(Received 8th Jan 2019; accepted 13th Jun 2019)

Abstract. One of the crucial elements having a direct impact on rainfall-runoff transformation is soil moisture of the catchment. Moisture conditions can be expressed by physical catchment descriptors, like PROPWET or FLATWET. Their values are represented by ratio between time when the soil is wet and analysed period, using wet-dry threshold R_g. The wet-dry threshold is based on climatic data and is constant for the PROPWET (R_g=6 mm) and for FLATWET (R_g=8.5 mm). The purpose of the present publication is to define a descriptor suitable for any area in Europe. The authors propose novel descriptor (GLEMOK) using additionally physical soil properties. Public SoilGrids250m soil database was applied, which served to develop a high-resolution soil map and pF curves. For the Raba river catchment (research area) the R_g. threshold is equal 11.5 mm. The GLEMOK descriptor for this research area has proportionally larger values than the other two, which is closer to real water regime in this region of Poland. The novel descriptor GLEMOK using physical soil properties is more universal compared to PROPWET and FLATWET. Use of the global SolidGrids250m soil database enables implementation of this method in any area in Europe.
Keywords: *PROPWET, FLATWET, SMD, SoilGrids250m, database, wet-dry threshold*

Introduction

So far, in hydrology, the problem of forecasting flow characteristics has been solved using mathematical modelling for which unambiguous procedures have not been determined (O'Connor, 2014). In United Kingdom, a methodology has been developed for the needs of engineering practice, which has been called design hydrology (Reed, 1999; Faulkner, 1999; Robson and Reed, 1999; Houghton-Carr, 1999; Bayliss, 1999). In design hydrology, the physical catchment descriptors (PCDs) play a fundamental role (Bayliss, 1999; Mills et al., 2014) in quantitative and qualitative description of the given catchment. Based on these descriptors, hydrological characteristics used in the design, management and analysis of changes taking place in the catchment can be determined. PCDs can be divided into three groups:

- **fixed** – related to the topography, orography and hydrography of the catchment, including for instance the catchment area, the river network density, the watercourse slope, etc.
- **variable** – representing spatial development of the catchment, for instance forest land cover, urbanization, length of watercourses under anthropopressure, etc.
- **process-related** – for instance, moisture conditions of the catchment, surface retention, flood attenuation by channels and lakes, urbanization pressure on the outflow, etc.

Process descriptors form the foundations for the development of formulas that allow linking engineering hydrology with dynamic hydrology, which until now has been used

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1266712681

in mathematical hydrological modelling. Such a combination provides the opportunity to extend the scope of its applicability to new areas, related for instance to determining the impact of climate change on hydrological characteristics (Apel et al., 2006; Vrijling et al., 1998; Zeleňáková et al., 2017) or to the impact of urbanized areas on flood risk (Zevenbergen et al., 2011).

Among the descriptors used around the world to define the dynamics of the transformation of rainfall (precipitation) into runoff, two are particularly noteworthy in terms of describing the watercourse supply. These are the PROPWET and BFI descriptors (Bayliss, 1999; Reed, 2007; Mills, 2014), which determine what part of the precipitation is transformed into runoff in the form of surface or subsurface runoff. The PROPWET descriptor is determined from the soil moisture deficit (SMD) (Hubbard et al., 2007), using the Hybrid Soil Moisture Deficit Model (Allen et al., 1998; Reed, 2007). SMD is calculated as follows:

$$SMD_t = SMD_{t-1} - Rain + ET_a - Drain \quad \text{(Eq.1)}$$

where:

- SMD_t, SMD_{t-1} – the SMDs on day t and day t-1 respectively (mm).
- *Rain* - the daily precipitation (mm d^{-1}).
- ET_a - the daily actual evapotranspiration for a reference grass crop (mm d^{-1}).
- *Drain* - the amount of water drained daily by percolation and/or overland flow (mm d^{-1}).

Climatic data used to determine the SMD include: atmospheric precipitation, temperature and air humidity, wind speed, and net radiation (Narasimhan and Srinivasan, 2005). Atmospheric precipitation is divided into effective precipitation and soil retention (*Figure 1*).

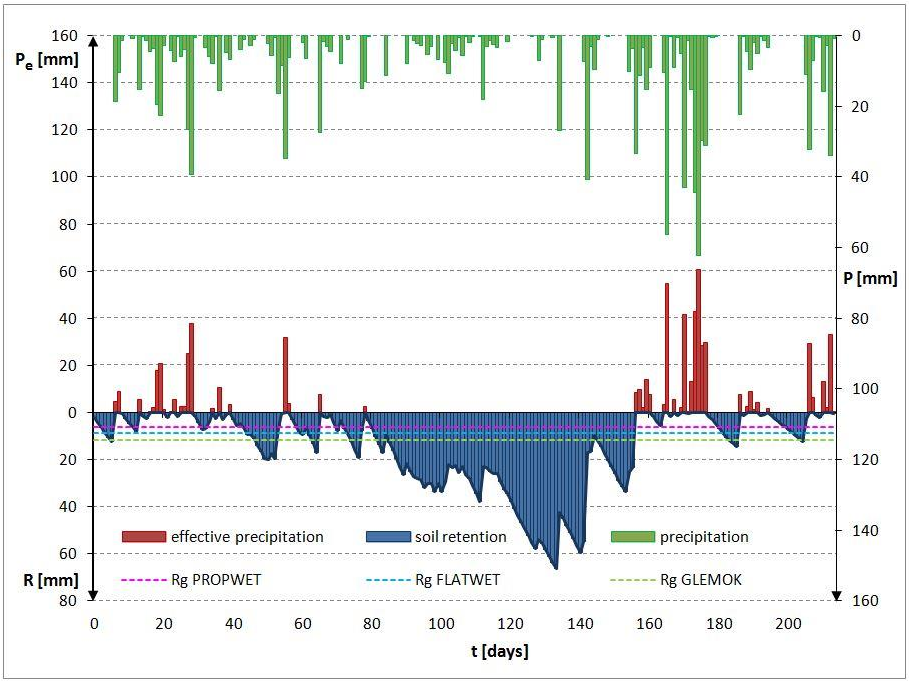

Figure 1. *Division of atmospheric precipitation into surface runoff and soil retention using the SMD*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1266712681

The soil moisture deficit assumes only positive values and represents soil retention *R*. In the case of precipitation exceeding the soil retention, excess precipitation flows down as surface runoff, and the *SMD* is set to 0 value. Increase in the *SMD* humidity deficit means soil drying, whereas the reduction of its value means the replenishment of water in soil by precipitation. The values of the *SMD* which are lower than the threshold values, presented in the form of dashed lines (*Figure 1*), denote wet soil. Dry soil is represented by values greater than the threshold values, in which case water is available only for plants.

Based on the SMD the PROPWET descriptor was designated. It represents the share of time in which the soil remains wet compared to the whole of the analysed period. For this purpose, it is necessary to determine the threshold of soil division R_g, into wet soil and dry soil. The search for the threshold between wet and dry soil is carried out in the optimization process. For a given threshold value (for instance R_g=2.5 mm) for all climate stations, the share of time during which the soil remains wet is calculated ($PROPWET_{2.5}$). The next step is to determine the differences between the calculated $PROPWET_{2.5}$ values for all pairs of climate stations. On this basis, the average value of these differences is calculated for a given threshold (2.5 mm). The threshold is determined for the assumed objective function, which is the maximum of the average differences. The threshold is chosen to maximise the inter-site variation in PROPWET across all gauged sites. For the United Kingdom R_g=6 mm (Reed, 2007), for the Ireland R_g=8.5 mm (Schulte et al., 2005), thus PROPWET descriptor has been renamed to FLATWET and is used only in Ireland (*Figure 1*).

FLATWET and PROPWET descriptors were developed for United Kingdom and Ireland, which according to the Köppen-Geiger division (Kottek et al., 2006) lies in the same climate zone as Poland (Cfb – warm temperate climate, fully humid, warm summer). The amplitude of air temperature changes throughout the year in Poland is greater than in the United Kingdom, resulting in four seasons. When estimating the values of these descriptors, the winter period poses a problem when the ground is frozen, and the precipitation occurs in the form of snow. This involves the growing season, which in Poland is between April and October (Olszewski and Żmudzka, 2000). Then the catchment's behaviour is completely different than in the growing season. In contrast to British Isles, the number of days with Tmin <0˚C ranges from less than 100 days on the Baltic coast to over 140 days in the east of Poland (Kejna et al., 2009). This causes freezing of the soil, which is associated with a change in water conduction properties. Under such conditions, the permeable soil becomes impermeable, sublimation or evaporation occurs without transpiration, and the precipitation occurs in solid form (snow). The outflow from the catchment in this period comes mainly from groundwater, whereas the surface runoff from the melting snow (thaw or snow-melt). For this reason, for the territory of Poland, the winter period should be omitted in the calculations related to establishing the threshold between wet and dry soil.

The purpose of the present publication is to define a descriptor that will take into account the moisture conditions of the catchment, suitable for any area in Europe. The authors propose the GLEMOK descriptor, specifying the share of time during which the soil remains wet, based on the PROPWET descriptor elaborated in United Kingdom and FLATWET descriptor used in Ireland. However, during the development of the descriptor, the winter period have been eliminated from the calculations, therefore the principle of the descriptor's determination had to be changed in relation to the original model.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1266712681

Determination of the threshold between wet and dry soil should be carried out for the area of Poland in a different way than for the PROPWET or FLATWET. For the latter two descriptors, the threshold is determined for climatic data from the whole calendar year. The very idea of PROPWET and FLATWET originates from dynamic hydrology, in which the issues related to the process of infiltration form the basis for solving the set of equations for the rainfall-runoff transformation (Eagleson, 1970; Ozga-Zielińska et al., 2002). One of the characteristics describing the physical properties of soil is the pF curve (*Eq. 2*), which illustrates the relationship between soil water content Θ and soil matric potential h_s affecting water molecules in soil (*Figure 2*).

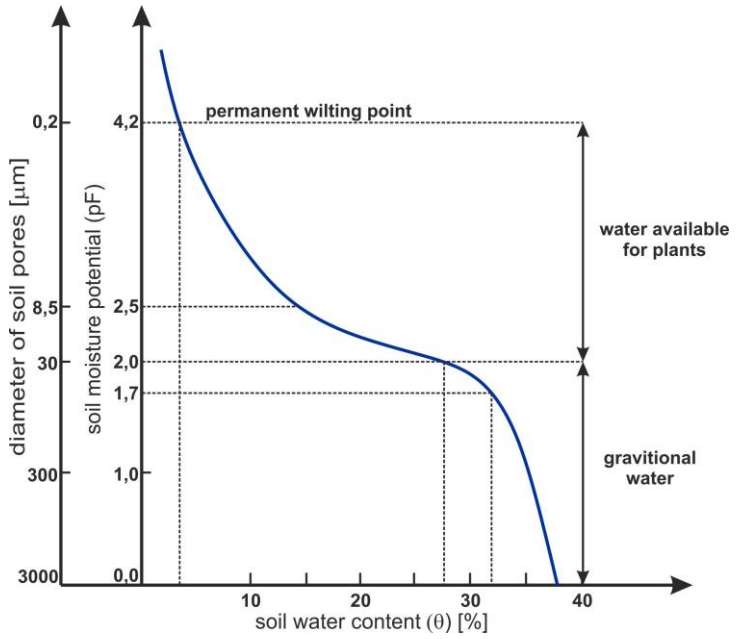

Figure 2. *Sample pF curve of the soil*

$$pF = log\ (-h_s) \qquad \text{(Eq.2)}$$

where:

h_s – soil matric potential (suction pressure) (cm).

On the basis of the pF curve, it is possible to determine points, which determine the state of soil moisture. These are:

- h_s = *-50 cm (pF = 1.7)* – from the value of h_s = *-50 cm* to the value of h_s = *0 cm* water in the soil moves mainly due to gravity (force of attraction) and it is assumed that this water is not available for plants, but it takes part in the direct supply of watercourses.

- h_s = *-100 cm (pF = 2.0)* – from the value of h_s = *-100 cm* to the value of h_s =*-50 cm* water moves mainly under the influence of gravity, and the process of evapotranspiration begins.

- h_s = *-300 cm (pF = 2.5)* – water is readily available for plants, and with lower values of suction pressure, the evapotranspiration process is gradually reduced.

- h_s = *- 15,000 cm (pF = 4.2)* is the point of permanent wilting of plants, and at this point evapotranspiration disappears.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1266712681

In 1986, Driessen proposed the equation describing pF curves for soils (*Eq. 3*), according to the European classification:

$$\theta(h_s) = \theta_s e^{-\mu[ln(-h_s)]^2} \quad \text{(Eq.3)}$$

where:

- Θ_s – maximum volumetric humidity ($cm^3\ cm^{-3}$).
- μ – parameter dependent on the type of the soil (cm^{-2}).

Soil classification can be made using the grain size information, which is described in the Feret's diagram shown in *Figure 3*.

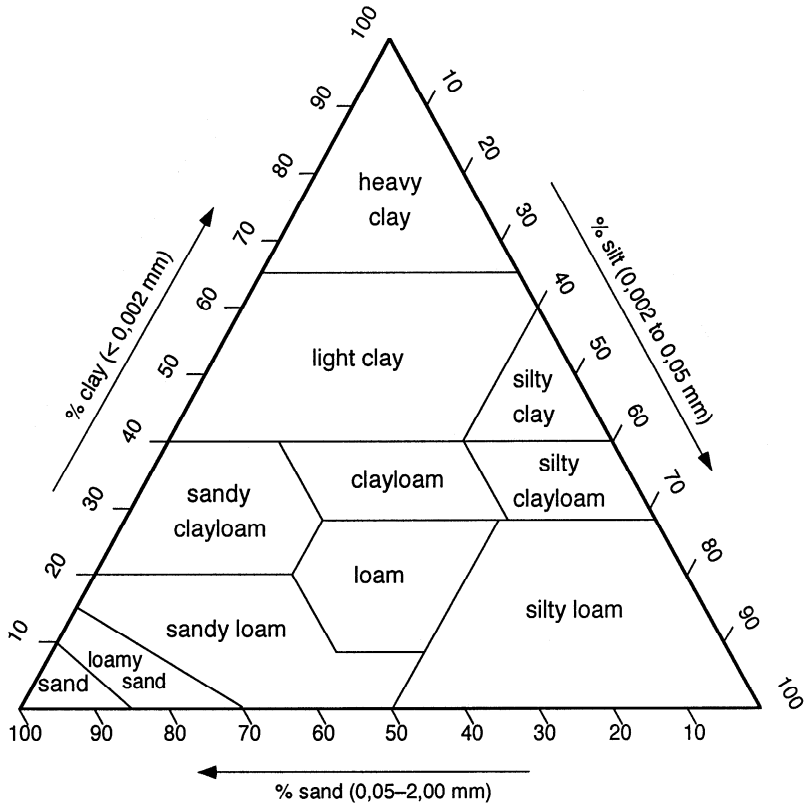

Figure 3. *Feret's diagram according to the European classification of soils (Dreissen, 1986)*

Materials and methods

The area and data under study

The Raba river catchment had been adopted as the study area. Raba river is a right-bank tributary of the Vistula river. It is about 132 km long and covers an area of 1537.1 km^2, flowing through three hydrological regions. The largest part of the catchment is located in the Carpathian zone, representing the mountainous terrain. The remaining part is located in the upland area, whereas the estuary part represents the lowlands. The average elevation of the catchment is about 500 m above sea level. The highest point of the catchment is Turbacz mountain, at 1310 m above sea level, and the lowest is 180 m above sea level, at the point where Raba enters the Vistula river.

DOI: http://dx.doi.org/10.15666/aeer/1706_1266712681

Within the Raba river catchment 9 water gauges were used in calculation, 7 of them located upstream water reservoir in Dobczyce. *Figure 4* shows sub-catchments for particular water gauges.

The values of the mean annual precipitation from the summer half-year, for all computational cross-sections, are presented in *Table 1*.

The calculations were carried out for the PROPWET, FLATWET and GLEMOK descriptors, for a 30-year measurement data series from April 1 to October 31 in the years 1983-2012. For each descriptor, the appropriate wet-dry threshold was accepted. Climatic data, including atmospheric precipitation in the years 1983-2006, comes from the station in Stróża, run by the Hydrology Department of the Institute of Engineering and Water Management of the Cracow University of Technology, whereas the data for the period 2007-2012 was obtained from the climate station of the IMGW PIB in Dobczyce. Small distance between Stróża and Dobczyce stations (15 km) with the same

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1266712681

measurement conditions (standard Hellmann rain gauge) enabled merge of data from those two series (Noone et al., 2016). The non-parametric Mann-Whitney-Wilcoxon test for yearly precipitation, with resulting p=0.001 at significance level α=0.05, confirmed hypothesis on series homogeneity (Yue and Wang, 2002). The spatial distribution of atmospheric precipitation and field evaporation for the whole catchment was elaborated on the basis of rainfall maps and evapotranspiration index for grass, published by IMGW PIB in the "Hydrological Atlas of Poland" (IMGW, 1987).

In order to determine the type of soils, raster layers of soil granulometry were used, derived from the SoilGrids250m project (Hengl et al., 2017). Soil grain size is available in the form of three fractions (sandy, loamy and silty), for seven depths in the soil profile (0, 5, 15, 30, 60, 100 and 200 cm).

SoilGrids250m database (https://soilgrids.org) is one of the few global soil information resources, making it possible to determine the type of soil in any area of the globe, with a spatial resolution of about 250 m (Hengl et al., 2017). The sources of data for the development of this database included:

- Approximately 150 000 soil profiles.
- Expert profiles for non-monitored areas.
- 158 satellite products, including MODIS land products, SRTM DEM, as well as climatic and lithological data, etc.
- Machine learning algorithms.

The data are available to the public in the form of raster layers on a free-of-charge license basis (ODbL - Open Database License).

Methodology

Using the Feret's diagram (*Figure 3*) and the grain size information for selected depths (0, 5, 15 and 30 cm), the type of soil was determined. This was accomplished by developed application (https://gitlab.com/OpenHydrology/soil-map), using the Python 3.7 programming language, with rasterio and python-ternary packages (Harper et al., 2015). Raster layers with a spatial resolution of 250 m from SoilGrids250m project were used as input data. For the processing and visualization of the spatial data QGIS 2.18 software was used (Sherman, 2014).

As a result, a high-resolution raster map of soils for the area of Poland was generated (*Figure 5*). This map was used to determine the threshold between wet and dry soil for the GLEMOK descriptor, which is determined for each soil individually. The name of this new descriptor is abbreviation of "wet soil" term (Polish: GLEba MOKra). Precipitation events causes the soil became moist, so descriptor value should exceed relative number of days with precipitation. Relative number of days with precipitation can be calculated as ratio between average number of days with precipitation and growing season lengths.

This is a different approach than in the PROPWET and FLATWET descriptors, where the threshold value is determined arbitrarily, by using optimization methods. When determining the wet-dry threshold in the GLEMOK descriptor, pF curves were applied that characterize the properties of a given soil type, as presented in *Table 2*.

Procedure for calculating the GLEMOK descriptor:

1. Based on climatic data, the soil moisture deficit SMD in the catchment, up to the gauge cross-section, is determined.
2. Based on the soil map, the average value of the wet-dry threshold R_g is determined (*Table 3*) according to the following ratio:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1266712681

$$\boldsymbol{R_g} = \frac{\sum_{i=1}^{n}(\boldsymbol{R_g^i} \cdot \boldsymbol{A_g^i})}{\sum_{i=1}^{n} \boldsymbol{A_g^i}} \quad \text{(Eq.4)}$$

where:

$\boldsymbol{R_g^i}$ – threshold between wet and dry soil, for a particular type of soil *i* (mm).

$\boldsymbol{A_g^i}$ – area occupied by a particular type of soil *i* (km^2).

n – number of soil types in the catchment (-).

3. Based on the soil moisture deficit and the calculated average wet-dry threshold R_g (*Eq. 4*), the time during which the soil remains wet is calculated.
4. The value of the GLEMOK descriptor is defined as the ratio of time during which the soil remains wet to the considered measurement period.

Results

Relative number of days with precipitation, calculated as ratio between average number of days with precipitation and growing season lengths, for Raba river catchment equals 0.458.

Four soil maps for individual soil depth layers according to SoilGrids250m: 0, 5, 15, 30 cm were developed for the Raba river catchment. Differences observed in soil classification for the elaborated maps did not exceeded 1%. Therefore, in order to determine the wet-dry threshold R_g, an average value from four soil layers.

On the basis of the developed soil map (*Figure 5*), the values of the wet-dry threshold R_g were calculated. The wet-dry thresholds for the GLEMOK descriptor were determined for all sub-catchments (up to the water gauge, and the outflow to the Vistula river). For most of these sub-catchments, the calculated value of the threshold between wet and dry soil R_g is set at 11.5 mm. The following constitute an exception: catchment of the Stradomka river up to the Stradomka cross-section, where R_g=11.7 mm and the Raba river catchment up to the Proszówki cross-section, where R_g=11.6 mm (*Table 4*). For the whole area of Poland R_g=9.1 mm. Raster maps of soils/Rg for Poland can be downloaded from project web page (https://gitlab.com/OpenHydrology/soil-map).

DOI: http://dx.doi.org/10.15666/aeer/1706_1266712681

It was found that for the catchment of the Raba river up to the Proszówki water gauge, the increase in the R_g value from 11.5 mm to 11.6 mm does not affect the GLEMOK value, whereas for the Stradomka river catchment up to the Stradomka section, the GLEMOK value increases by 0.002. This is considered a slight increase, and it has been assumed that in the whole Raba river catchment, the value determining the threshold between wet and dry soil can be set at $R_g = 11.5$ *mm*. *Table 5* presents the values of the calculated PCDs: PROPWET, FLATWET and GLEMOK, for individual sub-catchments of the Raba river.

Table 5. *Values of the PROPWET, FLATWET and GLEMOK descriptors in the Raba river catchment, determined for the period of 1983-2012, and for the adopted fixed threshold between wet and dry soil (the subscript of the descriptor)*

No.	River	Gauge station	A [km^2]	PROPWET$_{6.0}$ [-]	FLATWET$_{8.5}$ [-]	GLEMOK$_{11.5}$ [-]
1	RABA	Rabka	91.8	0.354	0.441	0.535
2		Mszana Dolna	157.2	0.352	0.427	0.514
3		Kasinka Mała	353.2	0.338	0.413	0.505
4		Stróża	643.7	0.326	0.406	0.486
5		Proszówki	1471.8	0.254	0.310	0.366
6		outlet to Wisła	1537.1	0.263	0.312	0.411
7	MSZANKA	Mszana Dolna	151.5	0.329	0.408	0.495
8	LUBIEŃKA	Lubień	47.8	0.326	0.404	0.491
9	KRZCZONÓWKA	Krzczonów	87.3	0.319	0.394	0.477
10	STRADOMKA	Stradomka	362.9	0.178	0.225	0.308

Based on the obtained results, a comparison was made between PROPWET, FLATWET and GLEMOK descriptors for all sub-catchments, determining absolute and relative changes. The relative increment in the GLEMOK value in relation to the PROPWET and FLATWET was calculated based on the following formula:

$$FLAT_{GLE} = \frac{GLE-FLAT}{FLAT}100 \; and \; PROP_{GLE} = \frac{GLE-PROP}{PROP} \qquad \text{(Eq.5)}$$

where:

- $FLAT_{GLE}$ ($PROP_{GLE}$) – increment of the GLEMOK$_{11.5}$ descriptor compared to FLATWET$_{8,5}$ or PROPWET$_{6.0}$.
- *GLE* – value of the GLEMOK$_{11.5}$ descriptor (-)].
- *FLAT* (*PROP*) – value of the FLATWET$_{8.5}$ descriptor or the PROPWET$_{6.0}$ descriptor (-).

The variability of the analysed descriptors is related to the topography of the area (*Figure 6*). The highest values of all descriptors can be observed in the upper (southern) parts of the Raba river catchment. Descriptors changes are visible, clearly dividing the catchment into two parts: mountains and uplands (*Figure 6*). The lowest values of all descriptors were obtained for the Stradomka river catchment, up to the Stradomka cross-section. This is probably due to the fact that there are lower precipitation heights in this catchment (*Table 1*) than in the remaining area, hence the relative increase in the value of the GLEMOK, as compared to PROPWET value, exceeds 70%.

Discussion

In the PROPWET and FLATWET descriptors calculation method, the wet-dry threshold R_g is determined using statistical analysis, as constant value for the whole area in analysed period. According to authors of PROPWET for Ireland "the choice of wet-dry threshold is rather arbitrary" (Reed, 2007).

The assumption that the threshold is constant in time and space, means that the ratio between precipitation and evaporation is maintained. When this ratio changes, the value of the wet-dry threshold R_g must be updated (Bayliss and Morris, 1999). These changes may be caused, among others by the climate change. The maximum daily precipitation changes have been documented in the studied area (Kundzewicz et al., 2005; Młyński et al., 2018) so direct implementation of PROPWET and FLATWET in Poland would be impractical.

The PROPWET values in the United Kingdom ranges from 0.51 to 0.75. Despite the high variability of the PROPWET value, one wet-dry threshold value R_g=6 mm was adopted (Reed, 2007). The wet-dry PROPWET threshold for the Ireland 8.5 mm was obtained. As a result, a new FLATWET descriptor was created with values from 0.55 to 0.74, referring only to the area of Ireland (Mills et al., 2014). Thus the various wet-dry threshold values for the PROPWET descriptors in the United Kingdom and FLATWET in Ireland indicate their regional nature. High descriptors values for relatively low R_g can be caused by higher precipitation for British Isles compared to Poland. Implementation of PROPWET and FLATWET descriptors in other area would required wet-dry threshold R_g determination for long-term data series from several climatologic stations.

To check regional nature and spatial variability of descriptors, the Raba river catchment (A=1537 km^2) with its sub-catchments was selected as research area.

Since the descriptors refer to the soil moisture condition, the parameter considering the soil type should be taken into account in the calculation process. The soil types are variable in space and soil data are available worldwide. The adopted method for determining the soil type, based on the physical soil parameters from the SoilGrids250m database (Hengl et al., 2017), enables the universal use of the GLEMOK descriptor. Value of this descriptor is based on the unambiguous determination of wet-dry threshold R_g, from type of soil and pF curves.

The wet-dry threshold R_g in Poland ranges from 6.2 to 14.1 mm with the average value 9.1 mm. For Raba river catchment the variability of R_g is small - maximum difference equals 0.2 mm (*Table 4*). It has been shown that even in such a small area compared to Ireland or United Kingdom, there is spatial variability in the values of the PROPWET, FLATWET and GLEMOK descriptors (*Figure 6*). The values are: for the PROPWET - from 0.178 to 0.354, for the FLATWET - from 0.225 to 0.441, and for the GLEMOK - from 0.308 to 0.535 (*Table 5*). Descriptors values should correspond to number of days with precipitation. For longer precipitation period descriptors values should be higher. It corresponds to wet soil conditions, when river supply comes mainly from surface and sub-surface runoff. In the remaining period, dry soil represents river supply only from groundwater.

The average number of days with precipitation in the analysed period is 98 per growing season in the Raba river catchment. The precipitation indicator determining the number of precipitation days for the growing season (214 days) equals 0.458. Therefore, it would be expected that the values of these descriptors will not be lower than the precipitation indicator. For the analysed area of Raba river catchment, this assumption

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1266712681

for PROPWET and FLATWET descriptors is not fulfilled - in both cases the values are lower than the precipitation indicator. However, precipitation indicator is in the range of GLEMOK descriptor values. Taking into account the physical soil properties (like in GLEMOK) results are more reliable.

Low values of PROPWET and FLATWET descriptors in the Raba river catchment imply that groundwater is the main source of water supply, which is not true.

The spatial variability of all three descriptors reflects the character of spatial variability of precipitation and evapotranspiration. The difference between GLEMOK and the other two descriptors is based on a different method of determining the wet-dry threshold R_g. Only GLEMOK descriptor includes local physical soil properties.

According to the authors, determining the value of the threshold R_g on the basis of physical properties of soils and the pF curve is more justified than statistical methods used to determine the PROPWET and FLATWET descriptors.

Conclusion

The wet-dry threshold R_g is a key parameter in determination of all three descriptors – PROPWET, FLATWET, GLEMOK. Calculation of wet-dry threshold value in PROPWET (R_g=6.0) and FLATWET (R_g=8.5) is based on meteorological records, which are combined into averaged value over whole research area. In GLEMOK descriptor this value (R_g=11.5 for the Raba river catchment, R_g=9.1 for Poland) is calculated from spatial distribution of meteorological records but additional information on soil types is provided. Difference in R_g values between British Isles and Poland is result of both climate and soil type.

Relative difference of the GLEMOK value in relation to the PROPWET is about 50%, whereas compared to the FLATWET, it is about 20% (Figure 6).

The GLEMOK descriptor better adopts runoff values comparing to those expected from the other two descriptors. Direct implementation of PROPWET or FLATWET for the area of Poland would cause unreliable water regime which is based on groundwater supply.

Direct implementation of PROPWET and FLATWET to locations outside British Isles requires long-term series of meteorological data from several stations. Implementation of GLEMOK is possible with data from just single meteorological station. It is a great advantage of proposed GLEMOK method.

The new method using the GLEMOK descriptor is more universal compared to PROPWET and FLATWET. Use of the global SolidGrids250m soil database enables implementation of this method in any area in Europe.

Abstract. Huge amounts of synthetic chemical herbicides are used to manage weeds. Heavy doses of synthetic chemicals for weed control are encouraging herbicidal resistance in weeds, risking human health and environment. Natural compounds, known as "bio herbicides" are environmentally safe herbicides, based on compounds produced by living organisms. The study was aimed to evaluate allelopathic activity of leaf powder of *Rhazya stricta, Pinus roxburghii, Carica papaya* and *Lantana camara* against selected weeds viz. *Phalaris minor, Avena fatua, Chenopodium album, Euphorbia helioscopia* and *Rumex dentatus* on 0.75 (w/v) agar, soil and filter paper at concentration of 10 and 50 mg leaf powder. Germination percentage (%), radicle length (cm) and plumule length (cm) were parameters to assess allelopathic potential. The STATISTIX 9 software was used to analyse data. Based on results, it was concluded that selected plants possesses potential inhibitory effects. Detailed analysis is required to establish allelopathic potential and onward application to be used as phytoherbicide.
Keywords: *factors affecting wheat production, weed infestation, harms of synthetic compounds, natural herbicides, growth retardation*

Introduction

Food security depends upon a sustainable agricultural production and higher levels of yield. It may also enable the agricultural sector less vulnerable to the threat of climate change (Shah et al., 2016). Agriculture is the backbone of Pakistan's economy. This sector gave 20.9% of the Gross Domestic Product (GDP) for the fiscal year 2014-15. Moreover, agriculture is a source of income for 43.5% of the village population of the country. Wheat (*Triticum aestivum* L.) is one of the most important cereal crops of the world. Its role is quite important in the provision of human

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1268312696

nutrition. Wheat caters to about 73% of the caloric portion of a common person's average diet. Its contents include starch (59-89%), protein (10-15.4%), fat (1.4-2.1%), inorganic ions (1.3-2.2%) and vitamins E and B-complex (Rueda-Ayala et al., 2011). As the world is progressively converting into a global village, globalization and market connectivity are presenting new hindrances in growth and development. The average annual production of wheat is quite low in Pakistan in comparison to other agricultural economies. There might be two ways for increasing wheat production: either by adding more area in cultivation or increasing its production per hectare. The first option is not practicable due to other essential crops, limited availability of the irrigation water occupation of the fertile soils by expanding cities. In this case, wheat production in Pakistan can only be increased by getting higher production per hectare. This can be obtained by efficient agricultural methods. There are many factors, which cause hindrance in wheat production, such as delayed sowing, less amount of fertilizers, water shortage, non-availability of better seed, diseases and dry periods.

Weed infestation is a serious threat to wheat production caused lowering wheat yield. If weeds management strategies are not devised, greater production losses in wheat yield can take place (Khan et al., 2016). It has been shown that wheat farmers are offering very little time and attention to the weed management practices, consequently, 15 to 25% wheat grain losses occur. Weeds are, at large, in causing annual damage of about 10% in agricultural yields globally (Cavero et al., 2011). In Pakistan, weeds cause 45% loss in wheat production (Anwar et al., 2016). In Pakistan, however, annual economic loss, due to weeds in agricultural production is estimated around 18.2 billion dollars. Including, 3-6 billion dollars spent on weeds control methods. There are around 30 different weed species generally found in the wheat crop, becoming the sources of losses. As the smaller farmers lack related tact and necessary resources, it becomes quite impossible to remove these weeds from the cultivated field. Weed harms most of the crops and grain. Moreover, it remains as a perennial problem in Pakistan's agriculture sector (Mubarik et al., 2015). According to an estimate, grain produce in Pakistan can be enhanced by up to 41% if weeds are managed properly. The controlling weeds through traditional methods is time consuming, weather hinged and exhibit more labour cost. While modern weed control techniques have not been up to the mark in solving this problem (Arafat et al., 2015).

Synthetic chemicals are in wider use for controlling weeds. These chemicals may enhance crop production, but concurrently these may have a negative effect on the environment as well as upon human health. In addition to these, the heading up of synthetic herbicides resistant weeds is another major area of concern. Excessive use of herbicides for controlling weeds during the last few years is becoming one of the noteworthy ecological and environmental threats for the world. Herbicide remnants in crops, soil and underground water which causes an evolution of various resistant weed biotypes, and linked health threats are some of the huge dangers that scientists are facing these days in devising various weed management techniques. Due to the negative effect of using synthetic chemicals, one may highly be in demand the new classes of chemicals, especially, biodegradable products such as those originating from plants, which have the potential of getting developed as herbicides (Aryakia et al., 2015). Allelopathy is a natural and eco-friendly technique. This strategy might be one of the very efficient tools for weed management and thereby increasing crop production (Kamran et al., 2017). Natural herbicides obtained from allelopathic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1268312696

plants can help in reducing usage of synthetic herbicides for weed control. Consequently, these may cause less pollution, better agricultural products as well as alleviate human health concerns. The most commonly available allelochemicals are cinnamic and benzoic acids, alkaloids, flavonoids, phenolics, glucosionates and various terpenes. These compounds are called as phytotoxic (Khan et al., 2014).

R. stricta, belongs to family Apocynaceae. It is poisonous perennial evergreen shrub of desert and possess tannins, triterpenes, glycosides, volatile bases and alkaloids (Ebid, 2016). *L. camara* belongs to family Verbenaceae, possess phenolic, alkaloids and aromatic compounds (Dobhal et al., 2010). *C. papaya* belongs to family Caricaceae. It possess organic acids, alkaloids, tannins and flavonoids (Canini et al., 2007). *P. roxburghii* belongs to family Pinaceae. Pinus needles possess phytochemicals like isopimaric acid, abietic acid, friedelin, car-3-ene, α-pinene, β-pinene, Longifolene, β- sitosterol, cetyl alcohol (Zafar et al., 2010).

Keeping all this in view, the present study was performed to evaluate *Rhazya stricta* Decne, *Lantana camara* L., *Carica papaya* L. and *Pinus roxburghii* Sarg., for their allelopathic activity against major weeds viz. *Phalaris minor, Avena fatua*, *Chenopodium album*, *Euphorbia helioscopia* and *Rumex dentatus*.

Materials and methods

Allelopathic potential of leaves of selected plants viz., *R. stricta*, *P. roxburgii, C. papaya*, *L. camara* was evaluated. Fresh leaves (~400 gm) for each species were collected (73°02' E longitude and 33°36' N latitude) during March-April, 2018. Collected plant material was washed under running tap water and dried at 30 °C in laboratory that was crushed using heavy duty blender to make fine powder (mesh size 2 mm) and preserved in air tight plastic zip lock bags (Ramsumair et al., 2014; Anwar et al., 2016). Seeds of test weeds viz. *Phalaris minor, Avena fatua, Chenopodium album, Euphorbia helioscopia* and *Rumex dentatus* were procured from the Barani Agricultural Research Institute (BARI), Pakistan. Seeds were surface sterilized by 2% solution of Sodium hypochlorite (NaOCl) (Biljana and Kragujevac, 2015). The sandwich method was followed by Fujii et al. (2003, 2004). Five ml of 0.75 percent (w/v) agar (Nalge Nunc Intl., Roskilde, Denmark, gelling temperature 30-31 °C) was poured in each well of the six-welled (10 cm^2 area per well) multi-dish plastic plate. The agar solution was left for solidification. Leaf powder of each test species @ 10 and 50 mg were placed in suitable wells of the plate and were roofed by a thin layer of 0.75 percent (w/v) agar. After solidification, 10 seeds of each test species were placed on agar gel in each well of the plate. The multi-well plastic plates were then wrapped with the plastic tape and incubated in the growth chamber (NTS Model MI-25S) at room temperature for 15 days. In the control treatment, only agar gel without dried leaves powder was used as a seed bed for test species seeds. Each treatment was replicated five times. The same procedure was repeated to screen phytoxic activity of plants using soil (25 gm/petri dish) and filter paper (Whatman filter paper 1) as medium (*Fig. 1*). Germination percentages (%), lengths of radicle and plumule (cm) for each test species were calculated by comparing with control (Anwar et al., 2017). The statistical analysis was carried out using STATISTIX 9 and means were separated by Fisher's protected LSD test (Nekonam et al., 2014).

Figure 1. *Test species seeds in petri dishes ready to be incubated (treated with plant powder and wrapped in aluminium foil)*

Results and discussion

Allelopathic potential of R. stricta

The data revealed that *R. dentatus, C. album* and *P. minor* showed 31%, 28% and 25% seed germination inhibition respectively as compared to control on filter paper, whereas, no significant effect on seed germination percentage of *A. fatua* and *E. Helioscopia* was observed. *R. dentatus*, *C. album* and *P. minor* showed 41%, 38%, and 33% germination inhibition respectively as compared to control in *R. stricta* leaf powder applied into soil. The results declared that maximum (98%) germination was shown by *A. fatua* and *E. Helioscopia* while minimum germination was noted for *R. dentatus* i.e. 69% and 59% on filter paper and soil, respectively. Highest germination reduction was noted for *R. dentatus* (35%), followed by *P. minor* (31%) and *C. album* (30%) at 10 mg conc. Similarly, the highest germination reduction was noted for *R. dentatus* (37%), followed by *P. minor* (32%) and *C. album* (30%) at 50 mg conc. The statistical data concluded that minimum germination was noted for *R. dentatus* i.e. 65% and 63% at 10 mg and at 50 mg conc., respectively. The statistics also recommended that with the increase of concentration, the inhibitory effect was progressively increased for *R. dentatus, C. album* and *P. minor* (*Table 1a*).

The data revealed that *R. dentatus* (41%) and *A. fatua* (38%) exhibited radicle length inhibition in *R. stricta* leaf powder on filter paper, whereas, no significant effect on radicle length of *P. minor, E. helioscopia* and *C. album* showing resistance to dry powder. It is also clear from the result that *R. dentatus* (49%) and *A. fatua* (46%) showed and radicle length inhibition respectively as compared to control in powder applied into soil. The results also declared that maximum (98%) radicle length was noted for *P. minor, E. helioscopia* and *C. album.* In the present study, it was demonstrated that minimum radicle length was noted for *R. dentatus* i.e. 59% and 51% on filter paper and soil, respectively. The experimental results of the current study indicated on agar the highest radicle length reduction was noted for *A. fatua* (40%), followed by *R. dentatus* (39%) at 10 mg conc. Similarly, the highest radicle length reduction was noted for *R. dentatus* (47%), followed by *A. fatua* (46%) at 50 mg conc. The statistical data concluded that minimum radicle length was noted for *A. fatua* i.e. 53% and *R. dentatus* i.e. 60% at 10 mg and at 50 mg conc., respectively (*Table 1b*).

The data revealed that *A. fatua* (32%) and *R. dentatus* (31%) exhibited significant plumule length inhibition in *R. stricta* leaf powder on filter paper, whereas, no

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1268312696

significant effect on plumule length of *P. minor, E. helioscopia* and *C. album* showing resistance to dry powder. It is also clear from the result that *R. dentatus* (34%) and *A. fatua* (33%) showed and plumule length inhibition respectively as compared to control in powder applied into soil. The results also declared that maximum (98%) plumule length was noted for *P. minor, E. helioscopia* and *C. album.* The results of the current study indicated on agar highest plumule length reduction was noted for *A. fatua* (30%) and *R. dentatus* (28%) at 10 mg conc. Similarly, highest plumule length reduction was noted for followed by *R. dentatus* (32%) and *A. fatua* (31%) at 50 mg concentration (*Table 1c*).

It was noted that maximum germination was observed for *A. fatua* and *E. helioscopia*. While minimum germination noticed for *C. album*. The maximum radicle length was noted for *P. minor, E. helioscopia* and *C. album*. While minimum radicle length was noted for *R. dentatus*. The data revealed that the maximum plumule length was observed for *P. minor, E. helioscopia* and *C. album*. Inderjit and Duke (2003) studied the effect of allelochemicals from the leaf powder of *R. stricta* on the weed species. The findings of current study were in accordance with that of Hussain et al. (2011) who noted similar allelopathic effects by other plants. Batish et al. (2002) observed phytotoxicity of *R. stricta* might be due to allelochemicals leached from its leaves in natural environment.

Table 1. *Allelopathic potential of R. stricta leaf powder against tested species on filter paper, soil and agar (a) germination percentage (b) radicle length (c) plumule length*

Allelopathic potential of L. camara

The data revealed that *A. fatua* (60%)*, R. dentatus* (58%), *P. minor* (54%) and *E. helioscopia* (53%) possessed significant germination in *L. camara* leaf powder on filter paper, whereas, no significant effect on germination of *C. album* showing resistance to dry powder. It is also clear from the result that *E. helioscopia* (65%)*, P. minor* (64%)*, A. fatua* (64%) and *R. dentatus* (61%) showed inhibition respectively as compared to control in powder applied into soil. The results also declared that maximum (95%) germination was noted for *C. album.* In the present study, it was demonstrated that minimum germination was noted for *A. fatua* (40%) and *E. helioscopia* (35%) on filter paper and soil, respectively. The experimental results of the current study indicated on agar the highest germination reduction was noted for *E. helioscopia* (59%), followed by *P. minor* (58%), *R. dentatus* (56%) and *A. fatua* (56%) at 10 mg conc. Similarly, the highest germination reduction was noted for *E. helioscopia* (63%), followed by *P. minor* (62%), *A. fatua* (60%) and *R. dentatus* (59%) at 50 mg conc. The statistical data concluded that minimum germination was noted for *E. helioscopia* i.e. 41% and 37% at 10 mg and at 50 mg conc., respectively. The statistics also recommended that with the increase of concentration, the inhibitory effect was progressively increased for *E. helioscopia, P. minor, A. fatua* and *R. dentatus*. The statistical results recommended that the germination percentage *C. album* were completely resistant to dry powder (*Table 2a*).

The data revealed that *C. album*, *P. minor* and *A. fatua* showing 52%, 5% and 50% radicle length inhibition respectively as compared to control in *L. camara* leaf powder on filter paper, whereas, no significant effect on radicle length of *R. dentatus* and *E. helioscopia* showing resistance to dry powder. It is also clear from the result that *C. album, P. minor* and *A. fatua* showed 55%, 53% and 52% radicle length inhibition respectively as compared to control in powder applied into soil. The results also declared that maximum (98%) radicle length was noted for *R. dentatus* and *E. helioscopia.* In the present study, it was demonstrated that minimum radicle length was noted for *C. album* i.e. 48% and 45% on filter paper and soil, respectively. The results of the current study indicated on agar the highest radicle length reduction was noted for *P. minor* (36%), followed by *A. fatua* (33%) and *C. album* (32%) at 10 mg conc. Similarly, the highest radicle length reduction was noted for *C. album* (53%), followed by *P. minor* (51%) *A. fatua* (50%) at 50 mg conc. The statistical data concluded that minimum radicle length was noted for *P. minor* (64%) and *C. album* (37%) at 10 mg and at 50 mg conc., respectively (*Table 2b*).

The data revealed that *E. helioscopia*, *C. album*, *R. dentatus* and *A. fatua* showing 54%, 53%, 51% and 50% plumule length inhibition respectively as compared to control in *L. camara* leaf powder on filter paper, whereas, no significant effect on plumule length of *P. minor* showing resistance to dry powder. It is also clear from the result that *E. helioscopia, C. album, A. fatua* and *R. dentatus* showed 64%, 61%, 59% and 56% plumule length inhibition respectively as compared to control in powder applied into soil. The results also declared that maximum (98%) plumule length was noted for *P. minor.* In the present study, it was demonstrated that minimum plumule length was noted for *E. helioscopia* i.e. 46% and 36% on filter paper and soil, respectively. The experimental results of the current study indicated on agar the highest plumule length reduction was noted for *R. dentatus* (43%), followed by *E. helioscopia* (42%), *C. album* (42%) and *A. fatua* (37%) at 10 mg conc. Similarly, the highest plumule length reduction was noted for *C. album* (59%), followed by *E. helioscopia* (57%), *A. fatua*

(56%) and *R. dentatus* (55%) at 50 mg conc. The statistical data concluded that minimum plumule length was noted for *R. dentatus* (67%) and *C. album* (41%) at 10 mg and at 50 mg conc., respectively (*Table 2c*).

Table 2. *Allelopathic potential of L. camara leaf powder against tested species on filter paper, soil and agar (a) germination percentage (b) radicle length (c) plumule length*

(a) Germination percentage (%)		***A. fatua***	***R. dentatus***	***P. minor***	***E. helioscopia***	***C. album***

	Control	8.05	9.21	10.6	7.13	10.2

It was detected that maximum germination was observed for *C. album*. The analysis further indicated that minimum germination was noted for *A. fatua* and *E. helioscopia* on filter paper and soil being most sensitive to *L. camara* leaf powder. It was detected that maximum radicle length was observed for *R. dentatus* and *E. helioscopia*. The analysis further indicated that minimum radicle length was noted for *C. album* showed being most sensitive to *L. camara* leaf powder. It was detected that maximum plumule length was observed for *P. minor.* The analysis further indicated that minimum plumule length was noted for *E. helioscopia* showed being most sensitive among all the test species. The leaf powder of *L. camara* had inhibitory potential on germination, radicle and plumule length of radish and lettuce (Qiaoying et al., 2009). The leaf powder of *L. camara* suppressed the seed germination and plumule elongation of *P. hysterophorus* (Mishra and Singh, 2012). Das et al. (2012) also noticed inhibition linked with the production of allelochemicals from the *L. camara* leaves that inhibit growth of adjacent

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1268312696

plants by outcompeting for soil nutrients and altering micro environment by forming dense thickets. Allelopathy is a form of plant interference that can significantly influence ecosystem and agro ecosystem dynamics (Michelangelo et al., 2016).

Allelopathic potential of C. papaya

The data revealed that *A. fatua, P. minor* and *E. helioscopia* showing 39%, 38% and 33% germination inhibition respectively as compared to control in *C. papaya* leaf powder on filter paper, whereas, no significant effect on germination of *R. dentatus* and *C. album* showing resistance to dry powder. It is also clear from the result that *E. helioscopia, P. minor* and *A. fatua* showed 51%, 49% and 47% germination inhibition respectively as compared to control in powder applied into soil. The results also declared that maximum (98%) germination was noted for *R. dentatus* and *C. album.* In the present study, it was demonstrated that minimum germination was noted for *A. fatua* (61%) and *E. helioscopia* (49%) on filter paper and soil, respectively. The experimental results of the current study indicated on agar the highest germination reduction was noted for *P. minor* (41%), followed by *A. fatua* (38%) and *E. helioscopia* (36%) at 10 mg conc. Similarly, the highest germination reduction was noted for *A. fatua* (51%), followed by *P. minor* (49%) and *E. helioscopia* (47%) at 50 mg conc. The statistical data concluded that minimum germination was noted for *P. minor* (59%) and *A. fatua* (49%) at 10 mg and at 50 mg conc., respectively. The statistics also recommended that with the increase of concentration, the inhibitory effect was progressively increased for *A. fatua, P. minor* and *E. helioscopia*. The statistical results recommended that the germination *R. dentatus* and *C. album* were completely resistant (*Table 3a*).

The data revealed that *P. minor* and *R. dentatus* showing 51%, 41% and 30% radicle length inhibition respectively as compared to control in *C. papaya* leaf powder on filter paper, whereas, no significant effect on radicle length of *C. album, A. fatua* and *E. helioscopia* showing resistance to dry powder. It is also clear from the result that*, R. dentatus* and *P. minor* showed 55%, 41% and 35% radicle length inhibition respectively as compared to control in powder applied into soil. The results also declared that maximum (98%) radicle length was noted for *C. album, A. fatua* and *E. helioscopia.* The experimental results of the current study indicated on agar the highest radicle length reduction was noted for *P. minor* (35%) and *R. dentatus* (31%) at 10 mg conc. Similarly, the highest radicle length reduction was noted for *P. minor* (45%) and *R. dentatus* (42%) at 50 mg concentration (*Table 3b*).

The data revealed that *P. minor* (31%) and *C. album* (30%) showing plumule length inhibition as compared to control in *C. papaya* leaf powder on filter paper, whereas, no significant effect on plumule length of *A. fatua, R. dentatus* and *E. helioscopia* showing resistance to dry powder. It is also clear from the result that *C. album* and *P. minor* showed 45% and 33% plumule length inhibition respectively as compared to control in powder applied into soil. The results also declared that maximum (96%) plumule length was noted for *A. fatua, R. dentatus* and *E. helioscopia.* In the present study, it was demonstrated that minimum plumule length was noted for *P. minor* (69%) and *C. album* (55%) on filter paper and soil, respectively. The experimental results of the current study indicated on agar the highest plumule length reduction was noted for *C. album* (41%), followed by *P. minor* (30%) at 10 mg conc. Similarly, the highest plumule length reduction was noted for *C. album* (50%), followed by *P. minor* (43%) at 50 mg conc. The statistical data concluded that minimum plumule length was noted for *C. album* i.e. 59% and 50% at 10 mg and at 50 mg conc., respectively (*Table 3c*).

	Control	8.25	7.45	8.39	7.85	8.06

It was detected that maximum germination was observed for *R. dentatus* and *C. album*. The analysis further indicated that minimum germination was noted for *A. fatua* and *E. helioscopia* on filter paper and soil, being most sensitive to *C. papaya* leaf powder. It was detected that maximum radicle length was observed for *C. album, A. fatua* and *E. helioscopia*. Similar, results were obtained in bioassays with lettuce seeds (Gherardi and Valio, 1976; Chow and Lin, 1991) and by Reyes et al. (1980) with cucumber seeds. Chow and Lin (1991) used extracts of papaya, which showed that there is a higher concentration of inhibitors in the sarcotesta, canceling the germination of lettuce seeds, which had already been observed by Gherardi and Valio (1976). They excluded the possibility that the germination inhibitor present in the sarcophagus of papaya seeds was abscisic acid, stating that such inhibitors are phenolic in nature.

Allelopathic potential of P. roxburghii

The data revealed that *C. album* and *A. fatua* showing 52%, 47% and 44% germination inhibition respectively as compared to control in *P. roxburghii* needles

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1268312696

powder on filter paper while on soil *C. album* and *A. fatua* showing 55%, 48% and 46% germination inhibition, whereas, no significant effect on germination of *R. dentatus, P. minor* and *E. helioscopia* showing resistance to dry powder. The results also declared that maximum (97%) germination was noted for *R. dentatus, P. minor* and *E. helioscopia.* The experimental results of the current study indicated on agar the highest germination reduction was noted for *C. album* (36%) and *A. fatua* (35%) at 10 mg conc. Similarly, the highest germination reduction was noted for *C. album* (48%) and *A. fatua* (43%) at 50 mg conc. The statistics also recommended that with the increase of concentration, the inhibitory effect was progressively increased for *C. album* and *A. fatua*. The statistical results recommended that the germination of *P. minor, E. helioscopia* and *R. dentatus* were completely resistant to dry powder (*Table 4a*).

The data revealed that *C. album* and *R. dentatus* showing 35% and 32% radicle length inhibition respectively as compared to control in *P. roxburghii* needles powder on filter paper, whereas, no significant effect on radicle length of *A. fatua, P. minor* and *E. helioscopia* showing resistance to dry powder. It is also clear from the result that *C. album* and *R. dentatus* showed 45% and 42% radicle length inhibition respectively as compared to control in powder applied into soil. The results also declared that maximum (96%) radicle length was noted for *A. fatua, P. minor* and *E. helioscopia.* In the present study, it was demonstrated that minimum radicle length was noted for *C. album* i.e. 65% and 55% on filter paper and soil, respectively. The experimental results of the current study indicated on agar the highest radicle length reduction was noted for *R. dentatus* (35%), followed by *C. album* (34%) at 10 mg conc. Similarly, the highest radicle length reduction was noted for *R. dentatus* (41%), followed by *C. album* (36%) at 50 mg conc. The statistical data concluded that minimum radicle length was noted for *R. dentatus* i.e. 65% and 59% at 10 mg and at 50 mg conc., respectively (*Table 4b*).

