig. 2a*). Infected leaves become chlorotic with warped periphery resulted in early defoliation. Hyphal appressoria were well developed, lobed (*Fig. 2d*) and present in opposed pairs (*Fig. 2*).

Cleistothecium was emerged and conidiophores appeared cylindrical and appressorium was observed and identified on 200 µm (*Fig. 2c, 2d*). The cells of conidiophores formed in a round straightway in shape. The conidia produced in the single oval-shaped round to oblong. Germ tubes recorded in the perihilar portion of conidia and identified with 20 µm magnification under microscope (*Fig. 2b*).

Discussion

The study regarding parasitic activity of powdery mildew (*Erysiphe polygoni* L.) having its pathogen strain HMLAC226 recorded on native prostrate knotweed (*Polygonum aviculare* L.) investigated best prediction model of coefficient of determination (R^2). These results correlated with previously explicated investigations that leaf area measured in grassland exposed good performance $R^2 = 0.88$ with RMSE = 0.96 (Francone et al., 2014).

Our results were in accordance to the researchers who reported that stable temperature models were accustomed to predict the evolution under changing temperatures. However, the pathogen development pressure reduced quickly at elevated temperatures than at lower temperatures comparable to optimum temperature (Xu, 1999).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1338313394

The temperature effect in this experiment are in line with the researchers who reported in their experiments that the prevalence of powdery mildew propelled by moderate temperatures (21-30 °C). Elevated temperatures can delay or stop the growth and spore formation of *Erysiphe*. Vulnerability of times depleted increases with elevated temperature, maximum temperature ranged between 22-27 °C played a vital role for the germination of conidia (Peduto et al., 2013).

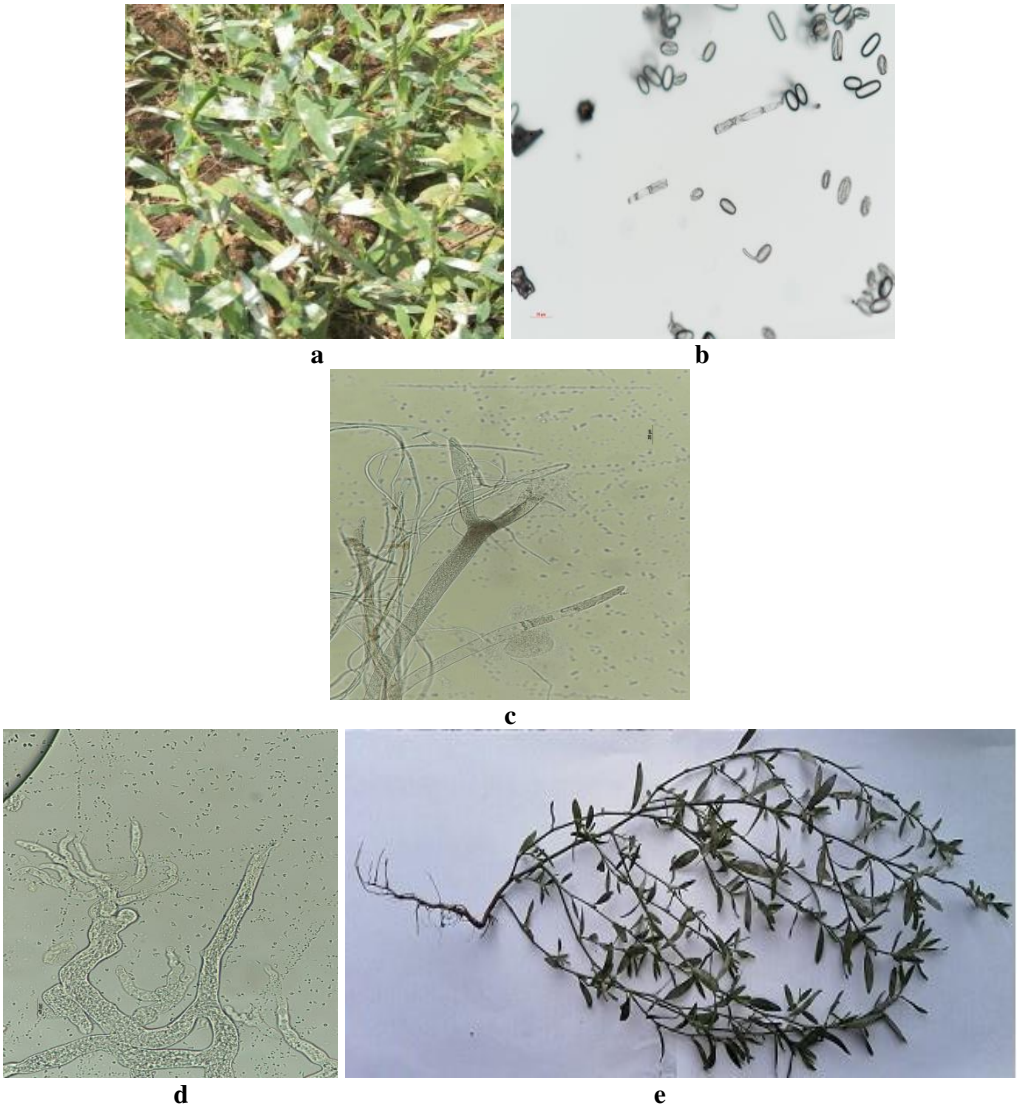

Figure 2. *Different stages of powdery mildew infection on Polygonum aviculare a. Infection; b. germ tube; c. Cleistothecium, Conidiophore; d. Appressorium; e. Healthy plant*

Exclusive growth models were fit to the expansion rate data with high significance value (Miller et al., 2003). As well as lower rate of development, supra-optimal temperatures resulted in higher spores mortality and faster rate at which leaves become resistant due to faster host growth than lower temperatures. This was the most likely explanation of the results obtained from inoculated plants exchanged between 20-30 °C (Xu, 1999).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1338313394

Our morphological results were in accordance with the researchers who reported that the spores of fungi present on the inoculated plants were similar in morphology compared to examine by diseased plants, fulfilling the Koch's postulates (Han et al., 2016). Prostrate knotweed (*E. polygoni*) is well known fungi distributed in the United States, Europe (United Kingdom, Czech Republic, Romania, Finland, and the former the Soviet Union), and China, Taiwan, Nepal, India (Lebeda et al., 2007) and Korea (Han et al., 2016). This study is in accordance with the investigations that powdery mildew was cosmopolitan and showed plant parasitic properties for angiosperm plants. Some species of *E. polygoni* are harmful specifically in agriculture and caused economic damage (Severoglu and Ozyigit, 2012); however, some may use as biological control agents (BCA's) on native and invasive weeds.

The Chinese climates vary from region to region with different ecological conditions and temperature fluctuates haphazardly resulted pathogen pressure can be increased. Our study was focused on prostrate knotweed (*Polygonum aviculare* L.), a plant parasitic powdery mildew (*E. polygoni*) investigated at roadsides, gardens and landscape range. This is a preliminary systematic study was conducted to identify powdery mildew in its conidial morphological states on prostrate knotweed and study its growth parameters compared to control. During field survey the infection of *E. polygoni* was observed on *Rumex acetosa*, *Plantago asiatica*, *Syringa oblata* and *Taraxacum mongolicum* which may become promising candidate for biological control agent (BCA's) in future.

Conclusion

Powdery mildew pathogen strain HMLAC226 is an important emerging parasitic agent of prostrate knotweed (*P. aviculare*) widespread as serious disease throughout the world. The symptom of this disease appeared with favorable environmental conditions demonstrated significant damage to the leave tissues. Maximum 25-30 °C and minimum temperature 17-20 °C along with 64-78% relative humidity are most conducive for pathogen establishment. According to the above analysis and findings, we encouraged researchers and ecologists to explore plant-pathogen interaction mechanism, resistance mechanism, host specificity test and genetic diversity in future.

Abstract. In this research we studied the effect of compost including phosphate flotation waste, phosphogypsum and cactus on chickpea (*Cicer arietinum* L.*)* plant growth and yield for 4 months under greenhouse systems in morocco. Chickpea development presented elevated variability. Phosphate flotation waste, contrary to the phosphogypsum, had positive effects on chickpea productivity; significant increase in biomass yield was demonstrated under phosphate flotation waste treatment (38.16%) and combination of phosphate flotation waste and cactus (48.87%). Phosphate flotation waste improved chickpea yield parameters and its effect was even more significant while adding cactus. Cactus might be a good material for enhancing the absorbance of nutrients by plants. When the phosphate flotation waste-cactus combination was optimal, supplementary parameters productivity was registered in certain situations. Furthermore, this research was the first to establish that the mixture including phosphate flotation waste, manure and cactus could not only enhance plant yield and growth but further assume for long-term agricultural productivity and right soil fertility.
Keywords: *phosphate flotation waste, phosphogypsum, cactus, physicochemical characterization of treatments, soil physicochemical properties, chickpea yield*

Introduction

Intensive cultivation and the failure to implement effective soil conservation practices for chickpea (*Cicer arietinum* L.*)* to meet the global demand has damaged the natural supply, and soil fertility and nutrients. Looking forward to obtaining a good fertility of soil and optimal yield, cultivated lands require proper management and recycling of organic wastes on land to protect agricultural soils.

In the last years, ammonium nitrate has been the best-known origin of nitrogen (N) on behalf of soil amendment in crop fertilization. Though, relative to else Nitrogen origin, ammonium nitrate is fairly luxurious and its production is probably to decrease during the decades to come (Wang et al., 2016). Under such scene, animal manure is getting more increasingly employed as an N origin nutriment for crop agriculture. To the same effect, in various countries, phosphorous (P) is the major growth restricting soil fertility; phosphate amendments have a critical role in pacing agricultural activity to shift human food productivity to the levels observed today. Though Yi et al. (2017) emphasize the utilizable deposits of phosphate are very restricted.

Further, evidencing the rooted dependency of food production on soil nutrients such P, in an alarming way (Cordel et al., 2009) prognostic a worldwide revolution in P production to arise by 2030. Yet the amendment production acknowledges the turn down in quantity and quality of international reserves along with the increasing costs of mining, meeting out and caring of P (Childers et al., 2011). Besides to these problems,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1339513405

there is a rising appreciation of the environmental expenses of the present system of food production. Unfortunate nutrient running of soils and sustained use of synthetic amendments have had harmful effects on soil fertility (Ke et al., 2017). To maintain food industry in excess of time and to provide effective utilization of accessible resources with maximum competence, it is crucial that enhanced methods and techniques for completing crop productivities are considered and agreed (Ganesapillai et al., 2015).

To this fact, Phosphate Flotation Waste (PFW) generated from beneficiation of Moroccan phosphate rocks is of great concern in composting as a low-grade phosphate rock (Elfadil et al, 2016). Phosphate rock, and for consequence PFW have been acknowledged as an alternating source for P nutrient. In Morocco, it is estimated that there are approximately 260 million tons of phosphate rock deposits and that material will present a shameful source of phosphate fertilizer for crop production (Tanner, 1961). Unfortunately, phosphor is not readily available to the plants in soils with a pH > 5.5– 6.0. Because of this, extension services are reluctant to recommend it and farmers are hesitant to utilize phosphate rock directly. furthermore, It was reported by Luo et al. (2013) and Hu et al. (2007) that phosphogypsum, the main by-product of phosphoric acid production, might be effective in composting in the sense where he can reducing NH_4 emissions during by increasing SO_4^{2-} content of the compost, and Luo et al. (2013) indicated that the addition of phosphogypsum at a rate of 10% of total compost mixture (dry weight) decreased NH_3 emissions significantly during pig manure composting.

Besides, cactus has been recommended as a bio-adsorbent because of it high retention (Sakr et al., 2015); so can it considered as a good quality–low charge substituted fertilizer that can offer a well-off source of amendment to improve agricultural productivity?

This research presents an original approach to increase soil fertility by the combined application including Phosphate flotation waste PFW, phosphogypsum (Pg), cactus and animal manure. While the use of Phosphate rock enriched composts has been the question of current studies (Moharana and Biswas, 2016), there have been awfully no information on the application of PFW, Pg and cactus in soils. Therefore, in the present study, the application of Phosphate flotation waste, phosphogypsum and cactus enriched animal manure on the plant development reply parameters of Chickpea (*Cicer arietinum L.*) was inquired.

Materials and methods

Sampling and sample pretreatment

Animal manure was obtained from forty farms in Chichaoua city with good-balanced regimes. Fresh manure samples were composed in air-tight comprising and refrigerated less than 20 °C to keep away from ammonia volatilization (Ke et al., 2017). The results of this study are summarized in *Table 1*.

Phosphate flotation waste and phosphogypsum tailings with 43.8% Ca_3PO_4 (20.05% P_2O_5) were obtained from industrial mines of Khouribga. Commercial grade Triple Super-Phosphate (TSP) with 45% P_2O_5 was obtained from Moroccan Institute for Agronomic Research in Settat city (INRA Settat). Composts are prepared with various mixtures of these raw materials;

Prior to the study, TSP was crushed and screened to size less than 2.5 mm.

the details of the treatments is: T1: the control (soil without addition); T2: soil and manure compost; T3: soil and compost of manure and PFW (6:4); T4: soil and compost of manure and phosphogypsum (6:4); T5: soil and compost of manure, PFW and cactus age under 6 mouth) (6:3:1); T6: soil and compost of manure, PFW and cactus (age above 6 mouth) (6:3:1); T7: soil and TSP. Three doses were applied of each treatment: 0.06 t/ha, 0.6 t/ha and 6 t/ha.

The experiments were carried out in the laboratory with an average room temperature of 25 ± 3 °C and relative humidity as 60%.

Experimental mode

A greenhouse experiment with chickpea plants was conducted from the beginning of September to the beginning of January 2015 (140 days) at the National institute of agronomic research (INRA) site located in Settat (Morocco), located at an altitude of about 400 m, Lambert coordinates X: 292.413 and Y: 263.664.

The site is located in the semi-arid bioclimatic stage with an average rainfall of between 300 and 350 mm concentrated between the months of October and May and a very temperate average temperature varying between 5 °C during the months December and January to 38 °C during the summer. Compound soil samples were obtained from a profundity of 0.2 m from the surface and screened throughout a 6 mm hole. The soil

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1339513405

used was red loam with 4.33% gravel, 92.84% sand and 2.83% fine; this soil was used for its proper properties and its impermeability. Trays (0.44 × 0.32 × 0.14 m) were packed with 4 kg of air-dried soil and studied with 3 replications. Trays were approved as plant divide arrays. Every array included plant replicates of the soil treatments, on a network including 3 rows by 18 columns of trays. Inside every array, the soil treatments were owed depending on a randomized complete block (RCB) plan, consequently this group of plant pots inside every line incorporated one repeat. 6 composts, prepared from phosphate flotation waste, phosphogypsum, animal manure and cactus, were additional to the respective trays 2 days previous to kernel planting and sprayed to ensure proper dissolution of composts in the soil. Trays were divided into plant slots and 3 seeds were planted in both pots at a profundity of 30 mm in greenhouse (*Fig. 1*). After germination, plants were watered down to 3 per slot for all the plates. All plants were periodically watered with de-ionized water through the research period. Upon maturity (about 4 months following planting the seeds) all plants were reaped and the plants phisico-morphological characteristics and biomass yield were identified. Preliminary pot experiment was set up with a set of 7 treatments.

For the seven treatments except the control, 3 doses are adopted with 3 replications:

- A dose of 0.06 t/ha of compost was selected for fertilization so 2 g of each compost. This dose was applied to the individual plots at the level of each treatment.
- A dose of 0.6 t/ha so 20 g of each compost.
- A maximum dose of 6 t/ha so 200 g of each compost.

During the experimental period, homogeneous irrigation (50 l for each plot) without chemical fertilizing was carried out regularly every five days with tap water using a drip system.

Plant physicochemical analysis

The unamended soil was included for its primary characteristics (*Table 2*). Post-harvesting, oven dried at 40 °C, plants was grinded at 2 mm screen. All the samples were characterize for total phosphorus, total nitrogen, total potassium and transferable cations (P, K, and N); pH was measured in 0.01 M $CaCl_2$ (1: 5) (Simpson, 1988). Total phosphorus and nitrogen were determined by means of the Dumas incineration method

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1339513405

at 900 °C with an oxygen run rate of 125 ml min^{-1}. P, N and K transferable were measured using absorption method. Exchangeable cations P (Olsenet al., 1960), K and N were measured using absorption method.

The contents of the air party of chickpea in fertilizing elements, in trace elements and in heavy metals, are determined by the Inductively Coupled Plasma Atomic Emission Spectroscopy (*ICP*-AES) to the laboratory Reminex of the company Managem of Marrakesh Morocco.

T1: the control (soil without addition); T2: soil and manure compost; T3: soil and compost of manure and PFW; T4: soil and compost of manure and phosphogypsum; T5: soil and compost of manure, PFW and cactus (age under 6 mouth); T6: soil and compost of manure, PFW and cactus (age above 6 mouth); T7: soil and TSP. Data are given as mean of three replicates (standard deviation)

Physiological analysis

The harvest of pods and plants was started on 140-day-old plants and the following characteristics were recorded for each collected plant: number and weight of pods, number and weight of seeds.

The roots of each plant were washed carefully and their lengths were determined.

Statistical analysis

The plant development data was originated to track normal distribution screening homogeneity of variances with correlation analysis. The data was statistically analyzed throughout SAS at a level of significance set at $P < 0.05$ using Anova followed by Dancun as a post-hoc test.

Results and discussion

Soil, compost, and potting mixture analysis

Nutrient condition of the soil, Composts and potting mixtures of soil and compost is exposed in *Table 1*. Among the macrofertilizers, availability of P was the uppermost, tracking by K and then N in the Composts, while soil presented upper concentrations of available N, tracking by K, and afterward P. Comparison of the results showed that the compost contained higher amounts of all macronutrients analyzed compared with the control. Upon substitution of soil with Composts, availability of macronutrients like N,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1339513405

P, and K in potting mixtures increased significantly with increasing proportions of compost substitutions (*Table 1*).

Chickpea biomass production

The treatments studied and the responsiveness of plant growth characteristics have been presented (*Tables 2* and *3)*. Intended for all treatments, the efficiency of PFW enriched animal manure was originated to be improved than that of the control (*Table 2*; $p < 0.05$). Relative to seeds weight, following tendency was showed for the control and 6 different treatments with all the three doses: T5 > T7 > T2 > T3 > T6 > T4 > T1 (*Fig. 2d*). A parallel tendency was showed for pods weight with the control, cactus 2 and phosphogypsum providing the lowly value. Relative to total plant biomass a different pattern was apparent: T7 > T6 > T2 > T3 > T1 > T5 > T4 (*Fig. 2c*); significant augment in biomass yield was confirmed in treatments T3 (38.16%) and T5 (28.87%) (*Fig. 2a*). However, enhancement of plant root length was most pronounced under T62 (0.06 t ha^{-1} of T2) (*Fig. 2b*).

Table 3. *Correlation matrix between quality parameters of PFW enriched composts*

Temperature	pH	K_2O	K_{ech}	Nitrate	P_2O_5	P_{assi}
pH	1.00000	0.19944* 0.5343	0.78039 0.0027	0.58550 0.0455	0.86056 0.0003	0.78785 0.0023
K_2O		1.00000	0.97254* 0.8227	0.31061* 0.6258	-0.28143* 0.8755	-0.05033* 0.8766
K_{ech}			1.00000	-0.94788 < .0001	-0.31589* 0.3172	-0.49368* 0.1029

P_2O_5					1.00000	0.95821 < .0001
P_{assi}						1.00000

*Correlation is significant at the 0.05 level

With compost input of 0.6 t P_2O_5 ha^{-1} to the soil, a different tendency was presented with rising compost dose adding. The majority of plant growth responsiveness parameters responded positively as P addition was augmented to 0.6 t ha^{-1}. Additional supplementation with P had resulting to decrease growth characteristics relatively to previous treatments while the results were still improved than that of the control. Hosseinpur et al. (2011) indicated comparable results for chickpea where they recommended that, rising application of inorganic P fertilizer further than 40 kg P ha^{-1} reduce leguminous P-fixation. They also recommend that for the benefits of starter P to be performed and the yield of chickpea to be improved, levels as significant as 0.6 kg N ha^{-1} could be necessary for optimizing the yields. While PFW input of 0.6 t P_2O_5 ha^{-1} yields positive results relatively to the control for all treatments, supplementary resource-use performance might be ensured throughout the optimal P additive identify. This study reports 0.6 t ha^{-1} as a positive level of chickpea agriculture. For instance, allowing for pod number as the responsiveness parameter; treatment T5 (6 t P ha^{-1})

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1339513405

relative to T5 (0.6 t P ha^{-1}) showed that supplementary P addition results in reduced number of pods (T5 is 86% of T4) nevertheless still considerably higher than the control T1 ($p < 0.05$) (*Table 2*). Parallel result and watching of tendency for P addition to soils cultivating chickpeas was indicated by many authors (Saini et al., 2004; Wei et al., 2015; Iyer et al., 2017).

On the other hand, mineral amendments have larger agronomic competence for the reason that their elements are available and effortlessly captivated by plants. This would be due to the rapid release of nutrients to soils and plants, as demonstrated by Abdelhamid et al. (2004) in a study comparing the economic profitability of inorganic and organic fertilizers in faba bean (*Vicia faba L.*). On the other hand, the dose of 0.6 t ha^{-1} of manure compost is much more efficient than 0.06 or 6 t ha^{-1}. These results (*Table 2; Fig. 2*) show the value and necessity of using low doses in case of low availability of organic materials. This confirms the studies of Ukem (2010) who advocate the use of small quantities of compost in vegetable and soybean crops.

Effect of cactus addition on chickpea biomass production

Cactus with PFW resulting in enhanced chickpea growth as well as dry matter increase could be awarded to mechanisms as the creation of indoleacetic acid along with dissolving of unsolvable phosphate alongside with uncharacterized characteristics making fertilizers more willingly available for plant uptake. Cactus facilitates enhanced mineral nutrient absorption as a result of varying the physiological rank along with morphological characteristic of inoculated roots, and therefore promotion of root growth is considered as one of the major markers by which the beneficial effect of plant growth promotion by cactus is measured. Increased root length in the seed treatments may thus be influenced by cactus (*Table 2; Figs. 2* and *3*).

Increase in growth as well as dry matter build-up in chickpea plants in the combined a of high compost use substitution as well as cactus and manure was better than the amount of their individual applications, possibly as an effect of the synergistic input of both parameters in the enhancement of the physico-chemical characteristics and nutritional factors. The benefits of this combination are more likely to synchronize nutrient release from the compost and soil with plant nutrition demand as well as involvement of cactus and manure modulation of the plant root architecture for more efficient acquisition of soil nutrients. In this study, cactus with manure improved the tested parameters of growth due to their synergistic effect. This supposed that manure substitution separately was powerless to provide the plants with enough quantities of willingly available fertilizers as well as enhancement of plant growth unlike the combinations.

Effect of toxicity of the novel composts on chickpea plant

Heavy metals are regarded as trace elements due to their existence in low contents (in ppm) in different eco-systems (Meharg, 2011). Their bio-assimilates is affected by various physical parameters (temperature, adsorption...), chemical parameters (thermodynamic equilibrium, complexation kinetics, lipid solubility…) (Hamelink, 1994) and biological parameters (species characteristics, biochemical/physiological adaptation…) (Martin, 1995).

The contents in cadmium and lead were low for all the treatments (< 2 ppm and < 26 ppm respectively); also the concentrations of nickel and chromium were weak

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1339513405

and stay below the international standards: AFNOR norme. The copper and zinc concentrations of the various plants were superior with regard to the no amended treatment especially for the treatment which contains of the small cactus, what can be to explain by the strong adsorption of the cactus of the zinc and the copper.

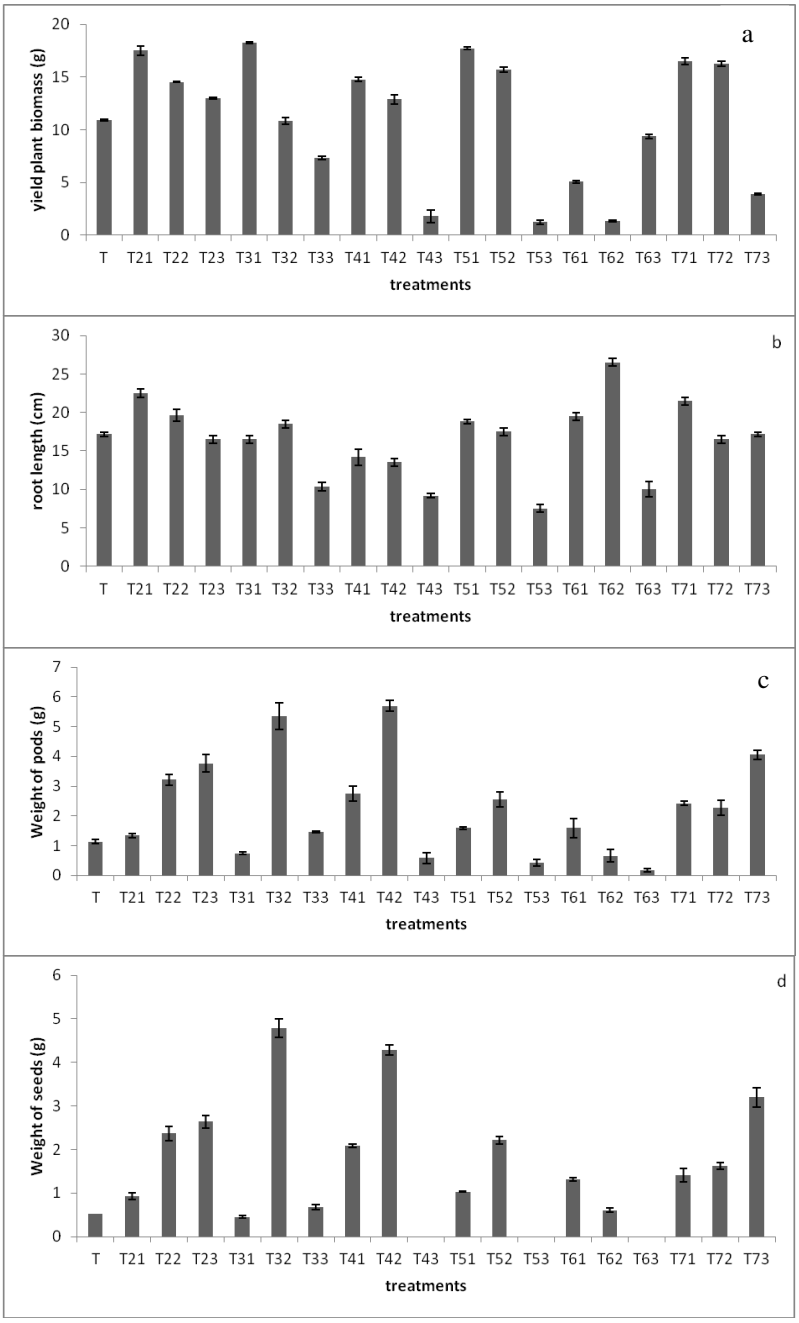

Figure 2. *Influence of enriched composts on (a) yield plant biomass; (b) root length; (c) Weight of pods; (d) Weight of seeds per plant in the various treatments. Conclusion

This research confirmed an approach to fertilize plants via the combined application of wastes resources; PFW, phosphogypsum, animal manure and cactus. That confirmed the elevated performance observed in reactivates parameters of Cicer arietinum as the product of treatment T4 (PFW at 0.6 t P_2O_5 ha^{-1} and cactus at 0.6 kg P ha^{-1}). The addition of PFW and phosphogypsum fitting nature of Cicer arietinum, chemical analyses of soil subsequent the harvest presented an augmentation in total soil phosphorus; cactus have clear beneficial effect to increased supply of Phosphorus, changes in the growth rate of chickpea and absorption of heavy metals by plants.

Unfortunately, some of the studied treatments exacerbate certain problems with mineral additives, especially regarding heavy metals accumulations. For this reason, research is in progress to ameliorate the physicochemical conditions for using these additives improvers and also to investigate the links between heavy metals accumulation in cultivated soils, the physical and hydraulic properties, and soil productivity.

Acknowledgments. The authors would like to thank anonymous reviewer for his useful comments and the high ministry of education of morocco. Mr A. Bousetta (Reminex Unit – Managem Morocco), is thanked for the help concerning ICP analysis. The authors would like Mr E. El Mzouri the Director of INRA Settat Morocco.

Abstract. Diameter at breast height (DBH) is one of the most important factors in forest inventories. A diameter tape is a traditional tool for measuring DBHs and is often used to obtain references when testing other DBH tools. However, reading measurements with this tool is subjective and may result in low-accuracy values. In this paper, two types of diameter tapes with barcoding (black & white tape and multicolour tape) were designed based the traditional diameter tape. A new algorithm was designed and developed as an application that can be installed on a smartphone with a wide-angle camera to decode and store readings of these new tapes. This system was tested in typical forest plots. The results showed that when comparing the mean values measured multiple times with reference values obtained with a traditional tape, the bias was not particularly significant (1.3 mm). The RMSE of measurements using these new tools (5.6 mm) was smaller than that obtained using a traditional tool (9.2 mm). Furthermore, this new approach reduced the subjectivity of different observers reading the data. Therefore, these new tapes may be better alternatives to a traditional tape.
Keywords: *forest inventory, standing tree, diameter at breast height, smartphone, automatic measurement*

Introduction

Field survey is an important means of gathering information from forests. The information collected usually includes diameter at breast height (DBH), tree height and crown width, which can be used to estimate stock volume and biomass models (Maia et al., 1999; Drexhage and Colin, 2001; Popescu et al., 2003; Ouimet et al., 2008) and to establish remote sensing inversion models (Riaño et al., 2003; Wieser et al., 2017). The accuracy of the collected information directly determines the accuracy of such models. DBH is easier to measure and more important than other variables. DBH has strong correlations with tree height, stock volume and biomass (Gering and May, 1995; Popescu et al., 2003; Ouimet et al., 2008; Sumida et al., 2013). Therefore, the accuracy, efficiency, and objectivity of DBH measurements are of great interest.

Caliper and diameter tape are traditional measurement tools. These tools are inefficient and yield subjective results because they require contact with the trees and the manual reading of measurements. Some new, non-contact tools, such as relascopes and dendrometers, have been developed and used for DBH measurements. Kalliovirta et al. (2005) tested a laser-relascope, which is a combination of a relascope and a dendrometer, under typical forest conditions. They compared the measurements with the values gathered by a steel caliper and obtained a standard error of 8.2 mm. The accuracy of the laser-relascope measurements depends on distance, tree measurement time, DBH and observer experience.

Terrestrial laser scanning (TLS) and mobile laser scanning (MLS) are considered alternatives to traditional measurement tools. These devices can be used to scan a sample plot and generate three-dimensional (3-D) point cloud data with high position accuracy. Through filtering, reconstruction and some additional steps, sample plot information including DBH measurements can be obtained from the data (Watt, 2005; Maas et al., 2008; Liang et al., 2012; Yu et al., 2013; Saarinen et al., 2013; Liang et al., 2014a; Srinivasan et al., 2015; Vastaranta et al., 2015; Olofsson and Olsson, 2017). Maas et al. (2008) used single-station and multi-station observations to measure the DBH of trees and compared the results with traditional caliper measurements. They found that the multiple-scan data was superior to the single-scan data, with a root mean squared error (RMSE) of 1.5 cm vs. an RMSE of 3.2 cm. Liang et al. (2014a) tested an MLS system composed of a high-performance laser scanner, a navigation unit, and a six-wheeled all-terrain vehicle in forest inventories, and the RMSE of the estimations of DBH was 2.36 cm. However, the high expense of the devices and the limited availability of cloud-processing software for the obtained cloud data of sample plots may limit the applications of TLS and MLS for forestry measurements.

A camera is another effective measuring tool that has been widely used in forest inventory (Juujarvi et al., 1998; Melkas et al., 2008; Liang et al., 2014b; Miller et al., 2015; Varjo et al., 2019). The device is typically used in one of two ways (to analyze a single photo attached to some conditions or a point cloud generated from multiple photos). Melkas et al. (2008) tested a laser-camera that combined a digital reflex camera with an integrated laser line generator. Tree diameters measured with the device were compared with measurements conducted with a steel caliper. The standard error of the diameter observations was 6 mm (5.3%), and the proportion of bias was 2.5 mm. However, this method may not be as efficient as the direct use of a diameter tape. Liang et al. (2014b) evaluated a point cloud generated from an uncalibrated hand-held camera and compared with measurements obtained with a steel tape. The RMSE of the DBH estimates of individual trees was 2.39 cm, which means that the results may not be very accurate. The color point cloud generated by this approach can be processed in the same way as a point cloud obtained by TLS or MLS, but the automated image matching procedure is very difficult and introduces more redundant error than does a TLS method.

A smartphone is a device that integrates sensors such as a wide-angle camera, gyro system, and GPS. As a low-cost, portable and developable device, the smartphone has been widely used in various industries including forest inventory (Villasante and Fernandez, 2014; Bijak and Sarzyński, 2015; Vastaranta et al., 2015; Molinier et al., 2016; Qu et al., 2017). Vastaranta et al. (2015) evaluated a related app (TRESTIMATM) in conducting sample plot measurements and included a function to measure stem diameter automatically. The app was used to measure basal area median tree diameter (DgM) in the test. The measurements were compared with values obtained by a caliper. Biases for the DgM measurements varied from -1.4% to 3.1%, and the RMSE ranged from 5.2% to 11.6% among different tree species. Clearly, these errors are larger than desired.

Although many advanced devices have been used for DBH measurements, a caliper and diameter tape are still considered the most accurate measurement tools, and measurements obtained with these devices have been widely used as true values for comparison tests. However, the observations made with these two instruments and the recording of results are subjective, which will affect the validity of comparative tests.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1340713421

To the present authors' knowledge, no tool has yet been developed that measures diameter as accurately as these two traditional tools and that does not yield subjective measurements.

In this study, a new diameter tape (barcode diameter tape) was developed. The scale on this tape was coded with special barcodes to allow measurements to be decoded and recorded using a smartphone with a wide-angle camera. A new algorithm to read and parse images with the barcodes was designed and developed into a smartphone application. This system seeks to obtain measurements of the same level of accuracy as traditional measurement tools and to overcome the subjectivity of observations and records. The new system was tested in typical forest conditions, and the accuracy of the DBH measurements was examined.

Barcode diameter tape

Structure of the barcode diameter tape

Diameter tape is a tool for measuring the diameter (D) of a tree at breast height. The measurement principle of conventional diameter tape is to measure the circumference (C) of the tree at breast height. D is obtained by the formula D=C/π. Thus, a linear relationship can be found between DBH and circumference, wherein each π cm on the diameter tape is equal to 1 cm DBH (*Fig. 1*). The unit interval on the diameter tape is designed for the π cm, sub-scale value for π/10, and the readout values from the tape are the DBH values.

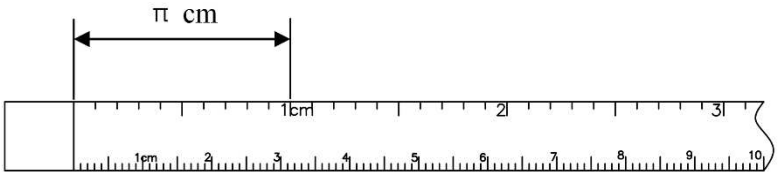

Figure 1. *Scale sample of traditional diameter tape*

The new barcode diameter tape designed in this paper separates the fractional area from the integer area without a dual scale (*Fig. 2*).

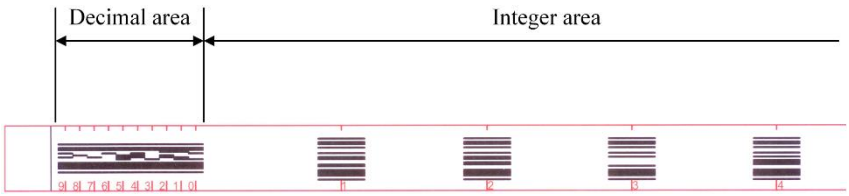

Figure 2. *Scale sample of barcode diameter tape*

The integer area of the scale interval is π cm; the fractional area of the overall length is π cm, with ten scales from 0-9; and the length of the scale interval is π/10 cm. The measurement principle of conventional diameter tape is shown in *Figure 3a*; the DBH of the tree is read along the bottom edge of the tape where the left and right ends of the tape cross at the 0-line. The measurement principle of the designed diameter tape is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1340713421

shown in *Figure 3b*. The user reads the integer value before zero on the scale and the minimum scale value from the integer value to zero on the scale, which is the sum of the integer value within the fractional area and the fractional value corresponding to the integer scale (*Fig. 3*).

Principle of barcode encoding

A barcode can accurately represent numeric and alphabetic data using patterns (black lines and white lines) that can be read rapidly. The diameter tape is a tool used to obtain numeric diameter data, and 1D barcode can represent its corresponding value. However, there is an excessive number of standard patterns of existing barcodes. For example, the classic European Article Number (EAN-13) encoding standard contains 113 patterns. Each pattern is 0.33 mm in width according to conventional standards. The total width of the barcode is approximately 38 mm, which requires a tape greater than 38 mm in width. However, the width of conventional diameter tape is approximately 10 mm and thus does not meet the requirements of existing encoding standards. Therefore, two sets of simple barcodes were designed in this study: a set of black & white barcodes, and a set of multicolor barcodes.

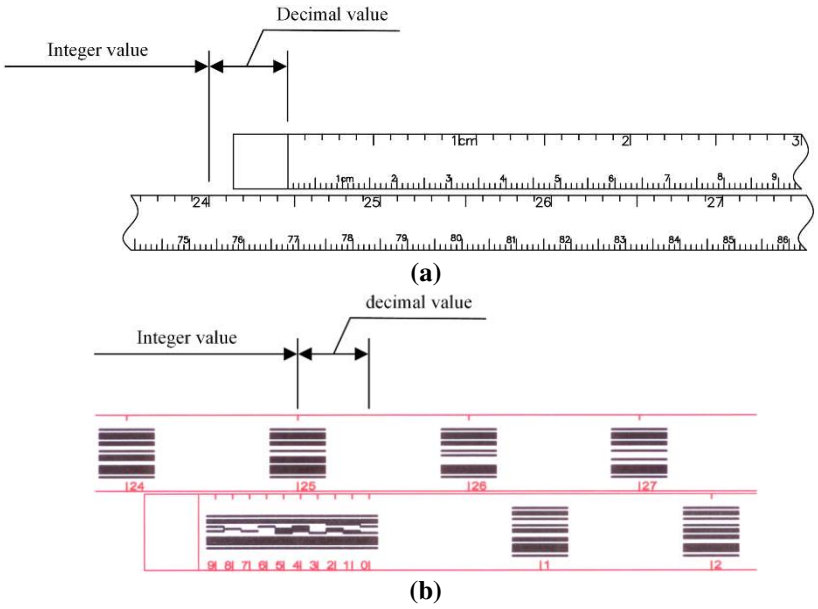

Figure 3. *Comparison of readout principle of diameter tapes*

The redesigned barcode consists of Left Quiet Zone, Start Character, Data Character, Stop Character and Right Quiet Zone. The pattern values of each zone except Data Character are shown in *Table 1*. In the set of black & white barcodes, the Data Character field refers to the EAN code and uses 7 patterns to represent a digit; the numbers corresponding to the code are shown in *Table 2*. The integer area requires two digits with 14 patterns, whereas the fractional area requires only one digit with 7 patterns. Different width-encoding modes are used for integer area and fractional area to allow the two parts to be distinguished accurately. The pattern width design is 0.4 mm, so the total tape width is 14 mm. Due to the limited space (3.14 mm) between scale lines in the fractional area, we made the pattern length 3.14 mm. The results are shown in *Figure 2*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1340713421

The structure of the multicolor barcodes is identical to that of black & white barcodes, except that two new colors (red and green) are added, which transforms the binary barcode to a quaternary barcode such that each zone can be represented with fewer patterns. The pattern values are shown in *Table 1* and *Table 2*. The pattern width design is 0.6 mm; thus, the total width is 9.6 mm. The results are shown in *Figure 4*.

Table 1. *Corresponding zone patterns of black & white and multicolor barcode*

Barcode type	Zone Pattern			
	Left Quiet Zone	Start Character	Stop Character	Right Quiet Zone
Black & White	000000	101	111101	000000

8	1001000	330
9	1010100	310

Figure 4. *Design of color barcode DBH tape*

Principle of barcode decoding

The redesigned barcode has two parts: an integer area and a fractional area. Neither part follows existing standard code, and there is no ready-made open source library or decoding methods to choose from. In this paper, a new set of decoding schemes was designed to meet the use of barcode diameter tape. The scheme can be used for decoding both black & white barcode and multicolor barcode. The decoding flowchart is shown in *Figure 5*.

Typically, a barcode-containing image (*Fig. 6*) can be captured through a camera-equipped device using the barcode diameter to measure DBH. The color of each pattern in the image can be determined by the values of the three channels of R, G and B. For example, the three-channel values for red are 255, 0, and 0 theoretically. However, the channel values are usually affected by the reflectivity and uniformity of light under natural conditions. In this paper, 3-channel values of the pixels on the mid-perpendicular of the image are counted, and the upper and lower quartiles are obtained. As shown in the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1340713421

Table 3, if the pixel's R-channel value is greater than the upper quartile (UQ) of this channel and the G- and B-channel values are less than their respective lower quartiles (LQs), then the pixel color is considered red.

To read the value represented by the barcode, the integer and fractional areas should be found in the image; in *Figure 7*, this means finding Points ①-④. If searching down from right above the image, the pixel color goes through the sequence of "(non-white)-(white)-(non-white & non-black)-(black)", and the last black pixel is on the topmost module. The width of this pattern can be obtained by continuing to search down, and the midpoint of the module is Point ①. Similarly, Point ④ can be obtained through bottom-up search. However, if the midpoint of Point ① and Point ④ is adjusted as the starting point for searching Point ② and Point ③, the product may not conform to this sequence.

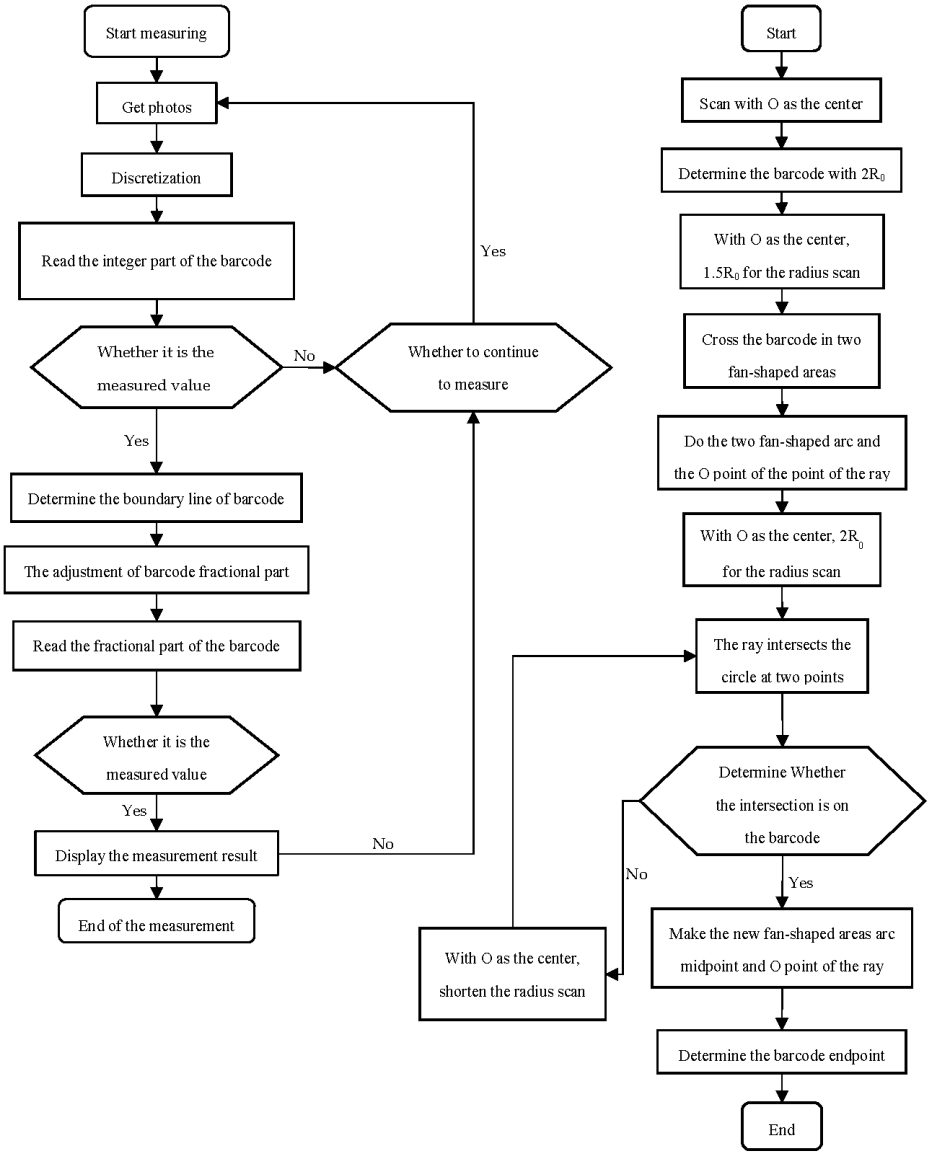

Figure 5. *Flowchart of the decoding method*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1340713421

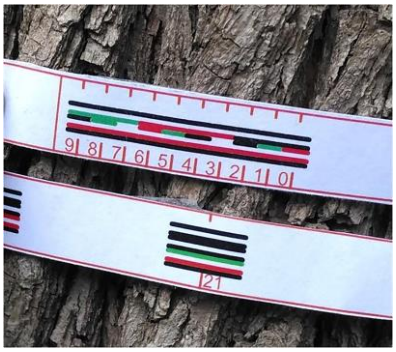

Figure 6. *Typical captured barcode-containing image*

Table 3. *Pixel channel characteristics of different colors*

color	R-channel value		G-channel value		B-channel value	
	<LQ	>UQ	<LQ	>UQ	<LQ	>UQ
white	-	Y	-	Y	-	Y
black	Y	-	Y	-	Y	-
red	-	Y	Y	-	Y	-
green	Y	-	-	Y	Y	-

"LQ": lower quartile; "UQ": upper quartile; "Y": yes

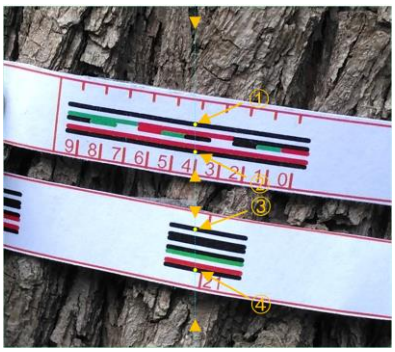

Figure 7. *Procedure of edge detection*

In this paper, the search starting points are adjusted to the pixel points at the corresponding distance above and below the midpoint. These starting points must be in the gap of tape or in the white area of the tape corresponding to the search direction. The distance is determined by the pattern structures of the barcode diameter tapes, which are shown in *Figure 8*. For black & white barcode diameter tape (*Fig. 8a*), the number of patterns between Point ① and Point ④ is calculated by *Equation 1*:

$$T = (23 - 0.5 + 6) + 2g + (9.5 + 16 - 0.5) = 53.5 + 2g \quad \text{(Eq.1)}$$

and the distance D should meet the following condition (*Equation 2*):

$$\frac{[(23 - 0.5 + 6) - T/2]N}{T} < D < \frac{[T/2 - (23 - 0.5)]N}{T} \quad \text{(Eq.2)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1340713421

where N is the number of pixels between Point ① and Point ④. This interval will be the smallest when g=0, and the range of D will be as follows (*Equation 3*):

$$0.0327N < D < 0.0421N \quad \text{(Eq.3)}$$

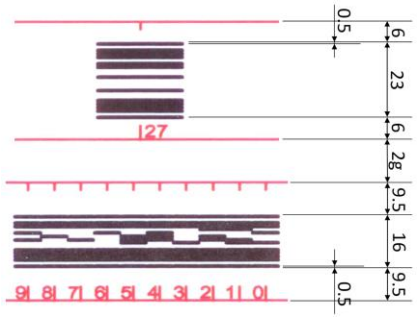
Similarly, the smallest interval of multicolor barcode diameter tape is as follows (*Equation 4*):

$$0.0319N < D < 0.0532N \quad \text{(Eq.4)}$$

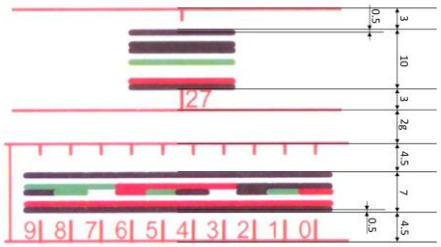
This allows the algorithm to be adapted to both types of tapes, with values in the range of the following (*Equation 2*):

$$0.0327N < D < 0.0421N \quad \text{(Eq.5)}$$

After determining the inner patterns and outmost patterns (or Points ①-④), the distance (D12) between Point ① and Point ② and the distance (D34) between Point ③ and Point ④ can be calculated, and the wider distance can be considered the integer area. In *Figure 7*, the area between Point ③ and Point ④ will be seen as the integer area. If the number of patterns in the integer area is M, the space between Point ③ and Point ④ is equally divided into M-1 parts, with each equidistant point being the midpoint of each pattern. In this way, the color type of the equidistant points can be read and compared with the code library to obtain the corresponding value.



(a)



(b)

Figure 8. *Pattern distribution of barcodes. The unit is "Patterns", and "2 g" represents the gap width (number of patterns) between the integer area and fractional area of the tape*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1340713421

The reading of the fractional area is primarily based on the corresponding integer area scale. However, it is difficult to ensure that there is no gap between the integer part and fractional part of tape and that the two parts are parallel during typical measurement. A new algorithm was developed to eliminate these difficulties, and the algorithm diagram is shown in *Figure 9*. From the figure, we can see that each mid-perpendicular of the pattern in the integer area crosses the corresponding scale line of the integral area, which can determine the scale position of the integer. In this context, the special pattern in the integer area that is closest to the fractional area is chosen as the target for obtaining a mid-perpendicular, and the endpoints of this pattern can be used to calculate the mid-perpendicular. The new algorithm needs to find the endpoints of this pattern; the new algorithm diagram is shown in *Figure 9*.

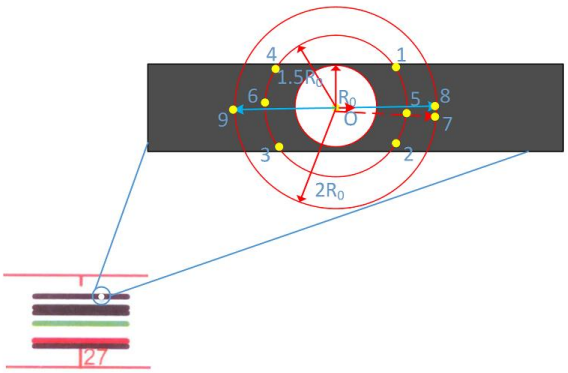


Figure 9. *Principle of the decoding algorithm*

In this algorithm, a circle, which has its center at Point O (Point ③ in *Figure 7*) and a radius of 2 pixels, is determined. If all the pixels in the circle have the same color type as Point O, the radius of the circle is gradually increased until a pixel of a color type different from the color type of Point O appears in the circle. At the end of this process, the pattern width is $2R_0$ assuming a radius of R_0. With Point O as the center and $1.5R_0$ as the radius of a circle, the circle will intersect with the pattern at arc (12)ˆ and arc (34)ˆ. Point 5 and Point 6 are the midpoints of arc (12)ˆ and arc (34)ˆ, respectively. With the midpoint as the center and $2R_0$ as the radius of a circle, the ray passing through Point O and Point 5 intersects with the circle at Point 7. If Point 7 is in the pattern, it will be corrected to the midpoint 8 of the arc where Point 7 is located. Then, the radius of circle continues to be increased until the intersection of the circle with the corresponding ray is not included in the pattern. The target endpoint should be close to this intersection point and can be obtained by adjusting the intersection point. Similarly, another endpoint can be obtained using this method. These two endpoints are similar to Point A, B in *Figure 10*, and Point C, D, E, F can be obtained by the same method. As shown in *Figure 10*, the mid-perpendicular of Point A, B intersects Line AB at Point P0 and Line CD at Point P1. To amend the error caused by the non-parallel and gap between the integer and fractional parts of the tape, the target fractional code is the code that is intersected by the line passing through Point P (midpoint of Point P0 and P1) and perpendicular to Line CD or the code between Point S1 and S2. The value can be read in a way similar to that of the integer area.

Materials and Methods

The profile of the study sites

Two plots in Xiangshan (40.00°N, 116.19°E), located in Beijing, China, were selected for study. A total of 94 standing trees in the plots (each 25*25 m) were investigated; descriptive statistics of the plots are summarized in *Table 4*. The tree species in Plot 1 are mainly conifer species, and those in Plot 2 are broad-leaved species. The data in the table were obtained using a caliper. The DBH of each tree was measured by six different observers, and the average values were taken as the true values of the trees.

Since the principles of the black & white barcode tape and the multicolor barcode tape are the same, the test data were obtained by a multicolor barcode tape. To study the subjectivity of different researchers in measuring DBH and the effect of observer experience on DBH measurement, the data were measured by six different observers. Numbered patches were attached to the breast height of trees as reference points to ensure that each measurement was collected at the same height.

The reference values were measured using a traditional diameter tape. For comparison with the measurement results obtained by barcode tape, each diameter was measured by the same six different observers.

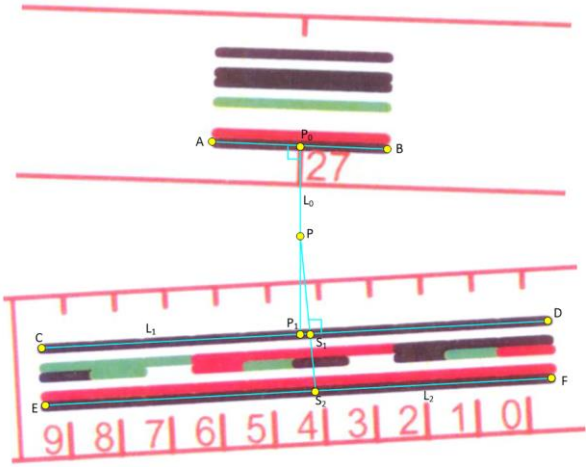

Figure 10. *Adjustment and reading of fractional area*

Table 4. *Summary statistics of DBH in the plots*

Plot	Species	N	Mean(cm)	S.D.(cm)	Minimum(cm)	Maximum(cm)
1	Platycladus orientalis	50	18.2	9.6	6.2	50.7
	Acer truncatum	4	8.0	2.0	6.2	10.4
2	Catalpa ovata	37	20.6	5.6	9.5	30.0
	Sophora japonicum	3	43.3	6.9	36.6	50.5

Methods

Error observation

To estimate the central trend and variability of measurements obtained by different observers using the barcode tape, bias, relative BIAS, root mean squared error (RMSE)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1340713421

and relative RMSE were used as evaluation indicators, as defined in (*Equation 6*) - (*Equation 9*).

$$Bias = \frac{1}{n}\sum_{i=1}^{n}(d_i - d_{ri}) \quad \text{(Eq.6)}$$

$$Bias\% = \frac{Bias}{\overline{d_r}} \times 100\% \quad \text{(Eq.7)}$$

$$RMSE = \sqrt{\frac{\sum_{i=0}^{n}(d_i - d_{ri})^2}{n}} \quad \text{(Eq.8)}$$

$$RMSE\% = \frac{RMSE}{\overline{d_r}} \times 100\% \quad \text{(Eq.9)}$$

where d_i is the ith measurement, d_{ri} is the ith reference value, $\overline{d_r}$ is the mean of references, and n is the number of measurements.

Generally, the measurements obtained by the traditional diameter tape are widely used as the reference values. Because these values also contain errors and because the purpose of this paper is to compare the accuracy of measurements between a traditional diameter tape and a barcode tape, the measurements obtained by a traditional diameter tape cannot be used as reference values. In this paper, when estimating the bias of the barcode tape measurements, the mean values of observations using the traditional diameter tape by six different observers were taken as the reference values. Furthermore, when comparing the variability of the measurements obtained by the diameter tape and the barcode tape, the means of measurements obtained using the barcode tape by the six different observers were considered as reference values.

Dependence of measurement error

The purpose of using a barcode tape is to reduce the subjectivity of human-read measurements or the differences in measurements between observers. A linear mixed model can detect differences between groups and is suitable for identifying the error associated with different observers. The model is defined as *Equation 10*:

$$y = X\beta + U\xi + \varepsilon \quad \text{(Eq.10)}$$

where y is an $n \times 1$ observation vector, β is the p×1 fixed parameters vector, X is the $n \times p$ matrix of the independent variables associated with the fixed parameters, ξ is the $q \times 1$ intragroup effect parameters vector, U is the $n \times q$ matrix of the explanatory variables associated with the intragroup effect parameters, and ε is a $n \times 1$ random error vector.

In this paper, measurement errors were treated as dependent variables, the intercept was the only fixed effect, and observer was considered a random variable. The proportion of errors in the total errors caused by different observers was used as a basis for comparison.

Results and Discussion

The measurements of DBH obtained by different observers are shown in *Table 5*. When the mean measurements observed by the traditional tool were used as the reference values, diameter was on average underestimated by 1.3 mm. However, this bias was not significant (0.67%). When the within-group means were used as the reference values, the bias variability (-1.8~1.4 mm) of the traditional tool was larger than that of the barcode tape (-0.7~0.7 mm). RMSE is an indicator used to assess variability. When the observer used the new measurement tool, regardless of whether the within-group or between-group means were selected as the reference values, the measurement values had less variability (2.71%, 3.92%) than those obtained with the traditional tool (4.46%).

Table 5. *Accuracies of the DBH measurements by observers M1-M6 (n = 94 trees measured by each observer)*

	Observer	Bias (W)	Bias% (W)	Bias (B)	Bias% (B)	RMSE (W)	RMSE% (W)	RMSE (B)

	Mean	-0.1	-0.03%	1.3	0.67%	5.6	2.71%	7.9

"W" means the within-group evaluations; "B" means the between-group evaluations; M1-M6 means different observers

Regarding the variability of measurements obtained with the diameter tape, 13.7% was due to differences among observers. When using the barcode tape, the corresponding value was 0%. However, if the means of measurements obtained with the traditional tape were selected as the reference values, the corresponding value was 21.0%. This larger variability was due to the differences between the mean values of different measurement tools; thus, the barcode tape was unable to eliminate the differences between observers. However, this new tool can reduce this difference. To determine the reduction in this difference, many comparative tests should be conducted over the long term.

The measurement results are expected to be better than the results from the remote sensing, such as relascope, TLS, MLS and camera. Kalliovirta et al. (2005) evaluated the availability of laser-relascope in forest inventory and reported an 8.2 mm standard error of DBH estimations, i.e. 4.7% from the mean diameter; obviously, the results have greater variability compared to our results due to our new tool using a contact measurement method. Vastaranta et al. (2009) evaluated the accuracy of the laser-camera in estimating the DBH of the tree; their results showed the standard errors

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1340713421

of DBH measurements were 8.3 mm and 8.5 mm. Although the device used a method of automatically estimating the DBHs to avoid subjective interference, it is less accurate than our tool because it is also a remote sensing measurement tool. Miller et al. (2015) used the digital photogrammetry to obtain point clouds to estimate the DBHs of the trees; the RMSE of the DBH estimation of individual trees was 2.39 cm. This approach avoided subjective interference and improved work efficiency, but its accuracy is still lower than our tool due to limited camera resolution and processing methods. Obviously, the accuracy of the barcode DBH tape data shows that it has the potential to measure DBH accurately. The results in this study indicated that the barcode DBH tape is an attractive and accurate technology for DBH measurements, which may be applied as the references to former remote sensing methods.

Conclusions

In this study, two barcode diameter tapes (black & white and multicolor barcode tapes) were designed. A new decoding algorithm was designed and developed as an application that was installed on a mobile phone with a wide-angle camera for parsing and recording the measurements of these new diameter tapes. The system was tested under typical forest conditions. When the mean values obtained with a traditional diameter tape were selected as reference values, the bias of the measurements was not significant (1.3 mm). The RMSE of the DBH was 5.6 mm. In addition, the DBM measurements obtained with a traditional tape were biased; specifically, they tended to be overestimates. The results also showed that the new tool could reduce the subjectivity of observers when reading observations and potentially replace traditional diameter tapes.

In the future, many comparative trials should be conducted to determine the precise amount of subjective improvement attained with the barcode tape. These tests should be conducted under different forest conditions, such as different canopy closures, ages, and forest types. In addition, there are some problems with the algorithm that cannot be completely solved. For example, when the angle between the integer tape and decimal tape is too large, the decimal value may not be accurately determined. This problem should be assessed quantitatively and appropriately resolved.

Abstract. Silicon (Si) enhances plant resistance to various forms of stress. However, the availability of Si as a plant nutrient is frequently limited. Bryophytes are able to grow on the surface of rocks and buildings with high Si accumulation. Therefore, bryophyte rhizoids might harbor microorganisms capable of solubilizing Si. In this study, silicate solubilizing bacteria (SSB) were isolated from the rhizoids of the bryophyte *Hypnum plumaeforme* L. to examine their effects on Si weathering and growth of maize (*Zea mays* L.). Molecular phylogeny and 16S rRNA gene sequence analysis demonstrated that the dominant bacterial strain B1-5 was a member of the *Kosakonia* genus. The concentrations of soluble Si released from the feldspar and quartz powder in liquid media with strain B1-5 inoculation were higher than those of the control. B1-5 inoculation in pot soil significantly increased the water-extractable Si content in soil, improved Si uptake and accumulation in maize plants, and promoted seedling growth. These results not only prove the existence of SSB in bryophyte rhizoids, but also demonstrate a new approach to searching for effective biological Si fertilizers.
Keywords: *silicate solubilizing bacteria, microbial weathering, molecular phylogeny, Kosakonia, biological fertilizer*

Introduction

Silicon (Si) is the second most abundant element after oxygen in soil. It occurs mostly in the form of dioxide and silicates (Myshlyaeva and Krasnoshchekov, 1974), which cannot be directly used by plants. Only water-soluble monosilicic acid [$Si(OH)_4$], a product of the weathering of rocks and soil minerals, is available to plants (Epstein, 1994; Raven, 1983). Si has not yet been recognized as an essential nutrient element for plants, but its beneficial effects on resistance have been extensively reported in numerous crops (Epstein, 1999). In 2015 Si was listed as a "beneficial substance" by the International Plant Nutrition Institute, USA (Reynolds et al., 2016). Increasing evidences indicate that Si can alleviate both biotic and abiotic stresses including pathogens, herbivores, extreme temperature, water deficiency, high salinity and nutrient stresses (Debona et al., 2017; Ma, 2004; Wu et al., 2017). Nitrogen (N), phosphorus (P) and potassium (K) fertilizers are widely applied in agricultural production, but Si fertilizer is usually neglected. Si deficiency frequently occurs as a result of Si removal by continuous crop harvest (Liang et al., 2015). Thus, it is of significance to effectively convert unavailable Si in the soils into a form plants can utilize.

Soil microbes play a crucial role in nutrient availability and mineral weathering from primary minerals (Vessey, 2003). Most related studies focused on the P and K solubilizing abilities of some microorganisms as seen in *Table 1*.

The role of silicate solubilizing bacteria (SSB), which can solubilize silicon from silicate bearing mineral and rocks (Bosecker, 1997), is largely ignored. Use of highly-efficient SSB is a promising approach for enhancing crop yield and defense in Si deficient soil.

An analysis of the Si contents in 175 plant species collected from a botanical garden shows that Bryophyta (3.46%) contains the highest Si, following by Pteridophyta (1.4%), Gymnospermae (0.5%), Angiospermae (0.13%) (Takahashi and Miyake, 1976a, b, c), suggesting that bryophytes are Si accumulators with high Si content. Therefore, we speculated that bryophyte rhizoids harbor certain SSB capable of solubilizing Si from poor nutrient habitats.

In the present study, our aims were to: (1) isolate and characterize bryophyte rhizoids-associated silicate bacteria, (2) determine the Si-solubilizing ability of selected bacteria, and (3) examine the effect of soil inoculation with selected bacteria on Si availability in the soil, Si uptake and plant growth in maize.

Materials and methods

Plants, soil and mineral

Bryophyte *Hypnum plumaeforme* was collected from rock walls in the back hill on Jinshan Campus of Fujian Agriculture and Forestry University, Fuzhou, China (119°54' E, 26°05' N) in July, 2018. Bryophytes from eight random sampling locations were kept in sterilized plastic Petri-dishes until the isolation experiment began in the same day.

The soils for maize potting were collected from a hillside near the university campus. The soil was a red soil (Typic Hapludults) (Soil Survey Staff, 2010). The properties of the soil were: pH (1:2.5 w/v water) 5.5; organic C 10.03 $g \cdot kg^{-1}$; total N 1.28 $g \cdot kg^{-1}$; available N 19.3 $mg \cdot kg^{-1}$; total P 0.13 $g \cdot kg^{-1}$; available P 12.6 $mg \cdot kg^{-1}$; total K 2.05 $g \cdot kg^{-1}$; available K 154.6 $mg \cdot kg^{-1}$, water-extractable Si 34.3 $mg \cdot kg^{-1}$. Seeds of

DOI: http://dx.doi.org/10.15666/aeer/1706_1342313433

maize (*Zea mays*, cultivar Yuecai) were obtained from the Crop Research Institute, Guangdong Academy of Agricultural Sciences, Guangzhou, China.

Mineral powders, feldspar ($KAlSi_3O_8$, SiO_2 68.09%) and quartz (SiO_2 98.81%), were manufactured by Foshan Hongda Ceramics Co., Ltd and passed through 0.075 mm mesh sieve. The powders were rinsed three times in pure water to eliminate soluble Si.

Isolation of silicate bacteria from bryophyte rhizoids

All collected bryophytes were slightly shaken to remove sands loosely adhering to the rhizoids. The rhizoids with the remaining adherd soil were swayed in 25 mL sterile water with tweezers, and the water was transferred to a 50 mL plastic tubes. The tubes were shaken with a vortex mixer for 15 s. The mixture was kept at room temperature for 30 min. The serially diluted suspension was plated on the surface of Aleksandrov's medium for silicate bacterial culture containing 0.5% sucrose, 0.05% $MgSO_4 \cdot 7H_2O$, 0.5% $FeCl_3$, 0.2% Na_2HPO_4, 0.01% $CaCO_3$, 0.1% $KAlSi_3O_8$, and 2% Agar, pH 7.2 (Hu et al., 2018). The Petri-dishes were placed in an incubator at 28 °C for 5 d. The growth of bacteria was checked every day. Fast-growing isolates with different morphology were further purified. The pure colonies were inoculated into liquid medium and preserved in 25% glycerol solution at -80 °C for future use.

Mineral dissolution experiment

The dominant strain was selected to test the ability to solubilize the mineral. The liquid medium consisted of 1% sucrose, 0.05% yeast extract, 0.1% NH_4SO_4, 0.2% Na_2HPO_4, 0.05% $MgSO_4 \cdot 7H_2O$, 0.01% NaCl, 0.01% $CaCO_3$, 5 g mineral powder, pH 7.2. Each conical flask (250 mL) contained 100 mL autoclaved liquid medium and 5 mL bacterial inocula (10^6 cfu mL^{-1}) as inoculation treatment. Five mL of sterilized inoculum were also added to the liquid medium to serve as control.

Feldspar and quartz were used as Si mineral respectively in two separate experiments. The inoculation and corresponding control were replicated three times. Each flask was maintained at 180 rpm for 7 d at 28 °C. The fermented broth was centrifuged at 8000 *g* for 20 min. The solubilized Si concentration in the supernatant was determined using the colorimetric molybdenum blue method described by Pettersson and Karlberg (1999).

Molecular identification

Genomic DNA was extracted using the DNA extraction Kit (Qiagen, USA) according to the manufacture's protocol. The universal primers for 16S rRNA sequence amplification were 27F (5′-GTTTGATCCTGGCTCAG-3′) and 1492R (5′-GGTTACCTTGTTACGACTT-3′) (Lin et al., 2012). The PCR reaction system had a volume of 25 μl, including Taq PCR Master Mix 12.5 μl, primer 2 μl, ddH_2O 9.5 μl, and DNA template 1 μl. The PCR was performed as follows: hot start at 94 °C for 5 min, followed by 30 cycles of denaturation at 94 °C for 30 s, annealing at 55 °C for 30 s, and extension at 72 °C for 60 s. A final extension step lasted 8 min at 72 °C. The PCR products were purified and sequenced by Shanghai Biosune Biological Technology Co., Ltd. The sequencing results were analyzed using NCBI database to find the closely related homologous sequences.

The sequence and the reference sequences with the highest similarities were aligned using Clustalx 1.83 and phylogenetic analyses was done using MEGA version 4 with

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1342313433

the neighbor-joining method, p-distance and 1000 bootstrap replicates (Tamura et al., 2007; Thompson et al., 1997).

Pot experiment

Maize seeds were surface-sterilized with 10% H_2O_2 for 10 min, and then rinsed 5 times with distilled water. The seeds were soaked in distilled water for 24 h, and then pre-germinated for 48 h at 28 °C. One seedling was transplanted to a 1 L plastic pot with 750 g dry sterilized soil. The soil were autoclaved thrice in three consecutive days. Meanwhile, the cells in cultured bacterial broth were collected by centrifugation at 8000 *g* for 20 min at 4 °C and washed with sterilized tap water. The pelleted cells were resuspended with sterilized water and then the cells were adjusted to around 10^6 cfu mL^{-1} as determined by a standard growth curve based on optical density reading at 600 nm using a spectrophotometer (Ling et al., 2009). The experiment was established with two groups: one group was inoculated with 10 mL bacterial suspension as inoculation treatment, and the other group was added with 10 mL distilled water as control. A total of 20 pots with maize plants were divided into two groups. After 7 d, all plants were fertilized with 50 mL Hoagland nutrient solution (Hoagland and Arnon, 1950).

All plants were harvested 5 weeks after transplanting. The roots were washed and cleaned, and stem diameters were measured. All plants samples were dried at 70 °C for 3 d, then weighed. The Si contents of dry samples were then analyzed by molybdenum blue colorimetric method described by Dannon and Wydra (2004). The water-extractable Si content of air-dry soil samples (1:10 w/v water) was determined by colorimetric molybdenum blue method described by Wang et al. (2004).

Statistical analysis

Si concentrations in culture solution, growth indexes and Si content of plants and soils were analyzed using t-test ($P < 0.05$) to determine difference between bacterial inoculation and control. All analyses were performed with the SPSS 13.0 software package (SPSS Inc.).

Results and discussion

Isolation silicate bacteria from the bryophyte rhizoids

Si-solubilizing bacterial isolates were obtained from the bryophyte *Hypnum plumaeforme* rhizoids on rock walls (*Fig. 1A*), and one of them showed the dominant colony which was named as B1-5, and kept for further study. On the Aleksandrov plates, the strain B1-5 formed round, smooth, convex, slimy, elastic, translucent and colorless colonies (*Fig. 1B*). Silicate solubilizing bacteria (SSB) can solubilize silicon from silicate mineral (Bosecker, 1997). Bryophyte with high Si-accumulation mostly can grow on the surface of rocks and buildings. So it raises the possibility that some SSB may adhere to the bryophyte rhizoids.

Molecular identification based on 16S rRNA analysis

About 1500 bp band was obtained from the amplification of 16S rRNA gene sequence from the strain B1-5. The 16S rRNA gene sequence of B1-5 clones was submitted to GenBank with accession number MH051262. Phylogenetic analysis

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1342313433

showed that B1-5 and all 6 *Kosakonia* species formed a branch, and that other outgroup species formed different branches (*Fig. 2*). Thus, the B1-5 strain belongs to the *Kosakonia* genus. *Figure 2* also showed that strain B1-5 shared the highest sequence similarities with *Kosakonia cowanii*. Thus, strain B1-5 was identified as a member of *Kosakonia*.

Several *Kosakonia* species isolated from soils and trees promote plant growth (Brady et al., 2013). Diazotrophic bacteria, *K. pneumoniae* and *K. radicincitans* were found to be associated sugarcane at Northeast Region of Brazil (Antonio et al., 2016). *K. radicincitans* improves fruit yield and quality of *Solanum lycopersicum* (Berger et al., 2017). *K. radicincitans* alters *Arabidopsis thaliana* root and root exudate metabolism (Witzel et al., 2017). *K. pseudosacchari* sp. nov., an endophyte of *Zea mays* was isolated (Kaempfer et al., 2016).

Si solubilizing activity of the bacteria

The ability of strain B1-5 to solubilize Si was assessed in liquid media containing mineral powders of $KAlSi_3O_8$ and SiO_2 (*Fig. 3*). After 7 days of incubation, a significant increase in soluble Si concentration of the medium with $KAlSi_3O_8$ ($t = -5.344$, $df = 4$, $P = 0.006$) or SiO_2 ($t = -43.466$, $df = 4$, $P < 0.001$) supplement was observed in inoculated versus control seedlings.

Values are mean ± standard error from three replicates*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1342313433

Here we found the B1-5 bacterial strain was able to solubilize silicate from Si-bearing mineral in fermentation liquid. Indeed, microbial leaching is a simple and effective technology for metal extraction from low-grade ores and mineral concentrates, and this method is being increasingly applied in mining industry (Bosecker, 1997). Mineral weathering mechanism has been increasingly clarified in terms of chemical weathering processes. These microbes have been indicated to accelerate the dissolution of silicates by perturbing mineral–water equilibria and reaction dynamics, the production of chelating agents, proton, organic ligands, hydroxyl anion, extracellular polysaccharides and enzymes, and silicate precipitation by metal sorption at the cell membrane (Bennett et al., 2001). However, the influence of bacteria in this process and its molecular mechanisms are still unclear (Uroz et al., 2009).

Effect of strain B1-5 on maize growth and Si content in soil and plants

Maize seedlings grown in soils inoculated with B1-5 showed greater shoot diameter ($t = -4.745$, $df = 18$, $P < 0.001$) and dry biomass ($t = -2.634$, $df = 18$, $P = 0.017$) than un-inoculated plants (*Fig. 4*). Soil inoculation with B1-5 strain significantly increased the growth of maize plants.

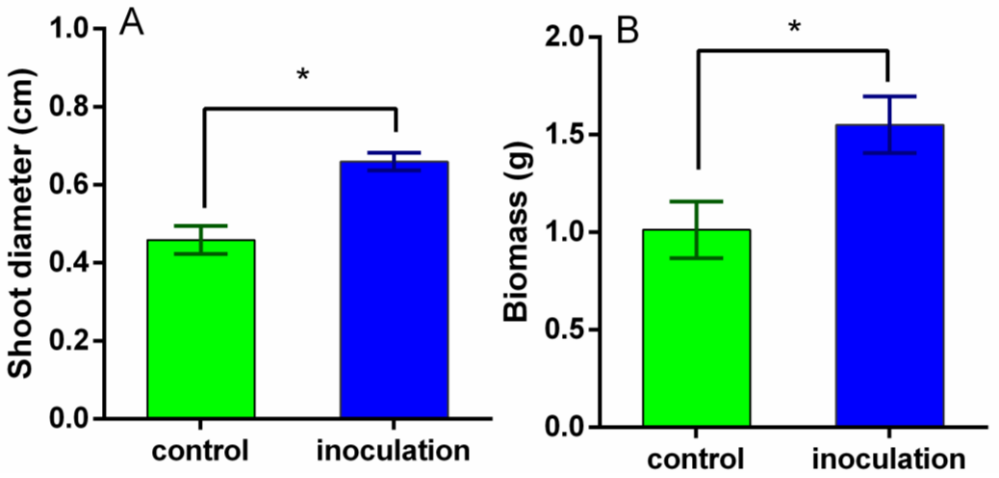

Figure 4. *Shoot diameter (A) and biomass (B) of maze seedlings grown in the soil with and without inoculation of strain B1-5. Significant differences ($P < 0.05$) between inoculation and non-inoculated control are indicated by asterisk above bars. Values are mean ± standard error from ten replicates*

The soluble Si content in the soil inoculated with B1-5 strain was higher than that in un-inoculated control ($t = -3.67$, $df = 18$, $P = 0.001$) (*Fig. 5A*). Maize plants grown in inoculated soil showed significantly higher Si level in shoots ($t = -2.55$, $df = 18$, $P = 0.020$) and roots ($t = -2.228$, $df = 18$, $P = 0.039$) than those in un-inoculated plants (*Fig. 5B*). Inoculation with B1-5 strain significantly increased soluble Si release from the soil and Si uptake by maize plants.

Our study clearly illustrated that the growth and Si content of maize plants were improved by inoculation with B1-5 strain via enhancement of soil Si availability and plant Si uptake. This is consistent with the findings that SSB, *Bacillus circulans Burkholderia eburnean* and *Enterobacter ludwigii*, increased the release of Si in soil and Si acquisition by plants (Kang et al., 2017; Lee et al., 2019; Zahra et al., 1984). Many studies have

DOI: http://dx.doi.org/10.15666/aeer/1706_1342313433

showed that Si application improves the growth of monocot crops including rice, sugarcane (*Saccharum officinarum*) and turf (*Lolium perenne*) (Nanayakkara et al., 2008; Savant et al., 1999; Snyder, 2001). Moreover, two field experiments in India have also reported that silicon solubilizing bacteria improve silicon uptake and crop yield in rice and sugarcane (Brindavathy et al., 2012; Pedda et al., 2016).

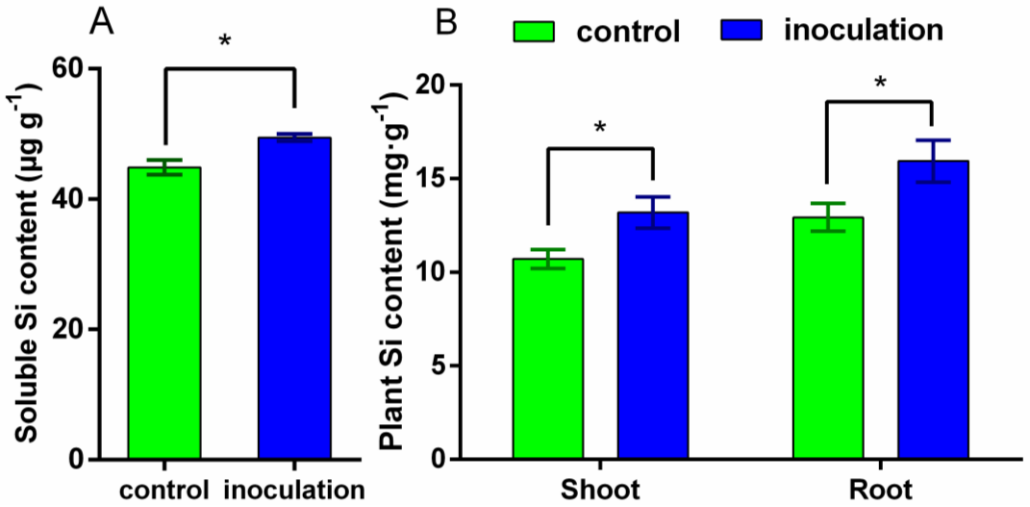

Figure 5. *(A) Soluble Si content in strain B1-5-inoculated and un-inoculated soils. (B) Si content in the shoots (left) and roots (right) of maize seedlings grown in strain B1-5-inoculated and un-inoculated soils. Significant differences ($P < 0.05$) between inoculation and control are indicated by asterisk by different letters above bars. Values are mean ± standard error from ten replicates*

Conclusion

In conclusion, this study not only highlights the existence of bryophyte rhizoids-associated silicate solubilizing bacteria, but also opens up a new approach searching for Si-solubilizing bacteria to increase Si availability in soil. Use of silicate solubilizing bacteria biofertilizer may serve as an important approach to increase Si availability and crop production. More detailed mechanisms of microbiological molecular biology and metabonomics about mineral weathering await further research.

Abstract. Diet changes the composition and function of the gut microbiota (GM). Short-chain fatty acids (SCFAs) are mainly produced through carbohydrate fermentation by the GM. It remains unclear whether changing the diet influences the accumulation of SCFAs in the grass carp (*Ctenopharyngodon idellus*) gut. To address this question, we compared SCFA accumulation with GM changes in the hindgut contents of grass carp in groups fed hybrid giant napier (*Pennisetum sinese* Roxb, HG), formula feed (FG), and broad bean (*Vicia faba*, BG). Our results showed that diet significantly influenced the SCFA concentrations in the hindgut of grass carp. By eliminating the influences of dietary SCFA, acetate and total SCFA accumulation in the hindgut of grass carp turned out to be positively associated with dietary cellulose contents. Most of the enriched bacterial biomarkers in the HG group that consumed the most dietary cellulose were SCFA-producing bacteria. These results implied that diet could regulate the relative abundances of potential SCFA-producing bacteria and SCFA accumulation in the grass carp hindgut. These findings shed light onto GM functions related to SCFA production and associative functions between SCFAs and the GM of grass carp.
Keywords: *aquaculture, carbohydrate fermentation, cellulose, high-throughput sequencing, microbial metabolism*

Introduction

In mammals, short-chain fatty acids (SCFAs) such as acetate, butyrate, and propionate are essential host energy sources (Stevens and Hume, 1998; Spiljar et al., 2017; Leblanc et al., 2017), which act as signal-transduction molecules via G protein-coupled receptors and as epigenetic regulators of gene expression by inhibiting histone deacetylase (Kasubuchi et al., 2015; Cohen et al., 2017). SCFAs are involved in regulating glucose and lipid metabolism, stimulating the proliferation and differentiation of intestinal enterocytes, and reducing the intestinal pH (thereby promoting the absorption of minerals by increasing their solubility) (Barczynska et al., 2016; Postler and Ghosh, 2017). SCFAs are also key regulators of virtually every aspect of the intestinal immune system, and they play key roles in the prevention and treatment of metabolic syndromes, bowel disorders, and cancer (Kasubuchi et al., 2015; Postler and Ghosh, 2017; Fukuda et al., 2012; Flint et al., 2015; Safari et al., 2016). Although

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1343513453

comparatively less research has been conducted with fish than with mammals, high intestinal SCFA concentrations occur in some marine herbivorous fishes and SCFAs produced by the hindgut microbiota are used as a blood fuel for energy purposes or for lipid synthesis by the host fish (Clements et al., 1994; Clements and Choat, 1995, 1997; Seeto et al., 1996; Mountfort et al., 2002).

Naturally, SCFAs are mainly produced through carbohydrate fermentation by gut microbiota in the host's intestines (Flint et al., 2015; Clements and Choat, 1995; Mountfort et al., 2002; Hao et al., 2017b). However, with the collapse of wild fishery resources, aquaculture has become the main way to produce fish protein. In addition, formula feed has replaced natural food to become the primary, or even sole food for cultured fish.

Diet is believed to be the major factor that changes the composition and functions of fish gut microbiota (Ni et al., 2014a; Faith and Gordon, 2011; Claesson et al., 2012; Bolnick et al., 2015; Miyake et al., 2015; Hao et al., 2017a). In addition, the quantities and number of SCFA species are markedly influenced by carbohydrate substrates (Hao et al., 2017a; Mountfort et al., 1993; Kihara and Sakata, 1997, 2002). Kihara and Sakata (2002) reported that alpha starch is the best substrate for producing SCFAs in the tilapia (*Oreochromis niloticus*) gut by microbial fermentation. Mountfort et al. (1993) isolated a bacterium, *Eubacterium* sp. P-1 (DSM 6788), from the mullet gut contents, which anaerobically ferments pectin to produce 163 mol acetate, 30 mol ethanol, 88 mol methanol, and 48 mol formate per 100 mol pectin monomer, whereas it anaerobically ferments hexose in cellobiose or starch to produce 39 mol acetate, 128 mol ethanol, and 41 mol formate per 100 mol hexose. However, it remains unclear whether changing the diet from natural food to artificial feed reduces SCFA accumulation in the fish gut. Since acetate absorption is driven by an SCFA concentration gradient between the blood and intestines, and the rates of absorption increase with intestinal concentrations (Titus and Ahearn, 1991), the answer to the question will show which feed formula promotes SCFA accumulation in hindgut and enhances the growth and health of fish, considering there are many studies have shown that using SCFAs and their salts as feed supplements enhance fish production (Goosen et al., 2011; Ringø, 1992; Da et al., 2013).

Grass carp (*Ctenopharyngodon idella*) is one of the most important native Chinese freshwater herbivorous fish, representing the largest freshwater aquaculture product worldwide (Ni et al., 2014a; FAO, 2014; Wang et al., 2015). Recently, a high-density culture formulation of grass carp feed with broad bean (*Vicia faba*) or formula feed in ponds has started spreading in China. The changes of the gut microbiota in grass carp caused by diet were described previously (Ni et al., 2014a). However, given that broad bean and formula feeds contain high protein and low cellulose concentrations, it is unclear whether those changes alter SCFA accumulation in the hindgut of grass carp. Considering the usability of carbohydrate substrates in fermentation by the gut microbiota, the nutritional contents of feeds, and the co-evolution between the gut microbiota and host's feeding habits, we hypothesized that whereas feeding formula feeds would increase grass carp growth and SCFA fermentation in the hindgut, feeding natural grass would enrich the cellulose- degrading bacteria in the hindgut of grass carp. To test this hypothesis, we compared the compositions of gut microbiota with cellulose levels and SCFA accumulation in hindgut of grass carp fed hybrid giant napier (*Pennisetum sinese* Roxb), formula feed, and broad beans.

Materials and methods

Experimental design and sample collection

The experiment was conducted in the precise aquaculture base of the Pearl River Fisheries Research Institute of China (113°13′02″ E, 23°04′07″ N) over a period of 60 days from May 23, 2015 to July 24, 2015. Grass carps weighing approximately 500 g individually from the same parents was collected from an artificial pond at Foshan Tongwei Fisheries Co. (Guangdong, China). The experiment was divided into three groups. Each group, including 30 individuals, was fed with hybrid giant napier (H), formula feed (F), or broad bean (B), respectively. The daily feed amount was 3% of the total weight of grass carps in formula feed group and broad bean group, and 10% of the total weight of grass carps in hybrid giant napier group. The uneaten feed was removed after 1 h of feeding. Broad beans were marinated in fresh water 24 h before they were fed to grass carp. After 2 months of being fed hybrid giant napier, formula feed, or marinated broad bean at 09:00 and 16:00 each day in the artifificial pond, three carps in each diet group were collected and euthanized by submersion in 60 mg/L tricaine methane sulfonate solution.

After two months, the grass carp were dissected under sterile conditions to obtain their hindgut contents for total microbial DNA extraction and SCFA concentration measurements, according to a previously described method (Ni et al., 2014a; Li et al., 2018). The groups were named based on the feed type. For example, FG indicates that the microbiota was collected from the hindgut of grass carp fed with formula feed.

Determination of nutritional contents in feeds

The crude fiber contents, crude ash contents, crude protein contents, and crude fat contents in fresh hybrid giant napier, marinated broad beans, and formula feed were determined according to standard methods (ISO 6541:1981, ISO 5984:2002, ISO 5983:1979, and ISO 6492:1999).

Determination of SCFA concentrations

SCFAs (acetate, propionate, butyrate, iso-butyrate, valerate, and iso-valerate) in feeds and the hindgut contents of grass carp fed with different feeds were analyzed by gas chromatography using the method proposed by Schwiertz et al. (2012), with some modifications. Briefly, each sample of 300 mg (wet weight) was weighed (10^{-4} g precision) and placed in a 2-ml EP tube with 1.2 ml ddH_2O. The mixture was vortexed for 30 s, homogenized in a ball mill for 4 min at 45 Hz, and sonicated for 5 min in ice water. The mixture was centrifuged at 5,000 rpm for 20 min at 4 °C, and the supernatant (0.6 ml) was collected for metabolite extraction. Next, 0.15 ml H_2SO_4 (50%) and 50 μg SCFA/ml ether were added to each supernatant, after which the supernatant was vortexed for 30 s and centrifuged (10 min, 12000 rpm, 4 °C). The supernatant was passed through a nylon filter (0.45 μm) into a gas chromatography vial. SCFAs were analyzed using a GC2025 gas chromatograph (Shimazdu; Kyoto, Japan) with an automatic injector (AOC20i) at 240 °C, using a flame-ionization detector (Shimadzu Deutschland GmbH, Duisburg, Germany) at 240 °C, equipped with an HP-Innowax capillary column (Agilent, Santa Clara, USA; 30 m × 0.25 mm i.d. × 0.25 μm f.d.). The injection volume was 1 μl, the carrier gas was helium (flow rate, 1 ml/min), and the mode of injection was splitless. The oven temperature program was 50 °C for 3 min,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1343513453

followed by an increase to 180 °C (held for 0 min) at 8 °C /min, and a further increase to 200 °C (held for 5 min) at 50 °C/min. Other parameters used were: gas helium flow, 30 ml/min; hydrogen flow, 40 ml/min; and airflow, 400 ml/min.

DNA extraction and sequencing

Total genomic DNA was extracted from the gut samples using a Gut Microbial DNA Extraction Kit (Omega, USA). DNA concentrations and purities were evaluated using 1% agarose gels. DNA samples were diluted to 1 ng/μl using sterile water before amplification was performed (Li et al., 2017).

The V4 region of the 16S rRNA gene was amplified using primers 515F and 806R, which contain sample-specific barcodes (Yan et al., 2016). PCR was performed in 30-μl reaction volumes with 15 μl of the Phusion® High-Fidelity PCR Master Mix (New England BioLabs, USA), 0.2 μM of the forward and reverse primers, and approximately 10 ng of template DNA. The thermal cycling conditions used were as follows: initial denaturation at 98 °C for 1 min; followed by 30 cycles of denaturation at 98 °C for 10 s, annealing at 50 °C for 30 s, and elongation at 72 °C for 60 s; and a final elongation step at 72 °C for 5 min (Li et al., 2018).

The PCR products were mixed with the same volume of 1× loading buffer (containing SYBR Green) and electrophoresed on 2% agarose gels for detection. Samples between 400 and 450 bp in size were chosen for further experiments. The PCR products were mixed at an equidensity ratio; then, the mixed PCR products were purified using the GeneJET Gel Extraction Kit (Thermo Scientific, USA).

Sequencing libraries were constructed using the NEB Next® Ultra™ DNA Library Prep Kit (NEB, USA), according to the manufacturer's recommendations, and index codes were added. The library quality was assessed using a Qubit@ 2.0 Fluorometer (Thermo Scientific, USA) and an Agilent Bioanalyzer 2100 system (Agilent Technologies, USA). Finally, the libraries were sequenced using the Illumina MiSeq platform, and 250-bp paired-end reads were generated.

Sequence data analysis

Paired-end reads from the original DNA fragments were merged using FLASH software. Paired-end reads were assigned to each sample based on the sample-specific barcodes. Sequences analysis was performed using the UPARSE software package with the UPARSE-OTU and UPARSE-OTUref algorithms (Edgar, 2013). QIIME 1.9.0 software (Caporaso et al., 2010) and the vegan package (Dixon, 2003) in the R platform (R Core Team, 2014) were used to analyze alpha (within samples) and beta (among samples) diversity. Sequences with $\geq 97\%$ similarity were assigned to the same operational taxonomic units (OTUs). We selected representative sequences for each OTU and used the RDP classifier to annotate the taxonomic information for each representative sequence (Wang et al., 2007). To compute alpha diversities, we rarified the OTU table and calculated three metrics: Chao1 estimated species abundance, observed species estimated as the number of unique OTUs found in each sample, and the Shannon index. Rarefaction curves were generated based on these three metrics.

Correspondence analysis (CA), non-parametric multivariate analysis of variance (MANOVA) (Anderson, 2001), and non-parametric significance testing of differences were conducted using the vegan package in the R platform. A heatmap profile was drawn using HemI 1.0 (Deng et al., 2014).

DOI: http://dx.doi.org/10.15666/aeer/1706_1343513453

All sequencing data were deposited in the NCBI Sequence Read Archive (SRA) under accession number SRP080980. The SRA records can be accessed at http://www.ncbi.nlm.nih.gov/sra/SRP080980.

SCFA data analysis

Statistical analysis was performed using R software, version 3.0.1. Data are displayed as the mean ± standard error (S.E.). The Kruskal–Wallis test was applied to analyze global differences among three groups. Tukey's method was used as a post-hoc test for multiple comparisons of means.

Results

Nutrient content in the three feeds and growth of grass carp

As expected, fresh hybrid giant napier contained the highest content of crude fiber (23.96 ± 1.68%, dry matter), followed by formula feed (9.70 ± 0.46%, dry matter) and marinated broad beans (1.98 ± 0.89%, dry matter). Fresh hybrid giant napier contained the lowest content of crude protein (12.36 ± 1.92%, dry matter), followed by formula feed (28.78 ± 0.00%, dry matter) and marinated broad beans (31.78 ± 1.86%, dry matter) (*Table 1*).

Table 1. *Nutrient contents in three feeds used to feed grass carp (% dry matter). The superscripted lowercase letters indicate significant differences observed between different feeds. The same superscripted letters reflect cases where no significant difference was found, whereas different superscripted letters represent cases where significant differences were found ($p < 0.05$)*

Nutrient component	Hybrid giant napier (%)		Broad bean (%)		Formula feed (%)	
	Mean	S. E.	Mean	S. E.	Mean	S. E.
Crude fiber content	23.96^{a}	1.68	1.98^{c}	0.89	9.70^{b}	0.46
Crude ash content	13.33^{a}	1.20	3.76^{c}	0.00	7.53^{b}	0.07
Crude protein content	12.36^{a}	1.92	31.78^{c}	1.86	28.78^{b}	0.00
Crude fat content	3.23^{b}	0.13	$< 1.11^{*a}$	NA	5.42^{c}	0.26

*The content of crude fat in the marinated broad beans was below the limit of detection

At the start of the experiment, the average weights of grass carp in groups fed hybrid giant napier, formula feed, and marinated broad bean were 501.5 ± 20.17 g, 501.33 ± 15.00 g, and 498.83 ± 21.44 g, respectively. No significant differences were observed. However, at the end of the two-month experiment, the average weights were 680.17 ± 15.17 g, 918.00 ± 46.67 g, and 602.50 ± 10.50 g, respectively. The weight increases were 178.67 ± 13.67 g, 416.67 ± 53.33 g, and 103.67 ± 15.11 g, which represented significant differences, in each case (*Appendix 1*).

Concentrations of SCFAs in feeds and gut contents of grass carp fed different feeds

The concentrations of acetate, propionate, and i-valerate in broad beans were the highest among the three feeds, whereas the absolute concentrations of all SCFAs in the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1343513453

hindguts of grass carp fed with formula feed were the highest (1.95 ± 1.06 mmol/kg, 0.54 ± 0.16 mmol/kg, and 0.13 ± 0.01 mmol/kg for acetate, propionate, and butyrate, respectively), followed by those from grass carp fed marinated broad beans and fresh hybrid giant napier (*Table 2*). Although the absolute concentrations were different, the three most dominant SCFAs in the guts of all of grass carp fed with different feeds were acetate, propionate, and butyrate. The ratios of their concentrations (approximately 14.3: 2.5: 1) were similar in all grass carp contents (*Table 2*). These results showed that the SCFA concentrations in the feeds and the metabolic activity of the hindgut microbiota markedly influenced SCFA concentrations in the hindgut of grass carp.

Table 2. *Absolute concentrations of short-chain fatty acids (SCFAs) in the three feeds and in the hindguts of grass carp fed with the three feeds. The same superscripted letter shows instances where no significant difference was found, and different superscripted letters indicate cases where significant differences ($p < 0.05$) were found. Data are displayed as the mean ± standard error (S.E.)*

	Sample size	Acetate (mmol/kg)	Propionate (mmol/kg)	Butyrate (mmol/kg)	Iso-butyrate (mmol/kg)	Valerate (mmol/kg)	Iso-valerate (mmol/kg)
HG	3	0.31 ± 0.03	0.02 ± 0.00^a	0.01 ± 0.00^a	0.01 ± 0.00^a	0.00 ± 0.00^a	0.00 ± 0.00^a
BG	3	1.07 ± 0.51	0.14 ± 0.03^a	0.04 ± 0.02^a	0.01 ± 0.00^a	0.00 ± 0.00^a	0.01 ± 0.00^a
FG	3	1.95 ± 1.06	0.54 ± 0.16^b	0.13 ± 0.01^b	0.03 ± 0.00^b	0.02 ± 0.00^b	0.03 ± 0.00^b
H	3	0.14 ± 0.01	0.01 ± 0.00	0.01 ± 0.00	0.01 ± 0.00	0.00 ± 0.00	0.00 ± 0.00
B	3	1.82 ± 1.15	0.26 ± 0.34	0.05 ± 0.06	0.02 ± 0.01	0.01 ± 0.00	0.04 ± 0.01
F	3	1.05 ± 0.04	0.20 ± 0.01	0.08 ± 0.00	0.02 ± 0.00	0.01 ± 0.00	0.02 ± 0.00

To measure the SCFA increment in the hindgut region of grass carp fed with different feeds, the ratios of SCFA concentrations in the hindgut of each group to those in the feed were calculated. In terms of the total SCFA concentration (i.e., the sum of the concentrations of acetate, propionate, butyrate, iso-butyrate, valerate, and iso-valerate), the ratio for HG was the highest (1.98), followed by those for FG (1.95) and BG (0.58). The crude fiber contents in different feeds positively associated with SCFA ($R^2 = 0.890$) and acetate ($R^2 = 0.989$) increments in grass carp, but negatively associated with propionate ($R^2 = 0.895$) and butyrate ($R^2 = 0.837$) increases (*Fig. 1*). These findings implied that incremental changes of SCFAs, especially acetate in the hindguts of grass carp, were associated with the fiber contents of feeds.

Gut microbiota composition of grass carp fed different feeds

In this study, 451,160 high-quality spliced sequences from 9 samples were obtained. To eliminate the impediment of sequencing depths for each sample in determining the reliability, each sample was re-sampled at 29,918 sequences to assess their microbiotas. After re-sampling, 628 OTUs from 284 genera were detected using the criterion of 97% sequence similarity. An average of 190 OTUs (ranging from 93

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1343513453

to 310) were detected in each sample (*Appendix 2*). The alpha diversity (Chao1 and Shannon indexes) of the gut microbiota was highest in the BG group, followed by the HG group, and lowest in the FG group (*Appendix 2*). The rarefaction curves of the OTUs showed that the sequence datasets could be used to represent the diversities and structures of each microbiota (*Appendix 3*).

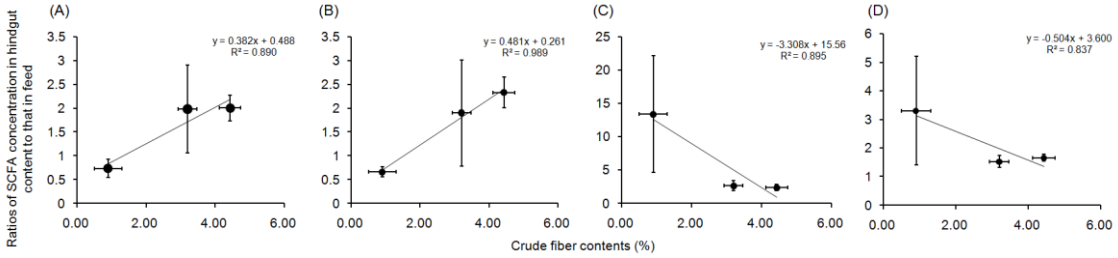

Figure 1. *Ratios of SCFA concentrations in the hindguts of grass carp to those in different feeds. (A) Ratios of all SCFA concentrations (i.e. total concentrations of acetate, propionate, butyrate, iso-butyrate, valerate, and iso-valerate). (B) Ratios for acetate. (C) Ratios for propionate. (D) Ratios for butyrate*

Except for a minority of sequences (ranging from 0.03% to 0.17%) that could not be classified into any phylum, 19 phyla consisting of 1 Archaea phylum and 18 Bacteria phyla were found. Fusobacteria (40.92%), Proteobacteria (26.40%), Firmicutes (25.04%), Bacteroidetes (5.61%), and Cyanobacteria (1.46%) were the dominant phyla in the gut microbiota of the grass carp (*Fig. 2A*). In this study, differences in the phylum compositions of the gut microbiota among the grass carp fed different diets were observed. The relative abundance of Bacteroidetes in the hindgut microbiota of the BG group was significantly higher than that found with the other diets, whereas the relative abundance of Fusobacteria was significantly lower (*Fig. 2B*). The relative abundance of Firmicutes in the hindgut microbiota of the FG group was significantly lower than that in the other groups (*Fig. 2B*). Moreover, the relative abundance of Proteobacteria in the BG group was significantly higher than that of the HG group (*Fig. 2B*). These results indicated that diet could fundamentally change the gut microbiota composition at the phylum level.

CA based on the OTUs and genus compositions of the samples showed a clear separation of the community composition among three treatment groups and revealed that diet significantly changed the hindgut microbiota of grass carp (*Fig. 3A* and *B*). MANOVA also revealed distinct differences among the gut microbiota of grass carp fed with different feeds ($P < 0.05$).

Fifty-three dominant genera (relative abundances > 0.1% in at least one sample) was detected. They clustered into three different groups according to diet (*Fig. 4A*). The relative abundances of *Cetobacterium* in the FG and HG were obviously higher than those in the BG group. The relative abundances of *Lactobacillus*, *Pediococcus*, *Bacillus*, an unidentified Streptophyta genus, and an unidentified Staphylococcaceae genus in the HG group were obviously higher than those in the FG and BG groups. The relative abundances of *u114* of Fusobacteriaceae and an unidentified Betaproteobacteria genus in the FG group were obviously higher than those in the BG and HG groups, whereas the relative abundances of *Bacteroides*, *Tolumonas*, an unidentified Lachnospiraceae genus, and an unidentified Enterobacteriaceae genus

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1343513453

were obviously higher in the BG group than those in the HG and FG groups (*Fig. 4A*). LEfSe results showed that the increased genus biomarkers in the HG group mostly concentrated in *Lactobacillus*, *Pediococcus*, *Streptococcus*, *Enterococcus*, and *Leptotrichia*; the increased genus biomarkers in the BG group mostly concentrated in *Rhodobacter* and *Uliginosibacterium*; and the increased genus biomarker in the FG group was mostly represented by *Fusobacteria* (*Fig. 4B*).

Discussion

Effects of diet on hindgut SCFA accumulation and the growth of grass carp

Our results showed that changing the diet from natural food to formula feed significantly influenced the accumulation of SCFAs in the hindgut of grass carp (*Table 2*). Two dietary factors influenced SCFA accumulation in the hindgut of grass carp. Firstly, the diet directly supplied SCFAs to the hindgut of grass carp. Although SCFAs are thought to be mainly produced through carbohydrate fermentation by microorganisms, all three feeds had detectable SCFAs in this study (*Table 2*). Secondly, the amounts and species of SCFAs are significantly influenced by carbohydrate substrates (Hao et al., 2017a; Mountfort et al., 1993; Kihara and Sakata, 1997; Probert et al., 2004; Geraylou et al., 2014). Starch is seemingly more easily utilized to produce SCFAs through fermentation by gut microbiota in many fish (Kihara and Sakata, 1997; Van, 1994; Leenhouwers et al., 2007). This could explain the increased growth in grass carp fed formula feed compared with those fed with hybrid giant napier or broad beans, as formula feed contains more starch and higher luminal concentrations of SCFAs (*Table 2*).

Proportional model and concentrations of SCFA metabolites in the grass carp hindgut

In mammals and fishes, the SCFA metabolites produced during gut fermentation were mostly acetate, propionate, and butyrate (Clements et al., 1994; Hao et al., 2017b; Bergman, 1990; Smith et al., 1996; Cook and Sellin, 1998), and these metabolites were produced at different ratios. Acetate accumulation was most abundant (~60%), followed by propionate (~25%) and then, to a much lesser degree, by butyrate (~15%) in human intestines (Fukuda et al., 2012). Although the ratios of acetate, propionate, and butyrate fluctuate among different species, the trends of these ratios (acetate > propionate ≥ butyrate) were identical between mammals and fishes (Clements et al., 1994; Hao et al., 2017b; Bergman, 1990; Smith et al., 1996), with few exceptions in marine fishes (Kandel et al., 1994). Mountfort et al. (2002) reported the ratio of their concentrations in three species of marine fish as ranging from approximately 6.4: 3.2: 1 to 28.8: 9.8: 1, on average. In this study, the ratio of these concentrations was approximately 14.3: 2.5: 1 (*Table 2*). Therefore, changes in the acetate concentration primarily influenced the concentration of total SCFAs.

We found that the SCFA concentration in the grass carp hindgut ranged from 0.35 to 2.70 mmol/kg, which is similar to findings reported by Hao et al. (2017a), but were lower than those reported by Paris et al. (Paris et al., 1977). Clements et al. (2014) compared the SCFA concentrations in the hindgut contents of 18 fishes. The SCFA concentrations ranged from 1.70 to 38.00 mM. In addition, the SCFA concentrations in hindgut contents of freshwater herbivore fish were commonly lower than in other fishes (Clements et al., 2014).

Effect of dietary crude fiber contents on the SCFA increment of the grass carp hindgut microbiota

Gut microbiota ferment dietary cellulose to SCFAs as energy sources and signal-transduction molecules in humans and mammals (Spiljar et al., 2017; Postler and Ghosh, 2017; Bindels et al., 2012; Hullar and Fu, 2014). Data from previous studies

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1343513453

also indicated that the gut microbiota in herbivorous fish are capable of cellulose fermentation (Hao et al., 2017a, b; Ni et al., 2014a). Hao et al. (2017a) studied the influence of diets on the SCFA concentrations in the grass carp hindgut. Although they found that diets influenced SCFA concentrations in the hindgut, the influence of dietary SCFA concentrations was not demonstrated. The association between SCFA concentrations and the dietary cellulose contents was also not analyzed. However, the intestinal SCFA concentrations were clearly influenced by the dietary contents, as also shown in this study. Here, we used the ratios of intestinal SCFA concentrations to dietary SCFA concentrations to (i) exclude the influence of dietary SCFA concentrations on intestinal SCFA concentrations and to (ii) determine the SCFA increment. We found that the SCFA increment associated positively with the dietary cellulose contents in the three diets. The acetate increment, which represented the largest proportion of SCFAs, was highly positively associated with the dietary cellulose contents, but the increments of propionate and butyrate associated negatively with the dietary cellulose contents (*Fig. 1*). These results implied that acetate was probably produced in the hindgut of grass carp through cellulose fermentation, and the produced rates were faster than hindgut-absorption rates in the HG and FG, as the ratios were more than 1. However, most propionate and butyrate were probably not produced through cellulose fermentation, and their production and absorption in the hindgut were probably influenced by other undetected factors.

Effect of dietary cellulose contents on the structure of grass carp hindgut microbiota

In our study, we verified that the diet significantly changed the hindgut microbiota of grass carp, as reported previously (Ni et al., 2014b; Hao et al., 2017a). Changes in the hindgut microbiota of grass carp fed different diets also emerged at the phylum, genus, and OTU levels (*Figs. 2–4*). Similar to previous reports in grass carp and other fish (Hao et al., 2017b; Ni et al., 2014b; Miyake et al., 2015; Zhang et al., 2017), we found that Fusobacteria, Proteobacteria, Firmicutes, Bacteroidetes, and Cyanobacteria were the dominant phyla in the gut microbiota of the grass carp. However, their relative abundances acutely fluctuated between individuals fed different feeds or living in different habitats. Proteobacteria species dominate the intestines of many fish species, with differences found in the resident microbes (Zhang et al., 2017; Xia et al., 2014; Piazzon et al., 2017). Overgrowth of Proteobacteria was commonly associated with gut microbial dysbiosis and over-accumulation of energy in mammals. For instance, in Western-style diets, which are low in fiber, decreased beneficial Bacteroidetes and increased Proteobacteria levels are found, compared with those in a high-fiber diet (Geraylou et al., 2013). Dulski et al. (2018) speculated that Proteobacteria inhabiting the gut microbiota at an early stage of life are a necessary component of the pikeperch (*Sander lucioperca*) microbiome that may support proper nutrition of the fish. Fusobacteria species also dominated the intestines of grass carp in this study, as observed in other studies (Xia et al., 2014). However, the relative abundance of Fusobacteria species showed large fluctuations among different individuals under different conditions (Xia et al., 2014; Piazzon et al., 2017). Fusobacteria has been found to produce butyric acid as a major product of fermentation (Anand et al., 2016), and some species have been associated with diseases in mammals (Bennett and Eley, 1993).

CA of the 16S rRNA gene-sequencing results also revealed that gut bacterial communities from grass carp fed different diets formed different clusters (*Fig. 3A* and *B*). The *Pediococcus*, *Lactobacillus*, *Streptococcus*, *Enterococcus*, and *Leptotrichia*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1343513453

genus biomarkers increased in the HG group (*Fig. 4B*). They were mostly represented by the Bacilli class, which contains many SCFA-producing bacteria, such as *Pediococcus* and *Lactobacillus* (Leblanc et al., 2017; Johansson et al., 1998; Li et al., 2016b, 2009; Dar et al., 2015).

Fermentation of cellulose by the gut microbiota is a major source of SCFA production (Leblanc et al., 2017; Kasubuchi et al., 2015; Flint et al., 2015). The grass carp is basically herbivorous (Ni et al., 2014a; Wu et al., 2012), and its cellulose-degrading capability is important for improving the utilization rate of plant polysaccharides and the production of SCFAs (Li et al., 2016a). In this study, most bacteria showing changes in abundance were related to SCFA production. For instance, the relative abundances of *Cetobacterium* in the HG and FG groups were obviously higher than that in the BG group. Tsuchiya et al. (2008) reported that the *Cetobacterium* abundance positively associated with acetic and propionic acid production through fermentation. The ratios of the SCFA concentrations in the HG and FG hindgut contents of grass carp to those in the feed were also obviously higher.

The ability of both lactobacilli and *Pediococcus* to produce SCFAs is well documented (Leblanc et al., 2017; Zhang et al., 2017). For instance, Geraylou et al. (2013) found that arabinoxylan-derived oligosaccharides could stimulate the growth of lactic acid bacteria and *Clostridium* sp. in the sturgeon gut and enhance the SCFA levels in the hindgut of sturgeon. Within 24 h, supplementation of *Lactobacillus salivarius* JCM 1230 and *Lactobacillus agilis* JCM 1048 in a simulated chicken cecum significantly increased propionate and butyrate formation (Meimandipour et al., 2010). Moreover, *L. acidophilus* CRL 1014 was also reported to increase the SCFA concentrations in a simulated human microbial ecosystem (Sivieri et al., 2013). Recently, *Lactobacillus rhamnosus* GG was included in a study with a mix of probiotic strains and prebiotics, where it could metabolize these prebiotics, leading to SCFA production (Leblanc et al., 2017). In our study, the relative abundances of *Lactobacillus* in the HG group were obviously higher compared to the other groups (*Fig. 4A*), as was the SCFA-production capability (*Fig. 1A*). Bacterial strains of *Pediococcus* have been widely reported as SCFA-producing bacteria (Dineshkumar, and Renu, 2008; Taheri et al., 2015). For instance, Iehata et al. (2010) reported *Pediococcus* sp. Ab1 treatment could improve the gut environment of the abalone, *Haliotis gigantea*. In our study, the relative abundances of *Pediococcus* in the HG group were obviously higher those in the other groups (*Fig. 4A*). Bacterial strains of *Bacillus* and *Bacteroides* were also reported to cause cell lysis and to be capable of SCFA and branched-chain short fatty acid biosynthesis (Kaneda, 1963; Mayhew et al., 1975; Dreher et al., 1976; Tsuchido et al., 1985; Pogribna et al., 2010; Ray et al., 2012; Hong et al., 2017). For instance, Li et al. (2016a) isolated some cellulolytic *Bacillus* strains from the gut contents of grass carp. Ray et al. (2012) reported that many *Bacillus* sp. could produce cellulase. Bacilli is the primary producers of butyrate (Flint et al., 2015; Kaoutari et al., 2013; Levy et al., 2016). Our results showed that the elevated genera in the HG group were mostly represented by Bacilli (*Fig. 4B*). These results implied that cellulolytic bacteria would be enriched with high-cellulose substrates in the hindgut of grass carp. In addition, SCFAs were also indirectly produced from other intermediates that were produced by polysaccharide fermentation. For instance, lactate, which is produced by many members of the human gut microbiome, can serve as a substrate for the bacterial production of propionate (e.g., *Coprococcus catus*) and butyrate (e.g., *Eubacterium hallii* and *Anaerostipes caccae*) (Duncan et al., 2004; Reichardt et al., 2014). These findings imply

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1343513453

that bacteria related to the SCFA concentration may not directly produce SCFAs, although they can increase the SCFA concentrations in the gut.

Conclusions

We conducted the first quantitative analysis of the association between SCFA accumulation and the dietary cellulose contents in this study. We found that the HG, which contained the highest dietary cellulose, exhibited the highest SCFA increase, even though the absolute concentration of SCFAs was higher in the FG, which contained more easily fermentable polysaccharides. Moreover, SCFA-producing bacteria, such as *Lactobacillus*, *Pediococcus*, and *Bacillus*, were significantly enhanced in the hindgut microbiota of the HG group. These results implied that the dietary cellulose content influenced the production of SCFAs in the grass carp hindgut by regulating the relative abundances of gut bacteria related to SCFA production. In addition, our results implied that adding appropriate proportion of cellulose or grass meal to grass carp feed could help to regulate the intestinal microbiota, and thereby increasing the content of SCFAs and increasing the growth and health of grass carp. However, the regulating mechanism of intestinal microbiota of grass carp to the productions of SCFAs needed to further study. These results would provide important reference for the design of grass carp feed formulation, and expand our understanding of the relationship between intestinal microbiota and grass carp metabolism.

Acknowledgements. We sincerely appreciate Yifei Wang and Wen Lou for their help in catching the experimental fish. We wish to thank Guangdong Meilikang BioScience, Ltd., for his help in analyzing the sequencing data and generating the pictures. This work was supported by the Central Public-interest Scientific Institution Basal Research Fund CAFS [2019XT0405, 2017HY-ZC0503] and the Modern Agro-industry Technology Research System [CARS-45-21].

Abstract. In this study, the nylon net bag method was used to explore the characteristics of straw decomposition and nutrient release under different organic fertilizer replacement rates, which provided a scientific basis for rational straw returning in corn (*Zea mays* L.) planting. The results showed that the characteristics of straw decomposition and nutrient release in different treatments were fast in the early stage (0-20 d) and slow in the late stage (20-100 d). At the end of decomposition (100 d), the decomposition rate and nutrient release rate were 47.69%-56.07%, 47.55%-61.73%, 47.40%-62.67%, 48.04%-66.35% and 82.20%-100.00%, respectively, decomposition rate and nutrient release rate were 8%OF (organic fertilizer replaces 8% N fertilizer) > 16%OF (organic fertilizer replaces 16% N fertilizer) > 24%OF (organic fertilizer replaces 24% N fertilizer) > CF (only chemical fertilizer) > CK (no fertilizer control). Through the model ($y = a \cdot x^b$) analysis of nutrient release rate, the time until complete release of C, N, P, and K was predicted to be 206-275 d, 167-271 d, 153-248 d, and 85-150 d, respectively, and it was verified that the nutrient release characteristics of fertilization treatment (CF, 8%OF, 16%OF, 24%OF) in this experiment were potassium (K) > phosphorus (P) > nitrogen (N) > carbon (C), and CK was K > P > N ≈ C. Based on the model and correlation analysis, the recommended organic fertilizer replacement rate is 12%, and according to the characteristics of straw decomposition and nutrient release, a strategy of rational straw returning and fertilization management was proposed.

Keywords: *corn straw returning, corn planting, nutrient, fertilizer reduction, fertilization strategy, model, prediction*

Introduction

Corn is China's main food and feed crop, and it plays an important strategic role in achieving food security. Excessive application of chemical fertilizers in agricultural production to ensure the increase of crop yields has caused problems such as increased planting costs, low nutrient use efficiency, reduced soil fertility, and agricultural non-point source pollution, and threatened the sustainable development of agro-ecology in China (Fischer, 2010; Jin and Zhou, 2018). In the past decade, corn has contributed 31.8% of the total increase in chemical fertilizer use in China. In 2015, the Ministry of Agriculture of China put forward the *2020 Fertilizer Use Zero Growth Action Plan* to reduce the use of chemical fertilizers (Jin et al., 2015). Therefore, reducing the consumption of chemical fertilizer in corn production is bound to be conducive to the realization of "Fertilizer Use Zero Growth". The increase in corn yield also produces many straw resources. Crop straw is a kind of biomass resource, but it has not been used reasonably. There are high amounts of straws being burned and discarded, which not only causes waste of resources but also brings a series of environmental issues, among them, straw burning has discharged many CO_2, CO, particulate matter, etc.,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1345513472

which wastes biomass energy and causes losses for the agricultural carbon pool, serious air pollution and soil health hazards (Feng et al., 2011; Sun et al., 2016; Li and Wang, 2013; Zhang et al., 2016). Therefore, reducing the use of chemical fertilizers and the effective use of straw resources has become a major challenge for sustainable development of green and traditional agriculture.

At present, straw returning and organic fertilizer replacing part of chemical fertilizer has become the main measures to realize the effective utilization of straw resources and reduce the use of chemical fertilizer. After organic fertilizer replaces part of chemical fertilizer, it can reduce the amount of chemical fertilizer, improve the physical and chemical properties and buffering properties of soil, improve soil fertility and microbial activity, and coordinate the balanced supply of nutrients in soil (Liu et al., 2013; Fu et al., 2017; Wen et al., 2018). Crop straw is an important renewable resource in the agricultural ecosystem. It contains abundant C, N, P, K and trace elements (Wang et al., 2010). After returning to the field, soil microorganisms and enzymes act together to decompose, release C, N, P, K and other nutrients to the soil, and provide crop absorption and utilization (Becker et al., 2014), which can improve soil fertility and soil physical and chemical properties, it can reduce the negative impact of burning straw on the ecological environment. Straw returning is the most economical and sustainable way to use straw resources (Yin et al., 2017).

In recent years, to solve the problems of waste of agricultural resources and alleviate the excessive application of chemical fertilizer, soil degradation and agricultural non-point source pollution, the nutrients released during the decomposition of crop straw are used to reduce the amount of chemical fertilizer application. Therefore, the research on crop straw decomposition has become a hot topic of many scholars' attention (Abdou et al., 2016; Wang et al., 2018; Gong et al., 2018). Some studies have found that with the increase of decomposition days, the decomposition rate and nutrient release rate of straw gradually increase and the decomposition speed gradually decreases. The decomposition rate of different straws is fast in the early stage and slow in the later stage (Li et al., 2009; Dai et al., 2010; Dai et al., 2017). The application of chemical fertilizer or decomposition agent in the soil can promote the decomposition of straw (Chen et al., 2016; Ngatia et al., 2014). For the different crop straw or the different forms and contents of nutrients in the straw, the release rates of nutrients are different. Some studies found that K > P > N > C (Dai et al., 2010; Wu et al., 2011), and others found that K > P > C > N (Li et al., 2017). Therefore, the study of the characteristics of straw decomposition and nutrient release is the theoretical basis for guiding straw returning in agricultural production.

There are many studies on straw decomposition, but there are few studies on straw decomposition under different organic fertilizer replaces chemical fertilizer rate. Xinjiang Province is one of the major corn planting regions in China. The resources of corn straw are abundant but not effectively utilized, and it has great potential to straw returning. At the same time, the phenomenon of excessive fertilization in production is more common. Therefore, this study is based on the phenomenon that straw resources are not effectively utilized and excessive fertilization. The nylon net bag method was used to carry out decomposition experiments because this method has little impact on soil water transport and is closer to the actual situation in the field; this method is suitable for studying the decomposition of crop straw in arid and semi-arid regions (Lin et al., 1992; Bocock and Gilbert, 1957). To explore the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1345513472

characteristics of decomposition and nutrient release of corn straw under different organic fertilizer replacement rate under equal nutrient conditions, establish and analyse decomposition and nutrient models, dynamically monitor and predict them, and recommend suitable organic fertilizer replacement rate, To provide a scientific basis for straw returning and rational fertilization in corn cultivation is of great significance for the effective utilization of straw resources and to reduce chemical fertilizer application and sustainable development of agriculture.

Materials and methods

Site description

The experimental site is located in the Demonstration Park of Agricultural Technology (DPAT) in Yining, Xinjiang, Northwest China (43°55'30"N, 81°33'29''E), the site has an elevation of 683 m and is moderate temperate arid inland mountain climate, four seasons are clear and sunshine is sufficient. The annual precipitation is 250-551.7 mm, the annual average temperature and maximum temperature are 10.6 °C and 35.8 °C, respectively, the effective accumulated temperature ≥ 10 °C is 3621.2 °C, the annual duration of sunshine is 2792.7 h, and the frostless season is 154-184 d. The soil type is irrigated lime-calcareous soil, and the physicochemical properties of the soil tillage layer (0-20 cm) are as follows: pH, 7.71; alkali N, 85.95 mg kg^{-1}; available K, available P, 23.94 mg kg^{-1}; 229.24 mg kg^{-1}; soil organic C, 7.38 g kg^{-1}; total N, 0.96 g kg^{-1}.

Materials

The experimental straw is corn straw (comprised the stems, leaves, and sheaths) preserved after harvesting and drying in the experimental site in 2017, and its initial nutrient contents were as follows: C, 413.50 g kg^{-1}; N, 19.47 g kg^{-1}; P, 3.09 g kg^{-1}; and K, 17.53 g kg^{-1}, C/N ratio, 21.24, C/P ratio, 133.82, C/K ratio, 23.59. The local conventional fertilizers (NPK fertilizer) mainly uses urea (contains 46.0% N), diammonium phosphate (contains 18.0% N, 48.0% P_2O_5), potassium sulfate (contains 51.0% K_2O); the commercial organic fertilizer (contains 1.77% N, 1.95% P_2O_5, 0.53% K_2O).

Experimental design

The experiment was conducted from 8 May to 16 August 2018. On the basis of equal nutrient conditions, straw decomposition experiments under different organic fertilizer replacement rates were carried out, and five treatments were set up: (1) CK: no fertilizer control; (2) CF: only chemical fertilizer; (3) 8%OF: organic fertilizer replaces 8% N fertilizer; (4) 16%OF: organic fertilizer replaces 16% N fertilizer; (5) 24%OF: organic fertilizer replaces 24% N fertilizer. Before spring tillage, commercial organic fertilizer, 40% N fertilizer and P and K fertilizer were applied as base fertilizer, and the remaining 60% N fertilizer was artificially applied urea (ditch application) at jointing stage. The fertilization scheme is shown in *Table 1*. Random block arrangement was adopted, with three replicates per treatment, and the area of the plot was 32.4 m^2 (4 m × 8.1 m), and the corn (*Zea mays* L., *cv.* Xinyu 50) is planted in the plot, the row spacing is 50.0 cm (8 rows in total), plant spacing is 21.5 cm, the planting density is 9.3×10^4 plants hm^{-2}.

Table 1. *Fertilization schemes for different treatments*

Treatment	*k* (%)	Base fertilizer						Topdressing chemical-N	Total nutrient contents		
		Chemical fertilizer			Organic fertilizer						
		N	P_2O_5	K_2O	N	P_2O_5	K_2O	N	N	P_2O_5	K_2O
CK	-	0	0	0	0	0	0	0	0	0	0
CF	0	120.0	180.0	60.0	0	0	0	180.0	300.0	180.0	60.0
8%OF	8	96.0	153.0	52.5	24.0	27.0	7.5	180.0	300.0	180.0	60.0
16%OF	16	72.0	127.5	45.0	48.0	52.5	15.0	180.0	300.0	180.0	60.0
24%OF	24	48.0	100.5	37.5	72.0	79.5	22.5	180.0	300.0	180.0	60.0

According to the organic fertilizer replacement rate (*k*), the replacement N content is calculated, and the organic fertilizer dosage and PK replacement amount are calculated according to the nutrient content of organic fertilizer

The decomposition experiment adopts the nylon net bag method, and the corn straw is dried and pulverized into 3 to 5 cm, mixed, weighed 30.0 g (equivalent to 5000 kg ha^{-1}, half amount of returning to the field) and then placed in a nylon net bag (whose length × width was 30 cm × 20 cm, with a pore diameter of 0.125 mm), after which the opening of each bag was tightly closed, and the bags were laid flat about 2 cm high, and each treatment was 15 bags, and the experiment was a total of 75 bags (5 treatments × 3 replicates × 5 samples). After corn emerged 2-3 cm, the bag was buried. The specific operational steps of the buried bag: at the centre of each plot, nylon net bags were buried 10 cm below the 2-6 inter-row tillage layers. When landfilling, the soil 10 cm depth between rows of corn is taken out, the soil deep in the 2 cm is dug out (no landfill), then the nylon net bag is laid horizontally, and then the soil is filled back and compacted to the level with the ground (*Fig. 1*). The experimental period was 100 days, and 15 nylon net bags were taken every 20 days for 5 times, and recorded the precipitation and temperature conditions during the decomposition period (*Fig. 2*). To avoid the interference of topdressing on the determination of nutrient content of corn straw residues, no topdressing was carried out in the area where straw was buried.

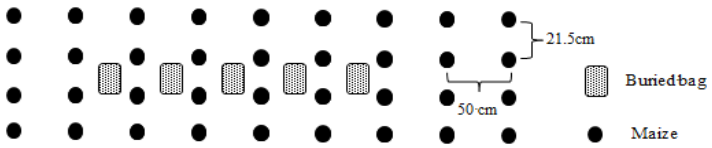

Figure 1. *Schematic diagram of buried bag of corn straw*

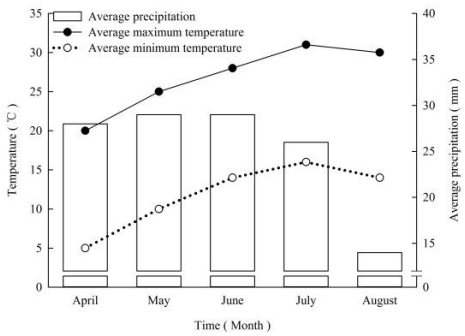

Figure 2. *Temperature during decomposition experimental period*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1345513472

Sampling and chemical analysis

Sampling began on May 28, 2018, sampling was performed at 20, 40, 60, 80, and 100 days (decomposition day is 20, 40, 60, 80 and 100 days) after the bag was buried (sampling a total of 5 times), and August 16th, 2018 was the last sample. After sampling, the surface of the nylon net bag and the root debris were removed, and the nylon net bag was rinsed clean, then the straw in the net bag was taken out and placed in an oven (KJ-DY02, Kejie Company, China) at 65 °C to dry to constant weight. The dry weight of the straw was measured, and the sieve was passed through a 1 mm sieve to determine the C, N, P, and K of the straw.

The dry matter weight of the straw was determined by a drying-weighing method. The carbon (C) of straw was determined by potassium dichromate (133 mmol L^{-1} $K_2Cr_2O_7$) external heating (at 170-180 °C) method. After the corn straw sample (0.25 g) was digested by the sulfuric acid-hydrogen peroxide (H_2SO_4-H_2O_2) at 380 °C, the nitrogen (N) of straw was determined by Nessler's colorimetry method (722N, JKI Company, China), the phosphorus (P) of straw was determined by vanadium molybdate yellow colorimetric method (722N, JKI Company, China), the potassium (K) of straw was determined by flame photometer method (FP640N, OEM Company, China). The above indicators are determined by reference to Bao (2000).

Statistical analysis and calculation

Data processing, analysis and plotting were performed using Microsoft Excel 2010 and SPSS 17.0 software. Correlation analyses were performed using the Pearson method.

Organic fertilizer replacement rates in different treatments were calculated as follows:

$$k = \frac{\text{Organic fertilizer N contact}}{\text{Total N contact}} \quad \text{(Eq.1)}$$

Calculate the decomposition rate, decomposition speed, nutrient release rate, and C/N ratio methods (Liu et al., 2016; Huang et al., 2017) (*Eqs. 2-5*):

$$\text{Decomposition rate (\%)} = \frac{M_0 - M_t}{M_0} \times 100\% \quad \text{(Eq.2)}$$

$$\text{Decomposition speed (g day}^{-1}\text{)} = \frac{M_0 - M_t}{t} \quad \text{(Eq.3)}$$

$$\text{Nutrient release rate (\%)} = \frac{M_0 \cdot C_0 - M_t \cdot C_t}{M_0 \cdot C_0} \times 100\% \quad \text{(Eq.4)}$$

$$\text{Ratio of C to nutrients in straw residue} = \frac{C_t\ (C)}{C_t\ (N,\ P \text{ or } K)} \quad \text{(Eq.5)}$$

where *t* (d) *is the decomposition day;* M_0 (g) is the initial straw dry weight; M_t (g) is the straw dry weight at t; C_0 (g kg^{-1}) is the initial straw nutrient content; C_t (g kg^{-1}) is the straw nutrient content at t.

Models of straw decomposition rate and nutrient release rate under different decomposition days (Chapman, 1997; Stanford, et al., 1972; Chen et al., 2009):

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1345513472

$$y = a \cdot x^b \quad \text{(Eq.6)}$$

where y is the decomposition rate or nutrient release rate; x is the decomposition day; a is the release rate of some nutrients in straw which can be achieved quickly; b is the release rate growth parameter, indicating that the release rate increases faster.

Results

Straw decomposition characteristics

As the decomposition progresses, the decomposition rate increased, and the decomposition speed decreased. The whole decomposition process showed the characteristic of fast in the early stage and slows in the later stage (*Fig. 3*). In the first 20 days, the decomposition speed was faster, reaching 254.83-308.83 mg d^{-1} and the decomposition rate increased rapidly, reaching 16.99%-20.59%, accounting for 33.43%-36.72% of the total decomposition rate, both decomposition rate and decomposition speed were 8%OF > 16%OF > 24%OF > CF > CK. After 20 days, the decomposition speed began to decrease, and then it was relatively stable, and the decomposition rate was slowed down. At the end of decomposition (100 d), decomposition speed was 143.33-170.00 mg d^{-1}, and the decomposition rate reached 47.69%-56.07%. The order of decomposition rate and decomposition speed was 8%OF > 16%OF > 24%OF > CF > CK.

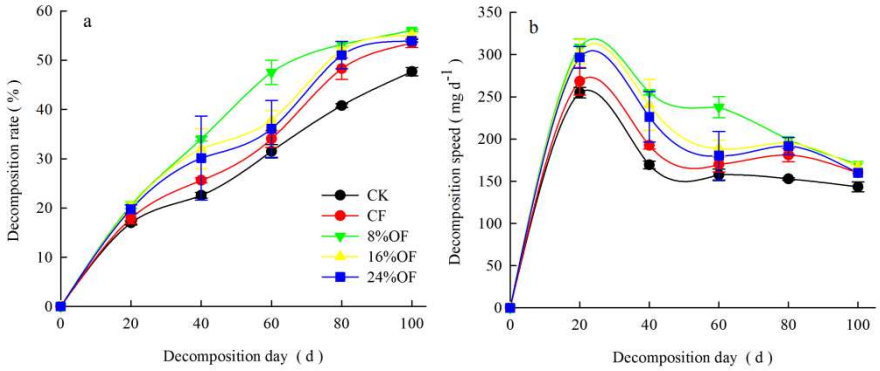

Figure 3. *Decomposition characteristics of corn straw under different amounts of returned straw. In the figure, a and b represent the decomposition rate and decomposition speed, respectively*

Nutrient release characteristics

The nutrient release characteristics are similar to the decomposition characteristics, showing that nutrient release was faster in the early stage (0-20 d) and slower in the late stage (20-100 d) (*Fig. 4*). The release rates of C, N, P and K in each treatment were 14.72%-25.91%, 14.99%-20.46%, 16.90%-23.68%, and 42.10%-61.36%, respectively, accounting for 30.96%-46.83%, 29.91%-34.79%, 34.15%-35.88% and 47.62%-61.36% of the total release rate, respectively, and the order of each nutrient release rate is K > P > C > N. After 20 days, the release rate of each nutrient increased slowly, and at 80 days, the K treated with 8%OF had been completely released. At the end of decomposition (100 d), the release rates of C, N, P and K in each treatment were

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1345513472

47.55%-61.73%, 47.40%-62.67%, 48.04%-66.35% and 82.20%-100.00% respectively. Among them, the order of release of nutrients in fertilization treatments (CF, 8%OF, 16%OF and 24%OF) were K > P > N > C, and the order of release of nutrients in CK treatment was K > P > N ≈ C.

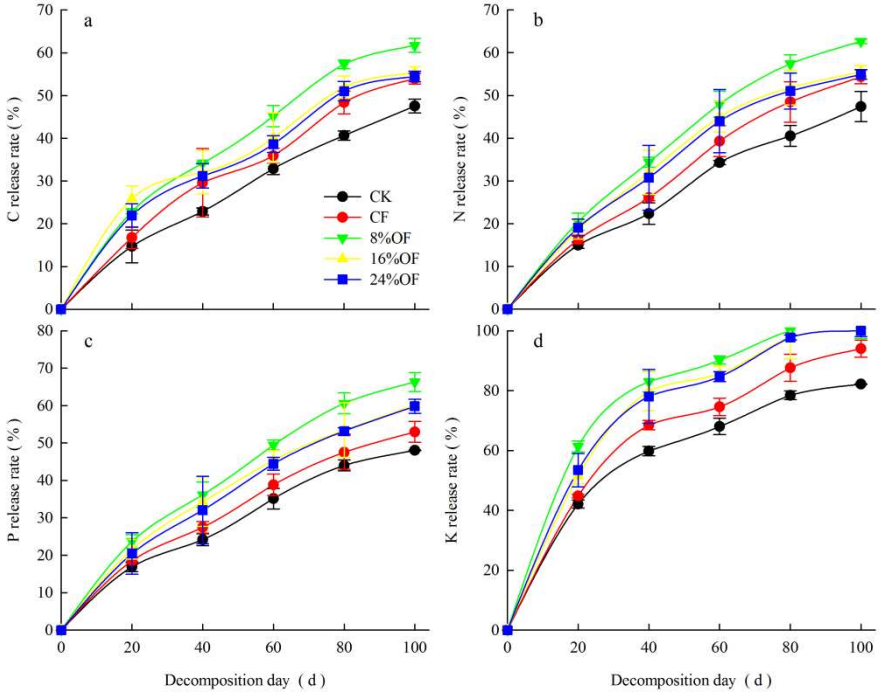

Figure 4. *Dynamic changes in C, N, P and K release rates of corn straw. In the figure, a, b, c, and d represent the nutrient release rates of C, N, P, and K, respectively*

The rate of nutrient release from corn straw increased faster in the early stage (0-20 d) and decreased in the late stage (20-100 d) (*Fig. 5*). In the first 20 days, the release rates of C, N, P, and K in straw reached 91.33-160.72 mg d^{-1}, 4.38-5.97 mg d^{-1}, 0.78-1.10 mg d^{-1}, and 11.07-16.14 mg d^{-1}, respectively. After 100 days of decomposition, the release rates of C, N, P, and K decreased to 58.98-76.58 mg d^{-1}, 2.60-3.55 mg d^{-1}, 0.45-0.62 mg d^{-1}, and 4.32-5.26 mg d^{-1}, respectively. After 100 days of decomposition, the release rates of C, N, P and K decreased to 58.98-76.58 mg d^{-1}, 2.60-3.55 mg d^{-1}, 0.45-0.62 mg d^{-1} and 4.32-5.26 mg d^{-1}, respectively, which were 35.42%-57.99%, 36.80%-44.09%, 41.45%-43.97%, 58.01%-67.40%, compared with the pre-decomposition period (0-20 d). During the whole decomposition process, the release rate of each nutrient in different treatments was 8%OF > 16%OF > 24%OF > CF > CK.

Changes of C and nutrients (N, P, and K) ratio of straw residue

As seen from *Figure 6,* the C/N ratio, the C/P ratio and the C/K ratio of the different treatments are substantially similar. Therefore, the different organic fertilizers replacement rate does not change the overall release characteristics of the nutrients. During the whole decomposition process, the C/N ratio fluctuated around 21, and there was a significant downward trend in the first 20 days. After 40 days, the C/N ratio of each treatment ranged from 20.8 to 20.98 (*Fig. 6a*). In the first 20 days, the C/P ratio increased rapidly, and P released the fastest. The order of the C/P ratio was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1345513472

8%OF > 16%OF > 24%OF > CF > CK, which was consistent with the P release characteristics. The C/P ratio decreased rapidly from 20 to 40 days, and stabilized after 40 days, ranging from 115.40 to 130.94 (*Fig. 6b*). The C/K ratio continued to increase with decompression days. In the first 60 days, the order of C/K ratio was 8%OF > 16%OF > 24%OF > CF > CK. At 80 days, K of 8%OF was completely released. At 100 days, K of 16%OF and 24%OF was completely released, and CF (185.08) was higher than CK (69.54), which was consistent with the characteristics of K release (*Fig. 6c*).

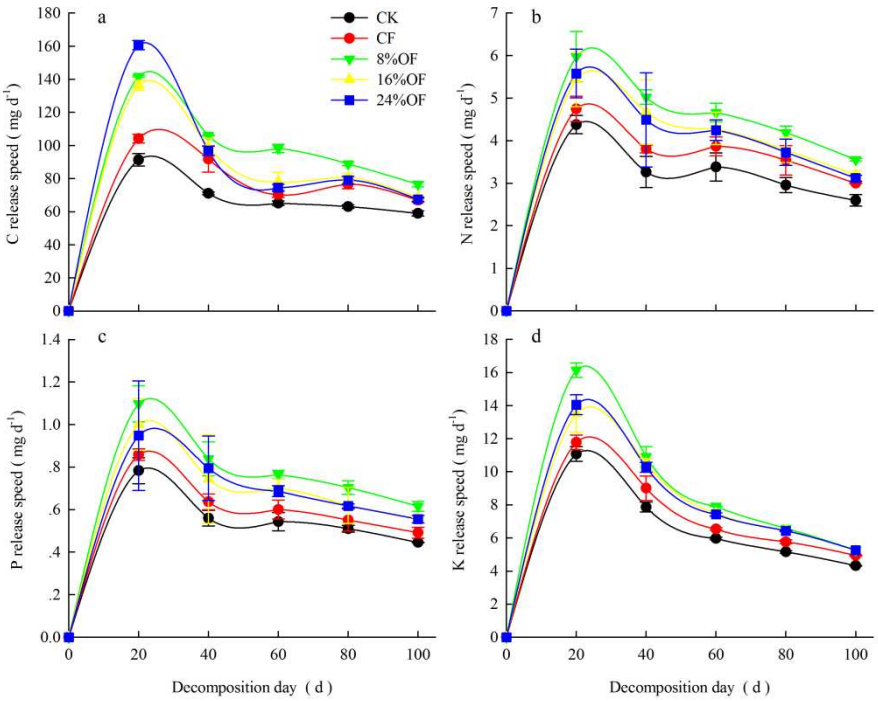

Figure 5. *Dynamic changes in C, N, P and K release speeds of corn straw. In the figure, a, b, c, and d represent the nutrient release speeds of C, N, P, and K, respectively*

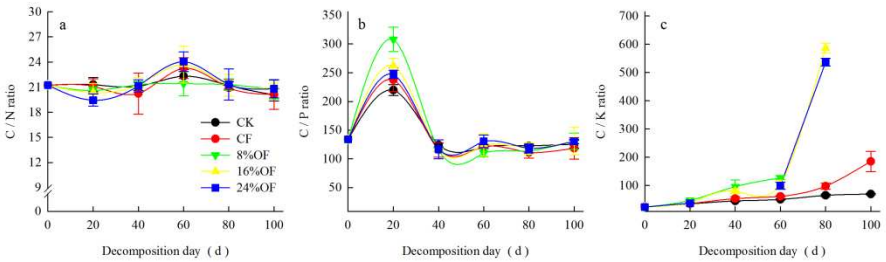

Figure 6. *Changes of C and nutrients (N, P, and K) ratio of straw residue during decomposition of corn straw. In the figure, a, b and c represent the C/N ratio, C/P ratio and C/K ratio, respectively*

Model analysis and prediction of decomposition rate and nutrient release rate

The decomposition rate, nutrient release rate (y) and decomposition days (x) were fitted to the regression equation, in accordance with the power function model $y = a \cdot x^b$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1345513472

(*Table 2*). It can be seen that the parameter a of the decomposition rate and the nutrient release rate of the fertilization treatments (CF, 8%OF, 16%OF and 24%OF) were both 8%OF > 16%OF > 24%OF > CF, and the parameter b has no obvious change, therefore, fertilization can promote the decomposition and nutrient release of straw, and the treatment effect of organic fertilizer replaces chemical fertilizer is more obvious. At the same time, the model can also predict that the days of complete decomposition and C N, P, and K complete release in different treatments are 217-330 d, 206-275 d, 167-271 d, 153-248 d and 85-150 d, respectively, The days required for complete decomposition is 8%OF < 16%OF < CF < 24%OF < CK and the days required for the complete release of C N, P, and K is 8%OF < 16%OF < 24%OF < CF < CK. The nutrient release rate of fertilization treatments (CF, 8%OF, 16%OF and 24%OF) were K > P > N > C, and the nutrient release rate of CK was K > P > N ≈ C, which was consistent with the test results.

Correlation analysis of decomposition rate and nutrient release rate under different organic fertilizer replacement rates, and recommending organic fertilizer replacement rate

During the whole decomposition process, there was no significant correlation ($P > 0.05$) between organic fertilizer replacement rate and decomposition rate or nutrient release rate, but there was a significant positive correlation between decomposition rate and nutrient release rate ($P < 0.05$) (*Table 3*), therefore, the nutrient release rate of the treatment with the high decomposition rate is also higher. The regression equation fitting of the relationship between organic fertilizer replacement rate (k is 0, 8%, 16%, and 24%, respectively) and decomposition rate (y) conforms to the one-variable quadratic function (*Schedule 1*).

Table 3. *Correlation analysis of decomposition rate and nutrient release rate (y) under different organic fertilizer replacement rate (k)*

Decomposition day	Item	Decomposition rate	Nutrient release rate			
			C	N	P	K
20 d	*k*	0.570	0.633	0.495	0.219	0.303
	Decomposition rate	1	0.947*	0.974**	0.961**	0.920*
40 d	*k*	0.416	0.176	0.431	0.410	0.528

* and **: Correlation coefficients significant at $P < 0.05$ and $P < 0.01$, respectively

Schedule 1. *Regression analysis of organic fertilizer replacement rate (k) and decomposition rate (y)*

Item (%)	Time (d)	Equation	R^2	*P* value	Best *k* (%)	Prediction y (*k* = 12%) (%)
Decomposition rate	20	$y = -0.0123k^2 + 0.3606k + 18.040$	0.8958	0.131	15	20.60
	40	$y = -0.0402k^2 + 1.1083k + 26.147$	0.8565	0.158	14	33.66
	60	$y = -0.0598k^2 + 1.3913k + 35.579$	0.5506	0.081	12	43.66
	80	$y = -0.0598k^2 + 1.3913k + 35.579$	0.8543	0.410	14	53.04
	100	$y = -0.0144k^2 + 0.3501k + 53.681$	0.8664	0.032	12	55.81

At the end of decomposition, the best organic fertilizer replacement rate was 12%, which is determined that the recommended organic fertilizer replacement rate was 12%, and bring it into the (*Schedule 2*) equation, predicting the decomposition rates and C, N, P and K release rates for different days (20 d, 40 d, 60 d, 80 d and 100 d) ranged from 20.60% to 55.81%, 25.02% to 59.08%, 19.77% to 59.69%, 23.03% to 64.11% and 57.31% to 100.00%, respectively. The predicted value satisfies the experiment result of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1345513472

K > P > N > C. Finally, the regression equation was fitted to the decomposition rate and nutrient release rate under the recommended organic fertilizer replacement rate (k = 12%), which is consistent with the power function $y = a \cdot x^b$ model (*Table 4*). Through the model, it can be predicted that the days for complete decomposition and the days for complete release of C, N, P and K under the organic fertilizer replacement rate of 12% are 176 d, 163 d, 159 d, 153 d, and 65 d, respectively (*Table 4*), and compared with the best treatment of 8%OF (k = 8%) in the experiment, it was advanced by 41 d, 43 d, 8 d, 0 d, and 20 d, respectively.

As shown in *Figure 7*, it is recommended that the straw returned per hectare under the replacement rate of organic fertilizer, after 100 days of decomposition, the release

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1345513472

amounts of C, N, P, and K are 1209.26 kg, 57.53 kg, 9.81 kg, and 86.77 kg, respectively. Among them, most of the nutrients released in the first 20 days were 512.12 kg, 19.05 kg, 3.52 kg, and 49.73 kg, accounting for 42.35%, 33.12%, 35.92%, 57.31% of the total release of C, N, P and K, which accorded with the characteristics of decomposition and nutrient release in this experiment.

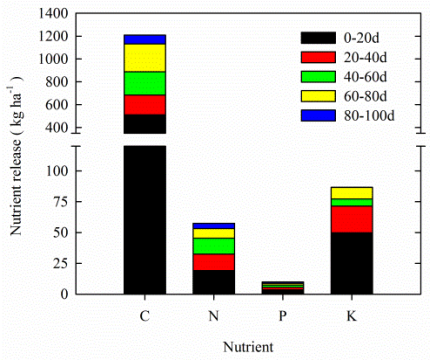

Figure 7. *Nutrient release under recommended organic fertilizer replacement rate (k = 12%) during corn growth period*

Discussion

Decomposition and nutrient release characteristics of straw

(1) Decomposition characteristics

This study found that the characteristics of decomposition and nutrient release during the whole decomposition process are fast in the early stage (0-20 d) and slow in the later stage (20-100 d), which is similar to previous studies (Wu et al., 2011; Zhao et al., 2011; Yang et al., 2015). It may be because: in the early stage of decomposition, corn straw contains a large amount of easily decomposable organic substances, which are easily used by microorganisms, resulting in faster decomposition; As the decomposition progresses, the easily decomposable organic matter in the straw is gradually reduced, and the remaining mainly coarse fibers and lignin which are difficult to decompose are difficult to be easily utilized by microorganisms, resulting in slow decomposition in the later stage (Li et al., 2009; Summerell and Burgess, 1989). In addition, temperature and precipitation in climatic conditions can also affect straw decomposition (Gupta and Singh, 1981). This experiment began in May, when the temperature rises and precipitation increases (*Fig. 1*), which improves microbial activity and promotes straw decomposition. At the later stage, excessive temperature inhibited microbial activity, which inhibited straw decomposition (Zhou et al., 2015; Nakajima et al., 2016).

(2) Nutrient release characteristics

There was a significant positive correlation ($P < 0.05$) between the decomposition rate and nutrient release rate (*Table 3*). Therefore, the nutrient release rate of high decomposition rate treatment was also higher. At the end of the experiment (100 d), the order of nutrient release rate was K > P > N > C, which was consistent with most studies (Dai et al., 2010; Gong et al., 2018; Liu et al., 2016). The nutrient release rate depends mainly on the morphology of each nutrient (C, N, P, and K) in the straw. Among them, the K content in the straw is high and mainly exists in the ionic state,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1345513472

which is easy to release; The P content in the straw is low, over 60% is in the ionic state, the release is faster, and the rest is more difficult to decompose, resulting in slower release in the later stage, so the K release is faster than P (Wang et al., 2013; Dai et al., 2017). C and N are the main components of straw, mainly insoluble organic matter, which is easier to release in the early stage. The remaining part is mainly organic matter with high cementation and difficult to decompose, resulting in a slower release of C and N (Murayama, 2010; Chen et al., 2016; Tang et al., 2016).

(3) Changes of C and nutrients (N, P, and K) ratio of straw residue

Changes of C and nutrients (N, P, and K) ratio of straw residue during the decomposition process can not only reflect the characteristics of the overall release of nutrients after the crop straw is returned to the field, but also reveal its relationship with the decomposition and nutrient release (*Fig. 6*). C/N ratio of straw is a major factor affecting straw decomposition and microbial activity (Ahlam, 2004). In the first 20 days, decomposition and nutrient release was the fastest, because the reduction of C/N ratio promoted decomposition (Dai et al., 2010), and the late C/N ratio was close to the appropriate range of microbial growth 25-30:1 (Devêvre and Horwath, 2000), but the C in the straw is mainly in the form of lignin, which is difficult to be used by microorganisms, leading to the slowing down of decomposition and nutrient release (Summerell and Burgess, 1989; Li et al., 2009), and the change in C/N ratio also reflects that the characteristics of decomposition and nutrient release is fast in the early stage (0-20 d) and slow in the later stage (20-100 d) (*Figs. 3–5*). The change of C/P ratio and C/K ratio of straw reflects that the release degree of nutrients of C, P and K is K > P > C (*Fig. 4*), and reflected the characteristics of nutrient release from different treatments are 8%OF > 16%OF > 24%OF > CF > CK.

(4) Models of decomposition and nutrient release

Through the establishment of decomposition and nutrient release models (*Table 2*), dynamic monitoring of straw decomposition and nutrient release from different treatments can be performed, and the days for complete decomposition and complete release of nutrients can be predicted, and verified the characteristics of decomposition and nutrient release in this experiment (*Figs. 3–5*). Therefore, the establishment of the model helps to establish a reasonable return time, which is of great significance for guiding reasonable straw returning.

Effects of different organic fertilizer replacement rates on straw decomposition and nutrient release and prediction of organic fertilizer replacement rate

The decomposition rate and nutrient release rate were 8%OF > 16%OF > 24%OF > CF > CK (*Figs. 3–4*). It can be seen that with the increase of the replacement rate of organic fertilizer, the decomposition rate, and nutrient release rate first increased and then decreased, and the fertilization treatments (CF, 8%OF, 16%OF and 24%OF) were higher than that without fertilizer application (CK), and the effect of organic fertilizer replacement treatment was obvious. It is because, on the one hand, chemical fertilizers are fast, but the utilization rate is low. Organic fertilizers improve soil physical and chemical properties and promote microbial activities and reproduction, but organic fertilizers release nutrients at a slower rate. The replacement of some chemical fertilizers by organic fertilizers can coordinate inorganic and organic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1345513472

nutrients, meet the nutrient requirements of crops, and improve soil fertility, thereby promoting microbial activities and straw decomposition (Hao et al., 2012). Some studies have also found that the application of chemical fertilizers in the soil can also promote the decomposition of straw, and the corn straw is decomposed faster under high fertility conditions (Zheng et al., 2004; Wang et al., 2009). According to the characteristics of fertilizer efficiency of chemical fertilizer and organic fertilizer, with the increase of organic fertilizer replacement rate, the available nutrients in the soil are reduced. The crop growth in the plot absorbs available nutrients from the soil, and there exists nutrient competition between crop growth and decomposition, thus inhibiting straw decomposition (Azam et al., 1991).

The correlation analysis (*Table 3*) shows the whole decomposition process. The organic replacement rate will not change the characteristics of the whole decomposition and nutrient release of corn straw, but the appropriate organic replacement rate can effectively coordinate the nutrient balance, promote the decomposition and nutrient release. Therefore, it is very important to determine the organic replacement rate for straw decomposition. In this study, model analysis of decomposition rates and nutrient release rates under different organic fertilizer replacement rates (*Schedule 1*) was performed to determine a recommended organic fertilizer replacement rate of 12% and a decomposition and nutrient release model was established (*Table 4*). Predicting the complete time required for decomposition and releasing is better than the optimal treatment (8%OF). Therefore, the recommendation of the replacement rate of organic fertilizer has important guiding significance for the comprehensive management of straw returning and rational fertilization.

The strategy of straw returning and rational fertilization in corn planting

Corn is one of the three major food crops in the world. It needs a lot of nutrients; excessive application of chemical fertilizer not only increases the cost of agricultural production but also causes soil acidification and agricultural pollution. This study found that suitable organic fertilizer replacement efficiency is conducive to the efficient use of straw resources and reduce the use of chemical fertilizer. Taking this experimental area as an example, the recommended fertilization amount is 300.0 kg N ha^{-1}, 180.0 kg P_2O_5 ha^{-1}, 60.0 kg K_2O ha^{-1}, On the basis of recommending the replacement rate of organic fertilizer 12%, the return of straw is carried out, and the fertilization scheme: the application of N, P_2O_5, K_2O in the form of chemical fertilizer is 264.0 kg ha^{-1}, 140.3 kg ha^{-1} and 49.2 kg ha^{-1}, respectively; the organic fertilizer is 2033.9 kg ha^{-1} kg ha^{-1}, of which the N, P_2O_5, K_2O contents are 36.0 kg ha^{-1}, 39.7 kg ha^{-1}, 10.8 kg ha^{-1}, respectively. During the growth period of corn (100 d), the release of N, P and K was equivalent to 19.18%, 5.45% and 144.61% of the fertilization amount of NPK fertilizer, and the K release amount exceeded the fertilization amount of K fertilizer, at the same time, a many C is released (*Fig. 7*), which effectively increases soil organic matter content (Wang et al., 2017). According to the characteristics of nutrient release from straw, it is fast in the early stage (0-20 d), slow in the late stage (20-100 d) and K > P > N > C. This study proposes that organic fertilizer and straw are applied as base fertilizers, while reducing the application amount of chemical fertilizers in base fertilizers. According to the general nutrient absorption characteristics of corn, the absorption of N, P and K was less in the seedling stage, the jointing stage was significantly increased, and the peak was reached from the booting stage to the heading stage (Denbaly and Vroomen, 1993), and reasonable fertilization measures were

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1345513472

formulated: reduce or delay the application of K fertilizer, increase N and P fertilizer after jointing stage, increase N fertilizer in the late stage of decomposition, avoid nutrient competition of corn and straw decomposition, promote corn growth and straw decomposition, and ensure crop yield, to achieve efficient utilization of straw resources and reduce the application of chemical fertilizer.

Conclusion

This study found that the straw decomposition and nutrient release characteristics of the whole decomposition process under different organic fertilizer replacement rates are fast in the early stage (0-20 d) and slow in the late stage (0-100 d). At the end of decomposition (100 d), the decomposition rate and nutrient release rate were 8%OF > 16%OF > 24%OF > CF > CK, and the nutrient release characteristics of fertilization treatment were K > P > N > C, while CK was K > P > N ≈ C. Through the establishment and analysis of decomposition and nutrient release models ($y = a \cdot x^b$), dynamic monitoring and prediction of decomposition and nutrient release during corn growth period can be carried out, and the characteristics of decomposition and nutrient release in this experiment can be verified. Through the establishment of different organic fertilizer replacement rate and nutrient release model and correlation analysis, the recommended organic fertilizer replacement rate was determined to be 12%, and according to the characteristics of nutrient release in this study, the strategy of comprehensive management of reasonable straw returning and fertilization in corn planting was proposed: On the basis of recommending the organic fertilizer replacement rate (k = 12%), the return of straw is carried out, Organic fertilizer and straw are applied as base fertilizer, and the amount of chemical fertilizer applied in the base fertilizer is reduced. This study is limited to the nutrient release of straw, and the nutrient absorption characteristics of corn needs further research, combined with the release characteristics of straw nutrients, which is conducive to the development of more scientific straw returning and fertilization management measures.

(Received 7th Jul 2019; accepted 2nd Sep 2019)

Abstract. Carbonic anhydrase enzyme catalyzes the reversible inter-conversion of CO_2 and HCO_3. The enzyme is crucial for the osmotic balance and acid–base regulation in the fish. It is well-known that gills of fish play the most important role in acid–base relevant ion transfer, the transfer of H^+ and/or HCO_3, for the maintenance of systemic pH. Many researches have shown that fish are the species that is the most susceptible to environmental toxins. In addition, these toxins firstly encounter the gill tissue in fish. In this study, the carbonic anhydrase enzyme was purified 198.6-folds with 58.8% yield from Shabut Fish (*Barbus grypus*) gill tissue by Sepharose-4B-L-tyrosine-sulfanilamide affinity column. The specific activity was determined as 2.92 EU/mg protein. The molecular weight determined by sodium dodecyl sulfate–polyacrylamide gel electrophoresis was found to be about 29.9 kDa. Inhibitory effects of some pesticides (Spinosad and Dimethoate) and metal ions (Al^{3+}, Cu^{2+}, Ba^{2+}, Fe^{2+}, Mn^{2+}, Se^{2+}) were examined on the purified carbonic anhydrase enzyme. Inhibition graphics were drawn in order to find the IC_{50} values of metals and pesticides showing inhibition. The kinetic parameters of this enzyme were determined for its esterase activity, with 4-nitrophenyl acetate as substrate.
Keywords: *pollution, inhibition, enzyme, chromatography, catalysis*

Introduction

According to the records of the Food and Agriculture Organization, Shabut, also known as *Barbus grypus*, is one of the most significant fish species listed in the fresh waters of Iraq and in the rivers along South and Southwest Iran, the Karoon river, and also in The Euphrates River and Tigris Rivers in Turkey (Olgunoglu et al., 2011). Shabut is one of the leading fish species of Siirt/Botan Stream which contributes to the city's economy.

In nature it is known that carbonic anhydrases (CAs, EC 4.2.1.1) are some of the most efficient enzymes probably due to the fact that uncatalyzed CO_2 hydration is a very slow process at neutral pH, and the physiologic demands for its conversion to ionic, soluble species (i.e., bicarbonate and protons) are very high. Actually, CO_2 is generated in most metabolic oxidative processes, and being a gas, it must be converted to soluble products quickly and efficiently. Otherwise, it could accumulate and damage cells and other organelles in the gaseous state without such an efficient hydration catalyst as the CAs (Supuran, 2018). At least 16 different CA isozymes have important roles in diverse processes, such as physiological pH control and gas balance, calcification, and photosynthesis, have been described in higher vertebrates up to this point. The role of CA in fish gills is considered to be related to gas exchange, acid-base balance, osmoregulation, ion regulation, and clearance of the waste products from nitrogenous metabolism. The shape of distribution of CA activity among gills pairs shows variety depending on habitat and osmoregulatory behavior of the animal. Gill epithelium is the first tissue of the organism exposed to the aquatic environment, and because of this, it is the primary frontier for the harmful effects of environmental pollutant in the case of fish (Lopez Mananes et al., 2000; Randall and Daxbaeck, 1984; Dincer et al., 2016; Hisar et al., 2004).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1347313483

The gill tissue is the primary tissue contacting with the contaminants in the water. Because of its small diffusion distance and large surface area between the blood and water, the gills are initially affected by contaminants such as pesticides and metals (Demir et al., 2016). In general, the gill cells react rapidly to several chemicals to handle tissue damage or physiological impairment. Chemicals may have a negative impact on the overall gill function, improving fish sensitivity to toxic compounds and potentially causing fish mortality (Cerqueira and Fernandes, 2002). Lately, the contamination of aquatic environment by pollutants has become a big problem. They are a threat to public water supplies and can damage aquatic life (Koca et al., 2005). Pesticides are substances that are used to kill or control the organisms considered to be destructive. The most broadly used ones are insecticides, herbicides, fungicides and rodenticides. They are the most common contaminants of the environment and cause water, soil and air pollution. They can also pile up in the living organisms like humans, animals, and so on (Anwar, 1997). They are attracted attention owing to the fact that they stay in the environment for a long time, can accumulate in food, and have a constant presence in food and drinking water (Tiemann, 2008). Generally, pesticides can interfere into rain water, irrigation water or river, plants and may be harmful for specific enzymes. It is known that many compounds, metal ions and pesticides can be hazardous for the living organisms in water. Scientific studies on pesticides make clear that these compounds show their destructive effects by inhibiting the enzymes even at low concentrations (Ceyhun et al., 2010).

Heavy metals have a toxic impact that is proportional to their concentration in fish. Heavy metals bring about toxicity in aquatic environments and this heavy metal damage is a crucial factor in many toxicological and pathological processes (Ekinci and Beydemir, 2010; Soyut and Beydemir, 2008). At the same time, heavy metals may lead to oxidative damage by decreasing the cellular antioxidant capacity and by directly rising the cellular concentration of reactive oxygen species (Topal et al., 2014; Ekinci et al., 2008). It has been reported that heavy metals and pesticides principally enter into the human/animal body through ingestion, such as food materials, inhalation and dermal contact, such as emissions of waste material in the form of smoke, dust particle, fume of chemicals from several industrial activities, such as mining, and manufacturing of batteries (Singh et al., 2017).

The aim of the study is to purificate and examine the inhibition effects of the some pesticides and metals on the activity of CA enzyme from Shabut Fish (*Barbus grypus*) gill tissue in the Tigris basin. Since it is frequently consumed by the people of the region and has high economic value, Shabut Fish was chosen as the source in the study. In addition, since CA enzyme has never been purified from this fish species before, this fish species was preferred in the study. The other aim of the study is the determination of some biochemical parameters of purified enzyme. For this purpose, the enzyme was isolated from gill of this fish. It was determined the inhibitory effects of these chemicals using 4-nitrophenyl acetate (4-NPA) as a substrate.

Methods and materials

Chemicals and devices

All chemicals used in this study were the highest grade purity available and were obtained from Sigma and E. Merck (Darmstadt, Germany). Sepharose 4B activated by CNBr, protein assay reagents, and chemicals for electrophoresis were obtained from Sigma-Aldrich Chemie (Taufkirchen, Germany). A UV–Visible spectrophotometer

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1347313483

(VWR UV-6300PC Double Beam Spectrophotometer) was used for the determination of enzyme activity. The peristaltic pump used for enzyme purification was (Masterflex L/S Digital Pump System 77921-60), the centrifuge machine was purchased from Thermo Scientific/Megafuge 16R and the electrophoresis system was a Bio-Rad Mini-PROTEAN®System.

Preparation of homogenate

Shabut Fish (*Barbus grypus*) gill tissues were obtained commercially from fishermen in Siirt/Botan Stream, Turkey. Gill tissues were brought to Siirt University Science and Technology Application and Research Center Laboratory in accordance with the cold chain rule. They (about 50 g) were cut off carefully with aid of scalpel for avoiding damage and were washed three times with 0.9% NaCl to eliminate blood and other contaminants. After the tissues were lysed by liquid nitrogen, were taken in 50 mM Tris-SO_4 buffer (pH 7.4). The homogenate was centrifuged for 60 min (15.000 rpm at + 4 °C). The pH of the resulting supernatant was adjusted to 8.7 with solid Tris and loaded onto the affinity column.

Purification of CA from Shabut Fish (Barbus grypus) gill by affinity chromatography

The solution was applied to a Sepharose 4B-L-tyrosine sulfanilamide affinity column equilibrated with 25 mM Tris–HCl/0.1 M Na_2SO_4 (pH 8.7). The affinity gel was washed with 25 mMTris–HCl/22 mM Na_2SO_4 (pH 8.7). CA was eluted with 0.1 M $NaCH_3COO$/0.5 M $NaClO_4$ (pH 5.6). The 280 nm absorbance of the protein in the column effluents was determined spectrophotometrically. All of the purification steps were performed at 4 °C.

Esterase activity assay

The CA activity was assayed by the esterase method by following the change in absorbance at 348 nm of 4-NPA hydrolyzed to 4-nitrophenolate ion in the presence of the enzyme, over a period of 3 min at 25 °C, using a UV–Vis spectrophotometer according to the Verpoorte procedure (Verpoorte et al., 1967). The enzymatic reaction, in a total volume of 1.0 mL, contained 0.59 mL Tris–SO4 buffer solution (50 mM, pH 7.4), 0.36 mL 4-NPA (3.0 mM), and 0.05 mL enzyme. The control cuvette did not contain enzyme solution. One enzyme unit of CA esterase activity is defined as hydrolysis of 1 μmol 4-NPA to p-nitrophenol and acetate in 1 min. Briefly, 4-NPA is hydrolyzed into p-nitrophenol and acetate by CA, and p-nitrophenol absorbance is determined spectrophotometrically at 348 nm for CA esterase activity. The absorbance of the non-catalyzed 4-NPA in this buffer was always subtracted from the enzymatic measurements reported in this article (Senturk et al., 2011). K_M and V_{max} values were calculated for NPA by Lineweaver–Burk graph (Lineweaver–Burk, 1934).

Protein determination

During each purification steps, protein determination was performed spectrophotometrically at 595 nm according to the Bradford method, using bovine serum albumin as the standard (Bradford, 1976).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1347313483

SDS polyacrylamide gel electrophoresis

Sodium dodecyl sulfate–polyacrylamide gel electrophoresis (SDS-PAGE) was carried out according to the method of Laemmli for the determination of purity and molecular weight of the Shabut Fish (*Barbus grypus*) gill CA using a 5% (w/v) stacking gel and 12% (w/v) separating gel (Laemmli, 1970). The molecular weight of the enzyme was determined using different protein markers from 8.5 kDa to 70 kDa. R_f values were also calculated for the enzyme and standard proteins, and R_f–LogMW graph was obtained (*Fig. 1*).