The data revealed that *A. fatua* (39%) and *R. dentatus* (37%) showing plumule length inhibition respectively as compared to control in *P. roxburghii* needles powder on filter paper, whereas, no significant effect on plumule length of *C. album*, *E. helioscopia* and *P. minor* showing resistance to dry powder. It is also clear from the result that *R. dentatus* (49%) and *A. fatua* (46%) showed and plumule length inhibition respectively as compared to control in powder applied into soil. The results also declared that maximum (95%) plumule length was noted for *C. album*, *E. helioscopia* and *P. minor.* In the present study, it was demonstrated that minimum plumule length was noted for *A. fatua* (61%) and *R. dentatus* (51%) on filter paper and soil, respectively. The results of the current study indicated on agar the highest plumule length reduction was noted for *R. dentatus* (42%), followed by *A. fatua* (40%) at 10 mg conc. Similarly, the highest plumule length reduction was noted for *R. dentatus* (49%), followed by *A. fatua* (44%) at 50 mg conc. The statistical data concluded that minimum plumule length was noted for *R. dentatus* measuring 68% and 61% at 10 mg and at 50 mg conc., respectively (*Table 4c*). The data attained from statistical analysis revealed that maximum germination was observed for *R. dentatus, P. minor* and *E. helioscopia.* The data attained from statistical analysis revealed that maximum radicle length was observed for *A. fatua, P. minor* and *E. helioscopia*. In the present study it was demonstrated that radicle length was noted for *C. album*. It was noted that maximum plumule length was observed for *C. album*, *E. helioscopia* and *P. minor.* In the present study it was demonstrated that minimum plumule length was noted for *A. fatua* and *R. dentatus* on filter and soil respectively. Blum (1998) observed that *P. divaricata* and *P. resinosa* needles leachates suggestively checked seedling growth and germination of *Epilobium*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1268312696

angustifolium, Agropyron repens and *Phleum pretense. The* seedling growth of *Lepidium virginicum* was significantly checked by *P. roxburghii* needles (Williams and Hoagland, 1982). The mechanism of retardation on the seedling growth produced by phytochemicals checked cell elongation and division (Node et al., 2003). Similarly, *P. densiflora* cones have high biological activity against select plant species (Lee and Monsi, 1963).

Some recent studies indicating the phytotoxic/allelopathic effect of weeds include Parthenium hysterophorus (Saranya et al., 2019), Brassica napus (Rodriguez et al., 2016), Raphanus raphanistrum (Ali, 2016) and Ageratum conyzoides (Kumar et al., 2018). All these studies indicate the release of phototoxic chemicals. Based on this, studies were further extended to explore the impact of selected species, as they possessed greater phytotoxicity on the emergence and growth of weed plants in wheat crop.

Conclusions

Present results indicated that water leachates from leaves of selected plants at higher concentrations reduce the seed germination, radicle and plumule length of weeds associated with the wheat crop. Results provided evidence about herbicidal potential of tested plant species viz. *L. camara*, *P. roxburghhii* and *C. Papaya* against weeds of wheat crop (*Avena fatua, Phalaris minor, Chenopodium album* and *Rumex dentatus*) while *R. stricta* was proved non-promising in the case as it affected growth parameters of wheat as well. Since *L. camara*, *P. roxburghhii* and *C. Papaya* inhibited growth of weeds without affecting wheat, the study seems effective than the other ones published in previous literature. Further work is, however, recommended to appraise the potential inhibitory effects of allelochemicals from the these plants in field.

(Received 29th Mar 2019; accepted 2nd Jul 2019)

Abstract. *Berberis baluchistanica* Ahrendt is an endemic species to Pakistan belonged to Berberidaceae family. Its ripened fruit is collected by the natives and consumed as wild fruit. The present study aimed at evaluating nutritional and phytochemical potential of wild fruits of *B. baluchistanica*. The proximate analysis revealed that the fruit possessed highest proportion of dry matter (92%), followed by crude fibre (35%), moisture content (8%), crude protein (7%) and crude fat (6.3%), while total ash percentage was the least (3.5%). Mineral analysis indicated that iron (Fe) was found in the highest quantity (3.835%), followed by zinc (1.039%), copper (0.851%), manganese (0.764%), potassium (0.101%), while the sodium was in least amount. This study further determined five major phytochemical compounds such as alkaloids, flavonoids, phenols, tannins and saponins trough six solvent extracts. Alkaloids were detected by all solvents, except the aqueous extract. Phenols and tannins were detected by three solvent extracts. Flavonoids were isolated by two solvent extracts, while, saponins were only detected by the aqueous extract. Based on results, it can be concluded that the investigated fruit has great potential owing to substantial quantity of essential nutrients, minerals and phytochemicals and requires further detailed investigation prior to commercial production and introduction in the market.
Keywords: *commercial production, essential nutrients, mineral analysis, phytochemical compounds, solvent extracts*

Introduction

It is an established fact that use of fruits may improve the rate of human health Nwachukwu et al. (2010). Fruits provide nutrients including minerals, vitamins, antioxidants, polyphenols, etc. (Sher et al., 2003). Furthermore, fruits and vegetables possess fairly low calories, high dietary fibre and beneficial to human health (Khalil et al., 2013). These further aid in maintaining healthy weight and decrease the risk of numerous persistent illness Nwachukwu et al. (2010), like cardiovascular disorders, diabetes cancers, etc.

Pakistan has moderate diversity in ecological zones having range of plants. Since majority of the human population is residing in rural areas, so they are facing food insecurity and malnutrition. According to Chakraborty and Newton (2007), if the food with high nutritive value is safe, accessible, affordable and available for the reasonable population can form food security. During certain period of time, several food crops may turn into limited and expensive either during planting season or famine particularly for low income earners. Such consequences experience malnutrition and poor health. Owing to such issues, scientists are looking into screening the wild edible fruit which may have latent to balance staple food.

Berberis baluchistanica Ahrendt, locally known as *Tor Zaralag* (Pashto) is an endemic to Pakistan belonged to Berberidaceae family. It is evergreen shrub up to 3 m tall with red to red-brown stem (*Fig. 1*). Leaves are thick, rigid, sub-orbicular to obovate-oblong, sessile to sub-sessile Flowers are approximately 7-10 mm across, yellow. Fruits are berries with ovoid to suborbicular shaped, dark red turned to black and pruinose blue. Its ripened fruit is collected by the natives and consumed as wild fruit. The decoction of roots has been reported in treating cough, infection and internal injury of human being as well animals (Ghafoor, 2002). Previously Abbasi et al. (2013) carried out antioxidant potential of leaves of *Berberis baluchistanica*. The present study aimed at evaluating nutritional, phytochemical and antioxidant potential of wild fruits of *B. baluchistanica*.

Figure 1. *The habit of Berberis baluchistanica*

Materials and methods

Location and area

Ziarat district is located at 30° 22′ 51 N and 67° 43′ 37 E at an altitude of 2453 m (8050 ft) in the north Balochistan province, Pakistan (*Fig. 2*). Khilafat Hills are the highest peak with an altitude of 11.400 ft (3.475 m) in Ziarat district. Ziarat District has the highest Human Development Index of all districts in Balochistan (District Profile Ziarat, 1997). This district is famous for its antique and splendid juniper forest which spreads over 126,000 acres and is the second largest in the world. Some of the trees are almost 4,000 years old (Anonymous, 2019).

Climate

The climate of the study area is mostly dry temperate characterized by excessive cold during the winter season and refreshingly cool and pleasant in summer. Snow mostly falls during December to March. Mean annual precipitation is about 282 mm/year, mainly received during winter in the form of snow. Some showers also occur in July and August. Temperature extremes are characteristics feature of the area with mean maximum temperature of 28 °C recorded in July and August and mean minimum temperature of -9 °C in January. The highest average relative humidity (67%) was recorded in December, while the lowest (23%) in October (Ahmed et al., 1990).

Collection and identification of plant material

The ripened fruits (1 kg) of *Berberis baluchistanica* Ahrendt were collected from the growing localities of Ziarat, Baluchistan during September to October, 2017 (*Table 1*). One set of voucher specimens of the species were prepared and identified by Dr. Rasool Bakhsh Tareen, Department of Botany, University of Baluchistan, Quetta. The determined specimens were deposited in the herbarium of Baluchistan University for record.

Table 1. *Collection of fruits and plant specimens of B. baluchistanica from different growing localities of District Ziarat, Balochistan, Pakistan*

S. No.	Locality	Longitude	Latitude	Elevation (m)
1	Ahmadun	30° 29′ 07.58″	67° 22′ 48.35″	2100
2	Zargi	30° 30′ 12.99″	67° 41′ 18.99″	2350
3	Zezri	30° 19′ 40.00″	67° 42′ 00.00″	2500

Ethnobotanical investigation

The traditional knowledge of *Berberis baluchistanica* was collected by using semi-structured questionnaire following the work of Qureshi (2004) and Qureshi and Bhatti (2008). Regular field trips were arranged in order to collect information about the folk knowledge of plants.

Proximate and mineral analysis

The proximate analysis was carried out from the dried powdered sample by using standard method (AOAC, 2005). The powdered samples were analyzed for proteins, fat,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1269712707

carbohydrates, moisture and ash. The mineral composition was analyzed by using Atomic Absorption Spectrophotometer (Agilent Technologies Model No. 200 series) in the department of Botany, Pir Mehr Ali Shah Arid Agriculture University, Rawalpindi, Pakistan. For statistical analysis, standard error was determined from the triplicates readings.

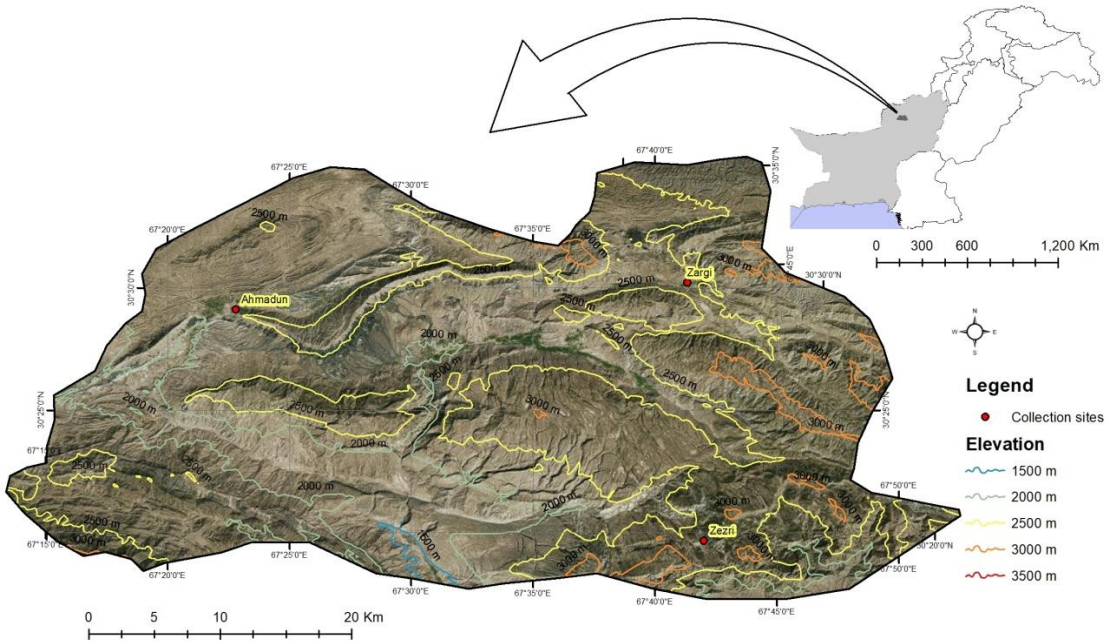

Figure 2. *Location map of the study area and collection sites of the plant material*

Preparation of fruit extract

The collected fruits were thoroughly rinsed with tap water and dried under shade. These were powdered to fine powder (80 mesh) by using grinder (Model No. MX1100XT21CE) and preserved in airtight bottle and kept in refrigerator. The powder was soaked in six solvents such as acetone, aqueous, Ethyl acetate, methanol, n-hexane and petroleum ether. The same was then shaken at 37 °C for 24 h. The same were subsequently sieved using Whatman filter paper (No. l) and then concentrated on reduced pressure at 40 °C by employing rotary evaporator (Rahim et al., 2013). These extracts were used the phytochemicals screening.

Determination of yield extracts

The crude extracts yield percentage was carried out by using following formula after Dellavalle et al. (2011) and Rahim et al. (2013):

$$Yield\ \% = \frac{\text{Weight of lyophilized extract}}{\text{Weight of dried fruit}} \times 100 \qquad \text{(Eq.1)}$$

Assay for phytochemicals screening

The chemical assays were carried out from six different solvents based fruit extracts of the *Berberis baluchistanica* by using standard protocols for the detection of phytochemicals after Egwaikhide and Gimba (2007).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1269712707

Analysis for alkaloids

The 0.2 mg fruit extract was warmed in 2% sulphuric acid for 2 min. The filtrate was mixed in few drops of Dragendorff's reagent**.** The appearance of orange red precipitate confirmed the presence of alkaloids (Egwaikhide and Gimba, 2007; Rahim et al., 2013).

Analysis for tannins

A small quantity of fruit extract was liquefied in water and heated on water bath. Then it was filtered and few drops of ferric chloride were poured in it. The emergence of dark green colour revealed the occurrence of tannins in the sample (Egwaikhide and Gimba, 2007).

Analysis for saponins

The 0.2 g extract was forcefully shaken in 5 ml of distilled water and boiled. The occurrence of bubble supposed to the presence of saponins (Egwaikhide and Gimba, 2007).

Analysis for flavonoids

The 0.2 g fruit extract was combined with diluted sodium hydroxide and few drops of hydrochloric acid were poured in it. This solution converted first into yellow colour and then colourless within few minutes. Such reactions indicated the presence of flavonoids in the test sample (Egwaikhide and Gimba, 2007).

Analysis for phenolic compounds

This test has two parts. In first part, 50 mg of each solvent extract was added with 5 ml distilled water and vigorously shaken for a minute. Then, five drops of 5% ferric chloride solution were supplemented. This mixture was resulted into dark green colour known as ferric chloride test. In the other test, 300 ml of distilled water were added to 50 mg of each solvent extract and shaken for a while. Then 3 ml of 10% lead acetate were poured. The appearance of white precipitates in the resultant mixture showed the presence of phenolic compounds (Munazir et al., 2015).

Results

Traditional uses

The leaves and branches are dried and made into powder and is then dusted upon the injury and wounds to heal. Once sheep of hill was fired and after some time that sheep was observed under shadow of *Berberis baluchistanica* with repaired injury revealing that the injury was repaired by eating of the leaves of this plant. Wild fruits are collected by the local communities and eaten as nutritional as well as iron supplement.

Extract yield

Different solvent based extracts showed range of ratios in terms of extract yield and quantity (*Fig. 3*). The maximum amount of the extract yield was obtained by methanol (12.95%). It was followed by water (6.7%), ethyl acetate (1.8%), acetone (1.15%), while n-hexane and petroleum ether yielded less quantity (*Fig. 3*).

DOI: http://dx.doi.org/10.15666/aeer/1706_1269712707

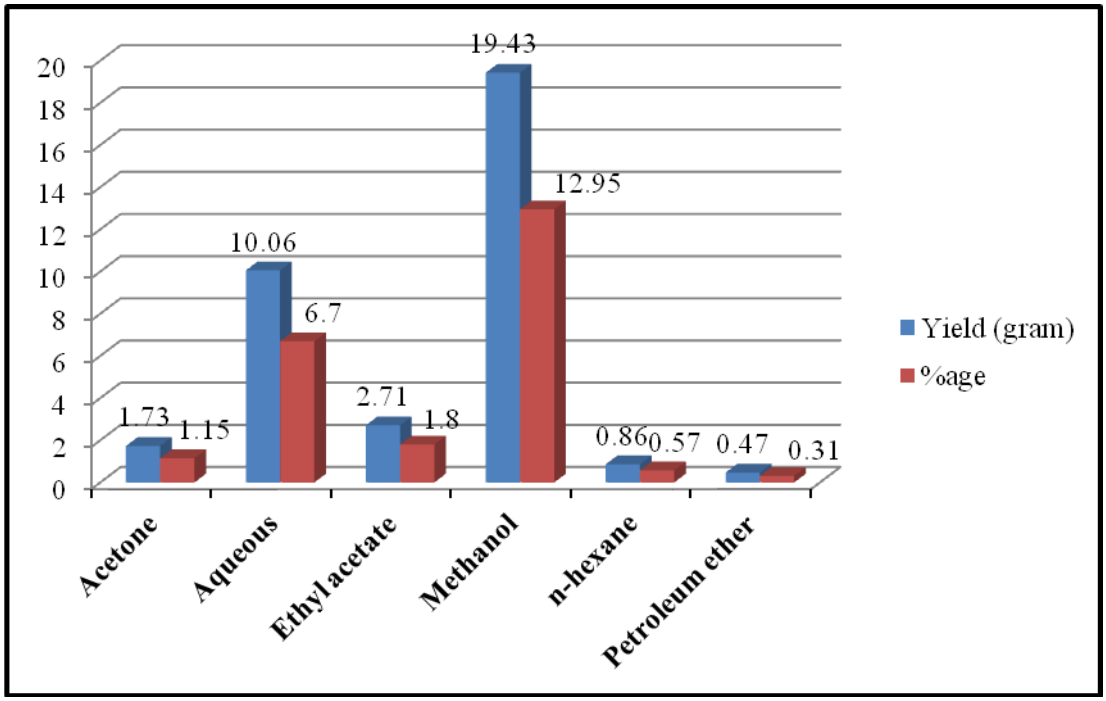

Figure 3. *Yielding potential of various solvent based extracts from B. baluchistanica*

Proximate and mineral composition

The proximate analysis of wild fruits of *Berberis baluchistanica* (Berberidaceae) was carried out and the data is provided in *Figure 4*. The data showed that the fruit possesses the highest proportion of dry matter (92%), followed by crude fibre (35%), moisture content (8%), crude protein (7%), crude fat (6.3%), while total ash percentage was the least (3.5%). It is apprising that the fruit retains an appreciable amount of all the beneficial elements. Iron (Fe) was found in the highest quantity (3.835%), followed by zinc (1.039%), copper (0.851%), manganese (0.764%), potassium (0.101%), while the sodium was in lesser amount (0.009%). The Na/K ratio was found as 0.089 in the fruit (*Fig. 5*).

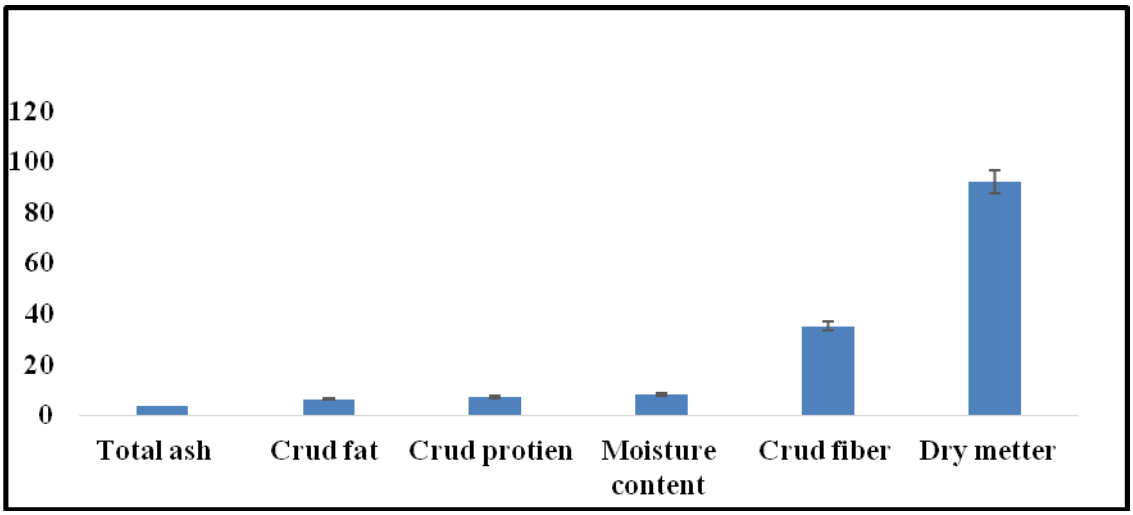

Figure 4. *Graphical presentation of proximate analysis of B. baluchistanica*

DOI: http://dx.doi.org/10.15666/aeer/1706_1269712707

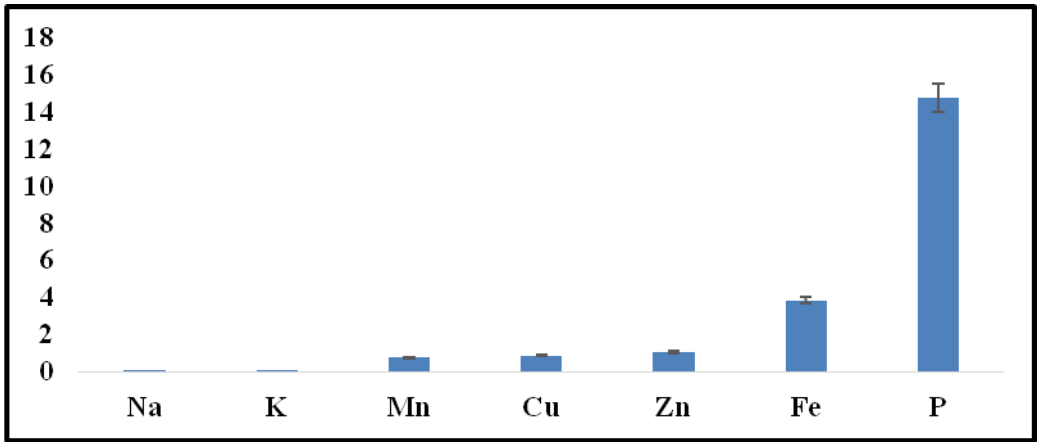

Figure 5. *Graphical presentation of mineral analysis of B. baluchistanica*

Qualitative phytochemical screening

The fruits of *Berberis baluchistanica* were screened for five major phytochemical classes namely alkaloids, flavonoids, phenols, saponins and tannins from six polarity based solvent extracts such as acetone, aqueous, ethyl acetate, methanol, n-hexane and petroleum ether. All the tested phytochemical classes were detected by various solvent extracts. Results of screening have been tabulated and shown in *Figure 6*.

In all, acetone and petroleum ether detected three groups of phytochemicals, while rest of the solvents such as aqueous, ethyl acetate, methanol and n-hexane screened two phytochemicals (*Fig. 6*). Alkaloids were detected by all solvents, except the aqueous extract. Saponins were only detected by the aqueous extract. Tannins were detected by three solvent extracts such as acetone, aqueous and ethyl acetate. The phenols were isolated by three solvent extracts like acetone, methanol and petroleum ether. In the case of flavonoids, it was detected by both the non-polar solvents i.e. n-hexane and petroleum ether.

Discussion

Due to food insecurity issues, indigenous wild fruits may alleviate nutrition deficiency especially in the case Pakistan being developing country. In order to test this hypothesis, the present research work was undertaken to investigate nutritional composition and phytochemical screening of wild fruit of *Berberis baluchistanica*.

The proximate and mineral analyses were carried out by employing the methodology of the Association of Official Analytical Chemists (AOAC, 2005). The results are shown in *Table 1*. It is apprising that the fruit retains an appreciable amount of nutritional and beneficial elements. The data showed that the fruit possesses the highest proportion of dry matter (92%), followed by crude fibre (35%), moisture content (8%), crude protein (7%), crude fat (6.3%) and ash content.

Protein is a vital to diet and deficient of it results in causing various diseases. Foods over its 12% calorific values obtained from proteins are considered good source from plants (Pearson, 1976). This study revealed that wild fruit of *Berberis baluchistanica* possessed good amount of protein. The species possessed values higher than the reported species by Abbasi (2013) such as *Prunus domestica, Grewia optiva, Juglans regia, Morus nigra*, etc. The fruit is also contained 6.3% crude fat from *Berberis baluchistanica* which would be a good source of lipids.

The crude fibre contents were richly found in the fruits of *Berberis baluchistanica* (35%). According to Ishida et al. (2000), taking fibre regularly can lower the jeopardy of cardiovascular disease including hypertension and diabetes as well as colon and breast cancer. The present results clearly indicated that the investigated wild fruits possessed higher values of dietary fibres that can mitigate human malnutrition.

It is worthwhile to mention that the moisture content was comparatively low in the tested fruit which may be due to drier conditions of soils. *B. baluchistanica* is growing in harsh climatic conditions such as poor in soil nutrition and less availability of moisture in hilly areas. Such conditions resulted in retaining lesser amount of moisture contents. It is evident from the results that the moisture content of the investigate fruit is low contrasting to that of *Xylopia aethiopia* (16.04) reported by Abolaji et al. (2007) and *Acalypha hispida* (11.91) by Iniaghe et al. (2009). Such results indicate that low moisture content is excellent for the long-term safeguarding from spoilage.

The ash content shows the presence of mineral contents in plant samples (Mammen et al., 2010). The fruits of *B. baluchistanica* possessed 3.5% total ash content (*Table 1*). Abbasi (2013) reported low values of ash contents from traditional fruits. Summarizing the results of proximate analysis, it is evident from the results that the investigated wild fruit possess nutritional component and can be used a good source nutrition. According to the literature, the values of proximate composition of the evaluated wild fruits were either higher or at par with the previous studies (Imran et al., 2007, 2010). The variations in values might be due to varied climates, soils, seasonal collection, nutrients uptake by plant species, etc.

Iron (Fe) was found in the highest quantity (3.835%), followed by zinc (1.039%), copper (0.851%), manganese (0.764%), potassium (0.101%), while the sodium was in lesser amount (0.009%). Our results far high as reported by Gani et al. (2018) who showed the data of various important fruits such as cherry. According to Davis et al. (2004), the mineral contents may be lower due to change of cultivars chosen for yield, rapid growth, pest resistance, herbivore resistance, etc. They are also in opinion that soil types and climate may also affect nutrient composition in food plants.

This study was carried out to screen chief phytochemicals such as alkaloids, flavonoids, phenols, saponins and tannins from six polarity based solvent extracts of wild fruits of *Berberis baluchistanica*. The selected phytochemicals were detected by various solvent extracts (*Fig. 6*). Alkaloids were detected by all solvents, except the aqueous extract. All these phytochemicals are well known to have curative properties (Rabe, 2000). Among them, alkaloids are accounted as the chief therapeutic agent (Njoku and Akumefula, 2007).

Flavonoids are group of natural antioxidants which play an important role in combating the jeopardy of deteriorating cells (Okwu and Okwu, 2004). Plants may produce these compounds to mitigate microbial infection (Dixon et al., 1983). The present study detected flavonoids from n-hexane and petroleum ether. This is the important and copious group of phytochemicals present in many medicinal plants (Singh et al., 2007) which is responsible in reducing carcinogenic development, possesses anticancer and antimicrobial (Okwu, 2004; Lewis and Elvin-Lewis, 1995) and anti-inflammatory activities (Cushnie and Lamb, 2005).

From this study, tannins were detected by acetone, aqueous and ethyl acetate. This group is believed to hold anti-diarrheal, anti-fungal, anti-hemorrhoidal and anti-oxidant properties (Asquith and Butter, 1986). Besides, this compound possesses a bitter principle of drinks and foods (Chikezie et al., 2008).

The present study revealed the presence of saponins which was detected by the aqueous extract only. These secondary metabolites hold anti-inflammatory effect (Just et al., 1998) and also responsible in coagulating red blood cells that include development of foams in water solutions, haemolytic activity, cholesterol binding properties and bitterness (Trease and Evans, 1985; Lewis and Elvin-Lewis, 1995; Okwu, 2004).

Conclusion

This study revealed that the wild fruits of *B. baluchistanica* hold substantial quantity of essential nutrients such as protein, fibre, carbohydrates, fats, iron, zinc, copper, manganese, potassium and various important phytochemicals. This fruit is locally consumed by the natives and requires further investigation prior to commercial production and introduction in the market. Such kind of fruit supplement will help to meet the dietary requirement and improve the malnutrition problem in the country. Besides, presence of various secondary metabolites in the fruit also requires thorough investigation which may be used as plant based antimicrobial and antioxidant molecules.

Abstract. Ants (Hymenoptera: Formicidae) are a diverse and abundant part of soil fauna with the ability to maintain and restore soil quality and to increase crop yields in agroecosystems. Some ant species are sensitive to land management, which makes them good bioindicators of soil function in land use management and conservation throughout the world. In Croatia, ants are understudied and they were never sampled on agricultural crops. In this study, we used pitfall traps to collect ants on three different land use types: annual crops, perennial crops, and semi-natural habitats. We found 12 ant species, out of which one species, *Tetramorium atratulum* (Schenck, 1852), is a new record for Croatia. We observed significantly lower ant abundance on annual crops than on both perennial crops and semi-natural habitats. Similarly, ant richness and diversity were lowest on annual crops, although this difference was not statistically significant. Our results contribute to the increasing evidence that intensive agricultural practices, particularly soil tillage, are detrimental to the arthropod diversity. The transition to sustainable agriculture will require utilizing the ecosystem services of naturally occurring insects, such as ants.
Keywords: *Formicidae, Tetramorium atratulum, sustainable agriculture, CAP, bioindicators, reduced tillage*

Introduction

Agricultural intensification across Europe has a severe impact on the environment, mainly through pesticide and nitrate pollution, soil erosion, loss of habitats, and simplification of animal and plant communities, all of which leads to the decline and extinction of wildlife (Skinner et al., 1997; Stoate et al., 2001; Schweiger et al., 2005; German et al., 2017). With additional pressures of human population growth and climate change (Piao et al., 2010; Myers et al., 2014) the intensive, industrial-scale crop production has become unsustainable, and the need is recognized for a transition to agroecological farming systems. Traditional farming, organic farming, and conservation agriculture all tend to govern management by ecological principles, to decrease the environmental impact, and to increase the nutritional value of the produced food (Hobbs et al., 2008; Reganold and Wachter, 2016; German et al., 2017). One of the important goals of agroecology is the efficient utilization of ecosystem services of naturally occurring organisms, in particular insects and other invertebrates (Lavelle et al., 2006). This includes using diversity and abundance of soil fauna as indicators of soil quality, integrated pest management, and incorporating agricultural practices that support the

DOI: http://dx.doi.org/10.15666/aeer/1706_1270912722

biodiversity of soil organisms, which are crucial for soil health (Power, 2010; Sanabria et al., 2014; Furlan et al., 2017).

Ants (Hymenoptera: fam. Formicidae) are ubiquitous, diverse, and dominant terrestrial insects (Holldobler and Wilson, 1990). Majority of ant species nest in soil, and have a well-documented impact on its biological, physical, and chemical properties (Stadler et al., 2006; Frouz and Jilková, 2008; Dorn, 2014; Farji-Brener and Werenkraut, 2017). By creating micropores ants aerate the soil and increase its water absorption, bring in minerals and nutrients (Lobry De Bruyn, 1999; Evans et al., 2011), improve soil fertility (Farji-Brener and Werenkraut, 2017), and ant nests are an important resource for other organisms. The vicinity of ant nests has 30 fold higher density of microarthropods, five-fold higher density of protozoa, and significantly higher mineralization rates (Lobry De Bruyn, 1999; Wagner et al., 2004). Large-scale exclusion experiments on ants in agricultural systems show that ants have a positive net influence (up to 50%) on crop yield, as they increase soil porosity and moisture; nitrogen, carbon and phosphorus content, microorganism biomass, and decrease pest populations (Evans et al., 2011; Wielgoss et al., 2013; Gras et al., 2016; Shukla et al., 2016).

Additionally, ants can be used as bioindicators of soil quality in land management (Read and Andersen, 2000; Andersen et al., 2002; Sanabria et al., 2014). Ants, in general, respond rapidly to environmental changes, they are abundant and easy to sample, and some species have specific ecological requirements (Dufrêne and Legendre, 1997; Lobry De Bruyn, 1999; Underwood and Fisher, 2006; Sanabria et al., 2014). The practice of using ants as tools in land management is more common in tropical and subtropical than in temperate agroecosystems (Dufrêne and Legendre, 1997; Lobry De Bruyn, 1999; Underwood and Fisher, 2006; Sanabria et al., 2014). Several studies in Europe show potential for using ants in land management. In Italy and France ants were good bioindicators of organic farming (Masoni et al., 2017) and environmentally safe soil amendment treatments (Castracani et al., 2015), as well as a useful tool in conservation, e.g. as indicators of restoration processes (Ottonetti et al., 2006).

Ant research has been relatively neglected in Croatia (Bračko, 2006). The national ant survey was never conducted, and collections focus on a series of small scale inventory studies in protected areas (Ješovnik et al., 2011; Ješovnik and Pečarevič, 2018). Ants were never investigated in the context of agricultural habitats in Croatia, unlike other arthropods, e.g., carabid beetles (Lemić et al., 2016, 2017; Pajač Živković et al., 2016). In this study, we investigate ant fauna associated with agricultural habitats in Croatia, determine which species are associated with intensive agriculture, and test whether ant species richness, abundance, diversity, and community composition differ between annual and perennial crops. We predict that agricultural intensity would negatively affect the abundance, richness, and diversity of ants.

Materials and methods

Study site and data collection

We conducted the fieldwork in Zagreb, Croatia (45°49′N 15°59′E, altitude 145 meters), on experimental fields of Faculty of Agriculture and surrounding semi-natural habitats. Zagreb has a temperate continental climate modified by the maritime influence of the Mediterranean and under the local influence of Mount Medvednica (Zaninović et al., 2008). Based on the last comprehensive review of Croatian ants Zagreb has 23 ant species (Bračko, 2006).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1270912722

We sampled ants on three plots per each land use type (nine plots total): on annual crops (potato, soy, corn), perennial crops (two apple orchards and vineyard), and on non-agricultural habitats as a control (three semi-natural habitats: meadow, meadow next to the forest edge, park-forest). Each plot was 25 x 11 meters in size. The annual crop fields were the most intensive agricultural management regime in our study, with standard and deep soil tillage and pre-planting soil preparation in autumn. The perennial plots represented the intermediate management regime, with no tillage or any other mechanical soil manipulation, and with mowing as only cultivation technique. Both annual and perennial crops had a variable degree of fertilization and insecticide use (details in *Table 1*). Sampled semi-natural habitats had no soil management regime, no fertilizer was used, and the mowing was the only cultivation regime. Semi-natural habitats were chosen to represent the gradation from open to closed habitats, and to be as natural as possible considering their location in the urban area. All plots were located on the University of Agriculture campus or adjacent to it (*Fig. 1*).

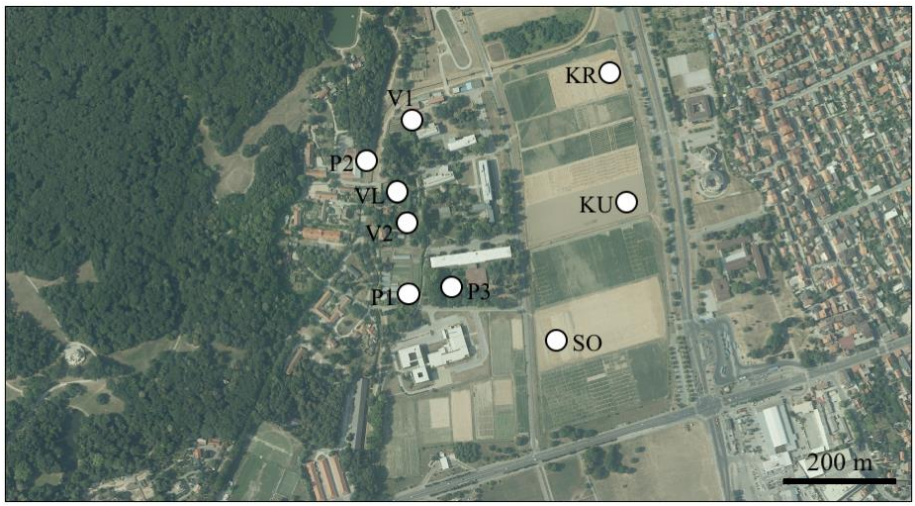

Figure 1. *Map with localities of sampling plots (P1, P2, P3 – control; V1, V2, VL – perennial; KR, KU, SO – annual plots) in Zagreb, Croatia*

We sampled ants using pitfall traps (100 mL container, 6 cm diameter), which are the standard sampling technique of ground-nesting ants (Agosti et al., 2000). We set up 10 pitfall traps per plot, five in each of two parallel rows, with a 4-meter distance between the individual traps, and a minimum of 4.5 m distance from the plot edge. Pitfall traps

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1270912722

were filled with 20–25 mL of the mixture of 90% ethanol, water, glycerol, and detergent. The traps were active for 48 hours, from 12–14 July 2018, after which they were collected, labeled, and ants were sorted into 90% ethanol. The 48-hour period of trapping is recommended as a standard protocol for the efficient estimate of abundance, occurrence, and community composition of ants (Agosti et al., 2000; Borgelt and New, 2006), and it is frequently used in similar studies (Castracani and Mori, 2006; Ribas et al., 2011; Frizzo and Vasconcelos, 2013).

Data processing and analyses

We identified collected ants to the species level using taxonomical keys (Agosti and Collingwood, 1987; Seifert, 2007; Wagner et al., 2017) and online resources (antweb.org). Specimens were counted, and at least one representative of each species was pinned and deposited in Croatian myrmecological society collection (HMD, Zagreb, Croatia). Map of the sampling plots was prepared in ESRI GIS ArcMap 10.1 software.

We calculated descriptive statistics, ant species richness (S), diversity (Shannon-Weiner's index, H' and Fisher's alpha), and abundance (individual counts per species) for each plot and each land use type. We conducted a one-way analysis of variance (ANOVA) on log-transformed data to compare the effect of agricultural intensity on ant richness, abundance, and diversity in our studied land use types (annual, perennial, and control habitat). When the results of ANOVA were significant, we ran the post hoc Tukey test to calculate the significant difference between individual groups (annual-control, annual-perennial, control-perennial). To investigate the differences in ant community assemblages between the land use types we used non-parametric multidimensional scaling (NMDS) based on pairwise distance (Bray-Curtis dissimilarity) using ant abundance data. We ran all of the analyses and created plots in R program language (R Development Core Team, 2014), using packages vegan, ape, picante, and psych. The custom R code we used is available online from https://github.com/anajesovnik/AgriAnt.

Results

Comparison of ant communities of different agricultural intensity

We collected a total of nine ant species in semi-natural habitats, eight on perennial crops, and six species on annual crops. The differences in ant abundances show a similar trend, with 175 individuals collected on semi-natural habitat, 158 on perennial, and 34 on annual crops (*Table 2, Fig. 2*).

Table 2. *Mean (± standard deviation) ant species richness, abundance, and diversity*

Land use	Richness	Abundance	Diversity (H')
control	5.67 (± 0.58)	58.33 (± 13.65)	1.3 (± 0.13)
perennial	4.67 (±1.53)	52.67 (± 13.65)	1.21 (± 0.3)
annual	2.33 (±1.15)	11.33 (± 9.24)	0.57 (± 0.52)

Ant abundance on plots with different agricultural intensity was statistically significantly different (ANOVA $F_{(2,6)}$=13.58, p=0.00593). The post hoc Tukey test found a significant difference in ant abundance between the annual and control (p=0.008) and annual and perennial groups (p=0.01). In contrast, ant richness and ant diversity (Fisher's Alpha) were not significantly different between different land use

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1270912722

plots (richness: ANOVA $F_{(2,6)}$=4.53, p=0.0631; diversity: ANOVA $F_{(2,6)}$=0.568, p=0.594), although they showed the same trend: both richness and diversity were decreasing with the increase in agricultural intensification (*Table 3*). The results of the NMDS analysis (stress value: 0.08, R^2=0.993) show an overlap of ant communities of different land use types (*Fig. 3*), with no clear clustering of plots based on land use type. One of the annual crop plots (potato field) grouped closer to natural and perennial plots.

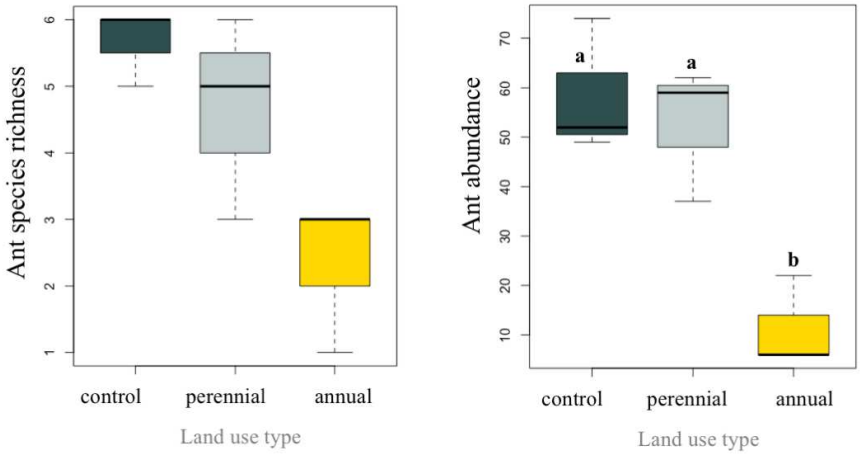

Figure 2. *Ant richness and abundance across different land use types. Significant level for post hoc test was 0.05*

The composition of ant communities

During this study, we collected 367 ants, belonging to 12 species within four ant subfamilies and nine genera (*Table 3, Fig. 4*). Eight of the species (*Formica cunicularia* Latreille, 1798; *Lasius myops* Forel, 1894; *Ponera coarctata* (Latreille, 1802); *Tetramorium semilaeve* André, 1883; *Aphaenogaster subterranea* (Latreille, 1798); *Myrmica scabrinodis* Nylander, 1846; *Solenopsis fugax* (Latreille, 1798)) are first

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1270912722

records for Zagreb, which reflects the lack of myrmecological investigations, rather than surprising discoveries. One species, a rare workerless social parasite, *Tetramorium atratulum* (Schenck, 1852), is a new record for Croatia as well. We collected a single queen of this species, on one of the annual crop plots (potato field).

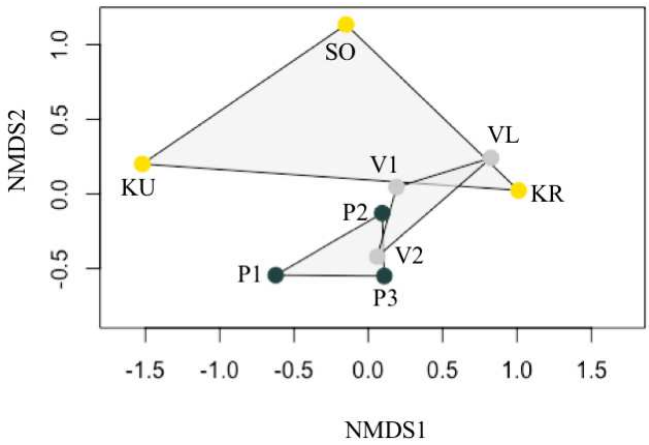

Figure 3. *Non-metric multidimensional scaling of ant community assemblages. The circles represent the position of the individual plots in the ordination space, labeled with plot codes (Table 1) and color-coded according to land use (blue- control, grey- perennial, yellow-annual)*

The most represented subfamilies were Myrmicinae (6 species) and Formicinae (4 species), while Ponerinae and Dolichoderinae were both represented by a single species. The species with the highest abundance was *Lasius niger* (Linnaeus, 1758) (31% of total ants collected, 115 individuals), which was present on all three land use types, and on 6 out of 9 plots. Three other species were present on all land use types and had a high abundance: *Solenopsis fugax* (17% of total ants collected, 63 individuals), *Tetramorium caespitum* (Linnaeus, 1758) (18%, 66 individuals), and *Formica cunicularia* (18%, 67 individuals).

Discussion

Effect of agricultural intensity on the ant fauna

Results of our study show that agricultural practices associated with annual crops significantly decrease ant abundance. In contrast, the perennial crops support ant abundance slightly lower but similar to those in semi-natural habitats. Although no significant difference was found in the ant richness and diversity between the different land use types the plots with high agricultural intensity have the lowest ant richness and diversity. The community composition showed no clear separation by land use type, and most plots were dominated by the four common, generalist species. Our sample size was relatively small, so some of the observed results are likely to change with a larger data set. However, our results are concordant with previous findings that intensive agriculture has a negative impact on arthropod abundance and diversity (Sánchez-Bayo and Wyckhuys, 2019).

In particular, the decline of ants and other soil invertebrates has been associated with conventional tillage (Radford et al., 1995; Wilson-Rummenie et al., 1999; Sharley et al., 2008; Fernandes et al., 2018; Hevia et al., 2019), use of insecticides (Sánchez-Bayo and Wyckhuys, 2019), lack of nesting habitats due to habitat simplification, and changes in soil temperature and moisture (Kaspari et al., 2000; Armbrecht, 2004; Sanders et al., 2007; Graham et al., 2009; van Oudenhove et al., 2011). How strongly these different factors influence ant communities is not straightforward. For example, ant communities in olive orchards in Spain are found to be most affected by tillage practices (Hevia et al., 2019), while ant communities in French vineyards are strongly correlated with pesticide use (Masoni et al., 2017). The combination of those factors (soil disturbance by tillage, pesticide use, and habitat simplification) decreases the diversity and abundance of ants, which in turn changes the ecological balance of soil fauna and physical and chemical properties of soil.

Our study design does not allow us to test the influence of individual factors, such as insecticide and fertilizer use, because they both varied across the two agricultural land use systems. However, we hypothesize that the soil disturbance caused by tillage, which was conducted on annual plots only, and which was the most substantial difference in agricultural practice between annual and perennial plots, was the strongest individual factor that influenced ant richness, abundance, and diversity. Conventional tillage includes mechanical plowing, which causes physical disturbance of soil structure and soil biota, and causes water loss and erosion (Faulkner, 1943; Stinner, 2002). In contrast, conservation tillage practices do not include ploughing and retain a minimum of 30% cover of crop residue on the soil surface. Consequently, conservation tillage reduces soil erosion and water loss and supports diverse beneficial soil fauna (Blevins and Frye, 1993; Radford et al., 1995; Wilson-Rummenie et al., 1999; Stinner, 2002; Li,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1270912722

2018). The other likely factor that influenced ant fauna in our study is severe habitat homogenization in annual plots and consequently reduced resource availability. A future study that would manipulate the individual treatments, e.g. tillage only, needs to be conducted to determine the relative effects of these factors.

Research such as our study can provide scientific evidence for changes in future policies. In particular, we hope conservation tillage will gain support in both research and practice in Croatia in the near future. Knowing how land practices affect insect communities is especially important in the context of the coming changes in Common Agricultural Policy (CAP), one of the core EU policies. Historically, CAP was production oriented and promoted agricultural intensification. Since reform in 2013, it also addresses the environmental issues through the cross-compliance system, although this was recognized as a weak attempt by the conservation sector (Pe'er et al., 2014). Cross-compliance defines a set of rules for farmers in order to receive the subsidies, and some of them require practices that reduce soil erosion or enhance plant and animal biodiversity. In the future CAP reform, for the 2021-2027 period, currently under negotiations, three out of nine objectives are the environment or climate change oriented, and preserving carbon rich soils will be one of the new obligations (European Commission, 2018). The CAP provides a framework for national rural development policies in EU member states. In Croatia, cross-compliance legislation is in force since 2013 (Ministry of Agriculture, 2013), and the future CAP will certainly initiate its changes. Ideally, the new legislation should regulate conventional tillage, or at least publish the set of guidelines that emphasize the benefits of conservation tillage.

The ant fauna of agricultural habitats

The ant fauna of agricultural habitats in Zagreb is similar to ant fauna described in previous studies of open, disturbed, urban, and agricultural habitats (Seifert, 2007; Slipinski et al., 2012; Castracani et al., 2015; Masoni et al., 2017). It is composed of opportunistic, thermophilic, and disturbance-tolerant species such as *T. caespitum*, *F. cunicularia*, *L. niger* (Collingwood, 1979; Seifert, 2018). Most of the collected species have generalist diets but are primarily predators and scavengers (e.g., *S. fugax*, *P. coarctata*, *T. caespitum*). Predator diversity is a crucial natural mechanism for prevention of pest outbreaks, and ants are known to decrease pest populations by direct predation, chemically deterring pests, and by causing pests to drop from the plants (Way and Khoo, 1992; Perfecto and Snelling, 1995; Schmitz et al., 2000). In contrast, some ant species can be harmful by farming herbivorous insects (e.g., aphids and scale insects), but considering the number of beneficial effects, the net impact is shown to increase crop yield (Wielgoss et al., 2013).

All species collected in this study are primarily soil nesting, and their nest size varies from around 30 (*P. coarctata*) to 10 000 workers (*S. fugax*). However, the majority of collected species have colonies of several hundred to 2000 workers (Taylor, 1967; Collingwood, 1979; Seifert and Schultz, 2009; Seifert, 2018). Soil nesting ant species contribute to maintaining and restoring soil quality (Lobry De Bruyn, 1999; Dorn, 2014; Sanabria et al., 2014). In particular, the impact of soil activities has been studied in two of the collected species. Studies in the USA found that *L. niger* move 885 kg of soil per hectare per year (Talbot, 1953; Lobry De Bruyn, 1999), *F. cunicularia* in China increases soil organic matter, total and available nitrogen, phosphorous, and potassium, electrical conductivity, and water content (Chen and Li, 2012).

We sampled a rarely collected *Polyergus rufescens* on two plots: control plot (P2, meadow at the forest edge) and the perennial crop plot (V2, apple orchard). This is the only European species of genus *Polyergus* (Mori et al., 1991; Trager, 2013) and it is an obligate parasite of ant genus *Formica* (Castracani et al., 2008; Mori et al., 2010). Because of their specific life history ant species from genus *Polyergus* are of high conservation value (Social Insects Specialist Group, 1996; Trager, 2013). This species was last reported for Zagreb more than 70 years ago (Vogrin, 1955). Its host in the studied habitats is most likely *Formica cunicularia,* a common host of this species in Central Europe (Trager, 2013).

Another surprising find is obscure *Tetramorium atratulum*, inquiline social parasite, for the first time found in Croatia. This is a West Palearctic species that takes permanent residence in the nests of its host, mostly *Tetramorium caespitum*. Worker caste of *T. atratulum* is entirely missing, which is considered the extreme form of social parasitism in ants (Crawley, 1912; Buschinger, 2009; Seifert, 2018). Because of its complex life cycle, restricted gene flow, and low population size, this species is listed as Vulnerable (VU) on IUCN Red List (Social Insects Specialist Group, 1996). In our study area, the most likely host of this species is *Tetramorium caespitum,* one of the four most abundant ants in our study, and the most abundant species on the plot where *T. atratulum* queen was collected.

Conclusion and recommendation for future study

Our study has two main outcomes. First, it shows that ants have the potential for use as tools in agricultural management in Croatia, thanks to their abundance and sensitivity to land use. Second, it shows the importance of future studies in agricultural habitats, as they hold some of the vulnerable species important for insect conservation. Future research of ants of agricultural land in Croatia should identify the particular ecological and physiological factors that support a diverse and abundant ant community. This was previously investigated in other countries (Armbrecht, 2004; Frizzo and Vasconcelos, 2013), but needs to be tested in regionally specific environmental conditions. For example, future studies should compare the ant communities of different levels of tillage (no-tillage, reduced, standard and deep), in different regions of Croatia. Knowing which agricultural practices are detrimental or beneficial to ants can inform sustainable management planning and increase crop yields (Evans et al., 2011; Wielgoss et al., 2013; Gras et al., 2016; Shukla et al., 2016). Another important direction for future research is identifying the ant species that can be bioindicators of soil quality and of High Nature Value (HNV) farming, like those already successfully developed for other regions (Perfecto and Snelling, 1995; Philpott and Ambrecht, 2006; Sanabria et al., 2014). This would require a comparative study of ants and physical and biochemical soil properties, across land use gradient. Ants are thermophilic, and successful in dry climates, unlike some other taxa important for soil quality (e.g., earthworms). Considering the effects of climate change, which among other hazards predict increased drought and higher temperatures (Myles et al., 2018), the development of ants as a tool for sustainable farming is urgently needed in Croatia.

Acknowledgments. Three anonymous reviewers provided comments and suggestions that improved this manuscript. We are indebted to Tanja Mihinjač, Marko Rajković, and Josip Živković for their help with fieldwork. Ivana Ilijaš was available for useful discussions about CAP and cross-compliance. Jelena

Bujan provided statistical advice, commented on the manuscript, and helped with lists. This study would not be possible if ants are not such interesting and resilient organisms that provide perpetual research inspiration.

(Received 22nd Apr 2019; accepted 11th Jul 2019)

Abstract. Concerns are on the rise over the impact of atmospheric nitrogen (N) deposition on forest ecosystems in the tropical and subtropical areas. This study used the conventional rainwater collection method and the ion-exchange resin (IER) method to measure through fall N deposition over time in the Picea abies forests in the Tibet Plateau. The results were compared, and their applicability in determining the atmospheric N deposition was analyzed. The results indicated a strong correlation between the IER method and the conventional method in determining the NH_4^+-N and NO_3^--N content (R^2=0.47 and R^2=0.75, P<0.001). However, the NH_4^+-N content measured with the IER method was generally lower, while the NO_3^--N was generally higher. The total mineral N deposition in through fall measured with both methods was about the same. Therefore, we can use the IER method instead of the conventional method for determining the total inorganic N deposition in forests at the Tibet Plateau.
Keywords: *Tibet Plateau, forest ecosystems, atmospheric nitrogen deposition, NH_4^+-N content, NO_3^--N content*

Introduction

From 1860 to 2000, the nitrogen (N) discharged into the atmosphere had increased from 15 Tg N a^{-1} to 165 Tg N a^{-1} due to human activities (Chen, 2007). Rainwater penetration is an important factor that keeps the nutrient balance of forest ecosystems, directly affecting the distribution of soil moisture and recycling of nutrients (Carly-Moses, 2004). Therefore, a quantitative assessment of N sediment in penetration rainwater is key in monitoring atmospheric N sediment received by the forest ecosystem, and also necessary for understanding the feedback mechanism of the forest ecosystem for atmospheric N sediment (Thimonier, 1998).