Optimum pH determination

In order to determine the optimum pH, K-phosphate and Tris–SO_4 buffers were used in the pH range of 5.0–7.5 and 7.0–9.0, respectively.

Optimum temperature determination

For determination of the optimum temperature, enzyme activity was assayed at different temperatures in the range from 5 to 70 °C. The desired temperature was provided by using a Grant bath.

Optimum ionic strength determination

For determination of optimum ionic strength, enzyme activity was determined using different concentrations of Tris–SO_4 buffer, pH: 7.5, in the range from 10 mM to 1000 mM.

Inhibition effect of some pesticides and metals on CA enzyme activity

The inhibitory effects of some pesticides (Spinosad and Dimethoate) and metal ions (Al^{3+}, Cu^{2+}, Ba^{2+}, Fe^{2+}, Mn^{2+}, Se^{2+}) were determined on Shabut Fish (*Barbus grypus*) gill CA enzyme activity. The effects of inhibitors were examined in the five diverse 4-NPA concentrations for each inhibitor. The CA activities were measured for different concentrations of inhibitors in spectrophotometer cuvette (1.0 mL). Control activity was assumed to be 100% in the absence of inhibitor. Reduced 50% activity of enzyme by used inhibitor concentration (IC_{50}) was calculated from the graphs using conventional polynominal regression software (Microsoft Office 2010, Excel).

Results

In present study, CA enzyme was purified from the Shabut Fish (*Barbus grypus*) gill tissue for the first time. The purification of the gill CA was carried out in one stage by chromatography column on L-tyrosine sulfonamide coupled to Sepharose 4B. The Shabut Fish (*Barbus grypus*) gill CA was purified with a specific activity of 2.92 EU/mg protein (198.6-folds) with a yield of 58.8% (*Table 1*).

To establishment of molecular weight of the enzyme, R_f values were also calculated for the enzyme and standard proteins, and R_f–LogMW graph was obtained according to Laemmli' method (*Fig. 1*). It was obtained a single protein band, evidence of purified enzyme having a molecular weight of the subunit was approximately 29.9 kDa, based on SDS-PAGE (*Fig. 2*). SDS-PAGE is one of the most greatly used laboratory methods to separate biological macromolecules including proteins and nucleic acids. In this

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1347313483

separation method, macromolecules are differentiated according to their electrophoresis mobility, which is a function of the length, conformation, and charge of the molecule. Ordinarily, macromolecules as proteins may be run in their native state or in denatured forms. To separate molecules based on their lengths, samples are run in denaturing conditions (Atasever et al., 2013).

Some biochemical parameters of enzyme were investigated such as optimum pH, optimum temperature and optimum ionic strength. The optimum pH, optimum temperature and optimum ionic strength were determined to be 7.5 Tris–SO_4 buffer, 40 °C and 50 mM Tris–SO_4 buffer for the CA enzyme, respectively. K_M and V_{max} values were calculated for NPA by Lineweaver–Burk graph. K_M constants were calculated as 0.32 mM, V_{max} values as 0.0025 mol × min^{-1} for NPA.

The inhibitory effects of some pesticides (Spinosad and Dimethoate) and metal ions (Al^{3+}, Cu^{2+}, Ba^{2+}, Fe^{2+}, Mn^{2+}, Se^{2+}) on CA purified from the Shabut Fish (*Barbus grypus*) gill tissue were determined. For the compounds showing inhibitory effects, the IC_{50} value was determined by activity% vs inhibitor concentration graphs for each compound. *Table 2* shows the *in vitro* effect of metal ions (Al^{3+}, Cu^{2+}, Ba^{2+}, Fe^{2+}, Mn^{2+} and Se^{2+}) on CA purified from the Shabut Fish (*Barbus grypus*) gill tissue. IC_{50} values of Al^{3+}, Cu^{2+}, Ba^{2+}, Fe^{2+} and Se^{2+} ions were determined to be 0.355, 3.46, 0.77, 0.303 and 1.57 mM, respectively.

Inhibition data for some pesticides (Spinosad and Dimethoate) on this enzyme are exhibited in *Table 3*. Very low IC_{50} values were obtained such as 0.41 and 0.52 mM in the presence of the Spinosad and Dimethoate as inhibitors (*Fig. 3a, b*).

Table 1. *Summary of purification procedure of CA enzyme from Shabut Fish (Barbus grypus) gill tissue*

Purification Steps	Activity (EU/ml)	Total volume (ml)	Protein (mg/ml)	Total protein (mg)	Total activity	Specific activity (EU/mg)	Yield %	Purification fold
Homogenate	45.33	30	2050	92250	1360	0.0147	100.0	1.0

the toxic effect of some pesticides and metal ions in endangered fish species. Some physiological aspects of CA-mediated processes in this type of less investigated vertebrate are in fact poorly understood, since most of the CA pharmacological/environmental researches have been done with the human and rodent enzymes. This research made from fish gill is important in this aspect.

Discussion and conclusion

Metals and pesticides generally have a negative effect on metabolism. Pesticides commonly used in agricultural fields and metals with industrial waste are particularly important determinants of the health of land and aquatic organisms. In recent years, issues such as the rapid increase in the use of pesticides in agriculture and the disposal of industrial wastes to the environment are need attention. When the distribution of heavy metals in the ecological system is examined, it is observed that the human hand is more effective in spreading to the environment than natural cycles. Kacar et al. studied to determine the concentrations of heavy metals (Cr, Mn, Fe, Co, Ni, Cu, Zn, Cd and Pb) in liver, gill and muscle of *Barbus grypus* in Batman Dam, Turkey. Their results indicated that heavy metal concentrations were higher in the liver and gill, while it was lower in the muscle (Kacar et al., 2017a). In another study, Kacar et al. studied the heavy metal concentrations in the tissues of fish taken seasonally from the Batman Dam. Their results indicated that in the winter; Cr, Fe, Ni, Co, Zn and Pb accumulations in the gills were more than in all seasons (Kacar et al., 2017b).

CO_2, produced in fish tissues, is hydrated quickly by the CA enzyme, converted into bicarbonate, and transported in the blood. Approximately, 98% of the transported and stored CO_2 is in the bicarbonate form (Demirdag et al., 2013). CA is a crucial enzyme in several other important physiological processes. For instance, the gills of aquatic organisms function in respiratory gas exchange, salt transport, and acid–base balance and CA can function in all three processes. The multiple functions of CA are a result of multiple isoforms that are localized to specific subcellular compartments/fractions within the gill (Cudennec et al., 2006; Sender et al., 1999). It has been understood that nearly all chemical reactions in the metabolism of the living organisms are catalyzed by enzymes, and the enzyme activities are influenced (decreased or increased) by many chemical substances including pesticides, fungicides, drugs and metal ions even at low concentrations (Soydan et al., 2017; Ozaslan et al., 2017). There are numerous studies about inhibition of CA enzyme activity with different pesticide and metals reported in the literature. For instance, Demirdag et al. investigated the inhibitory effects of some metals on the enzymatic activity of sheep liver CA. They found *in vitro* inhibition of the metals in the order of $Cu^{2+} > Zn^{2+} > Cd^{2+} > Co^{2+} > Ni^{2+}$ (Demirdag et al., 2012a). In another study, Ceyhun et al. studied the inhibitory effects of some metals on the enzymatic activity of the teleost fish *Dicentrarchus labrax* liver CA. Their results indicated that metal ions (Al^{3+}, Cu^{2+}, Pb^{2+}, Co^{3+}, Ag^{1+}, Zn^{2+} and Hg^{2+}) inhibited the enzyme activity at low concentrations (0.0692, 0.0715, 0.1128, 0.3165, 0.3790, 0.39 and 0.4484 mM), respectively (Ceyhun et al., 2011). Furthermore, Demirdag et al. investigated inhibitor effects of pesticides such as cyhalothrin, cypermethrin, dichlorvos, methamidophos, chlorpyrifos and methylparathion on purified enzyme from the European Seabass liver (Demirdag et al., 2012b). They showed that pesticides inhibit the enzyme even at very small concentrations. Soydan et al. studied the inhibitory effects of some pesticides on the enzymatic activity of Apis mellifera CA.

DOI: http://dx.doi.org/10.15666/aeer/1706_1347313483

Their results indicated that IC_{50} values for the tebuconazole, propoxur, carbaryl, carbofuran, simazine and atrazine pesticides were 0.0030, 0.0321, 0.0031, 0.0087, 0.0273 and 0.0165 mM, respectively (Soydan et al., 2017). In another study, Kılınc et al. studied the inhibitory effects of chlorpyrifos, cypermethrin, dichlorvos, glyphosate isopropylamine and lambda cyhalomethrin pesticides on the enzymatic activity of the sheep stomach CA-II. Their results indicated that glyphosate isopropylamine and dichlorvos were found to have the highest inhibitory effects on the purified enzyme (Kılınc et al., 2015). From the studies mentioned above, it can be distinctly understood that many pesticides and metals have inhibitory effects on CA enzyme activity. Hence, in this study; the inhibitory effects of some widely used pesticides and metals on the activity of purified Shabut Fish (*Barbus grypus*) gill CA enzyme are investigated (*Tables 2* and *3*). As gill carbonic anhydrases contact primary with habitat of fish, investigation of these functions' performance is necessary how affected by environmental factors. In this study, the carbonic anhydrase enzyme was purified for the first time from Shabut Fish (*Barbus grypus*) gill tissue, in a single step, by using affinity chromatography. Furthermore, this enzyme has been inhibited by the some pesticides inhibitors (Spinosad and Dimethoate), with the IC_{50} values of 0.41 mM and 0.52 mM, respectively.

Hisar et al. (2006) reported that the CA was purified 104.8-folds with a specific activity of 55.6 EUx (mg protein)$^{-1}$ from the rainbow trout gills by using Sepharose 4B-L-tyrosine-sulfanilamide affinity column. (Demirdag et al., 2015) purified a fish enzyme from Agrı Balık Lake trout gill (*Salmo trutta labrax*) and achieved a purification of 303.9-folds with a specific activity of 4130.4 EUx (mg protein)$^{-1}$ and recovery of 79.3% using the identical technique. It is indicated that the carbonic anhydrases derived from various organisms have molecular mass of from 18.9 to 29.3 kDa (Smith and Ferry, 2000). The subunit molecular weight of the Shabut Fish (*Barbus grypus*) gill CA enzyme was found to be about 29.9 kDa by SDS-PAGE. The values obtained are in harmony with the literature as seen. Dincer et al. (2016) reported that the molecular weight of the gill CA from Russian Sturgeon Fish (*Acipenser gueldenstaedtii*) is about 29 kDa while Hisar et al. (2006) reported that it to be 27 kDa from the rainbow trout gills and 29 kDa from Russian Sturgeon Fish erythrocyte (Kolayli et al., 2011).

Data of *Table 2* show that the gill CA was inhibited by metal ions, with IC_{50} values in the range of 0.303–3.46 mM. The most inhibitory ion was Fe (II) and the least inhibitory was Cu (II). Heavy metals possess different toxicological impacts on living organisms, especially in fish. It is that enter the food chain are not discharged from fish and are so accumulated in their bodies. Then, they can be ingested by humans via the consumption of fish. Thus, heavy metal ions probably do constitute a great danger for this fish, or at least they do inhibit significantly the CA found in the gill. Pesticides have been found to be a more potent inhibitor of gill CA when it is compared to heavy metals. It was observed that some pesticides such as (Spinosad and Dimethoate) inhibited the enzyme at very small concentrations such as 0.41 and 0.52 mM. Most of the enzyme studies in the literature are on humans and animals. Researches on the effects of environmental pollutants such as pesticides and metals on fish are limited. As the number of such studies demonstrating the metabolic effects of environmental pollutants on fish increases, we can become a more conscious society. It would be beneficial for researchers to give direction to their research by taking this into consideration.

Consequently, Shabut Fish (*Barbus grypus*) gill CA enzyme was purified in a one step affinity chromatography procedure for the first time, and analyzed characteristic features. In addition, inhibitory effects of some pesticides and metals on enzyme activity were reported. In the light of these results, the Shabut Fish (*Barbus grypus*) gill CA enzyme is inhibited by some environmental pollutants such as pesticides (Spinosad and Dimethoate) and metal ions (Al^{3+}, Cu^{2+}, Ba^{2+}, Fe^{2+} and Se^{2+}). Owing to their toxicity, pesticides and metal ions affect not only the target organisms but also animals and humans which are being exposed to these compounds. Therefore, some measures have to be taken to prevent excessive diffusion to the environment when using these compounds. As a precaution, farmers should be informed about the use of pesticides and trained on this subject at short intervals. Besides, harmful effects on health of these chemical substances must be considered carefully and the usage of them must be kept under control. The industries near the water supplies must be more conscious about the factory waste and metal residues. The fish in fresh water and sea have been consumed as an important food source until now and will be consumed in the future. Thus, due to the mixing of the pesticides through the rain and irrigation waters into the Siirt/Botan Stream, aquatic organisms in this area are at great risk of chemical toxicity.

Abstract. In this study, saline stress tolerance/sensitivity levels, germination rate of the seeds, and seedling growth of eight fig cultivars (Morgüz, Sarılop, Yeşilgüz, Sultan Selim, Halebi, Bursa Siyahı, Göklop and Izmir Bardacık) of Turkey were examined by *in vitro* screening. In fig, this is the first and guiding study reporting *in vitro* germination performance of the seeds in saline conditions for fig researchers. Salt stress *in vitro* condition was established by adding 0, 85.5, 171.1 and 342.5 mM NaCl to the MS basal medium in current experiment. In the examinations carried out 45 days after seedling, none of the cultivars could be obtained at a dose of 342.5 NaCl. Highest seed germination rates were determined in Sultan Selim (79.5%) and Bursa Black (75.0%) cultivars at 171.1 mM NaCl concentration. In other cultivars, this ratio has changed between 0.0-40.0%. High germination rate (90% <) and plant growth under the observed 85.5 mM NaCl dose was determined for Sultan Selim and Bursa Siyahı cultivars. The seeds and seedlings of Sarılop cultivar, one of the major cultivars for dried fig production, have been found sensitive to salt stress.
Keywords: *fruit, fig (Ficus carica L.), salinity tolerance, stress physiology, germination criteria*

Introduction

The fig, a subtropical fruit (*Ficus carica* L.) is grown in many parts of the world with mild climate. Turkey is one of the countries in the world with the largest share of producing and exporting figs. According to the latest reports, 305.7 thousand tons of fig are produced over 50.3 thousand hectares in Turkey. This value (1152.8 thousand tons) reaches 26.5% of the global fig production (FAO, 2017). Turkey is a very rich country in terms of the genetic resources of figs (Ercişli, 2004). Fig genetic diversity in Turkey is very valuable for classical and modern fig breeding programs. As indicated in previous studies, the genetic diversity found in cultivated plants and wild relatives provides rich resources for targeted cultivation characteristics and gene discovery that have not been used sufficiently yet (Ismail and Horie, 2017). It is important to reveal the genetic potential of the cultivars in terms of targeted character development. To evaluate genotypes in a short time, *in vitro* screening method can grant great convenience and time-saving. This technique has many advantages over *ex vitro* conditions to investigate the complex response of plants to stress factors as under aseptic and controlled environmental conditions (Jain, 2001; Lokhande et al., 2011; Rai et al., 2011). There are many studies in the literature that use these techniques for drought, salinity and other stress factors (Tal, 1994; Shibli et al., 2007; Shatnawi et al., 2009).

Figs are moderately tolerant (EC 3-5 dS m^{-1}) plants to the soil salinity (Mass and Hoffman, 1977; Golombek and Lüdders, 1994). The land where figs grow in the world usually contains above average saline levels. Therefore, salinity is a major problem for figs today and in the future (Golombek and Lüdders, 1994; Zarei et al., 2016; Soliman and Alhady, 2017). The result of dry and hot climatic conditions of the country, low precipitation and especially the improper irrigation practices implemented in the agricultural and landscaping applications, salinity problems arise in such areas where there are drainage problems. Salinity, one of the abiotic stress factors, negatively affects both the agricultural soil and the plants grown in the soil that is under the threat of salinity (Yılmaz et al., 2011). Against these stress factors, high yield producing and stress resistant species should be designated and cultivated in areas with salinity problem (Shannon, 1978; Epstein, 1985; Ashraf et al., 1986; Singh et al., 2018). Due to the expensive and difficult methods to eliminate the salinity problem in the cultivated land, salt-resistant plant species and the more tolerant genotypes of these species have been studied in recent years (Singh et al., 2018). Concordantly, seed reproduction has crucial value in the fig hybridization as well as in the seed reproduction mediated seedling production (Hartmann et al., 2011; Zarei et al., 2016; Nimbolkar et al., 2016).

In this study, seed germination and seedling growth performances of eight Turkish fig cultivars under salt pressure were resolved to effectively utilize *in vitro* screening technique. Likewise, the capability of germination of fig seeds under saline conditions has been demonstrated for the first time with this study by the wide application doses of NaCl and the susceptible/tolerance fig cultivars.

Materials and methods

Herein, mature seeds formed as a result of free pollination were used as vegetable material as Morgüz, Sarılop, Yeşilgüz, Sultan Selim, Halebi, Bursa Siyahı, Göklop, and İzmir Bardacık fig cultivars. For this purpose, the ripen fruits were obtained in season from Aydın Erbeyli Fig Research Institute located at 37° 51' 56.0" – 27° 39' 53.3" coordinates. First of all, the seeds are washed in the laboratory environment after being washed out and cleaned in a solution with sodium hypochlorite (5% active chlorine) with 0.1% (v/v). 20 g/L sucrose and 6 g/L agar containing hormone-free MS (Murashige and Skoog, 1962) medium were used as the main nutrient medium and the pH of the medium was set to 5.8. 0, 85.5, 171.1 and 342.5 mM NaCl were added to the basic nutrient medium. In the experiments, 25 ml medium in 100×15 mm petri dishes were used. 25 seeds were planted in each petri dish. While working with four replicas, the seeds were allowed to germinate for 45 days under saline stress. The cultures were incubated at 25 ± 1 °C under 16-h photoperiod with 35 $\mu mol \cdot m^{-2} \cdot s^{-1}$ supplied by cool-white fluorescent lamps. The number of seeds germinated during the trial period was recorded daily. At the end of the experiment, germination rate (%), seedling height (mm), number of leaves (pieces/seedling rootstock) and root length (mm) were recorded.

Data were analysed according to Minitab Package Program (MINITAB Inc.). Analysis of variance (ANOVA) was applied with the F test ($P < 0.05$). Significant differences were determined based on a 5% error limit with Duncan test and differences were determined with the help of letters. Angle values of percentages were used in the analysis.

Results and discussion

In this study, the interaction between the germination rates, seedling height, number of leaves and root length in terms of various doses of NaCl was found to be statistically significant (*Table 1*). In terms of germination rate, the seeds of Sultan Selim, Bursa Siyahı, Göklop, and İzmir Bardacık were found to have statistically similar high germination rates at 0 mM and 85.5 mM NaCl concentrations. However, germination rates in Morgüz, Sarılop, Yeşilgüz and Halebi seeds decreased significantly compared to control in 85.5 mM application. Significant decrease in germination rates was recorded in 171.1 mM NaCl concentration. In this saline concentration, no germination occurred in Sarılop and Yeşilgüz seeds. However, germination rates of 79.5% and 75.0% were determined in the seeds of Sultan Selim and Bursa Siyahı respectively which are the highest values of 171.1 mM NaCl administration. No germination was noted at a concentration of 342.5 mM saline in any of the fig cultivars (*Table 1*).

Seedling height values decreased in all genotypes with increasing salt concentration. Moreover, the seedling height of Sultan Selim and Bursa Siyahı has the highest values compared to other cultivars in increasing saline concentrations (*Table 1*). The number of leaves in seedlings decreased significantly with elevated NaCl concentration in all cultivars. At 85.5 mM NaCl concentration, Sultan Selim, Bursa Siyahı and Halebi had a higher number of leaves than the others. There was no significant difference in the number of leaves between cultivars in 171.1 mM NaCl concentration (*Table 1*). The longest roots in 85.5 NaCl concentrations were recorded in Bursa Siyahı (52.4 mm), İzmir Bardacık (50.9 mm) and Sultan Selim (46.7 mm). The root length was significantly reduced in all cultivars at the 171.1 mM NaCl concentration. There was no significant difference among cultivars at this concentration (*Table 1*).

This is the first scientific study to reveal germination performances of fig seeds under saline stress. However, there are studies conducted on this subject in other woody plant species, albeit limited. Although all of these studies vary according to genotypes, germination rates and plant growth in seeds have been reported to be significantly decreased with an increasing salt concentration in the environment (Vijayan et al., 2003; Rahneshana et al., 2018). Similar findings were obtained in our study as well. Experiments showed that germination rates of fig seeds under saline stress manifested a great change depending on the type of cultivars and NaCl concentrations. *In vitro* conditions, the germination rate in fig cultivars on nutrient media (control- no NaCl) was 83-98%. At 85.5 mM (0.5%) NaCl concentration, the germination rate in fig cultivars was 10.3-99%, and at the highest NaCl concentration 171.1 mM (1%) the germination rate in fig cultivars was 0-79.5% (*Table 1*). NaCl causes an increase in osmotic pressure in the environment and prevents the seed from receiving water (Ardakani, 2015). NaCl leads to ionic stress as well as osmotic effect. It can also affect the activity of many enzymes that play a key role in lipid degradation (Zaghdoudi et al., 2015). In our study, one of the striking findings was that there was no germination in Yeşilgüz and Sarılop in the nutrient medium containing 171.1 mM NaCl. On the contrary, the same saline stress onto Sultan Selim and Bursa Siyahı has the highest germination rates 79.5% and 75.0% respectively. These results are vital for salinity resistant fig breeding since the elimination of the salinity originate problems depends on improvements of the cultivated genotypes salinity resistance (Athar and Ashraf, 2009).

The lack of germination of the seeds in the high saline conditions is the biggest factor limiting the obtaining of plants (Zaghdoudi et al., 2015). Procurement of water, retaining chloroplast function and ion homeostasis dictates the plant competence in enduring saline stress. In addition to those, osmotically controlling metabolites, some proteins, enzymes that confine free radicals play an important role in the plant homeostasis during germination (Parvaiz and Satyawati, 2008).

Tolerance of the plants to saline stress generally varies according to their development stages (Zaghdoudi et al., 2015). It has been reported by different researchers that salinity reduces water intake in seeds, inhibits germination by suppressing genes encoding GA biosynthetic enzymes, and also reduces germination rate due to stimulating ABA accumulated in tissues (Doğan and Budaklı Çarpıcı, 2016; Kim and Park, 2008; Li et al., 2016). In our study, increasing salt rates significantly decreased germination rates of fig genotypes. However, germinated seeds continued to grow on the same saline media for approximately 30 days. The response of seedlings to saline stress varies according to the saline levels and in general, high saline levels have decreased plant growth significantly. Halted or impaired plant growth in high saline stress stems form, in particular: ion toxicity, nutrient constraints, osmotic and oxidative stress. These mechanisms lead to disruption in the membrane lipids, proteins, and nucleic acids via the inflated levels of reactive oxygen species. Sodium toxicity is the main stress factor in the high saline lands by causing an increased rate of accumulation of reactive oxygen species (Mudgal et al., 2010). In our study, we found that the size of the seedlings in six cultivars was reduced by approximately 80% at 171.1 nM NaCl concentration compared to no saline control. Bursa Siyahı was the least susceptible to saline stress in the size of the seedlings reduction (75.9%). In all cultivars, germination can take place at 85.5 mM NaCl dose, while the Bursa Siyahı and Sultan Selim cultivars are less affected by saline stress than other fig cultivars with respect to the size of the seedlings. Saline stress leads to a 45% decline in the size of the seedlings in Bursa Siyahı and Sultan Selim compared to no saline control. In other cultivars, this reduction ratio reached up to 70%. Another crucial finding in our study is that the root length in the Bursa Siyahı and Sultan Selim cultivars did not curtail compared to the control at the 85.5 mM NaCl concentration. In terms of root development, the 85.5 mM NaCl dose did not pose any threat in these cultivars. Therefore, Bursa Siyahı and Sultan Selim are defined as saline stress-tolerant fig cultivars. However, in the Sarılop and Yeşilgüz cultivars we have reported as sensitive to salt, root growth at the dose of 85 mM NaCl decreased by 60% compared to the no saline control. Saline stress tolerant plant species underwent certain adaptation to manage this stressful condition. A boost in the root/canopy ratio, changes in chlorophyll content, adjustments in the leaf anatomy contributes to hinder leaf ion toxicity. Hence, water homeostasis is maintained by these adaptations and photosynthesis can be sustained without any hindrance (Acosta-Motos et al., 2017). Our findings are partially compatible with the findings of Emek (2018), who investigated the response of Bursa Siyahı to saline stress *in vitro*. Emek (2018), in his study, evaluated the effects of 0, 40, 80, 120, 240, 320 and 480 mM NaCl concentrations on the plant growth in Bursa Siyahı after 6-week incubation. According to this research, plants were healthy at 0-80 mM NaCl concentrations, browning at 120-240 mM NaCl concentrations and chlorosis and deaths were detected at 320-480 mM concentrations. The researcher stated that the observations in Bursa Siyahı were done up to 120 mM NaCl. In our study, observations were made in 6 fig cultivars up to 171.1 mM NaCl concentration. However, in this study, we recommend the use of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1348513492

dose of 85.5 mM NaCl, which is more reliable in evaluating the response of many fig genotypes to saline stress as a result of plant growth, because some plants do not survive after exceeding this concentration. Abdolinejad and Shekafandeh (2014) investigated the effects of different saline concentrations (0, 80, 120 and 160 mM) in *in vitro* conditions on two Persian fig cultivars: Anjir Sabz and Shah Anjir. At 160 mM NaCl concentration, Anjir Sabz reported having more chloride ion accumulation. Soliman and Alhady (2017) revealed that in their *in vitro* replication study with five local fig cultivars, a five-week salt application resulted in a significant reduction in plant growth and rooting. In another study conducted with Brown Turkey and Royal cultivars of fig, salt was applied to irrigation water (Alswalmeh et al., 2015). This study announced that the Brown Turkey variant was less affected by saline stress than the Royal variant. In another *in vitro* replication study on Black Mission, Brown Turkey and Brunswick fig cultivars, different concentrations of NaCl were applied to replicating media containing different plant growth regulators. In the study, Black Mission, Brunswick, and Brown Turkey are listed as the most resistant cultivars to saline stress in Saudi Arabia respectively (Metwali et al., 2014). The effects of seven NaCl doses ranging from 1000-7000 mg L^{-1} (17.1-119.7 mM) on plant growth in four fig cultivars were tested *in vitro* (Yehia et al., 2018). Researchers suggested that 7000 mg L^{-1} (119.7 mM) NaCl is lethal. However, six fig genotypes showed development at 171.1 mM NaCl concentration in our study. The number of leaves of fig genotypes was recorded between 3.1 and 5.0 in 85.5 mM NaCl concentration. Yehia et al. (2018), reported that the number of leaves ranges between 2.4-4.0 at 5000 mg L^{-1} (85.5 mM) NaCl in the six-week-old plants. These values are consistent with our findings. In another study, saline stress resistance of four fig genotypes was tested by addition of 0.6, 4, 6, 8 dS m^{-1} saline containing water (6, 40, 60, 80 mM). Researchers found a negative correlation between increasing saline concentration and plant development. Of note, SxK genotype was determined as the most tolerant variant in their study (Zarei et al., 2016).

Conclusion

In this study, the growth performance of eight Turkish figs cultivars against saline stress was compared successfully *in vitro*. At 0 nM, 85.5 nM, 171.1 nM and 342.5 mM NaCl concentrations and 45 days after seed germination rate (%), seedling height (mm), number of leaves (pieces/seedling rootstock) and root length (mm) were assessed. The tolerance against saline stress differences between fig genotypes could be determined at highest 171.1 mM NaCl concentration regarding germination of seeds occur *in vitro*. In the study, the highest NaCl dose in which fig genotypes can be evaluated according to seedling development criteria was determined as 85.5 mM. A higher NaCl dose (171.1 mM), there were no germination in Sarılop and Yeşilgüz genotypes. When the germination rates and seedling growth were evaluated, it was revealed that Sultan Selim and Bursa Siyahı fig genotypes were more tolerant to saline stress than others. Sarılop, which is an important fig genotype in a dried fig market, was assigned as the most susceptible fig genotype to saline stress.

Most effective solution against prevailing salinity problem in agricultural areas is the development of tolerant cultivars and rootstocks to saline stress. Ratio of seed germination, which is important for hybridization and seedling production in fruit species, must be determined to the select genotypes under stress conditions in breeding

programs. Turkey is one of the important gene centers of the fig so it has large genetic variability for producing new fig cultivars tolerance to saline conditions by plant breeders of this country. In fig, this is the first study reporting *in vitro* germination performance of the seeds in salt conditions although some studies exist on the development of seedlings under salinity stress. It can be mentioned that a guiding and useful study has been presented for future fig breeding programmes.

Abstract. Monitoring the impact of climate change on forest ecosystems, particularly at the species level, can be currently observed in many parts of the world. In this study, Maxent species distribution modelling algorithm was used to predict the suitable habitat for the medicinally important species; *Panax pseudoginseng* in Sikkim Himalaya. The nineteen bioclimatic variables from Worldclim database were used to predict the current potential distribution. Representative Concentration Pathway (RCP) 4.5 and RCP 8.5 scenarios of IPCC 5th assessment was used for predicting the future distribution of species in 2050 and 2070. The Maxent model performed better than random with an average test AUC (Area under Curve) value 0.927 under the predicted current distribution. The projected distribution in future under the both RCPs scenarios showed upward shift of species (i.e., gain in suitable habitat area) in high elevation area over the years of 2050 and 2070. Areas with suitable climatic conditions predicted to decline by the 2050s and the 2070s under both RCP scenarios. The application of predictive Maxent modelling approach presented here may provide policymakers and conservationists, with a useful tool for prediction of species in future climate with only presence distribution records and therefore, can be an effective approach for species restoration and conservation actions.
Keywords: *Himalaya, climate change, conservation, Panax pseudoginseng, medicinal plants*

Introduction

Various components of a landscape (physical, biological and socio economic) are being affected by climate change, mostly along regional temperature changes where impacts due to changes in snow, ice and permafrost regions have influenced ground instability, enhanced glacial melt, enlargement and increase of glacial lakes in mountain regions, hence early and increased spring peak discharges in rivers (IPCC, 2014). Responses of species to impacts of climate change have been manifested in changes in phenology (Corlett et al., 1998; Settele et al., 2016), earlier onset of spring (Mohandass et al., 2015), migration process (Saltré et al., 2015), and lengthening of growing season (IPCC, 2014; Singh and Kushwaha, 2016). Changes in the abundance and distribution range of some species, changes in community composition, and local extinctions of species have been attributed to climate change (Davis and Shaw, 2001; Thomas et al., 2004; Moritz and Agudo, 2013; Maclean et al., 2015). The response of climate change on species distribution could be more rapid and expected to be faster in higher altitude areas, where species occur close to their physiological tolerance (Innes, 1991; Diaz and Bradely, 1997; Gratani, 2014). At regional scale these changes affects the natural

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1349313511

distribution of species, causing temporal reproductive isolation or even towards the extinction (Araujo et al., 2005; Schröter et al., 2005; Priti et al., 2016; Yi et al., 2016). To reduce the species extinction rates and conservation of its natural habitats in human dominated landscape, delineating protected areas are often the strategy by which conservation can be ensured. Species distribution models (SDMs) is useful in taking important decisions in developing conservation strategies particularly for poorly known or other species (Guisan and Thiller, 2005; Guisan et al., 2013; Cuyckens et al., 2016; de Siqueira et al., 2009; Kumar, 2012; Perez-Garcia et al., 2013; Khanum et al., 2013; Shrestha and Bawa, 2014; Sohel et al., 2016) by providing a strong predictive framework for identifying additional natural populations of species (Menon et al., 2010), and relocating the threatened population of species to natural suitable habitats (Adhikari et al., 2012).

The Himalayan region is experiencing warming at higher rate than the global average (three times high, 0.06 °C/year; Shrestha et al., 2012). Being a biodiversity hotspot region, Himalaya, and sensitivity towards climate change, information in this region is not adequate and limited to few studies on the aspects of response of species towards climate change (Saran et al., 2010; Kumar, 2012; Forrest et al., 2012; Telwala et al., 2013; Shrestha and Bawa, 2014; Manish et al., 2016). Therefore, this globally important region warrants more understanding on species response towards the climate changes and ecosystem functioning also due to its distinctive evolutionary history and rich species diversity (Pandit and Babu, 1998; Pandit et al., 2007).

Eastern Himalayan region has unique assemblage of endemic plant species and many of them are known for their medicinal values, and among them is *Panax pseudoginseng* Wall., also known as *Himalayan Ginseing* is a well known high value medicinal plant. The species is also one of the threatened plant species describes in Red Data Book of India (Nayar and Sastry, 1990). State of Sikkim in the Eastern part of Indian Himalayan region has 31% of the total geographical area under legal protection of protected area network through one National Park and seven Wildlife Sanctuaries which is much higher than the average of country (~4% of total geographical area). Whether the current situation of protected area network in Sikkim Himalaya would encompass the distribution of *P. pseudoginseng*, and what level of research and conservation strategies are required for protection and conservation to manage the natural habitats of *P. pseudoginseng* are key questions on the face of rapid climate changing scenario. In this rationale objectives of this study are: (1) to determine the important climatic variables that enhance prediction for *P. pseudoginseng* in current climatic situations, (2) to model the present predictive distribution range of *P. pseudoginseng* and potential future distribution under two climate change emission scenarios i.e., Representative Concentration Pathways (RCP 4.5 and RCP 8.5) for 2050 and 2070 year, and (3) to propose conservation strategies and management options under different scenarios.

Materials and methods

Study area

Sikkim State in Indian Himalayan Region (IHR) is located between 27°00'46" to 28°07'48" N latitudes and 88°00'58" to 88°55'25" E longitudes (*Fig. 1*). The State encompasses four districts (i.e., North Sikkim, East Sikkim, South Sikkim and West Sikkim) covering 7,096 km^2 geographical area. This mountainous state has - natural gradient of altitude ranging from 300 m to 8,586 m amsl. Biogeographically, Sikkim is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1349313511

part of Eastern Himalayan region and has been categorized in two biogeographic zones (Trans Himalaya and Himalaya) of India (Rodgers et al., 2002) - Trans-Himalaya - Sikkim (1C) and Eastern Himalaya (2D). Broad representative vegetation types (Champion and Seth, 1968) of the Eastern Himalayan region of India are tropical moist deciduous, subtropical broad leaved forests, Broad leafed and conifer mixed forests, wet temperate forests, sub alpine forests, and alpine meadows (moist and dry alpine scrubs). Protected Area Network in the Sikkim includes seven Wildlife Sanctuaries (Shingba Rhododendron Sanctuary, Kyongnosla Alpine Sanctuary, Pangolakha Wildlife Sanctuary, Fambonglho Wildlife Sanctuary, Maenam Wildlife Sanctuary, Barsey Rhododendron Sanctuary and Kitam Bird Sanctuary), and one National Park (Khangchendzonga NP), covering a total area of 2183.1 km^2, which is 30.8% of the total geographical area of the State.

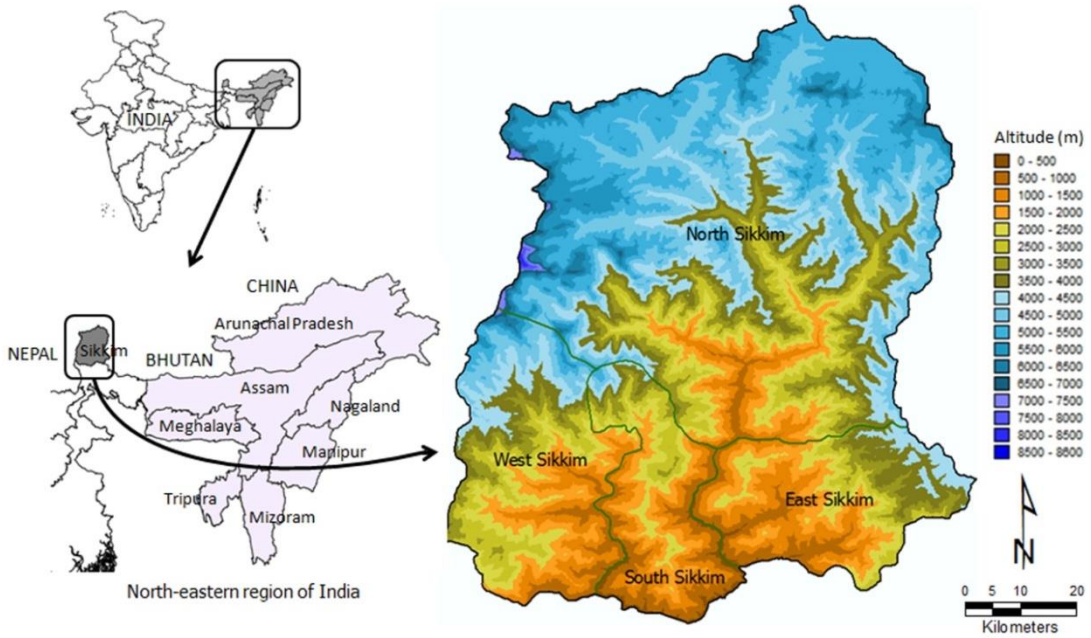

Figure 1. *Map of study area showing the districts and elevation gradients of Sikkim Himalaya*

Study species

Panax pseudoginseng Wall. (Araliaceae) [syn. *Aralia pseudoginseng* (Wall.) Benth. ex C.B. Clarke; *Aralia quinquefolia* Decne. & Planch. var. pseudoginseng (Wall.) Burkill; *Panax schinseng* var. *nepalensis* Nees; *Panax sikkimensis* R.N. Banerjee] is commonly known as *Himalayan Ginseng*, *Indian Ginseng* and *False Ginseng*. It is a perennial herb that grows up to 50 cm in height (Clarke, 1879). It is distributed in temperate zone of thick conifer-oak mixed and Himalayan birch forests where the soils has deep humus content. The species starts flowering during the months of May-June and fruiting during July-October. The flowers are terminal, unequal, umbellate and pale green or orange-yellow in colour. Its bear's dull green to black fruits measuring 3-5 mm with a black spot at the top part. Medicinally the Himalayan Ginseng is well-liked to known as elixir of life and its rhizomes uses for preparation of rejuvenating and revitalizing tonic. It is used to increase longevity, mental agility and to check hypertension. Locally it is used as a haemostatic for treating conditions such as

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1349313511

vomiting and coughing up of blood, blood in the urine or stool, bleeding nose and hemorrhagic disease.

Known habitats of *P. pseudoginseng* in this study are under sub-alpine zone between 3000 and 4000 m amsl, which comprises locations those remain moist for 8-9 months, and dry season for 3-4 months. A cold climate is normal for all the locations and dew, frosts or days under snow occur as regular events at some locations. The plant normally grows under shade and most abundantly under canopy of *Abies densa*, *Betula* spp., *Lithocarpus pachyphyllus* and *Rhododendron* spp., however, occasionally it can be found in open forests also.

Species presence data

Herbarium records of the species were analyzed from the collection of Botanical Survey of India, Sikkim Office. All the herbarium sheets (12 in number) were geo-referenced through location of collections on the maps, this was followed by field surveys and ten new locations were also recorded, thus leading to a total of 22 locations for current presence data. These locations were transferred to GIS platform using Arc GIS software.

Environmental predictors

Nineteen bioclimatic variables are available from WorldClim database (http://www.worldclim.org) at a resolution of approximately 1 km (Hijmans et al., 2005) was used for distribution modeling of *P. pseudoginseng*. These variables, derived principally from monthly temperature and precipitation data (*Table 1*), have proven relevance in modeling species distribution (Pearson and Dawson, 2003; Irfan-Ullah et al., 2007; Loiselle et al., 2008; Khanum et al., 2013). Intergovernmental Panel on Climate Change (IPCC) 5 data for future climate projection conditions for the years 2050s and 2070s were obtained from the Consultative Group on International Agricultural Research (CGIAR)'s Research Program on Climate Change, Agriculture and Food Security (CCAFS) climate data archive (http://www.ccafs-climate.org/) to project the potential distribution in future.

The future climatic projection datasets are based on of IPCC 5th assessment and were calibrated and downscaled using the current climatic data. Instead of using single global circulation model (GCM), we used data from three different global climate models for reducing the uncertainty. MRI-CGCM3, CSIRO-MK3.6 and HadGEM2-CC global climate models were selected for modeling the future prediction (Khanum et al., 2013; Barber, 2015; Dotchamou et al., 2016). Each GCM was tested under two future greenhouse gas concentration trajectories, called Representative Concentration Pathways (RCP) i.e., RCP 4.5 and RCP 8.5 for the periods 2050 and 2070. The RCP 4.5 ("intermediate stabilization pathways") was developed by Pacific Northwest National Laboratory's in the United States. It is relatively stable scenario in which total radiative forcing reaches 4.5 W/m^2 and stabilized shortly after 2100, without overshooting the long-run radiative forcing target level (Clarke et al., 2007; Smith and Wigley, 2006; Wise et al., 2009). The RCP 8.5 was developed by the International Institute for Applied System Analysis in Austria. It is characterized by increasing greenhouse gas emissions throughout the 21st century and radioactive forcing is predicted to reach up to 8.5 W/m^2 by 2100 (Riahi et al., 2007; Riahi et al., 2011). These two scenarios are being used by various workers to analyze impacts of climate change on predictive species

DOI: http://dx.doi.org/10.15666/aeer/1706_1349313511

distribution modeling (Monahan et al., 2013; Shrestha and Bawa, 2014; Li et al., 2015; Kang et al., 2016; Sohel et al., 2016; York et al., 2016). For future potential distribution predictions of *P. pseudoginseng*, we ran separate models (*Appendix*) and also by averaging the results (ensemble approach) from the CGCM3, CSIRO-MK3 and HadGEM2-CC future climate models (Araujo and New, 2007).

Table 1. *Percentage contribution (average of over twenty replicate runs) and permutation importance of the climatic variables in the Maxent models for Panax pseudoginseng*

Climatic variable	Code	Unit	Percentage contribution	Permutation importance
Annual mean temperature [AMT]	Bio1	°C	-	-

Predictive Maxent modeling

For the prediction modelling, maximum entropy based technique i.e., Maxent ver. 3.3.3k (http://www.cs.princeton.edu/~schapire/Maxent/) was chosen due to its better performance with small sample sizes relative to other modelling algorithms (Elith et al., 2006). This programme attempts to estimate a species distribution by finding the probability distribution of species occurrence i.e., closest to uniform subject to the constraint that the mean environmental conditions by the model should be close to the empirical average of the conditions at the presence localities (Phillips et al., 2006; Phillips and Dudik, 2008; Elith et al., 2011).

A total of twenty replicate runs were set for model building and averaged the result. In the replicated runs the cross validation technique was used, where samples divided into replicate folds and each fold was used for test data. Jackknife test and percent variable contributions were used to estimates the relative influence of different predictor variables, which estimate the training gain of every variable and recommend the best interpreter for the prediction of distribution of species. The AUC (area under curve), area under the ROC (Receiver Operating Characteristics) curve, was used to evaluate model performance. However, ROC AUC provides a threshold-independent measure of model performance compared to that of null expectations, such should provides an overall picture of the predictive nature of models (Stockwell and Peterson, 2002;

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1349313511

Fawcett, 2006). An AUC statistic closer to 0.5, indicates that model did not perform better than random whereas closer to 1.0, indicates perfect discrimination (Swets, 1988). Araujo et al. (2005) recommended the following interpretation of AUC for the models generated, viz., excellent if AUC > 0.90; Good if 0.80 > AUC < 0.90; Acceptable if 0.70 > AUC < 0.80; Bad if 0.60 > AUC < 0.70; Invalid if 0.50 > AUC < 0.60.

The multi-collinearity test was conducted using pairwise Pearson's correlation coefficient (r) to examine the cross-correlation among the climatic variables using the ENM tool (Warren et al., 2010). The variables with cross-correlation coefficient value of $\geq +0.90$ were excluded from the analysis (see *Table A1* in the *Appendix*). Based on such criterion, 13 bioclimatic variables were excluded and only 6 bioclimatic variables were used in the final model to predict the effect of climate change on the future distribution of *P. pseudoginseng*. For validating the model robustness a 10 percentile training presence threshold rule was executed over a twenty replicated model runs (Pearson et al., 2004). Other parameters were set to default as the program is already calibrated on a wide range of species datasets as suggested by Phillips and Dudik (2008). To avoid erroneous predictions of suitable habitat under future climate scenarios for 2050 and 2070 'fade by clamping' option was used in Maxent, which removes heavily clamped pixels from the final predictions (Fielding and Bell, 1997; Phillips et al., 2006). For each of the three habitat models, including the current *P. pseudoginseng* potential distribution and the two future predictions under the RCP scenarios (2050 and 2070), we calculated the total area of habitats, and amounts of stable/no change (areas of the current potential range predicted to remain suitable), unsuitable, lost (areas not predicted to remain suitable in future), and gained habitats (areas that are predicted to be suitable future that are not currently suitable) areas for each of the two future models under 2050 and 2070 years.

Results

The selected climatic variables, 6 in number, provided a satisfactory prediction of the potential current distribution of species (*P. pseudoginseng*) evident by mean test AUC value of 0.927 ± 0.043, and considered excellent (Araujo et al., 2005). Amongst these climatic variables, precipitation seasonality (PS) and mean temperature of coldest quarter (MTCQ) appeared significant for the occurrence of the species (collectively contributed to 85.8% of the model's variance; *Table 1*) indicating role of moisture and cold environment as apparent by contribution of Mean temperature of warmest quarter (MTWAQ) and precipitation of warmest quarter (PWAQ). Temperature annual range (TAR) and isothermality (ISO) made the lowest contribution to the predictive model. Considering the permutation importance, MTCQ had the maximum influence on model and contributed to 76.6%, followed by mean temperature of warmest quarter (MTWAQ), i.e., 21.9% (*Table 1*). Climatic profiles (based on the occurrence records; minimum, maximum and mean value of nineteen current climatic variables) for the species under investigation are presented in *Table 2*.

The current suitable habitats for *P. pseudoginseng,* covering 14.4% of the total geographical area, are confined to mainly in central part of North Sikkim district, north-eastern part of East Sikkim district, north-western part of West Sikkim district, with some patches in northern part of South Sikkim district (*Fig. 2a*). The Jackknife test estimated the training gains of each predictor variable, when a variable is used in separation, when it is excluded, and when all variables are utilized. The graph of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1349313511

Jackknife predictor test indicates that the MTCQ and PS as main factors influencing the distribution pattern and has highest training gain (*Fig. 3a*). The response curve of *P. pseudoginseng* showed that the predicted habitat suitability area was initially increased sharply with increasing PS and was bell shaped with MTCQ (*Fig. 3b, c*). Areas with suitable climatic conditions for *P. pseudoginseng* are predicted to decline by the 2050s and the 2070s under both RCP scenarios. Averaged future predictions from three climatic models under an intermediate scenario (RCP 4.5) of 2050 showed loss of suitable area (190.88 km^2; 2.69%); while further loosing the suitable habitat area over the year 2070 (266.1 km^2; 3.75%) (*Fig. 2b, c; Table 3*). The loss of suitable habitat area in average model of RCP 4.5 scenario was predicted mainly in patches form of northern part of West Sikkim and central parts of North Sikkim districts for year 2050, whereas in 2070 the loss predicted continuously over the north-western part of West Sikkim, northern part of South Sikkim, north-eastern part of East Sikkim and, central and north-eastern part of North Sikkim districts (*Fig. 2b, c*). Conversely, in higher scenario (RCP 8.5) the loss of suitable habitat areas was predicted continuously in northern part of West and South Sikkim districts, and in patches form of north-eastern parts of North and East Sikkim districts for year 2050, whereas in 2070 the loss predicted continuously over the entire four districts of Sikkim (*Fig. 2d, e*). However, the loss of suitable area predicted under a RCP 8.5 was more than RCP 4.5 for 2050 (307.26 km^2; 4.3%), which further continuously lost predicted suitable habitat over the year of 2070 (63,509 km^2; 8.95%) (*Fig. 2d, e; Table 3*). Those scenarios also decreased the number of suitable patches (i.e. no change/stable) in RCPs 4.5 by 8.21% to 7.51% and RCP 8.5 by 6.57% to 1.95%, over the years 2050 to 2070 respectively. Another common feature for projected distribution in future climate models under the both RCPs scenarios (4.5 and 8.5), was the upward shift of species (i.e., gain in suitable habitat area) in high elevation area over the years of 2050 and 2070.

Table 2. *Climatic profile of Panax pseudogensing based on herbarium and presence records*

Climatic variable	Code	Unit	Min.	Max.	Mean	SD
Annual mean temperature [AMT]	Bio1	°C	3.1	8.2	4.9	1.6

Discussion

The modelling result suggests that the suitable habitat area for *Panax pseudoginseng* (*Himalayan Ginseng*) would shrink under the predicted levels of climate change in future. The Maxent model performed better than random, with satisfactory mean test AUC value. Maxent predicted the upward shifts of (i.e., more than 4000 m high elevated zones) *P. pseudoginseng* suitable area under the both intermediate and high scenarios, with greater risk of habitat loss from current suitable predicted areas in Sikkim Himalaya. Field observation suggest the *Himalayan Ginseng* is highly dependent on local climates, the plant thrives only when there is moist soil humus content at places ranging between 3000-4000 m elevations, due to this the species has confined distribution in eastern Himalayan region of India. Maxent model result shows, predicted suitable habitat area under the current climatic condition would become unsuitable in predicted future climate change scenarios, resulting in local extinction of the species.

Considering climate sensitive plants, the seasonality (such as temperature, rainfall, humidity, soil temperature, soil moisture content and day length) expose them to regular periodic changes in the quality and abundance of resources (Franklin et al., 1992). All of these factors are known to play a role, only or in combination with, in triggering the phenological or physiological changes. Some species may be capable of adapting to future climatic condition through phenological changes (such as early or late flowering/fruiting) or through adaptation towards microclimate conditions responsible for survival of its natural population. In this investigation, *Himalayan Ginseng* showed the range expansions of suitable habitat towards higher elevated zones in future climate change scenarios, which may be to make possible through adaptation towards the changes in local climatic condition. Khanum et al. (2013) showed similar results of adaptation and range expansion of species for predicting the impact of climate change of three important medicinal asclepiads in Pakistan. Midgley et al. (2006) suggested that, in predicting the impact of climate changes on plant species the dispersal of seed is also a regulating factor for adaptation of species. A study across twenty-six mountains in Switzerland demonstrated that, the alpine flora expanded their ranges upward towards the peaks (Grabherr et al., 1994; Pauli et al., 1996) and a similar study by Moiseev and Shiyatov (2003) showed the upward movement of treelines in Siberia.

While generalizing the ecosystem responses towards the rapid warming in the Himalayan region, Singh et al. (2010) have reported that the woody species of higher elevated zones have began to invade the alpine meadows, and result in a complex series of changes in ecosystem functioning process with involvement of the soil subsystems. Another hypothesis is the future exploitations pressure on this plant species will make coping difficult against the climate changes and this could cause the extinction of this species despite good showing in the current and future climate suitable habitats (Svenning et al.,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1349313511

2009). The present study shows that *Himalayan Ginseng* is threatened under the predicting climate change scenarios in Sikkim, Himalaya; a similar kind of results have been reported from another studies for economically important species, viz., studies on Baobab trees by Sanchez et al. (2011); on medicinal Asclepiads in Pakistan by Khanum et al. (2013); on Caterpiller fungus in Nepal by Shrestha and Bawa (2014) and on *Dysoxylum binectariferum* by Sohel et al. (2016) in northeastern part of Bangladesh. Another parameter such as soil and land transformations would also become the contributing factor for predicting the species response in climate change (Pearson and Dawson, 2005), but the present study did not incorporate these parameters, due to unavailability of datasets.

Species with known economic importance value experiences pressures, (i.e., loss of natural habitats from climate change events, changes in landuse and land cover patterns, and overexploitation) because of their known utility (Pandit et al., 2007). These threats adversely affect natural plant resources in Himalayan region of India. The high medicinal important is responsible for their extraction from the wild which has already reduced the population sizes of *Himalayan Ginseng* in the natural population (Pandit and Babu, 1998). Loss of natural habitats due to deforestation, developmental works and expansion of agricultural practices have driven many of the endemic and medicinally important plant species to the brink of extinction in Himalaya region (Pandit et al., 2007). The *Himalayan Ginseng* is already listed as threatened taxa in the Red Data Book of India (Nayar and Sastry, 1990). On regional scale the climate change is one of the greatest challenges for conserving the biodiversity and forests ecosystems. Changes have already reported in different region, including impact of change on plant biodiversity in Europe (Thuiller et al., 2005), plant species vulnerability to climate change in Peninsular Thailand (Trisurat et al., 2011), declines of woody plant species ranges under climate change in Yunnan, China (Zhang et al., 2014) and extinction of freshwater swamp forest trees (*Pongamia pinnata* and *Barringtonia acutangula*) of Bangladesh in climate change scenarios (Deb et al., 2016).

Conservation of natural plant resources at species level has often failed owing to lack of proper knowledge of the target species in term of habitat suitability. The application of Ecological Niche Models (ENMs) to extract simple inventory data (such as presence records of species) may provide predictions of species under changing climates at both regional and local scale, and the models may be used to make recommendations for policymakers and conservationists in dealing with potential climate change (Sanchez et al., 2011). Here, we used the maximum entropy based modelling techniques, as implemented in the ENM software Maxent (Phillips et al., 2006; Elith et al., 2006, 2011), to summarize the climatic niche of the *Himalayan Ginseng* to predict changes in climate change emission scenarios. Maxent accounts for some consequences, for example, it does not estimate the probability of occurrence directly, but rather the environmental suitability for the species that can be mapped in a geographic space (Royle et al., 2012). Considerably, it is the most widely used and has good predictive power capabilities (Elith et al., 2006). Maxent have been used extensively for investigating plant and animal responses to climate change (Trisurat et al., 2011; Chitale and Behera, 2012; Khanum et al., 2013; Kumar, 2013; Shrestha and Bawa, 2014; Alamgir et al., 2015; Cuyckens et al., 2016; Sohel et al., 2016).

Conservation strategies

Considering the results in this study by predictive Maxent modelling on distribution of *Himalayan Ginseng* in Sikkim Himalaya, there will be moderate to high impacts under the future climate change scenarios. The most of suitable habitat area predicted for this plant

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1349313511

species might already be devoid of populations due to transformation of landuse, and overexploitations by local people for economic gain. A recent investigation on predicting the impact of climate change on a tree species (*Dysoxylum binectariferum*) in north-eastern part of Bangladesh by Sohel et al. (2016) suggested that the combined effect of human induced anthropogenic factors and change in climate condition in future will increase the extent of unsuitable habitat for the plant. Therefore, successful management plan for conserving the natural population in human dominated landscape is needed which can be used to address the issues and generate connectivity across protected areas (Urbina-Cardona and Flores-Villela, 2010). Besides designating a new protected area, the existing protected areas should have successful management plan for conservation and restoration of key species. These management plans should consider ecotourism, restriction of grazing, firewood collection and forest fire, involving the field researchers, NGOs and local communities. The subtropical to temperate and alpine areas of Sikkim is of special conservation interest as it is also suitable area for the conservation of key species such as the Snow Leopard (Sathyakumar et al., 2011b; Forrest et al., 2012), Red Panda (Ghose et al., 2011), Rhododendrons (Kumar, 2012) and for Galliformes (Sathyakumar et al., 2011a) in different protected area of Sikkim. This is also the area where *Himalayan Ginseng* exhibits the highest generic diversity (Sharma and Pandit, 2011).

Another possible conservation strategy for *Himalayan Ginseng*, especially for areas at high risk of habitat loss, e.g., in Pangolakha Wildlife Sanctuary and Barsey Rhododendron Sanctuary (*Fig. 2*), could be compensated by ex situ germplasm collection and micropropagation techniques, as suggested by Sanchez et al. (2011) for Baobab trees in Africa. Moreover, results of habitat loss do not necessarily suggest extinction but certainly increase the local extinction risk (Alarcón and Cavieres, 2015). The Convention on Biodiversity (CBD) suggested that a minimum representation of species habitat at ecosystem level should be under protection between 10-12% (Burgess et al., 2005; Tear et al., 2005), or 17% for terrestrial ecosystems (Moilanen et al., 2013). In this study, the current network of PAs accomplishes and even surpasses this suggestion area (at 30.8%) where, most of the natural population of *Himalayan Ginseng* are growing (*Fig. 4*). *Table 4* showed the area statistics of predicted potential habitats for *Himalayan Ginseng* in current climatic condition under different PAs network of Sikkim. The most effective strategy for protecting the *Himalayan Ginseng* viable populations in the areas of suitable future habitat is through conservation or sustainable utilization (Sanchez et al., 2011). For example, if local peoples are made aware that they may reap higher economic benefits from this plant left in their natural habitat than if grown as a crop this change in priority of action would yield better conservation outcome for the *Himalayan Ginseng*.

Table 4. *Present projection of suitable habitat area of P. pseudogensing in different PAs of Sikkim*

Protected area		**Predicted potential area habitat for *P. pseudogensing***	
Name	**Area (km^2)**	**km^2**	**%**
Khangchendzonga National Park	1784.00	290.46	16.28
Shingba Rhododendron Sanctuary	43.00	18.77	43.65
Kyangnosla Alpine Sanctuary	31.00	18.71	60.35
Pangolakha Wildlife Sanctuary	128.00	36.55	28.55
Maenam Wildlife Sanctuary	35.34	0.56	1.58
Barsey Rhododendron Sanctuary	104.00	8.60	8.27
Total	**2125.34**	**373.65**	**17.58**

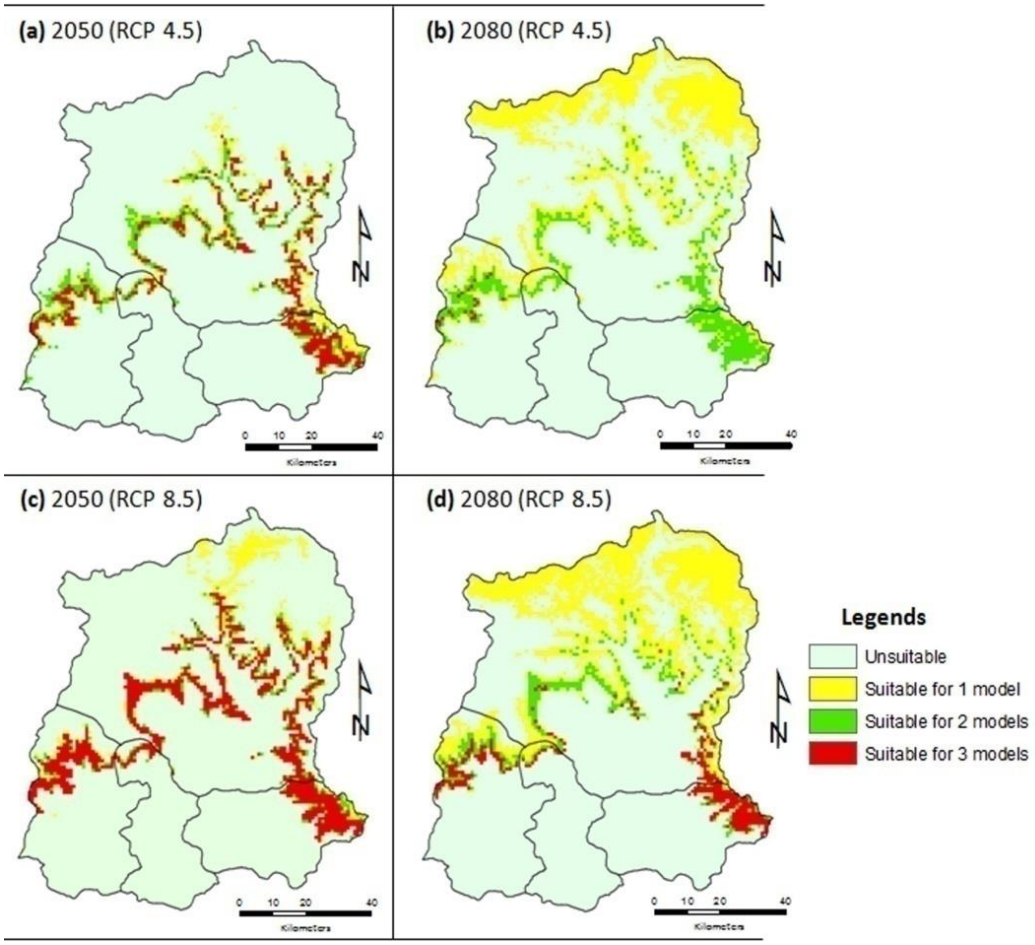
APPENDIX

Uncertainty among model predictions

It should be noted that only three global circulation models (GCMs; MRI-CGCM3, CSIRO-MK3.6 and HadGEM2-CC) under two future climate scenarios (RCP 4.5 and 8.5) were used in this study (*Fig. A1*).

Figure A1. *Differences in future potential predictions, among three different Global Circulation Models (GCMS) viz.; CGCM3, CSIRO-MK3 and HadGEM2-CC for Panax pseudoginseng. Where cyan color shows unsuitable prediction, yellow color shows predicted suitable habitat area by at least one of the GCMs, green color shows predicted suitable habitat area by two GCMs, and red shows predicted suitable habitat area by all three GCMs*



http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1349313511

Other scenarios and GCMs could give different results. Buisson et al. (2010) accounted that the Maxent or other modeling algorithms used could yield large variation in projections, followed by GCM, whose contribution increased over time. In order to report for certain future uncertainty Buisson et al. (2010) recommended using several GCMs and scenarios. Model projections also depend on the year. The years 2050 and 2070 are commonly used in studies dealing with the impacts of climate change on biodiversity (Thuiller et al., 2006; Khanum et al., 2013; Dowling, 2015; Hansen and Phillips, 2015; Koo et al., 2015; Al-Qaddi et al., 2016; Deb et al., 2016; Sohel et al., 2016). As expected, projections for 2070 displayed more negative impacts than projections for 2050(described by Thuiller et al., 2006; York et al. 2014) in RCP 8.5 scenario of climate change. However, in RCP 4.5 scenario projections for 2050 and 2070 displayed less likely to negative impacts.

A pertinent question which arises while studying the potential future distribution of a species is the validity and/or accuracy of the GCM and scenarios commonly used for this purpose, as different GCM from different climatic research centers show different results. However, to date, this is the best data available, and it is still commonly used to study the potential effect of climate change on species' distributions (Buisson et al., 2010; Marini et al., 2010; Khanum et al., 2013; Dowling, 2015; Hansen and Phillips 2015; Koo et al., 2015; Al-Qaddi et al., 2016; Deb et al., 2016; Sohel et al., 2016; Kang et al., 2016). The precautionary principle suggests that the uncertainty about predicted changes in climate does not justify lack of action. It is better to use the data which is available and carry out the studies required to make recommendations for conservation.

A SURVEY ON WEED MANAGEMENT IN DRY LENTIL FIELDS

PALA, F.

Department of Plant Protection, Faculty of Agriculture, Siirt University, Siirt, Turkey
(e-mail: firatpala@siirt.edu.tr; phone: +90-484-212-1111)

(Received 23rd Oct 2018; accepted 7th Jan 2019)

Abstract. A questionnaire consisting of 20 questions about weed, herbicide, tillage and crop rotation was applied to 100 lentil farmers to determine the current state of a weed problem in lentil fields in 2016. Common weeds were determined charlock mustard (*Sinapis arvensis* L., 36%), devil-on-all-sides (*Ranunculus arvensis* L., 16%), cleavers (*Galium aparine* L., 11%), makhobeli (*Cephalaria syriaca* L., 8%), and knapweed (*Centaurea depressa* L., 8%), respectively. The majority of participants used aclonifen (89%) as a post-emergence to control broadleaf, besides, clethodim (26%), haloxyfop-methyl-ester (17%), tepraloxydim (16%), quizalofop p-ethyl (15%), and fluazifop p-butyl (6%) for grass, respectively, and as a total herbicide glyphosate (4%) as well. But, respondents (66%) stated that lentils had crop injury from aclonifen. Growers took into account the price (43%), herbicides (38%), weeds (10%) and crop rotation (9%) to choose herbicides. Managing weeds with hand-picked (76%) were common in areas that did not use herbicides. Preventive measures were used such as crop rotation (61%), late sowing (10%), and deep tillage (4%), furthermore, farmers planted wheat (91%) and barley (9%) as a preceding crop. In this study, dissatisfaction was determined by the efficacy and selectivity of aclonifen which is registered herbicide on lentils in Turkey. Lentils have a short stature, slow early-season growth rate, and open-canopy growth habit, which make them poor competitors with broadleaf weeds. So weed management in the early period such as pre-planting, pre-emergence or early post-emergence herbicides, and IMI herbicide-tolerant lentil varieties (Clearfield) have been investigated.
Keywords: *lentils*, *mustard, aclonifen, crop rotation, late sowing, plow tillage*

Introduction

Lentils (*Lens culinaris* Medik.), which is well-known as nutritious food, is one of the important crops cultivated in the cool season. It grows as an annual bushy leguminous plant typically 20-45 cm tall, which produces many small purse- shaped pods containing one to two lens-shaped seeds each (SPG, 2017). It is not only a rich source of improved nutrition for people but also provides nutritious straw for animals. Lentil contains about 11 per cent water, 25 percent protein and 60 percent carbohydrate. The important lentil growing countries of the world are India (18.00 million ha), Canada (12.17 million ha), Turkey (2.43 million ha), Iran (1.68 million ha), Australia (1.62 million ha), Bangladesh 1.24 (million ha), Syria (1.11 million ha), USA (1.04 million ha) respectively. Turkey ranks third in the world in respect of production as well as area followed by India and Canada (FAOSTAT, 2014). One-third of the country's production of lentil is provided by Diyarbakir province (TUIK, 2016).

Lentil production provides several agronomic advantages and opportunities to increase profit margins. Besides tolerating drought conditions, cool temperatures, and a wide variety of soil types, leguminous pulse crops can also help fix nitrogen in the soil. However, growers should be aware of the challenges and opportunities of managing weeds in these crops (Pala et al., 2018). The common problem is weeds in lentils widely cultivated such as Native red, Firat-87, Seyran-96, Cagil, Altintoprak and Sakar. Weed management in varieties is generally considered to be a poor competitor due to its slow establishment and limited vegetative growth. Their productivity is adversely affected by the presence of weeds (Swanton et al., 2015). Lentil yield loss from the competition

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1351313521

with weeds can range as high as 80% (Beniwal and Dalkiran, 1995; Yenish et al., 2009). On the other hand, it is known that weeds host the sloe bug (*Dolycoris baccarum* L.) and gorse shieldbug (*Piezodorus lituratus* F.) that causing chalking problem on lentil (Akkaya, 2004; Ozberk et al., 2014). The prominent weed species infesting lentil crop are charlock mustard (*Sinapis arvensis* L.), field bindweed (*Convolvulus arvensis* L.), volunteer wheat (*Triticum* spp.), wild oat (*Avena* spp.), knapweed (*Centaurea depressa* M. Bieb), cow cockle (*Vaccaria pyramidata*), vetch (*Vicia* sp.), cleavers (*Galium aparine*), volunteer barley (*Hordeum vulgare*), pheasant's (*Adonis aestivalis*), fumitory (*Fumaria officinalis* L.) etc. (Guncan, 2014; Tepe, 2014; Kraehmer, 2016; Pala et al., 2018). The concept that high input provided for higher yield, also pose high risk, if weeds are not controlled.

Climate change and applied agricultural practices cause changes in the populations of harmful organisms (pests, pathogens, and weeds) that cause significant losses in crop plants (Flood, 2010; Ucak et al., 2017). Cultural practices to decrease weed pressure in lentil crops include prevention, seedbed preparation, variety selection, proper sowing and, crop establishment, insect and disease management. For example, Baird et al. (2009) observed that increasing the seeding density of lentil translated into increased yield and decreased weed biomass. However, while cultural practices such as allelopathy, cover crops, and crop rotations are at the backbone of integrated weed management (IWM) plan, they alone may not be enough to secure adequate weed control in lentil fields (Pala et al., 2018). In addition, cultivation of soil with smart sensitive cultivator, monitoring of plants and pests with a drone and local intervention, and the application of steam and soil disinfection on field crops, vegetables and fruits and the control of diseases, pests, and weeds should be investigated (Pala et al., 2017).

Mechanical weed control practices in lentil, such as harrowing or rotary hoeing fields in fall, after the emergence of weeds but before lentil planting. Also to control weeds generally hand weeding is in practice but it is now costly as well as difficult because of the non-availability of labor in peak periods (Bhan and Kukula, 1987). Crop rotation is one of the other powerful tools to manage weed problems. To high persistence herbicides commonly used in small grain crops such as iodosulfuron, metsulfuron, chlorsulfuron sulfosulfuron etc. can damage subsequent annual legumes, including lentil (Kraehmer, 2012; SPG, 2017). There are a number of herbicides registered to control grassy weeds in lentil, but few options exist for control of broadleaf weeds (Brand et al., 2007). To applicability and success of herbicides in lentil fields depend on the cropping system, land preparation methods, soil conditions, and weed problems. For example, challenge (aclonifen) is a selective herbicide that is in the diphenyl ether group, it is used for postemerge against broadleaf weed in lentils. When it applies at recommended rates provides effective control on some broadleaf weeds, but it is not effective enough some broad-leaved weeds or ineffective, in addition, it can cause crop damage in stressful conditions of cold weather, low fertility, disease, or insect damage. Also, although pursuit (imazethapyr) can be used to manage broadleaf weeds in no-till or minimum tillage systems, it has many application restrictions due to crop safety concerns, including leaf chlorosis, stand reduction, and decreased yields, especially cold and wet conditions occurring within a week of application can severely damage the crop (Friesen and Wall, 1986; Muehlbauer et al., 1995; Ghosheh and El-Shatnawi, 2003). These methods can be supported by other mechanical and cultural processes such as tillage, late sowing, and rotation (Kayan and Adak, 2006; Dogan, 2014). However, lentil is sensitive to weed competition. Weed growth reduces lentil yields by competing

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1351313521

for light, moisture, and nutrients. It is known that available practices in the control of weeds in lentil fields are inadequate (Harper, 1977; Swanton et al., 2015). The USA and Canada developed lentil varieties tolerant to the imidazolinone (an acetolactate synthase [ALS]-inhibitor) herbicides through mutation breeding in order to deal with the shortcomings in broadleaf weed control in lentil (Chant, 2004; Slinkard et al., 2007). Weed control in these ALS inhibitor herbicide-tolerant lentil varieties was initially excellent and, as a consequence, they have had very high adoption rates. Hence lentil is a suitable model crop to study on weeds and weed management due to the limitations of weed control for this crop.

In order to develop economic, effective and environmentally friendly IWM tactics in lentil, where weed competition is weak, it is necessary to monitor the distribution and the prevalence of weed species which are primarily a problem. There have been a limited number of studies on weed species in our country and in our province, but no detailed and up-to-date studies have been found. With this view, the study has undertaken the determination of existing weed control techniques in lentil fields.

Material and methods

The survey was conducted in Diyarbakir where it is located in the Southeastern Anatolia Region (SAR) of Turkey in spring 2016 (*Fig. 1*). Lentil is mainly grown in the non-irrigated areas.

Figure 1. *Location of surveys, Diyarbakir Turkey*

The most lentil growing districts, cultivated fields and sample number are given in *Table 1*.

The surveys were carried out in the Bismil, Cermik, Cinar, Dicle, Egil, Ergani, Hani, Hazro, Kayapinar, Silvan, and Sur. Sampling size and the settlements of the interviews were determined purposively according to the Turkish Statistical Institute (TUIK) database. In this regard, 100 farm enterprises were determined and interviewed to represent the study area. A questionnaire containing questions regarding a) common weeds agronomic practices including tillage, irrigation, crop rotation, fertilization,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1351313521

harvesting b) weed management practices, c) problematic weed rankings, d) knowledge of weed management and e) efficiency of extension services; was prepared and each grower was interviewed for answering the questionnaire. Using the proportional sample volume formula (*Eq. 1*) (Newbold, 1995).

$$n = \frac{N.p(1-p)}{(N-1)\sigma^2_{px} + p(1-p)} \quad \text{(Eq.1)}$$

The formula; σ^2_{px} = Variance of rate (90% confidence interval and 5% 5% tolerance), n: Sample volume, N: The main mass represents. p: rate (p: 0.5). The data collected during the survey were analyzed by using frequencies and simple percentages.

Table 1. *Districts surveyed in Diyarbakir province and number of samples taken (TUIK, 2016)*

Districts	Lentils field (ha)*	The number of participants
Bismil	24.580	48
Cermik	1.700	16
Cinar	3.350	12
Dicle	600	10
Egil	411	6
Ergani	5.500	3
Hani	521	1
Hazro	450	1
Kayapinar	800	1
Silvan	9.000	1
Sur	6.500	1
Total	**53.412**	**100**

Results and discussion

The outcome of the survey two out of three of the participants in the survey was between 30-50 years of age. Approximate half of them had education up to primary school and one-third of them had a secondary school. This shows the education level was low and a very small portion of respondents had higher graduate degrees. The farmers were asked; since how long you have been grown lentil. Response was 1-10, 10-20, 20-30 and > 30 years which ranged 19, 28, 45, and 8 respectively. The area of lentil production was < 5, 5-10, 10-20, 20-50, > 50 ha with percentages of 9, 38, 35, 12, and 6% respectively. This value showed that tw- thirds of the farmers produce lentil in the fields between 10 and 50 ha.

The preceding crops of lentil are wheat 91% and barley 9% (*Table 2*). The results of the survey showed that all of the farmers planted cereal before lentil production. Crop rotation strongly affects the density and composition of weed flora because the different crops in rotation require different agricultural practices and herbicide. Due to continuously changing agricultural practices as a result of crop rotation; the adaptation's success of certain species to a specific area under sole or mono-cropping could be prevented (Kayan and Adak, 2006; Erman et al., 2008; Dogan, 2014). Tepe et al. (2004)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1351313521

reported that crop rotation is an important part of a good weed control program in lentil agriculture. Certain weeds, especially broadleaf weeds in lentil, may be less difficult to control in a farming system having preceding crops such as cereal. Other benefits of crop rotation may include a reduction in insects, diseases and nematode problems in lentil.

Table 2. *The preceding crops of lentil grown by farmers in survey*

Preceding crop	Percentage (%)
Wheat	91
Barley	9
Total	**100**

When the respondents were asked for the tillage practices being used by them in lentil agriculture, 12% of respondents stated that the tillage practices included the plow in autumn, and 88% cultivator and harrow tillage before planting. Planting with the seeders/planters system is opted by the growers in the region. The 87% of respondents stated that they planted seeds after the rain due to moisture, and the rest before the rain in dry soil. When asked the effect of tillage systems on weed density, 76% of respondents stated that deep plowing reduces weed density. When asked for previous crop residue, the majority of respondents answered that they burned them usually. Previous crop residue and tillage practices can affect weed population dynamics, including weed seed distribution and abundance in the soil seed bank (Mulugeta and Stoltenberg, 1997). There are reports that weed control was improved by using plow for tillage (Durutan et al., 1989; Pala et al., 2000; Camara et al., 2003). When asked for irrigation and fertilization, 100% of respondents answered that they did not use both of them in lentil production. This crop produces a dry climate and does not need to use fertilizer in Diyarbakir. The most problematic weed species in the lentil field are represented in *Table 3*. *Sinapis arvensis* L. as a broadleaf, and *Avena fatua* L. as a grass were the first most problematic weeds, respectively. In the study carried out, important weed species found in the lentil fields were adapted to the agricultural products in winter and spread especially in these fields. For this reason, these species, which are found in the field of surveillance, are among the important weeds, which are problematic both in countries such as Canada and India, and in beans and pulses in our country (Holm et al., 1977; Guncan, 2014; Tepe, 2014; Kraehmer, 2016; SPG, 2017). So, this shows that the problematic weed species stated by farmers are similar to the majority of species reported in the lentil fields.

Weeds emerging in lentil fields and trouble for farmers are mostly broadleaves such as *S. arvensis, R. Arvensis,* and *G. aparine.* Majority of participants stated they combined tillage, hand-picking, and herbicides commonly. 89% of them used to control broadleaf weeds by using aclonifen as a chemical broadleaf weeds control method (*Table 4*). Hand-picking (76%) was common in areas that do not use herbicides. Guncan (2014) stated that fewer herbicides are available for use in lentil. It is known just there is just one registered herbicide for broadleaf weeds in the lentil fields of Turkey.

Participants used clethodim, haloxyfop-methyl-ester tepraloxydim, quizalofop p-ethyl, fluazifop p-butyl for grass ratios 26, 17, 16, 15, 6%, respectively (*Table 5*). But, 66% of aclonifen reported phytotoxicity, also few farmers (4%) applied glyphosate, pre-emergence.

The preventive measures were used in lentil fields by farmers such as crop rotation, late planting, deep tillage in order of 61, 10, 4% (*Table 6*).

Participants took into account the price (43%), herbicides (38%), weeds (10%) and crop rotation (9%) to choice weed management in the survey, respectively (*Table 7*).

Lentil has an early-season slow growth and open-canopy growth habit, which makes them poor competitors with weeds, so the control of weeds in the early period is too important. But we do not have much of a pre-plant, pre-emergence or post-emergence herbicide choice, especially to control of the broadleaf weeds emerging in lentil fields. Also, there is dissatisfaction with the efficacy and selectivity of aclonifen, the only registered herbicide in Turkey. This survey emphasizes the need to define the effects of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1351313521

weeds in lentil fields and to understand the effects of management on weed populations. It is essential to control weeds as tillage pre-plant, and herbicides post-plant are used in lentil production areas. Weed management systems significantly affect weed control and yield crops. Therefore, weed management in lentil has been a major challenge for crop producers from the start of agriculture.

Others*	25
Total	**100**

*Varieties, roller, more seeds, intra-row etc.

Weeds compete for factors such, nutrients, water and light, also some weeds host many plant pathogens and insects harmful to lentil, preventing certain agricultural practices in a fit and rapid manner. It was important that cultural measures (crop rotation with 61% and late sowing with 10%) were the first choice for preventing weeds from damaging lentil yield and quality.

Table 7. *Considerations when choosing methods for controlling weeds*

The matters considerations	Percentage (%)
Price	43
Herbicide diversity	38
Weeds	10
Crop rotation	9
Total	**100**

The fluctuations in labor, fuel and herbicide prices from year to year caused the input cost (price 43%) to be the main concern of farmers when deciding on weed control. In order to carry out economic analyzes in an appropriate way, it was understood that current studies on critical period and economic threshold were needed.

Conclusions

The available major agricultural issues are to feed the world without contaminating the environment. Weeds are the most important constraints in lentil production. Despite the fact that cereals are planted as previous crops, the fact that grains are not mentioned by farmers as a major weed problem is related to the destruction of grains by tillage and late sowing of lentils. The fact that weeds are problematic in the lentil production areas of the weeds expressed as a problem indicates that the farmers recognize weeds. Farmers complained that the market is not enough herbicides for broadleaf weeds control unlike the herbicides used in the control for grasses. It is good but insufficient to make crop rotation by little more than half of the farmers. It is also observed that the late tillage and plow deep tillage are not aware of the importance of weed control by

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1351313521

participants. While the method of weed control is chosen in lentil fields, firstly, the low cost and the availability of herbicides determine the behavior of farmers. As a result, the survey showed weeds, which are expressed as a problem in lentil fields by participants, have been the common weeds that cause significant yield losses in lentils and showed that the cultural measures, mechanical and chemical weed control are insufficient. To this end, herbicides are used to control weeds; however, overconfidence on herbicides is not sustainable in the long run. Therefore, there is a need to develop integrated weed management strategies in the lentil production systems, which aim to reduce the weed seed bank before lentil sowing and reduce weed emergence and weed growth in lentils. It was shown that weed management practices are inadequate in lentil fields. So new tactics should be improved such as imidazolinone (IMI) tolerant non-transgenic crops called Clearfield lentil varieties by ethyl methanesulfonate (EMS) which is a mutagenic, teratogenic, and possibly carcinogenic organic compound.

(Received 1st Dec 2018; accepted 15th Feb 2019)

Abstract. Palm oil mill effluent (POME) is the wastewater produced from palm oil refining activities like oil extraction, washing and cleaning processes in the mill that require an effective treatment before being discharged into waterways due to the effects it may have on the environment. The study was conducted in one of the mills that are located in Jerangau, Terengganu. This study was conducted to determine the physicochemical characteristics of POME on four different ponds which was mixing pond, facultative pond, algae pond and discharged pond. Discharged pond was the last pond for the POME treatment before it is discharged into the nearby river. The physicochemical parameters that have been determined to evaluate POME were pH, temperature, BOD, COD and TSS. The physicochemical characterization was carried out to determine the profile of POME at that time and the results showed that all parameters exceed the standards set by the Regulations of the Environmental Quality (Industrial Effluent) Regulations 2009 Standard B of the Environmental Quality Act 1974 except the temperature. In addition, this study also aimed to determine and compare the effects of cytotoxicity and genotoxicity of POME between the four ponds towards V79 cells. The cytotoxicity can be determined using MTT assay to evaluate the cytotoxic effect of POME on V79 cells. Meanwhile the genotoxicity was determined by using the alkaline comet assay to evaluate the genotoxic effect of POME on V79 cells. The study found that the POME in all ponds showed the cytotoxic effects on V79 cells and the POME in discharged pond showed the highest IC_{50} value compared to the other ponds which was 75% v/v. By using the IC_{25}, the treatment towards V79 cells showed the value of the moments tail in the discharged pond was the lowest compared to the others which was 0.898 ± 0.561. The values of the tail moment are much lower when compared to the positive control which was 6.58 ± 1.383. Therefore, it can be concluded that the POME in a discharged pond had a lowest cytotoxic and genotoxic effects on V79 cells compared to other ponds.
Keywords: *genotoxicity, palm oil mill effluent, physicochemical characterizations, V79 cells*

Introduction

Malaysia is the largest producer and exporter of palm oil. By 2010, Malaysia has contributed 41% of the world production for palm oil. While the palm oil industry has been recognized for its contribution towards economic growth and rapid development, it has also led to environmental pollution due to the production of large quantities of by-product from the oil extraction process (Rupani et al., 2010). The waste products from palm oil processing consist of oil palm trunks (OPT), oil palm fronds (OPF), empty fruit bunches (EFB), palm pressed fibres (PPF) and palm kernel shells, less fibrous material such as palm kernel cake and liquid discharge palm oil mill effluent (POME) (Rupani et al., 2010; Sulaiman, 2010). Among the waste generated, POME is considered the most harmful waste for the environment if discharged untreated (Rupani et al., 2010). POME is a thick brownish liquid that contains high amounts of total solids (40,500 mg/L), oil and grease (4000 mg/L), COD (50,000 mg/L) and BOD (25,000 mg/L). The disposal of this highly polluting effluent is becoming a major problem if it is not being treated

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1352313532

properly besides a stringent standard limit imposed by The Malaysian Department of Environment for effluent discharged (Latif Ahmad et al., 2003).

The discharge of effluents without proper treatment to the environment will lead to the severe pollution and will affect to the people. POME contains fatty acids, protein, carbohydrates and other plant materials in a high volumes which is capable to change the parameters of the environment, especially BOD, DO and COD levels (Verla et al., 2014). In addition, the effluent also contains a colloidal suspension that affects the water such as a brown solid color, colloidal and oily (Latif Ahmad et al., 2003). It was identified as the major source of water pollution in Malaysia. If it is not treated before being discharge, this effluent would be a major problem to the environment (Lai et al., 2011).

This study discovers the cytotoxic and genotoxic effect of POME towards V79 cells that can be beneficial as safety alert to industries and community. Besides that, this study also comparing the cytotoxicity and genotoxicity effects between four ponds of POME at the mills. This research study has proven that there were cytotoxic effects and genotoxic effects that can be seen in the POME for four ponds. The in vitro cytotoxicity and genotoxicity study in this work will help the researchers to uncover the critical issue regarding the health risk associated with wastewater produced from palm oil refining activities and increase awareness among industrial practisers, thus leading towards more efficient and safe wastewater management.

Materials and methods

Materials

Chemicals used in this study were trypan blue solution, ethidium bromide (TBR), sodium hydrogen carbonate ($NaHCO_3$), hydrochloric acid (HCl), sodium hydroxide (NaOH), sodium chloride (NaCl), disodium hydrogen phosphate (Na_2HPO_4), triton X-100, distilled water, low melting agar (LMA) and normal melting agar (NMA). In addition, COD digestion reagent low range and high range for measuring COD from Hach Company (USA), powdered DMEM medium (supplemented with L-Glutamine and without sodium bicarbonate hydrogen) obtained from Gibco, US also used. Other chemicals were fetal bovine serum (FBS) obtained from JR Scientific USA, and penicillin/streptomycin from PAA (Germany). MTT tetrazolium salt from Sigma-Aldrich, USA and a dimethylsulfoxide (DMSO) solution from Fiesher Scientific, UK is also used in this study. Finally, the materials used are ethyl diamine disodium tetraacetate (Na2-EDTA), potassium chloride (KCl) and potassium dihydrogen phosphate (KH_2PO_4) from Ajax Chemical Laboratories, Unilab (NSW, Australia).

Sampling location and time

The study was conducted at one of the mills that are located at Terengganu. The mill produced the products such as crude palm oil (CPO) and kernel palm oil. The sampling was conducted on November, 2016. The samples were taken in the morning which was at 10 am until 1 pm and the samples taken was three times (triplicate) from each ponds which the effluents was collected. There are four ponds of effluent at the palm oil mill where all the product of filtration and purification will be stored in those ponds before being discharged into a nearby river. The four ponds were mixing pond, facultative pond, algae pond and discharged pond.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1352313532

Physicochemical analysis

The physicochemical properties that are being determined in this study were pH and temperature. The readings of these parameters were determined during the sampling because the readings are direct reading (in-situ). In addition, the reading of biochemical oxygen demand (BOD), chemical oxygen demand (COD) and total suspended solids (TSS) were also be determined. All the three readings of these parameters are analyzed *ex-situ* where the reading of this parameter evaluated in the laboratory using appropriate equipment.

Cell line

The cytotoxicity study was performed on V79 cell line, which is a type of lung fibroblast cells derived from Chinese hamster male, Cricetulus griseus. The cells were cultured in complete growth media Dulbecco's Modified Eagle's Medium (DMEM) enriched with 10% fetal bovine serum (FBS) and 1% penicillin/streptomysin.

Cell viability assay

The viability of V79 cells were determine using 3-(4, 5-dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide (MTT) assay (Mossman, 1983). Cells were seeded in a sterile 96-well microplate at density of 5 × 104 cells/mL and incubated for 24 h. Later, the medium in each well was discarded and replaced with a fresh medium containing tested samples at concentrations 100, 50, 25, 12.5 and 6.25% v/v. After 24 h treatment, 20 µL of 5 mg/mL MTT solution was added to each well and incubated for 4 h. An approximate of 180 µL of media was removed and added with 180 µL DMSO in each well. After 15 min incubated, the plate was agitated using orbital shaker to ensure the complete dissolve of the crystal formazan. The Optical Density (OD) of each well was measured at 570 nm wavelength using iMark Microplate Reader (BioRad, USA). The inhibitory concentration that induced cytotoxicity in 50% cell population (IC_{50}) was calculated and compared with the positive control. Menadione was used as positive control and untreated cells as a negative control.

Alkaline comet assay

The genotoxic effect of POME on V79 cells was assessed using comet assay, carried out under alkaline condition (Singh et al., 1988). The cells were seeded in 6-well plate at density of 5 × 104 cells/mL and incubated for 24 h. After 24 h, the media was discarded from each well and replaced with a fresh media containing water sample treatment and incubated for next 24 h. The procedure was performed in dark condition to avoid any interfering factors that can contribute to DNA damage such as direct radiation from the light. After that, the cells were harvest and pellet was collected. Then, the pellet was suspended in 3 mL PBS and then was aliquot 1 mL each into eppendorf tube. The tubes were then centrifuged at 2500 rpm for 5 min at 4 °C. The pellet was then washed with PBS and centrifuged again. Later, the pellet was collected and stored in cold condition.

Fully frosted slides were covered with 0.6% normal melting point (NMP) agarose. When this slide was solidified, a second layer containing the cells mixed with 0.6% low melting point (LMP) agarose was placed on the slide. After 5 min of solidification on ice, the slides were covered with 0.6% LMP agarose. They were then immersed for 1 to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1352313532

24 h in 4 °C lysis solution. The slides were then placed on a horizontal gel-electrophoresis tank, facing the anode. The fresh electrophoretic buffer was filled into the tank in which the slides were put for 20 min to allow DNA unwinding and the expression of alkali-labile sites. Denaturation and electrophoresis were performed at 4 °C under dim light. Electrophoresis was carried out for 20 min at 25 V (300 mA). Subsequently, the slides were rinsed gently three times with a neutralization buffer in order to remove excess alkali and detergents. Then, each slide was stained with 30 µL ethidium bromide covered with a cover-slip. Fifty randomly selected cells were analyzed per sample. The slides were examined at 250× magnifications with a fluorescence microscope equipped with a 515-560 nm excitation filter and a 590 nm barrier filter, and images of cells were analyzed with the computerized image analysis system Comet Score III. The tail length was evaluated to quantify DNA damage.

Statistical analysis

All the investigated data were statistically analyzed using (SPSS). The comparisons between groups were done by one way analysis of variance (ANOVA). The level of statistical significance was set at P value of < 0.05.

Results and discussion

Physicochemical analysis

Table 1 showed the mean values ± SEM (standard error mean) for each parameter (pH, temperature, BOD, COD and TSS) in different types of ponds. The Environmental Quality (Industrial Effluent) Regulations 2009 Standard B, Environmental Quality Act 1974 was used as a standard for comparison. The pH value obtained for effluent sample in mixing, facultative, algae and discharge ponds was 4.51 ± 0.20, 7.62 ± 0.16, 8.58 ± 0.29 and 8.91 ± 0.12 respectively. All the values were below the standard limit allowed by the Environmental Quality (Industrial Effluent) Regulations 2009 Standard B, the Environmental Quality Act 1974 (pH 5.5- 9.0) except for effluent sample from mixing pond which has the acidic pH. This might be due to the accumulation of raw POME in mixing pond as the effluent collected in mixing pond was directly from the mill. As the POME underwent biodegradation process along the way to the next ponds which were facultative, algae and discharge ponds, the effluent turned out to be basic and increase the pH in the respective ponds. Biodegradation occurred whereas the active microorganisms used up organic materials in POME as their nutrients and decomposed them into methane, carbon dioxide, hydrogen sulphide and water. According to Okwute and Nnennaya (2007), the pH of the raw POME released is acidic but after the biodegradation occurs, it gradually turns into alkali. This is because long-term POME retention in each pond causes biodegradation to occur where it depends on active microorganisms, which use organic ingredients in POME as nutrients and ultimately elaborate these organic substances in the form of simple products such as methane, carbon dioxide, Hydrogen sulfide and water (Okwute and Nnennaya, 2007; Jameel et al., 2011).

For the temperature, the average value obtained from the mixing pond, facultative pond, algae pond and the discharged pond were 32.80 ± 0.61 °C, 30.00 ± 0.20 °C, 27.60 ± 0.20 °C and 27.47 ± 1.88 °C, respectively. Based on the standards, the temperature obtained did not exceed the temperature permitted (40 °C). However, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1352313532

temperature in mixing pond was slightly higher (32.8 °C) compared to another ponds. This is because mixing pond was the first pond introduced with effluent discharged from the mill which was normally in high temperature (80-90 °C) (Khalid et al., 1992). Nevertheless, the temperature of the effluent decreased by time as heat released. In our study, the sampling was conducted after a certain period the effluent was released (the effluent released in the morning), and thus gave the lower monitored temperature compared to the temperature when effluent was first released. Besides, the temperature also dropped as the effluent flew to the next ponds and that was why we could observe the temperature in the each pond was lower compared to the pond before.

Table 1. *Average value of pH, temperature, BOD, COD and TSS for POME obtained in mixing ponds, facultative ponds, algae ponds and discharged ponds*

Ponds	Parameters				
	pH	Temperature (°C)	BOD (mg/L)	COD (mg/L)	TSS (mg/L)
Mixing	4.51 ± 0.20	32.80 ± 0.61	25600.00 ± 300.00	2241.33 ± 18.95	22524.00 ± 2340.00
Facultative	7.62 ± 0.16	30.00 ± 0.20	71.00 ± 2.00	338.67 ± 7.02	151.67 ± 14.04
Algae	8.58 ± 0.29	27.60 ± 0.20	35.00 ± 2.65	161.33 ± 4.04	45.67 ± 4.16
Discharged	8.91 ± 0.12	27.47 ± 1.88	25.00 ± 3.61	136.00 ± 3.61	34.33 ± 4.16

In the other hand, the BOD and COD in mixing and facultative ponds were higher than standard limit. The value allowed for both BOD and COD were 50 and 200 mg/L. The value for BOD and COD in mixing pond were 25600.00 ± 300.00 and 2241.33 ± 18.95 mg/L, while in the facultative pond the value for both were 71.00 ± 2.00 and 338.67 ± 7.02 mg/L. Meanwhile, BOD and COD content in algae and discharge ponds were still in allowed level.

Meanwhile, the TSS value for mixing and facultative ponds exceeded the standard limit (100 mg/L) compared to the other two ponds. The value for each pond was 22524.00 ± 2340.00 mg/L, 151.67 ± 14.04 mg/L, 45.67 ± 4.16 mg/L and 34.33 ± 4.16mg/L respectively for each pond.

The results obtained for parameters of biochemical oxygen demand (BOD), chemical oxygen demand (COD) and total suspended solids (TSS) showed that the average value for those parameters of POME in the mixing pond was the highest than the others. The mixing pond normally contained the raw POME which was first released from the mill. Raw POME was a high pollution wastewater with high BOD and COD which can cause severe pollution to the environment that eventually polluted the water sources (Lam et al., 2011). Therefore, the values of BOD, COD and TSS in the mixing pond were higher compared to the other ponds. The BOD and COD values are important indicator to define the composition of wastewater and its effects towards the environment (Jameel et al., 2011). However, the content of BOD, COD and TSS decreased as the effluent distributed to the next ponds which were facultative, algae and discharged ponds, the value decreased. This was due to some processes that took place along the way the POME was released, such as a pre-treatment in the mixing pond, and biological treatments in the facultative and algae ponds. The pre-treatment was performed to reduce the suspended solids and oils by using flocculation, solvent extraction, adsorption and membrane separation processes (Latif et al., 2003).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1352313532

According to Wong (1980), the treatment system of POME usually consists of anaerobic and aerobic treatments. Aerobic treatment was required to reduce the concentration of BOD to produce effluents that comply with national effluent discharge standards (Salihu and Alam, 2012).

Based on the results of the study, all parameters such as pH, COD, BOD and TSS of POME in mixing pond were exceed the specified limits except for the temperature where the values are still in the range. Whereas the result obtained in the facultative pond for all parameters were above the prescribed standard except for pH and temperature. Meanwhile, for algae ponds and discharged pond, all parameters such as pH, temperature, BOD, COD and TSS do not exceed the prescribed standards.

Cytotoxicity of palm oil mill effluent sample on V79 cells

Figures 1–4 showed a graph of cell viability against sample concentration from each tested pond. The viability of V79 cells exhibited a decrease in concentration-dependent manner for sample from each pond. Based on *Figure 1,* the percentage of cell viability was 106.73 ± 0.025, 103.20 ± 0.026, 82.58 ± 0.05%, 57.88 ± 0.067% and 6.46 ± 0.03% at concentrations 6.25, 12.5, 25, 50 and 100% v/v. The IC50 was obtained at concentration 58% v/v. Meanwhile, for facultative pond (*Fig. 2*), IC50 value was 61% v/v. The cell viability reduced from 79.8 ± 0.018, 76.06 ± 0.028, 64.21 ± 0.029 59.32 ± 0.032% and 8.84 ± 0.01% for concentrations 6.25, 12.5, 25, 50 and 100% v/v. Next, IC50 concentration for sample from algae pond (*Fig. 3*) was determined at 62% v/v with cell viability decreased from 99.4 ± 0.043, 101.77 ± 0.022, 80.52 ± 0.014, 60.84 ± 0.024 and 13.85 ± 0.012% for concentrations as previous. For the discharged pond (*Fig. 4*), the graph also showed a slight increase in cell viability for concentrations 6.25, 12 and 5.25% v/v in which the viability was 94.8 ± 0.011, 107.33 ± 0.063, and 109.19 ± 0.051 respectively. However, the viability started to decrease to 83.02 ± 0.018 and 15.48 ± 0.015% when treated with 50 and 100% v/v sample. The IC50 value obtained was 72% v/v. Based on all the graphs displayed, we can observed that there were some points in the graphs where the cell viability at certain concentration was higher from the previous concentration and this might be due to adaptive response of the cells towards the certain concentration (Klassen and Eaton, 2001).

Based on the result obtained, the cytotoxicity of POME in the mixing pond was the highest than the others. The highly cytotoxicity of POME in mixing pond was caused by the content of oil and grease compounds present in the mixing pond where those compound can cause cytotoxic effects to POME. The highly oil and grease content is due to the production of POME directly from the mill without any treatment. The high content of oil and grease was proven by Latif Ahmad et al. (2003) where he stated that the raw sample consists of high oil and grease (191 mg/L). Furthermore, the production of raw POME is from the oil extraction, washing and cleaning process in the mill and it contained cellulose, fat, oil and grease (Rupani et al., 2010). In addition, oils and greases are considered dangerous pollutants especially in aquatic environments, since these compounds are highly toxic to aquatic organisms (Agamuthu, 1995).

On the other hand, the cytotoxicity of POME in discharged pond was the lowest compared to other ponds. The decrease of cytotoxicity in the discharged pond was due to the presence of biological treatments in the facultative pond and algae pond. POME in the discharged pond was the result from the treatment on those ponds. This biological treatment depends largely on active microorganisms, which use organic ingredients in POME as nutrients and ultimately degradation of these organic matter into simple products such as methane, carbon dioxide, hydrogen sulfide and water (Jameel et al., 2011). In addition, according to Azbar and Yonar (2004), wastewater treatment of palm oil refinery industry based on coagulation and biological methods caused in the overall removal of 92-96% COD, 83-98% TSS and 93-95% oil.

Genotoxicity

Comparison of DNA damages between mixing pond, facultative ponds, algae ponds and discharged pond

Figure 5 showed the tail moment of V79 cell treated with concentration IC25 of effluent sample from each pond together with menadione and untreated cells as positive and negative controls. The IC25 values was choose as the treatment concentration in order to avoid the highly damaged cells have gone into apoptosis and that the fragmented DNA disappeared from the gel, leaving only relatively undamaged cells.

Based on the bar graph, cells treated with POME from mixing pond gave tail moment 1.948 ± 0.187 while for the facultative pond the tail moment was 1.560 ± 0.220. Meanwhile, the tail moment value 1.234 ± 0.204 and 0.898 ± 0.561. was attributed for both algae and discharged ponds. On the other side, the tail moment values for positive and negative controls were 6.58 ± 1.383 and 0.328 ± 0.200, respectively. However, the genotoxic effecs of POME from all the four ponds was not significant when compared to negative control at $p < 0.05$.

Nevertheless, the genotoxic effect still could be detected in each pond as the tail moment was formed based on alkaline comet assay conducted. For example, POME sample from mixing pond induced the highest tail moment formation compared to other ponds. This might due to the presence of phenolic compounds in raw POME accumulated in mixing pond and suggested with finding by Jameel et al. (2011) that reported palm oil refineries contained some phenolic compounds such as Gallic, protocatechuic, 4-hydroxybenzoic, 4-hydroxylphenylacetic, caffeic, syringic acid, p-coumaric and ferulic acid. Based on Li et al. (2005), they found that phenol is a genotoxin evidence that can cause DNA damage. However, the biological treatments carried out as the effluent move to the next ponds eliminated those phenolic compounds

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1352313532

(Hussain et al., 2015) and thus, decreased the toxicity of POME by ponds. That was why the tail moment observed in this study reduced by ponds.

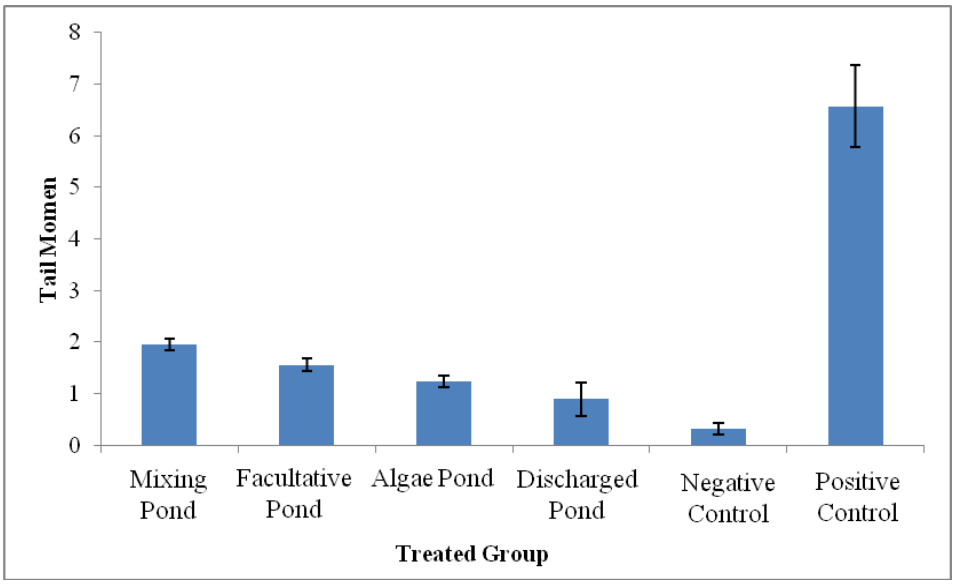

Figure 5. *Comparison of the tail moment of V79 cell for negative control, positive control and effluent samples for each pond which were mixing pond, facultative pond, algae pond and discharged pond according to their respective concentration of* IC_{25}

Conclusion

From this study, the physicochemical assessment of POME from the mixing and facultative ponds at the sampling location in Terengganu has exceeded the standard limit allowed by the Environmental Quality (Industrial Effluent) Regulations 2009 Standard B, Environmental Quality Act 1974. The other two ponds which were algae and discharged ponds were still under control. However, the MTT and alkaline comet assays conducted showed that POME sample from all ponds have cytotoxic and DNA damage effects towards V79 cells based on IC50 values and tail moments values obtained. Even though the treatment processes in each pond might be able to reduce the effects of POME before it was discarded into the nearby river, the long term effect of exposure of this wastewater is still under concern. Thus, a more efficient and proper management and treatment of wastewater in the sampling location are still required. For example is by performing a pre-treatment of POME wastewater using ultrafiltration membrane technique which coupled with absorption treatment (Azmi and Yunos, 2014). The ultrafiltration treatment coupled with adsorption treatment as pre-treatment is and advantageous method for the POME treatment. This treatment offer the easier operating conditions, more ability to combine with two technique and easier control of the system.

Acknowledgements. We would like to thank Palm oil mill at Jerangau, Terengganu for the cooperation given. Technical support from the laboratory assistants of Faculty of Health Sciences Universiti Kebangsaan Malaysia is gratefully acknowledged.

(Received 19th Mar 2019; accepted 4th Jul 2019)

Abstract. We investigated contributions of some tropospheric gases, meteorological parameters, and aerosol burden measured as aerosol optical depth (AOD) towards Tropospheric Ozone ($TropoO_3$) variabilities over Lahore by developing a stepwise multiple linear regression model. The tropospheric gases include; Methane (CH_4), Carbon Monoxide (CO), Carbon Dioxide (CO_2), and Sulphur Dioxide (SO_2), whereas the meteorological parameters include; cloud fraction (CLF), outgoing long-wave radiation (OLR), relative humidity (RH), temperature (Temp), and surface wind-speed (WS). Data products of these parameters have been retrieved from various satellite sensors during October 2004 – September 2015. Time series distributions of both observed and modeled $TropoO_3$ concentrations show similar increasing trends except for few months. Moreover, monthly-means of these observed and modeled $TropoO_3$ concentrations indicate similar decreasing trends with maximum during spring and summer (monsoon) seasons. Based upon weighted contributions of standardized regression coefficients, modeled $TropoO_3$ concentration was found dependent upon OLR[0.458], WS[0.262], CLF[0.256] $TropoSO_2$[–0.097], TropoCO[–0.231], and RH[–0.320] out of all parameters used in this study. Modeled $TropoO_3$ concentrations were validated against an independent source of $TropoO_3$ concentrations retrieved from original subtracted product of OMI-MLS over Lahore and the results were found in good agreement. The study is unique and would be helpful for further research investigations.
Keywords: *regression modeling, atmospheric outlook of Lahore, ozone contributors, ecology, atmospheric remote sensing*

Introduction

$TropoO_3$ is one of the short-lived but major atmospheric pollutants that plays a key role towards climate change (UNEP and WMO, 2011) by modifying the chemical composition of the troposphere and its oxidation capacity (Gauss et al., 2003). It is considered as a primary precursor for the production of hydroxyl radical (OH), that acts as an oxidizing agent severely disturbing the occurrence of tropospheric trace gases (Seinfeld and Pandis, 2016). $TropoO_3$ absorbs short-wave solar radiations and after attenuation re-radiates it in the form of long-wave radiations (Shan et al., 2008; Pal, 2010; Tan et al., 2014). $TropoO_3$ has harmful effects on human health, vegetation health & yield, and sensitive ecosystems (EPA, 2003; The Royal Society, 2008; Avnery et al., 2011; Burney and Ramanathan, 2014). Also, $TropoO_3$ is one of the major anthropogenic greenhouse gases, which is responsible for global warming (IPCC, 2013). Ozone in troposphere is either produced from chemical reactions of NO_x, CH_4, CO, and volatile organic compounds (VOCs) through non-linear, complex, and feedback-regulated processes in the presence of solar radiations (El-Fadel et al., 2002; Pulikesi et al., 2006;

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1353313553

Stevenson et al., 2006; Young, 2013; Seinfeld and Pandis, 2016) or transported directly from the stratosphere (Hsu and Prather, 2009). From an ecological point of view, both increased emission and destruction of VOCs by $TropoO_3$ may affect several of their multiple functions (Lerdau and Slobodkin, 2002; Holopainen, 2004; Van, 2009; Yuan et al., 2009). There are a number of anthropogenic and natural sources of these $TropoO_3$ precursors e.g.; crop-residue burning, biomass burning, fossil fuel combustion, enhancement of volatile organic compounds through convections of CO and aerosols, vehicular emissions, industrial processing, energy production activities, waste management, lightning NO_x, and soil emissions (Jaeglé et al., 2004; Satheesh and Moorthy, 2005; Stevenson et al., 2006; Aghedo et al., 2007; Wang et al., 2012; Ganesan et al., 2013; Ul-Haq et al., 2014). Anthropogenic activities pose numerous threats to the functioning, structural growth and diversity of natural and semi-natural ecosystems (Bobbink, 1989). Globally, an increase of 36% in $TropoO_3$ burden has been reported since 1850 (Cooper et al., 2014). $TropoO_3$ has strong effects on ecological interactions based on VOC signaling (Pinto et al., 2010).

Various natural, meteorological and anthropogenic factors are responsible for $TropoO_3$ concentration variability. Natural factors include; seasons, Earth-Sun distance, and location (altitude, latitude, and longitude), meteorological factors include; temperature, precipitation, humidity, soar flux, and wind speed, while anthropogenic factors include; emissions from precursor pollutants, biomass burning, vehicular emissions, and industrial processing (Ahmad and Aziz, 2013; Iqbal et al., 2014). Aerosols decrease $TropoO_3$ formation in polluted areas (Satheesh and Moorthy, 2005; Xing et al., 2017) and also decline its concentration after reacting with tropospheric gases (Sahoo et al., 2005). The primary objective of this study is to investigate the potential contributions of major tropospheric gases, meteorological parameters, and aerosol burden towards $TropoO_3$ variability over Lahore. $TropoO_3$ monitoring is being carried out either by onboard satellite sensors (Cooper et al., 2014; Ziemke et al., 2014) or via ground-based stations (Fioletov et al., 2008). Remote sensing techniques provide cost-effective, synoptic and repetitive coverages for spatio-temporal monitoring of tropospheric gases, meteorological parameters, and aerosol burden either at large or small scales. Whereas, data acquisition via ground-based stations is expensive, time-consuming, and almost impossible for inaccessible areas. The present study is carried out by retrieving datasets from onboard satellite sensors including; AIRS, AMSU-A, MODIS, MOPITT, OMI, and TRMM, as well as GLDAS model. To the best of our knowledge, no detailed study has so far been published for assessing $TropoO_3$ variability as functions of remotely sensed major tropospheric gases, meteorological parameters, and aerosol burden over Lahore.

Material and Methods

Location and description of the study area

Metropolitan corporation Lahore (31.5204°N, 74.3587°E) is the capital city of the Punjab province in Pakistan. As per 6th Population Census 2017 results, Lahore is the second-most populous city and financial hub of Pakistan after Karachi having population over 11 million and an area of 1,172 km^2 (*Figure 1*). Lahore is bounded by Sheikhupura District on the north and west bifurcated by Ravi River, Kasur District on its south, and Wagah Border along Indian province Punjab on the east. Lahore is the 16th largest and rapidly growing city in the world (CMF, 2018). Being financial hub, Lahore contains all types of Industrial, manufacturing, construction, business, and IT related activities

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1353313553

including but not limited to; pharmaceutical and chemical factories, steel mills, construction materials, power generation, manufacturing of motor vehicles, home appliance, electronics, leather goods, and paper products (Alam et al., 2012; Ali et al., 2014). Major air pollution sources in Lahore include automobile emissions, road dust, and biomass burning along with air pollutants transported from nearby regions (Alam et al., 2010, 2014). The Indian states of Punjab, Haryana, and Uttar Pradesh (shown in *Figure 1*) are reported to be the well-known air-pollutant emission sources from large scale rice and wheat crops generated residue burning and periodically transported to Lahore (Sidhu and Beri, 2008; Badarinath et al., 2009; Mishra and Shibata, 2012). Lahore falls under hot semi-arid and wet category based on the Köppen climate classification system with highly hot and wet summers (heavy monsoon rainfalls with frequent dust storms during June to September), while dry and cold winters (from December to February). Spring (March to May) and autumn (September to November with extensive crop residue burning in the surrounding regions) seasons are also observed in Lahore (Ali et al., 2014).

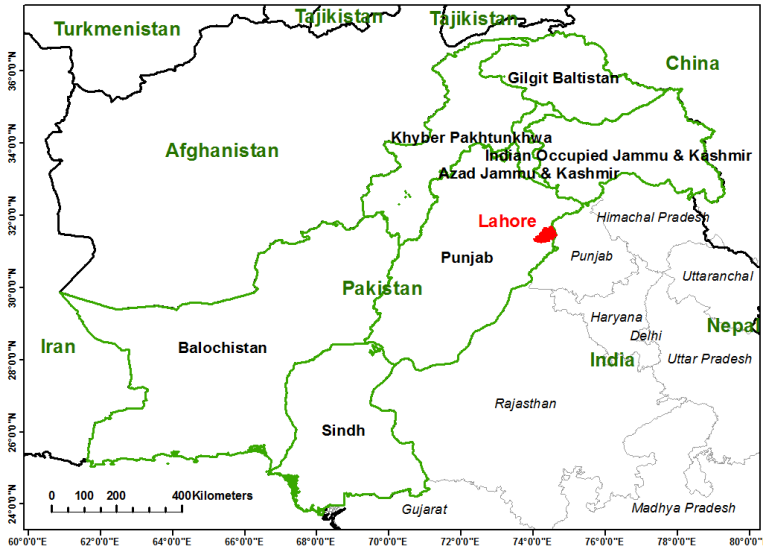

Figure 1. *Map showing the geographical location of Lahore (31.5204°N, 74.3587°E). (Source: https://www.statsilk.com/maps/download-free-shapefile-maps)*

Datasets

Host of satellite borne sensors have been providing online data products for monitoring and analyzing atmospheric gases, meteorological parameters, and aerosol burden measured as aerosol optical depth (AOD). For current study, we retrieved monthly-mean data products of TropoCH_4, TropoCO_2, CLF, and OLR, while daily datasets of RH, and surface temperature over Lahore from Atmospheric Infrared Sounder (AIRS, Pagano et al., 2003; Abed, 2017) and the Advanced Microwave Sounding Unit-A (AMSU-A, Aumann et al., 2003) onboard AURA satellite operational since 2002. The combined use of AIRS and AMSU-A data products basically offers new as well as improved measurements (Susskind et al., 2003). Data products of TropoNO_2 (daily), TropoO_3 (monthly-mean), and planetary boundary layer SO_2 (monthly-mean) were acquired from NASA's EOS Ozone Monitoring Instrument (OMI) onboard Aura satellite launched in a sun-synchronous polar orbit on July 15, 2004 at an altitude of 705 km and inclination of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1353313553

98.2° (Levelt et al., 2006a; Ziemke et al., 2011). OMI provides almost global coverage daily with a resolution of 13×24 km^2 at nadir while 13×100 km^2 at off-nadir (Boersma et al., 2006). It consists of hyperspectral imaging sensors to record radiances in the range of 270–500 nm (Levelt et al., 2006a,b). Additionally, monthly-mean data of TropoCO was retrieved from MOPITT onboard Terra, whereas, AOD from MODIS onboard Aqua deep blue. The datasets of surface level precipitation rate and near surface wind speed over Lahore were obtained from Tropical Rainfall Measuring Mission (TRMM, Liu et al., 2012) and Global Land Data Assimilation System (GLDAS, Fang et al., 2009), respectively. For validation of our resultant modeled, the original TropoO_3 data product of subtracted monthly-means of Total Column Ozone retrievable from OMI and Stratospheric Column Ozone retrievable from MSL onboard Aura satellite was utilized (Ziemke et al., 2006). Details about all the data products of major tropospheric gases, meteorological parameters, and aerosols used for this study are given in *Table 1*.

Methodology

We developed a bivariate correlation matrix representing tropospheric gases (CH_4, CO, CO_2, NO_2, O_3, and SO_2), meteorological parameters (CLF, OLR, PR, RH, Temp, and WS), and aerosol burden over Lahore using monthly-mean remotely sensed data during October 2004 – September 2015 (shown in *Table 2*). Each parameter mentioned in *Table 2* has either positive value (shown in blue colored bar) or negative value (shown in red colored bar), which indicates the type of correlation between the respective parameters. Longer the length of colored bars (either blue or red), stronger would be the correlation (either positive or inverse, respectively) between the corresponding parameters. Whereas, colored bars having smaller lengths (smaller values either positive or negative) indicate weaker correlations. In *Table 2*, correlation values written in bold text are significant at the 0.01 level (2-tailed), whereas, in italic text are significant at the 0.05 level (2-tailed). Respective statistical significance values, against each correlations of *Table 2*, are mentioned in *Table 3*. The highest statistical significance values at the 0.01 level (2-tailed) are highlighted in bold text, whereas, the statistical significance values at the 0.05 level (2-tailed) are mentioned in italic text in *Table 3*. The values written in regular text indicate least significance values. The highest correlation value [0.73] with 99% significance at 0.00 level (2-tailed) indicates that PR & CLF (meteorological parameters) are found to be positively highly correlated with each other in the study area during the observation period. Other higher positive correlations significant at 0.00 level (2-tailed) are; RH & CLF [0.70], RH & PR [0.69], Temp & AOD [0.69], and Temp & OLR [0.66]. Next equally higher but opposite correlations significant at 0.00 level (2-tailed) are; OLR & TropoO_3 [0.61], and TropoO_3 & TropoCO [–0.61]. Remaining relatively higher correlations significant at 0.00 level (2-tailed) are; WS & TropoO_3 [0.57], TropoCO_2 & TropoCH_4 [0.54], RH & TropoCH_4 [0.54], WS & TropoCO [–0.54], and RH & OLR [–0.52]. The parameters used in this study having weaker correlations with each other significant at 0.00 level (2-tailed) are (in descending order); OLR & CLF [–0.48], RH & TropoO_3 [–0.46], PR & AOD [0.45], PR & TropoCH_4 [0.45], RH & AOD [0.41], WS & TropoCO_2 [0.40], Temp & TropoCH_4 [0.39], AOD & TropoCH_4 [0.34], Temp & PR [0.33], OLR & TropoCO [–0.31], Temp & TropoO_3 [0.28], TropoNO_2 & TropoCO_2 [0.28], CLF & TropoCH_4 [0.27], WS & CLF [0.25], TropoCO_2 & TropoCO [–0.23], WS & TropoNO_2 [0.23], and TropoSO_2 & TropoO_3 [–0.23]. Out of all the tropospheric gases used in this study, TropoO_3 and TropoCO are found to be highly but inversely correlated with each other, whereas, TropoCO_2 and TropoCH_4 are next highly

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1353313553

and positively correlated gases significant at 0.01 level (2-tailed). Other tropospheric gases with weaker correlations including positive as well as inverse significant at 0.00 level (2-tailed) are; TropoNO_2 & TropoCO_2 [0.28], TropoCO_2 & TropoCO [–0.23], and TropoSO_2 & TropoO_3 [–0.23]. Only one correlation (least and positive) significant at 0.05 level (2-tailed) was found between TropoSO_2 & TropoNO_2 [0.18]. Positive as well as inverse correlations with 95% significance at 0.05 level (2-tailed) observed from this study are; OLR & AOD [0.22], CLF & TropoSO_2 [–0.22], AOD & TropoCO [–0.21], CLF & AOD [0.19], WS & RH [–0.19], and TropoSO_2 & TropoNO_2 [0.18]. All these correlations are also comparatively weaker ones.

Table 1. *Metadata of data retrieved from different satellite sensors (level-3 products) and models used in this study*

Product Name/Version	Sensor/ Model	Units	Spatial Resolution	Temporal Resolution	Observation Period	Description
a) Tropospheric Gases						
TropoCH_4 – Tropospheric Methane (AIR3STM_VMR_A.700hPa v006)	AIRS/ AMSU-A	ppbv	0.25°x0.25°	Daily	2002 – current	Tropospheric
TropoCO – Tropospheric Carbon Monoxide (MOP03JM v007)	MOPITT	ppbv	1° x 1°	Daily	2000 – current	Tropospheric
TropoCO_2 – Tropospheric Carbon Dioxide (AIR3C2M mole fraction v005)	AIRS/ AMSU-A	ppm	1° x 1°	Daily	2002 – current	Tropospheric
TropoNO_2 – Tropospheric Nitrogen Dioxide (OMNO2d v003)	OMI	x10^{15} molecules cm^{-2}	0.25°x0.25°	Daily	2004 – current	Tropospheric
TropoO_3 – Tropospheric Ozone (AIR3STM_VMR_A.700hPa v006)	AIRS/ AMSU-A	ppbv	0.25°x0.25°	Daily	2002 – current	Tropospheric
TropoSO_2 – Tropospheric Sulphur Dioxide (OMSO2e_PBL v003)	OMI	DU	0.25°x0.25°	Daily	2004 – current	Planetary boundary layer
b) Meteorological Parameters						
CLF – Cloud Fraction (AIRX3STM v006)	AIRS/ AMSU-A	Unit less	1° x 1°	Daily	2002 – current	Total column
OLR – Outgoing Long-wave Radiation (AIRX3STM v006)	AIRS/ AMSU-A	W m^{-2}	1° x 1°	Daily	2002 – current	Top of the atmosphere
PR – Precipitation Rate (TMPA/3B43 v007)	TRMM	mm $month^{-1}$	0.25°x0.25°	Monthly	1998 – current	Surface level
RH – Relative Humidity (AIRX3STD v006)	AIRS/ AMSU-A	%	1° x 1°	Daily	2002 – current	925 hPa
Temp – Air Temperature (AIRX3STD v006)	AIRS/ AMSU-A	Kelvin	1° x 1°	Daily	2002 – current	925 hPa

Annual trends (slopes and y-intercepts), overall changes (%), and R^2 of tropospheric gases, meteorological parameters, and aerosol optical depth over Lahore using their annual-means from October 2004 to September 2015 are tabulated in *Table 4*. All tropospheric gases except TropoCO indicate an increasing trend. Maximum positive

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1353313553

slope of 4.93±0.18 with R^2=0.99 observed for TropoCH_4 (having high correlations [0.54] significant at 0.01 level with TropoCO_2 and RH) indicates a maximum increasing trend than other gases used for this study. Similarly, slopes of PR (3.21±1.08) with maximum change of 49.61% (having strong correlation with CLF), and TropoCO_2 (1.97±0.04, having high correlation with TropoCH_4) show relatively increasing trends during the study period. However, a relatively large negative slope of TropoCO (–3.48±0.54) shows a decreasing trend over Lahore, which may be due to an overall decrease in TropoCO (-23.8%) during the entire study period. Moreover, TropoCO has inverse but high correlations significant at 0.01 level with TropoO_3 and WS. Relatively higher positive slopes (~21%) have been noticed for TropoNO_2, CLF, and WS, whereas little negative slopes have been observed for OLR (–0.05±0.21) and temperature (–0.10±0.04). It is worth mentioning here that the monthly-mean temperature values over Lahore during October 2004 – September 2015 show a little increasing trend (*Figure 3* refers).

Table 4. *Annual trends (linear equation showing slopes and y-intercepts), overall change (%), and R^2 based on annual-means of tropospheric gases including TropoCH_4, TropoCO, TropoCO_2, TropoNO_2 and TropoSO_2; major meteorological parameters including cloud fraction (CLF), outgoing long-wave radiation (OLR), precipitation rate (PR), relative humidity (RH), temperature (Temp) and surface wind speed (WS); and aerosol burden measured as aerosol optical depth (AOD) over Lahore during October 2004 – September 2015*

Parameter	Annual Trend Line	Overall Change (%)	R^2
TropoCH_4 (ppbv)	$y = (4.93\pm0.18)x + (1799.10\pm1.35)$	2.92	0.99
TropoCO (ppbv)	$y = -(3.48\pm0.54)x + (202.36\pm3.94)$	–23.80	0.81
TropoCO_2 (ppm)	$y = (1.97\pm0.04)x + (377.07\pm0.27)$	5.40	1.00
TropoNO_2 ($\times10^{15}$ molecules cm^{-2})	$y = (0.06\pm0.02)x + (2.23\pm0.17)$	21.62	0.40

AOD (unit less)	$y = (0.01\pm0.00)x + 0.62\pm0.02$	10.69	0.39

Results and Discussion

Parametric out-look of Lahore

Tropospheric gases

Concentrations of major tropospheric gases have been compared with those of TropoO_3 over Lahore during October 2004 – September 2015 and are shown in *Figure 2*. Large variations have been observed in TropoCH_4, TropoCO, and TropoNO_2, whereas, TropoCO_2 and TropoSO_2 show comparatively little variations. We also noticed that all tropospheric gases indicate increasing trends except TropoCO. Gradual increasing trend in TropoCH_4 indicates gradual increasing activities responsible for Methane production (Paddy crops, animals, industrial activities, and vehicular emissions etc.) in the study area

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1353313553

during the study period. Similarly, gradual increasing trend in $TropoCO_2$ is an indication of increased activities causing carbon dioxide to increase (Agricultural activities, population, animals, industrial activities, and vehicular emissions etc.) in Lahore. Whereas, slopes of $TropoNO_2$ and $TropoSO_2$ are quite gentle showing little increase similar to that of $TropoO_3$.

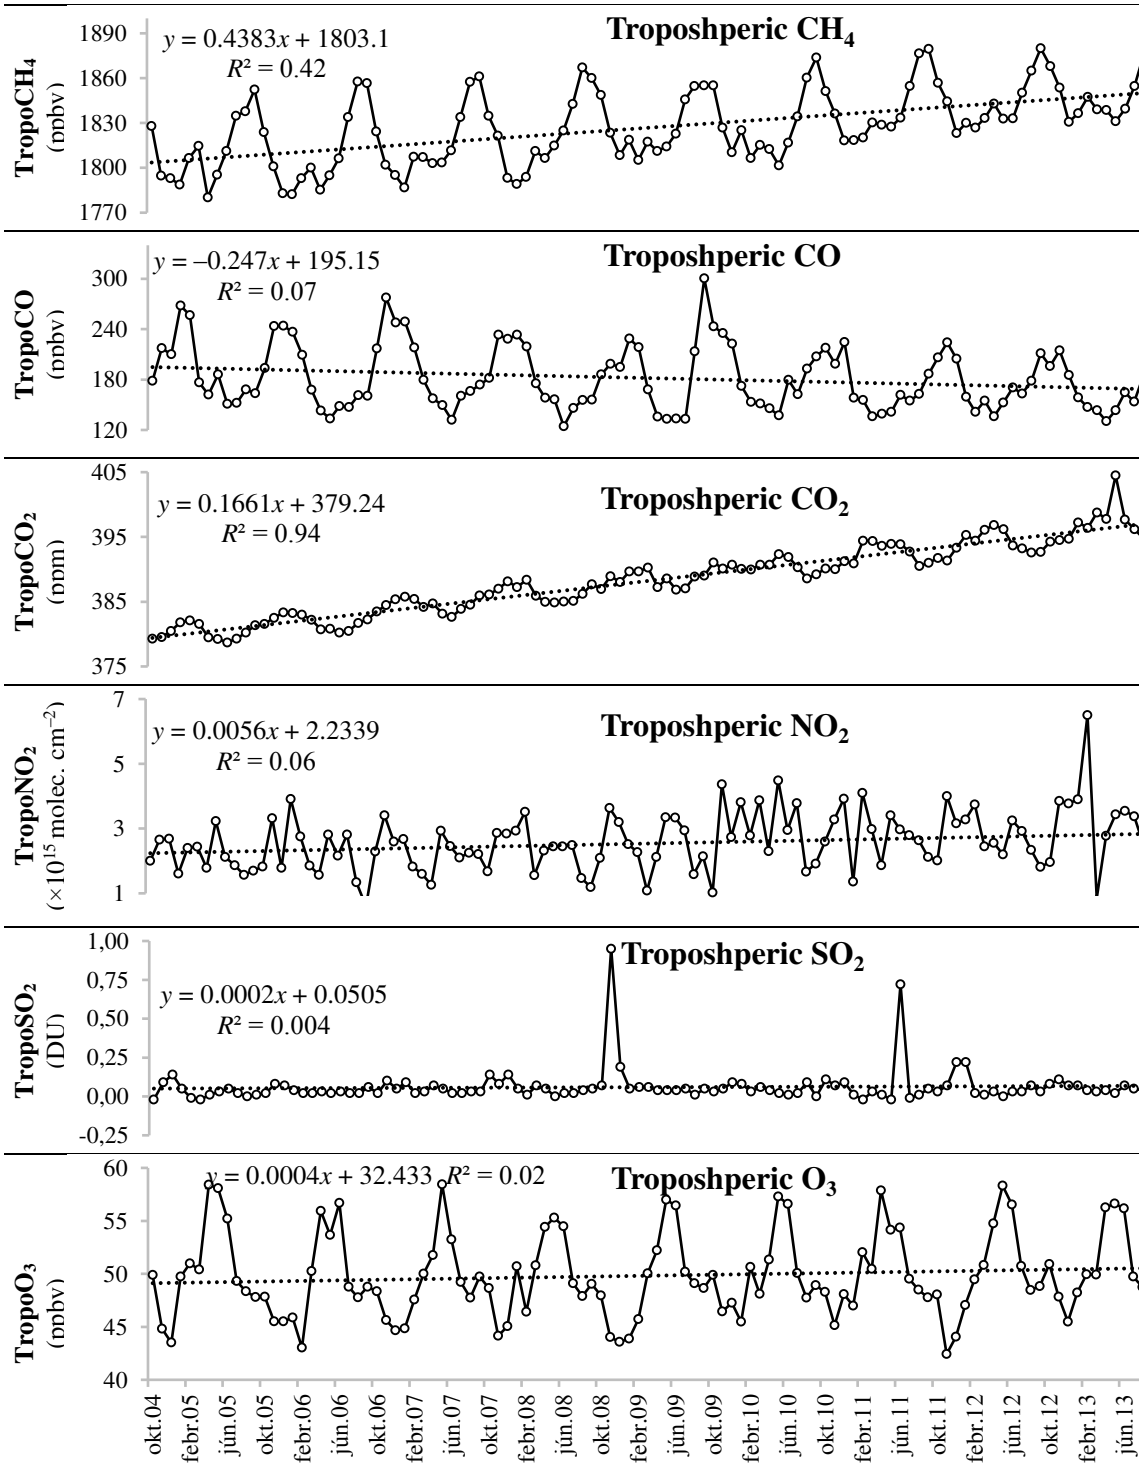

Figure 2. *Time series monthly-mean variations of major tropospheric gases over Lahore during October 2004 – September 2015. Dotted lines correspond to respective trend lines*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1353313553

Meteorological parameters

Monthly-mean data products of major meteorological parameters as well as aerosol burden measured as Aerosol Optical Depth (AOD) have been compared with $TropoO_3$ concentrations over Lahore during October 2004 – September 2015 and are shown in *Figure 3*. Large variations have been observed in all parameters similar to that of $TropoO_3$ during the entire study period. Positive slopes of all parameters including $TropoO_3$, except OLR, indicate increasing trends during the study period. Comparatively larger slope value of PR indicates a gradual increase in precipitation in the study area.

$TropoO_3$

Maximum concentration of $TropoO_3$ has been reported during spring and summer seasons across the globe (e.g., Cooper et al., 2014). Accordingly, maximum concentrations have been observed in $TropoO_3$ over Lahore during spring and summer (monsoon) seasons (March to July) in Pakistan shown in *Figure 4*. Major causes of this increased $TropoO_3$ concentration over Lahore are mainly due to increased ozone precursor gas emissions, enhanced biomass burning activities, biogenic emissions, polluted air-masses migrated from nearby regions, removal of NO_2 concentration due to increased OH radicalization (Yienger and Levy, 1995), photolysis of water vapors which reduces NO_2 concentration during high rainfall in monsoon (Jacob, 2003; Ghude et al., 2009; Seinfeld and Pandis, 2016), and enhanced intrusion of O_3 from stratosphere (Noreen et al., 2018). An overall decreasing trend has been observed in the monthly-mean values of observed $TropoO_3$ concentration over Lahore (slope=–0.4303, y-intercept=52.786, and R^2=0.1614) during the study period.

Modeling $TropoO_3$ concentration over Lahore

In order to investigate $TropoO_3$ dependencies, monthly-mean values of major tropospheric gases, meteorological parameters, and aerosol burden over Lahore during October 2004 – September 2015 have been incorporated in multiple linear regression model (e.g., Engel-Cox et al., 2004; Lin et al., 2012), mentioned in *Equation (1)*;

$$\text{Objective or Dependent Variable} = a_o + \sum(b_n \times w_n) + \varepsilon \qquad \text{(Eq.1)}$$

where a_o is an intercept, b=1,2,3,..…n are regular (unstandardized) regression coefficients, w=1,2,3,…...n are regressors or independent variables, and ε is an error term associated with the regression analysis. The resultant multiple linear regression model used in this study to model $TropoO_3$ (Objective/Dependent Variable) as functions of tropospheric gases, meteorological parameters, and aerosol burden (regressors or independent variables) is mentioned in *Equation (2)* below;

$$\begin{aligned} \text{TropoO}_3\text{(monthly mean)} &= a_0 + b_1 \times \text{TropoCH}_4 \\ &+ b_2 \times \text{TropoCO} \\ &+ b_3 \times \text{TropoCO}_2 + \\ b_4 \times \text{TropoNO}_2 &+ b_5 \times \text{TropoSO}_2 + b_6 \times \text{CLF} \\ &+ b_7 \times \text{OLR} + \\ b_8 \times \text{PR} + b_9 \times \text{RH} &+ b_{10} \times \text{Temp} + b_{11} \times \text{WS} \\ &+ b_{12} \times \text{AOD} + \varepsilon \end{aligned} \qquad \text{(Eq.2)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1353313553

where a_o is an intercept, b_1, b_2, b_3,……b_{12} are regular (unstandardized) regression coefficients; TropoCH_4, TropoCO, TropoCO_2, TropoNO_2, TropoSO_2, CLF, OLR, PR, RH, Temp, WS, and AOD are the monthly-mean regressors or independent variables; and ε is an error term associated with the regression analysis. The multiple linear regression model mentioned in *Equation (2)* closely measures the intrinsic relationships of TropoO_3 with all regressors, separately. Therefore, this model offers better predictability of TropoO_3 based on relative impacts with all regressors than by simple linear model which is based only upon single regressor.

To improve the results of *Equation (2)*, stepwise multiple linear regression procedure (Lin et al., 2012) was adopted. Resultant stepwise multiple linear regression model shown in *Table 5* was generated. The model provides statistical information for modeling TropoO_3 concentrations based upon weighted contributions from its regressors. This procedure simultaneously regresses multiple variables (gases, meteorological parameters, and aerosol burden) and removes un-important parameter(s) from the model. *Table 5* shows that the modeled TropoO_3 is mainly dependent upon OLR, WS, CLF, TropoSO_2, TropoCO, and RH out of all regressors mentioned in *Equation (2)*. The standardized regression coefficients (β) obtained from the stepwise multiple linear regression model show weight-wise dependence of TropoO_3 upon OLR [β=0.458] with the highest contribution, followed by nearly equivalent contributions from WS [β=0.262] and CLF [β=0.256], whereas, the least contribution has been observed from RH [β=–0.320]. This model also reveals that TropoSO_2 [β=–0.097] and TropoCO [β=–0.231] are negatively contributing against TropoO_3 concentration over Lahore during the study period. The values of multiple error (r=0.85) and standard error (2.14) for this TropoO_3 model appear to be reasonable.

A subsequent bivariate correlation matrix representing observed TropoO_3, modeled TropoO_3, and the parameters which contributed in the modeled TropoO_3 concentration (OLR, WS, CLF, TropoSO_2, TropoCO, and RH) as mentioned in *Table 5* above was generated and is shown in *Table 6* below. Blue color indicates positive correlations, while red color indicates negative/inverse correlations. Longer the length of colored bars (either blue or red), stronger would be the correlation (either positive or inverse, respectively) between the corresponding parameters. In *Table 6*, correlation values written in bold text are significant at the 0.01 level (2-tailed), whereas, in italic text are significant at the 0.05 level (2-tailed). Respective statistical significance values, against each correlations of *Table 6*, are written in *Table 7*. The highest statistical significance values at the 0.01 level (2-tailed) are highlighted in bold text, whereas, the statistical significance values at the 0.05 level (2-tailed) are mentioned in italic text in *Table 7*. The values written in regular text indicate least significance values. All correlations shown in *Table 6* exhibit the same corresponding values as mentioned in *Table 2* above along with additive correlation values against modeled TropoO_3. All bivariate correlations with the modeled TropoO_3 concentration are significant at 0.01 level (2-tailed) except for CLF. The highest correlation value [0.85] with 99% significance at 0.00 level (2-tailed) between modeled and observed TropoO_3 concentrations over Lahore during the study period reveals the high suitability of the modeled developed in this study mentioned in *Table 5* above. Out of two tropospheric gases used in this model, modeled TropoO_3 is found to be highly but inversely correlated with TropoCO [–0.72], whereas, OLR [0.71] and WS [0.68] are the next highly and positively correlated meteorological parameters significant at 0.01 level (2-tailed).

Table 7. *Based upon correlation matrix discussed in Table 6 above, matrix showing statistical significance values of observed TropoO_3, OLR (W m^{-2}), WS (m s^{-1}), CLF (unit less), TropoSO_2 (DU), TropoCO (ppbv), and RH (%) as well as modeled TropoO_3 concentrations over Lahore during October 2004 – September 2015*

Parameters	Observed TropoO_3	OLR	WS	CLF	TropoSO_2	TropoCO	RH
OLR	**0.00**						
WS	**0.00**	0.27					
CLF	0.44	**0.00**	**0.00**				
TropoSO_2	**0.01**	0.58	0.13	*0.01*			
TropoCO	**0.00**	**0.00**	**0.00**	0.06	0.13		
RH	**0.00**	**0.00**	*0.03*	**0.00**	0.68	0.18	
Modeled TropoO_3	**0.00**	**0.00**	**0.00**	0.42	**0.00**	**0.00**	**0.00**

The numbers written in bold text are statistical significance values for significant correlations at the 0.01 level (2-tailed). The numbers written in italic text are statistical significance values for significant correlations at the 0.05 level (2-tailed)

Other inverse correlations of the modeled TropoO_3 significant at 0.00 level (2-tailed) are noticed against RH [–0.53] and TropoSO_2 [–0.27]. The least and inverse correlation having 95% significance at 0.05 level (2-tailed) is against CLF [–0.07].

The observed TropoO_3 datasets retrieved directly from the AIRS/AMSU-A sensor over Lahore during October 2004 – September 2015 and the modeled TropoO_3 concentration values obtained from of the resultant step-wise multiple linear regression model (discussed in *Table 5* above) have been plotted in *Figure 5*.

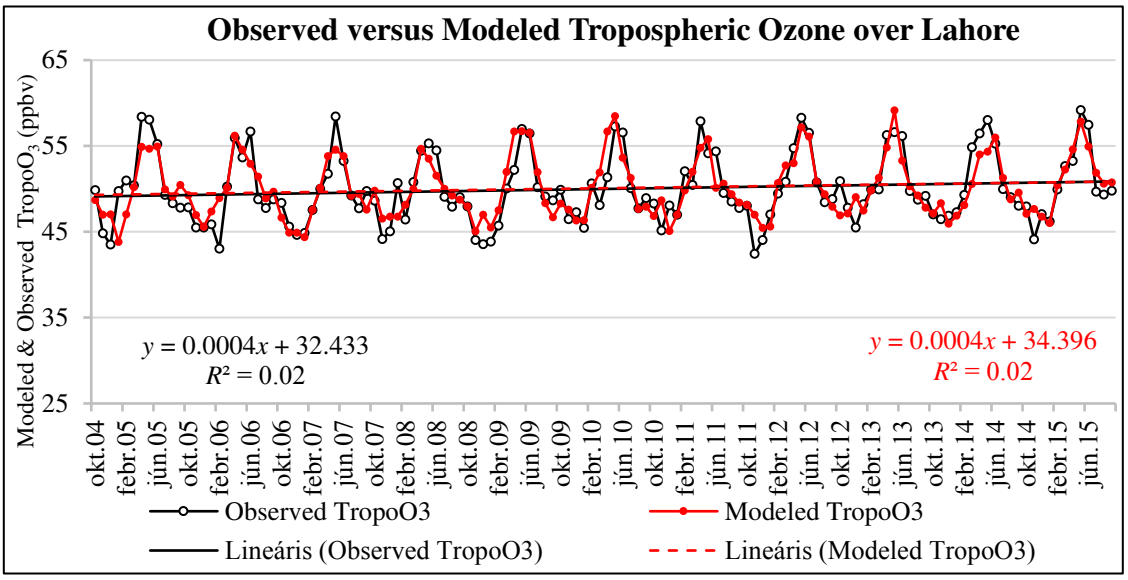

Figure 5. *Comparison of observed versus modeled time-series TropoO_3 (ppbv) concentrations over Lahore during October 2004 – September 2015. Dotted lines correspond to respective trend lines*

Time series distributions of these observed and modeled TropoO_3 concentrations show similar increasing and consistent trends except during the months of May 2005, Feb 2006, May 2007, Dec 2008, Nov 2011, Dec 2012, May 2014, and Nov 2014. The highest value in the modeled TropoO_3 concentration has been notice for the month of May 2013.

DOI: http://dx.doi.org/10.15666/aeer/1706_1353313553

Monthly-mean data analysis of modeled $TropoO_3$ concentration indicate a similar pattern as that of the observed $TropoO_3$ concentration over Lahore during the study period as shown in *Figure 6(a)*. We find higher concentrations of both modeled and observed $TropoO_3$ during spring and summer (monsoon) seasons, whereas, minima during the winter season. A similar observation about $TropoO_3$ variation was reported by Ahmad and Aziz, 2013. Our modeled $TropoO_3$ variation attributes a similar decreasing trend (slope=–0.3254, y-intercept=52.192, and R^2=0.12) over Lahore during the study period. Scatter plot drawn between observed and modeled $TropoO_3$ indicates a linear positive trend having a slope 0.732 and y-intercept 13.469 with R^2=0.73 as shown in *Figure 6(b)*.

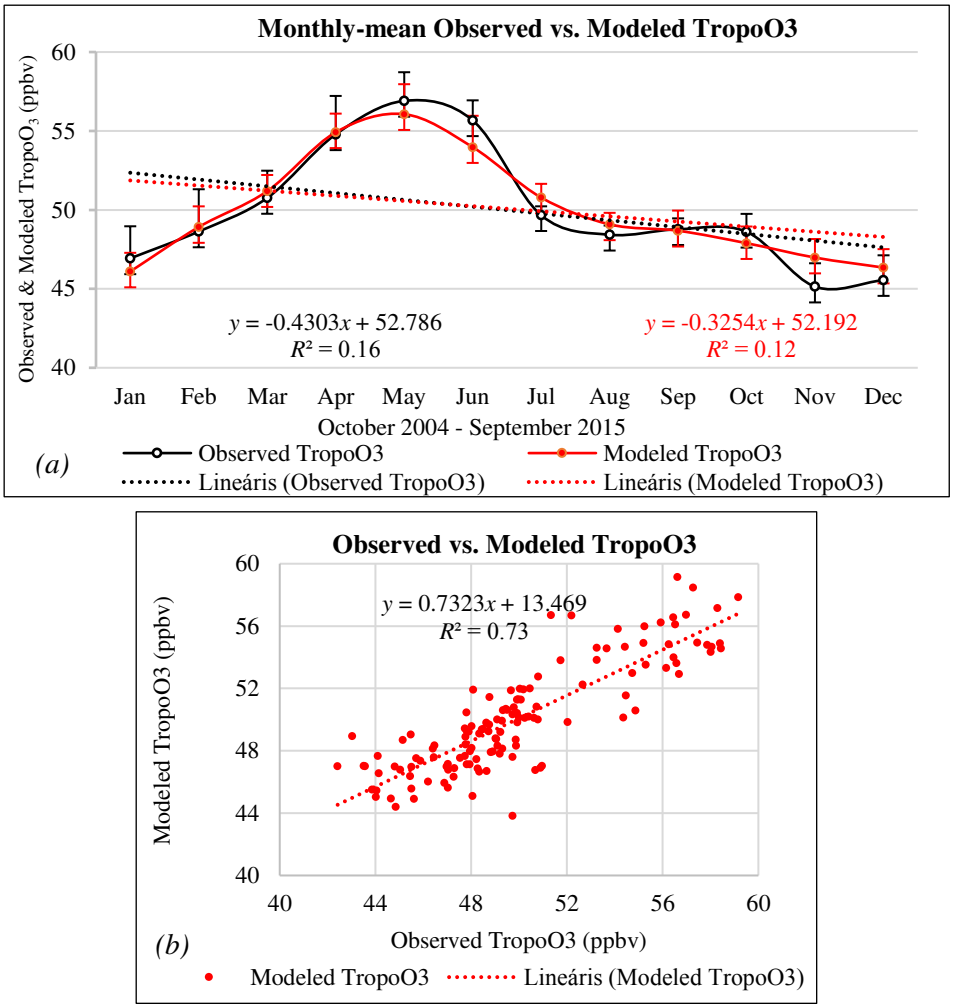

Figure 6. *(a) Monthly-means of observed $TropoO_3$ (used as dependent variable) and modeled $TropoO_3$ concentrations (all data in ppbv) over Lahore during October 2004 – September 2015. (b) Scatter plot of observed versus modeled $TropoO_3$ concentrations (ppbv). Dotted lines correspond to respective trend lines*

Annual trends, overall change (%), and R^2 based on annual-means of observed and modeled $TropoO_3$ concentrations over Lahore during October 2004 – September 2015 were calculated and are mentioned in *Table 8*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1353313553

Table 8. *Annual trends (slopes and y-intercepts), overall change (%), and R^2 based on annual-means of observed and modeled $TropoO_3$ concentrations over Lahore during October 2004 – September 2015*

Parameter	Annual Trend Line	Overall Change (%)	R^2
Observed $TropoO_3$ (ppbv)	$y = (0.29\pm0.08)x + (47.91\pm0.62)$	6.18	0.54
Modeled $TropoO_3$ (ppbv)	$y = (0.23\pm0.06)x + (48.48\pm0.42)$	4.89	0.62

Overall similar increasing concentrations of both observed (6.18%, R^2 = 0.54), and modeled (4.89%, R^2 = 0.62) $TropoO_3$ indicate good agreement of resultant model devised in this study. The slope of observed $TropoO_3$ [0.29±0.08] is little larger than that of the observed $TropoO_3$ [0.23±0.06], however, the values of y-intercepts of both concentrations are nearly similar. The increase in $TropoO_3$ concentration observed in Lahore and adjoining areas during the study period is possibly due to increased anthropogenic activities including; population and traffic densities, industrial activities, infrastructure development activities, and biomass burning etc. These results are almost in agreement with those obtained by Noreen et al 2018 for ozone column over Lahore. Some other studies had also discussed about the $TropoO_3$ concentrations, and production of its precursors through different anthropogenic activities (e.g., Kulkarni et al., 2010; Lal et al., 2012; Ahmad and Aziz, 2013).

Model validation

Modeled $TropoO_3$ concentrations were crossed checked against an independent source of $TropoO_3$ concentrations. For this purpose, original $TropoO_3$ data product of subtracted monthly-means of Total Column Ozone retrievable from OMI and Stratospheric Column Ozone retrievable from MSL onboard Aura satellite was utilized (available at https://acd-ext.gsfc.nasa.gov/Data_services/cloud_slice/new_data.html). $TropoO_3$ product calculated by mean volume mixing ratio (in ppbv) formatted in 1-degree (latitude) by 1.25-degree (longitude) resolution was extracted for Lahore during October 2004 – September 2015. Our modeled as well as the observed $TropoO_3$ (used as dependent variable) concentrations have been plotted in *Figure 7* against these independently available product of OMI-MLS $TropoO_3$ concentrations (ppbv) over Lahore during the study period.

The results show similar seasonality patterns as well as trends in all three datasets with good agreements in their slopes and error values mentioned in *Figure 7*. These promising results validate our resultant model. OMI-MLS $TropoO_3$ concentrations have been plotted against secondary axis due to its wider data range. OMI/MLS data measurements have some anomalies especially during 2007 and 2009 (Ziemke et al., 2006).

To further investigate this validation process, monthly-mean data of OMI-MLS $TropoO_3$ (independent data) was compared with modeled as well as observed $TropoO_3$ concentrations over Lahore during October 2004 – September 2015 (shown in *Figure 8*). Monthly-mean graphical patterns, slopes, and trends in all three datasets are similar with higher concentrations during the spring and summer (monsoon) seasons, whereas, minima during the winter season shown in *Figure 8(a)*. Comparison of scatter plots drawn between OMI-MLS $TropoO_3$ (independent data), and observed $TropoO_3$ (used as

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1353313553

dependent variable) against modeled $TropoO_3$ concentrations shown in *Figure 8(b)* indicates similar linear positive trends.

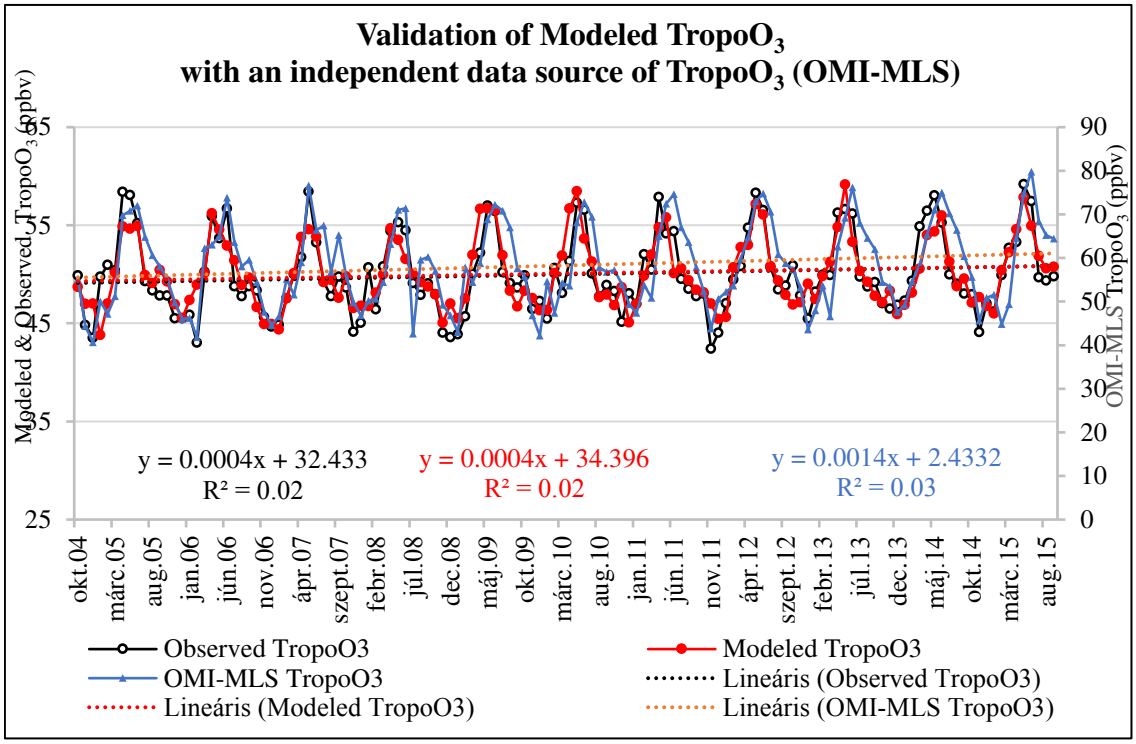

Figure 7. *Validation of modeled and observed (used as dependent variable) $TropoO_3$ (ppbv) against an independent source of $TropoO_3$ concentrations (ppbv) retrieved from OMI-MLS data product over Lahore during October 2004 – September 2015. Dotted lines correspond to respective trend lines*

Conclusions

The proposed step-wise multiple linear regression model reveals weighted contributions of major factors OLR, WS, and CLF, $TropoSO_2$, TropoCO, and RH (based on standardized regression coefficient, β) against $TropoO_3$ variability over Lahore during September 2004 – October 2015. Stepwise multiple linear regression modelling technique opted to model $TropoO_3$ concentrations over Lahore has shown highly consistent results as compared with the $TropoO_3$ observations retrieved directly from OMI satellite sensor. The trend-line of scatter plot drawn between observed and modeled $TropoO_3$ provides a steady linear increase analogous correlation with an overall increase of 6.18% in observed $TropoO_3$, while 4.89% in modeled $TropoO_3$ over Lahore during the study period. Based on the resultant value of multiple correlation coefficient (r=0.854) it can confidently be asserted that the stepwise multiple linear regression model opted to predict $TropoO_3$ over Lahore is quite reasonable. The modeled $TropoO_3$ concentrations were validated against an independent source of $TropoO_3$ concentrations retrieved from original subtracted product of OMI-MLS over Lahore for the study period and the results were found in good agreement. This study of modeling $TropoO_3$ variation as functions of satellite observations of major tropospheric gases, meteorological parameters, and aerosol burden over Lahore acquired during October 2004 – September 2015 using stepwise multiple

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1353313553

linear regression modelling technique is quite unique. The study would be helpful for further research investigations in this domain as well as provide useful information for policy/decision makers in Lahore, Pakistan.

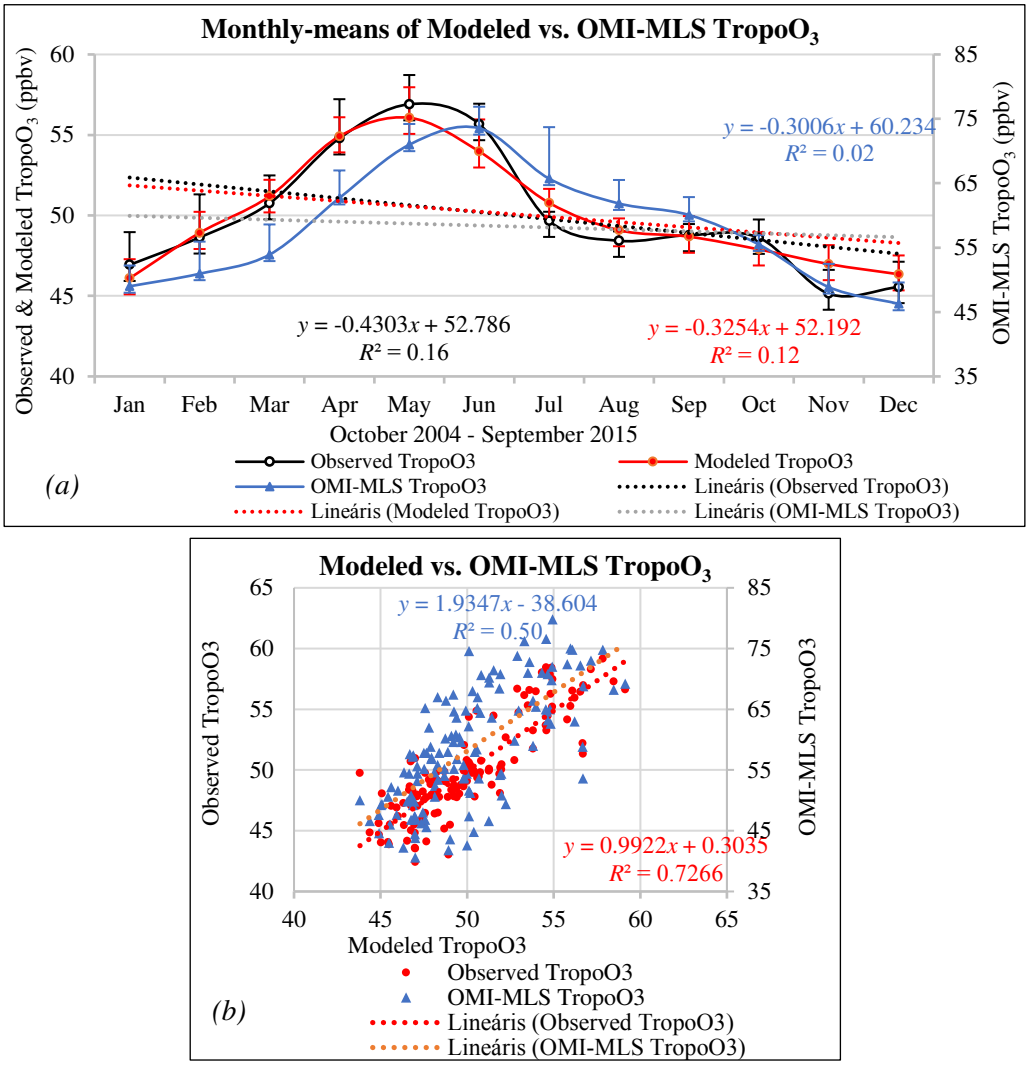

Figure 8. *(a) Monthly-means of OMI-MLS TropoO₃ (independent data), observed TropoO₃ (used as dependent variable) and modeled TropoO₃ concentrations (all data in ppbv) over Lahore during October 2004 – September 2015. (b) Scatter plot of OMI-MLS TropoO₃ (independent data), and observed TropoO₃ (used as dependent variable) against modeled TropoO₃ concentrations (all data in ppbv). Dotted lines correspond to respective trend lines*

Abstract. The Atlas pistachio (*Pistacia atlantica* Desf.), a rustic tree distributed in different bioclimatic areas, is rapidly declining, particularly in Algeria. Among the actions to be undertaken is the launch of a restocking program. Nevertheless, Atlas pistachio seed dormancy is an obstacle limiting its germination and obtaining seedlings. The aims of the present study are to define the nature of seed germination inhibitors and to propose pretreatments that would limit their effects. Seeds were collected from three locations in Algeria. Quantitative and qualitative traits of phenolic compounds and total antioxidant activity were determined at three levels, namely, seed, epicarp and kernel. Germination was investigated in seeds with epicarp, epicarp removed, and with or without H_2O_2 treatment. Results showed that whole seed germination is not effective. Scarification by removing epicarp did not improve the germination rate. Chemical analyses indicated that seeds, kernel and epicarp were rich in total phenolic compounds. These compounds are known to limit seed germination in several species. Application of hydrogen peroxide induced a significant increase in seed germination rate in the three ecotypes. H_2O_2 caused inhibition of polyphenol compounds effects on germination. The results indicated that the inhibitory effect of phenolic compounds can be found at the kernel level instead of the epicarp. However, studied genotypes indicated that only one ecotype was distinguished by seed dormancy that originated in the epicarp and kernel.
Keywords: *pistachio, seeds, germination, inhibition, polyphenols*

Introduction

Wild pistachio (*Pistacia atlantica* Desf.) is a rustic and xerophytic tree, adapted to dry climates. In Algeria, it even inhabits pre-Saharan areas where it plays important roles on the ecological and socio-economic levels. It is a tree species of the genus *Pistacia* L. which is endangered in Algeria. This species has been declining from year to year in response to anthropogenic factors and, in addition, due to the problems related to its regeneration. Similarly, plants that beyond the emergence stage by escaping pastures are confronted with arid climate problems that cause even more damage (Ait Said et al., 2011). Atlas pistachio produces oilseeds rich in polyunsaturated fatty acids,

DOI: http://dx.doi.org/10.15666/aeer/1706_1355513565

mainly oleic and linoleic acid (Yousfi et al., 2002; Farhoosh et al., 2009; Yazdanpanah and Baghereyanmanesh, 2015) and exhibit orthodox storage characteristics (Joley, 1960; Ayfer and Serr, 1961).

Seed germination is one of the most important stages of the plant life cycle. Germination in the narrow sense is an exceptionally complex process that begins with water uptake and is associated with many metabolic, cellular, and molecular events, which enable the radicle to emerge from the seed (Barba-Espín et al., 2012). The efficient progression of germination determines the nature of seedling formation and the proper development of mature plants. However, *Pistacia atlantica* seeds present a dormancy phenomenon which greatly limits their germination.

Seed dormancy is separated into two types, the first imposed by the epicarp and the second by the embryo (Joley, 1960; Bewley and Black, 1994). The endocarp can reduce the imbibition rate (Crane and Forde, 1974). Embryonic dormancy is related to the environmental conditions which occur at the time of harvest and when maturation of seeds takes place (Vallèe et al., 1999). Seeds of this tree are encompassed by a hard epicarp, which makes germination difficult (Isfendiyaroglu and Özeker, 2001; Abu-Qaoud, 2007).

Phenolic compounds are the products of secondary metabolism in plants, providing essential functions in their reproduction and growth, acting as defense mechanisms against pathogens, parasites, and predators, as well as contributing to the color of plants (Liu, 2007). The inhibitory effects of phenolic compound on seed germination are closely related to the regulation of endogenous auxins, epicarp permeability and oxygen supply to the embryo (Bewley and Black, 1994). Polyphenols and flavonoids produced in the fruit or seed can inhibit germination (Baskin and Baskin, 1998). The reactivation of metabolism following seed imbibition may supply an important source of reactive oxygen species (ROS) (Bailly, 2004). Hydrogen peroxide (H_2O_2) is a reactive molecule that plays a dual role in plant physiological and developmental processes, and in resistance to stress. The accumulation of H_2O_2 and of other ROS has been identified in seed physiology during imbibition and during early stages of germination (Schopfer, 2001; Bailly, 2004).

Preservation of the Atlas pistachio requires protection of the existing population, as well as planting of new trees. Realization of this last operation is based on the mastery seed germination and seedling production. Nevertheless under different conditions, the germination of pistachio seeds, though slow, requires the removal of factors which reduce its rate.

The poor germination of Atlas pistachio seeds seriously limits its regeneration. Different treatments have been used to increase the germination rate, without characterizing the factors that are responsible for seed dormancy. Abu Qaoud (2007) showed that germination rate was improved by seed scarification, which explains that seed dormancy is due to the mechanical resistance of the epicarp.

This study attempts to define the biochemical factors imposing the seed dormancy and their variation through the genetic variability thus the limitation of their effects by pretreatments application.

Materials and methods

Plant materials

Seeds of *Pistacia atlantica* accessions were collected from 10 trees in each of three locations in Algeria from the beginning of October to November 2015 (*Table 1; Figs. 1* and *2*).

Biochemical analysis

Plant sampling and preparation of extracts

One gram of each sample of seed, kernel and epicarp were crushed into powder using a mortar grinder (RM 200-Retsch) mixed with 20 ml of methanol and stirred for 48 h in the dark at room temperature. The mixture was filtered through a GHP filter with 0.45 µm pores. The solvent was then removed under reduced pressure in a rotary evaporator at 60 °C. The residue (crude extract) was dissolved in 3 ml of methanol for analysis.

Determination of total phenolic compounds

The total polyphenol content (TPC) was quantified using the Folin-Ciocalteau phenol reagent, according to the protocol of Singleton et al. (1999). The method is based on the colored reaction of phenolic compounds with the reagent. Folin-Ciocalteau reagent is reduced to a blue colored oxide at pH 9.0 upon reaction with phenols. In a typical

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1355513565

experiment, 200 µl of the final methanolic solution was mixed with 1 ml of Folin-Ciocalteu reagent (10%) and 0.8 ml of Na_2CO_3 (7.5%). After incubation for 30 min at room temperature in dark, the absorbance was determined at 765 nm using a UV-1800 spectrophotometer (Shimadzu UV–VIS). Results were expressed as mg of gallic acid equivalent per g of fresh weight (mg GAE/g FW). For each sample three replicates were analyzed. The choice of methanol as solvent was based on the results of Belyagoubi et al. (2016), who showed that crude methanolic extracts were more effective than petroleum ether, chloroform, acetone and water extracts for determining total phenolic content and antioxidant activity of *P. atlantica* seeds.

Evaluation of total antioxidant activity (TAA)

The total antioxidant activity (TAA) of methanolic extract samples was estimated using the phosphomolybdenum method of Prieto et al. (1999), based on the reduction of Mo (VI) to Mo (V) by the extractedion and subsequent formation of a specific green phosphate/Mo (V) complex at acidic pH. Aliquots (1 ml) of reagent solution (0.6 M sulfuric acid, 28 mM sodium phosphate and 4 mM ammonium molybdate) were added to 100 µL of each sample (three replicates) and incubated at 95 °C for 90 min. The mixture was then cooled at room temperature. The absorbance of all samples was measured at 695 nm. Total antioxidant activity was expressed as mg gallic acid equivalent per g of fresh weight (mg GAE/g FW).

Qualitative analysis of phenolic compounds

The chromatographic system for the separation, analysis of phenolic acids and flavonoids were carried out with Shimadzu model prominence liquid chromatography, thermostatic column compartment, online degasser and an UV-visible detector model SPD-20A (operating at 268 nm). An analytical column used was a Shim-pack VP-ODS C18 (4.6 mm×250 mm, 5 µm), (Shimadzu Co., Japan). A binary gradient linear system consisting of acetonitrile (A) and 0.2% acetic acid in water (B) was used. Gradient method was generated by starting with 90% B; then decreasing to 86% B in 6 min, to 83% B in 16 min, to 81% B in 23 min, to 77% B in 28 min, held at 77% B in 28-35 min, to 60% B in 38 min, to 90% B in 50 min; at a flow rate of 1 mL/min. Quantification of separated peaks was performed by calibration with standard gallic acid (GA), chlorogenic acid (CGA), vanillic acid (VA), caffeic acid (CA), p-coumaric acid (p-CA), vanillin (V), rutin (RU), naringin (NAR), and quercetin (QE). The volume injected is 20 µl. The phenolic compositions were quantified by plotting a standard curve with the respective standards (*Fig. 1*).

Seed germination rate

Seeds of *Pistacia atlantica* (*Fig. 2*) were divided into two groups, with and without epicarp (achieved by mechanical scarification). They were imbibed in distilled water (control) or 4% H_2O_2 as pretreatment for 48 h. A total of 216 seeds were used for each ecotype (with and without epicarp) and were placed in Petri dishes (9 cm diameter) with filter paper moistened with distilled water. The experimental design was completely randomized with three replications per treatment. Seeds were incubated at 25 °C in the dark. The rate germination (G %) was calculated according to the following equation: G% = (NGG / NTG) × 100, where NGG was the number of germinated seeds and NTG was the total number of tested seeds.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1355513565

Statistical analysis

All data were subjected to a one- and two-way analysis of variance (ANOVA) using the STATISTICA software package (StatSoft, Tulsa, USA). Mean comparison was performed by Duncan test at 5% probability level.

Results

Polyphenols and antioxidant activity

The results (*Table 2*) showed that there was a significant ecotype effect on the TPC content at the seed, epicarp and kernel level. Regarding the TAA, there was a significant effect only in relation to seed content.

Our results indicated that the phenolic compound content of the epicarp was significantly higher than seed or kernel, irrespective of the geographic origins (*Table 2*). The highest TPC content of the epicarp was observed in seeds from Djelfa and the lowest in seeds fromn Bechar. In the kernel, the total phenolic content increased by 20% from values in Bechar seeds to those from Djelfa (*Table 2*). The TAA at the seed level depended significantly on the nature of the ecotypes studied. However, seed origin had only a small influence on this activity in epicarp and kernel (*Table 2*). Total antioxidant activity was extremely different in seeds from different locations and values varied by nearly two-fold between ecotypes from Bechar and those from Batna (*Table 2*). The total antioxidant activity was highest at the epicarp level and the lowest values at the kernel level (*Table 2*). Indeed, TAA in the epicarp was nearly 1.7 and 4.5 times that in the whole seed and kernel, respectively (*Table 2*). Moreover, the higher the TPC value, the higher the antioxidant activity, irrespective of seed origin or the specific seed part investigated.

Table 2. *Means values of total phenolic contents (TPC) and total antioxidant activity (TAA) founded in seed, kernel and epicarp of Pistacia atlantica harvested from three geographic zones in Algeria*

Ecotype	TPC (mg GAE/g FW)			TAA (mg GAE/g FW)

*, **, ***: Significant at $P \leq 0.05$; $P \leq 0.01$; $P \leq 0.001$, respectively. ns: not significant. F values Means indicated by different letters are significantly different using the Duncan test at 0.05 probability and the significance of ecotype Factor it also displayed

Phenolic identification by HPLC

The phenolic compounds including gallic acid, chlorogenic Acid, vanillic acid, caffeic acid, Vanillin, p-coumaric acid, rutin, naringin and quercetin were identified and quantified in epicarp, kernel and seed (*Table 3a, b*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1355513565

The phenolic acid contents, which consist mainly of gallic and chlorogenic acids, are variable according to the ecotypes, at the three measurement sites (*Table 3a, b*). The highest phenolic acids content was recorded at the epicarp of Djelfa (D) seeds with 94.15 mg/gFW and the lowest value was measured at the Batna seeds epicarp (B) with 0.206 mg/gFW.

The results indicated that the quercetin is the major flavonoids constituent, identified in epicarp as well as in seed and kernel extracts. The total flavonoids highest levels were found in the epicarp of Djelfa and Batna seeds with respective values of 459.86 mg/gFW and 104.48 mg/gFW. The lowest levels of total flavonoids were found in the three ecotypes kernels, where the lowest grade has reached 2.26 mg/gFW (Bechar).

Finally, the results show that the different constituents of the Atlas pistachio seeds are poor in tannins. The condensed tannins are present at a low level, only in the epicarp of Djelfa and Batna ecotypes.

Seed germination rate

Seed germination was tested with or without an epicarp. The results showed that in both situations, seed germination was significantly influenced by ecotype origin, H_2O_2 treatment and their interaction (*Table 4*). No germination was observed, whatever the geographical origin, for whole seeds or for seeds without an epicarp. Pretreatment with H_2O_2 significantly increased the germination rate in all of the ecotypes studied (*Table 4*). However, the interaction between H_2O_2 treatment and seed origin had a significant effect on seed germination rate (*Table 3*). This relationship mirrored distinct reactions based on the seed origin with respect to the H_2O_2 pretreatment. In fact, H_2O_2treatment induced germination of seeds with or without an epicarp. Nevertheless, results of pretreatment with H_2O_2 were different depending on the presence of an epicarp or not (*Table 5*). Indeed germination rate of seeds without an epicarp with H_2O_2 application was 50% was higher than in whole seeds similarly treated with H_2O_2. Moreover, the ecotypes reacted differently to H_2O_2 pretreatment. The Batna ecotype had a 50% germination rate, while the lowest germination rate was observed in the Djelfa ecotype (*Table 5*). This difference in germination rate between Djelfa and Batna ecotype was reported for whole seeds and for seeds without an epicarp.

Table 4. *F-Test values and the significance of ecotype, H_2O_2 treatment and their interaction effects on seed germination on four ecotypes of Pistacia atlantica, with and without epicarp*

	Ecotype	**H_2O_2 Treatment**	**Ecotype*Treatment**
Seeds (with epicarp)	3.58^{ns}	45.74^{***}	3.5^{ns}
Seeds (without epicarp)	22.39^{***}	143.97^{***}	22.3^{***}

***Significant at $P \leq 0.001$; ns: not significant

Ecotype	**Treatment**	**Germination rate (%)**	
		With epicarp	**Without epicarp**
Djelfa	Control	0.00	0.00
Djelfa	H_2O_2	11.11 ± 11	14.7 ± 2.94
Bechar	Control	0.00	0.00
Bechar	H_2O_2	19.44 ± 8.3	25 ± 13.8
Batna	Control	0.00	0.00
Batna	H_2O_2	33.33 ± 0	50 ± 8.3

Discussion

Our results showed that removal of the epicarp did not improve seed germination whatever the ecotype (*Table 4*). This discrepancy may be a result of several environmental and genetic factors. Moreover, our results suggest that seed dormancy is chemical in nature and concerned, not only with the epicarp, but also the kernel (*Tables 4* and *5*). Among the chemical components that are involved in seed dormancy, phenols and their antioxidant activities are often cited (Panngom et al., 2018). Several methods have been used to overcome seed dormancy and to improve the seed

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1355513565

germination rate. Among these methods, the use of chemicals has been reported to be more effective (Wada et al., 2011; Barba-Espin et al., 2012; Panuccio et al., 2014; Panngom et al., 2018). In our study, we demonstrated that pretreatment with H_2O_2 greatly increased seed germination rates (*Table 5*). Similar findings have been reported using chemical components to break seed dormancy and increase seed germination in several species, including pea, coriander, carrot, zinnia and quinoa (Wada et al., 2011; Barba-Espin et al., 2012; Panuccio et al., 2014; Szopińska, 2014; Panngom et al., 2018). Many studies report that the progression of seed germination by hydrogen peroxide treatment may be the result of the oxidation of germination inhibitors present in the epicarp and pericarp (Duval and NeSmith, 2000; Ogawa and Iwabuchi, 2001; Conner, 2008; Klein et al., 2008; Huarte and Garcia, 2009; Panngom et al., 2018). The positive effect of H_2O_2 on seed germination has been explained by production of O_2 resulting by scavenging of H_2O_2 for the mitochondrial respiration and metabolic activities (Katzman et al., 2001). Chen et al. (1993) reported that H_2O_2 is useful in cracking hard seeds, allowing them to interact with water. The results obtained here showed that the origin of seed dormancy is related to both the kernel and the epicarp. Indeed, total phenol content and their antioxidant activities were higher in both compartments of the seed (*Table 2*). However, this result was dependent on the origin of the seeds used. Seeds from Batna locality showed similar inhibitory effects in the epicarp and kernel. Moreover, even though total phenol content was four times higher in the epicarp than in the kernel, antioxidant activity of the epicarp was only 2.5 times higher than the kernel. These results could be explained by the presence of chemical components other than phenols acting as antioxidants.

Total polyphenol compounds are mainly involved in the inhibition of seed germination in this plant species which limits water or oxygen absorption or both. Phenolic compounds and alkaloids that can be found in the epicarp and pericarp may inhibit seed germination (Tao and Buta, 1986; Gross and Parthier, 1994; Bhattacharyya et al., 1999). Isfendiyaroglu and Özeker (2001) reported that flavonoids and phenylpropanes played important roles in seed dormancy. Under natural conditions, the presence of total polyphenol compounds in seeds is effective in plant resistance to environmental conditions (Khoyerdi et al., 2016). The pretreatment with H_2O_2 that induced the germination (*Tables 3* and *4*) demonstrated that dormancy in Atlas pistachio seeds has a chemical basis. Among the functions of H_2O_2 is the oxidation of total phenolic compounds, contributing to the decomposition of the germination inhibitors (Ogawa and Iwabuchi, 2001). Klein et al. (2008) reported that faster germination of eastern gamagrass seeds exposed to H_2O_2 may result from breaking down the inhibitors present in the pericarp, although there may also be a direct physical scarifying effect of this compound. Some studies have reported that H_2O_2 is involved abscisic acid catabolism and gibberellin synthesis that, in turn, activates germination (Barba-Espin et al., 2012 and Panngom et al., 2018). The results also showed that the antioxidant activity increases with the increase of the polyphenol content of seeds. The antioxidant activity of phenolic compounds is mainly due to their redox properties, which allow them to act as reducing agents, hydrogen donors and singlet oxygen quenchers. Therefore reduces the endogenous concentration of ROS would improve seed germination (Sangmin et al., 2010).

The results of the present study showed that Atlas pistachio seeds (*Pistacia atlantica* Desf.) were characterized by a dormancy that inhibits their germination under optimal conditions. Seed scarification (removal of the epicarp) did not modify the germination

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1355513565

rate whatever the ecotype. Biochemical analysis showed seeds were rich in total phenolic compounds that were probably at the origin of their dormancy. This hypothesis was partly confirmed by the increase in germination rate after treatment of seeds with hydrogen peroxide. In fact, the total phenolic compounds were not only present in the epicarp but also the kernel, which may explain the absence of germination after scarification. Moreover, the distribution (content) of phenols between the kernel and the epicarp was different depending on ecotype studied. It seems that for ecotypes from Djelfa and Bechar, inhibition of germination was essentially localized at the level of the kernel, whereas for the ecotype from Batna this inhibition involved both the epicarp and the kernel. Further investigations are needed to confirm these results and to study the effect of different durations of pretreatment with H_2O_2 or other chemicals.

Conclusion

The low germination rates of Atlas pistachio seeds are due to their dormancy. This dormancy is of chemical nature and is localized at the level of the pericarp and kernel. It is explained by their high content of phenolic compounds that limit their metabolic reactivation during the emergence of latent life during their germination. In fact, there had been an absence of germination of whole or scarified seeds. Germination improved significantly after pretreatment with hydrogen peroxide (H_2O_2). The application of H_2O_2, which is one of the ROS, would inhibit the effects of phenolic compounds, accelerate the dormancy emergence and consequently improve the germination rate of *Pistacia atlantica*.

(Received 4th Apr 2019; accepted 31st Oct 2019)

Abstract. Using the felled tree data, subregions-based height-diameter models were developed for Dahurian larch (*Larix gmelinii* Rupr) in Daxing'an Mountains in China. Thirty frequently used nonlinear growth functions were fitted to individual tree height-diameter data. A total of 2411 for Dahurian larch trees were collected and measured. Parameter estimates and evaluation statistics were calculated using SAS PROC NLIN procedure for overall model, three regional models, and ten subregional models. The non-linear extra sum of squares method was used to assimilate the difference of the height-diameter relationships among different subregions. The results indicate that the Chapman-Richards growth function show the best for fitting tree height-diameter relationships at regional and subregional levels with a root mean square error RMSE = 2.193 and coefficient determination $R^2 = 0.8221$. It was revealed that, Dahurian larch height-diameter relationships showed the several differences among these regions and subregions ($P < 0.0001$) when overall, regional and subregional model was applied to predict tree height separately in each region and subregion. Among the 45 pairs of subregions, only four subregion pairs (e.g., XL versus SBZ, XL versus HJY, SBZ versus HJY, and XL versus JGDQ) showed the non-significant difference F-value ($P > 0.05$) and the data from those subregions were combined and applied to others subregions; all comparisons show the difference. The tree height-diameter relationships of Dahurian larch are significantly different among the geographic regions in Daxing'an Mountains, depending on local climatic, soil, and ecological conditions.

Keywords: *Chapman-Richards model, non-linear extra sum of square method, full model, reduced model, forest management*

Introduction

Individual tree diameter at breast height (D) and total height are the most fluently measured variables in study of forest inventory and growth and yield modeling. In practice, tree diameters can be readily measured inexpensively. However, collect tree height data are fairly more difficult and expensively. Often total tree heights are obtained by estimations from observed tree diameter at breast height outside bark. To estimate individual tree volume and site index, and describe stand growth dynamics and succession over time, necessitates accurate height–diameter models (Botkin et al., 1972; Curtis, 1967). Particularly in the northern and northeastern provinces of China, the genus Dahurian larch (*Larix gmelinii* Rupr.) is economically and ecologically important for tree species in China (Leng et al., 2008). Dahurian forests cover an area and volume in the forests of these provinces of 92.9 and 87.6 percent, respectively, of the total Dahurian in the country (Zang et al., 2016). It is a deciduous needle leaf conifer that is adapted to growing in very harsh climates and is widely distributed over a range from 72° 31' N 105° 03' E. In the Daxing'an Mountains forest ecosystem in northern China, it is the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1356713591

dominant tree species (Jiang et al., 2016). Recently, Dai and Jiang (2015) developed and evaluated 12 non-linear height-diameter models for Dahurian larch from three regions in Daxing'an Mountain of northeast China. They found that the Chapman-Richards function was one of the best models for this species across the study region. In this study, we will develop and evaluate 30 nonlinear diameter models for Dahurian larch in three regions subdivided into 10 subregions and we will select the best model according to the goodness-of-fit statistics. With a large number of models, we could expect that the best model for Dahurian larch could be other that of Chapman-Richards as found to the study quoted above. However, if another model is found better than for Chapman Richard; then this will lead us to understand that the Chapman-Richards is not the best suitable model for the Dahurian larch in the Daxing'an mountain, so there is another model better than this one. However, the height-diameter relationship of a given species is highly dependent on climatic patterns (e.g., temperature and precipitation). Application of regional models to local ecological sites may lead to biased predictions for tree heights knowing that these subregions are specified by climatic regimes (e.g. temperature and precipitation), soil moisture and nutrient regimes, and vegetation types. The variations are expected during their comparisons. Examples of models that represent such variation are found (Zhang et al., 2002; Özçelik et al., 2014; Huang, 1999; Huang et al., 1999, 2000; Huang and Titus, 1994; Peng et al., 2001 Pillsbury et al., 1995).

In recent years, the principles of multifunction, multipurpose and ecologically based forest management were approved in China. Therefore, in order to help forest managers and practitioners more realize the differences in these relationships among different subregions, the subregion-based height-diameter models are necessary. to: (1) evaluate tree height-diameter models for Dahurian larch at regional and subregional scales in Daxing'an Mountains at Northeast China; (2) establish the comparison of differences of the height-diameter relationships among the ten subregions; (3) evaluate the consequences and biases of incorrectly applying regional and subregional height-diameters models in different subregions.

Materials and methods

Study area and data

The study area is the cold temperate forest regions in Daxing'an Mountain in Heilongjiang Province and eastern part of Inner Mongolia, from 121° 12′ E to 127° 00′ E and from 50° 10′ N to 53° 33′ N in Northeastern China. The climate is continental monsoon climate. The average annual precipitation ranges from 500 to 750 mm. The mean annual temperature is between -1 and -2.8 °C, and the average January and July air temperatures are about -28 °C and +20 °C, respectively (*Table 1*). The study area was assigned to three distinct regions (Zhang et al., 1992): the eastern slope of Northern part of Daxing'an Mountains (NDXAM), the northwest of the northern slope of Yilehuli Mountains (NWYLHLM), and the southeast of the northern slope of Yilehuli Mountains (SAYLHLM). Sample trees were assigned to ten subregions in NWYLHLM, SAYLHLM, and NDXAM regions (*Fig. 1*). The NWYLHLM region covers four subregions, including Xilinji (XLJ), Tuqiang (TQ), Amuer (AME), Huzhong (HZ); The SAYLHLM region covers four subregions, including Xinlin (XL), Tahe (TH), Shibazhan (SBZ), Hanjiayuan (HJY); the NDXAM region covers two subregions, including Songling (SL), Jiagedaqi (JGDQ). These subregions are specified by climatic schemes (e.g., temperature and precipitation), soil moisture and nutrient regimes, and vegetation types.

A total of 2411 destructively sampled Dahurian larch trees were used in this study. These trees were felled throughout the forest inventory areas of northeast China and all sampled trees were selected to ensure a representative distribution across a range of height and diameter classes within stands varying in density, height, site condition, age and stand structure. The data is from an existing database, and was collected from December 2004 and February 2005. For developing taper and individual tree volume equations the data set was initially used. Diameters at breast height were measured for all sampled trees (D, defined as 1.3 m above the ground) outside bark, and total height (H). Trees possessing broken tops, obvious cankers or crooked boles were excluded from the analysis. Summary statistics for tree diameter and total height are provided for each subregion, the NDXAM, YLHLM-NW and YLHLM-SA regions, and all data combined (Overall) in *Table 2*.

Data analysis

The 30 height–diameter equations listed in Fang and Bailey (1998), Huang et al. (2000, 1992) and Peng et al. (2001) were examined and evaluated to select the best model for further analyses. The equations chosen for the comparison were concentrated on the verification of the height-diameter relationship, as shown by plotting tree height against D on a provincial basis (Huang, 1999). All selected functions are shown in *Table 3*. The validity of a homogeneous variance was investigated. In several studies, we observed the significant evidence of unequal error variances (Huang et al., 1992), while here there were not. Under this circumstance, weighted least-squares may not significantly improve model performance but may increase model fit slightly (Zhang, 1997). Therefore, ordinary nonlinear least-squares were used for parameter estimation instead than weighted least-squares. Every model was assessed using a coefficient of determination (R^2) and root mean square error (RMSE).

H = total height (m); D = diameter at breast height outside bark (cm); a, b, c, d = parameters to be estimated; e = base of the natural logarithm (≈2.71828); 1.3 = a constant commonly used to avoid the prediction of a height less than 1.3 meters when D is small

Through comparisons, the Chapman-Richards function was considered one of the best nonlinear functions for describing the relationship between height and diameter of the Dahurian larch and selected as the base model. The function on Chapman-Richards as represented by the following equation:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1356713591

$$H = 1.3 + a\left[1 - e^{-b.D}\right]^{c} \quad \text{(Eq.1)}$$

where: H: total tree height (m); D: tree diameter at breast height (cm); a: the asymptotic parameter; b: the rate parameter; c: the shape parameter.

The Chapman-Richards function was fit to: (1) the overall data (N = 2411); (2) the NWYLHLM region data (915); (3) the SAYLHLM region data (758); (4) the NDXAM region data (738); (5) each of ten subregions separately. Parameter estimates and evaluation statistics were calculated using SAS PROC NLIN procedure (SAS Institute, Inc., 1999) for overall model, three regional models, and ten subregional models. The non-linear extra sum of squares method was used (Bates and Watts, 1988) to assimilate the difference of the height-diameter relationships among different subregions. The non-linear extra sum of squares method demands the fitting of full and reduced models and has commonly been applied to evaluate if separate models needed for different species or different geographic regions (Huang, 2000; Peng, 2001; Zhang, 2002; Corral-Rivas et al., 2004, 2007; Castedo-Dorado et al., 2005). The full model varieties to different sets of parameters for each subregion and is gotten by enlarging each parameter by including an associated parameter and a dummy variable to distinguish among subregions. The reduced model corresponds to the same set of global parameters for all subregions. Using Indicator (dummy) variable approach, the full model of the Chapman-Richards function can be written as:

$$H = 1.3 + \left(a + \sum_{i=1}^{k} a_i z_i\right)\left[1 - e^{-\left(b + \sum_{i=1}^{k} b_i z_i\right).DBH}\right]^{\left(c + \sum_{i=1}^{k} c_i z_i\right)} \quad \text{(Eq.2)}$$

(1) To evaluate the overall differences among regions. Two indicator variables (k = 2) are needed in *Equation 2* for three regions. They are set as follows:
If region = NWYLHLM, $z_1 = 1$, $z_2 = 0$;
If region = SAYLHLM, $z_1 = 0$, $z_2 = 1$;
If region = NDXAM, $z_1 = 0$, $z_2 = 0$.

(2) To evaluate the differences between the three regions. A total of 3 region pairs can be formulated to test the pairwise differences between the three regions. The 3 testing pairs require 3 full models that take the form of *Equation 2*, and 3 reduced models that take the form of *Equation 1*. For example, to test the difference between region NWYLHLM vs. SAYLHLM, one indicator variable (k = 1) can be defined: if region = NWYLHLM, $Z_1 = 1$; and if region = SAYLHLM $Z_1 = 0$. Similarly, the full model (*Eq. 2*) has 6 estimable parameters.

(3) To evaluate the overall differences among subregions. Nine indicator variables (k = 9) are needed in *Equation 2* for ten subregions. They are defined as follows:
If subregion = SL, $z_1 = 1$, all other $z_i = 0$;
If subregion = JGDQ, $z_2 = 1$, all other $z_i = 0$;
If subregion = XL, $z_3 = 1$, all other $z_i = 0$;
If subregion = TH, $z_4 = 1$, all other $z_i = 0$;
If subregion = HZ, $z_5 = 1$, all other $z_i = 0$;
If subregion = SBZ, $z_6 = 1$, all other $z_i = 0$;
If subregion = HJY, $z_7 = 1$, all other $z_i = 0$;
If subregion = XLJ, $z_8 = 1$, all other $z_i = 0$;
If subregion = TQ, $z_9 = 1$, all other $z_i = 0$;

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1356713591

If subregion = AME, all other $z_i = 0$.

(4) To evaluate the differences between the ten subregions: A total of 45 subregion pairs can be formulated to test the pairwise differences between the ten subregions. The 45 testing pairs require 45 full models that take the form of *Equation 2*, and 45 reduced models that take the form of *Equation 1*. For example, to test the difference between subregion SL vs XL, one indicator variable (k = 1) can be defined: if subregion = SL, $Z_1 = 1$; and if subregion = XL, $Z_1 = 0$. Similarly, the full model (*Eq. 2*) has 6 estimable parameters. All the reduced models for these tests take the form of *Equation 1* with 3 parameters. The nonlinear extra sum of squares for comparing the full and reduced models follows an F-distribution and uses the following expression:

$$F = \frac{(SSE_R - SSE_F)/(df_R - df_F)}{(SSE_F)/(df_F)} \quad \text{(Eq.3)}$$

where SSE_R and df_R are the error sum of squares and degrees of freedom related with the reduced model and SSE_F and df_F are error sum of squares and degrees of freedom related with a full model. Generally, the F-test is meaningful if the p-value for the test is least than 0.05.

To evaluate the performances of applying a height-diameter model to different subregion; each of the fourteen models (overall model, three regional models, and ten subregional models) was used to predict total tree heights for each subregion. Using the observed and predicted total tree heights, the following criteria were used to assess the predictive capability and significant test (Zhang et al., 2002; Cutini et al., 2013; Peng et al., 2004):

$$\bar{e} = \frac{\sum_{i=1}^{m}(H_i - \hat{H}_i)}{m} \quad \text{(Eq.4)}$$

$$S_e = \sqrt{\frac{\sum_{i=1}^{m}\left(e_i - \bar{e}_i\right)^2}{m-1}} \quad \text{(Eq.5)}$$

$$\bar{e}\% = \frac{\bar{e}}{\bar{H}} X\ 100 \quad \text{(Eq.6)}$$

$$t = \frac{\bar{e}}{S_{e/\sqrt{m}}} \quad \text{(Eq.7)}$$

where e_i is the unlike between the observed (Hi) and predicted ($\hat{H}i$) height for the i the observation (i = 1, 2,…, m) with m being the number of observations in the concerned subregion, $\bar{e}$ is mean prediction error; Se is the standard deviation of the prediction error; $\bar{e}\%$ is percent prediction error, $\bar{H}$ is the mean of observed heights; t is a t-test used to test the null hypothesis that the mean prediction error equals zero. Although overall evaluation ($\bar{e}$, $\bar{e}\%$ and t-test) are good indicators of the consequences of inappropriately applying a height-diameter model in different subregions, they may not be indicated the quality of prediction for different diameter classes in each of the ten subregions. Therefore, the height-diameter models (Overall model, three regional models, and ten subregional models) were further assessed by use of plots of prediction errors against diameter classes (5-cm diameter intervals) in each of the ten subregions.

Results and discussion

Selection of the height-diameter model

Parameter estimates and fitting statistics for the candidate models are listed in *Table 4*.

The t-statistics for the parameters of these functions were all significant at the significant level of 0.0001. The coefficient of determination (R^2) of all functions was within the range from 0.7607 to 0.8221, and the RMSE was within the range from 2.193 to 2.5347 m. The Chapman-Richards function (model 5) had the smallest RMSE value and highest R^2 value.

Fitting the Chapman-Richards model to regional and subregional data

Based on the Chapman-Richards function, *Table 5* shows the sample sizes, parameter estimates, and mean square errors (MSE) for all the fourteen fitted models (overall model, three regional models, and ten subregional models). The four regional models (Overall, NWYLHLM, SAYLHLM, and NDXAM) have different model MSEs and parameter estimates. Among the ten subregional models, the lowest MSE value was found in the XLJ subregion (MSE = 2.1909), while the highest MSE value was found in the JGDQ subregion (MSE = 4.5703). The asymptote parameter (a in *Table 5*) ranged from 19.9264 to 32.8497, rate parameter (b in *Table 5*) ranged from 0.0197 to 0.1225, and shape parameter (c in *Table 5*) ranged from 0.6323 to 1.559. The parameter estimates varied among the ten subregions, indicating that each subregion may have a different height-diameter relationship with others.

Table 5. *Parameter estimations and model MSE of Chapman-Richards function for the regional and subregional models*

Comparison of height-diameter models among subregions and between regions

The fitting results of the reduced and full height-diameter models on combination data are provided in *Table 6* (first row). The F-test result reveals that there are overall significant differences ($P < 0.05$) among subregions. Since the divergences may be caused by as few as two or as many as all of the subregions implicated, indicator variable approach was also carried out for every eventual pair of subregions then, the source of the differences could be identified and data from similar subregion can be combined. Same analyses were realized for others subregions pairs and F-values were calculated (*Table 6*).

The F-values were calculated according to *Equation 3*. The number of observations is represented by *n*; *p* is the number of parameters; SSE_F, d*f*F, SSE_R and d*f*R are the sum of squared errors and the degrees of freedom associated with the full and reduced models, respectively

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1356713591

Among the 45 pairs of subregions, only four subregion pairs (e.g., XL versus SBZ, XL versus HJY, SBZ versus HJY, and XL versus JGDQ) showed the non-significant difference F-value ($P > 0.05$). Therefore, the data from these three subregions (XL, SBZ, and HJY) were then combined, and seven new subregion pairs were formed as follows:
Subregion (XL + SBZ + HJY) and SL;
Subregion (XL + SBZ + HJY) and JGDQ;
Subregion (XL + SBZ + HJY) and TH;
Subregion (XL + SBZ + HJY) and HZ;
Subregion (XL + SBZ + HJY) and XLJ;
Subregion (XL + SBZ + HJY) and TQ;
Subregion (XL + SBZ + HJY) and AME

Subsequent F-tests show that the height-diameter relationship for the combined subregions (XL + SBZ + HJY) is different from those for SL, JGDQ, TH, HZ, XLJ, TQ and AME ($P < 0.05$, *Table 7*).

Table 7. *F-test for testing the differences between combined subregions (XL + SBZ + HJY) with each subregion*

Subregion pairs	n	Full model			Reduced model			Extra sum of squares		
		SSE_F	*P*F	d*f*F	SSE_R	*P*R	d*f*R	d*f*R-d*f*F	F-value	Prob > *F*
(XL + SBZ + HJY) - SL	766	2467.85	6	763	2870.74	3	766	3	41.5217	< 0.0001

(XL + SBZ + HJY) - AME	837	2869.69	6	834	4205.94	3	837	3	129.4491	< 0.0001

The F-values were calculated according to *Equation 3*. The number of observations is represented by *n*; *p* is the number of parameters; SSE_F, d*f*F, SSE_R and d*f*R are the sum of squared errors and the degrees of freedom associated with the full and reduced models, respectively

Based on regional classification in *Table 2*, Dahurian larch has three regions with three pairs (NWYLHLM, SAYLHLM, and NDXAM), the three pairs require the fittings of the 6 nonlinear regression models to give error sums of squares, so that the F-test can be carried out for each pair. The F-test also indicates that there are over significant differences ($P < 0.05$) among regions (*Table 8*, first row). All of the three regional paired comparisons produced significant F values, suggesting that significant different height-diameter equations are required.

Table 8. *F-test for testing the differences between regions*

Region pairs	n	Full model			Reduced model			Extra sum of squares

Prediction errors of applying regional and overall models to each subregion

According to the above F-tests, there were significant differences for most subregion pairs in the height-diameter relationships. It has been shown that there are statistically significant differences between the tested subregions, but that does not imply that these differences have practical importance. In practice, incorrectly applying a height-diameter model in these subregions may result in prediction biases. To understand the consequences, all 14 models (overall model, NWYLHLM model, SAYLHLM model, NDXAM model, and ten subregional models) were used to predict total tree heights for a given subregion individually. The mean prediction error ($\bar{e}$), the percent prediction error ($\bar{e}$%), and the t-test for testing the null hypothesis that means prediction error equals zero were shown in *Tables 9* and *10.*

Table 9. *Prediction error of applying the overall model to each subregion*

Subregion	N	$\bar{H}$ (m)	$\hat{H}$ (m)	$\bar{e}$	$\bar{e}$%	Se	t	p-value
SL	214	19.58	18.99	0.58	2.99	1.79	4.79	< 0.0001

XL	240	18.7	19.54	-0.83	-4.48	2.08	-6.24	< 0.0001
TH	203	15.34	16.69	-1.35	-8.83	1.92	-10.01	< 0.0001
HZ	215	16.12	17.44	-1.31	-8.18	2.02	-9.56	< 0.0001
SBZ	237	17.93	18.56	-0.63	-3.51	1.88	-5.13	< 0.0001
HJY	128	17.7	18.55	-0.83	-4.69	1.93	-4.87	< 0.0001
XLJ	224	15.75	14.42	1.33	8.45	1.66	11.98	< 0.0001
TQ	191	17.44	17.02	0.41	2.41	1.75	3.29	0.001
AME	285	22.36	20.52	1.84	8.24	1.99	15.64	< 0.0001

N – sample size, $\bar{H}$ – average of observed tree height, $\hat{H}$ – average of predicted tree height from the overall model, $\bar{e}$ – average of prediction error, $\bar{e}$ % – percent prediction error, Se – standard deviation of prediction error

The overall model was used to predict trees heights in each subregion, over or under predictions occurred for different subregions. The p-value of the t-test was less than 0.05 for each of the ten subregions. On average, the overall model under-estimate (i.e., positive prediction error %) trees heights from 2.4% to 8.45% for subregions SL, XLJ, TQ and AME, and over-estimate (i.e., negative prediction error %) tree heights from -1.42% to -8.83% for subregions JGDQ, XL, TH, HZ, SBZ and HJY (*Table 9*). *Table 10* shows that when applying NWYLHLM model in each subregion, there is no difference between NWYLHLM–SL; NWYLHLM–TQ, while there is a difference in the others regions and subregions.

The same applies to SAYLHLM model, when the model is applied in each subregion, there is no difference between SAYLHLM–(subregions SBZ and HJY); there is a difference between others regions and subregions. When NDXAM model is applied in each subregion, there is no difference between NDXAM–(subregions JGDQ, XL, and TQ), although there is a difference between others regions and subregion. The prediction biases ranged from -11.97 to 8.46% in NWYLHLM model; from -3.52 to 13.82% in SAYLHLM model; from -8.69 to 8.58% in NDXAM model. Then, applying

regional height-diameters models in different subregions displays the variations bias in the predictions of heights that cannot help forest managers to predict the height of the model from other regions and make good decisions.

N – sample size, $\bar{H}$ – average of observed tree height, $\hat{H}$ – average of predicted tree height from the model, **ē** – average of prediction error, ē % – percent prediction error, S_e – standard deviation of prediction error

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1356713591

Figure 2 illustrates the average prediction errors across 5-cm D classes when NDXAM, NWYLHLM, SAYLHLM, Overall, and subregion models are applied to predict tree height in each of the ten subregions separately. Clearly, large negative values of the Overall model are observed in the TH and HZ subregions due an overestimation of large-sized trees. We also noticed negative values in the subregions JGDQ, XL, SBZ, and HJY. Large positive values of the Overall model are observed in the AME and XLJ subregions; it was also revealed that underestimations with positive values are observed in the SL and TQ subregions.

Prediction errors of applying subregional model to each subregion

Table A1 (*Appendix*) shows that when the ten subregional models were applied to each subregion, they generally performed well only in the subregions in which the models were developed (p-value for t-test > 0.05 for testing that the mean prediction error equals zero). Otherwise, the models produced significant prediction errors. The prediction biases ranged from -10.84% to 7.32% in SL; from -7.64% to 9.87% in JGDQ; from -5.89% to 11% in XL; from -0.17% to 18.3% TH; from -0.18% to 16.69% HZ; from -5.97% to 12.09% in SBZ; from -3.32% to 12.85% HJY; from -14.2% to 10.28% in XLJ; from -12.22% to 7.35% in TQ; from -17.02% to 2.44% in AME. The p-values of the mean prediction biases were calculated using the paired t-test procedure explained. When a model developed from one subregion was applied to other subregions, we found over- or underestimations significant. Sometimes, in order to know how well a model from one subregion will perform when it is used in a different subregion, the calculated percent prediction error can be used as a criterion for estimating as an approximation. The percent prediction error can serve as an accurate indicator to determine the applicability of a fitted model. It is possible to create an acceptable ē% according to the prediction intervals or select voluntarily without taking into account any statistical test, but it will have to depend on the required accuracy and available resources. The height-diameter models from several subregions may be used interchangeably for the height-diameter models, if a ± 5% average bias for height predictions is enabling.

Figure 3 shows the height-diameter performance when each subregional model is applied to predict tree height separately in each of the ten subregions. Compared to the overall and region models, the subregional model more closely followed the actual values for all subregions and indicated that subregional height-diameter model should be needed.

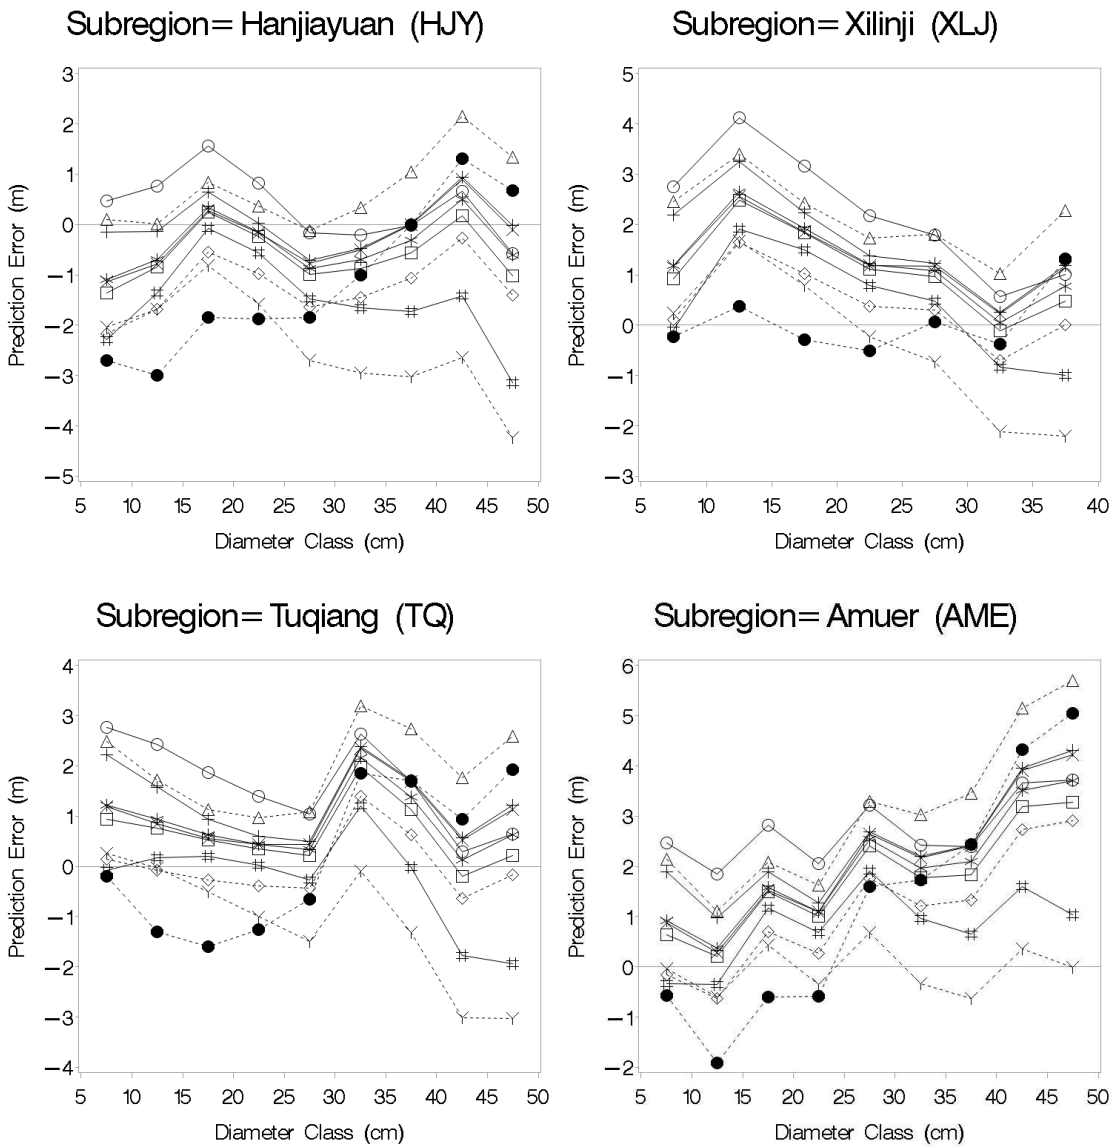

Figure 3. *Average prediction errors (m) across 5-cm diameter classes when each subregional model is applied to predict tree heights in each of the ten subregions with symbols: SL (hash), JGDQ (square), XL (star), TH (circle), SBZ (X), HJY (plus), HZ (triangle), XLJ (dot), TQ (diamond) and AME (Y)*

In the forest literature, there is a high number of local and generalized height-diameter equations available (Gadow et al., 2001; Soares and Tomé, 2002; Lopéz et al., 2003; Temesgen and Gadow, 2004; Brooks and Wiant, 2007; Stankova et al., 2013; Xu et al., 2014; Zhao et al., 2013; Adamec et al., 2015; Hassanzad et al., 2016; Yan-qiong et al., 2015). 30 nonlinear growth functions were fitted to a species of trees and 10 subregions in the Daxing'an Mountain at northeast China, based on their appropriate mathematical features and possible biological interpretation of parameters. The results from model statistics suggested that all thirty models fitted equally well to the tree height-diameter data of the species and the best is Chapman-Richards model. The analysis reveals that the height-diameter relationship is statistically different between the subregions identified in the current study. This was waited because biogeoclimatic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1356713591

conditions are not identical among different subregions. A climatic division is formed between the mountains, they differ from the arid region to the west as a result of the precipitation they take from the southeast winds and create a relatively humid climate (precipitation is more than 20 inches [500 mm] annually). The coldest part of eastern China is the northern mountain region with very rigorous winters (mean temperature -18 °F [-28 °C]) and large areas under permafrost. With January temperatures approximately -21 °C, annual rainfall of 10-12 inches (250-300 mm) and light relative snowfall, the southern region of the range is much warmer and drier than in the north. To the south, forests cover the higher ground above 5,000 feet (1500 m), while the highest meadows cover most of the area (https://www.britannica.com/editor/the-editors-of encyclopedia-Britannica/4419: Mountains China). But the rapidity and the characteristics of its growth are affected by the unique features of the subregions. It was revealed that, Dahurian larch height-diameter relationships showed the differences among these subregions. The using of separate height-diameter models for NWYLHLM, SAYLHLM and NDXAM regions; likewise, because of the singular characteristics of the subregions in landforms, geology, vegetation, and climate separate height-diameter relationships for the Xilinji (XLJ), Tuqiang (TQ), Amuer (AME), Huzhong (HZ), Xinlin (XL), Tahe (TH), Shibazhan (SBZ), Hanjiayuan (HJY), Songling (SL), Jiagedaqi (JGDQ), all are provable, as this is shown from the F-test results in *Tables 6, 7* and *8*. Therefore, the combination of all climatic, environmental and vegetation factors plays an important role in determining the different height-diameter relationships among ten subregions. Subsequent F- tests suggest that the height-diameter equation for the combined subregions (XL + SBZ + HJY) is different from those for SL, JGDQ, TH, HZ, XLJ, TQ and AME subregions (*Table 7*). Therefore, according to the F-tests, eight height-diameter equations relating to eight distinctly different subregion groups were separated. Analyzing of the subregion-based height-diameter models for Dahurian larch in Daxing'an Mountain suggested that the height-diameter relationships for XL, SBZ, and HJY subregions are statistically the same. The sameness of height-diameter patterns between XL, SBZ and HJY subregions is probably due to the similarity in habitats that stands of Dahurian larch.

It is apparent from *Table A1* (*Appendix*) outcome of the calculated $\bar{e}$, Se, and $\bar{e}$%. It is demonstrated by examples values over and underestimated when the height-diameter equation from XLJ was served to predict the tree height in subregion AME 10.28% underestimate appeared. Relatively, the value of $\bar{e}$ was 2.29 and for Se was equal to 2.95. When the height-diameter equation from subregion XLJ was served to predict the tree height in subregion TH, -14.2% an overestimate was observed. Carefully, the prediction errors values of $\bar{e}$ and Se were -2.17% and 2.48%. Globally, the percent prediction error varies from 16.69% an underestimate to -16.5% overestimate. The mean prediction errors vary from an underestimate of 3.73 (HZ applied to AME) to overestimate of 2.66 (AME applied to HZ). The paired t-test procedure outlined in Snedecor and Cochran (1989) was used to calculate the t-values of the mean prediction biases. It was revealed that significant over- or underestimations appeared when a model developed from one subregion was used to other subregions.

Founded on development data, we observed that the best-fitting model was the Chapman Richards model, which gives the most precise estimates with MSE values from 2.1909 to 4.5703 for all subregions (*Table 5*). When we fitted the Korf equation in each subregion, we found that this equation produced a largest parameter asymptotic, which is means the Korf equation doesn't have stability. This characteristic of the Korf

DOI: http://dx.doi.org/10.15666/aeer/1706_1356713591

function was also observed in Cross-validation of Non-linear Growth Functions (Zhang, 1997). The Chapman-Richards function was used to describe the height-diameter in several previous studies. Huang et al. (1992) declared that, when there is a weak relationship between the dependent and independent variables, this function approaches the asymptote too quickly. In this study, we found that the Chapman Richards model as the best for Dahurian larch produced some of the most satisfactory fits among many alternative model forms, considering the model mathematical features, biological interpretation of parameters, and accurate prediction. However, the performance of models, such as the Weibull, Schnute, Exponential and others was also very good. Comparing the model root mean squared errors (RMSE), the Richards, Korf and Weibull functions had relatively smaller RMSEs than the other twenty seven equations (*Table 4*).

Conclusion

Our study results suggest that there are distinct variations in height-diameter relationships for Dahurian larch among different subregions in the three forest regions (NDXAM, YLHLM-NW, and YLHLM-SA) in Daxing'an Mountain at northeast China. Usually, ecoregion-based height-diameter models report predictions with more reliability on a regional basis and avoid the likely expected errors that may arise while models are enforced in others areas. However, at any location where the data is favorable, it is advisable to develop different models by different ecoregions.

Abstract. This study examined the modification of foliar characters in the leaf of *Amaranthus caudatus* cultivated on formulated soils. The soil types namely; sandy clay loam, silty clay loam, clayey loam and loam were experimentally derived from sieved soil particles of sand, silt and clay that were re-mixed in relative proportions proposed by the United States Department of Agriculture (USDA, 1951) while unfractionated soil served as the control. The Energy Dispersive X-Ray Spectroscopy (SEM-EDX) showed variation in percentage elemental composition of the epidermal layers. Harvests from clayey loam soil (with relative equal compositions of sand, silt and clay) had the highest composition of the following elements; nitrogen, oxygen, sodium, phosphorus, calcium and zinc whereas other elements were present in various proportions on epidermal surfaces of harvests from other soils. The Scanning Electron Microscope revealed non-glandular dish-like peltate trichomes with membranous lids attached in some cases. On the abaxial layer, stomata densities of the harvests from various soils were in this order: clayey loam > loam > sandy clay loam > control soil > silty clay loam. This research, therefore, provided supportive data on the effect of formulated soil on stomatal development and distribution in *Amaranthus caudatus.*
Keywords: *Amaranthus caudatus, foliar characters, spectroscopy, stomata, dish-like peltate trichomes*

Introduction

Grain amaranths were important crops to the people of Mayan, Aztec and Incas of the pre-Columbian era. They belong to the family Amaranthaceae (now including former family Chenopodiaceae), comprising of grain crops, vegetables, ornamental herbs, shrubs and dye plants numbering about 2500 species globally (The Angiosperm Phylogeny Group, 2009; Christenhusz and Byng, 2016; Kadereit et al., 2003). The existence of wide taxonomic and morphology characters between and within *Amaranthus* species (Juan et al., 2007) makes it important to study possible cause due to environmental factors. *Amaranthus caudatus* is one of the few ancient dicotyledonous pseudo cereals of Amaranthaceae. Its origin has been traced to the Andean countries and it is well known to survive in marginal climates where other crops cannot be easily cultivated (Jimoh et al., 2018).

The technique of micromorphology has proven to be more reliable in provision of data for germplasm identification and in unravelling structures of taxonomic importance that are embedded in plant cell or tissue for adequate knowledge of genetic diversity

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1359313605

(Costea et al., 2006; Shah et al., 2018). Also, for the enhancement of cultivars for better yield, it is important to understand the magnitude of environmental influence on these factors (Rastogi and Shukla, 2013).

Many environmental conditions such as moisture, light, temperature and a host of other geographic factors have been reported to affect genetic make-up of species naturally or artificially. The soil environment plays a key role in plant gene expression (Viger et al., 2015). Also, it has been well established that soil texture determines the moisture retention capacity and water infiltration rate which in turn influences the amount of nutrients available to plant although for different soil structures, the two factors are inversely related (Olesen et al., 1999; Rabot et al., 2018). The photosynthetic biochemistry of plant coupled with soil factor and other environmental conditions drive the mechanism for stomatal acclimation to atmospheric carbon IV oxide (Maherali et al., 2002; Pillitteri and Torii, 2012). Since environmental condition is capable of altering the entire plant structures such as leaf size, stem girth and root length; its overall effect on stomatal size, density, distribution and conductivity cannot be underestimated (Casson and Gray, 2008; Maherali et al., 2002; Jimoh et al., 2019a).

Apart from being a depot for bioactive compounds, plant leaf houses important organs responsible for physiological functions and stomata, useful in taxonomic characterization. For example, epidermal features have been recently recognized as supportive tool for systematic delimitation within and between species implying that foliar micromorphology is a true reflection of interaction between plant and its environment (Fank-De-Carvalho et al., 2010; Sharaibi and Afolayan, 2017; Stuessy, 2009). The core objective of this research therefore, was to investigate induced morphological adjustments to foliar characteristics of *Amaranthus caudatus* cultivated plants on different soil types and incorporate newly acquired information into existing taxonomic database for the species.

Materials and methods

Experimental soil formulation

Top soil collected from the University of Fort Hare's Research Farm in May 2017 was air dried under shade for 4 weeks. The dried soil was later filtered with iron sieves of the designated mesh into parent particle sizes of clay (<2 μm), silt (<50–2 μm) and sand (<2000–50 μm). Experimental soil was then formulated by mixing sieved soil particles in relative proportions proposed by the United States Department of Agriculture (United States Department of Agriculture & Natural Resources Conservation Service, 1983) soil texture triangle as shown in *Table 1*.

Table 1. *Experimental soil formulation in proportions recommended by soil texture triangle technique (USDA, 1951)*

S/N	Soil types	% Sand	% Silt	% Clay
1	Control soil (SF_1)	Unfractionated	Unfractionated	Unfractionated
2	Sandy clay loam (SF_2)	66	13	21
3	Silty clay loam (SF_3)	10	60	30
4	Clayey loam (SF_4)	36	30	34
5	Loam (SF_5)	40	40	20

Plant material and experimental design

Seeds of *A. caudatus* collected from seedbank of the Medicinal Plants and Economic Development (MPED) Research Centre, Department of Botany, University of Fort Hare were broadcast in seedling trays and transplanted after three weeks into pots filled with the control and formulated soils types (*Table 1*) arranged in the green house in a Completely Randomised Design (CRD) in three replicates (*Fig. 1*). The experiment was conducted in the greenhouse (set at an average temperature of 25 °C; 64% relative humidity), sited on the roof of the Department of Botany building. At flowering stage, fresh and mature leaves were collected at five nodes to the shoot apices, from three different pots representing each of the soil types. Portions of 2-3 cm^2 were cut off from the standard median part of the leaf blade close to the mid-rib in preparation for micromorphological examination.

Figure 1. *Potted experiment of Amaranthus caudatus in a green house*

Scanning electron microscopy and energy dispersive X-ray spectroscopy (SEM-EDX)

Cut sections of the leaf were fixed in 6% glutaraldehyde solution buffered with 0.05 M sodium cacodylate (pH 7.5) for 24 h. The samples were soaked in distilled water and dehydrated in graded ethanol (10-100% concentration series) for 20 min per rinse (Munien et al., 2015). Samples were then soaked in 100% ethanol and dried in a Hitachi HCP-2 critical point drier. Dried specimens were fixed with two sided adhesive carbon tape on aluminium stubs and coated with a thin layer of gold using an Elko IB-3 Ion Coater. The abaxial and adaxial surfaces were examined in a JEOL (JSM-6390LV) Scanning Electron Microscope (SEM) operating at an accelerated voltage of 10-15 kV at different magnifications. The Energy Dispersive X-Ray Spectroscopy (produced by Thermo Electron Corporation, 6733B-IUUSN, USA) and the Noran System Six Imaging Software both connected to SEM were respectively used to analyse the elemental composition of the treated samples and capture electron images (Sharaibi and Afolayan, 2017). Both qualitative and quantitative features on the abaxial and adaxial layers of the leaf epidermis were assessed. Quantitative features examined were number

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1359313605

of trichomes; stomata density and distance between two stomata. The qualitative characters considered were stomata distribution; trichome types, size, shape and distribution; presence or absence of peltate scale; and oil sac frequency on both layers.

Statistical analysis

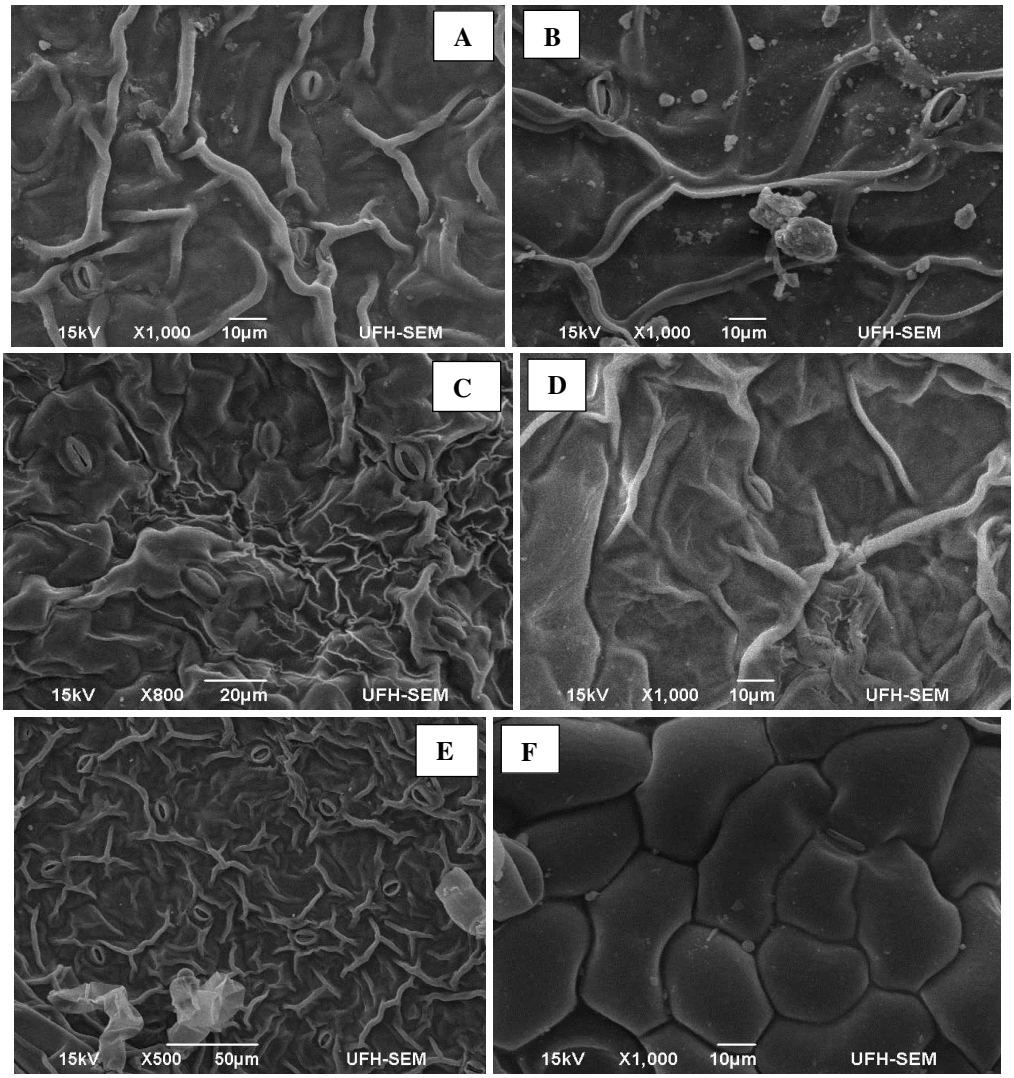
Data obtained from all treatments were analysed and expressed as mean ± standard deviation (SD) of 3 replicates. A MINITAB 17 statistical package was used to separate means of various replicate data for EDX percentage elemental compositions, stomata densities and distances between stomata.

Results

Foliar micromorphological characters

Stomata

Stomata types and distribution: Leaves are amphistomatic with both layers characterized by sunken, anomocytic stomata lacking subsidiary cells. Stomata were found to be prevalent on the abaxial surface than the adaxial in all soil types (*Fig. 2*).



http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1359313605

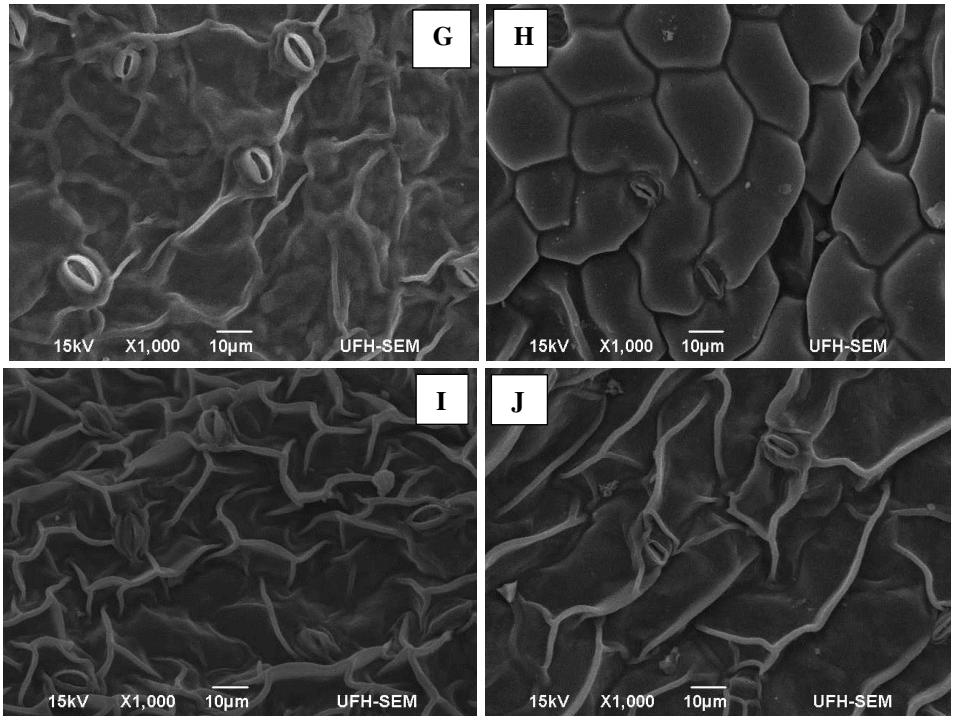


Figure 2. *Plates A, C, E, G & I showing stomata number and distributions on abaxial layers; Plates B, D, F, H & J indicating stomata number and distributions on adaxial layers of A. caudatus cultivated on control soil, sandy clay loam, silty clay loam, clayey loam and loam respectively*

Stomata density: This is defined as number of stomata per unit area. From SEM micrographs, stomata densities were higher on abaxial layers. In all soil types, the highest density (abaxial: 521.7 ± 0.5 stomata/mm^2; adaxial: 248.4 ± 0.3 stomata/mm^2) was observed in the clayey loam, followed by loam (abaxial: 397.5 ± 0.7 stomata/mm^2; adaxial: 198.8 ± 0.5 stomata/mm^2), sandy clay loam (abaxial: 372.7 ± 0.5 stomata/mm^2; adaxial: 99.4.4 ± 0.3 stomata/mm^2), control soil (abaxial: 223.6 ± 0.5 stomata/mm^2; adaxial: 99.4 ± 0.3 stomata/mm^2) and silty clay loam (abaxial: 198.8 ± 0.5 stomata/mm^2; adaxial: 99.4.4 ± 0.3 stomata/mm^2) with the least stomatal density (*Table 2*). The same stomata densities were evaluated for the adaxial layers of control (SF_1), sandy clay loam (SF_2) and silty clay loam (SF_3) soils. This was due to the fact that the same numbers of stomata were observed in their respective SEM micrographs.

Table 2. *Effect of soil types on stomata characteristics*

Leaf indices	**Adaxial surface**

*Letters a, ab, b and c are different values of mean separations obtained from MINITAB 17

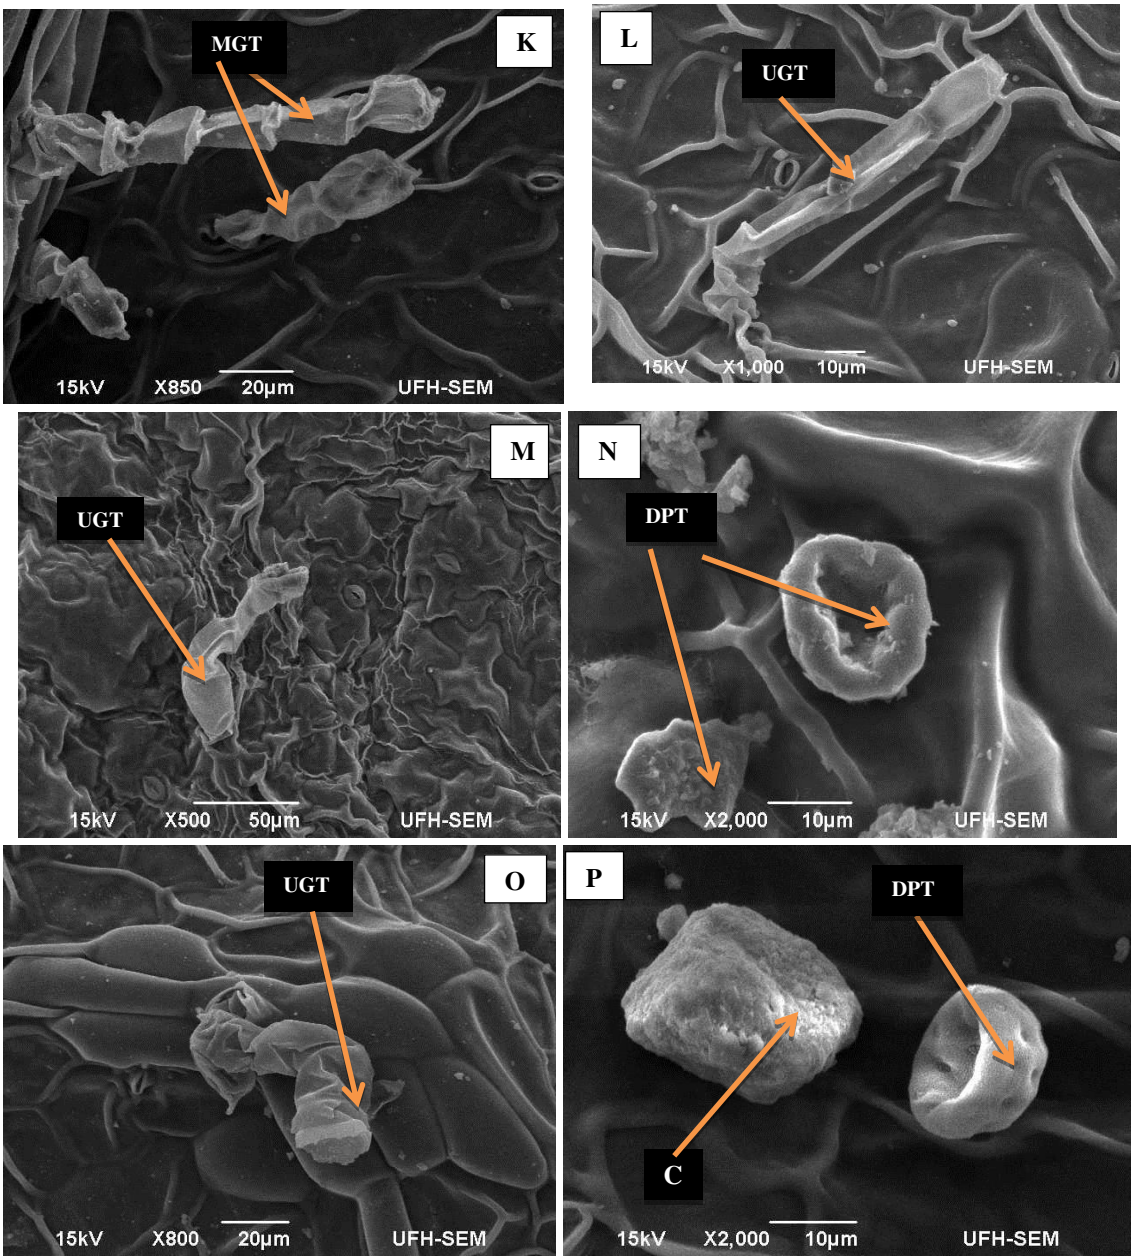
http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1359313605

Trichomes

Different kinds of trichomes namely; capitate, multicellular glandular, acicular and non-glandular dish-shaped peltate trichomes were seen on both layers of the epidermis of the plant samples examined. In some soils, the dish-shaped peltate trichomes had attached lids while in other cases, lids were absent. Both acicular and capitate trichomes were abundant on the upper surface than the lower surface (*Fig. 3*).

Distance between stomata

The distance between stomata and stomata density followed a characteristic trend. As stomata density increases, the distance decreases. Stomata were farthest away from one another on sandy clay loam (adaxial: 153.5 ± 14.3μm) and closest on clayey loam (abaxial: 34.4 ± 1.6μm) with each soil type following the trend earlier mentioned (*Table 2*).



http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1359313605

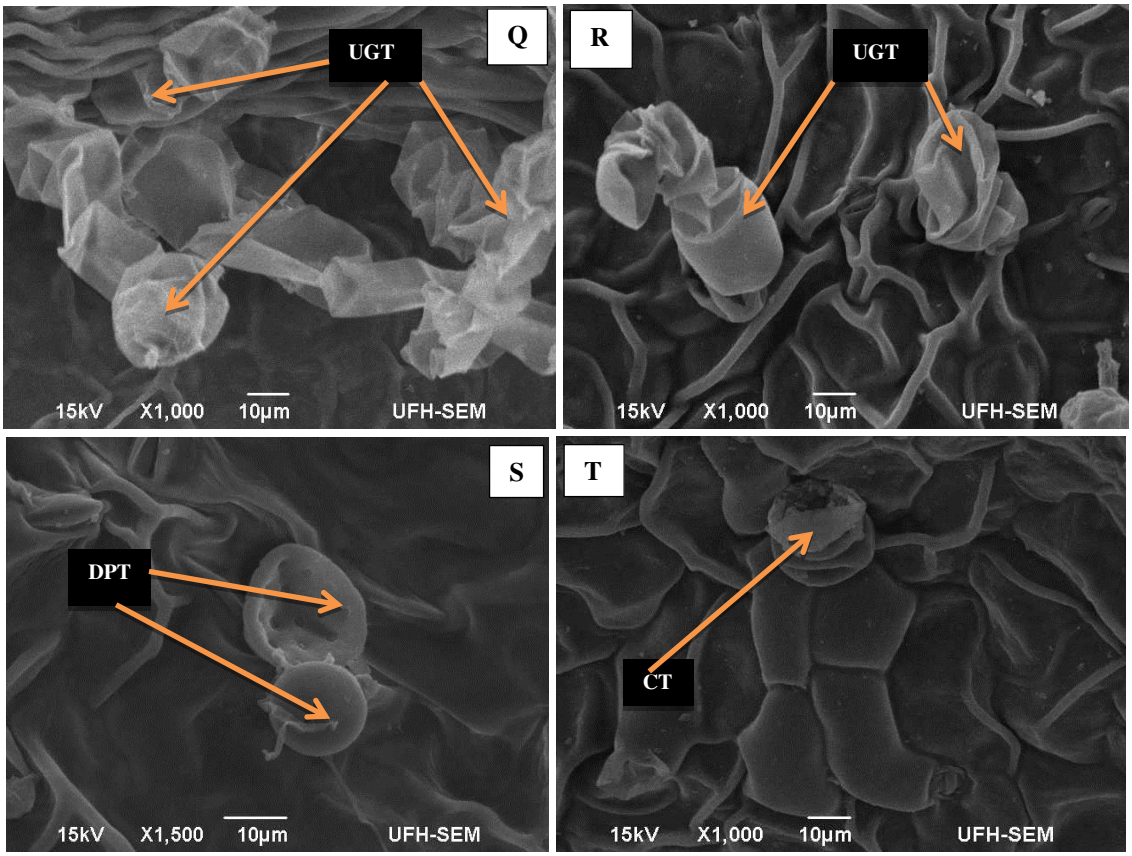


Figure 3. *Plates K, L, M, N & O showing different trichomes on abaxial layers; Plates P, Q, R, S & T indicating trichomes on adaxial layers of A. caudatus cultivated on control soil, sandy clay loam, silty clay loam, clayey loam and loam respectively. MGT = multicellular glandular trichome; UGT = unicellular glandular trichome; DPT = dish-like peltate trichome; CT = capitate trichome; C = crystal*

Epidermal cells

The epidermal cell walls in all soil types were irregular in shape, with curved anticlinal walls but later assumed polygonal shape when swollen. The anticlinal walls became straight when turgid, conferring the polygonal shape on the epidermal cell (*Fig. 4W & X*). The epidermal cells on the adaxial layer developed into distinct polygonal sacs that may serve as storage facilities for essential oil, water or phytochemicals. Also, crystal deposits were found on the epidermal layers which may indicate the presence of chemicals that offer mechanical support to the leaf (*Fig. 4*).

Energy dispersive X-ray (EDX) spectroscopy

The EDX analysis of the epidermal layers revealed percentage atomic composition of various elements as presented in *Table 3*. Presumably, high presence of gold was due to the gold coating. Beryllium was found in high quantity only in the control soil whereas it is absent in the plant grown on formulated soils. Elements such as carbon, nitrogen, oxygen, sodium, magnesium, silicon, phosphorus, sulphur, potassium and calcium were found in quantifiable amount from all harvested plants. Plants harvested from the control soil (SF_1) and sandy clay loam (SF_2) lack aluminium which is present in low

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1359313605

quantity in the harvest from other soil types. Chlorine, iron, manganese and zinc were found in extremely low amount although still lacking in some harvested samples of *A. caudatus* (*Table 3*; *Fig. 5*).

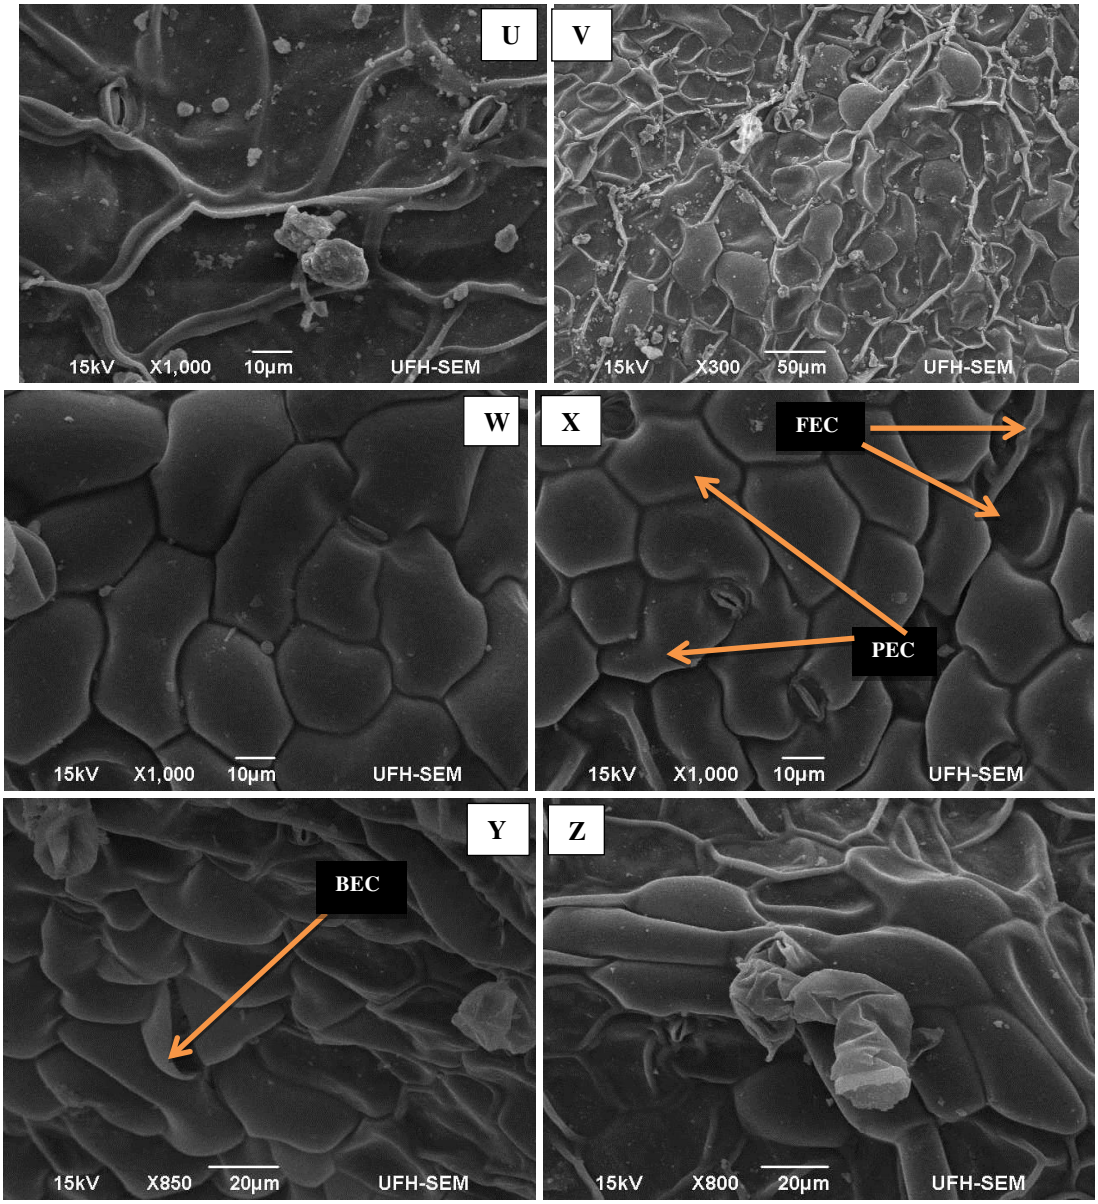

Figure 4. *Plates U & V showing flaccid epidermal cells on abaxial and adaxial layers of harvest from the control soil respectively; Plate W & X indicating turgid epidermal cells on adaxial layers of A. caudatus cultivated on sandy clay loam and clayey loam respectively.; Plate Y showing burst epidermal sac on adaxial layer of harvest from loam soil; Plate Z indicating swollen epidermal cell on adaxial layer of harvest from silty clayey loam*

Discussion

The taxonomic significance of micro-characters in delimiting *Amaranthus* species has been explored deeply; however, there is dearth of information on modifications induced by soil types to distribution, types and frequency of these characters. Recent investigations by Costea et al. (2006) and Ogundipe and Kadiri (2012) revealed some

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1359313605

diagnostic micro-molecular characters in Amaranthaceae. Among these ultra-structures of interest are stomata and trichomes. This study established how soil type modulates stomata densities, trichome types, sizes, frequency and protrusion of epidermal cells due to storage of water, accumulation of essential oils and phytochemicals.

The amphistomatic nature of the epidermal layers of *A. caudatus* remained intact in all soil types although with varying stomatal densities, distribution and, development of solitary, dish-like stellate trichomes that play major roles in secretion and storage of bioactive compounds (Ogundipe and Kadiri, 2012; Wagner et al., 2004). From the figures presented in this study, stomata densities increased in the order $SF_3 < SF_1 < SF_2 < SF_5 < SF_4$ (abaxial) and $SF_1 = SF_2 = SF_3 < SF_5 < SF_4$ (adaxial). This implies that SF_4 (clayey loam) with the highest clay content provided the most suitable environment for stomata development and proliferation than other soil types. This may not be unconnected with increased clay content (compared to other soil formulations) that must have conferred high water retention capacity on the soil since water retention capacity depends on soil physical characteristics (Rawls et al., 1991; Rabot et al., 2018). Thus, the plant may have been compelled to evolve an adaptive mechanism for a more efficient evapotranspiration, leading to increased number of stomata on both epidermal layers. Also, all harvested samples from different soils followed the common trend of higher stomata index on the abaxial layers compared to the adaxial (Babber and Dhingra, 1985; De Micco et al., 2011; Jimoh and Olowokudejo, 2017).

The non-glandular dish-shaped peltate trichomes are being reported for *Amaranthus caudatus* for the first time. This kind of trichome was not observed in the plant harvested from the control and clayey loam. In addition, no lid was found in the abaxial layer of plant harvested from silty clay loam. Also, membranous lid was seen attached to the trichomes on the adaxial surfaces of harvest from loam and sandy clay loam. This observation is a key contribution to the taxonomy of *Amaranthus caudatus* in particular, and Amaranthaceae at large.

Table 3. *Percentage compositions of the elements in A. caudatus leaf epidermis by EDX spectroscopy*

Elements	SF_1	SF_2	SF_3	SF_4	SF_5
Beryllium	8.83 ± 0.33	0	0	0	0

The analysis of percentage compositions of the elements in *A. caudatus* by EDX spectroscopy of the leaf epidermis revealed variations in elemental composition of the plant with regard to nutrient derived from the respective soil types used for cultivation. For example, harvests from clayey loam soil (with relative equal compositions of sand, silt and clay) had the highest composition of the following elements; nitrogen, oxygen, sodium, phosphorus, calcium and zinc whereas other elements were present in different proportions on epidermal surfaces of harvests from other soils. This finding might be a precursor to the highest biological activities recorded in harvests from clayey loam as reported in Jimoh et al., (2019b). This further corroborates earlier reports that nutrient uptake from the soil affects percentage composition of elements in plants (Ogundola et al., 2017; Ahmed et al., 2013).

Conclusion

Findings from this research revealed that formulated soil types modified the foliar epidermal characteristics in *Amaranthus caudatus*. Also, variabilities in stomatal densities and percentage elemental composition of the harvests further indicated that the relative proportion of primary soil particles (sand, silt and clay) in the formulated soils affects both nutrient uptake and the capacity for evapotranspiration via the stomata. The presence of special trichome; the dish-like non-glandular peltate trichome and other types may not be unconnected with secretion of essential phytochemicals responsible for high therapeutic effect of the plant. Undoubtedly, these soil types-induced modifications could be useful in achieving a robust taxonomic delimitation in *Amaranthus caudatus* as results obtained explained further, the impact of environment on foliar development.

(Received 10th Apr 2019; accepted 4th Jul 2019)

Abstract. The paper illustrates the application of at-site frequency analysis using relatively non-traditional probability distributions adopting four methods of parameter estimation using annual maximum rainfall series (AMRS) (from 1980 to 2015) of three sites; Muzaffarabad, Garhi Dupatta and Kotli of Azad Jammu and Kashmir, Pakistan. Critical assumptions related to AMRS for frequency analysis have been validated through run test (to check the randomness of AMRS at each site) and Mann Whitney test (to check the distribution of AMRS at given sites as identical or not). Two probability distributions; Frechet and Log-logistic have been used as candidate distributions to model AMRS at given sites. The parameters of these distributions have been estimated using four methods; Probability Weighted Moments Estimation (PWME), Maximum Likelihood Estimation (MLE), Bayesian Estimation (BE) and Moments Estimation (ME) methods. The Kolmogorov Smirnov test has been used as goodness-of-fit criteria. The results show suitability of the selected probability distributions for the observed AMRS series at given sites with BE and MLE methods as adequate for estimation. Moreover, the results indicate that ME method is not a preferred choice for the estimation of parameters and quantiles for various return periods.
Keywords: *at-site frequency analysis, Bayesian estimation, maximum likelihood estimation, method of moments, probability weighted moments*

Introduction

Frequency analysis is a technique for estimation of a specific event that occurs frequently. Estimation of a return period of geophysical events, for instance, extreme rainfall or floods of a site or many sites (together, assuming a homogeneous region) which occurs rarely is a familiar problem in environmental engineering. For rainfall frequency analysis (RFA), usually, at site and regional approaches with various typical probability distributions are in practice for the estimation of quantiles. Success depends on the availability and span of the observed data along with nature of the associated variables (site characteristics) having strong correlations with the observed data series at given sites. With the introduction of several new class of probability distributions in the literature, it is very important to examine the suitability of these distributions with optimum method of estimation for analysing the extremes of geophysical, hydrological and meteorological events like earthquakes, floods, rainfall, etc. It will bring variability in the choice of selecting best-fit distribution for the estimation of extreme events. The current study has used two atypical probability distributions in the family of extreme value distributions namely Frechet distribution (FD) and Log-logistic distribution

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1360713623

(LLD), with four methods of estimation of parameters to estimate rainfall quantiles for T-years return period.

Climate is a composition of temperature, sunshine, pressure, wind speed, humidity, rainfall and clouds, etc. Rainfall is an important characteristic as it can cause disasters like land slide or floods if extremely befallen. Scarcity of rainfall also affects the water management systems hence impacts agricultural productions. Pakistan is a populated country, economy based on agriculture and high vulnerable index to ecological disasters, like rainfall and floods. Therefore, it is also important to have estimates of rainfall using suitable methods in numerous climate zones of the country. This study illustrates the results of at-site frequency analysis using two relatively new probability distributions with four methods of estimation using rainfall data of three sites of Azad Jammu and Kashmir, Pakistan. The results of this study will be useful in terms of introducing new probability distributions, to bring variety and flexibility in the choice of probability distributions, for modelling of extreme events with various methods of estimation. The estimated quantiles with best suitable estimation method(s) would also be useful for officials dealing with water resources management and disasters management of the study area.

Based on the aforementioned details, the major objectives of the study are:

- Assessing the suitability of FD and LLLD for modelling extremes of rainfall using four methods of estimation namely Maximum Likelihood Estimation (MLE), Bayesian Estimation (BE), Moments Estimation (ME) and Probability Weighted Moments Estimation (PWME)
- Estimating rainfall quantiles for various return periods of the most suitable method(s) of estimation

Moreover, to establish the usefulness of the adopted methodology, in general, the quantile estimates obtained through this study has been compared with the results of the previously published study. The comparison reveals that the results are comparable in terms of forecasting the magnitude of extreme events at given sites for shorter as well as longer return periods.

Literature review

Various probability distributions with different methods of estimations using regional as well as at-site approach have been applied in the literature for modelling rainfall data all over the world including Pakistan. Some of the published international and indigenous studies are summarized below.

International studies

Zalina et al. (2002) performed rainfall frequency analysis using eight probability distributions including Gamma, Generalized Normal, Generalized Pareto, Generalized Extreme Value, Gumbel, Log Pearson Type III, Pearson Type III and Wakeby distribution to estimate extreme rainfall in Malaysia. The variable of analysis was annual maximum rainfall series of seventeen stations located in Peninsular Malaysia. The study concluded that the Generalized Extreme Value distribution is the most appropriate distribution for the study area.

Mohamed and Ibrahim (2016) analyzed annual rainfall data for fourteen rainfall stations in Sudan. Five distributions namely Normal, Log Normal, Gamma, Weibull and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1360713623

Exponential have been used and the study concluded that Normal and Gamma distributions are suitable probability distributions to model rainfall data.

Bahrawi (2018) investigates annual rainfall data of more than 20 stations in Makkah Al-Mukarramah, Saudi Arabia using Lognnormal, Normal, Extreme Value Type I, Pearson Type III and Log-Pearson Type III distributions. Different distributions have been identified as best-fitted distribution for different regions with suitability of Log-normal for 36% of the rainfall stations.

Few other studies include the work of Mo et al. (2019) in South China using Generalized Extreme Value and Generalized Pareto distributions with MLE method for analyzing rainfall data of eight gauging stations and concluded that Generalized Pareto distribution performed better relative to Generalized Extreme Value distribution. Liang et al. (2017) performed L-moments based regional frequency analysis and compared the results with at-site analysis using Generalized Extreme Value distribution analyzing rainfall data in the Taihu basin China; Wang et al. (2017) applied regional approach using fuzzy c-means and L-moments to analyze precipitation extremes in Mainland China; and Alam et al. (2018) performed at-site rainfall frequency analysis using Generalized Extreme Value, Pearson Type III and Log Pearson Type III probability distributions for various sites of Bangladesh and concluded that different probability distributions are suitable for different sites with Generalized Extreme Value distribution suitable for 36% of the stations.

Case studies of Pakistan

There are few published studies performing rainfall frequency analysis of different sites/areas of Pakistan using at-site or regional approach with various probability distributions using different methods of estimation of parameters and quantiles. Some of them are briefly summarized below:

Amin et al. (2016) performed at-site frequency analysis using four probability distributions; Log Pearson Type-III, Normal, Gumbel Maximum and Log-Normal distributions to model annual maximum rainfall for sites in the northern areas of Pakistan. The study concluded that the Normal and Log Pearson Type-III distributions are best-fit distributions for the study area. Iqbal and Ali (2013) performed at-site frequency analysis using extreme annual rainfall of four cities of Punjab and concluded that the General Extreme Value distribution is the best-fitted distribution for the study area. Shahzadi (2013) and Shahzadi et al. (2013) performed L-moments based regional frequency analysis using annual maximum rainfall series of 23 stations of Pakistan. The study area was divided into three homogenous regions. The study concluded that Generalized Normal, Generalized Extreme Value and Generalized Logistic distributions are suitable to model the observed data series for the regions under study. The study area of Shahzadi et al. (2013) includes the sites used in this study with similar variable of analysis, i.e. annual maximum rainfall series. Therefore, a comparison of the estimates provided by Shahzadi et al. (2013) with the results of current study has been provided in the later section of the paper, to establish the usefulness of the current methodology. In another study, Hussain et al. (2017) illustrated the application of regional rainfall frequency analysis using rainfall data of seven sites of Sindh, Pakistan with annual maximum monthly rainfall totals as variable of analysis. The study concluded that three distributions namely: Generalized Normal, Pearson Type III and Generalized Pareto are suitable for the observed data series of the study region. Ahmad et al. (2017) performed L-moments based regional frequency analysis using annual total

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1360713623

rainfall of 30 met sites of Pakistan. The study area (includes sites from Sindh, Punjab, Balochistan and Northern Areas) was divided into four homogeneous regions with different three-parameters probability distributions identified as best-fitted probability distributions. Ahmad et al. (2016) performed at site frequency analysis using annual daily maximum rainfall series. Different probability distributions have been used with methods of estimations as L-moments, TL moments and LH moments. The study area includes 9 sites from Sindh, 7 sites from Balochistan, 6 sites from Punjab, 3 sites from Khyber Pakhtunkhwa and 3 sites from Northern Areas of Pakistan. Hussain et al. (2010) applied Box-cox transformed hierarchical Bayesian multivariate spatio-temporal interpolation method to estimate space time monthly precipitation in the monsoon periods during 1974 to 2000, using 27 years monthly average rainfall data of 51 stations in Pakistan. Khan et al. (2017) performed regional frequency analysis using monthly precipitation data from 1999 to 2012 at 17 stations of Northern areas and Khyber Pakhtunkhwa. L-moments and partial L-moments have been used as estimation methods with four three-parameter probability distributions. The study concluded the suitability of Generalized Pareto distribution using L-moments and Generalized Normal distribution using partial L-moments for the study region.

The aforementioned details show that both at-site and regional approaches have been adopted to analyse rainfall frequency analysis in Pakistan using some typical probability distributions with various methods of estimation of parameters but non of the studies have used FD and LLD to model the extremes of rainfall in Pakistan.

Materials and methods

Study area and data utilized

The study area consists of three sites of Azad Jammu and Kashmir (AJ&K) namely Muzaffarabad, Kotli and Garhi Dupatta. AJ&K commonly known as Pakistan administered Kashmir borders Pakistan's Punjab province to the south and Khyber Pakhtunkhwa province to the west. It has a total area of 13,297 km^2 with a total population of 4,045,366 as per the 2017 census of Pakistan. The northern part of AJ&K encompasses the lower area of the Hamalayas. The region receives rainfall in both the winter and the summer. However, in the summer season, monsoon floods of the rivers Jhelum and Leepa are common due to extreme rainfall and snow melting. The southern parts of AJ&K including Kotli usually have extremely hot weather in summers and moderate cold weather in winters. This area receives rainfall mostly in monsoon (from June to September). The central and the northern parts of AJ&K including Muzaffarabad have moderate hot weather in summers and very cold (chilly) in winter with snowfall occurs in December and January.

Annual maximum rainfall series (AMRS) in millimeters, i.e. maximum value from the daily rainfall record of each year has been selected for the analysis, which usually considered as an important variable for rainfall frequency analysis as used in a number of case studies mentioned in the literature review section. Data for the years 1980 to 2015 have been used, provided by Pakistan Meteorological Department, head office Karachi, Pakistan. The site characteristics along with few summary statistics and geographical locations of the three sites are presented in *Table 1* and *Figure 1*, respectively. The descriptive statistics provided in *Table 1* are useful to understand the general trends and tendencies of AMRS at given sites.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1360713623

Among the three sites, Garhi Dupatta has the highest average value of observed AMRS as 75.72 mm whereas the average of observed AMRS at Kotli and Muzaffarabad is 59.91 mm and 74.46 mm, respectively. To observe the dispersion around mean of the given data series, standard deviation has been calculated which shows that there exist variations in the observed data series at different sites. The highest variation has been observed in AMRS of site Muzaffarabad.

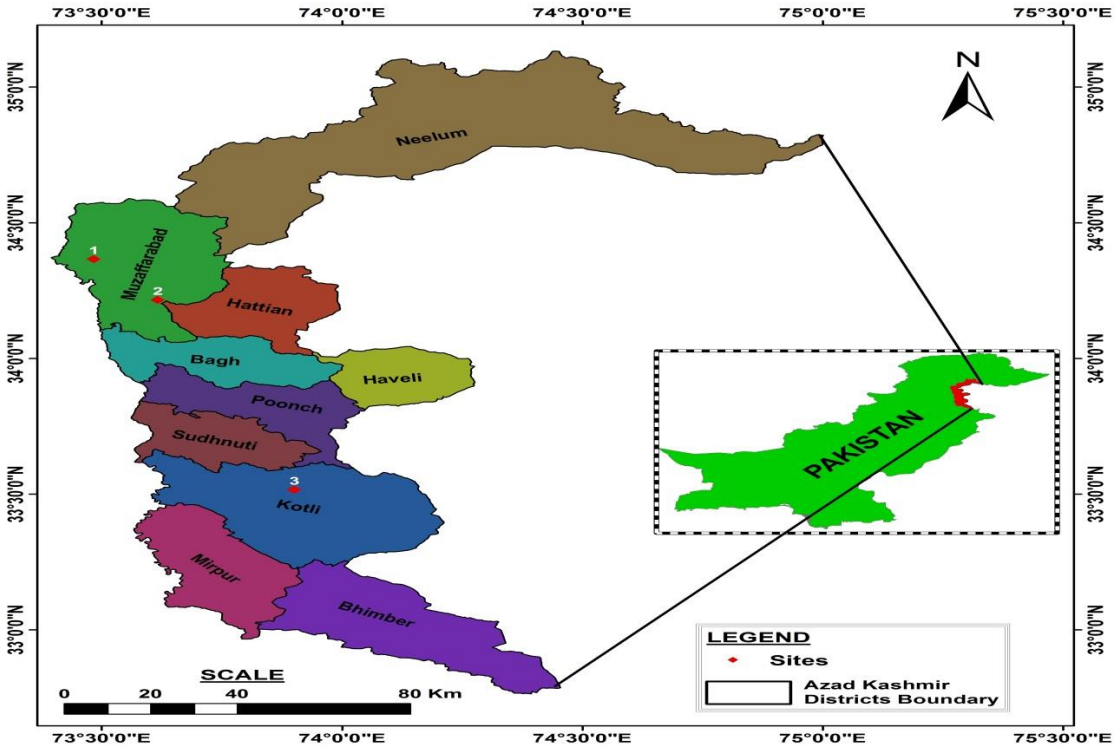

Figure 1. *Study area and geographical locations of the three sites of AJ&K, Pakistan*

Table 1. *Site characteristics and descriptive statistics of the data series at three sites*

Site name	Lat	Lon	Ele (m)	n	Mean (mm)	SD (mm)	CV	Min (mm)	Max (mm)	Skew
Garhi Dupatta	34°13’	73°37’	813.50	36	75.72	11.32	14.95	32.15	184.27	1.12
Kotli	33°31’	73°54’	614.00	36	59.91	24.55	40.98	28.72	129.28	1.29
Muzaffarabad	34°22’	73°29’	702.04	36	74.46	31.43	42.21	30.55	153.98	1.09

Lat, Lon, and Ele are the Latitude, Longitude and Elevation of the sites, mm denotes millimeters while n, SD, CV, Min, Max and Skew are the number of observations, standard deviation, coefficient of variation, minimum value, maximum value and moments measure of skewness of the observed data series at each site, respectively

Coefficient of variation (CV) has been calculated as a relative measure of dispersion. The values of CV show that the least consistency exists in AMRS of Muzaffarabad, followed by Kotli and Garhi Dupatta. The coefficient of skewness ranges from 1.09 to 1.29 indicates that the distribution associated to the observed data series at these sites is positively skewed (non-normal). Therefore, it would be appropriate to select positively skewed distribution(s) as candidate(s) for the observed data series at given sites. The

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1360713623

maximum of the observed AMRS at respective sites so far is 184.27 mm at Garhi Dupatta, 129.28 mm at Kotli and 153.98 mm at Muzaffarabad.

For rainfall frequency analysis, there exists certain commonly used probability distributions with variations in the methods of estimation as discussed in the literature review. However, this study has introduced FD and LLD to model the rainfall data at given sites using different methods of estimation. The illustration of the results of this application provides flexibility to the researchers performing inferential statistics of extreme events using probability distribution(s).

Basic assumptions of the observed data series

The procedure of rainfall frequency analysis is usually based on few assumptions related to the observed data series at given sites. For instance, the observed data series at given sites is random and identically distributed. Therefore, to check these assumptions Run test for randomness (Bradley, 1968) and Maan-Whitney test (Mann and Whitney, 1947) for identical distribution of the data series at given site have been utilized. Furthermore, Kolmogorov Smirnov (KS) test has been used as goodness-of-fit measure.

Estimation methods

For the two selected probability distributions, i.e. FD and LLD, four estimation methods, i.e. MLE, PWME, ME and BE methods have been used for the estimation of parameters and quantiles. Few details related to the procedures are:

FD was introduced by Maurice Frechet in 1927 for largest extremes (Frechet, 1927). It is a special case of Extreme value distribution (EVDs) and used to model the extreme events like floods, maximum rainfall, river discharge in hydrology, etc. The reason for selecting this probability distribution for the analysis is that various published studies related to rainfall frequency analysis found Generalized Extreme Value distribution as appropriate to model extremes of rainfall in Pakistan. Therefore, the idea is to provide a suitable alternative to bring flexibility in the choice of available probability distributions for modeling rainfall data. The probability density function (PDF) of FD is

$$f(x,\alpha,\beta) = \frac{\alpha}{\beta}\left(\frac{\beta}{x}\right)^{\alpha+1} exp\left[-\left(\frac{\beta}{x}\right)^{\alpha}\right], x > 0, \alpha, \beta > 0, \quad \text{(Eq.1)}$$

where α is the shape parameter and β is the scale parameter.

The LLD is also a type of extreme value distribution. It can be used for model the extreme values like maximum daily one day rainfall, river discharge per day or per month, etc. The PDF of LLD is:

$$f(x,\alpha,\beta) = \frac{\left(\frac{\beta}{\alpha}\right)\left(\frac{x}{\alpha}\right)^{\beta-1}}{\left[1+\left(\frac{x}{\alpha}\right)^{\beta}\right]^2}, x > 0, \alpha, \beta > 0, \quad \text{(Eq.2)}$$

where α is scale and β is shape parameter.

Estimates of parameters for FD using MLE

Let $x_1, x_2, , x_3, , \ldots, x_n$ be a random sample of size 'n' from two parameters FD, then the likelihood of function of *Equation 1* is:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1360713623

$$L(x,\alpha,\beta) = \alpha^n \beta^{n\alpha} \pi_{i=1}^n x_i^{-(\alpha+1)} \exp\left[-\sum_{i=1}^n \left(\frac{\beta}{x_i}\right)^\alpha\right], \quad \text{(Eq.3)}$$

The log-likelihood function is:

$$logL(x,\alpha,\beta) = nlog\alpha + n\alpha log\beta - (\alpha+1)\sum_{i=1}^n logx_i - \sum_{i=1}^n \left(\frac{\beta}{x_i}\right)^\alpha, \quad \text{(Eq.4)}$$

The score equations are

$$\frac{\partial logL}{\partial \alpha} = \frac{n}{\alpha} + nlog\beta - \sum_{i=1}^n logx_i - \sum_{i=1}^n \left(\frac{\beta}{x_i}\right)^\alpha \log\left(\frac{\beta}{x_i}\right) = 0, \quad \text{(Eq.5)}$$

$$\frac{\partial logL}{\partial \beta} = \frac{n\alpha}{\beta} - \alpha\beta^{(\alpha-1)} \sum_{i=1}^n \left(\frac{1}{x_i}\right)^\alpha = 0. \quad \text{(Eq.6)}$$

The above equations cannot be written in closed form, therefore, the BFGS (Broyden Fletcher GoldFarb Shanno), available in the R software, have been used to estimate α and β with MLE.

Estimates of parameters for FD using PWME

The Probability weighted Moments proposed by Greenwood et al. (1979) has the following form

$$M_{p,r,s} = \int X^p \{F(x)^r\}\{1-F(x)\}^s dF(x), \quad \text{(Eq.7)}$$

Hosking et al. (1985) presented the special case

$$B_r = E[X\{F(X)\}^r], r = 0,1,2,3,\ldots \quad \text{(Eq.8)}$$

For any population, the r^{th} non-central moments can be expressed as

$$\alpha_r = M_{1,0,r} = E[X\{1-F(X)\}^r], \quad \text{(Eq.9)}$$

by putting r = 1, 0 in *Equation 9*,

$$\alpha_0 = \beta\tau\left(1-\frac{1}{\alpha}\right), \alpha > 1, \quad \text{(Eq.10)}$$

$$\alpha_1 = \frac{\beta\tau(1-\frac{1}{\alpha})(2-2^{\frac{1}{\alpha}})}{2}, \quad \text{(Eq.11)}$$

from observed sample, the corresponding r^{th} moments are

$$a_r = n^{-1} \frac{\sum_{i=1}^n \binom{n-i}{r} X_i}{\binom{n-1}{r}}, \quad \text{(Eq.12)}$$

by substituting r = 1, 0 in *Equation 12*,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1360713623

$$a_0 = \bar{X}, \quad \text{(Eq.13)}$$

$$a_1 = \frac{\sum_{i=1}^{n}(n-1)x_i}{n(n-1)}, \quad \text{(Eq.14)}$$

Then equating *Equations 10* and *11* to *Equation 13* and *14*, estimates of α and β for FD using PWME are:

$$\hat{\alpha}_{PWM} = \frac{log2}{log2+loga_0-loga_1}, \quad \text{(Eq.15)}$$

$$\hat{\beta}_{PWM} = \frac{\bar{X}}{\tau(1-\frac{1}{\alpha})}, \alpha > 1 \quad \text{(Eq.16)}$$

Estimates of parameters for FD using ME

The r^{th} moment for FD is

$$E(X^r) = \beta^r \tau\left(1-\frac{r}{\alpha}\right), \quad \text{(Eq.17)}$$

by substituting r = 1, 2 respectively in *Equation 17*, the first and second moments for FD, i.e.

$$m_1^* = \bar{X}, \quad \text{(Eq.18)}$$

$$m_2^* = E(X^2) = \beta^2 \tau\left(1-\frac{2}{\alpha}\right), \quad \text{(Eq.19)}$$

By solving *Equations 18* and *19* using iterative method, the estimates of α and β for FD using ME can be obtained.

Estimates of parameters for FD using BE

The estimates of α and β using BE can be obtained by considering the reference prior, developed by Abbas and Tang (2015), i.e.

$$\pi_R(\alpha,\beta) = \frac{1}{\alpha\beta}, \quad \text{(Eq.20)}$$

Then the joint posterior distribution for α and β is

$$\pi_{(\alpha,\beta|x)} = \frac{\alpha^{n-1}\beta^{n\alpha-1}\pi_{i=1}^{n}x_i^{-(\alpha+1)}\exp[-\sum_{i=1}^{n}(\frac{\beta}{x_i})^{\alpha}]}{\int_0^{\infty}\int_0^{\infty}\alpha^{n-1}\beta^{n\alpha-1}\pi_{i=1}^{n}x_i^{-(\alpha+1)}\exp[-\sum_{i=1}^{n}(\frac{\beta}{x_i})^{\alpha}]d\alpha d\beta}, \quad \text{(Eq.21)}$$

Laplace approximation can be used to obtain the estimates of α and β using BE.

Estimates of parameters for LLD using MLE

Let $x_1, x_2, , x_3, , \ldots, x_n$ be a random sample of size 'n' from LLD, then the likelihood of function of *Equation 2* is:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1360713623

$$L(x_i;\alpha,\beta) = \beta^n \alpha^{-n\beta} \pi_{i=1}^n x_i^{\beta-1} \pi_{i=1}^n [1 + \left(\frac{x_i}{\alpha}\right)^{\alpha}]^{-2}, \quad \text{(Eq.22)}$$

Then the log-likelihood function can be written as:

$$logL(x_i;\alpha,\beta) = nlog\beta - n\beta log\alpha + (\beta-1)\sum_{i=1}^{n} logx_i - 2\sum_{i=1}^{n} \log\left[1 + \left[\frac{x_i}{\alpha}\right]^{\beta}\right], \quad \text{(Eq.23)}$$

Derivatives of *Equation 23* with respect to α and β are:

$$\frac{\partial logL}{\partial \alpha} = -\frac{n\beta}{\alpha} + \frac{2\beta}{\alpha}\sum_{i=1}^{n} \frac{(\frac{x_i}{\alpha})^{\beta}}{(1+(\frac{x_i}{\alpha})^{\beta})} = 0, \quad \text{(Eq.24)}$$

$$\frac{\partial logL}{\partial \beta} = \frac{n}{\beta} - nlog\alpha + \sum_{i=1}^{n} logx_i - 2\sum_{i=1}^{n} \frac{(\frac{x_i}{\alpha})^{\beta} \log(\frac{x_i}{\alpha})}{\left[1+(\frac{x_i}{\alpha})^{\beta}\right]} = 0. \quad \text{(Eq.25)}$$

Equations 24 and *25* do not have a closed form solution. Therefore, these may be solved to obtain the estimates of parameters of LLD using BFGS method which is available in R software.

Estimates of parameters for LLD using PWME

The estimates of α and β can be obtained as:

$$\beta_r = \frac{\alpha\Gamma(\frac{1}{\beta}+r+1)\Gamma(1-\frac{1}{\beta})}{\Gamma(r+2)}, \quad \text{(Eq.26)}$$

by putting $r = 0, 1$ respectively, in *Equation26*, we get

$$\beta_0 = \alpha\Gamma\left(\frac{1}{\beta}+1\right)\Gamma\left(1-\frac{1}{\beta}\right), \quad \text{(Eq.27)}$$

$$\beta_1 = \frac{\alpha}{2}\Gamma(\frac{1}{\beta}+2)\Gamma\left(1-\frac{1}{\beta}\right), \quad \text{(Eq.28)}$$

Their corresponding sample moments are

$$\widehat{\beta_r} = \frac{\sum_{i=1}^{n} \binom{i-1}{r} x_i}{n\binom{n-1}{r}}, \quad \text{(Eq.29)}$$

put $r = 0, 1$ respectively, in *Equation29*, we have

$$\hat{\beta}_0 = \bar{X}, \quad \text{(Eq.30)}$$

$$\widehat{\beta_1} = \sum_{i=1}^{n} \frac{x_i(i-1)}{n(n-1)}. \quad \text{(Eq.31)}$$

By comparing *Equantion27* and *Equation28* to *Equantion30* and *Equation31*, estimates of α and β through PWME can be obtained.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1360713623

Estimates of parameters for LLD using ME method

The r^{th} moment for LLD is:

$$E(X^r) = \int_0^\infty x^r f(x;\alpha,\beta)dx, \quad \text{(Eq.32)}$$

$$E(X^r) = \alpha^r \Gamma\left(\frac{r}{\beta}+1\right)\Gamma\left(1-\frac{r}{\beta}\right), \quad \text{(Eq. 33)}$$

By putting r = 1, 2 respectively in *Equation33*, the first and second moments for LLD are:

$$m_1^* = E(X) = \alpha\Gamma\left(\frac{1}{\beta}+1\right)\Gamma\left(1-\frac{1}{\beta}\right) = \bar{X}, \quad \text{(Eq.34)}$$

$$m_2^* = E(X^2) = \alpha^2\Gamma\left(\frac{2}{\beta}+1\right)\Gamma\left(1-\frac{2}{\beta}\right). \quad \text{(Eq.35)}$$

By solving *Equation34* and *Equantion35* by iterative method, the estimates of α and β through ME can been obtained.

Estimates for LLD using BE

Estimates of parameters for LLD using BE are obtained by considering the reference prior developed by Abbas and Tang (2016). The joint posterior distribution of α and β is:

$$\pi_{(\alpha,\beta|x)} = \frac{\alpha^{-n\beta-1}\beta^{n-1}\pi_{i=1}^n x_i^{\beta-1}\pi_{i=1}^n[1+\left(\frac{x_i}{\alpha}\right)^\beta]^{-2}}{\int_0^\infty\int_0^\infty \alpha^{-n\beta-1}\beta^{n-1}\pi_{i=1}^n x_i^{\beta-1}\pi_{i=1}^n[1+(\frac{x_i}{\alpha})^\beta]^{-2}d\alpha d\beta}. \quad \text{(Eq.36)}$$

Here Metropolis within Gibbs sampling algorithm has been used to obtain the Bayesian estimates.

Results and discussion

Initial data screening

To check for the randomness and identical distribution of the observed data series at given sites, *Table 2* illustrates the results of Run test and Maan-Whitney statistics (W). The corresponding p-values of observed number of runs indicates that the AMRS at given sites is random. For the calculation of W, the data series at each site has been divided into two groups. The corresponding p-values of W provide sufficient evidence that the observed data series at each site is identically distributed. Both the tests (Run test and Maan-Whitney) have been performed using 5% level of significance.

Estimation of probability distributions

The estimates of parameters of the two selected probability distributions along with p-values of Kolmogorov Smirnov (KS) test (used as a goodness of fit measure) are illustrated in *Table 3*. Based on the corresponding p-values, in general, all the methods of estimation have passed the goodness of fit criteria for the three sites considering both

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1360713623

the selected probability distributions at 5 percent level of significance. However, observing closely, the values of ME have the highest value of KS statistic so as the lowest p-values for both the probability distributions for the three sites. It indicates that the method of moments may not be a preferable choice for the estimation of parameters for the given data series at three sites. These results are consistent with the general practice of the application of extreme value probability distributions that the methods of moments is not an optimal choice for the data series having skewed distribution.

In particular, for FD the corresponding p-values of KS test are approximately similar with MLE and BE methods for Garhi Dupatta and Muzaffarabad, while PWME method have near similar tendency to MLE and BE as the skewness in the observed data series increases for the site Kotli. Similar tendencies hold for LLD (with PWME having similar tendency comparable to MLE and BE for Garhi Dupatta and Muzaffarabad); while MLE method outperforms for the site Kotli. Therefore, the results suggest that both the distributions (FD and LLD) using MLE and BE methods are suitable (with PWME method as a good alternative, if the observed data series exhibit large skewness) for modeling extremes of rainfall.

To graphically visualize the performance of both the probability distributions with four methods of estimation, the plots of probability density functions of FD and LLD have been constructed and presented in *Figure 2*. These graphs also suggest that, in general; the selected distributions are suitable for the observed data series at given sites. Particularly, for LLD, the behavior of pdf with BE method is relatively different for the sites Kotli and Muzaffarabad; while for the site Garhi Dupatta with PWME the curve seems to fit the observed data adequately and the performance of MLE, BE and ME methods is approximately similar. On the other hand, for FD, the graph using BE and MLE are comparable for all the three sites. These results are consistent with the findings of KS test.

Based on the aforementioned details both the distributions are suitable to model the extremes of rainfall with MLE or BE as preferred methods of estimation.

The quantile estimates for various return periods for each site can be obtained using the quantile function of the selected probability distribution(s). These quantiles have been calculated using MLE, BE and PWME methods (as ME is not a preferred choice of estimation). The results are illustrated in *Table 4*. The results of *Table 4* show that the estimated quantiles for F = 0.90 (10 year return period) and so on are greater than the average values of AMRS at given site. Moreover, the magnitude of 100 year return period is greater the maximum value of the observed AMRS (see *Table 1*) for the three sites (for both the probability distributions). These results are useful for the officials and researchers dealing with disasters and water resources management of the study for proper planning and effective management.

Table 2. *Results of run test and Maan-Whitney (W) statistics*

Site name	n	Runs	P-values	Groups	W	P-values
Garhi Dupatta	36	17	0.6920	18, 18	339	0.8619
Kotli	36	19	0.7510	18, 18	340	0.8371
Muzaffarabad	36	20	0.6750	18, 18	346	0.6927

n is the number of observations at each site, Runs are the observed number of runs, W is the calculated test statistic for Maan-Whitney test. These tests are performed at 5% level of significance

Comparison with previously published study

Though the illustrated results of this study indicates that the selected probability distributions are suitable to model the rainfall data at given sites so as the estimated quantiles are useful but the precedence through practical comparison of the adopted methodology (as an acceptable alternative to the conventional methods) is still requisite. To do so, the quantile estimates for 1, 10 and 100 year return period of this study have been compared with the quantiles provided by Shahzadi et al. (2013). Few details of the comparison are: the study of Shahzadi et al. (2013) has been selected as it is the only study with similar variable for analysis, i.e. annual maximum rainfall series and the same set of sites. The sites Muzaffarabad, Garhi Dupatta and Kotli were included in Region 2 by Shahzadi et al. (2013) and Generalized Extreme Value, Generalized Normal and Generalized Logistic distributions identified as regional distributions (for more details and regional quantiles see *Table 5* of Shahzadi et al., 2013). Those estimated regional quantiles are utilized to estimate the quantiles for the specific sites (for comparison) using index flood method, i.e. those estimates of regional quantiles (for 1, 10 and 100 year return period) are multiplied by the mean of the respective sites provided in *Table 1* of this study. The results are illustrated in *Table 5*. The comparison (of *Tables 4* and *5*) reveals that, for all the three sites, the estimates of FD and LLD distributions with BE, MLE and PWME are quite close to the results of L-moments based regional frequency analysis with Generalized Extreme Value, Generalized Normal and Generalized Logistic distributions for shorter return period, i.e. 1 and 10 year. Moreover, for longer return period, i.e. 100 year, LD distribution with BE method and FD with PWME method provides comparative results to the results of Shahzadi et al. (2013), hence can be a preferred choice to model the extremes of rainfall.

Conclusions

The study illustrates application of two atypical probability distributions with four methods of estimation of parameters to model the behavior of AMRS at three sites of AJ&K, Pakistan. Some of the major conclusions are:

i. The observed data series at given sites is random and identically distributed as validated by Run test and Man Whitney test.
ii. Summary statistics have shown that there exists variations in the observed data series and the distribution related to the observed data series at given sites is positively skewed.
iii. In general, both the distributions with suggested methods for the estimation of parameters have passed the goodness of fit criteria of KS test. However, the tendency of the KS values along with corresponding p-values have suggested that ME method is no a preferred choice for estimation.
iv. The graphs of probability density functions for FD and LLD have also illustrated that both the probability distributions are suitable for the observed data series at given sites. Moreover, the trends and tendencies of probability density functions are dissimilar using various methods of estimation. However, the results are in agreement with the results of KS test.
v. The study suggest that both the probability distributions using MLE and BE methods are preferred choice for modeling the extremes of rainfall of the study area. These results are encouraging to adopt relatively atypical probability distributions for the estimation of extreme events, like floods, rainfall, etc. This will bring diversity and flexibility in the choice of selection of a probability distribution for the modeling of extremes of geophysical events.
vi. The quantiles for various return periods have been calculated using the quantiles functions of the selected probability distributions. The estimated

DOI: http://dx.doi.org/10.15666/aeer/1706_1360713623

quantiles for 10 year return period and above are greater than the average values of the observed data series at given sites. Moreover, the estimates of 100 year return period are greater than the maximum values of the observed data series for all the three sites. Therefore, the concerned officials have to adopt preemptive measures in advance to deal with these extreme events of such magnitude.

vii. To establish the usefulness of the selected distributions along with the adopted methods of estimation, the quantiles for 1, 10 and 100 year return period are compared with the previously published studies related to this area of study and variable of analysis. The comparison reveals that LD distribution with BE method and FD distribution with PWME method provides comparative results relative to L-moments based rainfall frequency analysis using popular three-parameter distributions, especially for longer return period, i.e. 100 year.

The study provides useful guidelines for the concerned officials of study area, home-grown farmers, meteorologists studying precipitation and rainwater management planning. Moreover, the study provides illustration of some new probability distributions with different methods of parameter estimation for at site frequency analysis of extreme events. The procedure can be adopted in general to bring diversity and flexibility in the choice of probability distributions for modeling of extremes of events like floods, rainfall, etc.

Acknowledgements. We are thankful to the editorial office of the journal and anonymous reviewer(s) for their constructive comments and suggestions to improve the quality of the paper. We are also grateful to Pakistan Meteorological Department (CDPC, Head Office Karachi) for providing the rainfall data for the study.

(Received 10th Apr 2019; accepted 12th Jul 2019)

Abstract. Mineral nutrients are important factors in plant-disease interactions. Experiments were conducted under Completely Randomized Block Design (CRD) with three replications to find out the alterations in mineral status of citrus leaves infected with the canker. Leaves of susceptible (Grapefruit, Succari, Kinnow) and resistant (Kumquat, Jaffa, China lemon) varieties of inoculated and un-inoculated citrus plant leaves from 6 varieties were collected and analyzed by using Nested Structured Design to check the ionic status of nutrients and minerals. Variations ($p \leq 5$) were observed in the mineral status among the treatment groups (Un-inoculated and inoculated), types (susceptible and resistant) and in the citrus varieties in response of citrus canker infection. Resistant type of plants expressed 6.88, 1.39, 8.33, 2.19, 1.84, 1.46, 1.56, 2.82 and 1.89 while susceptible type expressed 5.39, 1.13, 5.90, 1.89, 1.44, 1.11, 1.03, 1.81 and 0.92 variations in concentration of N and P (%) while K, Ca, Mg, Na, Zn, Fe and Cu in (ppm) respectively. Susceptible varieties accumulated lower concentrations as compared to resistant varieties which have an increased level of minerals. Plants become more prone to pathogen infection due to the deficiency of these nutrients which help the plants in restricting the pathogens.
Keywords: *citrus canker, mineral nutrients, plant-disease interaction, CRD, nested structured design*

Introduction

Citrus is the most important cash and fruit crop grown all over the world. It grows best under tropical and subtropical ecological conditions (Jagtap et al., 2012; Wali et al., 2013). Worldwide, its total production estimated at 115 Million Metric Tons (MMT) while in case of Pakistan, it was 3.6 MMT (Memon, 2017). Citrus has much supplementary usage in various kinds of food and beverages having traditionally medicinal values (Gurib, 2006). Citrus is valuable due to its rich nutritional grade and is more precious because of its highly dietary status. It has large amount of sugars, amino acids, organic acids, vitamins, antioxidants like flavonoides, terpenes, macro and micronutrients minerals (calcium, magnesium) along with rich source of vitamin C (Ladaniya et al., 2010). In Pakistan, citrus area is 20.7 million hectares with 36 million tons production (Memon, 2017). Pakistan earned 17.78 billion Pakistani rupees (PKR) by exporting 3.8 million tonns kinnow during the year of 2017 (Memon, 2017). Citrus is spoiled by nearly one hundred and fifty pathogens and disorders caused by fungal, viral and bacterial diseases like canker, greening (HLB), scab, gummosis, whithertip, greecy spot, black spot, decline and citrus tristeza virus

DOI: http://dx.doi.org/10.15666/aeer/1706_1362513642

which results in severe losses but canker caused by *Xanthomonas axonopodis* pv. *citri (Xac)* is one of the major threat among all the constraints faced by the citrus crop in Pakistan (Ware, 2015). Pakistan which is one of the major exporters of citrus in the world, facing a huge economic losses due to this disease. During 2015-16, 144 consignments of citrus were rejected by the European Union due to the infection of *Xac* (Pervaiz, 2015). Overall, the yield losses due to canker is increasing day by day (Sahi et al., 2007).

Bacteria gain entry in to the leaves through stomata, wounds/injuries and penetrate into the intercellular spaces of leaves and attaches to the mesophyll cells using type III secretary system and releases effecter proteins (toxins) which causes hypertrophy, hyperplasia and and causes multiple infection and produces water soaked lesion with yellow hollow. Epidermis gets raised and began to rupture. After two weeks of infection, the watery lesions began to dry and form necrotic lesions. Copper-based chemicals are used in conventional management of canker. No doubt, these chemicals expressed quick response against canker but are not eco-friendly and have ill effects on human health. So, there is dire need to develop an alternate strategy which should be cost effective with least residual effects and is eco-friendly (Kumar et al., 2011). *Xac* forms a bio film on leaf surface and gains entry in to leaves via natural leaf openings or the wounds. Upon bacterial invasion the defense mechanism of plant which is composed of a series of well coordinated molecular networks is triggered, various transcriptomic reprogramming events, ultra-structural reinforcements and physiological changes takes place in a series of defense related events. The first line of plant's defence involves production of reactive oxygen species (ROS) as a part of PAMP-Triggered immunity (PTI). The second line of defense is triggered when certain pathogen effecter molecules are recognized by the R gene products which results in multiple responses including HR response and programmed cell death for pathogen confinement and preventing disease spread (Roeschlin et al., 2017).

Mineral nutrients are essential not only for plant growth and development but also play an important role in plant-disease interaction as well as in reducing disease to a tolerable level (Bradbury, 2016). Nutrients are not responsible for disease severity and resistance but they also take part in the disease development by fluctuating the functioning of the plants or the expansion of disease (Arshadi et al., 2013). Sometime, these nutrients may increase the plant growth which ultimately effects the pathogenic infection and their deficiency also takes the plant towards susceptibility against the pathogen (Bruning and Gabriel, 2003). In the same way these nutrients influence the disease susceptibility by inducing the chemical alterations in the host plant (Mubeen et al., 2015). When a pathogen attacks, it affects the physiology of plant and reduced nutrient uptake, assimilation, absorption, mobility and their consumption. In diseased tissues, translocation or consumption of nutrients are influenced by pathogens, result in nutrient deficiencies. These nutrients have a sound effect on all the key components which play role in the disease severity. Besides, plants have more chances of damage by pathogens that suffer with low level of nutrients which are necessary for building cell walls and other structural tissues (Ryan et al., 2011). In most of the bacterial diseases of plants, pathogen enter and multiply in to the host through the xylum vessels which is the main system for transportation of water and nutrients from the roots to the leaves (Honger et al., 2016). The presence of these pathogenic bacteria produce ooze and slime within the vessels which causing blockage of nutrients, produce rough water soaked lesions on the leaves and after on surface of fruits. Some plant nutrients play a vital role in reducing the capability of bacteria to produce vessels blocking slime (Spann and Schumann, 2010). In sustainable agriculture, management of nutrients has received little attention for control of disease. The physiological functions of plant nutrients are generally well

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1362513642

understood but still there is a little knowledge regarding the relationship between plant-pathogens and nutrients. It is reported that fundamental essential macro and micro nutrients for healthy citrus plants are N, P, K, Mg, Fe, Ca, S, Zn, Cu and B (Zekri and Obreza, 2015). Pathogen uses these nutrients in their growth and development, reduced their accessibility to the host plants and enhancing susceptibility of plant towards various infections (Sahi et al., 2010). Enhancement of plant health is an effective way of combating citrus canker. When bacteria attack on citrus plant, it induces different changes in its metabolism. It interferes with its defense mechanism by disturbing its ionic content which ultimately leads to disease development. A method for the enrichment of plant health and strengthening its defense mechanism against the pathogen attack is to analyze the mineral profile of healthy and diseased plants. The present study was designed to find out the biochemical alterations happened after the disease attack in citrus plants to pave the way towards successful management of citrus canker. For this purpose, mineral profiling of inoculated and un-inoculated plants of susceptible and resistant citrus varieties was conducted.

Materials and methods

One year old seedlings of six varieties (Grape fruit, Succari, Kinnow, Kumquat, Jaffa and China lemon) were collected from the research area Institute of Horticultural Science, University of Agriculture Faisalabad (UAF). All varieties were sown in three replications in pots (30 × 15 cm) containing field soil (sandy clay) previously sterilized by drenching 1% solution of formaline using a Completely Randomized Block Design (CRD) in the green house, research area of Department of Plant Pathology UAF. All the recommended horticultural practices were exercised including the doses of fertilizers and number of irrigations to keep the plants in healthy condition. Soil health analysis was also done to fulfill all requirements of minerals. A standard soil mix (2:1 clay and sand) was used in all experiments. The soil mixture tested 73 lb./acre phosphorus, 242 lb./acre exchangeable potassium. It was partially sterilized by (i) autoclaving for 2 h at 121 °C and 15 psi (ii) fumigating in a sealed plastic container in which 1% formalin solution injected. The soil mixtures were aerated for seven days after treatment. Leaves showed characteristics symptoms of canker were collected in brown paper bags (10" × 12") from research area of Institute of Horticultural Sciences and brought to the citrus pathology lab to isolate *Xac* by using streaking method. Nutrient Agar (NA) media (Beef extract 3 g, Peptone 5 g, Glucose 2.5 g and Agar 15 g, 1000 ml distilled water for 1 L media) was used to isolate *Xac*. For the preparation of inoculums for pathogencity, bacterial culture was grown overnight in 10 ml nutrient broth at 25 °C and put on shaker (RTSK-0300, Robus United Kingdom) at 200 rpm. Inoculum was measured equivalent to 10^8 colony-forming units (*cfu*) per ml with the help of spectrophotometer (Hitachi U-2001, model 121-003) (Francis et al., 2010). Inoculation was done at morning in the green house by using syringe method (using a 1 cm^3 needleless tuberculin syringe). Bacterial suspension (approximately 2 µl) was infiltrated into the leaf until the water-soaked area reached about 6 mm in diameter. Three areas on each side of the leaf mid-vein were infiltrated. Disease incidence was confirmed via Koch's postulates (Juhasz et al., 2013). For mineral analysis, total 300 samples (150 inoculated & 150 un-inoculated), 50 (25 healthy & 25 diseased) from each variety one time after inoculation were collected. Disease symptoms were appeared on the susceptible and resistant type of varieties after the inoculation (*Fig. 1*).

DOI: http://dx.doi.org/10.15666/aeer/1706_1362513642

Figure 1. *Disease symptoms after the inoculation of Xac on susceptible (left) and resistant (right) varieties*

Estimation of mineral gradient in citrus cultivar

The leaves samples comprising of inoculated and un-inoculated groups both from resistant and susceptible reaction types were taken, stored in the refrigerator (Dawlance DW 550) and standard analytical method were employed for the determination of different biochemical compound via 'Nested Structured Design (Gomez and Gomez, 1984). Leaves were surface sterilized by using 0.2% NaOCl solution to eliminate all debris, followed by washing with 0.8% HCL solution (to remove metallic contamination from them) and then with de-ionized water (to get rid of previous two solutions). After this, leaves were first air dried, later placed inside brown paper bags (23 × 15 cm) and then subjected to oven (BST/HAO-1122) drying at 70 °C for 3 days (72 h approx.) to attain a constant weight. After drying the leaf samples were grind in to a fine powder by using sterilized mortar and pestle. After thoroughly grinding, samples (100 mg) were boiled in 10 ml of 1.4 M nitric acid on a hotplate (TH-550; Advantec, Tokyo, Japan) at 100 °C for 25-30 min. The solution was left for cooling, afterwards the sample suspension was diluted up to 250 time using distilled water and analysis for determining concentrations of key elements including; N, P, K, Zn, Mg, Ca, Fe and Na were done by following Bhargava and Raghupathi (1995) method. Potassium, Zinc, Magnesium, Calcium, Iron and Sodium contents were measured on ppm (parts per million) while Nitrogen and Phosphorus were recorded on percent basis.

Estimation of phosphorus from citrus leaves

Sample solution of 0.1 ml was prepared by wet digestion method. Solution was taken in a volumetric flask (ASTM-E288) and 1 ml of ammonium molybdate reagent [$(NH_4)_6Mo_7O_{24}.4H_20$] along with 8.6 ml of distilled water was added. Amino nephtholsulphonic acid ($C_{10}H_9NO_4S$) was added after swirling the flask to mix solution. Sample solution placed at 720 nm on a spectrophotometer (Hitachi U-2001, model 121-003) and absorbency was measured by using distilled water as a reagent blank. Absorbency was compared to previously prepared standard curve (Bolts and Mellon, 1948; Fiske and Subbarow, 1925) by atomic absorption spectrometer (Hitachi polarized Zeeman) for determination of phosphorous concentration.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1362513642

Determination of potassium and sodium from leaves of diseased and healthy citrus plants

Determination of sodium and potassium contents was done by using Flame phorometer (PFP-7, Janway). Potassium chloride and sodium chloride were used as standards for the measurement of K and Na respectively. Four concentrations 10, 20, 30 and 40 ppm for both potassium and sodium were used for preparing the standard curves. Fresh working standards were prepared immediately before use.

Estimation of copper, magnesium, iron, calcium and zinc from citrus leaves

Determination of Calcium (Ca), Magnesium (Mg), iron (Fe), Copper (Cu) and zinc (Zn) was done using a spectrophotometer (Hitachi U-2001, model 121-003). Standards that used for the estimation of these ions were Iron sulphate ($FeSO_4$), Magnesium sulphate ($MgSO_4$), Zinc oxide (ZnO), Calcium chloride ($CaCl_2$) and Copper sulphate ($CuSO_4$). For obtaining standard curves, concentrations 10, 20, 40, 80 and 100 ppm for Ca; 2, 2.5, 3, and 3.5 ppm for Cu; 5, 10, 15 and 20 ppm for Mg; 0.2, 0.3, 0.5 and 2 ppm for zinc and 1, 2 and 3 ppm for iron were used. Standard solutions were prepared just before this activity. Atomic absorption spectrophotometer (GA 3202 HGA) was used for the analysis of these minerals both from resistant and healthy cultivars of citrus.

Estimation of total nitrogen from diseased and healthy citrus leaves

Determination of total nitrogen from the sample was done by using Micro Kjeldahl method (46MC; Quickfit, England) (Kjeldahl, 1983). Proper amount of sample was oven-dried (D6450 Hanus; Heraeus) and taken in long neck Kjeldahl flask. Concentrated sulphuric acid of 25 ml and five grams of digestion mixture containing K_2SO_4 and $CuSO_4$ was added. For boiling of the sample, Digestion hood (KB8S Kjeldatherm) was used. Contents of flask were distilled by using distilled water in 250 ml volumetric flask (ASTM-E288). 10 ml of this solution was distilled in micro Kjeldhal distillation apparatus (VAP20, Garhardt) in the presence of 10 ml of 40% sodium hydroxide (NaOH) solution. Ammonia produce in this reaction which was collected in a beaker containing 10 ml of 2% boric acid (H_3BO_3) solution. Boric acid with two drops of methyl red was used as an indicator. The solution was titrated against standard 0.1N sulphuric acid to light pink point. *Equation 1* was used to calculate the percentage of nitrogen.

$$\text{Nitrogen } \% = \frac{0.1 \text{ N } H_2SO_4 \times 0.0014 \times 250}{\text{WI} \times 100} \times 100 \qquad \text{(Eq.1)}$$

Total percentage of crude protein present in sample was estimated using *Equation 2.*

$$\text{Crude protein} = \text{Nitrogen } \% \times 6.25 \qquad \text{(Eq.2)}$$

Statistical analysis

The plant samples (all varieties) were divided in 2 groups i.e. un-inoculated and inoculated. Further each group contained of 2 reaction types: i) resistant, ii) susceptible, three susceptible citrus varieties were used: Grapefruit, Succari and Kinnow and three resistant varieties Kumquat, Jaffa and China lemon. Leaves sample of un-inoculated and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1362513642

inoculated plants from resistant varieties with a disease incidence ranging from 0-5% and susceptible plants showing above 25% incidence were acquired from the research area Department of Plant pathology near Center of Advanced Studies (CAS) University of Agriculture Faisalabad during 2018. For estimation of mineral contents, standard analytical methods via Nested Structured Design (Gomez and Gomez, 1984) were used and data were statistically analyzed by using PROC MiXED procedure of the Statistical Analysis System (SAS, 2009).

Results

Determination of minerals contents of N, P, K, Na, Zn, Ca, Mg, Fe and Cu from inoculated and un-inoculated citrus plant

Samples of un-inoculated and inoculated with *Xac* both from susceptible and resistant plants were addressed for the determination of N, P, K, Ca, Mg, Na, Zn, Fe and Cu. Inoculated and un-inoculated citrus varieties expressed significant variations (on an average 3.31% across inoculated plants) and (on an average 8.91% across un-inoculated plants) which point out that nitrogen contents were clearly affected by the attack of *Xac.* Resistant and susceptible type showed 6.88% and 5.39% variation at $p \leq 0.05$ and "Type" Component expressed 92.41% total variance. Total nitrogen variability which variety exhibited was 0.83% (*Table 1*). Resistant cultivar "Kumquat" displayed maximum nitrogen amount at 7.23% and susceptible cultivar "Grape fruit" minimum at 5.20% (*Table 2*). In case of phosphorus, there was seen a significant variation between inoculated (0.68%) and un-inoculated (1.81%) cultivars during the infection. Resistant and susceptible varieties showed total variance of 93.00% with 1.39% and 1.13% on individual basis respectively at $p \leq 0.05$ while the variance between the varieties that observed was 1.40%. Maximum and minimum concentrations of phosphorus were accounted by Jaffa (1.46%) and China lemon (1.00%) respectively (*Tables 3* and *4*). Total variability of potassium contents exhibited by the group was 11.09 and in case of type were 88.61% on canker infection (*Table 5*). Resistant and susceptible varieties showed significant variation averaging 8.33 and 5.90 ppm respectively. Inoculated (3.58 ppm) and un-inoculated (10.65 ppm) citrus cultivars also expressed significant variation under *Xac* infection. Resistant cultivar named as kumquat displayed maximum potassium concentration (8.60 ppm) while minimum concentration of potassium was expressed by Grape fruit (5.66 ppm) at $p \leq 0.05$ (*Table 6*).

Regarding the calcium concentration, statistically significant difference was attained by the group having total variance of 4.08% (on an average 1.36 ppm in case of inoculated citrus plants and 2.11 ppm for un-inoculated plants) as shown in *Table 7*. In the same way, resistant cultivars expressed 2.19 ppm while susceptible cultivars showed 1.89 ppm variation as compared to the types which had 91.84% variability in the result of canker infection at $p \leq 0.05$. Significant variation was also expressed by the varieties with the amount of 1.46% of the total variance. Calcium concentrations of 2.26, 2.11, and 2.19 ppm were showed by Kumquat, Jaffa, and China lemon (resistant types), while 1.75, 1.86, and 2.06 ppm concentrations were shown by susceptible varieties Grape fruit, Succari, and Kinnow, respectively as given in *Table 8*. Magnesium articulated a total variability of 4.93% with a significant variation between the inoculated (0.63 ppm) and un-inoculated (2.65 ppm) under the disease conditions. On an average, 1.84 ppm and 1.44 ppm were observed in case resistant and susceptible citrus varieties respectively with a total variation of 93.27%. Varieties showed a total variance of

DOI: http://dx.doi.org/10.15666/aeer/1706_1362513642

0.72 ppm for magnesium. Resistant variety Kumquat expressed maximum concentration of magnesium with 1.90 ppm and susceptible variety Grape fruit showed minimum magnesium contents with amount of 1.19 ppm (*Tables 9* and *10*).

In group, sodium concentration had significant variation in inoculated and un-inoculated citrus varieties expressed (on average 0.62% across inoculated plants) and (on average 1.95% across uninoculated plant) as given in *Table 11* and significant variations (92.19%) were attained by resistant and susceptible cultivar averaging 1.46 ppm and 1.11 ppm respectively. Kumquat with 1.60 ppm and Grape fruit with 1.03 ppm expressed maximum and minimum sodium concentration (*Table 12*).

In case of zinc, significant variation was displayed by the inoculated and un-inoculated citrus plants with the amount of 0.41 ppm and 2.19 ppm respectively (*Table 13*). Likewise, significant variation was also observed in resistant (1.56 ppm) and susceptible (1.03 ppm) citrus plants with total variability of about 86.06 of zinc. Kumquat (1.68 ppm) showed maximum concentration of zinc while Grape fruit (0.92 ppm) expressed minimum zinc concentration (*Table 14*). 15.82, 83.24 and 0.91% total variability was observed in groups, type and varieties respectively in case of iron contents under the disease stress conditions (*Table 15)*. Minimum and maximum iron concentration was showed by Grape fruit (1.60 ppm) and Jaffa (2.65 ppm) respectively (*Table 16*). Both inoculated (1.67 ppm) and un-inoculated (2.14 ppm) citrus plant leaves showed significant variation in cupper contents on pathogen infection. Resistant and susceptible plant also expressed significant variations of 1.89 and 0.92 ppm respectively with 59.87% of the total variance. Varieties showed a total variance of 1.89 ppm for copper. Kumquat (2.05 ppm) and Grape fruit (0.79 ppm) displayed their maximum and minimum concentration of copper contents after the attack of *Xac.* (*Tables 17* and 18).

Discussion

Mineral nutrients have a crucial role to play in plant- disease interaction. Determination of the effects of nutrients on disease development is based upon some major factors like concentration and forms of elements, disease type and weather conditions. Disease severity can be reduced by the accurate provision of nutrients and by understanding the dynamics between the nutritional status of plants and pathogens (Vandermeer et al., 2010). Establishment of pathogen on host surface, rate of penetration and development of disease are depending upon histological or morphological attributes of plant which are influenced by nutritional status of plant. Different types of nutrients have a distinct impact on resistance/susceptibility of host and virulence of pathogens which lead towards various kinds of alterations and consequences in the form of stresses (Bhaduri et al., 2014). Plants need balanced and in time availability of all required nutrients for their growth and development. This plant are more resistant against the various types of biotic and abiotic stresses, protected from new pathogenic infections and also enables to restrict existing infection better than the plants received deficient from proper nutrients supply. In the present study, nutritional requirements like N, P, K, Ca, Mg, Zn, Fe, Cu and B of citrus plant leaves for their growth and development was observed.

In plants, nitrogen is a major element for many compounds of great significance such as protein, coenzymes, amino acid, amides, nucleic acids, nucleotides, chlorophyll, cytosine and auxins (Lakitan, 2007). Nitrogen deficiency in plant happens due to the excessive run-off and leaching. Plants responded abruptly to the application of nitrogen because it required for normal growth and development (Spann and Schumann, 2010). Its deficiency produces many other symptoms while excess availability of nitrogen also favors some diseases in plants (Dordas, 2008). In present study, it was observed that inoculated citrus varieties contained less amount of nitrogen while un-inoculated and resistant cultivars have high nitrogen contents that were also witnessed by Zekri and Obreza (2015).

Plants get high energy compounds like phospholipids, nucleic acids, coenzymes NAD, NADP, ATP and several others by the utilization of phosphorus (Huber and Graham, 1999; Spann and Schumann, 2010). Better root development due to the phosphorus nutrition may survive plants from the attack of various pathogens (Huber, 2007). In the current study, there was a clear difference of phosphorus accumulation in inoculated and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1362513642

uninoculated plants of both resistant and susceptible varieties. Findings of this study associated with the conclusions of Amusa et al. (2005), who experienced variations in phosphorus concentration between inoculated and un-inoculated plant.

Potassium is essential in enzyme activation; many of these enzymes are involved in carbohydrate metabolism. It is also helpful in controlling different plant diseases and pests. In the cellular functions, potassium acts as a mobile regulator for several activities of enzymes which ultimately reduces overall severity of disease. Nitrogen balances with the potassium particularly affect plants susceptibility against the disease (Dordas, 2008). Further, potassium has a great influence on plant physiological functions like hardening of tissues, opening of stomata, rate of photosynthesis and infestation degree of intensity (Huber and Graham, 1999; Rice, 2007; Spann and Schumann, 2010). Disease susceptibility is also linked with the deficiency of potassium because it has major role in plant metabolism. Under its deficiency, the synthesis of starch, protein and cellulose is impaired. In current study, we found that un-inoculated and resistant citrus varieties contained more potassium concentration as compare to the inoculated and diseased varieties which is also confirmed by Olanya et al. (2000). Sodium is taken up by the plants in the form of Na^+ and great variations were observed in inoculated and un-inoculated citrus varieties during this study. Susceptible and infected citrus varieties accumulated less sodium concentration than resistant and un-infected varieties. Closely related findings were reported by Jadon and Shah (2012) which verify the findings of ongoing study.

Calcium is absorbed by the plant in the form of Ca^+ cation and specifically used in growth of roots and leaves, microbial activities and in the uptake of other essential nutrients. It also helps in defense of plants against the penetration of pathogen and disease resistance. Calcium being a structural and functional component of plant cell wall and membrane acts as a secondary messenger within the symplast in signaling pathways (Rice, 2007). It also plays a key role in maintaining cell integrity and permeability because it is a main part of middle lamella in the form of calcium pectate (Spann and Schumann, 2010). Reduction in the concentration of calcium in plants leads towards the susceptibility against the disease. Calcium also act as a barrier in the regulation of sugars and amino acid molecules in between the cells (from the cytoplasm to the apoplast), which stimulate in the case of calcium reduction and increase the chance of pathogen infection (Marschner, 1995). In current studies, a reduction in calcium concentrations inside infected leaves of citrus plant were observed which was further confirmed and supported by the findings of Amusa et al. (2005).

Magnesium takes part in chlorophyll synthesis, in photosynthesis as central atom for chlorophyll and in carbohydrates metabolism (Devlin and Witham, 1983; Spann and Schumann, 2010). Since Mg is a vital element of structural tissues and take part in different physiological and biochemical processes. It is necessary for integrity and safeguarding of ribosomes and is associated with growth factors, mitosis, protein level, carbohydrates metabolism and oxidative phosphorylation. It also takes part in respiration, DNA and RNA synthesis, energy transfer reactions and also acts as a co-factor for many enzymes (Marschner, 2011). In current study an increase in magnesium contents was observed in resistant and un-inoculated citrus plants as compare to the susceptible and inoculated varieties which showed a significant reduction in Mg contents due to the attack of pathogen and these results are in accordance with the conclusions of Jadon and Shah (2012).

Zinc is important for plants due to its role in resistance to various plant diseases. It acts as a co-factor for various enzymes but the actual role in disease resistance is unclear (Rice, 2007). Application of zinc to the soils reduced the attack of root pathogens

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1362513642

especially in vegetable crops (Kalim et al., 2003). It plays a significant role in starch and protein formation. A considerable variation in zinc concentration was observed in citrus varieties where there was a less concentration of zinc in inoculated and susceptible varieties as compare to un-inoculated and resistant varieties. Results of present study is supported by the work of Marschner (1995) and Dordas (2008) who also reported decrease in concentration of Zn due to disease.

Fe has a significant and lethal effect on the plant pathogens and its deficiency reduced the xylem lignifications (Evans et al., 2007). A clear variation was observed in the case of iron contents where leaves of un-inoculated and resistant citrus cultivars expressed high amount of Fe contents as compare to inoculated and susceptible one on the infection as witnessed by Zekri and Obreza (2003). It may due to the effect that plant pathogens generally have higher requirement of Fe and act as a virulence factor during the course of disease. The only justification may be the association of iron as a component of various flavoproteins (Metalloflavoproteins) which take part in biological oxidation and increase as a result of inoculation with the pathogen. Iron is found in iron-prophyrn proteins, which include cytochromes, peroxidases and catalases (these proteins may be responsible for increased catabolic activities in susceptible plants) and also act as a co-factor in reduction-oxidation reactions (Devlin and Witham, 1983). Copper is an important component of lignin and have a key role in protein and carbohydrate metabolism and acts as catalyst in different metabolic activities of the plant (Imran and Gurmani, 2011). In current study, reduction in copper contents was observed on the attack of *Xac.* It was confirmed from this study that there is a relationship between nutrients and disease occurrence because pathogen wants nutrients for their growth. Same results of relationship between nutrients and disease severity were reported by Zekri and Obreza (2015).

Conclusion

Reduction in concentrations of minerals like nitrogen, phosphorus, potassium, calcium, magnesium, zinc, sodium, and copper in the diseased host plants were due to the utilization of minerals by the pathogen for its growth and survival. Timely provision of these macro and micro nutrients to plants is helpful in fortification of physical and biochemical processes of citrus plants and also in enhancing the resistance of plants against the canker.

(Received 13th Apr 2019; accepted 19th Jun 2019)

Abstract. This study was carried out during two consecutive seasons on five date palm cultivars grown under the "environmental conditions". of El- Dakhla oasis, New Valley governorate, Egypt. Five date palm cultivars (Bartamoda, Sakoty, Soltany, Sewy and Barhy) were evaluated using morphological characteristics as well as inter- simple sequence repeats (ISSR) as DNA fingerprinting. Results revealed that, Barhy had the highest values through most of the study, it obtained the highest values in leaflet area (161.59 and 176.70 cm^2), fruit weight (15.23 and 16.33 g), flesh weight (13.89 and 14.99 g), flesh percentage (91.11 and 91.76%), number of bunches (18.8 and 18.66) and yield/palm (195.4 and 197.21 kg). In this study, the total number of ISSR bands were 52 bands, 31 bands were polymorphic "59.61%" and 21 bands were monomorphic "40.38%". The polymorphic bands contained 20 unique bands, these unique bands could be used to "discriminate" between the studied five date palm cultivars.
Keywords: *RAPD, morphological characteristics, DNA, ISSR*

Introduction

Dates are dioecious perennial monocotyledon fruit trees that belong to the Arecaceae family. Date palm (*Phoenix dactylifera* L.) is one of the most important and oldest fruit trees cultivated by man, it is considered to be the oldest tree with great genetic diversity (Popenoe, 1973). Date palm is an important fruit crop in Egypt where the total annual production of date fruits is about 1,730,000 tonnes (FAO Statistics, 2018). It is the most common fruit tree grown in semiarid and arid regions it plays an important role in the protection of interplant cropping system and the stabilization of the ecological system (Hasnaou et al., 2011). For this reason date palm is considered one of the suitable trees which could be cultivated in the new reclaimed desert regions. In Egypt, date palm is one of the most important fruits and widely distributed in different districts, where they are harvested and market at three stages of their development. The Arabic names for the various stages of development of dates are the terms used universally. After pollination, date fruits initially have a slow growth period essentially due to cell division up to the end of the six weeks from pollination. Thereafter fruits enter into the rapid phase of growth which is termed the "Kimiri" stage when fruits are young and green in color (16 weeks from pollination). Fruits then begin to change color and reach maximum weight and size at the "Khalal" (also called "Bisr") stage (20 weeks from pollination); this is considered as the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1364313655

maturi- ty stage. Fruits enter the ripening or "Rutab" stage (22 weeks from pollination) when the fruit begins to soften, lose moisture content and astringency, and starts acquiring a dark and less attractive color (Kassem, 2012). Finally, fruits con- tinue to lose their fresh weight and reach the lowest value at the "Tamr" stage (23 weeks from pollination) which may be considered as the senescence stage (Hobani et al., 2003; Taain, 2013). Soft cultivars are harvested and used at the "Khalal" and "Rutab" stages, but semi-dry and dry cultivars are harvested and used at the "Tamr" stage (Riad, 1993). Among all Egyptian governorates, New Valley ranked the fourth position after Sharkia, Behaira and Aswan according to acreage and the number of female palms. It is well known fact that morphological plasticity is a major weak point in assessment of phenotypic diversity. However, the study on inheritance of agronomic traits of fruit trees (citrus) is known to be controlled by multiple genes, which can be authenticated only through morphological characterization (Liu and Deng, 2007). The correct identification palms based on physiological and morphological markers is usually not possible until fruits are produced. Moreover, the characterization and evaluation of genetic diversity based on large set of phenotypic data is often difficult to assess due to environmental influences (Sedra et al., 1998). Molecular markers based on DNA sequence proved to be an ideal means for the identification and estimation of relatedness among genotypes of different origin. Different markers based on DNA sequences have been developed in the previous years for DNA fingerprinting and genome mapping (Naz et al., 2014). DNA-based molecular markers have been employed to provide reliable useful information on the genetic diversity, relationship between cultivars, DNA fingerprinting, and pedigree analysis (Ayesh, 2017; Haider, 2017; Purayil et al., 2018). Recently, inter simple sequence repeats (ISSR) markers have been emerged as an alternative system with reliability and advantages of microsatellites (SSRs) (Cregan, 1992). The ISSR strategy was therefore performed to access the DNA diversity among crop genotypes (Zehdi et al., 2004). ISSR markers are also believed to be simple, rapid, inexpensive and highly reproducible due to their primer length and to the high stringency achieved to be one of the most efficient techniques that can rapidly reveal high polymorphism and determine genetic diversity in date palm (Zehdi et al., 2004). Determination of genetic relationships among date palm cultivars is of major importance for characterization of date palm germplasm, breeding programs, and conservation purposes. The present study signifies the applicability of ISSR marker system in detecting genetic diversity of date palm cultivars. This may facilitate the conservation and improvement of date palm cultivars in the future. The aim of the study is the analysis of the genetic diversity among a set of Egyptian date palm varieties.

The aim of this work was elucidating the differences on growth, fruiting aspects and identify the genetic diversity between five date palm cultivars namely "Bartamoda", "Sakoty", "Soltany", "Sewy" and "Barhy".

Materials and methods

The present study was carried out during the two successive seasons of 2016 and 2017 on evaluated vegetative growth, physical and chemical fruit properties as well as genetic diversity analysis of some date palm cultivars grown at private orchards of El-Dakhla Oasis, New Valley governorate, Egypt (which lies between 22° and 31° North latitudes and between 25° and 35° East longitudes. Its climate (comprising a mild and wet winter from November to April and a hot and dry summer from May to October) is suitable for the production of many field and horticultural crops (Directorate of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1364313655

Intelligence, 2011).). These cultivars are classified and nominated according to their moisture content in to three groups as follows: a) dry date palm cultivars (Bartamoda, Sakoty and Soltany) b) semidry date palm cultivars (Sewy) c) soft date palm cultivars (Barhy). Three trees were chosen for each cultivar of about 23-25 years old, grown in sandy loam soil. The palms were similar in vigor and received the same orchard management. The inflorescences of the trees under this study were manually pollinated by one source of pollen. At first week of October vegetative characteristics of chosen trees were measured in both seasons. Leave length (m), umber of leaflet, number of spines, leaflet area (cm^2), leave zone (m), spine length (cm), leaflet length (cm) and leaflet width (cm) were measured. Total yield was determined at harvest, each spathe was weighed separately using weighing balance and was expressed in kilogram (kg). For fruit properties fifty fruits were randomly taken from each palm. Physical properties of fruits included fruit and seed weight as well as flesh weight, percentage of flesh, fruit length, seed length and fruit dimensions. The chemical constituents included: Moisture content was determined in about 50 g of chopped flesh sample which was taken and dried in draft oven at 70 °C until a constant weight was obtained, soluble solids content (SSC) was determined by using a hand refractometer according to Chen and Mellenthin (1981). Titratable acidity percentage in the flesh expressed as percentage by titration against NaOH (0.1 N) using phenolphethaline as an indicator as described by A. O.A.C. (1985). Total and reducing sugars concentration were determined according to Lan and Eynon method as described by the A.O.A.C. (1985).

Molecular analysis

DNA extraction

Fresh leaves of date palm were collected separately from different strains and cultivar. Then DNA extraction was performed as described by Dellaporta et al. (1983). About 0.1 g (fresh weight) of plant tissues was ground to fine powder in liquid N_2 using mortar and pestle. Before the tissue thawed, 1 ml extraction buffer (100 mM Tris-HCl pH 8.0, 50 mM EDTA and 0.5 M NaCl) and 0.2 ml 20% SDS were added. The mixture was incubated at 65°C in water bath for 20 minutes. Then 1 ml of phenol, chloroform and isoamyl alcohol (25: 24: 1) was added. Centrifugation was performed at 10,000 rpm for 10 min. The supernatants of each sample were transferred separately to new tubes, and then 1 ml of chloroform and isoamyl alcohol (24:1) was added. Centrifugation was performed at 10,000 rpm for 10 minutes. The supernatants of each sample were transferred separately to a new tube, then 1 ml of isopropanol was added and then kept overnight in a freezer. Centrifugation was performed at 10,000 rpm for 10 min. The resulted pellets containing DNA were re-suspended in 1 ml ethanol. Centrifugation was performed at 10,000 rpm for 2 min. The DNA pellets were re-suspended in 200 TE buffer (10 mM Tris-HCl pH 8.0 and 1 mM EDTA). DNA purity and quantity was determined by UV -spectrophotometer and gel electrophoresis.

ISSR-PCR analysis

ISSR-PCR reactions were conducted using five primers. Amplification was conducted in 25 µl reaction volume containing the following reagents: 2.5 µl of dNTPs (2.5 mM), 2.5 µl Mgcl2 (2.5 mM), and 2.5 µl of 10 × buffer, 3.0 µl of primer (10 pmol), 3.0 µl of template DNA (25 ng/µl), 1 µl of Taq polymerase (1U/µl) and 12.5 µl of sterile dd H_2O. the PCRs were programmed for one cycle at 94 °C for 4 min followed

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1364313655

by 45 cycles of 1 min at 94 °C, 1 min at 40-48 °C (according to the primer), 2 min at 72 °C, then the reaction was finally stored at 72 °C for 10 min. The PCR products were separated on a 1.5% agarose gels and fragments sizes were estimated with the 100 bp ladder DNA marker (Fermentas.com).

Inter simple sequence repeat (ISSR-PCR) procedure

PCR reactions were conducted using 5 arbitrary 10-mer primers. Their names and sequences are shown in *Table 1*.

Table 1. *List of the primer names and their nucleotide sequences used in the study for ISSR procedure.*

No.	Name	Sequence	Annealing temp.
1	14A	5' CTC TCT CTC TCT CTC TTG 3'	40
2	44B	5' CTC TCT CTC TCT CTC TGC 3'	40
3	HB-09	5' ACC CGC AAGG 3'	48
4	HB-12	5' CACCACCACGC 3'	45
5	HB-15	5' GTG GTG GTG GC 3'	48

Statistical analysis

The experiment was set as randomized complete block design with three replicates (each palm as a replicate) per treatment (cultivar) according to Little and Hills (1972) and analyzed by the standard methods according to Snedecor and Cochran (1980). The new L.S.D. test was used for comparison between means. The DNA bands generated by each primer were counted and their molecular sizes were compared with those of the DNA markers. The bands scored from DNA profiles generated by each primer were pooled together. Then the presence or absence of each DNA band was treated as calculate genetic similarity and to construct dendrogram tree among the studied date palm seedling strains and Bartamoda cultivars. Calculation was achieved using Dice Similarity Coefficients (Dice, 1945) as implemented in the computer program SPSS-10.

Results and discussion

Vegetative measurements

Data presented in *Table 2* showed the vegetative measurements of five date palm cultivars. Results showed that Soltany cv. gave the highest values of leaf length (5.39 and 5.53 m) and number of spins (54.2 and 53.66).

While Barhy cv., had the highest value of leaflet area (161.59 and 176.70 cm^2). Also, results indicated that Sewy cv. recorded the highest of leaflet zone/leave (3.37 and .366 m). Sakoty cv., gave the highest value of number of leaflet (212 and 214). On other hand, Bartamoda cv., gave the lowest value of leaf length (3.57 m), number of leaflet (173.2) and number of spines (25.2) in the first season and the number of leaflet (179.66) and leaflet zone/leave (2.81 m) in the second season. These results are in agreement with Abdalla (1979) found that with Iraq and Egyptian date palm cultivars, i.e., Brahee, Hallawy, Sayer and Samany the number of spines per leaf and spine length were in the average of 15-29 and 4-13 cm, respectively.

Yield parameters, number of bunches and fruit physical characteristics

It is clear from obtained data in *Tables 3* and *4* and *Fig. 1* showed that Barhy cv., had the highest values in most studied fruit physical characteristics as compared to other studied cultivars. It, was gave the highest fruit weight (15.23 and 16.33 g), flesh weight (13.89 and 14.99 g) and flesh percentage (91.11 and 91.76%). While, Sewy cv. gave the highest seed weight (1.71 and 1.80 g).

Table 3. *Yield parameters, number of bunches and fruit physical characteristics of five date palm cultivars grown under New Valley condition during first season (2016)*

Strains	Fruit weight (g)	Flesh weight (g)	Seed weight (g)	Seed length (cm)	Fruit length (cm)	Fruit diameter (cm)	Flesh %	No-bunch/ palm	Yield/ palm
Bartamoda cv	6.17d	5.16d	1.00c	2.3b	4.38b	2.04c	83.77c	10cd	89cd
Sakoty	8.34c	7.42c	0.91c	2.74a	5.00a	1.98c	88.98ab	8.8d	80.5d
Soltany	11.16b	9.52b	1.64a	2.46ab	3.36e	2.00c	85.16c	12.2bc	98.16c
Sewy	14.70a	12.98a	1.71a	2.4b	4.18c	2.58b	88.28b	13.8b	132.2b
Barhy	15.23a	13.89a	1.34b	1.8c	3.62d	3.12a	91.11a	18.8a	195.4a

Values with the same letter in the same column are not significant at ($P \geq 0.05$)

On other hand, Sakoty cv. gave the lowest value of fruit diameter (1.98 and 1.96 cm) and seed weight (0.91 and 0.91g). Also, Bartamoda cv., recorded the lowest value of flesh percentage (83.77 and 82.63%).

Table 4. *Yield parameters, number of bunches and fruit physical characteristics of five date palm cultivars grown under New Valley condition during second season (2016)*

Strains	Fruit weight (g)	Flesh weight (g)	Seed weight (g)	Seed length (cm)	Fruit length (cm)	Fruit diameter (cm)	Flesh %	No-bunch/ palm	Yield/ palm

Figure 1. *The fruit of five date palm cultivars.* ***1*** *Bartamoda,* ***2*** *Sakoty,* ***3*** *Soltany,* ***4*** *Sewy, and* ***5*** *Barhy*

Regarding number of bunches and yield/palm, Barhy cv., had the highest number of bunches (18.8 and 18.66) and yield/palm (195.4 and 197.21 kg) followed by Sewy cv. in both seasons. On other hand, Sakoty cv. gave the lowest number of bunches (9 and 8.8) and yield/ palm (80.5 and 81 kg). These results are in harmony with present results those obtained by Abo-Rekab et al. (2014), Idris et al. (2014), Mortazavi et al. (2015), Nasir et al. (2015), Omaima, et al. (2015), Qadri et al. (2016), Abd-El Hamed, et al. (2017). Who found that Sakoti gave the lowest seed weight in both seasons (0.961 and 0.985 g, respectively) (Abo Rekab et al., 2010). These data are in agreement with El-Merghany et al. (2013) they found that Barhy cv. gave the highest yield/palm in the second season.

Chemical properties

Data presented in *Table 5* showed the chemical properties of five date palm cultivars. Results showed that Sewy cv. gave the highest value of reducing and total sugar (65.41 and 64.88) and (74.64 and 74.46) respectively, while Barhy cv. recorded the highest moisture % (31.56 and 31.23%) as compared to other date palm cultivars.

Barhy	31.56a	31.23a	57.83c	58.16c	0.187c	0.188b	37.66b	38.00b	14.00d	13.66d	51.66d	51.66c

Values with the same letter in the same colum are not significant at ($P \geq 0.05$)

Also, Soltany cv. had the highest of acidity (0.223 and 0.223%). On other hand, Bartamoda cv. gave the lowest value of reducing sugar (7.33 and 7.48%). While, Sakoty cv. had the lowest of moisture % (12.93 and 12.96%). Also, Barhy cv. recorded the lowest of total sugars (51.66 and 51.66). These results are in agreement with many researchers such as Gadalla et al. (2013), Idris et al. (2014), Mortazavi et al. (2015), Nasir et al. (2015), El-Salhy et al. (2016), Qadri et al. (2016), Abd-El Hamed et al. (2017), who found that Barhy at khalal stage gave the lowest total sugars percentage (51 and 50%) in both season. Youssef et al. (1998) found that total sugars concentration in fruits of eight date palm cultivars (from different areas of Upper Egypt) were ranged from 73.65 to 81.77% for dry cultivars.

Identification of ISSR-PCR markers

To determine the genetic relationships among the 5 date palm cultivars, ISSR profile resulting from using 5 tested primers, i.e. 14A, 44B, HB- 09, HB-12 and HB-15 were illustrated in *Table 6* and *Figure 2*.

Table 6. *The ISSR analysis products produced by the five primers investigated of ten date palm seedlings strains as well as Bartamoda cultivar. (1 means presence and 0 means absence)*

Genetic similarity and cluster analysis based on ISSR-markers

The ISSR data were used to estimate the genetic similarity among five date palm cultivars by using UPGMA computer analysis as presented in *Table 8*.

Table 8. *Genetic similarity matrices among the ten dry seedlings strains as well as Bartamoda cultivar accessions as compute according to Dice coefficient from ISSR*

Similarity	Sewy	Soltany	Bartamoda	Sakoty
Soltany	0.81	1.00		
Bartamoda	0.77	0.61	1.00	
Sakoty	0.84	0.78	0.76	1.00
Barhy	0.84	0.78	0.77	1.00

The highest similarity index (1.00) was recorded between Barhy and Sakoty date palm cultivar, while the lowest similarity index (0.61) was detected between Bartamoda and Soltany.

A dendrogram for the genetic relationship among the five date palm cultivars was drawn in *Figure 3* which separated cultivars into two major cluster.

The first cluster contained the Bartamoda cultivar while the second cluster was divided into two subcluster where the first sub cluster included Soltany cultivar, while the second sub cluster consisted of two group, the first group included Sakoty and Bartamoda cultivars, whereas the second group included Sewy cultivar. The results of

DOI: http://dx.doi.org/10.15666/aeer/1706_1364313655

ISSR are in harmony with Sami et al. (2004). They concluded that the cultivar Siwi characterized by a unique positive marker (OPB05 $_{1700}$ bp). Zeinab et al. (2014) reported that using ISSR analysis which gave two specific DNA band with molecular size 640 and 160 bp were absent (negative marker) for Shamia and Sakoty cultivar, respectively.

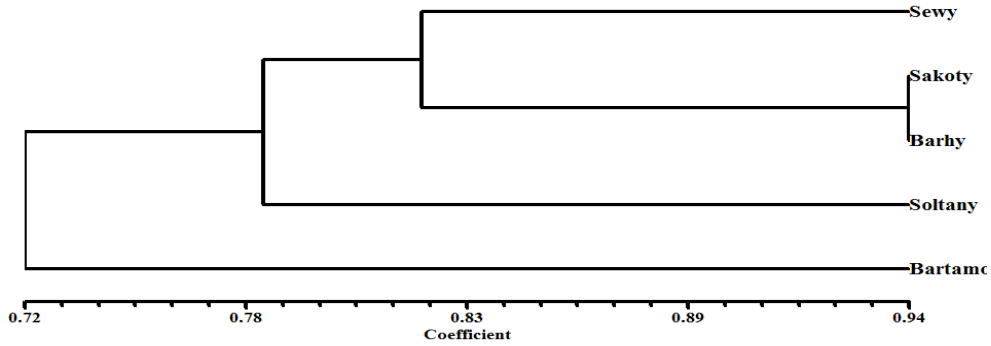

Figure 3. *Dendrogram for the five date palm cultivars as accessions constructed from the ISSR data using unweighed pair-group arithmetic (UPGMA) and similarity matrices computed according to Dice coefficient*

Conclusion

This morphological variation showed that the date palm varieties accessions under study were phenotypically different individuals. The results indicated the existence of diverse accessions in date palm germplasm in spite of similar morphological characters present in genotypes.

Thus, the SSR markers are effective to identify diversity or closeness in genotypes which may contribute to fasten the breeding programs and help in date palm crop improvement.

Abstract. Understanding the differences of labile soil organic matter between plastic film mulching at all growing stages (FM) and plastic film removal after the silking stage (RM) is essential to identify changes in soil quality and N availability. Compared to the FM treatment, the RM treatment significantly decreased the microbial biomass C (MBC) content, water soluble organic C content in the 0-20 cm layer and extractable organic C content in 2011 at milk stage (R3); however, it significantly increased the MBC content at planting time (PT) or the 6th leaf stage (V6) of the next growing season. Moreover, compared with the FM treatment, the RM treatment significantly increased the microbial biomass N content from silking stage to physiological maturity (R6) in the 0-20 cm layer and extractable organic N (EON) content at R6 in 2012; however, it significantly decreased the water soluble organic N (WSON) content at R3 and the WSON and EON contents at PT or V6 of the next growing season. Thus, plastic film mulching with film removal during the maize reproductive stages could be an excellent option for maintaining soil quality and improving soil N availability in the temperature- and rainfall-limited regions of northwest China.
Keywords: *plastic film mulching, microbial biomass carbon, microbial biomass nitrogen, dissolved organic carbon, dissolved organic nitrogen*

Introduction

Plastic film mulching is a worldwide agricultural technology with direct economic and environmental benefits, such as improving crop productivity, increasing water-use efficiency, improving soil quality, reducing greenhouse gas emissions, and reducing nitrate leaching (Wang et al., 2017; Liu et al., 2014b, 2015, 2016). The Loess Plateau has a typical semi-arid monsoon climate, in which maize (*Zea mays* L.) is one of the most common grain crops; however, low temperature and drought in the early growth stage of spring crops often lead to low crop yield (Liu et al., 2009). Up to this day, plastic film mulching has been widely used on the Loess Plateau (Zhou et al., 2012; Liu et al., 2014c; Li et al., 2018), which can significantly improve crop yield by increasing soil moisture and topsoil temperature (Liu et al., 2010; 2014a; Bu et al., 2013b). The rainy season on the Loess Plateau ranges from July to September and coincides with the spring maize reproductive stages (RS) (Liu et al., 2010). During this period, plastic film mulching is detrimental to crop yield, in some conditions (e.g., high air temperatures),

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1365713672

most likely because it increases soil temperature and accelerates leaf and root senescence during the spring maize RS (Liu et al., 2010, 2014a). Compared with plastic film mulching for the entire maize growing season, plastic film removal during the spring maize RS decreased the leaf and root senescence rate and increased the final crop yield (Liu et al., 2014a; Luo et al., 2016). Although there are some reports about the effects of different mulching periods during crop growing season on crop yield and soil properties (Wang et al., 2009; Luo et al., 2016), there is limited information about the effects of plastic film removal during the spring maize RS on labile soil organic matter (SOM) pools, relative to retaining them throughout the whole maize growing season. Our previous studies have shown that plastic film removal during the spring maize RS significantly increased soil organic carbon (SOC), total nitrogen (TN), extractable organic C (EOC), $KMnO_4$-oxidizable C ($KMnO_4$-C) and C management index (CMI) in the 0-20 cm layer, as well as light fraction organic C (LFOC), light fraction organic N (LFON), microbial biomass C (MBC), EOC, extractable organic N (EON), $KMnO_4$-C and CMI in the 20-40 cm layer after the 5-yr cultivation (Luo et al., 2016).

As labile SOM pools, soil microbial biomass and dissolved organic matter are strongly affected by soil management and therefore sensitive and important parameters of soil fertility and quality (Haynes, 2005). Soil microorganisms are responsible for transforming organic matter into inorganic nutrients (Ryan et al., 2009). Dissolved organic matter (DOM) represents a mobile source of energy and food for soil microorganisms (Kalbitz et al., 2000) and a primary source of mineralizable N, P and S, thus making a significant contribution to nutrient availability and cycling (Haynes, 2005). Accordingly, measuring labile SOM fractions such as MBC, microbial biomass N (MBN), water soluble organic C (WSOC), water soluble organic N (WSON), EOC and EON are essential to identifying changes in soil quality and fertility. A few studies have investigated the effects of fertilization and plastic film mulching on the changes of soil microbial biomass during maize growth (Liang et al., 2011; Liu et al., 2014c). Until now, little has been known about the effects of plastic film removal during the spring maize RS on the changes of soil microbial biomass and other labile SOM fractions in semiarid farmland. This study was designed to: (1) reveal the impacts of plastic film removal during the spring maize RS on the labile SOM pools during the whole maize growth; and (2) evaluate the effects on soil fertility and environmental sustainability. We hypothesized that the changes in labile organic C and N pools with the plant growth vary largely between retaining and removing plastic film during the spring maize RS, thereby generate the cumulative effect of early season residue inputs for the next growing season. This information will be useful for understanding the SOM dynamics and developing the integrated management practices to improve SOM quantity and quality in a spring maize cropping system on the semiarid Loess Plateau.

Materials and methods

Site description

The study was conducted in 2011 and 2012 at Changwu Agricultural and Ecological Experimental Station (35.28°N, 107.88°E, 1200 m altitude), which is located in semiarid area on the Loess Plateau of China (*Fig. 1*). The environmental information and soil properties of study site were described in Luo et al. (2016). The annual mean air temperature is 9.7 °C, and the average annual precipitation from 1957 to 2010 is 582 mm with 73% of this falls during the maize growth season. The soil at the study site

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1365713672

is developed from loess and had a silt loam texture according to the USDA texture classification system. The soil properties at the top 20 cm were: bulk density 1.3 g cm^{-3}, pH 8.4, SOC 8.2 g kg^{-1}, TN 1.05 g kg^{-1}, mineral N 28.8 mg kg^{-1}, available phosphorus (Olsen-P) 20.7 mg kg^{-1}, and available potassium (NH_4OAc-K) 133.1 mg kg^{-1} in April 2009, prior to the start of the experiment (Luo et al., 2016).

Experimental design and field management

The detail information of experimental design and field management were described in Luo et al. (2016). We applied two treatments, including plastic film mulching during all growing stages (FM) and plastic film removal at the silking stage (RM), to maize plots with a density of 85,000 plants ha^{-1}. A high-yielding maize hybrid (Pioneer 335) was used in this study. The treatments were applied to 56 m^2 (8 m × 7 m) plots arranged in a randomly block design with three replicates. After ridging the treatment plots, chemical fertilizers were broadcast over the soil at a rate of 90 kg N ha^{-1} in the form of urea (containing 46% N), 40 kg P ha^{-1} in the form of calcium super phosphate (12% P_2O_5), 80 kg K ha^{-1} in the form of potassium sulfate (45% K_2O), and 30 t ha^{-1} organic manure was broadcast over the soil; the soil was then plowed to mixed the fertilizer into the subsurface. Plastic film (0.005 mm thick, 1.2 m wide and transparent) was used to cover the soil. The maize was planted at 5 cm deep using a hole-sowing machine on 21 and 28 April in 2011 and 2012, respectively, and maize plants were harvested on 5 and 19 September in 2011 and 2012, respectively.