Rainwater penetration has strong spatial heterogeneity and will be influenced by various factors such as the altitude, landform, vegetation type and edge effect (Du et al., 2008; Parker et al., 2009; Schmidt et al., 2010). The conventional rainwater collection method used to observe the N sediment flux is labor intensive and largely limited by the sampling point distribution. The functional group of the ion-exchange resin (IER) can dissociate some cations or anions, while absorbing other original cations or anions in the solution, so the NO_3^- in the rainwater can be fixed on functional groups that have positive charges in the resin, and NH_4^+ can be fixed on functional groups that have negative charges in the resin, which keeps them more stable. With this approach, there

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1272312729

will be no need for rainwater collection. Instead, regularly replacing the IER will be enough to obtain the atmospheric N sediment. The IER method has been widely used globally to monitor rainwater N sediment (Simkin et al., 2004; Klopatek et al., 2006; Verburg et al., 2009).

Currently in China, anion exchange resins are widely used in the N cycle to measure soil N (Bo et al., 2001; Fang et al., 2004; Yang et al., 2005; Li, 2005). Wang et al. (2010) used the IER method to monitor the sediment of ammonium N and nitrate N in the different functional zones in Changchun. Wenping et al. (2010) focused on the man-made ecological forest in Qianyanzhou, compared the IER method and the conventional rainwater collection method, and determined the dynamic difference of N sediment in forest penetrated rainwater.

Due to a high average altitude of over 4000 meters, challenging transportation and working conditions, situ data from Tibet Plateau have been scarce. This study intended to establish the linear regression equation between the conventional and the IER methods for experimental data. The IER method is more suitable for collection in remote areas or in winter as the sampling is easier and less frequent.

This study took the Picea abies forest as the research object, used the conventional rainwater collection method and the IER method at the same time to monitor the change of rainwater N in forests of different temperate zones and the main factors influencing the N content. By comparing the two methods, the feasibility of the IER method in analyzing wet sediment of atmospheric N was determined, and the applicability of the IER method to determine N sediment flux of forest rainwater in Tibet Plateau was discussed.

Materials and methods

Overview of the studied area

The experimental plot of this study is located in the standard woodland (29°46'N, 94°44'E) of the South-East Tibetan Plateau Station for integrated observation and research of alpine environment of Chinese Academy of Sciences near Lulang town, Nyingchi district, Tibet Autonomous Region, which is flat and 3200 meters above sea level. Nyingchi district has the typical tropical humid and semi-humid climate that is affected by warm currents of the Indian Ocean and the Pacific Ocean. Dry and windy in spring, cool and foggy in autumn, it has a warm short summer and a sunny, cold, and long winter, and features a short frost-free period (about 170 days throughout the year) and a long frozen period. The average annual temperature is 7-16°C; the annual average rainfall ranges from 600 to 800 mm, and the 92.4% of the rainfall concentrates during the growing season.

In the studied area, the vegetation type is coniferous Picea abies forest in Tibetan Plateau, forest type is mature virgin forest, dominant tree species have more than 100 years of average age, the main tree species include: Abies georgei var. smithii, Picea likiangenses var. linzhiensis, Pinus yunnanensis and Pinus densata. The soil in this area is dark brown forest soil.

Sample collection and analysis

Rainwater samples were collected with self-made rain collectors, which consist of a funnel and a collecting bottle. 16 collectors were evenly placed around the experimental

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1272312729

area, and 2-3 times of irregular sampling monthly were performed from May to October in 2012 (a total of 8 times of sampling in the year) based on the change of seasonal rainfall intensity. In addition, a resin bag was placed beside each rainwater collector (a nylon bag, which contains 20 g of anion and cation resin, respectively, is horizontally placed in the PVC tube). Resin samples were taken when sampling the rainwater. The atmospheric N sediment content in two samples were then determined respectively.

This study chose the anion exchange resin 717 and the cation exchange resin 732 produced by Sinopharm Chemical Reagent Co., Ltd (Shanghai). The PVC tubes beside each precipitation collector had a diameter of 7.5 cm and a height of 5 cm. After each collection, new resin bags which with the same producing method would be placed in the PVC tubes to monitor the N content.

Calculation and statistical analysis

The NH_4^+-N and NO_3^--N content in rainfall and resin samples can be determined using the colorimetric method (Kim, 1995).

The units of N sediment fluxes of different forms and resin mineral N flux are mg N m^{-2}. The average values and standard error have been calculated. The correlated coefficient of atmospheric N wet sediment has been regressively analyzed and calculated with the SPSS.

Results

Changes of the N wet sediment flux of the coniferous Picea abies forest in Tibetan Plateau

Figure 1 shows the N wet sediment flux of different forms from May to October in 2012, and indicates that atmospheric N wet sediment flux changes with the seasons, with the highest flux in summer and low flux after the fall.

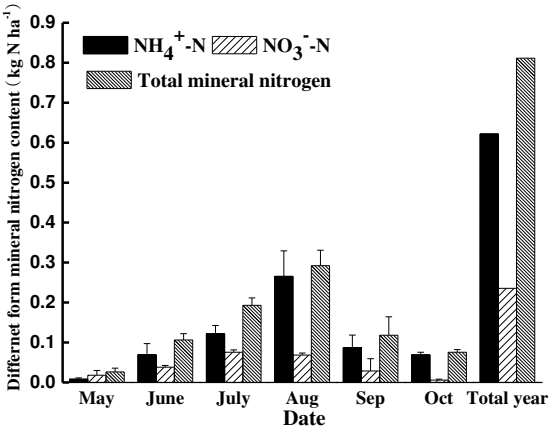

Figure 1. *Seasonal change of mineral N content of different forms in forest penetrated rainwater*

In 2012, $NH4_+^-$-N, NO_3^--N and total mineral N in atmospheric wet sediment amount of the coniferous Picea abies forest in Tibetan Plateau were 6.22, 2.36 and 8.58 kg N ha^{-1} yr^{-1}, and ammonium N accounts for about 77% of the mineral N. A significant positive

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1272312729

correlation has been found between the $NH4_+^-$-N (y_1) and NO_3^--N (y_2) mineral N sediment in rainfall and the monthly average temperature(°C) (x, unit: mm), $y_1 = 0.02x - 0.12$ ($R^2 = 0.41$, n = 6, $P < 0.01$), $y_2 = 0.01x - 0.06$ ($R^2 = 0.73$, n = 6, $P < 0.01$), and between NO_3^--N (y2) and the monthly average rainfall (x, unit: mm), $y_2 = 0.0006x - 0.0023$ ($R^2 = 0.5$, n = 6, $P < 0.01$). However, the correlation is weaker between $NH4_+^-$-N and the monthly rainfall ($R^2 = 0.08$).

Comparison between the IER method and the conventional rainwater collection method

The purpose of this study is to compare the IER method and the conventional rainwater collection method in determining mineral N wet sediment flux in the woodland. Depending on the result, the IER method may be considered for use in uninhabited areas in winter (for example, the Tibetan Plateau woodlands) instead of the conventional rainwater collection method.

From *Figure 2* and *Figure 3*, a relatively strong correlation can be observed between the IER method and the conventional method for determining mineral nitrogen in wet sediment flux in the coniferous Picea abies forest ($R^2 \geq 0.46$, $P < 0.001$), but the NH4+-N measured using the IER method is generally lower, while the NO_3^--N is generally higher. The total mineral N deposition in through fall measured with both methods is about the same (*Figure 3*).

Discussion

N deposition flux characteristics and influencing factors

The N sediment flux was higher in late summer and early autumn and began to decline in autumn and winter in southern China (Jianfen et al., 2005; Du et al., 2008). March, in particular, witnesses larger N sediment, in which NH_4^+-N takes up 64.6% of the mineral N sediment (Du et al., 2008). Results of this study are similar with that of Berger et al. (2008). Berger et al. (2008) measured the mineral N wet sediment in an Australian forest, which was lower than the mineral N wet sediment of forests in Germany and southern China.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1272312729

Berger et al. (2008) measured that mineral N wet sediment of the conifer and broadleaf forest in central Australian was 9.1-16.6 kg N $ha^{-1}yr^{-1}$, and the sediment amount was mainly influenced by rainfall. Stephan (2001) observed obvious seasonal changes of soluble organic N sediment contained in the rainwater of forests in southern Germany, and found a significantly positive correlation between the soluble organic N and the temperature (R^2 = 0.58). Fang et al. (2004) also found a significantly positive correlation between the atmospheric N deposition and the annual precipitation, when measuring the N deposition in through fall in 14 forests in southern China using the IER method (R^2 = 0.49).

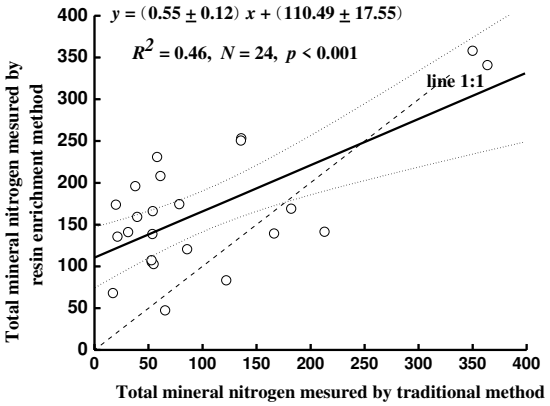

Figure 3. *Comparison between the IER method and the conventional rainwater collection method in determining total mineral N in wet sediment flux. The dotted line is 95% of upper*

Differences of results and applicability of the IER method and the rainwater collection method

The line 1:1 in *Figures 2 and 3* shows that the NO_3^--N content measured with the IER method is generally higher, and the possible reason might be that the conventional method collects samples 2-3 times a month according to the intensity of rainfall, while the IER method collects only 1 to 2 times a month. During the long sampling period, ammonium N converts into nitrate N, leading to a higher nitrate N value in the IER method (Xu et al., 2009). However, the NH_4^+-N content measured with the IER method is generally lower, because the current speed might be too fast in ion resin column with high precipitation intensity, which does not allow for complete exchange between the ammonium N and the ion resin (Wenping et al., 2010). In addition, with the increase of rainfall, the atmospheric N deposition increases (Berger et al., 2008).

Wenping et al. (2010) also found that the mineral N deposition measured with the conventional method is higher in the coniferous forest. This may be caused by the conversion of the organic N into mineral N facilitated by microbes during the longer sampling time with higher precipitation intensity. Fang's research (Fang et al., 2004) results show that due to reduced precipitation in winter (October to February), the dry deposition of atmospheric N on the canopy would increase, and then fall down to the ground in wet sedimentation due to spring rain, which explains why the N content is significantly higher after the first rain of spring than other seasons.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1272312729

In addition, previous studies seldom considered the living environment outside the forest or collect resin samples monthly. However, sufficient lighting and evaporation for resin surface may lead to underestimated N sediment when using the IER method.

Therefore, in an uninhabited area (such as the Tibet Plateau), the IER method may be used, instead of the conventional method, in the forest zone and the growing season to determine the N sediment flux in atmosphere, while in the living environment outside the forest or in winter, the sampling frequency of the IER method may be increased to monthly or half-monthly.

Conclusions

A strong correlation has been found between the IER method and the conventional rainwater collection method in determining the NH_4^+-N and NO_3^--N content ($R^2 = 0.47$ and $R^2 = 0.75$, $P < 0.001$). However, the NH_4^+-N content measured with the IER method is generally lower, while the NO_3^--N is generally higher. The total mineral N deposition in through fall measured with both methods is about the same. Therefore, we can use the IER method instead of the conventional method for determining the total inorganic N deposition in forest at the Tibet Plateau.

There is a correlation between atmospheric nitrogen deposition, soil nitrogen transformation, and nitrogen leaching. Atmospheric nitrogen deposition can also influence the mineralization and nitrification rate of forest soil nitrogen which can lead to woodland nitrogen loss and nitrogen storage change. China is the third largest nitrogen deposition concentration area in the world. But there is a lack of research on comprehensive assessment of the effects of deposition of different forms of nitrogen, different forest types, and different climatic factors on net mineralization flux of soil nitrogen.

(Received 22nd Apr 2019; accepted 20th Aug 2019)

Abstract. An experiment related to wheat cultivation was conducted at south of Sulaimani province, Kurdistan region- Iraq during autumn in 2016-2017. Completely Randomized Block Design was applied with split-split plot arrangement, and the experiment was conducted on two fallow lands, the first land was plowed in the spring and the other remained unplowed, two different sowing modes with rotary seed broadcaster were used, namely conventional and overlapped prose lines, and two similar sets of tillage systems were chosen for the study. The averages were compared by using Duncan's test. The coefficients of variance (CV) for overlapped and conventional seed spreading were 9.2% and 48.4%, respectively. The spring-plowed fallow land proved to obtain significantly different values compared to the unplowed land, which were higher by 51.9%, 48.5%, 47.1%, 26.9%, 31.6%, 6.7% and 30.1% for fuel consumption, draft, power losses due to slippage, working time, energy utilization, wheat yield and total cost, respectively. The average results for overlapped seed broadcasting were higher than those of the conventional manner by: 0.8%, 0.3% 1%, 0%, 3.3%, 6.7% and 14.5%. The lowest values were resulted from applying: MB plus seed distributor plus MB, while, the maximum yield was given by applying: cultivator plus seed distributor plus cultivator.

Introduction

Cereal crops are considered to have a fundamental importance in human life. They have had an essential role in the past. Cereal crops are the mainstay of food supply and the development of the world's people at all times. In Kurdistan region- Iraq, the availability of suitable agricultural land, labour, abundance of water and adequate climate for the cultivation of many of the strategic crops are regarded as the ingredients of successful agricultural operations. Wheat and barley are special crops which help to strengthen and install the status of the agricultural sector in a stable level position to provide a durable and robust economy of the region.

The total arable land area in Kurdistan region- Iraq, was 968468.48 ha, 664771.5 ha of wheat farms that produce 1019481 tons, and constituted 34% of Sulaymani area. Sowing patterns employed by farmers vary considerably from area to area. The vast majority of the farmers spread their seeds by broadcaster machines after preparing the field in different ways to avoid costs. In addition to fallow rotation few farmers who owned large farms drilled their seeds. Of course, production is noteworthy various in quantity and quality.

The main objective of tillage is to prepare the soil or the seedbed where the plants can easily grow. The crop rotation system, which consists of wheat-fallow, is widely applied in the Kurdistan Region, as is the case in other places in semi-dense and dry

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1273112751

areas, even in some rain-fed areas. Aims of fallow are to maximize soil water storage through improved water capacity, reduce evaporation; maximize plant nutrient availability; and minimize soil erosion risk (Greb, 1979).

Zengin and Ocakoglu (2013) found that the plowing (stubble fallow method) was more effective than the other methods in terms of high grain yield and yield components. Yield increase of ~50% was observed in both years when compared to the minimum tillage (stubble fallow method) when they studied the effect of different tillage patterns and fallow methods (minimum tillage/stubble fallow, plowing/stubble fallow and plowing/non-stubble Fallow) on wheat yield, and yield components.

Tillage methods have different tillage depths and ability to change soil physical and chemical properties that affect the crop yield and quality (Strudley et al., 2008). Farmers have begun to apply reduced and no-tillage management practices for production of grain in their fallow lands instead of conventional tillage systems. The main reasons for this idea of less tillage are reduced fuel and labour costs, lowered soil erosion, and enhanced water conservation. The growth in soil water decreases some of the hazard in semiarid and arid farming lands (Broder et al., 1984). Even though overall national yield data of wheat crop mention that it is increasing slowly. However, feasibility is declining due to soil fertility decline, weed problem, disease and insects, labour and power scarcity, and the high cost of inputs (Asheesh et al., 2017).

In general, wheat production in large areas will depend upon mechanized production systems efficiently used and managed. Special attention should be given during the selection of the appropriate machine for proper land preparation and suitable sowing methods for high and profitable crop yield (Mergani, 2006). Askari and Khalifahamzehghasem (2013), pointed out that the needed force to pull the Moldboard plow (16.30 kN) is about five times larger than the needed force of field cultivator (3.49 kN), which correlates with the data estimation that obtained from ASABE, 2016, that is 19.55 kN and 3.82 kN respectively.

Botta et al. (2006) and Kahloon et al. (2012) reported that, the maximum economic benefit of the farmers reduced when fuel consumption increased, so that tillage equipment was used in cultivating of wheat. As a principle, in general it can be said that one pass for planting compared to two or extra tillage implementations means fewer hours on a tractor operation, fewer labour hours to pay and may reduce production costs or more acres to farm. Çarman et al. (2013) mentioned that, currently, the search for alternative economic methods for tillage is an inevitable consequence of the high cost of energy spent on conventional tillage, on the other hand, conservation tillage means any plowing or planting method that leaves crop residues covering the field by at least 30% after seeding practice. Erosion in such soils is reduced by at least 50% compared to the fallow soil.

Hanna (2016) showed that the highest value of effective field capacity (A/hr) was recorded by the fertilizer spreader compared to other machines which were 4.1, 6.8, 14.4, 5.1 and 20.4 for Moaldboard plow, Chisel Plow, Field cultivator, Grain drill and Fertilizer spreader respectively. Mckyes (1985) defined energy efficiency as the number of cubic meters of soil raised by plows for each megajoule of consumed energy. This efficiency is affected by several factors, the most important of which is the depth of tillage. Muhsin (2017) mentioned that the energy utilization efficiency and the plowed soil volume rate increased by 34.30% and 87.38% when the plowing depth increased from 10 to 30 cm, respectively.

Bai et al. (2008) recommended that the absence of suitable machinery and the trepidation of a reduction of yield make it difficult for farmers to adopt an attitude towards the idea of reducing traffic. By minimizing the machines traffic, the bulk density in the 0–0.15 m of the soil layer was reduced, the total porosity in the 0–0.60 m soil layer was increased, better available water content and best saturated hydraulic conductivity were characteristic compared with the traditional mouldboard tillage treatment

In early American history, wheat was sown broadcast. Broadcasting has been observed to reduce plant establishment as seeds are said to be lost to pests and unsuitable weather conditions. Thus, high seed rates have been recommended when seeds are broadcast in order to compensate for seed loss. Presently in America almost all wheat is drilled. The main reason given for drilling wheat was better germination, which resulted in higher stands compared to broadcasting. Though favored crop incorporation and crop yield have been reported when wheat is planted by seed drill compared to other sowing patterns, however, wheat drilling is a costly technology regarding labor requirements for drilling or machinery employed in seed drilling. Thus, seed broadcasting is common in farmers' plots. It was observed, seed broadcasting even when followed by harrowing or raking does not bring seed in ideal contact with the soil for sufficient water uptake (Oyewole et al., 2001).

Broadcasting is the process of random spreading of seed on the surface of seedbeds at controlled rates. Hassann et al. (2009) studied the effect of different field plot area on wheat planting machinery performance. The results showed that it is important to notice that seed drill planter allowed a saving in wheat seeds of 26% compared with the seed spreader. Wuest et al. (1999) showed that, distinct technique of seeding and seed-soil contact had strong influence time to germination. Lan et al. (1999) confirmed that uniformity for seed spaces is important for crops because it has an influential role in crop production. There are a lot of environmental and economic reasons for using more accurate broadcasters as a device of reducing undesirable environmental effects (Sanaeifar and Sheihkdavoodi, 2012). The relevance of soil and its physiological effects on plants had not been specified perfectly yet, but it was estimated that unfavorable effects of non-uniformity of broadcasting would economically lose a considerable amount of money (Svensson, 1990). The basic performance parameter of a broadcaster is uniformity of spreading over a wide range of situations, this parameter determines the quality of broadcasting, if the broadcasting is suitable the quality will improve better (Speelman, 1979). To help avoid unregularly stands, the equipment should be driven close enough to overlap the previous spread pass to guarantee regular seed distribution (Zewdu, 2008).

All seed broadcaster operators in the region follow the conventional method to spread Wheat granules. The traditional method means spreading granules without overlapping broadcast applications, even the operators leave untreated areas, or sometimes the overlapping of the broadcasting curve may be within a distance not exceeding 2 m, the reason is the operator use visual oversight to the tractor wheel traces, also he often depends on his guessing and skill to achieve parallel swaths in the field. All this results in a heterogeneous distribution of seeds over the field surface. Of course, the production become uneven in quantity and quality from place to place in the field.

Even after all spreader adjustments obtainable have been tested, the distribution shape from a broadcaster is not adequately uniform. A common recommendation in many books and technical papers was mentioned to solve the problem of non-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1273112751

uniformity of the granular by making rate of application for half and cover the field twice at perpendicular angles (Colvin and Turner, 1980). But, also this technique is not the best manner to solve this problem (Parish, 1999). Effective overlap (30 to 50%) between adjacent passes is absolutely necessary to overcome this uneven distribution shape (UMass Extension, 2011).

Broadcasting not only requires higher seed rate but also results in lower plant population, whereas drill sowing method is recommended because of its uniform seed distribution and sowing at the desired depth, which usually results in higher germination and uniform stand. A key factor in the highest wheat production is the understanding of early crop establishment. Beside other agronomic factors seed rate and sowing method are major factors which determine the crop vigour and ultimate yield (Soomro et al., 2009)

It is known that the conventional mode for wheat sowing by seed spreader lead to distribute the wheat grains in a heterogeneous shape that leave places on the soil surface without seeds or light coverage, while other areas are covered with grain intensively which increases the competition between plants to obtain the necessary energy sources for appropriate growth, in addition the negative effects of irregular distribution of seeds results in the loss of a lot of money (Svensson, 1990). Therefore, the variation in the distribution of seeds on the soil surface and uneven emergence, depth and stands often result in lower production (Herbek and Lee, 2009). On the other hand, following the overlapping pattern for scattered lines by seed broadcaster is the best solution to the disadvantages of the uneven seed distribution that mentioned by Zewdu (2008).

It can be said, most farmers tend to raise their seeding rates when they used spinning disc type broadcaster. Higher seeding rates normally only lead to more seed costs and produce excessive plant populations. While bad stands as a result of poor seeding rate that prosed by broadcaster typically result in variation in soil–seed contact, seed scattered and seeding depth, predation of seed on the soil surface by birds, insects and mice in addition to high dense weed population that compete for available moisture (Brennan and Leap, 2014; Houk, 2009).

An effective technique to ensure improvement of the uniformity is to cut both the application rate and the swath width to half while preserving parallel swaths (Parish, 1986). For further explanation of half-width method, spread curve overlap of 100% is commonly needed to obtain uniform coverage. That mean, if the spread pattern width is 10 m wide, then a 100% overlap will result in a 5-m swath spacing width.

Generally, most farmers sowed own wheat by spinning disc type seed spreader by conventional mode after preparing the soil by variance tillage systems, which varies from place to another in the region, in terms of the type of machines used and the number of mechanical operations in order to get a quick profit through reducing time, effort and spent money, without taking into account the recommendations and the basis of the management of agricultural operations when using the machines with the right method. Here, the objective of this study was extracted.

The objective of this study is to evaluate the economic feasibility and relative profitability of various combinations of two sowing patterns for wheat crop in two different prepared fallow lands after introducing the advanced technique (overlapping manner) for wheat sowing by granules broadcaster machine at acceptable cost and energy consumption and comparing the results with those in conventional manner in order to improve wheat production through increasing the productivity per unit area.

Materials and methods

This study was carried out under rainfed conditions during the growing seasons at Experimental Farms of the College of Agricultural Sciences, University of Sulaimani at Bakrajo located in the southwest of Sulaimani province, Kurdistan region- Iraq (Latitude: 35° 33' N; Longitude 45° 27' E at an altitude of approximately 830 m). In this region, the climate is rainy and cloudy in winters, rainy in springs, hot and dry in summers, the information on agro-climatic conditions is given in *Table 1.* The physical properties of the soil of the experimental field were examined in the Soil and Water Department laboratories at the College of Agricultural Sciences *Table 2*.

Field experiment

For wheat cultivation, the year fallow system is one of the most common manners followed by growers as crop rotation in Iraqi-Kurdistan's large rain fed region. Therefore, two fallow lands were selected for conducting current research, the first fallow land as (F1) was plowed one time at the spring of 2016 at a depth of 0.25 m, while the second fallow land as (F2), was left in a resting stage without conducting any mechanical operation until the time of research. Adopting the overlapping ratios of 30% to 50% for prose lines of seed spreader was necessary to achieve acceptable values of the coefficient of variance (C.V.) (be as close to zero as possible). Values up to 15% are acceptable, but once the CV goes above 20% a crop and financial loss will happen (Forristal and Teagasc, 2017).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1273112751

Two sets of sowing patterns were selected for the current experiment, the sowing of wheat seeds was applied by following the conventional mode of seed scattering and the intertwined mode of prose lines. Each set was consisting of the following patterns:

1. Soil tillage by moldboard plow one pass plus sowing with seed broadcaster and covering the seeds by moldboard plow one pass as (T1).
2. Soil tillage by moldboard plow one pass plus sowing with seed broadcaster plus covering the seeds by field cultivator one pass as (T2).
3. Soil tillage by field cultivator one pass plus sowing with seed broadcaster plus covering the seeds by field cultivator one pass as (T3).
4. Sowing with seed broadcaster plus covering the seeds by moldboard plow one pass as (T4).
5. Sowing with seed broadcaster plus covering the seeds by cultivator one pass as (T5).

Therefore, the number of sowing patterns becomes ten, five of them conducted by conventional sowing mode (farmers practice) and five patterns applied by adopting the overlapping mode of seed prose lines, as illustrated in *Table 3*. The experiment was carried out in a randomized plot design with a split-split plot arrangement by placing the condition of the fallow lands (F1 and F2) in the main plots, the sowing modes (conventional and overlapped) were placed in sub plots and each sowing pattern represented plot as explained in *Table 3*, each plot was replicated three times. The preceding crop in the season of 2014-2015 was winter wheat for both fallow lands. The experiment was conducted in the second decade of November 2016 when the soil moisture was approximately 16% for both lands. The sowing by overlapping mode was carried out by adopting the mode that Parish (1999) and UMass Extension (2000) recommended by cutting each of the delivery rate and swath width to half while maintaining parallel swaths by applying: right-on-right, left-on-left overlapping with back-and-forth traffic system as shown in *Figure 1*.

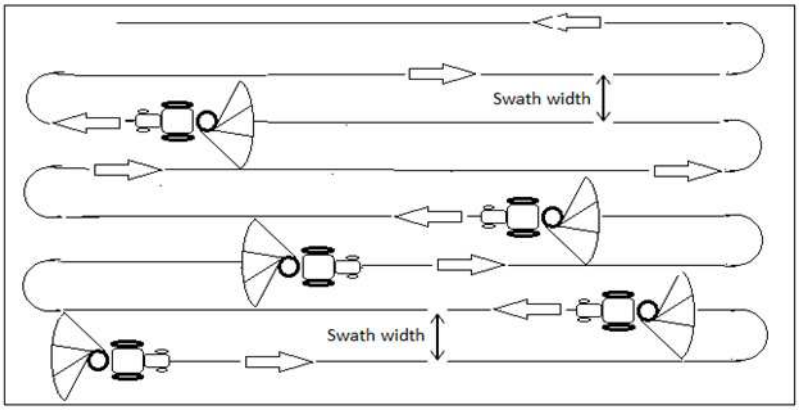

Figure 1. *Half-width method and half rate application (a right-on-right) and (a left-on-left) overlap manner*

Calibration

Centrifugal type broadcaster which used for this experiment had the following features: tractor mounted with P.T.O shaft driven at 540 rpm, hopper capacity of 0.8 m^3,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1273112751

single spinning disc and height of the spinning disc from the ground was 1.1 m during operation. *Table 4* shows the main features of the machines used in the present study. The seed broadcaster was calibrated for traditional sowing on rate 200 Kg/ha (5000000 kernel/ha) a day before the study considering wind speed less than 8 km/h. According to ASAE S341.2 (1999) and as followed by Sanaeifar and Sheikhdavoodi (2012), the calibration test begun by putting twenty collecting trays 1 × 1m (each had partitions barriers) for granules in a row with equal distances to the longitudinal center line of the tractor in symmetric shape.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1273112751

Table 4. *Main features for all machines participated in the experiment*

Tractor/equipment	Mod.	Weight Kg	Working width m	Specification	Type	Linkage with tractor
Tractor (56 kW)	ITM/Iran	2812	-----	4-stroke-direct injection	4WD	------
Mouldboard plow	Unlu/Turkey	330	O.85	3 furrow	General purpose MB	Mounted
Cultivator	Unlu/Turkey	240	2	9 vertical spring tines	Duck feet	Mounted
Seed broadcaster	Solano/Spain	68	16	500 Lt/hopper	Mono disc	Mounted

In accordance with Clark and Evans (1954) both the tractor and the spreader were put in a stable state and spreading begun 30 m before trays row and continued to 40 m after trays row. The calibrating tests were repeated three times at the same tractor forward speed 7.1 Km/h. The collected seeds in each tray were recorded and weighed in order to determine the quantity and the uniformity of seeds distributed within the field. The collected seeds from each tray were put in a tube as represented in *Figure 2*. This calibration result is consistent with which confirmed by UMass Extension (2011) that, in centrifugal type broadcasters, material distributed in a fan like pattern that the intensive rates applied to the center of the spreader path while the application rates reduce to left and right of center and seems like a bell shape curve with distance of the scattered.

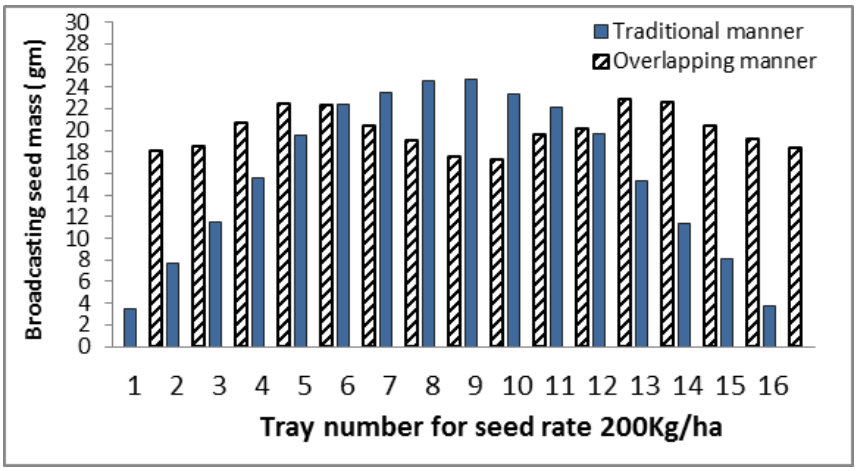

Figure 2. *Pattern of seed amounts distribution in each tray after broadcaster calibration on the seed rate of 200 Kg/ha*

To apply the advanced technique half-width method and half rate application for the seed broadcaster as overlap sowing mode in this study, another calibration was conducted in the same manner as the previously applied method that followed for sowing rate (200 Kg/ha) but this time for the rate of 100 Kg/ha (2500000 kernal/ha). This calibration started by the layout of 16 trays (the working width for the seed broadcaster as shown in *Fig. 2*) on a line perpendicular to the direction of tractor travel.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1273112751

After achieving the correct amount of seeds per hectare, the "progressive" application method conducted in alternate directions, back and forth, as mentioned before and as illustrated in *Figure 1*. This method was replicated several times. The results were very satisfactory in terms of the homogenous distribution of seeds and quantity.

Selected forward speed for any tillage or covering operation in this experiment was 7.1 Km/h. The recorded data when the fallow land was plowed in spring by moaldboard were: the drawbar force was 11.526 KN on 25 cm depth at a forward speed of 7.05 Km/h at 15% soil moisture. These values have been used and added to the relevant equations to measure the studied parameters. Necessary information for all machinery contributed in the study had given in *Table 4* and *Figure 3*. The averages resulted from ANOVA analyses were compared by using Duncan's test.

Seed broadcaster | Moldboard plow | Field cultivator

Figure 3. *Machines used in the study*

Studied indicators

Since the machines used in this research include a heterogeneous working width, the calculation of the studied indicators was carried out on 1 m of machine width so as to avoid bias in favour of a specific treatment and to show the results more clearly and accurately. After measuring the results for each operation within each sowing pattern the total was calculated and adopted.

The coefficient of variance (C.V)

The percentage of mean value is the standard deviation in the form of a relative scale of dispersion. The following formula was used by Laghari et al. (2014) to measure the coefficient of variance:

$$CV\% = \frac{100 \times Sd}{\bar{x}} \qquad \text{(Eq.1)}$$

$$sd = \sqrt{\frac{1}{n} \sum_{i=1}^{n} (xi - \bar{x})^2} \qquad \text{(Eq.2)}$$

where:
CV = coefficient of variation
Sd = standard deviation
Xi = value of an individual observation
$\bar{x}$ = mean value of all observations

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1273112751

Total fuel consumption (L/ha).m^{-1}

The fuel consumption was measured according to the standard method followed by observing the fuel needed for traveling 40 m long distance for completing each sowing pattern using a graduated cylinder which was directly attached to the fuel tank as Sümer et al. (2010) suggested.

Total draft force (KN/m)

Total draft force was measured by using mechanical dynamometer Dillon type (10000 Kg) for each plot.

Total power bar losses due to slippage (KW/m)

It was found as the same equation followed by (Abdullah and Ghazwan, 2014).

$$PFT\,(KW) = \frac{(FT \times (VT - VP) \div 3.6)}{W} \qquad \text{(Eq.3)}$$

where:
PFT: drawbar power lost by slippage (KW/m)
VT: theoretical speed (Km/h).

Working time (H/Ha)/m

It is measured as mentioned by Moitzi (2013), Firas et al. (2016) and ASABE Standards (2016) by using the following formula:

$$WT = \frac{1}{\mathrm{C_{theo}}} \qquad \text{(Eq.4)}$$

$$\mathrm{C_{theo}} = \frac{W \times V_{avg} \times 0.1}{\mathrm{m}} \qquad \text{(Eq.5)}$$

where:
WT: time required for completing any Mechanical operation (H/Ha)/m
C_{theo}: field capacity (Ha/h)
V_{avg}: practical speed (Km/h)

Energy utilization efficiency (η) (m^3/Mj)

Measured by the equation that McKyes (1985), Muhsin (2017) and Abdullah and Ghazwan (2014) followed:

$$SR = \frac{F}{\mathrm{A}} \qquad \text{(Eq.6)}$$

$$A = \frac{Bp}{\mathrm{Dp}} \qquad \text{(Eq.7)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1273112751

where:
η: energy efficiency (M^3/Mj)
SR: the amount of force used by the shears on the unit area
F: force
A: area
Bp: working width
Dp: working Depth
m: unit of length (m)

Wheat yield (Kg/Ha)

For each plot, the yield was harvested by using thresher.

Total cost for each sowing pattern (T.C)

The total cost of any agricultural pattern was calculated separately on costs associated only with mechanical repair and maintenance, as well as fuel, lubricants and labour wages.

Results

The coefficient of variance (C.V):

Based on *Table 5*, the calculated result of the coefficient of variance (C.V) of seeding by traditional distribution was very high 48.4%, indicating that homogeneity of distribution was very bad compared to the intertwined mode of grain distribution which gave 9.2% of variance, because, the lower the coefficient of variation, the better the distribution.

Table 5. *The coefficient of variance (C.V) for spreading uniformity for the samples of seeds collected for each traditional and overlapping prose*

Sowing manner	Collecting trays number (working width of the spreader)																C.V %

Effect of fallow land condition

As seen in *Table 6*, the fallow land condition clearly affected all studied parameters. The best averages were resulted by conducting mechanical operations on spring-plowed fallow land by: 23.80 (L/ha)/m, 11.22 kN/m, 2.72 kW/m and 5.29 (Hr/ha)/m for total fuel consumption, total draft need, power loss due to slippage and total time required respectively. These results differ from non-plowed land at spring with an increase of: 51.9%, 28.7%, 47.1% and 26.9% respectively. On the other hand, the fallow land that was non-plowed at spring, gave the highest averages compared to that plowed type land with percentages of 31.6% and 3.2% for both total energy utilization efficiency and total wheat production, respectively. The total cost spent on sowing the plowed fallow land at

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1273112751

spring was 8.56 USD/ha, which exceeds the cost spent on non-plowed land at spring by 30.2%.

Table 6. *Effect of fallow land condition on power requirements, total yield and total cost spent*

Fallow land condition	Tot. F.C (L/ha/)/m	Tot. draft kN/m	Tot. SDHp kW/m	Tot. W.t (Hr/ha)/m	Tot. E.U.E M^3/MJ/m*	Tot. wheat yield Kg/ha	Tot. cost USD/ha
F1	49.45 a	21.77 a	5.14 a	7.24 a	89.07 a	2809.36 a	8.56

Effect of sowing mode

From the results of *Table 7*, the sowing method had no effect on most measured characteristics except for total energy utilized efficiency. The given results from conventional sowing method were 36.47 (L/ha)/m, 16.52 kN/m, 3.91 kW/m, 6.26 (Hr/ha)/m, 73.72 (M^3/MJ)/m and 2721.10 Kg/ha for the parameters total fuel consumption, total draft force, total power loss due to slippage, total working time, total energy utilization efficiency and total wheat yield, respectively. As well as, the averages from applying overlapped sowing mode were 36.78 (L/ha)/m, 16.47 kN/m, 3.95 kW/m, 6.26 (Hr/ha)/m, 76.27 (M^3/MJ)/m and 2809.10 Kg/ha for the studied indicators, respectively.

As observed in *Table 7* the reduction percent of values obtained from using conventional manner were: 0.8%, 1% and 0% for total fuel consumption, total power loss due to slippage and total working time. However, the value of the draft force resulted by using overlapping method decreased at a time when it was supposed to increase. The values of the averages resulted from using sowing manners are too close to each other, and the difference between them can be considered as the amount of power spent for applying the second travel of the seed spreader in overlapped method during conducting the half-swath width and half-seed application rate. It can be said, the amount of power consumed by the seed distributor is too small compared to that consumed by other machines used for tillage operation, especially, the moldboard plow. Therefore, in practice, the amount of power consumed by the seed distributor can melt between the relatively large variations in the frequency of power values consumed by tillage machines due to the difference of the two fallow land conditions. The highest proportion of energy used to complete the agricultural process is consumed by the plows (Larson and Clyma,1995).

Table 7. *Effect of sowing manner on power requirements, total yield and total cost spent*

*Means with similar letters in each row or column are non-significant at the 5% level (Duncan's test)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1273112751

The highest amount of total energy utilization efficiency was73.72 (M^3/MJ)/m when conventional spreading applied, with an increase of 3.3% than in other applications. The total wheat production was 2809.06 Kg/ha when 7.84 USD/ha spent for applying overlapping mode of seed spreading with an increase of 7.17% than the yield resulted from using conventional method.

Effect of sowing patterns

The results in *Table 8* illustrate the averages of parameters studied that were affected by applying different sowing patterns. The lowest amounts for total fuel consumption, total draft force used, total power loss due to slippage and total working time were found by treating T5 pattern, which gave 20.33 (L/ha)/m, 9.37 kN/m, 2.08 kW/m and 5.05 (Hr/ha)/m respectively, with percent of 63.2%, 62%, 65.2% and 29.2% less than averages resulted from T1 treat. The draft force of Mouldboard plow was 78.6% more than the force needed to pull field cultivator. The reason of this increase is due to the variance of the resistance force of each machine during soil preparation which depends on many factors as Keller (2004) mentioned the draft requirement for each plow dependent on implement parameters; plowing depth, forward speed and soil strength.

As well as, the highest amount of total energy utilization efficiency and total wheat yield were 122.66 (M^3/MJ)/m and 2904.80 Kg/ha, respectively which resulted by applying the T3 system. While, the lowest amounts were: 73.1% and 13.9% less than the averages obtained by using T4 pattern. The lowest cost noted to complete sowing operation was 5.54 USD/ha spent on conducting T5 operation with a reduction of 38.6% than the highest cost which spent for conduct T1 treatment.

Effect of the fallow land condition and sowing modes interactive

The data are shown in *Table 9* indicate that there is a clear effect of the interaction between soil type and agricultural ethics on most of the characteristics involved. The averages produced by applying both traditional and overlapping seeding method for each of the studied parameters did not differ in either of the two fallow lands. Lower values were observed in the case of conducting conventional broadcasting on the non-spring plowed fallow land for fuel consumption, total draft, total power loss due to slippage and total working time were: 23.66 (L/ha)/m, 11.16 kN/m, 2.70 kW/m, 5.29 (Hr/ha)/m, 59.92 (M^3/MJ)/m and 59.92 (M^3/MJ)/m, respectively, with a reduction of 52.3%, 48.7%, 47.8%, 26.9% and 33.9% compared to the highest values resulted from overlapped spreading on spring plowed land. The increases of energy consumed are due to the fact of using extra tillage operation by moldboard at spring, The energy and draft

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1273112751

used for spring tillage at fallow land were more than in the case of only autumn plowing (Raper et al., 2000).

On the other hand, the interaction of studied factors had no effect on total wheat yield; the highest yield obtained was 2943.90 Kg/ha when the modern technique of seed scattering was adopted on the spring plowed land with total cost of 9.16 USD/ha. While, the minimum yield recorded was 2674.30 Kg/ha. The lowest spent cost appeared was 5.45 USD/ha when the sowing operation was done by applying a conventional mode on the non-plowed land at spring.

Effect of the interaction between fallow land condition and sowing patterns

Based on the results seen in *Table 10*, the interaction between the fallow lands condition and sowing pattern significantly affected all indicators included in the study. The lowest values for total fuel consumption, total draft, total power loss due to slippage and total working time by applying T5 operation either on F1T5 or on F2T5, were: 33.01 (L/ha)/m, 25.72 kN/m, 3.49 kW/m and 6.04 (Hr/ha)/m respectively, with: 51.5%, 49.4%, 50.2% and 25.4% less than the highest values obtained by applying T1 operation on each fallow land condition. While, the highest amount of total energy utilization efficiency was 138.74 (M^3/MJ)/m which was obtained from using F1T3 or F2T3 with an increase of approximately 67% than the amount resulted from using F1T4 or F2T4. The maximum total wheat production was 2977.82 Kg/ha obtained when F2T3 treatment was conducted, but, the minimum yield observed was 2473.18 Kg/ha by applying F1T4 treatment. The lowest cost was 4.17 USD/ha spent to complete the sowing operation of F2T5 by 60.3% less than the highest cost spent on using F1T1 treatment.

Effect of the interaction between sowing modes and sowing patterns

Table 11 refers to the significant effect of the interaction between sowing modes and sowing patterns on studied power indicators and total yield of wheat. The lowest values noticed for fuel consumption, total draft, total power loss due to slippage and total working time when the conventional sowing operation interacted with T5 treatment were 20.15 (L/ha)/m, 9.35 kN/m, 2.07 kW/m and 5.05 (Hr/ha)/m, respectively, the highest values were obtained by applying overlapped technique of seed spreading with T1 operation, that is 55.45 (L/ha)/m, 24.75 kN/m, 5.96 kW/m and 7.13 (Hr/ha)/m. The highest amount for total energy utilization efficiency was 125.43 (M^3/MJ)/m, observed at the interaction of overlapped sowing technique with T3 treatment by more than four times the average obtained by the interaction of T4 and overlapped seeding mode.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1273112751

On the other hand, the maximum wheat production was 3097.50 Kg/ha, given by the interaction of T3 pattern and overlapped sowing technique. The lowest amount of wheat production was 2437.50 Kg/ha resulted from the interaction of T4 with conventional seeding mode. The lowest spent cost was recorded by applying T5 operation with conventional sowing method by a reduction of 39.4% than the cost spent to complete T1 treatment with conventional sowing.

recorded from the interaction of F1, overlapped spreading and T1 operation, that is 68.19 (L/ha)/m, 29.64 kN/m, 7.02 kW/m and 8.10 (Hr/ha)/m for studied power indicators: total fuel consumption, total draft, total power loss due to slippage and total working time respectively, with an increase of 89%, 87.6%, 90.6% and 49.8% compared to the lowest values obtained from F1, overlapped sowing manner and T1 operation interaction. The highest amount of total energy utilization efficiency and total wheat yield were 141.57 (M^3/MJ)/m and 3235.00 Kg/ha resulted from applying F1, overlapped seeding mode and the T3 interaction. While, the lowest amount for both indicators were 21.05 (M^3/MJ)/m and 2399.50 Kg/ha respectively, which were observed when F2, conventional seeding mode and the T4 interacted. The lowest total cost was spent for conducting F2, conventional seed prosing and T5 operation interaction resulted in 3.71 USD/ha, which was less by 67.3% than the highest cost which spent for completing F1, overlapped spreading manner and T1 treatment interaction.

Discussion

From Table 5

The high percentage of coefficients of variance obtained from the traditional method of grain dispersion is due to the poor distribution of grains by rotatory type spreader as referred by most relevant research (Laghari et al., 2014). The reason of the variance may be that in centrifuge type of spreader, the grain is scattered by centrifugal force

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1273112751

which pushes those falling seeds out in all directions and far away from the center of the rotation, except the side behind the driver, where they fall on the ground near the distribution center which causes an increase in the number of grains compared to places far from the center. This fact is consistent with what was confirmed by Sanaeifar and Sheikhdavoodi (2012). While, the C.V values resulting from the use of the overlap method were much better, which serves as an evidence of the good distribution of seeds that affect the equal growth opportunities between plants and increase production (Herbek and Lee, 2009).

Table 6

The large difference between the results obtained from the two land types is due to the added values from plowing by MB at spring. These results encourage farmers to leave their fallow land in unplowed condition, to reduce input costs with less effort, they (the farmers) don't know, that spending extra few dollars (2.58 USD/ha) will generate more money by selling the difference of the yield results from the two lands types. This is confirmed by Moitzi (2013).

Table 7

Although there is no significant effect of sowing mode on the studied indicators, however, there are slight differences observed in their averages. In fact, these differences represent the value of the second traffic of the broadcaster during applying the overlapped technique of prose lines as observed in fuel consumption, power losses due to slippage and total cost of 1.14 USD/ha, which led to increase the wheat production by 3.1%. The increase in the yield was due to the homogenous distribution of the seeds, which has led to equal access for food sources, this is confirmed by Herbek and Lee (2009).

Results presented in Table 8

The reasons of the increases in the total amounts measured by using T1 treatment for most indicators compared to other treatments, is due to the large variation of soil resistance force towards differences of number of passes, operation depths and equipment shears as mentioned in *Table 3*. Therefore, farmers tend to apply a few tillage practices than conventional tillage to reduce the energy requirements associated with a low cost, as confirmed by Kumar et al. (2013).

The obtained wheat production by applying T3 pattern was more by: 11%, 13.9%, 0.9%, and 6.8% than applying T5, T4, T2 and T1 treatments, respectively. The reason of these variations of wheat yield is due to the suitable management of the soil which mean available seed-soil contact, which affects positively the soil physical and chemical properties in comparison to other practices, as mentioned by Strudley et al. (2008).

Table 9

As noticed from the averages, the interaction between the fallow land condition and sowing modes had a clear effect, at a time when the seeding manner had no effect on the measured characteristics, as illustrated in *Tables 9* and *8*. That means the effect of the fallow land condition is much greater than that of the sowing technique.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1273112751

Table 10

Applying minimum mechanical operation on each of spring plowed fallow land and non-plowed fallow land at spring gives minimum power consumption with lower cost in comparison to applying other tillage systems, which was also pointed by Broder et al. (1984) and Çarman et al. (2013).

Table 11

The lowest power needs and cost spent can be resulted by conducting T5 treatment with conventional sowing mode. The apparent variation in each sowing pattern in term of the number of operations, operation depth and difference of machines typically used in each agricultural process are the main reasons for the large variances between averages obtained from the overlapped factors, this is what Muazu et al. (2015) pointed out.

Table 12

The lowest power measurements and total cost need to be achieved by applying the sowing practice T5 with conventional or overlapped spreading technique on the unplowed fallow land at spring compared to the highest values resulted from using T1 operation on spring plowed fallow land. The reason for these wide variations is due to the differences in a number of operations applied, machine types and tillage depths.

In the spring, plowing operation killed a high percentage of weeds and insects, made the soil softer in terms of energy consumption and a more suitable environment was created for seed growth at the fall season than in the case of unplowed fallow land. The reduced tillage (T3), leaves more coverage of plant residues than using conventional tillage (Botta et al., 2006 and Kahloon et al., 2012). Also, the application of the overlapped seeding method was appropriate in obtaining the highest wheat production, This is consistent with what Mergani (2006) has indicated. Therefore, the growers must apply reduced tillage (T3) to minimize soil stress and to increase the yield.

Conclusion

The results obtained from the experiment can lead to the following conclusions

Applying sowing patterns on unplowed fallow land at spring gives lower power requirements and costs spent on wheat production as compared to spring-plowed fallow land cultivation, except, the total yield becomes less. Adoption of the overlapped mode of seed distribution by the broadcaster is better than applying the conventional technique to obtain high wheat production, despite the increased energy consumption and the slight increase in costs.

The lowest power consumption can occur by using conventional sowing plus field cultivator for covering the distributed seeds, and the highest power needs are occurred by excessive tillage. The recommendation is to apply reduced tillage with field cultivator for both tillage and seeds covering operations which results in the highest wheat production with acceptable cost and energy consumed. The effect of the fallow land condition is much greater than that of the sowing technique factor on the studied characteristics. Reducing a number of traffic reduces power spent and total cost.

DOI: http://dx.doi.org/10.15666/aeer/1706_1273112751

Exploiting a spring-plowed fallow land by conventional tillage is more expensive than applying reduced tillage system on unplowed fallow land at spring.

For future experiments the followings are suggested:

1. Using other sowing patterns which include other implements for soil tilling and covering the seeds which may give good results affect the plant growth. For example, Chisel plow plus disc harrow or, rototiller plus field cultivator.

2. Comparing the performance of twin disc type seed spreader with mono disc type through the coefficient of variance measurement which is an important factor for increasing the crop production.

3. We recommend testing further experiments on the uniformity of the seeds distribution on the soil by using both seed drill and broadcaster with overlapped lines mode and comparing the results.

4. Taking into account using different speeds and heights of the rotating disc from the ground and the forward speeds of the tractor, which are important factors affecting the ratio of the uniformity of seed spreading.

5. Studying the effect of the number of machines passes on the soil compaction and its reflection on roots, seed germination, plant growth and total yield.

(Received 29th Apr 2019; accepted 11th Jul 2019)

Abstract. Curled dock (*Rumex crispus* L.) is a common perennial toxic weed species in wheat crop. To our knowledge, this is the distinctive scientific study proposed to evaluate the efficacy of four new chemical combinations of herbicides viz. Starane-M @ 750 ml ha^{-1}; Clean Wave @ 800 ml ha^{-1}; Broad-X @ 875 ml ha^{-1} and Allymax @ 35 g ha^{-1} sprayed as foliar application in wheat crop. These applications conducted with control treatment for proper comparison. Results illustrated that broad-X afforded highly significant ($P < 0.001$) potential for controlling this weed resulting in strong positive R^2 (0.84) with RMSE (0.69 & 0.80) compared to clean wave proved the evidence for model fitness. Significant ($P < 0.01$) mortality of curled dock catalyzed by mist spraying of broad-X (91.16%; 91.55%) conferred better control efficacy 30 days after treatment. Significant ($P < 0.001$) increase in yield (33.29%) was observed as a consequent of spraying broad-X followed by clean wave (29.63%) herbicides. The interaction of leaf area (cm^2) with herbicides correlated as predicted, which indicated that manual quantification method is suitable. The productivity increased significantly by spraying broad-X (33.29%) and clean wave (29.63%) compared to control. According to our findings, the new chemical herbicides obtained a high potential for controlling this invasive weed in wheat crops.
Keywords: *broadleaves weed, mortality, quantification, weed yield interaction, Gujrat, Punjab, Pakistan*

Introduction

Being a significant bellicose weed, curled dock (*Rumex crispus* L.) belongs to Polygonaceae family, native to South-East Asia (Schuster et al., 2015) and now has become a severe problem in irrigated wheat ecosystems in Gujrat, Punjab-Pakistan. *Rumex obtusifolius* is another species of this family present in arable soils (Marshall et al., 2003); however, broadleaf dock (*R. dentatus*) density was present in different locations of Dera Ismail Khan (Marwat et al., 2013). Weed competition has become a significant discretion in limiting the yield of any crop (Siddiqui and Bajwa, 2010). Weeds fight with the crop for the place, fluorescence, moisture, nutrient and reduce the yield (Shehzad et al., 2013). Weeds can infest any ecosystems; therefore, researchers focus on how to weed diversity affect crop yield (Davis et al., 2009).

DOI: http://dx.doi.org/10.15666/aeer/1706_1275312767

Herbicide resistance created many problems (Délye et al., 2013a) in response to its numerous applications across many years (Moss et al., 2019). Herbicide resistance alleles create pleiotropic effects on a weed's life cycle (Délye et al., 2013b). The rising figure of resistant weed biotypes is a critical fear for agriculture as no new herbicide mode of action has been marketed for over 30 years (Duke, 2012; Westwood et al., 2018).

Further, as pointed out that the effectiveness of herbicides depends upon the proper time of application, dose and selectivity of herbicides (Steckel et al., 1997), high weeds intensity and competition cause maximum reduction in yield (Chaudhry et al., 2008; Dalley et al., 2006). Weeds account for a significant 37-50% reduction in yield (Nayyar et al., 1994; Waheed et al., 2009) among them curled dock is a significant pest of many agriculture crops that not only reduce and also spoil the quality of the produce. Its control measures are ineffective in most of the plants due to the taproot system (Zaller, 2004a, b). High weeds intensity and competition with crops affected negatively reducing the yield of wheat crops (Dalley et al., 2006).