All of the plots were top-dressed twice with 67.5 kg N ha^{-1} (urea, 46% N) during the 10th leaf stage (V10) and silking stage (R1) recorded according to the standardized maize development stage system (Ritchie et al., 1992), using the same handheld device as used for sowing.

Sampling and measurements

The standardised maize development stage system was used to identify the vegetative (VS, from seedling emergence to silking) and reproductive (RS, from silking to physiological maturity) stages of the entire growing season (Ritchie et al., 1992). During the growing season, three adjacent plants were sampled at the 6th leaf stage (V6), V10, R1, milk stage (R3) and physiological maturity (R6) to measure the aboveground biomass. At maturity, the grain yield was measured for all plants selected from a 10 m^2 area in each plot. The aboveground biomass and grain yield were determined based on the average of three plot replicates, and all samples were dried to a constant weight in a fan oven at 75 °C.

Soil samples were collected at planting time (PT, before fertilization and sowing), V6, V10, R1, R3 and R6. At each plot, soil cores were drilled randomly using a 4-cm diameter auger with five replications and then mixed together to form one composite sample for every soil depth (0-20 cm and 20-40 cm). Soil moisture of each sample was measured after removing visible plant residues and sands, and then soil sample passed through a 2-mm sieve. The samples were refrigerated (0-4 °C) until MBC, MBN, WSOC, WSON, EOC and EON were determined.

MBC and MBN were measured using a modified chloroform fumigation-extraction method (Brookes et al., 1985; Vance et al., 1987). Briefly, 12.5 g fresh soil samples were fumigated with alcohol-free chloroform at 25 °C for 24 h. Excess chloroform was removed by repeated evacuation, the fumigated and non-fumigated samples promptly were extracted with 50 mL 0.5 mol L^{-1} K_2SO_4 (soil/solution ratio of 1:4 w/v) on a rotary shaker at 220 r min^{-1} for 0.5 h. After shaking, the supernatant was filtered using a membrane filter, and then filtrate was immediately frozen at -20 °C. Total organic C concentration in the filtrate was measured using an automated total organic C analyzer (TOC-Vcph, Shimadzu, Japan). Total soluble N in the filtrate was followed by alkaline persulfate oxidation and measured by dual-wavelength ultraviolet spectrophotometry (Norman et al., 1985; Cabrera and Beare, 1993). MBC and MBN were calculated by taking the difference between total organic C and soluble N of the fumigated and non-fumigated soils, respectively. A K_C value of 0.45 (Vance et al., 1987) and a K_N value of 0.54 (Brookes et al., 1985) were used to calculate the C and N content of the microbial biomass.

WSOC and WSON were extracted from 20 g fresh soil with 40 mL deionized water (soil/solution ratio of 1:2 w/v) at 25 °C. After shaking at 250 r min^{-1} for 0.5 h, and then centrifuging for 10 min at 8000 r min^{-1}, the supernatant was filtered using a 0.45-μm membrane filter, and then filtrate was immediately frozen at -20 °C (Liang et al., 1998). EOC and EON were extracted from 10 g of fresh soil with 50 mL 0.5 mol L^{-1} K_2SO_4 (soil/solution ratio of 1:5 w/v) at 25 °C. After shaking for 1 h at a speed of 220 r min^{-1}, the supernatant was filtered using a 0.45-μm membrane filter, and then filtrate was immediately frozen at -20 °C (Jones and Willett, 2006). Total organic C concentration in the filtrate was measured using an automated total organic C analyzer (TOC-Vcph, Shimadzu, Japan). The filtrate was later defrosted at room temperature and analyzed for mineralization N (NH_4^+-N and NO_3^--N) with a continuous flow analyzer (FLOWSYS, Italy), and total soluble N by dual-wavelength ultraviolet spectrophotometry after alkaline persulfate oxidation (Cabrera and Beare, 1993; Norman et al., 1985). Total organic N concentration in the filtrate was calculated by taking the difference between total soluble N and mineralization N.

Statistical analysis

The effects of plastic film removal on the measured parameters were evaluated using Independent-Samples T-Test. In all cases, differences were deemed to be significant if $p < 0.05$ using SPSS version 20.0.

Results

Air temperature and precipitation

The monthly precipitation and mean air temperature at the study site during the two experimental years were measured at the Changwu meteorological monitoring station, which is situated within 50 m of the experimental site (*Fig. 2*). One wet year occurred in 2011 and one dry year occurred in 2012 compared with the average for the preceding 54 yr (1957–2010). In this study site, the annual mean air temperatures were both 9.4 °C in two years, and the precipitation was 644 mm in 2011 and 481 mm in 2012. During the maize growth season (May to September), the mean air temperature was 18.2°C in 2011 and 18.7 °C in 2012, which is lower than the 54-yr mean (19.0 °C), and the precipitation was 14% greater than the 54-yr mean (426 mm) in 2011 and 15% less than the 54-yr mean in 2012. The precipitation during the rainy season (July to September) was 25% greater than the 54-yr mean (310 mm) in 2011 and close to the 54-yr mean in 2012. Compared with the 54-yr mean, the precipitation was greater in spring maize reproductive stages of 2011, and lower in spring maize vegetative stages of 2012. The mean air temperature during the rainy season was 18.4 °C in 2011 and 19.1 °C in 2012, which is lower than the 54-yr mean (19.8 °C).

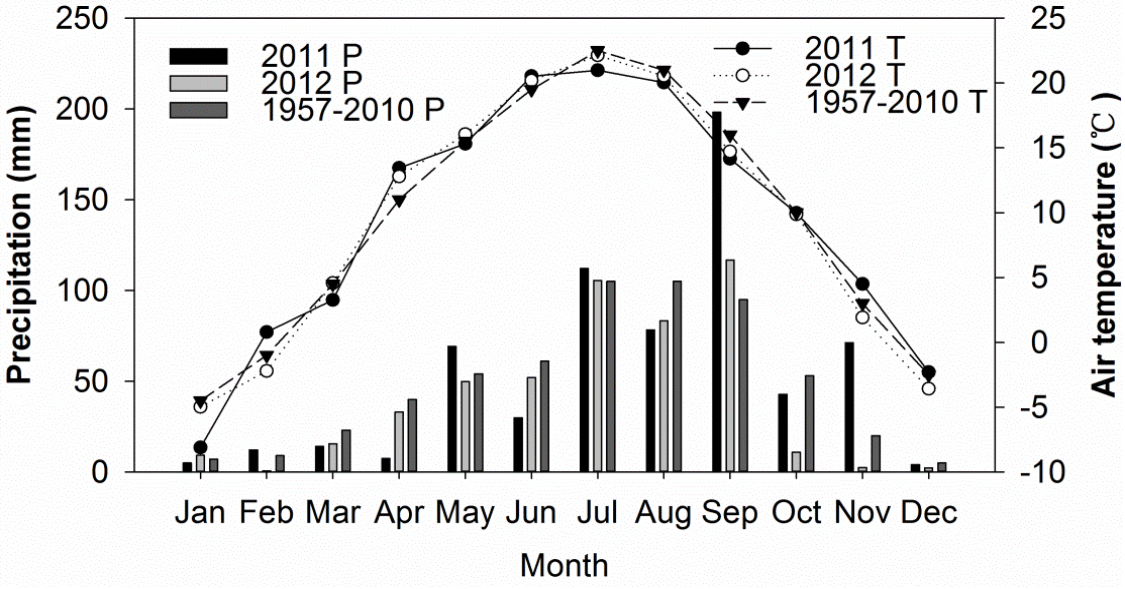

Figure 2. *The monthly precipitation (P) and mean air temperature (T) at the study site*

Total aboveground biomass and grain yield

Compared with the FM treatment, the RM treatment significantly increased the total aboveground biomass at V6 and V10 in 2011 and at V10 in 2012 (*Table 1*). However,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1365713672

there was no significant difference in the total aboveground biomass between the two treatments from R1 to R6 (*Table 1*). *Table 1* shows that plastic film removal had no significant effect on the aboveground biomass during the RS (from R1 to R6) of the current growing season, but it may promote the aboveground biomass during the VS (V6 or V10) of the next growing season. Compared with the FM treatment, the RM treatments lightly increased the grain yield by 8.7% in 2011 and 4.1% in 2012, while the differences were not significant (*Table 1*).

Table 1. *Effects of plastic film mulching (FM) and removal (RM) on the total aboveground biomass and grain yield in 2011 and 2012*

Sampling time		Total aboveground biomass (t ha^{-1})		Grain yield (t ha^{-1})	
		FM	RM	FM	RM
2011	V6	0.58b	0.71a		
	V10	4.92b	5.71a		
	R1	12.76a	11.78a		
	R3	19.69a	19.67a		
	R6	23.56a	24.43a	14.42a	15.67a
2012	V6	0.75a	0.76a		
	V10	5.25b	5.83a		
	R1	11.63a	11.79a		
	R3	17.10a	16.85a		
	R6	23.65a	24.17a	14.57a	15.17a

Means (n = 3) followed by different lowercase letters within a row are significantly ($p < 0.05$) different between mulching practices. V6, V10, R1, R3, R6 denote the 6th leaf stage, the 10th leaf stage, silking stage, milk stage and physiological maturity, respectively

Microbial biomass C and N

Microbial biomass C content ranged from 175.9 to 454.0 mg kg^{-1} in the 0-20 cm layer (*Fig. 3a, b*), compared to a range of 107.9 to 227.8 mg kg^{-1} in the 20-40 cm layer (*Fig. 3c, d*). The MBC content was higher in the 0-20 cm layer than that in the 20-40 cm layer ($p < 0.001$). Meanwhile, the MBC content was higher during the wet year (2011) than that during the dry year (2012) at sampling times from V6 to R1 ($p < 0.001$). For most of sampling times, the two layers had a similar trend in the MBC content. Compared with the FM treatment, the MBC content under RM significantly increased at V6 in 2011 and at PT in 2012 in the 0-20 cm layer (*Fig. 3a, b*), as well as at PT in 2011 and 2012 in the 20-40 cm layer (*Fig. 3c, d*); the MBC content under RM significantly decreased at R3 in 2011 and 2012 in the 0-20 cm layer (*Fig. 3a, b*). *Figure 2* shows that plastic film removal had a significant negative effect on the MBC content at R1 of the current growing season in the 0-20 cm layer, but it may promote the MBC content at PT or V6 of the next growing season in the two layers.

Microbial biomass N content ranged from 17.5 to 76.9 mg kg^{-1} in the 0-20 cm layer (*Fig. 3e, f*), compared to a range of 14.2 to 37.3 mg kg^{-1} in the 20-40 cm layer (*Fig. 3g, h*). The MBN content was higher in the 0-20 cm layer than that in the 20-40 cm layer

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1365713672

($p < 0.001$). The MBN content was lower during the wet year (2011) than that during the dry year (2012) at sampling times from V10 to R6 ($p < 0.001$). For most of sampling times, the two layers had a similar trend in the MBN content.

Water soluble organic C and N

Water soluble organic C content ranged from 51.2 to 122.7 mg kg^{-1} in the 0-20 cm layer (*Fig. 4a, b*), compared to a range of 29.3 to 76.5 mg kg^{-1} in the 20-40 cm layer (*Fig. 4c, d*). The WSOC content was higher in the 0-20 cm layer than that in the 20-40 cm layer ($p < 0.001$). For most of sampling times, the two layers had a similar change trend in the WSOC content. In 2011, compared with the FM treatment, the RM treatment generally decreased the WSOC content in the 0-20 cm layer, whereas increased that in the 20-40 cm layer (*Fig. 4a, c*). Compared with the FM treatment, the RM treatment significantly decreased the WSOC content in the 0-20 cm layer at PT in 2011 and at R3 and R6 in 2012 (*Fig. 4a, b*), whereas significantly increased that in the 20-40 cm layer from R1 to R6 in 2011 and from V10 to R3 in 2012 (*Fig. 4c, d*). *Figure 3* shows that plastic film removal had a significant active effect on the WSOC content in the 20-40 cm layer during the rainy season (from R1 to R3) in two years.

Water soluble organic N content ranged from 2.6 to 20.0 mg kg^{-1} in the 0-20 cm layer (*Fig. 4e, f*), compared to a range of 1.5 to 15.5 mg kg^{-1} in the 20-40 cm layer (*Fig. 4g, h*). For most of sampling times, the two layers had a similar change trend in the WSON content. Compared with the FM treatment, the RM treatment significantly decreased the WSON content in the 0-20 and 20-40 cm layers at R3 in two years (*Fig. 4e-h*); meanwhile, the RM treatment significantly decreased the WSON content in the 20-40 cm layer at PT in two years and at V6 and R6 in 2012 (*Fig. 4g, h*). *Figure 3* shows that plastic film removal had a significantly negative effect on the WSON content in the whole 0-40 cm layer at R3 and this negative effect may persist into the early stage of the next growing season in the 20-40 cm layer.

Extractable organic C and N

Extractable organic C content ranged from 58.7 to 144.3 mg kg^{-1} in the 0-20 cm layer (*Fig. 5a, b*), compared to a range of 27.9 to 68.1 mg kg^{-1} in the 20-40 cm layer (*Fig. 5c, d*). The EOC content was higher in the 0-20 cm layer than that in the 20-40 cm layer ($p < 0.001$). For most of sampling times, the two layers had a similar change trend in the EOC content. Compared with the FM treatment, the RM treatment significantly decreased the EOC content in the 0-20 and 20-40 cm layers at R3 in 2011 (*Fig. 5a, c*); meanwhile, the RM treatment significantly decreased the EOC content at R3 in the 0-20 cm layer in 2012 (*Fig. 5b*). *Fig. 4* shows that plastic film removal had a significantly negative effect on the EOC content in the 0-20 cm layer at R3 in two years and this negative effect may extend into the 20-40 cm layer at R3 in the wet year (2011).

Extractable organic N content ranged from 8.2 to 26.0 mg kg^{-1} in the 0-20 cm layer (*Fig. 5e, f*), compared to a range of 5.6 to 16.2 mg kg^{-1} in the 20-40 cm layer (*Fig. 5g, h*). The EON content was higher in the 0-20 cm layer than that in the 20-40 cm layer ($p < 0.001$). For most of sampling times, the two layers had a similar change trend in the EON content. Compared with the FM treatment, the RM treatment significantly decreased the EON content in the 0-20 cm layer from PT to V10 in 2012 (*Fig. 5f*) and in the 20-40 cm layer at PT in two years (*Fig. 5g, h*), but the RM treatment significantly increased the EON content in the 0-20 and 20-40 cm layers at R6 in 2012 (*Fig. 5f, h*).

Discussion

Effects of plastic film removal on soil microbial biomass C and N

Maintenance of satisfactory level of SOC and TN are necessary for crop productivity and sustainable agro-ecosystems (Dong et al., 2018), because they play crucial roles in the soil quality and fertility (Zhao et al., 2015). Soil nitrogen (N) is one of the necessary nutrients for plant growth and development, as well as a major nutrient limiting factor for crop yield (Karra et al., 2018; Huang et al., 2018). Soil organic N content of approximately 70%-90% in surface soil could not only maintain soil N fertility (Xu et al., 2003), but also has an important function for soil N supply capacity (Ju et al., 2004). However, it is difficult to detect the significant changes of SOC and TN in response to management practices in the short-term (Haynes, 2005; Gong et al., 2009). It is known that soil C and N cycling in agro-ecosystems is mediated by soil microorganisms. Due to the rapid generation time of soil microbial biomass, MBC and MBN are thought to be the most labile SOM fractions (Brookes, 2001; Chen et al., 2009). MBC regulates soil organic matter decomposition, and MBN represents both a source and sink of mineral N; thus, they play key roles in maintaining agricultural ecosystems sustainability. Our previous studies have shown that the RM treatment could decrease soil water and temperature during the maize RS compared with the FM treatment (Bu et al., 2013a; Liu et al., 2014a). The lower topsoil moisture and temperature might decrease the decay of plant roots (Liu et al., 2014a), which could lead to increased input of root biomass and rhizodeposits under the RM treatment. In this study, plastic film removal had a significant negtive effect on the MBC contentat R1 of the current growing season in the 0-20 cm layer, but it may promote the MBC content at PT or V6 of the next growing season in the two layers (*Fig. 3*). Meanwhile, the higher topsoil moisture and temperature provide more substrates for promoting microbial biomass activity, which could lead to higher microbial biomass (Li et al., 2004; Zhou et al., 2012). Taken together, these observations suggest that plastic film removal significantly increased soil microbial biomass at PT or V6 (the maize VS), which was affected by the cumulative effect of early season residue inputs; however, it significantly decreased soil microbial biomass at R3 (the maize RS), which was affected by the lower topsoil moisture and temperature during the current growing season. Moreover, the uptake capacities of inorganic and organic N by plants varied with development stages and seasonal changes (Simon et al., 2011). In this study, plastic film removal generally increased the MBN content in the dry year (2012), especially in the upper layer of the maize RS (*Fig. 3*). Considering soil microbes generally compete effectively against plant roots for mineral N in soils (Dunnet al., 2006), plant roots may shift towards enhancing the utilization of organic N to avoid the intense competition between plants and microbes during the active growing stages (e.g., the maize RS with high N demands), when plant N demands are highest in the fields with low N availability (Rennenberg et al., 2009). These results probably reflect that the plastic film removal decreases the decay of plant roots, therefore increases the plant N demands; therefore, the increasing plant N demand enhances the utilization of organic N by plants and increases the microbial N immobilization.

Effects of plastic film removal on soil dissolved organic C and N

Dissolved organic matter (DOM) is the main source of available C and nutrients (e.g., N and P) for soil microorganisms and plants, therefore, largely governs nutrient

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1365713672

cycling in soil ecosystems (Marschner and Kalbitz, 2003). Although DOM fractions (e.g., dissolved Organic C (DOC) and dissolved Organic N (DON)) constitute only a very small proportion of the total SOM pool, they respond rapidly to the changes in soil moisture and temperature resulting from management practices (Luo et al., 2015a, b; 2016). Among the DOM fractions, DOC is retained in mineral soil horizons mostly by sorption onto mineral surfaces (Kaiser and Guggenberger, 2000), and is a readily available substrate for microorganisms and contains a mineralizable proportion of up to 95% (Don and Kalbitz, 2005); meanwhile, DON is composed of amino acids and other light organic molecules, and may represent a labile N source for soil microorganisms (Jones and Kielland, 2002). Dissolved organic C and N pools have been measured in various extracts, e.g., hot water (hot water extractable), cold water (simply water soluble, refer to WSOC and WSON used in this study), 0.5 M K_2SO_4 (refer to EOC and EON used in this study), and 2 M KCl etc (Ghani et al., 2003; Jones and Willett, 2006).

WSOC is composed of an array of molecules generally reflecting the composition of total SOC because the soluble phase tends to be in equilibrium with the solid phase of SOC (Chantigny, 2003), and is regarded as an indicator of soil quality and functioning (Saviozzi et al., 2001). In this study, compared with the FM treatment, the RM treatment significantly decreased the WSOC content in the 0-20 cm layer, whereas significantly increased that in the 20-40 cm layer at R3 in two years (*Fig. 4*). This most likely reflects that the plastic film removal helps the upper WSOC infiltrate into the lower layer with soil water migration during the rainy season. EOC is the primary energy source for soil microorganisms and is an indicator of the carbon availability to soil microorganisms; moreover, microbial metabolites also constitute a significant proportion of EOC (Kalbitz et al., 2000). In this study, compared with the FM treatment, the RM treatment significantly decreased the EOC content in the 0-20 cm layer at R3 in two years; however, in the 20-40 cm layer, this negative effect was significant in the wet year (2011) and insignificant in the dry year (2012) (*Fig. 5*). These results probably reflect that plastic film removal leads to a lower microbial reproduction rate and is more significant in the case of wet year and upper layer (high soil water content condition). DON is derived from microbial degradation of fresh and partially decomposed organic residues, including autochthonous soil organic N (Murphy et al., 2000). In general, the salt solution (e.g., 0.5 M K_2SO_4) extracted more soil organic N than coldwater. A salt extraction may disturb the adsorption equilibrium on soil surfaces, and organic N measured in these extracts may include N originally adsorbed on the surface of soil mineral and organic clays (Murphy et al., 2000). WSON is widely used as a surrogate for DON in soil solutions and includes the DON present in macropores and some smaller pores (Chantigny et al., 2008). In this study, compared with the FM treatment, the RM treatment significantly decreased the WSON content at R3, which may persist into the early stage of the next growing season in the 20-40 cm layer (*Fig. 4*). Taken together, these observations suggest that plastic film removal leads to the less release of soluble N that occurs after microbial degradation of the crop residues and/or the more utilization of soluble N by plants. Meanwhile, compared with the FM treatment, the RM treatment generally decreased the EON content during the maize VS period, but significantly increased the EON content at R6 in 2012 (*Fig. 5*). Taken together, these observations suggest that plastic film removal reduces the release of EON, which may be due to the less amounts of extracted N that are originally adsorbed on the surface of soil mineral and organic clays and/or the greater amounts of extracted N that are reused by soil microbes.

Conclusions

Removing plastic film during the maize RS may promote the aboveground biomass during the VS (V6 or V10) of the next growing season. Meanwhile, compared with the FM treatment, the RM treatment significantly decreased soil microbial biomass and SOM mineralization, whereas significantly increased soil microbial N immobilization at R3 of the current growing season; however, it significantly increased soil microbial biomass, whereas significantly decreased the DON pools at PT or V6 of the next growing season. Thus, plastic film mulching with film removal during the maize RS could be an excellent option for enhancing crop productivity, improving soil N availability and maintaining soil quality in the temperature- and rainfall-limited region of northwest China. The response of net soil organic nitrogen mineralization to RM should be further investigated in the future.

(Received 22nd Apr 2019; accepted 12th Jul 2019)

Abstract. This study constructs a community carbon emission assessment system based on the greenhouse gas emissions inventory of the Intergovernmental Panel on Climate Change (IPCC). The system contains three activities, namely, building service, transport, and waste treatment and disposal. A street community in Ya'an, Sichuan, China is taken as a typical case for the study, and its carbon emissions during 2015–2017 are measured to demonstrate the practical application of the proposed assessment system. The results indicate that electricity consumption, transport, and natural gas consumption contribute the most carbon emissions in the community, accounting for 40.3%, 25.6%, and 25.1% of the total emissions on average over the 3 years. The study has policy implications for low carbon consumption, and thus, can promote sustainable community development. Limitations regarding the measurement are given to lay the foundations for future research.
Keywords: *IPCC inventory, building service, transport, waste disposal, sustainable development*

Introduction

Residential living is a notable source of carbon emissions, accounting for about 30% of global emissions (Natarajan et al., 2011; Xu et al., 2015). In urban communities, which act as spaces for daily residential life, carbon emission assessment is an effective way to identify the most carbon-intensive sector and to provide insight into emissions reduction and energy savings, thereby promoting low-carbon development (Kennedy et al., 2009).

Carbon emission assessment for households has been discussed by a number of studies. Kenny and Gray (2009) established a metabolism model for urban households to measure their carbon emissions from the perspectives of energy consumption and waste disposal. Using this model, Christen et al. (2011) further incorporated transport, building usage, and food into the assessment of carbon emission. The results were compared with actual emissions monitoring results to validate the model. Kellett et al. (2013) improved the emission model based on the theory of carbon balance. However, the indirect carbon emissions associated with residential activities were omitted. Life cycle assessment (LCA), an emerging environmental assessment tool, can effectively measure the environmental impact of a product or service at all stages of its life cycle (Hellweg and Canals, 2014). The application of LCA is effective in revealing the embodied carbon emissions from household activities, thereby allowing holistic carbon accounting (Jones and Kammen, 2011). For example, Cuéllar-Franca and Azapagic (2012) used LCA to measure the carbon emissions from three types of common residences in the United Kingdom. Heinonen et al. (2013) applied LCA to dividing the boundaries of household activities into 12 categories to measure their carbon emissions. Wang et al. (2015) coupled LCA with input–output analysis to measure the indirect carbon emissions from household consumption. A similar approach was implemented by Miehe et al. (2016), who assessed the carbon emissions of households to determine their spatial heterogeneity.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1367313684

Ding et al. (2019) employed process life cycle assessment (PLCA) to measure direct and indirect carbon emissions by China's households.

However, carbon emission assessment of urban communities is scarcely considered in relevant literature. Although LCA is an insightful method for carbon emission assessment, it is difficult for unpractised engineers or designers to use owing to its complexity in the division of the system's boundary, and the acquisition of available data (Chen and Corson, 2014; Zhao et al., 2018a). In such a context, there have been requests for a simplified method to facilitate implementation of assessment in managerial practice, thus to help decision-makers better understand the assessment results and their associated decomposition (Zhang et al., 2018).

The present study aims to fill this gap by applying an assessment to community carbon emissions of various sectors based on the greenhouse gas (GHG) emissions inventory of the Intergovernmental Panel on Climate Change (IPCC), including direct and indirect emissions. Yucheng District in Ya'an City, Sichuan Province, China is taken as the case region for the assessment, owing to its progress in the development of a low-carbon community. The sector with the largest carbon emission in the area is identified, in order to develop policy implications for the creation of low-carbon lifestyles, thereby promoting sustainable regional development.

Methods and data

The Kyoto Protocol classifies carbon emissions into three categories, namely: (1) direct emissions from fossil fuel combustion; (2) indirect emissions from energy consumption, such as power use, cooling, and heating; and (3) emissions from a product or service (Andrew and Cortese, 2011). As households consume various categories of products or services, it is difficult to determine their emissions levels (Fan et al., 2012). Hence, this study mainly focuses on the carbon emissions from use of buildings, transport, and waste disposal within a community. These activities define the emissions boundary for the community, as shown in *Figure 1*.

Carbon emissions measurement

Carbon emissions are GHG emissions measured by carbon dioxide equivalent (Lin et al., 2013a; Zhao et al., 2017). The carbon emission of an urban community is measured as follows (IPCC, 2006):

$$E_i = L_i \times EF_i \times PV_p \quad \text{(Eq.1)}$$

where E_i is the carbon emissions from the i-th activity, L_i represents the i-th activity level, EF_i denotes the emissions factor corresponding to the i-th activity, and PV_p is the global warming potential of the p-th GHGs, where CO_2 (PV_1), CH_4 (PV_2), and N_2O (PV_3) are 1, 28, and 265, respectively.

The direct carbon emissions (E_1) produced by fossil fuels consumptions are calculated as follows (Ou et al., 2010):

$$E_1 = \sum_j (A_{1j} \times LC_j \times CC_j \times OC_j) \times \frac{44}{12} \times PV_1 \quad \text{(Eq.2)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1367313684

where A_{1j} refers to the consumption of the j-th fuel (kg), LC_j is the lower heating value of the j-th fuel (kJ/kg), CC_j is the carbon content per unit of heating value of the fuel (kg/kJ), and OC_j refers to the oxidation rate (%).

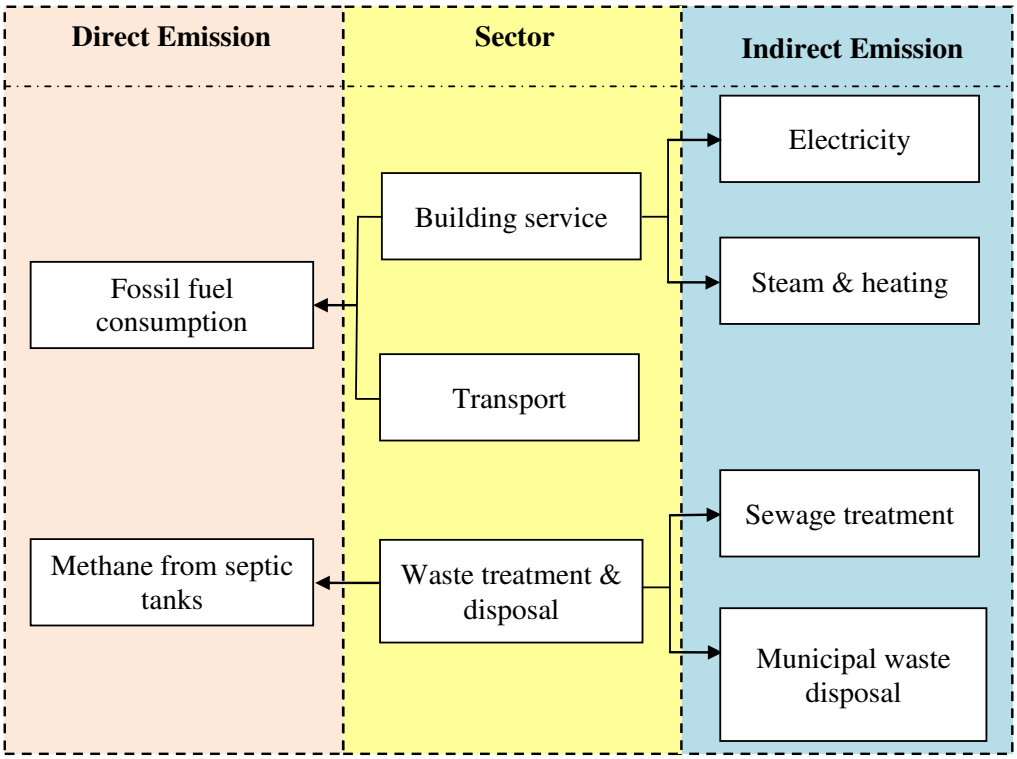

Figure 1. *Boundary of an urban community carbon emission assessment system*

The direct carbon emissions E_2 from septic tanks, which can be calculated based on the amount of escaped CH_4, are (Diaz-Valbuena et al., 2011):

$$E_2 = \left(A_{2j} \times \mathrm{DOC}_j \times \alpha_j - R_{2j}\right) \times \frac{16}{12} \times PV_2 \quad \text{(Eq.3)}$$

where A_{2j} is the amount of the waste disposed by the j-th septic tank (kg), DOC_j represents the degradable organic carbon content of the j-th septic tank (kg/kg), α_j refers to the disposal rate for the degradable organic carbon in the j-th septic tank (%), and R_{2j} is the amount of recovered CH_4 of the j-th septic tank (kg).

Indirect carbon emissions include emissions from electricity consumption, heating, and waste treatment and disposal. In particular, the indirect emissions from electricity consumption (E_3) are calculated as follows (Bi et al., 2011):

$$E_3 = A_3 \times F_3 \times PV_1 \quad \text{(Eq.4)}$$

where A_3 is power consumption (kWh), and F_3 is the average emission factor of the regional power grid (kg/kWh).

Indirect carbon emissions from heating (E_4) are calculated as follows (Bi et al., 2011):

$$E_4 = PV_1 \times \sum_j \left(S_j \times t_j \times F_{4j} \right) \quad \text{(Eq.5)}$$

where S_j is the residential area by using the j-th type of heating system (m^2), t_j is the time spent using the j-th heating system (h), and F_{4j} is the carbon emission intensity of using the j-th heating system (kg/(m^2·h)).

The carbon emissions from waste treatment and disposal are mainly composed of emissions from sewage treatment and municipal waste disposal. Among them, the carbon emissions from sewage treatment (E_5) are primarily converted from CH_4 and N_2O, and are calculated as follows (Listowski et al., 2011):

$$E_5 = [(TOW \times B_0 \times MCF_5) - R_5] \times PV_2 + C_N \times F_{N2O} \times 44/28 \times PV_3 \quad \text{(Eq.6)}$$

where TOW refers to the total amount of organic matters in the sewage (kg/kg), B_0 is the maximum production capacity of methane (kg/kg), MCF_5 is the methane correction factor, R_5 is the amount of recovered methane (kg), C_N refers to the nitrogen content in the sewage (kg/kg), and F_{N2O} refers to the N_2O emissions factor of the sewage (kg/kg).

The nitrogen content C_N in the sewage is calculated as follows (Listowski et al., 2011):

$$C_N = (P \times P_r \times C_{NPR} \times F_{NON\text{-}CON} \times F_{IND\text{-}COM}) - C_S \quad \text{(Eq.7)}$$

where P is the population (person), P_r is the per capita protein consumption (kg/person), C_{NPR} refers to the nitrogen content of proteins (kg/kg), $F_{NON\text{-}CON}$ refers to the non-consumption protein factor in the wastewater, $F_{IDN\text{-}COM}$ refers to the industrial and commercial protein factor, with a default value of 1.25, and C_S refers to the nitrogen removed from the sludge (kg).

The carbon emissions (E_6) generated from the disposal of municipal waste are measured as follows (Huang et al., 2018):

$$E_6 = (MSW_F \times L_0 - R_6) \times (1 - OX) \times PV_2 + PV_1 \times IW \times CCW \times FCF \times EF \times 44/12 \quad \text{(Eq.8)}$$

where MSW_F refers to the amount of municipal waste disposed in landfills (kg), L_0 refers to the methane production potential of the landfills (kg/kg), R_6 refers to the amount of recovered methane (kg), OX is the oxidation factor, IW refers to the total amount of municipal waste treated by incineration (kg), CCW refers to the carbon content of the municipal waste (%), FCF refers to the proportion of mineral carbon to the total carbon of the municipal waste (%), and EF is the combustion efficiency of incinerators (%).

The methane production potential (L_0) of landfills is measured as follows (Huang et al., 2018):

$$L_0 = MCF_6 \times DOC \times DOC_F \times F \times 16/12 \quad \text{(Eq.9)}$$

where MSF_6 refers to the methane correction factor of landfills (%), DOC is the content of degradable organic carbon in the municipal waste (kg/kg), DOC_F is the fraction of degradable organic carbon, and F refers to the proportion of methane in landfill gases.

Data sources

This study takes a community in Ya'an city as a case example to assess its carbon emissions from 2015 to 2017. The community was established in March 2002. It covers a total area of 1.8 square kilometers. It consists of administrative departments, vocational and technical colleges, primary schools, shops, and residential quarters. There are a total of 14,311 residents and 835 shops. Through a community survey, the major sources of carbon emissions have been identified, as shown in *Table 1*. Since the community has not established a central heating system, the carbon emissions are measured by electricity and natural gas consumption from household heating.

Table 1. *Identification of sources of carbon emission*

Activity	Emission source	Emission category
Building service	Natural gas consumption	Direct
	Electricity consumption	Indirect
Transport	Gasoline consumption	Direct
Waste treatment and disposal	Waste landfill disposal	Indirect
	Sewage treatment	Indirect

The data corresponding to different activity levels are shown in *Table 2*. The electricity and natural gas consumption of administrative departments, colleges, and primary schools, as well as their gasoline consumption from transport are obtained directly through questionnaire survey. Owing to a large number of households and shops in the community, a sample survey was conducted to obtain the corresponding activity levels.

Table 3 shows the emission coefficients, which are given priority over local emission coefficients, including the lower heating value of natural gas, the ratio of landfill disposal, and the degradable organic carbon content. The remaining emission factors are the default values provided by the Guide of Provincial Greenhouse Gases Inventory.

Results

The assessment results of the community from 2015 to 2017 are shown in *Table 4*. The carbon emissions for these 3 consecutive years are 14,446.69 t, 20,651.10 t, and 26,137.19 t, respectively. It is apparent that the carbon emissions of the community increase gradually, but their contributions differ by source.

From the perspective of carbon emission decomposition, *Figure 2a–c* illustrates that electricity consumptions contribute most of the total emissions during the period 2015–2017, accounting for 40.3% on average. The survey revealed that residents used a large variety of household appliances in their daily lives. In particular, because Ya'an has not implemented a central heating system, residents mainly rely on air conditioners for heating in winter, resulting in excessive power consumption and associated carbon emissions. The emissions caused by transport are the second largest, accounting for 25.6% of the total on average over the 3 years, followed by emissions from gas consumptions (25.1%). The findings are similar to those of Kellett et al. (2013) and Li et al. (2015), indicating that energy consumption and transport are major sources for household carbon emissions.

Table 2. *Activity levels of different emission sources in the case community*

Emission source	Data acquisition	Activity level			Unit
		2015	2016	2017	
Community population	Capita	9263	12982	14311	person
Natural gas consumption	Consumption	1,603,604	2,808,096	3,604,023	m^3
Electricity consumption	Consumption	10,305,642	15,852,530	20,760,705	kWh
Gasoline consumption	Consumption	1,944,096	2,303,386	2,922,453	L
CH_4 release from sewage treatment	Total organic matter	33.57	33.30	23.59	t
Waste disposal	Yield	3007.8	3363.7	3458	kg
N_2O release from sewage treatment	Per capita protein consumption	25.185			kg/person
	Non-consumption protein factor	1.5			%
	Protein factor in the sewage	1.25			%
	Nitrogen content in proteins	0.16			kg/kg
	Nitrogen removal by sludge	0			kg

Table 3. *Data of emission coefficient*

Emission source		Emission coefficient	Unit	Value	Source
Electricity consumption		Average emissions factor of the regional power grid	kg/kWh	0.5257	NDRC (2014)
Natural gas consumption		Lower heating value	kJ/m^3	34541	Field survey
		Carbon content per unit of heating	kg/kg	15.32	NDRC (2011)
		Carbon oxidation rate	%	99	NDRC (2011)
Gasoline consumption		Lower heating value	kJ/kg	43,070	SAC (2008)
		Carbon content per unit of heating	kg/kg	18.90	NDRC (2011)
		Carbon oxidation rate	%	98	NDRC (2011)
Sewage treatment	CH_4 emission	Maximum production capacity of CH_4	kg/kg	0.6	NDRC (2011)
		Methane correction factor	%	0.165	NDRC (2011)
		Amount of recovered CH_4	kg	0	NDRC (2011)
	N_2O emission	N_2O emissions factor	kg/kg	0.005	NDRC (2011)
Landfill disposal		Ratio of landfill disposal	%	100	Field survey
		Degradable organic carbon	kg/kg	0.1588	Local environmental protection agency
		Methane correction factor	%	40	NDRC (2011)
		Proportion of DOC	%	50	NDRC (2011)
		Proportion of CH_4 to landfill gases	%	50	NDRC (2011)
		Amount of recovered CH_4	kg	0	NDRC (2011)

Table 4. *Carbon emissions of the case community*

Emission source	Carbon emissions (t)		
	2015	2016	2017
Natural gas consumption	3,080.34	5,394.03	6,922.92
Transport	4,250.73	5,036.31	6,389.88
Electricity consumption	5,417.68	8,333.68	10,913.90
Municipal waste disposal	1,604.87	1,794.77	1,845.08
Sewage treatment	93.08	92.32	65.41
Total emissions	14,446.69	20,651.10	26,137.19

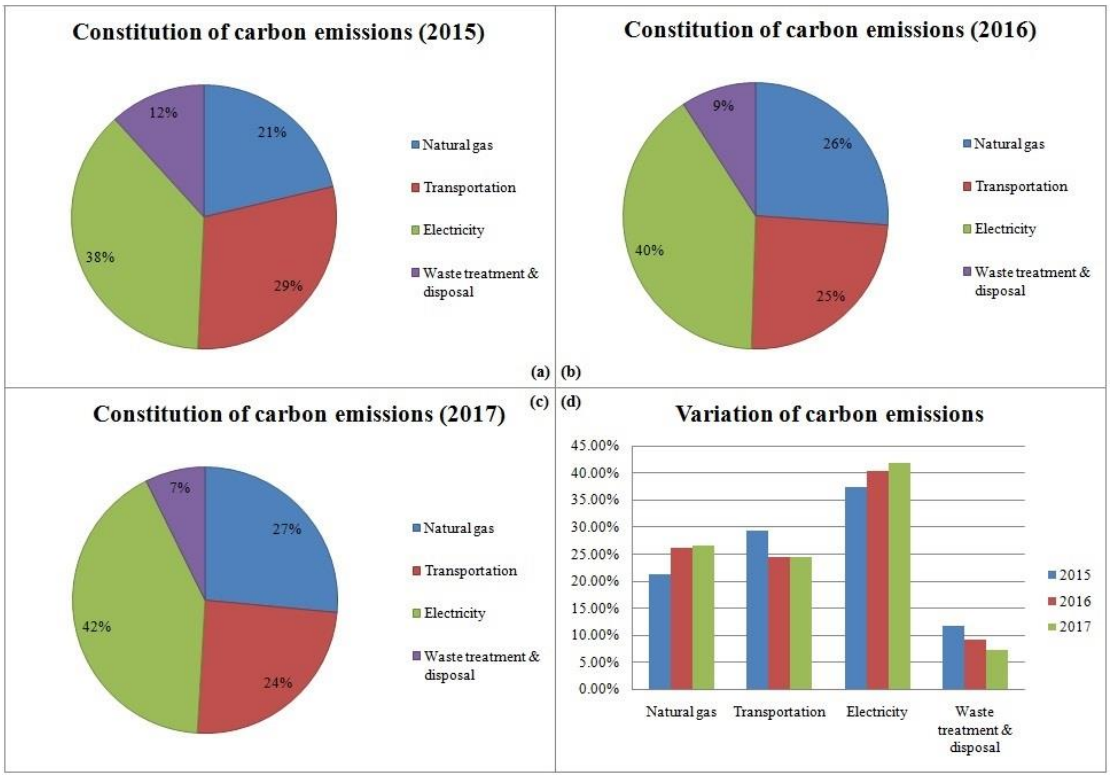

Figure 2. *The constitution of carbon emissions regarding the community*

Figure 2d shows that the proportions of carbon emissions contributed by electricity and natural gas consumptions increase gradually during the period 2015–2017. This may correspond to the population growth in the community. The carbon emissions contributed by transport increase slowly. On the contrary, the proportion of carbon emissions from waste treatment and disposal decreases during the 3 years. This may be the result of the promotion of waste sorting and recycling in the community, thereby reducing the volumes of landfill disposal.

Decomposition of the carbon emissions from building service

The carbon emissions of the community building usage in 2015, 2016, and 2017 are 8,498 t, 13,738 t, and 17,836 t, respectively. *Figure 3* shows that there are primarily three types of community building services that produce carbon emissions, namely,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1367313684

residential buildings, retail shops, and administrative departments. The emissions of the first two categories increase significantly during these 3 years.

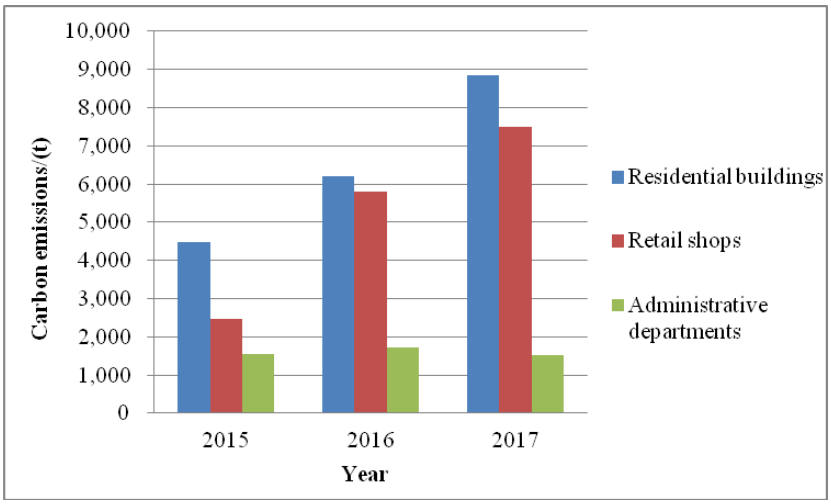

Figure 3. *Carbon emissions from usage of various buildings*

Decomposition of the carbon emissions from transport

The carbon emissions from transport in 2015, 2016, and 2017 are 4,250 t, 5,036 t, and 6,389 t, respectively, a significant increase, as shown in *Figure 4*. According to the survey, the transportation vehicles in the community are mainly comprised of private cars and business cars, of which the former contribute most of the carbon emissions.

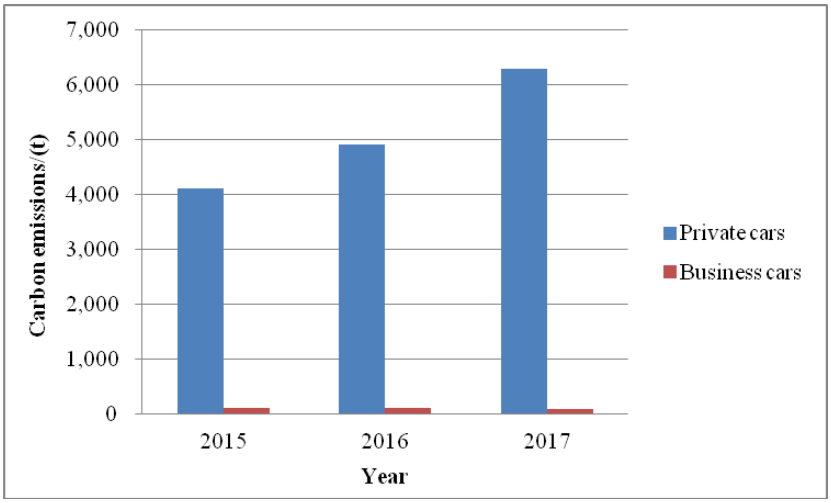

Figure 4. *Carbon emissions from transport*

Decomposition of the carbon emissions from waste treatment and disposal

Figure 5 shows that the carbon emissions from waste treatment and disposal in 2015, 2016, and 2017 are 1,698 t, 1,887 t, and 1,910 t, respectively. These account for approximately 4.7% of the total carbon emissions from the community. Sewage treatment contributes to less carbon emissions than waste disposal does.

Discussion

According to the assessment results, this study finds that electricity consumptions contribute most of the community's carbon emissions. This is similar to the findings of Lin et al. (2013b), indicating that more attention needs to be paid to emissions reduction of power supply. Transport and natural gas consumption account for 25.6% and 25.1%, respectively, of the total carbon emissions in the community, which is in line with the result of Ahmad et al. (2015). However, Büchs and Schnepf (2013) as well as Lee and Lee (2014) concluded that transport produces the most household carbon emissions. This difference may be due to variations in the boundary division, as the latter two studies incorporated long-distance travel of residents into the carbon emissions assessment by transport. Waste treatment and disposal produce a certain amount of carbon emissions, but the contribution is relatively small, indicating that it is not the key emissions source of the community (Kenny and Gray, 2009; Shirley et al., 2012).

Although electricity and natural gas consumptions are important sources of carbon emissions, our field survey reveals that there are huge variations among households. For example, the maximum average electricity consumption is 181 kWh per month while the minimum is only 74 kWh per month, indicating a polarization of carbon emission in the daily lives of households. In addition, there is large potential for emission reduction regarding transport in the community, since the residents mainly choose to use private cars. Thus, public transport can be encouraged through, for example, community buses and shared bicycles to reduce transport carbon emissions.

The research results have policy implications for low-carbon living. This study may provide impetus for the design of a community "carbon credit" incentive program (Zhao et al., 2018b). Through such a policy, the public can obtain credits to offset their carbon footprints through a number of environmentally friendly activities, such as green consumption, low carbon transport, waste sorting, and recycling (Starkey, 2012).

Conclusion

This study applies the IPCC GHG emissions inventory to assess the carbon emissions of a community located in Ya'an City during 2015–2017. The sector that

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1367313684

contributes to the largest emission is identified to propose appropriate policies on implementation of low carbon development. The results show that electricity, transport, and natural gas consumptions are the three largest emission sources, accounting for 40.3%, 25.6%, and 25.1% of the total, respectively. The energy consumption behavior significantly influences the community carbon emissions. Private cars leave large room for transport emission reduction of the community. The carbon emissions of waste treatment and disposal are lower than those of community building service and transport.

This study has certain limitations, mainly reflected in the uncertainties of the assessment results. First, the energy consumptions of shops and households are based upon the sampling estimation. Second, a number of default emission factors are used instead of actual measured values, which may have an impact on the results. Future study should focus on establishing a holistic inventory of emission related activities, and a corresponding emission factor database, to enable dynamic updates on urban community carbon emissions.

(Received 23rd Apr 2019; accepted 16th Jul 2019)

Abstract. Crop establishment methods and tillage practices significantly influence crop productivity by altering soil physical environment, root distribution and plant growth. The present study includes a combination of tillage practices for both rice and wheat i.e. deep tillage before rice (DTR) as well as wheat (DTW) along with conventional tillage before rice and wheat (CTRW) in main plots. The crop establishment methods i.e. no-tillage with residue (NTR) in wheat and direct seeded rice (DSR) were practiced in sub plots. These treatments were compared with traditional practices i.e. conventional tillage in wheat (CTW) and puddled transplanting in rice (PTR). It was reported that DTR and DTW results in 8% and 12% higher grain yields of rice and wheat, respectively over CTRW. Irrespective of crop establishment methods followed in rice, the NTR in wheat results in 7% higher wheat grain yield than CTW. The reduced soil mechanical resistance under deep tillage resulted in 18% and 22% more root length densities of rice and wheat than CT. Thus, among tillage practices, DTR and DTW and among crop establishment methods PTR and NTR are appropriate practices for sustaining crop productivity of rice-wheat systems in northwest India.
Keywords: *penetration resistance, deep tillage, direct seeding, puddled transplanting, water productivity*

Introduction

Rice-wheat is a prominent cropping system of Northwest India. The commonly followed practice in rice cultivation is puddled transplanting and for wheat it is conventional tillage (CT). These conventional practices are leading to soil degradation, poor productivity and environmental risks. For sustaining crop and water productivity of rice–wheat system, new tillage practices along with crop establishment methods need to be studied. No doubt puddling controls weed, reducing deep percolation losses of nutrients and water, but it also causes soil structural breakdown and create hard pan at shallow soil depth, which hinders root and water penetration and also cause poor aeration for succeeding wheat crop. Since, wheat is a deep rooted crop and requires favorable soil conditions without compaction for proper root proliferation. Many researchers have reported adverse effect of puddling on the yield of a subsequent wheat crop (Arora et al., 2006; Farooq et al., 2008; Gangwar et al., 2004). Sharma et al. (2003) noted that the negative effect of puddling on wheat is more pronounced in medium- to fine-textured soils than in light-textured soils. Ishaq et al. (2001) observed that subsoil compaction resulted in a reduction of both water and nutrient use efficiency in wheat by 38% owing to decreased root length. Unproductive losses of water in traditional rice cultivation resulted in alarming fall in water table that threatens sustainability of rice production. This fall has resulted in increased energy requirement and cost of pumping groundwater, increased tube well installation cost and deteriorated the ground water quality (AICRP, 2009; Kamra et al., 2002). Thus, there is a need to explore alternate techniques that can sustain rice production and are resource conservative. The underground water is being over exploited by excessive pumping to meet the water

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1368513699

requirement of transplanted rice. As a consequence, it has been causing a sharp decline in ground water table. Therefore, need has been felt to develop technically viable and economically feasible alternate techniques for growing rice in this region. The preliminary research conducted at Punjab Agricultural University indicated that DSR could be a viable alternative to PTR. The DSR offers many advantages such as more efficient water use, high tolerance to water deficit, less methane gas emission, reduced cultivation cost, prevents the formation of hard pan in sub-soil and minimizes labour input (Balasubramanian and Hill, 2002). It is more conducive to mechanization and also eliminates transplanting shock. However, the rice yield in most cases was higher (8-80%) under puddled transplanted rice (PTR) than under direct seeder rice (DSR). Other studies reported no difference in yield of rice under both crop establishment methods (Bajpai and Tripathi, 2000; Hobbs et al., 2002; Sharma et al., 1995, 2005). In India, yields were significantly lower (9-28%) in DSR than in PTR. However, DSR has several advantageous in poorly drained areas, it can be established earlier than PTR and does not incur growth delays from transplant injury; hence, it may hasten physiological maturity, reducing vulnerability to late-season drought (Tuong et al., 2000). Naklang et al. (1996) note that DSR had more root biomass than PTR. Some findings suggest that DSR achieves higher tiller density, leaf area, and vegetative biomass (Dingkuhn et al., 1990; Schnier et al., 1990), and that yields match or exceed PTR (Naklang et al., 1996; Saleh and Bhuiyan, 1995). Cultural practices like deep tillage in advance of soil puddling attempt to preserve the advantages of PTR while expanding the rooting zone above the plough sole. Akhtar and Quereshi (1999) found a depth-wise increase in root distribution from 12 to 20 cm and a yield benefit of 30% with adoption of deep tillage prior to PTR. By contrast, deep tillage preceding DSR may breech pre-existing plough soles, potentially exacerbating hazards posed by drought, weeds, and nutrient deficiencies from changes to the field water balance. As soil water dynamics in DSR is different from that of PTR, this is likely to affect water and nutrient uptake, and ensuing growth and crop yields. In semi-arid subtropical climatic conditions, DSR is expected to respond to changes in soil physical environment caused by deep tillage resulting in improved crop productivity. Deep tillage has emerged as a better option to improve deep root growth (advantageous for water extraction during drought in upland rice) of rice cultivars. Tillage under intensive cropping system has the additional challenges of ensuring high water use, nutrient use and energy use efficiencies through deeper and denser crop rooting (Gajri et al., 2002). The deep tillage before wheat also helps in enhancing root proliferation and enabling the plant to explore water and nutrient from deeper layers. Since, management of huge quantity of paddy straw produced every year is a serious problem in the region. Its management through no-tillage and surface residue retention (NTR) is another viable option for sustaining productivity. Keeping these points in view, a field study was conducted on sandy loam soil with the objective to evaluate impact of deep tillage on rice-wheat productivity under two crop establishment methods as DSR and PTR in rice and NTR and CT in wheat, respectively.

Materials and methods

Study area

This field experiment was conducted at the Research farm of Department of Soil Science, Punjab Agricultural University, Ludhiana. The site represent the Indo-gangetic alluvial plains situated at 30° 56’ N latitude and 75° 52’ E longitudes with an altitude of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1368513699

247 m above the mean sea level. The area is characterized by sub-tropical and semi-arid type of climate with hot and dry summer from April to June followed by hot and humid period during July to September and cold winters from November to January. The summer temperature touches 45 °C with dry summer spells. Winter experiences frequent frosty spells especially in December and January and minimum temperature dips up to 0.5 °C. The climatic data of study period is presented in *Figure 1*. The experiment comprised of three main tillage practices namely deep tillage before rice (DTR), deep tillage before wheat (DTW) and conventional tillage in both rice and wheat (CTRW). While, two methods of crop establishment for rice i.e. puddled transplanted rice (PTR) and direct seeded rice (DSR) and two methods of sowing for wheat i.e. no-tillage with residue (NTR) and conventional tillage (CT) kept in sub plots. The experiment was replicated thrice with plot dimensions of 4.0 m width and 10.0 m length. In CT plots the field was disked twice followed by two cultivators and one planking operation while in DT the field was deep ploughed up to 45 cm depth with 50 cm apart and then CT operations were performed for conventional till plots and only deep till operation was performed where, wheat has to be sown by no till practice. In NTR the sowing of wheat was made directly under no-till conditions with retention of loose crop residue and standing rice stubbles in the field. In PTR the rice seedlings of 30 day old nursery were transplanted in field, while in DSR the wet rice seed was sown directly with drill. The sole DT operation was performed even in no-tillage plots excluding all other CT practices i.e. disking, cultivator and planking operations. The soil was neutral, non calcareous in nature and sandy loam in texture (*Typic Ustochrept).* The data pertaining to physico-chemical characteristics of the studied soil is presented in *Table 1*. The sowing of DSR was performed following all recommended packages of practices in the first week of June, while PTR was transplanted in second week of June and wheat was sown in the first week of November. The row to row spacing was maintained as 20 cm in both rice and wheat. The harvesting of wheat and rice were performed in the month of April and October, respectively. The in-situ and laboratory determination were made for various soil physico-chemical characteristics at the end of the experiment.

EC = electrical conductivity; OC = organic carbon; BD = bulk density, FC = field capacity; PWP = permanent wilting point

Soil properties measurement

The in-situ determination of soil bulk density (ρ_b) was made with the help of cylindrical core having 7.5 cm height and 8.0 cm diameter at 0-15 and 15-30 cm depth. The cores were dried in an oven at 105 °C till the weight of the soil becomes constant. As given in *Equation 1,* the ratio of dry soil mass (M_s) and internal volume (V_t) of the cylindrical ring is expressed as ρ_b of soil (Mg m^{-3}) (Blake and Hartge, 1986).

$$BD = Ms / Vt \quad \text{(Eq.1)}$$

The penetration resistance (PR) of soil was measured with hand-held digital cone penetrometer (CP40II; Rimik electronics, RFM Australia) at five randomly selected locations within a plot. The soil PR was recorded up to 60 cm depth.

Soil infiltration rate was determined using double ring infiltrometer method while the saturated hydraulic conductivity (K_s) was determined using constant head method (Reynolds et al., 2002). For K_s determination undisturbed soil cores (8 cm diameter and 7.5 cm length) were collected from 0-7.5 and 7.5-15 cm depth. Samples were saturated in the laboratory. Saturated soil sample along with core was connected with another core and to avoid the water leakage grease was applied in the jointing place on the top of previous core. A thin layer of water was slowly poured on top of the sample by using siphons connected to a constant head device (Mariotte apparatus). The volume of water that percolates through the sample was measured at definite intervals of time. The K_s was calculated using *Equation 2.*

$$Ks = Q \times L / A \times t\,(H + L) \quad \text{(Eq.2)}$$

where: Ks = saturated hydraulic conductivity (cm hr^{-1}); Q = volume of percolate collected (cm^3); L = length of soil column (cm); A = cross sectional area of soil column (cm^2); t = time (hr); H = depth of water above soil (cm).

Determination of plant parameters, crop and water productivity

During the crop growing period of both the crops the agronomic data on plant height, straw and grain yield was recorded. The grain yield of both the crops were recorded in kg from 24 m^2 area in each plot and finally expressed in t ha^{-1}. The root distribution was measured at 120 days after sowing (DAS) in both rice and wheat, respectively. The root

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1368513699

samples were collected up to 40 cm depth in rice and 70 cm depth in wheat. For root sampling, the soil cores were taken with the help of core sampler of 5 cm diameter. Samples were taken in between the plant rows. The root-soil cores were then collected and washed in plastic nets. Roots were carefully separated from the soil by washing the nets under water. The washed roots were further cleaned to remove any leftover weed roots, seed and other organic debris. The root length density (RLD) (cm cm^{-3}) was calculated from the total length of roots measured by scanner to the volume of the core.

The water productivity (WP) was calculated by dividing the grain yield of corresponding treatment with the total water use (IW + RF + PWU) in particular treatment.

IW = amount of irrigation water applied (cm)
RF = rainfall during crop growth period (cm)
PWU = profile water use (cm)

The data collected on various aspects of the investigations were statistically analysed as prescribed by Cochran and Cox (1967) and adapted by Cheema and Singh (1991) in statistical package CPCS-I. The treatment comparisons were made at 5% level of significance.

Results

Land management impacts on soil mechanical and water transmission characteristics

Result revealed that soil bulk density (BD) was significantly influenced by tillage and crop establishment methods at both 0-15 and 15-30 cm soil depth (*Table 2*). Minimum soil BD (Mg m^{-3}) was recorded in DTW (1.53) followed by DTR (1.55) and maximum in CTRW (1.58) at 0-15 cm depth. Similar trend was observed for 15-30 cm depth. Among crop establish methods, lesser mean BD was recorded under DSR as compared to PTR for both the depth. Among combination of treatments the PTR-CT results in maximum BD (1.58 Mg m^{-3}), while DSR-NTR records minimum BD (1.53 Mg m^{-3}). However, these effects were found to be non significant (*Table 2*). The data pertaining to effect of tillage on mean penetration resistance (PR) is presented in *Figure 2*.

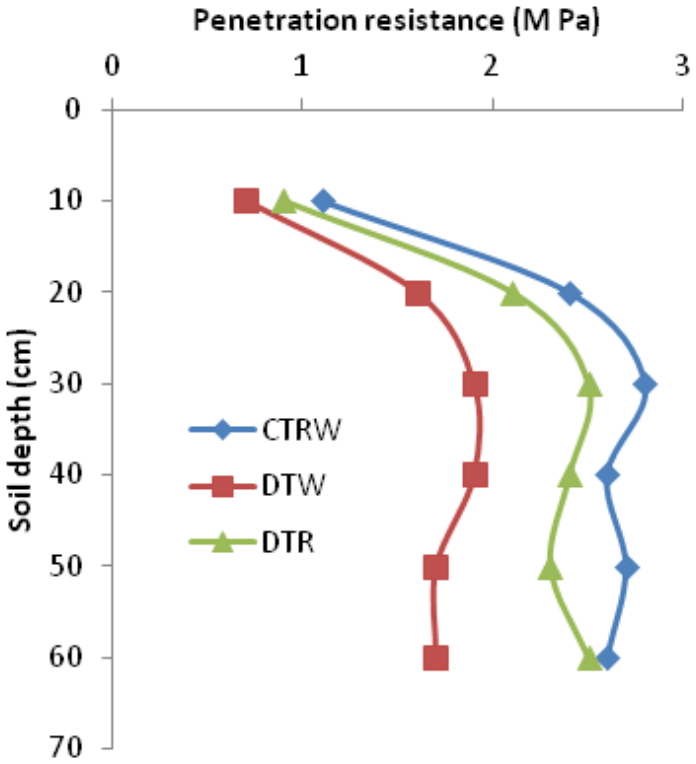

Figure 2. *Soil penetration resistance under different tillage practices (DTR = deep tillage before rice; DTW = deep tillage before wheat; CTRW = conventional tillage before rice and wheat)*

The PR is a measure of soil strength and the force required by the plant root to penetrate into the soil pores. The penetration resistance of soil increased with increase in soil depth. Likewise soil BD, the PR was also found to be significantly affected by tillage practices i.e. lowest PR was recorded under DTW (1.7 M Pa) and maximum under CTRW (2.9 M pa) at 30 cm soil depth. The data pertaining to steady state infiltration rate (IR) under different tillage practices has been presented in *Table 3*.

Table 3. *Effect of tillage practices and crop establishment methods on soil infiltration rate and saturated hydraulic conductivity (cm hr^{-1})*

DOI: http://dx.doi.org/10.15666/aeer/1706_1368513699

The steady state IR was higher under DTW (1.4 cm hr^{-1}) followed by DTR (1.1 cm hr^{-1}) and least in CTRW (0.9 cm hr^{-1}). However, among crop establishment methods higher mean IR was recorded in DSR than PTR. Likewise infiltration rate, maximum saturated hydraulic conductivity was recorded in DTW (1.7 cm hr^{-1}) followed by DTR (1.6 cm hr^{-1}) and least in CTRW (1.4 cm hr^{-1}). Among crop establishment methods maximum saturated hydraulic conductivity was recorded in DSR-NTR (1.8 cm hr^{-1}) and minimum in PTR-CT (1.4 cm hr^{-1}).

Plant height and root distribution

Data pertaining to plant height under different land management practices is presented in *Table 4*. The data revealed that, plant height significantly affected both by tillage and crop establishment methods. Maximum rice plant height was recorded in PTR-CT (102.8 cm) and least in DSR-HS (100.1 cm). Among main tillage practices, significantly higher rice mean plant height was recorded in DTR (103.0 cm) followed by DTW (101.3 cm) and lowest in CTRW (99.8 cm). In wheat also, the DTW recorded significantly higher plant height (104.0 cm) followed by DTR (102.3 cm) and least in CTRW (100.1 cm). However, among crop establishment methods maximum wheat mean plant height was observed in NTR-PTR (103.2 cm) and least in CT-DSR (100.7 cm). The mean root length density (RLD) of rice differed significantly under various tillage and crop establishment methods at different soil depths. The mean rice RLD in surface soil layer (10 cm) was 16 percent higher under DTR-PTR than DTR-CTRW (*Fig. 3*). However, at lower soil depths i.e. 20, 30 40 and 50 cm the RLD was observed to be 33%, 43%, 23% and 17% higher under DTR-DSR than CTRW, respectively.

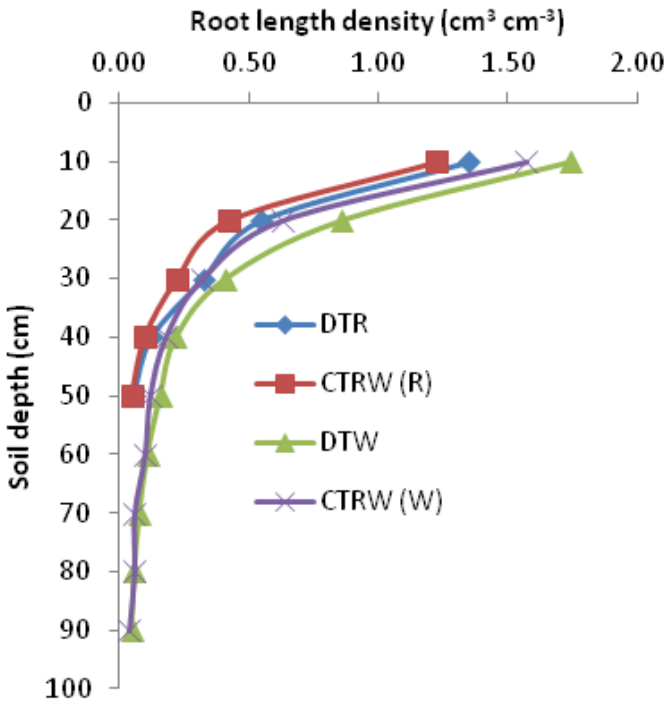

Figure 3. *Rice root length densities of rice and wheat under different tillage practices (DTR = deep tillage before rice; DTW = deep tillage before wheat; CTRW (R) = conventional tillage before rice and wheat for rice root; CTRW (W) = conventional tillage before rice and wheat for wheat*

Crop and water productivity of rice and wheat

The rice straw as well as grain yield was found to be significantly more under DTR (7.0 t ha^{-1}) followed by DTW (6.7 t ha^{-1}) and least in CTRW (6.4 t ha^{-1}). Among crop establishment methods maximum rice straw yield was recorded in PTR-CT (7.5 t ha^{-1}) and minimum in DSR-HS (5.9 t ha^{-1}). Similarly maximum rice grain yield was recorded in DTR (6.1 t ha^{-1}) and minimum in CTRW (5.6 t $ha^{-1)}$ (*Table 5*).

Discussion

Effect of tillage and crop establishment methods on soil compaction and water transmission

Conventional tillage practices including puddling in rice and performing five field operations for seed bed preparation in wheat have lead to destruction of soil structure by breaking macro aggregates into micro aggregates. Also due to physical compression there is formation of hard pan and increased bulk density at sub surface layer, which hinders growth of wheat roots to deeper depths. The bulk density of soil increases with the number of traffic passes and intensity whereas infiltration rate decreases with number of passes. However, with deep tillage practice due to shattering of soil up to 45 cm depth and 50 cm apart, the hard pan lying at 15-25 cm depth broken down leading to loosening of soil which further helps in increasing soil; water infiltration and saturated hydraulic conductivity of the soil. Among crop establishment the DSR showed lesser bulk density than PTR. This might be due to lesser number of field operations in DSR than PTR and also due to puddling and transplanting the chances of soil compaction increases as observed through higher bulk density and penetration resistance values. Prasad and Balanagoudar (2017) also reported lower soil bulk density in DSR than PTR as puddling resulted in destruction of soil aggregates and dispersion of soil particles to form compact layer having low porosity. Commonly all tillage practices accounts to reduced bulk density to the depth of tillage operation (Erbach et al., 1992; Osunbitan et al., 2005) and water infiltration rate was greater in tilled than no-tilled soil (Ferreras et al., 2000).

The water transmission characteristics of soil are also observed to be significantly affected by tillage and crop establishment methods. The various physical properties of soil such as bulk density, porosity and water holding capacity are fundamental indicators that show the effect of tillage on soils hydraulic properties (Strudley et al., 2008). The deep tillage improves soil properties by reducing soil bulk density and penetration resistance in the tilled layer (Varsa et al., 1997) and by altering soil porosity,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1368513699

increasing hydraulic conductivity and infiltration rate (Laddha and Totawat, 1997). Sojka et al. (1997) also found that deep tillage increases soil porosity, saturated and unsaturated hydraulic conductivity, improves the aeration status which leads to increased soil moisture storage (Velykis, 2004) in the loosened soil layer. Chan and Mead (1989) noticed that tilled soils exhibited greater hydraulic conductivities than untilled soils and attributed the difference to decreased soil bulk density and improved porosity than in soils under no tillage conditions. Higher infiltration rate recorded in DT than CT may be due to ample amount of macro pores which led to fast entry of water into the soil profile. Almouti et al. (2007) reported increase in infiltration rate with increase in tillage depth; the probable cause might be the decrease in bulk density.

Effect of tillage and crop establishment on crop growth and productivity

The deep tillage reduces the soil compaction, thereby increasing the water availability to the crops by facilitating well developed root system. Many reports over the world have shown that tillage practices influence root growth and crop yield by altering soil properties such as soil structure, water, aeration, fertility and other factors having strong influence on crop yield, water and fertilizer use efficiency of crops (Acharya and Sharma, 1994; Holanda et al., 1998; Lampurlanes and Cantero-Martinez, 2003). Cai et al. (2014) observed that DT to a soil depth of 50 cm have significantly improved root morphology and thereby increases the resistance to environmental stress. The various studies have reported that DT can increase the crop yield and resource use efficiency, largely due to the improved physical, biological, and hydraulic properties of the soil (Jabro et al., 2009). Further, soil manipulation and loosening by DT permits greater water movement and aeration in the soil, facilitates better root proliferation to deeper layers and allows the deeper chemical movement as compared to untilled soil (Diaz-Zorita, 2000; Strudley et al., 2008). High soil strength often limits the root proliferation to deeper layers and thus hinders the usage of water and nutrient resources (Bengough et al., 2011). The higher RLD under deep tilled conditions could be due to improved physical conditions of the soil which facilitates better root proliferation due to reduced mechanical resistance. The DSR do not perform well from productivity point of view. This may be due to higher weed infestation and iron deficiency. As above ground biomass is the function of the below ground biomass, i.e. root system. Better the root system more will be the exploration of soil volume by plant roots for water and nutrients, more will be the translocation of water and nutrients and hence the above ground biomass. Thus, higher grain yield was recorded under deep tillage than conventional tillage in both rice and wheat crops. However, among crop establishment methods, the PTR performed significantly better than DSR. The shallow and compacted topsoil in conventional tilled plots not only restricts the root development of plants, but hinders their absorption of nutrients and water (Wang et al., 2008). This could be due to the negative effect of residue retained on the following DSR crop. There was a consistent trend for poorer growth of DSR following wheat mulched with rice straw, suggesting the need to examine the possibility of allelopathic effects of surface rice straw retention in direct seeded rice-wheat systems (Gupta et al., 2016). The deep tillage reduces soil strength and soil bulk density (Laddha and Totawat, 1997), improves water storage in the soil, enhances the root growth (Holloway and Dexter, 1991) thereby increases crop production (Ghosh et al., 2006) as compared to conventional tillage. The crop productivity was higher under tillage depth of 35 cm as compared to tillage depth of 15 cm (Zhang and Li, 2010). Sub-soil compaction reduced both the water and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1368513699

nutrient use efficiencies of wheat by about 38% in a fine loamy soil (Ishaq et al., 2001). Deep tillage (chiseling), decreases soil bulk density and penetration resistance of this compact layer, increases depth of rooting, profile water use and yield of following wheat crop. Mosaddeghi et al. (2009) found that soil conditions under a zero-tillage conservation system were better than those under conventional system in arid and semi-arid environments. Residues accumulation in the soil acts as mulch which protects the soil from soil aggregate destruction enhances infiltration of water. It is an important organic source for retaining and improving soil fertility (Wang et al., 2002).

Conclusion

The deep tillage before wheat and rice improves crop and water productivity. Among crop establish methods puddled transplanted rice significantly improved rice yield and in wheat no-tillage with residue out yielded conventional tillage. The deep tillage provides healthy soil environment by reducing soil compaction and allowing water and roots to move to deeper soil layers. The greater root proliferation under deep tillage helps in extracting water and nutrient from lower soil depths. Thus, deep tillage helps in reducing mechanical strength and enhancing water transmission. Thus, in northwest Indian conditions in rice deep tillage along with puddled rice transplanting and in wheat, deep tillage along with no-tillage and residue are appropriate tillage and crop establishment techniques for enhancing crop and water productivity. However, further research needs to be carried out on impact of different tillage practices under variable irrigation and nitrogen regimes on cereals and pulse based cropping systems.

(Received 23rd Apr 2019; accepted 11th Jul 2019)

Abstract. The research was conducted in the hunting season 2017/18, during three group hunts. In total, 129 shot hares were covered. During the tests, body weight, age, and sex were determined. The achieved results indicate that the size of hunting harvest at the level of about 3 individuals/100 ha should be accepted as the highest in Poland, which is also a confirmation of the highest density of this species. They are also a confirmation of high individual condition expressed by body weight of both young (4.10 kg) and adults (4.65 kg). The structure of sex and age, as well as calculated reproduction rates (1.63) and reproductive success (2.42) indicate that the assessed population has developing features. The conducted research on the parameters characterizing the hare population in the area covered by the studies indicate high individual condition as well as reproductive potential, which allows to deduce about the potentially high potential for reconstruction of the number of hares.
Keywords: *brown hare, body mass, age structure, sex structure, Lublin Upland*

Introduction

In the last decades, a decreasing trend of the hare population has been observed in most European countries. Also in our country, the number and local density ratios, in many regions, have remained at a low and very low level for many years (Pielowski, 1976; Burel and Baudry, 1990; Dziedzic et al., 2002; Flis, 2009, 2016; Jezierski, 2004; Nasiadka and Dziedzic, 2014).

Although it is quite difficult to identify the unambiguous cause of this unfavorable trend, the most frequent changes are the changes in agrocenoses that are the main habitat for this species. Intensification of agriculture affecting quite significantly the heterogeneity of hare living environments, combined with the increase in the mechanization of all agrotechnical operations and the frequent use of plant protection products contributes to a significant simplification of agrocenosis structures (Lewandowski and Nowakowski, 1993; Panek and Kamieniarz, 1999; Dziedzic et al., 2000; Schmidt et al., 2004; Kryński et al., 2007; Kamieniarz et al., 2013; Schai-Braun et al., 2015; Panek, 2018). Another not less important factor influencing the hare population dynamics is predation, mainly free-living foxes (Pielowski, 1979; Goszczyński and Wasilewski, 1992; Panek et al., 2006; Panek, 2007; Wasilewski, 2007). The number of these predators in recent years has increased quite dramatically,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1370113711

which in turn was caused by the elimination of the basic mortality factor which was rabies. It is conditioned by the fact of conducting nationwide action of immunization of free-living foxes against rabies, starting from 2002 (Flis et al., 2017, 2018). Nevertheless, nowadays, in the conditions of low densities of hares populations occurring in many regions of the country, predation of foxes in hares in agrocenoses plays less and less influence on the dynamics of their numbers. The composition of the fox diet is more and more often sources of anthropogenic origin and small mammals (Gołdyn et al., 2003; Hušek et al., 2015; Panek, 2018). In addition, the negative impact of synanthropic predation on the population and thus the functioning of the population is also not without significance (Flis, 2013; Nasiadka and Dziedzic, 2014).

Quite significant factors affecting the dynamics of hares are also numerous disease entities. Coccidiosis and parasitic diseases are most often mentioned. However, bacterial and viral diseases such as brucellosis and hemorrhagic hare disease - EBHS and many other slightly less common (Pikula et al., 2004; Dubinský et al., 2010; Decors et al., 2011; Chroust et al., 2012; Kornaś et al., 2014; Nasiadka and Dziedzic, 2014; Flis et al., 2016). All described elements have a negative effect, and at the same time have a comprehensive impact on the functioning of the population of this species and they have led to a drastic reduction in densities. In the 70s of the last century, the average population density in our country remained at the level of about 50 individuals per 100 areas of field hunting grounds (Pielowski, 1976, 1979). At the beginning of the 21st century, the average level of hares density in the country was varied in individual regions and was in the range of 5-9 individuals/100 ha (Dziedzic et al., 2002; Wasilewski, 2007; Flis, 2009, 2016).

The most frequently used measure of the individual quality and health status as well as the survival rates of wild animals is the individual condition resulting directly from the body weight. This indicator, combined with climatic factors and intra-population parameters such as sex structure and age structure, determines the reproductive potential of the population. As a rule, individuals in a lower individual condition are more susceptible to natural selection factors (Frylestam, 1980; Hackländer, 2011; Flis, 2015).

The aim of the study was to assess the individual condition expressed by the body weight of males and females of young and adult hares in conditions of hunting areas with high acquisition of this species. The assessment also included sex structure and age indicators that directly affect the reproductive potential of this species.

Material and methods

Characteristics of the research area

The research was conducted in two hunting districts with a total area of 13.600 ha, the forest cover of which is 25.2%. They are located in the western part of the Lublin region, in the mesoregion of Kotlina Chodelska and the northern part of Wzniesienia Urzędowskie, in Poland, near the town of Opole Lubelskie (according to the WGS 84 reference system, the geographical coordinates are; width: 51°08′51″N, length: 21°58′08″E) (*Fig. 1*). This region is characterized by the presence of fertile soils of the chernozem type on the loess ground (Kondracki, 2000). Despite fairly fertile soils, it is distinguished by significant fragmentation of agricultural crops, and thus large heterogeneity of field environments. Field crops are dominated by plants with high soil requirements, with particular reference to orchards and plantations of perennial soft fruits, mainly raspberries and currants. In the agricultural landscape, there are numerous

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1370113711

wastelands as well as small wooded enclaves and forest complexes (Witek, 1991). Heterogeneity evaluation of the natural environment of agrocenoses in the area of research, performed according to the method proposed by Schrödel (1991) showed an average size of individual fields at the level of 0.95 ha, while the average distance between landscape elements ranged from 0.5 to 0.7 km. In turn, the relative length of contour lines in agrocenoses having significant impact on the functioning of small game population, despite the variation in individual regions of the study area, was on average at 0.1-0.2 km/km^2. All described elements determine quite significant mosaicism of field environments, creating almost optimal conditions for living and functioning of the hare population (Pielowski, 1979).

Figure 1. *Location of the research area*

Material for research

The research material were hares fired during collective hunts in November and December 2017. The hares were shot in the area with the highest density in the Lublin region. The annual number of assessments carried out by hunters indicate that the region has an average annual population size over the last 5 years, estimated at 1,100 individuals. With reference to the field surface of the area where the research was carried out, there is a density of 10 individuals per 1 km^2. In total, the analyzes were

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1370113711

carried out on 129 hares, of which 51 were male and another 78 females. Among the shots were 80 young hares and 49 adults. Additionally, in order to determine the level of compaction, a hunting analysis of this species was made during the last five hunting seasons.

Methods and measurements

All hares were weighed directly after the shot. Weighing was carried out with an accuracy of 0.1 kg. Gender assessments were made based on the appearance of secondary sexual characteristics. The hog age was also determined directly in the field on the basis of the palpation assessment of the occurrence or disappearance of the Stroh mark (cartilaginous elbow base cap). Such an assessment allows the division of hares into young (up to 1 year old) and adult (over 1 year old) (Stroh, 1931; Pielowski, 1979) (*Fig. 2*).

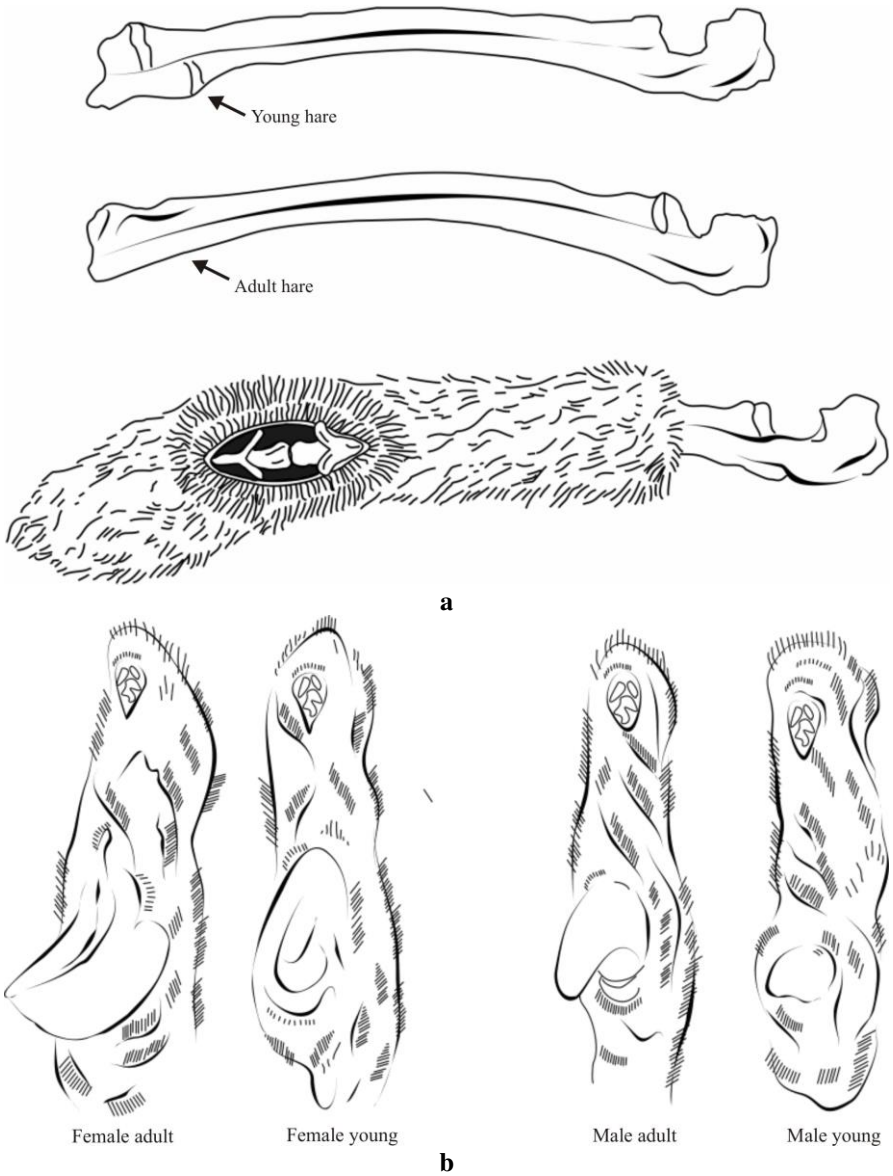

Figure 2. *Recognition of the age of shot hares based on the Stroh sign (a) and gender based on the appearance of the external reproductive organs (b)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1370113711

Analysis

The whole material was divided into age-gender groups, which allowed to determine the sex structure index and the age of the animals obtained. In order to determine the differences between average body weight values depending on the sex in separate age groups, hares were made a one-way analysis of variance. In order to verify the possible occurrence of differences between the averages, calculations were made using the Tukey test, in the Statistica program. The reproductive index and reproductive success rate were used to describe the dynamics of the population size (Pintur et al., 2006).

The reproduction rate was calculated as the ratio of the number of young hares that survived to the hunting season per 1 adult animal:

$$Wr = \frac{Njuv}{Nad} \quad \text{(Eq.1)}$$

The reproductive success rate was defined as the ratio of the number of young hares that survived to the hunting period per 1 adult female:

$$Wsr = \frac{Njuv}{Nadf} \quad \text{(Eq.2)}$$

Results

In the last five hunting seasons, hiring the hares in the areas constituting the research area showed a clear upward trend (*Fig. 3*). In this period, on average, over 300 hares were acquired in the circumferences constituting the research area on an annual basis (data from hunts conducted in this area by the hunting club). The acquisition rate from 100 ha of field area increased by over 100%, and on average in the hunting season more than 3 hares were obtained from every 100 ha of field area. This result in recent years is certainly the highest in Poland.

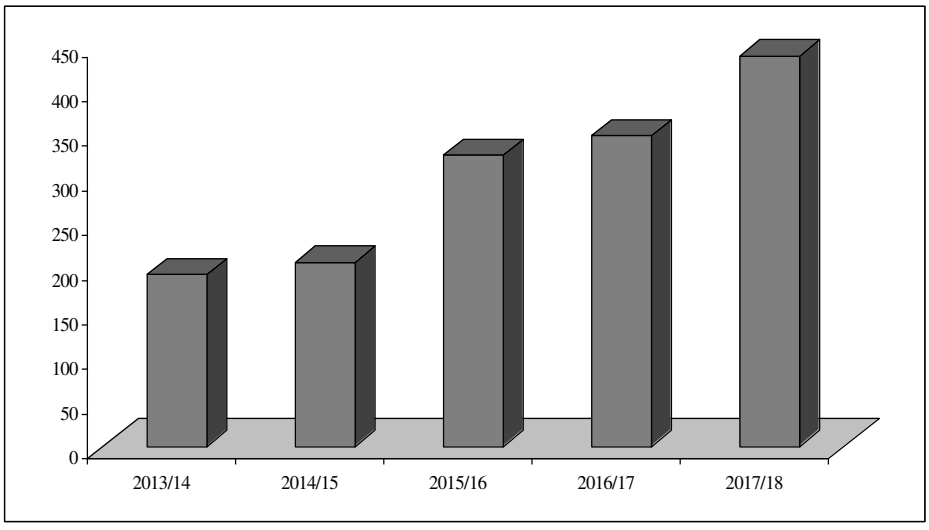

Figure 3. *The number and acquisition of a hare with 100 ha of area by shooting in the last 5 hunting seasons in the areas constituting the research area*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1370113711

The analyzes of hog body mass development carried out show a significant variation of this characteristic between young and adult individuals and the relative stabilization of young and adult hares in the sexual groups (*Table 1*). The average body weight of 35 young males was 4.18 kg and young females were lower by 0.14 kg. This difference was not statistically significant ($p > 0.05$). The average body weights of adult females and males varied only 0.02 kg. On the other hand, predictably, adult hares were much heavier than the young ones. The least stable was the weight value of young females, which is confirmed by the calculated values of standard deviation.

Table 1. *Mean and standard deviation of body weight (kg) of acquired hares*

The structure of the sex of hares obtained showed significant variation in the age groups (*Fig. 4*). Both females prevailed in both young and adult animals. In young hares, the sex structure index was 1:1.29 and in adults it was 1:2.06. The age structure of shot hares was differentiated by gender (*Fig. 5*), however, in both sexual groups, young animals predominated. In males, the age structure index was 1:0.46 in favor of young animals. In females, the prevalence of juveniles was slightly lower, and the age structure index was at the level of 1:0.73, also in favor of individuals up to one year old. The calculated population reproduction (*Eq. 1*) rate was 1.63, and the reproductive success (*Eq. 2*) rate was 2.42.

Discussion

Hunting hares in the last hunting seasons in the area covered by the research should be assessed as very high. The average index obtained from 100 ha of area, at the level of about 3 individuals, is not much lower than the size of this species given by Flis (2015), in the area of Wyżyna Lubelska in the hunting season 2004/05-2013/14. It is also close to the lowest indicators of this parameter in the 10-year monitoring period in the experimental circuit located also in the Lublin Upland (Flis, 2016), which data reflect the average national level from the beginning of the twenty-first century (Dziedzic et al., 2002). Densities in central and western Poland given by Kamieniarz and others (2013) in 2006, depending on the season, were within the range of 4.1-9.5 individuals, while the results of the same studies in Germany showed density at the level of 18.8-48.4 individuals/100 ha. Research conducted in Turkey also indicates the diversified density of this species, depending on the type of environment and the season, at the level within the range of 1.6-7.6/100 ha (Demirbas, 2015). The compaction index in Hungary in the 2014/15 season was in the range of 13-17 individuals/100 ha (Farkas et al., 2016). Nevertheless, in some European countries there are areas in which the population density is much higher and often exceeds 20 individuals per 100 ha area (Pikula et al., 2004; Pintur et al., 2006). The obtained results indicate, that in the area of research, the population density of this species is undoubtedly one of the highest in Poland, which is confirmed by the distributions of collective hunting and calculated index of acquisition from 100 ha.

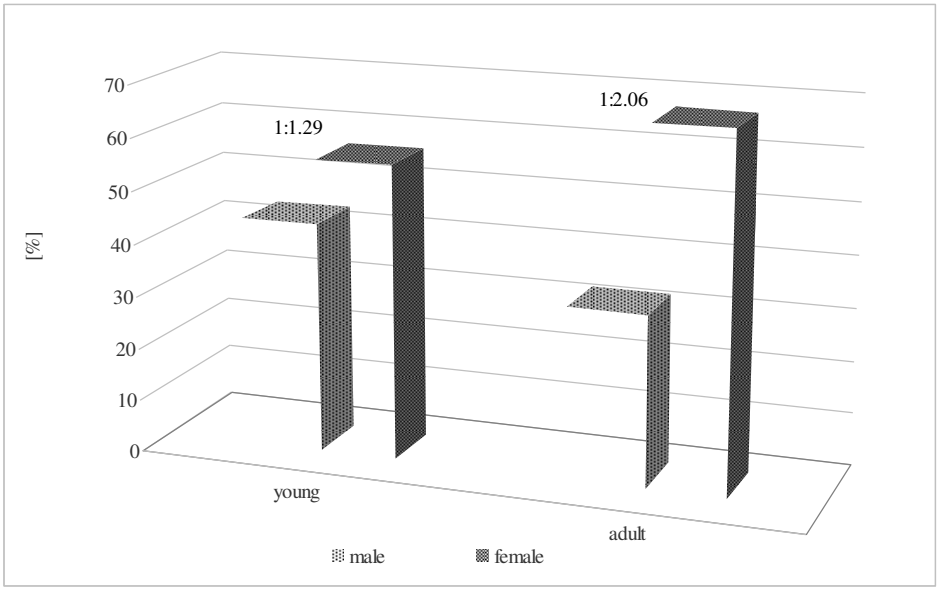

Figure 4. *Gender structure of acquired hares*

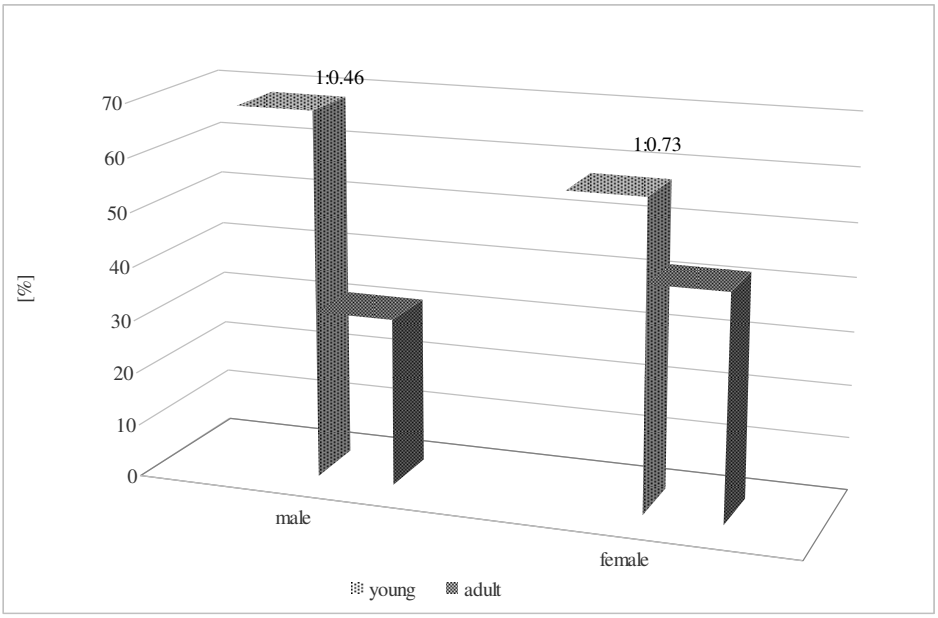

Figure 5. *Age structure of acquired hares*

The presented body weight results of both male and female hares are higher than those of Flis (2015) conducted in the hunting grounds of the Lublin Upland in the 2014/15 season. Currently, body mass is also slightly higher compared to the average values of this feature in the area of the Lublin Upland and Podlasie obtained in studies conducted in the mid-90s of the last century (Dziedzic et al., 1998). In turn, in Misiorowska and other studies (2014) conducted in areas of the highest population size of this species in our country, average hare body weight varied (3.42-4.32 kg), and a statistically significant difference between the averages was recorded only in age

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1370113711

groups. Also in the region of Central Pomerania in the years 1998-2001, significant differences between the hare body mass were found only in age groups, and the average value of this feature was 4.13 kg (Mysłek et al., 2004). The obtained data is also higher than in Croatia in the hunting season 2004/2005, given by Pintura and others (2006), as well as in Hungary in both age and gender groups (Farkas et al., 2016). Therefore, high density indicators in the area of research do not adversely affect the body weight of animals, because it is higher compared to the results presented by other authors from recent years, both from Poland and other European countries.

The obtained sex structure and age structure indicators showing a clear advantage of females and young individuals, regardless of gender, in the study population, are very optimistic, as they indicate that in the research area, the population exhibits developing features, which should directly affect its further development. The values of the reproduction rate and reproductive success indicate a high reproductive potential of the analyzed population, and thus suggest that there should be further dynamic growth. In the presented results, the reproduction rate was definitely higher than that from Misiorowska and other results (2014) carried out in the areas with the highest number of hares in Poland in the hunting season 2009/10, which ranged from 0.36 to 1.26. In turn, the reproductive success rate is only slightly lower than the upper value described by the same authors who fell within the range of 0.7-2.7. Pintur et al. (2006), conducting research in the diverse environments of Croatia in the 2004/05 hunting season, showed that the reproduction rate was environment-dependent and ranged from 0.61 to 1.50. In the same studies, the reproductive success rate was set at 1.33 to 3.40. In turn, in research conducted near Nitra in Slovakia, the value of the reproduction rate depending on the season was within the range of 0.76-0.92, and the reproductive success rate from 1.61 to 2.10 (Méres et al., 2016). Thus, the described indicators are within the upper range of this species obtained in some European countries.

Conclusions

1. The amount of hares obtained in recent hunting seasons on an average level of about 3 individuals from 100 hectares, confirms the high population density index, which can certainly be described as the highest in Poland and one of the highest in Europe.
2. The body weight of the hares obtained, both young (4.10 kg) and adults (4.65 kg) indicates that the individual condition of the animals is high, and the values of this feature definitely outweigh those from other regions of the country, as well as in some European countries.
3. The structure of sex with a clear predominance of females and the structure of the age where young specimens dominated, indicates a high reproductive potential of the population in the research area, and thus also shows the features of the developing population. This is also confirmed by the high values of the reproduction rate - 1.63 and the reproductive success rate, which value was 2.42.
4. Analysis of the basic parameters characterizing the population of the hares in the area covered by the study indicates that despite the decline in numbers in many countries, there are areas characterized by the existence of populations with high individual quality and reproductive potential. Thus, it allows to deduce about the potential possibilities of rebuilding the number of hares.

Absract. The aim of this study was to determine the contribution of native arbuscular mycorrhizal fungi (AMF) inoculation to growth, pigmentation and grain yield of wheat plants (*Triticum aestivum* L.) grown under different levels of water deficiency [D0, 100% Field Capacity (FC); D1, 75% FC; D2, 50% FC and D3, 25% FC]. The results suggested that AMF inoculation has a beneficial effect on plant drought tolerance and effectively improved biomass and crop productivity of wheat plants grown under drought. Mycorrhizal symbiosis alleviates the inhibitory effect of drought stress via improving water status and chlorophyll biosynthesis of wheat plants. Mycorrhizal colonization increased gradually and was higher at the maturity stage under a low level of drought (D1). The mycorrhizal wheat plants had higher shoot phosphorous than non-mycorrhizal plants at all samplings regardless of levels of drought stress. In general, with all treatments, the content of photosynthetic pigment fractions was inhibited as the level of drought increased in the soil pot experiment. However, the photosynthetic pigment contents of mycorrhizal wheat plant leaves were significantly ($p<0.05$) greater than those of non-mycorrhizal ones. The study/ concluded that the native mycorrhizae alleviate the drought stress by enhancement of the process of phosphorus uptake, pigment biosynthesis and accumulation of plant metabolites and may be used as a biofertilizer.
Keywords: *arbuscular mycorrhizal, drought stress, biofertilizer, phosphorus, wheat*

Introduction

Water shortage is considered one of the most significant environmental factors that affect plant growth and limit plant development and productivity in many arid and semiarid regions of the world. Also, seasonal water deficiency sometimes occurs in non-arid regions. Drought has a sharp decline in crop productivity, although many of these crops have many improved characteristics to withstand water shortage conditions (Bohnert et al., 1995; Zhu et al., 2012). Water deficit negatively influences the growth and metabolism of many plants, the response of plants differs depending on plant genotype, developmental stage, severity and duration of the stress (El-Enany et al., 2013, 2014).

Soil microorganisms are a very important component in the plant/soil system (Abd-Alla et al., 2014a,b; Kannenberg and Phillips, 2017). Symbionts can improve plant resistant to abiotic stresses by enhancing both plant nutrition and protection against the oxidative damage produced by the water deficiency (Ruíz-Lozano, 2003) and heavy metals (Rivera-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1371313727

Becerril et al., 2005). The symbiotic relation between arbuscular mycorrhizal fungi (AMF) and most plants provides nutrients, stimulates plant growth and increases the tolerance of plants against the stress (Barea et al., 2005; Abdel Latif and Chaoxing, 2014; Kyriazopouls et al., 2014; Shinde and Thakur, 2015). Arbuscular mycorrhizal fungi (AMF) can form mutualistic symbiotic associations with the roots of 80% of all terrestrial plant species (Smith and Read, 2008; Patale and Shinde, 2014). The AM symbiosis induced a higher improvement of physiological parameters in drought-sensitive plants than in drought-tolerant plants and drought-sensitive plants obtained higher physiological benefit from the AM symbiosis (Quiroga et al., 2017). Plants grown under water deficiency have a lower stomatal conductance in order to conserve water. Previous studies have indicated that drought stress severely affects plant growth through various mechanisms, such as reduced leaf water potential, reduced rate of cell division, and altered plant water and nutrient relationships. Consequently, CO_2 fixation is inhibited and photosynthetic rate reduced, resulting in less assimilate production for growth and yield of plants (Celebi et al., 2010; Farooq et al., 2012; Shinde and Singh, 2017).

There is considerable evidence suggesting that AMF has the potential to increase the tolerance of their host plants to water deficit stress (Asrar et al., 2012; Lazcano et al., 2014; Xiao-Qing et al., 2017). Studies have shown that the extraradical mycelia of AM fungi transfer water to their host plants under low soil moisture conditions and the AM fungi improve plant growth, development and yield (Augé et al., 2007), enhanced nutrient uptake (Michalis et al., 2013), an increase in the root hydraulic conductance (Bárzana et al., 2012), alterations in the soil's water retention properties (Augé, 2001), or improved osmotic adjustment (Aroca et al., 2007) and antioxidant activity (Bompadre et al., 2014). The beneficial functions of AMF may be of great importance to climate change, particularly with respect to water shortage and to the revegetation of degraded ecosystems; including coal mine spoil banks (Khalvati et al., 2010).

Wheat (*Triticum aestivum* L.) is the major food crop plants, are known to be commonly associated with AM fungi, which inhabit in agricultural soils contributing physiologically and ecologically to the health of both plants and soils (Li et al., 2012). Colonization of roots by AM fungi has been shown to increase the drought resistance of wheat (Al-Karaki and Clark, 1998). Therefore, our aim in the present study was to evaluate the potential of native species of AMF to mitigate the adverse effects of drought stress on wheat growth and for improved grain yield.

Material and Methods

Production of mycorrhizal inoculum

Native adapted AM fungi were isolated from the arid environment [Al-Uqair coast, Al-Ahsa, Saudi Arabia, (25°39'35.8"N 50°11'25.6"E)] and propagated for inoculums production. The most abundant mycorrhizal species selected and morphologically identified according to Schüessler and Walker (2010). Native AM fungi were propagated on maize (*Zea mays.* L) as host plant on the sterilized clay-sand mixture (50% soil and 50% sand). Plants were cultured in the greenhouse for 3 months. The roots colonized by AM fungi were checked during the culture, and the presence of spores was confirmed by sieving. One hundred grams of soil containing a mixture of mycorrhizal spores, extra-radical hyphae, and roots fragments applied as mixture culture inoculum. Non-mycorrhizal maize roots and sterilized soil used for the control treatment.

DOI: http://dx.doi.org/10.15666/aeer/1706_1371313727

Experimental design and growth conditions

Wheat grains (*Triticum aestivum* L.) were surface sterilized and grown in plastic pots filled with 4 kg sterilized soil at different levels of drought (D0, 100% FC-D1, 75% FC-D2, 50% FC and D3, 25% FC). The seedlings were thinned to 10 plants one week after germination. All pots were fertilized with 50 mg N-KNO_3 g^{-1} soil. Solutions of K_2HPO_4 were prepared and P was added at 30 or 60 mg^{-1} g soil. A control treatment was also included. The experiment in a completely randomized design was performed by fifty- gram inoculum of AMF mixture and placed in pots below the grain of the tested plant (approximately contain 90–100 spores/10 g soil). Pots of the control treatments received the same volume of autoclaved inoculums. All pots contain 10 seedlings were kept in the greenhouse with day and night temperatures of 27 and 15˚C, respectively, day and night relative humidity of 70 and 80%, respectively, and a photoperiod of 14 h. Each treatment was replicated three times.

Growth parameters and grain yield

After 42 days of planting, some wheat plants were removed gently from the pots, washed with water. Then, plants were separated into shoots and roots and part of fresh roots and shoots were immediately frozen for analysis. The dry weights of the plants were recorded by placed the samples in an oven at 80°C until the dry weight was constant. At maturity, yield components [spike length, the number of grains per spike, grain yield per plant and 100- grain weight (seed index)] were determined on 3 plants for each treatment. Also, days to flowering and days to maturity were recorded for all treatments.

Estimation of mycorrhizal colonization

Root segments were separated from the plant, washed and then cut into one centimeter long pieces. The segments were cleared with 10% (w/v) KOH at 70^{o}C for 20 min and stained with 0.5% (w/v) Trypan blue. The stain was prepared by mixing water, glycerin and lactic acid in proportions 1:1:1 (v/v/v). Mycorrhizal colonization was assessed by the method of Brundrett et al. (1984). Frequency of mycorrhizas (F%), the intensity of mycorrhizal colonization in the root (M%), and arbuscule frequency in roots (A%) was calculated according to Trouvelot et al. (1986) using the MYCOCALC (http://www.dijon. inra.fr/mychintec/Mycocalc-prg/download.html) program.

Quantification of phosphoros mycorrhizal dependency

According to Plenchette et al. (1983), the dependency of mycorrhizal plants growth and Phosphorous (P) uptake were calculated as:

$$\frac{[\text{P content (M)} - \text{P content (NM)}]}{\text{P content (M)}} \times 100 \qquad \text{(Eq.1)}$$

where M, mycorrhizal plants and NM, non-mycorrhizal plants.

The concentration of P in the shoot was determined after digestion in a mixture of concentrated nitric and perchloric acids (4:1). Each sample was placed in 50 mL measuring flasks and 10 mL of the acid mixture was added. The mixture was first heated on fry pans to 90°C for 30 min, and then temperature increased to 140°C to remove excess nitric acid. De-ionized water was added to make up to definite volume of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1371313727

the primary extract. An aliquot of this primary extract was diluted for determining phosphorus shoot concentration spectrophotometrically (Olsen and Sommers, 1982).

Determination of photosynthetic pigments

The fractions of pigments (chlorophyll a, chlorophyll b and carotenoids) were estimated using the spectrophotometric method recommended by Lichtenthaler (1987). The photosynthetic pigments were extracted from a definite weight of fresh leaf samples in 5 ml of 95% ethyl alcohol at 60˚C, until colorless. Then the total volume was completed to 10 ml with 95% ethyl alcohol and absorbance readings were followed with a spectrophotometer (Unico UV-2100 spectrophotometer. The extinction was measured against a blank of pure 95% ethyl alcohol at three wavelengths of 452, 644 and 663 nm. The concentration of chlorophylls and carotenoids were calculated as mg/g FW using the following equations:

$$\text{Chlorophyll a} = (13.36 \times A_{663}) - (0.918 \times A_{644}) \quad \text{(Eq.2)}$$

$$\text{Chlorophyll b} = (27.49 \times A_{664}) - (3.87 \times A_{663}) \quad \text{(Eq.3)}$$

$$\text{Carotenoids} = (4.2 \times A_{452}) - [(0.0264 \times \text{Chl.a}) + (0.46 \times \text{Chl.b})] \quad \text{(Eq.4)}$$

Statistical analysis

The data were subjected to one-way ANOVA using the SPSS 10.0 software program. Means and standard errors were calculated for 3 replicate values. Means were compared by Duncan's multiple range test and statistical significance was determined at a 5% level.

Results

A total number of 7 morphotypes of native species of AMF were recovered from rhizosphere plants grown in a harsh environment. Based on the number of spores the seven species in stressed soils were *Acaulospora* sp., *A. bireticulata* (Rothwell & Trappe), *A. capsicula* Blaszk., *Glomusaggregatum* Schenck and Smith, *G. clarum* Nicolson & Schenck, *G. geosporum* (Nicol. & Gerd.) Walkerand *G. mosseae* (Nicol. & Gerd.) Gerd. & Trappe. The most common native species (*Acaulospora capsicula*,*Glomus aggregatum* ,and *Glomus geosporum*) were propagated and used as mixture inoculum for further experiments.

The experiment was conducted on *Triticum aesativum* L. under different levels of drought (D0, D1, D2, and D3) and inoculated with or without a mixture of native AM fungi to grow for 3 months. Under well-watered conditions, mycorrhizal inoculation significantly increased all the growth parameters. The fresh and dry weights of mycorrhizal plants increased significantly than non-mycorrhizal plants. The drought treatments significantly reduced the growth criteria of both the mycorrhizal and nonmycorrhizal plants (*Table 1*). The data indicated that drought treatments were significantly ($p > 0.05$) reduced fresh or dry weights of wheat plant roots especially at the highest levels of drought (D2 and D3) as compared by reference control (D0). Inoculation of wheat plants with AM fungi stimulated the growth, especially the plants under drought. The data presented in *Table 1* shows that all water deficit levels exerted an inhibitory effect on the root and shoot dry yield of non-mycorrhizal wheat plants. On

DOI: http://dx.doi.org/10.15666/aeer/1706_1371313727

the other side, the fresh and dry shoot weights of mycorrhizal plants showed an increase at all drought levels as compared with control plants.

Analysis of the data revealed that drought significantly affected days to flowering of wheat plants of which delayed as compared with control. Days to the flowering of mycorrhizal wheat plants grown under drought stress were significantly early flowering than those of their respective non-mycorrhizal counterparts. The period of maturity of wheat spike plants showed the effectiveness of mycorrhizal inoculation as shown in *Table 2*.

The data showed that amongst all the treatments, days to maturity significantly ($P<0.05$) delayed under drought stress. Yield and its component consider the main target for the activity of plants. So the data recorded in *Table 2* show that wheat plants inoculated with AMF caused a marked effect on the seed yield per plant and its components (spike length, grains of a spike, grains per plants and grains index, the weight of 100 seeds) in comparison to the treated plants. The data in *Table 2* demonstrated that/ spike length of water deficit at all levels was significantly decreased with increased water deficit level in soil, especially at high water stress levels. The highest values of spike length obtained from wheat plants inoculated with AMF, while the minimum spike length recorded from non-mycorrhizal plants grown at high water deficit treatment soil. These results showed a general trend of an increase in grain per spike with inoculation of treated plants (*Table 2*). Seed index weight of 100 grains (g) was recorded and the data revealed that grain index was significantly increased in mycorrhizal wheat inoculated plant than those uninoculated wheat plants. The root colonization rate was affected by substrate, inoculation, and the interaction of the substrate with drought stress or inoculation. In general, different levels of drought stimulated development the frequencies of root colonization (F%), the intensity of root cortex colonization (M%), and arbuscular development (A%) by *Acaulospora capsicula*, *Glomus aggregatum*, and *Glomus geosporum* at different growth stages in wheat plants as shown in *Table 3*.

Table 3. *Mycorrhizal colonization of wheat plants under different levels (D0, D1, D2, and D3) of drought stress*

Growth stages	Mycorrhizal colonization (%)	Drought levels			
		D0	D1	D2	D3
Vegetative	F %	48.0	52.0	43.0	36.0
	M %	21.3	20.0	17.0	15.3
	A %	16.7	13.0	8.0	5.3
Flowering	F %	63.0	69.0	60.0	49.0
	M %	54.0	58.0	49.0	43.3
	A %	36.3	42.3	35.6	29.0
Maturity	F %	83.3	85.0	75.0	62.0
	M %	57.2	62.0	53.0	55.0
	A %	53.3	58.0	44.3	48.0

*F%: Frequency of mycorrhizal root segments, M%: the intensity of mycorrhizal colonization in the root, A%: Arbuscule frequency in roots

The microscopic assessment confirmed that plants of non-inoculation treatment were not colonized by AMF. As is evident from *Table 3*, at the vegetative stage, the highest value of frequency of mycorrhizal root segments recorded under a low level of drought. At the flowering stage, mycorrhizal colonization increased as compared with those of vegetative stage, and F%, M %, and A% recorded a maximum value under a low level of drought.

It was observed that the highest mycorrhizal colonization was recorded at the maturity stage (as compared with those of vegetative and flowering stage). Frequency percentage of mycorrhizae in roots reduced at the vegetative stage by about 4%, whereas increased by about 8% and 5% in flowering stage and maturity, respectively at low drought level (D1). The moderate (D2) and high (D3) drought levels obviously reduced the percentage of arbuscular mycorrhizae frequency in roots at the different

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1371313727

stages of plant growth. The mycorrhizae in roots of wheat plants consisted of arbuscules, vesicles, as well as intra-and extraradical hyphae. The arbuscules and vesicles were patchily distributed along the roots examined. The intraradical hyphae were evenly distributed and frequently formed coils.

The phosphorus content of wheat plant shoots inoculated with AMF grown at different levels of the drought was represented in *Fig. 1A*. The data revealed that P uptake was significantly reduced by drought treatments. The P contents of wheat shoots were used as indicators of mycorrhizal activity in the soil. Mycorrhizal inoculation of the wheat plant significantly raised the P uptake especially at low drought level (D1) and shoots of mycorrhizal wheat plants had significantly higher concentrations of P than those of nonmycorrhizal wheat plants.

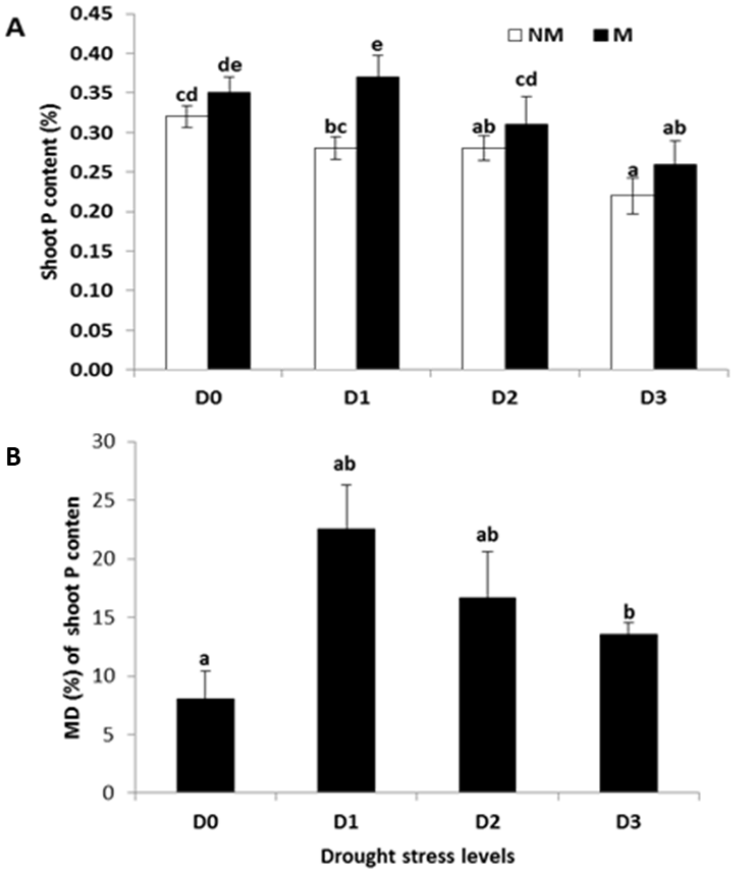

Figure 1. *Effect of different levels (D0, D1, D2, and D3) of drought on/ (A) wheat shoot phosphorus content (%); (B) Mycorrhizal dependency of P wheat shoot content (%). Means in each column followed by the same letter are not significantly different (P < 0.05) as determined by Duncan's test. Values are the means of three replications*

Photosynthetic pigments

The content of the photosynthetic pigments (chlorophyll a, chlorophyll b and carotenoids) of mycorrhizal and non-mycorrhizal in wheat plant leaves are presented as mg g^{-1} leaf fresh weight in *Figure 2*. The current study shows that photosynthetic pigment fractions are significantly affected water deficit and mycorrhizal inoculation as indicated by significant two-way interaction based on ANOVA. In general, with all

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1371313727

treatments, the content of photosynthetic pigment fractions was decreased as the level of drought increased in the soil pot experiment.

However, the contents of photosynthetic pigments of mycorrhizal wheat plant leaves were significantly ($p<0.05$) greater than those of non-mycorrhizal ones. In non-mycorrhizal plants a significant reduction in total pigments was recorded at high water deficit (D3).

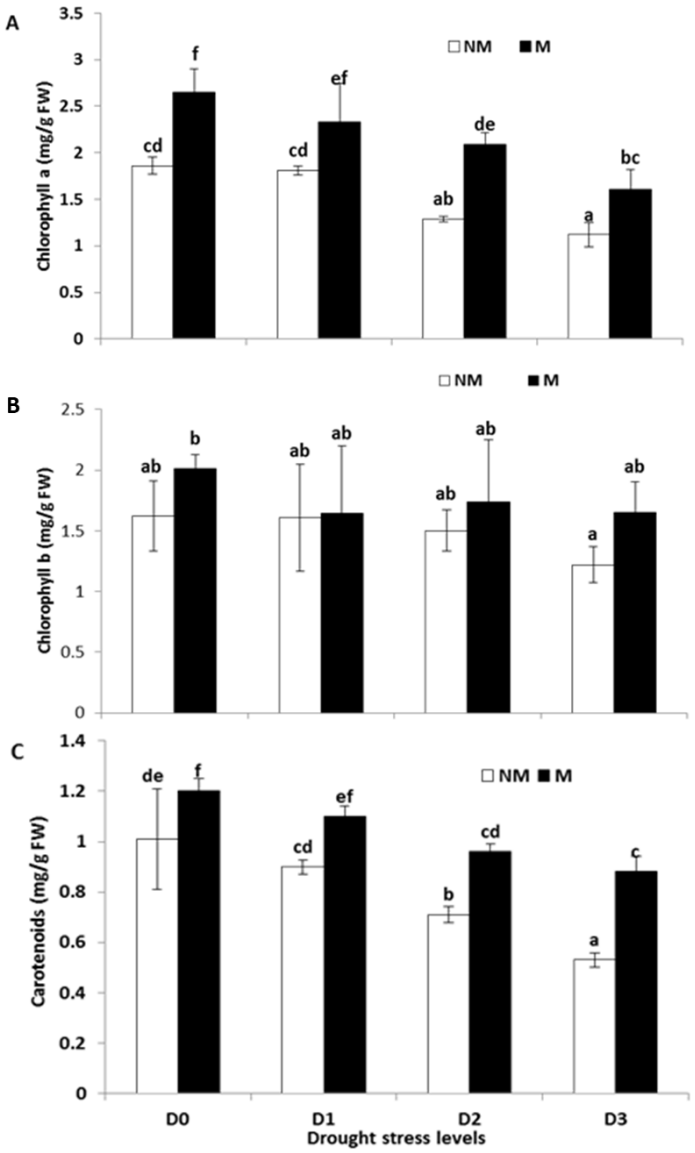

Figure 2. *Chlorophyll a (A); chlorophyll b (B); and carotenoids (C) contents in leaves of wheat plants inoculated with mycorrhizal fungi grown under different levels (D0, D1, D2 ,and D3) of drought stress. Means in each column followed by the same letter are not significantly different ($P < 0.05$) as determined by Duncan's test. Values are the means of three replications*

Analysis of variance of chlorophyll contents showed that mycorrhizal colonization significantly improved chlorophyll concentrations. Also, the interaction of drought and mycorrhizal inoculation exhibited a stimulatory effect on the different types of photosynthetic pigments (*Fig. 2*).

Discussion

In the present study, drought decreased the fresh and dry weights of wheat plants which are recorded by many studies (Auge, 2001; Celebi et al., 2010; Kyriazopouls et al., 2014). Previous reports have indicated that drought stress severely affects plant growth through various mechanisms, such as reduced leaf water potential, reduced rate of cell division, and altered plant water and nutrient relationships (Boomsma and Vyn, 2008; Kilic and Yagbasanlar, 2010; Farooq et al., 2012). The positive effect of AMF on wheat growth under different levels of drought suggested that the application of AMF technology may be a sustainable method for improving plant performance under the adverse conditions (Kyriazopouls et al., 2014; Malik et al., 2017). AM symbiosis drives an increase in the leaf area and coarse root mass and improves the plant-soil water relationship under drought stress, which can affect various physiological processes. The improvement of biomass in mycorrhizal plants may also be due to the enhanced water uptake (Subramanian et al., 2006; Habibzadeh et al., 2013). Our results in *Table 2* are in accordance with the current tendency for reduced use of agrochemicals, research is currently aimed at crop yield improvement and at yield sustainability; thus, microbial-based approaches have been proposed to improve crop yield (Covacevich et al., 2007). In this respect, numerous researchers have reported improvement in biomass production and grain yield in the grain of cereals after inoculation with AMF (Tarafdar and Marschner, 1994). The fungal filaments outside the root system can spread and explore soil areas not reachable by plant roots. One centimeter of colonized roots might produce 50 to 150 cm of extraradical hyphae (Harley, 1989). Through this mechanism, AMF associations may improve crop yield by increasing the capacity of plants to obtain nutrients that are relatively immobile in the soil such as phosphorus (P).

Our results in accordance with most studies which indicated that drought stress decreased the colonization rates (Kohler et al., 2009; El-Mesbahi et al., 2012) and may be due to the adaptation of AMF isolates to different substrates and different behaviors of plants under drought stress (Gholamhoseini et al., 2013). The decrease of root colonization by drought stress is due to reducing spore germination and plant photosynthetic capacity (Wu et al., 2013; Xiao-Qing et al., 2017). Michalis et al. (2013) concluded that soil moisture can have various effects on AMF spore germination and thus root colonization. Moreover, drought modifies various features of the root system which, in turn, may influence the degree of colonization and the frequency of different AM fungal structures (Fusconi and Berta, 2012). Some results opposite to our studies and showed that mycorrhizal colonization increased with increasing intensity of drought stress (Zhao et al., 2015). They concluded that under drought stress, watering caused lighter compaction, better pore structure and soil aeration, which benefits the development of mycorrhizae.

Drought stress may reduce nutrient mineralization by lowering nutrient availability (Heidari and Karami, 2014). Mycorrhizal symbiosis may improve plant nutrition, which is generally regarded as an important drought tolerance mechanism (Smith and Read, 2008; Li et al., 2012). Hijikata et al. (2010) noticed that the activity of high-affinity P transporters on the plasma membrane of extraradical hyphae is most likely directly involved in enhanced drought tolerance in plants. In the present study, the P contents in mycorrhizal plants were consistently higher than those in non-mycorrhizal plants, regardless of the intensity of drought stress. The increase in P concentrations of mycorrhizal plants may provide more RNA to meet the protein synthesis needs, resulting in a higher plant growth rate (Matzek and Vitousek, 2009). Under drought conditions, the RNA-directed synthesis of some protein or enzymes may be of physiological importance in helping the plants withstand drought stress (Fan and Liu, 2011).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1371313727

The results obtained showed that wheat plants under drought stress were strongly mycorrhizal dependent (*Fig. 1B*). The lowest mycorrhizal dependency recorded at the control drought level. SchiiBler et al. (2001) stated that arbuscular mycorrhiza is formed in about 80% of land plants with soil fungi belonging to *Glomeromycota*. Arbuscular mycorrhizal plants can take up more soil nutrients especially phosphate (P), micronutrients such as copper and zinc, than non-mycorrhizal plants (Smith and Read, 1997). They concluded that the growth of a host plant can be improved by mycorrhizal colonization provided that soil available P is a limiting factor for plant growth. The degree of growth improvement is affected by factors such as host plant species, fungal species, and soil conditions.

Analysis of variance of chlorophyll contents (*Fig. 2*) revealed that mycorrhizal colonization significantly improved chlorophyll concentrations and the interaction of drought and mycorrhizal inoculation exhibited a stimulatory effect on the different types of photosynthetic pigments. Chlorophyll status is a key index for evaluating plant photosynthetic efficiency and environmental stress. Augé (2001), Gemma et al. (1997) and Azooz and Youssef (2010) are in agreement with the results of other proved the differences of chlorophyll *a*, chlorophyll *b* and chlorophyll *a* + *b* concentrations were significant between AM and non-AM maize plants under drought stress conditions (Zafari et al., 2017). They suggest that drought stress interferes less with chlorophyll synthesis and/or more with chlorophyll breakdown (Evelin et al., 2009) or protects pigments against (Kyriazopouls et al., 2014) oxidative damage generated by drought (Shinde and Thakur, 2015). Drought stress caused a great decline in the chlorophyll *a*, chlorophyll *b* and the total chlorophylls content in many plant varieties investigated by some authors in non-mycorrhizal than mycorrhizal in plants (Ommen et al., 1999; Manivannan et al., 2007; Evelin et al., 2009). Also, unchanged chlorophyll level during drought stress has been reported in other species, depending on the duration and severity of drought (Kpyoarissis et al., 1995). The decrease in chlorophyll under drought stress may result in chloroplast damage caused by active oxygen species (Herbinger et al., 2002). Consequently, the rate of photosynthesis decreased (Kawamitsu et al., 2000) due to lower stomatal conductance in order to conserve water and the resistance of the stomata to CO_2 entry probably is the main factor limiting photosynthesis under drought, resulting in less assimilate production for growth and yield of plants.

Conclusion

The mycorrhizal root colonization rate was significantly affected by drought stress levels or the stages of plant growth of wheat plants. Also, it can be concluded that the AMF enhances the absorption of phosphorus and other nutritional elements and then improves the nutritional status of wheat plants during drought stress which resulted in an increase in chlorophyll contents than control plants. In spite of better performance of inoculation with mycorrhizae, there are still certain aspects that need critical consideration. One important aspect is the evaluation of this approach under natural field conditions. Most of the previous studies were conducted under controlled conditions, and the response of these organisms observed under such conditions may vary significantly in view of the variable ecology of these microorganisms in the natural environment. Additionally, the researches also have to face other harsh conditions like the toxicity of heavy metals and pathogen attacks. Therefore, the role of these microorganisms for providing relief from other stresses.

Abstract. In this study we compared the efficiency of frequentist approach with Bayesian approach by carrying out extreme value analysis of Annual Maximum Daily Rainfall (AMDR). For frequentist frequency analysis of AMDR, we used the data of one station i.e. Lahore in Punjab province, Pakistan while for Bayesian analysis we used the data of three other neighboring stations as prior information. During frequentist approach, Generalized Extreme Value (GEV) was found to be a best-fit distribution on the data. In frequentist method, the parameters of GEV distribution were estimated using Maximum Likelihood Estimation (MLE), while in the Bayesian framework the Markov Chain Monte Carlo (MCMC) simulation technique along with Metropolis-Hasting algorithm and Gibbs sampler were implemented. Findings of this study indicate that despite the asymptotic requirements of the MLE, its performance can be enhanced by adopting the Bayesian MCMC paradigm. In order to acquire the posterior densities of GEV parameters, non-informative and informative priors based on the historical data of surrounding weather stations were employed. The result of Bayesian MCMC might be affected by the choice of priors. In addition, the performance of the parameters estimation methods was verified by employing several robustness measures. Robustness measures results proved that the Bayesian MCMC method performed better than MLE in estimating GEV parameters and future return levels. Therefore, the findings of these analyses could be helpful in adopting proper flood protection measures and designing infrastructures of culverts, buildings, bridges and dams in the region.
Keywords: *annual maximum daily rainfall, generalized extreme value, the Markov Chain Monte Carlo, maximum likelihood estimation, Bayesian paradigm, priors specification*

Introduction

Extreme rainfall events are frequently connected with climatic fluctuations which may cause a series of natural disasters such as heavy floods and landslides. According to the United Nations Framework on Climate Change (UNFCC) the human lives, animal lives, and water resources, agricultural lands, food security, and coastal zones will be heavily affected

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1372913748

due to climatic changes in Asia. Pakistan is situated in the western part of the Indian subcontinent, with Afghanistan and Iran on the western borders, India on the eastern borders, and the Arabian Sea to the south. It is an agricultural country. The country with 70% of its population depends on agriculture and its products (Faisal and Sadiq, 2009). Most of the agricultural lands and other living organisms depend on rain-water. Rainfall occurs in Pakistan, not only in summer but also in winter. In summer, rainfall happens frequently during the monsoon period (from early July to September). The top-months of the monsoon rainfall in Pakistan are July and August (Ahmad et al., 2014, 2016). Rainfall is a major source of water for agriculture and energy production. According to Adnan and Khan (2009), the 60% of the total annual rainfall in Pakistan is due in summer. All Kharif crops are more dependent on monsoon rainfalls. These crops are also known as summer or monsoon crops. The major Kharif crops are rice, maize, cotton, jowar, bajra etc. Furthermore, winter rains are very beneficial for Rabi crops in the country (Shamshad, 1988; Ahmad et al., 2016). Rabi crops are sown at the beginning of winter season. The major Rabi crops are wheat, gram, peas and barley etc. Rabi crops are also known as winter or spring crops. In Pakistan, rainwater plays an important role in hydroelectricity and agricultural production. Agriculture is considered as the backbone of Pakistan's economy, but unfortunately, heavy rainfalls cause loss of lives, crops and infrastructures. This fact is undeniable that the society and the economy of any country can be affected due to extreme environmental events (Shabri et al., 2011). Therefore, the suitable modelling of extreme events can be done through statistical analysis.

The main purpose of the statistical analysis of extreme values is to enumerate the stochastic behavior of extreme environmental events (Smith, 1989; Coles et al., 2001). The most meteorological variables, such as rainfall, wind speed, temperature, floods and precipitation, are of under consideration because they have a terrific influence on humans and thus it is crucial to portray their behavior statistically due to their extreme positions.

Due to monsoon season in Pakistan; as heavy rainfalls are anticipated to take place frequently every year. According to the Federal Flood Commission (FFC) Pakistan, it is estimated that about cumulative financial loss US$ 38.171 million during the past 70 years. Around 616,598 km^2 of the total land area of Pakistan is prone to flood, some 197,275 villages were damaged and 12,330 people have lost their lives due to 24 major floods. Being a developing country like Pakistan, natural disasters unquestionably cripples the country's output. It is evident that any extreme environmental event is unpredictable. Nevertheless, the influence of heavy rainfall events may be abridged by precautionary measures based on the results from statistical analysis of Annual Maximum Daily Rainfall (AMDR) series, as suggested by Zin et al. (2010), Khamkong (2012) and Diriba et al. (2014). The major objective of statistical modelling of extreme rainfall was to estimate the quantiles that might occur for the next years to come.

There are two main statistical approaches to model AMDR series, namely the block maxima and peak over a threshold (POT). The block maxima approach models the highest value of each year collected from the large sample, whereas (POT) approach requires the observations that exceed a certain level of threshold in the collected data (Pickands, 1975; Davison and Smith, 1990). However, according to Madsen et al. (1997) and Eastoe and Tawn (2012) the block maxima is preferred since the method in selecting the appropriate threshold in (POT) procedure sometimes can be complex.

The AMDR series needs to be modelled by appropriate probability distributions that provide the better inferences of the future behaviour of extreme rainfalls. Various kinds of statistical distributions often are able to be used in AMDR. They are Generalized Extreme

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1372913748

Value (GEV), Gumbel, Generalized Pareto (GP), Generalized Logistic (GLO) and the lognormal distribution. Because of their suitability to modelling of extreme value, these probability distributions have numerous applications for environmental data (e.g., An and Pandey, 2005; Furrer and Katz, 2008; Chikobvu and Sigauke, 2013; Jonathan and Ewans, 2013; Diriba et al., 2015; Ahmad et al., 2016). Several studies based on frequentist approaches have been conducted for finding the best fit distribution and modelling the AMDR data in Pakistan by Rasul et al. (2004), Haroon and Rasul (2009), Rasul et al. (2009) and Ahmad et al. (2014, 2016). Ahmad et al. (2016) suggested that the (GEV) and (GP) are the most suitable distribution for the AMDR series in the different regions of Pakistan.

In this study, the five extreme value statistical distributions (such as GP, GEV, GLO, Pearson Type-III and Log-Normal three parameter) are applied to the extreme rainfall data of Lahore station of the Punjab province by using the frequentist procedure via linear moment (L-moment) estimation method. However, the results demonstrate the tendency that the GEV distribution among all others fits the data in a more appropriate way, attention is therefore limited to the GEV distribution.

Meanwhile, extreme data are sporadic by their nature, the statistical inference on extremes may be improved by the addition of other sources of information through a prior distribution. Unlike frequentist approaches (maximum likelihood and L-moments), a Bayesian analysis of extreme values is also not dependent on the fundamental assumptions that are required by the asymptotic theory of frequentist approaches (Smith, 1985; Coles et al., 2001; Smith, 2002). In addition, according to Hamed and Rao (2000) the MLE method that was unable to get an appropriate estimate with a small sample. The Bayesian method can be employed in estimating the parameter of GEV distribution. The basic theory of the Bayesian paradigm about extreme values has been discussed by many authors in a number of outstanding articles and books (Coles and Tawn, 1996, 2005; Beirlant et al., 2006; Naghettini, 2017, p. 505). In this study, the researcher has focused on its applications by using the GEV distribution. Additionally, the primary purpose of this article is the comparison of both estimation methods by using the robustness measures. The first one is the MLE method and the second one is the Bayesian method. In Bayesian analysis, the non-informative priors and informative priors based on the historical data of neighboring stations in term of extreme quantiles are formulated. In the previous study, Ahmad et al. (2014) discussed the behaviour of monsoon rainfalls in Pakistan through kappa distribution by employing L-moments estimation method. In another study Ahmad et al. (2016) used the data of extreme rainfall of 28 stations in Pakistan and found the best fit distribution among five extreme value distributions. After finding the best fit distribution the researcher carried out at-site frequency analysis on the same data by using L-moments and Trimmed L-moment estimation methods. However, they did not use the Bayesian paradigm for the modelling of extreme rainfall in Pakistan. The main purpose of this paper, therefore, is to study the extremes of rainfall by applying the GEV distribution to the Lahore station data, the province of Punjab, Pakistan. The frequentist approach, i.e. MLE and the Bayesian method were applied (Coles and Tawn, 1996; Diriba et al., 2017). The effects of non-informative and informative priors on the estimate of GEV parameters and return level are investigated and compared with MLE results. Despite the application of the Bayesian approach is progressively prevalent in many areas, a challenge when using this method is the computational problems. This can be solved by the application of Markov Chain Monte Carlo (MCMC) simulations (Coles et al., 2001). Moreover, the previous studies conducted on Bayesian Paradigm by using MCMC were Coles and Tawn (1996), Coles et al. (2003), Smith (2005) and Eli et al. (2012). The rest paper is organized as follows. We commence with description of data used in this study. Next, the probability

DOI: http://dx.doi.org/10.15666/aeer/1706_1372913748

distribution and parameters estimation methods used in this study will be described. After that, the results and discussion section of our analysis will be presented. Later on, the conclusion, recommendations concerning the plan for future studies will be discussed in final section.

Materials and methods

Data description

The modeling of extreme rainfalls in the province Punjab, Pakistan, the data of daily rainfall of Lahore station had been acquired from Pakistan Metrological Center Karachi for the period of 1985 to 2014, which is recorded in millimeters (mm). Data have been selected on the following standard criteria like as length of the data, variability, quality, urbanization and climate change. After that, the Annual Maximum Daily Rainfall (AMDR) series were extracted from the daily rainfall series. AMDR series is a single maximum value for any specific year and station among the all values of recorded daily rainfall. The AMDR series for 30 years of the same length were considered. For construction of informative priors for the Bayesian analysis, extreme rainfall characteristics of three sites at various distances from Lahore station were selected, namely Faisalabad, Sialkot and Jhelum.

The selected stations for informative priors were located to the south-west, north-east and north-west of Lahore station. Additionally, they are 118 km, 105 km, 164 km from Lahore station, respectively. The plots under spatial network comprise of selected weather stations studied in present research are shown in *Figure 1*. This study have 25 years of data at the same time points from 1990-2014 for each station considered for construction of informative priors.

Figure 1. *Spatial plots of network weather stations used in study for the period of 1985-2014*

Summary statistics of the selected stations

The statistical parameters for the amount of AMDR data of four selected stations are briefed in *Table 1*. Where the minimum, maximum, mean, standard deviation (SD), coefficient of variation (CV), skewness and kurtosis of AMDR series of the all included stations in this study are given. The AMDR data designates that the annual daily rainfall

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1372913748

was strongly positively skewed and highly leptokurtic for Jhelum station. It is also noted that AMDR data for Sialkot station is positively skewed and platykurtic. The CV of AMDR around 42-45% in the province Punjab, Pakistan.

The fundamental assumptions

Primarily, it is compulsory to check the basic assumptions of data before conducting the further analysis of an annual maximum series in the field of statistical hydrology; because the final results may be ambiguous without fulfilling the assumptions. The fundamental assumption of hydrological data are randomness, independence, homogeneity and stationarity. We tested these assumptions using different tests such as NERC test for randomness, Wald-Wolfowitz for independence, Mann-Whitney test for homogeneity with respect to location parameters and Spearman rank correlation test for stationarity. The results of these tests given in *Table 2* are calculated by using (ALEA 2.0) software.

Table 2. *Results of different tests for basic assumptions at 5% level of significance*

Study locations	NERC (P-value)	Wald-Wolfowitz (P-value)	Mann-Whitney (P-value)	Spearman Rank (P-value)
Lahore	-0.7445 (0.2283)	1.3505 (0.0884)	-0.3940 (0.3468)	0.7895 (0.2149)
Faisalabad	1.9358 (0.1264)	0.5230 (0.3005)	-2.0117 (0.1021)	2.4021 (0.0820)
Jhelum	1.0423 (0.1486)	1.5812 (0.0569)	-1.8043 (0.0556)	-1.3981 (0.0810)
Sialkot	-0.7445 (0.2283)	0.5039 (0.3072)	-0.4770 (0.3167)	0.2767 (0.3910)

The probability value of these tests for each stations is more than 5% level of significance showed that the relevant assumptions of the data are fulfilled, and the available data can be used for further frequency analysis (FA).

Generalized extreme value distribution

Jenkinson (1955) introduced the GEV distribution for the three limiting cases for maxima. Furthermore, the GEV distribution is very extensively used for the design structure of extreme events. Engineers, hydrologist and business analyst are most commonly used GEV distribution in the recent decade. Because, the risk always linked with the extreme type events such as risk in business, the stock market, and also risk is related to extreme floods, heavy rainfall, high wind speed and extreme temperature etc. The GEV probability density function and distribution function of a random variable w is given by:

$$f(w_i,\xi,\mu,\sigma)=\frac{1}{\sigma}\left[1+\xi\frac{(w_i-\mu)}{\sigma}\right]^{-\left(1+\frac{1}{\xi}\right)}\exp\left[-\left\{1+\xi\frac{(w_i-\mu)}{\sigma}\right\}^{-\frac{1}{\xi}}\right] \quad \text{(Eq.1)}$$

The range of w is: $-\infty < w \le \mu+\frac{\sigma}{\xi}$ if $\xi>0$; $-\infty < w \le \infty$ if $\xi=0$; $\mu+\frac{\sigma}{\xi} < w \le \infty$ if $\xi<0$.

$$F(w,\xi,\mu,\sigma)=\exp\left[-\left\{1+\xi\frac{(w-\mu)}{\sigma}\right\}^{-\frac{1}{\xi}}\right] \quad \text{(Eq.2)}$$

where $\{w:1+\xi(w-\mu)/\sigma\}$ and μ,σ and ξ are location, scale and shape parameters of GEV distribution (Beirlant et al., 2006). The shape parameter affects the nature of upper tail of the GEV distribution. Additionally, GEV distribution is the mixture of three limiting extreme value distributions i.e., Gumbel distribution, Freshet distribution and Weibull distribution. If $\xi\to 0$ the GEV distribution in *Equation 2* relates to the Gumbel distribution.

$$F(w,\xi,\mu,\sigma)=\exp\left[-\exp\left(-\frac{(w-\mu)}{\sigma}\right)\right];-\infty<w<\infty \quad \text{(Eq.3)}$$

It means that the probability of obtaining the maximum high observation come to be very small exponentially. For $\xi>0$ the GEV distribution in *Equation 2* converts to Frechet distribution, which is considered by a heavy tail that declines polynomially. Hence, obtaining higher values of maximum are larger probability in comparison with a Gumbel distribution. For $\xi<0$ the distribution in *Equation 2* becomes negative Weibull distribution and this is bounded above (Coles et al., 2003; Karim, 1995; Gingras and Adamowski, 1992). Consequently, there is a finite value that the maximum cannot exceed.

Parameter estimation of GEV distribution

Maximum Likelihood Estimation (MLE) method was primarily articulated by a German mathematician Johann Carl Friedrich Gauss. But later as a general method of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1372913748

estimation was initially developed by a British statistician Sir Ronald Aylmer Fisher in his series of papers discussed by Gupta (1982). MLE method involved a function that maximizes the parameters of the distribution, the function is known as the likelihood function. Likelihood function reaches to the maximum value when equating it to the conditions of unknowns and an identical number of equations in the system, whose solution produce the MLE estimators for unknown distribution parameters. The author was used MLE method to estimate the GEV distribution parameters. The density function of GEV distribution is given in *Equation 1*. Therefore the joint likelihood function associated with $w_1, w_2, ..., w_m$ follows from *Equation 1*.

$$L(\mu,\sigma,\xi;w_1,w_2,...,w_m)=\frac{1}{\sigma^m}\prod_{i=1}^{m}\left[1+\xi\frac{(w_i-\mu)}{\sigma}\right]^{-\left(1+\frac{1}{\xi}\right)}\times\exp\left[-\sum_{i=1}^{m}\left\{1+\xi\frac{(w_i-\mu)}{\sigma}\right\}^{-\frac{1}{\xi}}\right] \quad \text{(Eq.4)}$$

The maximum likelihood estimates of the parameters μ,σ and ξ, say $\hat{\mu},\hat{\sigma}$ and $\hat{\xi}$, are calculated by maximizing the logarithm of *Equation 4,* that is, maximizing

$$l(\mu,\sigma,\xi;w_1,w_2,..,w_m)=m\log\sigma-\left(1+\frac{1}{\xi}\right)\sum_{i=1}^{m}\log\left[1+\xi\frac{(w_i-\mu)}{\sigma}\right]-\sum_{i=1}^{m}\left\{1+\xi\frac{(w_i-\mu)}{\sigma}\right\}^{-\frac{1}{\xi}} \quad \text{(Eq.5)}$$

With respect to unknown parameters, say μ,σ and ξ. In other words, the log-likelihood function i.e., $\ln[L(\mu,\sigma,\xi;w_1,w_2,...,w_m)]=l(\mu,\sigma,\xi;w_1,w_2,..,w_m)$ is maximized instead of $L(\mu,\sigma,\xi;w_1,w_2,...,w_m)$, which simplifies the complication and gives the easy solution to the system. In a continuous parameter space the shape parameter of Gumbel distribution, $\xi=0$ is a single point, it will not be estimated by maximizing this log likelihood with probability 1. In practice the maximization of log likelihood functions is done by numerically iterations e.g., with a quasi-Newton procedure (Diriba et al., 2014, 2015).

Return level estimation for GEV distribution

The attention of extreme climatic events analysis does not sometimes lie on the estimates of GEV parameters, however the application of the fitted model to estimate the other measures. For illustration, it is very important the forecast of future extreme rainfall and heavy floods to make a proper plan to reduce its negative impact (for example landslides, human lives, animals and destruction of infrastructures such as power stations, buildings and roads) and return level or quantiles are used for such forecast. In other word, return level estimates play a dynamic role in rainfall frequency analysis to finding the future risk connected with a return period corresponding to a fitted model. The return level for GEV model corresponding the return period $T=\frac{1}{p}$ is acquired through quantile function, which is the inverse of *Equation 2* given by Coles (2001), denoted by w_p where $\mathrm{F}(w_p)=1-p$ and $0<p<1$.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1372913748

$$w_p = \begin{cases} \mu - \frac{\sigma}{\xi}\left[1 - \{-\log(1-p)\}^{-\xi}\right], \xi \neq 0 \\ \mu - \sigma \log\{-\log(1-p)\}, \xi = 0 \end{cases} \quad \text{(Eq.6)}$$

The return level w_p is a quantile of considered GEV distribution corresponding to the upper tail probability p. The ML estimate of the return level w_p, denoted by $\hat{w}_p$ is found by substituting the ML estimates $\hat{\mu}, \hat{\sigma}$ and $\hat{\xi}$. The standard error (SE) of $\hat{w}_p$ are acquired via delta method (Rao, 1973).

Bayesian paradigm

The Bayesian approach has been extensively used in extreme rainfall frequency analysis. Bayesian statistical analysis depends on Bayes Theorem, which describes us how to update prior information about parameters and hypotheses using the additional information of data, to produce posterior beliefs suggested (Jackman, 2009). According to Naghettini (2017) and Tang and Ang (2007) difference between Bayesian and frequentist approaches are based on the parameters of given probability distribution.

In a classical approach, the parameters have fixed, but unknown, they are estimated from given sample by maximizing the likelihood function. But in Bayesian approach the parameters are treated as random, they have their own probability distribution. The parameters are updated on the basis of prior knowledge and sample information, the updated information is called the posterior information of the parameters.

As in MLE method, suppose AMDR $w = (w_1, w_2, ..., w_m)$ are independently and identically distributed and their distribution belongs to a parametric family i.e. GEV. However, the parameters of GEV distribution (μ, σ and ξ) are treated as random variables for which the author describes the prior distributions. Let $\theta = (\mu, \sigma, \xi)$ and suppose the prior information about parameter θ can be articulated by a probability density function $g_\theta(\theta)$ with no reference to the actual data. After multiplication of likelihood and prior information using Bayes theorem to get the posterior density of θ has the form:

$$\pi(\theta / w) = \frac{L(\theta / w) g_\theta(\theta)}{\int_\Theta L(\theta / w) g_\theta(\theta) d\theta} \propto L(\theta / w) g_\theta(\theta) \quad \text{(Eq.7)}$$

where $L(\theta / w)$ is the likelihood function of GEV distribution given in *Equation 4* and $\pi(\theta / w)$ is the posterior distribution for θ. Furthermore, the integral is taken over the parameter space Θ. In this paper, both the non-informative and informative priors were used. The description about construction of these prior are given in previous sections.

Priors specification

Non-informative priors

The main demur in the use of Bayesian frame work is the requirement for postulating a prior knowledge $g_\theta(\theta)$. When the minimal or no information is available, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1372913748

Bayesian analysis is performed by using objective or non-informative and Jeffery's priors. The non-informative priors (also known as diffuse, flat or vague priors) used to indicate a set of principles about the concerned parameters of GEV distribution, because to betoken that the meaningful information of extreme rainfall is quite inaccessible at the moment. The AMDR series have a GEV distribution i.e., $W_i \sim GEV(\mu,\sigma,\zeta)$, the likelihood function is given in *Equation 4*. The parametrization $\varphi = \log\sigma$ is used in the place of σ, for the purpose of easier work to the specification of prior, σ is inhibited to be positive. The tri-variate normal distribution based on $\theta' = (\mu,\varphi,\xi)$ is used with prior density as follows:

$$g_\theta(\theta) \propto \frac{1}{\sigma}\exp\left\{-\frac{1}{2}(\theta' - u)^T \sum^{-1}(\theta' - u)\right\} \quad \text{(Eq.8)}$$

where the mean vector u is symmetric positive definite (3×3) covariance matrix and $\sum$ must be quantified. The prior density is preferred to be

$$g(\mu,\varphi,\xi) = g(\mu)g(\varphi)g(\xi) \quad \text{(Eq.9)}$$

The marginal priors of $g_\mu(.), g_\varphi(.)$ and $g_\xi(.)$ are:

$$\mu \sim N(0,10000)$$
$$\varphi \sim LN(0,10000)$$
$$\xi \sim N(0,100)$$

These are known as independent normal priors with large variances. The larger variances are preferred enough to create the distribution nearly flat, comparable to prior obliviousness (Eli et al., 2012; Fawcett and Walshaw, 2008).

Informative priors

Since the nonexistence of expert knowledge on extreme rainfalls in Lahore station, we have articulated the prior knowledge for the Bayesian analysis from rainfall characteristics of nearby weather stations in the same province. Hence, the informative priors were constructed by employing the approach given by (Coles and Tawn, 1996). Prior information were elicited in term of extreme quantiles. The brief description of the technique given in the following paragraph.

Remember that return level w_p [= q_p Coles and Tawn (1996) notation] for GEV distribution corresponding with the return period of $\frac{1}{p}$ is given in *Equation 6,* therefore $F(q_p) = 1-p$, and where $F(.)$ is the cumulative distribution function of GEV in *Equation 2*. Let q_{p_i}, $i = 1,2,3$ with $p_1 > p_2 > p_3$, be the quantiles calculated from the past extreme rainfall data of the nearby weather stations in the province Punjab other than Lahore. So, the independent quantiles q_{p_i} are calculated for each nearby station by means of ML estimates of GEV parameters in *Eq. 2*. A joint prior distribution for given

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1372913748

probabilities $p_1 > p_2 > p_3$ could be elicited from the quantiles ($q_{p_1}, q_{p_2}, q_{p_3}$) discuss by Coles and Tawn (1996). One slight compilation with this approach is that parameters must be ordered q_{p_i}, $i = 1,2,3$, i.e. $q_{p_1} < q_{p_2} < q_{p_3}$. Hence, the suggest quantile differences, because of the assumption of independent priors on q_{p_i}, $i = 1,2,3$ would not be valid.

$$\left.\begin{aligned} \tilde{q}_1 &= q_{p_1} - e_1 \\ \tilde{q}_2 &= q_{p_2} - q_{p_1} \\ \tilde{q}_3 &= q_{p_3} - q_{p_2} \end{aligned}\right\} \quad \text{(Eq.10)}$$

where e_1 is a physical lower end point for the process variable (rainfall) or naturally considered to be $e_1 = 0$. Perceive that the quantile differences confirm the ordering of quantiles. The marginal priors on the quantile differences are now supposed to independent Gamma distribution with parameters $(\alpha_i^*, \beta_i^*), i = 1,2,3,$ we can take in the form

$$\tilde{q}_{p_i} \sim gamma(\alpha_i^*, \beta_i^*),\ \alpha_i^* > 0, \beta_i^* > 0;\ i = 1,2,3. \quad \text{(Eq.11)}$$

From *Equations 10* and *11* we can get the joint prior for the (α_i^*, β_i^*), $i = 1,2,3$ in following form:

$$g(q_{p_1}, q_{p_2,} q_{p_3}) \propto \tilde{q}_{p_1}^{\alpha_1^*-1} \exp(-\beta_1^* \tilde{q}_{p_1}) \times \prod_{i=2}^{3} \tilde{q}_{p_i}^{\alpha_i^*-1} \exp(-\beta_i^* \tilde{q}_{p_i}) \quad \text{(Eq.12)}$$

provided that $q_{p_1} < q_{p_2} < q_{p_3}$. Then utilize *Equation 6* in *Equation 12* and multiplying by the Jacobean (J) of the transformation from ($q_{p_1} < q_{p_2} < q_{p_3}$) to $\theta = (\mu, \sigma, \xi)$, it gives to an expression for the prior in term of the GEV distribution parameters θ. Further, this can be written as

$$g_\theta(\theta) \propto \prod_{i=1}^{3} \tilde{q}_{p_i}^{\alpha_i^*-1} \exp\left(-\frac{\tilde{q}_{p_i}}{\beta_i^*}\right) \times J \quad \text{(Eq.13)}$$

provided that $q_{p_1} < q_{p_2} < q_{p_3}$. The Jacobean used in *Equation 13* is given by

$$J = \begin{cases} \dfrac{\sigma}{\xi^2} \left| \sum_{i<j} (-1)^{i+j} (y_i \times y_j) \log\left(\dfrac{y_j}{y_i}\right) \right|, [i, j \in \{1,2,3\}; \xi \neq 0 \\ \dfrac{\sigma}{2} \left| \sum_{i<j} (-1)^{i+j} \log y_i \times \log y_j \times \log\left(\dfrac{y_j}{y_i}\right) \right|, [i, j \in \{1,2,3\}; \xi = 0 \end{cases} \quad \text{(Eq.14)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1372913748

where $y_i = -\log(1-p_i), i = 1,2,3.$ The posterior density $\pi(\theta / w)$ is found by replacing the likelihood and prior density given in *Equations 5* and *12,* respectively, in *Equation 7*. However, the analytical calculation for *Equation 7* is completely intractable, because of the involvement of integrals in denominator. Therefore, the features of posterior distribution $\pi(\theta / w)$ of θ is to be estimated by using Markov Chain Monte Carlo (MCMC) method with the combination of Gibbs Sampler and Metropolis-Hastings algorithm.

In Bayesian analysis, to estimate the return levels, usually, the vectors of simulated values are found by employing the marginal posterior distributions of GEV parameters. Return level q_p is obtained for a specified return period $\frac{1}{p}$ by substituting the simulated samples of GEV parameters from posterior distribution. Furthermore, the summary statistics can easily be acquired.

Robustness measures

On the basis of robustness measures, the authors will also compare the performance between the classical (MLE) and Bayesian MCMC methods (both for non-informative and for informative priors) in estimating GEV parameters and return levels for AMDR data of Lahore weather station in the province Punjab, Pakistan.. The selected robustness measures are relative root mean square error (RRMSE), relative absolute square error (RASE) and probability plot correlation coefficient (PPCC). The first two measure comprises the assessment on the difference between the observed and the estimated values under the presumed distribution, while the third one is measure the relationship between the ordered values and associated estimated values (Zawiah et al., 2009). The formulae are given as:

$$RRMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}\left(\left|\frac{w_{i:n} - \hat{q}(F_i)}{w_{i:n}}\right|\right)^2} \quad \text{(Eq.15)}$$

$$RASE = \frac{1}{n}\sum_{i=1}^{n}\left|\frac{w_{i:n} - \hat{q}(F_i)}{w_{i:n}}\right| \quad \text{(Eq.16)}$$

$$PPCC = \frac{\sum_{i=1}^{n}(w_{i:n} - \bar{x})(\hat{q}(F_i) - \bar{q}(F_i))}{\sqrt{\sum_{i=1}^{n}(w_{i:n} - \bar{x})^2 \sum_{i=1}^{n}(\hat{q}(F_i) - \bar{q}(F_i))^2}} \quad \text{(Eq.17)}$$

where $w_{i:n}$ represents the observed sample values of *ith* order statistics of a random sample of size n, and $\hat{q}(F_i)$ are estimated quantiles linked with the *ith* Weibull plotting position, F. The Weibull plotting is defined as follows:

$$F = \frac{i}{n+1}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1372913748

where i denote the ranks of the observations arranged in ascending order. The minimum values of RRMSE and RASE will show the best method. In contrast, the value of PPCC that is closest to -1 or 1 will be reflected as the best method for elucidation the behavior of extreme rainfalls in Punjab, Pakistan.

Results and discussion

GEV distribution using MLE

To analyze the AMDR data, GEV distribution is fitted to the extreme rainfall values. The parameters of the fitted model are estimated by MLE method. Maximum likelihood estimates with their SE in (parentheses) and the 95% confidence interval (CI) in [square brackets] for fitted model at Lahore Station are given in *Table 3*. It can be seen that the entire results of the fitted model (i.e. GEV) supports the AMDR data.

Table 3. *Parameter estimates of location, scale and shape of GEV distributions, their standard errors and confidence interval*

Study locations	**Location ($\hat{\mu}$)** **(SE)** **[CI]**	**Scale ($\hat{\sigma}$)** **(SE)** **[CI]**	**Shape ($\hat{\xi}$)** **(SE)** **[CI]**
Lahore	72.8995 (5.9325) [61.2686, 84.5208]	28.6298 (4.3780) [20.0469, 37.2029]	0.0317 (0.1461) [-0.2544, 0.3180]

Furthermore, before calculating the return levels, we should have to check the goodness of fit of our model. The adequacy of the chosen model can be checked using the quantiles, probability and return level plot. The plots for GEV distributions fitted to the data of Lahore station are given in *Figure 2*. The quantiles and probability plots shows that the assumptions required for the GEV distributions have been fulfilled.

The return levels for best fitting model (i.e. GEV) could be estimated for next '*T'* year after base year using *Equation 6*. Therefore, the return levels estimates will be time varying. An estimate of the rainfall that the authors might assume to see at Lahore station in the next '*T*' years by employing the MLEs of the parameters in GEV distribution. Before estimating $\hat{w}_p$, the number of years should be converted to the probability (i.e. $p = \frac{1}{T}$). The predicted amount of maximum rainfall, that is, in context of return level, corresponding to return periods in *Figure 2* suggests that the return level falls below the 20-year return periods. Furthermore, it can be noted that the 95% confidence bounds are becoming very distant from the straight line for the return periods beyond the 20 years. Return levels for different return periods with corresponding the 95% CIs were estimated using the profile likelihood methods are given in *Table 4*.

Therefore, the return levels for AMDR increased slowly for the higher return periods. It can be seen that from *Table 4,* the profile likelihood intervals were gradually wider as return period increased.

This supports with the results showed in the return level plots given in *Figure 2*. However, since the profile likelihood method takes into account the skewness of the parameter distributions, it gives more accurate results for longer return periods.

Bayesian analysis

In Bayesian analysis, we were employed the non-informative and informative priors to the extreme rainfall data of Lahore weather station. The non-informative priors used (Coles and Tawn, 2005) were constructed for GEV parameters by assuming there is no reliable prior information available about the parameters given in priors specification

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1372913748

subheading (*non-informative priors*). Non-informative independent priors for GEV parameters were assumed $g(\mu) \sim N(0,10000)$; $g(\varphi) \sim LN(0,10000)$ and $g(\xi) \sim N(0,100)$.

The scale parameter of GEV (i.e. σ) was reparametrized as $\varphi = \log(\sigma)$ to hold the positivity of this parameter. The Gaussian distribution having zero mean and higher variance impose the flat marginal priors (also known as diffuse or vague priors), which show the absence of external information. The MCMC technique with combination of Gibbs Sampler (GB) and Metropolis-Hasting (M-H) algorithm was applied to AMDR series. Different starting points were used in simulations to check that the chains had converged to the original series and all the chains mixed well. The posterior means, standard deviation (SD) and 95% CIs of the parameters are given in *Table 4*. Furthermore, the posterior means, standard deviations (SD) are close to ML parameter of GEV distribution (see *Table 3*). The CIs of posterior parameters are little bit wider as compared to MLEs. It is expected that for flat-priors that posteriors means of GEV parameters with their CIs would be close to MLEs because they incorporate little information to the likelihood.

The informative priors were articulated by using historical records of rainfall data from three nearby weather stations to Lahore station. Moreover, the prior distributions were elicited using the method given by Coles and Tawn (1996) and discussed in subheading (*informative priors*) with quantiles $p_i = 10^{-i}$; for $i = 1,2,3$. By using this procedure, we have found $\tilde{q}_{p_1} \sim gamma(25.9065,4.015)$, $\tilde{q}_{p_2} \sim gamma(0.5702,117.4019)$ and $\tilde{q}_{p_3} \sim gamma(0.0999,804.3856)$ from Faisalabad weather station data. Similarly, the informative prior priors for Sialkot and Jhelum weather station were elicited by applying the same procedure. The posterior means and SD of GEV parameters with CIs are also given in *Table 5*. It can be seen the posterior means and CIs for GEV parameters based informative prior are close posterior means and CIs of non-informative priors.

The informative priors constructed from the surrounding weather stations reduced the posterior SD for all GEV parameters as compared to non-informative priors and MLEs. This abatement in the SD would possibly overcome in uncertainty due to using extra information from the surrounding weather stations. This impact became most important for the SD of location, scale and shape parameters.

The estimated posterior densities plots of GEV parameters are given in *Figure 3*. It can be noticed that the distributions of location and shape parameters are symmetrical for non-informative and informative priors, while the shape parameter is negatively skewed for the prior elicited from the Faisalabad weather station that is situated at 118 km distance from Lahore. But the densities of location, scale and shape parameters have high peaks at center for the informative priors which were constructed using the Faisalabad and Sialkot data.

The densities for scale parameter were slightly positively skewed for non-informative and for all informative priors. It can be observed from densities plots, the densities of location, scale and shape parameters are shifted lift for the priors elicited from Sialkot and Jhelum data. These variations indicate that the posterior results might be changed due to the choice of priors. Furthermore, the distance between a weather station was used to articulate priors and Lahore weather station.

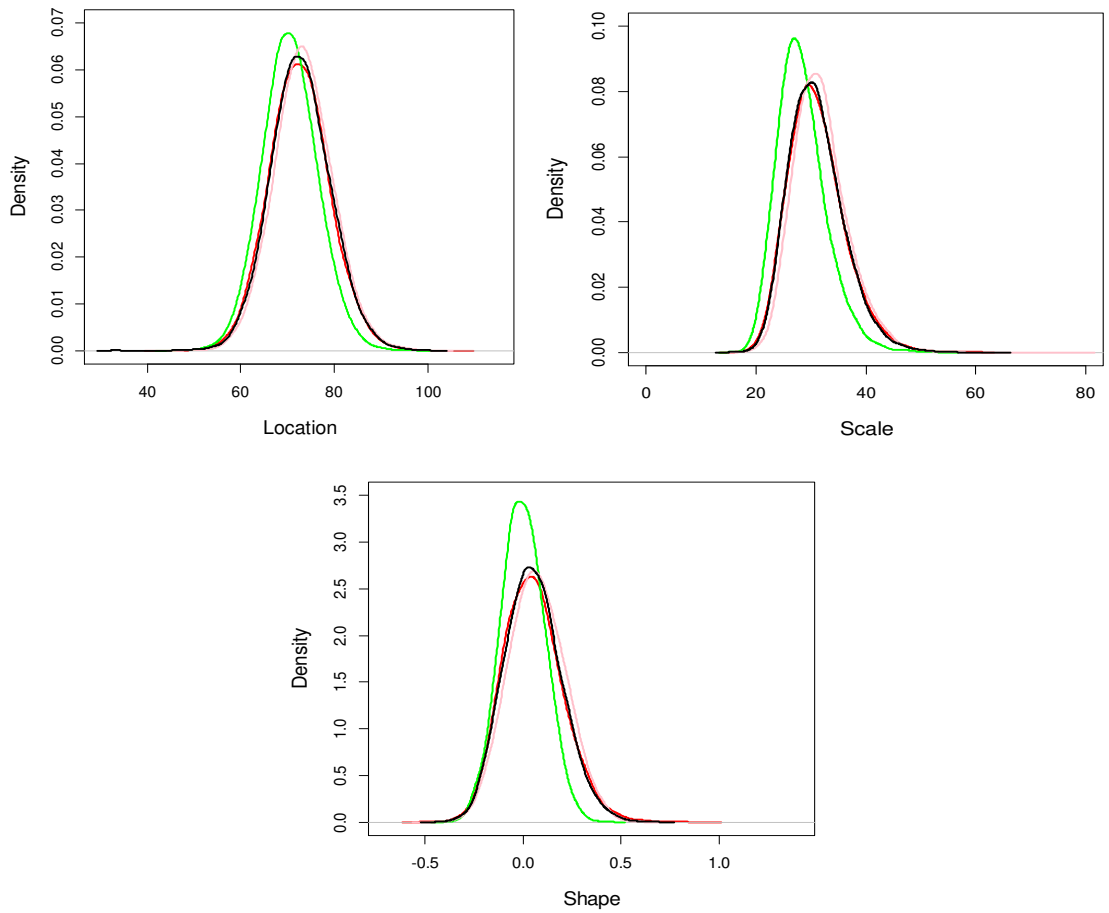

Figure 3. *Posterior densities plots of the GEV parameters to AMDR data using non-informative (red line) and informative priors (green line for Faisalabad, pink line for Sialkot and black line for Jhelum)*

Priors effect on return level

To look at how the non-informative and informative priors have affected the return levels, the authors obtained the posterior densities of the return levels. Additionally, the posterior density plots were constructed by employing the observations vectors obtained from the marginal posterior distributions of GEV parameters in *Equation 3,* for $0 < p < 1$. This process was carried out to attain the posterior densities of return levels for 10, 25, 50, 75, and 100 years return periods. Therefore, the posterior densities of these return levels for both non-informative and informative priors are given in *Figure 4*. The return level densities were symmetric and peaks high for the prior formulated from the Faisalabad weather station data, while the all other densities of the return levels were positively skewed and mesokurtic for both non-informative and the informative priors obtained from the Sialkot and Jhelum data. From this skewness, it can be cleared that the uncertainty might reproduce in the model for founding upper limits of the return levels as compare to lower limits for higher return periods (Coles and Tawn, 2005; Diriba et al., 2015). Furthermore, the posterior median of AMDR data for Lahore weather station was calculated. The results for different return periods are given in *Table 6*. The posterior medians of return levels for both non-informative and informative prior are not much different to their parallel MLEs. Moreover the results of *Tables 6* and *4* showed that the posterior medians of return levels for non-informative priors and informative priors constructed from nearby stations except Faisalabad are higher than MLEs across all considered return periods. The variations in higher medians of return levels (i.e. 75, 100) are smaller as compared to lower return levels. Hence the medians of returns levels vary due to distance of these stations (Faisalabad, Sialkot and Jhelum) and Lahore weather station, which was used to informative priors construction. However, the results of return level against different return periods are higher as compared to previous study which was conduct by Ahmad at el. (2016). Therefore, it is undeniable that these results are significant for policy implications in the region. They are also beneficial for meteorologists and hydrologists in water resource management.

Table 6. *Posterior medians for 10, 25, 50, 75 and 100-year return levels of AMDR using both non-informative and informative priors*

Priors	**Return levels**				
	10	**25**	**50**	**75**	**100**
Non-informative	146.7440	180.7501	207.0989	222.8688	234.2373
Informative					
Faisalabad	134.2359	161.0712	180.9693	192.5310	200.712
Sialkot	150.9387	187.5129	216.2855	233.6831	246.3059
Jhelum	146.8390	180.7752	207.0684	222.8045	234.1485

Robustness measures

On the basis of result given in *Table 7,* it can be decided the Bayesian MCMC paradigm for both non-informative and informative priors is slightly performed better than MLE. Because, the smaller values of RRMSE and RASE show little difference between the observed and estimated values. Furthermore, the smaller value of RRMSE and RASE corresponding to informative priors also indicate that Bayesian MCMC

DOI: http://dx.doi.org/10.15666/aeer/1706_1372913748

method provide more precise results, when the expert prior were used in estimation. With the support of the results of PPCC test, it can be declared that Bayesian MCMC method was superior in modeling of extreme rainfall in the Punjab, Pakistan.