The weed infestations suppress the quality and quantity of crops; directly effects on economic and increasing the chance of spreading diseases (Marwat et al., 2008). Ecological surveys carried out in different areas of Pakistan revealed that curled dock seeds are prolific (Qureshi et al., 2009). Curled dock germinated from seed but also regenerate from the underground part of roots (Zaller, 2004b; Zimdahl, 2018).

The negligence factor considered a vital role responsible for weed infestation; hence, there is a dire need to develop effective management policies. However, researchers would focus on intensity, competition between weed ecosystem and appropriate application of proper new chemical herbicides are essential factors in determining the yield losses. The researchers would adopt better weed management strategies (WMS) for controlling this invasive weed in the ecosystem of Pakistan (*Fig. 1*).

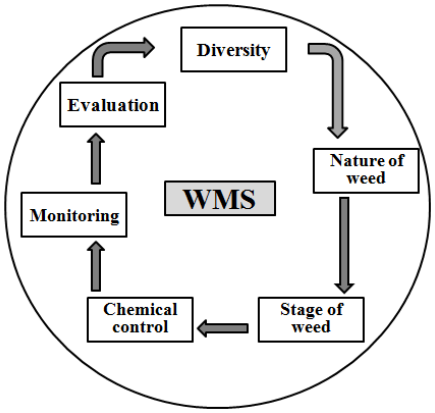

Figure 1. *Weed management strategies (WMS) for controlling curled dock*

The experiment suggested that the habitat of curled dock is annual present at roadsides, near the bank of ponds and non-cropped areas. In the arable areas, invasive weeds easily controlled by herbicides compared to agricultural lands (Crone et al., 2009). Nevertheless, in the present scenario curled dock (*Rumex crispus* L.) species shifted from non-cropped fellow lands to wheat crops, which creates alarming situations for researchers. This distinctive study aimed to screen out the best one herbicide for effective weed control, ensure better management and ultimately increasing the yield of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1275312767

the wheat crops. The hypothesis integrated that curled dock could control by foliar application of a mixture of two herbicides except one. Due to its hard phenotypic nature, new chemical combinations of herbicides tested for examining its better management. To sum up, the overall study planned to evaluate the response of new combinations of chemicals available in the market of Punjab, Pakistan. These chemicals sprayed to control curled dock according to its maximum abundance in wheat crops selected after extensive survey at different locations at Gujrat, Punjab-Pakistan during two consecutive years.

Materials and methods

Study sites

Table 1 shows two years of study designed after extensive field survey in Gujranwala division in order to evaluate the efficacy of four newly introduced combinations of herbicides for controlling Curled dock in wheat crop compared to control.

Table 1. *List of herbicides used in the study*

Chemical name	Trade name	Rate (g ai ha^{-1})	Chemical family	Dose (ml ha^{-1})
Control	Control	-	-	-
Fluroxypyr + MCPA	Starane-M	239 + 956	Phenoxy acetic acid	750
Fluroxypyr + Aminopyralid + MCPA	Clean Wave	350 + 25 + 956	Phenoxy acetic acid	800
Fluroxypyr + Clopyralid + MCPA	Broad-X	199.75 + 300 + 799.25	Pyridine carboxylic acid	875
Metsulfuron + Tribenuron	Allymax	357.5 + 357.5	Sulfonylurea	35 g

g = gram, ai = active ingredient, ha^{-1} = per hectare, ml = millilitre

The authors selected different sites in two villages of Tehsil Gujrat and Kharian in our experiments where the maximum abundance of this toxic weed recorded in wheat crops during 2015-16 and 2016-17 (*Fig. 2*).

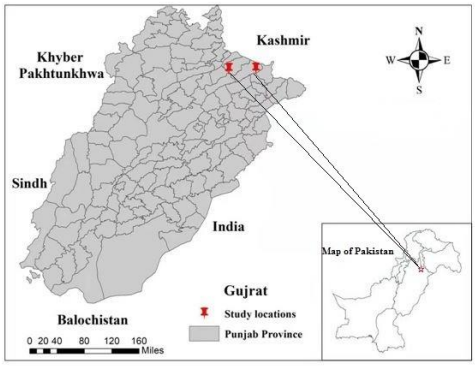

Figure 2. *ArcGIS map showing experimental sites in District Gujrat, Punjab-Pakistan*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1275312767

Experimental outline

The trial was exhibited by randomized complete block design (RCBD) with three replications having the net plot size for all treatments were 65 × 60 m, but for each treatment, the area designed was 13 × 20 m. Each plot or block was separated clearly by making paths (Dalga et al., 2014), and the experiment repeated in time, keeping in view the abundance of the curled dock. The wheat variety Faisalabad-2008 was cultivated in well-prepared soil using seed @ 125 kg ha^{-1} collected from Punjab Seed Corporation, Gujranwala. Di-ammonium Phosphate (DAP) 125 kg ha^{-1} and K_2O (SOP) @ 62 kg ha^{-1} were applied as a basal dose after planking by drilling method on last week of November each year. The wheat crops irrigated 30 days after cultivation and urea broadcasted uniformly in the field @ 125 kg ha^{-1}.

Foliar application

Herbicides sprayed at proper moist conditions with manually operated Knapsack hand sprayer with required spray and volume of water kept up to 300 L ha^{-1} using T-Jet nozzle with a droplet size of 225 µm and a fine mist of 2 PSI 45 days after sowing.

Data collection

The data collected randomly by quadratic ring using the diagonal method at three different locations in each treatment. The total populations of curled dock recorded before foliar application from each block/treatment. The wheat crop visited fifteen (15) days after applications, counted weed populations, and the same procedure adopted at the interval of 30 days each year, however, the experimental field monitored throughout the growing season. The mortality (%) of weed calculated (Alvi et al., 2004).

Leaf area measurement

Leaves from each treatment collected randomly for leaf area determination. These leaves placed on a white rectangular sketch of the whiteboard, calculated the leaf length (cm) and a maximum width of the leaf and multiplied by a constant value, i.e. 0.75 (Montgomery, 1911; Ahmad et al., 2015; Aldesuquy et al., 2014).

Root length measurement

At the time of harvesting, the root length (cm) of different treated plots calculated by measuring tape. The stems removed from the top portion of roots by a knife of each randomly selected plant. The total root length area from top to bottom measured compared to control (*Fig. 3*).

Figure 3. *Comparison of treated with control roots of curled dock*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1275312767

Collection of yield data

At the time of harvesting of wheat crops, yields recorded randomly from three positions of each treatment with 1 m^2 quadratic rings. Wheat plants were then removed manually by sickles from these rings and harvested these with mini thresher and assessed grain yield (Scursoni et al., 2011).

Statistical analysis

The data anatomized statistically by analysis of variance in Duncan's Multiple Range test with $P > 0.05$ level of probability. The analysis performed by SPSS 13.0 (Inc.) software and interaction between the observed and predicted variables by using R package, version 3.5.2. (MuMin, 2018) moreover, graphical representations were framed on Sigma-Plot 10 software (Iqbal et al., 2018).

Model validation

The coefficient of determination relationship conceded out for developing the model for leaf area versus herbicide treatments and comparison of R^2 and RMSE. This model was set out to determine the effectiveness of leaf area (cm^2), and root length (cm) ultimately provide the information concerning model fitness of how far away the fitted line is from the reference line. The researchers previously exposed how condensed or scattered the observed values are around the fitted line, which alternatively revealed about the validity and model fitness (Hossain et al., 2017). RMSE used to evaluate the performance of the model in the curled dock: chemical herbicides (Debaeke et al., 1997; Ahmed et al., 2019).

Results

Effect of herbicides on mortality

The effect of herbicides on mortality of curled dock (30 DAS) progression and analysis of variance resulted year wise comparison stated highly significant ($P < 0.01$) mortality (91.16%) by Broad-X with standard deviation (SD = 1.69), coefficient of variance (CV = 13.11) and standard error (SE = 4.788) after comparison with mean values by Duncan Multiple Range test. Clean wave followed this herbicidal treatment with statistically significant ($P < 0.05$) mortality (84.05%) with SD = 1.64 accordingly followed by Starane-M (79.92%), however, the lowest mortality was recorded by Allymax (61.21%) compared to control treatment during 2015-16 (*Table 2*).

The current research confirms the remarkable mortality of weed after the application of Broad-X (91.55%) with a probability value ($P < 0.01$) along with the SD (0.70) followed by clean wave (82.01%); Starane-M (77.86%). Allymax produced the lowest mortality (60.47%) compared to control treatment during 2016-17 (*Table 2*).

On the other hand, after 15 DAS (days of spray) mortality (70.84%) investigated by the application of Broad-X with SD = 3.84 differed statistically ($P < 0.05$) with clean wave (59.94%) along with rest of the treatments during 2016-17. In case of Broad-X (72.93%) and clean wave (63.52%) do not differ statistically from each other, but broad-X differed with Starane-M (56.57%) and other treatments during 2015-16 (*Table 2*).

DAS = days after spraying; t ha^{-1} = ton per hectare. The same letters do not differ statistically from each other at 5% significance level. C. V. = Coefficient of Variance; mean ± SD (Standard Deviation). Maximum (SD) means the sample of weed population was collected in the field conditions having maximum weed population in a replication

The curled dock leaf area displayed a steep asymptotic decrease using different new chemical herbicides compared to before spraying. However the evaluations of leaf area versus herbicides measured quantitatively recorded strong positive coefficient of determination $R^2 = 0.94$ and $R^2 = 0.93$, 15 and 30 days after treatment comparable before herbicide application as depicted (*Fig. 4*).

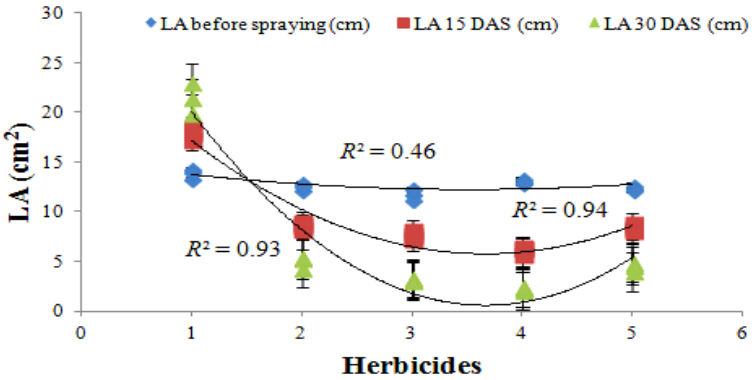

Figure 4. *Power relation of leaf area with different herbicides used in the experiment (1 = control, 2 = Starane-M, 3 = Clean wave, 4 = Broad X, 5 = Allymax) after 15, 30 days during 2015-2016, LA = Leaf area, R^2 = Coefficient of determination, DAS = days after spraying, cm^2 = centimeter square*

In wheat crop, all herbicide treatments had a similar influence shown by the mild asymptotic upright curve on leaf area development compared to before foliar application with $R^2 = 0.40$ (*Fig. 5*). The recorded leaf area 15 and 30 days after foliar application of broad-X performed maximum outcome on the weed followed by clean wave herbicides indicated that broad-X herbicide was most effective and potential for controlling this invasive weed. The power relation in wheat crop performed better coefficient of determination ($R^2 = 0.93$, $R^2 = 0.88$) indicated the evolution of observed leaf area recorded highly significant ($P < 0.01$) relationship with the progression of predicted leaf area during 2016-17 (*Fig. 5*).

DOI: http://dx.doi.org/10.15666/aeer/1706_1275312767

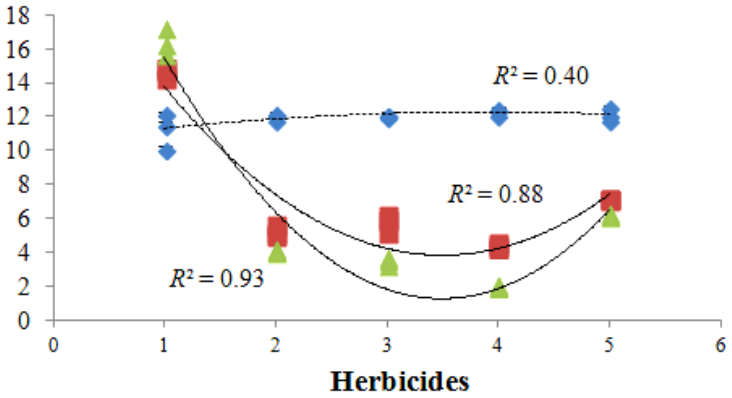

Figure 5. *Power relationship of leaf area with herbicide treatments (1 = control, 2 = Starane-M, 3 = Clean wave, 4 = Broad X, 5 = Allymax) used at 15, 30 days after spraying herbicides during 2016-17, R^2 = Coefficient of determination*

Response of herbicides with root damage (%)

The response of foliar herbicidal treatments performed statistically non-significant ($P > 0.05$) reduction in root damage (%), however highly significant ($P < 0.001$) responses were investigated by broad-X (97.15 ± 0.03%; 98.25 ± 1.08%) mean ± sd and (97.15 ± 0.017%; 98.25 ± 0.0626%) on mortality of curled dock during both seasons (*Fig. 6*).

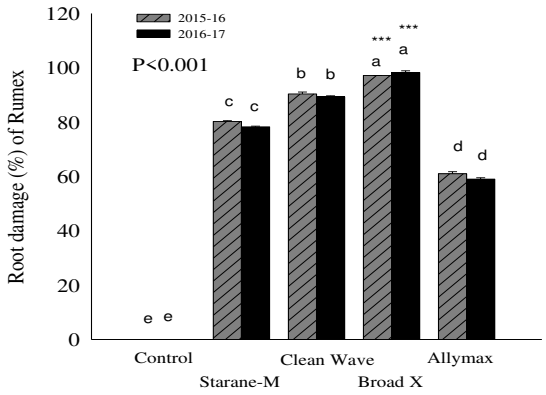

Figure 6. *Efficacy of new chemistry foliar herbicides used for controlling curled dock and herbicides influence on root damage (%) during 2015-16 & 2016-17. The means having the same lettering do not differ statistically from each other. *** indicated difference among treatments of herbicides with root damage (%) is highly significant*

Model validation performance of R^2

The polynomial relationship during both years for all treatments performed comparable arc trends, ensuring a decline after full ground cover. The R^2 for root length (0.93 and 0.88) were found statistically significant ($P < 0.001$) strong positive relationship in regards to observed and predicted root length (RL) during both the years

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1275312767

(*Fig. 7*) which indicated the best relation between two years resulting in the better fitting of the model.

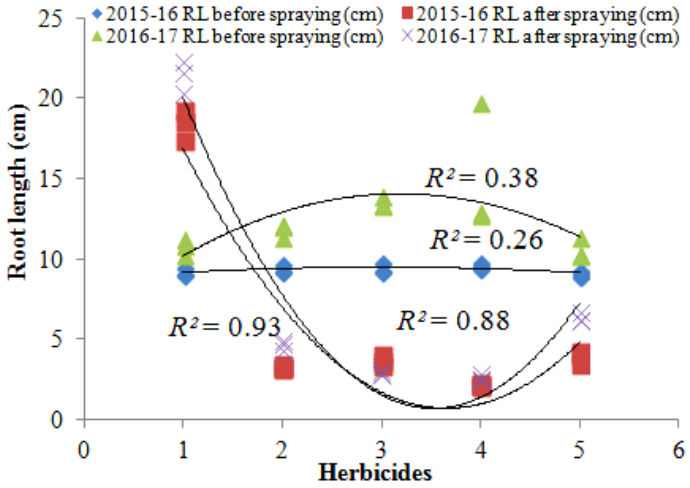

Figure 7. *Efficacy of different herbicides on root length (cm) of the curled dock during 2015-16 & 2016-17. Whereas power relation Root Length with herbicides (1 = control, 2 = Starane-M, 3 = Clean wave, 4 = Broad X, 5 = Allymax), R^2 = Coefficient of determination; RL = Root length, cm = centimeter*

Impact of herbicides on yield

Significant ($P < 0.001$) yield (3.43 t ha^{-1}) recorded by foliar application of Broad-X herbicides in a wheat crop with standard deviation (0.04); standard error (0.027) and coefficient of variance (1.71) during the first year 2015-16. Broad-X produced highly significant ($P < 0.001$) yield (3.69 t ha^{-1}) with (sd = 0.09) and se = 0.035 compared to rest of the herbicides during 2016-17. Year-wise accumulation by ANOVA also stated highly significant yield (CV = 1.97), however significant increase in yield produced by Broad-X (33.29%) followed by clean wave (29.63%) over control treatment (*Table 3*).

Table 3. *Co-efficient of determination (R^2) showing the effect of different herbicides on yield (t ha^{-1})*

Herbicides treatments	Yield (t ha^{-1})		R^2	RMSE	
	2015-16	2016-17		2015-16	2016-17
Control	2.420^{e}	2.327^{e}	0.72	0.67	0.81
Starane-M	2.920^{c}	3.067^{c}	0.72	0.58	0.81
Clean wave	3.297^{b**}	3.447^{b**}	0.83	0.67	0.75
Broad-X	3.433^{a***}	3.693^{a***}	0.84	0.69	0.80
Allymax	2.693^{d}	2.800^{d}	0.71	0.33	0.47

** P < 0.01; ***P < 0.001. The same letters do not differ statistically from each other. R^2 – Coefficient of determination; RMSE – root mean square error; t = tones; ha^{-1} = per hectare

Model validation performance for RMSE

Maximum yield was recorded by foliar application of Broad-X with a strong positive coefficient of determination R^2 (0.84) and RMSE (0.69 and 0.80). These results based on

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1275312767

highly signified accurate conclusions when comparing focused treatments in both years. The polynomial relation for all herbicides for corresponding years also exposed a linear arc pattern which strung with an initial linear stage followed by maximum asymptotic trend at the growth stage by R^2 (0.83) with RMSE (0.67 and 0.75) also indicated the best relationship that specified the method accuracy (*Table 3*).

Interaction of yield (t ha^{-1}) with mortality (%)

In *Table 4,* maximum interaction in yield (t ha^{-1}) with mortality (%) of curled dock 15 and 30 days after spraying conferred highly significant ($P < 0.0001$) performance during 2015-16 at Kharian. The interaction of yield versus herbicides 15 days after treatment and interaction of this with 30 days proved highly significant ($P < 0.0001$) mortality (%) that showed better performance during 2016-17. However, yield recorded significant ($P < 0.05$) interaction with mortality of curled dock 30 days after treatment (*Table 4*).

Table 4. *Analysis of variance of factors affecting yield (t ha^{-1}) interaction with mortality 15, 30 days after spraying postemergence herbicides*

Effect	D.f.	SS	MS	F	P
(a) Yield (t ha^{-1}) during 2015-16					
M15	1	7.221	7.221	849.99	< 0.0001
M30	1	0.186	0.186	21.86	< 0.0001

M15 x M30	1	1.144	1.144	144.647	< 0.0001
Residuals	41	0.324	0.008		

M15, M30 = Mortality after 15, 30 days of spray; the level of significance was $P > 0.05$, $P < 0.0001$***; $P < 0.001$**; $P < 0.01$*; $P < 0.05$; D.f. = degree of freedom; SS = Sum of square; MS = Mean square; F and P values. DAS = days after spraying; t = tones; ha^{-1} = per hectare

Discussion

Curled dock (*Rumex crispus* L.) is a common perennial (Ulber, 2010) invasive weed species in wheat crop. This weed characterized by high ecological plasticity and ability to spread in the wheat crop from non-cropped vicinity. Due to its high exotic potential, this weed becomes most economically important and creates many problems in irrigated wheat ecosystems. This invasive weed species can control easily in the non-cropped area, but this weed shifted into the wheat fields. No doubt, curled dock populations scattered in some areas of District Gujrat (Tehsil Kharian and Gujrat) in patches.

Broad-leaved dock is a common and troublesome grassland weed with a wide geographic distribution. In conventional farming, Curled dock managed by selective herbicides, however in an organic farming destructive method is the best option (van Evert et al., 2011) but it is laborious in large scale.

The studied chemicals (*Table 1*) disrupt hormone balance; protein syntheses in the curled dock and cause a variety of plant growth abnormalities. Cleave wave act as a growth regulator is synthetic auxin's (Yerkes et al., 2014) travel equally upward and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1275312767

downward inside the phloem to the growing points of the shoots and roots. Many herbicides in phenoxy acetic acids group are effective on perennial and annual broadleaf weeds (Gunsolus and Curran, 1999). Allymax selectively inhibits broad leaves by acetolactate syntheses ALS due to its systemic action. This herbicide belongs to sulfonylurea (SU) one of the most critical classes of herbicides worldwide. It is well known for its eco-friendly, extremely low toxicity towards mammals (Li et al., 2012). These are selective herbicides that kill dicots, sensitive to auxinic herbicides include abnormal growth, senescence, and plant death without affecting monocots (Song, 2014).

Weed management is significantly principal activity on agricultural and non-agricultural lands but faced with many types of challenges. There is a need to adopt broad-spectrum new approaches for its management strategies (Liebman et al., 2016; Calado et al., 2010). Therefore, critical challenges for invasive weed supervision comprised territory wise obstacle of weed emergence and expansion of cost-effective strategies would adopt for the control of invader (Buckley and Han, 2014) including biological control agents.

The response of foliar herbicide on mortality of curled dock performed highly significant ($P < 0.001$) responses by the application of Broad-X which is the combination of three herbicides (97.15 $\pm$ 0.03%; 98.25 $\pm$ 1.08%), i.e. (mean $\pm$ sd) and (97.15 $\pm$ 0.017%; 98.25 $\pm$ 0.0626%), i.e. (mean $\pm$ se) have a more significant potential for controlling curled dock under irrigated system of Gujrat (*Table 2*). The experimental effect was in agreement to Cheema et al. (2006) who described that the use of broad-leaved herbicides controlled maximum Chenopodium album. Curled dock controlled by Propanil herbicide (Price and Kelton, 2013) however, common sorrel (*Rumex acetosa*) species were susceptible to postemergence MCPA (Marshall et al., 2003) in wheat crops.

The study results were also in agreement with (Usman et al., 2010), who illustrated that 2,4-dichlorophenoxy acetic acid was effective for the better management of broadleaf dock (*Rumex dentatus*) in wheat crops. The previously described results against broadleaf dock were reported by (Naseer-ud-Din et al., 2011) that 2,4-dichlorophenoxy acetic acid (Bromoxynil + MCPA @ 0.49 kg a.i ha^{-1}) gave better performance compared to Pyroxasulfone @ 0.15 kg a.i ha^{-1} against Indian dock/broadleaved dock (*R. dentatus*) species in wheat crops during 2008-2009. These results are following the researchers who reported that the broadleaf dock (*R. dentatus*) having an identical family was controlled inadequately with 2,4-D. while, halauxifen + florasulam used @ 12.76 g; metsulfuron 4 g and etsulfuron + carfentrazone @ 4+20 g a.i ha^{-1} provided absolute control (Chhokar et al., 2015).

Isoproturon sprayed @ 1080 g a.i ha^{-1} reduced the density of Indian dock significantly (Shehzad et al., 2012).

The researchers reported that herbicides are most effective for controlling curled dock in their field experiments (Humphreys et al., 1999; Benvenuti et al., 2001; Eekeren et al., 2006). Maximum mortality investigated by Sulfosulfuran + Metsulfuran (92.27%) followed by Metsulfuran (81.69%) against this invasive weed after 30 days of spraying herbicides (Singh et al., 2017). Results of this and previous studies indicated that 2,4-DB (Butyrac 200) and Asulam @ 1.5 lb a.i $acre^{-1}$ (Asulox) provide better control efficacy against the dock in red clover field (Roerig et al., 2015).

The toxic effect of herbicides inhibited the growth of plants resulted in plant death. Scientists reported that herbicides killed weeds up to 90.5-94.1% after fifteen days of spraying; however, 100% mortality investigated after 21 days of foliar application

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1275312767

(Dimitrova and Marinov-Serafimov, 2008). Different doses of sulfosulfuron controlled weeds up to 98.7% (Paswan et al., 2017). Premix application of sulfosulfuron and metsulfuron methyl used @ 30 + 2 g ha^{-1} at 60 DAS was recorded highest mortality (%) compared to control treatment. Clodinofop + Metsulfuron methyl @ 60 + 4 g ai ha^{-1} was exercised by (91.75%) control followed by Sulfosulfuron @ 25 g ha^{-1} (87.60%) and Isoproturon + 2,4-D @ 1000 + 400 g ai ha^{-1} (87.42%) in the wheat crop after 90 days of post emergence application (Choudhary et al., 2016).

The studied leaf area of curled dock exhibited a steep declining curvature using different herbicides, which was comparable with low asymptotic development before spraying. The stable positive coefficient of determination developed in both of the seasons compared to control treatment (*Figs. 4* and *5*). Experimental findings correlate with previously reported work that leaf area measured exposed excellent performance $R^2 = 0.88$ and RMSE = 0.96. These results are conformity to (Ahmad et al., 2015) who reported $R^2 = 0.59$ in wheat crops by destructive method compared to non-destructive. The broadleaf dock (*R. dentatus*) controlled significantly by using different treatments; however, the effect of the relationship between crop succession and weed control treatments was significant (Fakkar and El-Dakkak, 2015).

Statistically yield (3.43 t ha^{-1}) recorded by foliar application of Broad-X herbicides in a wheat crop. The results of this study confirmed with (Malekian et al., 2013; Steckel et al., 1997) who recorded foliar spray of metsulfuron-methyl + sulfosulfuron @ 36g.a.i.ha^{-1} effectively controlled annual weed resulting in the highest yield of the wheat crops. Scientists previously revealed that severe infestation of weed plants in wheat crops resulting in 18-73% reduction in grain yield (Pandey et al., 2006). The researchers also described in their experiments that the mixture of Metsulfuran and Sulfosulfuron performed more efficient control with their foliar application resulting higher yield of crops (Singh et al., 2011). The model of density inhibition exposed effectively against the broadleaved dock; however its density reduced up to 69-88%, and wheat yield was enhanced up to 22-48% compared to control treatment by the application of Atlantis 3.6WG @ 14.4 g a.i ha^{-1} (Khaliq et al., 2011).

The invasive weed deteriorates the quality of grain by creating hindrance in cultural practices, i.e. fertilizer application and irrigation (Memon et al., 2003). The yield reduced up to 20-30% by the attack of broad-leaved weeds in wheat crop (Ashok et al., 2006). Due to the hard nature and invasiveness of curled dock, effective combinations of herbicides recommended for its better management.

Conclusion

Based on our knowledge, this is an exclusive comparative study in which the author used an applied combination of herbicides already present in the market having two and or three chemicals for controlling curled dock in wheat crops. These results screened out Broad-X herbicide performed better against the curled dock followed by Clean Wave in wheat crops. According to the above analysis and findings, the farmers in this region advised using these postemergence herbicides for controlling this toxic weed in ordered to obtain higher yield. We encouraged researchers to explore the mode of action, resistance mechanism of these herbicides and to find out suitable biological control agents (BCA's) against this toxic weed in future.

Abstract. The concepts of vulnerability and resilience are gaining popularity in the development literature but still lack conceptual integration with the theory and practices of livelihood dynamics. However, the livelihood system of a community is a key element of the social system which may frequently be disrupted by the ecological, financial, natural and human-made vulnerability. Therefore, the purpose of this study is to clarify the concept of vulnerability and resilience in the perspective of livelihoods in a climate vulnerable context. It also addresses the methodological gaps through translation of theory from existing literature. This study argues that vulnerability and livelihood resilience are inversely related. It recommends some indicators and pillars for a better understanding of the vulnerability and livelihood resilience drawing from assorted literature through analysing the concept from various dimensions. The study will be helpful in understanding the livelihood dynamics and its assessment in the perspective of vulnerability and resilience.
Keywords: *environmental management, security, climate change, adaptive capacity, environmental risk*

Introduction

Vulnerability of people to possible natural hazards was impossible to measure before 1990s due to a lack of data availability, appropriate scales, and appropriate measurement approaches. Though according to Janssen (2006), the word 'vulnerability' appeared about 939 times in 2286 publications of disaster literatures in the last 30 years. Vulnerability to natural disasters is a combined effect of nature, environment, society, financial condition and community sensitivity. It is characterized by the susceptibility to be victimized or disrupted by natural disasters. Natural disasters, particularly climate change is a global concern and a daunting challenge for humanity since time immemorial. Natural disasters affect the livelihood of people of developing countries lacking in resources the most. So, natural disaster is one of the major causes of vulnerability (Dyakov, 2013; Garamvölgyi, 2013; Jamali et al., 2018; Sarker et al., 2019). The devastation of natural disasters occur in ways such as gradually changing average temperature, humidity and other environmental factors, increasing annual and seasonal climatic conditions, gradually increasing the frequency of hazardous events and the speed at which catastrophe factors are changing (Tompkins and Adger, 2004; IPCC, 2014; Omotoso et al., 2018; Nistor et al., 2018; Akhtar et al., 2019).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1276912785

Vulnerability is the ability of people, organization, and societies to withstand the adverse effects of stressors (Ajibade et al., 2013; Lee, 2014; Hoa, 2019; Terin, 2019). Most of the cases, the socio-ecological vulnerability of the people is the same across the globe. People usually faces three vulnerability components viz. exposure, sensitivity and adaptive capacity (Cutter et al., 2003; Fatemi et al., 2017). Comprehensive vulnerability analysis requires a specific context for better understanding. Vulnerability analysis should be done to find out the root causes and provide a suggestion for tackling adverse effect. Resilience is a concept which has been applied to research and practice in every possible field from science to sociology, nursing (Ho et al., 2012), medicine (Garcia-Dia et al., 2013), psychology, business and public administration. It is a process of "bounce back" or "returning to form" (Weldegebriel and Amphune, 2017). Livelihood resilience is the ability of an individual, group, or community to bounce back to anticipating livelihood challenges, reducing the effect of vulnerabilities, recovering effects from past and present vulnerabilities, and thriving even in a difficult livelihood environment (Gwimbi, 2009). This study is going to assess the status of livelihood resilience of riverine island dwellers and recommend some measures for improving their livelihood resilience.

The word 'resilience' originates from Latin word *resilio* that means 'to jump back' (Manyena, 2006). Walker and Salt (2012) have claimed that 'resilience' originated from ecological research where Holling (1973) sought to differentiate between an ecological system that persists in a condition of equilibrium or stability, and response of dynamic systems when they are stressed and move from this equilibrium. A resiliency perspective is an understanding of a system's adaptive capacity. For livelihood systems, the four pillars of this perspective relate to activities and processes allowing for effectively (a) *anticipating* livelihood challenges and potential for surprises (b) *minimizing* the impact of present vulnerabilities (c) *recovering* from the impact of past as well as present vulnerabilities and (d) *thriving* from a complex livelihood situation (Gwimbi, 2009).

Livelihood resilience is a top policy concept in development context research which emerging from various disciplines (Tanner et al., 2015). It actually focuses the ability of a community to bounce back to normal condition i.e. previous conditions after suffering shocks. Resilience is a process which tackles a wide range of shocks, vulnerability, and stress like vulnerable livelihood, food insecurity, social protection, disasters and social conflicts (Zebrowski, 2013). United Nations (2013) has already declared resilience as an important agenda for working as part of an integrated and comprehensive approach to assessing and addressing factors that undermine communities' and countries' resilience, including climate risk, environmental sustainability and social inequalities or exclusion. Natural disaster particularly climate change is a global concern and worst challenges for humanity from the ancient period. The main effect of natural disasters is on the livelihood of the resource poor people of developing countries.

Some studies have already been done on resilience in the psychology literature, climate change literature, engineering literature and social sciences (Dyakov, 2013; Garamvölgyi, 2013; Jamali et al., 2018; Alam et al., 2018; Sarker et al., 2019). Most of them focus on ecological analysis and few of them explain clearly about the concept of vulnerability and resilience in the perspective of a society which resulted to fill the connection with livelihood dynamics. Therefore, this study attempts to fill the research gap by addressing this issue through an extensive review of the literature. This study also intends to add the methodological implication for understanding and measuring the livelihood vulnerability of a community with the clarification of the concept. It also provides a new lens of the suitability and superiority of resilient livelihood thinking over sustainable livelihood framework (SLF)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1276912785

by exploring the weakness of SLF and adding solution for achieving livelihood resilience in a disaster vulnerability context. Though the term "resilience" is gaining popularity in the literature irrespective of the disciplines and livelihood research, the meaningful integration of the concept through proper translation from theories to action is really challenging. The concept of vulnerability and resilience is focused on the mainstream literatures such as climate change (Adger, 1999; Alam et al., 2018); disaster management (Shah et al., 2018; Adger, 2005), urban management (Sarker et al., 2019), nursing and engineering management (Fox-Lent and Linkov, 2018). But some researchers used the concepts for social-ecological system literature (Chaffin and Scown, 2018; Adger, 2005). The present study focuses the concept in the perspective of the socio-ecological system which is a better fit to livelihood system.

The rest of the paper is organized as section 2 deals with the methodology, section 3 describes the result of the study, section 4 deals with discussion focusing resilience and resilience concept emphasizing livelihood through developing a conceptual framework and final section concludes the article.

Methodology

Research design

A systematic literature review has been conducted for obtaining research objectives. An extensive desk literature review has been done for obtaining recent literature (from 2005 to 2018). Concept analysis has been done to clarify the resilience concept and validate the concept through filed data. A case study (as part of the author's PhD study) also has been done to validate the conceptual framework through assessing the vulnerability of disaster-prone community.

Search strategy

This study emphasizes the resilience concept in the multidisciplinary aspects. An extensive literature search has been done on some renowned databases like web of science, engineering village, and Scopus databases by using keywords such as "resilience, resilient, vulnerability, capacity" (*Appendix A*).

Inclusion criteria

The literature search is guided by two criteria; first, the study must focus on vulnerability and resilience; and second, livelihood is the main concern of the study. Livelihood resilience focused and peer reviewed articles have been considered for the time from 2005 to 2018 which focuses on human population. The focal points of the study are to identify the important definitive research on vulnerability and livelihood resilience, and the trend of the modification and integration of the concept and meaning of resilience to other discipline and its potential implication to the society.

Exclusion criteria

This study excludes the journal articles which have no full text, duplication and published in other languages than English. It also excludes the articles in which content does not cover the concept of resilience and disaster vulnerability context.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1276912785

Review results

Preferred Reporting Items for Systematic Review and Meta-Analysis (PRISMA) guidelines has been followed in a systematic literature review (Moher et al., 2009). The review search has been done by following several steps; first, 575 documents are identified with 19 from references (*Fig. 1*). After removing the duplicates, 254 documents have been selected by abstract screening. Then 116 documents have been excluded due to lack of full text, irrelevant, not focusing on livelihood resilience. Finally, 29 documents have been selected from journal articles, books, book chapters, and working papers (*Appendix B*). The checklist of the Reporting of Observational Studies in Epidemiology (STROBE) is also followed for qualitative document selection (Vandenbroucke et al., 2007). This review has been conducted from December 2018 to January 2019. A conceptual model has been developed for livelihood resilience.

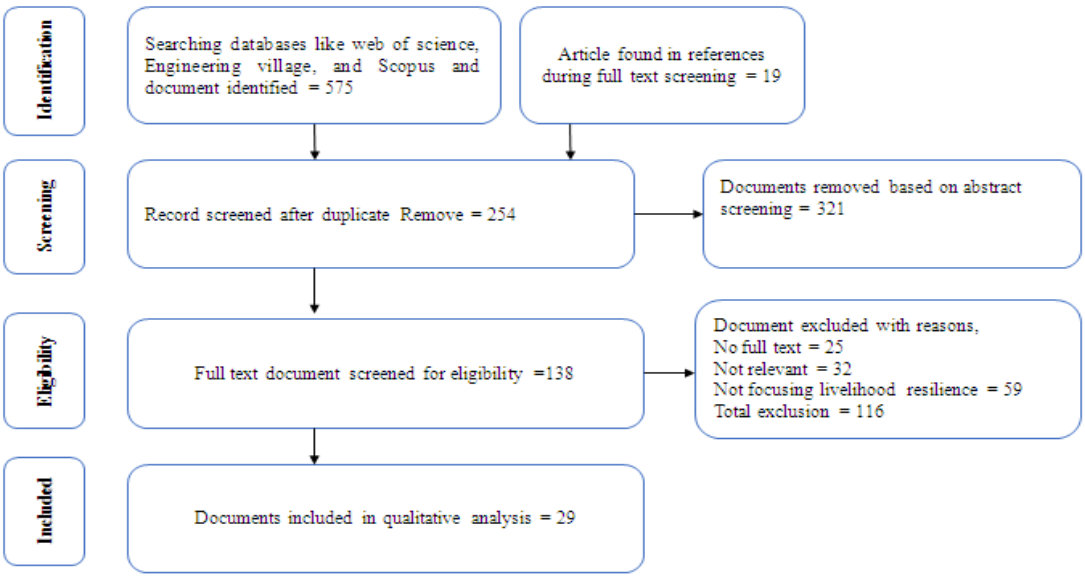

Figure 1. *PRISMA selection for qualitative study*

Discussion

The findings of this study have been presented into two following sub-sections; the first section deals with vulnerability and second section deals with livelihood resilience.

Vulnerability

The concept of vulnerability

The major characteristics of vulnerability are its dynamic nature that influences people's social and biophysical processes (IPCC, 2014). Significant attention is needed from the researchers and policymakers to develop successful adaptation strategies. Citizens of developing countries are highly vulnerable due to low income and dependency on agriculture (UNDP, 2008). These burdens should spark exploration of potential adaptive capacities for resource poor communities. People's susceptibility to the impact vulnerability of natural hazards are increasing to almost all spheres of life like social physical, human, financial, and natural dimensions. Though the effect of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1276912785

natural hazards may be occasional, seasonal or year-round, the extent of exposure varies across communities.

Rural livelihood is highly dependent on climatic variability as its dependence on agriculture. Livelihood vulnerability means the susceptibility of livelihood system of stressors. Since the livelihood system of a community comprises natural, human, social, physical and financial capitals that mean it solely depends on the socio-ecological system. According to DasGupta and Shaw (2015), rural livelihood is adversely affected by the effect of climate change. Abid et al. (2016) mention that rural livelihood is dependent on a complex system of institutional, biophysical, financial and political condition of the community. Livelihood vulnerability actually focuses the exposure, sensitivity as well as adaptive capacity of an individual's livelihood or a community's livelihood in the face of natural disasters.

Dimensions of vulnerability

The major three components of livelihood vulnerability are exposure, sensitivity and adaptive capacity (*Fig. 2*). Exposure addresses the extent of a system facing varying climate conditions. It generally focuses the condition of an individual or community during facing variable climatic situations. It shows the frequency, and extent of loss in terms of livelihood capitals. Sensitivity means the degree of a system which addresses how sensitive to the variable climatic conditions. It generally focuses the reaction of an individual or community during facing changing climatic situations. It also shows the frequency, and sensitiveness in terms of livelihood capitals. Adaptive capacity is the ability of a system to withstand against the stressors and shocks. It emphasizes the ability of an individual or a society to tackle or control the situation which occurs during natural hazards.

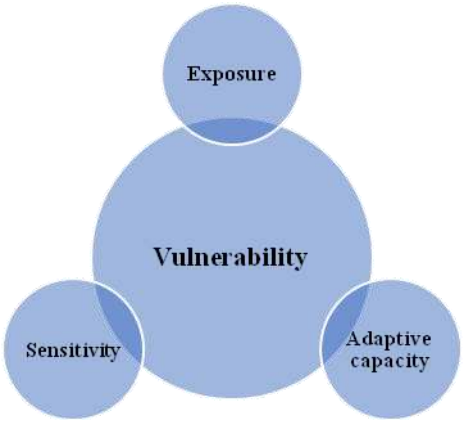

Figure 2. *The major elements of vulnerability in a socio-ecological system*

Vulnerability of the people of developing countries is almost similar all over the world such as flooding, riverbank erosion, drought, storm, cyclone, crop and livestock diseases infestation. Paavola (2008) conducted a study on livelihood vulnerability of Tanzanian farmers and reported that agricultural farming-based livelihood is highly vulnerable to climatic variability. Livelihood system is varied from community to community such as livelihood of the people of rural Burkin Faso is solely dependent crop cultivation, livestock and agroforestry and they suffer from seasonal food

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1276912785

insecurity due to climatic variability (Addisu et al., 2016). Jacobi conducted a study on the livelihood of the fish farming community in Kenya and reported that climatic variability was the main drivers of vulnerability to the community. Beckford and Rhiney (2016) assess the vulnerability of a community living in north eastern St Vincent and concluded that the main driver of poverty was livelihood vulnerability caused by environmental variability and globalization. Climate change is one of the main drivers of livelihood vulnerability of the people of coastal areas especially natural resources dependent people. Chinwendu et al. (2017) conducted a study on household vulnerability and adaptation to climate change in Kaduna river basin in Nigeria and reported that livelihood vulnerability was varied from village to village of riverbank community due to varies of sensitivity to risk, uncertainty and limited access to natural resources and institutional capacity. Antwi et al. (2015) assessed the community vulnerability of a flood prone community in Ghana and mentioned that climate induced disasters make the people vulnerable in terms of socio-ecological, financial and political aspects.

Natural disasters are the outcome of interaction among hazard and stake, living and non-living and fixed and moving elements which causes human, economic, environmental, socio-political losses and cultural crisis in people's livelihood. Most of the rural communities have faced vulnerabilities in terms of various livelihood capitals such as social, political, financial and natural assets due to dynamic changes of environment in Zimbabwe (Nyamwanza, 2012). Wilson (2014) conducted a study on livelihood vulnerability and politics of adaptation in Alaska and reported that subsistence livelihood of the people was highly vulnerable due to climate change impact which could be minimized through developing context specific adaptation strategies. Literature across the world shows that changing climate is the main driver of livelihood vulnerability which affects almost all aspects of human life.

Livelihood resilience

The concept of livelihood resilience

Livelihood is a way of living which is comprised of the capabilities, assets, and activities. Livelihood resilience is the ability of a people or a community to sustain and retain livelihood opportunities in a stress situation which caused by the disturbances of social-ecological system, political system, and financial reasons. Resilience is a set of behaviors that stimulate social transformation and empower a group of people or social system (Earvolino-Ramirez, 2007; Gaillard, 2010; Jorgenson et al., 2010; Scholz et al., 2012). Livelihood resilience integrates livelihood system with resilience in a way where people are the main actors in the adaptation practices. The environmental factors are responsible for hampering the livelihood system of resource poor and vulnerable people to conduct their daily life (Adger, 1999). It thus requires an in-depth investigation of how climatic factors influence the livelihoods of people. Though sustainable livelihood framework is developed for the use of international agencies for poverty alleviation through improving livelihood assets, it adds a new dimension for livelihood research especially for the livelihoods which associated with the vulnerability, shocks, and stress of social and ecological systems (Vogel et al., 2007; Zebrowski, 2013). Importantly, people are the central concern of livelihood thinking where ecological factors, social and political factors, market, technology and resources are the associated factors related to livelihood (Panthi et al., 2016).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1276912785

Livelihood resilience however, stimulates the capacities of an individual, community or administrative system to respond to the challenges, risks, stressors and disturbances. It also enables people to perceive the risks and uncertainties of social-ecological systems and to take anticipatory actions to tackle the adverse situation. An ideal resilience system requires natural resources, information and access to physical, economic and logistic assets for developing the system against the disturbances of the environment. Livelihood resilience also integrates social networks with human rights for resilience thinking. Both human rights and social network are essential elements of social system to develop the capacity of the system against any adverse situation.

Livelihood resilience thinking from sustainable livelihood framework

The present study borrows the concept of ecological resilience for livelihood inquiry for better explanation of livelihood resilience in the disaster vulnerability context. The other concept of resilience is indirectly related to livelihood system because of its relation to the changing climate, stress and shocks as well as physical infrastructure, social and economic system and institutional responses. Since ecological system is completely different from livelihood system, this study considers all related dimensions of social and ecological systems for better integration of livelihood inquiry to resilience. A sustainable livelihood approach is followed to assess the livelihood pattern which consists of the analysis in the context of people's livelihood. This approach confirms Sen's (1981) classic focus entitlement, Long's (1984) action oriented approach, and Chambers and Conway's (1992) seminal paper on sustainable livelihood. Sustainable livelihood approach is a well-accepted approach which has emerged in 1990s for assessing the livelihood system and strategies in the face of natural disasters and vulnerability of rural people. According to sustainable livelihood approach (following Chambers and Conway, 1992; Scoones, 1998), livelihood is a set of physical and social assets, and actions for living as well as it can be sustainable in such a condition when it is able to cope with and retain from risk, uncertainty and stress through enhancing capabilities and without hampering the natural resources.

The sustainable livelihood approach considers demographic, socio-economic, political and ecological context of people's life and access to social, economic, physical, natural and human capitals as well as institutional aspects for ensuring people's access and control over assets. Various scholars developed some analytical framework by using the diagrammatic checklist developed by Scoones (1998) such as vulnerability framework by Moser (1998), capitals and capability framework of Bebbington (1999) and micro-policy analytical framework by Ellis (2000). Using the principles of sustainable livelihood framework, some renowned organization already developed their operational SLF such as Cooperative for Assistance and Relief Everywhere (CARE), Department for International Development (DFID), Oxfam and the United Nations Development Program (UNDP). Since various organization developed their livelihood analysis framework in the light of SLF, this study only considers SLF for guiding own research direction.

There is an increasing trend of using the sustainable livelihood framework in assessing vulnerability, risk, uncertainty and livelihood literatures (for example, Can et al., 2013; Amos, et al., 2015; Addisu et al., 2016; Alam, 2016; Bhuiyan et al., 2017) all over the world. Sustainable livelihood framework (SLF) is a basis of rural vulnerability studies irrespective of the country (for example Li et al., 2018; Pandey et al., 2017). Theoretically, the sustainable livelihood framework (SLF) is developed to deal with

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1276912785

condition where the poor perform as 'strategic managers' in transferring the livelihoods outcomes, through a set of livelihood activities in accordance with the entitlements and access to resources, as decided by the conditions of institutional contexts (Moser, 1998). The sustainable frameworks point to assets as central concern which is mainly affected by the environmental stressors. Livelihood strategies and institutional process are the driver for transforming the vulnerable context to sustainable livelihood. Livelihood strategies are the strategies taken by the people for maintaining their livelihood and institutional process is responsible for translating the assets and strategies into action for making desirable and sustainable changes in people's livelihood. The major livelihood strategies of rural people are agricultural practices, diversification of livelihood, and migration (Ellis, 2008).

The SLF approach may be explained in three ways; first, framework for short-term livelihood trajectories; second, a way of development activities; and third, outline of overall development. In the livelihood related literature, the SLF was possibly envisioned as the earlier; as "a diagram to organize ideas into manageable categories, to identify entry points and critical processes, and assist with prioritizing catalysts for change that can improve people's livelihoods" (Ellis, 2000).

Strength of sustainable livelihood framework

Vulnerability assessment requires understanding of the SLF in terms of its strengths and weakness for building a concrete method of assessment (Pandey et al., 2017). Due to its strength, it is well accepted all over the world for livelihood assessment. The main strengths of SLF are focusing people-centeredness, people's capabilities and holisticness. First, SLF is people-centered approach which focuses people's realities, strengths and compromises to others. It emphasizes local complexities and realities for analyzing the issues in a better way. Second, SLF analyzes people's capabilities and strengths which is necessary for overcoming risk, uncertainty and livelihood insecurity (Ekblom, 2012). Third, SLF is a holistic in nature in terms of its recognition to multiple strategies, actors and outcomes where people's livelihood is connected. So, it is applicable to assess the dynamics of livelihood vulnerability of char dwellers in Bangladesh. Sustainable livelihood framework has broad aspects of inquiry covering vulnerability, shocks, risks, assets, institutional response, strategies of livelihood and outcomes which may be a toolkit for livelihood analysis. According to Clark and Carney (2008), SLF is a key analytical tool to assess and understand various aspects of the livelihood of people.

Weakness of sustainable livelihood framework

Though SLF is well accepted by various scholar but it is still criticized due to ignoring or avoiding some important issues. The main limitation of SLF is its inability to address the social, political, and institutional aspects (Scoones, 2009). It actually avoids focusing the role of structures, acting process, and institutions rather emphasizing assets and activities of household though the assets are not neutral due to its inclusion and exclusion nature (Antwi et al., 2015). SLF generally assess the livelihood status at household level which is a key to local context but less concentration to connect with national and global level. Livelihood vulnerability analysis requires an emphasize on a connection with institutional levels for better integration with the institutional capital irrespective of micro or macro level

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1276912785

perspectives. An importance on institutional process and political economy focusing structural forces is necessary to assess the dynamic of rural livelihoods and resilience (Scoones, 2009) but present form of SLF cannot meet this issue. Besides the term "sustainable," a core term of SLF, has not been properly focused in terms of variable local context (Bhattacharjee and Behera, 2018).

SLF cannot provide the answers to some quires such as 'sustainable to what and for whom' whose reality to be addressed? (Chambers and Conway, 1992) which are very much important in dynamic vulnerability context. According to Longley and Maxwell (2013), SLF is very much developed and applicable only for reducing poverty in relatively stable context. One of the major weak points of SLF is how to address sustainability in the dynamic vulnerability context where livelihood assets are recurrently hampered with environmental factors. SLF is basically outcome-based approach which cannot address the related process and capacities. It focuses only on short-term dynamics rather than long term which reduce the ability to address the dynamic vulnerability context of livelihood.

From sustainable livelihoods to resilient livelihoods thinking

This study attempts to develop a framework for addressing the weakness of SLF and assess the dynamic context of vulnerability and livelihood through including elements of adaptive, absorptive and transformative capacity. Resilience thinking is the advanced option of livelihood vulnerability assessment following SLF but addressing all weakness of SFL. This study adopted SLF for operationalization of the perspective of resiliency using the useful idea from SLF for better understanding the dynamic vulnerable context. The transformation from sustainable livelihood to resilient livelihood is summarized and presented in *Table 1*.

Table 1. *Summarizing main aspects on shifts from sustainable to resilient livelihoods thinking (Source: adapted after Nyamwanza, 2012)*

Sustainable livelihoods thinking	Resilient livelihoods thinking
Sustainability	Resiliency by adaptive, absorptive and transformative capacity
Assets	Institutions and assets
Linking household and geographical/spatial scales	Linking institution, community, household and temporal scales
Coping and short-term dynamics	Both coping and adapting – however focusing more on long-term adaptation dynamics
Outcome-oriented	Process-oriented

It is well established that the core ideas of sustainable livelihood framework form the central position of the analysis of dynamic vulnerability context. In this study, resilient livelihood thinking is focused on using the useful ideas from sustainable livelihoods for better understanding the dynamics of changing vulnerability context. The resiliency perspective as advanced in this work builds on the strengths of this thinking, blending it with new ideas in taking livelihood analysis forward – from thinking about 'sustainable' livelihoods to 'resilient' livelihoods. Ideas from Scoones's (1998) 'diagrammatic checklist' and Ellis's (2000) livelihoods framework were used in the adapted framework to guide analysis. This is because while showing general interrelationships and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1276912785

connections, these scholars' presentations provide room for re-arranging ideas and infusing new ones as they seem less rigidly formulated to show particular linear or contextual patterns. *Table 1* summarizes the major aspects vis-à-vis shifts from sustainable livelihoods to resilient livelihood thinking as raised in various discussions in this work so far.

The conceptual framework (*Fig. 3*) has been developed by following 'diagrammatic checklist' of Scoones (1998), livelihood framework of Ellis (2000) and livelihood framework for resilience of Nyamwanza (2012). This selection is due to the flexibility of their framework to include element, re-arranging ideas and developing new one for context specific livelihood analysis. The conceptual framework focuses vulnerability context (flood, drought, riverbank erosion, cyclones, shocks, and risks), livelihood assets (human, natural, social, physical and financial assets), institutions (household, community, sub-national, and national level), adaptive strategies (livelihood strategies), various capacities (adaptive, absorptive, and transformative capacity) and outcome related livelihood.

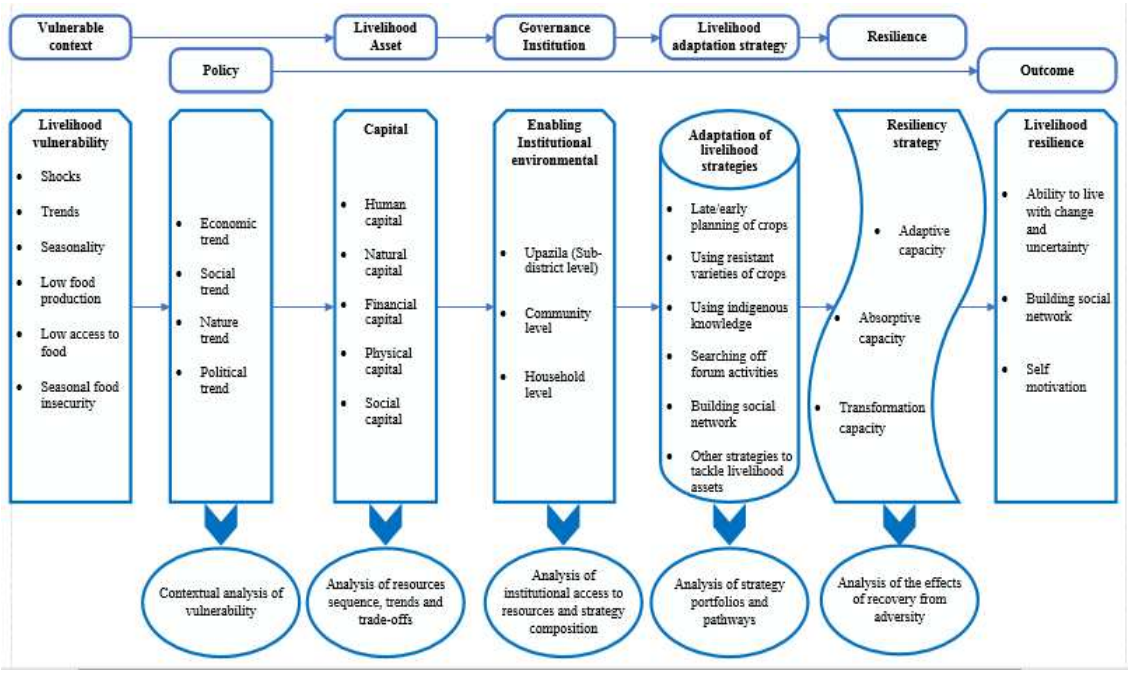

Figure 3. *Adapted livelihood framework for resilience (Source: adapted after Scoones, 1998; Ellis, 2000; Nyamwanza, 2012)*

The framework will be applicable to analyze the vulnerability of any community especially who are facing the adverse of climate change. It will help to interpret the factors responsible for livelihood vulnerability, and the positive effect of policy measures and livelihood assets to overcome the vulnerable condition. It also provides the direction of how government institution can solve and improve the vulnerability context and which level is most suitable for government intervention. This framework might be useful for its adaptation strategies for improving livelihood condition in a vulnerability context. It also focuses how resilience capacities developed and work in a vulnerable livelihood context for obtaining a self-motivation, strong social network and ability to live with uncertainty.

Conclusion

The concept of livelihood resilience is relatively new in natural disaster vulnerability context. This study attempts to clarify the livelihood resilience concept from the perspective of climate change vulnerability and natural disasters. It analyzes the resilience concept by focusing on various dimensions of vulnerability and resilience. It also integrates the livelihood system to the resilience concept successfully through analyzing more related existing literature of the renowned databases. This study reveals that vulnerability is a function of exposure, sensitivity and adaptive capacity of a system in which exposure and sensitivity are positively related to vulnerability while adaptive capacity is negatively related. Similarly, livelihood resilience is a function of the adaptive, absorptive and transformative capacity of livelihood system which enables people to sustain and retain livelihood opportunities in stress events caused by natural disasters. Livelihood capitals (e.g. social, natural, human, physical and financial capital) help to enhance the capacity of the people in the face of climate change vulnerability. This study also interprets the development of resilient livelihood thinking from traditional sustainable livelihood framework which is suffering from various weaknesses. This study argues that livelihood resilience is more advanced and suitable approach to address disaster related vulnerability issues. This study further argues that resilience livelihood framework and related indicators will help to assess the vulnerability of a socio-ecological system and to take proper measure to improve livelihood resilience of any vulnerable people, group or community. The study suggests conducting in-depth empirical study on livelihood resilience assessment in the natural disaster prone vulnerability context using specific indicators developed in this study for future research.

THE EFFECT OF AFFORESTATION ON BIODIVERSITY IN MALATYA, TURKEY

MUTLU, B.

Hakkari Forest Management Directorate, Hakkari, Turkey
(e-mail: basrimutlu44@hotmail.com; phone: +90-438-211-6224/+90-530-347-9860)

(Received 3rd May 2019; accepted 20th Aug 2019)

Abstract. Since 1960s, the Tepehan (Turkey) region had long been suffering from serious soil erosion. Therefore, large-scale afforestation with mainly coniferous species has continued during the past decades in order to control soil erosion and it has yielded quite successful results. However, since it has been unknown how afforestation influences biodiversity so far this study investigated it. Braun–Blanquette method was used to select a plot in each stratum which represents the vegetation characteristic of the whole area of the forest and to assess vegetation parameters. The results of the survey show that 77 species belonging to 58 genera were recorded in different layers including 7 trees, 4 shrubs and 66 herbs in the study area. Diversity index was used for measuring biological diversity and was found consistently and significantly greater in native Quercus forests than in exotic coniferous plantation forests. These results show that afforestation has a negative influence on species diversity. Therefore, it is recommended to develop strategies for biodiversity conservation in afforestation work in the country to maintain habitats and minimize loss of native species.
Keywords: *afforestation, biodiversity, biodiversity index, vegetation*

Introduction

For 5 to 6 thousand years in our world the delicate balance between soil, vegetation and water has been disturbed in natural environments as a consequence of the removal or destruction of natural vegetation for various reasons. Especially wrong land use with deforestation and erosion in sensitive ecosystems where semi-arid and arid climatic conditions dominated caused the loss of soil and the disappearance of plant species. Afforestation activities have an important role in re-equilibrating the degraded ecosystem as well as reducing the effects of some global disasters and fighting erosion. However, the impact of afforestation with single or several of exotic coniferous species has been discussed without much consideration of the ecological characteristics of the forests.

Whereas some afforestation efforts are believed to harm ecosystem biodiversity and interfere with biodiversity conservation goals (Cao et al., 2009; Calvino-Cassela et al., 2012; Pourbabaei et al., 2012), a large number of studies in many countries has shown that the plantation of forests can provide habitat for a wide range of native forest plants, animals, and fungi and can support a diverse array of native understorey plants (Barbaro et al., 2005; Carnus et al., 2006; Brockerhoff et al., 2008; Juying et al., 2017).

Usually, the used species show rapid growth instead of natural species in afforestation to control soil erosion, accelerate vegetation restoration, and improve ecological environments in Turkey and quite successful results have been obtained. However, the positive/negative impact of afforestation on biodiversity is not discussed so much in Turkey. Whereas it is important to identify the effects of afforestation on biodiversity and the functioning of ecosystems. Biodiversity has been shown to play a key role at all levels of the ecosystem service hierarchy (Mace et al., 2012; Gao et al., 2014). Therefore, the importance of measuring biodiversity increased.

Various diversity indices are used to measure biodiversity. Diversity index is a statistical method which is planned to evaluate the variety of a data group consisting of different types of components. Such as number of existing species (Richness), equal distribution of individuals (Evenness) and total number of existing individuals. Any changes in any of these three features are effectively used to identify changes in a population (Mısır et al., 2018).

The study area Tepehan (Malatya-Turkey) is on the southeastern Taurus Mountains where Davis describes in terms of floristic as medium, few or never worked and where studies suggest that the work should be done at a local level and in detail and had long been suffering from serious soil erosion since 1960s. So large-scale afforestation with mainly coniferous species has continued during the past decades in order to control soil erosion and quite successful results has been obtained. However, it has unknown how afforestation influences biodiversity so far. So in this study both inventories have been carried out and the influence of afforestation on the vegetation was assessed by using biodiversity indices.

Materials and methods

Study area

Study was conducted in Tepehan located at 38° 11’ 45.3” N and 38° 52’ 8.1” E. The first afforestation and erosion control works started here in Malatya in 1962.

In Tepehan and its surrounding, Puturge metamorphic consisting of gneiss, micaschist and amphibolite dominate the terrain. These are the oldest formations in the region and they form the foundation (*Fig. 1*).

Figure 1. *The location of the study area*

DOI: http://dx.doi.org/10.15666/aeer/1706_1278712798

Climate

The climate data of the Puturge Forest Station, which is the nearest meteorological station to the research area, are given in *Table 1*.

Table 1. *2017-2018 data of Puturge forest meteorological station (MGM, 2019)*

Meteorological data	Period	MONTHS											
		Jan.	Feb.	Mar.	Apr.	May.	Jun.	July	Aug.	Sep.	Oct.	Nov.	Dec.
Total rainfall (mm = kg÷m²)	2	72.7	24.75	53.6	57.95	117.3	25.25	3	1.55	6.3	42.65	51.6	32.4
Maximum rainfall (mm = kg÷m²)	2	22.9	12.95	15.75	22.3	35.8	10.4	1.8	0.55	4.6	20.15	13.9	12.15

Maximum temperature (°C)	2	6.15	10.55	16.65	21.5	25.35	32.3	34.6	34.4	31.4	23.25	15.95	9.8
Minimum temperature (°C)	2	-9.85	-8.05	-4.25	-2.2	5.6	8.05	12.75	14.75	10.35	1.8	-5.05	-6.1
Average wind speed (m÷sn)	2	2.3	2.6	3.2	3.15	2.6	2.8	3.15	2.95	2.45	2.4	1.85	2.25

Table 1 is to show that the average annual temperature is 11.51 °C, the annual rainfall is 489.05 mm and the average annual relative humidity is 47.01%. In terms of temperature regime, it is a summer season of 4-months between June and September, a winter season of about 4.5-months between November and late March and the spring and fall seasons of about 1.5-2-months.

According to the WALTER method, ombrotermik climate (precipitation-temperature) diagrams of Puturge was seen (*Fig. 2*).

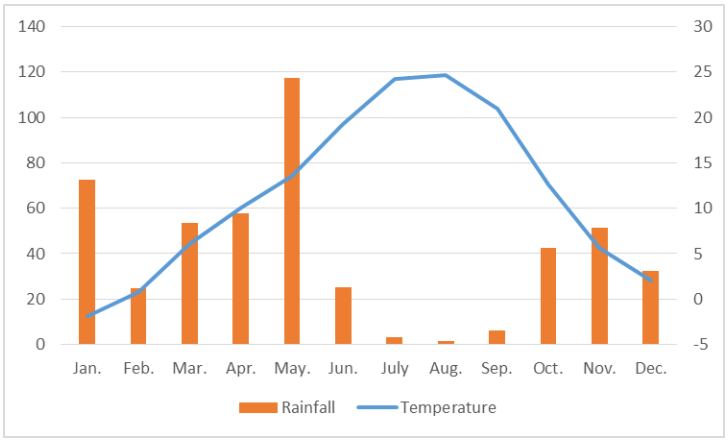

Figure 2. *Ombrotermik climate (precipitation-temperature) diagrams of Puturge*

Figure 2 shows that a drought period of four months has been from the end of May to the end of November.

Vegetation

According to Davis (1965-1988), the research area is located at the B7 Iranian-Turonian floristic region that is characterized with dwarf trees, grasses and meadow at a high rate although the number of tree species that is relatively few. Walter (1976) described the zonal vegetation as climate zone "Temperate arid- Step forest Zone", and Zohary (1973) classified it as "Persian xenophile Quercus brantii forest". These dry forests, which are generally pure oak communities constituted a narrow rung among Hakkâri, Malatya and Kahramanmaraş where the spreading of the oak-juniper forests

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1278712798

continued on the slopes of the west and central Taurus (Louis, 1939; Mayer and Aksoy, 1998).

The current vegetation of the research area consists of oak-bush communities, steppe communities with secondary characters created along with the anthropogenic influences for years, pine and cedar communities established with afforestation in 1962 (*Fig. 3*).

Figure 3. *A view of the vegetation of the study area*

Vegetation sampling

Sample plots were randomly selected in the field and Braun–Blanquette method was used to select a plot in each stratum which represents the vegetation characteristic of the whole area of the forest and vegetation studies was carried out in 9 plots of 20×20 m during periods of optimum development of the vegetation in 2018 (*Table 2*).

Table 2. *Geographical locations of the plots*

No	Name of plant community	Geographical location (WGS 84)	Altitude (m)
1	Pinus nigra afforestation area (Pn1)	477151-4220072	1500
2	Native Quercus sp. forest (Q1)	477164-4220086	1500
3	Pinus nigra afforestation area (Pn2)	475820-4220064	1510
4	Native Quercus sp. forest (Q2)	475799-4220076	1515
5	Pinus sylvestris afforestation area (Ps1)	478215-4219536	1575
6	Cedrus libani afforestation area (C1)	479417-4218245	1540
7	Mixed forest (M1)	477067-4222421	1280
8	Pinus nigra afforestation area (Pn3)	477670-4222935	1190
9	Native Quercus sp. forest (Q3)	477696-4222942	1200

The limit value of vegetation cover was determined according to Scamoni (1963) and showed *Table 3* (Aksoy, 1978).

Table 3. *Limit values of vegetation layer according to Scamoni (1963)*

> 5 m	T tree layer
50 cm – 5 m	S shrub layer
< 50 cm	H herb layer

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1278712798

According to Braun–Blanquette, the abundance-cover (density) scale is:
r: One species, the cover condition is ambiguous,
+: Species abundant, but cover is weak, cover is 1-5%,
1: Species abundant, but cover grade weak, cover 5-25%,
2: Species cover is between 25-50%,
3: Species cover is between 50-75%,
4: Species cover is between 75-100%.

Measuring plant diversity

There are some common diversity indexes. However, Shannon-Wiener index are most widely used for measuring biological diversity. When used species richness and species evenness together, the diversity of the community can be expressed and compared to other communities.

To calculate vegetation profiles, Braun–Blanquette scores were transformed to relative cover (r: 0.01; +: 0.02; 1: 0.04; 2: 0.15; 3: 0.375; 4: 0.625; 5:0.875) prior to analysis (Fontaine et al., 2007).

Species richness

Species richness is the actual number of species present in a community (Atlas, 1984; Patrick, 1949):

$$D = S$$

where D = species richness, S = number of species in the community.

Shannon-Wiener index

Shannon-Weiner diversity index (H') was calculated (Shannon and Weaver, 1949) as:

$$H' = -\sum_{i=1}^{s} P_i \, In \, Pi$$

where S = total number of species, Pi (Ni/N) = proportional abundance of species i, In Pi = the natural logarithm of the proportional abundance of species i. Values of H' can range from 0 to 5.

Species evenness

From the formula above we obtain Shannon evenness index J (Pielou, 1966) as

$$J = \frac{H'}{\ln S}$$

where J: Pielou Regularity Index, H: Shannon-Weaner Diversity Index, S: Number of species, J ranges from 0 to 1.

Results

Vegetation analysis

9 samples were established and 77 species belonging to 58 genera were recorded in the study area in different layers including 7 trees (T), 4 shrubs (S) and 66 herbs (H) (*Table 4*). Within the study area, there were important differences between exotic coniferous plantations and native species plots with respect to structural development. Exotic coniferous plantations had significantly greater numbers of planted tree species, higher stem density and crown cover, greater mean tree heights and stem diameters than native Quercus. On the other hand, the plant community in Quercus forest varied in structure and composition among sites due to physiographic and anthropogenic pressures. The density of grasses in the native forest is clearly a reflection of favourable light conditions. Species richness and species diversity correlated negatively with crown cover.

Biodiversity measurement

The sample which were the highest in species richness were also found to have the highest species diversity or Shannon-Wiener Index value (*Table 5*).

Table 5. *Biodiversity measurement in sampling plots*

Sampling plots no.	**Pn1**	**Q1**	**Pn2**	**Q2**	**Ps1**	**C1**	**M1**	**Pn3**	**Q3**
Shannon-Wiener Index (H')	2.27	2.47	2.29	3.01	1.69	2.46	2.88	2.02	3.08
Species richness	15	26	21	35	20	27	28	17	36
Species evenness	0.84	0.76	0.75	0.85	0.57	0.75	0.86	0.71	0.86

Species diversity

Results show that Q3 plot has the highest plant diversity as compared to other plots, followed by Q2 and M1 plots as the second and third most diverse respectively. Ps1 plot was the least diverse among all 9 plots (*Table 5*). Shannon-Weiner diversity index was 62% greater in native Quercus forest than in exotic coniferous plantations (pine and cedar) areas as a diversity index of 2.85 and 1.79 for the native Quercus forest and afforested areas was registered consecutively.

Species richness

It shows that Q3 plot has the highest plant diversity as compared to other plots, followed by Q2 and M1 plots as the second and third richest, respectively. Pn1 plot was the least rich (*Table 5*). Species richness was higher in native afforested areas than in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1278712798

afforested areas, where average species richness was 32.3 in native and mixed areas compared to 21.3 in exotic coniferous plantations (pine and cedar) areas.

Species evenness

It shows that Q3 plot has the highest as compared to other plots, followed by M1 and Q2 plots as the second and third most even, respectively. Ps1 plot was the least even (*Table 5*). We can see from our results that evenness in the native Quercus forest are much higher than in plantation area. But some samples with the most species (highest species richness) and species diversity did not have the highest species evenness.

Discussion and conclusion

Since the Şiro River Basin is risky in terms of erosion, studies were started in 1962 to protect soil in the basin to prevent the arrival of sediment to the Karakaya Dam. Soil conservation and afforestation activities have been achieved and it has been observed that sediment in the dam basin has been largely prevented. And in order to improve the distorted coppices in Tepehan, more regular and highly productive forests were created in terms of establishment characteristics as a result of plantation of oak seeds and afforestation of open and gradient areas.

However, the pine afforestation in this area can be anticipated for possible negative effects): (i) in pine plantations the dense and thick layer of needle litter represent a serious risk for uncontrolled, severe wildfires (*Fig. 4*); (ii) the change of the structure of these afforested heathlands means the loss of this dense scrubland vegetation type for its associated fauna; (iii) Leaves of quercus sp. constitute part of the diet of goats and sheep (*Fig. 5*). They are among the less resistant woody species in pine-tree stands and individuals lose foliage and are, subsequently, no longer valuable as food source for goats and sheep. This not only means an actual loss of resources, but also implies an increase of browsing by these large herbivores on adjacent open heathland stands, which would have negative consequences if that increase exceeded the heathland's carrying capacity (Andrés and Ojeda, 2002) and (iv) biological adaptation disorders such as resistance to biotic and abiotic pests.

Figure 4. *A view of the pine afforestation in the research area*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1278712798

Figure 5. *A view of the Quercus tree and shrub in the research area*

The general conclusion from the case studies clearly indicates that afforestation affects species richness of different functional groups in different ways. Especially the number of species of vascular plants is negatively affected by afforestation. Shade tolerant plant groups had replaced the original heathland communities.

On the other hand, this study shows that the species diversity (Shannon-Wiener index, H') followed very similar correlation for species richness, however, for species evenness it did not. All the same, diversity index was found consistently and significantly greater in native Quercus forests than exotic coniferous plantations forest. This result is in line with the findings of a number of research studies where the negative effects of afforestation on species diversity was highlighted (Andrés and Ojeda, 2002; Pourbabaei et al., 2012). Because species richness of vascular plants is affected by exotic coniferous species. This difference is mainly due to the amount of light which reaches the forest floor. Similarly, understorey biomass is related to the amount of light. So shade tolerant plant groups replace the original heathland communities. Namely, there is a negative correlation between tree coverage and grass density in afforestation areas. As the coverage of the tree layer increases, the degree of coverage of the shrub and grass decreases and the coverage of the shrub layer increases, the degree of coverage of the grass decreases. This situation has a negative effect on vegetation composition and species diversity. The number of endemic taxa decreased in subsamples under coniferous species compared to native broadleaved forests.

Another important finding of this study was that high species richness did not always indicate plant density. In other words, forests with a greater number of species were found to have less tree density were also found to have more shrub and grass density as compared to forests with low species richness in similar area size.

While the afforestation results appear favourable to stop erosion, it is very important to develop strategies for the conservation of biodiversity in afforestation. New forests must be designed in such a way that they conform to the other elements and the character of the landscape. With exotic and monocultural plant species, full coveraged and sharp, straight borders should be avoided. It is also important to maintain open areas within the forest, which will be largely successful in creating a dynamic and sustainable environment in terms of biodiversity in the arid and semi-arid region.

(Received 6th May 2019; accepted 20th Aug 2019)

Abstract. An optical microscope technique and paraffin method was used to conduct an anatomical study on the stems and leaves of *Aconitum umbrosum* (Korsh.) Kom. (Ranunculaceae). The results showed that the stem had scattered vascular bundles, without the intrafascicular cambium. The leaf epidermis possessed pseudo-bulliform cells. The mesophyll had no distinction between palisade tissue and spongy tissue. The leaves developed multiple vascular bundles of parallel leaf veins, which had the structural characteristics of monocotyledons.
The microscopic structure of the stems and leaves of *A. umbrosum*, a living fossil, were analyzed as part of an attempt to confirm the evolution of plants from dicotyledons to monocots; this study contributes to the completion of the theory of evolution as seen in the Takhtajan and Cronquist systems.
Keywords: *vascular bundles, vascular cylinder, bifacial leaf, isolateral leaf, mesophyll*

Introduction

The genus *Aconitum* has about 350 species worldwide, and is widely distributed in temperate regions of the Northern Hemisphere. About 200 species of *Aconitum* occur in China, many of which are distributed in Northeast China. In 2019, Qin et al. through ITS sequence analysis and secondary structure prediction of 9 species of aconitum, combined with data from the public database, established a molecular method for identification of plant species of aconitum, laying a foundation for subsequent studies on authentic medicinal materials in Qinghai-Tibet Plateau (Qin et al., 2019). Li (2018) applied optical microscope and scanning electron microscope to study the phytological identification of 33 species of liliaceae belonging to 15 genera in Changbai Mountains, and summarized, sorted out and classified the phytological identification results with mathematical statistics. Tian et al. (2017) summarized aconitum plants of ranunculaceae in Qinling area from several aspects including distribution, active components, resource utilization and application of active components. Wu (2015) studied the identification and systematic evolution of epigenetic phytoliths of 17 genera of ranunculaceae, providing first-hand microscopic evidence of external morphology and internal anatomical structure. Gao (2014) described the genetic polymorphism of 7 species of aconitum from Xinjiang.

Li et al.'s (2019a), research results: WVBF and CFA may have potential synergetic effects on the target genes of certain diseases such as inflammation, cancer and diabetes.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1279912806

Li et al. (2019b) proved a preparation of two Actinomycetes plays a role in the biocontrol of root diseases and growth promotion of A. carmichaelii by inhibiting pathogen growth and shaping the rhizosphere microbiota. Xionb et al. (2019) studied the chemical constituents of the aboveground parts of aconitum in the genus ranunculaceae. Results a total of 16 compounds were isolated from dried stems and leaves of monkshood with methanol percolation. Li and Feng (1990) studied the abnormal structure of root duct group of aconite. According to Wu and Zhao (2011) there are about 200 species of aconitum in China, of which about 76 species can be used for medicinal purposes. Most aconitum medicinal plants are root tubers and roots, most of which have the effect of dispelling wind and dehumidifying, warming meridians and relieving pain, among which alkaloids are the main active ingredients. Xu and Dong (2009) investigated some plant resources of aconite in north China, and believed that aconite plants could be used for cut flowers, potted flowers and flower borders in gardens and had high ornamental value. Tamura et al. (1993): Dicotyledons: Magnoliid, Hamameliid and Caryophyllid.

However, there is no systematic evolutionary structure study of aconitum. This research will make efforts and contributions in this field.

Materials and methods

A. umbrosum specimens were collected in the tundra zones of Changbai Mountain in Jilin, China (*Map 1*). 100 samples of plant experimental materials were collected.

Permanent slides were then made as follows. First, the paraffin method was used to preserve 10-μm-thick slices (Li, 2018). Then, the slices were dehydrated by alcohol, clarified by dimethylbenzene, dyed with safranine fast green, sealed in neutral gum and observed using an Eclipse 80 microscope. Microscopic photographs were taken (Wu, 2005).

Map 1. *Map of Changbai Mountain*

Results

Stem anatomical structure of A. umbrosum

The cross section of the stems of *A. umbrosum* was nearly round. The epidermis was composed of a single layer of tightly packed cells. Scattered heterocysts were observed, with stoma rarely seen on the epidermis (*Fig. 1*). In the epidermis, the epidermal cells of the external tangential wall had an average width of 2–3 μm. The cortex was divided into exodermis, and into parenchyma cells of the cortex and endodermis. The thickened part of the corners of the epidermis was approximately 110 μm thick. The intercellular spaces were not developed and there was an obvious thickening of the Casparian band in the endodermis. The stem had no obvious pith cell (*Fig. 2*).

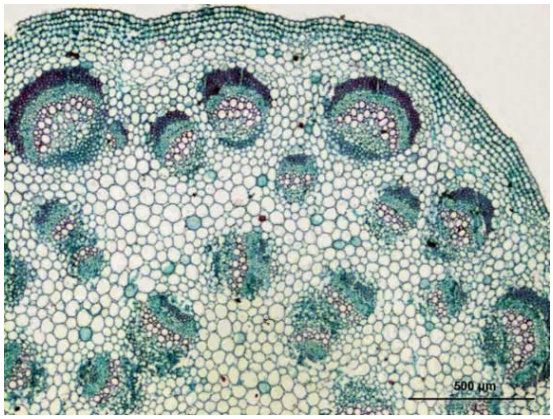

Figure 1. *Cross section of stems, with somewhat scattered atactostele*

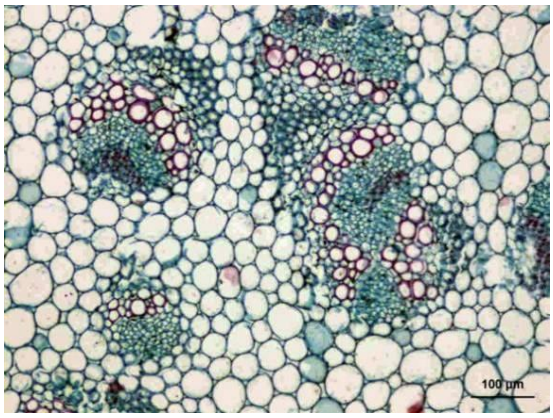

Figure 2. *Cross section of stems, abnormal vascular bundles*

Each stem had more than 40 vascular bundles distributed in the parenchyma tissues; bundles were either large or small in size and scattered in a disorderly fashion. The vascular bundles had obvious external contours. The vascular bundle sheath was formed by the outermost layer surrounded by sclerenchyma tissue (*Figs. 3* and *4*). The phloem were well-developed, composed of sieve tubes, companion cells, phloem parenchyma cells and phloem fibers. The xylem matured from the inside toward the outside. No vascular cambium was present in the bundles.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1279912806

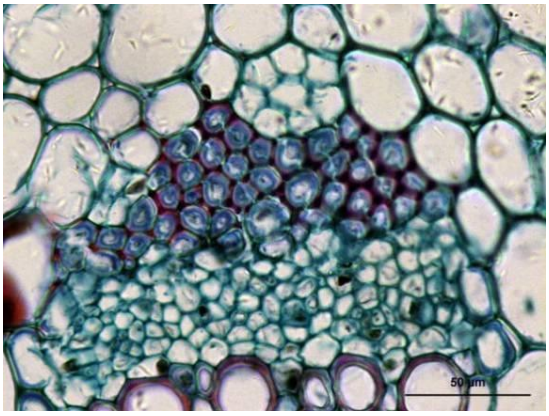

Figure 3. *Cross section of stems, phloem and phloem fibers*

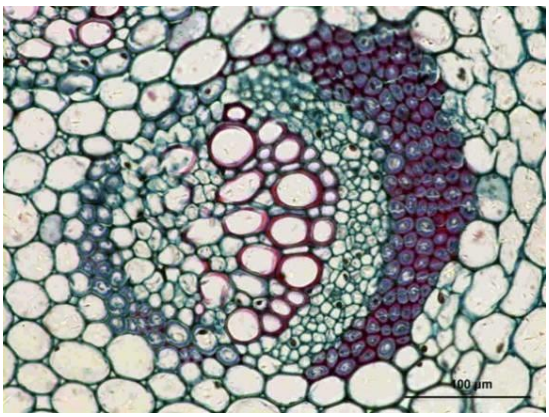

Figure 4. *Cross section of stems, lack of intrafascicular cambium in vascular bundles*

Leaf anatomical structure of A. umbrosum

The adaxial and abaxial epidermis was both composed of a single layer of tightly aligned cells. The epidermal cells varied in size with two or three large scattered heterocysts. The cuticle of the external tangential walls of the adaxial epidermis was more than 5 μm thick. Stomata were densely distributed on the abaxial epidermis. There was no distinction between the palisade tissues and spongy tissues in the mesophyll, which had the structure of an isobilateral leaf. Cells had abundant chloroplasts and well-developed aerenchymas (*Fig. 5* and *6*).

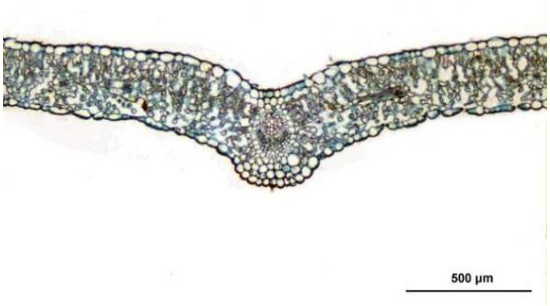

Figure 5. *Cross section of a leaf, epidermis of blade, mesophyll and structure of a leaf vein*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1279912806

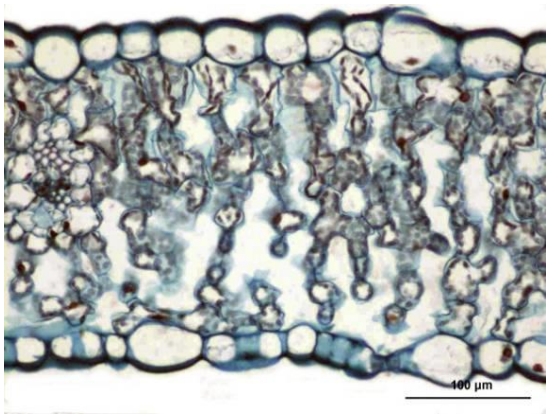

Figure 6. *Cross section of a leaf, structure of an isobilateral leaf*

The cross section of the main vein of the leaf was 400 μm × 450 μm. The leaf was 297 μm thick. The main vein was not well developed and had few mechanical tissues. The capillaries were mostly composed of small parallel vascular bundles. The main vein was composed of phloem and xylem, without intrafascicular cambium. A layer of the vascular bundle sheath was composed of parenchyma cells that had developed around the main vein (*Fig. 7*). At maturity, the xylem was neither aligned on the inside nor the outside. Instead, it was aggregated in a disorderly fashion to form a special type of leaf vein. This type of vein was completely different from the structure of leaf veins of typical dicots (*Fig. 8*).

Discussion

The stele of the vascular plants includes protostele, siphonostele, dictyostele, eustele and atactostele, etc. (Liu, 2008). The protostele is the most primitive, while the atactostele is well-developed in monocots.

The scattered vascular bundles in the stems of *A. umbrosum* look similar to the atactostele of monocots. However, the atactostele of monocots has large centripetal vascular bundles and small centrifugal vascular bundles. However, the centripetal vascular bundles were small in *A. umbrosum* while the centrifugal ones were large. The abnormal vascular bundles for *A. umbrosum* can be called scattered atactostele-like bundles. The scattered atactostele-like bundles provide strong evidence of the evolution of *A. umbrosum* from dicot to monocot, which also verified the viewpoint proposed by Tamura (1964) that the Ranales represent a living ancestor of the monocots.

The vascular bundles in the stem of *A. umbrosum* had sheaths composed of sclerenchyma, with a structure similar to that of the vascular bundle sheaths in the stem of monocots. The vascular bundles in the stem had no intrafascicular cambium, which is the same as the closed vascular bundles of monocots.

The scattered distribution of vascular bundles, the vascular bundle sheath of sclerenchyma and the lack of intrafascicular cambium are typical structures of monocots. The same structures were found in this investigation in the stems of a dicot (*A. umbrosum*) for the first time.

The epidermal cells on the top of the leaves of *A. umbrosum* had obvious heterocysts with a structure similar to that of bulliform cells in the adaxial epidermis of monocots. This structure provided microscopic proof for the evolution of dicots from Ranales to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1279912806

monocots. The leaves of dicots are typically net-veined, while those of monocots have parallel veins. The structure of the pseudo-parallel veins of *A. umbrosum* is not like the netted veins of dicots. Instead, they are extremely similar to the parallel vein of monocots.

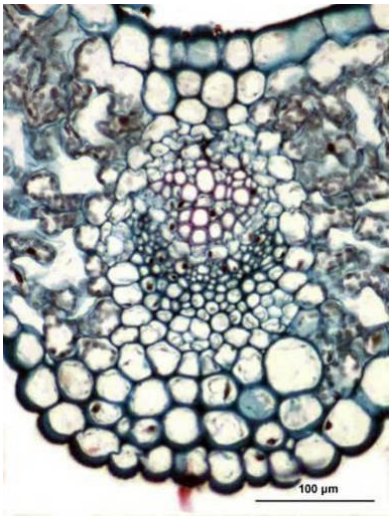

Figure 7. *Vascular bundle sheath of a leaf, main vein composed of parenchyma cells*

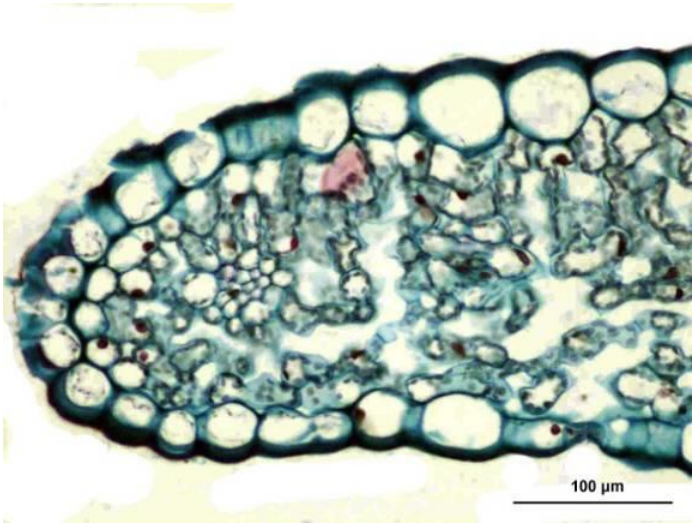

Figure 8. *Cross section of a leaf, bulliform cells and heterocysts*

No distinction can be seen between the palisade tissues and spongy tissues of the mesophyll of *A. umbrosum*, similar to those of the mesophyll of monocots which evolved into the structure of isobilateral leaf. There were multiple vascular bundles with small parallel leaf veins in the mesophyll in *A. umbrosum*; it can be considered to be a transitional type from the leaf veins of dicots (*A. umbrosum*) to those of monocots.

There was no intrafascicular cambium in the vascular bundles of the leaf veins, which conformed to the leaf structure of monocots. The mesophyll was not differentiated. The guard cells of the leaf stoma appeared to be transitional from the semilune type to the dumb-bell type. This type of structure has not been reported in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1279912806

dicots. This was the first time that the leaf of a dicot (*A. umbrosum*) was found to have a structure similar to that of monocots.

The anatomical structures of the stems and leaves of *A. umbrosum* provide microscopic proof that the study of the systematic evolution of *A. umbrosum* (*Aconitum,* Ranunculaceae) could prove useful. It also supplemented and improved the Takhtajan and the Cronquist systems of classification. Anatomical studies on the roots of *A. umbrosum* still need to be completed and discussed.

The evolutionary investigation in this article proves that the dicot (*A. umbrosum*) is a living fossil exhibiting the evolution from dicot to monocot.

This paper supports the idea of the evolution from dicotyledons of ranunculaceae to monocotyledons of liliaceae proposed by Tamura et al. (1993) that is, liliaceae originated from ranunculaceae.

Conclusion

The stem had scattered vascular bundles, without the intrafascicular cambium. The leaf epidermis possessed pseudo-bulliform cells. The mesophyll had no distinction between palisade tissue and spongy tissue. The leaves developed multiple vascular bundles of parallel leaf veins, which had the structural characteristics of monocotyledons. The microscopic structure of the stems and leaves of *A. umbrosum*, a living fossil, were analyzed as part of an attempt to confirm the evolution of plants from dicotyledons to monocots; this study contributes to the completion of the theory of evolution as seen in the Takhtajan and Cronquist systems.

This paper has obtained the first-hand experimental evidence of the evolution of dicotyledon into monocotyledon plants.

Today, we sincerely suggest that colleagues continue to carry out the structural experimental research of plant system evolution. The anatomical experiments will provide more powerful evidence of evolutionary structure for the study of plant system evolution.

(Received 9th May 2019; accepted 16th Jul 2019)

Abstract. The objective of this research was the study of research on the photosynthetic characteristics of four kinds of medicinal plants, to provide a reliable reference for the high quality cultivation of these four plants. Methods: the four kinds of medicinal plants were as the experimental materials. The photosynthetic rate, chlorophyll content, carotenoid content and photosynthesis of four medicinal plants were determined. The effects of net photosynthetic rate on photosynthetic effective radiation were studied, and the water use efficiency and transpiration rate were calculated. Results: through the comparison of net photosynthetic rate, it can be seen that the average photosynthetic rate, chlorophyll content and carotene content of the four medicinal plants are very different in the growing season. Conclusion: *Platycodon grandiflorum* has a wide range of adaptability to light intensity. It can not only utilize intense light efficiently, but also has shade tolerance. It is suggested to be cultivated in an intense light environment; *North Atractylodes* has high light utilization rate, but poor shade tolerance, it is suitable for cultivation in direct sunlight environment; *Carthamustinctorious* and *Menthahaplocalyx*has have strong shade tolerance, but are not resistant to intense light, and can adopt intercropping.
Keywords: *medicinal plants, photosynthetic rate, content of photosynthetic pigment, physiological and ecological factors, water use efficiency*

Introduction

Traditional Chinese medicine is an important weapon in the prevention and treatment of diseases in Chinese traditional medicine. It has been playing an important role in protecting health. Medicinal plants contain bioactive ingredients, is used for special economic crops and anticorrosion treatment (Kannan et al., 2018). As an important industrial raw material, it can be processed into drugs, pesticides and veterinary drugs (Qadir et al., 2018; Khosravi et al., 2018). China is the country with the largest species of medicinal plants in the world, and has a long history of cultivation. Because medicinal plants are natural, stable, with little toxic and side effects, they have the unique advantages that Western medicine does not have. Modern people are increasingly turning their attention from synthetic chemicals to natural medicines, and hoping to reduce the incidence of drug-induced diseases (Liu et al., 2014).

With the vigorous development of the pharmaceutical industry, the establishment of plant research institutes has been established (Kim et al., 2018; Allahdadi et al., 2018). The production of Chinese herbal medicines has reached an unprecedented level from the variety and scale (Zhu et al., 2014). Unlike the field crop production, the economic characters such as yield and quality of Chinese herbal medicines are not easy to control, and their adaptability is poor. Moreover, because of the "absolute heterogeneity" of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1280712826

natural plants, the quality evaluation of Chinese herbal medicines is more difficult. Therefore, it is of great theoretical and practical significance (Huang et al., 2016) to study the fertility laws and various physiological characteristics of traditional Chinese medicine. At present, standardized construction of traditional Chinese medicine production bases, breeding and utilization of germplasm resources and excellent varieties, and pesticide residues and heavy metals are all actively studied. However, there are few reports about the relationship between photosynthetic performance and diurnal variation of photosynthesis and ecological factors, especially the research on main limiting factors and physiological characteristics of photosynthesis in different medicinal plants.

Photosynthesis is the process of transforming inorganic matter into organic matter and converting light energy into chemical energy. It is the basis of plant matter production (Lee et al., 2016). Photosynthetic rate determines the ability of photosynthesis, and is the key to the formation of plant biomass. The photosynthetic rate increases with the increase of light intensity in a certain range.

In this study, for further understanding of medicinal plant photosynthesis and physiological changes, the photosynthetic and physiological characteristics and environmental factors of four kinds of medicinal plants (*Platycodon grandiflorum*, *North Atractylodes*, *Carthamustinctorious* and *Menthahaplocalyx*) are determined and analyzed, and the diurnal changes of net photosynthetic rate and the content of photosynthetic pigments (Chlorophyll a, b, and carotenoid) were measured. Through light saturation point, light compensation point and photosynthetic pigment content, the shade tolerance and photosynthetic capacity were determined, the response of net photosynthetic rate to photosynthetically active radiation was discussed, the transpiration rate and water use efficiency were calculated as well as the physiological effects of ecological factors on the diurnal variation of net photosynthetic rate. The photosynthetic and physiological characteristics of these four medicinal plants are further studied to provide experimental basis for the creation of the cultivation environment which is beneficial to improve its photosynthesis.

Materials and methods

Materials

Brief introduction of materials

Platycodon grandiflorum: a perennial herb of the family Platycodon, and it grows in the shrubs region of less than 2100 m above sea level. It has the effects of relieving sore throat, and eliminating phlegm, etc. (Kim et al., 2016; Wanget al., 2015). *Platycodon grandiflorum* is not only a kind of resource plant but also a kind of economic plant for medicine and food. As shown in *Figure 1* of *Platycodon grandiflorum*.

North Atractylodes: is a perennial herb of family Compositae, mainly divided into the North Atractylodes and the South Atractylodes. The North Atractylodes is mainly distributed in the north of China. It grows on the dry slopes of 300-900 m above sea level, with sparse broad-leaved forests or coniferous broad-leaved mixed forests (Gao et al., 2017; Shen et al., 2017). The site is the main use of Atractylodes rhizome, with eliminating heat and removing sweat, digestion and other effects, so the treatment used to ease bloating, diarrhea and edema disease, night blindness, rheumatism and diabetes and so on. As shown in *Figure 2* of *North Atractylodes*.

DOI: http://dx.doi.org/10.15666/aeer/1706_1280712826

Figure 1. *Platycodon grandiflorum*

Figure 2. *North Atractylodes*

Carthamustinctorious: is an annual herbaceous plant of family Compositae. It has special fragrance, warm and spicy taste, it has the effects of activating blood circulation, removing blood stasis, dysmenorrhea and relieving pain. It also has the effects of anti-inflammatory, improving myocardial blood supply, anti-aging and protecting liver. Safflower yellow is also a natural quality food pigment and dyestuff. As shown in *Figure 3* of *Carthamustinctorious*.

Figure 3. *Carthamustinctorious*

Menthahaplocalyx: is a perennial herb of the family Lamiaceae. Mint can grow in a region of less than 2100 m above sea level. It has the function of evacuating the wind and heat, clearing the head, and regulating the flow of vital energy and remove obstruction to it and relieving depression. It is good for preventing and curing cholesterol calculus, and has a role in central nervous system and digestive system. It is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1280712826

mainly for treating wind heat and common cold, headache and stuffiness, throat swelling and pain, rubella and itching. As shown in *Figure 4* of *Menthahaplocalyx*.

Figure 4. *Menthahaplocalyx*

Experimental materials

Study area survey: the test was carried out in the agricultural science and technology demonstration base of Tongzhou District Agricultural Technology Extension Station in Beijing. This area is a continental monsoon climate zone, the annual average temperature is 11.3 °C, the annual rainfall is 620 mm, and the annual sunshine is 2730 h. The soil fertility is medium, and the texture is medium loam.

Experimental materials: *Platycodon grandiflorum*: in mid-April, the seeds of *Platycodon grandiflorum*, which were full of maturity, were seeded after germination in early May, the line spacing was 20 cm × 20 cm, and the routine field management measures were adopted. *North Atractylodes*: was collected from the Dabie Mountains in Hubei Province, which was identified by the Institute of traditional Chinese medicine of Hubei province. At the end of the March, *Carthamustinctorious*, *Menthahaplocalyx* were sowed in the experimental base, soil preparation, fertilizing, weeding, ridging and field management were carried out according to agronomic measures of common origin.

Methods

Determination of photosynthetic rate of leaves

From each cultivated plant population, a number of leaves were selected to accept the natural solar radiation. The gas exchange measurement (Nie et al., 2014) was carried out by a portable optical gas analysis system (LI-6400, Li-CorInc, Lincoln NE, USA). The control of the environmental factors in the leaf chamber was 20 °C, the concentration of the gas source CO_2 was $350\ \mu mol\ \ CO_2^{\circ} mol^{-1}$, and the light flux density (PFD) was $1000\ \mu mol\ \ photo\ ns^{\circ} m^{-2\circ} s^{-1}$. The experiment was carried out on all sunny days and repeated 5~6 times.

The calculation of the quantum efficiency (AQY) of the leaves shows a linear regression of the net photosynthetic rate (P_n) between $0 \sim 200 \mu mol\ \ photo\ ns^{\circ} m^{-2\circ} s^{-1}$ in the response curve to PFD, and the regression equation is obtained.

$$P_n = R_d + AQY \times PFD \qquad \text{(Eq.1)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1280712826

when $P_n = 0$, PFD is the optical compensation point Φ_i for photosynthesis. Where, R_d is the rate of dark respiration.

The calculation of the carboxylation efficiency of the leaves was linear regression on the $0 \sim 200\ \mu mol\ CO_2^{\circ} mol^{-1}$ point in the C_i curve of the intercellular CO_2 concentration by P_n, and the regression equation was obtained.

$$P_n = R_p + CE \times C_i \quad \text{(Eq.2)}$$

when $P_n = 0$, C_i is the CO_2 compensation point Γ of photosynthesis. R_p is the rate of respiration in the light, and CE is the carboxylation efficiency. As dark breathing is very small, the rate of CO_2 release can be approximated as the rate of photorespiration.

Determination of chlorophyll content

The leaves of the mature leaves with the diameter of 0.7 cm were collected from 30 mature leaves. The leaves were divided into 3 groups. They were immersed in the extract of 10 ml 80% acetone. The sample bottle was tightly sealed, and it was colorless under low temperature. When the concentration of leaf green was detected, the concentration of chlorophyll was obtained by detecting the light intensity of the fluorescence (Ribeiro-Filho et al., 2014). Portable optical gas analysis system is designed based on the principle that different gases have selective absorption of light. It is often used to detect carbon monoxide, carbon dioxide and other gases. The formula for calculating the fluorescence intensity is:

$$F = kQI_0\left(1 - e^{-\varepsilon cb}\right) \quad \text{(Eq.3)}$$

in *Equation 3:* k is a constant; Q is the fluorescence efficiency; I_0 is the laser light intensity; c is the concentration of chlorophyll a; b is the light path for the test sample; ε is the molar absorbing coefficient.

In the way of logarithmic calculation, the formula is arranged and the logarithm is obtained.

$$C = A - B\log\left(D - F\right) \quad \text{(Eq.4)}$$

where $A = \frac{2.3}{\varepsilon b}\log kQI_0$, $B = \frac{2.3}{\varepsilon b}$, $D = kQI_0$.

A, B, D in *Equation 4* are constant. When the sample of the fluorescence is determined, ε, k, Q, and I_0 are constant. Therefore, by measuring the fluorescence intensity of chlorophyll a emitted from cells, it can determine the concentration chlorophyll a and the fluorescence intensity of chlorophyll b to determine the concentration of chlorophyll b.

Determination of carotenoid content

The mixture of ethanol: acetone as 1:1 was used to extract 24 h in the dark, then be measured by UV-2001 ultraviolet spectrophotometer. And then the carotenoid content was calculated according to *Equation 5*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1280712826

$$C_x = (1000D_{470} - 2.05C_a - 114.8C_b)/245 \quad \text{(Eq.5)}$$

D_{470} is the absorbance at the wavelength of 470 nm. Pigment content = (pigment concentration× extract volume) / fresh weight of leaves.

Response of net photosynthetic rate to photosynthetically active radiation ($P_n - PAR$)

Using the red and blue light source, the light quantum flux density (PFD) in the Li-6400 portable photosynthetic system were 0, 400, 800, 1200, 1600, 2000, 2400 $\mu mol \cdot m^{-2} \cdot s^{-1}$, respectively. The temperature was 27 °C and the concentration of CO_2 is set by CO_2 injection system to 390 $\mu mol \cdot mol^{-1}$, which was actually $390 \pm 10 \mu mol \cdot mol^{-1}$. The response of the net photosynthetic rate to the photosynthetic effective radiation was measured by the non-right angled hyperbolic model.

$$P_n = \frac{aI = P_{\max} - \sqrt{(aI + P_{\max})^2 - 4akIP_{\max}}}{2k} - R_d \quad \text{(Eq.6)}$$

According to the light response equation, the simulated photosynthetic response curve was estimated, the light compensation point (LCP) and the optical saturation point (LSP) were calculated. That is to say, when the P_n reaches a certain level of $P_{\max}$, the I value was obtained, and the light saturation point was estimated (Shen et al., 2016). The value of I is used to estimate optical compensation point with P_n at 0. In *Equation 6*, P_n is the net photosynthetic rate ($\mu mol \cdot m^{-2} \cdot s^{-1}$), a is the use efficiency of optical quantum, I is the light flux density ($\mu mol \cdot m^{-2} \cdot s^{-1}$), $P_{\max}$ is the maximum total photosynthetic rate ($\mu mol \cdot m^{-2} \cdot s^{-1}$), R_d is dark respiration efficiency ($\mu mol \cdot m^{-2} \cdot s^{-1}$), and k reflects the degree of curvature of the photosynthesis curve.

Determination of photosynthesis and ecophysiological factors

Li-6400 portable photosynthesis measurement system produced by LI-COR Company was used. The net photosynthetic rate (P_n) of plant leaves was measured under natural condition. The time interval was 8:00–18:00, every 2 h was measured once, five values were recorded each time, and the average value was recorded. Li-6400 portable photosynthesis measurement system also recorded physiological and ecological factors such as temperature (T_a), relative humidity (RH), photosynthetically active radiation (PAR), stomatal conductance (G_s) and transpiration rate E, etc. (Ding et al., 2015).

Water use efficiency

Water use efficiency (WUE) = net photosynthesis rate * 44 / transpiration rate * 18, unit: $mgCO_2 / gH_2O$.

Data analysis

The following results are derived from the experiments in the previous section.

Comparison of photosynthetic rate in whole growth period

From *Figure 5,* we can see that in the whole growth period, the net photosynthetic rate of medicinal plants propagated by seeds showed a single peak curve: that is, the seedling stage is low, and the net photosynthetic rate increases with the expansion of vegetative body. When it reached high in the period of flower and fruit, it was gradually reduced; while the change curve of net photosynthetic rate of the medical plants propagated by rhizome showed bimodal curve. This is because the physiological and biochemical characteristics of medicinal plants are also different. Therefore, there are some differences in net photosynthetic rate.

The seasonal variation of net photosynthetic rate

Figure 9 showed that plant leaves had matured in June, and the photosynthetic rate of the four medicinal plants began to rise, and the maximum of the growth season was reached about July. With the change of season, photosynthetic rate began to decrease. In October, photosynthetically active radiation and air temperature decreased, leaves began to senescence, physiological activity decreased, and photosynthetic rate decreased to the minimum value in growing season. In addition, four kinds of medicinal plant photosynthetic rate in the growing season was significantly higher than that at the end of the growing season, this was because the higher leaf physiological activity of plant growth season (Chen et al., 2015). But with the leaf senescence and seasonal variation of environmental factors, the physiological activity of leaves decreased, the efficiency of photosynthetic apparatus declined, and the ability of assimilating CO_2 decreased, which showed that the photosynthetic rate of all plants decreased.

Diurnal changes of environmental factors

The environmental factors that affect plant photosynthesis include temperature, moisture, photosynthetic effective radiation, etc. The changes of temperature (T_a), relative humidity (RH) and photosynthetically active radiation (PAR) in the test day were shown in *Figure 6*.

In one day, the change of three environmental factors showed a single peak. PAR increased from $589\ \mu mol \cdot m^{-2} \cdot s^{-1}$ to $1989\ \mu mol \cdot m^{-2} \cdot s^{-1}$ in 8:00-14:00, and then dropped to a minimum at 18:00, only $91\ \mu mol \cdot m^{-2} \cdot s^{-1}$. T_a was mainly affected by PAR (r = 0899**), the largest was at 12:00, as 40.9 °C, and to 22.3 °C at 18:00. RH and PAR was significantly negatively correlated with T_a ($p < 0.01$). The correlation coefficient r_1 and r_2 were -0.945**.-0.941**, respectively.

Diurnal variation of stomatal conductance (G_s) and net photosynthetic rate (P_n)

It can be clearly seen from *Figure 8* that the changes of G_s and P_n of *Platycodon grandiflorum* and *North Atractylodes* were typical bimodal curve in one day, and the first peak > the second peak. This is due to the low light intensity and low temperature in the morning. At about 10:00, it reached the first peak, at this time PAR was $1161\ \mu mol \cdot m^{-2} \cdot s^{-1}$, and T_a was 32 °C. At about 12:00, *Platycodon grandiflorum* and *North*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1280712826

Atractylodes were in the "noon break" state of photosynthesis, G_s decreased, and P_n decreased. At about 14:00, G_s and P_n reached second peak. G_s and P_n of *Carthamustinctorious* and *Menthahaplocalyx* were the largest at 8:00, and they were at a lower level since then, and there was no obvious "noon break" phenomenon.

The daily change of net photosynthetic rate of *Platycodon Platycodon* and *North Atractylodes* was bimodal curve, and the "noon break" phenomenon of photosynthesis appeared. This is a kind of beneficial ecological adaptation and self-regulation mechanism for the hot summer in the plant.

The relationship between the diurnal variation of net photosynthetic rate (P_n) and ecophysiological factors

The path analysis results of P_n and eco physiological factors (*Table 3*) showed that P_n and PAR of *Platycodon grandiflorum* and *North Atractylodes* was significantly positively correlated with G_s, but without correlation of RH and T_a. P_n of *Carthamustinctorious* and *Menthahaplocalyx* were positively correlated with G_s, not related to RH and PAR, but negatively correlated with T_a. According to the physiological and ecological factors, the decision coefficient P_n of the four medicinal plants in a day showed that the determinants that affected the diurnal variation of *Platycodon grandiflorum* and *North Atractylodes* were PAR and G_s, and PAR was the main determining factor. Limiting factors were T_a and RH, where T_a was a major limiting factor for the diurnal variation of *Carthamustinctorious* P_n, and the limiting effect of T_a and RH on *North Atractylodes* P_n was small. G_s was the main determinants of the diurnal variation of *Carthamustinctorious*, T_a and PAR also had certain promoting effect on P_n, but the effect was very small; RH was a limiting factor of diurnal variation of *Carthamustinctorious* P_n. T_a, RH, PAR and G_s were the limiting factors of the diurnal variation of *Menthahaplocalyx* P_n, and T_a of them were the most important limiting factor.