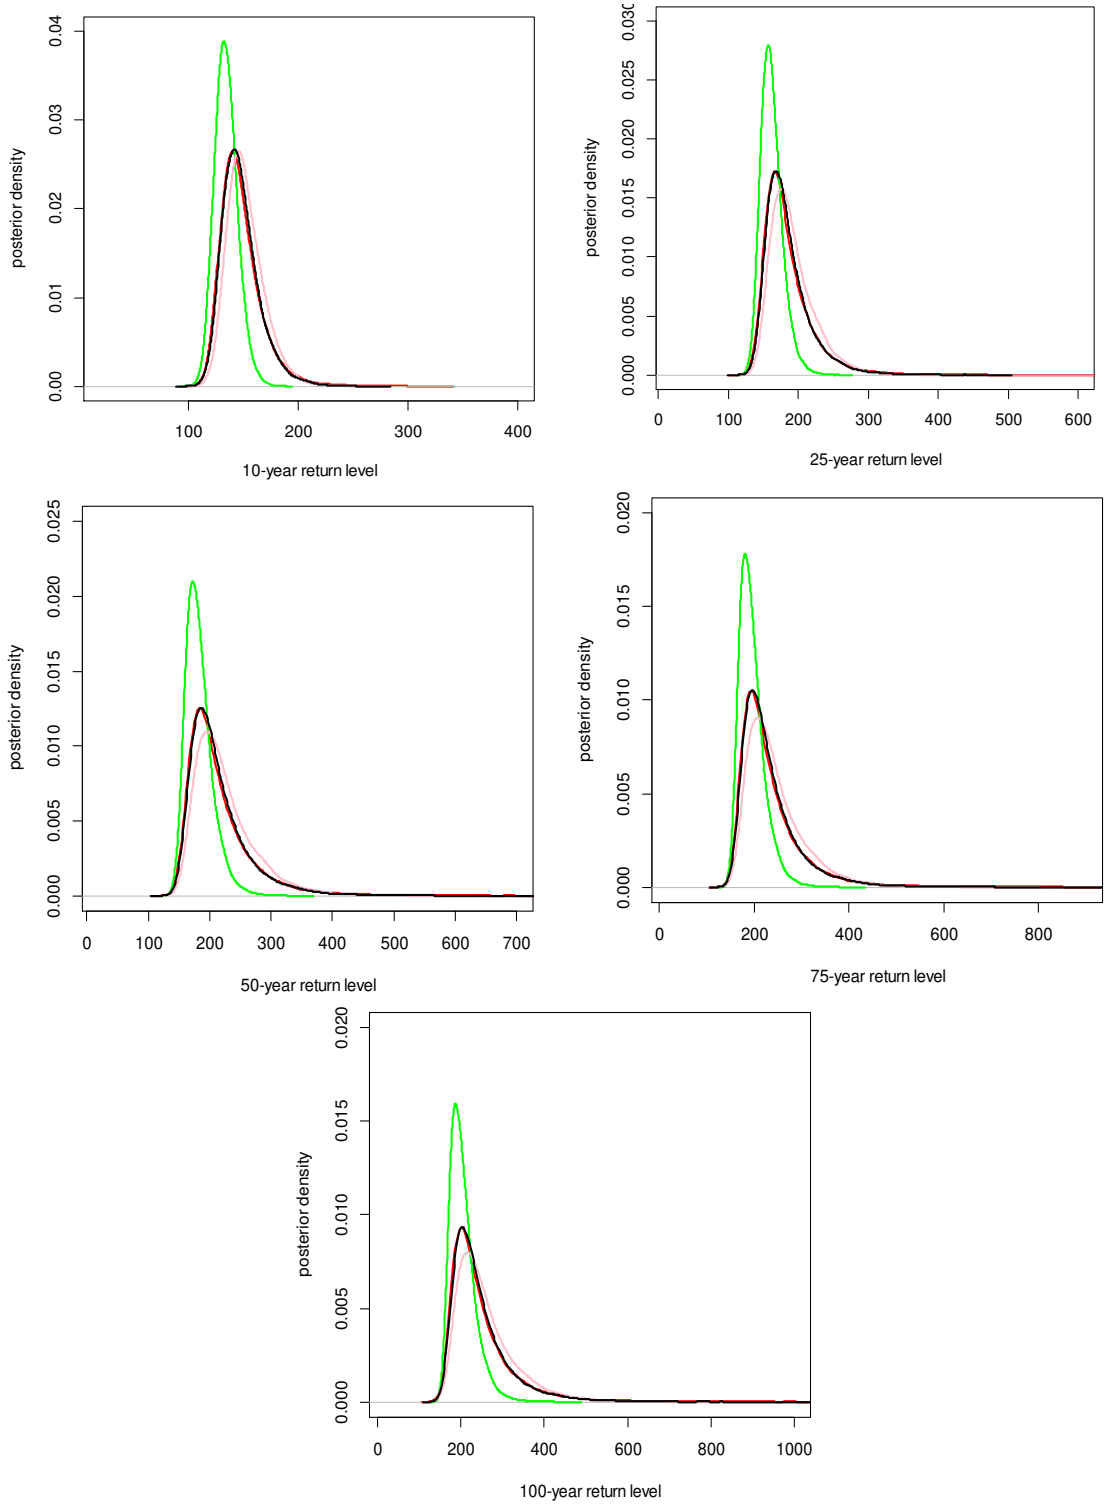

Figure 4. *Posterior median densities plots for the 10, 25, 50, 75 and 100 year return levels using AMDR data using non-informative (red line) and informative priors (green line for Faisalabad, pink line for Sialkot and black line for Jhelum)*

Conclusion

Our objective was to conduct the extreme value analysis for the modelling of AMDR data of Lahore weather station, Punjab, Pakistan through frequentist and Bayesian approaches. The AMDR data was shown to follow GEV distribution which has a positive shape parameter, frequently appealing as it has a finite upper limit. In frequentist method, the return levels for (10, 25, 50, 75 and 100 years) were estimated by using parameter estimates obtained via MLE. These results indicated that there would be an extreme rain event occurring in future. In addition, the authors used Bayesian MCMC approach, which provide a more efficient analysis and predictions. Therefore, the results found for both non-informative and informative priors using MCMC techniques and were compared with MLEs and each other. As the posterior means of best fit distribution parameter estimates attained using non-informative priors were close to MLEs of parameters. In addition, the influence of the informative priors used in the statistical analysis on posterior mean and SE depend on the distance among the weather stations used for construction of informative priors and the weather station where GEV model was best fitted. Furthermore, the SE of posterior means of the parameters were smaller due to shorter distance. The smaller values of robustness measures were directed precision of Bayesian MCMC method (both for non-informative and informative priors). Although, the Bayesian analysis offers a more suitable and straight way to handling and expressing uncertainties suggested (Coles et al., 2003).

The Bayesian paradigm presented in this study to model the behavior extreme event at Lahore weather station is suitable when climatological information is scare. The limitation of the method is that it considers the behavior of extreme rainfall is same over the weather stations in the province from which the data were acquired. However, the extreme rainfall behavior at different parts of the province Punjab can be affected by the topography of the area and other information. To construct the prior distributions for weather stations in addition to historical records, the authors suggest that the Bayesian analysis should utilize this kind of information. Moreover, this study shows that the effects of informative priors on posterior means and accuracy of parameter estimates of GEV depend on distance. In general, the results of this work are very helpful to future plan in the designing of dam, bridges, culverts, and flood control devices in the province Punjab, Pakistan. These findings could be enhanced further with the practice of spatial modelling and this is the theme of future research.

Abstract. Arbuscular mycorrhizal association is ubiquitous and can be found in majority of natural habitats. Arbuscular mycorrhizal fungi (AMF) play a key role in the absorption of plant nutrients, soil aggregation and fertility. The basic role of AMF in the plant growth is to increase the absorption and translocation of relatively immobile ions and elements. In the past, studies have focused primarily on the mycorrhiza development and their general role in the growth of plants. Here, in this review manuscript, we highlight the role of AMF in the growth of old forests. In many studies, it has been found that concentration of phosphorous (P) decreases with the stand age which as a result leads to phosphorous (P) deficiency. This phosphorous (P) deficiency is considered as a cause of slow growth of old forests. In this review article, we argued that apart from the low concentration of phosphorous (P), weak arbuscular mycorrhizal associations are also a cause of slow growth of old forests. Furthermore, we also highlight the ecological role of AMF in the soil carbon storage. AMF provide physical (hyphae frame) and chemical support (Glomalin) to the dispersed soil particles to create stable aggregated soil structure. The Glomalin compound which is released by AMF acts like a glue and consequently increases soil aggregation. The soil organic matters stored in soil aggregates are less exposed to decomposition. Hence, soil can be used as a large sink where a huge amount of carbon can be stored in the form of soil organic matters which as a result can contribute to the mitigation of global climate change.
Keywords: *spore germination, Glomalin, phosphorous (P), heavy metals, soil aggregation*

Introduction

The permanency and functioning of a terrestrial ecosystem are determined by plant biodiversity and species composition (Bond et al., 1993; Tilman and Downing, 1994; Naeem et al., 1994; Tilman et al., 1996; Hooper and Vitousek, 1997; Wang et al., 2006, 2008). The collaboration between aboveground and belowground mechanisms in all terrestrial ecosystems impacts community and ecosystem-level processes (Wardle et al., 2004). Typically, in a terrestrial ecosystem, different mycorrhizal symbiotic links develop between plants and fungi in an extensive range (Finlay, 2008). These symbiotic associations are abundant and occur in 75 to 80% plants (Clasen et al., 2018). Mycorrhizal association plays very important role in ecosystem which improves plants growth and existence through a mutualistic relationship (Kernaghan, 2005) as can be seen in *Figure 1*. There is a give-and-take influence or "feedback" between plants and mycorrhizal fungi. For instance, the diversity of mycorrhiza promotes several plants community traits which in turn can promote mycorrhizal diversity (Castelli and Casper, 2003; Reynolds et al., 2003).

The term 'Mycorrhiza' was first used in 1885 by Frank to define the modified root structures of forest trees (Frank, 2005). In the mycorrhizal associations, arbuscular

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1374913758

mycorrhizal fungi (AMF) is the result of the mutual adaptation of plants and fungi (Smith and Smith, 1990). AMF symbiosis is one of the oldest association on ground and hired in to the phylum Glomeromycota and order Glomales (Smith and Read, 1997; Schüßler, 2002).

In terrestrial ecosystem, AMF is the essential component (Smith and Read, 2008) and can be found in many herbaceous plant communities in abundance (Allen et al., 1995; Kennedy et al., 2005). Generally, the distribution of AMF species is dependent on many factors, for instance, environmental conditions and host plant species (Koske, 1981; Hetrick and Bloom, 1986). Hence, richness and diversity of AMF vary across different community types (Gai et al., 2009).

Previous studies have focused primarily on the mycorrhiza development and their general role in the growth of plants. Here, in this review manuscript, we highlight the role of AMF in the growth of old forests. In many studies, it has been found that concentration of phosphorous (P) decreases with stand age which as a result leads to phosphorous (P) deficiency (Jiao et al., 2013; Li et al., 2013). This phosphorous (P) deficiency is considered as a cause of slow growth of old forests. In this review article, we argue that apart from the low concentration of phosphorus, weak Arbuscular mycorrhizal associations are also a cause of the slow growth. We suggest that the growth of old forests can be made better if suitable environment for the germination and development of arbuscular mycorrhizal fungi (AMF) associations is provided which as a result can increase above ground biomass. Furthermore, we considered a portion on the ecological role of AMF in the soil carbon storage. The Glomalin compound which is released by AMF plays a very important role in the soil aggregation. The soil organic matters stored in soil aggregates are less exposed to decomposition. In this study, we highlight the importance of soil as a large sink where a huge amount of carbon can be stored in the form of soil organic matters which as a result can mitigate the problem of global climate change.

Role of AMF in forest growth

The main role of AMF is to increase the absorption and translocation of relatively immobile ions and elements (Cooper and Tinker, 1981; Liu et al., 2000). These immobile ions (phosphate, ammonium and nitrate) and elements (such as P, Zn, Ca, S and N) are translocated through hyphae of AMF. In return, AMF receive carbon from the plant in the form of photosynthates (*Fig. 2*). About 5 to 10% of plants taken carbon during photosynthesis is usually released to the soil via roots (Farrar et al., 2003; Zhang et al., 2016).

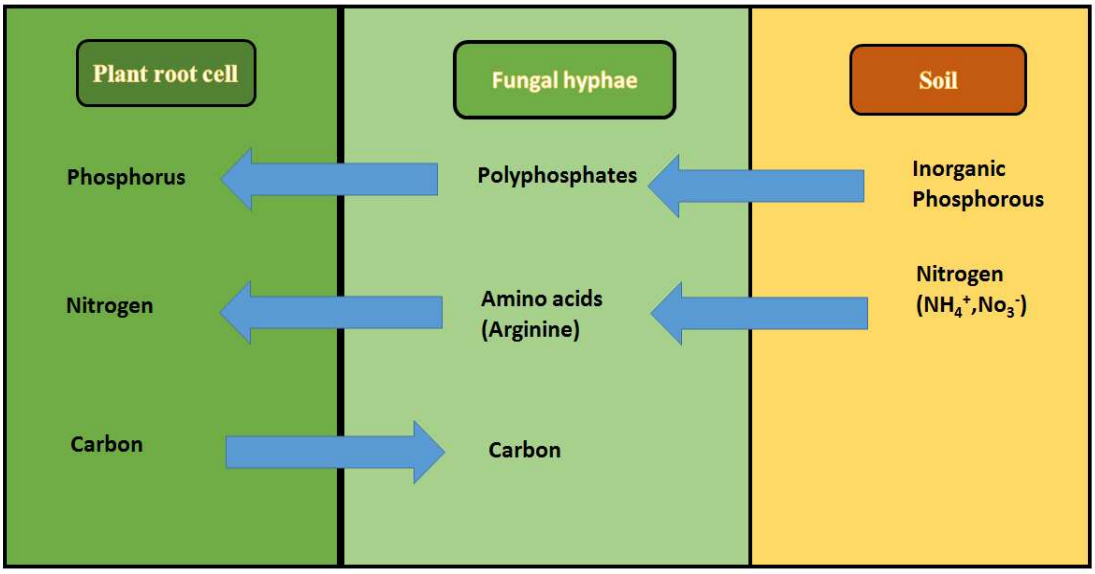

Figure 2. *Mutual nutrient supply between plant and AMF hyphae (Selosse and Rousset, 2011)*

Among AMF translocated immobile elements, phosphorous (P) is considered one of the primary nutrients for plant growth (Hinsinger, 2001). In soil, phosphorous (P) usually present in both organic and inorganic forms. Majority of it is in insoluble form as in acid soil, phosphate ions are mostly adsorbed in the form of Fe and Al phosphates, while in alkaline and calcareous soils, it is adsorbed in the form of Ca and Mg phosphates (Mehrotra, 2005). As already mentioned, AMF plays a very important role in the up-taking of these phosphorous (P) immobile ions (Cooper and Tinker, 1981; Liu et al., 2000). It is found that AMF is more efficient than plant roots at up-taking of phosphorous (P). The rate of up-taking can be six times faster than root hairs (Bolan, 1991). The up-taking phosphorous (P) is needed to maintain optimum plant quality, cell division, plant metabolisms, reproduction and energy storage (Zapata and Zaharah, 2002; Epstein, 1972). Moreover, phosphorous (P) plays an important role in the availability of nutrients, root development, root morphology and its branching (López-Bucio et al., 2003; Jin et al., 2005). The deficiency of phosphorous (P) usually leads to undersized, necrotic and erect leaves, lateral buds and subnormal root development. Hence, the availability of phosphorous (P) is very important for the growth of forest and it has been found that the growth of some regions is more effected by Phosphorous (P) than Nitrogen (N) (Jiao et al., 2013). The reason behind it is that AMF do not directly increase the up-taking of nitrogen but actually help plant in absorbing phosphorus which as a result also affects the absorption of other nutrients such as nitrogen (Mehrotra, 2005).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1374913758

As stated earlier, the concentration of phosphorous (P) does not remain the same with the stand age and it decreases with the passage of time from early successional stage to late successional stage (Li et al., 2013; Jiao et al., 2013). As a result, many old forests with phosphorous (P) deficiency, have less growth, productivity and less carbon biomass. Here we propose that phosphorous (P) deficiency is not the only reason behind the slow growth of old forests. There are other factors which are accounted for the slow growth such as AMF spore germination and spore density. In a forest, AMF spore germination and AMF spore density are directly connected to the up-taking of phosphorous (P) which means that less spore germination and less spore density result in the decrease of phosphorous (P) absorption which is the case for an old forest. There are many factors which affect spore germination and spore density such as plant cover, soil sampling depth, soil fertility, seasonal variations, altitudinal gradient, soil moister, PH, and heavy metals concentration (Hepper and Smith, 1976; Jansa et al., 2005; Weissenhorn et al., 1993; He et al., 2002; Pawlowska and Charvat, 2004a). But here we discuss only three factors, e.g. heavy metals concentrations, soil fertility and plant cover which can be important in the context of old growth forests. The first factor, heavy metal concentration affects the initial stage of spore germination of AMF. It has been found that from early successional stage to late successional stage, the concentrations of heavy metals (Zn, Fe, Cu) increases which has negative impact on the initial stage of AMF spore germination (Li et al., 2013; Jiao et al., 2013; Pawlowska and Charvat, 2004b). The other two factors are related to spore density. Generally, increase in the concentration of different elements (e.g. N. Ca, K, and Mn) with stand age indicates increase in the fertility. It is well known that AMF possess higher spores density in low fertile soil due to slower decomposition rates and longer lived roots which is not the case for old forests (Eissenstat and Yanai, 1997; Zak and Pregitzer, 1998; Lovelock et al., 2003; Nadelhoffer, 2000). On other hand, plant cover which increases with the stand age of a forest negatively affects the spore density (He et al., 2002). Spore density and spore germination are crucial stages for AMF occurrence, distribution and colonization which play important role to provide phosphorous (P) for growth. Hence, apart from the phosphorous (P) deficiency, increase in the heavy metals concentration, fertility and plant cover also affect the growth of old forests through weak arbuscular mycorrhizal associations. Hence, we claim that the growth of old forests can be made better if suitable environment for the germination and development of arbuscular mycorrhizal fungi (AMF) associations is provided.

Here, we suggest that the development of rich food sites (like grasslands) around the boundaries of old forests can improve the distribution and density of AMF spores inside the old forests. The food sites will attract mammals, rodents, ungulates, migratory and local birds (endozochoorous co-dispersers, transfer usable propagules of both mutual associates-plants and AM fungi) (Bueno and Moora, 2019) that can spread spores of arbuscular mycorrhiza through bird droppings and faeces in old forests. In addition, the use of information and communication technology (ICT) for the management of old forests can improve plant community structure, ecosystem health, biodiversity and above ground biomass.

Role of AMF in soil carbon storage

Globally, forest soil contains approximately half of the earth terrestrial carbon (1146 × 1015 g) and about two-thirds of this amount is retained in soil pools (Dixon et al., 1994; Goodale et al., 2002). Understanding of the mechanisms through which we

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1374913758

can control soil carbon storage is crucial for the climate change (Averill et al., 2014). The soil organic carbon pool is an important regulator of the carbon exchange between biosphere and atmosphere. In order to achieve carbon loss-gain balance and mitigate global climate change, the soil carbon storage should be increased (Díaz et al., 2009). Soil carbon storage is directly related to the microbial community contribution, dynamics, biomass, balance between formation and degradation of microbial by-products and indirectly related with carbon cycling and soil aggregation (Six et al., 2006). To increase the storage capacity of the soil for carbon, the role of AMF cannot be ignored. As can be seen from *Figure 2,* the transfer of carbon from the host plant to AMF hyphae occurs in the form of photosynthates. This transfer usually takes place within few hours (Johnson et al., 2002). It has been found that the presence of mycorrhizal associations increases significantly plant carbon assimilation during photosynthesis (Miller et al., 2002; Grimoldi et al., 2006; Calderón et al., 2012) and as a result can increase carbon induction into soil (Grimoldi et al., 2006). AMF take carbon from the host plant in exchange for phosphorous (P) to expand the hyphae network. Generally a large fraction of soil carbon is labile and can readily undergo changes and decomposition if exposed to high moisture and temperature (Davidson and Janssens, 2006). Any significant increase in the decomposition of soil organic matter (SOM) can make the problem of global climate change severe. So we need to protect this soil organic matter from decomposition and as result we can dump more and more carbon inside soil in the form of SOM. This can be done if we store SOM in soil aggregates. In soil aggregation, insoluble Glomalin glycoprotein produced by AMF hyphae and spore plays very important role (Driver et al., 2005; Gonzalez-Chavez et al., 2004). The hyphae which behave like wall boards and soil particles which behave like insulation fills spaces between these boards (hyphae). The Glomalin covers it like a protective layer of paint on a wall (*Fig. 3*). Glomalin is very important for the stability of these soil aggregates. In the case of weak aggregation, aggregates can easily eroded by rainfall and all the organic matter and nutrients stored in these aggregates will be lost.

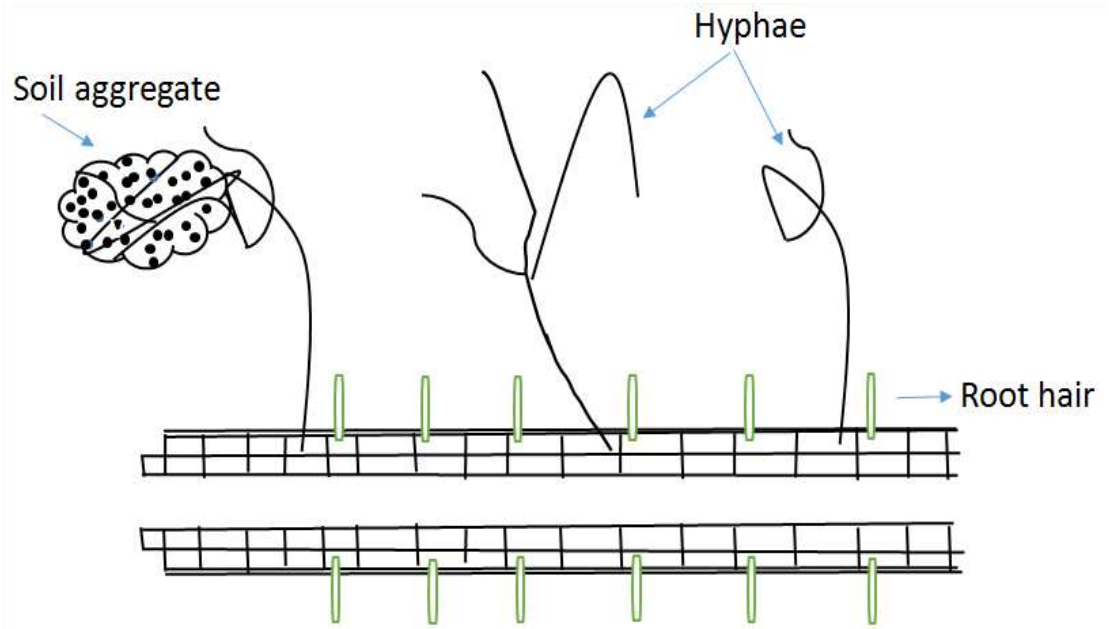

Figure 3. *Hyphae collect soil particles and then coat it with Glomalin to form soil aggregates (Rillig, 2004)*

DOI: http://dx.doi.org/10.15666/aeer/1706_1374913758

Glomalin for the first time was discovered by soil scientist Sara F. Wright of the United States Department of Agriculture (USDA) and Agricultural Research Service (ARS) in 1996 (Wright and Upadhyaya, 1996). Glomalin is a compound which is not soluble in water and also resistant to heat degradation. Glomalin is still not defined biochemically. It consists of 4 to 6% Hydrogen, 33 to 49% Oxygen, 36 to 59% Carbon, 3-5% Nitrogen and 0.03 to 0.1% Phosphorus. Glomalin has reddish color and it is because of the 0.8 to 8.8% of Iron. This range of Iron concentration makes Glomalin resistive to degradation, increases thermal stability and strengthens Glomalin antimicrobial properties (Fokom et al., 2012).

As already explained, AMF especially Vesicular Arbuscular Mycorrhizal (VAM) is very important for the growth of a plant because of the hyphae hair like projections which can explore soil better than plant roots for different nutrients. Fungus supply different nutrients especially Phosphorus to the plant and in return plant provides carbon to the fungus for the growth. The excreted Glomalin covers the hyphae with hydrophobic sheet to stop any leakage of nutrients. When the roots grow and hyphae stop supply of nutrients, the Glomalin is generally released to the soil where it sticks to the organic materials and minerals. In soil, its presence increases soil aggregation and because of its ability to protect organic matters inside aggregates, it is also associated with carbon sequestration (Rillig et al., 1999). Functions of Glomalin can be summarized as:

- Acts like glue and helps in soil aggregation (Wright and Upadhyaya, 1998)
- Mitigates water and soil erosion (Andrade et al., 1998)
- Increases percolation of water (Prasad et al., 2018)
- Increases retention of water close to the roots (Bitterlich et al., 2018)
- Makes improvements to the recycling of nutrients (Singh, 2012)
- Improves carbon and nitrogen storage (Ariza et al., 2008)

Summary and future perspectives

To summarize, we have reviewed the role of AMF in the growth of old forests. Previously, researchers have found that low concentration of phosphorous (P) is the main cause of the slow growth of old forests. In this review article, we argued that apart from the low concentration of phosphorus, weak Arbuscular mycorrhizal association is also a cause of the slow growth. In old growth forests, the concentration of heavy metals has increased with the stand age which negatively affects the initial germination stage of AMF spores. Furthermore, an increase in fertility and plants cover with stand-age also decreased AMF spore density. These all factors over all affected the AMF associations in the old forests. Thus we claim that the growth of old forests can be improved provided that spore germination and spore density are increased which as a result can increase above ground biomass. In this study, we suggested that the development of rich food sites (like grasslands) around the boundaries of old forests can improve the distribution and density of AMF spores inside the old forests. The food sites will attract mammals, rodents, ungulates, migratory and local birds (endozochoorous co-dispersers, transfer usable propagules of both mutual associates-plants and AM fungi) that can spread spores of arbuscular mycorrhiza through bird droppings and faeces in the old forests. In addition, the use of information and communication technology (ICT) for the management of old forests can improve plant community structure, ecosystem health, biodiversity and above ground biomass. Apart from the role of AMF in the old forests,

DOI: http://dx.doi.org/10.15666/aeer/1706_1374913758

we also highlighted the importance of AMF in soil aggregation. The Glomalin compound which is released by AMF (spores and hyphae) acts like glue and consequently increase soil aggregation. The soil organic matters stored in soil aggregates are less exposed to decomposition. Hence, soil can be used as a large sink where a huge amount of carbon can be stored in the form of soil organic matters which as result can mitigate the problem of global climate change.

Abstract. Irrigated artificial grasslands can help in achieving a large amount of forage in the Inner Mongolia typical steppe areas of China. However, developing irrigated artificial grasslands requires the consumption of water resources, and also affects the hydrological cycle. In this study, mapping evapotranspiration at high resolution with internalized calibration (METRIC) model has been used to estimate regional evapotranspiration during the crop growth season (from May to September) in irrigated artificial grasslands in 2011. The results were verified based on the data obtained from eight monitoring points of irrigated silage maize farms using water balance method, with a mean relative error value of 13.8%. The average evapotranspiration for irrigated artificial grasslands during the crop growth season is 611.42 mm. To further analyze the consumption of local water resources, concept of groundwater consumption (GW) is proposed. The GW value for irrigated artificial grasslands during the crop growth season was estimated to be 457.96 mm; the GW values at each of these farms, including Woyuan cow, Maodeng, Baiyinxile, Hezhongmumin, exceeded 400 mm. The results show that these areas, which exhibit high water consumption face difficulties in water resource management, particularly when there is no external water supply.

Introduction

Irrigated artificial grasslands are arable lands planted with artificial herbage in pastoral areas. It is supplemented by modern irrigation facilities to achieve a high forage yield. Irrigated artificial grasslands can produce a large amount of forage in the Inner Mongolia typical steppe areas of China (Niu and Jiang, 2004). The development and construction of irrigated artificial grasslands on a significant scale in the areas with better water resources can improve the yield of high-quality forage and resolve the problem of livestock forage shortage. This can also play an important role in improving the carrying capacity of pastures, thereby reducing the pressure on natural steppes and promoting water-forage-livestock system balance (Lu et al., 2016, 2018). However, irrigated artificial grasslands in the Inner Mongolia typical steppe areas are restricted by arid climate. In most cases, irrigation can only be obtained via pumping groundwater, because these areas are mainly distributed in the semi-arid region of Eurasia (Tong et al., 2004), in which the vast majority of the rivers are seasonal inland rivers (Batnasan, 2003), among which hydrological and geographical features are characterized by precipitation rarely flowing into rivers or groundwater. Evapotranspiration (ET) is the main mode of water vapor exchange between the underlying surface and atmosphere (Yamanaka et al., 2007). This hydrographic feature has led to a lack of local surface

water resources, which in turn makes it difficult for agricultural development. The Xilin River is the only seasonal inland river in the basin, and supplies water for various purposes, except irrigation. Therefore, the water required for irrigating artificial grasslands is sourced from local groundwater, in addition to precipitation. Owing to limited precipitation, crops grown on artificial grasslands must be irrigated. Pumping groundwater to satisfy the crop growth needs of irrigated artificial grasslands bring benefits to the regional economy, but consumes a large amount of groundwater, affecting the hydrological cycle in the steppe areas. The advantages and disadvantages of this water consumption need to be determined. Therefore, accurate monitoring of the water consumption for irrigated artificial grasslands, especially local groundwater consumption, can help determine regional irrigation water consumption and water resource management decisions (Liou and Kar, 2014; Pedro-Monzonís et al., 2015; Numata et al., 2017; Talsma et al., 2018).

Many ET monitoring and estimation methods have emerged with related theoretical research. These include the water balance method, aerodynamics methods, and scintilla meter measurements (Bowen, 1926; Thornthwaite, 1948; Howell et al., 1991; Rana and Katerji, 2000). These methods have displayed the ability to describe the characteristic rules of the ET processes at micro and farmland scales in detail (Liou and Kar, 2014). In addition, they have also provided important references and basic information for water vapor exchanges on underlying surfaces, decision-making with respect to farmland irrigation, comprehensive water resource management, and so forth (Long and Singh, 2013; French et al., 2015; Xu et al., 2015). However, in terms of regional ET estimation, owing to fluctuations in weather conditions and the dynamic nature of water-heat transfer processes (Gao et al., 2008), it has been determined that these traditional point-scale monitoring methods and approaches cannot fully reflect the actual characteristics of spatial changes in ET (Su et al., 2003; Cai et al., 2009; Monteith and Unsworth, 2013; Taherparvar and Pirmoradian, 2018). It has been determined that remote sensing technology can offer a new approach for regional ET estimation. Because of the spatial continuity and large span characteristics of remote sensing, the water that is consumed during ET can be derived directly, without the need to quantify other complex hydrological processes (Trezza et al., 2013).

ET models using remote sensing technology have been developed in recent years, including empirical methods and mechanism methods. Many achievements in theory innovation and method techniques have been presented (Khand et al., 2017). Among these proposed methods, two-source energy balance (TSEB), surface energy balance index (SEBI), simplified surface energy balance index (S-SEBI), surface energy balance algorithm for land (SEBAL), mapping evapotranspiration at high resolution with internalised calibration (METRIC) model have been widely used to calculate regional ET based on the theory of energy balance (Menenti, 1993; Norman et al., 1995; Bastiaanssen et al., 1998; Roerink et al., 2000; Su, 2002; Allen et al., 2007; Yang et al., 2010). As a typical representative of estimating regional ET by using remote sensing, the METRIC model is a variant of the SEBAL model that implements the residual method to calculate regional ET (Spiliotopoulos et al., 2017; Zamani Losgedaragh and Rahimzadegan, 2018). The METRIC model has been successfully used in many areas, as a physical model for high-precision estimation of regional ET (Allen et al., 2007, 2013; Morton et al., 2013; Paço et al., 2014; Reyes-González et al., 2017; Spiliotopoulos et al., 2017).

DOI: http://dx.doi.org/10.15666/aeer/1706_1375913776

The objective of this paper is to use high-resolution Landsat images as an example to estimate the regional ET for irrigated artificial grasslands in the Inner Mongolia typical steppe areas by the METRIC model. Based on the development model of current groundwater by irrigated artificial grasslands, groundwater consumption (GW) and its law in the crop growth season are analyzed to accurately simulate and monitor the hydrological cycle in the Inner Mongolia typical steppe areas.

Materials and methods

Study area

The Xilin River Basin is a typical inland river basin in the Inner Mongolia typical steppe areas of China (Chen, 2002). The basin, with an area of approximately 11,172 km^2 (115.53°−117.25°E, 43.41°−44.63°N), has a typical continental temperate semi-arid climate. In accordance with the statistical data of the Xilinhot Station detailed on the National Meteorological Data website, the multi-year (period 1971-2011) average precipitation, ET from the water surface, air temperature, and wind speed are 263.5 mm, 1,904 mm, 3 °C, and 3.4 m s^{-1}, respectively. The average precipitation gradually decreases from the southeast to northwest (Sheng, 2017) (*Fig. 1*).

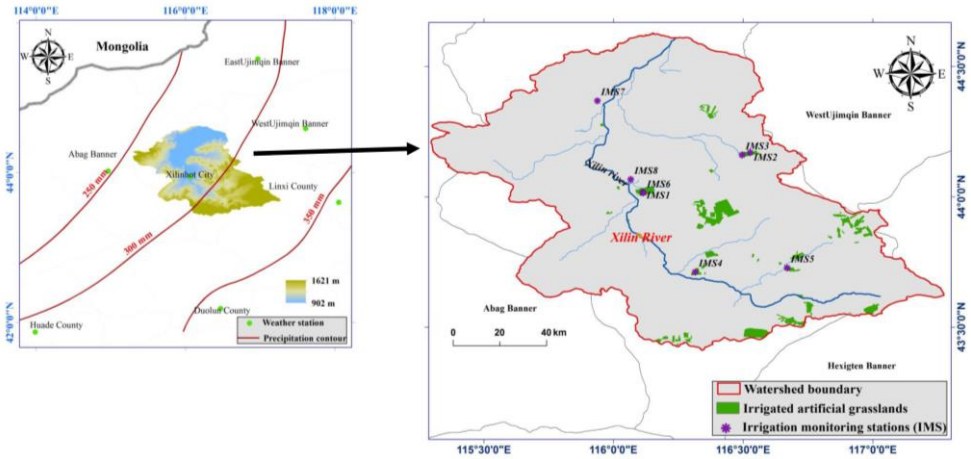

Figure 1. *Distribution for irrigated artificial grasslands in Xilin River Basin*

The planted area of the irrigated artificial grasslands in 2011 was approximately 257.3 km^2 (*Fig. 1*). The crops were silage maize (128.6 km^2), potato (96.5 km^2), alfalfa (25.8 km^2), and green millet (6.4 km^2). The management departments included co-ops (such as Hezhongmumin farm) and companies (Woyuan cow farm, Maodeng farm, Baiyinxile farm). Because of the effective accumulated temperature restriction, the crop growth season is from May to September every year with an irrigation quota of 400-700 mm. These crops bring benefits to the regional economy while consumes a large amount of water. In addition, amid limited precipitation, the crops grown on artificial grasslands must be irrigated. However, there is only one seasonal inland river in the basin, the Xilin River that supplies water for various purposes except irrigation. Therefore, the water required for irrigating artificial grasslands is sourced from local groundwater, apart from precipitation. Irrigation has a great impact on local water resource management.

Data

Landsat images

In this study, Landsat-5 and Landsat-7 images were chosen to estimate ET. In the data bands of these images, visible light and near-infrared bands have a high spatial resolution of 30 m, which satisfies the validation requirements for the spatial accuracy of ET estimation results in this study. In combination with the cloud cover of the study area, the effective 8-day sunshine data during the crop growth season (from May to September) of 2011 (day of the year from 121 to 273) were used to calculate the long-time scale of ET (*Table 1*). All the data were obtained from the United States Geological Survey (http://glovis.usgs.gov/).

Meteorological data

Meteorological data included air temperature, wind velocity, water vapor pressure, solar radiation, humidity, and precipitation in the seven weather stations of East Ujimqin Banner, Abag Banner, Huade County, West Ujimqin Banner, Xilinhot City, Linxi County, and Duolun County (*Fig. 1*). Among these, the air temperature data were used to calculate the surface temperature and net radiation by the METRIC model; the wind velocity data to calculate the aerodynamic resistance by the METRIC model; and the water vapor pressure data to calculate atmospheric transmittance and surface albedo by the METRIC model (Bastiaanssen et al., 1998; Allen et al., 2007). Other parameters such as solar radiation and humidity were used to calculate reference crop evapotranspiration (ET_0) by FAO Penman-Monteith equation (Allen et al., 1998). The meteorological data were obtained from the National Meteorological Data Information Center (http://data.cma.cn/).

Evapotranspiration measurement data

The ET measurement data were obtained from the eight irrigation monitoring stations (IMS) (*Fig. 1*). The crop cultivated in the monitoring station was silage maize. The average volumetric weight of soil was 1.54 - 1.82 g cm^{-3} for a thickness varying from 0 to 100 cm. The field water holding capacity (θ_f) was 14.3% - 19.0% (accounting for the dry soil weight), and the buried depth of the groundwater level was over 3 m. Based on water balance method, the water consumption data of the silage maize growth period were calculated to evaluate the results of the METRIC model.

Methods

METRIC model

The SEBAL model is the theoretical basis of the METRIC model (Bastiaanssen et al., 1998a, b; Allen et al., 2007). In the model, by considering the interference of the underlying surface elevation, slope gradient, slope direction, and other factors, the surface information obtained through remote sensing are converted to surface albedo, surface emissivity, vegetation index, roughness length, surface temperature, and other characteristic parameters. This model is combined with the meteorological observational data of the underlying surfaces to calculate the regional ET (Allen et al., 2007; González-Dugo et al., 2012). The theoretical equation is given as follows:

$$LE = R_n - G - H \quad \text{(Eq.1)}$$

where LE is the latent energy consumed by ET; R_n is the net radiation; G is the soil heat flux; and H is the sensible heat flux. Each energy component is generally expressed in W m^{-2}.

(1) Net radiation

R_n denotes the difference in the whole-band radiation quantity between the downward projection from the sky (including the sun and the atmosphere) and the upward projection from the Earth's surface (including soil, plants, and water). This parameter represents the main power source for the energy and water transmission of the underlying surfaces (Allen et al., 2007):

$$R_n = (1-\alpha)K_{in} + (L_{in} - L_{out}) - (1-\varepsilon)L_{in} \quad \text{(Eq.2)}$$

where α is the surface albedo (dimensionless); K_{in} is the incoming short-wave radiation (W m^{-2}); L_{in} is the incoming long-wave radiation (W m^{-2}); L_{out} is the outgoing long-wave radiation (W m^{-2}); and ε is the broad-band surface emissivity (dimensionless).

(2) Soil heat flux

G refers to the part of energy stored in vegetation and soil due to conduction, and its changes are mainly affected by net radiation, surface temperature and the vegetation cover on underlying surfaces. For the comprehensive analysis in this study, the achievements of Wright and Bastiaanssen are referred as follows (Wright, 1982; Bastiaanssen et al., 1998):

$$G = \frac{T_s - 273.15}{\alpha}(0.0038\alpha + 0.0074\alpha^2) \times (1 - 0.978NDVI^4)\ R_n \quad \text{(Eq.3)}$$

where T_s is the surface temperature (K); and NDVI is the normalized difference vegetation index (dimensionless).

(3) Sensible heat flux

H is a parameter, describing the exchange of energy between land surfaces and atmosphere, in which energy is transferred from the Earth's surface to the atmosphere

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1375913776

through convection or conduction. The calculation of H in the METRIC model is based on the following assumptions: dry and wet pixels exist in the study area; and there is a linear relationship between the temperature difference dT ($dT = T_1$-T_2) at z_1 and z_2 above the height of the zero-plane displacement and T_s. The space interpolation of the meteorological data on the underlying surfaces can then be avoided. Furthermore, the errors due to T_s are corrected to calibrate the calculation results of each pixel in remote sensing imaging through the elevation, slope gradient, and slope direction:

$$H = \rho_{air} c_p \frac{dT}{r_a} \quad \text{(Eq.4)}$$

where ρ_{air} is the air density (kg m^{-3}); c_p is the air specific heat capacity at a constant pressure (1,004 J kg^{-1} K^{-1}); and r_a is the aerodynamic resistance between two near surface heights, which has been calculated by the Monin–Obukhov theory (Allen et al., 2007); The calculation equations is given as follows:

$$dT = aT_{s,adtum} + b \quad \text{(Eq.5)}$$

$$T_{s,adtum} = T_s + 0.0065\Delta Z \quad \text{(Eq.6)}$$

where a and b are empirical constants; $T_{s,adtum}$ is the surface temperature adjusted to a common elevation data for each image pixel by using a digital elevation model and customized lapse rate (K); For non-planar areas, it is necessary to use the numerical elevation difference ΔZ for the corrections; and ΔZ is the difference between the elevation of each pixel and the reference elevation (m).

Dry and wet pixels are the two extreme pixels required for calculation using the METRIC model. Dry pixels refer to the dry idle wasteland or bare land areas without vegetation cover; these pixels are characterized by high temperature and almost zero ET (Bastiaanssen et al., 1998; Allen et al., 2007). In this study, dry pixels approximately satisfied LE≈0. The dry end of the dT function is estimated by rearranging *Equation 4* for a selected dry pixel in the image:

$$dT_{dry} = \frac{(R_n - G)_{dry} r_{a\,dry}}{\rho_{air\,dry} c_p} \quad \text{(Eq.7)}$$

where $r_{a\,dry}$ is r_a computed for the roughness and stability conditions of the dry pixel; and $\rho_{air\,dry}$ is ρ_{air} calculated at the dry pixel.

Wet pixels refer to areas with adequate water supply, dense vegetation growth, low temperatures and potential ET levels in the remote sensing images (Bastiaanssen et al., 1998; Allen et al., 2007). These could include completely covered areas or open water masses with good plant growth. For the wet pixels, H≈0 is usually set in the SEBAL model, and such H values are considered in the METRIC model (Allen et al., 2007).

$$dT_{wet} = \frac{(R_n - G - H)_{wet} r_{a\,wet}}{\rho_{air\,wet} c_p} \quad \text{(Eq.8)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1375913776

where $r_{a\ wet}$ is ra computed for the roughness and stability conditions of the wet pixel; $\rho_{air\ wet}$ is ρ_{air} calculated at the wet pixel.

The distribution of dT is obtained by extracting the information regarding the dry and wet pixels (de la Fuente-Sáiz et al., 2017). The values for a and b in *Equation 5* are estimated from these two pairs of dT and associated $T_{s,adtum}$.

$$a = \frac{dT_{dry} - dT_{wet}}{T_{s,adtum,dry} - T_{s,adtum,wet}} \quad \text{(Eq.9)}$$

$$b = dT_{dry} - aT_{s,adtum,dry} \quad \text{(Eq.10)}$$

(4) Surface parameters

Surface parameters contain α, ε, NDVI, T_s and Momentum roughness length (Z_{om}) which are crucial in the atmospheric-surface interaction and consequently affect the ET estimation. Among them, α is computed by integrating band reflectance within the short-wave spectrum using a weighting function (Allen et al., 2007); ε is computed using an empirical equation (Tasumi, 2003); NDVI is the ratio of the differences in reflectivity for the near-infrared band and red band to their sum (Allen et al., 2007); T_s is computed the single window algorithm proposed by Qin (Qin et al., 2010); Z_{om} for each image is specified by the corresponding NDVI (Allen et al., 2007).

(5) Long-time scale of the daily evapotranspiration

In addition, it is assumed that the instantaneous ET ratio (EF_{inst}, $EF_{inst} = \mathrm{LE_{inst}}/(R_n\text{-}G)_{\mathrm{inst}}$) is equal to the daily ET ratio (EF_d, $EF_d = \mathrm{LE_d}/(R_n\text{-}G)_{\mathrm{d}}$), when the instantaneous ET is used to calculate the daily ET ($\mathrm{ET_d}$) (Bastiaanssen et al., 1998a, b). In this study, in order to estimate long-time scale of the daily ET, the daily reference ET ratio ($\mathrm{ET_rF}$ is the ratio between $\mathrm{ET_d}$ and daily $\mathrm{ET_0}$, $\mathrm{ET_rF} = \mathrm{ET_d}/\mathrm{ET_0}$) of the eight DOYs were calculated, and the crop growth season was divided into seven intervals (*Table 1*). Each interval consisted of two DOYs of effective sunshine satellite images. Thereafter, by assuming that the $\mathrm{ET_rF}$ change between two adjacent effective sunshine days is linearly correlated with the DOY, interpolation was used to calculate the daily ET during the period:

$$ET_{d,DOY} = (c \times DOY + d) \times ET_{0,DOY} \quad \text{(Eq.11)}$$

$$c = \frac{ET_r F_n - ET_r F_m}{DOY_n - DOY_m} \quad \text{(Eq.12)}$$

$$d = ET_r F_n - c \times DOY_n \quad \text{(Eq.13)}$$

where c and d are constants; $\mathrm{ET_{d,DOY}}$ and $\mathrm{ET_{0,DOY}}$ are the daily ET and $\mathrm{ET_0}$ between two adjacent effective sunshine days respectively; and $\mathrm{ET_rF_n}$ and $\mathrm{ET_rF_m}$ are the $\mathrm{ET_rF}$ when the DOY is n and DOY is m, respectively (DOY_n: 278,262,254,222,214,142,134; DOY_m: 262,254,222,214,142,134,102).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1375913776

Evapotranspiration of silage maize at irrigation monitoring stations by the METRIC model

The evapotranspiration of silage maize consumed by the crops were calculated using the water balance method as follows (Kang, 2007):

$$ET_{IMS} = P_a + I - L + K - \Delta W \quad \text{(Eq.14)}$$

where ET_{IMS} is the ET value of IMS; P_a is the effective precipitation; I denotes irrigation; L is the amount of deep leakage; and K is the groundwater recharge amount. Because of the fact that the buried depth of the groundwater was greater than 3 m, as per the observations of a buried negative pressure meter, groundwater recharge was observed to be minimal; therefore, $K \approx 0$. ΔW represents the variation in planned soil moisture layer during the growth cycle of silage maize. All the above parameters are in units of mm (*Fig. 2a*).

Groundwater consumption for irrigated artificial grasslands

Each irrigated artificial grassland is regarded as an independent land unit. According to the "one piece of sky corresponding to one piece of land," a land unit is divided into three spatial structure components: atmosphere, irrigated artificial grasslands, and groundwater. The inflow of water to irrigated artificial grasslands during the crop growth season includes P_a from the atmosphere, and K and I from groundwater. Water consumed by irrigated artificial grasslands includes ET from irrigated artificial grasslands to the atmosphere, and L from the irrigated artificial grasslands to groundwater. It is considered that the local groundwater supplements the unsaturated zone of the irrigated artificial grasslands. This water is still stored in the irrigated artificial grasslands; thus, it is classified as internal consumption of local water resources. The rest of the water separates from the irrigated artificial grasslands by ET, which is the net consumption and defined as the local groundwater consumption. From another perspective, for the amount of water consumed by the irrigated artificial grasslands on the underlying surface, and aside from the P_a supply of the atmosphere, the remainder of the water is sourced from groundwater. Therefore, GW is estimated using the difference between ET and P_a (*Fig. 2b*).

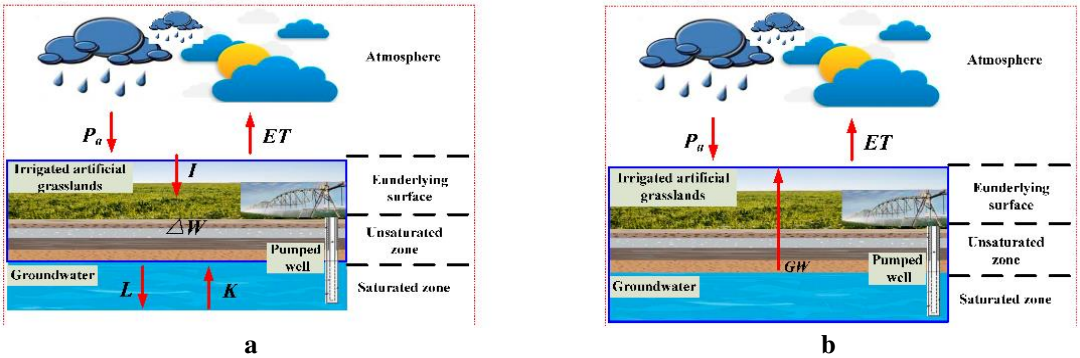

Figure 2. *Water balance for irrigated artificial grasslands: (a) evapotranspiration of silage maize based on water balance; (b) groundwater consumption for irrigated artificial grasslands based on water balance*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1375913776

The GW was calculated using the water balance for irrigated artificial grasslands as follows:

$$GW = ET - P_a \quad \text{(Eq.15)}$$

$$P_a = \sum P_s \times \sigma \quad \text{(Eq.16)}$$

where P_s denotes a single rainfall; and σ is the effective precipitation coefficient, which is determined from the measured data. For areas without measured data, the following values can be referred to as: $\sigma = 0$ when $P_s < 5$ mm; $\sigma = 1.0$ when $5 < P_s \leq 50$ mm; $\sigma = 0.7$ - 0.8 when $P_s > 50$ mm (Kang, 2007).

The value of GW is the net groundwater consumption of the irrigated artificial grasslands in the Inner Mongolia typical steppe areas (*Fig. 2b*). By calculating the value of GW during the crop growth season, it is possible to visually reflect the amount of local water consumed by the irrigated artificial grasslands.

Comparison of ET_{METRIC} and ET_{IMS}

ET_{METRIC} was accurately estimated by computing the mean absolute error (MAE) and mean relative error (MRE). The values of MAE and MRE were computed as follows (Mayer and Butler, 1993):

$$MAE = \frac{\sum_{i=1}^{n} \left| ET_{METRIC} - ET_{IMS} \right|}{n} \quad \text{(Eq.17)}$$

$$MRE = \frac{1}{n} \sum_{i=1}^{n} \left| \frac{ET_{METRIC} - ET_{IMS}}{ET_{IMS}} \right| \times 100\% \quad \text{(Eq.18)}$$

where ET_{METRIC} is the estimated ET by the METRIC model; and n is the number of observations.

Results and discussion

Estimated accuracy of evapotranspiration by METRIC model

All the crops grown at the eight monitoring stations were silage maize, with an average growth period of 97 days. The irrigation methods included central pivot sprinkler irrigation (CPSI), drip irrigation (DI), low-pressure pipeline irrigation (LPPI), and semi-fixed irrigation (SFI). The average actual water consumption of silage maize during the growth period was determined to be 445.10 mm using *Equation 14*. The average value of ET_{METRIC} of silage maize in the eight stations during the growth period was determined to be 428.73 mm, in which MAE = 16.37 mm and MRE = 13.8%. By summarizing the previous research results, Kalma reviewed the various estimation methods of different remote sensing ET, and observed that when compared with the ground-based ET measurement value, the majority of the relative errors ranged from 15.0% to 30.0% (Kalma et al., 2008). Therefore, in this study it was believed that the accuracy of long-term scale ET estimation was reasonable and consistent with the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1375913776

previous research related conclusions (Allen et al., 2011; Lian and Huang, 2015) (*Table 2*).

The estimation results summarized in *Table 2* show that the MRE of CPSI and DI is lower than that of SFI and LPPI by approximately 32.1% and the cause of this phenomenon was analyzed in this study. The ET_{METRIC} is the regional comprehensive water consumption of the underlying surface. Within the corresponding time period, the researchers randomly sampled the field water consumption data, and CPSI and DI was employed to reflect the actual situation of field water consumption more objectively than SFI and LPPI, because historical measured data are applied to confirm that the uniformity of CPSI and DI is better than that of SFI and LPPI. Therefore, ET_{IMS} by SFI and LPPI may not accurately reflect the regional comprehensive water consumption as CPSI and DI do.

Evapotranspiration for irrigated artificial grasslands in the crop growth season

The value of ET for the irrigated artificial grasslands in the Xilin River Basin during the crop growth season varied from 241.99-741.55 mm, with an average of 611.42 mm, standard deviation of 80.73 mm, and daily average ET intensity of 4.0 mm d^{-1} (*Fig. 3a*). Because of the combined effects of climatic conditions, irrigation water volume, soil texture, vegetation cover, and other factors, the estimation of ET shows obvious spatial differentiation characteristics. For example, the water consumption in the CPSI areas were significantly higher than that in the surrounding areas that are not effectively irrigated (*Fig. 3b-e*).

Groundwater consumption for irrigated artificial grasslands and its law for different periods

Precipitation and effective precipitation for irrigated artificial grasslands

The values of P and P_a for the irrigated artificial grasslands, which were determined to be 207.18 mm and 153.46 mm in 2011, respectively (*Table 3*) were obtained from precipitation statistics of the seven weather stations. The Linxi County and Duolun County stations in the southeast part of the basin presented the greatest precipitation, while the Abag Banner station in the northwest part of the basin showed the least. P values during the crop growth season show a parabolic change of first increasing, and then decreasing, with the maximum appearing in July.

P and P_a of the irrigated artificial grasslands were calculated on the basis of the inverse distance weighted interpolation method (*Fig. 4*). The results indicate that the corresponding spatial distribution trend of precipitation decreases from southeast to northwest (*Fig. 4a*), which is consistent with the trend of precipitation statistics in China for many years (Huang et al., 2011; Sheng, 2017). Thus, it can be concluded that the interpolation results are valid.

Groundwater consumption for irrigated artificial grasslands

The value of GW of the irrigated artificial grasslands during the crop growth season in 2011 was calculated to be 457.86 mm by using *Equation 15*. According to statistics,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1375913776

the planted area of the irrigated artificial grasslands in 2011 was approximately 257.3 km^2, and the equivalent water volume was approximately 118 million m^3. In addition, it can be observed that at Woyuan cow farm, Maodeng farm, Baiyinxile farm, and Hezhongmumin farm, the value of GW of groundwater exceeded 400 mm (*Fig. 5b-e*). The local water consumption in these areas was significantly higher than other areas, making high water consumption areas.

Laws of groundwater consumption in different periods

The crop growth season of the irrigated artificial grasslands is divided into five periods by month, with an accumulated 153 days (*Table 4*). In accordance with the Landsat images and meteorological data, the values of ET, P_a, and GW in different periods were obtained (*Table 4; Fig. 6*).

Table 4. *Groundwater consumption of the irrigated artificial grasslands in different periods (all parameters are in units of mm)*

	May	**Jun.**	**Jul.**	**Aug.**	**Sep.**	**Accumulation**
DOY_m - DOY_n	121 - 151	152 - 181	182 - 212	213 - 243	244 - 273	153
*Avg.*ET	71.22	136.72	141.63	160.45	101.40	611.42
Avg.P_a	7.28	44.80	86.25	12.86	2.27	153.46
*Avg.*GW	63.94	91.92	55.38	147.59	99.13	457.96

*Avg.*ET, *Avg.*P_a, *Avg.*GW are calculated by average of ET_{METRIC} values, P_a values, GW values in the Xilin River Basin, respectively

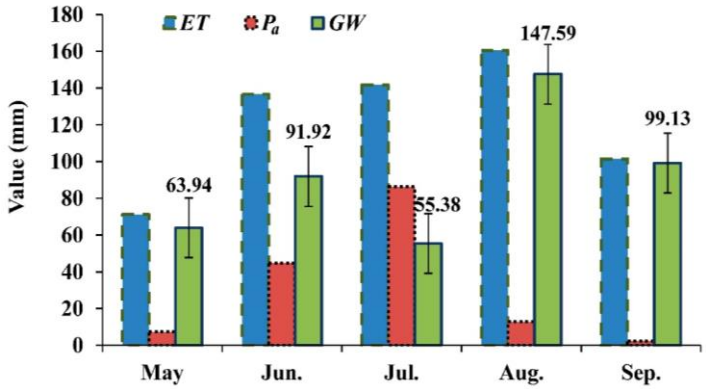

Figure 6. *Laws of groundwater consumption in different periods (all parameters are in units of mm)*

The values of ET_{METRIC} of the irrigated artificial grasslands during the crop growth season show a parabolic change of "first increasing, and then decreasing". With the increase in temperature, the value of ET is the maximum in July and August. The change in values of ET are highly consistent with the water consumption laws of crop growth (Tong et al., 2014). However, because of the influence of precipitation, the variation in the values of GW and ET change during different periods are significantly different, with details as follows: During the high-water consumption period of the crop growth season (July), precipitation is higher, while the values of GW of the irrigated artificial grasslands are relatively low. In addition, the value of precipitation in the study area is significantly lower in August, which results in the water consumption of the underlying surface being chiefly provided by regional groundwater resources, and the value of GW for the irrigated artificial grasslands is maximum. The above results show that the change in the values of GW are affected by not only the crop growth period on the underlying surface but also by weather factors such as precipitation, which cannot be ignored.

Conclusions

In this study, the METRIC model was used for estimating the regional ET of the irrigated artificial grasslands in the Inner Mongolia typical steppe areas. The results were verified through the water balance method of eight irrigation monitoring points, with an MRE = 13.8%. Combined with the previous remote sensing estimation of regional ET, the results show that the use of the METRIC model to estimate the ET of the Xilin River Basin, which is located in a typical steppe area, is reliable.

To analyze the consumption of local water resources, the spatial structure of the irrigated artificial grasslands are reclassified. The value of GW is introduced as the net consumption of local groundwater resources. Furthermore, the value of GW during the crop growth season in the Xilin River Basin is calculated. The crops planted over an area of 257.3 km^2 of the irrigated artificial grasslands consumed a total of 118 million m^3 of groundwater during the crop growth season. The net groundwater consumption of each of the farms, including that of Woyuan cow farm, Maodeng farm, Baiyinxile farm and Hezhongmumin farm, exceeded 400 mm. These areas with high water consumption face difficulties in water resource management, particularly when there is no external water supply**.**

The water consumption of the underlying surface of a typical steppe is complex, and has several influencing factors such as climate and anthropogenic influence. In addition, its characteristic laws are variable at different time scales. In order to determine the impact of irrigation artificial grasslands on local groundwater resources, future studies performed on GW should be conducted based on monitoring data of groundwater level.

Abstract. The aim of this study was to evaluate the relative contributions of nitrification and denitrification in rice paddy soils under various water events. A laboratory incubation study was conducted in China to quantify N_2O production during alternate wetting and drying cycle (AWD) versus permanent flooding (PF). The soils were treated with long-term chemical fertilizer (CF); chemical fertilizer plus pig manure (PMCF); and chemical fertilizer plus rice straw (SRCF) for 5 years. The results showed that N_2O flux during AWD was consistently higher than PF. The highest N_2O flux during AWD was 1.94 mg m^{-2} h^{-1}. The PMCF and SRCF soils had higher N_2O emissions compared to CF and CK soils. Ammonia oxidizer community peaks were found at 60% field capacity (FC) ($p < 0.0001$), while, for denitrifier, this increase was maintained for a certain period of time (10d) and then started to decrease. Autotrophic nitrification appeared to be an important and dominant process of N_2O emissions during AWD and PF, contributed 79.03% of N_2O emissions during AWD, while 36.53% during PF. Thus, the results concluded that under AWD event the addition of pig manure and rice straw plus chemical fertilizer significantly increased the N_2O flux, by stimulating the growth of microbial communities.

Introduction

Ecosystems are adversely affected by the global warming if actions to mitigate it are not taken. Besides industrial emissions, biological processes can also contribute to the greenhouse gas emissions (GHG), especially nitrous oxide (N_2O). N_2O is an important greenhouse gas and its concentration in the atmosphere is comparatively lower than CO_2 concentration but its global warming potentials (GWP) is relatively 265 times higher over 100 years than that of CO_2 (IPCC, 2013). Agricultural soils contribute about 60% to anthropogenic N_2O emissions which is mainly due to fertilizer application (Charles et al., 2017; Liu et al., 2017). Fertilization of agricultural soils is considered to be an important source of N_2O emissions, which contributes about 13-24% of annual emissions (IPCC, 2007). Among these agricultural soils, rice paddy soils are considered to be a main source of N_2O emissions. Rice is a staple food for half of the world's population and approximately 155 million ha. is grown annually, around the globe (Abid et al., 2018).

Alternating wetting and drying (AWD) practice is a common practice which is being used to save water in rice fields. AWD reduce water use by 23-33% in rice paddy soils (Carrijo et al., 2017). It has been used in many countries such as Philippines (Belder et

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1377713792

al., 2004), China (Cabangon et al., 2004) and Japan (Chapagain and Yamaji, 2010). The AWD practice has been found to give higher or equal rice yield (Zhang et al., 2009) compared to conventional practice, i.e. continuous flooding practice, where surplus of N_2O is produced during this process (Peng et al., 2011). However, the underlying causes, e.g. microbial mechanisms of N_2O emissions are generally unknown.

Nitrous oxide is mainly emitted by nitrification and denitrification processes (Wrage et al., 2001), and both processes may occur in soil simultaneously (Abbasi and Adams, 2000; Garrido et al., 2002; Webster and Hopkins, 1996). To what extent each of these processes contributes to the N_2O emissions in the rice during AWD and permanent flooding (PF) are not fully understood. This is mainly attributed to oxygen content of the soil, and further estimation of water filled pore space (WFPS) has been considered as a major influencing factor. Nitrogen stable isotopes with acetylene (C_2H_2) can offer a precise information about nitrogen cycle in ecosystems (Ostrom et al., 2002). It is of interest to use ^{15}N as a tracer because a negligible isotope fractionation is being used as a tracer during biological processes. Acetylene (C_2H_2) inhibits NH_3^+ oxidation at low concentration (10 Pa) and start to inhibit N_2O reductase at high concentration (10 kPa) during denitrification (Berg et al., 1982). Also, C_2H_2 may inhibit NH_4^+ oxidation by autotrophs but inhibition by heterotrophic nitrifiers is not documented (Moir et al., 1996; Hynes and Knowles, 1982; Daum et al., 1998). Recently, stable isotope signatures coupled with C_2H_2 (10 Pa; 0.01% v/v) are being used to estimate N_2O source and relative contributions of denitrification, heterotrophic nitrification and autotrophic nitrification processes in soil (Baggs et al., 2003; Stevens et al., 1997).

The obvious benefits of implementing AWD strategy are to save irrigation water and reduce CH_4 emissions. On the other hand, the combined effect of long term fertilization and AWD on N_2O is still inconclusive. Also, the N_2O production source during AWD and PF events is still poorly understood. Therefore, the objectives of the present study were: (1) to determine the potential of AWD to produce N_2O from rice paddies as compared to the normal practice of rice (PF); (2) to determine the effect of long term organic (PMCF, SRCF) and inorganic (CF) fertilizers along with different water events (AWD, PF) on N_2O gas emissions; and (3) to quantify the contribution of different processes (nitrification, denitrification) to N_2O emissions under AWD and PF related to long term fertilization, using ^{15}N stable isotopes in combination with C_2H_2.

Materials and methods

Soil sampling site

A long-term fertilized experiment (LTFE) was conducted from 2010 to 2014 and soil samples were collected. This site was located in Jintan county, Jiangsu province, China (120° 0' 41" East, 29° 57' 9" North). The annual mean precipitation and temperature of study area are 1452.5 mm and 16.27 °C, respectively. A rice paddy field was selected with 5-yr canola-rice rotation history. The soil samples were grouped into four treatment groups, including no fertilization (CK), 100% chemical fertilization (CF: N 314 kg ha^{-1}, P_2O_5 31.5 kg ha^{-1}, K_2O 153 kg ha^{-1}), pig manure compost plus 50% chemical fertilization (PMCF: Pig manure 6000 kg ha^{-1} + N 157 kg hm^{-2}, P_2O_5 31.5 kg ha^{-1}, K_2O 153 kg ha^{-1}) and rice straw plus 50% chemical fertilization (SRCF: rice straw 6000 kg ha^{-1} + N 157 kg ha^{-1}, P_2O_5 31.5 kg ha^{-1}, K_2O 153 kg ha^{-1}). Just after the rice harvested in 2014, five soil cores were collected at a depth of 15 cm from three replicates of each treatment and five hundred grams of soils were packed. The soil cores

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1377713792

were put in sterile plastic bags, zipped and transported to the laboratory and stored at 4 °C. Each replicated sample was divided and one sub sample was air-dried and sieved through a 2.0 mm for subsequent chemical analysis and another sub sample was incubated under different dry and wet conditions.

Incubation design

The incubation was carried out at 25 °C with two water events including: (a) alternating with 7 days continuous flooding followed by 7 days of air-drying (AWD); (b) permanent flooding for 14 days (PF). The detailed methodology of the incubation experiment was as follows (*Fig. 1*). Two hundred g of soil collected from CK, CF, PMCF and SRCF treatments were put in 1000 mL glass pots and to make flooding conditions additional water was added. For AWD, soils were incubated as flooded for 7 days, with gas and soil samples were collected after 1 and 7 days of flooding incubation (100%FC, 1 d; 100%FC, 7 d). Then the water was removed to reach 80% field capacity (80%FC, 10 d) and 60% field capacity (60%FC, 14 d), samples were also collected at 80%FC, 10 d and 60%FC, 14 d). For PF, the same treatments were incubated with flooded conditions for 14 d and gas and soil samples were collected after 1, 7, 10 and 14 d. Headspace gas samples were collected after 1, 7, 10 and 14 d immediately after closing the jars and 30 min later using a hypodermic needle and a polypropylene syringe. These gas samples were used to analyze the isotopic ^{15}N-N_2O. N_2O was calculated using GC 2010 plus (Shimadzu).

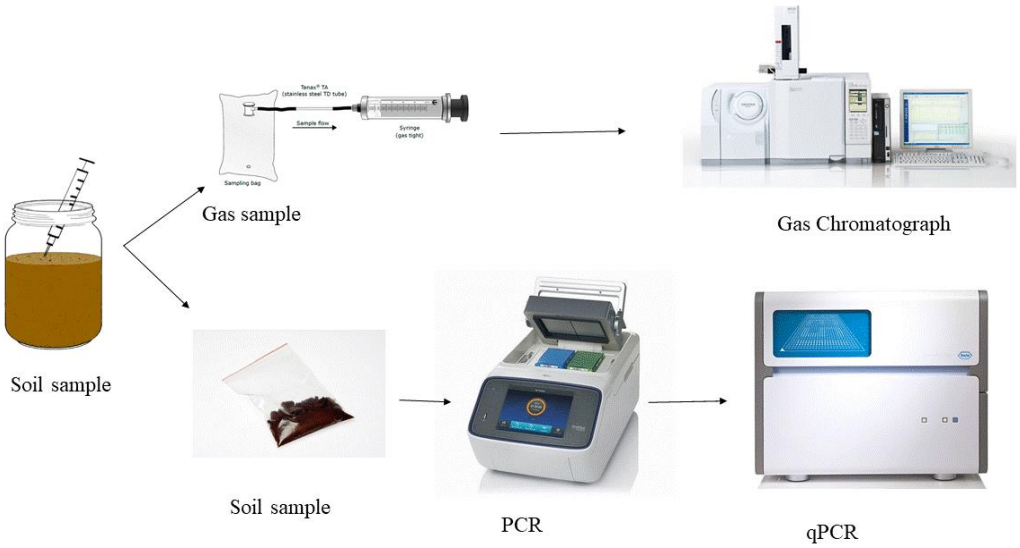

Figure 1. *Schematic diagram of whole study plan*

After 14 days of incubation, all soils were treated with (a) $^{14}NH_4{}^{15}NO_3$, (b) $^{15}NH_4{}^{15}NO_3$, (c) $^{15}NH_4{}^{15}NO_3 + C_2H_2$ (0.01% v/v), and (d) no N addition. $^{14+15}N$ was applied at 200 mg total N m^{-2} (20% atom % excess ^{15}N) combined with C_2H_2 (10 Pa) (*Table 1*). Additional water was added to achieve the desired moisture contents (flooding). Also, three replicates of each treatment was created for gas analyses. To create gas-tight incubations, the lids of the jars were then closed. Five ml (1% v/v in air) of C_2H_2 gas was injected to the headspace of a further three replicates of the $^{15}NH_4{}^{15}NO_3$ fertilizer treatments (treatment c) (*Table 1*) to make a final concentration of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1377713792

0.01% (v/v) which was considered sufficient to inhibit oxidation of NH_3^+ (Bateman and Baggs, 2005). Five days after fertilizer additions, the jars were opened because inhibition continued for about 3 days after 0.01% (v/v) C_2H_2 addition, and there was no effect of jars opening on trace gas production (Bateman and Baggs, 2005). Seven days after fertilizer addition, 20 ml gas samples were collected at 0 and 30 min after closing the glass jars from each treatment using poly-pyrine syringe. The ^{15}N was analyzed using isotope ratio mass spectrometer (Europa PDZ 20:20).

Table 1. *Outline of the ^{15}N fertilizer and C_2H_2 inhibition treatments used to estimate the contribution of denitrification and autotrophic and heterotrophic nitrification to ^{15}N-N_2O emissions*

Treatment	Source of ^{15}N-N_2O
(a) $^{14}NH_4{}^{15}NO_3$	Denitrification
(b) $^{15}NH_4{}^{15}NO_3$	Denitrification and nitrification (autotrophic and heterotrophic)
(c) $^{15}NH_4{}^{15}NO_3$ + C_2H_2(0.01% v/v)	Denitrification and heterotrophic nitrification
(d) (c) minus (a)	Heterotrophic nitrification

q-PCR to determine the abundance of nitrifiers and denitrifiers

After 1, 7, 10 and 14 d of different water application, soil samples were collected and 0.5 g sampled soil was used to extract DNA using TAKARA DNA standard protocol. Nano drop technology was also used to quantify DNA (Nano Drop Technologies, Wilmington, DE, USA). Real time quantitative PCR was used to quantify the abundance of denitrifier (*nirS, nir*K) and nitrifier (AOA *amo*A, AOB *amo*A) communities. Serial dilutions of linearized plasmids were used to produce standard curves by using cloned AOA, AOB, *nirS* and *nir*K genes amplified from denitrifying and nitrifying strains. The cloning kit (V007 TsingKe China) was used to prepare standard (www.tsingke.net). The qPCR primers sets used to target desired genes are indicated in *Table 2*. A reaction mixture of 20 μL containing 1 μL target gene primer, SYBR Premix 10 μL, total DNA template 1 μL, and deionized distilled water to make final volume 20 μL. The copy number of these plasmids was directly calculated based on the concentrations and lengths (base pairs) of them. The copy number of the target genes in unknown soil DNA were analyzed by comparing with their reactive standard curves.

Statistical analysis

SPSS 16.0 package was used to perform all statistical (SPSS, Chicago, IL, USA). One way analysis of variance (ANOVA) test was used to analyze significant differences among different treatments. ANOVA, followed by the least significant difference (LSD) test, in which $P < 0.05$ was considered statistically significant. Also, Duncan's Multiple Range Test was used to determine significant mean differences. Correlation analysis was performed to analyze the correlation between variables. All results were accepted at significant probability 0.05.

Results

N_2O gas emission

Nitrous oxide (N_2O) fluxes of the incubated soils showed different trends during AWD and PF events (*Fig. 2*). N_2O flux increased with reducing moisture contents over time during AWD. N_2O emitted over 14 days (60% FC) was significantly higher ($P < 0.001$) throughout the experiment during AWD than PF. While comparing fertilizer treatments, the highest emissions were recorded from SRCF (1.88 mg m^{-2} h^{-1}) and PMCF (1.34 mg m^{-2} h^{-1}) over 14 days, which were 12 and 20 times greater than those over 10 days and 7 days of AWD, respectively. N_2O emissions from fertilized soils decreased after one day throughout trial period but were greater than unfertilized controls. The highest fluxes were measured at 60% FC over 14 days. In the CK and CF treatments, N_2O fluxes were minimal over 1 day which was 0.02 and 0.01 mg m^{-2} h^{-1}, while the treatments of PMCF and SRCF showed slightly higher N_2O emissions, ranging from 0.12 to 0.28 mg m^{-2} h^{-1} with same moisture contents. No significant differences were observed in total N_2O produced over 1 day and 7 days of flooded conditions. During AWD, the emissions of N_2O increased when exposed to air-drying conditions after continuous flooding over one week. While During PF, the fluxes significantly decreased with time and the lowest fluxes were measured over 14 days of continuous flooding ($P < 0.0001$).

Sources of N_2O

Labelling of ^{15}N is the only way to differentiate N pool, as a possible substrate for N_2O production. N_2O emitted from C_2H_2 treatments could be produced either by heterotrophic nitrification or denitrification (treatment c), and ^{15}N-N_2O production from $^{14}NH_4{}^{15}NO_3$ (treatment a) could be produced by denitrification (*Table 1*). The difference in the emissions of ^{15}N-N_2O between the $^{14}NH_4{}^{15}NO_3$ (treatment a) and $^{15}NH_4{}^{15}NO_3$ (treatment b) was attributed to nitrification, and the difference in the emissions of ^{15}N-N_2O between $^{14}NH_4{}^{15}NO_3$ (treatment a) and $^{15}NH_4{}^{15}NO_3 + C_2H_2$ (treatment c) was used to quantify heterotrophic nitrification. Results of the present study showed relatively higher ^{15}N-N_2O emissions were measured during AWD than PF (*Fig. 3*) but this relation was not significant. The total ^{15}N-N_2O emissions were recorded during AWD condition in PMCF and SRCF treatments (0.23, 0.24 mg m^{-2} h^{-1}), which were significantly higher than CK and CF treatments. ^{15}N-N_2O emissions during 60% FC in the presence of C_2H_2 were significantly lower than the other treatments, indicating autotrophic nitrification as main contributor to N_2O emissions (*Table 2*). In the presence of C_2H_2, N_2O produced was accredited to denitrification and/or heterotrophic nitrification. A strong significant positive correlation was found between autotrophic nitrification nitrous oxide production,

DOI: http://dx.doi.org/10.15666/aeer/1706_1377713792

indicating autotrophic nitrification as a predominant ^{15}N-N_2O source during both AWD and PF ($P < 0.01$, $R^2 = 0.77$) (*Table 3; Fig. 4*). The maximum N_2O production from autotrophic nitrification was 0.19 mg N m^{-2} h^{-1} during AWD. Between 57 and 72% of N_2O production during both AWD and PF emitted from autotrophic nitrification in all fertilized treatments and significantly higher compared to CK. The mean ^{15}N-N_2O emissions during AWD were 0.89 mg N m^{-2} h^{-1}, contributing 79% by autotrophic nitrification, while during PF, the N_2O emissions were 0.13 mg N m^{-2} h^{-1}, and 52% was contributed by denitrification and 36% by autotrophic nitrification (*Table 4*).

AWD: alternate wetting and drying, PF: permanent flooding

Abundance of nitrifier and denitrifier

The AOA *amo*A gene abundance was found in the range of 2.16E + 06 - 1.61E + 08 copies g^{-1} of the soil (*Fig. 5*). The copy numbers increased with time during both AWD and PF events. The AOA *amo*A gene abundance was found significantly higher at 60% FC (14 days) in the CK, PMCF and SRCF ($P < 0.0001$). While, during PF, PMCF only increased AOA *amo*A gene abundance, especially after 10 days and 14 days.

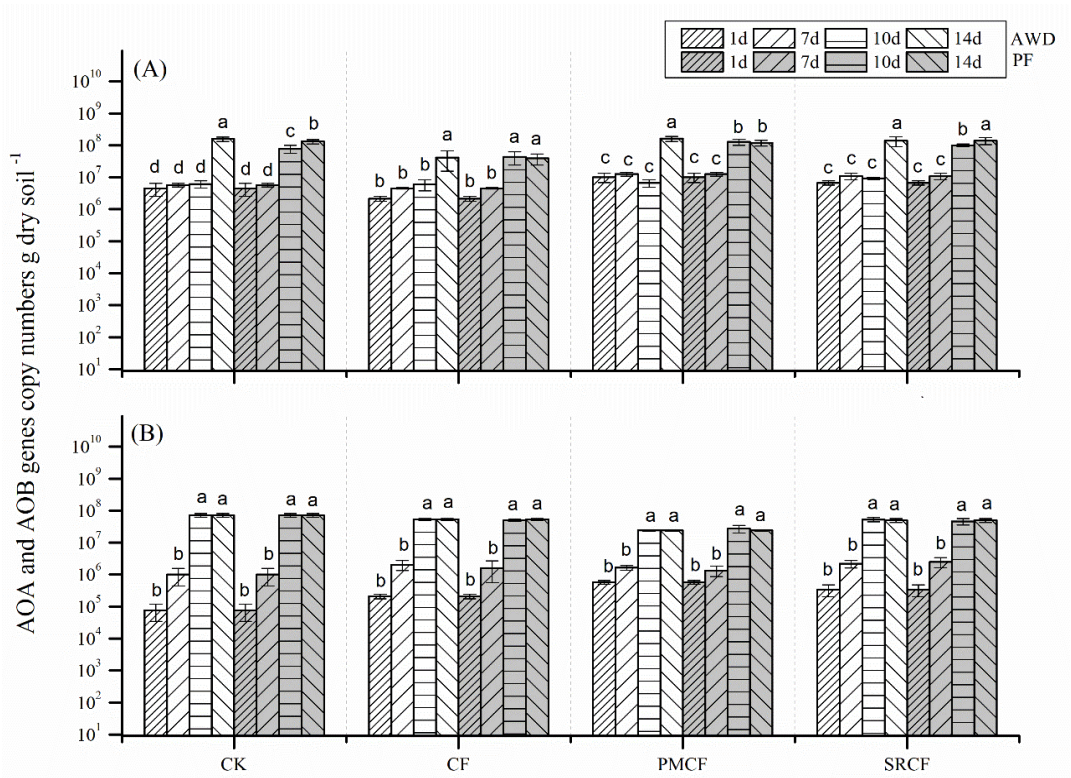

Figure 5. *Abundance of (A) AOA and (B) AOB gene (copy numbers g dry $soil^{-1}$) after 1, 7, 10 and 14 days of incubation during AWD and PF events. AWD represents alternate drying and flooding conditions while PF represents permanent flooding conditions. Arrow bar above the line shows standard deviation (n = 3, P < 0.0001). CK: control, CF: Chemical fertilization, PMCF: Pig manure plus chemical fertilizer, SRCF: Rice straw plus chemical fertilizer*

DOI: http://dx.doi.org/10.15666/aeer/1706_1377713792

The AOB *amo*A gene abundance was found in the range of 7.68E + 04 - 7.13E + 07 copy numbers g^{-1} of dry soil, with the highest value at 60% FC (14 days) in CK and CF treatments (*Fig. 5*). While, during AWD, a gradual increase in copy numbers were noted with time and relatively high at 80% FC and 60% FC. Also, during PF, this increase in copy numbers were recorded with time in all treatments. It was interesting that significant increases in copy numbers were found in CK and CF treatments during early stages ($P < 0.0001$). After 14 d, significant differences were noted between treatments.

The abundance of the *nir*S gene significantly increased with time during both water events. Significant differences were found among treatments during the later stage of experiment ($P < 0.0001$). During PF event, this increase in copy numbers were in certain limit and after that it started to decrease or remain constant. Moreover, relatively higher gene abundances were found in PMCF and SRCF during the whole trial period during both water events.

Although the abundance of *nir*K gene varied with time under all moisture conditions i.e. 60% FC and 100% FC. The high genes abundance was found during flooded condition in all treatments but relatively higher abundance was in PMCF treatment (*Fig. 6*). The highest value (6.94E + 06) of *nir*K was observed in the PMCF treatment after 14 days of PF.

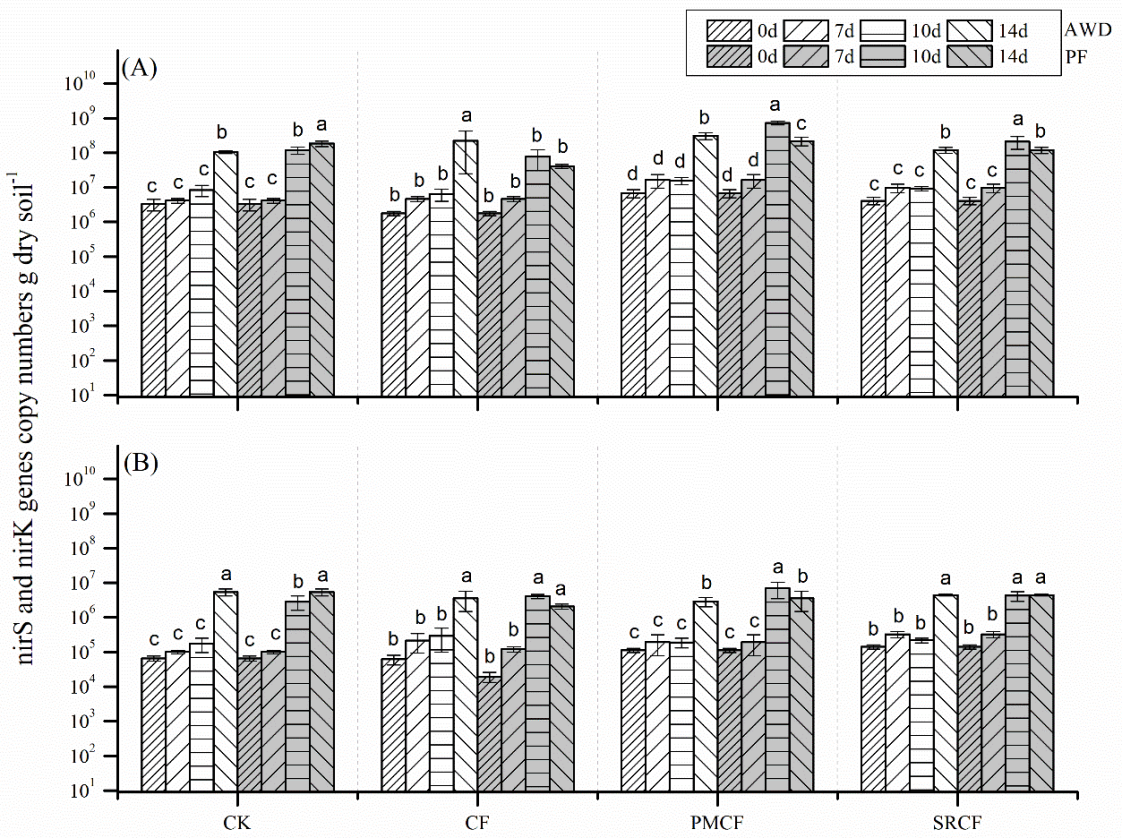

Figure 6. *Abundance of (A) nirS and (B) nirK genes (copy numbers g dry soil^{-1}) after 1, 7, 10 and 14 days of incubation during AWD and PF events. AWD represents alternate drying and flooding conditions while PF represents permanent flooding conditions. Arrow bar above the line shows standard deviation (n = 3, P < 0.0001). Proportion of greenhouse gases emission associated with microbial biomass and water condition

The relationship of nitrifiers and denitrifiers with N_2O emissions under AWD and PF conditions are given in *Table 5*. A significant correlation was observed between AOB and N_2O emissions during both AWD and PF, suggesting that AOB is responsible for N_2O emissions whatever the water events are (AWD or PF). The correlation between N_2O and nitrifiers and denitrifiers suggested that N_2O emissions is mainly affected by AOB.

Table 5. *Correlation between N_2O, AOA, AOB and nirK genes (n = 24)*

	N_2O	**AOA**	**AOB**	***nir*S**	***nir*K**

**Correlation is significant at level 0.01 (two tail test)

Discussion

Effect of moisture contents on N_2O emissions

A plethora of previous literature have described the significant changes in N_2O emissions during alternate flooding and air drying events in paddy fields (Toyoda et al., 2011; Nishimura et al., 2011). AWD generally promotes N_2O emissions compared to PF in most of studies (Prieme and Christensen, 2001; Wu et al., 2017; Zou et al., 2005; Hou et al., 2012). Although, significant higher N_2O fluxes were observed when the water was removed from the all treatments (10d, 14d), confirmed by earlier findings (Toyoda et al., 2011; Nishimura et al., 2004, 2011). Jorgensen et al. (1998) and Scholes et al. (1997) have reported a rise in N_2O flux during AWD after submerged conditions, and these results were due to the combined effect of high microbial activity and escape of entrapped N_2O (Rice and Smith, 1982). Moreover, the N_2O emissions in PMCF, SRCF and CF treatments were greater than control (CK) suggesting that the application of long-term inorganic or organic fertilizers increase N_2O productions during soil drying-rewetting events (*Fig. 2*). This high N_2O emission in the PMCF and SRCF might be due to the high concentration of organic N fertilizer in the PMCF and SRCF. In this study, N_2O fluxes were positively affected by fertilization (CF, PMCF, and SRCF). Similar results were reported in previous studies conducted in rice paddies (Hou et al., 2012; Zou et al., 2005) presenting that fertilization had a noticeable effect on N_2O emissions because majority of inorganic N is supplied by fertilization in the form of NH_4^+-N and NO_3^--N, which promotes N_2O production (Liu et al., 2015). Harrison-Kirk et al. (2013) revealed N_2O fluxes increased exponentially by increasing C up to 50 mg g^{-1} soil by organic fertilizer application. It is interesting that N_2O fluxes always showed the following order: CK < CF < PMCF < SRCF during whole trial period.

Effect of water conditions on nitrifier and denitrifier abundance based on long term fertilization

AOA abundance in our results was more dominant compared to AOB, which was consistent with previous studies (He et al., 2007; Alam et al., 2013). This increase in AOA compared to the abundance of AOB might be due to high AOA affinity for oxygen (Szukics et al., 2009). However, Soil pH is another sole factor which may increase AOA abundance, producing favorable conditions for AOA in the paddy fields. Meanwhile, AOB abundance was mainly increased by pH (Nicol et al., 2008). In addition, some previous studies revealed that fertilization rate is the main driver of AOB and AOA abundances to decrease or remain unaffected (Zhong et al., 2016; Di et al., 2014). Also, the influence of fertilizer application on AOA and AOB were reported in some other filed studies (Dai et al., 2013; Alam et al., 2013) and laboratory incubation (Di et al., 2009). NH_4^+ availability produced by organic nitrogen mineralization or either by added inorganic NH_4^+ is the sole factor responsible for the abundance of AOA and AOB (Tourna et al., 2008). However, the pH might influence NH_4^+availability because under low pH it would be ionized to NH_4^+ (Nicol et al., 2008; He et al., 2007). Therefore, in the rice paddies, the drop of soil pH by fertilization, was a more significant factor to increase the availability of substrate for AOA.

The abundances of *nirK* and *nirS* genes had dramatically increased with time after 7 days in AWD and in PF until 10 days and then maintained or decreased (after 14 days). These results were in agreement with previous study of Uchida et al. (2014), indicated that under the absolute anaerobic conditions, the denitrifier abundance was reduced. In addition, the denitrifier abundance was influenced by flooding-drying pattern because denitrifier growth usually stimulate near anaerobic conditions (Uchida et al., 2014; Di et al., 2014). Alternatively, Cui et al. (2016) recognized a notable increase in denitrifiers abundance (*nirK*, *nirS*) after long-term fertilization which is similar to our results in which the abundance of denitrifiers were found high in PMCF and SRCF treatments. Hamonts et al. (2013) reported that dissolved organic carbon (DOC), NO_3^- and NO_2^- might increase denitrifiers copy numbers in fertilized soils. Moreover, low pH is recognized to reduce the assembly and turnover of N_2O reductase (Bergaust et al., 2010). In a recent study, DOC and NO_3^- contents increased by fertilization could decrease soil pH (data not shown). Together, these factors might have led to a neutral effect on the denitrifiers abundances.

Contribution of nitrification and denitrification on N_2O emissions with respect to water conditions

Nitrous oxide in soil are produced by various N transformation processes, i.e. nitrification (heterotrophic or autotrophic) and denitrification (Ruser et al., 2006; Beare et al., 2009; Hayakawa et al., 2009). However, in rice paddy soil, the water contents and fertilization rate are the main drivers for particular N transformation process. According to our results, the main contributor to N_2O production was autotrophic nitrification at 60% FC while denitrification was the predominant source during PF, consistent with Bateman and Baggs (2005). It is interesting that denitrification and autotrophic nitrification produce equally in PMCF and SRCF treatments during PF events and this relation is not significant however in CK and CF this relation was significant. The predominant contribution of autotrophic nitrification might be due to favorable conditions for substrate and O_2 diffusion. Similarly, autotrophic nitrification contributed

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1377713792

equally during PF because it proceeds under limited short-term O_2 during process of nitrifier denitrification (Poth and Focht, 1985; Goreau et al., 1980; Wrage et al., 2001 Bollmann and Conrad, 1998). In addition, nitrifier denitrification at higher water level might be another reason of high autotrophic nitrification contribution (Bollmann and Conrad, 1998). Alternatively, at high concentration of 200 kg N ha^{-1} NH_4NO_3 (>10 μg g^{-1}) inhibited the conversion of N_2O to N_2 for a limited time because NO_3^- is more suitable electron acceptor over N_2O (Blackmer and Bremner, 1978). Although, a very low heterotrophic nitrification contribution was observed during both water events, and this might be due to a limited C and O_2 availability for heterotrophic nitrification or that N_2O emission during heterotrophic nitrification process was unable to be detected (Bateman and Baggs, 2005). I has been assumed that both denitrification and nitrification processes had contribution to N_2O emission at 60% FC. In addition, the contribution of nitrification in fertilization treatments was higher than denitrification because fertilization always promotes nitrification in the soil.

Conclusions

Rewetting and drying conditions had an important impact on N_2O emissions, growth of denitrifier and nitrifier communities along the experiment. However, denitrifier and ammonia oxidizer growth (AOA, AOB, *nir*S, *nir*K) were significantly affected by soil moisture contents. Meanwhile, AWD event promoted N_2O fluxes compared to PF. PMCF and SRCF increased N_2O emissions during both water events (AWD, PF). After finding out the dominant contributor it had been evaluated that autotrophic nitrification had a dominant role in both AWD and PF conditions. Moreover, a significant correlation between the N_2O emission and AOB copy numbers were found in different wetting-drying conditions, showing that AOB has dominant role in N_2O emission by the process of nitrification. Thus present study emphasizes that the PF water conditions are the better option to mitigate nitrous oxide form terrestrial environment to atmospheric environment. However, further study needed to emphasize the underlying process of nitrous oxide emissions.

(Received 10th May 2019; accepted 16th Jul 2019)

Abstract. Environmentally friendly methods for obtaining nanomaterials see a great interest. In addition to being inexpensive, the easy implementation process and the advantages of synthesis without toxic chemicals are the main reasons of interest. In this study, silver nanoparticles (AgNPs) were successfully synthesized using fig (*Ficus carica*) leaf extract. The formation and the presence of AgNPs were observed using ultraviolet-visible spectrophotometry (UV-Vis). Peaks with a maximum wavelength of 419 nm are identified in the measurements. Phytochemicals in the extract responsible for functional groups providing reduction and stability were evaluated using Fourier transform infrared spectroscopy (FT-IR) data. The Scanning electron microscopy-Energy Dispersive X-Ray Spectrum (SEM-EDX) analysis showed that the AgNPs were spherical and the elemental composition contained mostly silver. X-ray diffractometer (XRD) results revealed that the peaks 111°, 200°, 220° and 311° belong to the characteristic structure of silver and have a crystal dimension of 17.30 Nm using Debye-Scherrer equation. In thermogravimetric - differential thermal analysis (TGA-DTA) analysis, the degradation temperatures of AgNPs were evaluated. AgNPs showed antimicrobial activity on various microorganisms even at very high concentrations. As a solution to the antimicrobial search, it can be developed in medical industry.
Keywords: *XRD, SEM, TGA-DTA, AgNPs, Ficus carica*

Introduction

Nanomaterials are used in medical, electronic, food and cosmetic industries, textile industry, agricultural applications and many other areas (Alqahtani et al., 2017; El-Batal et al., 2018; Silva-Ichante et al., 2018; Rolim et al., 2019). Among nanomaterials, AgNPs have a large facial area, good thermal and electrical conductivity (Elemike et al., 2016). AgNP are obtained using different methods (*Fig. 1*) (Mittal et al., 2013). Since physical and chemical methods are being synthesized by using high amounts of energy and toxic chemicals, they are a disadvantage compared to biological methods. Biological source synthesis methods are cheaper and the process is simpler and easier. It also makes these methods more advantageous because they do not contain toxic chemicals during the synthesis phase (Pantidos and Horsfall, 2014; Tippayawat et al., 2016; Kanchi et al., 2018). Phytochemicals such as polyphenols, flavonoids, proteins, alcohols and sugars found in plants, rather than harmful chemicals, are responsible for both reduction and stability (Kumar et al., 2015). Phytochemicals are responsible for the synthesis of AgNPs by reducing the Ag+ form to AgO (Prakash et al., 2013). Obtaining nanoparticles from plant sources provides advantages such as easy processing and no culture (Pallela et al., 2018). Furthermore, AgNPs have been shown to exhibit anti-microbial activity in some studies (Veerasamy et al., 2011; Ghosh et al., 2012; Ashajyothi et al., 2016).

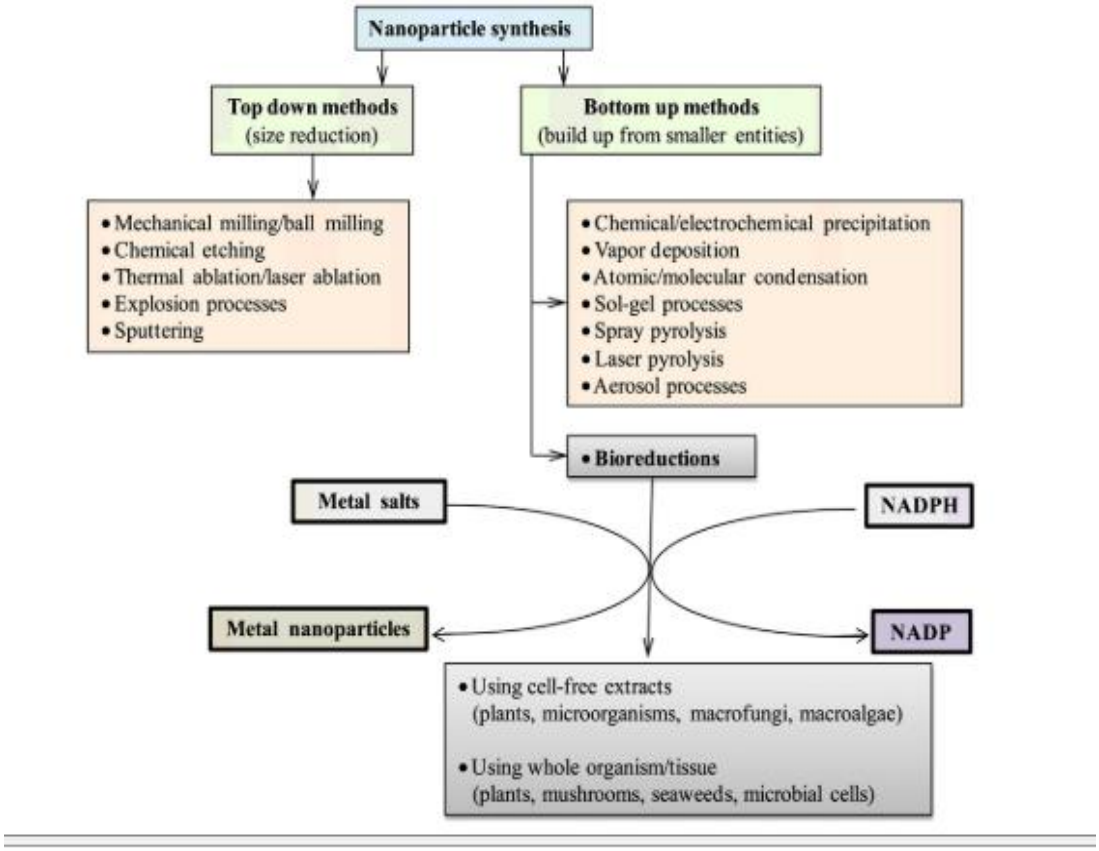

Figure 1. *Nanoparticle forming methods (Mittal et al., 2013)*

The aim of this study is to synthesize AgNPs with fig (Ficus carica) leaf extract in an inexpensive and simple way and to investigate the anti-microbial effects of these NPs characterized by different analysis data.

Materials and methods

Plant leaf

Fig *(Ficus carica)* leaf used in the study was obtained from Mardin, Sultan Village/Turkey in May-June 2018. 500 g samples stored in the Microbiology-Biochemistry Research Laboratory of Mardin Artuklu University

Microorganisms

For testing antimicrobial activity; *Escherichia coli* ATCC 25922, Staphylococcus *aureus* ATCC 25923, *Streptococcus pyogenes* ATCC 19615 *Pseudomonas* aeruginosa ATCC 27853, standard bacterial strains with *Candida albicans* ATCC 10231 strains are available in the Microbiology-Biochemistry Research Laboratory of Mardin Artuklu University.

Preparation of fig (Ficus carica) leaf extract and silver nitrate ($AgNO_3$) solution

The green leaves of fig fruit were collected in the center of Mardin, Sultan Village/Turkey. After washing with tap water, washing was done several times with distilled water. Dried leaves were minimized prior to preparation of the extract. 100 g was taken and mixed with 500 ml distilled water and left to boil. After boiling, the room was cooled and filtered several times by using the rough filter paper first and then the Whattman No.1 filter paper. After being filtered for several times, it was kept at +4 °C for synthesis. 1 mM aqueous solution was prepared with silver nitrate (AgNO3) of 99.8% purity was purchased from Alfa Aesar.

Synthesis and characterization

500 ml extract and 2000 ml $AgNO_3$ solution were mixed and kept constant in room conditions. The color change was observed for 50 min depending on the time. The presence of AgNPs was checked by examining absorbance values for the color change using Perkin Elmer one UV Visible Spectrophotometer. The characterization of silver nanoparticles was carried out as follows according to the methods described earlier (Baran, 2018). FTIR analysis was performed to evaluate phytochemicals responsible for reduction by using Perkin Elmer Spectrum One. The post-synthesized content in liquid form was centrifuged with OHAUS FC 5706 model device at 6,000 rpm for 25 min and the particles used for further characterization steps were precipitated. The particles were dried at 65 °C. RadB-DMAX II computer-controlled Energy Dispersive X-Ray diffractometer (EDX) was used to evaluate the elemental composition of the particles. Morphological images were examined with scanning electron microscope EVO 40 LEQ (SEM) data. The crystal structure of the particles was evaluated by RadB-DMAX II computer-controlled X-ray diffractometer (XRD) analysis. Crystalline particle size was determined by using the debye-Scherrer equation, using the Shimadzu TGA-50 device to control the decomposition temperature of the particles with TGA-DTA.

Determination of antimicrobial effects of silver nanoparticles

The antimicrobial effects of the particles on gram negative *Escherichia coli* ATCC 25922, *P. aeruginosa* ATCC 27853, gram positive *Staphylococcus aureus* ATCC 29213, *S. pyogenes* ATTC 19615 bacteria and *Candida albicans* yeast were determined by using micro dilution method to determine the minimum inhibition concentration (MIC). In practice, the muller Hilton medium was added to the microplate wells and incubated overnight at 37 °C by addition of an appropriate amount of the microorganism mixture and the AgNP solution adjusted to 0.5 in turbidity according to the Mc Farland standard. The lowest concentration in the absence of reproduction after incubation was determined as the MIC value (El-Batal et al., 2018; Vishwasrao et al., 2018). Commercial antibiotics were used as control for Gram (+) (vancomycin), Gram (-) (colistin) bacteria and fungus (fluconazole). In addition, the effect of $AgNO^3$ solution was investigated. The study was performed with 3 repetitions and the mean values were determined as MIC value.

Results and discussion

After mixing 1 mM $AgNO_3$ solution with leaf extract, the color rapidly changed from light to dark brown was observed after 30 min. Maximum absorbance data at 419 nm is given in *Figure 2*.

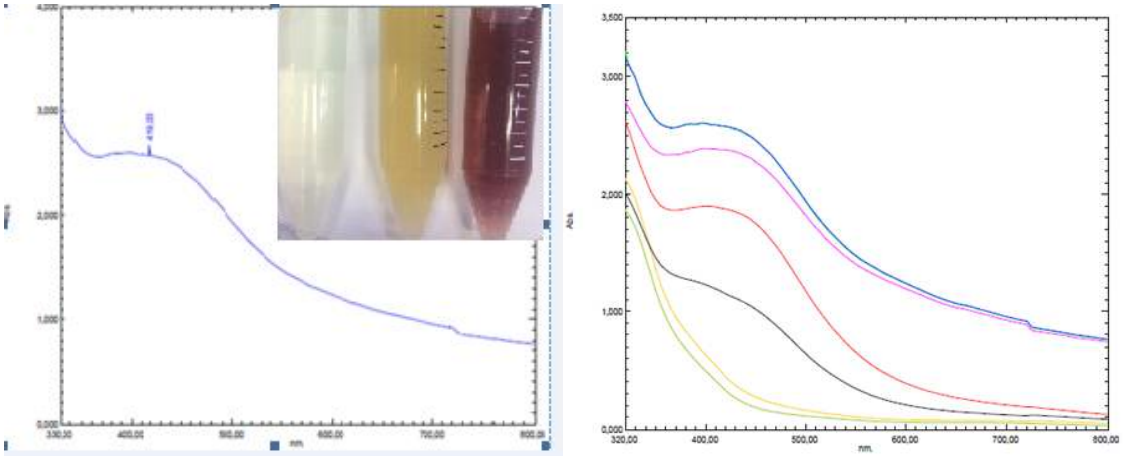

Figure 2. *UV-Vis. analysis result data*

Functional groups involved in the reduction of AgNPs were investigated by FTIR analysis (*Fig. 3*).

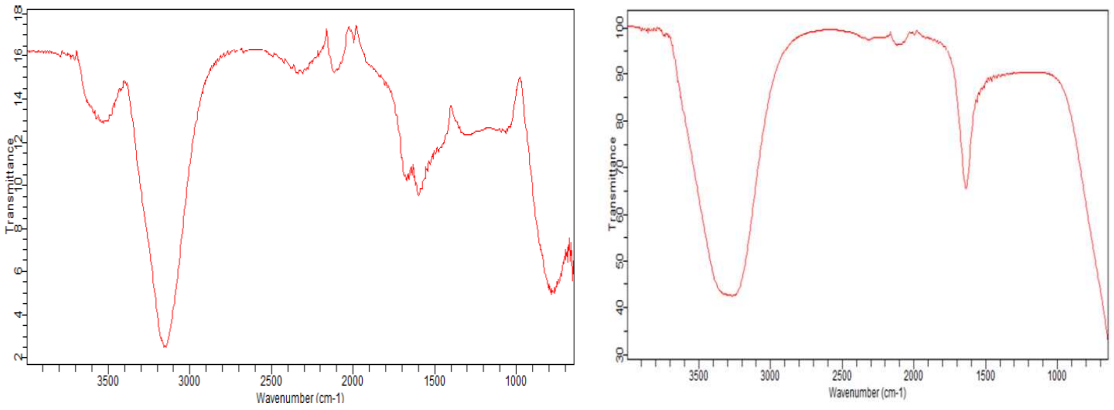

Figure 3. *With FTIR analysis result data.* ***A*** *Extract,* ***B*** *evaluation of functional groups after synthesis*

In the XRD results, the peaks 111°, 200°, 220° and 311° are the peaks that correspond to 2 θ, which represent the cubic crystal structure of silver (*Fig. 4*). The numerical values corresponding to these peaks were found to be 38.10, 44.24, 64.54 and 77.50. The crystal size of AgNPs were calculated 17.30 nm by using the Debye-Scherrer formula (*Eq. 1*) (Baran, 2019).

$$D = K\lambda / (\beta \cos\theta) \qquad \text{(Eq.1)}$$

In *Equation 1:* D = particle size (nm), K = fixed (0.90), λ = wavelength X-ray (1.5406°A), β = half of the highest peak value is specified in radians (FWHM), θ = fracture angle.

When the SEM analysis data were examined, it was found that AgNPs were in spherical appearance (*Fig. 5*).

DOI: http://dx.doi.org/10.15666/aeer/1706_1379313802

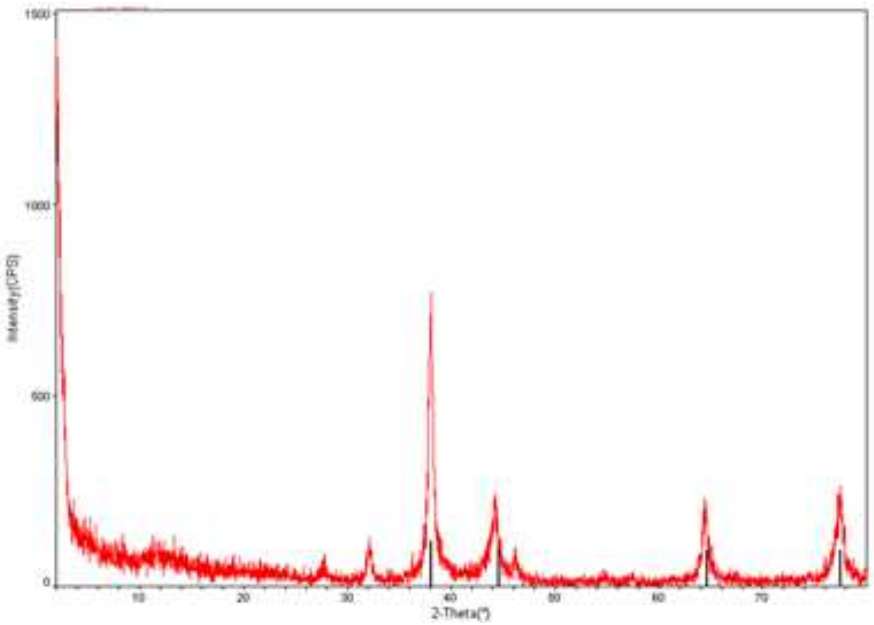

Figure 4. *Investigation of crystal structure and silver phases of AgNPs by XRD analysis*

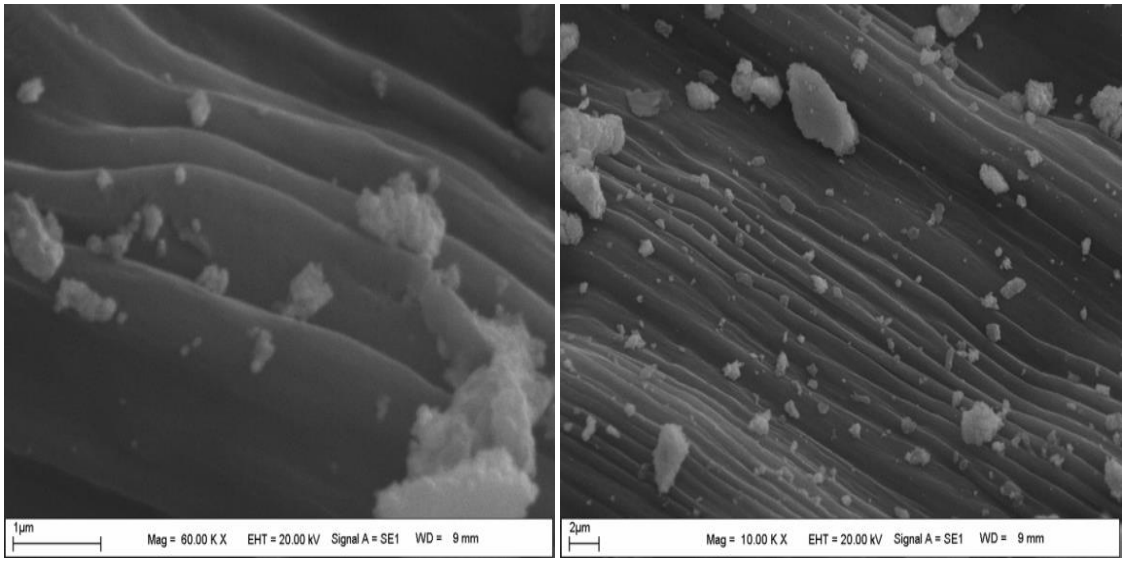

Figure 5. *Evaluation of morphology of AgNPs in SEM results*

The results of EDX showed a large percentage of the element content (*Fig. 6*). The TGA-DTA findings of the synthesized AgNPs were analyzed at a flow rate of 20 mL/min in the N_2 (g) atmosphere with a heating rate of 10 °C/min between 12 and 1000 °C (*Fig. 7*) (Eren and Baran, 2019).

In the study, AgNPs were found to be effective at lower concentrations than antibiotic and 5 mM silver nitrate solution. The MIC values of *S. aureus, S. pyogenes E. coli P. aeruginosa* and *C. albicans* respectively *0.225, 0.056, 0.112, 0.112* and *0.450 mg* L^{-1} results were obtained (*Table 1*). Compared with silver nitrates and antibiotics, AgNPs synthesized using plant extract can be used as an alternative to existing antibiotics as a result.

3529 cm^{-1} is – NH stretching, the peak at 1599 cm^{-1} may belong to – C = O or I amide band, and the peak in cm^{-1} 3180 is considered to be phenol or alcohol-induced-OH. During the formation of nanoparticles, role of -OH, -NN and C = O groups shift in the reduction is shown. In the synthesis studies to obtained AgNPs, almost identical functional groups were said to be responsible for reduction (Baran, 2019). In the XRD results, the peaks 111°, 200°, 220° and 311° are the peaks that correspond to 2 θ, which represent the cubic crystal structure of silver. Some studies have characterized these data with AgNPs (Narayanan and Sakthivel, 2010; Hemmati et al., 2019). The crystal size of AgNPs was calculated 17.30 nm by using the Debye-Scherrer formula. After the synthesis of nanoparticles, there are studies that calculate crystal size using this equation (Senapati et al., 2014; Palanisamy et al., 2017). The SEM results indicate that AgNPs have spherical morphology. In other studies, it has been reported that AgNPs have a spherical appearance (Pugazhendhi et al., 2018; Vishwasrao et al., 2018; Rolim et al., 2019).

Table 1. *MIC values of Synthesized silver nanoparticles (AgNP) (mg mL^{-1}) on Silver nitrate solution and vancomycin, fluconazole, colistin antibiotics, S. Aureus, S. pyogenes, S. albicans and E. Coli, P. aeruginosa microorganisms*

	Organism	**AgNPs**	**Silver nitrat**	**Antibiotic**
Gram positive	*S. aureus ATCC 29213*	0.225	2.65	1
	S. pyogenes ATTC 19615	0.056	1.32	1
Gram negative	*E. coli* ATCC25922	0.112	0.66	2
	P. aeruginosa ATCC 27853	0.112	0.66	2
Fungi	*C. albicans*	0.450	0.66	2

In the EDX analysis, it was observed that the content of the element belonged largely to silver. In similar studies, the element composition was evaluated (Owaid et al., 2015; Khan et al., 2018; Acay et al., 2019). In TGA-DTA data, it is understood that the mass loss of the nanoparticles at 12-232 °C is due to moisture and the mass loss at 232-467 °C is due to the structure of the extract and that the material is now gradually degraded at 467-876 °C in *Figure 5* (Baran et al., 2018; Baran, 2019). We have investigated the effective antimicrobial activity of AgNPs. This activity was effective even at lower concentrations than commercial antibiotic and 5 mM silver nitrate solution. Studies have shown that AgNPs have a negative effect on the reproduction of microorganisms and that they have put pressure on them (Pugazhendhi et al., 2018). These NPs produce ROS (Reactive Oxygen Species), suppressing the membrane structure, proteins, DNA and other vital functions of microorganisms and suppressing their function (Acay et al., 2019). Environmentally friendly synthesis methods for the production of nanomaterials are in the focus of interest due to their lack of toxic chemicals, economical and easier synthesis process. At the same time, the fields of use are becoming widespread every day.

Conclusions

The advantages of nanoparticles synthesized by biological methods are hygienic working environment, health and environmental protection, less waste and providing the most stable products. Green-synthesized Ag-NPs can be evaluated in a variety of applications including cardiovascular implants, dentistry, medicine, therapeutics, biosensors, agriculture and more, both now and in the future. In this context, It was synthesized AgNPs from the leaves of the *Ficus carica* plant with an easy, inexpensive, environmentally friendly method and without creating any special conditions (temperature, rinse, light, etc.). It was revealed that these particles are in a spherical view with a maximum absorption of 419 nm and that the crystal particle size is 17.30 nm. The degradation temperatures of these AgNPs were found to be 876 °C, and this is an indication of the durability of the product. It was found that these particles showed strong anti-microbial activity. NPs increasingly used for medical applications are of great interest as an approach to killing or reducing the activity of a large number of microorganisms. As a result, the AgNPs obtained is an alternative that can be developed and used in biotechnological and medical applications

(Received 12th May 2019; accepted 28th Aug 2019)

Abstract. This study investigates the farmers' willingness to pay for ecosystem services of organic farming in Valikamam area of Sri Lanka. Choice modeling employed indicates that farmers are willing to pay more for big reduction in nitrate leaching and soil quality improvement than biodiversity improvement. It indicates that farmers give more weight to the short term benefit than the long term sustainable benefit. Income and education level of farmers positively influence farmer's willingness to pay for soil quality improvement and Biodiversity. Young farmers are willing to pay more for soil quality improvement than old farmers. It shows that young farmers are willing to invest more to develop the farms than old farmers as young farmer value economic objective more than old farmers do. Middle aged farmers are willing to pay more for biodiversity. As middle aged farmers value social actions, environment responsibility more than young farmers do and are willing to invest more than old farmers do, middle aged farmers are willing to pay more for biodiversity than other farmers. Increasing farmer's income, organizing awareness programs on sustainable agriculture and providing subsidies could be the most effective ways to adopt organic farming in Valikamam.
Keywords: *biodiversity, choice modeling, conditional logit model, nitrate leaching, soil quality*

Introduction

Ecosystems provide a range of services which are very important to human well-being, livelihoods, health and survival. Ecosystem functions provide goods and services that satisfy human needs, directly or indirectly. Therefore, a growing human population and associated increasing food demands make the challenge to maintain and enhance ecosystem services in agriculture greater than in other ecosystems. Jaffna district in Sri Lanka is facing many problems such as high nitrate level in ground water, declining soil fertility, loss of biodiversity and declining crop productivity due to the overuse of agrochemical in agricultural production. Intensive agriculture that utilizes large quantities of inputs in the form of fertilizers, pesticide, labour and capital made it possible to grow enough food to meet the current global needs. However, these practices lead to environmental damage and degradation of several ecosystem services. Agro ecosystems not only provide ecosystem services but also consume them. Agro ecosystem is a highly managed ecosystem and provides food, forage, fiber, energy and pharmaceuticals. This agro ecosystem strongly depends on ecosystem services provided by natural ecosystem. Supporting ecosystem services comprise of genetic biodiversity for the use of breeding, soil formation, soil fertility, nutrient cycling and water purification (Sandhu et al., 2010). Regulating services include the services of pollinators and natural enemies (Power, 2010).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1380313815

As the economic value of ecosystem services is substantial, the utilization of these services for the long-term sustainability of agro-ecosystems and their ability to provide increased production while maintaining ecosystem services becomes very imperative (Sandhu et al., 2005). Sustainable agriculture seeks to make the best use of nature's goods and services while maintaining them for future generations. Organic agriculture is considered to be one of the production systems that aim to achieve sustainability by utilizing and maintaining ecosystem services. The estimated value of several ecosystem services is very high in organic agriculture than that of intensive agriculture. It is well known that organic agriculture delivers more environmental benefits than does intensive farming. Organic farming reduces the use of labour, fuel and agrochemicals and lowers external costs to human health and the environment (Sandhu et al., 2005). Scientists have been involved in enhancing the knowledge about how ecosystem services are produced for over a decade. Most studies had focused on estimating the value of one or two well understood ecosystem services. Better understanding of the processes of ecosystem could help to predict the range of ecosystem services from that ecosystem (Polasky, 2008). The valuation of ecosystem services generally includes both market and non-market valuation. Since agricultural commodities are traded in markets, valuing the provisioning services of agriculture is relatively simple.

Value of supporting services of ecosystems such as pollination services and biological control services can be estimated from in the quantity or quality of agricultural production when the services are removed or degraded (e.g. Losey and Vaughan, 2006; Gallai et al., 2009). Replacement cost method can be used to estimate the values of biological control as pesticides replace natural pest control and values of pollination services as hand-pollination replaces pollination by bees. Non-market valuation methods are used to estimate both the use value and the non-use value of various environmental amenities (Mendelsohn and Olmstead, 2009). Non-market valuation can be based on revealed preference or stated preference. In contingent valuation method, consumers are asked what they would be willing to pay for the ecosystem service. The goal of valuing ecosystem services is to use that information to form policies and incentives for sustainable management of ecosystems. There are difficulties in managing ecosystem services since many ecosystem services are public goods. Farmers' agronomic practices may strongly influence the ecosystem services available to others. Policy makers are facing challenges on how to use emerging information about ecological production functions and valuation to develop policies and incentives to achieve sustainable ecosystem management. In US and many European countries, incentives are provided to the farmers through government program to support for environmentally sound farming practices that support ecosystem services. The impacts of these programs are inconsistent, however, and their success is debated (e.g. Baulcombe et al., 2009).

Market imperfections of environmental goods and services distort their real prices or values and also consumers' willingness to pay on them cannot be readily observed. Market imperfections exist when public goods, externalities, and incomplete markets or property rights are involved (Baumol and Oates, 1975). Market imperfections have been categorized into public goods, externalities, and incomplete markets or property rights (Baumol and Oates, 1975). Since environmental resources produce benefits or costs for which markets do not provide an appropriate price, Market for these benefits and costs can be imperfect. Economic valuation methods generally can be divided into two broad categories: revealed preference methods and stated preference methods (Freeman,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1380313815

1993). Revealed preference methods depend on actual consumer behavior in the market. Stated preference method is used to estimate the value of non-market goods and services. In the stated preference method respondents were asked to state their preferences in one or more hypothetical scenarios (Mitchell and Carson, 1989). Stated preference methods could estimate both use and nonuse values. Use values are the monetary value of the utility derived from the direct or indirect consumption of a good or service. Nonuse values are less tangible and are naturally motivated by the wish to leave some existing assets to future generations.

Contingent valuation approach estimates respondent's maximum willingness to pay for a hypothetical change in an environmental good or service (Mitchell and Carson, 1989; Hanley et al., 2001). Conjoint analysis and choice modeling both value the multiple attributes of a product. Conjoint valuation analyzes one combination of attributes at a time. Choice modeling analyzes the values for multiple attributes of a product and their tradeoffs simultaneously (Merino-Castello, 2003). Multi-attribute techniques can be grouped into two categories: preference-based approaches, choice-based approaches. Preference-based approaches ask individuals to rate alternative scenarios on a cardinal scale, whereas choice-based approaches ask consumers to choose among alternative products on ordinal scale. Conjoint analysis is a technique that applied in marketing for many years, but it has recently been employed in economics (Louviere, 1991). The application of conjoint analysis to environmental economics is limited. Choice experiments have some advantages over contingent valuation methods.

In contingent valuation method, Respondents are asked to state their maximum willingness to pay for the improved good or service. The improvements in goods or services are needed to describe precisely. A problem arises in this approach is that if any errors in the information discovered after the fact cannot be changed. However, the choice experiment approach depends on the representation of a choice situation using a range of attributes. Therefore, it relies less on precise description of the good or service, but more on description of the situation. In choice experiment approach, respondents are asked about a sample of events drawn from the universe of possible events of that type (Louviere, 1994). Using attributes and levels of specific choice situations, choice modeling approach are used to make choice sets of attributes that reflect different states of the environment. Individuals are asked to choose their preferred alternative choice set from different choice sets. Thus, the choice modeling approach makes each individual tradeoff between the attributes of the situation. When a cost factor is included as one of attributes in a choice set, it becomes possible to estimate economic values of the other attributes. Choice modeling is attractive for environmental valuation because this type of analysis is based on random utility theory (McFadden, 1974; Ben-Akiva and Lerman, 1989).

The objectives of this study are to estimate the values of ecosystem services of organic farming such as reduction of nitrate leaching, improvement of soil quality improvement and biodiversity and make suggestions or recommendation to policy makers in local and central government to encourage organic farming in Valikamam area in Jaffna district. Intensive agriculture in Valikamam area created many environmental problems such as high nitrate level in ground water, declining of soil fertility, loss of biodiversity and declining crop productivity. Jaffna district is one of the districts in Sri Lanka that is endowed with significant natural and human resources that can be exploited for the agricultural purposes. The total land area including inland water

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1380313815

is 1025.2 km^2 (Jaffna District Secretariat, 2014). Jaffna district is divided into four sub divisions. They are Islands, Thenmarachi, Vadamarachi, and Valikamam. Total population of the district is around 600,000. Agriculture and fisheries have been the principle economic activities of the district. Agriculture sector is the leading sector and 1/3 of the population mainly depends on agriculture. About 86,000 families are engaged in agriculture while 15,000 families engage in fishing. Agriculture in the district contributes substantially to the GDP of the country. Agriculture is the dominant productive sector in the Jaffna district. *Figure 1* shows five divisional secretariats of Valikamam area: Valikamam East, Valikamam North, Valikamam South, Valikamam South west and Valikamam West. Total populations of those areas are 73087, 37579, 51099, 52423, and 48703, respectively. The climatic condition and the soil type of this area are conducive for the agricultural activities (Jaffna District Secretariat, 2014).

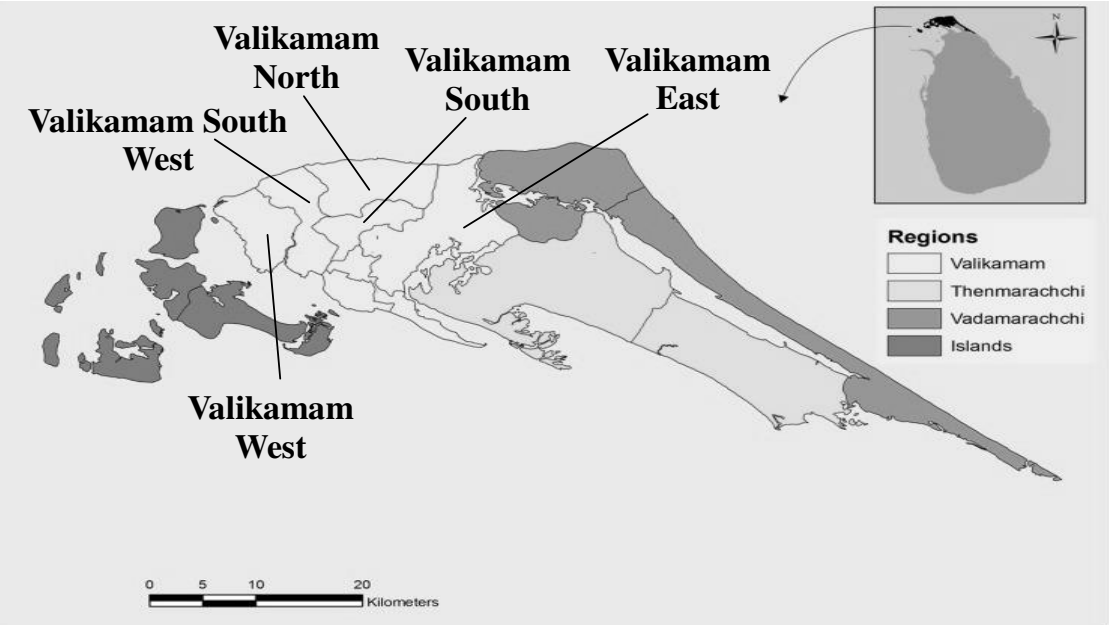

Figure 1. *Map of Jaffna District*

Methodology

Our primary aim is to assess marginal economic values of ecosystem services and benefits to the society; hence we employ choice modeling that is one of stated preference techniques. Discrete Choice Experiment (DCE) initially developed by Louviere and Hensher (1982) and Louviere and Woodworth (1983). The first application of a DCE in valuing environmental goods was reported by Adamowicz et al. (1994). In the recent years, the number of applications of choice modeling has significantly increased and become a popular stated preference method for environmental valuation. A complete summary of this valuation method can be found in Ben-Akiva and Lerman (1985), Louviere et al. (2000), Train (2003), Hensher et al. (2005) and Kanninen (2007). Choice modeling aims to assess the utility that individuals derive from the attributes of non-market environmental good or service under valuation. Choice modeling can also provide the opportunity to understand the trade-offs between different attributes (Adamowicz et al., 1998; Jin et al., 2006).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1380313815

Choice modeling was formulated in a random utility framework that permits measurement of the values of non-market goods and services. The Utility function (U) is a function of an observable component (indirect utility function) and an unobservable error component,

$$U = V + \varepsilon \quad \text{(Eq.1)}$$

where V is the indirect utility function and ε is the stochastic error term. We assume that the indirect utility is a linear form,

$$V_i = \beta_i X_{ki} + \alpha m = \beta_1 + \beta_2 x_{2i} + \beta_3 x_{3i} + \ldots + \beta_k x_{ki} + \alpha_i m_i \quad \text{(Eq.2)}$$

where ($X_{ki} = \{x_{1,2}, \ldots, x_k\}$) is a vector of k attributes associated with alternative i, β is a coefficient vector, m_i is income for a respondent choosing the alternative i bundle, and α is the coefficient vector of income. If the stochastic error term is logistically Gumbel distributed (Type I extreme value distributed), the choice probability for alternative i is given by

$$\Pr(i) = \frac{\exp(\rho V_i)}{\sum_{j \in C}^{J} \exp(\rho V_i)} \quad \text{(Eq.3)}$$

where ρa positive scale parameter and C is is the choice set for an individual. For convenience we generally make the assumption$\rho = 1$. To estimate willingness to pay for a change from the status quo state to the chosen state, the following formula is used:

$$V_i(X_i, y) + \varepsilon_i = V_j(X_j, m - CV) + \varepsilon_j \quad \text{(Eq.4)}$$

where V_i and V_j represent utility before and after the change and CV is compensating variation, the amount of money that makes the respondent indifferent between the status quo and the proposed scenario. Conditional logit model can be applied to estimate the welfare measure in *Equation 4*. *Equation 4* can be restated as:

$$\beta_i X_{ki} + \alpha_i m + \varepsilon_i = \beta_j X_{kj} + \alpha_j (m - CV) + \varepsilon_j \quad \text{(Eq.5)}$$

α_i and α_j are assumed to be equal if marginal utility of income for a respondent is constant. The welfare change is estimated by:

$$CV = -\frac{1}{\alpha}\left[(\beta_i (X_{ki} - X_{kj}) + (\varepsilon_i - \varepsilon_j)\right] \quad \text{(Eq.6)}$$

In conditional logit model, coefficient of k attributes across the all alternatives are the same, and $\beta_i = \beta_j$; only the attribute levels differ across the alternatives. Under this condition, welfare change is estimated by the following:

$$CV = -\frac{1}{\alpha}\left[(\beta (X_{ki} - X_{kj}) + (\varepsilon_i - \varepsilon_j)\right] \quad \text{(Eq.7)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1380313815

Equation 7 is used to estimate welfare changes in ecosystem services, assuming the impact of the attributes across the all alternatives same.

The attributes of selected ES provided by organic farming in this study were nitrate leaching, soil quality improvement, and biodiversity enhancement of organic farming. Each attribute has several discrete levels of delivery. For the nitrate leaching from organic farming, there were three levels present to respondents: big reduction (50% reduction in nitrate leaching to ground water; small reduction (20% reduction in nitrate leaching to ground water); and no change from current level of nitrate leaching to ground water. The attribute of soil quality of organic farming is limit to two level: soil quality improving and no change. The third attribute, biodiversity enhancement of organic farming is limit to two levels; more variety and no change.

The choice modeling surveys contain multiple choice sets about alternative policies for improving three ecosystem services. In the surveys, before the choice set questions, respondents were briefed about the three attributes of ecosystem services and associated cost to the household. The cost to the household, the payment vehicle, was defined as an additional annual payment to the regional office of environmental authority responsible for management of the environment. The discrete range of cost alternatives given to respondents was LKR 10, LKR 30, LKR 60, and LKR 100. In the choice questions, respondents were asked to select an option they favoured the most out of the three alternatives provided. Each option contains the three attributes and the cost to the household with various levels of attribute combinations. The cost to the household in option A was designed higher than in option B, and option C was set as the status quo across all choice sets. Respondents were asked to answer similar types of choice questions sets multiple times. As there are three levels for nitrate leaching attributes, two levels in the soil and biodiversity attributes, and four levels in the cost to household, there are 2^2 x3 x4 factorial designs. For statistically efficient choice designs, a D-efficient design excluding unrealistic cases was adapted to each of the choice questions. Definitions of selected Ecosystem Service Attributes on cropping farms are presented in *Table 1*. So 48 orthogonal choice combinations are possible but it is impossible to include the all the choices into to the questionnaire and impossible to ask the respondent to select the choice among the choice sets, so we reduce the number of choices in to half. We select 24 choice combinations among the 48 orthogonal combinations. Here we assume, interaction effects between attributes are insignificant. Among 24 choices, 3 unrealistic options were excluded, so 21 choices were selected. "No change" in the current attributes levels (Option C) was included in the each choice set. Levels of the attributes change from one alternative to the other except option C. Attributes, levels, payment of cost, organic farming benefits, and different levels of intensive organic farming are briefly introduced to the farmers during the survey. Each option in the choice set has different level of intensive organic farming. A sample of choices from 21 choices was given in the *Appendix*. In this study only four attributes with few levels were selected to reduce the number of choices and allows farmers to make a clear choice. After giving brief knowledge to the farmers individuals are asked to select the most preferred alternative among the choice sets. Conditional logit model was estimated for the selection of choices.

For this study, 107 farmers from Valikamam east and 104 farmers from rest of the Valikam area, a total of 211 farmers were randomly selected. Data were gathered from personal interviews with Farmers using structured questionnaire. Questionnaire include farmer's demographic and social characteristics such as age education, income, residents

in rural or urban area and occupation, number of people in household, number of children, agricultural farming practices, environmental problems in their area and the 21 intensive organic farming management scenarios. Discrete choice modeling was used to estimate the economic value of three non-marketed ecosystem services: water quality improvement, soil quality improvement and Biodiversity enhancement associated with organic farming. Definitions of the effect codes for attributes and variable description are presented in *Tables 2* and *3,* respectively. Farmers' age and education level were categorized into 4 groups and income was classified into two groups.

Table 1. *Definitions of selected ecosystem service attributes on cropping farms*

Attributes	Levels	Definitions
Nitrate leaching	Big reduction (NLB) Small reduction (NLS) No change	50% reduction in nitrate leaching to ground water 20% reduction in nitrate leaching to ground water Maintain current nitrate leaching to ground water
Soil quality	Improved (SQ) No change	Soil organic matter and structure are improved Maintain current slow rate of soil degradation
Bio diversity	More variety (BD) No change	More variety of species on crop farms Maintain current variety of species on crop Farms
Cost to household	10:30:60:100	Annual payment to a regional office (LKR) Next five years

Table 2. *Effect codes: choice modeling*

Attributes	Variables	
Nitrate leaching	NLB	1 if big reduction; 0 if small reduction; -1 if no change
	NLS	1 if small reduction; 0 if big reduction; -1 if no change
Soil quality	SQ	1 if improved; -1 if no change
Biodiversity	BD	1 if more variety; -1 if no change

Table 3. *Variable description*

Variable	Description	Unit
East	Valikamam East	1 if Valikamam East; 0 if other areas
Income1	Income	1 if monthly income is less than 135 USD (20,000 LKR) 0 if monthly income is 135 USD (20,000 LKR) and more
Edu1	Education level	1 if farmer's education is $\leq 5^{th}$ grade Otherwise 0
Edu2	Education level	1 if 5^{th} grade < farmer's education $\leq$ 8th grade Otherwise 0
Edu3	Education level	1 if 8^{th} grade < farmer's education $\leq$ 11th grade Otherwise 0
Age 1	Age	1 if farmer's age is $\leq$ 40 years Otherwise 0
Age 2	Age	1 if 40 years < farmer's age $\leq$ 55 years Otherwise 0
Age 3	Age	1 if 55 < farmer's age $\leq$ 65 years Otherwise 0

Results and discussion

The descriptive statistics of Valikamam east and rest of the Valikamam are given in *Table 4*. The descriptive statistics show that farmers from both places have almost similar statistics regarding income level and farmers age, but on average farmers from rest of the Valikamam have higher education level than the farmers from Valikamam East.

Table 4. *Descriptive statistics*

Variable	East of Valikamam					Rest of Valikamam				
	Obs	**Mean**	**Std. dev.**	**Min**	**Max**	**Obs**	**Mean**	**Std. dev.**	**Min**	**Max**
Income	3,204	10981	7663	3000	45000	3,120	10782	7463	3000	50000
Age	3,204	53	11	30	82	3,120	53	11	27	80
Education	3,204	8.8	3.2	2	13	3,120	10	2.7	2	13

Five conditional logit models were developed using effective codes for three ecosystem service attributes. Results of five conditional logit model were presented in *Table 5*. As a simple model, model 1 includes no social characteristics and no dummy values for divisional area of Valikamam and estimated as a simple pooled model. All variables except small reduction in nitrate leaching are significant at 5% level. The negative coefficient of cost indicates that farmers are likely to accept the policy option with lower cost to them. Dummy values for Valikamam East and rest of the Valikamam are included in the Model 2 as interaction terms with each ecosystem service attribute. The interaction term of Valikamam East and biodiversity is negative and significant at 5% level. It indicates that farmers from Valikamam east are willing to pay less for biodiversity than farmers from rest of Valikamam. Social characteristics such as income, education level and age are included in model 3, 4 and 5, respectively.

Mean welfare values from the improvement of each ecosystem service were estimated by using *Equation 7* and the Estimated mean willingness to pay for each attribute were presented in *Table 6*. Mean welfare values of big reduction in nitrate leaching and soil quality improvement are almost similar between Valikamam east and rest of the Valikamam, which are around 0.53 USD (80 LKR) and 0.52 USD (79 LKR) per annum respectively. Farmers in Valikamam east give less weight for the improvement of biodiversity when compared to the farmers in rest of the Valikamam area. Farmers in Valikamam East and rest of the Valikamam are willing to pay for biodiversity improvement 0.1 USD (10 LKR) and 0.2 USD (30 LKR) per annum respectively. Mean welfare values of all three ecosystem services in Valikamam East and rest of the Valikamam are 1.25 USD (188 LKR) and 1.05 USD (158 LKR) per farm household per year respectively. Farmers from both areas are willing to pay more for large reduction in nitrate leaching and soil quality improvement policies than the policy for biodiversity improvement. This result indicates that, for the farmers from both areas, the big reduction in nitrate leaching and soil quality improvement are more important than the improvement in biodiversity. This indicates that farmers give more weight to the short term benefit than the long term sustainable benefit.

Total willingness to pay for these ecosystem services attributes can be calculated from the mean values. According to the Jaffna District statistics, there are about 12353 farming families from Valikamam East and 19450 families from rest of the Valikamam. Based on these numbers and estimated mean willingness to pay, the total WTP for each ecosystem services are estimated and presented in *Table 7*. Results of these models show that farmers who get monthly income less than 135 USD (20,000 LKR) are willing to pay less for soil quality of improvement than farmers who get monthly income more than 135 USD (20,000 LKR).

Table 7. *Total WTP per farming family per year USD (million LKR)*

Area	NLB	SQ	BD
Rest of Valikamam	10400 (1.56)	10200 (1.53)	4000 (0.6)
Valikamam East	6133 (0.92)	6066 (0.91)	800 (0.12)
Total	16533 (2.48)	16266 (2.44)	4800 (0.72)

The interaction term of education levels with Soil Quality and Biodiversity attributes are negative and significant at 5% level. It indicates that farmers who have education level of 11^{th} grade or below are willing to pay less for soil quality improvement and Biodiversity than farmers who have education level above 11^{th} grade. The interaction terms of age with soil quality attributes is positive and significant at 5% level. It indicates that farmers who are 55 years old or below are willing to pay more for soil quality improvement than who are above 55 years old. The interaction terms of age and biodiversity attributes indicates that farmers whose age is between 40 years and 65 years are willing to pay more for biodiversity than farmers whose age are below 40 years and above 65 years. These findings are consistent with the previous study which found that young farmers were the most active at developing their farms and old farmers were the least active. Young farmers value economic objective slightly more than old farmers, whereas they valued social actions, environment responsibility objectives less than did others (Rantamäki-Lahtinen and Väre, 2012).

Conclusion

Welfare values for changes in levels of three ecosystem services associated with organic farming were estimated using choice modeling method. Estimated mean willingness to pay for each attribute indicates that farmers from both areas are willing to pay more for large reduction in nitrate leaching and soil quality improvement policies than the policy for biodiversity improvement. Soil quality is directly linked to the agricultural productivity and farmers waste their economic resources due to strong nitrate leaching. Nitrate leaching increase the nitrate level in the ground water which is used as drinking water and causes health problem. Therefore, for farmers, the both big reduction in nitrate leaching and soil quality improvement became more important than the improvement in biodiversity. It also indicates that farmers give more weight to the short term benefit than the long term sustainable benefit.

Farmers from both places have almost similar statistics regarding income level and farmers age, but on average farmers from rest of the Valikamam have higher education level than the farmers from Valikamam East. Therefore, Farmers' unawareness about

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1380313815

the benefits of biodiversity in Valikamam east might be one of the reasons for low willingness to pay for biodiversity improvement. Total willingness to pay for all three ecosystem services in rest of the Valikamam and Valikamam East are 24600 USD (3.69 million LKR) and 13000 USD (1.95 million LKR) per year respectively. It shows that there is a potential to impose minimal tax on farmers and provide this tax revenue as a subsidy to the farmers who practice organic farming. This will encourage more farmers to practice organic farming. Farmers with lower monthly income are willing to pay less for soil quality of improvement than farmers with higher monthly income. Farmers with lower education level are willing to pay less for soil quality improvement and Biodiversity than farmers with higher education level. Young farmers are willing to pay more for soil quality improvement than old farmers. Middle aged farmers are willing to pay more for biodiversity than young and old farmers. It indicates that young farmers are willing to invest more to develop the farm than middle aged and old farmers. As middle aged farmers value social actions, environment responsibility more than young farmers do and are willing to invest more than old farmers do, middle aged farmers are willing to pay more for biodiversity. This study concludes that creating opportunities to earn extra money from off-farm and on-farm economic activities and organizing awareness program on the benefits of reducing nitrate leaching and improving soil quality and biodiversity for farmers, especially young and middle aged farmers and providing subsidy to the farmers who practice organic farming from the tax revenue collected by Central Environmental Authority could be an effective way to adopt organic farming in Valikamam area.

(Received 13th May 2019; accepted 20th Aug 2019)

Abstract. Tomato (*Solanum lycopersicum* L.) is one of the most popular vegetable species grown worldwide. Functional genomic analysis of genes in the early flower and fruit stages are the key factors for genetic enhancement of tomato fruits for increased yield and quality. In the current study, RNA-Seq datasets were generated for the Chico cultivar at six growth stages, 0, 3, 5, 7, 9 and 12 days after pollination (DAP). The computational analysis of transcriptomes and heat map showed close relationships among transcripts regulated at 3 and 5 DAP and at 7 and 9 DAP, whereas transcripts regulated at 12 DAP were more distant. Annotated transcripts and KEGG analysis showed that starch and sucrose pathway experienced the most dynamic changes resulting in the synthesis of several soluble sugars, e.g., sucrose, β-D-fructose, α-D-glucose, trehalose, maltose and 1,4-β-D-xylan. Enzymes

activated in this pathway included levansucrase, phosphotransferse, invertase, pectin methyl esterase (PME), glucan synthase and cellulase. In general, the results provided improved insights into the mechanisms underlying early fruit development in tomatoes.

Introduction

Tomato (*Solanum lycopersicum* L.) is one of the most important vegetable crops worldwide due to its economic and agronomic importance (Zhang et al., 2016). Cultivated tomatoes are diploid with 12 chromosomes and a genome size of approximately 950 Mb with 35,000 genes (Guigó Serra et al., 2012) and wild forms range from diploids to hexaploids (Bonierbale et al., 1988; Gupta et al., 2013). Tomato fruit development begins with fertilization and ends at the red ripe stages (Gillaspy et al., 1993; Picken, 1984). Wild tomatoes are important for tomato breeding and also cultivating plants belonging to family Solanaceae because information gained from studies in tomato genome sequencing can be applied to these plants (Kimura and Sinha, 2008).

Functional genomic analysis at the fruit ripening stage with mature, full-sized green fruit has been studied intensively (Gapper et al., 2014), while studies at earlier stages of fruit development are limited. The early developmental stage is very important for tomato fruit formation because the fruit weight and size are widely dependent on the pericarp cell number which is genetically controlled during cell division (Xiao et al., 2008), which leads to cell expansion and increases in average cell size. Transcription factors organizing early steps of the development also appear to have roles in tomato flower and fruit development (Silva et al., 2014). DNA replication is essential during both phases, although it is followed by mitosis in the earlier phase and endomitosis (replication progresses several times without mitosis) in the later phase. The resulting cells can possess multiple genome copies (polyploidy); an important process during cell expansion (Bergervoet et al., 1996).

Parallel with these processes, differentiation of the tissues into pericarp (fruit wall), peel, placenta and locular tissue ("jelly") is completed (Bertin, 2005; Mintz-Oron et al., 2008). Many of the final fruit quality parameters, such as size, shape, taste (soluble solids), texture (wateriness, mealiness), firmness, proneness to cracking, peelability, and properties during processing (viscosity), are co-determined during early stages by signals of some hormones that are stimulated in pericarp developmental stages. Carbohydrates are the main component in early developed tomato fruits. Metabolism of carbohydrates is regulated by many genes that contribute to cell wall synthesis (Zhang et al., 2016).

Web-based resources for genetic control and development of tomato are available at Tomato Genetics Resource Center (TGRC) (http://tgrc.ucdavis.edu) which contains a collection of wild relatives and miscellaneous genetic stocks of tomato (Kimura and Sinha, 2008). Expressed sequence tags (ESTs) library largely replaced microarray technologies in most plant systems because it provides a large-scale picture of gene expression during ripening in tomato (Gapper et al., 2014) and responses to treatment or environmental stresses (Bahieldin et al., 2015a). However, RNA-Seq provides an accurate statistical assessment of gene expression and clusters of genes based on their expression patterns (Bahieldin et al., 2015b). Therefore, RNA-Seq datasets of gene expression in tomato were generated in the present study and verification of gene

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

expression profiles involved in several metabolic pathways shed the light on genetic mechanisms that might regulate early developmental stage and the formation of fruit during ripening stage in tomato.

Materials and methods

Plant material

Tomato cv. Chico III seeds were germinated in pots filled with Peat moss soil and grown in the glasshouse under controlled conditions (16-h-light/8-h-dark cycle at 21 ± 2 °C (day/night), light intensity of ~200 uE m^{-2} s^{-1} for the 16-h photoperiod and 80% humidity) (Zhan et al., 2018). Recovered plantlets were watered every other day for 60 days until buds started to develop. Then, flower and bud samples were taken at six growth stages, i.e., 0 day after pollination (DAP), 3 DAP, 5 DAP, 7 DAP, 9 DAP and 12 DAP. Each sample was collected from two pots with four plants each in order to recover enough RNA for further analysis.

RNA extraction, library construction and sequencing

Total RNAs were extracted using SV Total RNA Isolation System (Promega) and the Truseq™ RNA Sample Prep Kit (Illumina) was utilized for library construction following the manufacturer's instructions. Then, the library was shipped to Beijing Genomics Institute (BGI) in China for sequencing on Illumina HiSeq™ 2000. For every sequencing read, the indexes were trimmed using SeqPrep program (https://github.com/jstjohn/SeqPrep) and the paired ends were merged . The remaining optimized reads were mapped to the tomato reference genome (ftp://ftp.solgenomics.net/tomato_genome/annotation/ITAG2.3_release/) using Tophat (Trapnell et al., 2009) and SOAPaligner/soap2 software (http://soap.genomics.org.cn) (Robinson et al., 2010). The mapped reads were then assembled with Cufflink (Trapnell et al., 2010). The experiment was submitted to National Center for Biotechnology Information (NCBI) as BioProject accession number PRJNA298353 and as BioSample accession numbers SAMN04214820 to SAMN04214831. RNA-Seq reads were placed in Sequence Read Archive (SRA) database (http://www.ncbi.nlm.nih.gov/Traces/sra/) under the accession number SUB1151548. The differential expression profiling and further annotation analysis utilized the merged and assembled sequences, as well as the original genome annotations.

The Bowtie aligner software of trinity package (http://trinityrnaseq.sourceforge.net/analysis/extract_proteins_from_trinity_transcripts.html) was used to predict the mapping of the assembled transcripts reads to the reference genome and annotated genes or open reading frames (ORFs). Sequence-similarity Blast searches of transcripts were conducted against the tomato reference genome, the NCBI genome database (http://www.ncbi.nlm.nih.gov/), the gene ontology (GO) database (http://www.geneontology. org/) and the Kyoto encyclopedia of genes and genomes (KEGG) database (http://www.genome.jp/kegg/) (Kanehisa and Goto, 2000).

GO terms for tomato transcripts were obtained using Blast2GO (v.2.3.5) (http://www.blast2go.org/) with default parameters (Kanehisa and Goto, 2000). Differential expression analysis was performed via Tophat (http://tophat.cbcb.umd.edu/) and Cufflinks (http://cufflinks.cbcb.umd.edu/) programs and RPKM (Reads per kilobase of exon model per million mapped fragments) values were detected within 95%

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1381713831

confidence limit. Differential expression was calculated according to the count values of each transcript in the library using edge R software (Robinson et al., 2010). False discovery rate (FDR) of < 0.05 and $\log^2$ fold-change ($\log^2$ FC) of ≥ 1 were used as the thresholds for judging significant differences in transcript expression. Transcripts with $\log^2$ FC of < 0.25 were assumed to have no change in expression levels.

Data verification via qRT-PCR

Quantitative real-time reverse transcriptase (qRT-PCR) consideration was performed to verify the expression patterns of randomly selected transcripts of RNA-Seq datasets. Aliquots of the originally purified RNA samples were reverse-transcribed using the PrimeScript RT Reagent kit with gDNA Eraser (Takara, Dalian, China) following the manufacturer's protocol. Eight gene-specific qRT-PCR primer pairs (18-20 bp) (*Table 1*) were designed using primer Premier 5.0 software (Premier Biosoft International, Palo Alto, CA). These genes are *sacB(LS)*, *scrA(PTS)*, *sacA(WIV-1), PME, xyl1, cre (Glucan synthase)* and *phd (Cellulase)* encode enzymes at the starch and sucrose metabolic pathway. RNA-Seq data indicated that these eight genes were regulated during fruit development. Of which, the first four genes were downregulated, while the other three genes were upregulated. qRT-PCR was performed using SybrGreenqRT-PCR master mix (Ruian Biotechnologies, Shanghai, China) in an ABI 7500 FAST Real-Time PCR system (Applied Biosystems, Foster City, CA, USA). PCR conditions were 2 min at 95 °C, followed by 40 cycles of heating at 95 °C for 10 s and annealing/extension at 60 °C for 40 s and 72 °C for 2 min. Three replicates were performed, and the amplicons were used for melting curve analysis to check the amplification specificity. The relative expression level of each gene was calculated as $2^{-(\Delta\Delta Ct)}$ and the housekeeping gene glyceraldehyde-3-phosphate dehydrogenase or GAPDH (accession no. U93208) from *S. lycopersicum* was used to normalize the amount of template cDNA added in each reaction.

Results

Transcriptomic analysis

RNA-Seq analysis of flowers and buds harvested from tomato cultivar Chico III was done at early fruit development stages ranging from 0, 3, 5, 7, 9 and 12 DAP. Over 24 Gb of data were generated from six datasets comprising 274,981,532 paired-end reads of 90 bp in length after trimming. The dataset of each sample had > 44 million reads, which represented a sufficient read density for the subsequent quantitative analysis of gene expression (*Table 2*).

The clean sequence reads were aligned to the tomato reference genome database allowing two base mismatches. Alignment and assembly resulted in 27,527 transcripts in the transcriptome. This number represents over 65% of the genes available in the tomato Unigene database (42,257), and 29.2-43.1% were differentially expressed with ≥ 2 fold at different time points compared to the control (0 DAP) (*Table 2*). The percentage of transcripts of different sizes with 150-200, 200-600, 600-1000, 1000-1600, 1600-2200, 2200-3000 and > 3000 bp were 8.14, 32.53, 20.28, 20.72, 9.44, 5.41 and 3.48%, respectively (*Fig. 1*). The latter four size categories more likely recover fragments long enough to likely detect function domains of the transcripts. The total number of transcripts expressed at different time points was 4335 in the control group (0 DAP), while 2588 at 3 DAP, 3529 at 5 DAP, 3549 at 7 DAP, 4054 at 9 DAP and 5,968 at 12 DAP.

The heat map indicated that the differential response at 0 DAP was distinct from the later stages (*Fig. 2*). Transcripts regulated at 3 and 5 DAP and 7 and 9 DAP clustered together, and transcripts regulated at 12 DAP were more distant compared to these four stages. A Venn diagram was constructed to compare the yield of transcripts shared between the following pairs of developmental stages, e.g., 0/3 DAP, 0/7 DAP and 0/12 DAP (*Fig. 3*). The number of shared transcripts were 8,054 (A + AB + AC + ABC), 8,750 (B + AB + BC + ABC) and 11,875 (C + AC + BC + ABC), respectively out of the total of 14,182 different transcripts. The highest number of shared transcripts was across the three stages (5307) followed by 0 and 7 DAP (1,871). The highest number of unique transcripts (3,276) in the developmental stage pairs was 0/12 DAP followed by 0/7 DAP (981). These unique transcripts across the three developmental stages indicate the occurrence of differential expression during the flowering stages.

Annotated transcripts with known function were classified into 52 functional groups, including 13 in cellular component (*Fig. 4*), 12 in molecular function (*Fig. 5*) and 19 in biological process (*Fig. 6*) categories comprising 1,364 regulated transcripts. In the cellular component category, 337 transcripts were regulated. Of which, 96, 75, 56 and 37 transcripts were regulated in the "cell", "organelle", "membrane" and "extracellular region", respectively (*Fig. 4*). In the molecular function category, 251 transcripts were regulated. Of which, 90, 88, 22 and 13 transcripts were regulated in the "catalytic activity", "binding", transporter activity" and "nucleic and binding transcription factor activity", respectively (*Fig. 5*). In the biological process category, 778 transcripts were regulated and most of these belong to "metabolic process" (118), followed by "cellular process" (105), "single organism process" (101), "response to stimulus" (68), "biological regulation" (58), cellular component organization or biogenesis (54) and "developmental process" (49) (*Fig. 6*). Results of the functional groups indicate that the highest activities were at the cell, organelle and membrane levels as well as at the extracellular region level. These activities induced catalysis, binding, transportation and those required for transcription factors binding in the nucleus and cytoplasm. Major processes include metabolism and responses to stimulation and development. The latter two processes are essential for the flower in early developmental stages.

Verification of RNA-Seq data

In order to verify the gene expression profiles of enzymes involved in starch and sucrose metabolism obtained from the RNA-Seq datasets, quantitative real-time PCR was utilized. Eight genes were selected for the analysis based on their regulation during starch and sucrose metabolic pathway. They are *scrA*, *sacB*, *phd*, *cre*, *sacA*, *pg2*, *pme* and *xyl1* (*Fig. 7*). These genes encode phosphotransferse (EC:2.7.1.69), levansucrase (EC:2.4.1.10), cellulase (EC:3.2.1.4), glucan synthase (EC:2.4.1.34), invertase (EC:3.2.1.26), exopolygalacturonase (EC:3.2.1.67), pectin methylesterase (EC:3.1.1.11) and beta-xylosidase (EC:3.2.1.37).

Figure 8 shows that eight genes were divided into three groups depending on its expression profile, first group were down regulated containing *PME2.1, PTS (scrA), Cellulose (phd) and sph1(cre or Glucan synthase)*, the second pattern was up-regulated *WIV-1(sacA) and the third* pattern was partially down regulated *LS (sacB).*

Discussion

The results are concomitant with those of Silva et al. (2014) who found that miR156-targeted *S. lycopersicum* SBP genes were dynamically expressed in developing flowers and ovaries as the cell is active in metabolism and likely to be sensitive to external stimuli. Hydrolase, transferase and oxidoreductase enzymes are predominant across the different stages of fruit development (*Fig. 9*). Recent reports indicate that one family of the hydrolases, e.g., xyloglucan endotransglycosylase/hydrolase (XTH), plays an important role in the remodeling of cell wall hemicelluloses during ripening (Han et al., 2015). One of the transferase families, e.g., quercetin-3-O-glucosyl transferases (3-GT), has a role in forming the flavonoid quercetin-3-rutinoside or rutin during tomato fruit ripening (Capanoglu et al., 2012). One important enzyme family of oxidoreductase, or quinone oxidoreductase, is ripening-induced and catalyzes the formation of 4-hydroxy-2,5-dimethyl-3(2H)-furanone (HDMF), the key flavor compound in strawberry (Klein et al., 2007). Family of this enzyme has previously been isolated from kiwi, raspberry and tomato as natural products (Schwab, 2013).

DOI: http://dx.doi.org/10.15666/aeer/1706_1381713831

Kyoto Encyclopedia of Genes and Genomes (KEGG) has recently moved the exopolygalacturonase enzyme to the "pentose and glucuronate interconversions" pathway, while the latter two enzymes were moved to "amino sugar and nucleotide sugar metabolism" pathway. The correlation coefficients (R2) ranged in value between 0.9900 and 1.0000, and PCR amplification efficiencies over 94% were obtained from the standard curves generated using a 10-fold serial dilution of cDNA.

KEGG annotation assigned 846 transcripts to 89 KEGG pathways. The pathway most strongly represented was "starch and sucrose metabolism" (seven activated enzymes). Tomato fruit is very powerful sink for carbohydrate especially in early stages of development. Sucrose is the major photoassimilate transported from photosynthetic leaves to developing fruit. Carbohydrates comprise the most abundant and widely distributed food components derived from plants. Their contents vary greatly in tomato fruit during development and ripening. Selection in this fruit was oriented towards sweetness as sugar, mainly sucrose, glucose and fructose, level (~60% of the total fruit dry weight) is the indicator of ketchup's quality (O'donoghue et al., 1994). Invertase enzyme cleaves sucrose, which may regulate the rate of carbon import to developing tomato fruit (Fei Wang, 1993). It was demonstrated that changes in sugar composition contribute to alterations in fruit size. Mach (Fridman et al., 2004) discussed the role of apoplastic invertase, which contributes to starch accumulation in pericarp and columella tissues, in determining the soluble solids content of mature fruit (Dinar and Stevens, 1981; Schaffer and Petreikov, 1997).

Invertase and sucrose synthase, along with the other regulated enzymes of the starch and sucrose metabolism in the present study seem to play a major role during early development of tomato fruits. It is well-known that sucrose, fructose and glucose are stored in the cell vacuole (Mach, 2014).

Figure 8 indicates the overproduction of several soluble sugars, e.g., sucrose, β-D-fructose, α-D-glucose, trehalose, maltose and D-xylose. This conclusion was reached as enzymes upstream these sugars were activated, enzymes downstream them were suppressed or both. Sucrose accumulated due to the suppression of levansucrase (encoded by *sacB*) and phosphotransferase (encoded by *scrA*), while β-D-fructose and α-D-glucose accumulated due to activation of invertase (encoded by *sacA*). High

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1381713831

activity of the enzyme also results in the synthesis of D-glucose and D-galactose in the "galactose metabolism" pathway (data provided upon request). Trehalose and maltose also accumulated due to suppression of phosphotransferase. In addition, the high activity of the enzyme pectin methyl esterase (PME) can result in approaching "Ascorbate metabolism". Two other enzymes, glucan synthase and cellulase (or endo-1,4 β-D-glucanase), were suppressed. This action results in the accumulation of UDP-glucose and cellulose, respectively (*Fig. 1*).

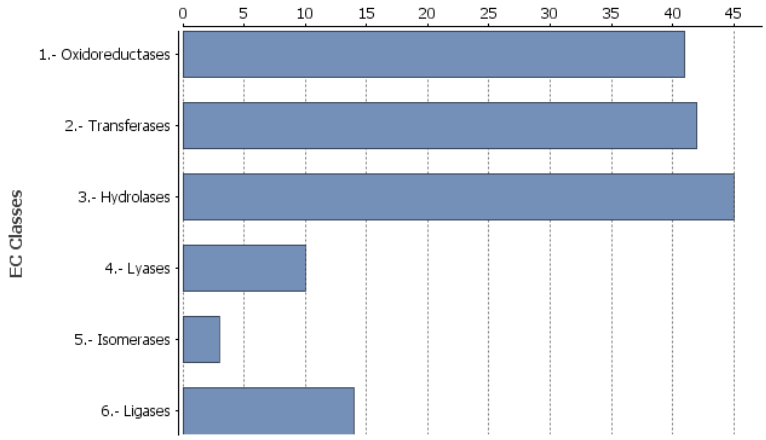

Figure 9. *Enzyme code distributions. All transcripts were aligned to the GO database to predict possible enzymatic functions. the total putative proteins were functionally classified into 6 groups*

Invertase is encoded by the *invertase 5* (or *lin5*) gene, accumulates in the cell wall and is known to act exclusively in flowers and young fruit (Fridman and Zamir, 2003). The enzyme is important in controlling total soluble solid content in these two organs. Overexpression of the enzyme resulted in increased partitioning of photosynthates to the fruit, hence, enhanced fruit yield (Baxter et al., 2005; Fridman et al., 2004; Schauer et al., 2006).

Zanor et al. (Zanor et al., 2009) reported that knockdown of the gene resulted in decreased levels of glucose and fructose in the fruit. The knockdowns were also characterized by the reduction in fruit size, seed number per plant and levels of phytohormones (LeClere et al., 2008).

Cellulase activity has previously been identified to contribute to cell wall disassembly and fruit softening (Brummell and Harpster, 2001). In avocado, cellulose was also found to contribute to the fruit ripening process (O'donoghue et al., 1994; Pesis et al., 1978). It is likely that this enzyme is suppressed at early stages of fruit development to allow complete maturity before the fruit commits to softening, while high cellulase activity in the abscission zone results in organ abscission in tomato (Brummell et al., 1999; Lashbrook et al., 1994, 1998; Sexton et al., 1980).

β-d-xylosidase was previously reported to have a role in the hydrolysis of arabinoxylans, xylans, and xyloglucans (Takizawa et al., 2014). The gene was shown to be involved in pear and tomato fruit development and ripening (Itai et al., 1999; Sozzi et al., 2002). The enzyme was also potentially involved in the softening process in strawberry (*Fragaria ananassa*) fruit (Bustamante et al., 2006). Frenkel et al. (1998) indicated that the production of methanol as well as ethanol in mature tomato fruit is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1381713831

positively regulated by activation of pectin methylesterase (PME). The explanation of these results is based on the fact that suppression of the ethanol ADH-catalyzed production is due to methanol accumulation during tomato fruit ripening (Brummell and Harpster, 2001). Earlier reports indicated that mRNA/protein stability and delayed protein synthesis influence the level of PME activity during the development of tomato fruit (Harriman et al., 1991).

Conclusion

The computational analysis of transcriptomes and heat map showed close relationships among transcripts regulated at 3 and 5 DAP and at 7 and 9 DAP. Transcripts regulated at 12 DAP were more distant compared to the latter four stages. Annotated transcripts and KEGG analysis showed that starch and sucrose pathway experienced the most dynamic change resulting in the synthesis of several soluble sugars and activation of some enzymes. In general, the results provide better insights on the mechanisms underlying early flower and fruit development in tomatoes, which will be valuable for genetic enhancement of tomato fruits in the future.

The authors recommended for further studies to complete all stages involved on fruit repining and development to get complete picture about tomato fruit development.

Abstract. It is particularly important to improve soybean yield and its management in the middle and late stage. Therefore, in view of the difficult problems of traditional field management machines, such as difficult operation, seedling pressing and so on. In this paper, the following two aspects of experimental research are carried out: the wind field distribution characteristics of single-rotor Unmanned Aerial Vehicle (UAV); the contrast test of the deposition distribution of different types of UAV. The spray test of single-rotor UAV in the middle and late stage of soybean was carried out to optimize the operation parameters of UAV. The experimental data is provided to improving the application of field management and UAV application technology in the middle and late stages of soybean production. The results show that the droplets of single rotor UAV can reach the lower part of soybean canopy, and the density of droplets can be more than 15/cm2. The data also provides technical support for experimental study.
Keywords: *plant protection, unmanned aerial vehicle, Huang-Huai-Hai area, wind field, droplet density*

Introduction

Agriculture is the foundation of China's economic construction and development, and the guarantee of the country's prosperity and strength. For a long time, soybean has been loved by people all over the world because of its high quality edible oil, excellent plant protein and many kinds of active substances which are beneficial to the human body (Yang, 2010; Chen et al., 2017[a]; Zhang et al., 2015). Soybean, as a feed crop, food crop, oil crop, cash crop and vegetable crop, has a large cultivation area and yield in the United States, Brazil and other countries. With a long planting history, China is one of the major producers of soybean (Zhang, 2007).

In recent years, the domestic demand for soybean has increased year by year, but the soybean output in our country is far from satisfying the domestic demand, which leads to a situation where we have to rely on a large number of imported foreign soybeans. This situation directly threatens the food security of China (Yang et al., 2008; Chen et al., 2017[b]).

Figure 1 shows the statistics of Chinese soybean imports from 2012 to 2017. According to the statistics of the General Administration of Customs from January to December 2017, the total amount of imported soybeans has reached 9.55×10^7 t, an increase of 1.16×10^7 t compared to 8.391×10^7 t in 2016.The data of the National Bureau of Statistics shows that the total output of legumes (soybeans and other miscellaneous beans) in China is about 1.9×10^7 t, which is the direct result of the 6.52×105 hm^2 increase in soybean planting area (Lou et al., 2017).

At present, the largest soybean production area in China includes three provinces in northeast China, followed by the summer soybean production area in Huang-Huai-Hai region, where the annual soybean production accounts for about 30% of the total

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1383313844

soybean production in China. Compared with the large-scale self-propelled spraying machinery and the operation mode of agricultural plant protection aircraft in the three provinces of northeast China, soybean plant protection in Huang-Huai-Hai area is mainly carried out by manual sprayer and backpack motor sprayer. This limits the operation of large-scale plant protection machinery because of the characteristics of land management mode and small plot in Huang-Huai-Hai area. At the same time, the development of pesticide application technology in our country, especially the development of pesticide application machinery, is lagging behind in the worsening of diseases and insect pests (Liu et al., 2015; Chen et al.,2017[c]; Qin et al., 2014). There are still many problems in the prevention and control of disease and pests, and the demand for soybean in China has been high all the time, but the soybean output cannot meet the change of this situation, which results in the need to import a large number of foreign soybeans, posing a direct threat to food security in our country. 86% soybean demand depends on imports and the imports in 2017 set a high record again, which is a further increase trend.

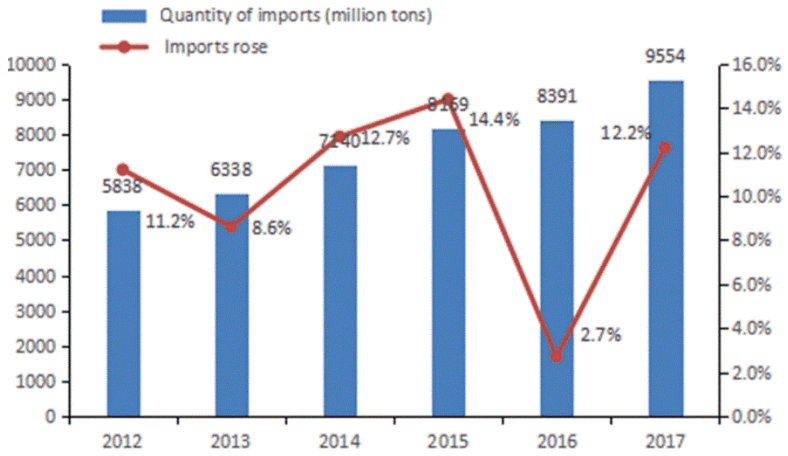

Figure 1. *Soybean import quantity statistics*

The development of UAV for plant protection in recent years has offered a new idea for soybean field plant protection (Jin et al., 2016). Single-rotor UAV has been widely used in agricultural plant protection because of its single wind field, uniform spraying, strong penetration, etc. (Gong and Fu, 2008; Guo et al., 2014; Xu et al., 2017). In order to solve the problems existing in soybean field management at the present stage, single rotor plant protection UAV was used in the field experiment in the middle and late stage of soybean, in order to solve the difficulty of traditional field management machine, which enter the soybean field in the middle and late stage of soybean, whose ridge was sealed. It solves pressing seedlings and other difficult problems, too. The field operation parameters of UAV were optimized, and the experimental data and technical support were provided for the application of field management and UAV application technology in the middle and late stages of soybean production. So wind field tests for a single-rotor UAV were carried out in this paper.

The influence of operation speed, flight height and the addition of flight control auxiliary equipment on droplets deposition was analyzed, and the optimal operation parameters in different periods were obtained. Providing field operation and the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1383313844

optimization of key operation parameters for the applicability of plant protection unmanned aerial vehicle in soybean, are to solve the problem of landing for traditional spraying way during the middle and late stage.

Wind field tests for single-rotor UAV

Material

The test model is the electric single-rotor UAV (Mercury one), which is powered by a high-performance polymer lithium battery and is equipped with a remote control and a matching spray system, as is shown in *Figure 2*.The spray rod is adjustable which is installed with two fan-shaped spray nozzles with spray width of generally 7 m, different types of sprayers can be changed according to the use of different pesticides. Meanwhile, in order to measure wind speed, wind direction and temperature and humidity, we need to prepare multichannel anemometer, computer, temperature and humidity tester (CEM DT-615), portable anemometer (LB-SD2) and timer.

Figure 2. *Anelectric single-rotor UAV (Mercury one)*

Test method

The experiment was carried out in an experiment plot of Henan Agricultural University. During the test, the wind direction and wind speed were measured with a multichannel anemometer and a handheld anemometer (LB-SD2) at the test site. A temperature and humidity tester (CEM DT-615) is used to record the temperature of the test site and the time required for the test is recorded by a timer. The schematic diagram of the working principle is shown in *Figure 3*.

The wind field test of single-rotor plant UAV needs to determine the boundary of wind field. The multichannel anemometer and the handheld anemometer were used to find the boundary of the wind field (wind speed less than 0.2 m/s), and the boundary of the wind field was recorded.

Before the wind field test was carried out, it was necessary to determine the measurement point of the test, which started from the vertical bottom of the rotor of the UAV (as shown in the *Fig. 3*). Below the rotor of the plant protection UAV was the "O" point of the center. The wind field was measured all the way to the boundary, which was measured with a tape ruler every 0.5 meters. And eight directions were measured in one torus. In the direction of height Z, the height of soybean at branching stage and pod-setting stage were recorded at 0.5 m, 1 m, 1.5 m and 2 m respectively. The median

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1383313844

volume diameter (D_{50}) of agriculture flat-fan nozzle were used (Zhao et al., 2009).The spraying dose was 450 L/ha. The speed of the UAV was 5 m/s. The experiments had been replicated for three times.

Through the wind field test, the best flying altitude range of the single-rotor UAV was obtained. Within the same scope, the single-rotor plant UAV can achieve better spray drop deposition distribution compared to the multi-rotor UAVs.

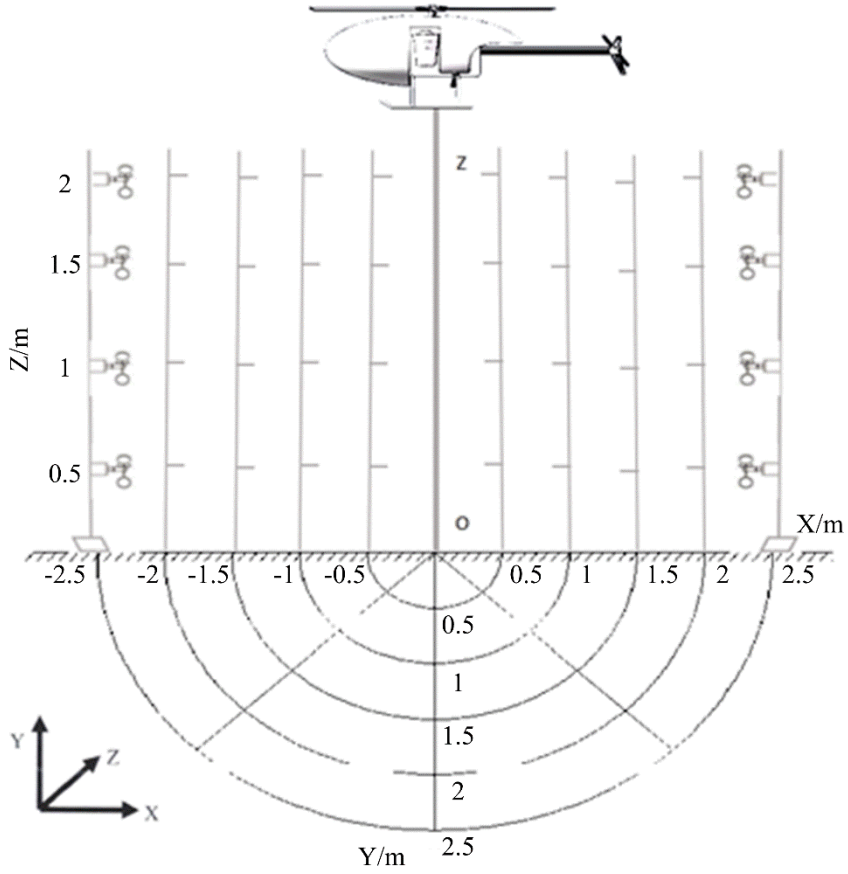

Figure 3. *Wind farm test layout*

Results and discussion

In the wind field test, the temperature is 17.5 °C, the wind speed is 0.2 ~ 1.5 m/s and the wind direction are southwest. During the experiment, the head of the drone was placed westward, and the fixed height of the drone was adjusted to 2.88 m. The measured data of each measurement point in the test are shown in *Table 1*.

As shown in *Figure 4*, the wind speed distribution of 0.5 m, 1 m, 1.5 m and 2 m from the plant canopy below the rotor shows that the distribution of wind field at different altitudes is basically similar. With the decrease of distance from the plant canopy, the wind speed is smaller. The decrease of the velocity below the center of the rotor is the fastest. From the wind field test data of *Table 1* and *Figure 4* and the simulation diagram of actual wind field test, it can be seen that the wind speed increases gradually with the increase of the center distance of the rotor axis in the range of rotor span of the single-rotor UAV. Outside the wingspan of the rotor, the wind speed decreases

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1383313844

gradually. In the rotor height direction, the wind speed increases first and then declines with the rise of the distance from the rotor. The trend is that the maximum wind speed is in the range of 1.5 m below the rotor, and the wind speed reaches about 12 m/s.

It can be seen from *Figure 5* that the wind speed gradually decreases with the decrease of the rotor height within the span of the rotor, and the wind speed is affected by the plant canopy effect about 0.5 m away from the plant canopy, and the wind speed decreases gradually from the center of the rotor to the outside. Outside the wingspan, the wind velocity in the direction of height is not obviously weakened.

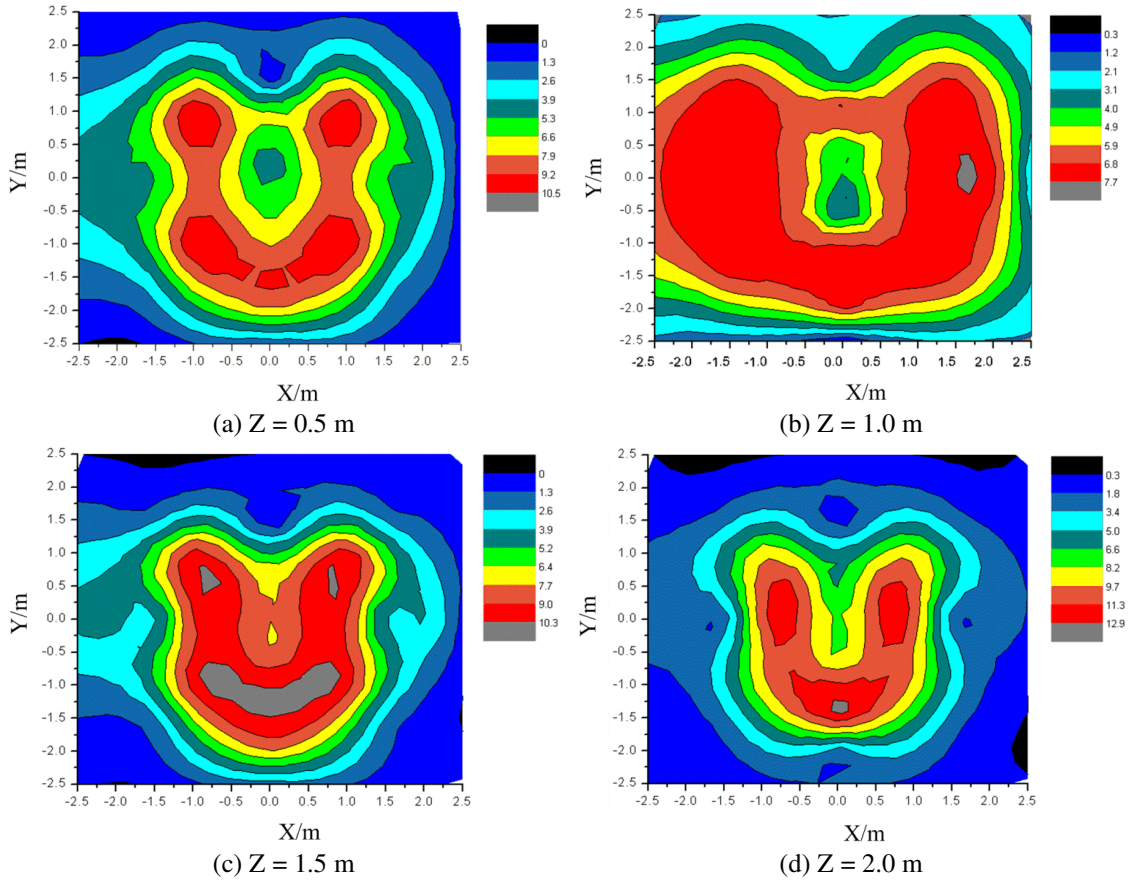
DOI: http://dx.doi.org/10.15666/aeer/1706_1383313844



(a) Z = 0.5 m (b) Z = 1.0 m

(c) Z = 1.5 m (d) Z = 2.0 m

Figure 4. *Different heights wind farm test plan. (Note: Z is the height from the plant canopy)*

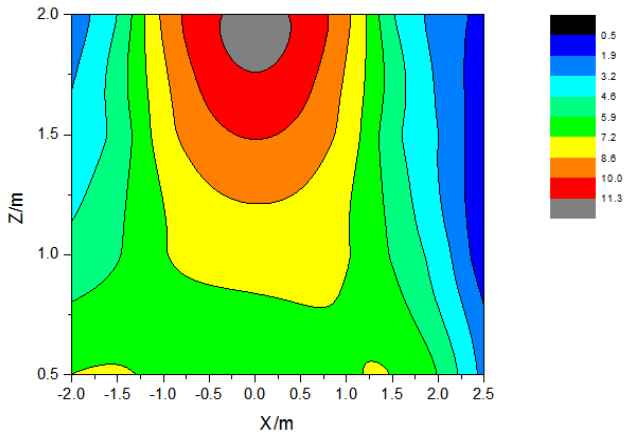


Figure 5. *Wind farm distribution map in the vertical direction of the rotor*

Taking the plant canopy as the reference and the rotor axis of the single-rotor UAV as the center, the vertical wind field were measured vertically up the plant canopy, and the vertical wind field data were obtained. The following conclusions are drawn from the analysis:

1. At the same height from the plant canopy, the wind velocity value is positively correlated with the axis distance within the wingspan range, and the wind

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1383313844

speed increases gradually with the increase of the distance, and decreases gradually beyond the wingspan range until the boundary of the wind field.
2. In the direction of altitude, the value of wind velocity is positively correlated with the height off the plant canopy.
3. The maximum wind speed is 1-2.5 m above the plant canopy, and the maximum wind speed is 12.9 m/s. Therefore, in the field operation, the flying altitude of the single-rotor UAV is best within this range, which is favorable for the airflow and droplets to reach the bottom of the canopy.
4. Under the influence of plant canopy effect, turbulence will appear in the wind field below 1 m, and there is no definite rule.

Spray deposition contrast test

In order to test the difference between single-rotor plant UAV and multi-rotor plant protection drone, different models were selected to carry out. The spray tests of S40 single rotor, M23 electric four rotors and M8A electric eight rotor plant protection UAV were carried out in soybean field, and the spray drop deposition distribution of different types of UAV was compared and analyzed.

Materials and methods

Experimental laboratory materials and equipment

In order to compare the effects of droplet deposition with Mercury 1 electric single-rotor UAV, three different UAV were prepared for soybean field experiments, as shown in *Figure 6*. The parameters of the three UAV are shown in *Table 2*.

Reagent preparation

The analytical instrument is micro-spectrophotometer with a maximum absorption wavelength of 508 nm. First, prepare labeling group, use500 ml volumetric flask to prepare 1 g/L liquid containing carmine, extract 50 ul, 150 ul, 250 ul, 350 ul, 450 ul, 550 ul, 650 ul, 750 ul, 850 ul, 950 ul solution with pipette to be placed in 10 ml volumetric flask, balance, measure the absorbance, repeat each test three times to obtain average standard curve. In order to indicate deposition quantity with ratio of carmine, curve model of absorbance versus carmine solution concentration was established. Determination coefficient was calculated by linear regression curve fitting as $R^2 = 0.997$. As measurement of deposition quantity needs test of dilution concentration, relationship between carmine solution concentration and absorbance was obtained via variable conversion:

$$C = 0.0363A - 0.0016 \quad \text{(Eq.1)}$$

where C is mass concentration (g/L) of the carmine solution and A is absorbance of the carmine solution.

Test method

The experiment was carried out in Liangshan county demonstration base of "Research on high-yield and high-efficiency mechanization production technology and supporting equipment of soybean". The experiment was carried out in the middle and late stages of soybean growth. The row spacing and plant height of soybean in the experimental field were 40 cm and 90 cm respectively. The spray liquid used in this experiment is 4 g/L rouge aqueous solution, and the droplet collection card is used to collect the droplet. In the field experiment of soybean, three groups of spray tests were compared in the range of spraying in the same plant protection unmanned aerial vehicle (UAV) operation, and 8 points were continuously arranged at 1.2 m interval in the transverse direction, and 8 points were arranged continuously in the same plant protection unmanned aerial vehicle (UAV) operation. Longitudinally: corresponding transverse, control test every 5 meters, continuous arrangement of 3 each collecting point, the upper, middle and lower layers are arranged to collect droplets acquisition card (*Fig. 7*). Every time the plant protection drone flies along the set axis, in order to stabilize the test operation, the aircraft hovers and takes off at 10 m in the acquisition point, and stops operation after 10 min away from the acquisition point. The temperature and humidity meter and wind speed and wind direction meter were used to measure and record the environmental parameters during the plant protection unmanned aerial vehicle operation.

Analysis of droplet distribution uniformity

As shown in *Figure 8*, the three UAV were all carried out under the best operating parameters. It can be seen from *Figure 8*, the deposition distribution of droplets in each collecting point is different under different operating parameters. The deposition amount and uniformity of each collecting point are relatively good on the whole, and the droplets of each collecting point are relatively good. The coefficient of variation is 37.37%, the coefficient of variation is 69.34%, and the coefficient of variation is 110.88%. The coefficient of variation reflects the droplet deposition uniformity of the UAV, and the results show that the droplet distribution uniformity of the single rotor UAV is better than that of the multi-rotor UAV as a whole.

It also can be concluded that the drift on the right side is larger than that on the left side, and the drift is smaller when the operating speed is 5 m/s. It can be seen from that there is little difference in droplets deposition data collected from at different operating parameters. Under different operating parameters, it can be concluded that the single-rotor UAV has a single and stable downwind field and less ground loss and drift.

The wind field of S40 single-rotor plant UAV is relatively stable. It has a strong penetrating and a better droplet deposition and uniformity. The six nozzles of M8A eight-rotor UAV are arranged under the fuselage, and there is disturbance between the wind field, so the distribution of turbulence is not uniform. The M23 four-rotor drone with one nozzle under each rotor, has enough atomization and less deposition.

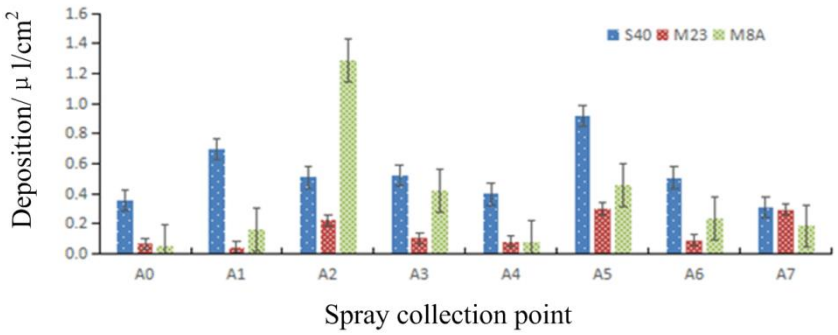

Figure 8. *Plant protection UAV deposition layout*

Comparative analysis of penetration of fog droplets

As can be seen from *Figure 8*, the density of droplets in each sampling point of soybean canopy can reach 15/cm^2. As shown in *Figure 9*, the distribution of droplets in the upper, middle and lower canopy of three UAV can be visualized to show the penetration of droplets in different UAVs.

Figure 9 shows when the S40, M23, and M8A UAVs are operated, droplets can reach the lower layer of the soybean blade. The density of droplets deposited in the lower layers decreased gradually. The density of droplets in the middle layer of soybean decreased by 14.75% compared with that in the upper layer, and that in the lower layer decreased by 71.85% compared with that in the middle layer. During the spraying operation with M23 electric four-rotor UAV, the droplet density of the middle blade is higher than that of the upper layer and the lower layer, and the deposition density of the middle layer is higher than that of the lower layer. The density of droplets in the lower

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1383313844

layer was 60.77% less than that in the middle layer. During the spraying operation with the M8A electric eight-rotor UAV, the droplet deposition density of the middle layer blade was 10.27% higher than that of the upper layer blade, and the lower layer was 66.67% lower than that of the middle layer.

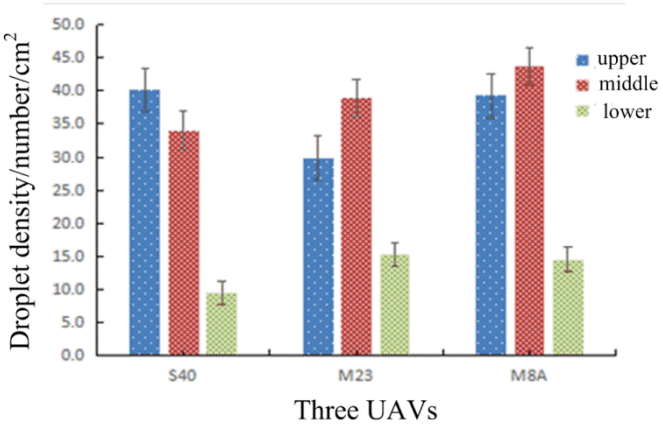

Figure 9. *Droplet distribution in soybean canopy*

Conclusions

The main parameters of S40 electric single rotor, M23 electric four rotor and M8A electric eight rotor UAV are briefly introduced. The spray experiments in the soybean pod period are carried out with these models.

Under different operating parameters, height and velocity have significant influence on the deposition and distribution of droplets. As the wind field of the single-rotor plant protection unmanned aerial vehicle is single, droplets can reach the bottom of the soybean canopy under different working parameters. At different speeds and heights, the deposition amount and distribution uniformity of droplets are different. The deposition density of upper, middle and lower canopy droplets of soybean has certain regularity. The results of droplet deposition show that the droplets of single rotor and multi-rotor UAV can reach the lower part of soybean canopy, and the density of droplets can be more than 15/cm^2. The single rotor UAV has a single wind field, uniform distribution and strong penetration.

Abstract. Understanding the sea-level change in the geological past is helpful for the future coastal protection. Information of sea-level changes has been documented in various archives in the coasts. In this study, the well-preserved peat in three representative Holocene ditches in Dayanghe Plain in the Yellow Sea China were investigated using radiocarbon dating and diatom analysis. The widely distributed buried peats at elevation of ca. 2-10 m above sea-level (a.s.l.) in Dayanghe Plain are classified as marsh and limnological peats, which were formed after seawater receding from the drowned ditches. The peat layers lower than 4 m a.s.l., overlain the marine sediments conformably, correspond to the late-Holocene regression. Timing of the highstand sea-level in North Coast of North Yellow Sea is limited to 6182-5466 cal. a BP by radiocarbon dating. Shell banks at west of the Dagu Mountain which was at a 7-10 m height were thought not to be indicative of the Holocene highstand sea-level.
Keywords: *diatom assemblages, sea-level rise, radiocarbon dating, peatland, Yellow Sea*

Introduction

The Yellow Sea is one of margin seas in East China, located at the low-gradient shelf between the Chinese mainland and the Korean Peninsula. Thick sediments have been deposited in the Yellow Sea since the Late Pleistocene (Zheng, 1991), containing rich palaeo-environmental information under the sea-level changes in the geological past (Chappell et al., 1996; Kim and Kennett, 1998; Yokoyama et al., 2001; Chappell, 2002; IPCC, 2007; Liu et al., 2004). A multitude of investigations and research on relative sea-level change and environmental evolution in east China have been carried out during the last half century (e.g. Zhao, 1996). Multiple transgressions since late Pleistocene were defined widely in the Bohai Sea, Yellow Sea and East China Sea. Corresponding to the global sea-level change (Shi et al., 2016), three transgression-regression cycles are identified in the coast stratigraphy (Zhao, 1986; Wang et al., 1986; IOCAS, 1985). The transgression-regression sequences have been studied in the chronology (e.g. Liu et al., 2016; Li et al., 2019; Yi et al., 2013), sedimentary processes (e.g. Yi et al., 2012; Liu et al., 2016; Wang et al., 2015), sea-level change (Yi et al., 2012; Liu et al., 2004; Xue, 2014) and driven factors, e.g. palaeo-climate and environment during the geological past (e.g. IOCAS, 1985; Yi et al., 2012).

The uppermost transgressive succession overlying the widely distributed peat or organic-rich sandy interlayer over the coastal areas in the east marginal seas results from the Holocene sea-level rise. The pattern of the Holocene sea-level has been well studied using benthic foraminiferal and stable isotopic approaches with well-established

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1384513857

radiocarbon chronology (Kim and Kennett, 1998; Liu et al., 2004). Several approaches have been employed for a well understanding of environmental evolution and sea-level change during the Holocene in North Yellow Sea. Peats and shell bars in the Liaodong coastal stratigraphy are likely to deposit during the Holocene sea-level highstand and then dated using radiocarbon (GIGCAS, 1977; Wang et al., 1991; Gao, 1986, 1992). Environmental evolution was interpreted by pollen (GIGCAS, 1977; Liu, 1992), foraminiferal (Yang, 1985) and archeological record (Shi, 2006). Static tectonic movement or slow subsidence in coast of the North Yellow Sea was proposed in former research, e.g. Xiao (1981), Ding (1958) and Zhao (2000), while some researchers assumed a relatively slow uplifting occurring identified by abrasion terrace which is 250 a.s.l. in Dalian, coastal bars and terraces in Liaodong Peninsula (Liu, 1986; Xia et al, 1986). Although the timing of the Holocene transgression in the North Yellow Sea is well restricted, the transgressive process and height of sea-level highstand are still not precisely confirmed mainly due to lack of stratigraphic correlation and reliable sea-level indicators on the background of tectonic uplifting in the North Coast of the Yellow Sea (Fu et al., 1989, 1995; Wei et al., 1984; Zhong and Chang, 1988; Lu, 1985).

Widely distributed marsh peat in the coastal plain is treated as the marker for sea-level highstand (Shennan and Horton, 2002; Engelhart and Horton, 2012). However, the peat formation could be misunderstood due to lack of identification of the contacting layer. As sensitive to salinity, pH and temperature, diatom is a well indicator to the water-lain sedimentary environments, such as the coast and lacustrine (Kosugi, 1988; Horton, 1997; Horton et al, 2006, 2007). In this paper, we investigated the well-preserved peat in the three representative ditches in the Dayanghe Plain, the North Coast of the North Yellow Sea. Diatom analysis was applied to identify the types of peat in the different depths. The timing of the marsh peat, indicating the Holocene sea-level highstand, was determined using radiocarbon dating.

Materials and methods

Study area

The Yellow Sea is a margin sea of China with average water depth of 60-80 m. It is covered by seawater due to the subsidence of the Zhe-Min Uplift in the early Quaternary (Jin and Yu, 1978; Qin et al., 1989; Yi et al., 2014), Yellow sea is geographically divided into two parts, the North Yellow sea and the South Yellow sea, by Dabie-Linjin fault zone (Qin et al., 1989). The North Yellow Sea is a semi-enclosed sea surrounded by Shandong peninsula, Liaodong peninsula and Korea peninsula. It is a fault basin during Cenozoic on the base of Jiaoliao palaeo-Uplift. Since the Late Tertiary, regional subsidence and stable sedimentation have occurred in the whole Yellow sea, remarked by process of depression sedimentation (IOCAS, 1985; Qin et al., 1989). Current system in the North Yellow sea contains the Yellow Sea Warm Current (YSWC), which is known as a branch of Tsushima Current, and the coastal currents along Chinese and Korean coasts (*Fig. 1a*). The tide in the North Coast of the Yellow sea is irregularly semidiurnal in range of 4.08 m (Qin et al., 1989). Due to the strong tide and the flat terrain, 6-10 km wide tidal flat develops in the coastal area. The sedimentary process is dominated mainly by fluvial and tide currents from alluvial plain, estuary to tidal flat.

The study area is the Dayanghe alluvial plain located in southern Liaodong Peninsula. The plain is divided into several small drowned ditches. Sediments in the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1384513857

Dayanghe alluvial plain were mainly transported by two local rivers, the Dayanghe River and the Xiaoyanghe River, both originating in the region of Xiuyan in the North Liaoning Province. The Dayanghe River, with length of 201 km, flows from the northeast direction into study area. While the Xiaoyanghe River, 57.40 km long, flows from the northwest direction into study area. These two rivers meet in the north of alluvial plain, and turn to the direction of south, pouring into the Yellow Sea. The average slopes of Dayanghe alluvial plain are 0.6 and 0.2‰, respectively (*Fig. 1b*).

The Holocene stratigraphy in southern Liaodong Peninsula was studied in sedimentology, pollen analysis and radiocarbon dating. Southern Liaodong Peninsula was influenced by transgression in early and mid-Holocene, as a result of the regional sea-level rise to the highstand sea-level, then declining with fluctuation to a stable sea-level as present (GIGCAS, 1977). Timing of high-stand sea level between 8000 and 6000 a BP is mainly determined by dating the widely distributed peat layer and shell bar (GIGCAS, 1977; Wang et al., 1991; Gao, 1986, 1992; Fu et al., 1995). Archeological records in southern Liaodong Peninsula provide the evidence of the Holocene transgression using the shells excavated in archeological sites (Shi, 2006).

The Bohai Sea, Yellow Sea and East China Sea are the three marginal seas of China. Current system in Yellow Sea is shown in *Figure 1a* (1. Yellow Sea Warm Current (YSWC), 2. Yellow Sea Coastal Current (YSCC), 3. Taiwan Warm Current (TWC), 4. North Yellow Sea Coastal Current (NYSCC), 5. Zhe-Min Coastal Current (ZMCC), 6. Tsushima Strait Warm Current (TSWC)). Sites of the studied boreholes in the North Coast of the Yellow Sea are shown in *Figure 1b* (Source of the Digital Elevation Model: http://srtm.csi.cgiar.org/).

Studied boreholes

To investigate the stratigraphic characteristics in the Early and Middle Holocene in the Dayanghe alluvial plain, three boreholes (referred to as LD-1, LD-2 and LD-3, *Fig. 1b*) from Dayanghe plain were drilled with the manual sampling device in the three representative ditches. Elevation of each borehole was measured by using level points on topographical map in scale 1:10 000 (1956 Yellow Sea elevation system) and leveling instrument.

The length of core LD-1 (39°55’32”N, 123°13’35”E, elevation 4.9 m a.s.l.; *Fig. 2*) was 550 cm. The top 113 cm of the core consists of silt, with the upper part in yellow-brown and the lower part in grey-brown. A 37 cm-thick layer contains brown-black peat, which can be recognized widely in this area. The depth of brown-grey clayey silt is from 150-165 cm, while the lower blue-grey layer, containing vegetation debris, is from 165 cm to 505 cm. The lowest part contains brown silt with breccias (505-550 cm).

Core LD-2 (39°55’42”N, 123°39’48”E, elevation 6.5m a.s.l.; *Fig. 1*), 560 cm long, can be described as follows: 0-205 cm, silt with the upper part (0-150 cm) in yellow-brown and the lower part (150-205 cm) in grey-brown; 205-238 cm, brown-grey clay with two thin organic-rich layers; 238-266 cm, brown-black peat layer; 266-505 cm, blue-grey organic-rich silt layer; 505-560 cm, blue-grey medium sand with gravels.

Core LD-3 (40°01’21”N, 123°38’35”E, elevation 4.8 m a.s.l.; *Fig. 1*), with the length of 400 cm, is described as follows: 0-35 cm, brown-grey silt; 35-86 cm, dark grey clay; 86-123 cm, coarse sand in light grey with gravels; 123-150 cm, peat layer; 150-170 cm, brown-black clay with organic-rich materials; 170-352 cm, silty clay in light blue; 352-400 cm, coarse sand in dark grey with gravels.

DOI: http://dx.doi.org/10.15666/aeer/1706_1384513857

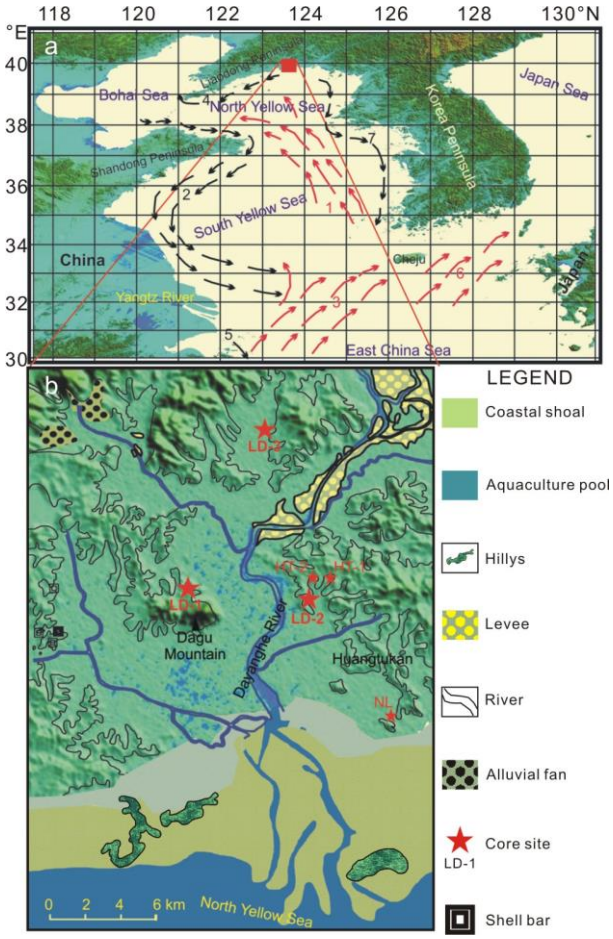

Figure 1. *Location of study area.* ***a*** *shows the marginal seas in the East China and the location of the Dayanghe alluvial plain.* ***b*** *shows the geomorphological characteristics of the Dayanghe alluvial plain and the drilling sites.*

Several additional boreholes were drilled to investigate the stratigraphy in both three ditches. Peat or black organic-rich clay layers distribute widely in these three ditches, with brownish clay/silt layer overlying and blue clay layer underlying. Peat or black organic-rich layer between 2 m and 4 m a.s.l. can be recognized as a mark layer, while peat in 9 m in ditch LD-1, in 7 m and 10 m in ditch LD-2 were distinguished from the mark peat layer not only the appearance of height, but also the contacting layers as the peat layer develops between gravely coarse sand, gravely coarse sand and brownish clay/silt layer in ditch LD-1 and LD-2, respectively.

To compare with the previous research, two boreholes were drilled in region of the Huangtukan (labeled as HT-1 and HT-2, *Fig. 1b*), which were sampled for investigation of peat layer and diatom analysis and comparison. The elevations of HT-1 and HT-2 are 11.0 m and 10.8 m, respectively. Peat layer appears in 8.80 m a.s.l. in core HT-1, with underlying grey peat-clay layer, while in 8.35 m a.s.l. in core HT-2, with underlying blue-grey medium and coarse sand. Borehole NL was drilled in the modern coast area, at east of the Dayanghe River estuary, for diatom analysis and radiocarbon dating (*Fig. 1b*). Top elevation of this borehole is 4.7 m a.s.l., described as: -0.55 - -1 m a.s.l., yellowish medium sand; 1.7 - -0.55 m a.s.l., light-grey fine sandy silt and clay interlayers with shell; 4.7-1.7 m a.s.l., brown-grey silt/light-grey silt.

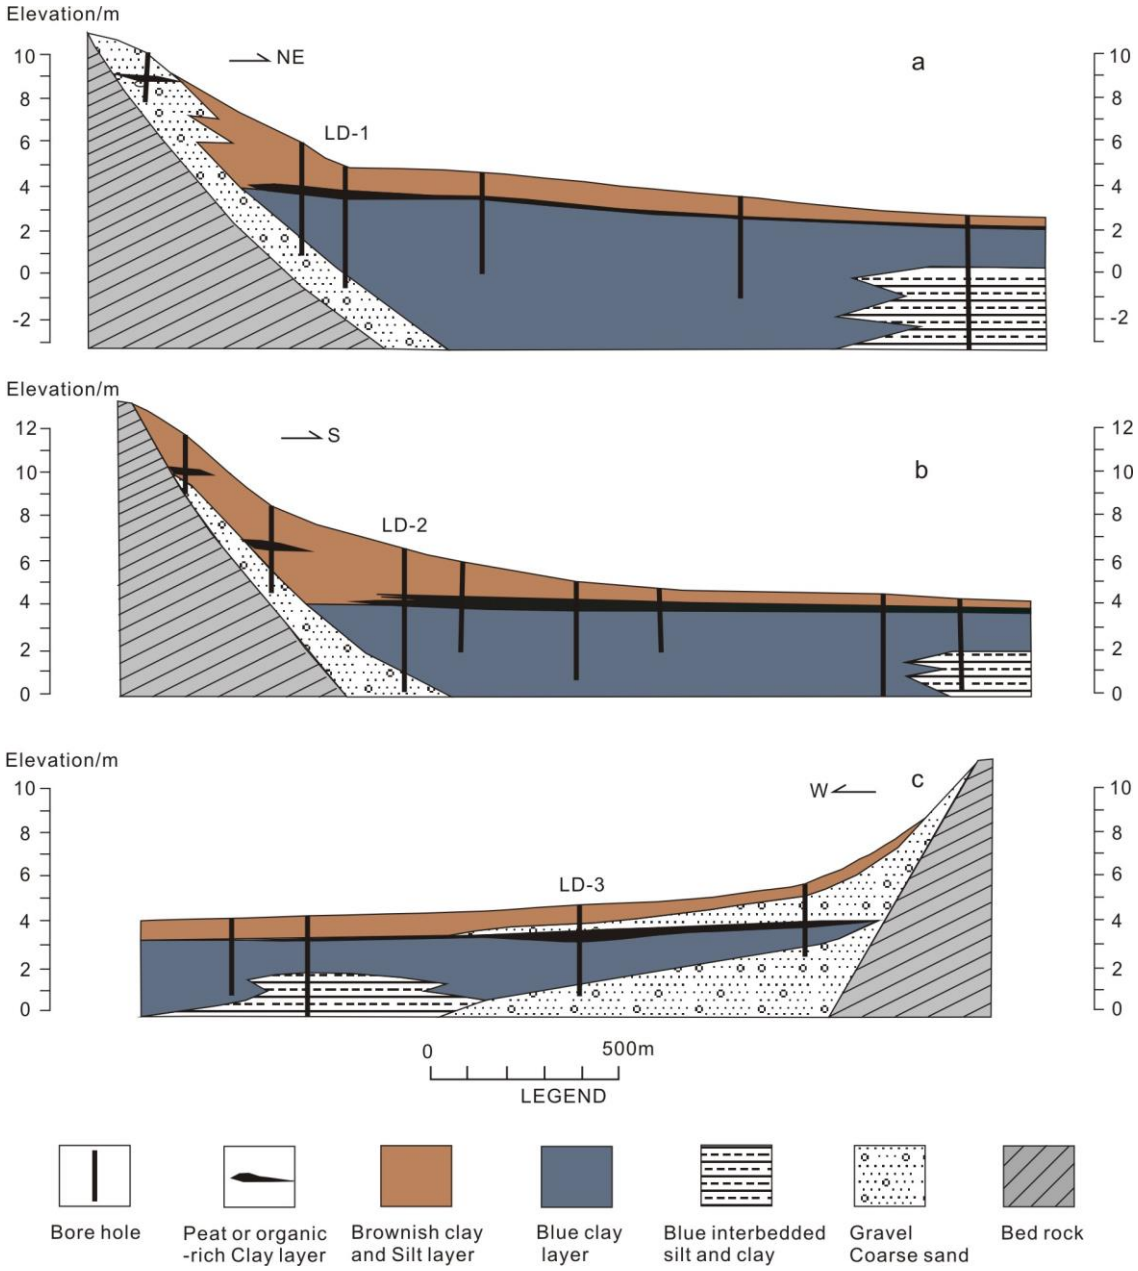

Figure 2. *Stratigraphic distribution in three ditches*

Radiocarbon dates

Three samples from the bottom of peat layers were extracted for radiocarbon dating. All radiocarbon dating experiments were conducted at Center for Chronological Research, Nagoya University, using the Accelerator Mass Spectrometry (AMS) method. Radiocarbon dates were calibrated using Calib 5.0.1 (Stuiver et al., 2005). All ages (*Table 1*) are reported as calibrated calendar ^{14}C ages before AD 1950 (cal BP).

Diatom analysis

4-6 g sediments were collected at -20 cm intervals for diatom analysis. Samples were pre-treated with 30% H_2O_2 to remove organic matter, rinsed with deionized water for

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1384513857

several times. The coarse sand and gravel fraction were removed by sedimentation method. After abundant precipitation, 1 mL of liquid was removed to cover slip by transfer pipet, then dried and agglutinated with ground slide by resin. 4-6 slices were made for one sample. Diatom assemblages were identified at 400× magnification on microscope (smaller individuals at 1000× magnification). At least 200 diatom valves were counted and identified from each slice. Diatom identification and nomenclature were based on KASHINA (1986), KOSUGI (1988) and ANDO and FUJIMOTO (1990). Based on the living environment, three kinds of diatom were classified, as 1) marine-brackish species (M-B), living in marine and inner bay environment under seawater; 2) brackish-fresh species (B-F), living in environment influenced by mixture of fresh water and brackish water, but not existing in marine environment; 3) fresh species (F), living in the fresh water environments, such as wetland, marsh and river, etc.

Results and discussion

Diatom analysis for core LD-1

Core LD-1 was divided into four diatom assemblage zones (*Fig. 3a*).

Zone I (505-330 cm)

Marine-brackish species, including marine species *Thalassionema nitzschioides*, indicate the open marine environment. *Cyclotella stylorum, Paralia sulcata, Actinocyclus* spp.*, Cosinodiscus* spp. are indicative of the inner bay environment. Brackish species *Diploneis smithii* are found in the lower part of blue-grey layer in Zone I. The component of species above reaching 75-95% is related to a process of transgression that this area was covered by seawater.

Zone II (505-330 cm)

In Zone II, the marine-brackish species decrease from 94 to 61%, while an increase of brackish-fresh and fresh species from 6 to 40% indicate a process of regression with a w seawater influence and a stronger influence by freshwater.

Zone III (163-150 cm)

Various species appear in Zone III. 20% are marine-brackish, while the fresh and brackish-fresh species reach 80%, including *Pinnularia* spp. (29%), which inhabited in marsh environment, and the fresh-brackish species *Rhopalodia gibberula*, 14% of total species. The dominating assemblages with mixture of fresh and brackish-fresh taxa are commonly observed in the wetland environment influenced by seawater.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1384513857

Zone IV (150-133 cm)

In Zone IV, constrained to the peat layer, nearly all taxa were fresh species, with wetland species *Pinnularia* spp. (34-47%), *Eunotia* spp. (3-8%) and *Cymbella* spp. (5-11%), and fresh benthonic species *Hantzschia amphioxys* (6-11%). The diatom assemblages in the peat layer showed a wetland environment influenced rarely by seawater.

DOI: http://dx.doi.org/10.15666/aeer/1706_1384513857

Diatom analysis for core LD-2

Core LD-1 was divided into five diatom assemblage zones (*Fig. 3b*).

Zone I (430-350 cm)

The main taxa are marine-brackish species (57-66%), accompanied by fresh species (22-32%) and fresh-brackish species (5-12%). Among the taxa, Percentage of the marine indicator taxa, *Thalassionema nitzschioides*, was 12-14%, while marine-brackish species such as *Diploneis smithii* were reaching 12-18%, indicating a drowned ditch environment.

Zone II (350-290 cm)

With the same lithological characteristics as Zone I, Zone II contained nearly the same diatom assemblages, with a notably declining trend of marine-brackish species from 66% to 34% and increase of fresh and fresh-brackish species. The indicators of the marsh and wetland such as *Pinnularia* spp. and *Eunotia* spp. with a percentage of 15-20%, show there was a declining trend of sea-level, accompanied by environment changing from drowned ditches to salty marsh.

Zone III (290-266 cm)

In Zone III, constrained to upper part of blue-grey peaty clay layer, the marine-brackish species declined to 21%, with an increase of fresh species to 69%. The marsh and wetland indicators such as *Pinnularia* spp. and *Eunotia* spp. were with a percentage of 29%. The limnological environment indicator *Melosira ambigua*, known as a plankton species, appeared within this interval with a percentage of 16%, indicating a salty marsh environment covered by water.

Zone IV (266-230 cm)

Zone IV is the peat layer, containing only 4% marine species and nearly 95% were fresh species. The marsh and wetland indicators such as *Pinnularia* spp. and *Eunotia* spp. declined to 6%, accompanied by limnological environment taxa such as plankton *Melosira ambigua* and *Stephanodiscus astrae* with a drastic increase to 87%. It suggests that the environment changed from a marsh wetland to limnological environment.

Zone V (230-205 cm)

The brown-black peat and brown-grey silt occur in Zone V. *Pinnularia* spp. and *Eunotia* spp. increased rapidly, with the percentage of 18% and 28%, respectively. *Melosira ambigua* and *Stephanodiscus astrae* decline to 19% and 5%, respectively. We infer that the environment changed from fresh lake to marsh and wetland covered by shallow water.

Diatom analysis for core LD-3

Three diatom assemblage zones were found in core LD-3 (*Fig. 3c)*.

Zone I (290-170 cm)

In Zone I, marine-brackish species dominated with a percentage of 68-98%. There was an increase trend of *Diploneis smithii* from 16% to 35%, indicating a period of inner bay environment covered by shallow seawater.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1384513857

Zone II (170-80 cm)

Zone II was characterized by conspicuous increase of fresh species without marine-brackish species, although constrained to a combination of peaty clay, peat and coarse sand with gravels layers. A fresh lake environment appeared in this period, characterized by a significant increase of fresh limnological taxa such as *Melosira ambigua* and *Stephanodiscus astrae* with percentage of 24-67%.

Zone III (80-35 cm)

In Zone III, *Melosira ambigua* and *Stephanodiscus astrae* met a clear declining trend to 3-5%, with *Pinnularia* spp. and *Eunotia* spp. increasing rapidly reaching 35%. A stream environment indicator *Gamphonena* spp. appeared in this zone (6-11%), indicating a wetland environment influenced by stream.

Diatom analysis for core HT-1 and HT-2

Peat, grey peat in core HT-1 and blue-grey medium and coarse sand in core HT-2 were employed for diatom analysis. Results from both the cores show that few diatom species exist in underlying layers with small amount of fresh species such as *Pinnularia* spp., *Eunotia* spp. and *Hantzschia amphioxys*.

Diatom analysis for core NL

Overlying the yellowish medium sand to 4.2 m a.s.l., M-B species play a dominate role, containing *Coscinodiscus excentricus,* indicator of coastal environment and inner bay, and *Thaiassionema nitzschioides*, indicator of coastal environment, with significant percentages of 33-25% and 10-28%, respectively. A declining trend of the number of diatoms above 4.2 m a.s.l. is observed, with the dominant species indicative of freshwater environment, such as *Pinnularia* spp. and *Eunotia* spp. (18-37% and 18-25%, respectively).

Diatom species and covered water change

The diversity of diatom assemblage in Core LD-1 shows that the environment changed gradually from the bottom to the top, as marine-brackish species dominated in the lower part, while fresh-brackish and fresh species dominated in the upper part, suggesting that the environment varied from drowned ditch covered to salty marsh, and then to fresh wetland and marsh. The gradual change shows that the sediments provide continuous environment records, documenting the waning of seawater influence. Diatom species in the peat layer were mostly fresh indicators, especially inhabited in marsh and wetland environment, while the underlying part contained brackish-fresh species with gradual increase of brackish-marine diatoms, which indicated that these organic-rich materials were formed in a marsh environment with sea level regressed in the semi-enclosed drowned ditch. Hence, the base of peat layer which contacted with underlying layer can be used as the turning point from sea-level highstand to regression, with 3.40 m a.s.l. The calibrated radiocarbon age of 5466 cal. a B.P., indicating that the shoreline retreated from 5466 a B.P. from the position of core LD-1 with elevation of *ca.* 3.40 m a.s.l.

Sedimentary environment change can be identified from the vertical change of diatom assemblages in Core LD-2. From the bottom of LD-2, five diatom assemblage

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1384513857

zones were constrained to drowned ditch covered by seawater, drowned ditch with shallow seawater, salty marsh, lacustrine bog and wetland, respectively. Similar with LD-1, the peat layer contacted conformably with underlying part, which contained gradual increase of fresh-brackish species from the base to the top, showing a gradual declining of sea level. The radiocarbon date showed that the seawater had regressed from the small drowned ditch since 6052 cal. a B.P., in height of 3.84 m a.s.l.

Without gradual change of the diatom assemblages, the fresh-species dominant peat directly contacted with underlying by marine-brackish sedimentary layer in core LD-3, in disagreement with the cores LD-1 and LD-2. It is likely related to erosion or drastic increase of fresh water level. The elevation of 3.10 m a.s.l. for the peat layer in core LD-3 is thus not applicable to indicate the sea-level in this site. The radiocarbon date is 5446 cal. a BP for this peat layer.

Peatlands and its implication of the mid-Holocene sea level change

The Dayanghe Plain is geomorphologically separated into several drowned ditches with a static sedimentary environment. The distribution of the buried peat layers in these three drowned ditches could be recognized from the boreholes. The elevation of the peat layer declines from head to mouth, corresponding to the sea-level regression. Determined by diatom assemblages, this layer is classified as the marsh or limnological peat, rarely influenced by seawater. The distribution of peat in LD-3 ditch indicates that seawater reached to the LD-3 ditch, which is 20 km to the present estuary, occupying the whole Dayanghe Plain. The lower blue-grey clay layer likely resulted from shallow marine environment during the Early-Middle Holocene. The boundary of peat and the lower blue-grey layer corresponds to seawater regression in the Dayanghe Plain. In the LD-3 ditch, peat and black clay appeared at elevations of 6.4 m and 9.0 m a.s.l., whereas the underlain sediment succession contains no marine-brackish species. Therefore, the noncontinuous peat and organic-rich clay in the LD-3 ditch are not result of the Holocene sea-level change.

It demonstrates that the boundary between the peat layer and the blue-grey marine strata is approximately 4 m a.s.l. in the head of ditches. It is consistent with the mean high tide line at that time. The tidal range in this area is 4.08 m at present, with mean regional sea-level in 0.36 m a.s.l. We assume that the situation in mid-Holocene was consistent with present, and the mean sea level could be calculated as: high tide level minus half of the tidal range (4 – 4.08 / 2 m = 1.96 m), which implies that the sea-level was approximately 1.60 m higher than present. Although one radiocarbon date for the LD-3 peat is doubtful to indicate the seawater regression due to the unconformable contact between the peat and the underlain silt layer, the age results from cores LD-1 and LD-2 suggested the Holocene regression started during 6052-5466 cal. a BP. It challenges the outcomes from the previous studies. The buried peat at the height of 8 m a.s.l. in Huangtukan area has been thought to be related to the high sea-level since 7840 cal. a BP. Similarly, the shell banks in the west Dagu Mountain at height of 7-10 m a.s.l. have been considered as the result of sea-level rise and tectonic uplifts, which was 3-6 m higher than result from buried peat and diatom analysis. Moreover, the upper grey silt layer in core NL, deposited in the coastal environment, was dated back to 6182 cal. a BP using the shell collected from the bottom of this layer. It suggests that seawater reached to the Dayanghe Plain not before ca. 6000 cal. a BP. More evidence was provided by diatom analysis from cores drilled in Huangtukan area. Buried peat was found in core HT-1 and HT-2, in height of 8.80 and 8.50 m a.s.l., respectively.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1384513857

Only several diatom species inhabiting in fresh water were found in lower parts of both two cores. Therefore, the peat in the Huangtukan area is not indicative of sea-level change during the Holocene.

The sea-level of 1.60 m higher than the present during the Holocene sea-level highstand is also supported by the results of the previous research in Japanese coastal areas, e.g. Hokkaido, Tsugaru Plain, Osaka Bay and Tamagawa. They suggested that the sea-level highstand occurred during 6000-5500 cal. a B.P. The sea-level was 0-5 m higher than the present (UMITSU, 1994). Therefore, the height of highstand sea-level in the North Coast of the Yellow Sea in the Middle Holocene (6052-5466 cal. a BP) is constrained to ca. 1.60 m a.s.l. by radiocarbon dating and diatom analysis approaches.

Conclusions

Using diatom assemblage analysis and radiocarbon dating approaches, the sea-level highstand and the timing of the sea-level highstand termination in the North Coast of the Yellow Sea were investigated. We draw our conclusions as follows.

(1) The widely distributed buried peat, at elevation of 2-10 m a.s.l. in the Dayanghe Plain was classified as marsh and limnological peat, which formed after seawater regressing from the drowned ditches. Only the peat layer below 4 m a.s.l., contacting the lower marine section conformably, were related to regression.

(2) The peatland at < 4 m a.s.l. formed during the period of 6182-5466 cal. a BP, indicating the Holocene highstand sea-level was 1.60 m higher than the present.

(3) According to the diatom assemblages in the studies cores, the shell banks at west of Dagu Mountain at height of 7-10 m is not indicative of sea-level change. The shell banks are also excluded as sea-level indicator as they are much higher than the results of the regional sea-level investigations.

(4) It is necessary to investigate the notches, terraces and buried peat in the adjacent areas for comparison to better understand the Holocene sea-level change.

Abstract. The purpose of this study was to explain the phenomenon of seawater intrusion (SWI) by numerical simulation and analysis. In this paper, a numerical method was introduced for solving the one-dimensional advection-dispersion equation by the explicit finite difference method, and the corresponding convergence conditions and the boundary attenuation factor, β, were given, which can be convenient in studying the impact of different influencing factors on seawater intrusion. Additionally, the effects of six hydraulic factors on seawater intrusion were explored under steady state, namely, hydraulic conductivity, longitudinal dispersivity, hydraulic gradient, flux, evaporation and rainfall. Moreover, two different seawater intrusion types were also studied, namely active seawater intrusion and passive seawater intrusion. Meanwhile, the control variates method was adopted to explore the influence of a single factor on seawater invasion. According to the calculated results, with the increase of hydraulic conductivity, longitudinal dispersion, flux and evaporation, the degree of it will be aggravated, but the rainfall can play a role in mitigating seawater intrusion. Besides, under active seawater intrusion conditions, the growth of the numerical value of hydraulic gradient will aggravate seawater intrusion, while under passive seawater intrusion conditions, it will slow down the degree of invasion. All in all, the results and achievements are consistent with the actual situation, which can explain the phenomenon of seawater intrusion.
Keywords: *seawater intrusion, numerical simulation, explicit finite difference method, active and passive seawater intrusion, seepage tank*

Introduction

In coastal and island areas, seawater intrusion (SWI) has become one of the major geological hazards due to the over-exploitation of groundwater (Li et al., 1996). Seawater intrusion arising from aquifer depletion is often classified as active or passive, depending on whether seawater moves in the same direction as groundwater flow or not (Werner, 2017). Generally, hydrodynamic and hydrogeological conditions are essential for the formation of seawater intrusion (Xue et al., 1992). There are a variety of factors affecting seawater intrusion, which can also be divided into hydrodynamic factors and hydrogeological factors under natural conditions excluding human factors. Hydrodynamic factors include hydraulic gradient, flux, evaporation, rainfall, recharge and tidal action, while hydrogeological factors include hydraulic conductivity, longitudinal dispersivity, adsorption and porosity (Chen et al., 2013). According to the *Technical regulations for monitoring and evaluating sea water intrusion* issued by the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1385913874

State Oceanic Administration (Mao, 2014), the concentration of chloride ion at 250 mg/L can evaluate the degree of seawater intrusion.

Zhao et al. (2018) investigated the effects of some influencing factors on seawater-freshwater mixing zones, namely, saturated hydraulic conductivity, porosity, molecular diffusivity, longitudinal and transverse dispersivity, by analyzing their uncertainty and sensitivity for the predicted seawater-freshwater mixing zones in simulation experiments. Moreover, based on the measured data of groundwater level and content in the transition zone, Zhang et al. (2015) and Zhen et al. (2015) found that there was a significant negative correlation between the seasonal variation of groundwater level and the seasonal variation of groundwater content. Then, Zhang (2015) determined that the correlation coefficient was above 0.92. Adel et al. (2014) found that salinization of fresh groundwater is highly associated with groundwater withdrawal based on historical hydraulic heads data. Qing et al. (2013) determined that rainfall and tidal effects have an important impact on seawater intrusion, and that rainfall can lower the degree of seawater intrusion. Liu et al. (2007) obtained that the increase of elevation difference between seawater and freshwater level will increase the speed of SWI. Zhang and Chen et al. (2015) proposed that local groundwater is subjected to anthropogenic activities and geochemical processes, such as evaporation, water-rock interaction, and ion exchange, thus affecting the degree of seawater intrusion. Emna et al. (2018) found local shallow groundwater is threatened by seawater intrusion because of the reduced rainfall and recharge capacity.

Based on the above research contents, six hydraulic factors were considered including hydraulic conductivity, longitudinal dispersivity, hydraulic gradient, flux, evaporation and rainfall in this paper. In order to study the influence of these six hydraulic factors on seawater intrusion and its final steady state, the control variates method was adopted in this paper. With other conditions unchanged, the influence of the change of one factor on the final steady state was considered separately. In this paper, the explicit finite difference method was adopted to solve the one-dimensional advection-dispersion equation. The purpose of this method was to simulate the real salt migration phenomenon from the viewpoint of numerical calculation, analyze the mechanism of seawater intrusion, and explain the influence of various factors on the seawater intrusion under both steady state and two kinds of SWI types, active SWI and passive SWI (active seawater intrusion and passive seawater intrusion).

The one-dimensional advection-dispersion equation has been widely applied to describe the transportation process, which is utilized for the study of seawater intrusion (Yu, 2018). Compared with two-dimensional and three-dimensional models, it requires fewer parameters and remains as a simple and feasible method, and it is convenient to study the impact of the above six hydraulic factors on seawater intrusion. Nie et al. (2002) explained the problem of seawater intrusion through the advection-dispersion model of miscible fluid. Purnaditya et al. (2018) developed the mathematical model of groundwater flow and solute transport which is applicable to seawater intrusion mechanism.

With respect to solve one-dimensional advection-dispersion equation by finite difference method, Yu et al. (2018), from China, implemented Homotopy Analysis Method (HAM) to solve the one-dimensional advection-dispersion equation. Savovic et al. (2012), from Russia, solved one-dimensional advection– dispersion equation with variable coefficients by using explicit finite difference method and shown that explicit

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1385913874

finite difference method is effective and accurate for solving the equation. Yang et al. (2016), from China, proposed a boundary value method for solving fractional order advection-dispersion equation. In the traditional numerical solution of the advection-dispersion equation, the longitudinal dispersivity coefficient is often regarded as a constant, but it is directly proportional to the size of the flow velocity. When the distribution of the flow velocity in space is not equal, neither the velocity nor the longitudinal dispersivity coefficient can be regarded as a constant. Comparing the methods described above, the methods presented in this paper combined the characteristics of seawater intrusion, considering active SWI and passive SWI, introducing the boundary attenuation factor, and giving the convergence conditions, which can simulate the real situation of seawater intrusion.

Therefore, the article aimed to study seawater intrusion through the introduction of a numerical method to solve the one-dimensional advection-dispersion equation using the finite difference method, and additionally investigated influencing factors, the effect strength of a single such factor, and seawater intrusion types.

Research methods

One-dimensional advection-dispersion equation

In the steady seepage field, if the change of water density caused by the change of solute concentration can be ignored by solving the advection-dispersion equation, the flow equation and the solute transport equation can be solved independently. The velocity components in the seepage field are obtained from the solution of the flow equation, and then the velocity is substituted into the advection-dispersion equation as input. This method called decoupling method has high computational efficiency (Zheng et al., 2016). In this paper, the decoupling method was adopted to solve the problem of the flow velocity term in the advection-dispersion equation. According to the different influencing factors, different formulas for calculating the velocity term were given. The velocity term was substituted for the difference formula of the concentration, and the calculation results were expressed as the spatial distribution of chloride ion concentration in the seepage interval under this single influencing factor.

In the paper, the one-dimensional advection-dispersion equation was taken as the research object. It was considered that seawater and freshwater were miscible, regardless of source and sink terms, and the porosity n is constant (Khakimov et al., 2017).

$$\frac{\partial c}{\partial t} = \frac{\partial}{\partial x}(D_l \frac{\partial c}{\partial x}) - \frac{\partial}{\partial x}(V_x c) \quad \text{(Eq.1)}$$

$$V_x = -k \frac{\partial h}{\partial x} \quad \text{(Eq.2)}$$

$$D_l = \alpha_L |V_x| \quad \text{(Eq.3)}$$

In the above equations, k is the hydraulic conductivity, unit m/s; D_l represents the longitudinal dispersivity coefficient, which is the physical quantity reflecting the dispersivity of soluble substances through the permeable media, unit m^2/s; a_L represents the longitudinal dispersivity, unit m.

Explicit differentiation of differential equations

In terms of one-dimensional advection-dispersion seawater intrusion model, there are two kinds of cases. Namely, the one case that seawater head is higher than freshwater head is defined as active SWI, and the other case that freshwater head is higher than seawater head is defined as passive SWI (Badaruddin et al., 2017). Under active SWI conditions, $h_0 > h_N$, as shown in *Figure 1,* the direction of flow velocity is the same as the direction of salt migration as well as the direction of X-axis. Furthermore, under passive SWI conditions, $h_0 < h_N$, as shown in *Figure 2,* the direction of velocity is opposite to the direction of salt migration as well as the direction of the X-axis. The diffusion of salinity under constant flux, head and steady-state conditions was studied in this paper. Therefore it is assumed that the water head and flow velocity have reached a steady state before salinity diffusion.

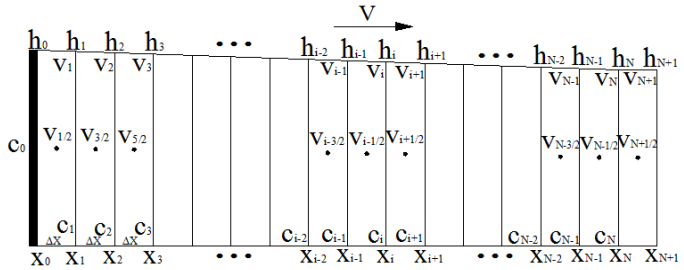

Figure 1. *The seepage interval node division under active SWI conditions*

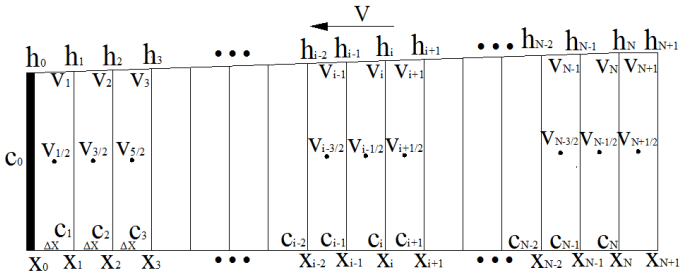

Figure 2. *The seepage interval node division under passive SWI conditions*

Under active SWI conditions, *Equation 1* can be transformed into differential iterative formula as follows:

$$\frac{c_i^{n+1}-c_i^n}{\Delta t}=\frac{\alpha_L[V_{i+\frac{1}{2}}(c_{i+1}^n-c_i^n)-V_{i-\frac{1}{2}}(c_i^n-c_{i-1}^n)]}{(\Delta x)^2}-\frac{V_i c_i^n-V_{i-1}c_{i-1}^n}{\Delta x}\quad(1\le i<N)\qquad\text{(Eq.4)}$$

When $i=N$, then $c_{N+1}^n=\beta c_N^n$, $V_{N+1/2}=V_N$, β is the boundary attenuation factor, and its value is between [0,1], reflecting the degree of attenuation of the concentration at the boundary. Therefore, *Equation 1* can be transformed into *Equation 5* as follows:

$$\frac{c_N^{n+1}-c_N^n}{\Delta t}=\frac{\alpha_L[V_N(\beta-1)c_N^n-V_{N-\frac{1}{2}}(c_N^n-c_{N-1}^n)]}{(\Delta x)^2}-\frac{V_N c_N^n-V_{N-1}c_{N-1}^n}{\Delta x}\quad(i=N)\qquad\text{(Eq.5)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1385913874

Equations 4 and *5* can be transformed into standard difference formulas as follows:

$$\begin{cases} \Delta t/(\Delta x)^2 = \lambda \\ c_i^{n+1} = \lambda\alpha_L V_{i+\frac{1}{2}} c_{i+1}^n + [1-\lambda(\alpha_L V_{i+\frac{1}{2}} + \alpha_L V_{i-\frac{1}{2}} + \Delta x V_i)]c_i^n + \lambda(\alpha_L V_{i-\frac{1}{2}} + \Delta x V_{i-1})c_{i-1}^n (1 \le i < N) \\ c_N^{n+1} = \left\{[1-\lambda[\alpha_L(1-\beta)V_N + \alpha_L V_{N-\frac{1}{2}} + \Delta x V_N]\right\} c_N^n + \lambda(\alpha_L V_{N-\frac{1}{2}} + \Delta x V_{N-1})c_{N-1}^n \quad (i = N) \end{cases} \quad \text{(Eq.6)}$$

The value of Δx and Δt should satisfy the corresponding convergence conditions. Under active SWI conditions, when the value of Δx and Δt should satisfy *Equation 7,* the one-dimensional explicit difference schemes are absolutely convergent.

$$1 - \frac{\Delta t}{(\Delta x)^2}(\alpha_L V_{i+\frac{1}{2}} + \alpha_L V_{i-\frac{1}{2}} + \Delta x V_i) \ge 0 \quad \text{(Eq.7)}$$

q stands for flux per unit width, whose calculation equation is shown in *Equation 8,* and its unit is m^2/s (Qi, 2016).

$$q = \frac{k\left(h_0^2 - h_N^2\right)}{2L} \quad \text{(Eq.8)}$$

Equation 9 is for calculating node water head height under active SWI conditions.

$$h_i = \sqrt{h_0^2 - i\frac{(h_0^2 - h_N^2)\Delta x}{L}} \quad \text{(Eq.9)}$$

Equations 10 and *11* are for calculating flow velocity under active SWI conditions.

$$V_i = \frac{q}{h_i} = \frac{k(h_0^2 - h_N^2)}{2L\sqrt{h_0^2 - i\frac{(h_0^2 - h_N^2)\Delta x}{L}}} \quad \text{(Eq.10)}$$

$$V_{i+\frac{1}{2}} = \frac{k(h_i - h_{i+1})}{\Delta x} = \frac{k(\sqrt{h_0^2 - i\frac{(h_0^2 - h_N^2)\Delta x}{L}} - \sqrt{h_0^2 - (i+1)\frac{(h_0^2 - h_N^2)\Delta x}{L}})}{\Delta x} \quad \text{(Eq.11)}$$

Under passive SWI conditions, the calculated value of the velocity substituted is negative. Considering that D_l, the longitudinal dispersivity coefficient, is not affected by the forward or negative effect of the velocity, but only related to its size, *Equation 1* can be transformed into *Equation 12* as shown below to ensure that the coefficients of the velocity term in the explicit difference equation are forward.

$$\frac{c_i^{n+1} - c_i^n}{\Delta t} = \frac{\alpha_L[V'_{i+\frac{1}{2}}(c_{i+1}^n - c_i^n) - V'_{i-\frac{1}{2}}(c_i^n - c_{i-1}^n)]}{(\Delta x)^2} + \frac{V'_i c_i^n - V'_{i-1} c_{i-1}^n}{\Delta x} \quad (1 \le i < N) \quad \text{(Eq.12)}$$

Similarly, *Equation 12* can be transformed into standard difference formulas as follows:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1385913874

$$\begin{cases} \Delta t/(\Delta x)^2 = \lambda \\ c_i^{n+1} = \lambda\alpha_L V'_{i+\frac{1}{2}} c_{i+1}^n + [1-\lambda(\alpha_L V'_{i+\frac{1}{2}} + \alpha_L V'_{i-\frac{1}{2}} - \Delta x V'_i)]c_i^n + \lambda(\alpha_L V'_{i-\frac{1}{2}} - \Delta x V'_{i-1})c_{i-1}^n (1 \le i < N) \\ c_N^{n+1} = \left\{[1-\lambda[\alpha_L(1-\beta)V'_N + \alpha_L V'_{N-\frac{1}{2}} - \Delta x V'_N]\right\} c_N^n + \lambda(\alpha_L V'_{N-\frac{1}{2}} - \Delta x V'_{N-1})c_{N-1}^n \qquad (i = N) \end{cases} \quad \text{(Eq.13)}$$

Under passive SWI conditions, its convergence conditions are shown as below:

$$\begin{cases} 1 - \dfrac{\Delta t}{(\Delta x)^2}(\alpha_L V'_{i+\frac{1}{2}} + \alpha_L V'_{i-\frac{1}{2}} - \Delta x V'_i) \ge 0 \\ \alpha_L V'_{i-\frac{1}{2}} - \Delta x V'_{i-1} \ge 0 \end{cases} \quad \text{(Eq.14)}$$

Equation 15 is for calculating node water head height under passive SWI conditions.

$$h'_i = \sqrt{h_N^2 - (N-i)\frac{(h_N^2 - h_0^2)\Delta x}{L}} \quad \text{(Eq.15)}$$

Equations 16 and *17* are for calculating flow velocity under passive SWI conditions.

$$V'_i = \frac{q}{h'_i} = \frac{k(h_N^2 - h_0^2)}{2L\sqrt{h_N^2 - (N-i)\frac{(h_N^2 - h_0^2)\Delta x}{L}}} \quad \text{(Eq.16)}$$

$$V'_{i+\frac{1}{2}} = \frac{k(h'_i - h'_{i+1})}{\Delta x} = \frac{k(\sqrt{h_N^2 - (N-i)\frac{(h_N^2 - h_0^2)\Delta x}{L}} - \sqrt{h_0^2 - (N-i+1)\frac{(h_N^2 - h_0^2)\Delta x}{L}})}{\Delta x} \quad \text{(Eq.17)}$$

In order to study the effects of discharge variation, precipitation and evaporation on seawater intrusion, the flux is changed by keeping the hydraulic gradient constant and controlling the water head on both sides to increase at the same time.

The effects of rainfall and evaporation are considered to be uniform in the seepage field, and water exchange exists in each subzone. The position diagram of the influencing factors such as flow change, precipitation and evaporation was drawn, as shown in *Figure 3*.

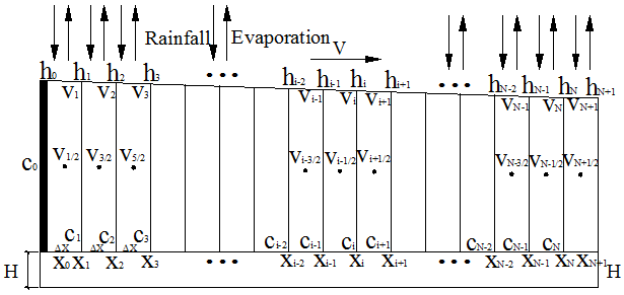

Figure 3. *Influencing relationship of flux, rainfall and evaporation*

As shown in *Figure 3, H* represents the numerical value of simultaneous rise of water head on both sides. If *H* is positive, it means water head would increase H meters

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1385913874

simultaneously on both sides. Conversely, negative H means decreasing. That is to say, the seawater head rises *H* meters, at the same time, the fresh water level also rises *H* meters. Meanwhile, the hydraulic gradient does not change. However, the flux changes with the change of *H*, which is a special flow quantity change, thus affecting the seepage velocity and the final concentration distribution. The formulas for calculating discharge, head and velocity can be seen in *Equation 18.*

$$\begin{cases} q_H = \dfrac{k[(h_0+H)^2-(h_N+H)^2]}{2L} \\ h_{H_i} = \sqrt{h_0^2 - i\dfrac{(h_0^2-h_N^2)\Delta x}{L}} + H \\ V_{H_i} = \dfrac{q_H}{h_H}, V_{H_{i+\frac{1}{2}}} = \dfrac{k(h_{H_i}-h_{H_{i+1}})}{\Delta x} \end{cases} \quad \text{(Eq.18)}$$

As to rainfall and evaporation, the influencing factors on seawater intrusion, the annual average rainfall is represented by *R*, and the annual average evaporation is represented by *E*. The unit is mm/yr, and 1 mm/yr = 3.171 $\times 10^{-11}$ m/s. Rainfall and evaporation are directly affected on the unit seepage length, and water exchange occurs in each spatial grid. Rainfall and evaporation will affect the flux in the seepage region. Thus, the flow velocity and salt diffusion are affected.

Under active SWI conditions, the equations of flux and flow velocity under the influence of the evaporation factor were shown below.

$$\begin{cases} q_{E_i} = \dfrac{k\left(h_0^2-h_N^2\right)}{2L} - iE \\ V_{E_i} = \dfrac{q_{E_i}}{h_i}, V_{E_{i+\frac{1}{2}}} = \dfrac{k(h_i-h_{i+1})}{\Delta x} \end{cases} \quad \text{(Eq.19)}$$

Under active SWI conditions, the equations of flux and flow velocity under the influence of the rainfall factor were shown below.

$$\begin{cases} q_{R_i} = \dfrac{k\left(h_0^2-h_N^2\right)}{2L} + iR \\ V_{R_i} = \dfrac{q_{R_i}}{h_i}, V_{R_{i+\frac{1}{2}}} = \dfrac{k(h_i-h_{i+1})}{\Delta x} \end{cases} \quad \text{(Eq.20)}$$

Under passive SWI conditions, the equations of flux and flow velocity are similar to those under active SWI conditions.

Numerical examples

It is assumed that there is a seepage tank, which is used to simulate seawater invasion. The length of the tank is 1.5 m, the width is 0.1 m, and $k = 0.0001$ m/s, $\alpha_L = 0.2$ m. The left side is the boundary of constant head and concentration, the left side of seawater head is 0.5 m, and the initial chloride ion

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1385913874

concentration of the left side seawater is 18.000 mg/L, which can be prepared by seawater salinometer measuring. The right side is the fixed head boundary, the fresh water head on the right side is 0.35 m, and the chloride ion concentration is 0. Under this condition, it is considered that there is no concentration decay at the right side boundary ($c_{N+1}^n = c_N^n$), which is a case of active SWI, as shown in *Figure 4.* As to passive SWI, in the left side, the seawater head is 0.35 m and the initial chloride ion concentration is 0; and in the right side, the fresh water head is 0.5 m and the initial chloride ion concentration is 18.000 mg/L, as shown in *Figure 5.* Besides, the physical photograph of the applied seepage tank is shown in *Figure 6.* Taking $\Delta x = 0.03$ m, $\Delta t = 100$ s and $\beta = 1$, the relationship will be calculated between the steady concentration and the diffusion distance of seawater salt in the seepage field after 6,000 iterations. The initial and boundary conditions are as shown below.

$$\begin{cases} \dfrac{\partial C}{\partial t} = \dfrac{\partial}{\partial x}(a_L|V_x|\dfrac{\partial C}{\partial x}) - \dfrac{\partial}{\partial x}(V_x C) \qquad (0 < x < 1.5, t > 0) \\ C|_{t=0} = 0 \\ C|_{x=0} = 18000 \\ \dfrac{\partial V}{\partial x}|_{x=1.5} = 0 \end{cases} \tag{Eq.21}$$

While the finite difference method to calculate the above examples are used, under the condition of convergence, after 6000 iterations, the concentration of the node position basically does not change with the increase of iterations. Meanwhile, the calculation results represent the chloride ion concentration under steady state, then the degree of seawater intrusion in the region will be judged.

Result discussion

The effects of six hydraulic factors on seawater intrusion were explored in this paper, namely, hydraulic conductivity, longitudinal dispersivity, hydraulic gradient, flux, evaporation and rainfall. Besides, the initial and boundary conditions utilized for calculation and simulation were based on the contents described in the numerical examples above. In this paper, the finite difference method was utilized to solve one-dimensional advection-dispersion equation. Meanwhile, the control variates method was adopted to explore the influence of a single factor on seawater invasion. After iteration calculation, the distribution of chloride ion concentration in the seepage field was compared under steady state.

Hydraulic conductivity

Hydraulic conductivity k, which is defined as the unit flux under the unit hydraulic gradient, represents the difficulty of fluid passing through the pore framework. The hydraulic conductivity can affect the flow velocity of seepage flow and the salt migration. In order to study the influence of hydraulic conductivity on salt migration, five different numerical values of hydraulic conductivity were formulated in this paper, namely, $k = 0.00005$ m/s, 0.0001 m/s, 0.00015 m/s, 0.0002 m/s and 0.00025 m/s. Hydraulic conductivity of sandy soil is related to many factors, such as material composition, particle size, shape, gradation and compactness of soils (Liu et al., 2017), and it can be monitored nondestructively and rapidly in real time by the resistivity measurement (Yuan et al., 2019).

Keeping other conditions unchanged, considering the forward and reverse seepage type conditions, the influence of hydraulic conductivity on seawater intrusion and its final state was analyzed, as shown in *Figure 7*.

According to the calculated results, the concentration of the final steady state rises with the increase of the hydraulic conductivity, but its growth rate is small. In the steady seepage field, the hydraulic conductivity is the time that affects the salinity to reach the final steady state. The larger the hydraulic conductivity is, the smaller the time to reach the steady state will be. Moreover, the hydraulic conductivity is forwardly correlated with the degree of seawater invasion.

Longitudinal dispersivity

Longitudinal dispersivity is related to the properties of porous media, unit m, describing the degree of the dispersion in the migrating direction of flow, which is one

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1385913874

of the most important parameters representing the dispersion feature of aquifer (Cheng, 2002), and it can be compute by the dispersive-area (DA) method and the linear graphic (LG) method (Zhang et al., 2010). Therefore, five different numerical values of longitudinal dispersivity were formulated in this paper, namely, $\alpha_L = 0.1$ m, 0.2 m, 0.3 m, 0.4 m and 0.5 m. Keeping other conditions unchanged, considering the forward and reverse seepage type conditions, the influence of longitudinal dispersivity on seawater intrusion and its final state was analyzed, as shown in *Figure 8.*

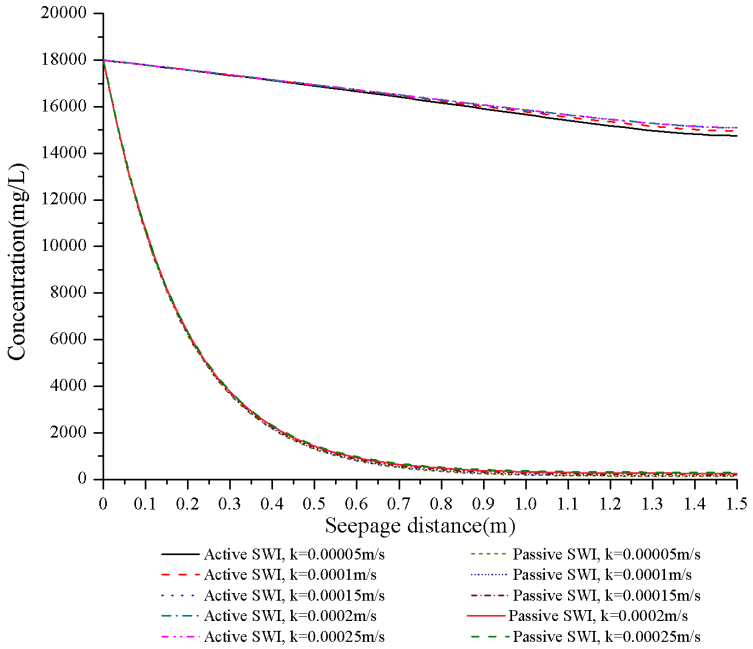

Figure 7. *The concentration distribution map under the changing hydraulic conductivity*

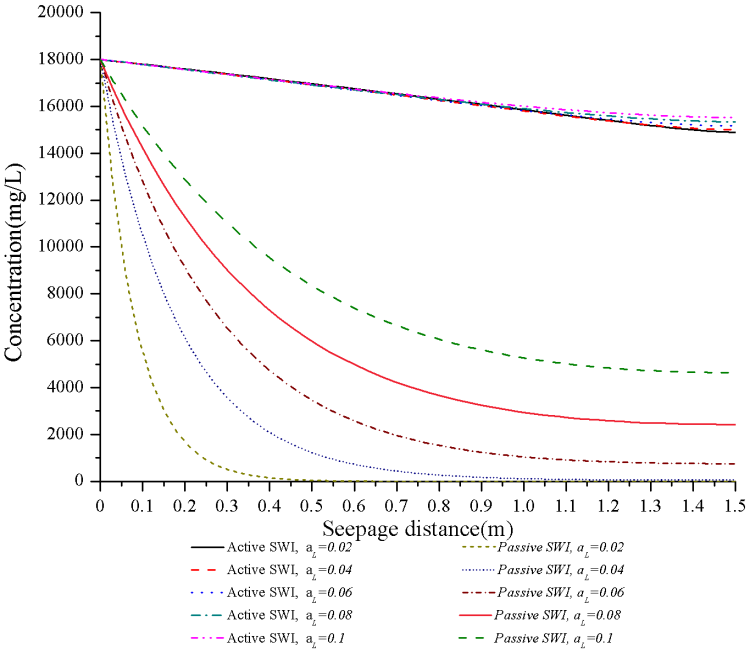

Figure 8. *The concentration distribution map under the changing longitudinal dispersivity*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1385913874

According to the calculated results, when the longitudinal dispersivity increases in the test condition, the concentration under steady state also grows, indicating that the longitudinal dispersivity is forwardly correlated with seawater intrusion. From *Figure 8* it is found that the longitudinal dispersivity has a great influence on the degree of seawater intrusion under both steady state and passive SWI conditions, and this phenomenon is particularly evident under passive SWI conditions but inapparent under active SWI conditions. The greater the longitudinal dispersivity is, the severer the seawater invasion will be under both active and passive SWI conditions.

Hydraulic gradient

Hydraulic gradient, *J*, refers to the loss of head per unit distance of flow, $J = |h_0 - h_N| / L$. Five different numerical values of hydraulic gradient were formulated in this paper, namely, J = 0.1 m, 0.2 m, 0.3 m, 0.4 m and 0.5 m. Keeping other conditions unchanged, considering the forward and reverse seepage type conditions, the influence of hydraulic gradient on seawater intrusion and its final state was analyzed, as shown in *Figure 9*.

According to the calculation results, under the condition of active SWI, with the increase of the numerical value of hydraulic gradient, the concentration of chloride ion shows an increasing trend in the seepage field. However, under passive SWI conditions, with the increase of the numerical value of hydraulic gradient, the concentration of chloride ion decreases in the seepage field. That is to say, when the groundwater head increases, it will slow down the degree of seawater intrusion. On the contrary, when the head is reduced, the degree of seawater intrusion will be aggravated. In addition, this phenomenon is particularly evident under active and passive SWI conditions. Finally, the results of numerical simulation are the same as the achievements by the field measurements of Zhang et al. (2015) and also accord with the numerical experiments of Werner (2017).

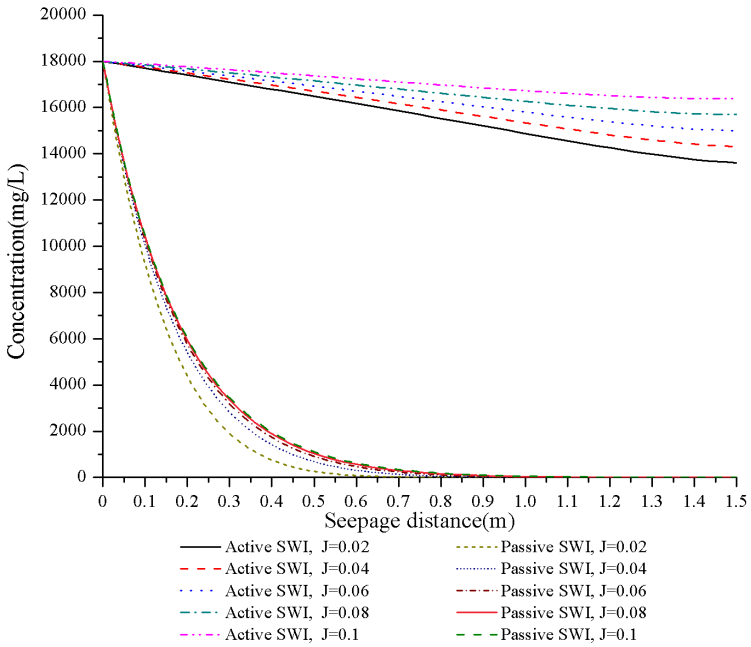

Figure 9. *The concentration distribution map under the changing hydraulic gradient*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1385913874

Flux

With the influence of flux, it was proposed that under the condition of constant hydraulic gradient, the water heads on the left and right sides should be raised or lowered at the same time, so as to make the flux increase or decrease while the hydraulic gradient remains unchanged. In order to explore the distribution of salt migration and chloride ion concentration under steady-state in different flow states, five working conditions were proposed. They were water head on both sides dropping by 0.1 m and by 0.05 m, respectively, water head remaining unchanged and water head on both sides rising by 0.05 m and by 0.1 m. Keeping other conditions unchanged, considering under the forward and reverse seepage types, the influence of flux on seawater intrusion under steady state was analyzed, as shown in *Figure 10*.

According to the calculation results, under active SWI conditions, the concentration of the final steady state increases with the increase of the flux. Although the final concentration also rises under passive SWI conditions, it was also slightly in terms of the extent of growth. Therefore, the flux was forwardly correlated with the degree of seawater intrusion.

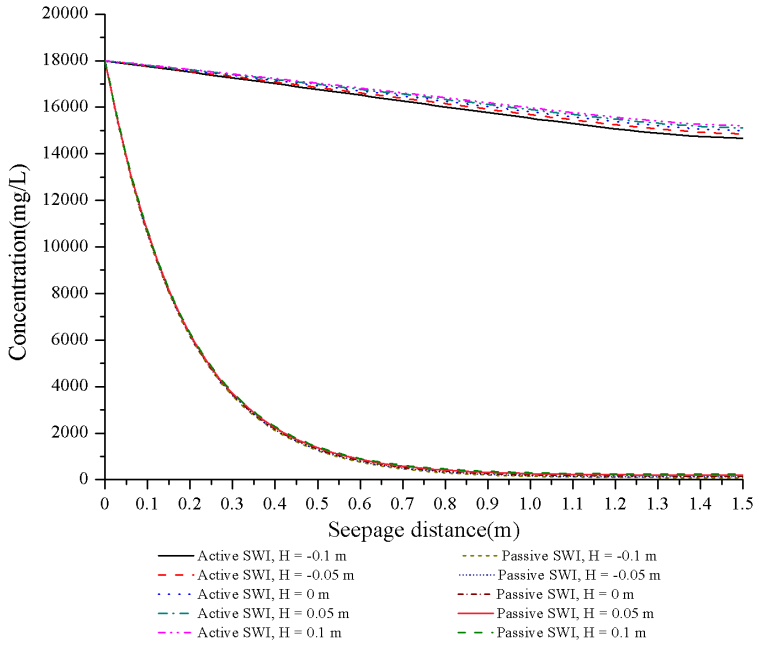

Figure 10. *The concentration distribution map under the changing flux*

Annual average evaporation

Evaporation refers to the amount of water that evaporates into the air over a certain period of time, which is usually expressed in millimeters of the thickness of the evaporated water layer, and it can be measured by the evaporimeter. In extremely arid areas, the average annual evaporation can reach more than 3000 mm/yr, for example, in western Ordos Plateau, China (Sun et al., 2017). Therefore, five different numerical values of annual average evaporation were formulated in this paper, namely, 1000 mm/yr, 2000 mm/yr, 3000 mm/yr and 4000 mm/yr, 5000 mm/yr. Keeping other conditions unchanged, considering the forward and reverse seepage type conditions, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1385913874

influence of annual average evaporation on seawater intrusion and its final state was analyzed, as shown in *Figure 11*.

According to the calculated results, under active SWI conditions, with the increase of the average annual evaporation, the concentration of the final steady state increases with a small range. Although the final concentration also grows under passive SWI conditions, it was also insignificantly in terms of the extent of growth. Therefore, the annual average evaporation was forwardly correlated with the degree of seawater intrusion. That is to say, the greater the degree of evaporation is, the severer the seawater invasion will be.

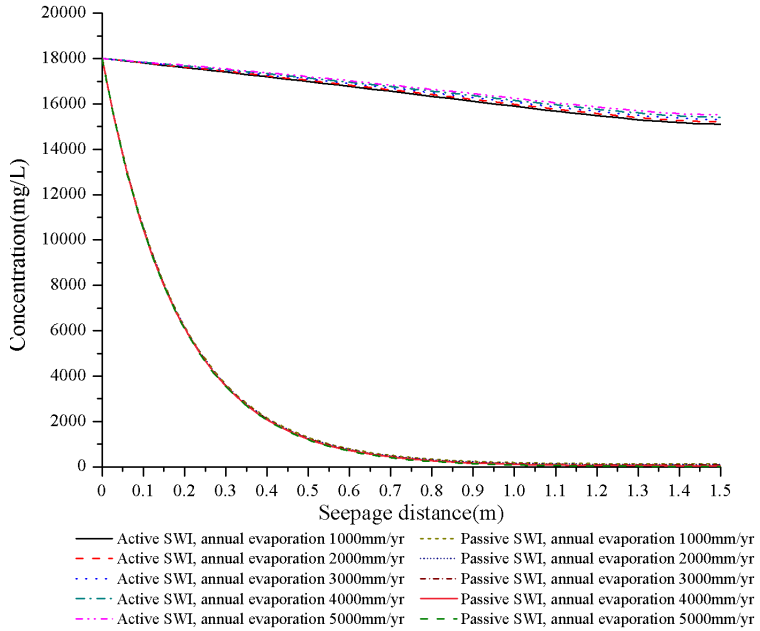

Figure 11. *The concentration distribution map under the changing annual average evaporation*

Annual average rainfall

Rainfall refers to the depth of the water layer falling to the ground in a certain period of time, which is generally measured by the rainfall measuring cylinder. The average annual rainfall in China is about 630 mm/yr, but in some extremely humid areas, the average annual rainfall can reach more than 10.000 mm/yr. Therefore, five different numerical values of annual average rainfall were formulated in this paper, namely, 0 mm/yr, 1000 mm/yr, 2000 mm/yr, 3000 mm/yr and 4000 mm/yr. Keeping other conditions unchanged, considering the forward and reverse seepage type conditions, the influence of annual average rainfall on seawater intrusion and its final state was analyzed, as shown in *Figure 12*.

According to the calculated results, under active SWI conditions, with the increase of average annual rainfall, the concentration in the final steady state decreases with a small extent. Under passive SWI conditions, the concentration also reduces slightly. Therefore, the rainfall is negatively correlated with the seawater invasion degree, and rainfall can slow down the degree of seawater invasion. Finally, the results of numerical simulation accord with the achievements of Qing et al. (2013).

Conclusion

(1) In this paper, this numerical simulation method of solving one-dimensional advection-dispersion equation by explicit finite difference method can obtain distribution of chloride ion concentration at spatial nodes under steady state. Moreover, this method can be utilized to explore the influence of different factors on the degree of seawater intrusion, and the results and achievements are efficient, robust, reliable and consistent with the actual situation, which can explain the phenomenon of seawater intrusion. In addition, the numerical method for solving the one-dimensional advection-dispersion equation by the explicit finite difference method is correct and worthy of being used for reference. Compared with the one-dimensional advection-dispersion equation, the two-dimensional equation can more accurately explain the salt transport process under different SWI conditions. Therefore, it should be worth studying with the two-dimensional Taylor's theorem and finite difference method.

(2) It can be seen from the results of numerical simulation that, with the increase of the numerical value of hydraulic conductivity, longitudinal dispersivity, flux and evaporation capacity, the degree of seawater invasion will be aggravated, but the rainfall can play a role in mitigating seawater intrusion. Besides, under active SWI conditions, the growth of the numerical value of hydraulic gradient will aggravate seawater intrusion, while under passive SWI conditions, it will slow down the degree of invasion. As for the reason, the six factors can affect the distribution of groundwater velocity field (the size and direction of groundwater velocity), thus affecting seawater intrusion. In addition, some other factors should be worth studying, for example, pumping positions and pumping quantity.

(3) It can be seen from the results of numerical simulation that under both active and passive SWI conditions, the above six hydraulic factors have a significant influence, to a certain extent, on the seawater intrusion under steady state. Furthermore, the effect of hydraulic gradient on seawater intrusion is greatly obvious under both active and

DOI: http://dx.doi.org/10.15666/aeer/1706_1385913874

passive SWI conditions. Additionally, it is found that the longitudinal dispersivity has a great influence on the degree of seawater intrusion under both steady state and passive SWI conditions, and this phenomenon is particularly evident under passive SWI conditions but inapparent under active SWI conditions.

Abstract. In order to understand the interactive mechanism between Mekong River and Tonle Sap Lake, long-series hydrological statistics were studied to analyze the variation characteristics, influencing factors and hydrological conditions of the reverse flow from Mekong River to Tonle Sap Lake. It was found that the reversal in the flood season lasts 122 days, with the flow volume reaching 37.7 billion m^3 and flood peak flow reaching 8402 m^3/s on average. The reversal reaches the maximum in August, accounting for 43% of the total yearly volume and 17.7% of the flow in Mekong River. Main factors influencing reversal flow include the difference in the runoff and water level between Mekong River and Tonle Sap Lake, and the water level of Tonle Sap River. The hydrological conditions presupposed that the reversal flow is linearly correlated to the product of water-level of Tonle Sap River to the power of 1.36 multiplied by that water-level difference to the power of 0.46. The result is expected to provide a scientific basis for the management of Mekong Delta and Tonle Sap Lake.
Keywords: *river-lake relationship, reverse flow, backflow intensity, water level difference*

Introduction

Lancang-Mekong River is the most important transboundary river in Asia that runs through six countries including China, Myanmar, Laos, Thailand, Cambodia and Vietnam. It stretches over a total of 4880 km and drains an area of 812400 km^3 (Royal et al., 2010; Mekong River Commission, 2011). The main stream of Mekong River is connected to the Tonle Sap Lake – the largest freshwater lake in Southeast Asia (with an annual average level of water at 4.64 m, covering an area of 6177 km^2 and a volume of 15.1 billion m^3) via the Tonle Sap River in Phnom Penh. The Lancang-Mekong River basin is shown in *Figure 1*.

Tonle Sap Lake closely resembles the Poyang Lake, China's largest freshwater lake, because they are both seasonal freshwater lakes with water flowing in and flowing out. Besides, Yangtze River connects with Poyang Lake at Hukou, and Mekong River connects with Tonle Sap Lake at Phnom Penh, giving rise to a complicated and world-famous river-lake relationship where the water of the lake drains into the river or the water in the river flows back to the lake (Cochrane et al., 2014; Luo et al., 2008; Hu et al., 2011; Fang et al., 2012). So far, there have been many systematic studies on the correlation between Yangtze River and Poyang Lake (Huo, 2011; Zhong et al., 2008; Yin et al., 2007; Hu et al., 2007; Dai et al., 2015; Zhang et al., 2014, 2015; Guo et al., 2012), and the conclusions show that the river-lake relationship has complicated internal mechanisms which are demonstrated in several ways including the main stream's drainage capacity, the river-connected-lake channel's capacity to diverge flows and discharge sediments, as well as the lake's flood control capacity. Among the few studies on the relationship between Mekong River and Tonle Sap Lake (Mekong River

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1387513895

Commission, 2005; Republic of Korea et al., 2008), most of them focus on the time and volume of the reverse flow from Mekong River to Tonle Sap Lake or analyze the balance between the inflow and outflow of water in Tonle Sap Lake. However, there are no in-depth studies on the variation characteristics of duration and volume of the reversal flow, and research on factors influencing the reversal flow and related hydrological conditions is also absent. Therefore, it is advisable to make full use of the latest research achievements on the correlation between Yangtze River and Poyang Lake to probe into the correlation between Mekong River and Tonle Sap Lake while giving due attention to the differences between Poyang Lake and Tonle Sap Lake.

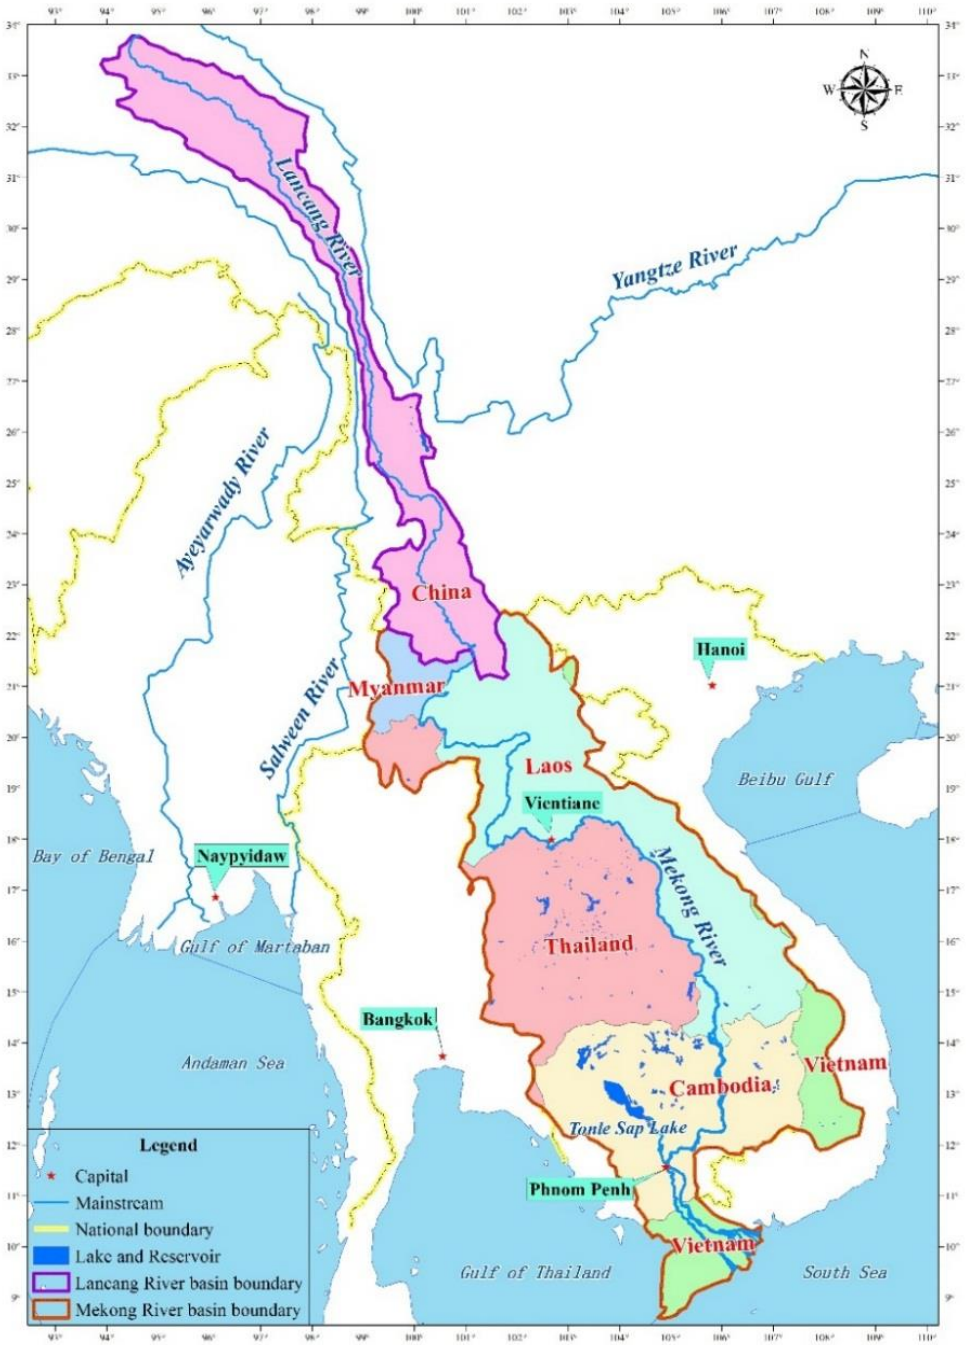

Figure 1. *Watershed map of Lancang-Mekong River*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1387513895

Salient geomorphic differences

Poyang Lake is a lake when the water level is high, but it resembles a river when the water level is low, creating a unique landscape of a wide stretch of lake in the flood season while a narrow watercourse in the dry season. The maximum surface area of the lake (3708 km^2) accounts for 2.29% of the area of the whole basin (162200 km^2) (Mak et al., 2012; Changjiang Institute of Survey, Planning, Design and Research, 2015; You et al., 2013; Li et al., 2018a). In contrast, the terrain of Tonle Sap Lake is plain; the average gradients for the outlet watercourse of Tonle Sap Lake, the lake area and the watercourse of Tonle Sap River are 0.0988‰, 0.0024‰ and 0.0354‰, respectively. The water surface gradient is mild, which averages at 0.0062‰ and reaches its maximum at 0.0189‰. The maximum surface area of the lake equals approximately 17.75% of the total area of the basin (86000 km^2), thus Tonle Sap Lake retains the appearance of a lake both in the flood and the dry seasons. As Tonle Sap Lake is situated in a plain, its difference of water level, surface area and volume in flood and dry seasons fall below those of Poyang Lake. In the case of Poyang Lake, when it reaches the highest water level at 20.7 m, its surface area reaches 3708 km^2 and its volume 30.363 billion m^3; when it falls to its lowest water level at 4.01 m, its surface area shrinks to 28.7 km^2 and its volume to 63 million m^3; the ratio of these two extreme surface areas is 129, and that of the extreme volumes is 482. In the case of Tonle Sap Lake, when it reaches the highest water level at 10.54 m, its surface area is 15261 km^2 and its volume is 78.7 billion m^3; when it reaches the lowest water level at 1.11 m, its surface area shrinks to 2053 km^2 and its volume to 780 million m^3; the ratio of the extreme surface areas is 7 and that of the extreme volumes is 101. The largest surface of Tonle Sap Lake is 4.12 times as large as that of Poyang Lake, and its maximum volume 2.59 times as much as that of Poyang Lake; while its minimum surface area and minimum volume are 71.53 times and 12.38 times the size of Poyang Lake, respectively (Li et al., 2018a). The map of Tonle Sap Lake in different hydrological conditions is shown in *Figure 2*.

Geomorphic differences in the watercourse

The mainstream of Yangtze River in Hukou section is located between the upper reaches and the lower reaches of the river. Embankments are built to defend tremendous flood that may occur every two decades, and optimal coordination of the upper stream and the local flood detention-retention basin will meet the requirement to defend a flood resembling that happened in 1954. The mainstream of Mekong River that runs through Phnom Penh is located at the Mekong Delta in Cambodia where a low plain prevails, and the flow discharge capacity of the river in this section is far from enough to handle the enormous flow volume from the upper stream. When the water level of Kompong Cham reaches above 13 m, vast flooding plain of left and right banks in Mekong River are easily inundated through the branch watercourses or irrigation channels, resulting in inundation that lasts an annual average of 19 to 48 days, with an annual average overland flood volume in the floodplain of approximate 42.3 billion m^3 (Changjiang Water Resources Commission of the Ministry of Water Resources, 2019).

Different inflow from the mainstream

The mainstream of Yangtze River in Hukou station has a surface area of 1.68 million km^2, accounting for 93% of the area of the whole basin, and is about

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1387513895

338 km away from the boundary with the lower-stream tidal areas at Datong station. The surface area of the entrance where Tonle Sap River drains into Mekong River is about 749000 km^2, accounting for 92% of the total area of the basin. Aside from the inflow from the upper stream, the mainstream of Mekong at Phnom Penh is also subject to tidal movements in the downstream area. As a result, the flood lasts long in this region and subsides slowly, with an average rate of flood flow at 1.5 to 2.0 km/h.

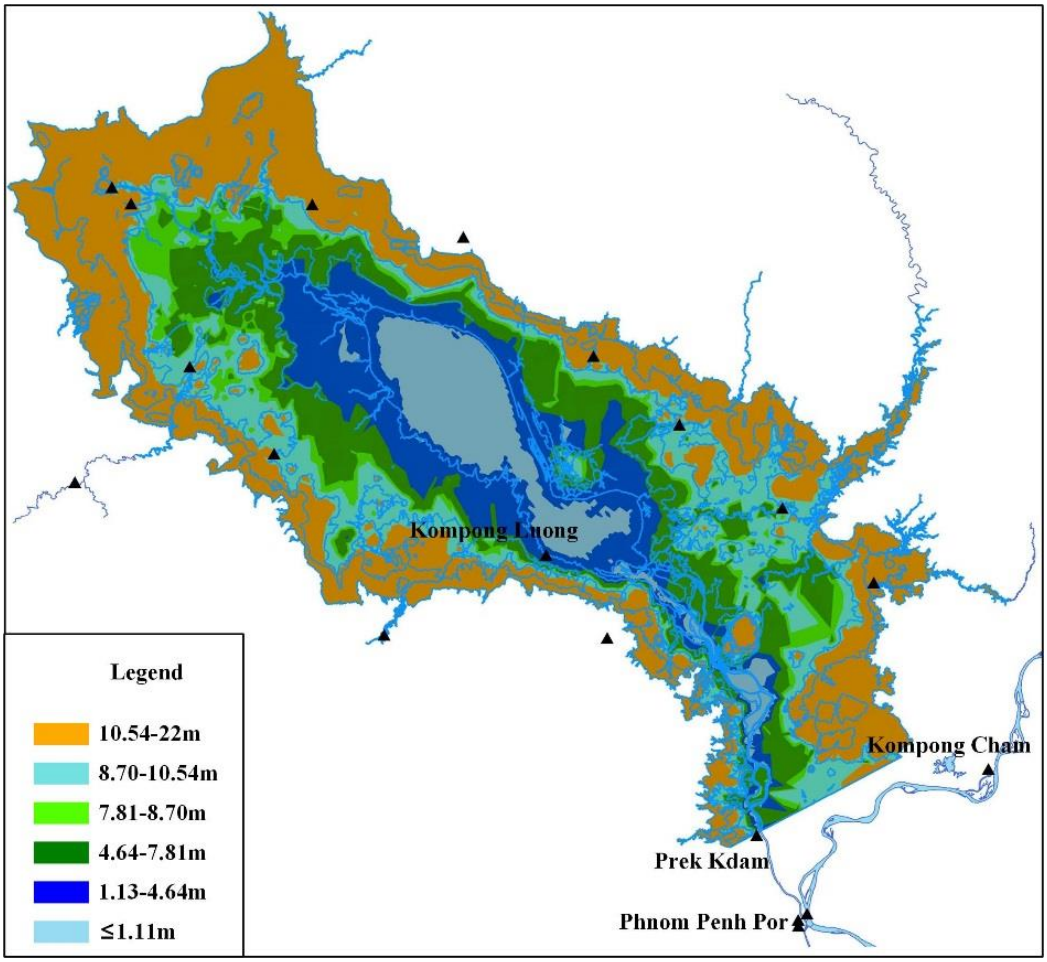

Figure 2. *Area distribution of Tonle Sap Lake under different characteristic stage*

Different water exchange intensity between Mekong River and Tonle Sap Lake

Due to conditions of the watercourses, geomorphic features and inflow of water, Tonle Sap Lake is much more capable than Poyang Lake in terms of flood control and water storage (Li et al., 2018a, b). The water exchange between Mekong River and Tonle Sap Lake is more frequent and active than that between Yangtze River and Poyang Lake. Every year on average, the reversal flow from Mekong River to Tonle Sap Lake lasts 122 days and the volume of the reverse flow reaches 37.7 billion m^3. In contrast, the reversal flow from Yangtze River to Poyang Lake lasts an average of 15 days every year, merely 12% of that from Mekong River to Tonle Sap Lake, and the annual average volume of the reverse flow is 2.843 billion m^3, only 7.5% of that from Mekong River to Tonle Sap Lake (Li et al., 2018c; Changjiang Water Resources Commission of the Ministry of Water Resources, 2013).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1387513895

Poyang Lake accounts for a crucial part in the watershed of Yangtze River and the overall ecological system; likewise, Tonle Sap Lake plays an important part in the watershed of Mekong River and the ecological system. Therefore, it is the key to ensure the ecological health of the river and the lake by fully understanding the correlation between Mekong River and Tonle Sap Lake and providing a scientific basis for river and lake regulation. By referring to the research achievements on the relationship between Yangtze River and Poyang Lake, this study made use of long-series hydrological data of several hydrological monitoring stations on the mainstream of Mekong River (*Fig. 2*), including the Kompong Cham station, Phnom Penh Port station on Tonle Sap Lake, Prek Kdam Station and Kompong Luong Station, to analyze the characteristics of changes in water volume, influencing factors and hydrological conditions of the reverse flow from Mekong River to Tonle Sap Lake. Here, the Kompong Cham station is similar to Jiujiang Station on Yangtze River, the Phnom Penh Port station is a stream gauging station, which is similar to Hukou station on Poyang Lake, the Prek Kdam Station is a hydrological station, which is similar to Xingzi Station on Poyang Lake in terms of the water-level monitoring location, but similar to Hukou Station on Poyang Lake in terms of the flow monitoring location, the Kompong Luong Station is also a stream gauging station, which is similar to Duchang Station on Poyang Lake.

The objectives of this study were as follows: 1) characterize the variation of duration and volume of reversal flow from Mekong River to Tonle Sap Lake; 2) identify the major factors of reversal flow; 3) analyze the hydrological conditions of reversal flow.

It is expected to facilitate an in-depth understanding of the interactive mechanism between Mekong River and Tonle Sap Lake, and provide a scientific basis for the integrated treatment of Tonle Sap Lake, thereby better understand the interactive mechanism between Yangtze River and Poyang Lake.

Materials and methods

Study area

Tonle Sap Lake basin is situated on the Cambodia Mekong Delta, and covers a total area of 81,763 km^2. It is the important sub-area within the Lower Mekong Basin due to its complex hydrological and ecological system, rich biodiversities and critical basin development issues (Mak et al., 2012). The Tonle Sap Lake, located at the center of the sub-area as shown on *Figure 3,* is the largest permanent freshwater lake in Southeast Asia. The Lake is connected to the Mekong through the Tonle Sap River at Chaktomuk conjunction in Phnom Penh, about 120 km to the southwest outlet of the Lake. The lake is 371 km long, with an area of around 2,744 km^2 in the dry season and during the wet season it can swell to four or seven times this area. The most prominent feature of the sub-area is the Tonle Sap Lake with its interesting hydrological and ecological functions for the whole Mekong River basin. The water flow of the Tonle Sap River and lake is closely related to the hydrological performance of the Mekong River. The lake discharges water (out-flow), through the Tonle Sap River, into the Mekong River during the dry season. During the wet season, however, the Mekong River becomes bloated by run-off, thus forces the Tonle Sap River to reverse its flow direction (from out-flow to in-flow), filling the lake instead of draining it. The inflow inundates the surrounding forested floodplains, and supports the rich biodiversity of the lake eco-system.

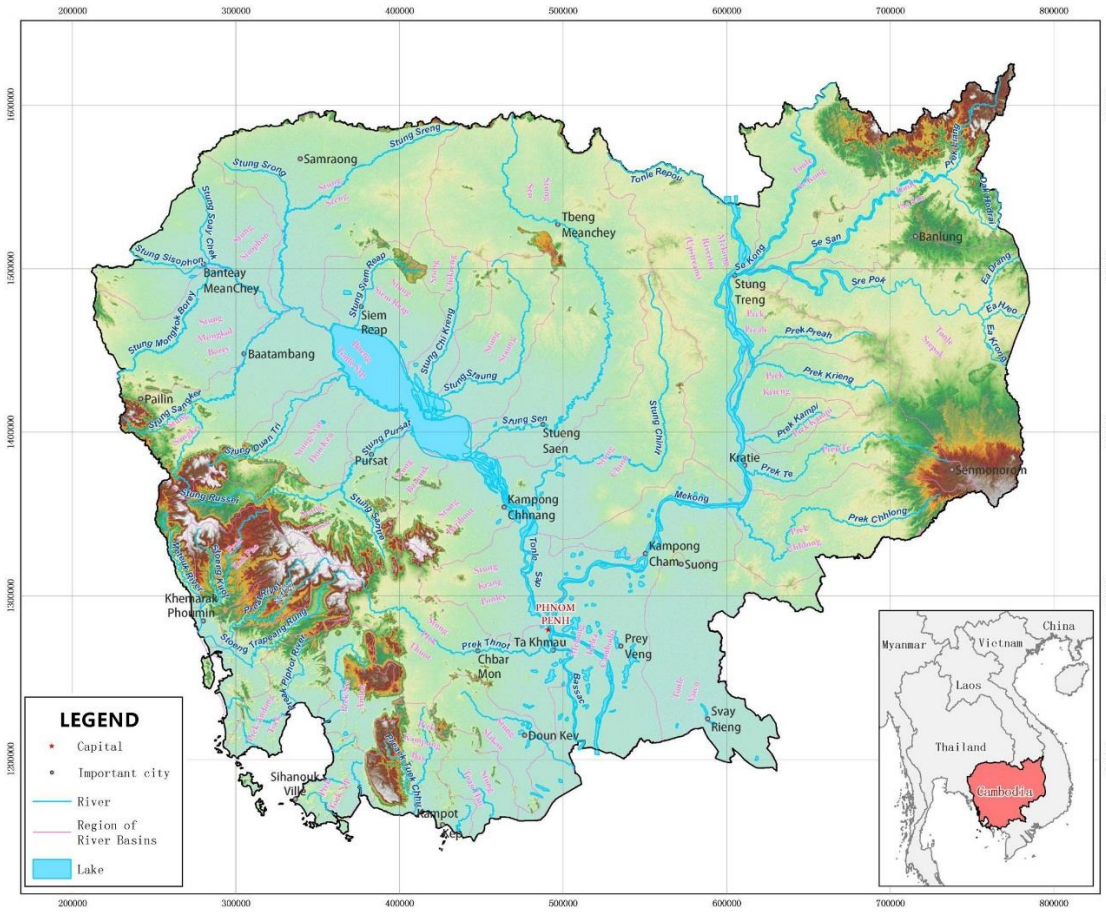

Figure 3. *Map of River Basin in Cambodia*

Hydrological stations and data collection

There are are four controlling hydrological stations installed on the Tonle Sap Lake Area and Cambodia Mekong Delta, namely, Kompong Cham Station, Phnom Penh Port Station, Prek Kdam Station and Kompong Luong Station, as shown in *Figure 2*. Among them, Kampong Cham Station is located at the mainstream of Mekong River, with a distance of around 103 km from the exit of Tonle Sap River and a catchment area of 660,000 km^2 which accounts for 81% of the total area of the whole basin; Phnom Penh Port Station is located at the end of the Tonle Sap River, with a distance of about 1 km from the exit of Tonle Sap River, so it can be used as the water level representative station at the intersection of the Mekong River and the Tonle Sap River; Prek Kdam Station is the inflow-outflow controlling station of Tonle Sap Lake, about 32 km from the exit of Tonle Sap River; Kampong Luong Station is the water-level representative station of Tonle Sap Lake, which is about 172 km far from the exit of Tonle Sap River.

The hydrological data for the above four river-lake controlling stations collected from Ministry of Water Resources and Meteorology in Cambodia and Mekong River Commission are not homogenous, because not all records started in the same time and/or not all stations have the same number of records. 52 years of daily discharge data from 1960 to 2011 is available for Kompong Cham Station, 58 years of daily water level data from 1960 to 2017 is available for Phnom Penh Port Station, 17 years

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1387513895

of daily water level data from 1995 to 2011 and 58 years of daily water level data from 1960 to 2017 are available for Prek Kdam Station, and 19 years of daily water level data from 1999 to 2017 is available for Kampong Luong Station.

To ensure the consistency of hydrological analysis, the discharge data with the same period from 1995 to 2011 of Kompong Cham Station and Prek Kdam Station, and the water level data with the same period from 1999 to 2011 of Phnom Penh Port Station, Prek Kdam Station and Kampong Luong Station were used. The water level data uses the Cambodian National Elevation Datum (M.S.L. Hatein datum).

Data analysis

The inflow from the Mekong River via the Tonle Sap River can be computed from the observed discharge data at Prek Kdam Station. Therefore, the timing of when flow reversal occurs, the variation characteristics of duration and volume of reversal flow, and the ratio of the reverse volume accounts for the total volume of Mekong River at the Kompong Cham Station, which are of importance for the ecological functioning of the Tonle Sap system and wider Lower Mekong River Basin, have been statistically analysed at the Prek Kdam monitoring site. The water level at Phnom Penh Port Station, Prek Kdam Station and Kampong Luong Station and a correction for backwater based on the water level difference between Phnom Penh Port and Kampong Luong were used to identify the major factors and hydrological conditions of reversal flow from Mekong River to Tonle Sap Lake.

Results

Time series variation characteristics of reversal volume

According to measured flow records from 1995 to 2011 at the Prek Kdam station, this study concluded the duration and volume of reverse flow from Mekong River to Tonle Sap Lake during flood seasons, as shown in *Figures 4* and *5*. It can be seen that the flow reversal from Mekong River to Tonle Sap Lake occurs every year, and the reverse flow duration is long and reversal volume is large. On average, it lasts 122 days and reaches 37.7 billion m^3 in volume every year. The reversal occurs from May to October, especially from July to September – these three months account for 71% of the whole time and 88.6% of the total amount of reversal in a year. The reversal usually reaches its maximum in August during which flow reversal happens every day and reaches an annual average volume of 16.2 billion m^3, making up 43% of the yearly total.

According to *Figure 4,* the longest duration of backflow lasted 149 days in 1999, and the shortest lasted 73 days in 1995, with a variation amplitude of 76 days and a variation coefficient of 0.14. The maximum annual reversal volume is 49.6 billion m^3 in 2005 and the minimum is 21.3 billion m^3 in 1998, with a variation amplitude of 28.3 billion m^3 and a variation coefficient of 0.24. The annual average of flood peak flow from Mekong River was 8402 m^3/s, with the maximum at 10679 m^3/s in 1997 and the minimum at 4584 m^3/s. Thus, the maximum/minimum ratio of flood peak flow and annual volume were both 2.33. In general, the reversal duration and volume increased slightly year by year, with the average reversal duration increased by one day per year, and the average reversal volume increased by 365 million m^3 per year.

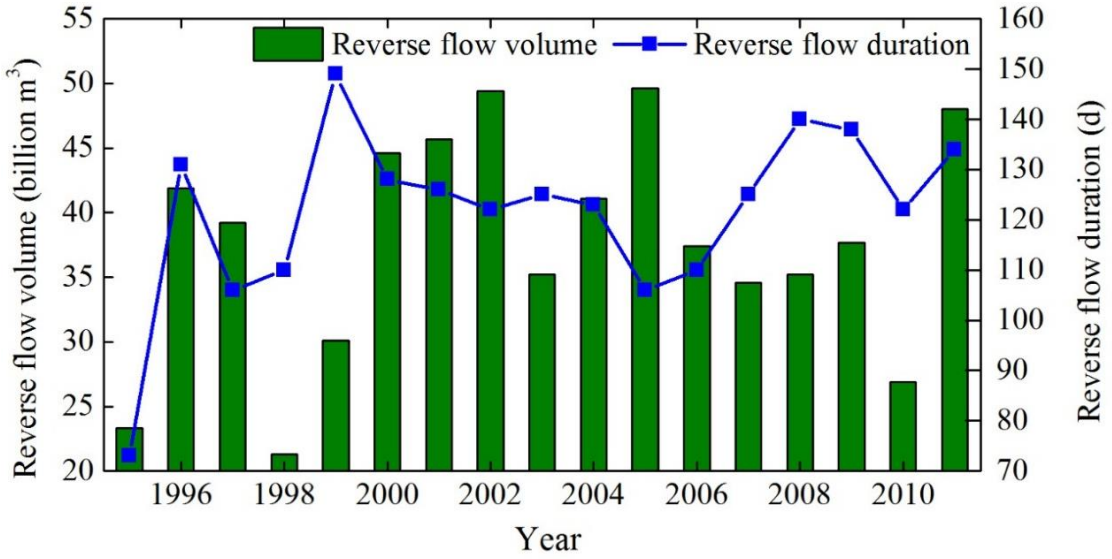

Figure 4. *Inter-annual variation of reverse flow duration and volume from Mekong River to Tonle Sap Lake*

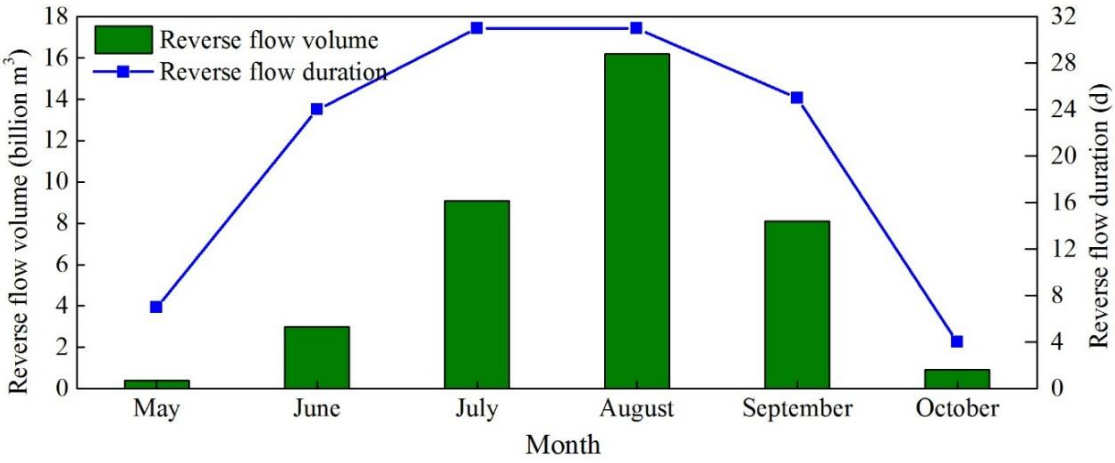

Figure 5. *Annual distribution of reverse flow duration and volume from Mekong River to Tonle Sap Lake*

Proportion of reverse volume to total volume from Mekong river in the same period

According to flood statistics from 1995 to 2011, this study achieved the ratio of the reverse volume against the total volume from Mekong River at the Kompong Cham station, as shown in *Figure 6*. By means of reversal flow, Tonle Sap Lake regulates and stores 10% to 18% (averaged at 14%) of the total flood volume of Mekong River in the flood season. The diversion percentage reaches the peak in August at 17.7%, followed by July (16.6%), June (13.2%), September (10.5%), May (8.9%) and October (8.5%). When the backward flow reaches the peak, the Tonle Sap Lake reduces the flood peak discharge of Mekong River by 15% to 24%, averaged at 20% over the from 1995 to 2011. Overall, the annual variation of the proportion of reverse volume to total volume from Mekong River in the same period is not obvious, and it is slightly increasing.

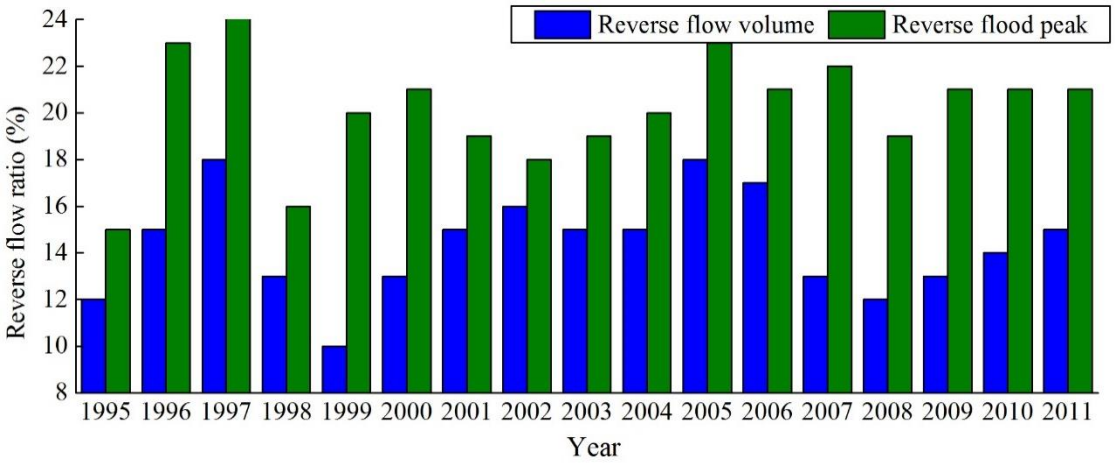

Figure 6. *The ratio of reverse flow volume in flood season accounting for Mekong River runoff in the same period*

Discussion

Influencing factors of reversal flow

The factors that affect the reversal flow from Mekong River to Tonle Sap Lake include the inflow of Mekong River, incoming water from the tributaries of Tonle Sap Lake, runoff difference (or water level difference) between Mekong River and Tonle Sap Lake, tidal water level difference at the beginning of flood season, etc.

(1) Runoff of Kompong Cham Station in Mekong River

According to the observation data in the flood season (May - October) from 1995 to 2011, the correlation between the flood runoff of Kompong Cham Station in mainstream of Mekong River and reversal flow volume is shown in *Figure 7*. It can be seen that the correlation is scattered, indicating that the flood runoff of the Mekong River is not a decisive factor of reversal flow.

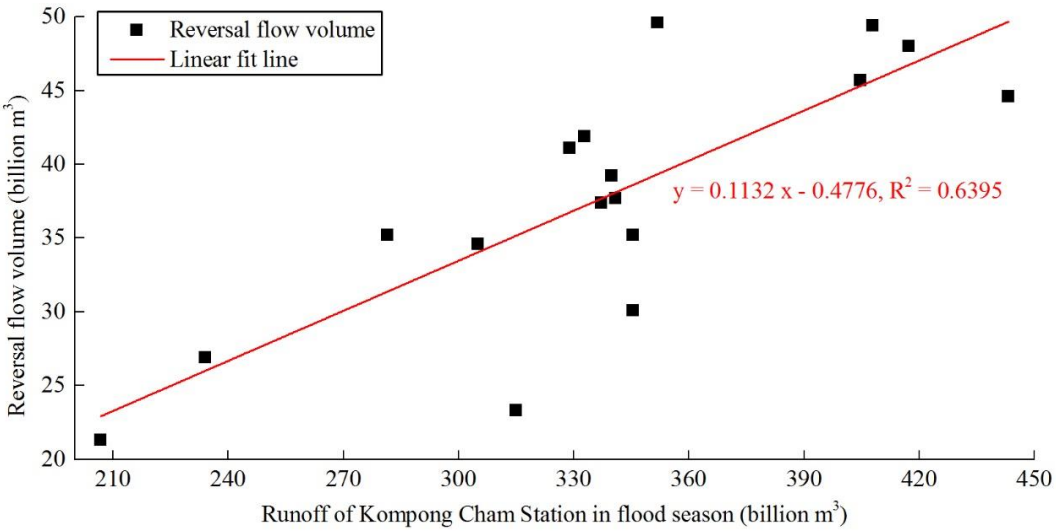

Figure 7. *Correlation between the flood runoff of Kompong Cham Station in mainstream of Mekong River and reversal flow volume*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1387513895

The flow of Kampong Cham Station at the main stream of Mekong River when the flow reversal of Tonle Sap River occurs is shown in *Figure 8*. It can be seen that when the flow of Kampong Cham Station is above 3000 m^3/s, the phenomenon of backflow may occur. Among them, the probability of backflow is the largest when the flow of Kampong Cham Station is from 10000 to 40,000 m^3/s, which accounts for 67.31% of the total days of backflow. The reversal flow increases with the rise of the flow of Kampong Cham Station, but the correlation between them is scattered. In May when the runoff of Mekong River is small, the probability and flow of backflow are the minimum, with average annual reverse duration of only 7 days and reverse flow of 471 m^3/s. From June to July, the runoff of Mekong River has increased significantly, and the probability and flow of backflow increased accordingly, with average annual backflow duration of 24 days and 31 days respectively, and average reverse flow of 1286 m^3/s and 3407 m^3/s respectively. In August, the runoff of Mekong River above Phnom Penh reaches the peak, which accounts for 21.0%~23.1% of the annual runoff, makes the reversal probability and backflow reach the maximum, the backflow has occurred in the whole month, and the average reversal flow is 6049 m^3/s. From September to October, with the increase of inflow from the tributaries of Tonle Sap Lake (reaches its peak) and the decrease of runoff from Mekong River, the probability of backflow and the reversal flow began to decline, with average backflow time of 25 days and 4 days, and average reverse flow of 3775 m^3/s and 2392 m^3/s, respectively.

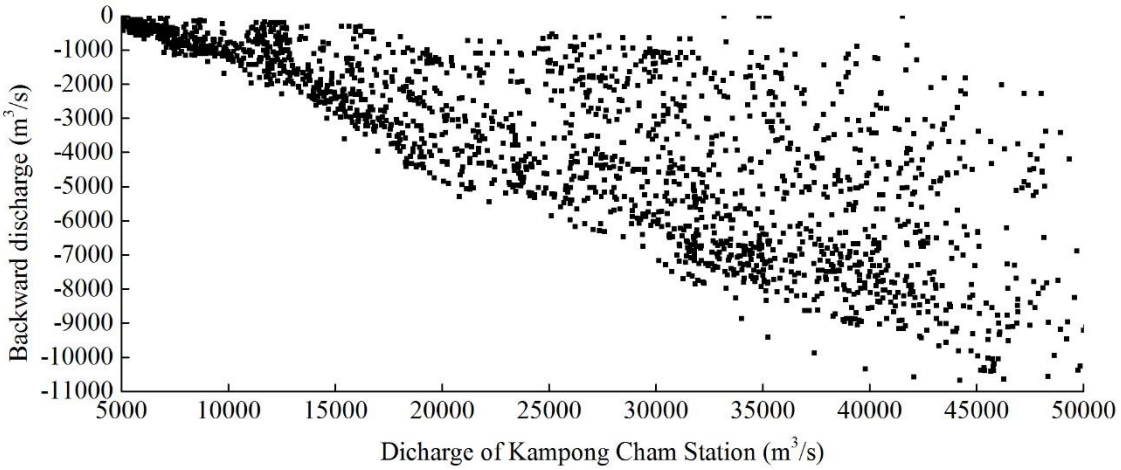

Figure 8. *The flow of Kampong Cham Station when the flow reversal of Tonle Sap River occurs*

Figure 9 compares the average daily runoffs between the Kompong Cham station on Mekong River and the Prek Kdam station on Tonle Sap River during the flood season from June to September in multiple years from 1995 to 2011. It shows that the volume of reversal flow increases with the increase of discharge from the Mekong River (expressed by the rate of increase) and has little connection with the rate of flow of Mekong River.

(2) River-lake runoff difference

Figure 10 compares the discharge from Mekong River and that from Tonle Sap Lake for multiple years from 1995 to 2011. It shows that the ratio of discharge of Mekong River against that of Tonle Sap Lake reaches the peak in August (15:1), followed by

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1387513895

July (11:1), September (10:1) and June (8:1), October (7:1) and May (5:1). The volume of reverse flow follows the same order in time (i.e. August marks the maximum and May the minimum), which implies the influence of the difference in the runoff between Mekong River and Tonle Sap Lake on the volume of the reverse flow.

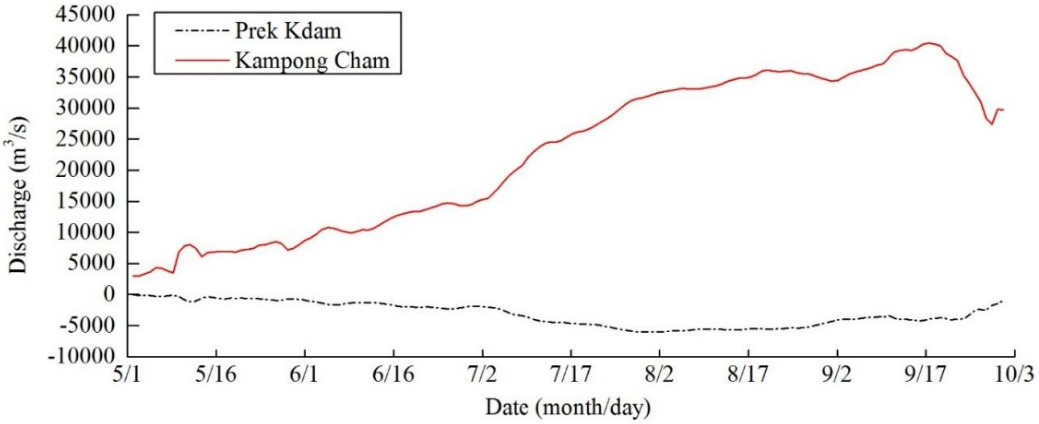

Figure 9. *Multi-year average daily discharge of Prek Kdam station and Kompong Cham station in reversal flow season*

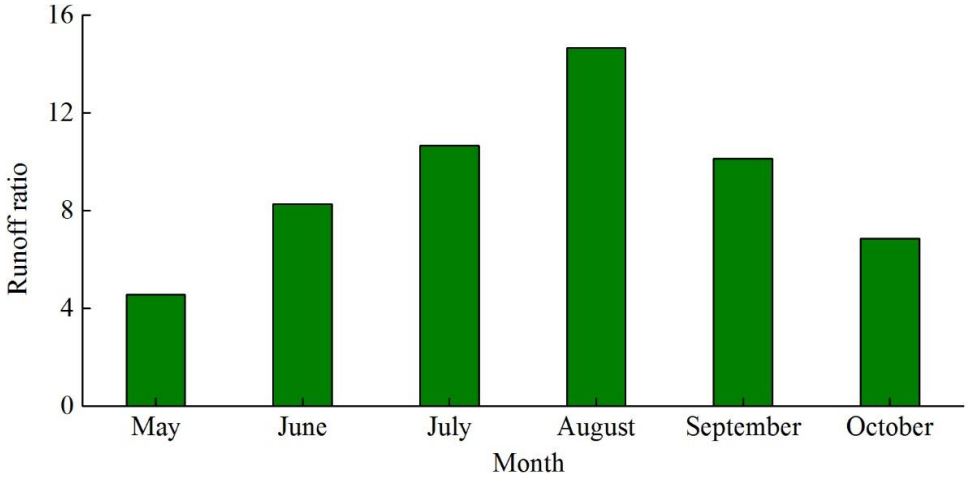

Figure 10. *Monthly runoff ratio between Mekong River and Tonle Sap Lake*

The deviation (the annual value - the average value of the years from 1995 to 2011) of the runoff difference between Kampong Cham Station in Mekong River and Tonle Sap Lake area during the flood season and the deviation of backwater volume were compared and shown in *Figure 11*. It can be seen that in 2001, 2002, 2005 and 2011, the runoff of Mekong River in flood season is abundance, and that of Tonle Sap Lake area is dry, so the backwater volume in each year is more than the average annual value; the runoff of Mekong River in 2006 and 2007 is dry, and that of Tonle Sap Lake area is abundance, so the backwater volume is less than the average annual value. In general, the amount of backwater is basically corresponding to the river-lake runoff difference, except for the partial years, which indicates that the reverse flow is not only related to the inflow from Mekong River and Tonle Sap Lake, but also affected by other factors.

DOI: http://dx.doi.org/10.15666/aeer/1706_1387513895

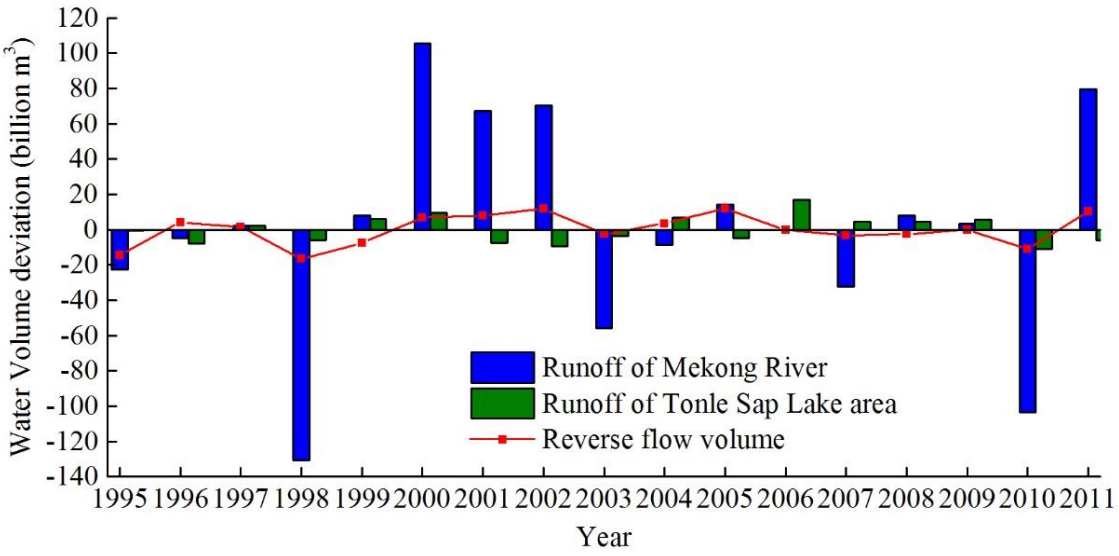

Figure 11. *The deviation comparison between river-lake runoff difference and backwater volume during the flood season*

(3) River-lake water level difference

The water level of Phnom Penh Port, Prek Kdam and Kampong Luong stations in the Tonle Sap Lake area in 2001 is shown in *Figure 12*. It can be seen that when the flood of Mekong River backward flows into the Tonle Sap Lake, the water levels of the above three stations are successively lowered from the bottom to the upper, indicating that the water level difference between Mekong River and Tonle Sap Lake is one of the conditions for the reversal flow of Mekong River.

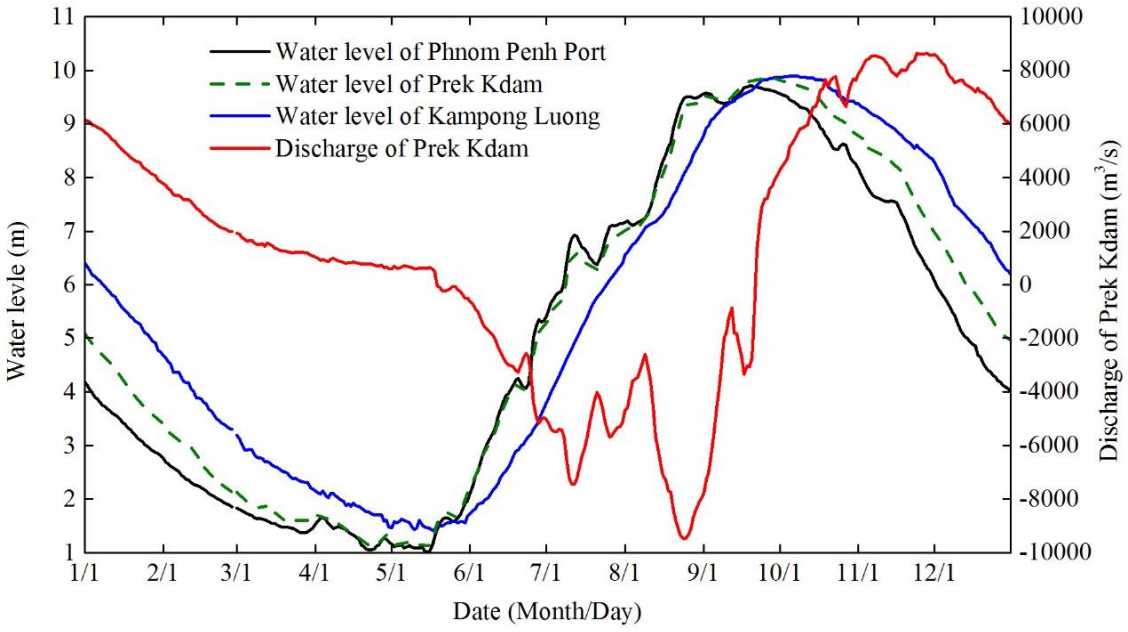

Figure 12. *Water level process in 2001 of hydrological stations in Tonle Sap Lake area*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1387513895

According to long-series statistics of the daily water level obtained from major monitoring stations, the water level during the flood season in Mekong River changes more frequently than that in Tonle Sap Lake. The annual average increase rate of water-level declines from 0.16 m/d at the Kampong Cham station on Mekong River, to 0.09 m/d at the Phnom Penh Port station at the Tonle Sap River entrance, 0.08 m/d at the Prek Kdam station on Tonle Sap River and 0.06 m/d at the Kampong Luong station on the Tonle Sap Lake. It indicates that difference in the level of water between Mekong River and Tonle Sap Lake, when the former is higher than the latter, is the major hydrodynamic force that drives the reversal flow, as shown in *Figure 13*.

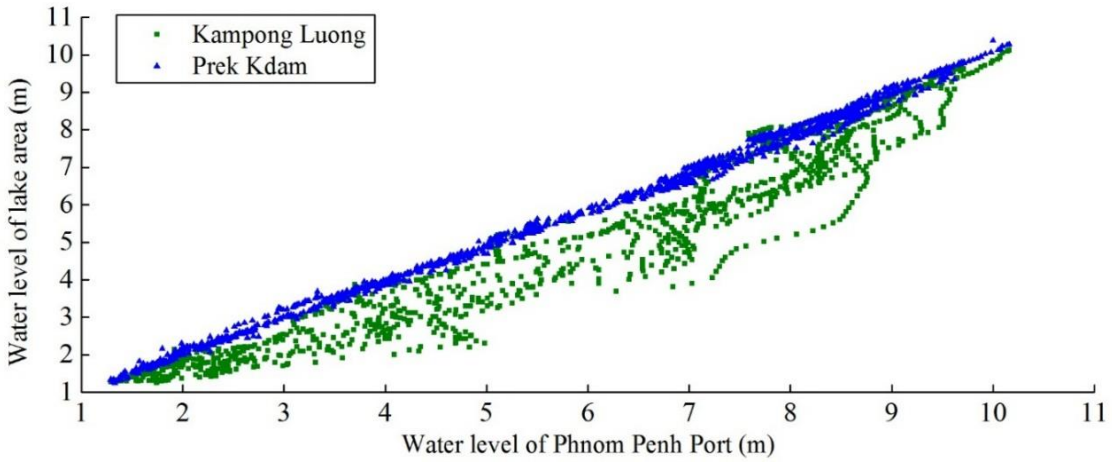

Figure 13. *Water level correlation among Prek Kdam station, Kompong Luong station and Phnom Penh Port station*

Figure 14 shows the correlation between the reverse flow and the difference in the water level between the river and the lake at the Prek Kdam station. It can be seen that the water level difference between the water level at the Kompong Luong station and the water level at the Phnom Penh station is negative most of the time (92%), which indicates that difference in the water level is a major contributor to the reversal flow.

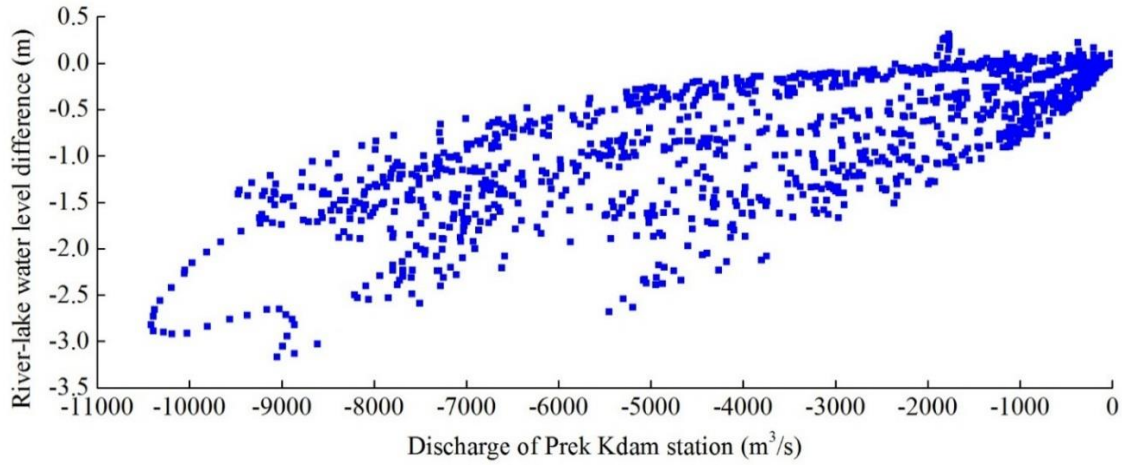

Figure 14. *Correlation between discharge and water level difference in Prek Kdam station*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1387513895

According to statistics, the reverse flow from Mekong River to Tonle Sap Lake increases with the increase of difference in their water levels when the water level at the Prek Kdam remains the same, as shown in *Figure 15*.

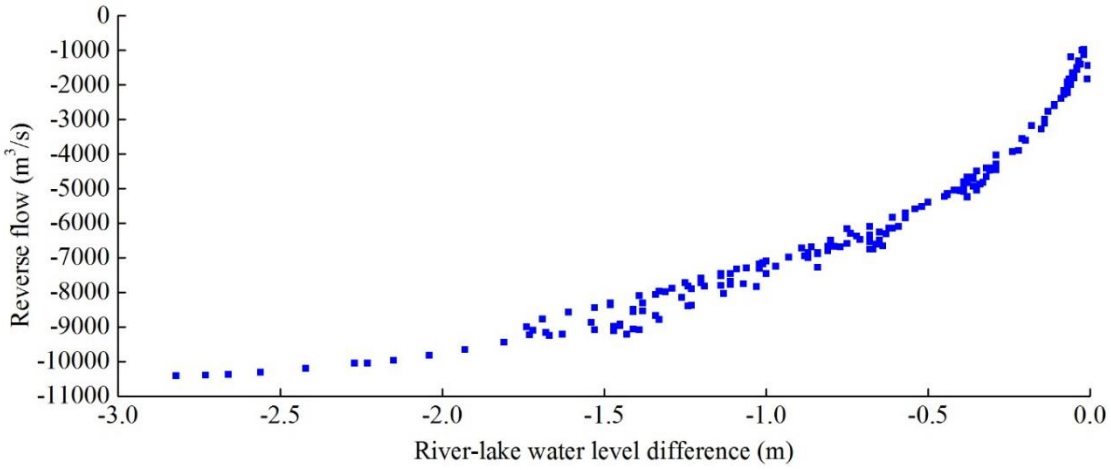

Figure 15. *Correlation between backward discharge and water level difference when the water level of Prek Kdam station reaches 8~9 m*

With the difference in the water level between Mekong River and Tonle Sap Lake as the parameter, this study plots a chart of the average daily flow of Tonle Sap River at the Prek Kdam station, the average daily water level of Tonle Sap Lake at the Kompong Luong station and the average daily flow of Mekong River at the Kompong Cham station. The cluster of correlation between the amount of reverse flow and the flow of Mekong River, as well as the correlation between the water level of Tonle Sap Lake and the discharge of Mekong Lake are established according to the center of point groups, as shown in *Figure 16*. It can be seen that when the difference in the levels of water between Mekong River and Tonle Sap Lake remains constant, the amount of reverse flow increases with the increase of the flow of Mekong River; when the flow of Mekong River remains constant, the volume of reverse flow increases with the increase of difference in the water levels. Therefore, the discharge from Mekong River and the difference in the levels of water are both factors of the reverse flow, and the difference in runoffs directly determines the difference in the levels of water.

(4) Water level of Tonle Sap River

According to statistics from 1999 to 2011, the reverse flow increases linearly with the rise of water level at the Prek Kdam station when the river-lake water level difference remains constant, as shown in *Figure 17*. Therefore, the water level of Tonle Sap River accounts for another factor that influences the reversal flow.

(5) Tidal water level difference at the beginning of flood season

According to the analysis, only the reversal flow at the beginning of the flood period from May to June may be affected by the tides in the South China Sea. The average tidal range is less than 0.2 m, which may result in backflow phenomenon when the daily average water level of Kampong Luong Station in Tonle Sap Lake is higher than that of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1387513895

Phnom Penh Port Station in Tonle Sap River. According to the statistics from 1999 to 2011, the phenomenon occurred for 34 days in total for 10 years. Except for the water level difference between Mekong River and Tonle Sap Lake reached 0.29 m on May 15, 1999, the river-lake water level difference on other dates was less than 0.12 m. The average river-lake water level difference is 0.05 m, and daily average backflow is 147 m^3/s.

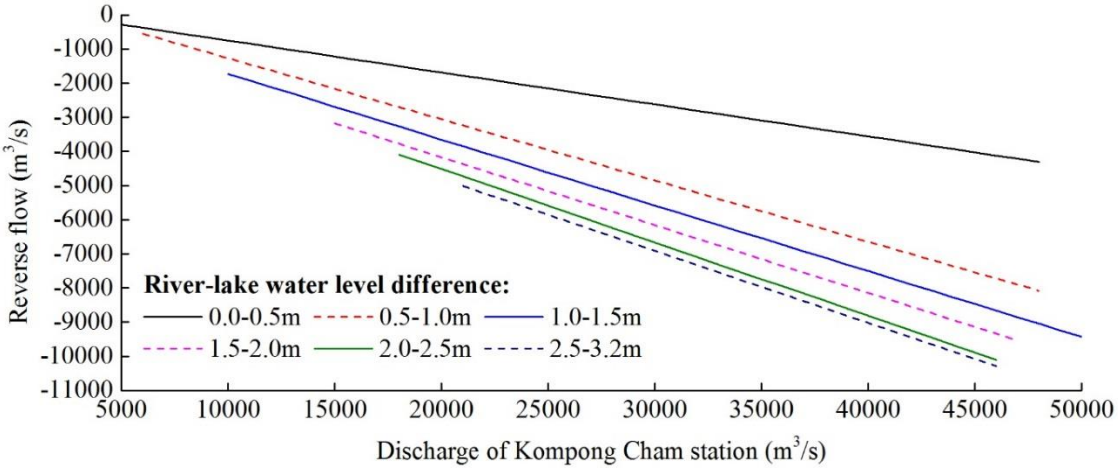

Figure 16. *Correlation between the discharge of Prek Kdam station and Kompong Cham station*

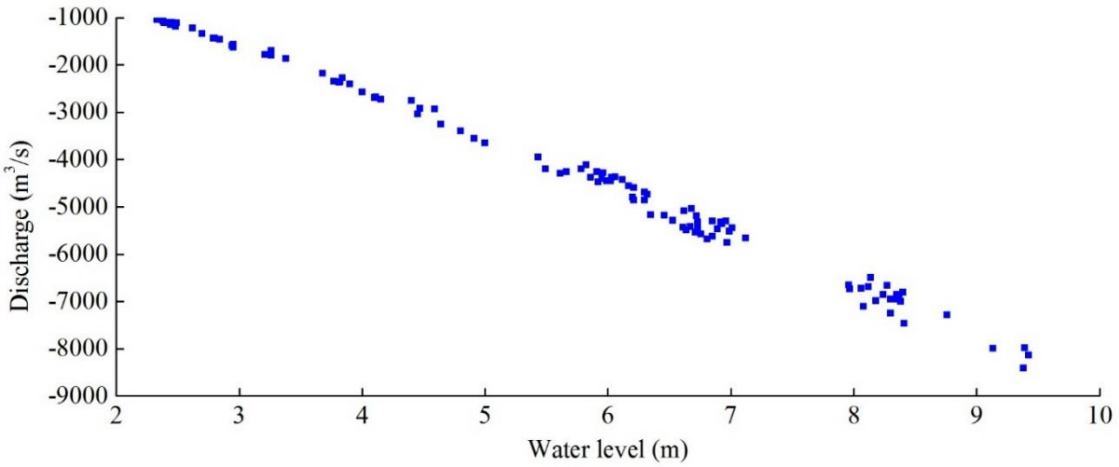

Figure 17. *Correlation between water level and discharge of Prek Kdam station when the water level difference between Mekong River and Tonle Sap Lake reaches 0.8~1.0 m*

Hydrological conditions of the reversal flow

The time, duration and volume of reversal flow are closely linked to the hydrological conditions of Mekong River and Tonle Sap Lake. In light of the geomorphic and hydrological features of Cambodia Mekong Delta and Tonle Sap Lake area, this study selects the water level difference between Mekong River and Tonle Sap Lake (representing the flow resistance) and the water level at the Prek Kdam Station (representing the wetted cross-section area of Tonle Sap River) as the control indices to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1387513895

study the hydrological conditions of reversal flow. The water level difference between the Kompong Luong Station and Phnom Penh Station is the precondition for the reverse flow as it leads to a difference in the potential energy between the Mekong River and the Tonle Sap Lake. The water level at the Prek Kdam Station is the driving condition of the reversal. When the flow rate remains constant, the higher the water level is, the larger the wetted cross-section area of Tonle Sap River and the larger the discharge will be.

According to statistics from 1999 to 2011, the correlation between the reverse flow and the river-lake water level difference under different water levels at the Prek Kdam station is shown in *Figure 18* and *Table 1*. It can be found that when the water level at the Prek Kdam station remains the same, the reverse flow increases with the increase of the water-level difference between Mekong River and Tonle Sap Lake; when the reverse flow remains the same, the river-lake water level difference declines with the increase of the water level at the Prek Kdam station; when the river-lake water-level difference remains the same, the reverse flow rises as the water level at the Prek Kdams station rises. The correlation coefficient between the reverse flow and the water-level difference between Mekong River and Tonle Sap Lake varies from 0.85 to 0.98 when the water level at the Prek Kdam station varies from 1.0 to 10.5 m, and the correlation is stronger when the water level is higher.

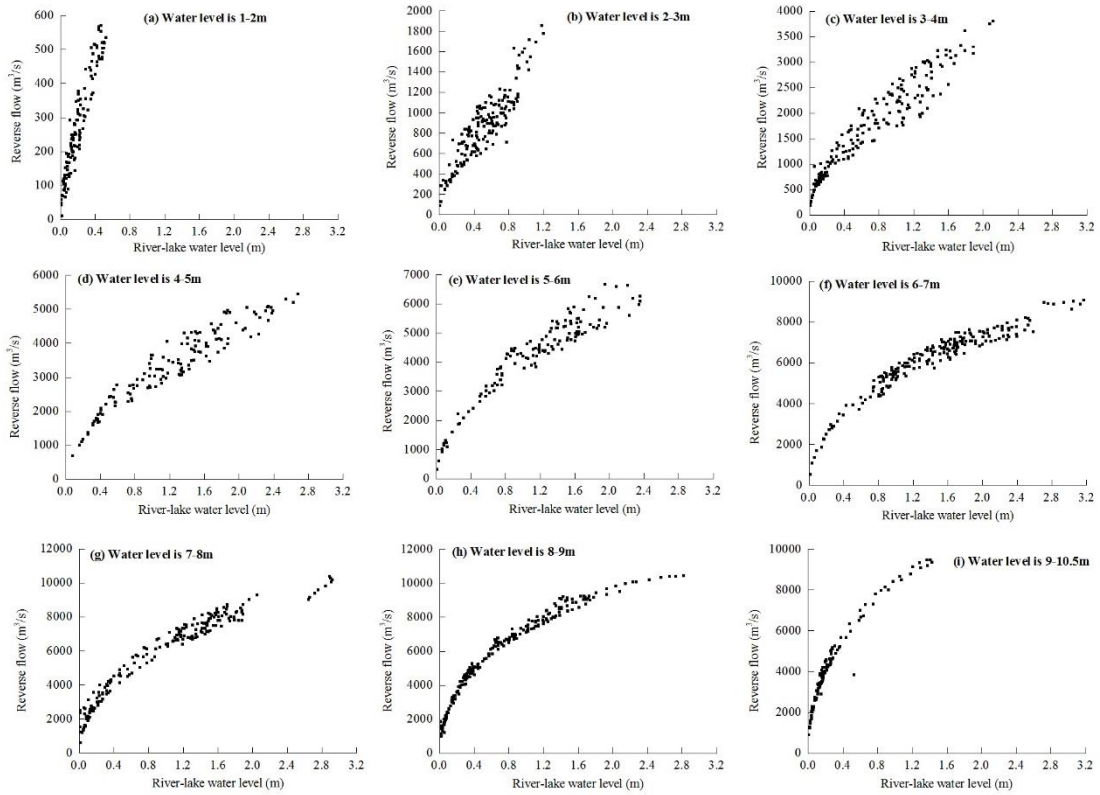

Figure 18. *Correlation between reverse flow and river-lake water level difference*

As the reverse flow and the water-level difference are positively correlated to the water level at the Prek Kdam station, the product of the water-level difference and the water level of the Prek Kdam station are set as the independent variable to identify its correlation to the reverse flow. On the basis of sufficient simulation and analyses, two

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1387513895

respective power function coefficients are assigned to the water-level difference and the water level at the Prek Kdam station to reduce the error of simulation. On that basis, this study builds an optimization model for the correlation among the reverse flow, the water-level difference, and the water level at the Prek Kdam station, as shown in *Equation 1* and *Figure 19*. It shows that the reverse flow is linearly correlated to the water-level difference and the water level at the Prek Kdam station, and the correlation coefficient reaches 0.9966, which proves the rationality of the model.

$$Q_{PK} = -413.73H + 80.54 = -413.73h_{PK}^{1.36}\left|h_{KL} - h_{JBG}\right|^{0.46} + 80.54 \quad \text{(Eq.1)}$$

where Q_{PK} refers to the discharge (m^3/s) at the Prek Kdam station; h_{JBG}, h_{PK} and h_{KL} are the respective water level (m) at the Phnom Penh station, the Prek Kdam station and the Kompong Luong station.

Table 1. *Correlation coefficient between reverse flow and river-lake water level difference*

Water level of Prek Kdam station (m)	a	b	Correlation coefficient R^2
1.0~2.0	852.49	0.7029	0.8751
2.0~3.0	1264.3	0.5542	0.8489
3.0~4.0	2203	0.5306	0.9554
4.0~5.0	3059.3	0.5599	0.9472
5.0~6.0	4072.1	0.5419	0.9753
6.0~7.0	5318.6	0.4838	0.9757
7.0~8.0	6321.5	0.4258	0.9247
8.0~9.0	7304.9	0.4526	0.9690
9.0~10.5	8549.5	0.4741	0.9779

The correlation between the reverse flow and the water-level difference is presented as $Q_{PK} = a \cdot (h_{JBG} - h_{KL})^b$, where Q_{PK} denotes the reverse flow at the Prek Kdam station (m^3/s), h_{KL} and h_{JBG} denote the respective level of water (m) at the Kompong Luong station and the Phnom Penh station; a and b are the fitting parameters

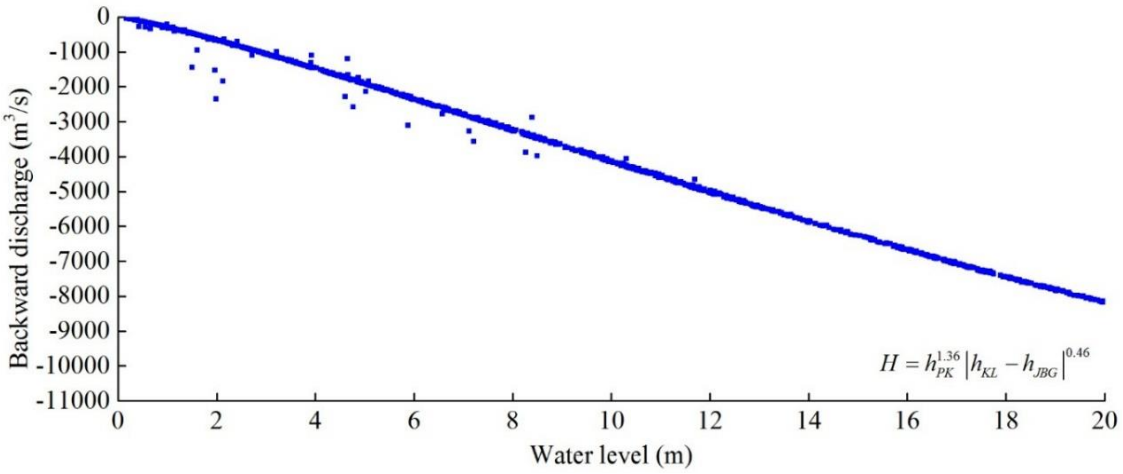

Figure 19. *Correlation among reverse flow, water level difference and water level of Prek Kdam station*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1387513895

According to quantitative analysis by *Equation 1,* the relationship among the reverse flow from Mekong River to Tonle Sap Lake, the water level at the Prek Kdam station and the difference in the water level between Mekong River and Tonle Sap Lake are achieved, as shown in *Table 2.* It shows that the reverse flow is small when the water level of Tonle Sap Lake is low or when the water level difference is small, and the reverse flow rises when the water level of Tonle Sap Lake or the hydraulic head difference increases. That is to say, the volume of reverse flow is positively correlated to the water level difference between Mekong River and Tonle Sap Lake. When the reverse flow reaches 3000 m^3/s, the required hydraulic head difference between Mekong River and Tonle Sap Lake declines from 1.31 m, 0.68 m, 0.40 m, 0.26 m, 0.17 m to 0.12 m as the water level at the Prek Kdam station rises from 4 m, 5 m, 6 m, 7 m, 8 m and 9 m. When the water level at the Prek Kdam station remains at 8m, the respective reverse flow from Mekong River to Tonle Sap Lake are 3000 m^3/s, 4000 m^3/s, 5000 m^3/s, 6000 m^3/s, 7000 m^3/s, 8000 m^3/s and 9000 m^3/s when the hydraulic head difference between Mekong River and Tonle Sap Lake reaches 0.17 m, 0.30 m, 0.48 m, 0.71 m, 0.99 m, 1.36 m and 1.84 m. When the difference in the water level between Mekong River and Tonle Sap Lake is 1 m, the respective water level of the Prek Kdam station needs to reach 2.11 m, 3.33 m, 4.38 m, 5.33 m, 6.23 m, 7.11 m, 7.98 m, 8.88 m and 9.86 m so that the reverse flow can reach 1000 m^3/s, 2000 m^3/s, 3000 m^3/s, 4000 m^3/s, 5000 m^3/s, 6000 m^3/s, 7000 m^3/s, 8000 m^3/s and 9000 m^3/s.

Table 2. *Correlation among reverse flow from Mekong River to Tonle Sap Lake, river-lake water level difference and water level of Prek Kdam station*

Water level of Prek Kdam station (m)	**Water level difference between Mekong River and Tonle Sap Lake (m), reverse flow (m^3/s)**

10	3185	6905	9137	10329	10885

Conclusion

According to the statistical analysis, some conclusions are included as follows:

(1) The flood reversal flow from Mekong River lasts long and is large in volume during the flood season. For long series of years on average, the reversal lasts 122 days and the volume of reverse flow is 37.7 billion m^3, with the flood peak remaining at 8402 m^3/s. The reversal volume accounts for 14% of the volume of Mekong River in the same time period and cuts 20% of the flood peak on average for years. The reversal occurs mainly from July to September and the maximum volume of reverse flow occurs in August, accounting for 43% of the volume in a whole year and 17.7% of the total volume from Mekong River in the same time period. The volume of reverse flow shows

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1387513895

little change over the years and the extreme ratio of the volume and flood peak of reverse flow remain at 2.33.

(2) The reverse flow is mainly subject to factors including the difference in runoff between Mekong River and Tonle Sap Lake, the difference in the water level between Mekong River and Tonle Sap Lake, and the water level of Tonle Sap River. Among these factors, the difference in runoff determines the difference in the water level. When the water level at Tonle Sap River remains constant, the volume of reverse flow increases as the difference in the water level between the river and the lake (flow resistance) increases. When the difference in the water level remains constant, the volume of reverse flow increases as the water level (the wetted cross-section area) of Tonle Sap River increases.

(3) The hydrological conditions of the reverse flow include the difference in the water level between the river and the lake and the water level at Tonle Sap River. When the water level of Mekong River exceeds that of Tonle Sap Lake, the reverse flow is linearly correlated to the product of the water level of Tonle Sap River to the power of 1.36 multiplied by that water-level difference between Mekong and Tonle Sap Lake to the power of 0.46. When the level of water at the Prek Kdam station on Tonle Sap Lake is 8 m, the hydraulic head difference between the river and the lake needs to reach 0.17 m, 0.30 m, 0.48 m, 0.71 m, 0.99 m, 1.36 m and 1.84 m so that the reverse flow can reach 3000 m^3/s, 4000 m^3/s, 5000 m^3/s, 6000 m^3/s, 7000 m^3/s, 8000 m^3/s, 9000 m^3/s respectively. When the difference in the water level between the river and the lake is 1 m, the water level at the Prek Kdam station has to reach 2.11 m, 3.33 m, 4.38 m, 5.33 m, 6.23 m, 7.11 m, 7.98 m, 8.88 m and 9.86 m, hence the reverse flow can reach 1000 m^3/s, 2000 m^3/s, 3000 m^3/s, 4000 m^3/s, 5000 m^3/s, 6000 m^3/s, 7000 m^3/s, 8000 m^3/s, 9000 m^3/s, respectively.

Objective understanding the variation characteristics, influencing factors and hydrological conditions of the reverse flow from Mekong River to Tonle Sap Lake is conducive to the comprehensive management of Cambodia Mekong Delta and Tonle Sap Lake area. Limited to data conditions, this study is mainly based on the flow records from 1995 to 2011 and the water level records from 1999 to 2011, so further collection and analysis based longer series of hydrological data are needed in the future. The regulation and storage effect of Tonle Sap Lake on the flood of Mekong River, and the positioning of Tonle Sap Lake from the perspective of overall flood control of Mekong River should be further studied. In addition, in order to further study the internal mechanisms of the relationship between Mekong River and Tonle Sap Lake, the discharge capacity of Mekong River, the diversion flow and discharge sediments capacity of Tonle Sap River, the flood control capacity of Tonle Sap Lake should be considered, so it is recommended to strengthen the prototype observation of the river topography.

Acknowledgments. This research was financially supported by the National Key Research and Development Program of China (2017YFC0405301) and China-Asean Maritime Cooperation Fund "Langcang-Mekong Water Resources Cooperation Project".

(Received 22nd May 2019; accepted 25th Oct 2019)

Abstract. The aim of this study was to assess the effect of ecological and integrated farming on the occurrence of epigeic animal groups. The earth trap method was used, were exposed in *Pisum sativum* and *Hordeum vulgare*. The experiment was performed from 2015 to 2017 at the research fields of the Plant Biology and Ecology Centre in Nitra. During the three-year period, 11,866 exemplars were collected from 21 taxonomic groups. Under integrated farming of 5,456 exemplars belonging to 20 groups were collected, in the ecological farming of 6,410 exemplars belonging to 19 groups were collected. The decreasing tendency of abundance in most groups was recorded. Both types of farming showed the Coleoptera, Acarina, Araneida, Collembola as the highly dominant groups. The Opilionida occurred subdominantly. The occurrence of others was recedent or subrecedent. The presence of these animal groups in the agroecosystem increases its biodiversity. The impact of cultivated crops, temperature and type of farming on occurrence of animal epigeic groups was significant. The impact of precipitation was non-significant. The faunistic similarity was of 85.71%, the identity of dominancy was of 95.57%. The highest value of diversity was recorded in the integrated farming with *Pisum sativum*, in ecological farming with *Hordeum vulgare*.
Keywords: *Coleoptera, ecological farming, ground traps, integreted farming*

Introduction

The soil is an important natural resource, and few phenomena on our planet match the complexities of the processes in it. Farming is the most widely used environ technology with its positive and negative impacts on the land. The agricultural land is a type of modified land with a significant human influence and with a disturbed course of natural processes. Biodiversity loss, an important consequence of agricultural intensification, can lead to reductions in agroecosystem functions and services. Increasing crop diversity through rotation may alleviate these negative consequences by restoring positive aboveground–belowground interactions. Compared to the natural ecosystems, in agroecosystems the biodiversity is more reduced (Tieman et al., 2015),

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1389713908

but according to Baranová et al. (2015) the artificial habitats often provides the shelter of biodiversity in anthropogenic land, because of its valuable natural biotope analogs.

One of the indicators reflecting the biotope burden is soil edaphone, which is an important component of biocoenosis and an important bioindicator of environmental quality. Fazekašová and Bobuľovská (2012) reported that communities of soil organism play an irreplaceable role in decomposition of organic matter, in cycle of biogenic elements of carbon, nitrogen, sulfur, phosphorus, in transformation and degradation of waste and toxic substances, etc. and its presence is irreplaceable. Afterwards, the impact of soil organisms becomes a key component of the strategy leading to the sustainability of the soil ecosystem. The biodiversity of epigeic groups, including its abundance in soil, directly depends on the abiotic and biotic factors that are typical of the biotope. In the agroecosystems, in addition to the natural factors, there is also a strong human impact, such as soil cultivation, crop rotation, cultivated crop, organic and artificial fertilizer inputs, and more. These interventions affect the level of agroecosystems biodiversity and contributes mainly to the reduction of the edaphic groups abundance (Baranová et al., 2013; Porhajašová et al., 2013).

In general, floristic and faunistic biodiversity in ecological farming systems is higher than in integrated systems. However, if integrated systems are well managed, it can also improve the biodiversity in agricultural areas (Bavec and Bavec, 2014; Dobrovodská et al., 2019).