Comparison of photosynthetic parameters

The light compensation point (LCP), the light saturation point (LSP) and the maximum net photosynthetic rate can directly reflect the tolerance and photosynthetic capacity of plants. The low LCP of plants means that plants have strong ability to use weak light. The low LSP showed that the photosynthetic rate of plants increased rapidly with the increase of light quantum density, and quickly reached the maximum efficiency. Therefore, lower LCP and LSP enable plants to maximize photosynthetic capacity under low light density and maximize their photosynthesis under light limitation, thereby enhancing the accumulation of organic matter and meeting their energy needs for survival and growth.

It can be seen from the light response of P_n (*Fig. 7*) that the order of respiration rate of four medicinal plants were: *Menthahaplocalyx* < *Carthamustinctorious* < *Platycodon grandiflorum* < *North Atractylodes*. In the PAR range of $0 \sim 100 \mu mol \cdot m^{-2} \cdot s^{-1}$, the P_n and PAR of four kinds of medicinal plants was closed tothe linear relationship. The P_n of *Menthahaplocalyx* in the range wasthe maximum and that of *North Atractylodes* was the minimum. P_n of *Carthamustinctorious* and *Menthahaplocalyx* increased slowly in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1280712826

that PAR was $100 \sim 300\ \mu mol \cdot m^{-2} \cdot s^{-1}$ and reached saturation, and then tended to be stable after $300\ \mu mol \cdot m^{-2} \cdot s^{-1}$. P_n of *Platycodon grandiflorum* and *North Atractylodes* increased rapidly in that PAR was $100 \sim 1000 \mu mol \cdot m^{-2} \cdot s^{-1}$, and closed to saturation in about $1000 \mu mol \cdot m^{-2} \cdot s^{-1}$ and $1600 \mu mol \cdot m^{-2} \cdot s^{-1}$. The light compensation curve (LCP), light saturation point (LSP) and maximum net photosynthetic rate of the four medicinal plants were estimated according to the fitting equation of light response curve, shown in *Table 3*.

The results showed that the LCP, LSP and the maximum net photosynthetic rate of the *North Atractylodes* were significantly higher than those of the other 3 medicinal plants, indicating that they had strong ability to use intense light and high photosynthetic capacity under intense light, and $106 \mu mol \cdot m^{-2} \cdot s^{-1}$ of LCP showed their shade tolerance. The LCP of *Carthamustinctorious* and *Menthahaplocalyx* was lower than that of the *North Atractylodes*, indicating that they had high ability to use weak light and strong shade tolerance. The LCP of *Platycodon grandiflorum* was close to *Carthamustinctorious*, while LSP was higher, and has a higher maximum net photosynthetic rate, indicating that its photosynthesis was effective and its adaptability to light was the largest. The maximum net photosynthetic rate of *Carthamustinctorious* and *Menthahaplocalyx* was significantly lower than that of *Platycodon grandiflorum* and *North Atractylodes*, while *Platycodon grandiflorum* was lower than that of *North Atractylodes*.

Water use efficiency in the production of photosynthetic substances in medicinal plants

It can be seen from *Tables 6* and *7* that in the 4 medicinal plants, except the *North Atractylodes*, the remaining plants have a common characteristic in the water use efficiency, that is, the single peak curve changes in the whole growth period.

Differences between species in water use efficiency: Although the change of water use efficiency during the growth period is a single peak curve, for different plant species, water use efficiency has the characteristics of species, mainly in the following areas:

Firstly, the comparison of the whole growth period, *Platycodon Grandiflorum* has the highest water use efficiency of $15.62 \sim 23.22\ mgCO_2 / gH_2O$, followed by *Carthamustinctorious*, *Menthahaplocalyx*, and the lowest is the *North Atractylodes*.

Secondly, the period of highest water use efficiency has interspecific difference: *Platycodon grandiflorum*, *Carthamustinctorious* and *Menthahaplocalyx* propagated by seeds is at flowering stage, while the *North Atractylodes* propagated by vegetative is in accumulation stage.

Thirdly, the water use efficiency of *Platycodon grandiflorum* is relatively stable during the whole growth period, that is, there is little difference in the growth period. For example, the water use efficiency of *Platycodon grandiflorum* at different growth stages was 7.21%-11.63% compared with the water use efficiency of the whole growth period, while the differences in the three other medicinal plants was more than 50%.

Change of transpiration rate of medicinal plants in the whole growth period

Transpiration is the process of loss of water from the surface of the living plant (mainly leaves) in the state of water vapor into the atmosphere. It is different from the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1280712826

evaporation process of physics. Transpiration is not only influenced by environmental conditions, but also regulated and controlled by the plant itself, so it is a complex physiological process.

Transpiration is of great importance to plants, providing the main motive force for the plant to absorb and transport water, and also to lose the water. Photosynthesis is a way for plants to produce organic matter by means of light energy. It is often related to the importance of plant growth and crop yield.

The results of *Tables 4* and *5* showed that the change of transpiration rate of different medicinal plants was similar to that of their net photosynthetic rate.。 The total change trend of transpiration rate in the whole growth period of the medicinal plants propagated by seeds showed a single peak curve: that is, the seedling stage was low, and transpiration rate gradually increased with the continuous expansion of the vegetative body. After reaching the highest level, it gradually reduced to the lowest in the late growth stage, and the transpiration rate of *Platycodon grandiflorum* varied greatly, While the *North Atractylodes*, which propagated with rhizomes and tubers, showed the bimodal curve.

There are some differences between the transpiration rates of medicinal plants: the *Platycodon grandiflorum* has the maximum transpiration rate, especially in the branching stage and the early flowering stage, between $2.43 \sim 4.02\ m\ mol\ \mathrm{H_2}O / \mathrm{m}^2 / s$, followed by *Carthamustinctorious* and *Menthahaplocalyx*, and the lowest is Atractylodis sinensis. The changes of the whole growth period of the Atractylodis sinensis is more stable.

Discussion

Photosynthesis is the process of green plant uses visible light energy to synthetize the carbon dioxide and hydration to become carbohydrate (usually glucose) through the chloroplast, and release oxygen (Zhu et al., 2016). The reaction equation of photosynthesis is: $6CO_2 + 12H_2O \xrightarrow[\text{Chloroplast}]{\text{Luminous energy}} C_6H_{12}O_6 + 6O_2 + 6H_2O$. Net photosynthetic rate is closely related to its own factors, such as chlorophyll content, leaf thickness and leaf maturity. It is also affected by light intensity, air temperature, air relative humidity and soil water content (Schwinghamer et al., 2015).

Analysis of photosynthetic rate during the whole growth period

Among the four studied medicinal plants, *Platycodon grandiflorum* should be C4 plant and the other three species of medicinal plants are C3 plants. In each growth period, the net photosynthetic rate of *Platycodon grandiflorum* was significantly higher than that of *North Atractylodes*, *Carthamustinctorious*, *Menthahaplocalyx* cultivated in the same medicine Park. This is due to the C4 pathway of *Platycodon grandiflorum*, which has a fixed CO_2, and the source of energy is continuously supplied and fully utilized by CO_2, so it has a higher net photosynthetic rate (Schwinghamer et al., 2015).

The results showed that the photosynthetic rate of *Carthamustinctorious* and *Menthahaplocalyx* was slightly lower than that of *North Atractylodes* in the early stage of growth, while in the middle growth stage, it was significantly higher than that of *North Atractylodes*. The reason may be related to the difference of propagation mode (Peng et al., 2015): rhizome was used as propagating material for North Atractylodes, and soon entered fast growing stage, which showed strong photosynthetic ability. In

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1280712826

addition, the time when the *North Atractylodes* entered the flowering and fruiting stage was earlier than that of *Carthamustinctorious* and *Menthahaplocalyx*, and there was a strong physiological bank.

In the middle growth period, the rapid growth of *Carthamustinctorious* and *Menthahaplocalyx* needs large amounts of organic material for the vegetative growth (Almeida et al., 2014), and although Atractylodes sinensis at this time also began to rapid growth of vegetative, because the strain was smaller and the consumption of organic substances were also relatively less. The net photosynthetic rate of the former is not high.

The difference in the medicinal parts was different: rhizome was the storage location of *North Atractylodes*, and it had swelling and nutrient accumulation in the late growth stage (Kjaer et al., 2014), thus showing another peak of net photosynthetic rate.

The seasonal variation of net photosynthetic rate is discussed

In June to July, the ability of *Platycodon grandiflorum*root, *Carthamustinctorious* and *North Atractylodes* to use high temperature and high light intensity was obviously better than that of *Menthahaplocalyx*; In August and September, the photosynthetic capacity of *Menthahaplocalyx* increased slightly, indicating that *Menthahaplocalyx* could make use of relatively low light and temperature conditions more effectively. The photosynthetic rate of the *North Atractylodes* was the lowest in September and October, indicating that its ability to use relatively low light and temperature conditions was the lowest in four medicinal plants. The results showed that in the growing season, the order of average photosynthetic rate of four species of medicinal plants was: *Platycodon grandiflorum* > *Carthamustinctorious* > *Menthahaplocalyx* > *North Atractylodes*.

The diurnal variations of stomatal conductance and net photosynthetic rate are discussed

The plant self-factors that cause the net photosynthetic rate of plant leaves decreased at noon including stomatal and non-stomatal factors. At noon, in the field, the intense light, high temperature, low humidity and other environmental factors caused by plant stomatal closures, CO_2 was blocked to enter into the leaves and photosynthesis decreased, while non-stomatal factor was because the temperature was too high, resulting in a decline in net photosynthesis in mesophyll cells. In addition, under high light intensity for a long time, light inhibition and photorespiration can also lead to a decrease in net photosynthetic rate at noon. The response of P_n from *Platycodon grandiflorum* and *North Atractylodes* to PAR showed that *Platycodon grandiflorum* and *North Atractylodes* still had high P_n (above 19.5 and 26, $26.6\ \mu\text{mol}\cdot\text{m}^{-2}\cdot\text{s}^{-1}$) under intense light (above $1800\ \mu\text{mol}\cdot\text{m}^{-2}\cdot\text{s}^{-1}$), so photoinhibition and photorespiration were not the factors limiting P_n at this time. At 12:00, RH dropped to the lowest point of the day, and G_s was also lower than 10:00 and 14: 00, so the stomatal factor was one of the reasons for the low net photosynthetic rate at this time. In addition, T_a reached 40.9 °C at this time. Previous studies found that the optimum activation temperature for the key enzyme of Rubisco in photosynthesis was at 25~30 °C, its activity directly affects the photosynthetic rate. When the leaf temperature is too high, it will affect the activities of some related enzymes in the body, which is not conducive to the photosynthesis.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1280712826

Therefore, the decline of P_n in the two plants is also caused by the decrease of the non-stomatal factors, the activity of the carboxycarboxylase of mesophyll cells.

The net photosynthetic rate of *Carthamustinctorious* and *Menthahaplocalyx* had a diurnal variation. The maximum net photosynthetic rate of the two plants was $9.1\mu mol \cdot m^{-2} \cdot s^{-1}$ and $5.8\ \mu mol \cdot m^{-2} \cdot s^{-1}$ respectively. After that, the net photosynthetic rate declined rapidly, which was similar to the results of the diurnal variation of the photosynthesis by Zhang Jingguang, et al. In the response of the P_n of the two plants to the PAR, the P_n decreased at PAR > $1400\ \mu mol \cdot m^{-2} \cdot s^{-1}$, indicating that the photoinhibition might have occurred under the intense light. The correlation analysis between diurnal variation of photosynthesis and physiological and ecological factors showed that G_s is the main influence factor of *Carthamustinctorious* P_n, while G_s of the *Carthamustinctorious* is low in a day, so stomatal limitation is a cause of low P_n in the daytime. It is believed that high temperature and intense light cause the potential activity of the active center and the primary light conversion efficiency decreasing, which hindered the photosynthetic electron transport. It is the limiting factor of photosynthesis (Zhang et al., 2015).

Content of photosynthetic pigment

The pigment that absorbs light in photosynthesis is called photosynthetic pigment, and there are two main types in higher plants: chlorophyll (including chlorophyll a, b) and carotenoids. The color of the leaves is mainly a comprehensive representation of the proportion of green chlorophyll and yellow carotenoid. The chlorophyll a/b of the leaves of the common sun plants is about $3:1$, and the chlorophyll a/b of the shade plants is $2:3:1$. The relative increase of chlorophyll b content may make more effective use of the blue violet light in the leaching light. So the chlorophyll b has the name of the chromophore system. The chlorophyll content of plants depends not only on site conditions, but also on the characteristics of plant species, and determines the ability of plants to absorb and convert light energy (Li et al., 2016).

The content of chlorophyll is also related to the resistance of plants to the shade. The chlorophyll content of *Platycodon grandiflorum* and *Menthahaplocalyx* had not significantly different, but the LSP and the maximum net photosynthetic rate of *Platycodon grandiflorum* were significantly higher than that of *Menthahaplocalyx*. The chlorophyll content of the *North Atractylodes* was significantly lower than that of *Platycodon grandiflorum*, but LSP was significantly higher than that of *Platycodon grandiflorum*, and the maximum net photosynthetic rate of them had no significant difference. The results showed that the content of chlorophyll was not directly related to LSP and the maximum net photosynthetic rate. The LCP of *Platycodon grandiflorum*, *Carthamustinctorious* and *Menthahaplocalyx* were lower than that of the *North Atractylodes*, so does the chlorophyll a/b value, but the content of chlorophyll and carotenoid was higher than that of the *North Atractylodes*, this may be because the plants with high chlorophyll content have weak absorption ability of light, it has better resistance to shade. In addition, it was found that low chlorophyll a/b value increased the absorption of far red light. Therefore, plants with low chlorophyll a/b value also had higher photosynthetic activity under low intensity of light.

In the experiment, the chlorophyll content of *Carthamustinctorious* was the highest in the four medicinal plants, followed by *Platycodon grandiflorum* and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1280712826

Menthahaplocalyx, and that of *North Atractylodes* was the lowest. However, the content of chlorophyll a/b of *North Atractylodes*'s is the highest, followed by *Platycodon grandiflorum* and *Carthamustinctorious*, and that of *Menthahaplocalyx* leaves is the lowest. *Carthamustinctorious* and *Menthahaplocalyx* in four medicinal plants have the highest carotenoid content.

Conclusions

With the continuous progress of the social development and the accelerated process of industrialization, agriculture and green land area is decreased. The study of Photosynthetic Physiology plays a very important role in the selection of germplasm resources, the rational allocation of planting environment and the increase of yield in medicinal plants (Niakan et al., 2015). According to the first two chapters, we can further understand their photosynthetic and physiological characteristics by studying and discussing four kinds of medicinal plants of *Platycodon grandiflorum*, *Atractylodis sinensis*, *Carthamustinctorious* and *Menthahaplocalyx*.

The Atractylodis sinensis has high utilization rate of intense light, but it belongs to the light plant, and has poor shade tolerance. Thus, it should be cultivated in the environment of direct sunlight enough to increase the yield. *Carthamustinctorious* and *Menthahaplocalyx* are shade loving plants, but they are not resistant to intense light. The cultivation environment outside the forest is easy to inhibit their photosynthesis. Therefore, the intercropping way of forest and medical plants can be adopted. *Platycodon grandiflorum* has great adaptability to light intensity. It can not only efficiently use intense light but also have a characteristic of certain shade tolerance. If it wants to increase photosynthetic rate and increase yield, it is recommended to cultivate it in an intense light environment.

In the future research stage, the ecological characteristics of the same species of medicinal plants in different growing areas will be studied in depth, so as to provide more theoretical support for the development and utilization of medicinal plants.

(Received 9th May 2019; accepted 20th Aug 2019)

Abstract. We studied the different patterns of nutrient accumulation, root-shoot ratio, and yield of soybean plants observed in response to the changes in the soil bulk density and plow depth; this was achieved by adopting the frame-planting method and taking two soybean varieties, Jiyu 79 (JY79) and Heinong 44 (HN44), as the test materials. The results showed that soybean dry matter; the accumulation of nitrogen (N), phosphorous (P), and potassium (K); and the yield had a single-peak curve change at the bulk density of 1.00 g/cm^3-1.45 g/cm^3, with the most appropriate soybean growth and yield observed at the bulk density of 1.15 g/cm^3-1.30 g/cm^3. Soybean dry matter; N, P, and K accumulation; and yield with the increase in plow depth, with the 30 cm plow depth being the optimal plow depth for the soybean field. The root-shoot ratio of the soybean plants was relatively high during the early growth period and decreased with the progression of the growth. In the R_1 stage, the root-shoot ratio showed a "V"-shaped change with the increase in bulk density in the plow layer, with the smallest root-shoot ratio occurring under the treatment with the bulk density of 1.30 g/cm^3; in the R_5 and R_8 stages, the root-shoot ratio was not significantly affected when the bulk density in the plow layer was between 1.00 g/cm^3 and 1.30 g/cm^3, but the root-shoot ratio significantly increased under the treatment with the bulk density of 1.45 g/cm^3. In the R_1 stage, no significant difference existed in the root-shoot ratio between the treatments with plow depths of 0-20 cm, and their root-shoot ratios were higher than those under the treatment with plow depths of 30 and 40 cm; in the R_5 and R_8 stages, no significant difference existed in the root-shoot ratio between the 10 to 40 cm plow depths.
Keywords: *bulk density, plow depth, soybean, nutrient accumulation, yield, root-shoot ratio*

Introduction

The average soil bulk density of China's terrestrial ecosystems is 1.32 g/cm^3. Soil bulk density increases with the depth of the soil layer (Chai and He, 2016) and has a significant effect on the soil water content characteristics (Blouin et al., 2004; Zhong et al., 2016). Soil bulk density also affects the soil microbial community structure (Kaiser et al., 1991) and physiological characteristics (Williams and Rice, 2007), thereby affecting the physiological and biochemical indicators and dry matter accumulation in crops (Assaeed et al., 1990; Siczek et al., 2013). Buttery et al. (1998) found that when bulk density increased from 1.2 g/cm^3 to 1.5 g/cm^3 in clay loam and 1.6 g/cm^3 in sandy loam, the soybean dry matter and root weight decreased significantly (Nunes et al., 2015a); the increased bulk density also reduced the number of pea root nodules and the root nodule dry weight, as well as the nitrogen (N) fixation enzyme activities and total N content (Siczek and Lipiec, 2011; Siczek et al., 2013).

Soil bulk density is an important indicator of soil physical properties. Excessive bulk density results in a decrease in the number of large pores in the soil, an increase in the soil compaction, and a decrease in the gas exchange rate (Kaiser et al., 1991).

Differences in soil compactness can have a significant impact on the growth and penetration of the crop roots (Colombi and Walter, 2016; Maganti et al., 2005). Siczek et al. (2015) found that the root number, root dry weight, root length, and root vigor of the crops all decreased with the increase in bulk density and that the increase in soil bulk density interfered with the growth of the pea roots and plants, leading to thicker roots and thus to less uptake of nutrients. Bengough et al. (1994) found that when soil bulk density was increased from 0.85 g/cm^3 to 1.40 g/cm^3, the growth rate of the pea roots was significantly reduced, and when the root growth encountered an increased resistance, the pea root elongation rate was decreased by 50% within half an hour; after the resistance was removed, the root growth rate increased slightly. The responses of the different crops to soil compactness are basically the same. Rosolem et al. (1998) studied the effect of soil compaction on the growth of cotton roots and showed that when the soil strength reached 2.5 MPa, the cotton roots would no longer grow. Freitas et al. (1999) disclosed that when the compaction of the soil increases, the morphology pattern of the lateral roots of maize also changes correspondingly, developing a thicker root diameter, a greater number of lateral roots and root hairs, and changing their direction of growth (Barley, 1962; Goss and Russell, 1980). Iijima et al. (1991) found that an excessive soil bulk density in the lower soil layers would inhibit growth in rice roots and corn roots, which in turn would promote the formation of lateral roots in the upper layer; this finding indicates that the growth of roots in different soil layers exhibits certain compensation effects. The results of previous studies in our laboratory showed that the effect of the soil bulk density on the N content and accumulation amount in soybean exhibits a parabolic change in trend, with soils that are too loose or too tight soil being unfavorable (Zhang et al., 2017). Johnson et al. (1989) found that the compaction in the 0 to 30 cm surface soil layer reduced the soybean yield by 15%, but the compaction of subsoil below the 30 cm layer had little effect on soybean yield. Gaultney et al. (1980) reported that the compaction of soil at lower layers can significantly affect the growth and final yield of corn. Bushamuka and Zobel (1998) argued that when the soil layer bulk density was 1.6 g/cm^3, the corn root system could not penetrate. However, Stypa et al. (1987) claimed that bulk density threshold in the soil layer for corn root growth could reach 1.8 g/cm^3. Increasing the subsoiling depth can effectively reduce the soil bulk density in the lower layers (Wang et al., 2015), which essentially increases the plow depth and increases the crop yield (Nunes et al., 2015b). Qi et al. (2015) conducted a subsoiling test under the same regional conditions, and the results showed that the resistance of the subsoiling blade increased in a quadratic curve as the subsoiling depth increased in the subsoiling operation. The above studies show that crop growth and yield have an appropriate range of bulk density and depth in the plow layer (Gayosso-Moralesl et al., 2017; Gomez-Lopez et al., 2018; Ufuk Kasim and Kasim, 2017; Vicente-Molina et al., 2018). When the bulk density in the plow layer is greater than the appropriate bulk density, the soil should be loosened; when the bulk density is too loose, the soil should be compacted. The tillage depth should be within the range of the appropriate plow depth, whereas tilling too deep would increase the cost and would not achieve the effect of increasing production (Fu and Liu, 2017; Peng et al., 2017).

The Northeast black soil region in China is the main soybean-producing area in China. The appropriate ranges of bulk density and plow depth in the plow layer in this region have not been determined by systematic study. In this study, the frame-planting method was used to simulate different bulk densities and plow depths to study their

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1282712842

effects on the growth and yield of the soybeans, thereby providing a theoretical basis for determining the appropriate bulk density and plow depth in the plow layer of the soybean field and providing a reference for scientific farming of field soybeans.

Materials and methods

Test materials

The experiment was conducted using the frame-planting method in the research field of the college of Agriculture, Northeast Agricultural University, China, in 2016. The round frame was made from a PVC circular tube (with an inner diameter of 20 cm, a height of 45 cm, and no bottom); 40 cm of the soil was packed, and the upper frame extended to 5 cm above the soil layer. The test soil was taken from the maize field and was of the black soil type (with a soil specific gravity of 2.65). Soil organic matter was 32.49 g/kg, available N was 65.01 mg/kg, available phosphorus (P) was 60.53 mg/kg, and available potassium (K) was 192.45 mg/kg. Soybean varieties included the Jiyu 79 (JY79) and Heinong 44 (HN44). The fertilizer application rate included 0.47 g (150 kg/hm^2) of diammonium hydrogen phosphate (P_2O_5: 46%) per frame and 0.24 g (75 kg/hm^2) of potassium sulfate (K_2O: 54%) per frame.

Experimental design

The soil density of the 20 to 30 cm soil layer of farmland in the black soil region was approximately 1.43 g/cm^3 (Zhao et al., 2010). The maximum value of the soil bulk density in this study was set as 1.45 g/cm^3.

Bulk density treatment: Four bulk density levels, including 1.00 g/cm^3, 1.15 g/cm^3, 1.30 g/cm^3, and 1.45 g/cm^3, were established and respectively denoted by B1.00, B1.15, B1.30, and B1.45. For each bulk density treatment, 30 frames were included, for a total of 120 frames in this study. The method was applied as follows: by measuring the soil water content, the weight of the soil 40 cm high in the frame was calculated, and a jack was used to compact the test soil in the round frame according to the different bulk density settings.

Plow depth treatment: The test soil within the round frame was divided into two layers (upper and lower layers) for simulation; that is, the upper layer was taken as the plow layer, and the lower layer was the layer below the plow layer. The soil bulk density in the plow layer was uniformly set to be 1.15 g/cm^3, and the soil bulk density in the layer below the plow layer was uniformly set to be 1.45 g/cm^3. Five plow depths were included, which were 0 cm, 10 cm, 20 cm, 30 cm, and 40 cm, respectively, and these depths were denoted as D0, D10, D20, D30, and D40, respectively. For each plow depth treatment, 30 frames were included, for a total of 150 frames. Specifically, for D0, the bulk density of the 40 cm of soil within the round frame was uniformly set as 1.45 g/cm^3; for D10, the bulk density of the upper 10 cm soil layer within the frame was set as 1.15 g/cm^3, and the bulk density of the lower 30 cm soil layer was set as 1.45 g/cm^3; for D20, the bulk density of the upper 20 cm soil layer within the round frame was set as 1.15 g/cm^3, and the bulk density of the lower 20 cm soil layer was set as 1.45 g/cm^3; for D30, the bulk density of the upper 30 cm soil layer with the round frame was set as 1.15 g/cm^3, and the bulk density of the lower 10 cm soil layer was set as 1.45 g/cm^3; and for D40, the 40 cm

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1282712842

soil bulk density in the round frame was uniformly set as 1.15 g/cm^3. A jack was used to first compact the soil below the plow layer and then to compact the upper soil.

For sowing, the soil within the frame was watered to saturation, and then, four seeds were sown in hills and covered with 3 cm of soil; after seedling emergence, final thinning of the seedlings was conducted, with two plants being retained per frame.

Sampling and nutrient determination

Sampling methods: Samples were taken at the R_1 (incipient flowering stage), R_5 (granule stage), and R_8 (maturity stage). During sampling, the aboveground part of the soybean plant was removed at the cotyledon trace, and the roots were rinsed with clean water. The various parts were respectively placed in different envelopes, which were subjected to fixation at 105 °C for 30 min and oven drying at 65 °C; samples were weighed for determination of the nutrient contents.

Nutrient determination: Plant N and P contents, respectively, were measured by using $CuSO_4$ and K_2SO_4 as catalysts, and after digestion of the sample with concentrated H_2SO_4, the N was measured by the Kjeldahl method, and the P was measured by the molybdenum antimony anti-colorimetric method. Following digestion of the sample by the concentrated H_2SO_4, the K content in the plants was determined by the flame spectrophotometry method by using hydrogen peroxide as a catalyst.

The accumulated amounts of N, P, and K were determined, respectively, by multiplying the corresponding N, P, and K content by the dry matter amount.

Results and analysis

Effects of soil bulk density and plow layer on soybean nutrient accumulation

Effect of soil bulk density on soybean nutrient accumulation

Table 1 shows the dynamics of the dry matter accumulation and the accumulation of the N, P, and K in soybean plants under the different soil bulk density conditions. As show in *Table 1*, under the four bulk density levels, the dry matter and the N, P, and K accumulation amounts of the two test soybean varieties increased with the progression of the growth stages. The dry matter and the N, P, and K accumulation amounts for the two test varieties under the various soil bulk density treatments showed a descending order of B1.30 > B1.15 > B1.00 > B1.45, showing a single-peak curve with the increase in soil bulk density. Specifically, in the R_1 stage, the dry matter and K accumulation amounts for the two varieties, as well as the N accumulation amount for JY79, were not significantly different between the B1.30 and B1.15 treatments; in the R_5 stage, the dry matter and the K accumulation amounts for the two test soybean varieties, as well as the N accumulation amount for HN44, were not significantly different between the B1.30 and B1.15 treatments; and in the R_8 stage, the P accumulation amounts for the two test soybean varieties were not significantly different between the B1.30 and B1.15 treatments. In the other stages, the B1.30 treatment showed significantly higher nutrient accumulation than the other treatments.

Vertical comparison, 5% significant level

Effect of plow depth and soil bulk density on soybean nutrient accumulation

Table 2 shows the changes in the dry matter and the N, P, and K accumulation amounts of soybean plants under the different plow depths. From *Table 2*, under the five plow depths, the dry matter and NPK accumulation amounts of the two test varieties increased as the growth stage progressed and increased as the plow depth increased. Specifically, in the R_1 stage, the dry matter amount and the N accumulation amount of the two varieties showed a descending order of D40 > D30 > D20 > D10 > D0, and significant difference existed among the various treatments. The P accumulation amounts of the two varieties showed a descending order of D30 > D40 > D20 > D10 > D0; for JY79, significant differences existed among the various treatments and for HN44; and the P accumulation amount under D30 showed no significant difference from that under D40 but was significantly higher than those under

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1282712842

the other treatments. The K accumulation amounts of the two varieties were different because JY79 showed a descending order of D40 > D30 > D20 > D10 > D0, whereas HN44 showed a descending order of D30 > D40 > D20 > D10 > D0; for the two varieties, the P accumulation amount under D40 showed no significant difference from that under D30 but was significantly higher than those under the other treatments. In the R_5 stage, the dry matter and the N, P, K accumulation amounts for the two test soybean varieties showed a descending order of D40 > D30 > D20 > D10 > D0, and significant differences existed among the various treatments. In the R_8 stage, for JY79, the dry matter and the N and K accumulation amounts showed a descending order of D40 > D30 > D20 > D10 > D0, with significant differences existing among the various treatments; the P accumulation amount showed a descending order of D30 > D40 > D20 > D10 > D0, and the P accumulation amount under D30 showed no significant difference from that accumulation under D40 but was significantly higher than those under the other treatments. For HN44, the dry matter and the N, P, and K accumulation amounts showed a descending order of D30 > D40 > D20 > D10 > D0, and the dry matter and K accumulation amounts under D30 showed no significant difference from those under D40 but showed significant differences from those amounts under the other treatments.

Effects of soil bulk density and plow depth on the root weight and root-shoot ratio in soybean

Effect of soil bulk density on the root weight and root-shoot ratio in soybean

Table 3 shows the dynamic changes of the root weight and root-shoot ratio under the different soil bulk densities. As shown in *Table 3*, the root weights of the two test soybean varieties showed a single-peak curve with the increase of bulk density in the growth process, but differences existed in the changes of the root weight in the different stages among the various treatments. In the R_1 and R_5 stages, both varieties had the highest root weights at the bulk density of B1.15. In the R_1 stage, for HN44, the root weight under the B1.15 treatment showed no significant difference from that under the B1.30 treatments but was significantly higher than those under the other treatments. In the R_5 stage, for JY79, the root weight under the B1.15 treatment showed no significant difference from that under the B1.30 treatment but was significantly higher than those under the other treatments; however, for HN44, the root weight under the B1.15 treatment showed no significant difference from those under the B1.00 and B1.30 treatments but was significantly higher than that under the B1.45 treatment. In the R_8 stage, both varieties had the highest root weights at the bulk density of B1.30. Specifically, for JY79, the root weight under the B1.30 treatment showed no significant difference from that under the B1.15 treatment but was significantly higher than those under the other treatments; for HN44, the differences in the root weight between B1.30 and the other treatments all reached the level of significance. The effect of the soil bulk density on the root-shoot ratio of the soybean plants showed that the two test varieties showed a consistent pattern. In the R_1 stage, the root-shoot ratio of the soybean showed a trend in a "V"-shaped curve with the increase in the soil bulk density; the root-shoot ratio under B1.30 was the lowest and showed significant differences from those under the other treatments; and the root-shoot ratio under B1.15 showed no significant difference from that under B1.00 but was significantly lower than that under B1.45. In the R_5 and R_8 stages, the root-shoot ratio showed a consistent pattern: the ratio under

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1282712842

B1.30 showed no significant difference from those under B1.15 and B1.00 but was significantly lower than those under the B1.45 treatment. These results showed that the soil bulk density had a great influence on the root-shoot ratio in the early growth period, but the soil bulk density had no significant effect when it was 1.00 g/cm^3-1.30 g/cm^3 during the mid-to-late period; in contrast, when the soil bulk density reached 1.45 g/cm^3, the root-shoot ratio increased significantly.

Effect of plow depth on the root weight and root-shoot ratio in the soybean

Table 4 shows the changes in the root weight and root-shoot ratio under the different plow depths. As shown in *Table 4*, the root weights of the two soybean varieties during the growth process also increased as the plow depth increased. In the R_1 stage, for JY79, no significant difference existed in the root weight between D40 and D30, but the root weights under these two treatments were significantly higher than those under the other treatments; for HN44, the root weight under D40 was significantly higher than those under the other treatments. In the R_5 stage, the root weights for the two soybean varieties under D40 were significantly higher than those under the other treatments. In the R_8 stage, for JY79, the root weight under D40 was significantly higher than those under the other treatments; for HN44, the maximum root weight was observed under D30, with the D30 root weight showing no significant difference from the weight under D40 but showing a significantly higher root weight than those under the other treatments. In addition, in terms of the effect of the plow depth on the root-shoot ratio of soybean plants, the two test varieties showed a consistent pattern because both showed a decreasing trend with the increase in plow depth. In the R_1 stage, for JY79, no significant difference existed in the root-shoot ratio under D0, D20, and D30, but these ratios were significantly higher than those under D30 and D40; no significant difference existed between those ratios under D30 and D40. For HN44, no significant difference existed between D0 and D10, but their root-shoot ratios were significantly higher than those under D20, D30, and D40, with no significant difference existing among D20, D30, and D40. In the R_5 stage, the two varieties showed a consistent pattern in that the root-shoot ratio under D0 was significantly higher than those under D10, D20, D30, and D40, with no significant difference existing between the latter four treatments. In the R_8

stage, for JY79, the root-shoot ratio under D0 was significantly different from those under the other treatments, with no significant difference observed among those under the D10, D20, D30, and D40 treatments; for HN44, the root-shoot ratio under D0 showed no significant difference from that under D10 but was significantly higher than those ratios under the other treatments, with no significant difference existing among those ratios under the D20, D30, and D40 treatments.

Effects of the soil bulk density and plow depth on soybean yield

Effect of the soil bulk density on the soybean yield

As shown in *Table 5*, the plant height, node number, grain number, 100-seed weight, and yield in the soybeans all showed a single-peak curve with the increase in the soil bulk density, with maximum values observed under the B1.30 treatment and minimum values observed under the B1.45 treatment. The plant heights of the two varieties both showed a descending order of B1.30 > B1.15 > B1.00 > B1.45. Specifically, the plant heights of JY79 under the B1.30 and B1.15 treatments showed no significant difference and were significantly higher than that under other treatments; the plant height of HN44 under B1.30 was significantly different from that under the other bulk density treatments. The node number of JY79 showed a descending order of B1.30 > B1.15 > B1.00 > B1.45, with no significant difference existing between B1.30 and B1.15; the node number of HN44 showed a descending order of B1.30 > B1.00 > B1.15 > B1.45, with B1.30 being significantly different from the other

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1282712842

bulk density treatments. The grain numbers of the two varieties both showed a descending order of B1.30 > B1.15 > B1.00 > B1.45. Specifically, the grain numbers of JY79 under B1.30 and B1.15 showed no significant difference and were significantly higher than those under the other treatments, and the grain number of HN44 under B1.30 was significantly different from the grain numbers under the other bulk density treatments. The 100-seed weights of the two varieties showed a descending order of B1.30 > B1.15 > B1.00 > B1.45; the 100-seed weight under B1.30 showed no significant difference from those under B1.15 and B1.00 but was significantly higher than that under the B1.45 treatment. The yields of the two varieties showed a descending order of B1.30 > B1.15 > B1.00 > B1.45, and except for the yields of HN44 under B1.00 and B1.15 showing no significant difference, the yields under the other treatments were significantly different. The results from the SPSS regression analysis show that for the two soybean varieties, the best-fitting equation between the yield and soil bulk density is cubic: for JY79, the equation is $y = -448.923x^3 + 799.66x^2 - 292.617$ ($R^2 = 0.946$), and the highest yield was achieved at the bulk density of 1.19 g/cm^3 out of the 1.00 g/cm^3-1.45 g/cm^3 range; for HN44, the equation is $y = -315.164x^3 + 554.203x^2 - 184.55$ ($R^2 = 0.899$), with the yield being the greatest at 1.17 g/cm^3. No significant difference existed in the optimal soil bulk density between the two varieties.

Effect of plow depth on soybean yield

Table 6 shows that with the increase in plow depth, the plant height, grain number, 100-seed weight, and yield showed increasing trends. The plant height of JY79 showed a descending order of D40 > D30 > D20 > D10 > D0; D40 showed no significant difference from D30 but showed significant differences from other various treatments. The plant height of HN44 showed a descending order of D30 > D40 > D20 > D10 > D0; D30 was significantly higher than other treatments, and D20 was not significantly different from D40 but was significantly higher than D10 and D0 treatments. The node number of JY79 showed a descending order of D40 > D20 > D30 > D10 > D0; no significant differences existed among D40, D20, and D30, among D30, D20, and D10, and between D10 and D0. The node number of HN44 showed a descending order of D30 > D40 > D20 > D0 > D10, and no significant difference existed among these treatments. The grain number of JY79 showed a descending order of D40 > D30 > D20 > D10 > D0, with no significant difference existing between D40 and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1282712842

D30; the grain number of HN44 showed a descending order of D30 > D40 > D20 > D10 > D0, with no significant difference existing between D30 and D40. The 100-seed weight of JY79 showed a descending order of D40 > D30 > D20 > D10 > D0; D40 showed no significant difference between D30 and D20 but was significantly higher than D0 and D10; the 100-seed weight of HN44 showed a descending order of D30 > D20 > D10 > D40 > D0, with D30 showing no significant difference from D20 but being significantly higher than the other treatments. The yield of JY79 showed a descending order of D40 > D30 > D20 > D10 > D0; D40 showed no significant difference from D30, and D40 and the yield for D30 was significantly higher than with the other treatments. The yield of HN44 showed a descending order of D30 > D40 > D20 > D10 > D0, and D30 was significantly different from the other plow depth treatments. SPSS regression analysis showed that, for the two soybean varieties, the best-fitting equation between yield and plow depth is cubic: for JY79, the equation is $y = -0.001x^3 + 0.078x^2 + 0.677x + 18.438$ ($R^2 = 0.985$), and 30-40 cm is the optimal plow depth range within the 0 to 40 cm plow range; for HN44, the equation is $y = -0.005x^3 + 0.244x^2 - 1.376x + 16.95$ ($R^2 = 0.987$), with the yield being the highest at 29.4 cm, and 27.9-30.9 cm is the optimal plow depth range in the 0 to 40 cm plow range.

Table 6. *Soybean yield components and morphology indexes under the different plow depth treatments*

Discussion

Appropriate soil bulk density for soybean field

Soil bulk density is an important factor affecting soil porosity (Kaiser et al., 1991), and changes in soil bulk density cause changes in soil moisture characteristics. The changes in soil bulk density do not affect soil composition, but rather multiple soil physical indicators. The increase of soil bulk density causes significantly decreased saturated hydraulic conductivity, infiltration rate, and water diffusivity, thereby affecting crop growth and yield. A soil compaction test by Assaeed et al. (1990) found that when the bulk density was increased from 1.03 g/cm^3 to 1.51 g/cm^3, the barley yield was reduced by 29%; when the bulk density was increased from 1.49 g/cm^3 to 1.75 g/cm^3, the yields of barley, corn, and peas decreased by 29%, 33%, and 14%,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1282712842

respectively; when the bulk density was increased from 1.35 g/cm^3 to 1.58 g/cm^3, the yield of peas decreased by 25%. Zhang et al. (2017) studied the relation between the N uptake and accumulation in soybean and the soil bulk density, and found that the impact of soil bulk density on soybean yield exhibited a single-peak curve, with the optimal bulk density being 1.23 g/cm^3-1.31 g/cm^3. In this experiment, the dry matter; N, P, and K accumulation; and the yield of soybeans showed a single-peak curve change when soil bulk density had the range of 1.00 g/cm^3-1.45 g/cm^3, with the optimal bulk density being 1.30 g/cm^3. The experiment shows that the yields of the two test soybean varieties at the soil bulk density of 1.30 g/cm^3 increased, respectively, by 6.3%, 30.2%, and 341.4% and by 11.8%, 18.4%, and 289.3%, respectively, compared to their yields at bulk densities of 1.15 g/cm^3, 1.00 g/cm^3, and 1.45 g/cm^3. The difference in yield was small between the bulk densities of 1.30 g/cm^3 and 1.15 g/cm^3, and 1.15 g/cm^3 – 1.30 g/cm^3 could be considered the appropriate range of bulk density for soybean growth. Therefore, when the bulk density is lower than 1.15 g/cm^3, the soil needs to be compacted properly, and when the bulk density is higher than 1.30 g/cm^3, the soil needs to be cultivated and loosened.

Significant differences exist in the soil bulk density under the different tillage measures, and as the soil bulk density increases, the number of pea root nodules and the dry weight of the root nodule, as well as the N-fixation enzyme activities and the total N content, would increase accordingly (Siczek and Lipiec, 2011; Siczek et al., 2013). Buttery et al. (1998) also found that in the clay loam, when the soil bulk density was increased from 1.2 g/cm^3 to 1.5 g/cm^3, the dry matter amount and the root weight of the soybean declined by 76.7% and 68.2%, respectively; in sandy loam, when the soil bulk density was increased from 1.2 g/cm^3 to 1.6 g/cm^3, the dry matter amount and the root weight of the soybean were reduced by 70.5% and 48.1%, respectively. In this study, the soybean root weight also showed a single-peak curve trend with the increase in the soil bulk density. Specifically, the maximum values for the two test varieties in the R_1 and R_5 stages occurred under the treatment with the bulk density of 1.15 g/cm^3, and the maximum value in the R_8 stage occurred under the treatment with the bulk density of 1.30 g/cm^3. When the bulk density was increased to 1.45 g/cm^3, the root weight was decreased significantly, which agreed with the findings of Buttery et al. (1998).

The increase in soil bulk density obstructs the growth of crop roots and of plants and results in thickened roots and poor nutrient uptake, leading to changes in crop root-shoot ratio. The root-shoot ratio of the soybean can indicate the distribution of the dry matter in the root and aboveground parts. Bengough et al. (1994) argued that when the soil bulk density increased from 0.85 g/cm^3 to 1.40 g/cm^3, the growth rate of the pea roots declined significantly; when the root growth resistance increased, the root elongation rate in the pea decreased by 50% within half an hour, and upon the removal of the resistance, the root growth rate increased slightly. In this experiment, the root-shoot ratios of the two test soybean varieties were high during the early growth period and decreased with the progression of the growth stages. The change of soil bulk density did not alter the pattern of gradual decrease in the root-shoot ratio during the progression of the soybean growth stages. However, a significant difference occurred in the root-shoot ratio among the different bulk density treatments. In the R_1 stage, the root-shoot ratio showed a "V"-pattern change with the increase of soil bulk density and reached its minimum value at the soil bulk density of 1.30 g/cm^3. The root-shoot ratios in the R_5 and R_8 stages showed no significant

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1282712842

difference among the treatments with the soil bulk densities of 1.00 g/cm^3, 1.15 g/cm^3, and 1.30 g/cm^3, but the ratios were significantly lower than those observed under the treatment with the soil bulk density of 1.45 g/cm^3. Notably, the treatment with the soil bulk density of 1.30 g/cm^3 was the most conducive to the growth of soybean, with the dry matter and the N, P, and K accumulation amounts being the highest when the root-shoot ratio was the smallest and the treatment with the soil bulk density of 1.45 g/cm^3 being the most unfavorable to the growth of soybean when the root-shoot ratio was the highest. These results indicate that when the soil bulk density was too high, root growth was hindered, and soybean plants had to allot more dry matter to the root system, resulting in an increase in the root-shoot ratio. When the soil was too loose (i.e., the bulk density was too low), bulk density only had a significant influence on the root-shoot ratio in the early soybean growth period; in contrast, excessive bulk density had a significant impact on the entire growth period.

Appropriate plow depth for the soybean field

Increased tillage and subsoiling depth can effectively reduce the soil bulk density in the lower layer and increase the plow depth, promoting crop growth and yield increase. Wang et al. (2015) conducted a comparative study between subsoiling of 30 cm, rotary tillage of 10 cm, and no-till treatments, and they found that the bulk density in the 20 to 30 cm soil layer under the subsoiling treatment decreased by 10.3% compared with that under the rotary tillage and no-till treatments; under the subsoiling treatment, the dry matter in the corn showed an increase, and the yield was 8.9% and 10.6% higher, respectively, than that under rotary tillage and no-tillage. Johnson et al. (1989) found that with a plow depth of 0-30 cm, the yield of crops gradually would increase with the increase of plow depth and would not increase significantly below the plow depth of 30 cm. Gaultney et al. (1980) noted that the soil compaction of the lower soil layers can significantly affect the growth and final yield of corn. Increasing the subsoiling depth can effectively reduce the soil bulk density in the lower soil layers (Wang et al., 2015), and with the increase in plow depth, the crop yield also increases (Nunes et al., 2015b). In this experiment, the dry matter and the N, P, and K accumulation amounts of plants increased as the growth stage progressed. Among the two test soybean varieties, for JY79, the accumulation of dry matter and of N, P, and K and yield during the three sampling periods showed an increasing trend with the increase in plow depth, with the maximum values occurring under the 40 cm plow depth treatment (albeit, no significant difference in yield existed between the 30 cm and 40 cm plow depth treatments). For HN44, the dry matter, the N, P, and K accumulation amounts, and the yield in the R_8 stage all had a single-peak curve, with the maximum value occurring under the 30 cm plow depth treatment.

Increased plow depth promotes soybean root growth toward the lower soil layers. In this experiment, the root weights of the two test soybean varieties showed an increasing trend with the increase of plow depth in the three sampling periods, but the root-shoot ratio decreased with the increase of growth stage and plow depth. Plow depth had a large impact on the root-shoot ratio during the early soybean growth period but had a small impact during the late growth period. In the R_1 stage, no significant difference was observed in the root-shoot ratio between the 0 to 10 cm plow depths, but the root-shoot ratios for these two depths were significantly higher than those for the 30 cm and 40 cm plow depths, whereas no significant difference existed between the 30 cm and the 40 cm plow depths. In the R_5 and R_8 stages, only

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1282712842

the 0 cm treatment had a relatively large root-shoot ratio, and no significant difference existed among the other depths. The above results showed that increasing the plow depth promotes the growth of aboveground parts of soybean and underground root systems, and it also promotes the distribution of nutrients toward the aboveground parts.

According to Qi et al. (2015), traction resistance in subsoiling increases quadratically with depth, with the subsoiling depths of 10 cm, 20 cm, 30 cm, and 40 cm showing resistance values of 0.42 kN, 0.85 kN, 2.56 kN, and 5.49 kN, respectively. In this test, the average yield of the two test soybean varieties showed an increase of 92.2% in yield when the plow depth was increased from 10 cm to 20 cm and an increase of 35.3% in yield when the plow depth was increased from 20 cm to 30 cm. When the plow depth increased from 30 cm to 40 cm, JY79 showed an increase in yield of 6.5% but without a significant difference; HN44 did not show an increase in yield. When the plow depth was greater than 30 cm, the increase in soybean yield was not significant, but the traction resistance during field preparation increased greatly, resulting in a significant increase in the operating costs. Therefore, a plow depth of 30 cm for soybean field setting is appropriate.

Conclusions

(1) Soybean dry matter; N, P, and K accumulation amounts; and yield exhibited a single-peak curve change when the bulk density reach a range of 1.00 g/cm^3-1.45 g/cm^3, with 1.15 g/cm^3-1.30 g/cm^3 being the appropriate ranges for soybean growth and yield formation. The soybean dry matter; the N, P, and K accumulation amounts; and the yield increased with the increase in plow depth. When the plow depth increased from 30 cm to 40 cm, the two test soybean varieties did not show a significant increase in yield, and the 30 cm plow depth could thus be determined to be the appropriate plow depth for the soybean field.

(2) The root-shoot ratio of the soybean plants was higher at the early growth period and decreased as growth progressed; the changes in bulk density and plow depth in the plow layer had a greater impact on the root-shoot ratio in the early soybean growth period, but they did not alter the pattern where the root-shoot ratio gradually decreased during the growth of the soybean. In the R_1 stage, the root-shoot ratio exhibited a "V"-shaped trend for change as the bulk density in the plow layer increased, with the minimum root-shoot ratio occurring under the 1.30 g/cm^3 treatment; in the R_5 and R_8 stages, the root-shoot ratio was not significantly affected when the bulk density in the plow layer was 1.00 g/cm^3-1.30 g/cm^3, but the root-shoot ratio significantly increased under the 1.45 g/cm^3 treatment. In the R_1 stage, no significant difference was observed in the root-shoot ratio between the 0 to 20 cm plow depth treatments, and their root-shoot ratios were higher than those under the treatments with the 30 cm and 40 cm plow depths; in the R_5 and R_8 stages, the root-shoot ratio was not significantly different between the 10 to 40 cm plow depth treatments.

Abstract. The growing population and industrialization is causing air pollution. In some cities pollution has reached to a point where it is threatening human lives. Pollution has become one of the biggest issues of today's world. Pollutants are produced by exhaust gases, car wheels, and vehicles. Heavy metals (HM) are one of the major culprits that cause air pollution. This is due to the fact that HM can exist in the environment for a long time without deterioration, and their concentration in the atmosphere is ever-growing. They also tend to bioaccumulate. Therefore, determining HM concentration levels is crucial in terms of identifying risk zones and levels. Bioindicators are the most important determinants that can indicate the change in the concentration of HM in the atmosphere. This study aims to monitor the changes in Pb, Cr and Cu concentrations in the leaves, seeds and branches of cherry plum (Prunus ceracifera), horse chestnut (Aesculus hippocastanum), Tilia (Tilia tomentosa), European ash (Fraxinus excelsior) and Norway maple (Acer platanoides) species, which can be used for monitoring the traffic-induced HM concentration. We observed that the concentration of all the elements increased according to the traffic density, this is especially visible in the case of Pb and Cr.

Introduction

The increasing number of people living in urban centers in addition to the increase in the world population in recent years has brought along many problems with it. This process causes the destruction of nature, pollution of air, water and soil, as well as the deterioration of the ecological balance (Cetin, 2015a; Cetin et al., 2017a, b, 2018a, b, c, d, e, 2019a, b; Yucedag et al., 2019; Bozdogan Sert et al., 2019; Cetin 2019; Varol et al., 2019a, b). Air pollution is one of the most serious problems of today (Aricak et al., 2019; Kaya, 2009; Kaya et al., 2009, 2018; Yucedag and Kaya, 2016, 2017; Yucedag et al., 2018; Bozdogan Sert et al., 2019; Cetin, 2019; Sevik et al., 2019a, b, c). In fact, it is stated that approximately 6.5 million people die every year due to air pollution (Cetin, 2015a; Cetin et al., 2018a; Cetin et al., 2019a, b; Cetin, 2019). Even in Turkey, where

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1284312857

air is considered to be quite clean compared to many other countries, 29 thousand people lost their lives in 2016 due to air pollution (Cetin, 2015a, b, c; Cetin et al., 2019a, b, 2018c, d, e).

Since heavy metals tend to bioaccumulate, and they may be toxic even in low concentrations, they are of particular importance among the air pollution culprits. Although micronutrients such as Mn, Zn, Cr, Cu, Fe and Ni are necessary for living organisms, including plants, higher levels of them can have detrimental effects. Metals such as Hg, Cd, As and Pb have serious toxic effects on organisms even at low levels (Shahid et al., 2017). Many studies were conducted on heavy metals due to the importance of the subject (Turkyilmaz et al., 2018a, b; Sevik et al., 2019a; Akarsu et al., 2019; Bozdogan Sert et al., 2019; Jawed and Abo Aisha, 2019).

Plants are often used as bioindicators in monitoring heavy metal concentrations. However, different heavy metals accumulate at different levels in different plant species and organs. For this reason, it is necessary to determine which plant organs have what levels of heavy metal accumulation, so they can be used as bioindicators. In this study, we aim to determine the traffic-induced changes of Pb, Cr and Cu concentrations in the leaves, seeds and branches of four different plant species.

Materials and methods

Materials

The study was conducted in the Kastamonu town center. Kastamonu town center is built within a valley as a general view, and it is where the traffic is the densest. Within the scope of the study, the samples were collected from the areas with dense traffic, with low density traffic, and with almost no traffic as well as the areas with no roadway within 50 m vicinity (*Fig. 1*).

Figure 1. *Study region, traffic intensity, and sampling points*

Kastamonu town center, where the samples are collected from within the scope of the study, with dense traffic is an area where a 4-lane highway passes through with 2 lanes on

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1284312857

each direction. In this area, the traffic is generally dense during the day. The areas with low-density traffic are en route to the main road but outside the town center where the traffic is flowing. Taskopru and Inebolu routes were selected as the areas with low-density traffic. There is a two-lane road in this area, the traffic is flowing and the traffic density is quite low compared to the town center. Kastamonu University campus area was selected as the area with no traffic, and the points, where there was no roadway found within 50 m vicinity, were selected from the campus area, and samples were collected from those points.

Within the scope of the study, samples were collected from cherry plum (Prunus ceracifera), horse chestnut (Aesculus hippocastanum), tilia (Tilia tomentosa), European ash (Fraxinus excelsior) and Norway maple (Acer platanoides) plant species, which are often used in landscaping works. The samples were taken from last year's shoots, namely the one-year-old parts. Seeds of horse chestnut were used as the seed, whereas the seeds of tilia, European ash and Norway maple were used together with their coat and wings. However, the fruit flesh of cherry plum was used together with the peel. The samples were collected at the end of vegetation season of 2017, in August, and were brought to the lab after being packed and labelled.