The aim of this study was to asses the epigeic groups biodiversity in stands of *Pisum sativum* and *Hordeum vulgare* cultivated under the conditions of ecological and integrated farming.

Materials and methods (Experimental)

The collection of epigeic material was carried out by the earth traps method in 2015 to 2017 during the growing season (April to October) in stands of *Pisum sativum* and *Hordeum vulgare* cultivated under the conditions of ecological and integrated farming. Both types of management are governed by the following principles. Integrated management is based on ensuring sustainable management, achieving higher quality yields without burdening the environment, maintaining or improving soil fertility, a consistent system approach to all cultivation technology to optimize the economic and environmental aspects of production. Organic farming is based on the assumption that crops use natural resources, for example to combat pests, maintain or increase soil fertility, etc. Without resorting to synthetic chemicals such as fertilizers, pesticides, antibiotics, and without the use of any organisms that have been genetically modified. In this way, more natural, healthier and nutritious foods are obtained. In addition, it helps to achieve greater environmental sustainability, with minimal impact on the environment. One earth trap was located in the center of the plot is exposed in the crops under investigation. A solution of 4% formaldehyde was used as a fixing liquid. Traps were collected at monthly intervals (once a month), the collected biological material was determined in the department's conditions according to keys (Hůrka, 1996; Pokorný, 2002, 2004).

Epigeic groups of monitored agroecosystems were evaluated on the basis of abundance, dominance and species identity according to Jaccard (IA), dominance identity according to Renkonnen and on the basis of diversity degree according to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1389713908

Shannon-Weaver (H´) (Losos et al., 1994). Prediction of the richness of edaphic animal species was performed and the homeostasis of agroecosystems was evaluated.

Study area

The monitored area is located in the western part of the Žitava upland on the site of Nitra – Dolná Malanta (research fields of the Plant Biology and Ecology Centre, the Faculty of Agrobiology and Food Resources of the Slovak University of Agriculture, GPS 48°31´ N, 18°14´E) in the lower part of the Selenec stream and its tributaries (Hrnčiarová, 2001), (*Fig. 1*). The altitude of monitored area is of 175 to 180 m above sea level.

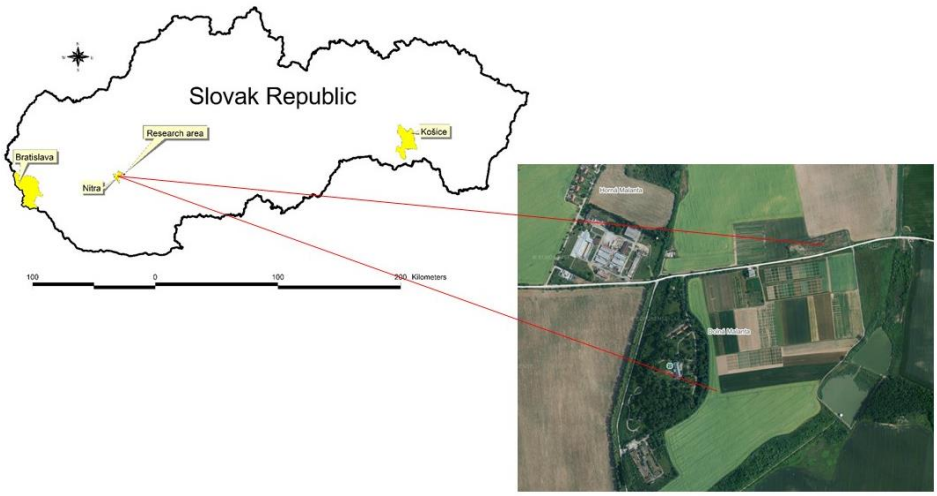

Figure 1. *Map of study area – Dolná Malanta*

The research was performed in stands of *Pisum sativum* and *Hordeum vulgare* cultivated under the conditions of ecological and integrated farming. Legumes have a lower autoregulatory and compensatory ability than cereals. Therefore, good soil preparation, soil types and agroecological conditions play an important role in pea cultivation technology (Candráková, 2014; Černý et al., 2017).

Data analyses

Diversity and equitability were calculated using the Shannon Diversity Index – H' by PAST software (Hammer, 2015).

The prediction – rarefaction of the richness of edaphic animal groups was performed by the PAST software using a confidence interval of 95% based on the amount of caught dragonfly material in the *Pisum sativum* and *Hordeum vulgare* stands cultivated under the conditions of ecological and integrated farming.

The data distribution normality of the individuals of animal epigeic groups from monitored areas was tested by the Shapiro-Wilks W test. Due to the violation of the data distribution normality, non-parametric tests – Friedman (ANOVA) and Kruskal-Wallis test (ANOVA) were used to H_0 hypotheses testing. We observed the influence of factors (temperature, total rainfall, management (integrated, ecological), type of cultivated crop (*Pisum sativum, Hordeum vulgare*)) on the number of individuals of individual epigeic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1389713908

groups. Post hot test (LSD test) we added statistical significance of pairs in combination year, farming, plant in Friedman´s test. H_0 hypotheses were tested at the significance level of $p\alpha = 0.05$ (if $p > p\alpha$, we cannot reject H_0 at the level of selected statistical significance of $p\alpha = 0.05$) (i) random selection comes from a normal distribution file, (ii) the number of individuals of the animal epigeic groups does not differ due to the type of farming and the type of crop cultivated, (iii) the average monthly temperature had not an effect on the number of individuals in the animal epigeic groups, (iiii) the average monthly precipitation had not an effect on the number of individuals in the animal epigeic groups. The data matrix with the number of individuals of the all animal epigeic groups was used.

To the data analysis the statistical program Statistics Cz, version 7.0 was used (StatSoft, Inc.).

Results and Discussion

The exemplars of 11,866 pieces of the animal epigeic groups belonging to 21 taxonomic groups, which are part of the zoological taxonomic unit Arthropoda, during the three-year period were collected. Of the number of individuals obtained, 5,456 individuals belonging to 20 groups were collected within under the integrated farming conditions. Exemplars of 6,410 pieces belonging to 19 taxonomic groups were collected in the ecological farming (*Tables 1, 2*). Muridae and Larvae were not further determined, it represented the developmental stages of the epigeic groups present.

(D* – dominance; ∑** - total)

Acarina and Coleoptera were assessed as an eudominant groups in both types of farming and in both crops cultivated. Araneida and Collembola were dominant (*Tables 1, 2*). With integrated farming in stands of *Pisum sativum*, the dominant group was Araneida. In the *Hordeum vulgare* stands the Araneida and Collembola were dominant. With ecological farming, the Araneida and Collembola groups were dominant in both crops cultivated. The occurrence of Acarina is limited by many factors, especially by its dependence on the substrate type. Gormsen et al. (2006) states that the ending of agricultural measures, i.e. soil management is associated with an increase of the Acarina population. Fox et al. (2017) confirmed the increase of Acarina abundance in soil with application of organic fertilizers. Authors also confirmed higher number of Acarina in soil with shallow ploughing than in soil with deep ploughing applied. According to Boháč et al. (2015), the Coleoptera represents a large and functionally dominant group of soil macrofauna, which sensitively reacts to anthropogenic activity in forest but also in non-forest habitats. Coleoptera, especially Carabidae, represent an important bioindicating organisms in both artificial and natural ecosystems. Authors Tieman et al. (2015) and Vician et al. (2011, 2018) state that the main factors affecting the diversity of its communities are elements of environment such as vegetation, humidity, temperature and shadow. Migration of Coleoptera is significantly affected by microclimatic conditions of the habitat. According to Baranová et al. (2013), the species variability of Carabidae (Coleoptera) is mainly influenced by soil moisture, herbal stratum of 0-200 mm, intensity of agrotechnical interventions and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1389713908

humus content. Carabidae (Coleoptera) react sensitively to the toxic substances (herbicides, insecticides), pH change and soil moisture and to the excessive use of artificial fertilizers (Vician et al., 2011; Tieman et al., 2015; Nietupski et al., 2015). In agroecosystems, macropterous species of Carabidae (Coleoptera) with a smaller body size are predominate. It is an indicator of lower ecological stability of the agroecosystems (Langraf et al., 2017, 2018, 2019). The abundance of Araneida and Collembola was almost equal in both monitored types of farming. According to Vician et al. (2015), the arachnocenosis are most sensitive to insecticide application and soil cultivation. During the monitored years, the abundance of Araneida and Collembola in both cultivated crops decreased. The most frequent occurrence of these groups was recorded in 2015, which is probably related to the appropriate climatic conditions of the environment (temperature and precipitation). In the integrated farming system, reducing the number of agrotechnical interventions affects the increase of Araneida and Coleoptera abundance. The population of Collembola varies in abundance and species representation, depending on the type of vegetation and soil conditions. The impact of agricultural management, such as crop harvesting, insecticide and herbicide application and conventional ploughing, has a significant negative effect on the occurrence of Collembola, but the application of organic fertilizers has a positive effect on the increase of its populations (Querner et al., 2008; Jasinski et al., 2016). The subdominant representation in both types of crops and in both types of farming was recorded with Opilionida. Recedent representation was recorded with groups of Dermaptera, Diplopoda and Formicoidea. The others groups were subrecedent. Even though its low presence, its importance in ecosystems is irreplaceable (e.g. Heteroptera are involved in the elimination of acarinocenoses and Thysanoptera, Orthoptera regulates insect pests, Diplopoda are an important saprophytophages, Dermaptera performs the function as a saprophages to polyphagous nocturnal insects). Presence of this epigeic groups contributes to the biodiversity of agroecosystems and also to its ecological stability. It showed that also intensively exploited agroecosystems allow the existence of a relatively wide range of zoofauna. Recorded epigeic groups represents a diversified component of soil fauna. These groups are characterized by different adaptations to the soil environment and different sensitivity to the stress (Porhajašová et al., 2012). The abundance and biodiversity of these epigeic groups supports the natural conditions of ecosystems (Kalivoda et al., 2010; Swaminathan, 2014). According to Lenoir and Lennartsson (2010) believe that the high abundance and dominance of Coleoptera, Araneida and Formicoidae in agroecosystems is mainly related to its trophic preference and tolerance to the soil environment.

In addition to the quantitative evaluation of the obtained epigeic material, qualitative indicators were identified. The qualitative composition of populations influences mainly the vegetation cover, abiotic and biotic environmental factors in the form of intra-species and inter-species relationships which depends on environmental conditions.

Based on the calculated values of faunistic similarity (85.71%), when two types of farming were compared, it can be stated that the ecological and integrated farming are the similar types of ecosystems.

Based on the dominance of populations mutual in both cultivation systems, the dominance identity value was of 95.57%.

The diversity value in the *Pisum sativum* stands cultivated under the conditions of integrated farming was of H´ = 2.61 (H´min = 2.56, H´max = 2.65), in the ecological farming it was of H´ = 2.40 (H´min = 2.36, H 'max = 2.44). In the stands of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1389713908

Hordeum vulgare, the value of diversity in integrated farming reached of H´ = 2.62 (H´min = 2.57, H´max = 2.66), in ecological farming it was of H´ = 2.67 (H´min = 2.61, H 'max = 2.71).

The equitability value is in the range of e = 0 – 1, more balanced communities has an equitability value reaching of 1. The value of equitability in the *Pisum sativum* integrated cultivation system was of e = 0.68, in the *Hordeum vulgare* e = 0.69; in ecological cultivation system of *Pisum sativum* e = 0.63, in *Hordeum vulgare* e = 0.70. The equitability values are relatively low, reflecting imbalances number of specimens represented by individual taxa.

On the basis of the total species richness of the taxa of all the areas studied (the number of individuals), the prediction of the richness of animal epigeic groups of the monitored areas was predicted by the individual rarefraction with confidence interval of 95% (*Fig. 2*).

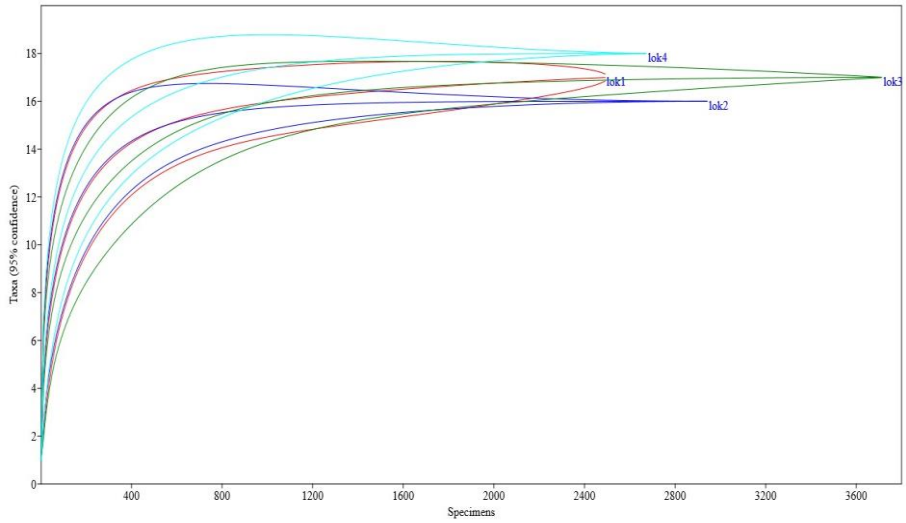

Figure 2. *Rarefaction curves of prediction of animal epigeic groups in integrated Pisum sativum (lok 1), Hordeum vulgare (lok 2) and ecological farming Pisum sativum (lok 3) a Hordeum vulgare (lok 4)*

The length of the rarefaction curve is a reflection of row saturation and prediction confidence. The cultivated area of *Pisum sativum* under the ecological farming (N = 3,727 individuals, 17 animal groups, predicted 18) had the longest rarefaction curve, indicating a greater predictive value for the prediction. According to experimental results, this site had the most complete spectrum of animal epigeic groups. Locations in stands of *Pisum sativum* (N = 2,505 individuals, confirmed 17, predicted 17 animal groups) and *Hordeum vulgare* (N = 2,951 individuals, confirmed 16, predicted 17 animal groups) with integrated farming and locality in stands of *Hordeum vulgare* (N = 2,683 individuals, confirmed 18, predicted 19 animal epigeic groups) with ecological farming were characterized by a short rarefaction curves, reflecting a reserve in animal epigeic saturation and a higher degree of prediction uncertainty. According to Litavský et al. (2018), Vician et al. (2015) and Filho et al. (2016) reported that the presence of epigeic groups in the soil in different types of ecosystems is mainly related to its trophic preference, but also to its tolerance to particular habitat conditions.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1389713908

Using the non-parametric Friedman test, the effect of the farming method and the type of cultivated crop on the number of individuals of the animal epigeic groups was tested (H0: the number of individuals of animal epigeic groups was not differ due to the type of farming and type of cultivated crop, pα = 0.05). The result of the test is of p = 0.00, H0 is rejected at a significance level of 95%. Our experimental data showed that the farming and crop cultivated type had an impact on the number of individuals of animal epigeic groups (*Fig. 3*).

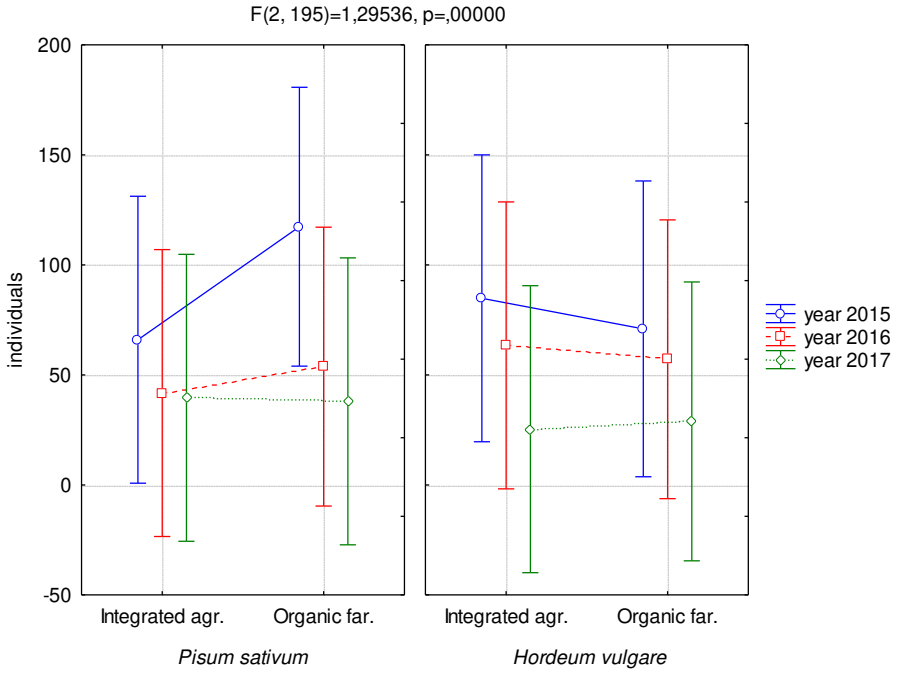

Figure 3. *Impact of farming and crop cultivated type on the number of individuals of animal epigeic groups*

By the Post hot test we have identified which management pairs differ at the level of statistical significance (pα = 0.05) during the years 2015 - 2017 (p < 0.05). The results are shown in *Table 3*.

In the stands of *Pisum sativum* cultivated under the conditions of ecological farming, an average number of individuals was higher than in the same crop cultivated under the conditions of integrated farming. However, in the stands of *Hordeum vulgare* cultivated under the conditions of integrated farming, an average number of individuals was higher.

In view of the impact of the cultivated crop (*Pisum sativum, Hordeum vulgare*) on the occurrence of animal epigeic groups, it is mainly the creation of suitable conditions, shading, moisture, realized agrotechnical interventions during crop cultivation, etc.

Using the non-parametric Kruskal-Wallis test, the effect of the average monthly temperature on the number of individuals of animal epigeic groups was tested (H0: the average monthly temperature had not an effect on the number of individuals of animal epigeic groups, pα = 0.05). The result of the test is of p = 0.01, H0 is rejected at a significance level of 95%. Our experimental data showed that the average monthly temperature had an impact on the number of individuals of animal epigeic groups during the research period (*Fig. 4*).

Conclusions

The impact of two types of farming, integrated and ecological, on the occurence of animal epigeic groups was monitored during the three-year period. The individuals of 11,866 pieces belonging to 21 taxonomic groups were collected. Within the integrated farming of 5,456 individuals, with the determination of 20 groups, within the ecological farming of 6,410 individuals belonging to 19 groups. Coleoptera, Acarina, Araneida and Collembola were dominant in the both types of farming. The occurrence of Opilionida was subdominant. The occurrence of Dermaptera, Diplopoda, Formicoidea, Isopoda, Lumbricidae and others was evaluated as recedent and subrecedent. The impact of cultivated crop, temperature and the type of farming on animal epigeic groups was significant. The impact of precipitation was non-significant. According to different types of farming comparison, the faunistic similarity was of 85.71%, the dominance identity of 95.57%. The higher value of diversity was recorded in integrated farming with *Pisum sativum*, in ecological farming with *Hordeum vulgare*. In conclusion, the abiotic and biotic environmental factors had an effect on the qualitative composition of present animal populations.

(Received 22nd May 2019; accepted 9th Sep 2019)

Abstract. This study is conducted to analyze the effect of socioeconomic factors on households' diet pattern w.r.t shares of calorie intakes from protein, fat and carbohydrate in Pakistan. Cross sectional data are taken from a national level survey i.e. Household Integrated Income and Consumption survey (HIICS) 2015-2016. Compositional Data analysis (CODA) regression approach is followed to compare the effects of explanatory variables on share of calorie intakes from protein versus share of calorie intakes from fat and share of calories intake from carbohydrate versus shares of calories intake from protein and fat. Moreover, elasticities of macronutrient shares from household income, household size, dependency ratio and wealth index are also computed. The model's results explore that rising households' income causes an increase in fat consumption and a decrease in protein and carbohydrate consumption. The household size and rural areas are important factors increasing fat consumption to a higher degree than protein and carbohydrate consumption. Our findings matched with existing literature and they have the benefit to help the substitution effects between macronutrients in the setting of nutrition change. This study is very helpful to know the importance of healthy dietary balance and to avoid the non-communicable diseases as obesity and heart diseases at household level of Pakistan.
Keywords: *calories, macronutrient shares, elasticity, ternary diagram, regression model*

Introduction

Macronutrients are required in diet, as each makes energetic functions in the body by providing energy (calories). Each of the macronutrients, i.e. carbohydrate, protein, and fat, has different properties that affect health but all are considered source of energy. The optimum stability of their dietary contribution has been a topic of discussion for many years (Carreiro et al., 2016) and unbalance in the proportion of these macronutrients may increase the risk of chronic diseases and obesity. For a given calorie intakes, if one macronutrient share increases, then one or more other macronutrient shares decrease definitely. For instance, a diet containing high fat would be low in carbohydrate or protein. Hence, unbalance shares of macronutrients consumption may adversely affect Body mass index (BMI) (Miller et al., 1990; Ahluwalia et al., 2009; Austin et al., 2011 and Satia et al., 2002). Furthermore, the acceptable macronutrient distribution ranges (AMDR) for healthy adults are given as 20–35%, 45–65%, 10–35% shares of energy from fat, carbohydrate and protein respectively to minimize the risk of coronary heart diseases, diabetes, and obesity recommended by the Food and Nutrition Board of the Institute of Medicine (Institute of Medicine, 2005). The risk of non-communicable diseases (NCD) may increase when the shares of these macronutrients are out of these acceptable rages. Overall, the NCD contributed 63% of the total 57 million deaths in 2008 and nearly 80% of these NCD related deaths occurred in developing countries (WHO, 2010). Previous studies show

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1390913929

that obesity is an important cause of NCD and can lead to severe cardiovascular morbidity and early deaths. The prevalence of obesity has increased globally during the past 30 years due to macronutrients malnutrition (Swinburn et al., 2011 and WHO, 2018). As a result of imbalance diet in term of macronutrients shares, overweight and obesity are increasing in developing countries. Protein-energy malnutrition is the most significant risk factor for diseases and deaths which particularly affects hundreds of millions of pregnant women and young children (Olaf and Michael, 2005). Low-carbohydrate, high-protein diets can be a better choice for weight loss, increased satiety, and improved metabolic parameters (Kushner and Doerfler, 2008).

Pakistan is among the countries with high prevalence of obesity (Tanzil and Jamali, 2016). Findings of Satti and Khalid (2019) show that overweight and obesity prevalence is 21% and 9% respectively in Pakistani adults. According to WHO, 46% of all deaths in 2008 with estimated deaths in males and females of around 380,000 and 300,000 respectively are due to NCD in Pakistan (WHO, 2013). According to estimates of global disease burden research, Pakistan ranks 9th among 188 countries in obese population (Ng, et al., 2014) and 40% of reproductive age Pakistani women are either overweight or obese (NIPS and ICF, 2013). Hence, health situation is alarming in Pakistan due to rising obesity and all other Non-communicable diseases. To overcome this alarming situation, public health policy may be helpful for balancing of diet and of macronutrient shares. It requires to understand the factors affecting diet pattern in term of macronutrient shares at household level in Pakistan.

In order to estimate the association between nutrient intakes and socioeconomic factors, various regression models are frequently used with the different regressors and the different nutrients and calories intakes as response variables (Liaskos and Lazaridis, 2003; You et al., 2016; Akerele et al., 2014; Iyangbe and Orewa, 2009; Zhou, et al., 2018 and Trinh, et al., 2018). All the previous studies in Pakistan explain the importance of macronutrients consumption or volumes from food items. For example (Shabnam et al., 2016) show that the calorie and macronutrient consumption at household level depend upon food prices in Pakistan. Khattak and Khan (2009) explore imbalance energy intakes w.r.t macronutrients in female students of Pakistan. Shakoor et al., (2017) show that the majority of Pakistani female students had low consumption of macronutrients than recommended levels except fat.

To the best of authors' knowledge, no study has been conducted to analyze the factors affecting unbalance diet pattern in term of macronutrients shares at household level in Pakistan. Hence, major objective of this study is to fill this gap in literature by analyzing the impact of some important factors on macronutrient shares in energy intake at household level in Pakistan. This study is conducted to fill this research gap in the literature of food security in Pakistan. Moreover, Compositional data analysis (CODA) is considered instead of conventional regression inference to analyze macronutrients shares as the response variable and to avoid the problem of unbalance diet. CODA is known as a well traditional area of statistics with various areas of application, such as geology or economics (Egozcue et al., 2011; Pawlowsky-Glahn et al., 2015). This CODA technique has been applied recently in the field of nutritional and medical epidemiology (Dumuid et al., 2018; Leite, 2016; Mert et al., 2018). Hence, CODA technique is considered to analyze the phenomenon under consideration. Rest of the article contains material and methods, results, discussion and concluding remarks in the following sections.

Materials and methods

Materials and methods consists of three sub-sections, i.e. theoretical framework and specification of model, data and description of variables, and methodology of analysis.

Theoretical framework and model's specification

To investigate the impact of socio-economic factors and households characteristics on the Nutrition status or macronutrients intake follows the conceptual frame work (world food program, 2012) of food and nutrition security at household level which is the extension of UNICEF (1991) and Smith and Haddad (2000). This conceptual frame work is the composition of three main layers of causes, i.e. immediate causes, underlying causes and basic causes and each comprises of different factors. The factors at basic causes affect the factors at underlying causes which in turn influence the factors at immediate causes. Our response variable is macronutrient intakes which belongs to immediate level causes whereas the explanatory variables are taken from other two layers of causes in the conceptual frame work. Thus, the theoretical model of macronutrients shares is specified as follows:

$$M_i = \beta_0 + \beta' X' + \varepsilon_i \quad \text{(Eq.1)}$$

where M_i shows the shares of macronutrients from total energy intakes of ith households, β_0 represents constant term, β' is the vector of slopes and X' is vector of explanatory variables while ε_i is the error term.

Data and description of variables

This study uses data taken from Household integrated income and consumption survey (HIICS) 2015-2016 published by Pakistan Bureau of Statistics. This survey was collected in 2015-2016 by applying two stage stratified random sampling technique. Its sample comprises of 24238 households from all the four provinces of Pakistan. However, our sample size for this study is 14948 households due to non-availability of data regarding some variables. In this survey quantities of 72 food items are given from different food groups like meat, fish, milk, cheese, eggs, fresh fruits, dry fruits, vegetables (fresh/chilled/frozen/dried), sugar, jam, honey, chocolate & confectionery, condiments and spices (whole and powder), non-alcoholic beverages, readymade food eaten out of home, public places, offices, bread & cereals, and edible oils.

We calculate total calorie intake (in Kcal), protein and fat intakes (in grams) per day from all consumed food items for each household using Food Consumption table for Pakistan (Khan et al., 2001). The amount of protein and fat in grams are converted into calories for each household by multiplying 4 and 9 respectively (Trinh et al., 2018). Then we compute per capita calorie consumption (namely Cal_p), per capita volume of calories calculated from protein V_P, and per capita volume of calories calculated from fat V_F as follows. An per capita calorie consumption (Cal_p) is calculated by dividing the total consumption of calories per day by an adult equivalence conversion factor (AE) computed for each household. An adult equivalence conversion factor is the ratio between calorie requirement of individual according to age and the estimated adult reference value (Claro, et al., 2010). Similarly, per capita calories from fat and protein are computed for each household using the above procedure. Three types of macronutrients (Fat, protein and carbohydrate) are the source of total calorie intakes per capita, so the following

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1390913929

relation exist between total per capita calorie intakes and macronutrients which help to calculate the per capita volume of calorie intake calculated from carbohydrate V_C

$$1 \text{ gram protein} = 4 \text{ kcal}$$

$$1 \text{ gram Fat} = 9 \text{ kcal}$$

$$V_p = 4 \times \text{Protein in grams}$$

$$V_F = 9 \times \text{Fat in grams}$$

$$Cal_p = V_F + V_p + V_C$$

$$V_C = Cal_p - V_p - V_F$$

$$Cal_p = \frac{\text{Total calorie intakes of household per day}}{AE}$$

$$AE = \frac{\text{Requirement of individual according to age}}{Adult\ reference\ value}$$

The shares of macronutrient S_F, S_P and S_C are defined as proportion of calorie from fat, protein and carbohydrate respectively as follows.

$$S_F = \frac{V_F}{Cal_F}, S_P = \frac{V_P}{Cal_F}, S_C = 1 - S_F - S_P$$

Some socioeconomic and demographic factors are taken as explanatory variables on the basis of the theoretical framework while considering availability of data. These explanatory variables include residential status, marital status of household head, paid employment dummies of father, mother and couple, Provinces dummies of Punjab, Sindh, Khyber Pakhtunkhwa (KPK) and Baluchistan, household head age, family size, dependency Ratios, dummies of livestock, own cultivation and Benazir income support programme (BISP), per capita income and education dummies of father and mother like no education, primary education, middle education and high education. The description of all the variables used by the study is given in *Table 1* whereas *Table 2* presents descriptive statistics of the variables.

Table 2 shows that the total number of calories per capita is 2451.5 calories which mean that, while households of Pakistan fulfil their calories requirement according to FAO (2013) is 2440 calories per person. Descriptive results show that 626.7, 283.66 and 1541.2 calories come from the Fat, protein and carbohydrate respectively. The sum of the volumes of calories from these three macronutrients equal to 2451.5 calories. The shares of calories from Fat, protein and carbohydrate are 25.9%, 11.4%, and 62.7% respectively and *Table 2* also represents the percentages of all categories of Categorical variables which included for the analysis.

Methodology of analysis

Methodology of analysis consists of two sub sections i.e. introduction to CODA, and compositional regression model to explain macronutrient shares.

Introduction to CODA

We can not apply traditional methods of regression when the dependent or independent variable consists of a vector of shares (Aitchison, 1982; Pawlowsky-Glahn, et al., 2015) because these shares are positive real numbers and carry relative information with constant sum (Chen et al., 2017). In the previous studies, many types of models are used to apply regression with shares (Morais et al., 2018). When a vector of shares (e.g. the shares of macronutrients) is the response variable and other regressors are traditional quantitative or qualitative variables, a proposed model known as CODA (compositional data analysis) is considered as the valid modelling technique (Trinh et al., 2018, Egozcue et al., 2011, Pawlowsky-Glahn et al., 2015, Aitchison, 1986). This model depends on a log-ratio transformation of shares. In the simplex space S^D, a composition S of D shares can be denoted as

$$S^D = \{S = (S_1, S_2, \ldots\ldots\ldots\ldots, S_D)' = S_j > 0, j = 1, \ldots. D; \sum_{j=1}^{D} S_j = 1\}$$

It is interesting to know that if the total sum of these fitted shares equal to one, then we cannot apply classical regression models directly. These shares are therefore converted using the transformation of an isometric log-ratio (ILR) (Egozcue et al., 2003) (for example) in D-1 coordinates which can be denoted in the classical Euclidean space so that the linear regression models can be applied separately to the D-1 coordinates. These coordinates of ILR are explained as follows (Trinh et al., 2018):

$$ilr\,(S) = W'\,log\,(S) = S^* = (S^*_1\ ,\ldots\ldots,\ S^*_{D-1})'$$

where W defined as the $D \times (D-1)$ contrast matrix (Chen et al., 2017) which helps the forecasting of shares on the orthogonal basis of S^D. For instance, we have D = 3, it is possible to use the following contrast matrix (this matrix used by the function "ilr" in R package "Composition"):

$$W = \begin{bmatrix} -\frac{1}{\sqrt{6}} & -\frac{1}{\sqrt{2}} \\ -\frac{1}{\sqrt{6}} & \frac{1}{\sqrt{2}} \\ \sqrt{\frac{2}{3}} & 0 \end{bmatrix}$$

Guiding to the following two ILR coordinates of $S = (S_1, S_2, S_3)$:

$$S^*_1 = \frac{1}{\sqrt{2}}\, log \frac{S_2}{S_1}$$

$$S^*_2 = \frac{2}{\sqrt{6}}\, log \frac{S_3}{\sqrt{S_2 S_1}}$$

In this shape, the first ILR coordinate S^*_1 protein shares have all the relative data of S_2 compared to the fat shares. Similarly, the second ILR coordinate S^*_2 carbohydrate shares have all the data of S_3 compared to the geometric mean respectively of the remaining protein and fat shares (Muller et al., 2016). At the end, with the help of the inverse

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1390913929

transformation to go back to the simplex to interpret the shares model. This inverse transformation is defined as

$$ilr^{-1}(S^*) = C(exp(WS^*))'.$$

Here, C(.) denote the closure operation which permitting to go from a vector of volumes V to a vector of shares S

$$C(V_1, \ldots, V_D)' = \left(\frac{V_1}{\sum_{j=1}^{D} v_j}, \ldots\ldots, \frac{V_D}{\sum_{j=1}^{D} v_j}\right)' = (S_1, \ldots, S_D)'.$$

Compositional regression model for macronutrient shares

We want to check the impact of socioeconomic factors and household characteristics of Pakistani households on macronutrient composition. *Equation 1* can be written as an adapted compositional regression model as follows (Trinh et al., 2018):

$$\begin{gathered} S_i = a_0 \bigoplus_{k=1}^{K} (Z_{ki}) \odot b_k \oplus \epsilon_i \\ S_i = a_0 \oplus Age_i^h \odot b_1 \oplus Size_i \odot b_2 \oplus Res_i \odot b_3 \oplus Mar_i^H \odot b_4 \\ \oplus P_i^{kp} \odot b_5 \oplus P_i^p \odot b_6 \oplus P_i^s \odot b_7 \oplus I_i \odot b_8 \oplus EM_i^c \odot b_9 \oplus EM_i^m \odot b_{10} \oplus EM_i^p \odot b_{11} \\ \oplus E_i^{mp} \odot b_{12} \oplus E_i^{mm} \odot b_{13} \oplus E_i^{mh} \odot b_{14} \oplus E_i^{pp} \odot b_{15} \oplus E_i^{pm} \odot b_{16} \oplus E_i^{ph} \odot b_{17} \oplus \\ L_i \odot b_{18} \oplus DR_i \odot b_{19} \oplus W_i \odot b_{20} \oplus C_i \odot b_{21} \epsilon_i \end{gathered} \quad \text{(Eq.2)}$$

In *Equation 2,* $S = (S_F, S_P, S_C)'$ i represents the ith households and $\boldsymbol{Z_k}$ are classical regressors as $Res_i, Mar_i^H, P_i^{kp}, P_i^p, P_i^s, EM_i^c, EM_i^m, EM_i^p, E_i^{mp}, E_i^{mm}, E_i^{mh}, E_i^{pp}, E_i^{pm}, E_i^{ph}, L_i,$ *and* C_i are the dummy variables representing residential status, household head marital status, Khyber Pakhtunkhwa origin, Punjab origin, Sindh origin, couple paid employment, maternal paid employment, paternal paid employment, maternal primary, middle, and high education, paternal primary, middle, and high education, livestock and own cultivation respectively. $Age_i^h, Age_i^{sh}, Size_i, Size_i^2 I_i, DR_i,$ *and* W_i are the variables representing household head age, household head age square, household size, household size square, household total income, dependency ratio and wealth index respectively. Detailed explanation of the variables is provided in *Table 1*.

As in Dumuid et al. (2018), Muller et al. (2016) and Nguyen et al. (2018) for the fitting and interpretation of the model in *Equation 2,* we required to run $D - 1 = 2$ ordinary linear regression model, i.e. one for every ILR coordinates of S: S^*_1 and S^*_2 for each period j = 1,2 (Egozcue et al., 2012).

$$\begin{gathered} S^*_{j,i} = a_{0j}{}^* + \sum_{k=1}^{K} b^*_{j,k} X_{ki} \check{n}^*_{j,i} \\ S^*_{j,i} = a_{0j}{}^* + b^*_{j,1} Age_i^h + b^*_{j,2} Size_i + b^*_{j,3} Res_i + b^*_{j,4} Mar_i^H + \\ b^*_{j,5} P_i^{kp} + b^*_{j,6} P_i^P + b^*_{j,7} P_i^S + b^*_{j,8} I_i + b^*_{j,9} EM_i^c + b^*_{j,10} EM_i^m + \\ b^*_{j,11} EM_i^p + b^*_{j,12} E_i^{mp} + b^*_{j,13} E_i^{mm} + b^*_{j,14} E_i^{mh} + b^*_{j,15} E_i^{pp} + b^*_{j,16} E_i^{pm} + \\ b^*_{j,17} E_i^{ph} + b^*_{j,18} L_i + b^*_{j,19} DR_i + b^*_{j,20} W_i + b^*_{j,21} C_i + \check{n}^*_{j,i} \end{gathered} \quad \text{(Eq.3)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1390913929

where $a_{0j}{}^{*}$, $b^{*}{}_{j,k}$, $\epsilon^{*}{}_{j}$ are the j^{th} ILR coordinates of a_0, b_k, ϵ.

Since we fit the two transformed models in *Equation 3* using the method of ordinary least square (OLS) and ϵ^{*} is assumed to follow normal distribution. The model's parameters calculation in the simplex and *Equation 2* can be obtained by using inverse transformation from the transformed model in *Equation 3* computed parameters. For example:

$$\hat{b}_2 = C(exp(W\,\hat{b}^{*}_2))', where\ \hat{b}_2 = (\hat{b}^{*}_{1,2}, \hat{b}^{*}_{2,2})'$$

All parameters are estimated in compositional regression model using the method of OLS. The value of compositional models can be assessed to the share data, called adjusted "R^{2}" (Van den Boogaart and Tolosana-Delgado, 2013). The adjusted R-squared value shows that our compositional models explain about 11.87% and 12.54% of the total compositional data variability, respectively. To estimate the parameters of compositional regression model, the package " Compositions" in R language has been used. The R package " Plotly" used to make ternary diagrams.

Results

Results consist of three sub sections i.e. comparison of urban and rural households, results of compositional regression model and Elasticities of macronutrients shares.

Comparison of urban and rural households

Figure 1 displays that the overall households in our sample have on the average 2283 calories per capita per day which looks nearly equal to the requirement of (FAO). But the rural households consume on the average 2657.56 calories which is higher than urban households as well as overall average of households which is 2196.15. We can see the clearly difference between the macronutrients shares in calories for both regions.

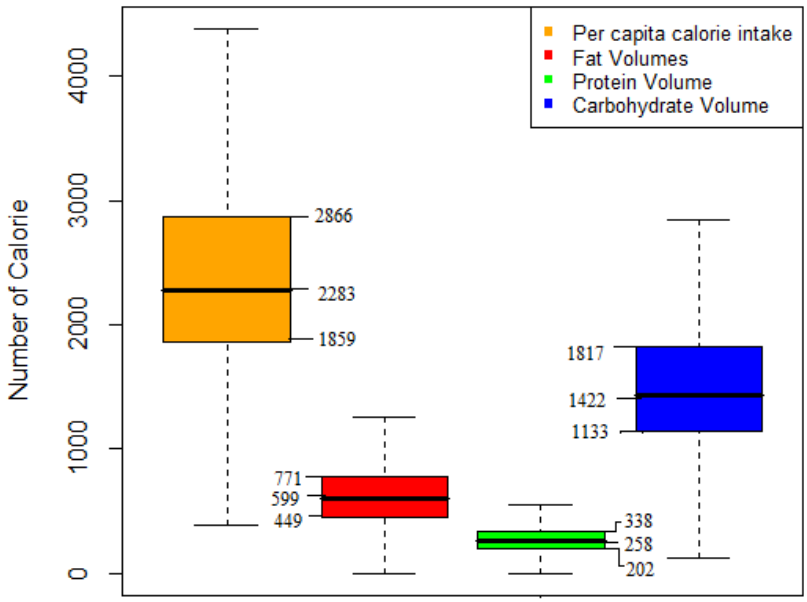

Figure 1. *Per capita calorie intake and volume of macronutrients using overall households*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1390913929

Figures 2 and *3* show the comparison of urban and rural site of per capita calorie intake and volume of macronutrient shares using box plot which bases on lower quartile, median and upper quartile. The rural region has the high median i.e. 2627.56 per capita calorie than urban region i.e. 2196.15 calories. Lower and upper quartiles of the rural households of calories are 2082.71 and 3370.31 respectively which are more than urban households i.e. 1807.82 and 2697.25 respectively. Similarly, all three macronutrient shares of rural site having greater values of lower, median and upper quartile compared to the urban households. According to *Table 3,* it is clear to see that there is significant difference between all variables of urban and rural areas.

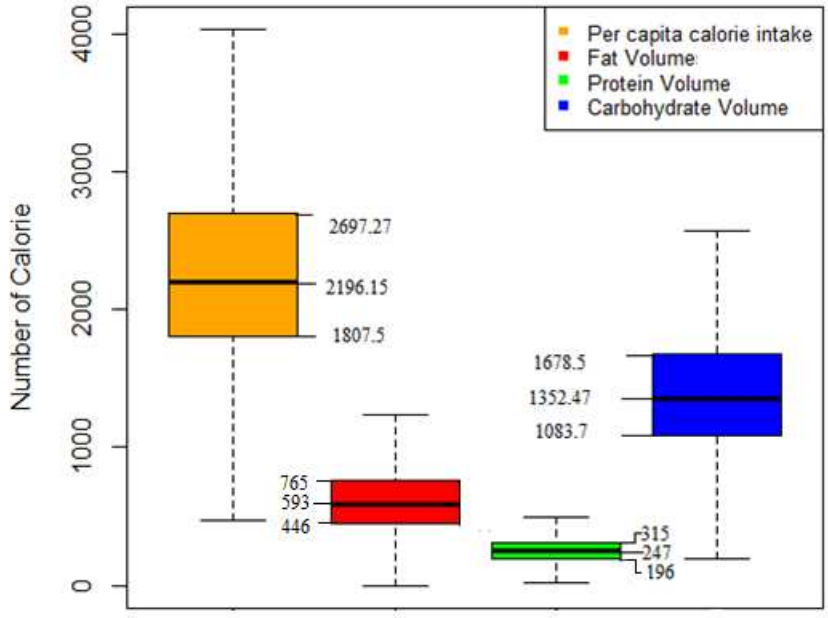

Figure 2. *Per capita calorie intake and volume of macronutrients using urban site*

Table 3. *Comparison of means using unpaired t test*

Variables	Region	Mean	Standard deviation	95% confidence interval	t-value	P-value
Per capita calorie intake	Urban	2836.93	1079.13	2802.4-2871.4	26.94	0.0000
	Rural	2321.813	790.68	2307.1-2336.4		
Calories from fat	Urban	639.31	288.74	630.1-648.5	3.12	0.0018
	Rural	622.42	279.30	617.2-627.6		
Calories from protein	Urban	331.41	144.65	326.7-336.0	24.84	0.0000
	Rural	267.52	108.19	265.5-269.5		
Calories from carbohydrate	Urban	1866.1	764.9	1841.7-1890.6	32.26	0.0000
	Rural	1431.8	535.9	1421.9-1441.7		

H_0 = there is no difference between means, versus H_A = there is difference between means

Figure 4 represents the tri plot of three macronutrients shares in calories for urban households. This figure shows that most of the urban households have more than 30% shares of carbohydrate, but a few have 40% or below. According to this ternary diagram most of the urban households have less than 20% shares of protein in calories. It can be seen that most urban families have less than 60% shares of fat in calories. *Figure 5* shows the ternary plot of macronutrient shares for rural households and this represents that all rural households have more than 40% shares of carbohydrate and less than 20% shares of protein. All households in the rural region have less than 60% shares of fat in calories. Moreover, t test is employed to test the difference between means of calories intake, shares of calories intake from fat, protein and carbohydrate assuming that there are two independent samples consisting of rural and urban households. The results are reported in *Table 3*. All the t statistics are significant which shows that there is significant difference between rural and urban households w.r.t energy intake from the three macronutrients.

Compositional regression model results

We now fit a CODA regression model describing the impacts of socioeconomic factors on macronutrients shares using estimation method of OLS. The First isometric log ratio (ILR) coordinate compares protein against fat shares, while second ILR coordinate compares carbohydrate versus geometric mean of fat and protein shares. *Tables 4* and 5 describe the parameters of the compositional model in ILR coordinates. The two ILR coordinates treated as response variables and associated with explanatory variables.

Estimation results given in *Tables 4* and *5* are interpreted as (Trinh et al., 2018 and Dumuid et al., 2018). *Table 4* shows the coefficients of first coordinate consisting of protein versus fat shares. Estimate of income shows that 1% rise of income for a given household causes decline of the relative dominance of protein versus fat share ($e^{0.0798} = 1.083$) approximately by 0.083%. This analysis shows that rising household's income is not helpful to improve protein shares in calories than fat shares. Similarly, an increase of one more year of household head age, the relative dominance of protein share ($e^{0.00158} = 1.0058$) decreases approximate by 0.0058%. The impact of household size and dependency ratio on the protein share as 1 more person increase of family member and dependency ratio then relative dominance of this first ILR coordinate ($e^{0.0105} = 1.0105$ *and* $e^{0.1148} = 1.13$) increase approximately 0.0105% and 0.13% respectively to fat share. These results are in line with Trinh et al., (2018).

The first ILR coordinate is explained by residential status, hence $Z^{\wedge(\text{protein})^*}{}_1 = 1.56$ is the fitted value of the coordinate $Z^{(\text{protein})^*}{}_1$ for rural while $Z^{\wedge(\text{protein})^*}{}_1 = 1.7696$ for urban. It means that the relative dominance of protein in the composition response is ($e^{1.56} = 4.75$) for rural and ($e^{1.7696} = 5.8685$) for urban. Further, it can be conclude that the relative dominance of protein for rural households is $e^{0.0628} = 1.0648$ times greater than for urban households. Coefficient estimate of marital status of household head shows that a household with married head compared to a household with unmarried head would likely to have more share of protein versus fat. The relative dominance of protein shares for province Sindh is less than other provinces and dominance of protein shares for

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1390913929

Khyber Pakhtunkhwa is 1.064 times greater than for other provinces compared to fat shares. Hence, the households of KPK compared to other households are likely to have more shares of calories obtained from protein than fat. Similarly, the relative domination of protein shares versus fat share for the households operating agricultural land and the households having livestock are 1.07 and 1.06 times greater than the households who are not operating agricultural land and the households who have not livestock. All educational dummies of maternal and paternal may not be helpful to improve protein shares compared to fat shares in the balanced diet. The households with education of maternal and paternal may increase their fat shares in the diet.

Table 5 shows the coefficients of second coordinate i.e. carbohydrate shares vs geometric mean of fat and protein shares. 1% increase of income for a given household results into decline of carbohydrate share ($e^{0.2101} = 1.2289$) approximately by 0.233 with respect to geometric mean of other fat and protein shares. The second ILR coordinate

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

shows that the households with high income have low proportion of carbohydrate share in calories than other shares. Household size shows positive impact while dependency ratio shows inverse impact on the relative dominance of carbohydrate share versus fat and protein share in energy intake.

Coefficient estimate of residential status shows that the rural households compared to urban households have more dominance of carbohydrate share than fat and protein shares. Results show positive impact of couple paid employment and Household head paid employment on carbohydrate shares versus fat and protein shares. The relative dominance of carbohydrate share for households having couple and Household head paid employment ($e^{0.0496} = 1.05$ *and* $e^{0.0192} = 1.02$) 1.05 and 1.02 times larger than other households respectively.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1390913929

In second ILR coordinates, the negative coefficients show that the dominance of carbohydrate share for Province Punjab and Sindh 1.12 and 1.07 times less than base category Baluchistan province respectively. The households which lie in the province Punjab and Sindh have less carbohydrate shares proportion in calories than base category Baluchistan. Hence these two provinces have more proportion of protein and fat shares than carbohydrate shares. The effect of educational dummy variables like middle and high education of household head on carbohydrate shares is not useful. The dominance of carbohydrate shares compares to other shares for these variables is less than households which do not have an education.

Elasticities of macronutrients shares

Elasticity is very popular tool to overcome the difficult interpretation of coefficients in ILR regression. For regressors X, the elasticity of response variable Y calculates the change rate between two values of response variable Y.

To link these findings with the existing previous studies, we also use standard classical linear regression model to explain the shares of macronutrients by same household characteristics than in the model (1) as estimated separately for each share of macronutrients using ordinary least square (OLS).

$$S_{j,i} = a_{0_j} + \sum_{k=1}^{K} \beta_{0_{j,k}} X_{ki} + \varepsilon_{j,i} \qquad for\ j = 1,2,3$$

Now elasticities of macronutrient shares define with respect to different regressors as

$$Elast\,(S_{j,i}, X_i) = \frac{\frac{\partial S_{j,i}}{S_{j,i}}}{\frac{\partial X_i}{X_i}} = \frac{\partial (S_{j,i})}{\partial (X_i)} = \beta_{j,k}$$

The elasticity is the fix term which is independent of considered households. For these households, the elasticity of the macronutrient share S_j depends on all intakes of macronutrient shares, that is households diet balance.

Elasticities of macronutrient shares relative to income, household size, dependency Ratio and wealth index are presented in *Table 6*. It is clear that fat share is the most elastic income based macronutrient. The positive change rate of 1% of household's income is linked on the average to a positive change rate of 1.15% in the shares of fat, 0.47% increase in protein share, and 0.50% decrease in carbohydrate share in the total calories consumption. Similar is the case of dependency ratio which shows that as dependency ratio increases, it causes to increase the share of fat and protein with a decline in carbohydrate share. However, wealth index shows opposite effects as these are negative for fat and protein but positive for carbohydrate. Moreover, The positive change rate of 1% of family members in the household links on average to a positive change rate of 0.0028% in the share of fat whereas it agrees to a negative rate of change of 0.000466% and 0.0008877% for protein and Carbohydrate respectively. *Figure 6* represents the box plot of income elasticities with respect to macronutrient shares. The lower quartiles of fat, protein and carbohydrate shares are 0.8086, 0.4101 and -0.5298 respectively. The median of fat, protein and carbohydrate shares are 0.9411, 0.4572, -0.4749 and upper quartiles are 1.1163, 0.5095 and -0.4295 respectively.

Discussion

Comparison of urban and rural households shows that there is significant difference in calorie intakes as well as in the volume of all macronutrients. The people residing in rural areas consume more calories than urban people because they are involved in heavy physical work in field, which need more energy. The results of income are consistent with the fact that the households with high income use more fatty foods than protein foods. These results are in line with the findings of Trinh et al., (2018) which shows that the fat shares in calories increase when food expenditure increase. This implies that rising household's income is not helpful to improve protein and carbohydrate shares in calories than fat shares. The results show that household size is directly related to more consumption of protein and carbohydrate compared to fat in diet. Most of the households live in rural areas which have more share of calories obtained from protein and carbohydrate than fat because they consume large amount of vegetables and dairy products like as milk, yogurt and cheese than urban.

The study explores that maternal and paternal education is not helpful in improving protein and carbohydrate shares of energy intake in Pakistan. It implies that education is playing an effective role to increase the shares of fat in calories at household level in Pakistan. In the case of Pakistan, knowledge related to nutrition and health practices is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1390913929

not part of syllabus at school or college level and therefore, most of the educated people are not aware about the concepts related to balanced food and nutrition, the food items containing macronutrients shares in calories. It implies that education without awareness of nutrition does not affect eating pattern. Moreover, estimates of all other education dummies also support the view that education is not performing well in healthy diet in term of protein and carbohydrate shares in Pakistan. The results of household head paid employment and couple paid employment dummies are not consistent with all shares of macronutrients. It implies that the healthy diet in term of macronutrient shares do not depend on paid employment of couple and household head.

Conclusion and policy implementation

CODA model is employed to evaluate the role of some important socioeconomic and demographic factors on balancing of macronutrient shares in energy consumption at household level as a case study of Pakistan. Cross sectional data of households are taken from a national level survey data, i.e. HIICS-2015-16. Household per capita income, residential status, household size, Dependency Ratio, household head and couple paid employment, Sindh dummy, middle and high educational dummies of household head also play significant role for carbohydrate shares than other shares. We may conclude that the rising income of households increases fat consumption and decreases protein and carbohydrate consumption. It implies that significant increase of households' income level will make economic access easy which may improve fat consumption in Pakistan. It induces that policy steps to raise overall households' income level on the basis of higher economic growth rate may be the most effective tool to fulfil fat requirement in healthy diet. Household size and rural residence are key factors for increasing fat shares than other shares. Hence, effective family planning strategies and birth control programs must be implemented in order to improve fat shares. Paternal education is another important factor for increasing fat shares and the low educational level leads to a reduction in protein and carbohydrate consumption. It implies that education is not playing an important role for protein and carbohydrate shares in balance diet. It is because diet related topics are not part of syllabus in education system of Pakistan and even educated people are not aware of the importance of healthy diet. Hence, it is strongly recommended that the topics of nutrition and balance diet along with its all health related impacts must be included as part of syllabus at primary and secondary education levels in order to make awareness of educated parents as well as children. The livestock and own cultivation cause to improve protein shares. Hence, development of agricultural sector and live stock is imperative to tackle the problem of protein shares in balanced diet in Pakistan

We calculated and compared the elasticities of macronutrient shares using income, household size, dependency ratio and wealth index. Our findings support to the existing literature, the most elastic macronutrient is fat share with respect to the income, household size and dependency ratio compared to other shares. But the carbohydrate share is negatively elastic to income, household size and dependency ratio. Moreover, for example the positive elasticity of macronutrient shares with respect to income represent that the positive impact of income on macronutrient shares.

In this study the important results are very helpful to support the previous studies about the development of nutritional diets at the national level. There is strong correlation between nutritional change and the non-communicable diseases risk factor

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1390913929

such as heart diseases an obesity (Bloom et al., 2012), country level strategies are required to help Pakistani people to recover their pattern of diet with respect to macronutrients.

In additional research, same kind of studies which based on dietary shares of macronutrients can be done for other countries to see the entire food consumption pattern. Moreover, focusing on the association between macronutrient shares in calories and non-communicable diseases as obesity and heart diseases at the country level will be very interesting.

Abstract. Compactness and moisture content are important and mutually influential soil parameters that affect plant growth, nutrient absorption, and nutrient transportation. To simultaneously measure these two parameters, we developed a combined penetrometer standing wave ratio (PSWR) probe; acceleration measurement was facilitated to eliminate the error caused by varying penetration speeds. The performance of the instrument was analyzed and verified through laboratory and field measurements. The cone-index measurements from an SC-900 sensor and the moisture content calculated by the drying method and a TDR sensor were used to evaluate the performance. The results prove that acceleration compensations can improve the accuracy of cone-index measurements. Further, the sensitive range of the PSWR probe was the area a 10 cm diameter. The linear-fitting coefficient of output voltage and volumetric moisture content exceeded 0.96, and the output was stable; therefore, the moisture content measurements using the PSWR probe were validated. Furthermore, the accuracy and stability of measurements using the PSWR probe and a TDR sensor were similar. The field-measurement results agreed with the results from the drying method, and satisfied the practical implementation requirements. Conclusively, the validated efficiency and the cost-effective stainless-steel structure of the probe render it suitable for practical applications.

Introduction

Soil is a loose, porous, dielectric material composed of water, air, and soil particles (Schaap, et al., 1997). The compactness and moisture content are important soil parameters that affect the plant growth, water movement, seedling emergence, and root penetration (Cui et al., 2015; Goutal et al., 2013; Ogée and Brunet, 2002). In early days, soil compactness was measured primarily by destructive sampling (Ronai and Shmulevich, 1995); later, instruments based on pressure-based soil cone-index measurement (ASABE Standards, 2009; Erbach et al., 1991; Pillinger et al., 2018; Perumpral, 1987), microwave reflection measurement (Luo and Perumpral, 1995; Zoughi et al.,1994), and volume and porosity measurement were used (Ronai and Shmulevich, 1995). In the recent years, CT technology has been used to scan the soil to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1393113944

analyze its compactness (Mossadeghi-Björklund et al., 2016). The measurement techniques for soil moisture are primarily classified into sampling and in-situ techniques. Drying method is typically used to analyze the moisture content in the sampling techniques, and electrical measurements are conducted in localization techniques. In 1980, Topp et al. proposed the use of time-domain reflectometry in the field of soil moisture measurement (Topp et al., 1980). The Topp equation brought a new dimension to the soil moisture evaluation. In addition, many scholars have developed moisture measurement devices using electrical measurement methods (Jin-Hong et al., 2008; Tranter et al., 2008; Zegelin et al., 1989).

Topp et al. initiated the research on the simultaneous measurement of compactness and moisture of the soil. For this purpose, they attempted to combine a cone penetrometer with a TDR moisture sensor. They installed a waveguide coil and mounted it on a static cone for simultaneous measurement (Topp, 2003; Yanuka et al., 1988). Vaz et al. installed the waveguide coil on the conical head of a dynamic cone (Vaz et al., 2001; Vaz and Hopmans, 2001). However, this device takes 10 min to complete a measurement, and its practical application is difficult; therefore, it is still in the laboratory research stage. Subsequently, Hummel proposed a composite sensor combining the cone-index and near-infrared methods (Hummel et al., 2004). Although this sensor could quickly synchronize the measurement, it had a complicated structure and was expensive. In 1997, Singh et al. proposed to embed an FD-type soil-moisture sensor on the head of the cone to ensure that the measurement structure of the cone is not damaged (Singh et al., 1997). Sun et al. further embedded FD-type moisture sensors into cones in 2003 and developed composite sensors in 2004 (Sun et al., 2004). Lin et al. designed a composite cone-index and moisture measurement device in 2014 (Lin et al., 2014). In order to avoid the influence of uneven insertion speed on the measurement results of compactness, ASABE stipulates that penetration speed should be uniform with a maximum penetration speed of 30 $mm \bullet s^{-1}$ (ASABE Standards, 2009).

The concept of combined measurement of compactness and moisture content was previously presented and designed, but there are two disadvantages in the existing systems. First, during the practical application, the operator faces difficulties in maintaining a uniform speed of penetration, which leads to errors in the cone-index measurement; second, such instruments are very expensive. Therefore, this study aimed to design and evaluate a low-cost standing wave ratio probe to be used in combination with a cone penetrometer to determine the moisture content and compactness of the soil, and to reduce the error caused by the non-uniform penetration speed by facilitating acceleration measurement. The combined PSWR probe was first tested in the laboratory, and the results were analyzed. Further, field measurements were conducted, and the results are presented.

Materials and methods

PSWR probe design

As shown in *Figure 1a,* the structure of the penetrometer consists of a cone head, a connecting rod, and a fixed base. The cone head and the connecting rod are marked with scales to measure the insertion depth of the probe with an accuracy of 1 mm. The connecting rod is a hollow steel tube of outer diameter 10 mm, inner diameter 4 mm, and length 700 mm. It is connected to a pressure sensor through the thread; the pressure sensor and acceleration sensor are installed on the base. The cone head is fabricated

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1393113944

according to American Society of Agriculture and Biological Engineers (ASABE) requirements; the conical diameter is 20 mm and conical angle is 30°. The double-metal-ring SWR probe is mounted on the cone head to form the PSWR probe.

The double-metal-ring SWR probe is shown in *Figure 1b*. Two metal rings are mounted on a solid nylon column with grooves, and three PVC rings are installed between them for insulation, the probe spacing is 10 cm. The metal rings are connected using wires as electrodes to the circuit, which measures the SWR. The wires and metal rings are welded together and installed in the grooves. The circuit, which measures the SWR, is located on the upper part of the probe to reduce the error caused by a change in the impedance around the wires, and is filled with waterproof glue to render it waterproof. The probe has an overall length of 150 mm. The fabricated physical model is shown in *Figure 1c*.

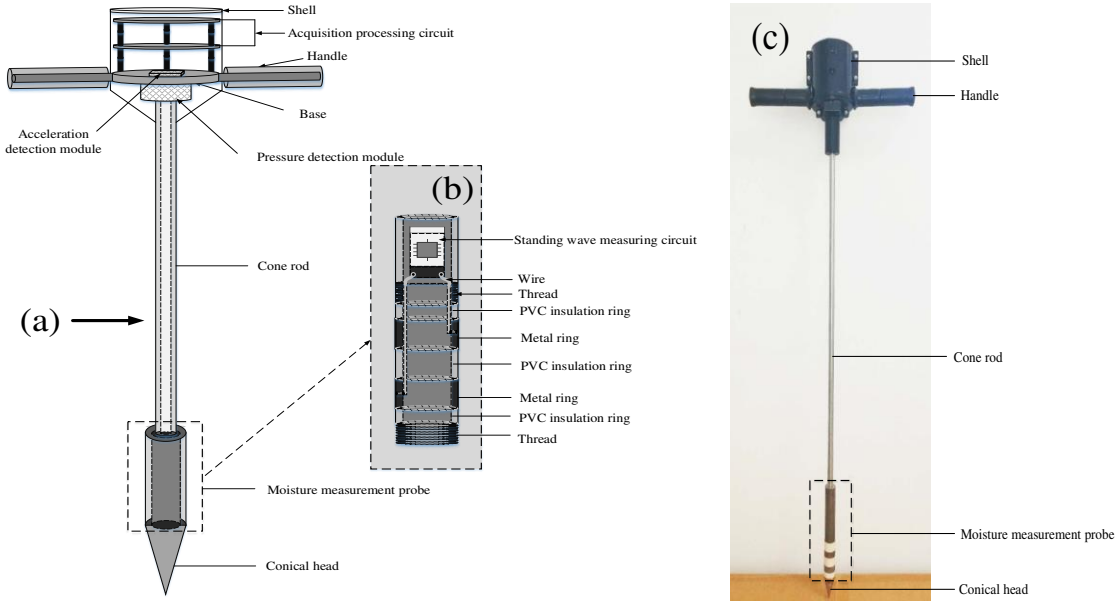

Figure 1. *The assembly of a combined PSWR probe is illustrated: (a) Detailed schematic diagram showing the parts of the instrument; (b) Components of the double-metal-ring SWR probe are detailed; (c) Photograph of the actual physical model fabricated during the study is shown*

Soil compactness measurement based on cone index

The ASABE (formerly the American Society of Agricultural Engineers) stipulates that when the standard cone is penetrated into the soil at a constant speed, the average pressure per unit area is the cone index (*CI*), which can be used to characterize the soil compactness (ASAE S313.3 FEB04., 1998; ASABE Standards, 2009). The formula to calculate *CI* is as follows *Equation 1:*

$$CI = N / S = (F + G) / S \quad \text{(Eq.1)}$$

where N is the pressure at the bottom of the cone head, S is the bottom area of the cone head, F is the external force exerted by a person on the penetrometer, and G is the force due to gravity on the instrument.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1393113944

However, during the actual measurement, it is difficult to maintain a uniform insertion speed; therefore, errors persist in the measurement results because of the complexity in the soil composition and non-standard manual operation. Hence, this study suggests a synchronous measurement of the external force (F) and acceleration (a) during the insertion of the cone. The pressure at the bottom of the cone can be calculated as follows *Equation 2:*

$$N = F + G - m * a \quad \text{(Eq.2)}$$

where m is the cone instrument quality. With this pressure, the corrected cone index can be calculated according to *Equation 1,* and the error caused by the variation in the velocity during the insertion can be eliminated.

Measuring volumetric moisture content of soil based on SWR

Moisture sensors based on SWR measure the dielectric constant of the soil. When high-frequency electromagnetic waves propagate along a transmission line, some of the incident waves are reflected by the probe placed in soil of different dielectric constant, because the impedance of the probe does not match with the impedance of the transmission line. Due to the interference of the reflected wave and the incident wave, a standing wave is formed on the transmission line, which causes a change in the voltage difference across the transmission line (Gaskin et al., 1996; Paltineanu et al., 1997). The moisture sensor designed in this study consists of a 100 MHz crystal oscillator, coaxial transmission line, and double-metal-ring probe (*Fig. 2*). The voltage difference across the transmission line can be expressed as follows *Equation 3:*

$$\Delta U = 2A \frac{Z_P - Z_L}{Z_P + Z_L} \quad \text{(Eq.3)}$$

where A is the electromagnetic wave amplitude (V), Z_P is the probe impedance (Ω), and Z_L is the transmission-line impedance (Ω). Z_L is dependent on the physical dimensions and the dielectric constant of the insulating material (50 Ω in this research). Z_P is determined by the probe size, soil permittivity, and operating frequency. The probe size and operating frequency are fixed values, which implies that a difference in the soil dielectric constant at the measurement site will change the impedance of the measuring probe, which results in a change in the voltage difference (ΔU) across the transmission line. The volumetric moisture content of soil has a relatively unique mathematical relationship with its dielectric constant (Topp, 2003; Yanuka et al., 1988); therefore, the moisture content can be measured by measuring the probe impedance.

Filed sampling and instrument

The soil samples were collected from Beijing Gongqing Forest Farm (116.73° E, 40.11° N) and Beijing Forestry University Sanqingyuan Experimental Base (116.34° E, 40.00° N), which are primarily used for teaching and research in the Beijing Forestry University. These sites experience a typical continental climate, with an average annual temperature of 11.6 °C and an average annual precipitation of 600 mm. Areas of uniform soil were identified at the collection sites, and 30 kg of soil samples were extracted. These samples were dried (48 h, 105 °C) in an oven shown in *Figure 3d*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1393113944

After drying, the samples were screened through a 40-mesh sieve shown in *Figure 3c* to remove impurities, such as stones, dead branches, fallen leaves, and roots. Thus, the soil samples for the experiment were obtained, which were identified as sand soil (sand mass fraction 85%, powder mass fraction 10%, clay mass fraction 5%) shown in *Figure 3a* and clay loam soil (sand mass fraction 11%, powder mass fraction 71%, clay mass fraction 18%) shown in *Figure 3b*.

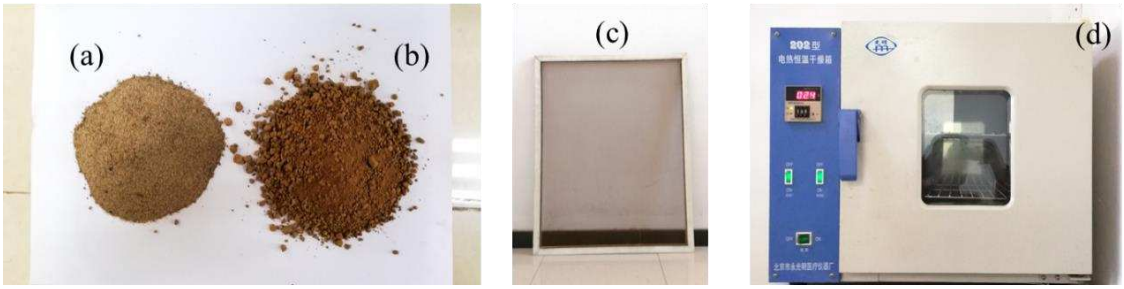

Figure 3. *The details of soil sampling are presented: (a) Picture of the sampled sand soil; (b) Picture of the sampled clay loam soil; (c) 40-mesh sieve used for screening the impurities; (d) Drying oven used for drying the samples*

The contrast instrument is SC-900 sensor (American Spectrum production, measuring unit KPa, resolution is 35 KPa, measurement accuracy is 103 KPa, the range is 0-45 cm and 0-7000 KPa, maximum insertion speed is 25 mm•s-1, maximum load is 95.25 kg) and TDR sensor (German IMKO production, model TRIME-PICO32, measurement range 0-100% volume moisture content, measurement accuracy ± 2%, probe diameter 3.5 mm and probe length 110 mm).

The field experiments were conducted at Beijing Forestry University Forest Farm (altitude 642 m, 116°4’36”E, 40°3’42”N) and Beijing Forestry University Sanqingyuan Experimental Field (altitude 52 m, 116°20’15”E, 40°0’44”N).

Experimental procedure

Two different soil samples of 10 kg each were weighed by a precision electronic weighing machine. A certain quantity of water was added to the samples and mixed thoroughly. The samples were detained for 48 h until the water movement attained

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1393113944

equilibrium, and were subsequently placed in PVC buckets (20 cm high, 30 cm diameter) and compacted uniformly using a nylon rod (50 cm length, 5 cm diameter). Different trials were conducted by varying the water quantity and compaction of the soil samples; the combined probe was inserted into the soil samples to a penetration depth of 20 cm, and the pressure and acceleration of the penetrations were recorded. The compactness of the samples was also measured using an SC-900 soil compactness meter, the SC-900 sensor is mounted on permanent magnet direct current motor (BXTL150, made in China, working voltage 12 V, power 30 W), the rotation of the motor drives the gear to rotate, which makes the SC-900 sensor move vertically downward uniformly (12 $mm \bullet s^{-1}$) along the guide rail to ensure that the SC-900 sensor measurement can obtain accurate soil compactness and be used as the true value of sample. The relation between the pressure and acceleration during the penetration were analyzed, and the effect of variation in the acceleration on the measurement results was investigated. The sensitive range of the double-metal-ring probe was analyzed by HFSS (High Frequency Structure Simulator) modeling and experimental analyses. Lumped port excitation method was assigned, and the value of frequency was set as 100 MHz and fill dielectric constant as 21 (corresponding to a volumetric moisture content of 36%). The metal ring was the ideal electric field boundary; a cylindrical body of diameter 20 cm and height 20 cm was assumed as the radiation boundary. Meanwhile, the soil column used for the experiment was thinned in steps of 1 cm thickness, the volumetric water content, compactness and height of soil columns remain unchanged, and the combined probe was inserted into the center of the sample; the output voltage of the probe corresponding to the diameter of the soil column was recorded for each step. After the calibration of the combined probe by the drying method, the accuracy and stability of the moisture measurement were analyzed by comparing the results with that from a TDR soil moisture sensor. Field experiments were finally carried out to verify the performance in practical conditions.

Results and discussion

Relationship between penetration acceleration and pressure

The acceleration (a) and force (F) data observed during the penetration were normalized, and the variations in pressure and acceleration are shown in *Figure 4*. Initially, the penetration force (F) remains constant before the cone makes contact with the soil; it increases gradually as the cone touches the soil and continues the penetration, and then decreases rapidly to zero when penetration is stopped after reaching a certain depth (20 cm in this case). Meanwhile, because it is difficult to main a uniform cone penetration manually, there is a fluctuation in the acceleration along the vertical direction. The initial penetration acceleration (a) varies drastically when the cone reaches the soil, and the variation decreases as the cone continues to penetrate into the soil. The influence on the force at the bottom surface of the cone was calculated using *Equation 2,* and the measurement results after the acceleration correction were calculated. *Table 1* is the measurement results of soil samples with different compactness and the depth of measurement is 10 cm. It can be observed that the measurement error is reduced by measuring the penetration acceleration of the cone.

Table 1. *The results obtained from the two sensors are tabulated for comparison. For the composite sensor, the results before and after the acceleration correction are presented along with the corresponding error values*

Sample number	SC-900 measurement results (KPa)	Combined PSWR probe			
		Cone index (not counting acceleration)		Cone index (calculation acceleration)	
		Measurement results (KPa)	Relative error ($cm^3 \cdot cm^{-3}$)	Measurement results (KPa)	Relative error ($cm^3 \cdot cm^{-3}$)
1	344	379.47	10.31%	363.55	5.68%
2	380	392.90	3.40%	379.33	0.18%
3	421	442.79	5.18%	428.70	1.83%
4	526	541.28	2.90%	532.68	1.27%
5	632	658.95	4.26%	651.75	3.12%

PSWR probe detection sensitive area

The HFSS software was used to establish the simulation model of the probe. The electric field distribution of the annular probe is shown in *Figure 5*. It can be seen that the electric field strength gradually decreases as the diameter increases; at the boundary of 10 cm diameter, the electric field strength attenuates to 8 V/m (1% of the center electric field strength). The variation of soil column diameter is shown in *Figure 6*. The variation of the voltage with the diameter of the soil column is shown in *Figure 7;* the output voltage begins to decrease rapidly when the diameter is 10 cm, indicating that the sensitive range of the probe is within 10 cm diameter from the cone. Hence, to ensure accuracy in the measurement, it should be guaranteed that the soil within 10 cm diameter around the cone is uniform and does not contain debris and other impurities.

Laboratory experiment for calibration

For different values of volumetric moisture content of the soil samples, the corresponding voltage of the combined probe was measured and recorded; the relationship between the voltage and the volumetric moisture content is shown in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1393113944

Figure 8. For the clay loam and sand samples, the linear-fitting coefficient of output voltage and volumetric moisture content were 0.9694 and 0.9824, respectively, and the fitting determination coefficients were higher than 0.96. This indicates that the output voltage has a good linear relationship with the volumetric moisture content, and the volumetric moisture content can be calculated by fitting the curve.

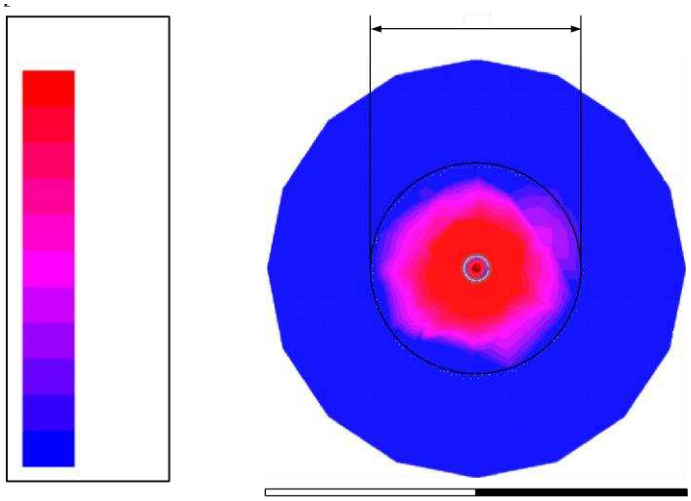

Figure 5. *Electrical field distribution of double-metal-ring probe obtained by simulation is shown: top view of the model, which shows the distribution along the plan*

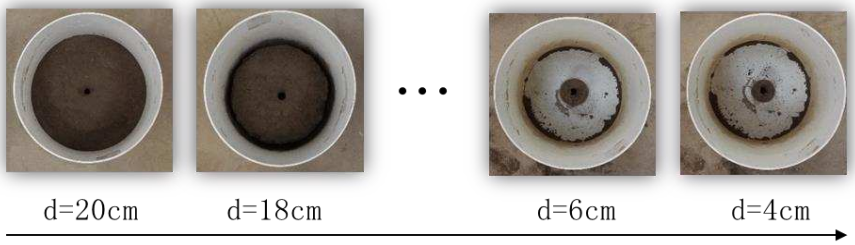

Figure 6. *The gradual reduction of the soil column thickness of the sample during the metal-ring lateral-diameter test process is shown*

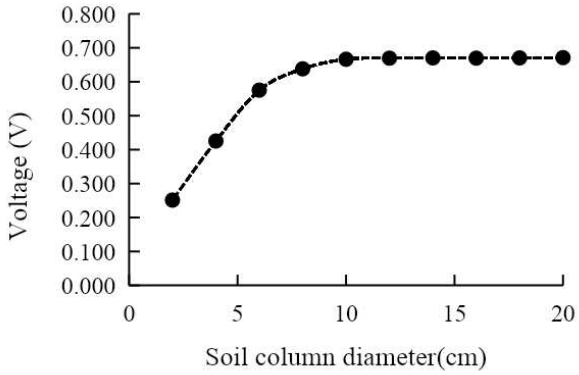

Figure 7. *The variation in the output voltage with the diameter of the soil column is illustrated*

DOI: http://dx.doi.org/10.15666/aeer/1706_1393113944

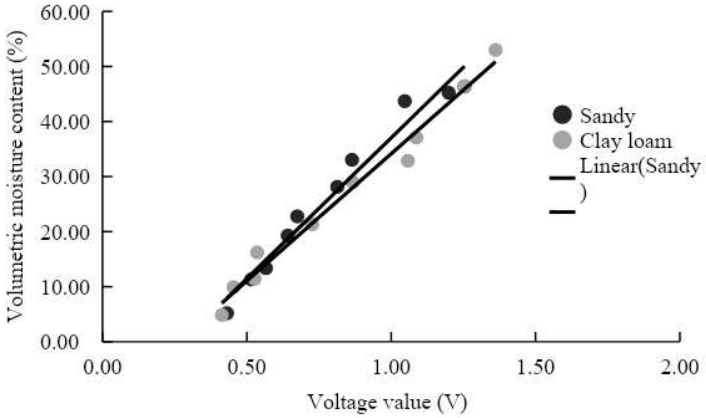

Figure 8. *Relationship between the volumetric moisture content and the voltage value is depicted*

Laboratory measurement

Figure 9 shows the variation in the volumetric moisture content of the soil measured by the probe in 100 repeated measurements in a sand sample of diameter 100 cm and height 20 cm. It can be observed that the measurement results fluctuate very less; the maximum and minimum values of volumetric moisture content were 10.68% and 8.74%, respectively, and the standard deviation was 0.49%. Therefore, it is verified that the PSWR probe can be used for repeated measurements.

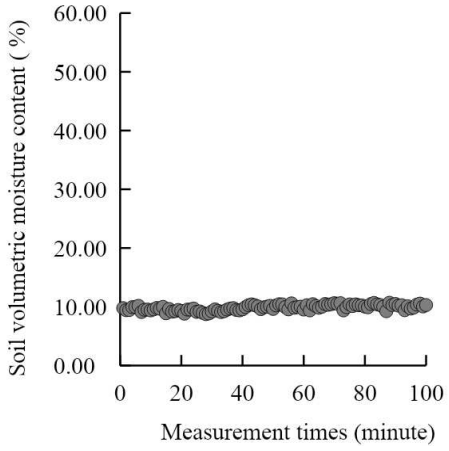

Figure 9. *Results obtained from the repetitive measurements of moisture content are plotted*

Figure 10 is a comparison of the results obtained from the proposed PSWR probe and TDR sensor in two soil types; twelve samples of different volumetric moisture content were prepared for each soil type. Measurement soil volumetric moisture content of the same sample with PSWR probe and TDR sensor respectively. It can be observed from *Figure 10* that the results from the proposed probe are consistent with those from the TDR sensor. The results from the proposed PSWR probe and the TDR sensor were linearly fitted, as shown in *Table 2*. The fitting determination coefficients prove that the measurement accuracies of the two devices are comparable, which satisfies the requirements of practical application.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1393113944

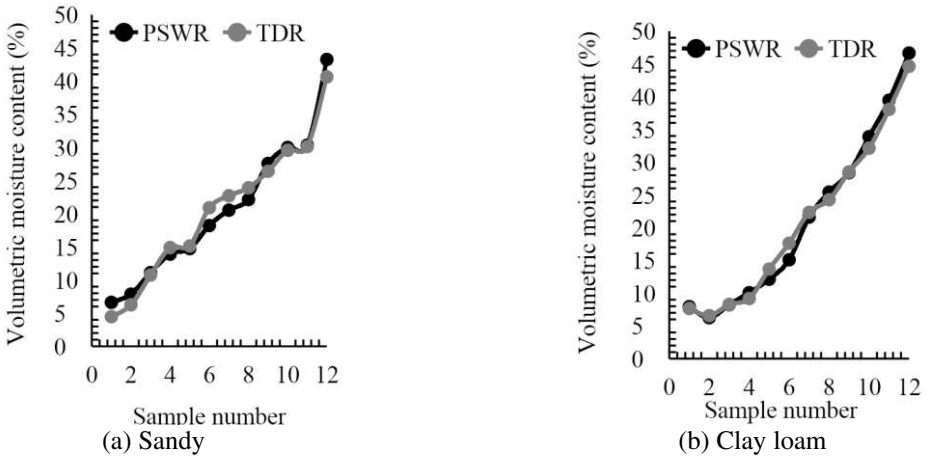

Figure 10. *The measurement results of the two devices are plotted together for comparison: Comparison of results obtained in (a) sandy soil, (b) clay loam soil*

Table 2. *The linear fitting expression and fitting determination coefficient (R^2) of the results from the two devices are tabulated*

Soil type	Linear fit expression	R^2
Sandy	y = 0.9745x + 0.4743	0.975
Clay loam	y = 0.9555x + 1.2446	0.9881

Six samples of different volumetric moisture contents prepared using clay loam were subjected to three measurements per sample, simultaneously with the TDR sensor and the proposed PSWR probe, and the samples were dried to obtain the actual values of the volumetric moisture content. The data was recorded and the standard deviation of the measurements was calculated. As shown in *Figure 11,* the error fluctuation in the measurements of the six samples are approximately equivalent; the standard deviation of the results from the PSWR probe and TDR sensor were obtained as 2.32 and 1.63, respectively. This indicates that the measurement stability of the PSWR probe is equivalent to that of the TDR sensor.

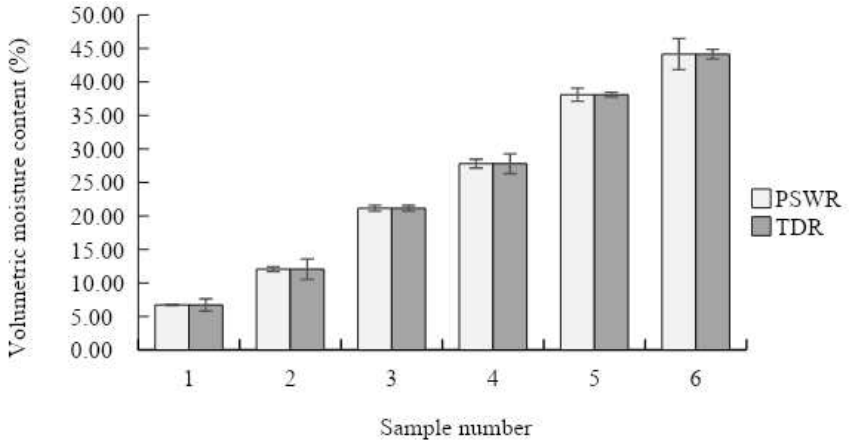

Figure 11. *The moisture content obtained using the two devices are plotted to compare the measurement stability*

Field measurement

A square, flat land of area 9 m^2 was selected at the sites, and the volumetric moisture content at five points were measured by the combined probe and by the drying method, as shown in *Figure 12*. The measurement depth was 20 cm, and the comparison of measurement results is shown in *Table 3.* It can be observed that the measurement results are comparable; the maximum error was obtained as 2.10%, which is less than 3%; therefore, the proposed probe meets the accuracy requirements for practical use.

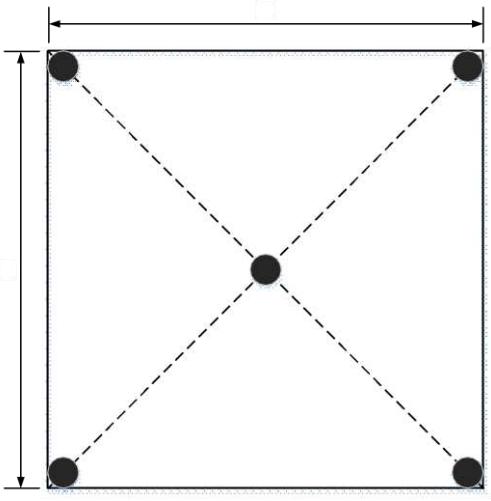

Figure 12*. This diagram illustrates the points selected for the field measurements at the site*

Table 3. *The field measurement results obtained using the proposed probe and the drying method are tabulated for both the sites, θ_V is drying method and θ_S is PSWR method*

Measuring point	Sanqingyuan experimental field		Forest farm	
	θ_V ($cm^3\ cm^{-3}$)	θ_S ($cm^3\ cm^{-3}$)	θ_V ($cm^3\ cm^{-3}$)	θ_S ($cm^3\ cm^{-3}$)
1	18.86%	19.90%	16.89%	17.21%
2	21.44%	21.85%	15.67%	17.35%
3	23.45%	21.35%	15.18%	16.39%
4	21.11%	19.61%	14.80%	16.57%
5	21.22%	20.05%	16.96%	15.16%

Three sites were randomly selected in the field experimental site, The comparison of measurement results is shown in *Figure 13,* the soil compactness was measured by SC-900 sensor and PSWR, the measured depth was 2.5 cm, 5.0 cm, 7.5 cm and 10.0 cm. The results showed that the accuracy of PSWR measurement was the same as that of SC-900 sensor, and met the practical application requirements.

Advantages of combined PSWR probe

The existing compactness sensors based on cone index method are difficult to ensure uniform penetration due to manual operation, resulting in measurement errors due to different vertical velocities (Alaoui and Diserens, 2018; Pillinger et al., 2018; Lin et al., 2014). Moreover, the internationally recognized TDR sensor for moisture measurement has the disadvantage of high price and easy damage of probe (Rudnick et al., 2018; Sun

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1393113944

et al., 2004; Yan et al., 2018). In view of the above shortcoming, the PSWR probe can simultaneously measure soil compactness and moisture content, the measurement error can be effectively reduced, and the accuracy of cone-index measurement can be improved by synchronously measuring the acceleration during the penetration. In addition, the PSWR probe has a lesser manufacturing cost and a more stable ring structure, and the soil compactness and volumetric moisture content can be measured synchronously by PSWR probe.

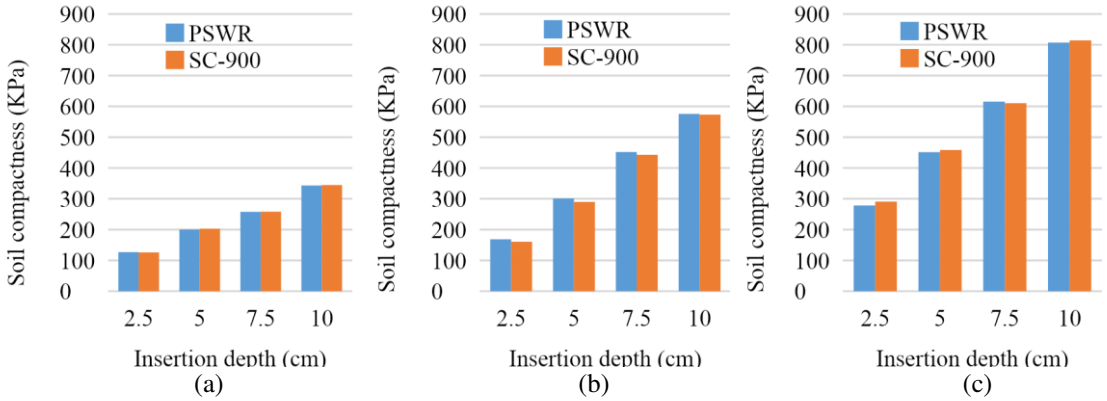

Figure 13. *Comparison of field soil compactness measurement. (a) First, (b) second, (c) third measurement site*

Conclusions

In this study, a combined penetrometer-SWR probe was designed and its performance was evaluated. Considering the errors caused by a varying penetration speed due to manual insertion during the cone-index measurement, we proposed to include synchronized acceleration measurement during the penetration process, and studied the acceleration and external force during the penetration process. The measurements errors were computed by comparing the results with that obtained from an SC-900 sensor, and the variation in the error after the acceleration compensation was observed. In addition, the measurement range of the double-metal-ring probe was analyzed and tested, and its performance was compared with that of a TDR sensor after calibration. Based on the experimental results, the following conclusions can be drawn:

First, there is a fluctuation in the penetration acceleration in the vertical direction, which causes a measurement error because of the complexity in the soil composition and non-standard manual operation during the penetration. The PSWR probe reduces the measurement error and improves the measurement accuracy by simultaneously measuring penetration acceleration.

Second, the HFSS simulation analysis and experiments show that the sensitive range of the PSWR probe designed in this study is within 10 cm diameter around the cone. To ensure accuracy in the results, the point of measurement should be selected such that the soil within a diameter of 10 cm is uniform and does not contain other impurities, such as gravel.

Third, calibration of the PSWR probe in the laboratory indicates that the output voltage has a significant linear relationship with the volumetric moisture content of the soil. The indoor tests prove that the moisture measurement probe can maintain a stable

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1393113944

output across multiple measurements; the results are comparable to that of a TDR sensor in terms of accuracy and stability.

Finally, the field measurement results obtained using the combined probe was compared to the drying-measurement results, and the maximum error in the volumetric moisture content measurement was obtained as 2.10%, which is less than 3%. This implies that the measurements by the combined probe are consistent with the results from the drying method, which satisfies the requirements for the practical implementation of the proposed probe.

Soil volumetric water content is closely related to soil compactness, soil porosity and soil bulk density, exploring the coupling relationship between them and establishing the coupling model will be the focus of future research.

Abstract. Forests play a major role in the regional and global carbon cycle. Climate change events have become serious issue, forests from various geographical regions have different sensitivities to climate variation. Therefore, we examine the effect of annual precipitation and annual temperature from 1950-2016 of white birch (Be*tula platyphylla)* stem biomass and composition in Daxing'anling Mountain Inner Mongolia China. We conduct a field survey, a total of 27 plots were established as the research area. In this study, we used allometric equation including the following components: diameter at breast height (DBH) and tree height (H). Our result showed that the response of *Betula platyphylla* stem biomass has a strong correlation with annual precipitation (R^2 = 0.80), and with temperature (R^2 = 0.75). A positive correlation was found for height with annual precipitation (R^2 = 0.76) and annual temperature (R^2 = 0.51). Additionally, a slightly positive correlation was observed for density with annual precipitation (R^2 = 0.26) and annual temperature (R^2 = 0.20). Our results also predicted that competition for survival played a significant role in tree growth. To achieve fast tree growth and high stem biomass response, systematically based forest management strategies, including thinning operation and selective cuttings could be established even under harsh Mongolian weather conditions. Our finding could suggest forest management guidelines for the normal growth of *Betula platyphylla* forest.
Keywords: *Betula platyphylla, stem biomass, forest ecosystem, global warming, carbon stock*

Introduction

Understanding the prediction and response of forest ecosystem to climate change is a crucial challenge for scientists worldwide (Pan et al., 2013). During the last decade, most studied forest ecosystem characters are the tree biomass and carbon storage. The knowledge of the forest distribution is an essential feature for the conservation strategies, including the reduction of global warming by carbon store in forest ecosystem (Saatchi et al., 2011; Baccini et al., 2012). To study boreal forest is particularly important because they store 460 billion tons of carbon in their biomass and soil, which is equal to the total atmospheric carbon stock (Pan et al., 2011), and process 40 billion tons of carbon annually (Beer et al., 2010). Because they cover a large area of land and play an important role in global climate, regulating energy balance and evaporation at the earth. Inverse modeling of biomass and carbon sink sources from the latitudinal distribution of atmospheric carbon dioxide concentration indicates that a major terrestrial carbon sink is located in ecosystem of the northern hemisphere (Tans et al., 1990; Menon et al., 2007) and also believed that significant fraction of this carbon sink occurs in the northern boreal forest (Hyvönen et al., 2007). Boreal forests also contribute to the diversity, richness, productivity in Daxing'anling Mountain in Inner Mongolia China, which exists under a wide range of harsh environmental conditions (Fang et al., 2012). Recently, boreal forest to sequester a substantial amount of atmospheric carbon dioxide and store carbon in its biomass has focus attention from worldwide (Kasischke, 2000; Donato et al., 2011; Alongi, 2014). A recently conducted study on *Larix gmelinii* and *Betula platyphylla* suggested that stem biomass have a strong correlation with annual precipitation and maximum temperature (Khan et al., 2019).

Northern Mongolia Daxing'anling Mountains is the transaction zone between Siberian taiga and Asian steppes. This line of transaction takes place over several hundred kilometers from north to south (Walter, 1974). The climate of this region is strongly seasonal, characterized by short mild summers and long very cold winter with annual precipitation and temperature variation (Korpela et al., 2013). More than 90% annual precipitation fall as rain during the growing season and another hand annual temperature in Mongolia increased by 2014 ◦C from last 70 years, which is higher than the rise of global average temperature. Precipitation almost decreases in every region at least 0.1 mm/year (Oyuntuya et al., 2015). Further decreasing of precipitation is expected in inner mountains (Sato et al., 2007). Current climate change, is considered the main driver of the vegetation change and observation showed that regional climatic variation has resulted in change in the natural and biological system, such as snow melting and the extension of growing season in the mid-high latitude areas (Douville, 2006; Shea et al., 2015; Rangecroft et al., 2016). Forest degradation significantly impact carbon stock (Baccini et al., 2012), and the recent climatic trend is already impacting forest biomass worldwide (Phillips et al., 2009). Recent studied describe that precipitation and temperature influence the forest ecosystem. Such as a change in temperature and precipitation is directly associated with global warming (Hidalgo-Muñoz et al., 2011; Coumou and Rahmstorf, 2012; Coumou et al., 2013; Omondi et al., 2014). During the last decades, due to the change of precipitation and temperature, many forest sites are replaced by steppe vegetation, while the composition of remaining species changes in the favor of pioneer tree species. Therefore, regeneration of different species increase their interest, while the effect the growth of the native tree species such as white birch (*Betula platyphylla)* (Dulamsuren et al., 2011; Khishigjargal et al., 2014; Gradel et al., 2017). *Betula platyphylla* growth pattern relationship with climate change is also useful for the forecast of species distribution and forest productivity (James, 2011; De Grandpré et al., 2011).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1394513959

Betula platyphylla was also known as, Manchurian birch or Asian white birch. *Betula platyphylla* is one of the common tree species in Daxing'anling Mountains Inner Mongolia. This species is drought sensitive, have good resistance against frost and able to grow under different climatic condition (Gradel et al., 2017). *Betula platyphylla* had good economic value and its height can reach up to 27 m along with the life duration of 140 years (Zyryanova et al., 2010). It is also one of the pioneer tree species from the south forest outposts in Inner Mongolia. Still, it is the most dominant tree species in the forest instead of human disturbance, cutting and use is a fire due to its fast sprouting capability (Otoda et al., 2013). It is important to protect this species to maintain their forest cover because of its play a significant role in biomass storage as we as in carbon sequestration potential (Hansen et al., 2013). Numerous approaches examine to understand forest biomass. Some are based on a comparison of remote sensing data with standing variables, such as diameter, height, and density to estimate above-ground biomass of trees (Baraloto et al., 2011). This type of correlative studies provide spatially explicit and to verified the estimate the above-ground biomass for an extensive assessment of carbon stock (Saatchi et al., 2011). This method has great importance for mapping carbon stock and evaluating risk from land-use change, which is beneficial for policy involvements (Asner and Mascaro, 2014).

Therefore, allowed the author to investigate the effect of climatic factors and stand characteristics of stem biomass allocation pattern of *Betula platyphylla* species. Although the dataset of China has used to evaluate the temperature effect on biomass allocation in the forest (Lie and Xue, 2016). While data about the effect of climatic factors on stem biomass and composition of *Betula platyphylla* forest is still lacking. Therefore, we want to find out the relationship between climatic factors such as precipitation and temperature from 1950-2016 with *Betula platyphylla* stem biomass. We also want to examine the influence of climatic factors on the height and density of Betula platyphylla.

Material and methods

Study area

Daxing'anling mountains are located at (E'7118.19.10-W'126.41.52, N'47.48.35-S53.33.12) in the Heilongjiang province of China which cover the area of 83000 km^2 with an altitude of 3556 m (*Figure 1*). This area has cold continental monsoon weather with an annual temperature of 2.8°C. Annual precipitation mostly received in July to August from 350-500 mm. snow covers the land for five months in the winter season, which have depth up to 30-50 cm in the forest area with wind flow of 1106 miles per hours. *Betula platyphylla* is the dominant tree species along Dahurian larch (Larix gmelini), Scots pine (Pinus sylvestris var), Mongolian oak (mongolica) among others are common tree species. During the months of summer from April to July of each year usually occur thunderstorms, lightning fires which become a cause burning to this area.

Field data collection

To take forest data a field survey was conducted in 2017 in Daxing'anling mountain of Inner Mongolia Autonomous Region of China. We used a random sampling method and a total of 27 circular plots was taken in the study area. Each selected sampling plot have a radius of 17.84 m. To find out stem biomass and carbon stock of *Betula platyphylla* stand forest, tree diameter at breast height (DBH), tree height (H) and Density (D) were measured in the study area.

DOI: http://dx.doi.org/10.15666/aeer/1706_1394513959

Climatic data collection

Climatic factors, such as annual precipitation and annual temperature from 1950 to 2016 were chosen as the parameters in the study area of Daxing'anling Mountain Inner Mongolia, China (*Figure 2*). Data of annual precipitation and annual temperature were download from the (0.50) grid data with help of KNMI climate Explorer [https://climexp.knmi.nl]. The climate station was uniformly distributed in northeastern Inner Mongolia China. Climatic data of each sample plot was download from its coordinate using a global positioning system (GPS) with an accuracy of 1-meter distance. It is used to extract the geographical data of each sample plot. Climate record has been assessed by China metrological administration (CMA) to assure consistency with continuity and to maintain the quality of instrument location and relocation of the stations.

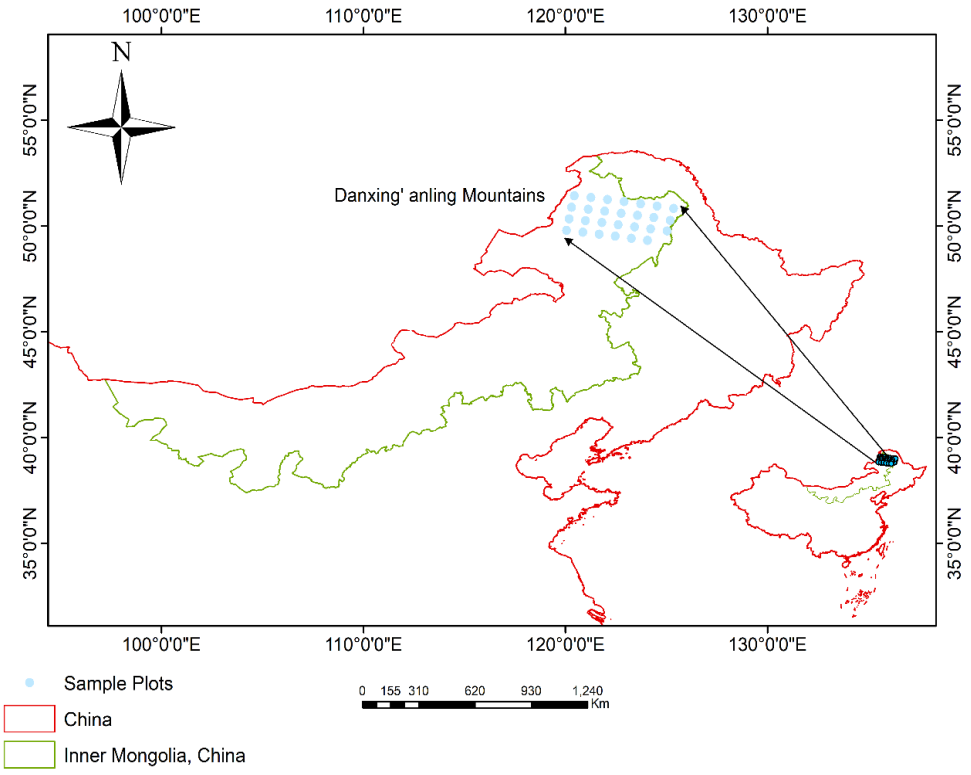

Figure 1. *Geographical Mapping of the study area. Map showing the geographic location of Betula platyphylla plots in Daxing'anling Mountains Inner Mongolia, China*

Stem biomass estimation

Several allometric equations have been developed by researchers to estimate biomass of different tree species using several variables as predictors or independent variables. DBH, total height, volume, basal area, density, and crown radius are the common variables used for estimation of tree biomass (Chave et al., 2005; Mandal et al., 2013; Goodman et al., 2014). The allometric equation gives us a result of the linear and nonlinear correlation between variables in two dimensions (Picard et al., 2012). The quality of the allometric equation is necessary for ensuring the accuracy of forest biomass estimation. It is not only the matter of error but also a statistical toll during the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1394513959

process should be considered (Picard et al., 2012). Stem biomass should be measured from the recommended component such as diameter at the breast height and height of the tree (H) (Chave et al., 2006). A model is considered reasonable if it yields estimates with minimum standard error (SEE), the minimum sum of the square of the residual error (SSE) throughout the range of data, does not give negative estimates and does not show a decrease in biomass with an increase in diameter or height (Ali et al., 2016).

The following allometric equation was used for *Betula platyphylla* to find out stem biomass and carbon stock which is developed by (Cheng and Li, 1989).

$$Ws = 0.1193 (D2\ H)\ 0.8372 \quad \text{(Eq.1)}$$

To estimate the stem biomass having a coefficient of determination of (R^2) of 0.1193. Where (Ws), is the stem biomass, tree diameter at breast height (D) and tree height (H). To find out total stem biomass per plot was summed for all plots and average to get the mean stem biomass, which was then converted to tons per hectare. Biomass fraction analysis was used to convert the value to its carbon equivalent. Carbon stock was determined as the product of the carbon sink and corresponding biomass of the individual tree.

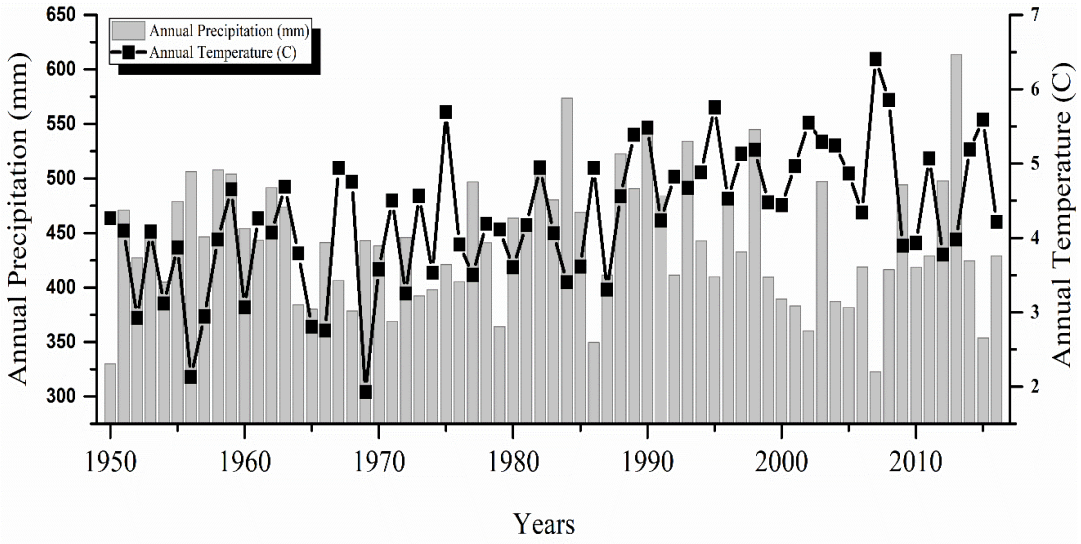

Figure 2. *Yearly climate diagram. Yearly climate diagram of annual precipitation and annual temperature from 1950-2016 in Daxing'anling Mountain Inner Mongolia, China*

Statistical analysis

Regression analysis was performed between dependent variables like stem biomass and carbon stock with explanatory variables like diameter, density, height and climatic variables Such as annual precipitation and annual temperature. The coefficient of determination (R^2) and probability level ($p \leq 0.05$) was used to determine the quality of curves. To check the variables relationship accuracy, we used linear regression analysis to check the variables relationship accuracy. All statistical analysis Analyses were performed using Origin-2016.

Results

The growing stock of Betula platyphylla

Betula platyphylla is the second most dominant species of Daxing'anling Mountains Inner Mongolia China, instead of human's disturbance, cutting and fires, due to its sprouting capability. The result revealed that average stem density ranged from 71.7 ± 21.6 (trees ha^{-1}) while, the total range between low to high stem density was 34.0 ± 111.0 (trees ha^{-1}). The mean diameter of the tree was in the range of 16.3 ± 3.3 (cm) to 11.4 ± 23.8 (cm). The value of average height ranges from 20.8 ± 4.49 (m) to 14.0 ± 29.0 (m), (*Table 1*).

Table 1. *Growing stock characteristics of Betula platyphylla*

No	*Betula platyphylla*	Average density	Average diameter	Average height
1	Mean & Standard deviation	71.7±21.6	16.3±3.3	20.8±4.4
2	Minimum & Maximum	34.0±111.0	11.4±23.8	14.0±29.0

In order to study the relationship between stem biomass (ton/ha), height (m), density (ha^{-1}) with annual precipitation (mm) and annual temperature (^{0}C) regression models were developed in detail which is given below in (*Table 2*).

Table 2. *Relationship type, equation and R^2 value of the Betula platyphylla stand*

Climatic factor	Parameters	Relationship type	Equation	R^2 Value
Precipitation	Stem biomass	Polynomial, Linear	y = -115.9592+ 0.6129*x	0.8014
	Height	Polynomial, Linear	y = -21.9297 + 0.1015*x	0.7674
	Density	Polynomial, Linear	y = 81.8608+ 12.4413*x	0.0696
Temperature	Stem biomass	Polynomial, Linear	y = 81.8608+ 12.4413*x	0.7562
	Height	Polynomial, Linear	y = 12.4017 + 1.7366*x	0.5144
	Density	Polynomial, Linear	y = 54.3686 + 3.5805*x	0.0921

Relationship of precipitation (mm) and temperature (^{0}C) with stem biomass (ton/ha), height (m) and density (ha^{-1}) of *Betula platyphylla*

Biomass and carbon stock of Betula platyphylla with climatic factors

Total tree biomass distribution of *Betula platyphylla* forest was recorded at a range of 142.2±26.2 (ton/ha) with, variation from minimum to maximum 26.2±188.3 (ton/ha) was absorbed. While the total average stem biomass 142 (ton/ha) were found. Carbon stock recorded at the range of 68.7 ± 23.0 to 23.0 ± 134.4 (ton/ha) with, total average carbon stock of 71 (ton/ha) in the study area. The total average precipitation 421 (mm) recorded with the range of 421.2±38.3 along, variation from minimum to maximum 38.3±490.0 mm. The temperature range was 4.9±1.8 to 1.8±134.4 (^{0}C) with a total average temperature of 5 (^{0}C), which are given in the following (*Table 3*).

Effect of climatic factors on stem biomass, height, and density of Betula platyphylla

To study the influence of climatic variables such as annual precipitation and annual temperature from 1950-2016 on stem biomass, height and density of *Betula platyphylla* in Daxing'anling Mountains Inner Mongolia. Annual precipitation and annual temperature have a positive correlation with *Betula platyphylla* stem biomass and height. While a negative correlation was absorbed with a density of *Betula platyphylla*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1394513959

According to coefficient correlation ($P \leq 0.05$), the result showed that annual precipitation ($R^2 = 0.80$) and annual temperature ($R^2 = 0.75$) have the strongest correlation with stem biomass (*Figure 3*).

While, height have strong correlation with annual precipitation ($R^2 = 0.76$) and annual temperature ($R^2 = 0.51$), respectively (*Figure 4*).

Table 3. *Biomass and carbon parameters with climatic variables of Betula platyphylla*

Betula platyphylla	**Mean & Standard deviation**	**Minimum± Maximum**
Stem Biomass	142.2±26.2	26.2±188.3
Carbon Stock	68.7±23.0	23.0±134.4
Precipitation	421.2±38.3	38.3±490.0
Temperature	4.9±1.8	1.8±134.4

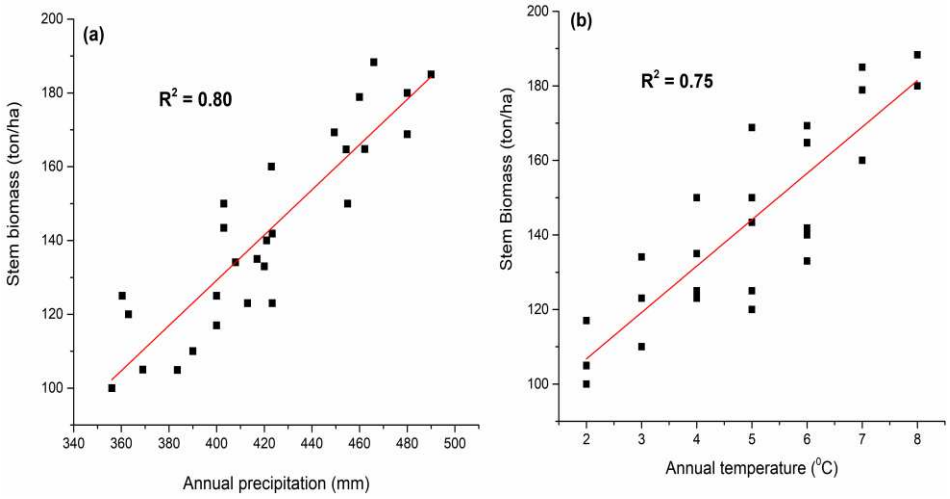

Figure 3. *Stem biomass correlation with annual precipitation and temperature. Betula platyphylla stem biomass correlation with Annual precipitation (a) and Annual temperature (b) from 1950 – 2016*

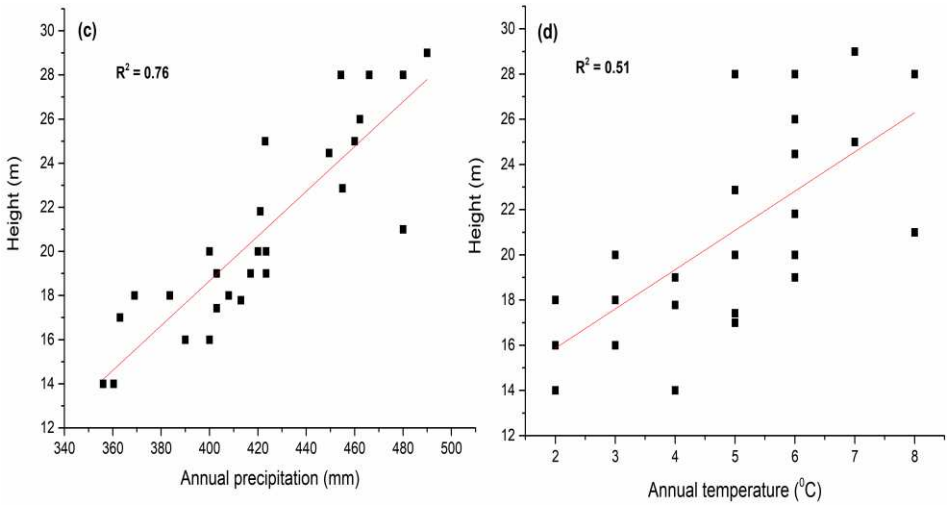

Figure 4. *Height correlation with annual precipitation and temperature. Betula platyphylla height correlation with Annual precipitation (c) and Annual temperature (d) from 1950 – 2016*

DOI: http://dx.doi.org/10.15666/aeer/1706_1394513959

In addition, slightly positive correlation was found between *Betula platyphylla* density with annual precipitation (R^2 = 0.26) and annual temperature (R^2 = 0.20) (*Figure 5*).

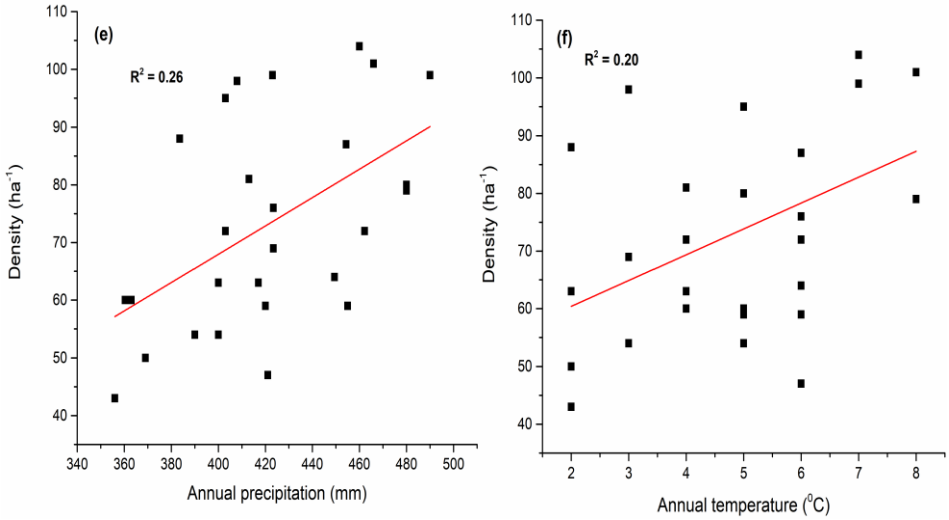

Figure 5. *Density correlation with annual precipitation and temperature. Betula platyphylla density correlation with Annual precipitation (e) and Annual temperature (f) from 1950 – 2016*

Discussion

Daxing'anling Mountains of Inner Mongolia is the important region of northern China. It is located at the high latitude of the northern hemisphere. Which is considered the most sensitive zone to global climate change (Dai et al., 2002; Wang et al., 2012). *Betula platyphylla* forest of this region plays a key role in the contribution of global carbon flux (Wang et al., 2006; Cai et al., 2015), as well as, in the establishment of forest lands consequent harvest and wildfires (Wang et al., 2015). It holds 8.39 million hectare of forest land and 0.76 billion m^3 of timber stock, respectively (Fang et al., 2001; Wang et al., 2006). Wide distribution with transaction character from boreal to the temperate zone, make it important in its prime production and carbon sequestration potential (Wang et al., 2006, 2008). Boreal forests in Inner Mongolia also have tremendous carbon storage mainly due to their vast forest area and living wood stock volume, though their coverage and carbon density lag behind many other provinces in China. Thus, as a whole, they play a significant role in the Chinese terrestrial ecosystem carbon cycle and in turn play an important role in the global carbon cycle (Sun et al., 2008). Meanwhile, there are many challenges as well as opportunities for a long-time forest in the area is lack of management with the extensive degradation of existent stands and poor stand quality and low productivity. The aggravation of desertification accompanying warming and drying trend under climate change is a huge threat to the forests.

Forest vegetation under different climate conditions reacts with a different way to their climatic factors. Climatic variables assessment of the last 66 year annual precipitation and annual temperature predict positive correlation with *Betula platyphylla*. *Betula platyphylla* stem biomass has a strong correlation with annual precipitation (R^2 = 0.80), and annual temperature (R^2 =0.75). While, positive correlation was found

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1394513959

for height with annual precipitation (R^2 = 0.76) and annual temperature (R^2 = 0.51). Forests response positively to the impact of rising precipitation and temperature (Fang et al., 2003; Piao et al., 2005), and they have a positive effect on forest biomass (Lindner et al., 2010). Increase in precipitation and temperature will increase the absorption of carbon dioxide in the forest vegetation (Grant et al., 2004). In term of, stand age had an influence on forest carbon storage. Increasing of stand age also increase carbon storage capacity (Yu et al., 2017). At last, at last, the carbon storage in the forest decreases to a relatively stable level, due to the limiting of hydraulic resistance (Zaehle et al., 2006), and the growth of wood become very slow, which is almost not change (Liu et al., 2012). Some studies also predicted that precipitation and temperature are the main climatic factors that affect forest vegetation in the mid-western United States and China (Peckham et al., 2012), Russia (Alexeyev et al., 1995), Canada, and the Netherlands (Nabuurs and Mohren, 1993) among other places. While the response of vegetation types to precipitation and temperature has differed among places. The rising of precipitation and temperature have been found to increase the forest biomass in colder and wetter ecoregions (Dymond et al., 2015), but reduce the net rate of stem biomass in the Amazon rainforest (Brienen et al., 2015), and the growth rates of mature rainforests (Hopkin, 2007).

Additionally, the results showed that precipitation and temperature were significantly affected by plant density. Due to which the response of density of *Betula platyphylla* has a slightly positive correlation with the annual precipitation (R^2 = 0.035) and annual temperature (R^2 = 0.09), Similarly to the previous studies on tropical elevation transect forest (Leuschner et al., 2007; Girardin et al., 2010). Increase in plant density creates the interplant competition over light and precipitation which cause the disturbance in the balance of growth regulators. Under these conditions, plant density increases while, decrease in light and precipitation penetration into middle and lower layers of canopy and auxin decomposition (Imam and Ranjbar, 2000). Increase in plant density had a significant effect on *Betula platyphylla* plant height. Which tends to decrease because the plants compete over other growth affecting parameters than light (Mukhopadhyay and Sen, 1997).

Generally, denser *Betula platyphylla* stands forest results in higher total production, but the growth of the individual trees will be small (Ohtsuka et al., 2005). The increased volume production can though easily be lost through damages caused by wind or snow (Nykänen et al., 1997). With an increased number of stems density, the dimension decreases, while the volume concentrates in weaker dimensions (Coomes and Allen, 2007). The utility of wood products will be increased with lower stem densities (King et al., 2006). When pre-commercial thinning is performed competition for light and nutrition will decrease and the single stem will have the possibility to increase its diameter growth (Pothier, 2002; Karp and Shield, 2008). The main role of *Betula platyphylla* Silviculture is to have dense stands initially and then successively widening the spacing between the stems (Almgren, 1990). The green crown should never be smaller than half the stem length (Lapidge et al., 2000; Hörnfeldt, 2014). Since shad intolerant species like *Betula platyphylla* has a strong relationship between tree crown diameter and growth (Dolezal et al., 2004). *Betula platyphylla* stands with less than 50% of the living crown will have a small possibility to respond positively to future thinning (Dolezal et al., 2004). Thus, other stand variables such as height, diameter, and stem biomass could be important parameters to driving this observation,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1394513959

however, the data of wood density in mountain forests is infrequent and requires more sampling effort (Chave et al., 2009).

Demonstrating to find out stem biomass quantification in the *Betula platyphylla* forest in Daxing'anling Mountain. The destructive sampling method was not possible in our study site. That's why we attempt to minimize the uncertainty, we used the allometric equation developed in a similar climate condition with similar tree composition (Cheng and Li, 1989). In general tree diameter at the breast height and height of the tree is commonly used is a parameter to find out tree biomass in most equations (Wang, 2006; Dong et al., 2014; Wang et al., 2017). Furthermore, its depend on research goals and three components to investigate tree biomass with the help of equation (Zou et al., 2015; Kralicek et al., 2017).

Thus, during 1950–2016, the response of stem biomass and height of *Betula platyphylla* forest have a strong correlation with annual precipitation and annual temperature. While density has a negative correlation. That's mean, it also needs further research on forest management and the relative contribution of human activities to forest vegetation in Inner Mongolia.

Conclusion

In this study, we examined the effect climate factors, such as precipitation and temperature from 1950-2016 on *Betula platyphylla* forest ecosystem in Daxing'anling Mountains Northeast China. The response of *Betula platyphylla* to precipitation and temperature was positively correlated with stem biomass and tree height but negatively correlated with the density. Which predict that forest ecosystem also needs a proper management practice for normal growth. As we know, forests are an important component of the global carbon cycle. *Betula platyphylla* forest management can contribute towards emissions reductions and to carbon sequestration. To increase *Betula platyphylla* forest capacity regarding biomass and carbon sequestration providing incentives for the maintenance of future and existing forest resource, enhancing regeneration to increase species composition and stocks, increase people participation in forest management, decelerating hot spot for carbon sequestration and protected area.

(Received 24th May 2019; accepted 25th Oct 2019)

Abstract. In winter, low sludge activity, low microbial abundance and low C/N directly affect the quality of wastewater and the removal of total nitrogen in wastewater treatment plants. In this paper, the CAST process for treating low C/N domestic sewage is selected as the experimental reactor, and the method of a combining solid carbon source with biological reinforcement is used to raise the discharge of effluent up to the standard. The target bacteria were immobilized with artificial filler, and different bacterial components were placed in different positions of CAST reactor. The ammonia nitrogen, total nitrogen and COD in the effluent of the system were measured, and the changes of microbial community structure in the treatment process were analyzed by PCR-DGGE technology, so as to determine the effect of solid carbon source and biological reinforcement on the denitrification performance of CAST process.
Keywords: *domestic sewage, activated sludge, high efficiency denitrification, aerobic denitrifying bacteria, community structure*

Introduction

Nitrogen discharged into it will have a great impact on the water body. Therefore, denitrification is an important part of sewage treatment. At present, sewage treatment plants around the world need to be upgraded, and efficient denitrification is a key issue in sewage treatment (Adouani et al., 2015). For domestic sewage, the main influent nitrogen is ammonia nitrogen. At present, the denitrification process in activated sludge system is mainly composed of nitrification process and denitrification process. Any link of the process is limited, which will affect the final denitrification effect of the system and directly affect the quality of the effluent (Magrí et al., 2012). For the traditional denitrification principle of activated sludge system, the main factors that restrict the nitrification process include insufficient aeration and low abundance of nitrifying bacteria; the main factors that restrict the denitrification process include excessive aeration leading to the restriction of denitrifying bacteria and insufficient carbon source restricting the denitrification process (Bellucci et al., 2013).

In this paper, Cyclic Activated Sludge Technology (CAST) process for treating low C/N domestic sewage was selected as the experimental reactor. Biological enhancement and solid carbon source were used to enhance the denitrification performance of the reactor. Nitrification and denitrification can improve the denitrification performance simultaneously. Nitrifying bacteria, anoxic denitrifying bacteria, aerobic denitrifying bacteria and corn cob solid carbon source were used to enhance the denitrification performance of CAST process for treating low C/N domestic sewage (Chen et al., 2016). The changes of COD, NH_4^+-N and TN in the control group and the experimental group with biological agents and corncob were investigated during the experiment. The changes of activated sludge community structure in the two reactors were analyzed by

DOI: http://dx.doi.org/10.15666/aeer/1706_1396113974

PCR-DGGE technology, and the adaptability and stability of artificial enhanced biological agents in the system were determined.

Materials and Methods

Experimental materials

Strains and activated sludge

Nitrobacteria were gathered from the compound nitrifying agent M preserved in the laboratory. Anoxic denitrifying bacteria come from the compound anoxic denitrifying bacteria agent Q preserved in the laboratory. Aerobic denitrifying bacteria were compounded by *P.sp., P.stutzeri, P.aeruginosa* according to 1:1:1. Activated sludge is taken from the surplus sludge of Sewage Treatment Plant close to river in a county.

Corncob

Corn cob for experiment comes from Shapingba District of Chongqing City and is cut after recycling, screened by 1 mesh screen, and then screened by 2 meshes screen. Corncobs on the screen were used as experimental materials. Corncobs were about 1-2 cm in diameter. Two days after drying in an oven at 30℃, it was stored in a dryer.

Inlet

The background monitoring of the influent quality of domestic sewage treatment plant close to river in a county was carried out. The actual influent COD was 100-150 mg/L, TN was 20-40 mg/L, and NH_4^+-N was 15-30 mg/L. In order to better simulate the water quality of the sewage treatment plant, the water used in this experiment was diluted and $(NH_4)_2SO_4$ and $NaNO_3$ were prepared for school domestic sewage. The control of COD was about 150 mg/L, TN was about 40 mg/L, and NH_4^+-N was about 30 mg/L. It is generally considered that the wastewater with COD less than 200 mg/L and wastewater COD/TN is 5.6.

Design and operation of CAST reactor

Two groups of parallel reactors were set up, the control group and the experimental group respectively, the reactor schematic diagram is shown in *Figure 1*. Volumes of anaerobic selective zone, pre-reaction zone and main reaction zone in CAST reactor are 10.5L, 12L and 126L, respectively. The anaerobic selective zone L×B×H = (300×100×350) mm; the pre-reaction zone is L-type, 300 mm long, 100 mm wide on the top and 200 mm wide on the bottom, 350 mm high on the front and 600 mm high on

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1396113974

the back; the main reaction zone L×B×H = (700×300×600) mm. The operation period is set up to be 4 hours, water intake 1 hour, aeration 2 hours, standing 1 hour, drainage 1 hour, and aeration begins during water intake. MLSS is set at 3500 mg/L, water filling ratio is 1/3, reflux ratio of mixed liquid is 30%, bottom microporous explosion is used, DO is controlled at aeration stage to be 4.0-5.0 mg/L. During the experiment, no sludge was discharged and reactor operated at room temperature, and the temperature was about 20℃.

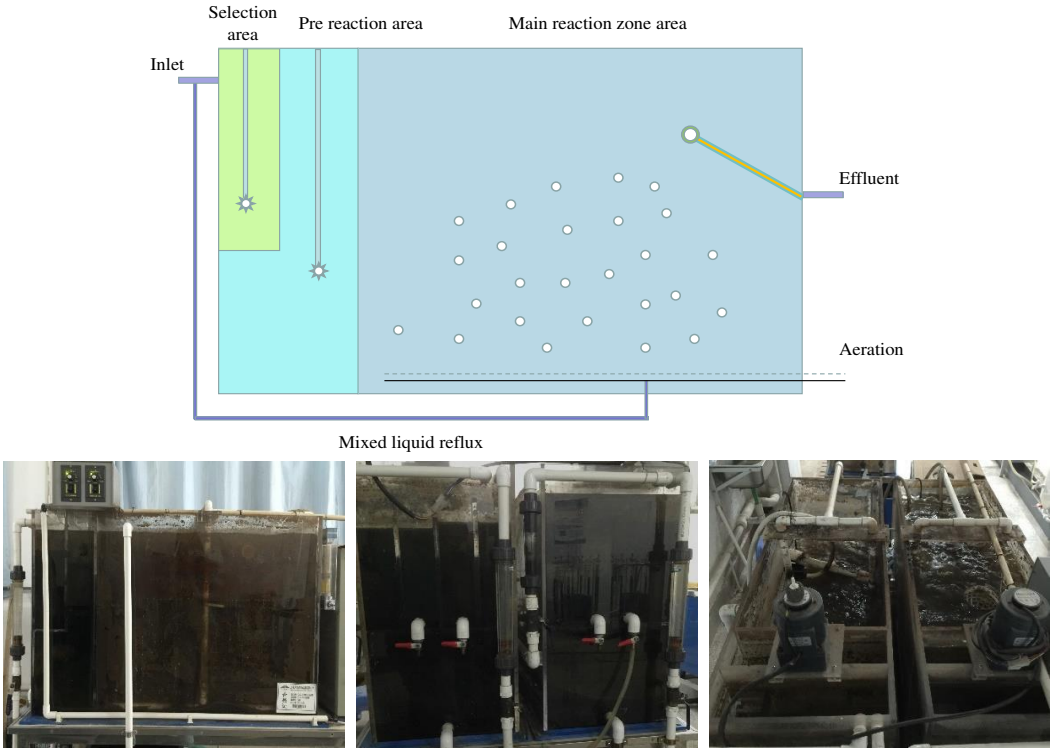

Figure 1. *Diagram and physical diagram of CAST reactor*

PCR-DGGE method of sewage sludge

Principle of PCR-DGGE

By using polyacrylamide gel with chemical denaturant gradient, DGGE can dissolve PCR products differently. The same length of different DNA was amplified in the process of PCR, so all DNA fragments in the product of PCR had the same length, but the nucleotide sequence was different. Through the DGGE experiment, different DNA fragments will stop migration at different positions of the gel due to the different chain breaking behavior along the chemical gradient. Therefore, PCR-DGGE technology can distinguish sequence differences with the same size fragments.

DNA extraction and PCR amplification from sludge

DNA extraction method was carried out according to the instructions of OMEGA soil DNA extraction kit. The 16SrDNA V3 region was selected as the amplification region, and the common primers 338F-GC and 518R were used as the primers. Marker

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1396113974

uses DL2000 and the corresponding fragment size from top to bottom is 2000, 1000, 750, 500, 250, 100.

Primer sequence is:

338-GC: 5`-CGCCCGCCGCGCGCGGCGGGCGGGGCGGGG
GCACGGGGGGACTCCT ACGGGAGGCAGCAG -3`
518R: 5`- ATTACCGCG GCT GCTGG-3`

PCR reaction system was as follows: Total reaction volume was 50 μL, including 10×Taq buffer 5 μL, dNTPmix 4 μL, upstream and downstream primers (10 μM) 2 μL, DNA template 4 μL, Taq enzyme 0.5 μL, sterilized ultra-pure water 32.5 μL. Reaction conditions were as follows: pre-reaction at 95℃ for 5 minutes; denaturation at 95℃ for 1 minute; annealing at 58℃ for 45 s; elongation at 72℃ for 1 minute; reaction cycle 35 times and elongation at 72℃ for 5 minutes.

DGGE experimental steps

Preparation of gel for DGGE: Firstly, after 24 g urea was completely dissolved in water bath at 50℃, 10 ml deionized formamide, 3.896 g acrylamide, 0.1038 g methylene bisacrylamide, 1 ml 50×TAE and 50 μL glycerol were added to the volume of 50 mL. Finally, 80 μL 10% persulfate amine and 110 μL TEMED were added rapidly. After mixing, gel was poured immediately and placed for more than 3 hours to be gelled.

Silver staining: 1) Fixation: fixed with 10% glacial acetic acid of 300 mL for 30 minutes; 2) Cleaning: rinsed with deionized water for 3 times, 2 minutes each time; 3) Silver staining: added 37% formaldehyde 400 mL in 0.1% $AgNO_3$ solution, dyed with this silver staining solution for 25 minutes; 4) Washing: washed with pre-cooled deionized water for three times, the time was 30S, 15S, 30S, respectively. 5) Development: weigh 15 g NaOH, 0.19 g sodium tetraborate, dissolve in sterile deionized water, constant volume to 1000 mL, add 1.5 mL 37% formaldehyde (before use). The developer was used to develop for 12-15 minutes. The development time should not be too long, when the development is less than what you need, it will be terminated in advance, and color rendering time can be prolonged in winter. 6) Termination: When the strip appears, terminate for 3 minutes with fixative. Wash twice, 2 minutes each time (note: if the termination time is too long, the strip will fade). After developing, the UVP gel imaging system was photographed and stored under white light and analyzed by Quantity One-4.6.2 software.

Result and Discussion

Design of experimental group

CAST process for treating low C/N domestic sewage was selected as the experimental reactor in this paper. CAST process is completely mixed in space, anaerobic, anoxic and aerobic in time (Dvorák et al., 2013). If the aeration process and static precipitation process are not properly controlled, it will easily lead to the short anoxic section in the system due to excessive aeration, which directly affects the denitrification process. The main removal site of organic matter is the main reaction area, heterotrophic bacteria carry out nutrient metabolism under aerobic condition to achieve carbon removal; the main reaction area is also the main place for nitrogen removal. By controlling DO in the reactor, nitrification and denitrification can be realized in the same reactor, and then nitrogen removal can be realized.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1396113974

Phosphorus-accumulating bacteria can absorb excessive phosphorus by PHB in the main reaction zone under aerobic conditions, forming phosphorus-rich sludge, and then complete phosphorus removal through sludge discharge (Duan et al., 2012). In addition, sludge-water separation is realized at the end of one cycle in the main reactor. During the settling stage, the reactor does not receive water, which ensures a good static settling effect. In this stage, denitrifying bacteria can denitrify by using carbon sources in sludge.

CAST process usually has better carbon removal effect, but nitrogen and phosphorus removal is limited (Fang et al., 2015). (1) Nitrification is incomplete. Nitrification is mainly realized in the main reaction zone of CAST process. In the aeration stage, NH_4^+-N is oxidized to NO_3^--N and NO_2^--N by nitrifying bacteria and nitrosobacteria. In this process, nitrifying bacteria compete with heterotrophic bacteria DO, which makes nitrification need longer aeration time, which directly leads to lower water filling in CAST process, the ratio of influent volume to total volume is difficult to improve in each cycle, and the volume utilization rate is low. (2) Denitrification is not complete. CAST process consists of two parts of denitrification, 20% of which is refluxed to realize denitrification using front-end carbon sources; 80% of denitrification is achieved in the main reaction zone, mainly in the period of static precipitation and drainage, but after sludge precipitation, sludge and water are insufficiently mixed, nitrate can not effectively contact with activated sludge, which limits denitrification. The main reaction zone of CAST process can achieve anaerobic, deficient and good plugging flow in time, and realize simultaneous nitrification and denitrification. However, the changing environment also leads to the failure of dominant bacteria to play their role to the greatest extent at all stages. At the same time, the abundance of dominant microorganisms will also be affected by environmental changes, resulting in a decline in abundance.

Denitrification performance of CAST process for treating low C/N domestic sewage is affected by many factors. Considering from the point of view of microorganisms and carbon sources, it mainly includes low types and abundance of denitrifying microorganisms and insufficient organic matter content in low C/N water body. In view of the above problems, biological enhancement and solid carbon source were used to enhance the denitrification performance of the reactor (Huang et al., 2013).

(1) Selection of biofortifier and solid carbon source. The selection of biofortifier mainly starts with the species and abundance of denitrifying bacteria. As far as the CAST process is concerned, it mainly includes nitrifying bacteria to strengthen the nitrification process and denitrifying bacteria to strengthen the denitrification process. In order to remedy the shortage of denitrification caused by the short anoxic section in the same reactor, anoxic denitrifying bacteria and aerobic denitrifying bacteria were selected as denitrifying bacteria. Corn cob was selected as the additional carbon source of CAST process. By adding corn cob, the system C/N was improved, which provided conditions for efficient denitrification of the system.

(2) Dosage mode of biofortifier. In order to immobilize microorganisms to the greatest extent, the method of combining polyethylene biological filler with biofortifier with rough surface and loose fibers was adopted. The fillers with diameter of 80 mm were selected, and the biofortifier was first expanded, then the fillers were connected in series and immersed in the bacterial solution for film hanging. Five days later, the filler was added to the reactor.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1396113974

(3) The way of adding solid carbon source of corn cob. In order to ensure that the solid carbon source of corn cob does not cause secondary pollution to the reactor, polyethylene biological filler was used to wrap and fix the reactor. The combination of corn cob and filler not only can provide carbon source for the system, but also can be used as biological carrier to increase the microbial abundance of the system. In order to improve the space utilization rate of solid carbon source of corncob and avoid unnecessary waste of carbon source of corncob, the biofortifier was fixed on the solid carbon source of Corncob by spraying microbial agent, and then added to the reactor. Carbon release experiments show that 80% of the carbon source will be released in the first two days of corn cob immersion. When the system needs additional carbon source for a long time, in order to avoid secondary pollution caused by high COD in the initial stage of solid carbon source immersion, the corn cob should be immersed for two days before drying and then using. When the system needs to add carbon source for short-term emergency treatment, corn cob soaking solution can be used instead of methanol which is currently used more (Huang et al., 2013; Islas-García et al., 2015).

(4) Reactor was operated initially. In order to investigate the carbon and nitrogen removal performance of the system and determine the solid carbon source dosage of corn cob in the experimental group, COD, NH_4^+-N and TN were measured in a stable CAST reactor for 5 consecutive days.

(5) Solid carbon source of corn cob and the dosage of biofortifier in the experimental group were preliminarily determined. The results of background monitoring for 5 days showed that the quality of artificial controlled influent water was basically stable, COD was about 150 mg/L, TN was about 35 mg/L and NH_4^+-N was about 25 mg/L. The effluent COD is about 50 mg/L, NH_4^+-N is about 10 mg/L, the removal rate is about 60%, TN is about 25 mg/L, the removal rate is about 30%. The denitrification performance of corn cob combined with biofortifier in activated sludge system showed that when corn cob existed in activated sludge system for 20 days, the removal rate of NO_3^--N of 30 mg/L was maintained at 35%-40%. In order to achieve the initial TN standard of CAST process, the rough calculation group needs to add 500 g solid carbon source of corncob. Corn cob solid carbon source is hung in series at the back end of CAST main reaction zone. The number of nitrifying bacteria film-forming fillers is 16 in a series, which are vertically attached to the front end of the main reaction zone of CAST in series, and 12 in a series of denitrifying bacteria film-forming fillers, which are vertically attached to the front and back end of the main reaction zone of CAST respectively. In order to enhance the mixing degree of microorganisms and water and avoid sludge loss, all packings in series are fixed at the bottom, and the top packings are guaranteed below the water surface at the end of the reactor drainage (Krustok et al., 2015).

Packing observation of CAST reactor experimental group

Solid carbon source of filler and corncob after 20 days operation of CAST reactor is observed in *Fig. 2*. Microscopic observation showed that there were a large number of microorganisms on the surface of film-forming filler and corncob., which could be fixed by bio-strengthening bacteria agent to reduce bacterial loss, increase the microbial abundance on the filler, and then increase the contact area of sludge during the static settling period, which was conducive to the improvement of the nitrogen removal performance of the reactor (Joo et al., 2005).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)

Effect of bioaugmentation and solid carbon source on denitrification performance of CAST process

In order to investigate the ability of corn cob and biofortifier to improve the denitrification performance in low C/N domestic sewage treatment, a pilot study was carried out by using CAST process to treat low C/N domestic sewage (Jianhua et al., 2016). The experimental results are shown in *Figure 3*.

Figure 2. *Physical drawings of stuffing and corncob after film hanging*

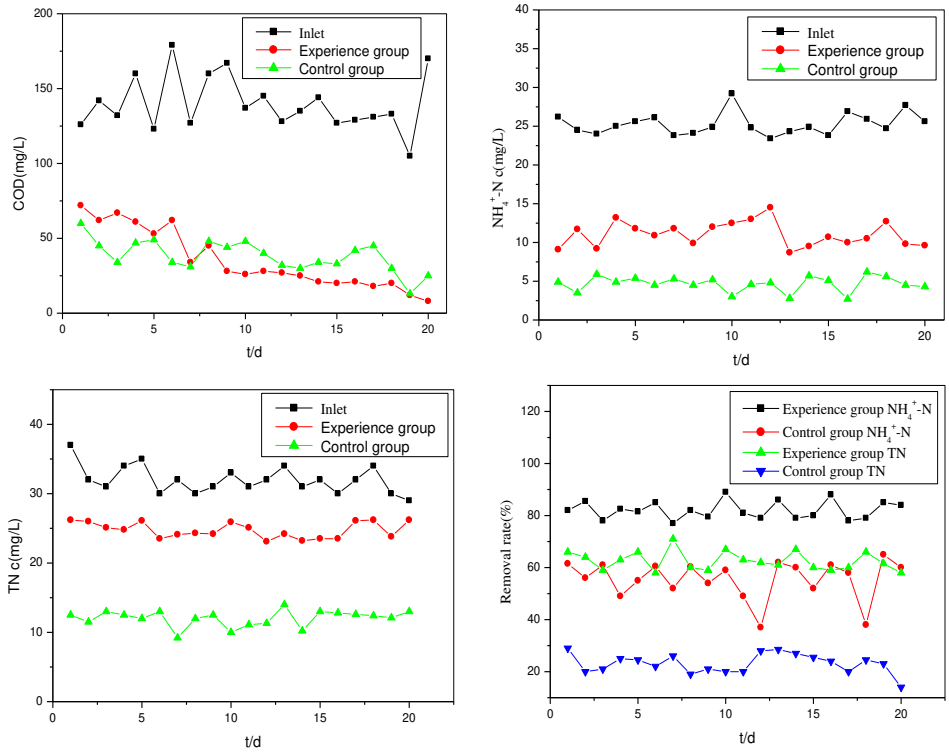

Figure 3. *Changes of water quality index of reactor before and after intensification treatment*

The change of COD in the effluent of the experimental group and the control group showed that the effluent COD of the control group was basically stable and the average COD in the effluent was 41.8 mg/L, reaching the first grade A standard (50 mg/L). The effluent COD of the experimental group did not increase significantly. Before 9 days,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1396113974

the effluent COD was similar to that of the control group and maintained at about 45 mg/L (Lu et al., 2014). After that, COD decreased slightly, and the average COD of effluent was 30.1 mg/L, and remained below 50 mg/L all the time. It is speculated that the nitrogen removal performance of the system and the utilization rate of microbial carbon source may be improved by adding biofortifier, which may lead to the decrease of COD in the effluent of the experimental group. The results showed that the COD of effluent from the experimental tissues did not increase significantly. When corn cob was used as carbon source of external reinforcement in activated sludge system, it would not cause secondary pollution to the raw water. The change of NH_4^+-N concentration in the effluent of the experimental group and the control group showed that the removal rate of NH_4^+-N in the control group was limited. The average removal rate of NH_4^+-N in the effluent was 11.35 mg/L, which was about 55%. The effluent NH_4^+-N concentration in the experimental group was significantly lower than that in the control group, with an average NH_4^+-N concentration of 4.58 mg/L. The addition of nitrifying bacteria increases the abundance of nitrifying bacteria in the system (Liu et al., 2015). When the aeration condition is the same, increasing the abundance of nitrifying bacteria can enhance the nitrification and reduce the concentration of NH_4^+-N in the system.

The change of TN concentration in the effluent of the experimental group and the control group showed that the removal rate of TN in the control group was low, and the average TN concentration in the effluent was 25.03 mg/L. The TN concentration in effluent of the experimental group was significantly lower than that of the control group, with an average concentration of 12.11 mg/L, reaching the first a standard (15 mg/L). Bioaugmentation has an obvious effect on the removal rate of TN in the system (Quan et al., 2011). It is speculated that bioaugmentation improves the denitrification performance of the system. Anoxic denitrifying bacteria increase the abundance of conventional denitrifying bacteria in the system, and then improve the denitrification performance of the system under anoxic conditions (Szogi et al., 2015). Anaerobic, anoxic and aerobic alternation occurs in the same vessel in CAST process, which makes it difficult to strictly control dissolved oxygen. After the main reaction zone stops aeration, there is no anoxic stirring in the system, resulting in short anoxic period in the main reaction zone of CAST and insufficient slurry mixing in the anoxic period, which directly restricts denitrification and denitrification of the system (Shoda and Ishikawa, 2014). Adding aerobic denitrifying bacteria can realize the nitrification and denitrification process at the same time under the aeration condition in the main reaction zone of CAST, and improve the denitrification performance of the system (Urakawa et al., 2006).

The removal rates of NH_4^+-N and TN in the experimental group and the control group showed that the experimental group had obvious effect on the denitrification of the system. Denitrification performance of CAST process for treating low C/N domestic sewage can be improved by the combination of bio-intensifying bacteria and solid carbon source of corncob.

Electron microscopic analysis of CAST reactor sludge

The initial sludge of the experimental group and the control group and the sludge after 20 days of operation were observed by scanning electron microscopy. The results are shown in *Fig. 4*. A and B represent the sludge at the initial stage of the experiment and the sludge after 20 days of reactor operation. The results showed that at the beginning of the experiment, the sludge structure of the experimental group and the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1396113974

control group was basically the same, crisp and porous, and filamentous bacteria and bacilli could be clearly seen (Skouteris et al., 2012; Pan et al., 2015). After 20 days of operation of the reactor, the sludge structure of the experimental group basically did not change much, a large number of rod-shaped bacteria could be clearly seen, and the sludge performance was good. The structure of the control group was slightly loose. It was speculated that the starvation of some microorganisms in the activated sludge might be due to insufficient carbon sources in the water, and the sludge structure began to loosen.

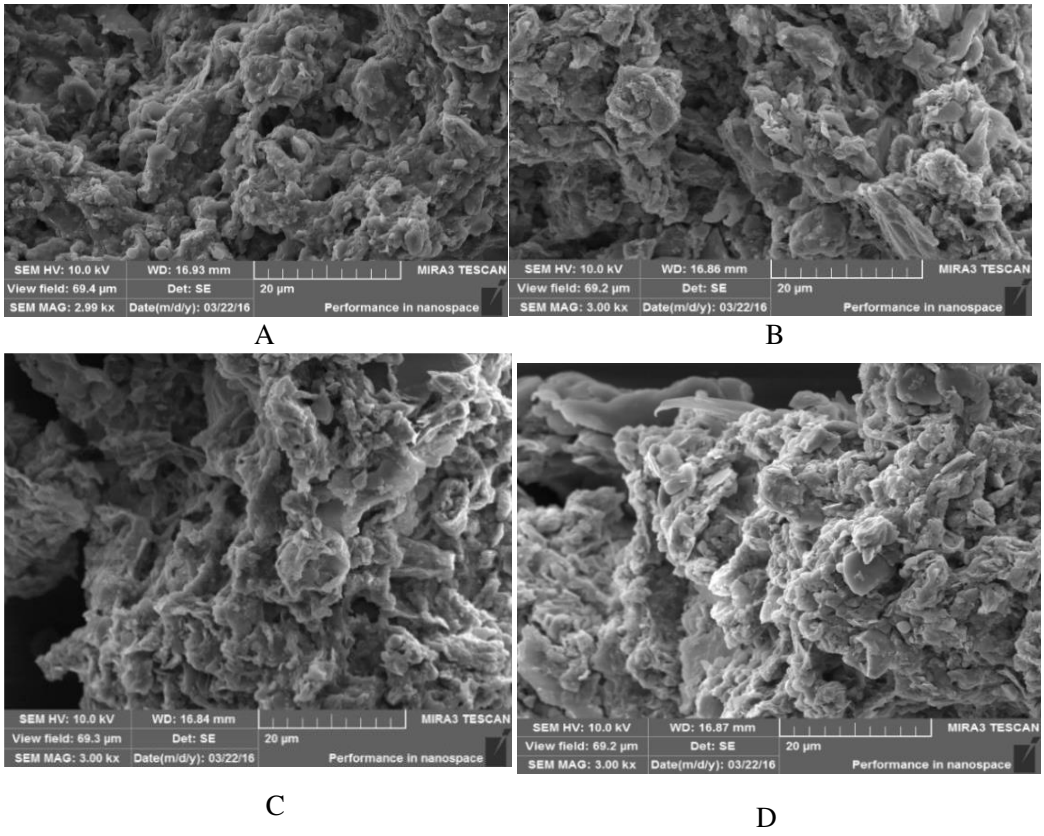

Figure 4. *A-D: Electron Microscopic Scanning of Sludge from Two Reactors at Different Stages*

Analysis of sludge community structure in CAST reactor

Results of sludge PCR in DNA16SrDNAV3 region

The results of 16SrDNAV3 region PCR amplification of total DNA of the samples are shown in *Fig. 5*. From the figure, we can see that all the DNA of the five samples was amplified. The size of the fragments is about 250 bp. The band brightness is suitable and there is no non-specific amplification, which meets the requirements of the follow-up DGGE experiments.

Analysis of sludge community structure

The sludge DGGE and swimming lane recognition maps of the experimental group and the control group after 20 days of operation are shown in *Fig. 6*, respectively. A is the band corresponding to the added anoxic denitrifying agent, B is the band

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1396113974

corresponding to the added nitrifying agent, C is the band corresponding to the added aerobic denitrifying agent, D is the band of sludge after 20 day operation of the experimental group reactor and E is the band of sludge after 20 days operation of the control group reactor.

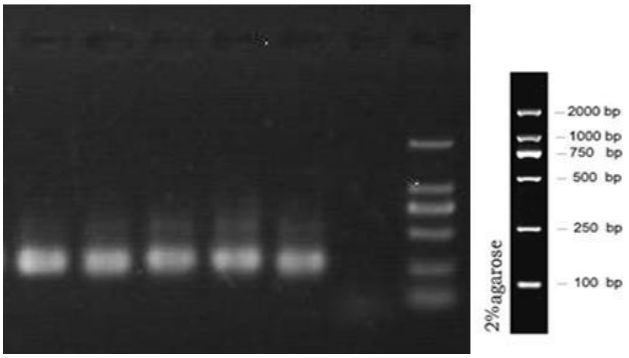

Figure 5. *Gel electrophoresis of PCR product in total DNA16SrDNAV3 region of sample*

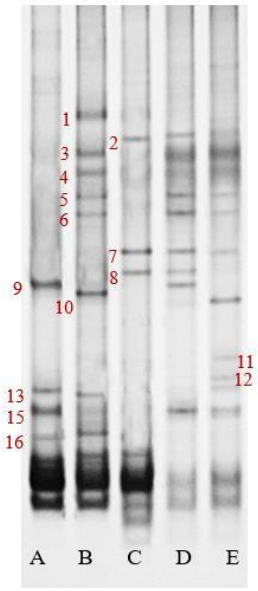

Figure 6. *Sludge DGGE Map. A: anoxic denitrifying bacteria agent; B: nitrifying bacteria agent; C: good nutrient denitrifying bacteria agent; D: Sludge in the experimental group after 20 days; E: Sludge in control group after 20 days*

DGGE map showed that the bands below No. 17 were not separated and no analysis was done. As far as the obvious characteristic bands are concerned, the added anoxic denitrifying bacteria agent includes three characteristic bands, 9, 13 and 15 respectively; the added nitrifying bacteria include six characteristic bands, 1, 3, 4, 5, 6 and 10 respectively; and the added aerobic denitrifying bacteria include three characteristic bands, 2, 7 and 8, respectively. In the control group, 2, 3, 4, 5, 6, 7, 10, 13 and 15 bacterial agents were detected, which indicated that the above eight bacterial species existed in the original activated sludge system and were not exotic and had good adaptability. The dominant denitrifying bacteria in the control group were 3, 4, 10, 2, 7,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1396113974

13 and 15, and the characteristic strips in the experimental group were 2, 3, 4, 5, 6, 7, 8, 9 and 15. Analysis of the sludge bands of the experimental group and the control group after 20 days of operation showed that compared with the control group, the abundances of the experimental group 2, 3, 5, 6, 7 and 15 increased, the abundances of 4 decreased, and the abundances of 10 and 13 completely disappeared. The change of dominant nitrifying bacteria in the control group showed that the addition of biofortifier gradually replaced the dominant nitrifying bacteria corresponding to 4 in the original activated sludge system, completely replaced the corresponding nitrifying bacteria of 10, and increased the abundance of nitrifying bacteria corresponding to 3, 5 and 6, and gradually became the dominant nitrifying bacteria in the system. The change of dominant denitrifying bacteria in the control group showed that the dominant denitrifying bacteria corresponding to 13 in the original activated sludge system were completely replaced and the corresponding denitrifying bacteria of 2, 7, 13 and 15 were strengthened by adding biofortifier. In addition to the above characteristic bands, 11 and 12 bands of sludge in the control group disappeared. It was speculated that the corresponding strains of 11 and 12 bands were heterotrophic bacteria. While the species and abundance of denitrifying bacteria increased, the species of heterotrophic bacteria decreased. In addition to the above characteristic bands, 8 and 9 in the sludge Atlas of the experimental group are new bands, representing an aerobic denitrifying bacteria and anoxic denitrifying bacteria, which belong to exotic microorganisms. The appearance of 8 and 9 bands indicates that 8 and 9 corresponding strains can exist stably in the sludge system, and 9 bands corresponding denitrifying bacteria gradually become the dominant denitrifying bacteria of the experimental group.

In summary, 2, 3, 4, 5, 6, 7, 10, 13 and 15 of the added biofortifiers exist in the original sludge system, indicating that the above eight bacteria are not alien species and have high stability. The enrichment of 4 decreased and 10 and 13 completely disappeared, indicating that the corresponding strains of 4 were gradually replaced, and the corresponding strains of 10 and 13 were completely replaced within 20 days. The abundance of 2, 3, 5, 6, 7 and 15 strains increased, which indicated that the six strains could grow steadily in the system. The corresponding strains of 1 in the added biofortifier were not detected in the sludge of the experimental group, which indicated that the two strains could not exist stably in the system. The corresponding strains of 8 and 9 could exist stably in the sludge of the experimental group, and the denitrifying bacteria corresponding to 9 bands gradually became the dominant denitrifying bacteria in the experimental group.

Among the six kinds of nitrifying bacteria added, there are three kinds which can exist stably in the system; among the three kinds of anoxic denitrifying bacteria added, there are two kinds which can exist stably in the system length; and among the three kinds of aerobic denitrifying bacteria added, there are three kinds which can exist stably in the system length. The results showed that the structure of denitrification bacteria and the denitrification performance of the sludge system could be effectively improved by adding biofortifier.

Conclusion

In view of the low denitrification performance of CAST process in treating low C/N domestic sewage, biological strengthening and solid carbon source were used to enhance the denitrification performance of CAST process. By increasing the abundance

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1396113974

of nitrifying bacteria and anoxic denitrifying bacteria, the abundance and species of denitrifying microorganisms in the system can be improved; by adding aerobic denitrifying bacteria, the problem of inadequate denitrification caused by too short anoxic section in the same reactor in CAST process can be remedied; by adding corn cob solid carbon source, the carbon source in the treatment of low C/N wastewater system can be increased. This experiment can overcome the limitation of denitrification process caused by excessive aeration and insufficient carbon source.

(1) The COD of the effluent of the reactor with corn cob solid carbon source and nitrifying bacteria, anoxic denitrifying bacteria and aerobic denitrifying bacteria was maintained at about 30 mg/L, the average effluent concentration of NH_4^+-N decreased from 11.35 mg/L to 4.58 mg/L in the control group, and the average effluent TN concentration decreased from 25.03 mg/L to 12.11 mg/L in the control group. The average removal rate of NH_4^+-N in the bio-enhanced reactor increased from 55.8% to 82.1% in the control group, and the average removal rate of TN increased from 23.2% to 62.3% in the control group. The addition of biological agents improves the abundance of denitrifying microorganisms in sludge, increases the types of denitrifying microorganisms, and then improves the denitrification performance of the system, so that the effluent reaches the first A standard. When corn cob is used as carbon source of external reinforcement in activated sludge system, the COD of effluent is stable and low, which will not cause secondary pollution to raw water.

(2) The sludge of the experimental group strengthened by bio-agent and solid carbon source of corncob did not change significantly after 20 days of operation of the reactor. The structure of the sludge was compact and filamentous bacteria and bacilli could be observed obviously. Under the condition of insufficient carbon source in the water environment, the sludge structure of the control group becomes loose and has a certain solution.

(3) Among the six kinds of nitrifying bacteria added, there are three kinds which can exist stably in the system, two of the three kinds of anoxic denitrifying bacteria added can exist stably in the system length, and three kinds of the three kinds of aerobic denitrifying bacteria added can exist stably in the system length. The results showed that the addition of biofortifier could effectively increase the species and abundance of denitrifying microorganisms, change the structure of denitrifying bacteria in sludge system, and improve the denitrification performance of the system.

When corn cob is added to the activated sludge system as a solid carbon source, the amount of corn cob can not be controlled accurately, which may cause secondary pollution. It is suggested that in the future practical application, when external carbon sources need to be added urgently, the leaching solution soaked in corn cob for 2 days should be used instead of the liquid carbon sources commonly used at present; when carbon sources need to be provided slowly for a long time, the corn cob after 2 days should be added to avoid the secondary pollution of water caused by the large amount of COD leached in the initial stage.

(Received 24th May 2019; accepted 11th Oct 2019)

Abstract. Drought stress is one of the major yield limiting factors and causes significant yield losses in different crops. This study was conducted to screen the 50 maize accessions of diverse origin of Pakistan against moisture deficit on the basis of their performance *vis.*, plant height, cob length, kernel rows per ear, kernels per ear, leaf area, days to 50% anthesis, grain yield, 100-seed weight, chlorophyll contents, stomata size, harvest index and drought index. Drought stress was imposed through alternate irrigation (10 recommended irrigations) and normal irrigation (no drought stress) (15 recommended irrigations). The germplasm consisting of 8 parents and 15 crosses was evaluated in field under normal and water deficit conditions in spring season. Out of these 50 accessions five drought and three drought sensitive lines were selected. The selected drought resistant lines were crossed with drought sensitive lines (testers) in line × tester mating design and were evaluated on the basis of yield and yield contributing traits. The inbred lines W64TMS and W82-3 expressed higher general combining ability (GCA) for grain yield, and other yield related traits (cobs per plant, grains per cob, 100-seed weight) under normal and water deficit conditions. The F1 hybrids W64TMS × USSR150 and W82-3 × 150P-1 showed higher specific combining ability (SCA) for grain yield and other related traits under normal and drought stress. Positive correlation was observed between grain yield and cob length, cob diameter, kernel rows per ear, kernels per ear, plant height, number of leaves per plant, leaf area, chlorophyll content, 100-seed weight, stomata size and stomata frequency. It was suggested that the present breeding material may be used for the improvement of grain yield and water deficit tolerance in maize.
Keywords: *moisture deficit, germplasm, accessions, general combining ability*

Introduction

Maize (*Zea mays* L.) is an important food and feed crop due to its high demand as compared to wheat and rice. In 2020 in developing countries maize demand would increase as compared to wheat and rice owing to high consumption as fresh and treated forms like sweeteners, maize bread, corn flakes, maize chips, corn flour, and corn porridge. Moreover maize is used as raw material in industries like textile, refineries, foundry, fermentation, and food industries for production of ethanol as biofuel for vehicles, corn oil, dextrose, corn syrup and alcohol for beverages. In developed countries 40-80% maize used as fodder for livestock (Farnham et al., 2003).

Water deficit is a major factor of abiotic stress which diminishes the grain yield of many crops (Aslam et al., 2015). Maize plants are sensitive to water shortage due to extraordinary evaporation and weak root structure (Abayomi et al., 2012). Globally 20-25% of total planting area of maize is affected by drought stress (Golbashy et al., 2007). Water shortage at flowering stage in maize causes 40-85% yield loss (Bänziger et al., 2002) and at anthesis to grain filling 40-80% yield losses are caused. The deficiency of water reduces photosynthesis, turgor in phloem cells and flow of sucrose from

DOI: http://dx.doi.org/10.15666/aeer/1706_1397513988

conducting cells to sink (seeds) (Sevanto et al., 2014). Moisture deficit limits vegetative growth by decreasing the leaf water contents (Valentovic et al., 2006) and stomatal transpiration/conductance (Anjum et al., 2011). Drought stress damages the membranes (Awasthi et al., 2014), chlorophyll (Rahbarian et al., 2011), photosynthesis (Anjum et al., 2011) due to stomatal or non-stomatal link (Sehgal et al., 2018). Drought stress cause severe losses at reproductive growth stage compared to vegetative growth stage owing to flower abortion, poor kernel set and reduced numbers of seeds (Pushpavalli et al., 2014; Seghatoleslami et al., 2008). Moreover, moisture deficit at grain filling stage reduced the seed size owing to slow down of grain filling rate and duration (Moradi et al., 2013; Sehgal et al.,. 2018).

Drought stress is single most important factor which adversely affects the maize production (Nelson et al., 2007; Nuccio et al., 2015). Water deficiency reduced the survival rate of seedling and cause increase of post-pollination embryo abortion ultimately leading to reduction of yield (Chohan et al., 2012; Kakumanu et al., 2012; Mao et al., 2015). Limited supply of water negatively affects plant development and photosynthesis (Yordanov et al., 200). Water deficit results stunted plant growth, tassel blast, top firing, wilting, low plant density, silk delay and poor seed set which ultimately decreases of grain yield (Chen et al., 2015). To improve tolerance against water deficit, the use of genetics is a main factor. Agronomic interventions also have their significance however; genetic solutions are more cost effective and sustainable (Edmeades et al., 2004) as agronomic practices depend on input availability, skill in soil preparation and crop management but genetics can crammed in kernel and easily amended (Campos et al., 2004). Under drought stress, development of drought-resistant germplasm is an effective and feasible approach (Athar and Ashraf, 2009). For breeding it is indispensable to find the superior genotypes to develop the high yielding hybrids (Ganagappa et al., 1997). The general combining ability (GCA) and specific combining ability (SCA) are essential breeding approaches. General combining ability has main character in yield parameters (Ali et al., 2013; Kanwal et al., 2019; Sindagi et al., 1997) and specific combining ability is more effective as compare the general combining ability for kernel yield. The current study was conducted to i) screen inbred lines for various physio-genetic traits under limited water conditions, ii) development of water deficit tolerant F1 crosses in maize and iii) to estimate gene action, general and specific combining ability effects.

Material and methods

Experimental site, collection and screening of genetic material

This study was conducted in the field of the Department of Plant Breeding & Genetics, University of Agriculture, Faisalabad (latitude 31° N, longitude 73° E, altitude 184.4 m above sea level), Pakistan during 2014 to 2016.

The seed of 50 maize genotypes were taken from maize research group of the Department of Plant Breeding & Genetics, University of Agriculture Faisalabad. The germplasm particularly accomplished for water deficit tolerance and the studied parameters have direct and indirect correlation with water deficit tolerance. Seeds of collected genotypes were multiplied by self-pollination during 2014. Genetic purity within each genotype was maintained by controlled pollination. The collected maize germplasm was evaluated against water deficit stress during spring season under normal and stress condition. Seeds of 50 genotypes were sown in triplicate in the field of the Department of Plant Breeding and Genetics, University of Agriculture Faisalabad. Line

DOI: http://dx.doi.org/10.15666/aeer/1706_1397513988

to line and plant to plant space were kept 0.75 m and 0.25 m, respectively with total crop area of 40 × 50 m. Suggested agronomic and plant safety measures were practiced to nourish crop. Two irrigation treatments were:
T_0: Normal irrigations (15 recommended irrigation)
T_1: Alternate irrigation was skipped (10 irrigations)

Drought stress was imposed by skipping the alternate irrigation (10 irrigations) compared to normal (15 recommended irrigations). Data were recorded on ten random plants per replication from each experiment for the physiological and agronomic parameters. The 5 water deficit tolerant lines were selected.

Recording of data

Number of days to 50% tasselling, 50% silking, anthesis-silking interval and leaf area

Plants with in replication were measured to have started anthesis, if one anther becomes visible. Number of days taken to tasselling was counted from the date of sowing to the time when 50% plants completed tasselling. Plants with in replication were measured to be at silking if at least one silk on a plant emerges. Number of days to 50% silking was recorded by counting the number of days from date of sowing to the date when 50% plants complete emergence of silks. Anthesis-silking interval (ASI) is the period between the maturity tasseling and silking. It was calculated by subtraction of days to 50% silking from days to 50% tasseling. For leaf area measurement length and width of three leaves was measured from top, mid and bottom on each selected and guarded plant with measuring tape in cm. Leaf area was calculated with the following equation after taking average (Montgomery and Cheo, 1971):

$$\text{Leaf area (cm}^2\text{)} = \text{length (cm)} \times \text{width (cm)} \times 0.75$$

Yield and yield contributing traits

Plant height and numbers of leaves was measured from ten plants per replication with the help of meter rod from tassel to ground surface in centimeters and was averaged. Length of ear was measured after harvesting in (cm) with the help of measuring tape from selected plants of replication. Cob diameter of each plant was calculated with measuring tape in centimeters from 10 selected plants of each entry. Leaf angle was measured from fifth leaf of each plant with the help of protractor from 10 plants of each entry. Leaf rolling was measured of each plant by scaling from 1 to 5 from 10 selected plants of each entry.

Numbers of grain rows per ear were counted from each cob of the selected 10 plants and was averaged. The total number of kernels threshed from the ears was counted manually. It was recorded in grams with an electronic balance from three samples obtained each from the bulk grain produce obtained from the ear-marked plants and was averaged. The kernels of each ear were threshed separately and weighed with electric balance. Harvest index was calculated from each plant per replication with the help of following formula. The biological yield was recorded by drying complete plants under shade which was used for the calculations of total harvesting index.

$$\text{HI} = (\text{Grain yield} / \text{Biological yield}) \times 100$$

Drought index was calculated for selected plants with the help of following formula:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1397513988

$$DI=\frac{\text{Yield under drought condition}}{\text{Yield under normal condition}}+\frac{\text{Mean performance under drought condition}}{\text{Mean performance under normal condition}}$$

Biometrical approaches

Analysis of variance

The recorded data on maize germplasm for assessment of variability were analyzed using analysis of variance following Steel et al. (1997). A computer software Statistical was used for the analysis.

Line × Tester analysis was conducted as proposed by Kempthorne (1957) to estimate the GCA and SCA effects. Heterosis over mid parent and better parent was determined following the method of Falconer and Mackay (1996). To find the strength of relationship among traits correlation analysis was used as proposed by Kwon and Torrie (1964).

Combining ability effects were calculated according to following formulae:

Estimation of general combining ability (GCA) effects

$$\textbf{Lines}: gi = \{(xj.. / tr) - (x\ldots / ltr)\}$$

$$\textbf{Testers}: gt = \{(x.j. / lr) - (x\ldots / ltr)\}$$

where: l = number of lines; t = number of testers; r = number of replications; xi.. = Total number of F_1 resulting from crossing ith lines with all the testers; x... = Total of all the crosses.

Estimation of specific combining ability (SCA) effects

$$si = \{(xij.) / r) - (xi.. / tr) - (x.j. / lr) + x\ldots / ltr$$

where: xij = total of F_1 resulting from crossing ith lines with jth tester; xi = total of all the crosses of ith line with all testers; xj = Total of all the crosses of jth tester with all lines.

Data analysis

The means were computed and data for all the traits of genotypes were subjected to ordinary analysis of variance (Steel et al., 1997) in order to determine genotypic differences. Biplot analysis based on Principal Component Analysis (PCA) was made using statistical package (XLSTAT) for the selection of tolerant and susceptible genotypes on the basis of all traits along with yield.

Results

Genetic variability

Significant differences were observed among the genotypes for all studied traits. Treatments were significantly different for all the traits except leaf rolling. Genotypes × treatments interaction was also significant for all the traits (*Table A1* in the *Appendix*).

Principle component analysis

Genotype away from origin is good performer relative to the genotypes nearer to the origin. Principal component analysis (PCA 3) showed that accessions 4, 19, 12, 37, 26

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1397513988

and 28 were fall in quadrate I and accessions 30, 33, 50, 39, 22 and 13 were fall in quadrate IV. The PCA 4 showed that accessions 4, 19, 26, 37 and 9 were fall in quadrate I and accessions 1, 30 and 50 were fall in quadrate IV. The genotypes in quadrate I was selected as lines and in quadrate IV was selected as testers (*Figs. 1* and *2*).