Method

The measurements of heavy metal analyses were made in 2018. The samples, which were taken to the lab after being collected and labelled, were subjected to a separation process by being laid on the cardboards. The leaves, branches and seeds were separated and grouped. Then the branches were broken to enable them to dry thoroughly, and the seeds were crushed. The crushing of the seeds was carried out using marble pieces, and no metal tool was used during this process. The prepared samples were placed in glass settle plates and they were re-labelled. The fruit flesh of plum fruits was separated from the seed and was taken into glass settle plates and labelled. The samples prepared in such way were kept waiting for 15 days to be come air-dried, and the lab was ventilated every day throughout this process.

The air dried samples were made fully dried in a drying-oven at 45 °C for a week. In the next step, the plant samples were pulverised into powder and each weighing 0.5 g, powdered samples were placed in tubes designed for microwave. 10 mL of 65% HNO3 was added onto the samples. Fume cupboard was used during this process. The prepared samples were then burned at 280 PSI pressure and 180 °C in the microwave device for a period of 20 min. The tubes were removed from the microwave after the process was completed and left to cool down. The cooled samples were filled in until they reached 50 ml by adding deionized water. The prepared samples were read on the ICP-OES device at proper wavelengths after being filtered through the filter paper.

The data obtained were analyzed by using SPSS package program, and variance analysis was applied to the data. Homogeneous groups were obtained by applying Duncan test to the values with differences at 95% of confidence level statistically. The data obtained were interpreted after being simplified and tabulated.

Results

Change of Cr concentration depending on traffic density

Changes in Cr concentration of study samples were determined in the areas with no traffic, with low-density traffic and with dense traffic, and variance analysis and Duncan

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1284312857

test were applied to the data obtained. The mean values, F value and significance level obtained as a result of variance analysis, and homogeneous groups formed as a result of Duncan test are given in *Table 1*.

Table 1. *Concentrations of Cr in plants and organelles in different vehicle flow paths*

Species	Organ	Traffic density			F value
		No traffic	Low-density traffic	Dense traffic

	Seed	951.0 a	992.6 a	1776.3 b	794.866***
	Branch	759.3 a	871.0 b	1001.3 c	21.065**

**Significant at 0.01 level. ***Significant at 0.001 level. The letters a, b, c, etc. mean according to Duncan test results show that the group is located. It is statistically different from the values contained in different groups, starting with the letter a the numerical value grows

As a result of the variance analysis conducted, it was determined that the traffic-induced change in Cr concentration in all organs was statistically significant at minimum of 95% confidence level. When the mean values and the groups formed as a result of Duncan test are examined, it is seen that in all organs, the values obtained in the areas with no traffic are in the first homogeneous group, whereas the values obtained in the areas with dense traffic are in the last one. Therefore, we can surmise that the Cr concentration correlatively increases with traffic density

When the values are examined, we can observe that Cr concentration varies between the areas with no traffic and the areas with dense traffic in the same organs, as well as between different organs of the same species and the same organs of different species. The highest difference due to traffic density was determined in European ash leaves, and the value of 548.5 ppb in areas with no traffic increased up to 3538.4 ppb in areas with dense traffic, thus increasing by 6.5 times.

Change of Pb concentration depending on traffic density

Pb is one of the heavy metals most associated with traffic density. Within the scope of the study, the change in Pb concentration was determined for each factor, separately, and the mean values, F value and significance level obtained as a result of variance analysis, and the homogeneous groups formed as a result of the Duncan test are given in *Table 2*.

*Significant at 0.05 level. **Significant at 0.01 level. ***Significant at 0.001 level. The letters a, b, c, etc. means according to Duncan test results; show that the group is located. It is statistically different from the values contained in different groups, starting with the letter a numerical value grows

When the change of Pb concentration depending on the traffic density was examined, it was determined that the change of Pb concentration was statistically significant at a minimum of 95% confidence level in all the samples, except cherry plum and European ash seeds and tilia branches. When the mean values and homogenous groups formed as a result of Duncan test are examined, it can be observed that Pb concentration also correlatively increases with traffic density. As a result of the Duncan test, in all organs the values obtained in the areas with no traffic were in the first homogenous groups, whereas the values obtained in the areas with dense traffic were in the last one. When all values are examined, it is seen that the lowest value of 39.6 ppb is obtained in the horse chestnut seeds in the areas with no traffic, and the highest value of 6801 ppb is obtained in cherry plum seeds in the areas with dense traffic.

When the traffic-induced changes in the organs are examined, the ratio of the values obtained in the areas with dense traffic to the values obtained in the areas with no traffic is found to be lowest in the tilia seeds (approximately 1.38 times), and the highest ratio is found in the horse chestnut seeds (approximately 19.7 times).

Change of Cu concentration depending on traffic density

Changes in Cu concentration of study samples were determined in the areas with no traffic, with low-density traffic and with dense traffic, and variance analysis and Duncan test were applied to the data obtained. Afterwards, the mean values, F value and significance level obtained as a result of variance analysis, and homogeneous groups formed as a result of Duncan test are given in *Table 3*.

When the change of Cu concentration depending on the traffic density is examined, it is seen that the traffic-induced change is statistically significant at a minimum of 95% confidence level in all organs, and that the Cu concentration correlatively increases together with the traffic density in general. While in 11 out of 15 study organs, the areas with no traffic were determined to be in the first homogeneous group, in 13 of them, the areas with dense traffic were in the last homogeneous group.

All in all, Cu concentration increases correlatively with traffic density in 11 out of 15 organs. While the minimum Cu concentration value of 0.3 ppm was obtained in the horse chestnut seeds in areas with no traffic, the highest value of 286.5 was obtained in Tilia seeds in the areas with dense traffic. However, other than this value, the maximum value was found to be 45.3 ppm.

Discussion

The study results showed that the elements subjected to study changed significantly on the basis of species. While the highest values of the metals other than Cu metal were obtained from the cherry plum, it was determined that the European ash was found in the first homogeneous group in all the metals. It was found that the concentrations of the metals subjected to study significantly varied among the species, and that sometimes the said difference was more than five times among the species.

In the studies carried out to date, it was found that the heavy metal concentration changed significantly on the basis of species. In his study, Mossi (2018) states that the difference between species is approximately twice more in Pb, which has a toxic effect even at low doses, approximately 2.75 times in Cr, which is one of carcinogenic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1284312857

elements, and more than 5 times in Cu with toxic effects. Saleh (2018) states that the difference between species is more than 5 times in Cu, and even more than 24 times in Cd.

In the studies conducted, it is found that heavy metal concentrations change significantly on the basis of species, which means that different heavy metals are retained by different plants more intensely (Turkyilmaz et al., 2018a, b, c, d, 2019; Sevik et al., 2019a). This situation is primarily associated with the anatomical structure of the plant (Mossi, 2018; Saleh, 2018). The heavy metal intake of leaves varies depending on some factors such as the physical and chemical properties of the metals, their forms, morphology of the leaves, surface area, plant habitus next to the surface texture, heavy metals exposure time, environmental conditions and gas exchange (Beckett et al., 2000; Shahid et al., 2017; Turkyilmaz et al., 2018a, c; Sevik et al., 2019a; Mossi, 2018).

Within the scope of the study, it is found that heavy metal concentrations can change significantly on the basis of organs. However, the more important result is that the heavy metal concentrations in organs on the basis of species are different. For example, while the highest concentrations in Pb and Cr, which were some of the most important elements, were obtained in the seeds of P. ceracifera in the areas with dense traffic, they were obtained in the leaves of other species. However, the highest concentrations in Cu in the areas with dense traffic were obtained in the seeds of P. cerasifera, T. tomentosa and A. platanoides, while they were obtained in the leaves of A. hippocastanum and F. excelsior.

The change of heavy metal concentrations on the basis of organs became the subject of many studies as well. Mossi (2018) found organ differences between the leaf and branch organs, while Turkyilmaz et al. (2018d) and Turkyilmaz (2019) found it between bark and wood organs, Erdem (2018) and Sevik et al. (2019a) between leaf, seed and branch organs, and Elfantazi et al. (2018a, b) between the leaf and branch organs. Also in these studies, the heavy metal concentrations were found to be changing significantly on the basis of organ.

The main aim of the study is to determine the change of the elements subjected to the study depending on the traffic density. As a result of the study, it was determined that the concentrations of Pb and Cr elements correlatively increased with the traffic density in all organs of all species subjected to study, and the concentration of Cu element correlatively increased with traffic density in 11 out of 15 organs. Industrial and traffic activities are regarded as the most important sources of heavy metal pollution (Martley et al., 2004; Shahid et al., 2017; Erdem, 2018). In the studies conducted, it was found that the heavy metal concentrations in the plant organs changed significantly depending on the traffic density (Assirey et al., 2015; Galal et al., 2015; Saleh, 2018; Turkyilmaz et al., 2018a, b; Mossi, 2018; Sevik et al., 2019a; Akarsu et al., 2019; Jawed and Abo Aisha, 2019).

Cr, one of the heavy metals subjected to study, is one of the most toxic heavy metals in terms of potential toxicities and exposure to living organisms (Shahid et al., 2015, 2017). When taken into the human body through respiration, as it may cause nasal discharge, nasal bleedings, itching and perforation in upper respiratory tract it may also cause people, who are allergic to chromium, to get asthma attacks (Asri and Sonmez, 2006). As for plants, it is toxic for many high plants at the level of 100 mg/kg dry matter (Asri and Sonmez, 2006). Non-essential metals such as Cr are able to enter the plant leaves through leaf transfer (Shahid et al., 2017).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1284312857

Within the scope of the study, it was found that Cr concentration ranged between 443.3 ppb and 7046.6 ppb. It was determined that the Cr concentration changed significantly depending on the traffic density, for example in the European ash leaves, and that the difference between the areas with no traffic and the areas with dense traffic was approximately 6.5 times.

Similar results were obtained in many studies conducted. Turkyilmaz et al. (2018b) reported that the Cr concentration was 16.595 ppm in the areas with no traffic, and that it increased up to 23.716 ppm in the areas with dense traffic. Sawidis et al. (2011) reported that the Cr concentration in the control group of Platanus orientalis leaves was 0.227 µg/g in Salzburg, 0.404 µg/g in Belgrade and 0.558 µg/g in Thessaloniki, while in polluted areas it increased up to 0.388 µg/g in Salzburg, 0.472 µg/g in Belgrade and 0.621 µg/g in Thessaloniki.

Pb, another element of the study, is of particular importance among heavy metals. Pb, which is widely used in industrial and agricultural activities, and thus is a common element, is a heavy metal which is emitted to the atmosphere as a metal or compound, and it is toxic in any case. Pb is one of the heavy metals that damages the ecological system most through human activities (Mossi, 2018; Erdem, 2018; Pinar, 2019).

Pb takes place near the top among the metals causing environmental pollution as well as being an important metal for people for many years (Mossi, 2018). Lead may be present more than normal levels especially in vegetable and food of animal origin grown in areas close to the town center and industrial zones (Kahvecioglu et al., 2007; França et al., 2017). In addition to these, lead-containing gasoline is an important resource as well (Pinar, 2019). Therefore, there are many studies available documenting the relationship between Pb and traffic density (Qing et al., 2015; Lei et al., 2015; Assirey et al., 2015; Galal et al., 2015; Begum et al., 2017).

Within the scope of the study, the Pb concentration was found to be ranging between 39.6 ppb and 6801 ppb. Aksoy and Sahin (1999) found that the average Pb concentration in the unwashed leaves of E. angustifolia was 180.21 µgg-1 in industrial zones, 75.82 µgg-1 by the roadside, 50.56 µgg-1 in the town centre, 30.45 µgg-1 close to the town, and 16.81 µgg-1 in rural areas. Tam et al. (1987) found that the Pb concentration in the Bauhina varigeata leaves in Hon Kong was 12 µg g-1 in the unwashed leaves of the control group, while it was as high as 276 µg g-1 in the unwashed leaves by the roadside. Celik et al. (2005) reported that the average Pb content in Robinia pseudoacacia L. in Denizli province was 180.85 µgg-1 in the samples collected from the industrial zone, 336.55 µgg-1 in the samples collected from the urban roadsides, 74.86 µgg-1 in the samples collected from outside the town center and 34.26 µg g-1 in the samples collected from rural areas.

As a result of the study, the Cu concentration was found to be ranging between 0.3 ppm and 286.5 ppm and increased with traffic density, in general. Cu is quite an important element due to its involvement in enzyme activation, carbohydrate and lipid metabolisms within the plant body (Asri and Sonmez, 2006). Although different plant species need different amounts of copper, it is a highly toxic metal. Some effects of copper poisoning can be regarded as tissue damage, deterioration of roots and darkening of plant colour. Other effects are ion loss in the stem cells due to deterioration of membrane permeability and DNA damage due to deterioration of photosynthesis process (Okcu et al., 2009). Even though copper is an essential trace element for human and animal metabolism, acute copper intoxication may cause abdominal pain, nausea, vomiting and diarrhoea (Asri and Sonmez, 2006). Low levels of copper ion intake may

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1284312857

cause liver cirrhosis, Wilson's disease, systemic rheumatic diseases and kidney diseases, while high levels of copper ion intake may cause leukaemia (Hayta, 2006).

For this reason, many studies have been conducted on the determination of copper concentration in plants and its correlation with traffic density (Turkyilmaz et al., 2018a, b; Erdem, 2018; Mossi, 2018; Ozel, 2019). Turkyilmaz et al. (2018b) reports that the Cu concentration changes depending on the traffic density, and that Cu concentration, which is 69.615 ppb in areas with no traffic, increases up to 110.441 ppb in areas with dense traffic. Suzuki et al. (2009) states that Cu concentration in Rhododendron pulchrum leaves in Okayama, Japan goes up to 22.22 mg kg-1, while Demirayak et al. (2011) state that the average Cu concentration in M. grandiflora leaves in Samsun province is around 35 ppm. Li et al. (2007) reports that Cu concentration in the leaves of Sophora japonica L. is higher in individuals by the roadside than individuals in the parks.

The studies conducted show that heavy metal concentrations are at different levels in plant species and organs depending on the traffic density. There are different reasons of this situation. First of all, traffic-induced heavy metal pollution in the atmosphere increases. This because the car wheels, vehicles, vehicle wear and exhaust gases in the urban areas cause heavy metals to be emitted into air (Zhuang et al., 2009; Schreck et al., 2012; Shahid et al., 2017; Turkyilmaz et al., 2018a). However, after emission into the atmosphere, heavy metals can be carried for miles away with the help of wind. In fact, studies conducted show that many heavy metals, especially Pb, can be carried far from their source (Uzu et al., 2009; Schreck et al., 2012; Shahid et al., 2017; Mossi, 2018). After the heavy metals are mixed into the atmosphere, the accumulation process within the plant is also very complex and under the influence of many factors. This process is primarily related to the structure of plant organs and heavy metals (Mossi, 2018; Erdem, 2018; Sevik et al., 2019a).

Accumulation of heavy metals within the plant body is closely related to environmental conditions as well. Heavy metals can be carried far from the source with the help of wind. Apart from this, environmental conditions have direct influence on the plant metabolism, and the entry of heavy metals into the plant structure is different within this process. It is also stated that there is a significant relationship between the entrance of heavy metals into the plant body and the air humidity and precipitation, in particular (Uzu et al., 2009; Schreck et al., 2012; Shahid et al., 2017; Mossi, 2018; Turkyilmaz et al., 2018a, b, c, d, 2019).

There are also some factors that are likely to affect the heavy metal concentration. For instance, the change in heavy metal concentration depending on the plant species was shown in this study as well as in others (Sevik et al., 2019a, b, c; Saleh, 2018; Erdem, 2018). However, heavy metal concentrations may be expected to be at different levels in the sub-types, forms, varieties and origins of plants. Likewise, many studies show that many phenological, morphological and anatomical structures vary according to these characteristics. In this case, it is inevitable for the plant metabolism to change and this situation to affect the heavy metal absorption (Sevik et al., 2012; Mossi, 2018).

The heavy metal absorption in plants is closely related to plant metabolism (Speak et al., 2012; Shahid et al., 2017). Therefore, it is possible for many factors, which affect the plant metabolism significantly such as the plant's stress level, (Sevik and Cetin, 2015; Sevik and Karaca, 2016), plant origin (Sevik et al., 2019a, c), chlorophyll content (Sevik et al., 2013; Cetin, 2017; Zeren et al., 2017; Zeren Çetin et al., 2018) and genetic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1284312857

structure (Sevik, 2012), to affect heavy metal absorption, and hence heavy metal concentration in plants.

As a consequence, the change in heavy metal concentration in plants is the result of a complex mechanism due to the interaction of many factors (Mossi, 2018). However, the studies are not sufficient to gain a clear understanding of this mechanism, and thus to clearly reveal the factors affecting the change of heavy metal concentration. For this reason, studies on this subject should be increasingly continued and diversified.

Conclusions

Air pollution is one of the most important problems of today's world. Air pollution has gained a particular importance with the increase in the consciousness level in this field along with the population density in town centers, and many studies have been carried out to solve this important problem. Increasing green spaces is considered as one of the most effective methods among the solution proposals. The studies conducted showed that green spaces and the plants used in such spaces decreased the air pollution of all types and levels (Cetin et al., 2017a, b).

Plants can reduce air pollution significantly. However, the impacts of different species on different pollution factors are also at different levels. Although a large number of plant species have been the subject of studies to date, these studies are not at a sufficient level yet. There is no information on the heavy metal accumulation potentials of many plant species. However, great differences were determined between the heavy metal accumulating potentials of plant species in the studies conducted. For this reason, it is necessary to use the species, which have not been subjected to any study, in similar studies and to identify the plants, which are to be more effective in both monitoring and reducing the heavy metal pollution. Therefore, it can be recommended to continue and diversify similar studies.

One of the important results of the study is that some heavy metal concentrations are very high, especially in the seeds. For instance, heavy metal concentrations were found to be quite high in the seed of cherry plum. This shows that it can be highly risky to consume the plants grown in areas with high level of heavy metal concentration such as industrial zones and urban centers as food. However, the number of studies on this subject is not quite sufficient yet. Priority should also be given to the studies on this subject.

(Received 13th May 2019; accepted 28th Aug 2019)

Abstract. This research aims to find the habitat-dependent variation of micromorphological characteristics in the leaves of *Fraxinus excelsior* (European ash), *Platanus orientalis* (Plane tree) and *Tilia tomentosa* (Silver lime) collected from 6 different cities of different climates. The leaves were collected in Turkey in the cities of Rize, Samsun, İzmir, Antalya, Sivas, and Ankara. Samsun and Rize fall under the Black Sea climate region, Ankara and Sivas under the continental climate, whereas Antalya and İzmir enjoy a Mediterranean climate. Using scanning electron microscopy (SEM) to highlight the visible morphological characteristics of the plant, we hoped to uncover how stress affects the micro-morphological properties of the plant but does not affect its vital functions. Leaf epidermis images were obtained with SEM and stoma width (μm), length (μm), pore width (μm), pore length (μm), and density (in an area of 1 mm^2) measurements were obtained using Image J (https://imagej.net) software. A Duncan test and variance analysis were performed via SPSS® (IBM Analytics) and the habitat-dependent change of these characteristics was evaluated statistically. Accordingly, we determined that the stomatal characteristics varied depending on the habitat, but trees were affected differently by climate conditions. The micromorphological characteristics on the leaves depending on growth conditions were also investigated.

Keywords: *cities, various climates, micromorphlogy, SEM, landscape plants, Fraxinus excelsior, Platanus orientalis, Tilia tomentosa*

Introduction

Parallel to the increasing rate of urbanization, destruction of green areas around the world has led to an inevitable and undesirable consequence. Along with increasing urbanization, today's modern individuals with increasing incomes and consciousness have begun to realize the importance of green spaces, and as a result, landscape architecture projects have become an integral part of modern life (Sevik and Cetin, 2016; Sevik et al., 2016; Bozdogan Sert et al., 2019; Cetin et al., 2019; Cetin 2019). Landscape studies gain value in proportion to the plant variety used in the design, and the use of uncommon plants in the design process makes the designs even more valuable. This approach has resulted in growing plants in areas that differ from their natural habitats. So much so that although Turkey is located in a region dominated by three main climate types, similar plants have begun to be grown in all three of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1285912868

climate zones. A frequently encountered issue in landscaping is that plant species are often faced with stress factors due to being grown in areas outside their natural habitats. In addition to the visible morphological characteristics of the plant, stress influences not only the micromorphological features of the plant that are not visible to the naked eye but also their vital functions (Cetin et al., 2017; Cetin et al., 2019; Cetin 2019). However, since the number of researches in this field is insufficient, the level of information on the subject is limited. In fact, the changes that occur on the micromorphological level in plants depending on different growth environments and habitats may provide useful insights in many areas including the stress level to which the plant is exposed, its ability to adapt to the growth environment, and the effect of climatic factors on phenotype (Cetin, 2016; Sevik et al., 2017; Sevik et al., 2019; Cetin et al., 2019; Cetin 2019; Bozdogan Sert et al., 2019).

In landscaping, plants used outside the natural distribution areas often do not show their performance in natural habitats, do not reflect their forms in the natural distribution area, and often remain alone with stress factors. These stress factors affect the plant's visible morphological features as well as micromorphological features that are not visible to the eye. If we can determine how these changes at the micro level change in relation to the climate parameters, we can have a lot of ideas from plant stress levels to adaptation levels. However, in order to determine how these changes in micromorphological characteristics should be interpreted, it is necessary to first determine the conditions under which these changes take shape.

The scope of this research was to find the variation of some micromorphological characteristics according to climate type in *Fraxinus excelsior* L. (European ash), *Platanus orientalis* L. (Plane tree) and *Tilia tomentosa* Moench (silver lime) plants grown in various regions of Turkey dominated by different climate types. The hypothesis of the study: Micromorphological characteristics of individuals grown in regions dominated by different climate properties are shaped depending on climate type.

Material and methods

This work was conducted on the leaves of *Fraxinus excelsior, Platanus orientalis*, and *Tilia tomentosa* species. Among these species, *Fraxinus excelsior* is generally found in Caucasia, North and South Europe. In our country, its general spreading zone is Northern Anatolia, but it also grows naturally in Hatay. It grows naturally between an elevation of 900-2100 m on the edges of creeks and in mixed forests with deciduous and coniferous leaves, but it is also used in landscaping in nearly the whole of Europe. *Platanus orientalis* naturally grows in Southeast Europe and Western Asia, and nearly in all regions in our country on banks of streams, riversides, at the bottom of valleys, and on leaky and gravelly slopes up to an elevation of 1100 m from sea level. It is commonly preferred in landscaping as a dust and noise barrier, and widely used in parks and gardens as an alle tree. The natural habitat of *Tilia tomentosa* species in the world consists of Southeast Europe and Western Asia. In our country, it grows naturally in the deciduous forests of Western and Northern Anatolia between the elevations of 400-1500 m, but it is also widely used in landscaping thanks to its drought-tolerant characteristic and being an alle tree (Kaya et al., 2009).

Leaf samples of the determined species were collected from individuals in Turkey in the cities of Rize, Samsun, İzmir, Antalya, Sivas, and Ankara (*Fig. 1* and *Table 1*). The patterns were collected from individuals used in landscape architecture arrangements in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1285912868

centers of city. Among these cities, Samsun and Rize are located in a region where Black Sea climate type is dominant, Ankara and Sivas are located in a region where Continental climate type is dominant, and Antalya and İzmir are located in a region where Mediterranean climate type is dominant. Ten leaves were sampled form five trees of each species. Although these cities are located in regions where a certain climate type is dominant, there is a great variability between their climatic data (*Table 2*).

Mature leaf specimens collected during the vegetation season (25 August 2017) were pressed and dried, brought to the laboratory and tested under the electron microscope. Scaled images were obtained of the leaf blade abaxial surface near the midvein using scanning electron microscopy (SEM) and transposed into .jpeg photos for use with ImageJ software. SPSS® (IBM Analytics), analysis of variance (ANOVA) and a Duncan's test were used to evaluate measurements of stoma width (SW), stoma length (SL), stoma pore width (PW), stoma pore length (PL), and stomatal density (across 1 mm^2, SDEN) were evaluated potential statistically significant relationships between the selected characteristics (*Fig. 2*).

SL, stoma length; SW, stoma width; PL, stoma pore length; PW, stoma pore width; SDEN, stomatal density across 1 mm^2. Values with same letter were not significantly different according to a Duncan test. ***Statistically significant at the $p < 0.001$ level of probability
Each value is the average value of 50 leaves, of which 5 are individual leaves

When the results of the study were examined; it was determined that among the three species studies, only *Tilia tomentosa* did not demonstrate any statistically significant difference between the cities in terms of pore characteristics. All other species showed statistically significant differences among the values obtained from different cities in all characteristics studied at a confidence level of 95%. For *Fraxinus excelsior*, the lowest values except for SDEN were obtained in Samsun, and the significantly higher values were obtained in Rize. For SDEN, the lowest values were obtained in Ankara, and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1285912868

significantly higher values were obtained in Sivas. For *Platanus orientalis*, the lowest values except for SDEN were obtained in Rize, and the significantly higher values were obtained in Samsun. For SDEN, the lowest values were obtained in İzmir, and significantly higher values were obtained in Ankara and Rize. In addition, the highest PW value was obtained in Izmir. For *Tilia tomentosa*, the values obtained in İzmir were in the last homogeneous group for SDEN, while they were in the first homogeneous group for all other characteristics; conversely, the values obtained in Rize were the lowest values for SDEN, whereas the values were in the last homogeneous groups for other characteristics.

According to the results, we concluded that each species give different reactions to climatic demands. For example, while the lowest values for characteristics other than SDEN were obtained in samples collected from Rize for *Platanus orientalis*, for *Tilia tomentosa* and *Fraxinus excelsior,* the significantly higher values for characteristics other than SDEN were obtained in samples collected from Rize. Similarly, for *Fraxinus excelsior*, the lowest values for all characteristics except SDEN were obtained in Samsun, while the significantly higher values for *Platanus orientalis* for all characteristics except SDEN were obtained in Samsun. This is the case with most of the characteristics.

Different values were also obtained in the same species for samples gathered from cities located in the same climate zone. For example, in *Fraxinus excelsior*, the lowest values in all characteristics except SDEN were obtained in Samsun and the significantly higher values were obtained in Rize. In fact, Rize and Samsun are located in areas dominated by the same climate type. A similar situation was also observed in *Platanus orientalis*.

In order to determine the direction and magnitude of the relationships of the studied characteristics with each other, a correlation analysis was applied to the data and the results of this analysis in *Table 4* are given.

Table 4. *Relevance of the species characters in relation to the level of each other*

	SW	**PL**	**PW**	**SDEN**
SL	0.887**	0.711**	0.688**	0.300**
SW		0.551**	0.554**	0.205**
PL			0.726**	0.300**
PW				0.152

Weak correlation (0.10-0.29); moderate correlation (0.30-0.49); strong correlation (0.5-1.0). **Statistically significant at the $p < 0.01$ level of probability

According to correlation analysis results, it was determined that there is a statistically significant relationship between all characteristics except PW and SDEN. According to Cohen (1988), the relationship between two variables is weak if the value of the correlation coefficient is between 0.10 and 0.29, moderate if it is between 0.30 and 0.49, and strong if it is between 0.50 and 1.0. When we take a look at the level of relationship between the characteristics accordingly, we see that there is a weak or moderate relationship between SDEN and other characteristics. While there is a strong relationship between other characteristics, it was found that the strongest relationships were between STL and SW (0.887), and PL and PW (0.726).

Discussion

Plants have positive effects such as reducing air and noise pollution in the environments they are in. In addition to these positive effects, they also perform many functions such as reducing wind speed, being an economic resource, and supporting wild life (Kaya et al., 2009; Guney et al., 2016, 2017; Sevik et al., 2016; Cetin and Sevik, 2016; Cetin et al., 2019; Cetin 2019). Used and grown for various purposes in urban centers today, plants are accepted as an indicator of quality and liveability in urban life (Cetin, 2015, 2016; Cetin et al., 2017; Cetin et al., 2019; Cetin 2019).

Plants are living organisms, and fulfilling these functions depends primarily on being grown in areas where optimum climatic and edaphic factors are present for them. Otherwise, plants are exposed to stress conditions, and cannot properly fulfill the functions expected from them. It is therefore a very important matter to determine whether plants are exposed to stress conditions in their growth environment. In landscaping studies, plants are usually exposed to stress factors, depending on whether the plants are used outside their natural habitats. These stress conditions are known to affect the morphological characteristics of the plant. Studies have shown that plant morphological characteristics are influenced by many stress factors such as light (Cetin, 2016; Guney et al., 2016; Cetin et al., 2017), salt stress (Romero-Aranda et al., 2001), and water stress (Ferris et al., 1996). Therefore, it is quite possible that stomatal characteristics are also affected by environmental conditions and especially stress factors (Banon et al., 2004).

Stomata are the most important organelles in terms of leaf activity. Water evaporates from the leaf and stomata control the entry of CO_2 (Xu and Zhou, 2008). The number and size of stomata are significantly affected by environmental factors (Pearce et al., 2006; Galmés et al., 2007; Xu and Zhou, 2008). It has been pointed out in many studies that stoma density, in particular, is affected by environmental conditions and stress factors (Dunlap and Stettler, 2001; Guerfel et al., 2009; Bosabalidis and Kofidis, 2002).

There were significant differences in values obtained in different cities under the same climatic conditions. For example, for *Fraxinus excelsior,* the lowest values for all characteristics except SDEN were obtained in Samsun, while the significantly higher values were obtained in Rize. In fact, both of these cities are located in a region dominated by the Black Sea climate type. This suggests that microecological conditions may have more impact on leaf micromorphological characteristics. It is known that phenotypic character is the result of the interaction between genetics and the environment, and is shaped by the influence of many environmental factors (Sevik and Cetin, 2015) as well as genetic factors (Yigit et al., 2016). Therefore, genetic and microenvironmental conditions may be more effective on stomatal characteristics.

This situation also explains the fact that species can respond differently to the same climate conditions. As a matter of fact, it has been determined in the study that species do react differently to the same climate type. For example, for *Platanus orientalis*, the lowest values for all characteristics except SDEN were obtained in samples collected from Rize, whereas for *Tilia tomentosa* and *Fraxinus excelsior* the significantly higher values were obtained in samples collected from Rize. This can be explained by the fact that genetic structures of these species are different and therefore they are affected differently from the same climatic type.

It is known that morphological characteristics vary among species depending on many factors, especially origin. Researches have also demonstrated that micromorphological characteristics vary considerably among species (Maiti et al., 2016;

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1285912868

Galmés et al., 2007). In this case, it is not surprising that different origins of the same species respond differently to the conditions of the growth environment and also to stress factors. As a matter of fact, similar results have been obtained in various studies (Yigit et al., 2016; Sevik and Cetin, 2016; Bozdogan Sert et al., 2019; Sevik et al., 2019).

The correlation analyses performed in this study noted significant relationships between stomatal characteristics as was previously described by Cetin et al. (2017).

Conclusions

The variation of micromorphological characteristics detected on the leaves depending on growth conditions was investigated in this study. Scanning electron microscopy provides very high zoom levels thanks to high-resolution imaging techniques. Therefore, it is possible to obtain morphological, structural and elemental information from plants under these high zoom levels. The data obtained this way has the potential of being used in many areas such as determination of plant stress level, genetic variation studies, and determination of optimal plant growth conditions. However, in order for these characteristics to be effectively used in these specified areas, similar studies need to be replicated and diversified in different areas. The data in this study indicated a distinct morphological shift in size as trees are exposed to drier conditions, an indication that localized adaptation responses to stress can be observed using measurements. In particular, the studies to be done in natural populations where microclimatic conditions and human effects are absent or limited can provide much more reliable data.

(Received 13th May 2019; accepted 28th Aug 2019)

Abstract. Here, we describe the novel biosynthesis of silver nanoparticles (AgNPs) using the extract of *Indigofera oblongifolia* (Hasr) leaves. The synthesized AgNPs were confirmed and characterized using ultraviolet–visible spectrophotometry, Fourier transform infrared spectroscopy (FTIR), energy dispersive spectroscopy (EDS), scanning electron microscopy (SEM), and transmission electron microscopy (TEM). An extreme absorption was detected at a wavelength near 400 nm after the formation of AgNPs. FTIR determined the extract biomolecules responsible for the reduction of the synthesized AgNPs. An EDS signal at 3 keV confirmed the presence of the Ag signal using surface plasmon resonance. SEM and TEM revealed the generally circular shape of AgNPs with sizes ranging from 8 nm to 25 nm (average particle size 15 nm). The antibacterial activity of AgNPs was pronounced for all bacteria studied.
Keywords: *nanoparticles, I. oblongifolia, biosynthesis, bacteria, biotechnology*

Introduction

Nanoparticles (NPs) play significant roles in biotechnology and pharmaceutical industries (Vijayakumar et al., 2013). The physical, biological, and chemical characterization of manufactured NPs is one of the fastest growing areas of science. The biosynthesis of NPs using plants (Peter et al., 2013, 2015; Deenadayalan et al., 2014), bacteria (Husseiny et al., 2006; El-Shanshoury et al., 2011), and fungi (Ingle et al., 2009; Neveen-Mohamed, 2014) has been described.

Interest has grown concerning the use of silver (Ag) NPs, which are inexpensive, safe, and ecologically-friendly. Recent studies have successfully biosynthesized AgNPs using plant components including the *Eriobotrya japonica* (Thunb.) leaf extract (Yu et al., 2019), cowpea (*Vigna sp*. L) seed extract (Mohammadi et al., 2016), *Pandanus odorifer* leaf extract (Hussain et al., 2019), *Ribes nigrum* fruit extract (Dobrucka et al., 2018), *Rosmarinus officinalis* leaf extract (Ghaedi et al., 2015), *Terminaliachebula* leaf extract (Chandra et al., 2016), and *Diospyros paniculata* root extract (Hanumanta et al., 2016). *Indigofera oblongifolia* is a perennial shrub that belongs to the family Fabaceae. It grows throughout Asia and Africa (Abdel and Ahmed, 2016). It is commonly known as Hasr in the South of Saudi Arabia and Yemen. As a traditional medicine, the leaves of this plant are used to treat some diseases due to their analgesic and anti-inflammatory activities. Moreover, in Saudi Arabia, *I. oblongifolia* is cultured in regions with a high occurrence of malaria, such as Nagran and Jazan (Nzila, 2013). The plant contains indigoferic acid and indigin as the fatty acid esters of hydroxy (E)-cinnamic acid and alkylated xanthenes, respectively, and also 3-hydroxybenzoic acid and β-sitosterol (Sharif et al., 2005).

DOI: http://dx.doi.org/10.15666/aeer/1706_1286912876

To our knowledge, this is the first study to examine the use of the extract of *I. oblongifolia* (Hasr) leaves for the biosynthesis of AgNPs. AgNPs biosynthesized as such were characterized using different physical techniques that included ultraviolet (UV)–visible spectrophotometry, Fourier transform infrared (FTIR) spectroscopy, energy dispersive X-ray spectroscopy (EDS), scanning electron microscopy (SEM), and transmission electron microscopy (TEM). Finally, the antibacterial activity of the biosynthesized NPs against select gram-negative and gram-positive bacteria was studied.

Materials and methods

Plant material and preparation of extract

I. oblongifolia leaves were collected from Shabwah, South of Yemen. The plant was verified by the staff of the Herbarium, Department of Botany and Microbiology, King Saud University. Fresh leaves of *I. oblongifolia* were rinsed thoroughly numerous times using distilled water and allowed to completely air-dry in the dark. The powder prepared from the dried leaves (10 g) was placed in 100 mL deionized water and boiled for 10 min with stirring. The liquid extract was filtered using Whatman No. 1 filter paper. The residual extract was stored at 4 °C until processed.

Biosynthesis of AgNPs

Ten milliliters of the aqueous plant extract was mixed with 100 mL of 0.01 mM aqueous solution of silver nitrate ($AgNO_3$) with constantly stirring for 5 min at 25 °C. The resulting mixture was maintained undisturbed until the neutral solution changed to a brown color. Then, the molecules were by centrifugation at 13,000 rpm for 20 min. Finally, the obtained AgNPs were dried in oven at 40 °C for 2 h prior to characterization of AgNPs.

Characterization of AgNPs

UV–Visible spectroscopy

The formation of AgNPs in suspension was monitored using UV–Visible spectroscopy of the solution at wavelengths ranging from 300 to 800 nm using an Ultrospec 2100 Pro UV/visible spectrophotometer (Biochrom, UK).

FTIR spectroscopy

FTIR spectroscopy was performed to screen for functional groups in the phytoconstituents in the synthesized AgNPs and aqueous extract of *I. oblongifolia*. FTIR spectra were obtained by scanning from 400 to 4,000 cm^{-1}.

SEM and EDS

SEM used a model JSM-6380 LA microscope (JEOL, Japan). EDS was done using an Altima IV device (Regaku, Japan).

TEM

TEM examination of AgNP size, shape, and morphology was performed using a JEM-1011 microscope (JEOL).

Antibacterial studies

Bacteria

The bacteria were obtained from the Microbiology Laboratory of the College of Science, King Saud University. The gram-positive bacteria examined were *Staphylococcus aureus* (29213 ATCC), *Bacillus subtilis*, and *Streptococcus pyogenes*. The gram-negative bacteria examined were *Escherichia* coli (25922 ATCC) and *Salmonella typhimurium* (14028 ATCC). All bacteria were inoculated on nutrient agar (Sigma–Aldrich, Munich, Germany) and incubated at 37 °C for 24 h.

Antibacterial activities

The antibacterial activity of the synthesized AgNPs was studied using the agar well diffusion technique (Valodkar et al., 2011). Petri plates containing 20 ml Mueller Hinton Agar medium (Sigma–Aldrich) were inoculated with each bacterium to obtain a lawn of growth. Wells 6 mm in diameter were cut into the medium using a sterile agar borer. Then, synthesized nanoparticles (100 µl) were added to each well, and the plates were incubated at 37 °C for 24 h. Inhibition of growth was evident as a clear zone around the well. The control used was distilled water.

Statistical analysis

The results of antibacterial activity were expressed as the mean ± standard deviation (SD), and all experiments were performed in triplicate. The statistical results were calculated by one-way analysis using the SPSS statistical software (SPSS Inc., USA), A P-value < 0.05 indicated statistical significance.

Results and discussion

Biosynthesis of AgNPs and their visible spectrum

Immediately after mixing the *I. oblongifolia* extract with an $AgNO_3$ solution, a dark brown color developed. The color change indicated the formation of AgNPs, which was confirmed by the UV–Visible absorption spectrum (*Fig. 1*). UV–Visible spectroscopy has been used to investigate the shape and size of AgNPs in aqueous solution (Ranjit et al., 2013) and provided primary evidence for the formation of AgNPs (Nanda and Saravanan, 2013). Presently, the biosynthesized mixture was evaluated at wavelengths ranging from 200 to 800 nm; the highest peak absorption was observed at 400 nm as a result of AgNP formation.

FTIR

FTIR was used to confirm the presence of biocompounds in the extract of *I. oblongifolia* that were responsible for the formation of AgNPs. *Figure 2A* and *B* depict the FTIR spectra of the *I. oblongifolia* extract and AgNPs. The extreme band at 3,413 cm^{-1} in the *I. oblongifolia* extract was attributed to the O–H stretching band of phenols and alcohols (Preeti and Mausumi, 2013), which shifted to 3,433 cm^{-1} after reduction of the synthesized AgNPs as a result of protein binding. The other bands at 2917 and 1448 cm^{-1} in *I. oblongifolia* extract corresponded to C-H (alkane) and C-N (aromatic amines), respectively, which were absent from the FTIR spectrum of AgNPs. A second intense peak was observed at 1,614 cm^{-1} in the *I. oblongifolia* extract. It

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1286912876

changed to 1596 cm^{-1} with the formation of AgNPs, signifying the presence of carbonyl (C–O) stretching vibrations. The findings indicate that effective groups like phenols, alcohols, alkane, and aromatic amines present in the extract of *I. oblongifolia* may be responsible for the bioreduction of silver into AgNPs.

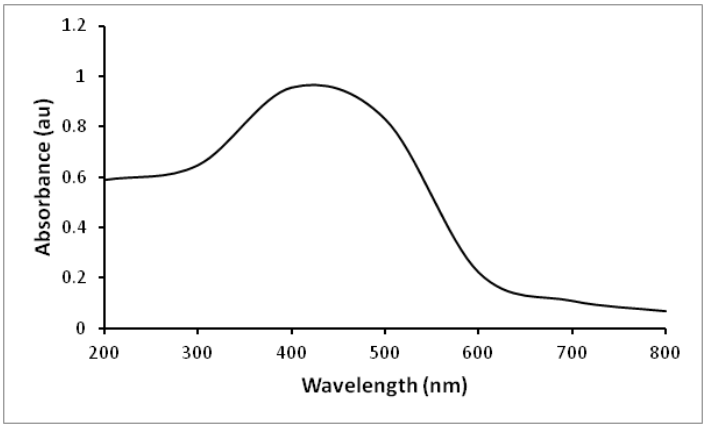

Figure 1. *UV–Visible spectrum for the reaction of the I. oblongifolia extract with the $AgNO_3$ solution*

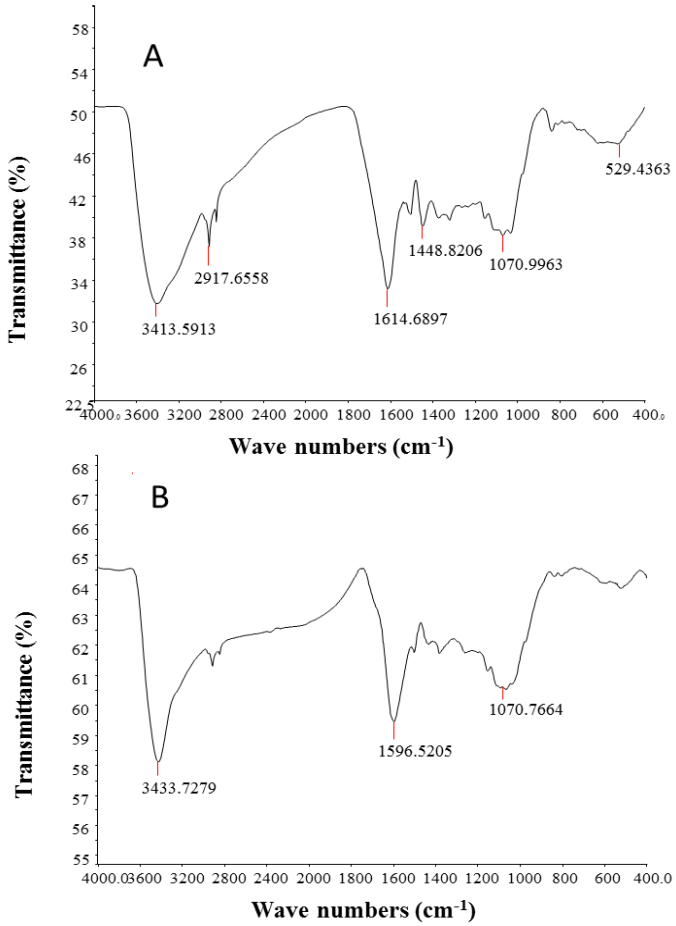

Figure 2. *FTIR spectra of the I. oblongifolia extract (A) and AgNPs produced using the I. oblongifolia leaf extract (B)*

DOI: http://dx.doi.org/10.15666/aeer/1706_1286912876

SEM and EDS analyses

SEM of the biosynthesized AgNPs revealed various sizes of the irregularly formed AgNPs (*Fig. 3*). Clusters of AgNPs were evident in some images, which can be associated with the aggregation of NPs during the sample synthesis. The EDS spectra of AgNPs for study of elemental composition of the silver particles are presented in *Figure 3* and displayed strong signals in the silver region at 3 keV. An exemplary absorption peak of AgNPs at approximately 3 keV was reported using surface plasmon resonance (Nadagouda et al., 2011; Khan et al., 2014). EDS analysis revealed the existence of silver (68.94%). The appearance of chlorine and oxygen signals in the image may be due to X-ray emissions from the proteins present in the plant extract.

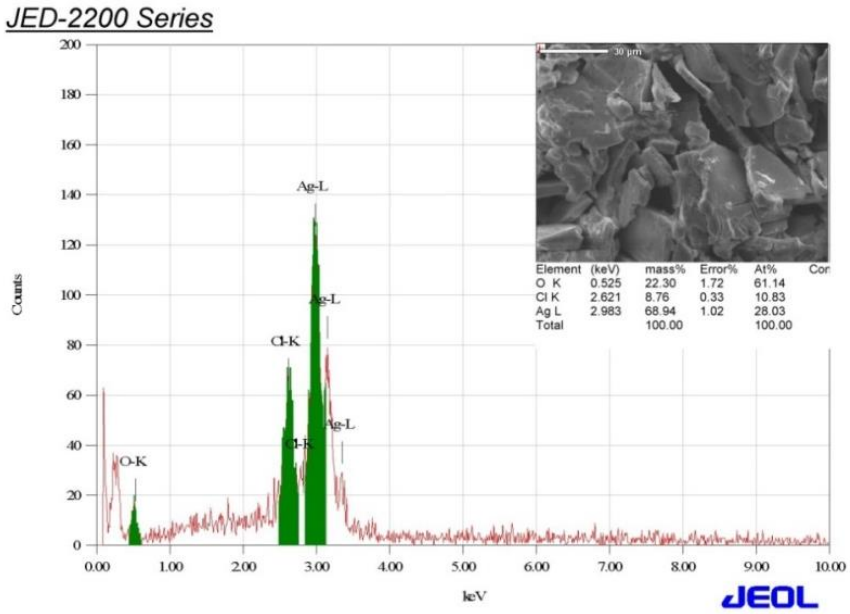

Figure 3. *SEM image and EDS of AgNPs synthesized using I. oblongifolia leaf extract*

TEM

TEM was performed to observe the morphology and sizes of the AgNPs. A representative image is presented in *Figure 4*. The AgNPs were extremely stable, smooth, and circular. The NPs ranged in size from 8 nm to 25 nm with an average particle size of 15 nm. No accumulation of AgNPs was observed.

Antibacterial activity

The growth inhibition caused by the AgNPs biosynthesized using the *I. oblongifolia* extract against representative gram-positive and -negative bacteria are presented in *Table 1*. The growth of all the bacteria was impeded, however, *E. coli* and *B. subtilis* were most sensitive to the inhibitory effect of the AgNPs, showing larger zones of growth inhibition compared to those of *S. aureus, S. typhimurium*, and *S. pyogenes*. As anticipated, growth was not inhibited for the control. These findings are consistent with those of other studies demonstrating the preparation of AgNPs with potent antibacterial and anti-fungal activities using plants extracts (Puiso et al., 2014; Ismail et al, 2017; Khalil et al., 2017; Matinise, et al., 2018; Premkumara et al,. 2018).

Conclusions

This is the first description of the biosynthesis of AgNPs using the extract of *I. oblongifolia* leaves. The method is rapid, simple, eco-friendly, and safe. UV–Visible spectrophotometry, FTIR spectroscopy, EDS, SEM, and TEM confirmed the production of AgNPs. The success of the *I. oblongifolia* leaf extract to synthesize AgNPs is very promising for the eco-friendly and sustainable production of nanomaterials. The potency of the antibacterial activity of the AgNPs synthesized in this study was evident, and the results of this study are in agreement with those of other recent studies regarding the use of plant extracts for the synthesis of nanoparticles.

Abstract. Nanotechnology has become a revolutionary science over the past few decades with the potential for positive environmental, health and constructive effects. Nanoparticles (NPs) can be applied almost in every field of science, including the agricultural sector, and attaining great importance in current years. In the present study, Silver nanoparticles (AgNPs) were applied *in vitro* to examine their effects on economically important crop, pearl millet (*P. glaucum* L.*)* grown on MS basal medium supplemented with variable concentrations (T1 = control, T2 = 20 ppm, T3 = 40 ppm, T4 = 60 ppm and T5 = 80 ppm). Effects of AgNPs were assessed by analysing the seed germination, seedlings growth and biochemical profile of pearl millet, which were significantly affected ($p \leq 0.05$) and observed to be superior under T3 of AgNPs. The highest seed germination, seedling vigour index, root length, shoot length and biomass accumulation were achieved under T3 as compared to other treatments. Antioxidant enzymatic activity, Proline content, Catalase (CAT), Superoxide dismutase (SOD), Peroxidase (POD) including total flavonoids and total phenolic contents were also determined. AgNPs under (T5), inhibited the seed germination and seedlings growth and negatively influenced the biochemical profile by decreasing biomass accumulation. High doses of AgNPs proved to be a stressor and produced more ROS and toxicity, whereas it was indicated that AgNPs at suitable ratio minimized the production of ROS and stabilized the existing mechanisms of plantlets by increasing their growth and biomass production.
Keywords: *agriculture, constructive, germination, biochemical, accumulation*

Introduction

The world human's population is predicted to reach 9 billion by 2050, from the point of the current 7.4 billion (Hakeem, 2015). Current agricultural practices will not meet the expected demand for food due to the decrease in crop production by various factors, including inefficient means of fertilizers, industrial pollution, insecticides, heavy metals and climatic stresses (Hakeem, 2015). The agriculture sector is a significant contributor of greenhouse gases (CO_2, NO) due to overuse of mineral fertilizers, which emitted about 12% of total greenhouse gases (Hakeem, 2015). A rapid increase in population, depletion of natural resources and climatic issues are the key elements which create pressure on the environment to use chemical fertilizers for projected demand for food

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1287712892

(Mittal and Mittal, 2013). Demand for environmentally safe agricultural products is growing up with increasing technological advancement. Application of mineral fertilizers and pesticides causes serious intimidations to the environment, resulting in more production of unhealthy food products. For example, the application of nitrogen fertilizers generates the nitrous oxide, which is a greenhouse gas (Vejan et al., 2016). Long term use of mineral fertilizers has resulted in a reduction of soil organic matter leading to acidification of soil and causing severe threats to the survival of plants (Patra et al., 2016). Consequently, excessive use of fertilizers to get more production can result in damaging effects such as pollution, leaching, destruction of friendly insects and micro-organisms which ultimately reduction in soil fertility (Hazra and Das, 2014).

In recent eras, most of the research work has been focused on exploring the effects of nanoparticles (NPs) on plants, including other living organisms (Austin et al., 2016). NPs characterizes significant physiochemical properties and are extensively being used in physics, chemistry, agricultural science, environmental and medicinal field (Majdalawieh et al., 2014; Tripathi et al., 2017) but their interactions with plant metabolism is still needed more attention to exploring on large scale. The application of nanotechnology in agriculture reduces the environmental risks along with high production of agronomical crops (Chaudhuri and Malodia, 2017). In agriculture, metal-based development of NPs such as copper (Cu), iron (Fe), silver (Ag), zinc (Zn) and titanium dioxide (TiO2) has great potential to produce alternative nano fertilizers for crop improvement. Among these, silver nanoparticles (AgNPs) possess more positive effects on the plant's growth and development at suitable concentrations which depend on the size and distribution of AgNPs (Yasur and Rani, 2013).

Several agricultural concerns related to crop production under stress conditions have been elevated and improved by using AgNPs due to their diverse range of chemical and physical properties. Antifungal, antibacterial and antimicrobial properties of AgNPs provide a supreme edge to the farmer for the synthesis and utilization of nano fertilizers that may lessen the cost of agronomic production and enhance sustainable agriculture. Furthermore, AgNPs are cheaper, less toxic and environment-friendly, resulting in more constructive effects on crop yield and production by enhancing seed germination rate, increased seedling growth, i.e. root and shoot length and chlorophyll contents (Rafi and Ramezanian, 2013). Different plant species (e.g. *Phaseolus vulgaris, Zea mays* and *Lycopersicon esculentum)* have been exposed to a various dosage of AgNPs, resulted in a significant increase in plant total biomass, lower oxidative stress, increased flavonoid contents and high level of total phenolic contents (Berahmand et al., 2012). AgNPs have been applied with fungicide by seed priming, which enhanced the root length, shoot length and total biomass at lower concentrations while high levels of dosage reduced morphological profile at germination stage in plants. In order to know the beneficial facets of nanotechnology applied to agriculture, penetration, accumulation and transport of NPs should be investigated, which are unexplored yet (Parveen and Rao, 2015). Among the best methods of AgNPs application, foliar spray is demonstrated as most exceptional for agronomic viewpoint as plant leaves may able to intake essential elements more proficiently than roots which are directly in contact with leaf surfaces due to high magnetic properties of AgNPs as compared to other NPs (Chaudhuri and Malodia, 2017; Thakkar et al., 2010).

Pennisetum is the rich genus of Poaceae family. It comprises approximately 140 species that grow under various environmental conditions all over the world (Zhou et al., 2018). *P. glaucum* is one of the premium and important food crops which occupy

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1287712892

the sixth rank in the world with the substantial cultivated area (60%) in Africa and (35%) in Asia. It covers about half of the total global production of millets and is utilized as a staple food, source of protein for human beings and fodder for livestock (Basavaraj et al., 2010; Wang et al., 2018; Zhou et al., 2019b). Seedling stage of plants is susceptible to different types of stresses, which leads to significant loss of crop production in the agriculture system while NPs enhance the germination potential (Parveen and Rao, 2015). Some evidence has shown the excellent effects of phenolic compounds to minimize the risk of non-communicable diseases (NCD) caused by nutritional imbalance and protection against oxidative stress within the human body (Okarter and Liu, 2010).

AgNPs are now widely used in various fields, including agronomic crop production and revealed as stress-reducing agents; however, more research work is still needed to be known that how AgNPs affect antioxidant enzyme essay. The principal objective of recent research work is to explore the influence of AgNPs on seed germination, seedlings growth and biochemical profile in *P. glaucum,* which is still unexplored. To our best knowledge, this is the first report on the biochemical profiling of *in vitro* germinated *P. glaucum* seedlings under different concentrations of AgNPs.