General combining ability effects

Under normal condition (no drought stress) the general combining ability (GCA) test indicated that lines A427-2 showed maximum GCA effects for leaf area and leaf temperature. Line W64TMS revealed maximum values of GCA for seed per cob, rows of kernel per cob, 100 seed weight, and harvest index. For grain yield, chlorophyll content, stomata size and harvest index significant effects were observed in line W82-3 (*Table 1*). Maximum GCA was observed in line A556 for days to 50% anthesis, leaf area, leaf angle and leaf temperature. Line W64TMS expressed positive significant GCA effects for grain yield.

Under normal condition (no drought stress) testers M14 expressed good GCA effects for plant height, anthesis-silking interval, and stomata size. Positive GCA effects were observed in USSR150 for leaf area, leaf rolling and leaf temperature. Tester 150p-1 considered s good general combiner leaf rolling, grains per cob, epidermal cells and harvest index. The tester M14 had positive significant GCA effect for cob length, it is good general combiner because cob length is directly proportional to kernels per ear.

Under water deficit conditions genotypes showed different response for GCA in all parameters (*Table 2*). Line A427-2 considered as good combiner for plant height, days taken to 50% anthesis, anthesis-silking interval, chlorophyll content, stomata size and stomata frequency due to good GCA. Line W64TMS had greater effects for anthesis-silking interval, grain per cob, grain yield, and harvest index. The W82-3 line revealed good GCA effects for days to 50% silking, days to 50% anthesis, leaves per plant, cob

length grain yield, leaf temperature and harvest index. The line A556 exhibited significant GCA effects for cob diameter and cob length. In testers M14 showed favorable GCA effects for leaves per plant, cob diameter, chlorophyll content and leaf temperature. Tester USSR150 had good GCA effects for days taken to 50% silking, days taken to 50% anthesis, grain yield,100 seed weight and stomata frequency (*Table 2*).

Specific combining ability effects

Under normal conditions (no drought stress) specific combining ability (SCA) effects of crosses indicated that cross A427 × M14 showed positive SCA effects for kernel rows per ear and leaf temperature. Cross W64TMS × USSR150 had positive and significant SCA effects for cob length, anthesis-silking interval, plant yield, and harvest index (*Table 3*). Cross W64TMS × 150P-1 showed positive and significant SCA effects for cob diameter, kernel rows per ear, grins per cob, plant yield, chlorophyll content, stomata size, and harvest index. Cross W82-3 × 150P-1 exhibited positive and significant SCA effects for cob length, grains per cob, plant yield, and harvest index. Cross N-18 × M14 showed positive and significant SCA effects for cob length, cob diameter, kernel rows per cob, anthesis-silking interval, plant yield and stomata size (*Table 3*). Under drought stress significant SCA effects were observed in cross A427 × M14 for days to 50% silking, days to 50% anthesis and anthesis-silking interval, and stomata size. Cross A427 × 150P-1 exhibited significant SCA effects for number of leaves per plant, kernel rows per cob, leaf angle, anthesis-silking interval, stomata size, and harvest index. Cross W64TMS × USSR150 revealed positive and significant SCA effects for plant height, leaf area, anthesis-silking interval, plant yield, stomata

frequency, and harvest index (*Table 4*). Cross W82-3 × 150P-1 showed positive and significant SCA effects for number of leaves per plant, cob length, number of grains per cob, plant yield, and harvest index. Cross N-18 × M14 had positive SCA effects for plant height, number of leaves per plant, leaf area, kernel rows per cob, leaf angle and leaf temperature. Cross N-18 × USSR150 revealed positive and significant SCA effects for cob diameter, anthesis-silking interval and 100 seed weight. Cross N-18 × 150P-1 showed positive and significant SCA values for cob diameter, anthesis-silking interval and 100 seed weight (*Table 4*).

Discussion

Drought stress negatively affected the grain yield and yield contributing traits in maize (*Tables 2* and *3*). Different management approaches are used to avoid yield losses in maize such as water management and agronomic practices as sowing on beds etc. However, developments of drought tolerant germplasm are the main tools which are explored across the world to improve the production of maize under moisture deficit conditions (Ali et al., 2017; Aslam et al., 2015). The different genotypes of maize had genetic variability against drought stress (*Tables 1–3*) which could be explored by the screening of different germplasms (Aslam et al., 2015). To develop tolerant genotypes creation of genetic variability and gene combination through intercrossing of targeted parents is the main practices most widely used owing to intercrossing followed by suitable selection which develop an ideotype plant which is suitable for environment specific cultivation (Bänziger et al., 2000; Kanwal et al., 2019; Mahmood et al., 2019). Maximum GCA was recorded in line A556 for days to 50% anthesis, leaf area and line W64TMS had significant GCA for grain yield (*Tables 1–3*) as assessment of yield limiting traits with morphological approaches help conventional breeding for yield improvements (Cattivelli et al., 2008; Ali et al., 2013). The selection of superior traits is a good general combiner for evolving high yield hybrids through transgressive segregation, the similar findings were reported by (Ivy and Howlader, 2000; Paul and Duara, 1991).

The cross W82-3 × 150P-1 had positive SCA effects for number of leaves per plant, cob length, number of grains per cob, plant yield, and harvest index (*Tables 1–4*). Cross W64TMS × USSR150 had significant SCA effects for cob length, anthesis-silking interval, plant yield, and harvest index (*Table 3*), the longer is ear length the higher will be grain yield and similar findings were found by different scientist across the world (Konak et al., 2001; Mendoza et al., 2001; Rahman et al., 2010). Against drought stress, yield and yield contributing traits are primary target for yield improvement. Moreover, secondary traits are also important for yield improvements as they had strong positive correlation with grain yield and are easy to measure (Edmeades et al., 2001). The association of near isogenic lines helped the breeder to find association of targeted secondary traits with economic yield (Bänziger et al., 2000; Ali et al., 2014) as economic yield is the ultimate goal. Under drought stress, testers M14 had positive GCA effects for leaves per plant, cob diameter, chlorophyll content and leaf temperature. While, tester USSR150 had good GCA for days taken to 50% silking, days taken to 50% anthesis, grain yield, 100 seed weight and stomata frequency (*Table 2*) and the intrapopulation improvement for drought stress can be done through plant selection, pre-performance, test crosses using individual plants and parental testers (Bänziger et al., 2000; Ali et al., 2016).

Conclusions

The inbred lines W64TMS and W82-3 expressed higher general combining ability (GCA) for grain yield, and other yield related traits (cobs per plant, grains per cob, 100-seed weight) under normal and water deficit conditions. The F1 hybrids W64TMS × USSR150 and W82-3 × 150P-1 showed higher SCA for grain yield and other related traits under normal and drought stress. It was suggested form our findings that the present breeding material may be used for the improvement of grain yield and water deficit tolerance in maize.

(Received 24th May 2019; accepted 25th Oct 2019)

Abstract. *Euphorbia hirta* (asthma weed) has been documented as an effective herb for the treatment of asthma and associated symptoms. This study was aimed at comparing the bioactive constituents and *in vitro* antiradical activity of asthma weed with other commonly growing anti-asthmatic plants such as *Pergularia tomentosa*, *Dipterygium glaucum* and *Acalypha indica* in Tabuk region of Saudi Arabia. The results showed that the total phenol and flavonoid content of methanolic leaf extract of *E. hirta* was highest compared to the other anti-asthmatic plants. *E. hirta* was also recorded to have the maximum total antioxidant capacity, 1, 1-diphenyl-2-picryl-hydrazyl (DPPH) antiradical activity and nitric oxide (NOX) scavenging activity. However, hydrogen peroxide scavenging activities and metal chelating activities were as the highest for the methanolic extracts of *D. glaucum* and *P. tomentosa*, respectively compared to the other anti-asthmatic plants. It may be concluded that the abundance of phenol and flavonoids along with maximum antioxidant capacity, DPPH antiradical activity and NOX scavenging activity of *E. hirta* makes it worthy of using as an effective anti-asthmatic plant.
Keywords: *flavonoids, oxidative stress, antioxidant capacity, antiradical scavenging activity, phenols*

Introduction

Asthma is a chronic lung disease, inducing narrowing of airways and changes in the levels of eosinophils, mast cells, lymphocytes, cytokines and other inflammatory cell products (Rivera et al., 2011). Asthma is a common chronic disease that is estimated to affect as many as 339 million people worldwide (WHO, 2018). However, Bousquet et al. (2005) predicted that 100 million more will be affected by asthma by 2025. It causes a high global burden of death and disability, with around 1000 people dying each day from asthma, and is in the top 20 causes of years of life lived with disability (WHO, 2018). Nearly 2 million people are affected by asthma in the Kingdom of Saudi Arabia. There are no complete cures of asthma and currently available modern therapies have been associated with many side effects. So, to find an effective low risk, a non-drug strategy that may furnish a valuable adjunctive or alternative therapy in asthma management is both alluring and timely.

Of late, medicinal plants have attracted a huge interest due to the inherent antioxidant potential of the phytochemicals that reduce the free-radical induced oxidative damage. It is estimated that 80% of the world population rely on drugs obtained from plants, for their primary health care needs (WHO, 2019). It has been established that climate change may affect the chemical composition and, ultimately the survival of some medicinal plants. Climate change has a remarkable effect on secondary metabolites and other compounds that plants produce, which are usually the basis for their medicinal

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1398914000

activity (Khan et al., 2016; Yang et al., 2018). Phytochemical screening by several workers has unveiled the presence of various bioactive constituents such as phenols, flavonoids, alkaloids, terpenoids and saponins (Altemimi et al., 2017; Verma et al., 2018; Sai et al., 2019; Batool et al., 2019). Medicinal plants that may be employed for the treatment of asthma should have anti-allergic, anti-inflammatory, antihistaminic and immunomodulatory properties. It has been observed that the supplements with antioxidant properties are potentially effective in decreasing the degree of bronchoconstriction as they suppress the pro-inflammatory episodes by counteracting reactive oxygen species and reactive nitrogen species (Kurutas, 2016; Bagatini et al., 2018).

Tabuk, the northern province of Saudi Arabia (*Fig. 1*) is a region largely characterized by asymmetrical topography ranging from plains to low and high mountains that create a highly distinct environmental variable of extreme cold to extreme hot (Khan et al., 2016). Diversified topography coupled with varied environmental conditions supports the growth of several medicinally important plants in this region. Of these, *Euphorbia hirta (Euphorbiaceae)*, *Pergularia tomentosa* (Asclepiadaceae), *Dipterygium glaucum* (Capparidaceae) and *Acalypha indica* (*Euphorbiaceae*) have long been used in traditional medicine to treat asthma (Kumar et al., 2010; Youssouf et al., 2007; Zahidin et al., 2017; Alamgeer et al., 2018; Rayyan et al., 2018). *Euphorbia hirta* is known as asthma weed, spurge or milkweed and used to treat respiratory complications. Although, various studies have been performed on the phytochemical constituents of these plants, but meagre research was carried out on the comparative study of antioxidant potential of these plants. Therefore, the objective of the current study was to compare the antioxidant potential and secondary metabolites of asthma weed with other anti-asthmatic plants found in Tabuk region.

Figure 1. *Map showing sampling site (Tabuk, Saudi Arabia). (Source: Google images)*

Materials and methods

Plant collection

The plants were collected from Tabuk, the Northern Province of Saudi Arabia (latitude 28°22'59" N; 36°34'59" E, altitude 773 m). The region is characterized by its

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1398914000

hyper-arid climate, high evaporation rate and low precipitations during December to February. The region is bounded by Red sea on the west to the Hufa depressions in the east. Four plant species (*E. hirta, P. tomentosa, D. glaucum and A. indica*) were collected at flowering stage. At collection site five 10 m × 10 m plots, at the distance of 20 m each, were established randomly during the study. Four plants of each species from each plot were collected randomly. Finally, five healthy plants of each species were selected and were used for assessing various characteristics. The plant materials were authenticated by Dr. M. Nasir Khan. Collected plants were dried in shade under dark. Air-dried leaf samples were ground to a fine powder (80 mesh) using an electric blender and stored in a clean labeled air-tight container as replicates for assessing various characteristics.

Plant extracts

Powdered leaf sample (100 g) of each plant was extracted with methanol for 24 h using Soxhlet apparatus (Borosil, BRL_3840020). The extracts were separated from the solids by filtration with Whatman No. 1 filter paper. The remaining solids were extracted twice with the same methanol and extracts combined. The extracts were concentrated under reduced pressure at 45 °C in a rotary evaporator (EYELA, Tokyo, Japan) and kept in a refrigerator at 4 °C until analyzed.

Estimation of total phenol

The content of total phenols was estimated by the Folin-Ciocalteu method with little modification of Cevallos-Casals and Cisneros-Zevallos et al. (2005). From each sample, 0.5 ml of methanolic extract was added to 2.5 ml of Folin-Ciocalteu reagent and 2 ml of sodium carbonate 1 M. The tubes were incubated at 45 °C for 30 min. The absorbance of total phenolics was measured at 765 nm using Hewlett Packard, UV/visible light. Total phenolics content was expressed as mg gallic acid equivalents per g dry weight.

Estimation of total flavonoids

Total flavonoid content in the methanolic extracts was measured spectrophotometrically (CE 2021, Cecil, Cambridge, England), following the method of Marinova et al. (2005). 4 ml of water was added to 1 ml (500 mg/ml) extract or standard catechin solution and 0.3 ml of 5% $NaNO_2$. After keeping it for 5 min, 0.3 ml 10% $AlCl_3$ was added. To this mixture, after 6 min 2 ml 1 M NaOH was added and the total volume was made up to 10 ml with water. The solution was thoroughly mixed, and the absorbance was recorded against a prepared reagent blank at 510 nm. Total flavonoid content of was expressed as catechin equivalents in mg per g dry weight.

Assay of total antioxidant capacity

Total antioxidant capacity was determined by the method described by Prieto et al. (1999). 0.1 ml of methanolic plant extract was added to 1 ml of reagent solution (0.6 mol/l sulfuric acid, 28 mmol/l sodium phosphate and 4 mmol/l ammonium molybdate). The tubes were heated at 95 °C for 90 min. The absorbance of each solution was recorded at 695 nm against a blank. The antioxidant capacity was expressed as mg gallic acid equivalent per gram dry weight (mg GAE/g DW).

DOI: http://dx.doi.org/10.15666/aeer/1706_1398914000

Anti-radical capacity

Determination of 1, 1-diphenyl-2-picryl-hydrazyl (DPPH) free radical scavenging

The free radical scavenging capacity of methanolic extracts of different plants was recorded using DPPH method as described by Thaipong et al. (2006). 5 ml of 0.004% freshly prepared methanolic solution of DPPH (2, 2-diphenyl-1-picrylhydrazyl) were added to 50 µl of different concentrations of sample. After 30 min in the dark at room temperature, the absorbance was recorded spectrophotometrically against a blank at 517 nm. DPPH free radical scavenging activity was expressed as the percentage inhibition.

Nitric oxide (NOX) scavenging activity

To estimate NOX radical inhibition activity, method described by Marcocci et al. (1994) was followed with little modifications. Briefly, sodium nitropruside (5 mM, pH 7.4) in phosphate buffer saline was mixed with 3 ml of different concentrations of methanolic plant extracts and incubated at 25 °C for 150 min. From this incubated solution, 0.5 ml was taken and mixed with 0.5ml Griess reagent [(1.0 ml sulfanilic acid reagent (0.33% in 20% glacial acetic acid at room temperature for 5 min with 1 ml of naphthylethylenediamine dichloride (0.1% w/v)]. After 30 min of incubation, absorbance was recorded at 540 nm. A standard solution of ascorbic acid was treated in the same way with the Griess reagent as a positive control. NOX scavenging activity was expressed as the percentage inhibition.

Hydrogen peroxide (H_2O_2) scavenging activity

The ability of the extracts to scavenge H_2O_2 was estimated based on the method of Ruch et al. (1989). A solution of H_2O_2 (40 mM) was prepared in phosphate buffer (pH 7.4). The concentration of H_2O_2 was determined by absorption at 230 nm using a spectrophotometer. Plant extracts in methanol were added to a H_2O_2 solution (0.6 ml, 40 mM). The absorbance of H_2O_2 at 230 nm was noted after 10 min against a blank solution containing phosphate buffer without H_2O_2. Ascorbic acid was used as positive control. H_2O_2 scavenging activity was expressed as the percentage inhibition.

Metal chelating activity

The formation of ferrous ion-ferrozine complex was recorded to estimate the ferrous level according to Decker and Welch (1990). The reaction mixture consisted of different concentration of plant extracts and 0.1 ml of 2 mM ferrous chloride. 0.2 ml of 5 mM ferrozine was added to this mixture to initiate the reaction and left to stand at room temperature for 10 min. The absorbance of the solution was measured at 562 nm. Ascorbic acid was used as positive control. The chelating activity was expressed as percentage of inhibition.

Statistical analyses

The data were analyzed statistically using analysis of variance (ANOVA), data were presented as average of five determinations with LSD at 5% ± SE. Differences between the means were compared by Duncan's multiple-range test at the level of $p < 0.05$ using SPSS Ver. 11 statistical software (SPSS Inc., Chicago, IL, USA). IC_{50} values were calculated by employing linear regression analysis.

Results and discussion

Asthma is an inflammatory disease of the lungs and the present endevour is to control the inflammation. As in *Table 1,* methanolic leaf extracts of *E. hirta, P. tomentosa, D. glaucum and A. indica* showed significant amount of phenolic compounds. The total phenol content of the investigated plants differed significantly. *E. hirta*, the asthma weed has 13.9%, 21.1% and 7.3% more phenol than the *P. tomentosa*, *D. glaucum* and *A. indica*, respectively. We have recorded a higher amount of total phenol in these anti-asthmatic plants than that of other anti-asthmatic plants such as *Matricaria recutita* (Al-Dabbagh et al., 2019) but lower than the *Helichrysum* species (Albayrak et al., 2010).

Table 1. *Total phenols, flavonoids and antioxidant capacity of methanolic extracts of leaves of anti-asthmatic plants Euphorbia hirta, Pergularia tomentosa, Dipterygium glaucum and Acalypha indica*

Anti-asthmatic plants	Total phenols (mg GAE/g DW)	Total flavonoids (mg CE/g DW)	Antioxidant capacity (mg GAE/g DW)
Euphorbia hirta	87.7 ± 4.2	74.3 ± 3.1	67.4 ± 3.2
Pergularia tomentosa	75.5 ± 3.1	51.7 ± 2.1	61.2 ± 2.9
Dipterygium glaucum	69.2 ± 2.9	45.7 ± 2.0	54.9 ± 2.3
Acalypha indica	81.3 ± 3.7	58.7 ± 2.7	63.7 ± 3.5
LSD at 5%	3.09	2.41	1.86

Average of five determinations is presented with LSD at 5% ± SE

Flavonoids, low-molecular weight polyphenolic plant secondary metabolites are known to play a role in prevention and management of asthma. Recent *in vitro and in vivo* studies on anti-allergic and anti-asthmatic properties of flavonoids have strongly indicated that a suitable intake of flavonoids may complement the dietary treatment and/or preventive strategy for asthma or other allergic diseases in humans (Tanaka, 2014; Tanaka et al., 2019). Perusal of the data shows a significant difference among the species in the level of flavonoids (*Table 1*). Higher level of flavonoids were noted in the asthma weed *E. hirta* (74.3 ± 3.1 mg CE/g DW) which was 30.4%, 38.5% and 21% higher than *P. tomentosa* (51.7 ± 2.1 mg CE/g DW), *D. glaucum* (45.7 ± 1.98 mg CE/g DW) and *A. indica* (58.7 ± 2.7 mg CE/g DW), respectively. Garcia-Larsen et al. (2018) have found a direct association between flavonoid intake and asthma prevalence and severity.

We carried out the phosphomolybdenum assay to determine the antioxidant capacity of methanolic leaf extracts of *E. hirta*, *P. tomentosa*, *D. glaucum* and *A. indica*. This method is based on the reduction of Mo (VI) to Mo (V) by the antioxidant compounds and the formation of green Mo (V) complexes with a maximal absorption at 695 nm (Prieto et al., 1999). Analysis of variance showed that there was a significant difference among the studies plant species for antioxidant capacity. The methanolic extract of *E. hirta* had the maximum antioxidant activity with a value of 67.4 mg GAE/g DW. The minimum antioxidant capacity was recorded in the methanolic extract of *D. glaucum* with a value of 54.9 mg GAE/g DW (*Table 1*). Anti-asthmatic plant s such as *Eriobotrya japonica* and *Tussilago farfara* showed a much higher antioxidant capacity than the plants which we studied (Song et al., 2010; Norani et al., 2019). Phytochemical

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1398914000

attributes such as flavonoids, carotenoids and cinnamic acid derivatives have been ascribed to contribute to the total antioxidant capacity (Tyśkiewicz et al., 2019). As, we know that oxidative stress is strongly linked with most of the features of asthma. The phytochemical preparations that are being able to scavenge these free radicals may help to relieve the symptoms of asthma. The free radical scavenging activities of methanolic leaf extracts of *E. hirta*, *P. tomentosa*, *D. glaucum* and *A. indica* were assessed by DPPH method. DPPH, stable free radicals that accept an electron or hydrogen radical and get converted in to yellow-coloured diphenylpicylhydrazine, a diamagnetic molecule. The reduction capacity of DPPH is estimated by decrease in the absorbance at 517 nm induced by antioxidants. As shown in *Figure 2,* the DPPH radical scavenging activities of methanolic leaf extracts of different plants shown to occur in a dose-dependent manner. The concentration required to inhibit 50% radical-scavenging activity (IC_{50}) was established from the results of a series of concentrations evaluated. A lower IC_{50} value corresponds to a larger scavenging activity. The rank order of potency showed that the methanolic leaf extracts of *E. hirta* was 2.7-, 2.5- and 1.9 -fold more powerful than the

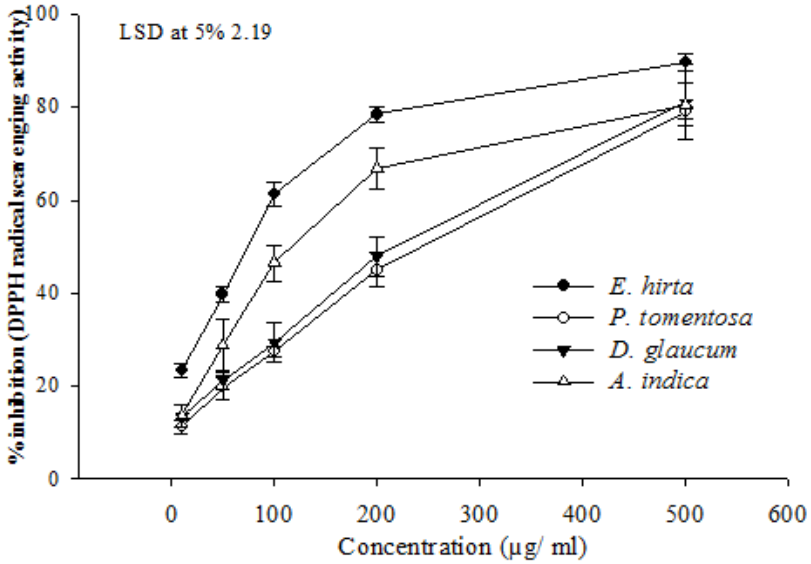

Figure 2. *DPPH radical scavenging activities of the methanolic extracts of anti-asthmatic plants Euphorbia hirta, Pergularia tomentosa, Dipterygium glaucum and Acalypha indica. Average of five determinations is presented with LSD at 5% ± SE*

P. tomentosa, *D. glaucum* and *A. indica*, respectively. The scavenging effect of methanolic extracts on the DPPH radical expressed as IC_{50} values was in the following order: *E. hirta* > *A. indica* > *D. glaucum* > *P. tomentosa* (*Fig. 3*). The substantial antioxidant activity of *E. hirta* could be due to the presence of sesquiterpene lactones and quercetin in flavonoids in the methanolic extracts (Williams et al., 2004; Gupta et al., 2017).

H_2O_2 is very lethal as being able to cross the biological membrane and serve as a precursor for potentially toxic hydroxyl radical (Das and Roychoudhury, 2014). The hydroxyl radical is an extremely reactive free radical capable of damaging almost every molecule found in living cells (Das and Roychoudhury, 2014). As in *Figure 3,* the methanolic leaf extracts of all the plants investigated, have shown a concentration

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1398914000

dependent H_2O_2 scavenging activity. Statistical analysis of the data shows a significant difference ($p < 0.05$) among the plants in relation to H_2O_2 scavenging activity. Lowest H_2O_2 scavenging activity was recorded for *E. hirta* which was 1.6-, 1.9- and 1.1-fold lower than *P. tomentosa*, *D. glaucum* and *A. indica*, respectively (*Fig. 3*). The H_2O_2 scavenging activity of methanolic extracts expressed as IC_{50} values was in the following order: *D. glaucum* > *P. tomentosa* > *A. indica* > *E. hirta* (*Fig. 3*). According to Mobin et al. (2014), H_2O_2 scavenging activity of these methanolic extracts could be assigned to the presence of active constituents that that may donate electrons to H_2O_2 and thereby neutralizing it to water.

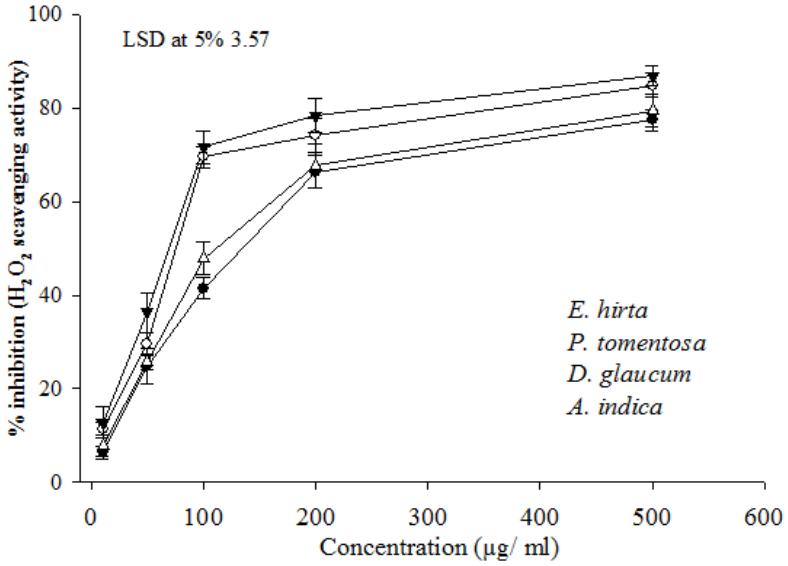

Figure 3. *H_2O_2 scavenging activities of the methanolic extracts of anti-asthmatic plants Euphorbia hirta, Pergularia tomentosa, Dipterygium glaucum and Acalypha indica. Average of five determinations is presented with LSD at 5% ± SE*

According to Terao (2009), NOX regulates many pathological conditions, especially acute inflammatory condition. Nitrite and peroxynitrite anions are generated when oxygen reacts with the excess NOX that may acts as free radicals (Radi, 2018). In this study, methanolic leaf extracts of all the investigated plants compete with oxygen to react with NOX and thus inhibits the generation of the anions in a dose dependent manner. As in *Figure 4* the highest NOX scavenging activity among the analyzed plant extracts were displayed by *E. hirta* ($IC_{50} = 135$ µg/ml). We noted that the NOX scavenging activity of *E. hirta* was 1.2-, 1.4- and 1.1-fold more than *P. tomentosa*, *D. glaucum* and *A. indica*, respectively (*Fig. 4*). The bioactive constituents of *E. hirta* include flavonoids (quercetin and myrcetin), sterols, tannins, and triterpenoids (Attah et al., 2013; Onyeka et al., 2018; Salehi et al., 2019). The abundance of these bioactive substances makes them powerful scavengers.

As in *Figure 5,* the metal chelating ability of the methanolic leaf extracts of *E. hirta, P. tomentosa*, *D. glaucum* and *A. indica* were quantified by the formation of ferrous ion-ferrozine complex of red colour which absorbs at 562 nm (Yamaguchi et al., 2000). The ability of a chelating agent to form σ bond with a metal, may act as effective scavenger as they lower the redox potential and stabilize the oxidised metal ion (Duh et al., 1999). In the present study the plants show a significant difference response in metal chelating

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1398914000

activity. Highest and lowest metal chelating activity was noted in *P. tomentosa* and *D. glaucum*, respectively. Based on IC_{50} value, the rank order of potency for metal chelating activity of methanolic leaf extracts of all the samples were; *P. tomentosa* > *E, hirta* > *A. indica* > *D. glaucum* (*Fig. 6*). Fe^{2+}, a transition metal can transfer a single electron and can trigger a series of radical reactions even with non-transition metals. Fe^{2+}- chelating activity depends on flavonoid structures, however, the position of the hydroxyl ion in the molecule determines the proton donating and radical scavenging activity as suggested by Mira et al. (2002), Hou et al. (2003) and de Castilho et al. (2018).

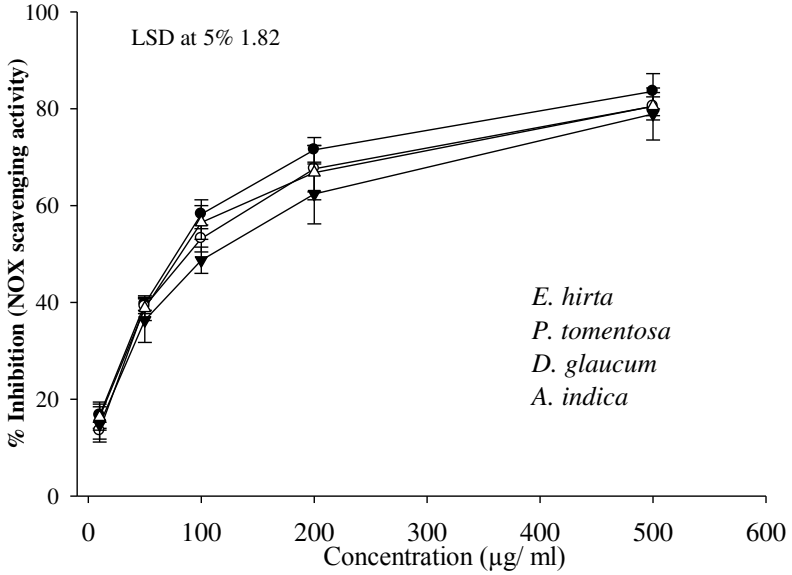

Figure 4. *Nitric oxide (NOX) scavenging activities of the methanolic extracts of anti-asthmatic plants Euphorbia hirta, Pergularia tomentosa, Dipterygium glaucum and Acalypha indica. Average of five determinations is presented with LSD at 5% ± SE*

Average of five determinations is presented with LSD at 5% ± SE*

Conclusions

The findings of the present study have provided the biochemical evidences for the ethno-pharmacological applications of these anti-asthmatic plants. Based on statistical analysis of the data, it can be postulated that affluence of phenol and flavonoids along with maximum antioxidant capacity, DPPH antiradical activity and NOX scavenging activity in *E. hirta* makes it worthy of using as an effective anti-asthmatic plant. However, future work should be directed towards the isolation, identification and mode of action of bioactive constituents responsible for strong anti-asthmatic action of these plants.

(Received 24th May 2019; accepted 3rd Sep 2019)

Abstract. Organic farming is an environmentally friendly agricultural system which is very important in terms of the environment, human and plant and animal health. Thanks to organic farming, soil and water resources and air are protected from excessive contamination. In this respect, organic farming also contributes to the sustainable use of natural resources. Seen from this perspective, the adoption and application of organic farming by farmers is very important. This research was conducted to determine the factors affecting the adoption of organic farming by farmers. The study was executed in the Bafra district of Samsun province in Turkey. Within the context of the study, face-to-face administration of a questionnaire to a total of 54 farmers from nine different villages was performed. The proportional sampling method was used to determine the number of producers to be surveyed. It was determined that the most important factors are the health factors for farmers to adopt organic farming. They are followed by environmental protection factors, economic factors, social factors and innovativeness factors. All the farmers participating in the current study were determined to want to go on with organic farming in the future.
Keywords: *farmers' preference, organic agriculture, conversion, adoption, environment*

Introduction

The history of organic farming dates back to the 1940s, first each country started its development in itself and then its structure and trade developed worldwide. The first worldwide organization was founded in 1972 with the establishment of International Federation of Organic Agriculture Movements (IFOAM). World trade began to develop in the late 1970s and reached the market size in the 1980s (Altındişli and Aksoy, 2010). Organic farming is an alternative production method that aims to improve not only the quantity but also the quality of production and includes human and environmentally friendly production systems for reestablishing the natural equilibrium which is lost as a result of faulty practices in the ecological system, and prohibits the use of synthetic chemical pesticides, hormones and mineral fertilizers while recommending the use of organic and green fertilization and alternation (Aksoy and Altındişli, 1999).

Organic farming started in Turkey in 1984-85 with the demand of European companies for the production of traditional products such as dried fruits and nuts organically (Aksoy, 2002). The organic farming model generally implemented in Turkey is carried out in the form of contract farming between companies and organic producers. According to these contracts, the producers stipulate not to use synthetic fertilizers and pesticides in line with the direction of the project managers of the organic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1400114008

companies and carry out other necessary agricultural practices (use of organic inputs and agricultural methods) (Demiryürek, 2011).

In 2018, the number of farmers engaged in organic plant production was 54666. The total area of organic farming was 365889.54 hectare. When organic animal production data for the year 2018 was analyzed, it was found that a total of 148 farmers raise organic animals. When the data for the organic beekeeping were examined, it was found that 334 farmers were in the business of organic beekeeping and the number of hives under such conditions was 51742 (Anonymous, 2019a).

Organic farming started in Samsun province in 1994 with the production of organic hazelnuts. The use of pesticides and chemical fertilizers in areas other than Bafra and Çarşamba plains is quite low. In this respect, Samsun has an important potential for organic farming. In 2018, the number of farmers engaged in organic crop farming in Samsun province was 1013. The total area of organic farming was 3343.65 hectare (Anonymous, 2019a). In the current study, it was aimed to reveal the process of adoption of organic farming and the factor affecting this process in the Bafra district of the Samsun province.

Materials and methods

The main material of the current study is made up of the data collected by means of face-to-face administration of a questionnaire to a total of 54 producers engaged in organic farming in the villages of Çalköy, Darboğaz, Dikencik, Elifli, İkizpınar, Köseli, Ozan, Sürmeli and Uluağaç in the Bafra district of the Samsun province in Turkey (*Fig. 1*). Moreover, previous research on organic farming has also been capitalized on.

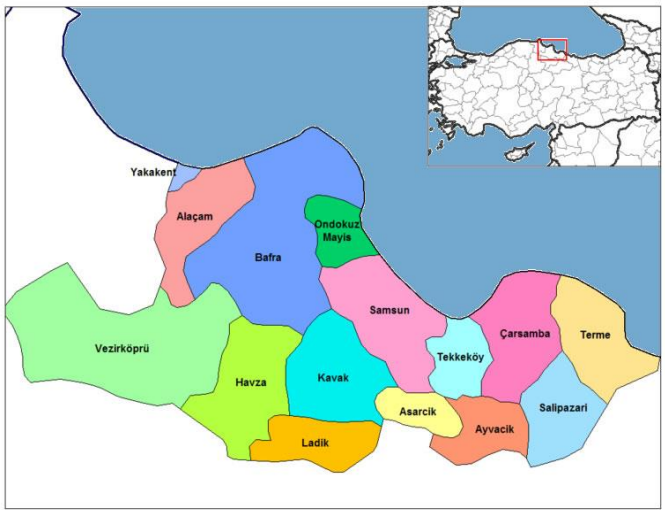

Figure 1. *Map of Samsun Province. (Source: Anonymous, 2019b)*

The questionnaire consists of four parts. These parts are; socio-economic features of the producers, general features of the agricultural enterprises, the farmers' state of plant production and the farmers' state of organic production. The questionnaires were administered in February and March, 2017.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1400114008

After the research data had been collected, the analysis process was initiated. In the analysis of the collected data, means and frequencies were calculated. Moreover, in order to determine the farmers' attitudes towards organic farming, a five-point Likert scale was used. The obtained results are summarized in tables and then interpreted and evaluated.

Results

Socio-economic features of the farmers

Within the context of the socio-economic features, the farmers' age, gender, education level, the number of people in the family, income sources, income level and their membership to any agricultural association were investigated in the current study. Of the participating farmers, 92.59% are males and 7.41% are females. The mean age of the participating farmers was found to be 59.54. When the education levels of the farmers were examined, it was found that 53.70% are elementary school graduates, 16.67% are middle school graduates, 12.96% are high school graduates, 11.11% are university graduates, 3.70% are literate and 1.86% are illiterate. The mean number of members in the family was found to be 5.15.

It was determined that 87.04% of the farmers do not keep their business records regularly. All the farmers participating in the current study were found to be a member to an agricultural association. When the agricultural associations subscribed were examined, it was found that all of them are members to the Chamber of Agriculture.

It was also found that the participating farmers are engaged in the production of many organic products. These products include nuts, walnuts, wheat, corn, eggplant, peppers, apples, strawberries, tomatoes, cucumbers and beans. The production areas of these products are as follows: Nut 20.67 decares, walnut 13.30 decares, wheat 3 decares, corn 10 decares, eggplant 2 decares, pepper 2 decares, apple 5.50 decares, strawberry 3 decares, tomato 2 decares, cucumber 3.67 decares, bean 1.37 decares.

Some characteristics of the farms investigated

The farms investigated were found to have 45.06 decares arable land on average and the number of average parcels was calculated to be 6.56. In the current research, it was determined that all of the farmers perform their agricultural activities on the property land. Besides, it was determined that 11.11% of the farmers conduct their agricultural activities on the rented land and that only one producer conducts his/her agricultural activities in the jointly operated land. In the current research, it was also found that 11.11% of the farmers are also engaged in animal breeding.

In the current research, 79.63% of the farmers were found to have non-agricultural income sources. The farmers were asked the question "How is your income level compared to other farmers in your village?" Majority of the farmers (77.78%) were found to be in the middle income group, 14.81% were found to be in the low income group and 7.41% were found to be in the high income group.

Findings related to organic farming

When how the farmers were first introduced to the concept of organic farming was examined, it was found that 57.41% of them first heard of the concept of organic farming from agricultural associations, 12.96% from universities, 11.11% from

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1400114008

television and radio, 9.26% from books/journals/newspapers, 5.56% from friends and relatives and 3.70% from pioneering farmers. When the farmers were asked the question "How long time passed between your first introduction to the concept of organic farming and your starting organic farming?", 66.67% stated that they immediately started, 24.07% stated that they started 1 to 5 years later and 9.26% stated that they started after 5 years had passed. When how long the farmers had been in the business of organic farming was investigated, it was found that 92.59% had been in the business of organic farming for 0-5 years, 5.56% had been in the business of organic farming for 6-10 years and 1.85% for 11-20 years.

In the current study, it was determined that the most effective factors on the adoption of organic farming by the farmers are health factors. They are followed by environmental protection factors, economic factors, social factors and innovativeness factors (*Table 1*).

Table 1. *Factors affecting the adoption of organic farming*

	Not effective at all		**Little effective**		**Effective**		**Very effective**		**Extremely effective**		**Scale mean**

The percentage of the farmers thinking that organic farming does not any effect on the income level was found to be 77.78. While 11.11% of the farmers stated that organic farming has an income increasing effect, 11.11% stated that it has an income decreasing effect.

The primary purpose why the farmers are engaged in organic production is to produce healthy products (*Table 2*).

Table 2. *The purpose why the farmers are engaged in organic production*

When the ways through which the farmers engaged in organic production market their products were examined, it was found that 77.78% of the farmers market their products through wholesalers while 22.22% market their products in local markets.

Among the problems encountered by the farmers while performing organic production, first place is taken by lack of consciousness on the part of consumers with 35.19%. On the other hand, 7.40% of the farmers were found to have no problem in organic production (*Table 3*).

Table 3. *Problems encountered while performing organic production*

Total	54	100.00

It was found that all the farmers participate in meetings, trainings and seminars organized in their villages and find these training activities useful.

All of the participating farmers were found to be willing for going on with organic farming in the future. A high majority of the farmers (77.78%) were found to want to go on with organic farming as healthy products are created through organic farming. The percentage of the farmers wanting to go on with organic farming as it does not harm nature was found to be 9.25 (*Table 5*).

Discussion

In the current study conducted to determine the factors affecting the adoption of organic farming in Samsun province, it was found that the most effective factors are health factors. That is, the farmers stated that due to the negative effects of chemical inputs used in conventional production on human health, they turned to organic farming. Similarly, Karki et al. (2011) found that health awareness and environmental awareness affected the decision of farmers to switch to organic farming. In a study conducted by Çukur and Işın (2008), it was found that the economic aspect of agriculture is very important for farmers, the ecological aspect of agriculture is important and the social aspect of agriculture is relatively less important. Rezvanfar et al. (2011) determined that there were many factors affecting the adoption of organic farming by farmers, including the socio-economic characteristics of farmers, the characteristics of enterprises, the information sources of farmers, the membership of farmers to farmer associations and the attitudes of farmers. Ceylan et al. (2010) found that economic and environmental factors were effective in farmers' adoption of organic farming. In a study conducted by Meda et al. (2018) in Burkina Faso, it was found that fertilizer support and the use of credit for grain production facilitated farmers' adoption of organic cotton production. Crawford et al. (2015) found that the communication network between farmers is very useful for the farmers engaged in organic farming. In the study conducted by Azam and Shaheen (2019), it was determined that there are 5 important factors in the adoption of organic farming. These factors were identified as economic, social, marketing, tillage and government policy.

It was determined that the majority of the farmers started organic production immediately after hearing of the concept of organic farming and had been in the business of organic farming at least for five years. Burton et al. (2003) also found in the first 5 years, the rate of adoption of organic farming is high. In a study conducted by Kallas et al. (2009), it was found that farmers who like to take risks, who care about the environment and who create employment in their businesses adopt organic farming in a shorter time. In a study conducted by Issa and Hamm (2017) with fresh vegetable and fruit producers, it was determined that farmers have positive views on organic farming and intend to switch to organic farming within 5 years.

A significant proportion of farmers think that their starting organic farming has no notable effect on their income. Artukoglu et al. (2009) determined that the income level of the farmers did not have an effect on their decisions to adopt organic farming.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1400114008

In the current study, it was found that according to the producers, the most important characteristics differentiating organic farming from conventional farming are producing quality food and protecting nature. In the current study, it was found that the meetings, trainings and seminars organized in villages about organic farming were found to be beneficial by the producers. Sodjinou et al. (2015) found that communication with agricultural extension services facilitated the adoption of organic farming by farmers. The research conducted by Adebayo and Oladele (2013) has revealed a positive relationship between the frequency of communication with extentionists and the adoption of organic farming by farmers.

In the current research, it was determined that all of the farmers wanted to continue their organic production in the future. In a study conducted by Çukur (2015) however it was determined that farmers do not want to continue organic production in the future as they do not have sufficient knowledge about organic farming.

Conclusion

It was determined that all of the farmers interviewed in the study wanted to continue their organic production in the future and their aim was to cultivate healthy products. This is important for the sustainability of organic farming. Agricultural extension and training programs should be implemented for the adoption of organic farming by more farmers in the district. For this purpose, it is necessary to identify the regions that are suitable for organic farming in the district and where the use of chemical inputs is very low and works should be conducted for farmers to adopt organic farming.

In the current research, it was determined that farmers need technical knowledge about organic farming and they also need information about subsidies, legal regulations and prices. Therefore, a comprehensive extension program should be prepared and put into practice to provide farmers with extension and consultancy services.

In the current study, it was determined that most of the farmers did not keep their business records. Business records are an important source of data for farmers to make the right decision. Therefore, farmers should be informed about the importance of keeping business records.

Consumers should be informed about the importance of the products of organic farming for health and their awareness about organic farming should be increased. The number of organic markets should be increased to make it easier for consumers to access organic products.

Organic farming is very important for sustainable agriculture. The increase in organic farming subsidies is thought to be effective in the adoption of organic farming by more farmers.

Determination of the factors that affect farmers' adoption of organic agriculture seems to be important in terms of using it as data for the development of policies related to organic farming.

Abstract. The present study aimed to transfer *nod* and *nif* genes from *Rhizobium* and *Azotobacter* to *Bacillus* by: the transformation technique which used to transfer *nod*D2 and *nod*D3 from *Rhizobium leguminosarum* to *Bacillus megaterium*; and the conjugation mechanism which performed the transfer of *nif*H2 and *nif*H3 from *Azotobacter chroococcum* to transformant *Bacillus megaterium*. The results showed that: 12 colonies were obtained after transformation on Sperber's agar plates which contained tetracycline and ampicillin. While after conjugation; 166 colonies were obtained on Sperber's agar plates which contained ampicillin and erthymycinem, indicating that the transformation and conjugation were successful. To confirm this, a molecular study was performed based on the followings: the extraction of the plasmid DNA from *Rhizobium leguminosarium* and transformant *Bacillus megaterium* to detect *nod*D genes; and the extraction of the genomic DNA from *Azotobacter chroococcum* and transformant-conjugant *Bacillus megaterium* to detect *nif*H genes by PCR and gel electrophoresis. The PCR products on gel electrophoresis showed that *Rhizobium leguminosarium* and transformant *Bacillus megaterium* contained *nod*D2 and *nod*D3; and *Azotobacter chroococcum* and transformant-conjugant *Bacillus megaterium* contained *nif*H2 and *nif*H3. Furthermore, the new *Bacillus megaterium* which obtained these genes successfully, can be used as biofertilizer for nitrogen fixation and phosphorus solubilization at the same time.
Keywords: *nod gene, nif gene, DNA transferring, PCR, Gel electrophoresis*

Introduction

Rhizobium and *Azotobacter* interact with a wide range of other soil microorganisms in the rhizosphere of plants. These interactions are sometimes stimulatory where they increase the growth response of the host in the presence of other microorganisms (Kennedy and Islam, 2001; Nosheen et al., 2011). *Azotobacter* and *Rhizobium* are known to be good non-symbiotic and symbiotic nitrogen fixers, respectively (Siddiqui et al., 2014). This biological nitrogen fixation process in *Azotobacter*, and between *Rhizobium* strains and their legume partners can happen under low levels of available nitrogen with the help of many different genes such as *nod, nif, fix*, production of polysaccharides, competition, infection process, and host specificity (Shamseldin, 2013). *Rhizobium nod* genes, and their product, *Nod* Factor (NF), have been recognized as essential for the development of nitrogen-fixing nodules on legume roots (Lerouge et al., 1990). *Nod*D is present in all *rhizobia* (Shamseldin, 2013). *Nod*D is the core signaling protein, reacting to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1400914024

plant flavonoids then binding to nod boxes, binding sites upstream of nod genes, typically *nod*A and/or *nod*B, trigger the expression of a *nod* gene cascade and thus the construction of the *Nod* Factor (Jones et al., 2007). The *nif* genes are able to fix nitrogen in both the free-living and symbiotic states, and the *nif* genes can transcript in both free-living and symbiotic diazotrophs (Dixon and Kahn, 2004). The expression and regulation of *nif* genes, while sharing common features in all or most of the nitrogen-fixing organisms in nature, have distinct characteristics and qualities that differ from one diazotroph to another (Spaink et al., 1998). The structural gene *nif*H, as an important *nif* gene, is involved in the formation of the Fe-protein complex (Cocking, 2003), and *nif*H is the gene that encodes the iron protein subunit of nitrogenase, which is highly conserved among all nitrogen-fixing groups and serves as an ideal molecular marker for these microorganisms (Deslippe and Egger, 2006). *Bacillus megaterium* has the ability to solubilize phosphorus, which is good for the plant (Velineni and Brahmaprakash, 2011). *Bacillus megaterium* produces organic compounds such as lactic acid, gluconic acid, citric acid, succinic acid, propionic acid and enzymes that help solubilize the fixed phosphorus into exchangeable form (Agrilife, 2008).

In the bacterial population, DNA can be transferred from one organism to another by the horizontal transfer mechanism. The DNA thus transferred by the lateral/horizontal method can be stably incorporated in the recipient, and changes the genetic composition of the recipient permanently. Three broad mechanisms mediate efficient movement of DNA between cells: transformation, conjugation, and transduction (Acharya, 2013). Bacterial plasmid transformation is a process by which genetic material, often a plasmid, is inserted into a bacterial cell. Though transformation does occur naturally, scientists have developed many techniques to ensure DNA uptake by bacterial cells (Yoo, 2010). Genetic transformation occurs when a cell takes up (takes inside) and expresses a new piece of genetic material—DNA, and it literally means change caused by genes and involves the insertion of one or more gene(s) into an organism in order to change the organism's traits, this new genetic information often provides the organism with a new trait which is identifiable after transformation (www.explorer.bio-rad.com). Transformation takes place to a limited extent in many bacteria. But laboratory techniques have been developed that increase the rate of DNA uptake. (www.kullabs.com). Bacterial transformation is a process which involves genetic alteration of bacteria by the incorporation and stable expression of foreign genetic material from the environment or surrounding medium. Since DNA is a very hydrophobic molecule, it will not normally pass through a bacterial cell membrane. In order to uptake foreign DNA, the bacterial cells must first be made competent. Competence is the ability of a cell to take up extracellular DNA from its environment (www.himedialabs.com. a). In bacteria, the haploid genome is a single circular chromosome. This differs from eukaryotic genomes like those of plants and animals, where the genetic material is diploid and arranged into linear chromosomes. Bacteria can also possess additional nonessential pieces of circular DNA called plasmids (www.towson.edu/cse). Plasmids are small circles of DNA that contain an origin of replication (ori) and a small number of genes, some of which may confer a survival advantage on a host. Some plasmids can transfer between different species; even between different kingdoms (Slonczewski, 2006). Plasmid transformation into bacterial competent cells is a key technique in molecular cloning (Tu et al., 2005).

Many bacteria from different species frequently exchange their genetic materials by a process called conjugation, which occurs by cell-to-cell contact (Fernandez-Lopez et al.,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1400914024

2005). Conjugation is a recombination process where two live bacteria come together, and the donor cell transfers genetic material to the recipient cell. Conjugating bacteria are of two mating types. Certain "male" types (designated as F+) donate their DNA, and other "female types" (designated as F-) receive the DNA, F- cells become F + when they acquire a small amount of DNA. Hence the F factor is called as the Fertility factor. In contemporary microbiology, the donor's F factors are known to be plasmids which are extra-chromosomal elements. The factors (plasmids) contain about 20-30 genes, most of which are associated with conjugation. These genes encode enzymes that replicate DNA during conjugation and structural proteins needed to synthesize special pili at the cell surface which known as F pili or sex pili, these hair-like fibers contact the recipient bacteria, and then retract so that the surfaces of donor and recipient are very close or touching one another. At the area of contact, a channel or conjugation bridge is formed. Once contact via sex pili has been made, the F factor (plasmid) begins replicating by the rolling circle mechanism. A single strand of the factor then passes over or through the channel to the recipient. When it arrives, enzymes synthesize a complementary strand, and a double helix is formed. The double helix bends to a loop and reforms an F factor (plasmid), thereby completing the conversion of the recipient from F- cell to F + cell. Meanwhile, back in the donor cell a new strand of DNA forms, to complement the leftover strand of the F plasmid. The transfer of F factors involves no activity of the bacterial chromosome; therefore the recipient does not acquire new genes other than those on the F factor (www.himedialabs.com).

Transformation process holds key step in molecular biology (Das et al., 2017), and it has been a handy tool in several areas of bacterial research because the genotype of a strain can be deliberately changed in a very specific way by transforming with an appropriate DNA fragment. For example, transformation is used widely in genetic engineering (Pimda and Bunnag, 2010). The goals of gene transfer experiments with other organisms are to study gene regulation and to obtain stable inheritance and expression of new characteristics (Moses, 1987).

Conjugation gene transfer is considered to be an important mechanism for the establishment of new genetic traits in diverse environments (Hausner and Wuertz, 1999). Conjugation is used in nature to share beneficial genetic material between bacteria, such as antibiotic resistance. However, manually inserting genes into the F-plasmid would allow for scientists to have bacteria transfer almost any gene to other cells (Griffiths et al., 2000).

Materials and methods

The country and location of the study

The present study was performed in Sulaimani city/Iraq. All bacteria were isolated from the organic farm of Bakrajow, and the molecular studies were done at the laboratories. The farm and the laboratories are located inside the College of Agricultural Sciences, University of Sulaimani.

Isolation of bacteria

Rhizobium leguminosarium spp. were isolated from healthy, unbroken, firm and pink nodules of Broad bean from the organic farm of Bakrajow using YMA medium in accordance with Agrawal et al., 2012, while *Azotobacter chroococcum spp.* were

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1400914024

isolated from Bakrajow soil on modified Ashby's medium according to Marwa et al., 2010, and *Bacillus megaterium* was isolated from same soil using Sperber's medium based on Shiva et al., 2010.

Purification of isolated bacteria

A loop of actively growing of each bacterial species (48 h old surface film) was streaked on their selective media, the growth was observed depending on the type of bacteria, *R. leguminosarium* and *B. megaterium* after 24-48 h and *A. chroococcum* after 3-7 days at 28 °C of incubation. The well separated and apparently un-contaminated colonies appearing on the plates were streaked on agar medium, plating and picking were repeated at least 4-5 times.

Maintenance and storage of bacterial culture

The cultures were maintained for a short time at slant medium, and for a long time in 20% glycerol and stored at -70 °C (Ausabel et al., 2003) without losing their activity.

Identification of bacteria by molecular protocol

Depending on the molecular protocol, *B. megaterium* was identified by the extraction of genome DNA using PrestoTM Mini gDNA Bacteria Kit Protocol to detect and check the presence of *B. megaterium* in the region by two random primers, *R. leguminosarium* was identified by the extraction of plasmid DNA using Genetbio, PrmePrep Plasmid DNA isolation kit to detect the *nod*D2 and *nod*D3 genes which we wanted to transfer to the *B. megaterium* by the transformation process, and *A. chroococcum* was identified by extraction of genomic DNA using PrestoTM Mini gDNA Bacteria Kit Protocol to detect the *nif*H2 and *nif*H3 genes which we wanted to transfer to the transformant *B. megaterium* by the conjugation process using specific primers for each gene in order to obtain a new model of the *B. megaterium* which would contain both of the *nod* and *nif* genes and then could be used as bio-fertilizers to provide available nitrogen and phosphorus to plants.

PCR amplification conditions

The conditions of PCR amplification: for *nod*D2 and *nod*D3 were performed according to the modified method of Del Cerro et al., 2015a at cycling conditions consisted of a single cycle of 95 °C for 10 min, followed by 45 cycles of 95 °C for 2 min, 60 °C for 30 s and 72 °C for 30 s, and a final extension cycle at 72 °C for 6 min, while PCR reactions for *nif*H2 and *nif*H3 were done in accordance with Setubal et al., 2009), and for random primers 1 and 2 of *B. megaterium* was carried out in accordance with Patil et al., 2013). The forward, reverse and random primers are shown in *Table 1*.

Gel electrophoresis (Helmut et al., 2004)

Gel electrophoresis was used to identify the extraction of each of genome DNA, chromosomal DNA, and plasmid DNA, and it was also used to check the DNA amplification of each product by dissolving 0.5, 1, 1.5 and 2% (w/v) of agarose gel depending on the size of amplified DNA in 100 ml (IX) TBE buffer by heating it in a micro-wave oven for 3 min, then cooling the solvent to 45 °C at room temperature. The gel was stained with 5 µl of 5 $mg.ml^{-1}$ ethidium bromide, and the gel was soaked in a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1400914024

gel tank containing TBE. The gel tank was covered by a lid, and electrophoresis was run at (80 to 100 V) for 2-3 h depending on the product. DNA fragments were visualized at 312 nm with a UV- transilluminator image.

Antibiotics resistance test

Table 2 shows the 8 common antibiotics including Chloramphenicol, Gentamycin, Tetracycline, Ampicillin, Cefotaxim, Erthymycine, Streptomycin and Rifampicin which were used for testing the sensitivity of: *R. leguminosarium* and *B. megaterium* for transformation technique, and transformant *B. megaterium* and *A. chroococcum* for conjugation process.

Table 2. *The antibiotics used in accordance with Shoukry et al., 2013; American Type Culture Collection, 2013; Giacopello et al., 2016*

Antibiotic	Recommended stock concentration	Recommended working concentration
Chloramphenicol	10 mg/ml in ethanol	25 µg/mL
Gentamycin	10 mg/ml	10 µg/mL
Tetracycline	10 mg/ml in (50% D.W + 50% ethanol)	10 µg/mL
Ampicillin	10 mg/ml in water	20 µg/ml
Cefotaxime	10 mg/ml in water	30 µg/ml
Erthymycine	10 mg/ml in water	15 µg/ml
Streptomycin	10 mg/ml in water	10 µg/ml
Rifampicin	10 mg/ml in methanol	5 µg/ml

Preparation of competent cells from B. megaterium

A modified method of Sambrook et al., 1989 was used for the preparation of competent cells of *B. megaterium* for transformation. An overnight culture of *B. megaterium* was prepared by suspending a colony from a fresh Sperber's plate in 100 ml of Sperber's broth medium. The culture was incubated in a shaking incubator at 100 rpm for 24 h at 28 °C, then 10 ml of this culture was suspended in 90 ml of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1400914024

fresh Sperber's broth and grown at 28 °C for 90 min in a shaking incubator until an OD $_{600}$ nm of approximately 0.3-0.6 was attained, then 10 ml aliquots was centrifuged at 4000 Xg for 10 min at 4 °C to pellet the cells. After that, the supernatant was discarded and cells were re-suspended in 10 ml of 0.1 M $CaCl_2$ over 1 h on ice, and re-centrifuged twice, following the third washing with 5 ml 0.1 M $CaCl_2$. Finally the cells were re-centrifuged and gently re-suspended in 2 ml of ice-cold 0.1 M $CaCl_2$ containing 20% glycerol. The cells could be used immediately for transformation or stored at -20 °C.

Bacterial transformation (Ausabel et al., 2003)

A total of 200 µl of competent cells (*B. megaterium*) were mixed with 2 µl of the extracted plasmid from *R. leguminosarium* in a tube, and the tube was left on ice for 30 min. After that the tube was incubated for 30 s at 42 °C in a water bath and then placed on ice for 5 min, then 800 µl of Sperber's broth was added and the tube was incubated at 28 °C for 1 h. Then the cells were centrifuged at 6000 Xg for 1 min. Next, the pellet was re-suspended in 200 µl of Sperber's broth. A total of 100 µl of the cells were plated out on Sperber's agar medium containing two antibiotics which were used as genetic markers. After post-incubation at 28 °C for 28 h the colonies were screened, then the molecular study was performed using PCR and gel electrophoresis techniques for detection of transferred *nod*D2 and *nod*D3 genes in transformant *B. megaterium* that transferred by transformation process.

Bacterial conjugation (Olsen et al., 1992)

A 10 ml of modified Ashby's broth medium was inoculated with a single colony of *A. chroococcum* (donor cell), and 10 ml of Sperber's broth medium was inoculated with a single colony of transformant *B. megaterium* (recipient cell), then they were incubated at 28 °C for 48 h. with shaking at 100 rpm. After incubation, 0.8 ml of the *A. chroococcum* (donor cells) were mixed with 0.2 ml of transformant *B. megaterium* (recipient cells) and 1 ml of Sperber's broth, the mixture was incubated at 28 °C for 3 h under aerobic condition. Then 0.1 ml of the conjugated mixture was spread on Sperber's agar medium plates containing two antibiotics that were used as genetic markers, and control plates were prepared by spreading 0.1 ml for each donor and recipient suspensions separately on agar plates containing the same markers, then all plates were incubated at 28 °C till the colonies appeared. To verify the transfer of nitrogen fixation genes (*nif* genes) from *A. chroococcum* to transformant *B. megaterium*, the transformant-conjugant colonies were screened, then the molecular study was performed using PCR and gel electrophoresis techniques for the detection of transferred *nif*H2 and *nif*H3 genes, that were transferred by conjugation process, in transformant-conjugant *B. megaterium*.

Results

DNA isolation from bacteria

The DNA was isolated from bacterial cultures, and the molecular method based on the extraction of the genomic DNA from *A. chroococcum* and *B. megaterium* and plasmid DNA from *R. leguminosarium,* which were detected by agarose gel electrophoresis, the results are shown in *Figure 1* lane 2, 4, 6 respectively.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1400914024

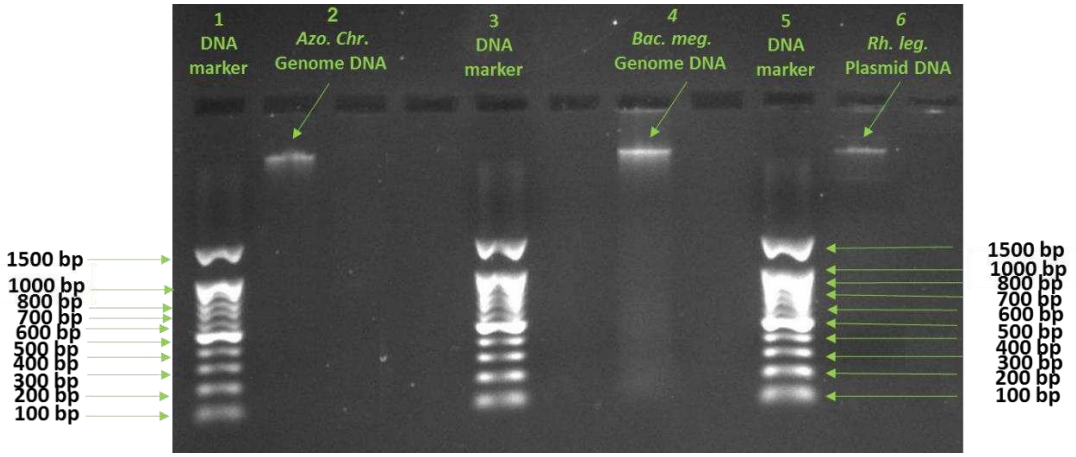

Figure 1. *Agarose gel electrophoresis shows DNA marker lanes 1, 3, and 5, extracted chromosomal DNA from A. chroococcum, genome DNA from B. megaterium and plasmid DNA from R. leguminosarium lanes 2, 4 and 6, respectively*

Molecular based identification of Bacillus megaterium

The PCR amplification was performed to check the presence of *B. megaterium* in the region using two random primers. The PCR products showed high amplification rate and reproducible banding pattern which confirmed the existence of *B. megaterium* (*Fig. 2,* lanes 2 and 3).

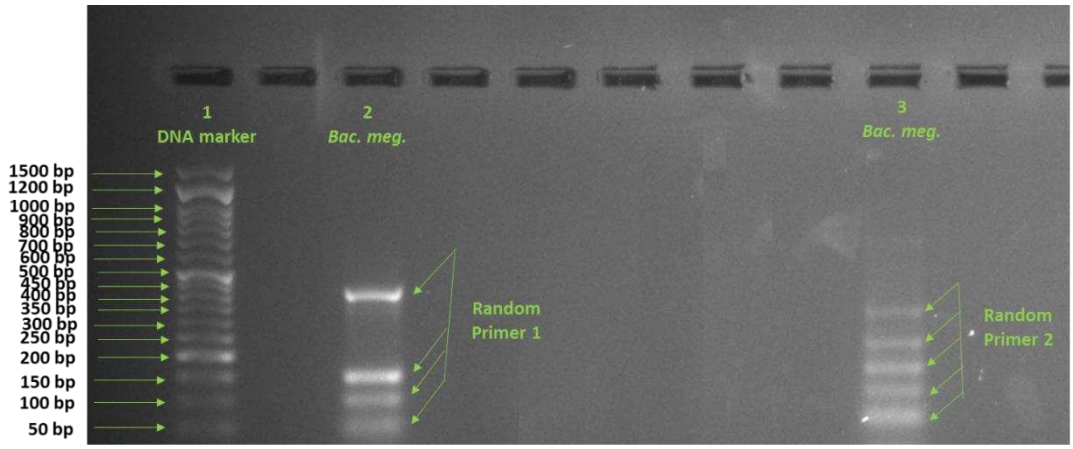

Figure 2. *Agarose gel electrophoresis shows the PCR amplified products of the B. megaterium generated using 10-mer random primers: Lane 1: DNA marker, lanes 2 and 3: random primers 1 and 2 respectively (+ve PCR products)*

Antibiotics resistance of R. leguminosarium, B. megaterium, transformant B. megaterium and A. chroococcum

The resistance screening of *R. leguminosarium, B. megaterium*, Transformant *B. megaterium,* and *A. chroococcum* was evaluated for eight antibiotics that are widely used. Depending on the results in a *Table 3,* tetracycline and ampicillin were used as genetic markers for transformation experiment, while ampicillin and erthymycine were used as genetic markers for the conjugation experiment.

Transformation of plasmid genes (nodD2 and nodD3) from R. leguminosarium to B. megaterium by transformation process

Transformation experiment was carried out to transfer the genes responsible for the nodulation (*nod*D genes) which were *nod*D2 and *nod*D3 from *R. leguminosarium* to *B. megaterium.* After the transformation, 12 colonies were gained on Sperber's medium supplied with tetracycline and ampicillin as genetic markers and the colonies were resistant to both antibiotics. These results confirmed that the resulting colonies were transformant colonies and the transformation technique was successful between *R. leguminosarium* and *B. megaterium*. To confirm if *nod*D2 and *nod*D3 genes transferred from *R. leguminosarium* to *B. megaterium* by transformation technique, the molecular study was performed using specific primers to detect the *nod*D2 and *nod*D3 genes in transformant cells and compared to the *nod*D2 and *nod*D3 genes in *R. leguminosarium* by PCR technique and gel electrophoresis.

PCR amplification of nodD2 and nodD3

After extraction and purification of plasmid DNA from *R. leguminosarium*, *B. megaterium* and transformant *B. megaterium* using the Genetbio, PrmePrep Plasmid DNA isolation kit according to the manufacturer's protocol, PCR and gel electrophoresis were carried out in order to amplify and check the existenc of *nod*D2 and *nod*D3 in the plasmid DNA of *R. leguminosarium, B. megaterium* and transformant *B. megaterium* using specific oligonucleotide primers that flank the DNA sequence to be amplified.

Figure 3 shown positive PCR products on gel electrophoresis in *R. leguminosarium* and transformant *B. megaterium* which contained *nod*D2-F- and *nod*D2-R- primers with 100 bp in lanes 2 and 4, respectively, while in *Figure 4*, the results show the positive amplification on gel electrophoresis of *nod*D3 in *R. leguminosarium* and transformant *B. megaterium* with 150 bp in lanes 2 and 4, respectively using *nod*D3-F- and *nod*D3-R- primers, but the negative control and *B. megaterium* were negative PCR products and they did not produce bands, which can be seen in lanes 3 and 5, respectively in *Figures 3* and *4*.

Transferring of chromosomal genes (nifH2 and nifH3) from A. chroococcum to transformant B. megaterium by conjugation process

Conjugation experiment was done between *A. chroococcum* as donor cells and transformant *B. megaterium* as recipient cells to investigate the transference ability of nitrogen fixation genes (*nif*H genes) which were *nif*H2 and *nif*H3 from isolated *A. chroococcum* to transformant *B. megaterium*. *A. chroococcum* was successful in conjugation technique with transformant *B. megaterium*, and (166) transformant-conjugant colonies were obtained on Sperber's agar plates containing ampicillin and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1400914024

erthymycine. In order to confirm the mobilization of nitrogen fixation genes (*nif*H2 and *nif*H3) from donor to recipient, a molecular study using PCR technique and gel electrophoresis was done for detecting these genes in each of *A. chroococcum, B. megaterium,* and transformant-*conjugant B. megaterium.*

PCR amplification of nifH2 and nifH3

After extraction and purification of genomic DNA from *A. chroococcum*, *B. megaterium* and transformant-conjugant *B. megaterium* using the PrestoTM Mini gDNA Bacteria Kit according to the manufacturer's protocol, PCR was performed for amplification of *nif*H2 and *nif*H3 via the use of specified oligonucleotide primers that flanked the DNA sequence to be amplified, and gel electrophoresis was carried out in order to check the presence of *nif*H2 and *nif*H3 in the chromosomal DNA of *A. chroococcum*, *B. megaterium,* and transformant-conjugant *B. megaterium*.

Results in *Figure 5* indicated that *A. chroococcum* and transformant-conjugant *B. megaterium* samples which contained *nif*H2-F and *nif*H2-R primers exhibit positive PCR products of *nif*H2 on the gel in lanes 2 and 4 respectively with (250 bp). Also the results in *Figure 6* indicated that the gel electrophoresis shows positive amplification of *nif*H3 (130 bp) in *A. chroococcum* and transformant-conjugant *B. megaterium* samples using *nif*H3 -F- and *nif*H3 -R- primers and they produced clear bands in lanes 2 and 4, respectively, while *B. megaterium* and negative control were shown negative PCR products in lanes 3 and 5, respectively and they did not produce bands in *Figures 5* and *6*.

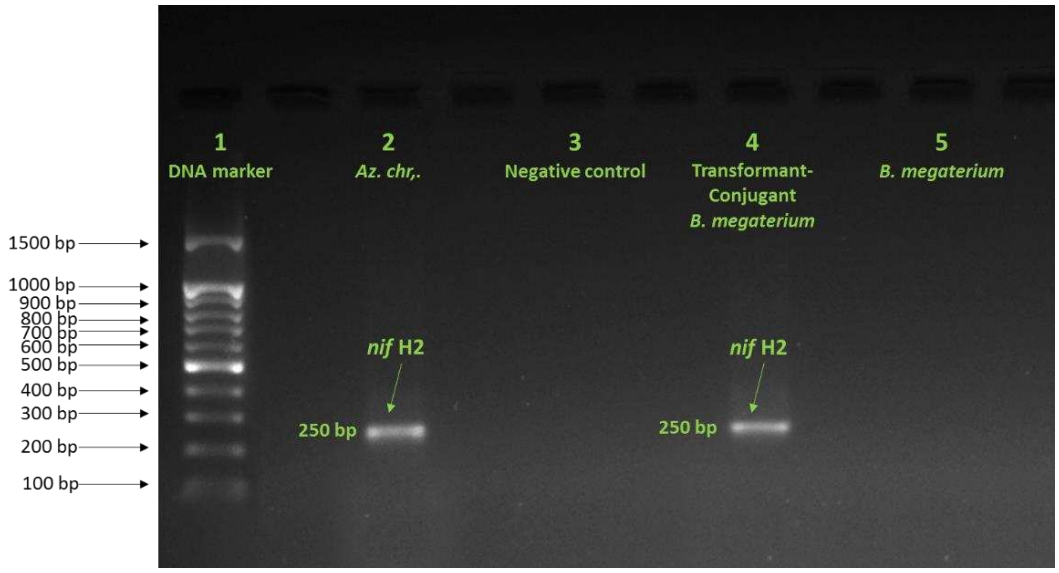

Figure 5. *Agarose gel electrophoresis shows the PCR amplified products of the nifH2 gene (250 bp). Lane 1: DNA marker, lane 2: A. chroococcum (+ve PCR product), lane 3: negative control (-ve PCR product), lane 4: transformant-conjugant B. megaterium (+ve PCR product) and lane5: B. megaterium (-ve PCR product)*

Discussion

This research work was carried out to find out the transference ability of *nod*D2 and *nod*D3 genes from *R. leguminosarium* by transformation technique, and *nif*H2 and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1400914024

*nif*H3 genes from *A. chroococcum* by conjugation process, to the *B. megaterium* in order to obtain a new model of *B. megaterium* which can then be used as a biofertilizer that provides available nitrogen and phosphorus for plants. *Nod*D genes act as a family of regulatory genes (Kidaj and Wielbo, 2010). The *nod* genes are controlled by *nod*D genes, *nod*D proteins act as transcriptional activators of inducible nod genes (Kumari and Sinha, 2011). *Nif*H acts as dinitrogenase reductase, obligate electron donor to dinitrogenase during dinitrogenase turn over and are required for FeMo-Co biosynthesis and apodinitrogenase maturation (Shamseldin, 2013). The region of chromosome which contain *nifK, nifD, nifM, nifA, nifN, nifB, nifQ, nifZ, nifP, nifF, nifW, nifB, nifL* and *nifY* genes are located between the fragment of chromosome which contains *nif*H1, *nif*H2, *nif*H3 and the fragment containing *nif*V, *nif*S and *nif*U (Hamilton et al., 2011). So the importance of the *nod*D genes which are located on the plasmid, and *nif*H genes which are located between fragments of chromosomal DNA, and their role in nitrogen fixation process gave importance to our choice of these genes for this study.

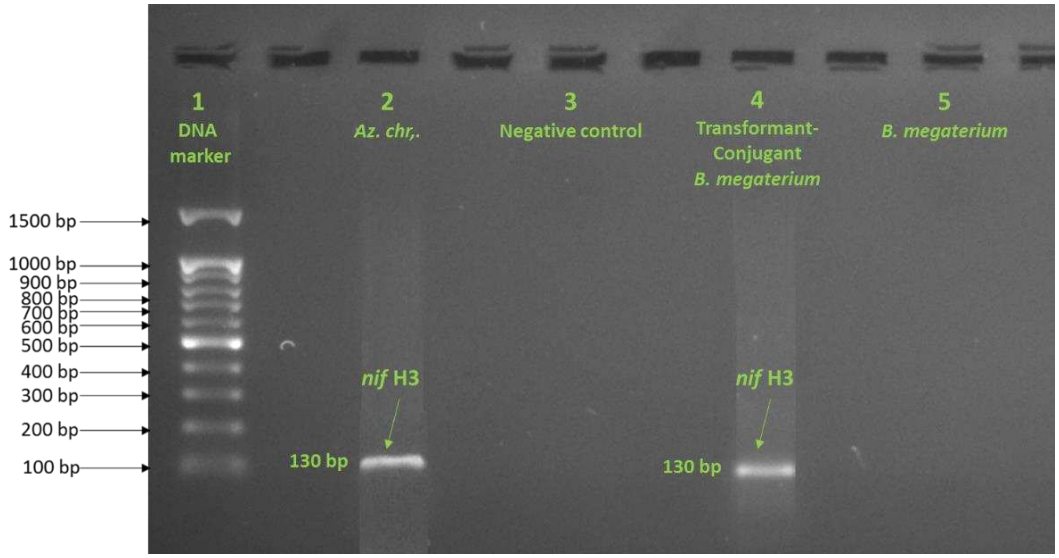

Figure 6. *Agarose gel electrophoresis shows the PCR amplified products of the nifH3 gene (130 bp). Lane 1: DNA marker, lane 2: A. chroococcum (+ve PCR product), lane 3: negative control (-ve PCR product), lane 4: transformant-conjugant B. megaterium (+ve PCR product) and lane5: B. megaterium (-ve PCR product)*

Firstly, *R. leguminosarium, A. chroococcum* and *B. megaterium* were isolated and identified by classical and molecular approach, classical approach included cultural, morphological and biochemical tests (the results did not show), while molecular characterizations of isolated bacteria based on the detection of genomic DNA of *B. megaterium* and *A. chroococcum* and the plasmid DNA of *R. leguminosarium*, have been successfully applied (*Fig. 1* lanes 2, 4, 6 respectively), and PCR technique and gel electrophoresis were carried out to detect and check the presence of *B. megaterium* by using two random primers 1 and 2. The banding patterns were intense, clear and reproducible which confirmed the existence of *B. megaterium* in the region (*Fig. 2*) lanes 2 and 3. Previous studies by Shiva et al. (2010) and Patil et al. (2013) indicated the presence of *B. megaterium* in a different area by these primers. Also the molecular study to identify *R. leguminosarium* was depended on the detection of the *nod*D2

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1400914024

*nod*D3 on the plasmid using specific complementary primers by PCR technique and gel electrophoresis, because nodulation genes (nod genes) are located on the plasmid which is also called mega plasmid. Kumari and Sinha, 2011; Giraud et al., 2007 indicated that the common nodulation genes (*nod* ABCD) are found in all bacteria that nodulate legumes, and Black et al. (2012) reported that all fourteen species of *Rhizobium* contained *nodD,* as well Rossen et al. (1985) showed and confirmed the presence of *nod*D in *R. leguminosarium*, and for the detection of the *nif*H2 and *nif*H3 in the *A. chroococcum* using specific complementary primers to amplify them, PCR and gel electrophoresis were carried out after extracting the genomic DNA of the *A. chroococcum*. Previous studies by Dashti (2011), Khider (2012), Abid (2013) and Mohamed (2017) proved the existence of different *nif* H genes in *A. chroococcum* in some regions of Kurdistan. Iraq.

The transformation technique was based on the extraction of the plasmid from *R. leguminosarium* and preparation of the competent cells from *B. megaterium* in order to transfer *nod*D2 and *nod*D3 genes from *R. leguminosarium* to *B. megaterium*, The process succeeded when 12 colonies were gotten on Sperber's agar plates containing tetracycline and ampicillin which were used as genetic markers, these transformant colonies may be due to transferring the plasmid DNA from *R. leguminosarium* to *B. megaterium*, to confirm that, PCR technique and gel electrophoresis were carried out to amplify and detect the presence of the *nod*D2 and *nod*D3 genes in each of *R. leguminosarium, B. megaterium* and transformant *B. megaterium* using specific complementary primers after extracting the plasmid DNA from them. The results presented in *Figures 3* and *4* showed positive PCR products of *nod*D2 with 100 bp and *nod*D3 with 150 bp for *R. leguminosarium* in lane 2 and transformant *B. megaterium* in lane 4, and negative PCR products for negative control in lane 3 and *B. megaterium* in lane 5 and they did not produce any bands, these results indicated that the plasmid transferred to transformant bacteria by transformation process. Mohamed (2017) also transferred *nod*C from *R. leguminosarium* to *B. megaterium* by the transformation technique and proved the success of the process between these two bacteria.

Based on these results, the conclusion is that the plasmid with all the *nod* genes (*nod*A, *nod*B, *nod*C *nod*D, *nod*E, nodF, *nod*G, *nod*I, *nod*M, *nod*P, and other *nod* genes) were transferred to the *B. megaterium* and all of them expressed and encoded for nitrogen fixation process in transformant cells, because all of them were located on the plasmid DNA. Plasmid transformation into bacterial competent cells is a key in molecular cloning technique (Tu et al., 2005). Plasmids are replicating circular pieces of DNA, they are smaller than the bacterial genome which encoded their transfer by replication into another bacterial strain or species. They can carry and transfer multiple resistance genes, which may be located on a section of DNA capable of transfer from one plasmid to another or to the genome-transposon or jumping gene (Snyder and Champness, 1997). Chemical transformation includes the usage of calcium chloride, this mode of transformation is easy to perform and requires a minimum number of equipment (www.himedialabs.com a). Because bacteria hosts are not readily convertible to transgenic cells, they need to be treated chemically with calcium chloride and physically with heat shock (Jones & Bartlett Learning, LLC., 2016). Cohen and his colleges in 1973 successfully transformed R-factor and recombinant plasmids into *E. coli* cells using a calcium chloride method, since that time this method has been widely used due to its convenience (Tu et al., 2005).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1400914024

The conjugation technique was based on the transfer of *nif*H2 and *nif*H3 genes from *A. chroococcum* which acted as donor cells to *B. megaterium* which acted as recipient cells. The process succeeded when 166 colonies were obtained on Sperber's agar plates containing ampicillin and erthymycine that were used as genetic markers. The growth of the transformant-conjugant colonies may be due to the formation of the conjugation bridge between the donor and recipient bacteria and transmission of ori T genes across this bridge (Snyder and Champness, 1997). To prove the completion of the conjugation process, PCR technique and gel electrophoresis were carried out to amplify and detect the presence of the *nif*H2 and *nif*H3 genes in each of *A. chroococcum, B. megaterium* and transformant-conjugant *B. megaterium* using specific complementary primers. The results in *Figures 5* and *6* showed positive PCR products of *nif*H2 with (250 bp) and *nif*H3 with (130 bp) for *A. chroococcum* in lane 2 and transformant-conjugant *B. megaterium* in lane 4, and negative PCR products for negative control in lane 3 and *B. megaterium* in lane 5 and they did not produce any bands. The conjugation technique of *nif* genes have been proved and reported previously by Davis et al. (2000) when they transferred many *nif* genes from *A. chroococcum* to *Klebsiella pneumonia* and they observed the expression of these genes in transconjugant bacteria, while Khider (2011) and Dashti (2011) transferred some chromosomal *nif* genes by conjugation from *A. chroococcum* to *Lactobacillus planetarium*, also Mohamed (2017) proved this process by transferring some chromosomal *nif* genes from *A. chroococcum* to *B. megaterium.* Many bacteria from different species frequently exchange their genetic materials by a conjugation process which occurs by cell-to-cell contact. This process has been extensively studied because of its significance in genetic manipulation studies (Fernandez-Lopez et al., 2005) as well as in horizontal gene transfer and the resulting spread of multiple antibiotic resistance and virulence.

Conclusion

As a result, the two techniques: transformation to transfer *nod*D2 and *nod*D3, and conjugation to transfer *nif*H2 and *nif*H3 to *Bacillus megaterium* cells were succeeded perfectly. The aim of the presented manuscript is to obtain a new bacteria containing beneficial genes besides its advantageous genes that can be used as an important biofertilizer to plants. Our recommendation is using a new *Bacillus megaterium* bacteria that received *nod* and *nif* genes as a biofertilizer for providing nitrogen by two methods and solubilized phosphorus for plant nutrition, and improving the quality and quantity of plants.

Acknowledgment. We wish to thank Assistant Professor Dr. Zaid Khalaf Khidhir and Professor Dr. Nawroz Abdul-razzak Tahir from the Faculty of the Agricultural Sciences University of Sulaimani for their cooperation.

(Received 26th May 2019; accepted 10th Sep 2019)

Abstract. This study was carried out to investigate the effect of some factors on birth weight (BW), weaning weight (WW), marketing weight (MW), average daily gain (ADG), daily milk yield (DMY), total milk yield (TMY), protein and fat percentage. A 135 ewes from three flocks used, 114 of them were lambed. The mean ± SE of BW, WW, MW, ADG, DMY, TMY, protein percentage and fat percentage were 4.14 ± 0.65, 16.37 ± 2.87, 23.60 ± 4.42, 0.12 ± 0.02, 0.236 ± 0.10, 34.07 ± 5.94 kg, and 5.33 ± 0.62% and 5.30 ± 12.93%, respectively. All studied traits were significantly ($P \leq 0.05$) affected by flock except BW, protein and fat percentages. Month of lambing had significant effects ($P \leq 0.05$) on MW, ADG and Post daily gain. Stage of lactation had a significant effect ($P \leq 0.05$) on daily milk yield and protein percentage. The lowest and highest BLUP values for BW, WW, MW, ADG, DMY, TMY, protein and fat percentages were -1.6411, 1.6889kg, -6.5307, 10.1293kg, -9.9775, 13.1725 kg, -10.5293, 10.7504 kg, -31.02, 7.38kg, -2.0546, 2.0097%, -1.703, 1.40% respectively. These results indicated that there are high genetic variations among animals for all above studied traits. It means that selection can play a big role in improving economical traits.
Keywords: *Birth Weight, Weaning Weight, Marketing Weight, Milk Yield, BLUP, Fat %, Protein %*

Introduction

Small ruminants (sheep and goat) are important investments in Iraq. They play a major role in strengthening the backbone of the rural economy. The Karadi sheep which comprises about 18-20% of the total sheep population to the northeastern mountain, villages and undulating dry-farming plain of Kurdistan region of Iraq (Alkass and Juma, 2005). Sheep and goat population in Kurdistan region had been estimated to be around 3,500,000 (Ahmad, 2011). Productivity of this breed is low due to the fact that animals are naturally selected for survival under suboptimal environments. Assessment of the amount of milk produced by ewes provides information for the implementation of optimum management and feeding strategies for female sheep and their lambs (Cardellino and Benson, 2002).

Many studies analyzing the factors affecting ewes' growth performance, milk yield and milk composition were reported (Al-Barzinji and Hassan, 2005; Antonič *et al.,* 2013). The main factors were flock (Meraï *et al.,* 2014; Everett-Hincks, *et al.,* 2014; Rahimi *et al.,* 2014), ewes age (Ramakrishanappa *et al.,* 2015; Sezenler *et al.,* 2016; Siddalingamurthy *et al.,* 2017), sex of lamb (Al-Samarai *et al.,* 2016; Al-Bial *et al.*, 2016; Malik *et al.,* 2016), month of lambing (Al-Samarai *et al.,* 2016; Malik *et al.,*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1402514038

2016). The effect of stage of lactation on milk yield and composition were also reported by (Kuchtik *et al.,* 2008; Komprej *et al.,* 2012).

In order to devise effective breeding plans for genetic improvement of Karadi ewes, information on the extent of genetic and environmental factors on performance traits is the pre-requisite. Therefore, this study was planned to generate information on the relative importance of genetic and environmental factors on the growth and milk traits of Karadi ewes in addition to estimating the Best Linear Unbiased Prediction (BLUP) for some growth and milk traits.

Materials and methods

The data were obtained from Karadi ewes in three private flocks (*Fig. 1*) at different location, Arbat District (Latitude, 35° 25' 14", Longitude, 45° 03' 36", W, elevation 681 m), Sharazoor District (Latitude, 35° 15' 27", Longitude, 45° 42' 21", W, elevation 614 m) and Mawat District (Latitude, 35° 52' 34", 45° 24' 35", W, elevation 858 m) around Sulamania governorate in Kurdistan Region of Iraq (*Fig. 2*). All animals were apparently healthy and were fed on pasture under open field conditions. In this study, 114 ewes were utilized. At lambing ewes and lambs were identified with spray in addition to the plastic tags with numbers. Lambing date, birth weight, sex of lambs, and other relevant information were recorded. Body weights of lambs at birth and at age of 90 (Weaning weight) and 150 (Marketing weight) days, were also recorded. Milk yield was recorded monthly starting from the second week of lambing until the 150 days (less than 50 gm milk/ewe/day) post partum using lamb-suckling technique plus hand milking (Mousa and Shetawi, 1994). Lambs were separated from dams at 7.00 pm on the day before measuring test milk production. In the following day, lambs were weighed at 7.00 am., and left to suckle their dams until satisfaction, then reweighed and kept away from their mothers, while the residual milk in the udder of each ewe were hand milked and weighted, and the amount of milk was recorded and then multiplied by 2 to calculate the daily milk yield, which multiplied by 30 then summed to calculate the total milk yield (ICARDA and FAO, 1995). Protein% and fat% of milk were estimated from the milk sample monthly using Milkoscan TM minor machine (P/N 6004 4208, Issue 1 GB, March 2010, FOSS Analytical, 69, Slangerupgade, DK 3400 Hillerod, Denmark).

The PROC GLM (General Linear Model) procedure in SAS programs (2010) was used to analyze the data for weights at different ages, average daily gain as well as milk yield traits. Fixed effects studies were: parity, sex of lamb, the month of birth, and age at weaning were fitted in the following model (1) and (2):

Model I for weight traits

$$Y_{ijklm} = \mu + V_i + N_j + O_k + H_l + E_{ijklm} \quad \text{(Eq.1)}$$

where Yijklm = Weights of lambs at different ages and average daily gain (ADG) of individual lambs; μ = Over all mean; Vi = Fixed effect of flock (i = 1,2,3); Nj = Fixed effect of age of dam (j = 1,2,3,4,5); Ok = Fixed effect of sex of lams (k = male, female); Hl = Fixed effect of month of lambing (l = November, December, January and February); Eijklm = Random/error effect.

Figure 1. *Sheep photo with flocks*

Figure 2. *Study locations*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1402514038

Model II for milk traits

$$Y_{ijklmn} = \mu + Vi + Nj + Ok + Hl + Zm + E_{ijklmn} \quad \text{(Eq.2)}$$

The notation of the second model is similar to the first model except Zm = Fixed effect of stage of lactation (m = 1, 2, 3, 4, 5).

Tukey tests used to compare between means for all traits under study because its suitable test to comparing least square means with this program. For genetics evaluation of ewes for various performance traits, Best Linear Unbiased Prediction (BLUP) procedure described by (SAS, 2010) was applied. The model used for this purpose was the Mixed Model (fixed + random effects) of (SAS, 2010) software.

Results

Growth traits of Karadi lambs

Least square means ± SE of BW, WW, MW, ADG, pre-weaning and post weaning daily gain of the Karadi lambs are presented in *Table 1*. The overall means of BW, WW, MW, ADG pre-weaning and post weaning daily gain were 4.14 ± 0.65 kg, 16.37 ± 2.87 kg, 23.60 ± 4.42 kg and 0.12 ± 0.02 kg, 0.13 ± 0.02 kg and 0.12 ± 0.04 kg, respectively.

Milk traits of Karadi ewes

The least square means ± SE of to identify the effect of fixed effects on the observed milk production performance recorded such as daily milk yield, total milk yield, protein% and fat% are given in *Table 2*. The overall means were 0.236 ± 0.10 kg/day, 34.07 ± 5.94 kg/day, 5.33 ± 0.62% and 5.30 ± 12.93% for DMY, TMY, protein% and fat% respectively.

The BLUP values of ewes for some studied traits are shown in *Table 3*. The lowest BLUP values for BW, WW, MW, DMY, TMY, protein% and fat% were -1.641, -6.530, -9.977, -10.52, -2.054, -34.20 and -1.703 kg respectively. The corresponding values of highest BLUP values were 1.688, 10.12, 13.17, 10.75, 2.009, 7.380 and 1.406 kg.

Discussion

Growth traits of Karadi lambs

The mean of the BW (4.14 ± 0.65 kg) in current study was moderately high and the birth weight have significant effect on other last weights, for that the increase this trait is very importance in sheep breeding. This result was agreement with other studies reported earlier by several investigators in different breeds of sheep (Hussain *et al*., 2006; Jawasreh and Khasawneh, 2007). Also the mean of WW/lamb (16.37 ± 2.87 kg) and MW/Lamb (23.60 ± 4.42 kg) were moderately high and marketing weigh determines the outcome of sheep breeders, for that increases these traits necessary in sheep breeding. The effects of flock on WW, MW, ADG pre-weaning and post weaning were significant ($P \leq 0.05$). The significant differences in weaning weight due to flock was in agreement with results obtained by Baneh *et al*. (2010), Tariq *et al*. (2011), Everett-Hincks *et al*. (2014) and Rahimi *et al*. (2014). The significant differences due to flock on ADG and pre-weaning daily gain were in agreement with resulted reported earlier by Baneh and Hafezian (2009) and Tariq *et al*. (2013). Flock can have a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1402514038

significant effect on body weight at different ages and average daily gain and could be attributed mainly to differences in management and environmental conditions. This results show the good management and conditions have significant effect on lambs weight traits, because these type of trait classified as a quantification trait which controlled by each genotypic and environmental effect with interaction between them.

The ewe age seems to have no significant effect on all lambs body weight such effect of ewe age on lambs birth and weaning weight are in agreement with some earlier studies (Al-Barzinji, 2003; Jalil-Sarghale *et al*., 2014; Al-Bial *et al*., 2016). Similar results of pre-weaning daily gain in different breeds have been noticed by other (Khalaf *et al*., 2010; Gokdal, *et al*., 2006). Non significant effect of post-weaning gain due to the age found under the present study was disagreement with that reported by (Baneh and Hafezian, 2009; Marufa *et al*., 2017).

Male lambs were statistically heavier than females at birth, although, this difference was statistically no significant for other growth traits (*Table 1*). Similarly, many authors claimed that sex of lamb had no effect on birth and weaning weight of different breeds of sheep (Al-Bial *et al*., 2016; Siddalingamurthy *et al*., 2017). Moreover, the findings in this study for pre-weaning daily gain was also in agreement with those previously obtained by Gokdal *et al*. (2006) and Abbas *et al*. (2010). Likewise, daily weight gain after weaning stage by sex of lamb observed in the present study was in accordance with reported finding by Marufa *et al*. (2017). Although average daily gain was heavies for male than female lambs, differences between them lacked significance. Their averages were 0.15 ± 0.01 and 0.13 ± 0.00 kg, respectively.

The month of lambing also influences MW, ADG and post daily gain. Lambs born early in the lambing period (December and January) gained weight better than those born late (February) due to the accessibility to the pastures in spring season. Lambs born late will not be able to use pasture in spring because of their young age besides they may have higher exposure to internal parasites which thrive in the high temperature. Thus, their weaning and yearling weights will be lower than those lambed early (Elwakil *et al*., 2009). Heaviest lambs at birth and marketing weight were at December, whereas the lighter lamb's birth weight and marketing weight were at February. It is known that month of birth may cause variations in weight and performance of lambs due to climatic variations and/or management (Bathaei and Leroy, 1997). For weight at marketing age, lambs born at December and January were significantly ($p \leq 0.05$) heaviest than those lambs born at February. However, results of the present study were similar to those reported earlier claiming that month of lambing was not significantly affect birth weight in different breeds of sheep (Khalaf *et al*., 2010; Al-Bial *et al*., 2016) and weaning weight (Mohammed, 2008). The present results for pre-waning daily gain agreed with those reported by Abbas *et al*. (2010) who reported pre-weaning daily gain from birth to weaning did not significantly affected by month of lambing. The differences among different reports may be due to breed, size of the data set or method of estimation used in different studies, production system, climatic conditions and ecological zones, where sheep farming were practiced. The significant influences of environmental factors on body weight in the present study can be explained in part by differences in environment, feeding, grazing resources, male and female endocrine system, limited uterine space, and inadequate availability of nutrients during pregnancy, maternal effects and maternal ability of dam at different ages (Rashidi *et al*., 2008).

Means in the same column for each factor with different letters are significantly ($p \leq 0.05$) different from each other. NS: non significant

Milk traits of Karadi ewes

The least square means ± SE of to identify the effect of fixed effects on the observed milk production performance recorded such as daily milk yield, total milk yield, protein% and fat% are given in *Table 2*. The overall means were 0.236 ± 0.10 kg/day, 34.07 ± 5.94 kg/day, 5.33 ± 0.62% and 5.30 ± 12.93% for DMY, TMY, protein and fat respectively. The average of daily and total milk yield observed in this study were lower than the range reported earlier by several investigators in different breeds of sheep (Oramari, 2009; Abd Allah *et al*., 2011). However, protein and fat percentage were similar to other studies reported earlier by several investigators in different breeds of sheep (Bendelja *et al*., 2009; Abd El-Fatah and Awad, 2014).

Flock significantly ($P \leq 0.05$) affected milk production traits. Daily milk yield and total milk yield produced by ewes that were in the third flock was higher (0.312 ± 0.01 and 45.59 ± 2.05 kg) than those produced by ewes from first and second flock (0.220 ± 0.01, 0.211 ± 0.02 and 32.32 ± 1.24, 33.45 ± 3.40 kg) respectively. Many results are in agreement with the significance effect of flock on daily milk yield (Gardi, 2008; Pérez-Cabal *et al*., 2013). Moreover, similar significance effect of flock on total milk yield was also reported by (Pérez-Cabal *et al*., 2013; Meraï *et al*., 2014).

Means in the same column for each factor with different letters are significantly ($p \leq 0.05$) different from each other. NS: non significant

In the present work no significant effect of ewe's age on daily and total milk yield was found, There results were in agreement with those reported earlier by (Merkhan, 2014; Akreyi, 2015). Also, the effect of ewe's age on protein and fat% lacked significance. Such results were also reported earlier by (Abd Allah *et al*., 2011; Oramari and Hermiz, 2012). The effect of sex of lamb and month of lambing on the DMY, TMY, protein and fat% was no significance, these findings were in agreement with those reported on DMY and TMY by (Al-Samarai and Al-Anbari, 2009; Merkhan, 2014 and Akreyi, 2015). Also, an author found that month of lambing had no effect on daily milk yield and total milk yield (Abd-Al-Noor, 2011). Moreover, differences in protein and fat percentage studied in ewes lambed in the four months were not significant (*Table 2*). In an earlier study in Iraq, Gardi (2008) did not detect a significant effect of month of lambing on protein and fat% in milk of Karadi, Awassi and Hamdani ewes. Also, Martini *et al*. (2008) and Augusta *et al*. (2008) observed no remarkable monthly changes in protein%. Stage of lactation has significantly ($P \leq 0.05$) effected DMY and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1402514038

protein%. Similar results were also obtained by Pavic *et al*. (2002) and Kuchtik *et al*. (2008). While stages of lactation had no significant effect on fat%, which the lowest percentage (4.83) was obtained in the first stage of lactation and highest (7.62%) during the 3rd stage of lactation. This result was in agreement with results obtained by Sevi *et al*. (2006) and Oravcova *et al*. (2007).

As in *Tables 2* and *3* there are variance differences among fixed effect on all traits under studies, it means there are ability to make selection process among sheep to choices the best parents and mated them altogether to speed up the weight and milk traits in the next generation. To removed the effect of fixed factors mixed model was used to calculate the BLUP value which is one methods used to evaluation the animal upon his performances to obtained the realized value for each animals under study to ranking them according to his BLUP values for each trait to select the best one among all animals to speed up the production in next generation.

Table 3 shows the BLUP values for BW, WW, MW, DMY, TMY, protein% and fat%. The lowest and highest BLUP value was (-1.6411 and 1.6889 kg) for BW, (-6.5307 and 10.1293) for WW, (-9.9775 and 13.1725) for MW, (-10.5293 and 10.7405) for DMY, (-31.02 and 7.38) for TMY, (-2.0546 and 2.0097) for protein% and (-1.7033 and 1.4067) for fat%, respectively. The wide range between the BLUP values of ewes for some above traits indicated that selection of elite ewe will improve all these traits in the present sample. Hussain *et al*. (2006) reported that BLUP value for weaning weight ranged from -1.799 to 2.421 kg/ewe in Thalli sheep. Al-Barzinji (2009) reported that BLUP values for ewes ranged from -12.338 to 11.6023 kg for total weight of lambs weaned. In Hamdani sheep predicted BLUP value for daily milk yield from two flocks was reported by Al-Barzinji (2003), from two flocks. Values ranged from -155.56 to 214.58 gm and from -162.46 to 240.39 gm in the two flocks respectively. BLUP values for top 10% of the ewes to be selected as dam of ram lambs ranged between 102.87 to 214.58 gm and 187.63 to 240.39 gm in first and second flocks, while the values for culling 20% ranged from -155.56 to -66.50 gm and from -162.46 to -98.44 gm for first and second flock, respectively. Al-Rawi *et al*. (2002b) revealed that BLUP values for total milk yield ranged from -28.29 to 82.61 kg in Awassi sheep respectively. In Awassi sheep Abdulnoor (2004) reported that BLUP values for total milk yield for selecting 90, 80, 70, 60 and 50% of ewes were 1.98, 3.64, 5.07, 6.62 and 8.15 kg, respectively. Al-Barzinji (2009) reported that BLUP values for total milk yield in ewes ranged from -68.160 to 139.951 kg.

These results show that the breeder can select 10% from top BLUP value (Male) and 70% from top BLUP value (Female) and mate these parents altogether can speed up improvement of weight and milk traits among this population of sheep under study.

Conclusion

In conclusion, some of the fixed effects including the flock and the Month of lambing affect lamb's body weights significantly, as well as, it appears that flock had a significant influence on daily milk yield and total milk yield and stage of lactation affects test-day milk yield as well as protein percentage significantly. The wide range between the BLUP values of ewes for many growth and milk traits and this indicate that selecting ewes according to their records at early ages will improve their later performance. The recording of data in sheep breeding from breeder side is necessary because the availability of large data and information's on animal's gives better and accurate values for animal evaluation in selection process and breeder must select his animals upon the accurate and analyzed data which obtained from good managements.

Abstract. To determine the influence of different bulk densities and texture on soil water infiltration after remediation in gravel-mulched areas, we subjected two different soil types were to a battery of tests to determine their soil infiltration characteristics. The results show that the soil infiltration capacity decreases with increasing soil bulk density. A logarithmic negative correlation was identified between stable infiltration rate and the bulk density of the two soils ($R^2 > 95\%$). Moreover, the larger the bulk density, the smaller the cumulative infiltration, and there is a significant linear negative correlation between density and infiltration. The Kostiakov infiltration model better describes the infiltration process of the Lou soil at all stages and the infiltration of Yellow-brown soil before 40 min. Finally, as soil water is redistributed, and its content increases with soil depth, and the greater the bulk density, the greater the water storage capacity of the soil from 0 to 30 cm. Overall, the soil bulk density should be no less than 1.5 g/cm^3 when Lou soil is chosen to cover on gravel-mulched land, and not less than 1.4 g/cm^3 for Yellow-brown soil.
Keywords: *bulk density, infiltration model, infiltration rate, cumulative infiltration, soil moisture*

Introduction

Given the importance of land for development, the shortage of cultivable land resources is an important factor restricting social and economic construction in China. Bringing new land under cultivation is therefore of critical importance, and one type of reserved land that may be suitable for new cultivation are gravel-mulched areas, of which China has about 1.04×10^6 km^2. Such land is widely distributed, and often possesses good light and heat conditions, thereby conferring great potential for development (Yi et al., 2013). Development of gravel-mulched areas involves constructing a new soil layer by covering the existing gravel layer. However, the soil covering process is relatively expensive, and there is a lack of corresponding theoretical research on the desired texture, density, or structure of the source soil. This is a notable limitation, since ineffective soil coverage can result in poor soil cultivation and/or inefficient water usage (Zhang et al., 2017, 2018). In order to solve

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1403914052

this problem, it is necessary to further clarify the optimal bulk density of the overlying soil on the gravel-mulched areas.

Soil moisture is critical for simulating physical processes affecting soil such as surface runoff, soil erosion, and solute transport (Chen et al., 2007). Soil infiltration capacity is mainly determined by characteristics such as soil bulk density, texture and structure (Hillel, 1998; Tejedor et al., 2013). However, existing studies on the effect of bulk density on soil water infiltration focus on the differences between soil structures with single or different textures (She et al., 2012; Li Z. M. et al., 2009; Zeng et al., 2017; Sun et al., 2017). As basic physical properties of soil, changes in bulk density and pore condition cause changes in soil infiltration performance. Zeng et al. (2017) studied the effect of bulk density on water infiltration of red soil, and found that both the cumulative infiltration and infiltration rates decreased with increasing of soil bulk density. Li et al. (2009a) studied the relationship between soil water infiltration and bulk density in soils of different consistencies and reached a similar conclusion. This relationship is due to the fact that as soil bulk density increases, the aggregate structure of the soil is destroyed, decreasing porosity and making the soil tight and solid, reducing infiltration capacity (Kang et al., 2016; Wang et al., 2017). The studies about water movement in large porous media such as gravel focused on the effects of gravel cover and soil:rock ratio on soil water movement. For example, Mandal et al. (2005) and Cerdà (2001) studied water infiltration in gravel-covered soils from two sites, one in a tropical, semi-arid region of India and another in southeastern Sweden. They found that infiltration rate and humidification peak migration velocity increased with the increasing gravel cover. In addition, Zavala et al. (2010) studied the relationship between gravel coverage, runoff generation, and soil erosion in the Spanish Mediterranean coast. Novák et al. (2012) developed a simulation-based modelling approach to analyze soil water content and water transport at different soil depths, and identified the complexity of the gravel content as a major determinant of water flow. These results agreed with the findings of Zhou et al. (2009), who showed that when the gravel content is < 40%, infiltration rate and hydraulic conductivity decrease with increasing gravel content, although both increase with increasing gravel content when it is > 40%. Most research on the influence of gravel on soil infiltration focuses on the effect of mountain sand and/or gravel cover on water infiltration, or on moisture infiltration characteristics in mixtures of earth and stone.

However, when there is a large porous medium layer such as gravel in the lower part of the soil, a distinct layered interface is formed between the soil and gravel. Moreover, when the textures and bulk density structures of the overlying soil are different from the large-pore gravel layer, gas may be generated there. The ease of formation of water flow channels affects water movement, thereby affecting soil fertility and water retention even after gravel remediation.

Therefore, this study aimed to provide the influence of covering soil texture and bulk density on water infiltration and compare the infiltration process of two typical soils in gravel-mulched areas, which would be beneficial to determine the appropriate soil bulk density based on different soil texture in the grave-mulched land consolidation project. This information would provide a theoretical and technical basis for the development and remediation of gravel-mulched areas, and would thus facilitate to determine the reasonable bulk density of the covering soil.

Materials and methods

Test soil

Natural soil used in experiments was collected from Lou soil deposits in Fuping County, Guanzhong, Shaanxi Province, and from Yellow-brown soil deposits in Hanzhong City, southern Shaanxi. Soil samples were collected 30 cm below the surface to minimize contamination by organic matter content found in the plough layer. In the actual soil-covering process, the soil is often disturbed, to ensure the same initial conditions of the experiment. Collected soil was naturally air-dried, ground, and passed through a 2 mm sieve. The particle composition of each stage was determined using the sedimentation method. The results of these analyses are shown in *Table 1*.

Table 1. *Test soil particle composition*

Test soil type	Sand (2-0.05 mm)	Silt (0.05-0.002 mm)	Clay (<0.002 mm)	Soil texture
Lou soil	13.37%	77.10%	9.53	Silt loam
Yellow-brown soil	7.09%	65.19%	27.72	Silty clay loam

Test methods

Next, we performed water infiltration tests to compare characteristics of infiltration. The test device has two parts: a soil column and a water supply system (*Fig. 1*). The soil column is a transparent plexiglass column with a diameter of 10 cm and a height of 50 cm, 4 taking soil holes with a diameter of 1 cm are set each layer around the soil column, a total of 6 layers of soil taking holes are set to take soil for determination moisture after infiltration. The lower part of the plexiglass column contains a steel wire mesh that is highly permeable to water. The water supply (Mariotte Bottle) has the same specifications as the soil column device (i.e. a diameter of 10 cm and a height of 50 cm), the water depth is controlled at 4-5 cm. Each test soil sample was examined at four volumetric weight levels of 1.3 g/cm^3, 1.4 g/cm^3, 1.5 g/cm^3, and 1.6 g/cm^3. In order to simulate the gravel, the lower part of each test soil sample was filled with 1 cm diameter glass bead with the thick of 5 cm, a layer of gauze was placed between the glass beads and the soil layer to prevent soil particle migration. Before filling, the inner wall of the pipe was coated with Vaseline. Air-dried soil samples were weighed and hierarchically filled (5 cm/layer) according to the designed bulk density. The total height of the soil was 30 cm. A layer of filter paper was placed on the surface of the soil column to prevent the soil surface from being eroded. Infiltration measurements were made every 1-3 min at the beginning of the test, and every 5 min afterward until 100 min. After this point a measurement was recorded every 10-30 min. The test was performed for 300 min. After completion of the infiltration test, samples were taken every 5 cm under the surface of each soil column and the water content of each layer was determined. Samples were taken through the taking soil holes just after the 300 min had elapsed, as well as 1 d, 3 d, and 10 d after the experiment. To eliminate the confounding influence of temperature, the indoor temperature was maintained in a range from 22 to 24 °C. Each set of experiments was repeated 3 times. The regression was used to fit the measured results.

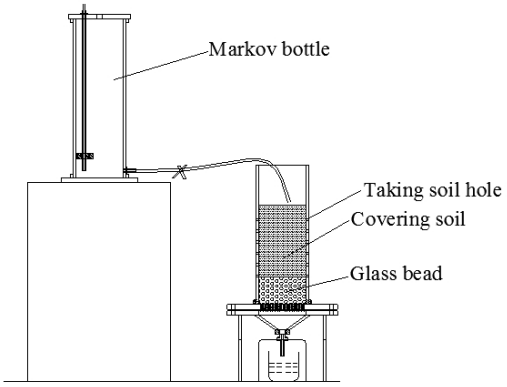

Figure 1. *Schematic diagram of test device*

Infiltration model

Kostiakov and Philip models were used to simulate the soil water infiltration process in gravel soil (Mehuys et al., 1975), and its applicability was evaluated. The Kostiakov model formula is:

$$I_t = K \cdot t^{1-\alpha} \quad \text{(Eq.1)}$$

Here, I_t is the cumulative infiltration amount at time t, cm; t is the infiltration time, min; K is the empirical infiltration coefficient, and its physical meaning is the cumulative amount of infiltration at the end of the first period after the infiltration began. It is also numerically equal to the average infiltration rate of the soil in the first unit period; α is the empirical infiltration index, which reflects the decay rate of the soil infiltration capacity. In the initial stage of infiltration, the parameter K plays a leading role. As the infiltration process continues, the parameter α becomes the main factor affecting the rate of infiltration.

The Philip model formula is:

$$I_t = S \cdot t^{0.5} + A \cdot t \quad \text{(Eq.2)}$$

Here, S is the infiltration rate in cm/min$^{0.5}$; A is the steady infiltration rate (usually less than the saturated hydraulic conductivity), also in cm/min.

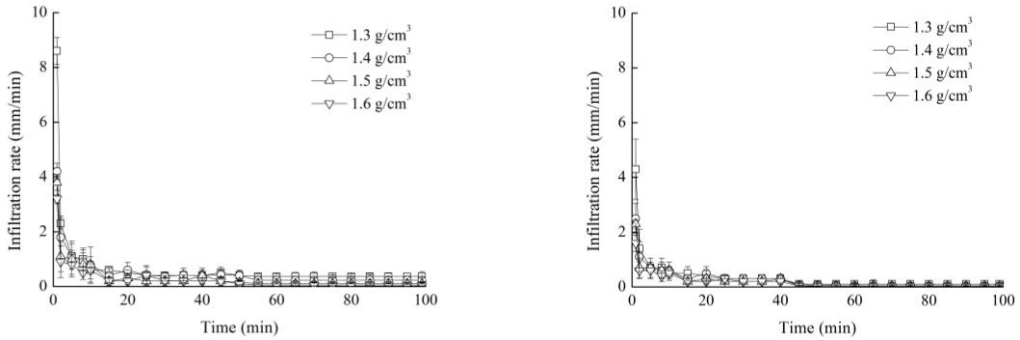
Results

The infiltration rate changes over time

The infiltration rate is defined as the amount of water permeating into a unit of soil per unit area through the surface. *Figure 2* reflects the infiltration rate of different soils of different weights in the gravel area over time. The variation of soil infiltration rate over time among soils of different textures and bulk densities shows a rapid decrease followed by stabilization. For the two texture soils, the infiltration rate showed a rapid decrease after 5 min of infiltration, mainly due to a decrease in the absolute value of the matric potential and the rapid decrease of the soil negative pressure. After 10 min of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1403914052

infiltration, the soil matric potential gradient begins to decrease slowly, finally approaching zero. The soil infiltration rate is generally stable, but the time required to reach stable infiltration of different soils with different textures differ. The Lou soil reached a stable infiltration state after 20 min, while the Yellow-brown soil gradually reached stable infiltration after 40 min. During the infiltration process of both soils, the larger the bulk density, the smaller the infiltration rate. The curve of the late infiltration is close to a horizontal straight line, indicating that the influence of soil bulk density on the infiltration rate decreases gradually over time.



(a) Lou soil (b) Yellow-brown soil

Figure 2. *Infiltration rate over time*

Taken together, our soil infiltration test data suggest that soil bulk density has a significant effect on the stable infiltration rate. The stable infiltration rate in turn characterizes the infiltration capacity of the soil infiltration stage. *Figure 3* shows the relationship between the soil bulk density and the stable infiltration rate of two different textures, and shows that the bulk density of Lou soil increased from 1.3 g/cm^3 to 1.6 g/cm^3, and the steady infiltration rate decreased from 0.365 mm/min to 0.051 mm/min. In contrast, the bulk density of Yellow-brown soil increased from 1.3 g/cm^3 to 1.6 g/cm^3, and the steady infiltration rate declined from 0.065 mm/min to 0.012 mm/min. At the same bulk density, the stable infiltration rate of Yellow-brown soil is less than that of Lou soil, and the decrease in the soil infiltration rate in Lou soil is greater than the corresponding decrease in Yellow-brown soil. We also found that the soil infiltration rate and bulk density showed a highly significant log-negative correlation (equation shown in *Fig. 3*). These results showed that the stable infiltration rate of cover soils above gravel was greatly affected by soil bulk density. The steady infiltration rates of the two types of test soils decreased with increasing bulk density. Moreover, both soils showed nearly linear logarithmic relationships. However, the shape of this linear relationship in Lou soil had a relatively steep slope, while Yellow-brown soil showed a relatively flat linear relationship.

Influence of soil bulk density on cumulative infiltration

The cumulative infiltration amount is defined as the total amount of water infiltrated into the soil through the surface per unit area. Analyses of cumulative infiltration in different soil types under different soil weights over 100 min is shown in *Figure 4*. These results show that the cumulative infiltration of soils with different bulk density increases over time. At the same time, the larger the bulk density, the smaller the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1403914052

cumulative infiltration. We found a significant linear negative correlation between permeability and bulk density ($R^2 > 0.95$), and the relationship between bulk density and cumulative infiltration is shown in *Figure 5*. In this figure we see that when the bulk density increased from 1.3 g/cm^3 to 1.6 g/cm^3, the cumulative infiltration decreased from 54.6 mm to 20.3 mm. Moreover, we also see that when the bulk density of Yellow-brown soil increased from 1.3 g/cm^3 to 1.6 g/cm^3, the cumulative infiltration decreased from 29.1 mm to 16.5 mm. The infiltration amount of the two soils was significantly different at 40 min. The process from the initial state to the final stable infiltration of Lou soil was relatively smooth, and the Yellow-brown soil showed an obvious turning after 40 min. This may be due to the differences in soil texture of the two soils.

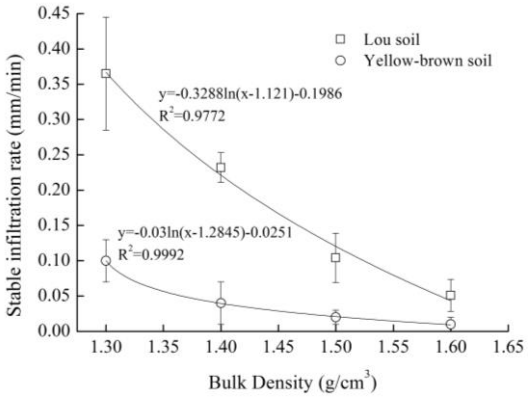


Figure 3. *The relationship between stable infiltration rate and soil bulk density*

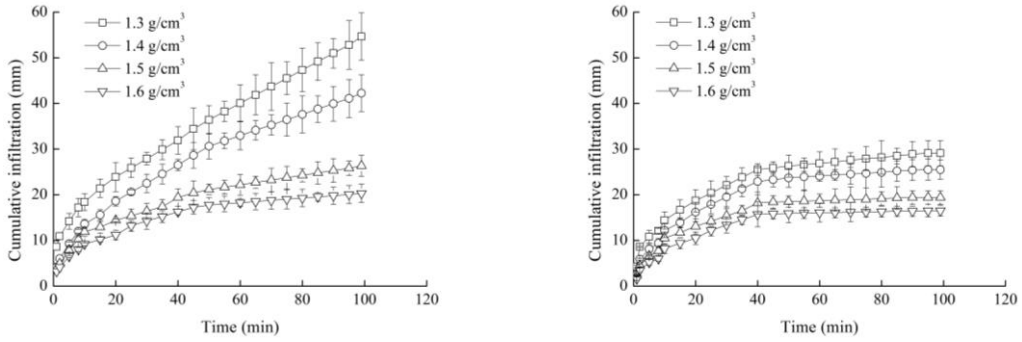

(a) Lou soil (b) Yellow-brown soil

Figure 4. *Cumulative infiltration over time*

Infiltration model for soils with different textures and bulk densities

To further study the influence of covering soil bulk density on soil water infiltration in gravel areas, we used Kostiakov (*Eq. 1*) and Philip models (*Eq. 2*) to simulate soil water infiltration in gravel soil. The results of these simulations for both Lou and Yellow-brown soils are shown in *Tables 2–4*. Lou soil can be better fitted with Kostiakov model. However, fitting of Yellow-brown soil revealed that the infiltration process slowed significantly after 40 min. Neither model simulated Yellow-brown soil well over then 100 min study period, so we then performed model segmentation: the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1403914052

Kostiakov and Philip models were used for the first 40 min, then another linear model was fitted after the turning. It can be seen from *Tables 2* and *3* that the Kostiakov model effectively simulates the results of the whole infiltration process of the Lou soil as well as the first 40 min of the Yellow-brown soil infiltration (i.e. $R^2 > 0.98$), while the overall simulation results of the Philip model are poor. Thus the Philip model has poor applicability when describing soil water infiltration processes the gravel cover soil. The infiltration process of the Yellow-brown soil after the first 40 min can be better described by a linear equation ($R^2 > 0.95$). Taken together, our data support the use of the Kostiakov model for further analysis of water infiltration in the two soils.

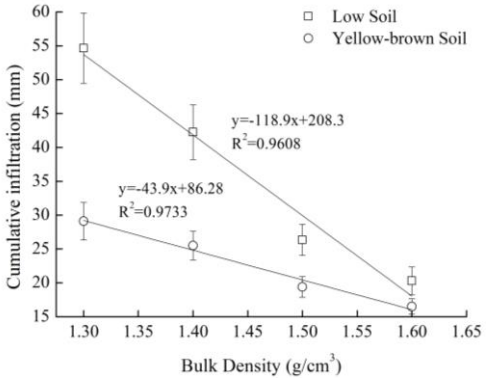

Figure 5. *The relationship between cumulative infiltration and bulk density of test soil*

The K value indicates the cumulative infiltration rate at the end of the first period after the start of soil infiltration—i.e. the initial infiltration rate, which is mainly affected by the soil structure. For samples of the same soil texture type, the main factors affecting the K value are the pore distribution characteristics of the soil, which are mainly determined by soil bulk density. In general, the larger the bulk density, the smaller the porosity and the denser the soil. It can be seen from *Tables 2* and *3* that as the bulk density increases, the K value decreases gradually. When the bulk density of Lou Soil increased from 1.3 g/cm^3 to 1.6 g/cm^3, the K value decreased from 5.776 to 3.953. In Yellow-brown soil the K value decreased from 5.387 to 2.168 in response to the same change, and the K values of the Yellow-brown soil was consistently lower than the K values of Lou soil. In the initial stage of water infiltration, the macropores in the surface soil are first filled with water by the action of the soil matric potential. This water is affected by the gravitational and the matric potentials, and eventually migrates deeper in the soil, given small bulk density and large pores. With increasing bulk density, the soil macropores decrease and the initial infiltration capacity decreases. Therefore, the K value generally decreases as volume density increases.

The empirical infiltration index α reflects the decay rate of the soil infiltration capacity. The larger the α value, the faster the infiltration capacity decays. *Tables 2* and *3* show that the Lou and Yellow-brown soils have opposite relationships between bulk density and the α value. Increasing the bulk density of Lou soil results in an increase in the α value—e.g. when the bulk density of Lou Soil increased from 1.3 g/cm^3 to 1.6 g/cm^3, the α value increased from 0.521 to 0.634. In contrast, increasing the bulk density of Yellow-brown soil resulting in a decrease in the α value—e.g. when the bulk density of Yellow-brown soil increased from 1.3 g/cm^3 to 1.6 g/cm^3, the α value decreased from 0.583 to 0.464. For Lou soil, the larger the bulk density of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1403914052

overburden, the faster the soil water infiltration capacity decays with time. Moreover, the smaller the bulk density of the soil, the slower the decay rate of soil water infiltration capacity with time, resulting in the accumulation of water. This results in a curve that becomes more horizontal as bulk density increases. A change in bulk density causes a large change in the α value, the smaller the soil bulk density and the larger the pores, the better the internal connectivity of the soil, which facilitates moisture penetration. Large pores also result in the discharge of air, thereby reducing the influence of air resistance on the infiltration process. Soil structures with larger bulk densities have less macroporous content, and the pores of such soils are enriched by infill of soil particles, thereby reducing internal connectivity. When soil moisture enters the pores, it often forms due to the surface tension of water. Smaller bubbles cause reduced gas discharge and increase the resistance to soil moisture infiltration. Gas resistance can cause a rapid decay in infiltration capacity. Therefore, the α value increases with increasing bulk density.

DOI: http://dx.doi.org/10.15666/aeer/1706_1403914052

Yellow-brown soil behaves differently—soil samples of the same texture will show large differences in α value from small changes in bulk density. The α value of Yellow-brown soil showed a slight decrease with increasing bulk density. This is mainly due to the relatively high content of clay in the soil and the low number of macropores present. The initial infiltration rate is small, and the larger the bulk density, the smaller the degree of attenuation of the infiltration velocity; therefore the relationship between the bulk density and the α value differs.

The K/α ratio reflects the whole infiltration process. On the whole, larger K/α ratios indicate stronger infiltration ability. In our data, we found that K/α decreased with increasing bulk density in both soils. At the same time, we also found that there was a significant inflection point in cumulative infiltration of Yellow-brown soil. The variation in cumulative infiltration over time after turning can be described linearly, and the linear slope decreases with increasing bulk density (*Table 4*).

Effect on soil water content and water storage capacity

The redistribution of soil moisture affects the distribution of water content in all layers of soil, and therefore directly affects the availability of soil moisture for plants (Liang et al., 2015). *Figures 6* and *7* show distribution curves of the water content of each layer of soil at the end of the infiltration test, as well as the degree of redistribution at 24 h, 72 h, and 240 h for different soil bulk densities of Lou and Yellow-brown soil. At the end of infiltration, both soils showed the same pattern: the greater the soil bulk density, the smaller the water content at the same soil layer height. This is likely due to greater soil bulk density resulting in weaker water holding capacity. At the bottom of the soil layer, due to the gravel having poor water holding capacity and strong permeability, the soil moisture in contact with the gravel layer moves downward, and the water content is the lowest. Water redistribution, under the joint action of matric and gravity potentials, involves soil moisture migrating to the vertical deep and dry soil. Moreover, we found that the soil bulk density became smaller as the redistribution period progressed. This is because as water migrates downward during redistribution, the gravity potential becomes more influential, causing the soil moisture content to increase with soil depth, thus decreasing bulk density. For instance, in our Yellow-brown soil trials the moisture content of the lower soil layer was low at all bulk density values, and the redistribution process was slower than it was in Lou soil.

Following water infiltration, changing soil water storage capacity varies in response to the redistribution of soil moisture among soil layers, as shown in *Figure 8*. The Bulk density of the soil covering the gravel has a significant effect on the water storage capacity of soil layers up to 30 cm below the surface. At early stages of water redistribution, the smaller the bulk density, the greater the water storage capacity. However, as time progresses, soil types with small bulk density have a high water capacity but lose water quickly. In contrast, soils with slower redistribution phases generally have better water retention. At a bulk density of 1.3 g/cm^3, water storage capacity of Lou soil decreased from an initial volume of 12.2 cm to a volume of 5.8 cm 10 d after infiltration. When the bulk density was 1.6 g/cm^3, the water storage capacity was 9.6 cm at initial infiltration, and was reduced by 17.7% (i.e. to 7.9 cm) after 10 d. This was different in Yellow-brown soil. At a bulk density of 1.3 g/cm^3, its water storage capacity declined from 11.8 cm to 6.4 cm (45.8%) over the same time period. Moreover, at a bulk density of 1.6 g/cm^3, the soil water storage declined from 11.0 cm to 9.7 cm, a reduction of only 11.8%.

Discussion

The infiltration rate reflects the infiltration performance of the soil. When the gravel is covered with soil, it is especially important to consider the soil infiltration performance of the resulting soil mixture. The bulk density structure, which strongly affects the water storage capacity and drainage capacity of the soil, can cause crops to be flooded when infiltration capacity is too low to discharge accumulated water quickly. However, if the infiltration capacity is too high, it is difficult to retain water in the soil. The effect of bulk density on water infiltration capacity is determined by the number of macropores present. According to Darcy's seepage law of unsaturated soil, the infiltration of soil moisture is determined by soil hydraulic conductivity and soil water potential gradient, while soil hydraulic conductivity is mainly determined by soil texture, bulk density, structure, moisture content, and matric potential (Wang et al., 2017). The initial stage of infiltration is mainly affected by the soil matric potential. Due to the low initial soil water content, the soil negative pressure is large and the matric potential gradient at the interface between the accumulated water and the soil column is also large, resulting in a higher initial infiltration rate. The infiltration process is gradually influenced by the gravity potential, and the infiltration rate decreases rapidly. Soil texture and bulk density affect the hydraulic conductivity of soil by affecting the size and distribution of soil pores, especially macropores and conductive pores.

In this study, we examined differences in soil moisture infiltration among different topsoil cover treatments for gravel-mulched areas. Our findings were similar to those of Kang et al. (2016), who confirmed that both the infiltration rate and cumulative infiltration decreased with increasing soil bulk density. The cumulative infiltration amount and its relationship over time is important to analyse the effect of rainfall and irrigation after soil covering in gravel-mulched areas. Soil bulk density had a great influence on cumulative infiltration during the infiltration process, and the cumulative infiltration was negatively correlated with soil bulk density. The infiltration capacity depends on the distribution of macropores in soil, because water migration channels in soil mainly depend on the presence of conductive pores and macropores (Fu et al., 2008). Soil bulk density is determined by the size and quantity of pores in the soil and the degree of soil compaction. The smaller the soil bulk density, the higher the pore content and the stronger the infiltration capacity and the moisture flux (Zhao et al., 2008). At the same time, we also found a negative linear correlation between the stable

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1403914052

infiltration rate and the logarithm of soil bulk density. This finding is consistent with those of Li et al. (2009b). Water infiltration into soil layers on a gravel base is well described by the widely-used Kostiakov model. However, we also found that the sticky soil texture of Yellow-brown soil has a turning point late in the process of infiltration, which agrees with the findings of Song et al. (2013) on their studies of water retention in water-repellent soils. Finally, we found that as infiltration progresses, the rate of infiltration rate changes slowly before stabilizing. Our results showed that after infiltration, the redistribution of soil moisture proceeded in a way similar to that described by Zeng. The major difference between the findings of that study and our results is that here the middle and lower soil layers were composed of gravel, and the loss of soil moisture at the end of the redistribution process was relatively small.

Conclusions

In this study, indoor simulated soil column tests were used to examine the relationship between soil traits and infiltration performance. We found that covering soil bulk density and texture strongly influenced infiltration and soil moisture levels present in different soil strata in gravel-mulched areas. We also note three key findings from this study.

First, when gravel is covered in soil, the importance of soil weight and textures is larger. This is because the soil porosity of the topsoil layer is smaller than the gravel underneath, reducing the connectivity between soil pores. This results in a lower infiltration rate. Moreover, the stable infiltration rate has a logarithmic negative correlation with soil bulk density. We also found that at the same bulk density, the stable infiltration rate of Yellow-brown soil is lower than that of Lou soil, and the decrease in the soil infiltration rate caused by the increase of bulk density in Lou soil was much greater than the corresponding increase in Yellow-brown soil.

Second, we found that the cumulative infiltration of soil at all bulk densities increases with time. At the same time, the larger the bulk density, the smaller the cumulative infiltration. After 100 min of infiltration, we found a significant linear negative correlation between the degree of infiltration and soil bulk density ($R^2 > 0.95$). Moreover, we used a Kostiakov model to characterize the first 100 min of infiltration in Lou soil and the first 40 min of infiltration in Yellow-brown soil. The Yellow-brown soil showed obvious turning after 40 min of infiltration, and the infiltration process can then be described by a linear equation.

Finally, at the initial moment of the end of infiltration, the soil moisture content of the bottommost layer of soil (30 cm below the surface) was small, even where the soil water content at other depths was close to saturation. Moreover, 10 days after the end of infiltration, the soil moisture of greater bulk density in the same soil layer is larger than it was of smaller bulk density. After infiltration, redistribution causes the soil water content to increase with increasing soil depth, although the redistribution process in Yellow-brown soil lags behind that of Lou soil. In the initial stage of soil water redistribution, smaller bulk density was linked to greater water storage capacity in the soil. As time progresses, soils with smaller bulk densities lose water faster.

Considering that the gravel-mulched land is used for crop planting after covering soils, the soil should stabilize and retain water, we suggest that the soil bulk density should be no less than 1.5 g/cm^3 when Lou soil was chosen to cover on gravel-mulched land, and not less than 1.4 g/cm^3 for Yellow-brown soil.

DOI: http://dx.doi.org/10.15666/aeer/1706_1403914052

In order to further clarify the law of water infiltration after covering soil in the gravel-mulched areas, the effect of gravel particle size on water infiltration and the migration of nutrients may be studied with undisturbed soil in future researches.

Abstract. The purpose of this study was to study the effects of salt natural geothermal water (SNGW) treatment on the physical, mechanical, shrinking and swelling properties of wood materials from two pine species. This study used the SNGW of Eynal, Çitgöl, and Naşa from Kutahya in Turkey on sapwood samples of black pine (*Pinus nigra* Arnold.) and Brutia pine (*Pinus brutia* Ten.). The absorption, retention, density, moisture content, modulus of rupture (MOR), modulus of elasticity in bending (MOE), compression strength parallel to the grain (CSPG), shrinking, and swelling values were measured for the treated and non-treated wood samples. The results showed that the absorption and retention values increased by depending on the concentrations of the dissolved salts in the SNGW used. In addition, the density and moisture content values of the SNGW-treated pine wood species were significantly higher than those of the untreated wood, whereas the values of MOR, MOE, CSPG, shrinking, and swelling were lower. In general, the Eynal treatment had the highest effect on pine species' wood properties, whereas the Naşa treatment had the least effect.
Keywords: *renewable, preservative, impregnation, ecofriendly, treatment*

Introduction

The idea of eliminating the environmentally harmful aspects of industrial processes has led researchers to develop not only new alternative resources but also new environmentally compatible wood preservatives. New alternatives alleviate some environmental problems caused by the wood preservative industry. Hence, natural resources have been used and preferred for worldwide application to limit and control pollution (Bozkurt et al., 1993). SNGW can be considered as an environmentally safe sustainable natural resource for wood preservatives. In recent years, research into wood preservatives has led to the development of several new methods that are able to produce pine wood with properties near those treated by conventional methods. The use of SNGW in the impregnation processes is a new idea and could be a useful approach.

It is well-known that geothermal waters naturally contain high amounts of dissolved chemicals, including various mineral salts; and this resource is valuable for different areas, such as heating, livestock farms, drying of organic materials, recreation, and health tourism, all of which depend on the water temperature and the chemicals contained in the water. In this regard, the use of geothermal waters has expanded appreciably from agriculture, livestock, and medical applications (Ilgar, 2005).

Moreover, wood impregnation with preservatives is a process that often uses synthetic and toxic chemicals that are not environmentally compatible. New

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1405314068

environmentally safe chemicals are needed to preserve the wood that is used for indoor and outdoor applications. Due to their high levels of dissolved mineral salts, geothermal waters have potential as wood preservatives, in which this resource may resolve some environmental issues facing the wood preservative industry. For this reason, these salt natural waters should be studied as a wood preservative agent.

To date, much research has been conducted on the physical, mechanical, shrinking and swelling properties of various impregnated wood species. Examples of these species are European beech, pine, spruce, Scots pine, yellow poplar, and red oak treated with waterborne preservatives such as chromated copper arsenate (CCA), ammoniacal copper arsenate (ACA), ammoniacal copper zinc arsenate (ACZA), and alkaline copper quaternary (ACQ) compounds (Winandy, 1995); pine treated with linseed oil (Megnis et al., 2002); yellow pine treated with CCA, ACQ-1900, ACQ-2200, Tanalith-E 3491, and Wolmanit CX-8 (Yildiz et al., 2004); oriental beech, oak, Scots pine, oriental spruce, and Uludag fir treated with Imersol-Aqua (Ors et al., 2005); pine and American beech treated with copper chloride, sodium borate, and phenol-formaldehyde resin-pyrolytic oil (Mourant et al., 2007); jack pine and sugar maple treated with copper chloride, copper chloride-sodium borate mixture, and phenol formaldehyde-pyrolytic oil resins (Mourant et al., 2008); beech and pine treated with aqueous solution of borates (Simsek et al., 2010); rowan treated with Tanalith-E, Vacsol Azure, Imersol-Aqua, borax, and boric acid (Keskin et al., 2013); fir treated with citric acid (Ville et al., 2014); oriental beech treated with Turkish sweetgum balsam as an aromatic resinous wood preservative (Degirmentepe et al., 2015); and beech, walnut, poplar, ash, and pine treated with Tanalith-E (Keskin and Daglioglu, 2016); shrinking and swelling minimization of wood treated with the synthetic resin-forming materials (Stamm and Seborg, 1936); beech wood impregnated with NH_3 (Bariska, 1975); Corsican pine wood treated with ammonia (Coles and Walker, 1978); swelling of wood in liquid ammonia (Stamm, 1955). Some of the wood preservatives mentioned above are now prohibited in several countries, and are being used less frequently in other countries due to their negative impacts to the environment. Currently, new research is being conducted to develop new impregnation agents for wood preservation.

In contrast, the economic use of SNGW could only be possible by evaluating the dissolved chemicals in those waters, including various minerals. However, there are few studies that evaluate geothermal water properties. Var (2009) discussed whether geothermal waters could potentially be used for wood preservation. Another study reported results that included absorption, retention, and swelling values of Brutia pine treated with geothermal waters from Izmir, Turkey (Var et al., 2013). A third study examined the effects of condensed geothermal waters from Aydin, Turkey on wood properties (Yaldiz and Var, 2017). In these investigations, which study the wood treated with geothermal waters, a definite result was not obtained regarding the wood's physical and mechanical properties. The potential wood impregnants content in geothermal waters was observed, as well as some properties such as absorption, retention, and swelling of wood treated with such natural saltwater. Also, this observation showed that more than half of the naturally dissolved minerals contained in the SNGW could be used as potential wood preservative in the wood preservation formulations; the absorption and retention properties of treated wood had increased due to the concentration of naturally dissolved salts in the SNGW; the swelling properties of treated wood decreased compared to the untreated control wood. However, it has been noted that there are few studies that have reported the physical, mechanical, shrinking

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1405314068

and swelling properties of wood that was impregnated with preservatives. For instance, Var et al. (2017) only examined the modulus of elasticity and compressive strength of wood impregnated with hot geothermal waters. Sen et al. (2017) only reported some of the mechanical properties of wood treated with geothermal and mineral waters.

It should be realized that geothermal waters contain diverse mineral salts at various concentrations. These natural resources could be useful as waterborne wood impregnation agents for wood preservation (Var, 2009). It is known that waterborne wood impregnation agents affect the mechanical properties of wood. These effects can be related to many factors, such as types of dissolved mineral salts within the natural water, types of woods treated, sizes and grades of woods being treated, and environmental conditions of wood exposure; other influencing factors include the type of preservative used and its retention. However, the effects of SNGW on wood properties have not been reported. Such studies are needed to determine if SNGW have certain effects on the properties of wood.

In this paper, the goal is to investigate the effects of treatment with various SNGW on the physical, mechanical, shrinking and swelling properties of various pine wood species. The SNGW contain various inorganic ions such as chloride, sodium, calcium, sulfate, potassium, magnesium, silicate, fluoride, boron, ammonia, and borate. These inorganics are used as water-based wood preservatives added to wood preservative formulations (Var, 2009). When pine wood materials are treated with SNGW, such dissolved ions can affix to the cell walls, lumens, and intercellular spaces, or react with wood constituents, to result in precipitates within the wood structure. In contrast, it is still challenging to find natural and environmentally compatible processes for wood protection. Hence, the determination of effects on such properties of pine wood of the natural saltwaters can be useful as an environmentally friendly wood preservative. In this sense, the use of SNGW in the wood protection systems can also reduce the environmental problems related to the health and ecology when compared to other conventional wood preservatives.

Materials and methods

Materials

Preparation of wood specimens

Two different pine wood species, black pine (*Pinus nigra* Arnold.) and Brutia pine (*Pinus brutia* Ten.), were collected from a natural forest located in Isparta, Turkey. The specimens were obtained from air-dried sapwood portions in the radial direction in accordance to ISO 3129 (2012) standard. Clear and defect-free specimens were prepared with the following dimensions: 30 mm radial (R) × 30 mm tangential (T) × 15 mm longitudinal (L) for the absorption and retention tests; 20 mm R × 20 mm T × 30 mm L for the density, moisture content, shrinking and swelling tests; 20 mm R × 20 mm T × 300 mm L for the modulus of rupture (MOR) and modulus of elasticity in bending (MOE) tests; and 20 mm R × 20 mm T × 100 mm L for the compression strength parallel to grain (CSPG) tests. Prior to wood impregnation treatments, 15 samples for each test were placed in a conditioning cabinet, and held at a relative humidity of 65% ± 3% and temperature of 20 °C ± 2 °C until a stable mass was obtained in accordance to the ISO 13061-1 (2014) standard. To avoid potential

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1405314068

fluctuations in the moisture content, the samples were placed into plastic bags and stored until the treatments were conducted.

Preparation of SNGW

SNGW was obtained from the Eynal (E-6), Çitgöl (C-1), and Naşa (N-1) geothermal fields of Kutahya, Turkey (*Table 1; Fig. 1*). These waters were refrigerated at 23 °C ± 2 °C in 20-L containers. The SNGW was used without filtration and sterilization in the wood impregnation processes. The chemical compositions of SNGW, their concentrations, and their dosage levels have been described in Var et al. (2015). This study reported that SNGW contained boron, sodium, potassium, calcium, magnesium, arsenic, chlorine, fluorine, aluminum, silicon dioxide, sulfate, and ammonia. Also, the study determined that the highest concentration (1930.47 mg/L) was for the E-6 geothermal, and the lowest concentration (1421.56 mg/L) was for the N-1 geothermal.

Table 1. *The GPS coordinates of the survey localities from Turkey's Kutahya province*

Survey localities	GPS coordinates
Eynal	39.126875, 28.995479
Çitgöl	39.132907, 28.967043
Naşa	39.143784, 28.961431

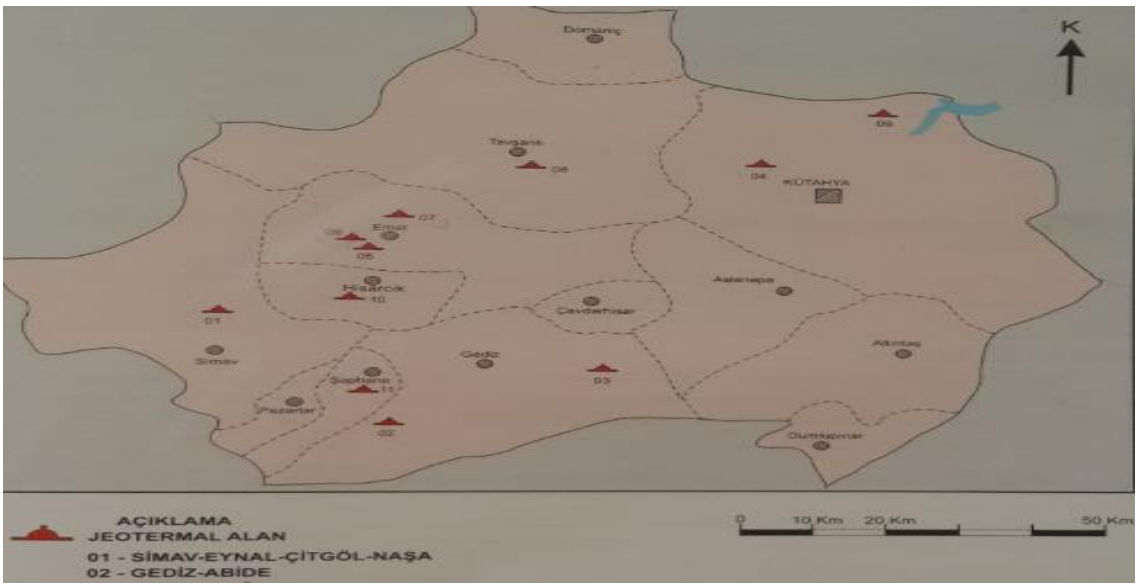

Figure 1. *Geothermal area map of the survey localities in Kutahya, Turkey (Akkuş et al., 2005)*

Methods

Treatment process

The treatment process was performed at room temperature in the laboratory. Wood samples were treated with one of the three SNGW in accordance to the ASTM D1413–07e1 (2007) standard. A dipping treatment was used for the wood impregnation process.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1405314068

The samples were immersed in the selected SNGW for 24 h. After the treatment, the excess SNGW was wiped off the surfaces of the sample. The treated specimens were immediately weighed to determine the gross SNGW uptake; afterwards, the specimens were then conditioned at 20 °C ± 2 °C and 60% ± 3% relative humidity prior to physical, mechanical, swelling, and shrinking testing in accordance to ISO 13061-1 (2014).

Measurement of physical properties

The physical properties of the wood samples were determined in accordance to the following international laboratory standards: ASTM D1413-07e1 (2007) for absorption and retention values, ISO 13061-2 (2014), for density measurement, and ISO 13061-1 (2014) for moisture content measurement.

Measurement of mechanical properties

The mechanical properties of the wood samples were determined in accordance to the following international laboratory standards: ISO 13061-3 (2014) for modulus of rupture in bending (MOR), ISO 13061-4 (2014) for modulus of elasticity in bending (MOE), and ISO 13061-17 (2017) for compression strength parallel to the grain (CSPG). Mechanical tests were performed with a 4000 kp universal testing machine (Marestek, Istanbul, Turkey) using a constant 6 $mm \cdot min^{-1}$ crosshead speed.

Measurement of shrinking and swelling properties

The shrinking and swelling properties for the wood samples were determined accordance to the following international laboratory standards: ISO 4469 (1981) for radial and tangential shrinking, ISO 4858 (1982) for volumetric shrinking, ISO 4859 (1982) for radial and tangential swelling, ISO 4860 (1982) for volumetric swelling, and Kantay (1978) and Bozkurt et al. (1993) for anisotropic shrinking and swelling.

Statistical analysis of data

The data collected from the experimental measurements were analyzed using an analysis of variance (ANOVA) at a 95% significance level ($p \leq 0.05$); statistical comparisons among the groups were made using the Duncan test. A computerized program, SPSS 20 Statistics (IBM Corp., New York, NY, USA), was used for the analyses. Statistical evaluations *via* the Duncan test were made using homogeneity groups, in which different letters reflected significant differences among the groups.

Results and discussion

Physical properties

Table 2 shows the physical data for absorption, retention, density, and moisture content tests for both pine species treated with salt natural geothermal waters. It appeared that the SNGW had a clear effect on these physical properties. The E-6 treatment yielded the highest measured physical values for both wood species. For black pine, the highest absorption (2.06 g), retention (0.60 kg/m^3), density (0.56 g/cm^3), and moisture content (9.89%) values were obtained. Likewise, for Brutia pine, the highest values for absorption of 2.41 g, retention of 0.72 kg/m^3, density of 0.59 g/cm^3, and

DOI: http://dx.doi.org/10.15666/aeer/1706_1405314068

moisture content of 10.57% were observed for the E-6 treatment. Furthermore, the N-1 treatment yielded the lowest measured physical values of 1.82 g (absorption), 0.48 kg/m^3 (retention), 0.53 g/cm^3 (density), and 9.44% (moisture content) for black pine, and 2.15 g (absorption), 0.52 kg/m^3(retention), 0.58 g/cm^3 (density), and 9.93% (moisture content) for Brutia pine.

Table 2. *Physical properties of pine wood species treated with SNGW*

Wood species	Geothermal water	Absorption (g)	Retention (kg/m^3)	Density (g/cm^3)	Moisture (%)
Black pine	Control*	-	-	0.52 (0.05) e	9.11 (0.70) h
	N-1	1.82 (0.22**) a	0.48 (0.04) c	0.53 (0.04) ef	9.44 (0.83) h
	C-1	1.96 (0.16) ab	0.56 (0.12) d	0.55 (0.04) ef	9.75 (0.79) i

*Untreated. **Values in parentheses are the standard deviation; the same letters in each column indicate no statistical difference at the 95% confidence level among treatments

There were no significant differences found between the N-1 and C-1 treatments in the amount of absorption for both wood species, whereas there was a significant difference between E-6 and N-1 (*Table 2*). With regards to retention, there were considerable differences among the SNGW. There was no remarkable difference in density among the control, N-1, and C-1 treatments for black pine, whereas there was a noticeable difference between the E-6 and control. Moreover, there was no substantial difference among the three SNGW used to treat the Brutia pine. With regards to moisture content, there was no significant difference between the control, N-1, and C-1 treatments versus the E-6 treatment for black pine, while there was a significant difference among the E-6, N-1, and control treatments. For Brutia pine, there was no considerable difference between the N-1 versus C-1, and E-6 versus C-1, but there was a remarkable difference among the E-6, control, and N-1 treatments.

Based on these results, it was deduced that SNGW with higher concentrations of dissolved inorganics resulted in higher values of measured physical properties. Hence, the values measured for absorption, retention, density, and moisture content of the treated wood increased depending on which SNGW was used, and the concentration of dissolved salt species the SNGW contained. Such increases in physical properties were attributed to the dissolved salts in the SNGW affixing to the walls and lumens of the wood fibers, which increased the mass, as well as the volume (by swelling) of the wood. In the treatment with chemical preservative solutions it has been reported that chemical substances attached to the cell walls and lumens, resulting in an increase in mass and volume of the treated wood (Ozciftci and Batan, 2009). Ammoniacal-based waterborne wood preservatives are commonly used for wood protection (Yildiz et al., 2004). Ammonia can react with lignin and hemicelluloses of the wood cell wall (Ostmeyer, 1987; Winandy, 1995) to cause the wood to swell, and thereby increase the penetration of chemicals within its structure (Megnis et al., 2002). However, the absorption increase could also have been attributed to the expansion of lumens within the wood fibers,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1405314068

which absorb the SNGW into the wood structure (Ors and Keskin, 2001). The retention increase could result from affixation or precipitate of the wood preservatives to the cell walls, lumens, and intercellular spaces due to passage pairs performing the liquid flow within the wood structure (Ozciftci and Batan, 2009). Several investigations have stated that chemical treatments with different water-soluble preservatives, such as copper chrome boron (CCB) (Peker et al., 1999), CCA (Temiz et al., 2004; Sreeja and Edwin, 2013; Gezer and Cooper, 2016), and ammonium tetrafluoroborate (Atilgan and Peker, 2012), increase the retention value of the treated wood sample, which is also related to the concentration of the wood preservatives in the solution. The increase in moisture content of the treated versus the untreated sample may be caused by the absorption of water by the wood structure from the SNGW (Ors and Keskin, 2001). Moisture levels increase upon wood exposure to water-based preservatives, which could be due to the high amount of water that is used as the solvent (Yildiz et al., 2004). In addition, there are hygroscopic salts that absorb and retain water within the wood fiber walls, which causes the wood fibers to swell (Militz, 1993). Moreover, it has been reported that waterborne wood preservatives, such as borate (Simsek and Baysal, 2015), ammonium tetrafluoroborate (Atilgan and Peker, 2012), silicon dioxide (Dong et al., 2015), boric acid, borax, and sodium perborate (Toker, 2007), increase the density of the treated wood when compared to the untreated control. In certain studies, this increase in wood density due to preservative treatment has been shown to be statistically significant (Simsek and Baysal, 2015). Other defined parameters of wood preservatives, such as its toxicity against wood-destroying agents and its leaching, as well as aging, should be examined. Ors et al. (2005) and Var (2013) studied wood that was treated with Imersol-Aqua and SNGW, respectively, and reported that such treatments increased the values of retention, density, and moisture content. Hence, it was concluded that the results in *Table 2* were consistent with the reported data in the literature.

Mechanical properties

The results for MOR, MOE, and CSPG for the pines treated with the SNGW is presented in *Table 3*. For black pine, the highest MOE values were obtained with the N-1 treatment (11175.22 N/mm^2), while the C-1 treatment gave the maximum MOR (91.41 N/mm^2) and CSPG (42.31 N/mm^2). The lowest MOR values were observed for the C-1 treatment (88.05 N/mm^2), whereas the lowest MOE and CSPG values were observed for the E-6 treatment (9759.96 N/mm^2 and 39.71 N/mm^2, respectively). Additionally, the MOR, MOE, and CSPG values of the untreated control samples were observed to be 99.55 N/mm^2, 11365.18 N/mm^2, and 44.54 N/mm^2, respectively. For Brutia pine, the highest CSPG (41.63 N/mm^2) was observed for the C-1 treatment, whereas the N-1 treatment had the highest MOR (86.82 N/mm^2) and MOE (11015.93 N/mm^2). The lowest MOR (79.71 N/mm^2), MOE (10484.65 N/mm^2), and CSPG (37.89 N/mm^2) were noted for the E-6, C-1, and N-1 treatments, respectively.

Statistically significant differences for the MOR and CSPG values were noted for the treatments of both pines versus the untreated controls (*Table 3*). With regards to MOE values for black pine, there were significant differences in the C-1 and E-6 treatments versus the control, but not for the N-1 treatment. There were no significant differences observed among the geothermal water treatments for Brutia pine in the MOE values when compared to the control. Moreover, no significant differences in the MOR were noted among the geothermal water treatments, whereas there were significant differences detected between the E-6 and N-1 treatments for Brutia pine. No significant

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1405314068

differences in CSPG were observed between the N-1 and E-6 treatments for black pine, and no significant differences were observed between the C-1 and E-6 treatments for Brutia pine. In general, these findings indicated that SNGW treatments significantly decreased the mechanical properties of the two wood species when compared to the respective untreated controls. This observation was attributed to the fact that geothermal salts or minerals tend to increase the equilibrium moisture content of the wood samples.

Table 3. *Mechanical properties of pine wood species treated with SNGW*

Wood species	Geothermal water	MOR (N/mm^2)	MOE (N/mm^2)	CSPG (N/mm^2)

*Untreated. **Values in parentheses are the standard deviation; the same letters in each column indicate no statistical difference at the 95% confidence level among treatments

These results indicated that all of the treated samples had lower mechanical strength values when compared to the untreated control samples. This decrease could also have been due to the acidity of the SNGW, which caused some hydrolysis of the wood structure. Bozkurt and Erdin (1997) reported that if the moisture content of wood increases at temperatures above 0 °C, then the resistance of wood against the forces causing deformation can decrease, and the chemical solutions whose pH value is in the acidic zone can strengthen the hydrolysis of wood polysaccharides, and therefore, lower the mechanical properties of wood materials. The SNGW contain many chemical components that are commonly found in waterborne wood preservation formulations (Var, 2009). Such substances account for more than half (55% to 87%) of the total chemicals contained in SNGW (Var and Yaldiz, 2017). Wood treatments with such chemicals generally decrease the mechanical properties of the substrate because the waterborne preservatives physically react with the cellular wood components (Winandy, 1996). Many acidic substances used in waterborne formulations hydrolyze wood sugar components, which can decrease the strength values of the wood structure (Hamel, 1988). It has been reported that different concentration levels of waterborne wood preservatives result in more than a 20% reduction in CSPG values for Calabrian pine and beech (Toker et al., 2008). It has been determined that waterborne treatments have caused some decreases in other mechanical properties of wood materials (Laks and Palardy, 1990). The effect of different waterborne wood preservatives is related to the chemistry of the system and the severity of the fixation reaction (Winandy, 1996). Waterborne systems, such as borates, decrease the CSPG and MOR values of the impregnated wood. As the borate concentration in this system increases, the CSPG and MOR values of the impregnated wood decrease (Simsek et al., 2010). In other studies, it has been reported that waterborne formulations, such as boric acid (Colakoglu et al., 2003; Ayrilmis et al., 2005), borate (Wu et al., 2002; Simsek et al., 2010), CCA (Hesp

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1405314068

and Watson, 1964; Yildiz et al., 2004), and boron compounds (Toker et al., 2009), decreased the MOR and MOE of the preserved wood compared to the untreated control.

The measured results in *Table 3* were compared to the results in certain studies; for example, Sen et al. (2017) and Var et al. (2017) studied the properties of wood treated with the geothermal and rich mineral waters, and geothermal hot waters, respectively. It was reported that such treatments decreased the values of MOR, MOE, and CSPG. The data in *Table 3* indicated that the treatment of pine woods with SNGW lowered their mechanical strength values. Hence, it was concluded that these observations are consistent with the findings reported in the aforementioned studies. According to these results, it could be useful that the wood materials from pine woods treated with SNGW are used under the conditions of air-dry moisture content for the potential use areas exposed to the effects of mechanical strengths such as MOR and CSPG. However, for potential applications of wood materials, the users of pine woods should consider the physical and mechanical properties such as strength type and moisture content for pine woods treated with such SNGW.

Shrinking properties

Table 4 presents the data for shrinking tests for both pine wood species treated with SNGW. For black pine, the lowest shrinking values for the tangential of 5.89% and anisotropic of 1.19 were measured for the N-1 treatment, while the C-1 and E-6 treatments gave the minimum shrinking values for the radial (4.49%) and volumetric (10.36%), respectively. Also, the C-1 treatment gave the highest tangential (6.18%) and anisotropic (1.38) shrinking values, while the maximum radial (4.96%) and volumetric (10.77%) shrinking were obtained with the N-1 treatment. For Brutia pine, the lowest radial (5.29%) and volumetric (12.00%) shrinking were observed for the C-1 treatment, whereas the E-6 treatment yielded the lowest tangential (7.02%) and anisotropic (1.13) shrinking. Furthermore, the N-1 treatment gave the highest measured shrinking values of 7.72% (tangential) and 13.17% (volumetric), while the highest radial (6.25%) and anisotropic (1.35) shrinking were noted for the E-6 and C-1 treatments, respectively.

Table 4. *Shrinking properties of pine wood species treated with SNGW*

Wood species	Geothermal waters	Radial shrinking (%)	Tangential shrinking (%)	Volumetric shrinking (%)	Anisotropic shrinking
Black pine	Control*	5.52 (0.18**) a	6.94 (0.22) d	12.20 (0.32) g	1.26 (0.04) j
	N-1	4.96 (0.22) b	5.89 (0.15) e	10.77 (0.28) h	1.19 (0.06) k
	C-1	4.49 (0.10) c	6.18 (0.20) f	10.45 (0.29) i	1.38 (0.05) l
	E-6	4.53 (0.14) c	6.13 (0.17) f	10.36 (0.28) i	1.35 (0.05) l
Brutia pine	Control*	6.08 (0.33) m	7.48 (0.36) p	13.11 (0.59) r	1.23 (0.08) t
	N-1	5.91 (0.31) m	7.72 (0.36) p	13.17 (0.65) r	1.31 (0.10) u
	C-1	5.29 (0.27) n	7.10 (0.38) q	12.00 (0.40) s	1.35 (0.07) u
	E-6	6.25 (0.35) o	7.02 (0.47) q	12.83 (0.50) r	1.13 (0.09) w

*Untreated. **Values in parentheses are the standard deviation; the same letters in each column indicate no statistical difference at the 95% confidence level among treatments

Statistically significant differences for the shrinking values were found for the treatments of black pine versus the non-treated controls, except for the C-1 and E-6

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1405314068

treatments (*Table 4*). The similar situations were observed between the N-1 treatment and other geothermal water treatments for the black pine. For Brutia pine, the significant differences between the C-1 and E-6 treatments were found for all shrinking values, excluding the N-1 treatment, when compared to the untreated control. With regards to shrinking, for Brutia pine, there were significant differences among all geothermal water treatments in the radial values, while no significant differences in the volumetric values were found between the N-1 and E-6 treatments; no significant differences in the anisotropic values were also observed between the N-1 and C-1 treatments. Furthermore, the significant differences between the C-1 and E-6 treatments were noted for the radial, volumetric, and anisotropic shrinking for Brutia pine, while no significant differences were yielded for the tangential shrinking.

Here results showed that the SNGW treatment significantly decreased the shrinking properties of treated samples versus the non-treated samples for both pine woods. For black pine, the anisotropic shrinking reduced in the N-1 treatment, whereas it increased in the E-6 treatment; but the vice versa was for Brutia pine. Moreover, for black pine, the N-1 treatment significantly reduced the tangential and anisotropic shrinking versus the C-1 and E-6 treatments, while it increased the radial and volumetric shrinking. Also, both the C-1 and E-6 treatments had not indicated a significant effect on the shrinking properties of black pine. For Brutia pine, the E-6 treatment significantly increased the radial shrinking when compared to the N-1 and C-1 treatments, whereas the C-1 treatment significantly had reduced the volumetric shrinking versus the N-1 treatment. However, the N-1 treatment had significantly improved tangential and anisotropic shrinking of Brutia pine when compared to the E-6 treatment.

According to these findings, it was observed that the shrinking values of pine woods treated with the distilled water after the SNGW treatment lowered when compared to the non-treated control wood. This lowing could be due to the following: In the SNGW, the geothermal chemicals that are initially absorbed by pine wood could plasticize the lumen linings and cell walls within the wood structure (Stamm, 1955). The woody cells that are lose its plasticity during evaporation of the SNGW from the lumen system within the wood structure could force the more plastic cells to shrink inwards, towards them, and cause an overall shrinking in the wood volume (Pollisco et al., 1971.

The results in *Table 4* were compared to the findings in some studies; for instance, Bozkurt and Erdin (1997), and Bozkurt et al. (1993) had studied on the wood technology, and wood impregnation technique, respectively. It was reported that the shrinking values of black pine are 5.60% for the radial, 8.20% for the tangential, 13.90% for the volumetric, and 1.46 for the anisotropic. Likewise, it was nopted that the shrinking values of Brutia pine are 4.90% for the radial, 6.80% for the tangential, 12.20% for the volumetric, and 1.39 for the anisotropic. Also, some of earlier studies had investigated the properties of wood impregnated with the ammonia (Bariska, 1975; Coles and Walker, 1978), the liquid ammonia (Stamm and Seborg, 1936), and the ammonia vapor (Pollisco et al., 1971). It was noted that such treatments decreased the shrinking properties of wood. The obtained results in *Table 4* showed that SNGW treatments lowered the shrinking values of pine woods. Hence, it was concluded that these results in *Table 4* were agree with the findings in the aforesaid studies. According to these results, it could be advantageous that the pine woods treated with SNGW is utilized under the low relative humidity conditions for potential uses. Otherwise, in such treated pine woods, it could be an overall volumetric shrinking and dimensional change.

DOI: http://dx.doi.org/10.15666/aeer/1706_1405314068

Swelling properties

The results of swelling tests for both pine wood treated with the SNGW is shown in *Table 5*. For black pine, the lowest radial (4.15%) and volumetric (11.20%) swelling values were obtained with the N-1 treatment, while the E-6 treatment gave the minimum volumetric (11.45%) and anisotropic (1.37) swelling values. The highest tangential and volumetric swelling values were measured for the C-1 treatment (7.08% and 12.00%, respectively), whereas the E-6 and N-1 treatments had the highest radial (4.72%) and anisotropic (1.63) swelling values, respectively. For Brutia pine, for the radial, tangential and volumetric swelling, the C-1 treatment gave the lowest values (5.08%, 7.20%, and 12.65%, respectively), while the highest values were observed to be 5.76%, 7.79%, and 14.00%, respectively (with the N-1 treatment). Additionally, for the anisotropic swelling, the highest value was noted for the C-1 treatment (1.43), whereas it was reported that the minimum value is 1.28 for the E-6 treatment.

Table 5. *Swelling properties of pine wood species treated with SNGW*

Wood species	Geothermal waters	Radial swelling (%)	Tangential swelling (%)	Volumetric swelling (%)	Anisotropic swelling

	E-6	4.72 (0.11) c	6.46 (0.16) g	11.45 (0.28) k	1.37 (0.04) o
Brutia pine	Control*	6.20 (0.27) ö	9.07 (0.34) r	15.85 (0.32) t	1.47 (0.10) v
	N-1	5.76 (0.47) p	7.79 (0.38) s	14.00 (0.76) u	1.36 (0.11) yz
	C-1	5.08 (0.48) q	7.20 (0.37) ş	12.65 (0.67) ü	1.43 (0.15) vy
	E-6	5.72 (0.51) p	7.27 (0.30) ş	13.41 (0.67) w	1.28 (0.10) z

*Untreated. **Values in parentheses are the standard deviation; the same letters in each column indicate no statistical difference at the 95% confidence level among treatments

For the swelling values, the statistically significant differences were observed for the treatments of both pine woods versus the non-treated controls (*Table 5*). For black pine, there were significant differences observed among the SNGW treatments in the swelling values. For Brutia pine, with regards to radial swelling, there were remarkable differences between the N-1 and E-6 treatments *vesus* the C-1 treatment, whereas there was no significant difference between the E-6 and N-1 treatments. Besides, significant differences in the tangential swelling were observed between the C-1 and E-6 treatments *vesus* the N-1 treatment for Brutia pine, while no significant differences were observed between the E-6 and C-1 treatments. Moreover, significant differences in the anisotropic swelling were noted between the E-6 and C-1 geothermal waters used to treat the Brutia pine, whereas there were no considerable difference observed between the N-1 treatment versus the C-1 and E-6 treatments.

The data noted in *Table 5* saw that the swelling values of pine wood samples treated with the distilled water after the SNGW treatment decreased when compared to the untreated control samples. One of the major disadvantages of wood material is also its swelling due to the moisture content of the air. The wood material swells when used under the high moisture content conditions. Likewise, the same cases are also observed in the wood materials treated with the hygroscopic wood preservative salts. But, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1405314068

swelling values of wood treated with the hygroscopic chemicals are less than that of the untreated wood (Bozkurt et al., 1993). The decrease of a general swelling in the volume of wood treated with the SNGW could be from the hygroscopic geothermal chemicals absorbed by the woody cells within the wood structure. The strength of hydrogen bonding could be decrease as the absorption of hygroscopic chemicals increases; consequently, the water sorptive capacity of the cell wall and the volumetric swelling of wood in water could be decrease with increasing of the hygroscopic chemical absorption (Coles and Walker, 1978). Also, the swelling of wood in water could be related to hydrogen bonding and by changes in the cellulose structure (Stamm, 1955). Compared to the untreated wood, this swelling phenomenon could be due to the cellulose chains that are the less swelling within the SNGW-treated wood structure, and the cellulose chains that remain in the less swollen state within this structure after the SNGW evaporation (Stamm and Seborg, 1936).

The results in *Table 5* were compared to the results of earlier studies; for example, some workers had studied the properties of wood treated with the ammonia (Coles and Walker, 1978), the liquid ammonia (Stamm and Tarkow, 1955), and the liquid ammonia-solvent combinations (Pentoney, 1966). It was reported that such treatments decreased the swelling properties of wood. Our own observations in *Table 5* indicated that the SNGW treatments lowered the swelling values of pine woods. Hence, it was concluded that the results of *Table 5* are consistent with these studies. According to the results noted here, it could be helpful that the pine wood species treated with such SNGW is not used under the high moisture content conditions. If not, it could be a general volumetric swelling and dimensional modify for such treated pine wood materials.

Conclusions

This study investigated how the impregnation of black and Brutia pine wood species with three different SNGW from Turkey (as environmentally safe resources) affected the physical, mechanical, shrinking, and swelling properties of the wood. The absorption and retention values for all treated pine wood samples significantly increased depending on the concentration of the mineral salts found in the SNGW. The highest physical values were observed for the E-6 treatment, whereas the lowest physical values were observed for the N-1 treatment.

In general, the SNGW treatments increased the values of density and moisture content of the two pine wood species, but decreased the values of MOR, MOE, CSPG, shrinking, and swelling. The decreases in the MOR, MOE, CSPG, shrinking, and swelling of the treated pine woods were higher compared to the non-treated wood, but the increases in density and moisture content were lower. For the E-6 treatment, the increases in density and moisture content were higher than those of the other treatments. For the N-1 treatment, the decreases in MOR, MOE, and CSPG were less than those of the other SNGW treatments. For example, in the E-6 treatment the density increased 7.69% and 3.51% for black pine and Brutia pine, respectively; for the N-1 and C-1 treatments, the increases in density were 1.92% and 5.77% for black pine, respectively, and were 1.79% and 3.75% for Brutia pine, respectively. Similar increases were also observed for the moisture content values. In the N-1 treatment, the MOR values decreased 11.55% and 8.01% for black pine and Brutia pine, respectively, whereas for the C-1 and E-6 treatments, the decreases were 8.14% and 9.67% for black pine,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1405314068

respectively, and the decreases were 11.88% and 15.54% for Brutia pine, respectively. Similar reductions were also observed for the MOE, CSPG, shrinking, and swelling.

Based on these laboratory results, the effects of SNGW on the physical, mechanical, shrinking, and swelling properties of pine woods can be directly related to several important factors related to: wood type and quality; saltwater absorption and mineral retention amounts within the wood; variety and content of chemical compounds within the SNGW; treatment method used; wood drying temperature; and wood treatment processing factor.

The pine wood materials treated with such SNGW can be used in the application areas, where no dense humidity, static bending and pressure parallel to grain effects for long periods. Therefore, for such application areas, the users or designers should consider the loading type and humidity criteria calculation for pine wood materials treated with such natural salt waters.

This study is not an indication that the SNGW can be used as wood preservatives. Therefore, for the examination protective performance of SNGW treatment, some analyzes such as decay test, leaching test, and weathering test could be done. Because those tests could be a requirement to determine the usability of SNGW as a wood preservative.

Acknowledgments. The authors are grateful for the support from the TR Suleyman Demirel University Department of Scientific Research Projects Coordination (Grant No. 3365-YL1-12).