Materials and methods

Plant material and sterilization

Seeds of *Pennisetum glaucum* (L.) R. Br. were obtained from the key laboratory of Grassland Science, Sichuan Agricultural University, China and used as an explant for this experiment. Seeds were well washed with simple tap water and dipped in ethanol for 30 min. Then sterilized in 0.1% mercuric chloride ($HgCl_2$) for 4 minutes and rinsed with autoclaved distilled water.

Seed germination experiment

The experiment was carried out in the key laboratory of Grassland Science, Sichuan Agricultural University, China. In this experiment, synthesized silver nanoparticles (AgNPs) were obtained from NANOCS (Nanocs lnc. New York, NY 10001, USA), manufactured according to > 0.75A520 units/m having 100 nm sizes (solution form). Firstly, the dilution of nanoparticles was taken out by using a stock solution. Five different types of treatments of AgNPs (T1 = control, T2 = 20 ppm, T3 = 40 ppm, T4 = 60 ppm and T5 = 80 ppm) were applied to MS medium. Sterilized seeds were inoculated in the conical flasks having MS solid medium and allowed them to germinate under controlled laboratory conditions at the temperature of 30 ± 5 °C (Hussain et al., 2017). Seed germination was experiential in 4-5 days and data were collected after ten days of germination. The experiment was repeated in twice, and data were taken out in triplicate.

Germination parameters

Germination frequency percentage

Seeds were considered as germinated when radical has taken out from the seed coat (Hussain et al., 2017).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1287712892

Germination frequency = No. of seeds germinated × 100 / total no. of seeds

Shoot and root morphology

Length of shoot and root was measured in cm and compared by using a bar chart.

Seedling vigour index (SVI)

This was calculated by using the method of Ushahra and Malik (2013) and expressed as:

SVI = [root length + shoot length] × germination percentage

Biochemical profiling

DPPH activity

For the estimation of antioxidant activity, a protocol described by Abbasi et al. (2010) was used for DPPH (2, 2-diphenyl-1-picrylhydrazyl) free radical scavenging assay (FRSA). 10 mg of dried plant samples were dissolved in 4 ml methanol and then mixed with 0.5 ml of DPPH solution. The mixture was gently vortexed for fifteen seconds and placed at room temperature for 30 min. Final results were concluded when the sample absorbance was checked by spectrophotometer at 517 nm. FRSA was calculated and expressed as:

DPPH discoloration %age = 100 x ($1-A_s/A_b$)

A_s: Absorbance of the solution with extract addition. A_b: Absorbance of the solution without extract addition.

Proline contents

Proline contents were measured according to Bates et al. (1973), 0.5 g of plant samples were homogenized by pestle and mortar in 5 ml of 3% sulphosalycylic acid. 2 ml of ninhydrin reagent and 2 ml of glacial acetic acid were added to the test tube having 2 ml of extract. The mixture was placed in a water bath and boiled at 100 °C for 30 min. 6 ml of toluene was added to a reaction mixture after cooling and transferred to separating funnel. Thoroughly mixing resulted separation of the chromophore with toluene and absorbance was measured at 520 nm by using a spectrophotometer DU-730 (Beck Man Coulter Inc., USA)

Antioxidant enzyme extracts were prepared by using mortar and pestle. Plant samples (1 g) were homogenized with 10 ml of extraction buffer containing (50 mM potassium (K)-phosphate buffer with 1% polyvinyl polypyrrolidone at pH 7). The mixture was centrifuged at 15,0000 g for 30 min at 4 °C and supernatant was used for Antioxidant enzyme activity (Ullah et al., 2015).

Superoxide dismutase (SOD)

One of the methods described by Ullah et al. (2015) with some improvements was used to measure the SOD activity. 1 ml of the reaction mixture was composed of 1 millimolar (mM) EDTA, 130 millimolar methionine, 0.05 molar phosphate buffer (pH 7) 0.02 millimolar riboflavin and 0.75 millimolar nitroblue tetrazoliums (NBT). The

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1287712892

reaction mixture was placed under the fluorescent light for 7 min and absorbance was measured at 560 nm using spectrophotometer DU-730 (Beck Man Coulter Inc., USA). By using the Lambert-Beer law equation, SOD activity was calculated:

$$A = \varepsilon LC$$

A: absorbance, ε: extinction coefficient, L: length of each wall, C: concentration of enzymes.

Catalases and peroxidases activity

The protocol of Aebi (1984) was used with some modifications to determine the catalase activity. Enzyme extract (0.5 ml) was added to 3 ml of reaction solution (50 mM phosphate buffer, pH 7.0 and 30% w/v H_2O_2). The catalase activity was examined at the decrease of absorbance at 240 nm using spectrophotometer DU-730 (Beck Man Coulter Inc., USA). The estimation of peroxidase activity was measured by following the method of Chance and Maehly (1955). 3 ml of reaction solution containing (20 mM guaiacol, ten mM phosphate buffer and ten mM H_2O_2) was mixed with 0.5 ml of enzyme extract (heated in a water bath at 45 °C for 5 min before mixing). Increase in absorbance was measured at 470 nm using spectrophotometer DU-730 (Beck Man Coulter Inc., USA) due to the formation of tetraguaiacol (Klapheck et al., 1990).

Estimation of total phenolic content (TPC)

For TPC estimation, 0.75 ml of Folin–Ciocalteu reagent was added to 100 µl plant extract, gently mixed and placed them at 22 °C for 5 min. 0.75 ml of Na_2CO_3 solution was then added to the mixture and kept at 22 °C for 90 min. Final results were concluded by checking sample absorbance at 725 nm at UV/Vis-DAD spectrophotometer (UV-2250, Kyoto, Japan) (Velioglu et al., 1998).

Estimation of total flavonoids content (TFC)

For the estimation of TFC, $AICI_3$-$NaNO_2$-NaOH reaction complex was used according to the protocol given by Lopez-Contreras et al. (2015). 0.2 ml of extract was added to 3.5 ml of distilled water. Furthermore, (0.15 ml) 5% $NaNO_2$, (0.15 ml) 10% $AlCl_3$ and (1 ml) 1 M NaOH were added to mixture by equal 5 min time intervals each and placed it at room temperature for 15 mins. Reaction absorbance was measured at 510 nm by using UV/Vis-DAD spectrophotometer (UV-2250, Kyoto, Japan).

Statistical analysis

All the data were analysed by using Statistical software (version 7.0; StatSoft). Significance was determined via one-way analysis of variance. Values are presented as mean ± standard error (SD) from three independent biological replicates. A comparison of the means (control + treatments) was confirmed by Duncan's multiple range test at $p < 0.05$.

Results

Silver nanoparticles and germination percentage

In the recent study we have explored the *in vitro* phytotoxic and beneficial aspects of synthesized metallic silver nanoparticles (AgNPs) in *Pennisetum glaucum* (L.), AgNPs were purchased from China which possessed the size of 100 nm (*Fig. 1A)*. AgNPs did not show any adverse effect on seed living mechanism. Interestingly, AgNPs have boosted the seed germination in *P. glaucum* (L.) as compared to non-treated. The enhancement in seed germination has been assessed as dispersed AgNPs could create 'nanoholes' in the seed coats and make their entry easier to seeds via seed coat, resulting in enhanced germination conditions, slow and slight release of silver ion (Ag^+) could be a second primary reason for Ag-nanoparticles to have no deleterious effects on germination of *P. glaucum* (L.) seeds at optimal concentrations.

Moreover, the maximum seeds germination percentage (99%) was recorded in T3 of AgNPs *(Fig. 1B)*. This was observed as the appropriately applied ratio of AgNPs, which resulted in enhanced germination of seeds *in vitro* and possible to utilize in the agricultural system for better crop production. This may elucidate, at the optimal range of applied AgNPs, seeds germination was not altered harmfully so AgNPs could be used as conventional fungicides to protect the seeds against fungi and reduce environmental sways of fungicides as well as lower the cost of agricultural production.

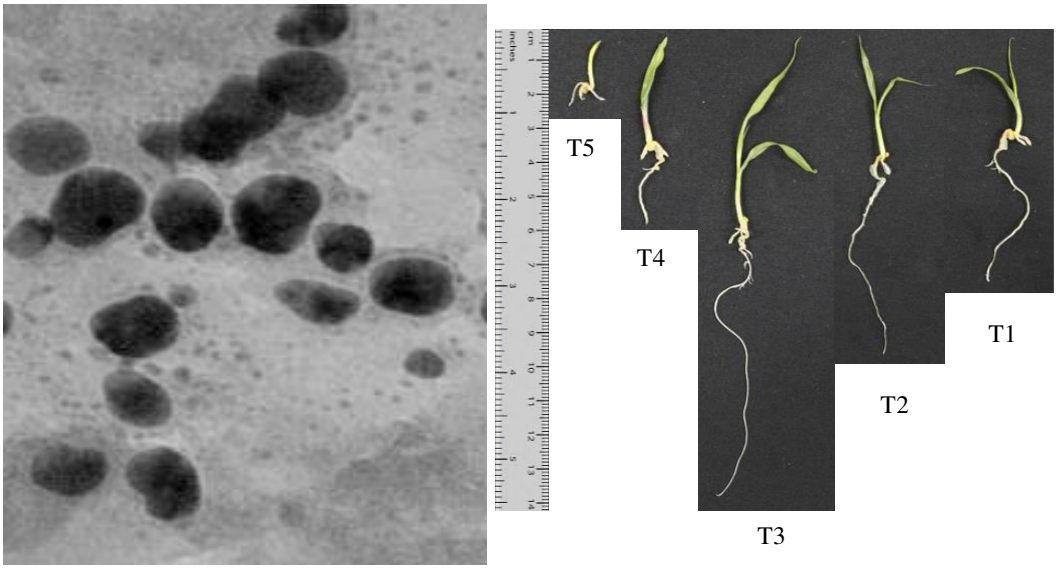

Figure 1. *(A) Transmission electron microscopy (TEM) images of metallic silver nanoparticles having size of 100 nm. (B) Effect of different treatments (T1 = 0 ppm, T2 = 20 ppm, T3 = 40 ppm, T4 = 60 ppm and T5 = 80 ppm) of metallic silver nanoparticles (AgNPs) on growth of Pennisetum galucum (L.) seedlings. Each seedling represented an experimental unit*

The *Figure 2A* and *B* indicate that seed germination percentage and seed vigour index affected by various treatments of AgNPs. Germination percentage at control (T1) and T3 was 92% and 99% respectively while in comparison with T5, it was strongly reduced to 66%. These results revealed that AgNPs application at T3 sharply boosted the germination potential by increasing emergence speed of radical and plumule in *P.*

DOI: http://dx.doi.org/10.15666/aeer/1706_1287712892

glaucum (L.) seeds on MS solid media. Though the emergence response of seeds was dependent on applied concentration in T5, a noticeable reduction in germination was observed.

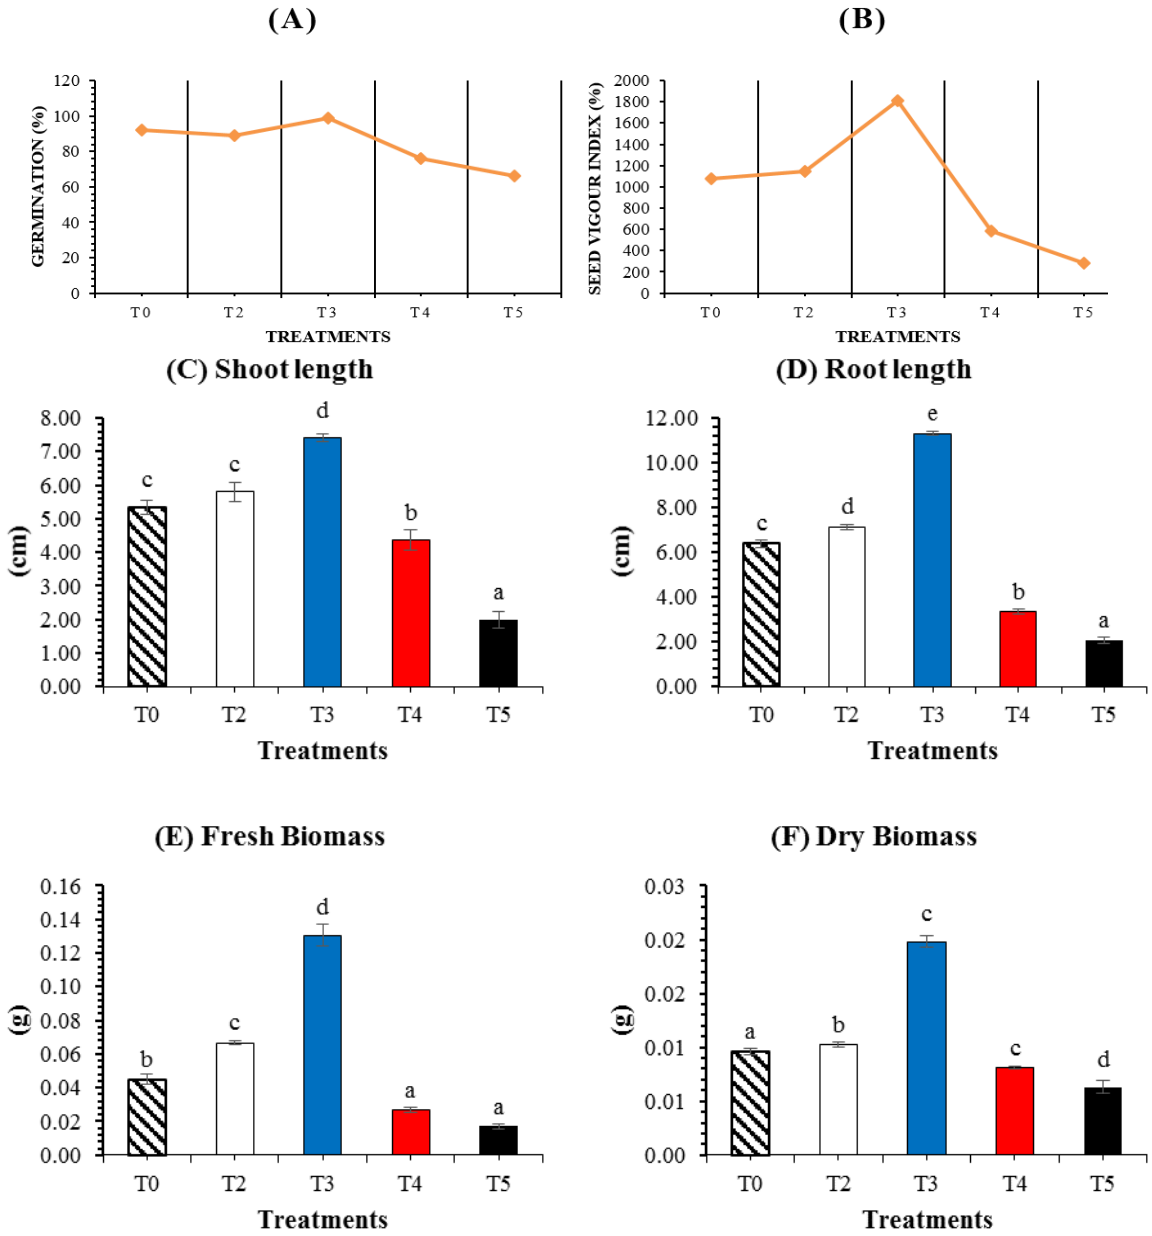

Figure 2. *The response of seed germination and seedling growth treated with AgNPs (A) Seed germination potential, (B) Seed vigour index, (C) Shoot length (D) Root length (E) Fresh biomass (F) Dry biomass. Values are the average of three repetitions. Means (n = 3) and standard errors (±) were calculated by analysis of variance (one-way). A comparison of the means (control + treatments) was confirmed by Duncan's multiple range test at p < 0.05*

Morphological parameters and total biomass

Under T5, root length, shoot length and seedling vigour index (SVI) were significantly reduced, as shown in *Figure 2*. In case of seedlings growth, the length was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1287712892

enhanced up to 76.5% and 38.8% in root and shoot respectively in T3 which showed best results as compared to control while rapidly reduced as concentrations of nanoparticles increased or decreased. It was noticed that higher concentrations of AgNPs had a deleterious effect on plantlets, resulting in a significant reduction in root and shoot length and SVI. Consequently, the fresh and dry biomass were dependent on better seedling growth. In comparison with control, fresh and dry biomass were enhanced (190.1%) and (106.2%) respectively in T3 and readily decreased to 163.2% and 52.38% at high doses (T5) (*Fig. 2E, F*). The highest reduction in biomass could be due to more accumulation of ions released from nanoparticles, which reduced the availability of nutrients to seedlings for growth at higher doses (Hussain et al., 2017).

Antioxidant activity

DPPH radical scavenging assay

DPPH (2, 2-diphenyl-1-picrylhydrazyl) free radical scavenging activity of plantlets treated with AgNPs is presented in *Figure 3*. AgNPs suspension significantly influenced the DPPH activity in *P. glaucum* (L.). The highest DPPH activity (26%) was recorded in the plantlets which were exposed to T5 while others showed less. In contrast with others, T3 had reduced the antioxidant activity (9%) even then control (13%), revealed less production of ROS at this concentration which was advantageous for plant metabolisms and successful growth (Zhou et al., 2019a) as found in *Figure 3*.

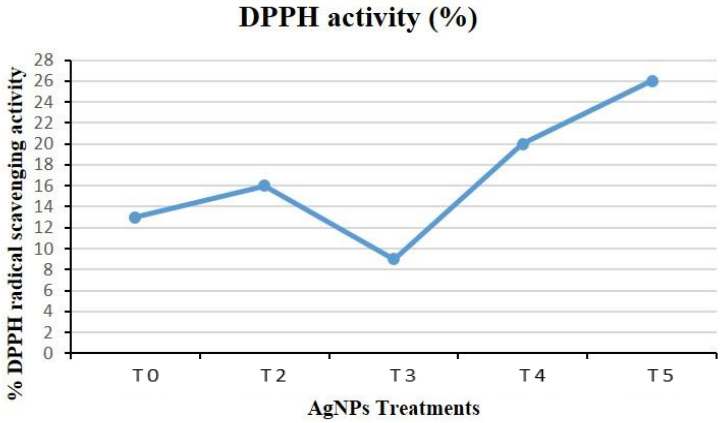

Figure 3. *Percentage DPPH radical scavenging activity of P glaucum L. against different treatments of metallic silver nanoparticles (AgNPs)*

Proline and superoxide dismutase (SOD) activity

Proline contents and SOD activity also have been evaluated in the present investigation, as shown in *Figure 4A, B*. Proline contents were relatively less (1.12 ± 0.0152 µg/mg) in the seedlings treated with T3 as compared all other treatments, including control (1.17 ± 0.0264 µg/mg). However, the highest value (2.15 ± 0.435 µg/mg) was found at T5, which reflected the stressed conditions faced by plantlets. By increasing the AgNPs doses, SOD activity tends to become more and highest at T5 (0.048 ± 0.0043 µmol/mg) and lower at T3 (0.031 ± 0.0020 µmol/mg). Stress could be a critical factor which enhanced the Proline and SOD activity (Mohamed et al., 2017).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1287712892

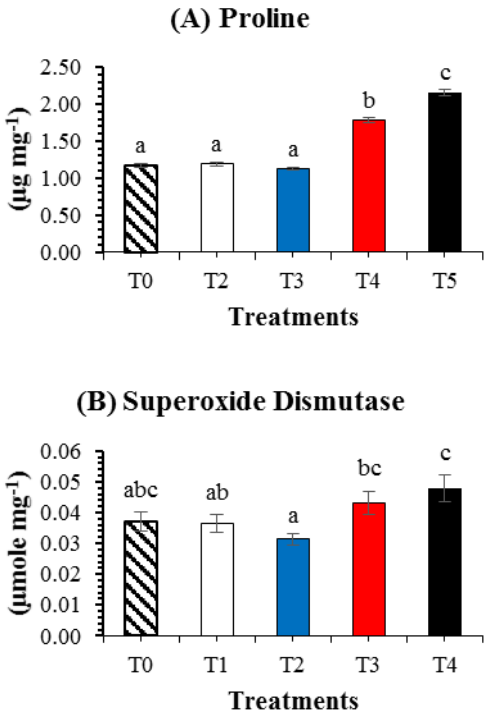

Figure 4. *Antioxidant enzyme activity in P glaucum L. seedlings treated with AgNPs. (A) Proline content. (B) Superoxide dismutase (SOD) activity. Values are the average of three repetitions. Means (n = 3), and standard errors (±) were calculated by analysis of variance (one-way). A comparison of the means (control + treatments) was confirmed by Duncan's multiple range test at p < 0.05*

Catalases (CAT) and peroxidases (POD) activity

Our results showed a negative relationship between CAT and POD activity as seen in *Figure 5A, B*, at higher dose (T5) more POD activity (1.03 ± 0.723 µg/g) was recorded, however POD activity was significantly decreased to 101.9% and 68.8% in T3 and T1 respectively, which strongly reflected the consistent and sustainable living mechanism of plantlets whereas, more POD activity resulted in more stress on plantlets. The CAT activity was seemed to be higher (141 ± 2.081 mg/g) in T3 and lower as the dosage increased from T3. However, lowest CAT activity (100 ± 3.833 mg/g) was recorded in the plantlets treated with T5, at this concentration plantlets were observed in stress condition which could be due to more production of ROS. Furthermore, CAT is found in peroxisome (Alberts et al., 2002) so, AgNPs at the suitable ratio may cause more production of catalases that provide longevity to plantlets under different environmental settings.

Total phenolic contents (TPC) and total flavonoids contents (TFC)

Total phenolic contents in the seedlings which treated in T3 were comparatively more (0.56 ± 0.0152 µg/mg) than control and T2, as shown in *Figure 5D*. On the contradictory, there were significant effects ($p \leq 0.01$) in the phenolic compound's accumulation since the rise in doses from T3 to T5, declined in the accumulation of total phenolic contents (12.1%) and (35.2%) under T4 and T5 respectively when compared with T1. These results indicated that seedlings exposed to higher doses of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1287712892

AgNPs faced more stress by which they accumulated less phenolic compounds because a high dosage of AgNPs acted as a stressor and inhibited the accrual of TPC.

Unlike phenolic compounds, the flavonoid contents were higher as the concentrations of AgNPs increased from T2 to T5 as in *Figure 5C*. Total flavonoid contents were significantly enhanced to 0.58 ± 0.0233 µg/mg under T3 than T1, resulting from the proper entry of nanoparticles into seeds at the time of germination which provided signals to emerging seedlings by which these could cope with different environmental settings. Therefore, significant differences have been recorded at high doses of AgNPs when compared with T3. A higher concentration of nanoparticles produced more TFC (0.76 ± 0.055 µg/mg), but a significant reduction in seedling growth was observed.

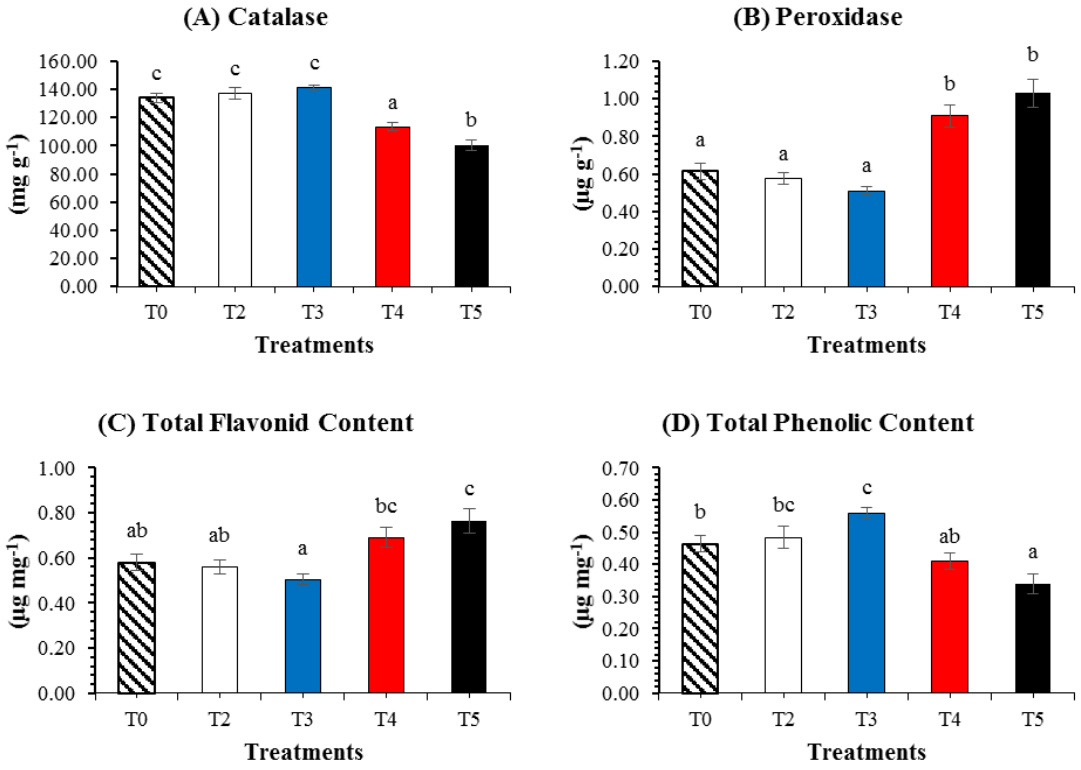

Figure 5. *Antioxidant enzyme activity and phenolic content in Pennisetum galucum L. seedlings treated with AgNPs. (A) Catalase (CAT) activity, (B) Peroxidase (POD) activity, (C) Total flavonoid content (TFC) (D) Total phenolic content (TPC). Values are the average of three repetitions. Means (n = 3) and standard errors (±) were calculated by analysis of variance (one-way). A comparison of the means (control + treatments) was confirmed by Duncan's multiple range test at $p < 0.05$*

Discussion

Results of recent research work disclosed that suitable concentrations of AgNPs significantly enhanced the seed germination, growth attributes and improved the biochemical profile of *P. glaucum* (L.) while high dosage acted as a stressor or toxic to plants at germination stage and reduced the total biomass. Study of the toxicity of nanomaterial is the nanotoxicology, which is dependent on their sizes, shapes and effects because nanoparticles have distinctive properties. Although toxicity mechanism

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1287712892

of nanoparticles is still unknown nonetheless, it would depend upon the nanomaterials chemical composition, chemical structure, sizes and surface area. Two major key factors can be the cause of toxicity (1) release of more toxic ions and (2) stress due to size, shape or surface of nanomaterial. NPs bearing small sizes have more surface area, so these are more toxic (Parveen and Rao, 2015). In case of metallic nanoparticles (MNP), small-sized CuNPs have been observed more toxic on two plant species wheat (*Triticum aestivum*) and mung bean (*Phaseolus radiatus*) by reducing seedling growth than other MNPs (Lee et al., 2008). However, High emergence percentage of root and shoot from seeds is triggered by the positive role of plant hormones. Nanoparticles were entered to seeds successfully and filled the space between permeable membrane which enhanced the biosynthesis of hormones especially auxins and gibberellins to degrade seed reserves resulted from increased seed germination and seedling growth (El-Kereti et al., 2013; van Dongen et al., 2003).

It was observed in our findings that maximum germination percentage and seedling growth were attained at T3, this range could be a suitable for rapid entry of AgNPs and positive acceleration of seed metabolism for the enhancement of seedling growth as shown in *Figure 1B*. Kumari et al. (2011) reported that AgNPs influenced the cell division process of plant and caused cell enlargement, where they interfered with plant components in plant systems and translocated from stem to leaves. Interestingly, lower concentrations of AgNPs were seemed to be useful to increase the seed vigour and seedlings growth and had no deleterious effects to cell division process and seedlings growth in kinnow (Hussain et al., 2018). High dosage of AgNPs inhibited or reduced the seed germination, decreased seedlings growth, chlorophyll contents, and plant biomass in *Hordeum vulgare* and *Spirodela polyrhiza* which strongly affirm our recent findings in case of *P. glaucum* (L.). Besides, AgNPs possess antiviral, antifungal, antibacterial properties and can be utilized as potent fungicides due to their strengthening shielding role against fungi and enhanced germination frequency as described by Karimi et al. (2012), who reported the better germination potential and seedling growth from the seeds, coated with a suitable concentration of AgNPs solution compared with fungicides coated seeds. Same results for growth parameters were investigated by Hussain et al. (2017), who achieved 98.6% germination vigour which was about 7% better than control and 22% more seedling growth compared with control in Artemisia under suitable concentrations (30 mg/L) of AgNPs. Study of AgNPs on rice (*Oryza sativa*) seedlings also have been examined, and results revealed, as a dosage of NPs increased from 60 mg/L all the growth attributes including seed germination, root length, shoot length, leaf length, leaf area and biomass readily decreased (Mirzajani et al., 2013). Total biomass reduction in wheat (*Triticum aestivum*) and *(Pennisetum glaucum)* under high concentrations of AgNPs was also reported by Mohamed et al. (2017) and Khan et al. (2019). Reduction in total biomass (fresh and dry) accumulation due to the high amount of AgNPs has been shown in *Figure 2*. We have applied AgNPs to *P. glaucum* on MS basal medium while most of the above described findings were achieved in soil experiments in which other plant species have been experienced, but all these strongly affirm our best germination results under suitable concentrations and poor results under the high ratio of NPs as in *Figure 1B*.

In the present study, ranges of AgNPs above T3 negatively affected the root and shoot growth, alternatively increased the antioxidant activity, total flavonoids and proline contents. Likewise, under stressed conditions, *Triticum aestivum* increased MDA contents and H_2O_2 level resulting in increased antioxidant activity to cope with

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1287712892

the stress for better survival of plant (Mohamed et al., 2017). A higher concentration of AgNPs led to more production of ROS and such behaviour caused the blockage of electron transfer that induced the oxidative stress (Zou et al., 2016). It was in support of our findings, as shown in *Figure 3* that more the DPPH activity at the maximum NPs concentration. A similar report was described by García-López et al. (2018), in the case of ZnNPs, increased DPPH activity was recorded at high concentrations in *Capsicum annuuam*. Proline, as a multifunctional amino acid triggered the plant growth through signalling mechanism, upregulated and accumulated in a large amount under stressed conditions and optimal under normal growth settings (Yang et al., 2009). Our results demonstrated that a high level of proline was observed in T5 while lower at T3 than T1 that is associated with the above findings and presented in *Figure 4*. Our results indicated healthy and progressive plants growth under an ideal range of NPs (T3) by minimizing proline contents less than control because plants enhance the endogenous proline level when suffered from more stress (Szabados and Savoure, 2010).

Furthermore, we have observed that changes in morphology and accumulation of secondary metabolites with greater efficacy under high ranges of AgNPs resulted in oxidative stress in *P. glaucum* (L.). More ROS lead to more antioxidant production, which was previously reported by Sewelam et al. (2016) as ZnNPs applied to plants in higher concentrations. Our results exhibited increased SOD and POD activities at higher AgNPs ranges than T1. This reflects the development of a well-defined antioxidant defensive mechanism to cope with stress (Gill and Tuteja, 2010). However, the optimum range of NPs (T3) showed less SOD and POD activity and in plantlets instead of control which indicated a small amount of ROS production by decreasing cell damage risk due to NPs and enhanced the plant growth. According to present research work, this optimal concentration of NPs could be used under stress condition for the inhibition of ROS production. Our findings are associated with Parry et al. (1994), who reported more production of antioxidants under stress condition which mitigated the biosynthesis of the enzymes that produce ROS, and provides tolerance to plants for their better survival. AgNPs at 75 mg/L, have increased the SOD and POD activities in tomato plants (Parry et al., 1994) and this has reaffirmed our present findings.

In another investigation, AgNPs at higher ratio decreased the CAT activity than control in mustard seedlings, but comparatively less reduction was observed (Vishwakarma et al., 2017). However, in the present study higher CAT activity was observed at T3 while significant reduction recorded at T5 as presented in *Figure 5* which might be due to interactions of silver nanoparticles with proteins found in lipid bilayer and cytosol; thereby changing the proteins configuration resulting destruction of antioxidant defensive systems (McShan et al., 2014). Our findings are not in line with Krishnaraj et al. (2012) who have described less CAT activity in *Bacopa monnieri* under suitable concentrations of AgNPs. Variations in responses by different plant species have been reported by researchers whereas, the enhanced activity of CAT indicating that it plays important role to scavenge the ROS and decreases the ROS production with greater efficacy (Hayashi et al., 2013; Sneha et al., 2014).

Our findings revealed that seedlings under T3 exhibited higher TPC while lower in T5 as compared with T1 however these results are different from the previous researchers (Zaka et al., 2016) who have described increased TPC in *Eruca sativa* under stressed conditions along with AgNPs application. The main reason could be that high NPs ratio causes discrete changes in the proteome and interfere with cell signalling (Saptarshi et al., 2013) while on the other hand, a linear expression was observed in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1287712892

TFC. TFC were showing a significant progressive response in all treatments of AgNPs than control, reflecting improved plant growth with reduced toxic effects. In order to assess the TFC, (García-López et al., 2018) examined high TFC contents under high ZnNPs concentrations. Overall, our results are the pioneer for the evaluation of advantageous and phytotoxic effects of AgNPs in *Pennisetum glaucum* by stabilizing the biochemical profile and serve as guidelines for crop producer to use AgNPs instead of fungicides to get high production at low cost. Previously, the antioxidant mechanism of *P. glaucum* under AgNPs application was unknown, but recent findings will provide a particular direction to other researchers to explore genetic and molecular mechanisms for the action of AgNPs in plants.

Conclusions

This study concluded that AgNPs showed different responses to germination, seedlings growth and antioxidant activity under variable concentrations in pearl millet (*P. glaucum* L.*)*. The optimum concentration of AgNPs (T3) significantly increased all the growth parameters and improved the biochemical profile as compared to other treatments. Seedlings exposed to higher doses of AgNPs showed a reduction in growth and more toxicity. Desirable secondary metabolites may be produced in plants by inducing the changes in physiological and biochemical processes with the help of nanoparticles. High doses of AgNPs seemed like a stressor and caused significant reduction in biomass. It is confirmed that higher doses of NPs are toxic to plants, even in stressed conditions (salt, drought, heat, etc.). Moreover, AgNPs at suitable concentrations can be used as a fertilizer for better crop production and fungicides to produce safe food. Shortly, this preliminary study warrants a comprehensive work to understand the toxicity of NPs at a genetic level and molecular mechanisms against undesirable molecules (free radicals) for better crop production under different environmental conditions.

Abstract. This study aimed to investigate the concentrations of Cd, Cr and Pb in the water and sediment, and to compare the concentrations of these metals in fish muscles, the levels of plasma oxidative stress biomarkers (malondialdehyde and protein carbonyl) and the genetic differentiation between experimental tilapia fish from the contaminated reservoir near municipal landfill and the reference area after chronic exposure to the metals. The concentrations of Cd, Cr and Pb in the water exceeded the Thailand water quality standard, whereas the concentration of Cd in the sediment exceeded the Thailand soil quality standard. The concentrations of these metals in fish muscles were below Thailand food quality standard. In comparison to the reference fish, the fish in the landfill reservoir revealed a significant increase in malondialdehyde and protein carbonyl ($p < 0.05$). The dendrogram results demonstrated values of genetic similarity for the fish from the reference and the landfill areas at 0.84-0.94 and 0.65-0.97, respectively, implying that the values of genetic differentiation as a consequence of genotoxicity of the fish from the landfill were greater than those of the fish from the reference area. The results indicate that chronic heavy metal exposure could induce oxidative stress and genotoxicity of tilapia fish in the reservoir near municipal landfill.

Keywords: *oxidative stress, genetic differentiation, heavy metal, tilapia fish, municipal landfill*

Introduction

In the past few decades, industrial, commercial and urban communities have continuously and rapidly grown in Khon Kaen Province, Thailand (PCD, 2014). This growth has inevitably been accompanied by rapid increases in municipal and industrial solid wastes. Due to poor management of landfill waste, toxic leachate that can spread heavy metals and other toxic substances around the landfill environment is present (Papadimitriou and Loumbourdis, 2003). The major heavy metals found in the Khon Kaen municipal landfill were cadmium (Cd), chromium (Cr), lead (Pb) and arsenic (As) (Sarun, 2004; Sriuttha et al., 2017; Intamat et al., 2017). Sriuttha et al. (2017) demonstrated that concentrations of Cd, Cr and Pb in the water and sediment near the municipal landfill were as not detected, 0.016 ± 0.009, 0.009 ± 0.0006 mg/L and 0.47 ± 0.23, 19.91 ± 0.96, 5.40 ± 0.13 mg/kg, respectively, while Intamat et al. (2017) determined that As values in the water, sediment and tilapia fish in the landfill environment were 0.006 ± 0.002, 1.08 ± 0.64 and 0.16 ± 0.16 mg/kg, respectively. From previous reports, these toxic metals can always spread from hazardous waste such as

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1289312907

batteries, light bulbs, chemical containers and lubricants, into leachate and surrounding reservoirs (Oost et al., 2003; ATSDR, 2007), and can be taken up and accumulate in aquatic organisms, including fish (Luoma and Rainbow, 2008). Intamat et al. (2017) revealed that the As concentrations in *Oreochromis niloticus*, *Barbonymus gonionotus, Rasbora tornieri* and *Anabas testudineus* exceeded Thailand food quality standards. Sriuttha et al. (2017) found that the Cd concentrations in *O. niloticus* and *B. gonionotus* exceeded the limit of International standard for fish, additionally the Cr concentration in *R. tornieri* and *A. testudineus* exceeded the International standard, and the Pb concentration in all four fish species exceeded the International standards. Fish that inhabit heavy metal-contaminated reservoirs generally take in toxic metals by absorbing metals through their skin, gills and alimentary tracts (Kamunde et al., 2002; Papadimitriou and Loumbourdis, 2003; Robinson et al., 2003) and can demonstrate biomagnification, and these contaminated fish can result in health risks to consumers (Godt et al., 2006).

Several research studies have demonstrated that heavy metals can cause an imbalance between the production and reduction of free radical species, i.e., causing oxidative stress in fish (Livingstone, 2003; Sevcikova et al., 2011). The free radicals can attack protein and lipid molecules to induce oxidative stress products as well as cause negative consequences such as increases in malondialdehyde and protein carbonyl as well as fragmentation of deoxyribonucleic acid (DNA) (Castano and Becerril, 2004; Talas et al., 2008; Velma and Tchounwou, 2013; Vilela et al., 2018). Recently, the amount and diversified species of oxidative stress products have been considered biomarkers for environmental monitoring indices in terms of both status and situation of aquatic ecosystems (Skorbiłowicz, 2009; Burlibasa and Gavrila, 2011; Webb, 2011; Authman et al., 2015). The consequences of oxidative stress from toxic metals to aquatic animals have been reported, but information on their effects on fish with either acute or chronic exposure time in landfill ecosystems is limited. Therefore, the objectives of this study were to investigate heavy metal accumulation in a landfill reservoir, and to compare oxidative stress biomarkers as well as genetic differentiation between the experimental tilapia fish (*Oreochromis niloticus*) from the contaminated reservoir near municipal landfill and the reference area after chronic exposure to the metals.

Materials and methods

Study site

The study site was a reservoir located approximately 100 meters from the municipal landfill, Maung District, Khon Kaen Province, Thailand at latitude 16°35’41.30”N and longitude 102°48’12.11”E (*Fig. 1*). Geographic coordinate is UTM 48Q N 1,835,718 E 266,085 at a height of 200 m from the sea level.

Fish and experimental design

Juvenile tilapia fish at an average weight of 10.3 grams were reared at a density of 20 fish/m^2 in 2 × 2 m floating cages in the reservoir that received metal-contaminated leachate from the Khon Kaen municipal landfill. The experimental fish were randomly allocated into 2 treatments (reference and landfill) with 3 replications of each treatment, and they were fed a commercial pellet diet (Charoen Pokphan Co., Thailand) at 10%

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1289312907

w/w, 3 times/day for 4 months during April-July 2018 simulating the length of the tilapia production as in general practice. At the end of the experiment, fish muscles were measured for heavy metal accumulation, blood was collected from the caudal vessels for the plasma oxidative stress test, and the gills and livers were excised for the DNA study and genetic differentiation analysis. The control fish were collected from the Khon Kaen Inland Fisheries Research and Development Center, Thailand. Aquaculture in the Department of Fisheries is non-affected heavy metal contamination which has control of contamination for human food. Therefore, the control fish of this study is expected to not receive heavy metals.

Figure 1. *Overview of the municipal landfill and the location of the contaminated reservoir*

Water quality parameters

Temperature, dissolved oxygen, pH, total dissolved solids and electro-conductivity were measured at the sampling site using digital mobile meters. Total ammonia nitrogen was measured using the titration method (APHA, 2005) (*Table 1*).

Table 1. *Methods used for analyses of water quality parameters*

Water quality parameters	Analysis methods
Temperature	Thermometer
Dissolved oxygen	DO meter, model 966, Mettler Toledo
pH	pH meter, model EcoScan pH 5, Eutech
Total dissolved solid	Total dissolved solid, model CH-8603, Mettler Toledo
Electro-conductivity	EC meter, model CH-8603, Mettler Toledo
Total ammonia nitrogen	Titration method

Heavy metal measurements

The water samples were acidified in the field by adding concentrated nitric acid until the pH was less than 2, the sediment samples were wrapped in aluminum foil to prevent oxidation, and the live fish were put into oxygenated plastic bags. All collected samples

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1289312907

were digested following EPA method 6010, and the Cd, Cr and Pb concentrations were analyzed using inductively coupled plasma optical emission spectrometry (ICP-OES) (Chand and Prasad, 2013; Neeratanaphan et al., 2017). The detection limits of each analyzed element were as follows: Cd and Cr: 0.001 mg/kg and Pb: 0.005 mg/kg. The ICP-OES wavelengths for the Cd, Cr and Pb analyses were set to 188.979, 226.502 and 267.716 nm, respectively.

The analysis of blanks and quality control standards was performed after every 10th sample. The concentrations of the elements in the procedural blanks were typically < 5% of the mean analyzed concentrations for all the heavy metals. Replicate analyses and standard reference materials were used to guarantee the precision and accuracy of the measurements for all elements. The results were found not to deviate by more than 2% of the certified values, indicating the accuracy of the analysis (APHA, 2005). The heavy metal recovery values were calculated by acceptance criteria in the range of 85-115% (USEPA, 2000). The results were 90-100% of the acceptable values and considered accurate.

Oxidative stress biomarkers

After being reared for 4 months in the landfill reservoir, the blood plasma of the experimental fish were collected at the reservoir site to determine malondialdehyde (MDA) by measuring thiobarbituric acid reactive substances (Luangaram et al., 2007; Nakmareong et al., 2011) and to measure protein carbonyl (PC) by its reaction with 2,4-dinitrophenylhydrazine (Reznick and Packer, 1994; Nakmareong et al., 2011). For the genotoxicity study, DNA from the livers and gills of the fish were extracted and amplified by 46 inter-simple sequence repeats (ISSR) primers (*Table 2*) in a PCR thermal cycler (Flex Cycler^2, Analytikjena) (Tengjaroenkul et al., 2018). Each DNA band was evaluated and recorded as the following diallelic characters as present = 1 and absent = 0. All of the bands were imported to construct dendrogram by the NTSYSpc 2.1 program (Rohlf, 2009) for analysis of genetic differentiation as a consequence of genotoxicity.

Statistical analyses

Statistical analyses of the oxidative stress biomarkers in experimental and control fish were analysed using the Mann-Whitney U-test. The genetic differentiation was analyzed to construct dendrogram by the NTSYSpc 2.1 program (Rohlf, 2009). All of the statistical tests were conducted at a 95% confidence level.

Results and discussion

Water quality parameters

The water quality parameters of the reference and the landfill reservoir water samples after 4 months of the experiment are shown in *Table 3*.

Water quality describes conditions of water medium and its related suitability to sustainably support aquatic ecosystems as well as public health. Low water quality could influence the stress, metabolism, health, reproduction, genetics and biodiversity of fish (Jezierka and Witeska, 2001; Buet et al., 2006; Da Rocha et al., 2009). In this study, the water quality parameters from both the reference and the landfill reservoirs were within the Thailand standard concentration limits for surface water sources (Ip et

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1289312907

al., 2001; PCD, 2014); therefore, plasma oxidative stress and genotoxicity biomarkers in long-term experimental tilapia tended to have fewer effects from the water quality parameters in both areas.

Heavy metal concentrations

The heavy metal concentrations in the water, sediment and fish muscles from the reservoir near the municipal landfill are shown in *Table 4*.

[a]Water quality standards for surface water sources, Pollution Control Department, Ministry of Natural Resources and Environment, Thailand (PCD, 1994)
[b]Soil quality standard, Pollution Control Department, Ministry of Natural Resources and Environment, Thailand (PCD, 2004)
[c]Thailand food quality standards, Ministry of Public Health, Thailand (Ministry of Public Health, 2003)

The concentrations of Cd, Cr and Pb in the water exceeded the Thailand water quality standards for surface water sources (PCD, 1994), whereas the concentration of Cd exceeded the Thailand soil quality standard (PCD, 2014). The concentrations of the metals in the fish muscles were below those of Thailand food quality standards (Ministry of Public Health, 2003). Waste segregation and management in the Khon Kaen municipal landfill were not appropriate, resulting in the disposal of municipal waste and hazardous waste, which can be potential sources of heavy metal exposure in fish (Sarun, 2004). As in other polluted areas, heavy metal contamination in the Khon Kaen landfill leachate can lead to metal accumulation in the soil and sediment of the reservoir, and can then be absorbed and accumulated into aquatic plants and animals (Luoma and Rainbow, 2008). These bioaccumulation processes were identified by the studies of Promsid (2014): and Intamat et al. (2017): who found heavy metal accumulation in plants and animals in the reservoir, especially emerged plants (*Limnocharis flava*, *Diplasum esculentum* and *Nymphea lotus*) and aquatic animals such as *Monopterus albus*, *Clarias batrachus* and *Channa striata*. Intamat et al. (2017) revealed that As in *Oreochromis niloticus*, *Barbonymus gonionotus, Rasbora tornieri* and *Anabas testudineus* exceeded the Thailand food quality standard. Sriuttha et al. (2017) found that the Cd concentration in *O. niloticus* and *B. gonionotus* exceeded the limit in the International standards for fish (FAO, USA), whereas the Cr concentration in *R. tornieri* and *A. testudineus* exceeded the limits in the International standards, and the Pb concentration in four fish species exceeded the limit in the International standards. Furthermore, this study investigated the Cd, Cr and Pb concentrations in the tilapia as the major commercialized fish consumed throughout local communities in Khon Kaen Province. Generally, tilapia fish culture in Thailand of 4 months was the model condition that simulated the practice. As the experimental tilapia fish had a relatively long exposure period of 4 months, they could continuously accumulate heavy metals from water and sediments into their organs (Chen and Liao, 2004; Cumberlidge, 2009; Abdulali et al., 2013; Abdel-mohsien and Mahmoud, 2015). This continuous accumulation in the tilapias occurs probably because they have a large body size and surface area with the contaminated environment. In accordance with several reports, chronic exposure of Cd, Cr and Pb to experimental tilapia fish may lead to stress, metabolic changes, physical damage and hematological, hepatological, and immunological alterations (Mishra and Mohanty, 2008; Paul et al., 2014; Pereira et al.,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1289312907

2016). Furthermore, after consumption, a fish that has accumulated heavy metals can do harm to humans in surrounding communities by causing detrimental diseases and disorders related to these metals (Godt et al., 2006; Tiwari et al., 2011). In general, the levels and potential of risk from the accumulated metals in the fish in the landfill reservoir to consumer health depend on several factors, including speciation, dose, time and toxicokinetics of the heavy metals contained in the exposed animals (Abu-Daabes et al., 2013; Wachirawongsakorn and Sangyoka, 2013).

Oxidative stress biomarkers

Malondialdehyde

Levels of plasma MDA in the tilapia fish are shown in *Figure 2*. In comparison with the reference fish, the fish from the reservoir near the Khon Kaen municipal landfill demonstrated a significant increase in plasma MDA ($p < 0.05$).

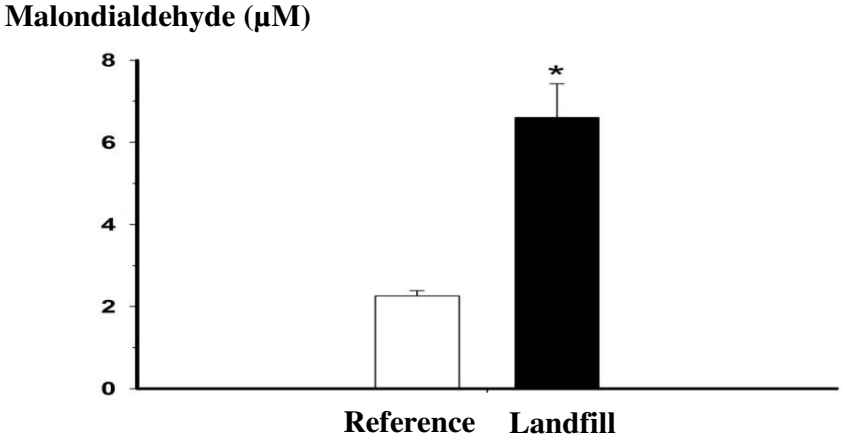

Figure 2. *The levels of plasma malondialdehyde in both treatments of the Nile tilapia fish. Values are expressed as the mean ± SEM of 10 fish. *p < 0.05 compared with the reference fish*

Contaminated landfill leachate as well as reservoir water and sediments usually contain complex mixtures of heavy metals capable of accumulating in aquatic organisms (Luoma and Rainbow, 2008). Heavy metals can induce reactive oxygen and nitrogen species, i.e., causing oxidative stress or free radical overload in aquatic organisms, including fish (Sevcikova et al., 2011). Assessments of oxidative damage in fish can directly reflect metal exposure in an aquatic environment, which could affect the health of the creatures (Livingstone, 2003). Contaminated heavy metals in living fish generally interact with nuclear proteins, lipid molecules and nuclear nucleic acids, resulting increases in MDA and PC and fragmentation of DNA strands (Livingstone, 2003; Sevcikova et al., 2011).

MDA is one of the lipid peroxidation products derived from oxidative attacks on cell membrane phospholipids and circulating lipids, and its increased level directly involves the degree of oxidative damage induced by the contaminants, including heavy metals (Banerjee et al., 1999; Ercal et al., 2001). A measure of MDA content provides the relative consequence of the potential for pollutants to cause oxidative injury (Vlahogianni et al., 2007; Calapoglu et al., 2017). In this study, a significant increase in plasma MDA concentration was found in the tilapia fish, indicating that the presence of heavy metals could cause oxidative stress as well as negative effects on cell homeostasis such as protein

DOI: http://dx.doi.org/10.15666/aeer/1706_1289312907

metabolism, glutathione pathways and mitochondrial functions. Several other reports revealed similar results related to increases MDA in fish, including killifish, mullet, flounder, catfish and stickleback, after exposure to pollutants (Bakanskas et al., 2004; Ferreira et al., 2005; Farombi et al., 2007; Sanchez et al., 2007; Bayir et al., 2011).

Protein carbonyl

The levels of plasma PC in the tilapia fish are shown in *Figure 3*. In comparison with the reference fish, the fish from the reservoir near the landfill area demonstrated a significant increase in plasma PC ($p < 0.05$).

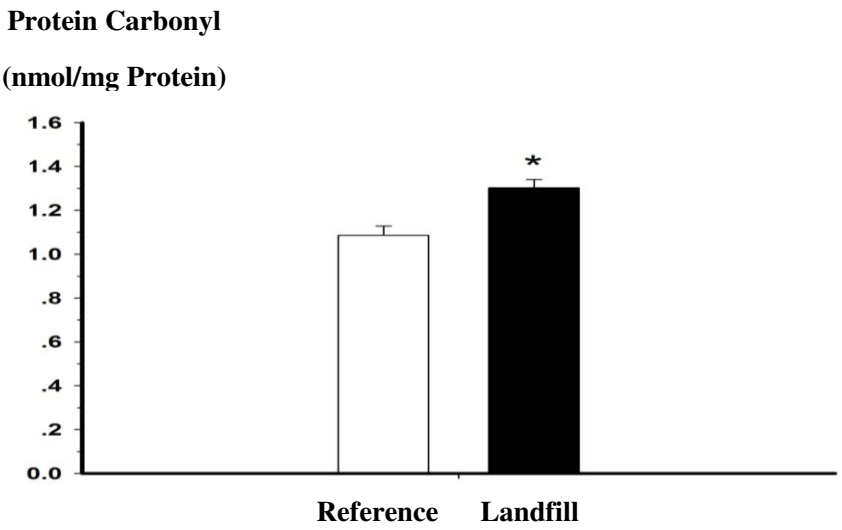

Figure 3. *The levels of plasma protein carbonyl in both groups of the Nile tilapia fish. Values are expressed as the mean ± SEM of 10 fish. * $p < 0.05$ as compared with the reference fish*

PC formation can occur as a result of oxidative stress, and has been shown as a number of tissue lesions and disease issues (Requena et al., 2003). An increase in the number of carbonyl groups correlates well with protein damage caused by oxidative stress; therefore, PC can be a distinctive marker to induce the degradation of enzymes, to change amino acid structures and to alter protein functions (Grune, 2000; Parvez and Raisuddin, 2005; Dalle-Donne et al., 2006; Craig et al., 2007). In accordance with previous reports, the elevated level of PC in the Nile tilapia from the landfill reservoir could suggest that metal pollutants may cause protein damage as a consequence of oxidative stress. Furthermore, the significant increase in oxidative stress biomarkers in tilapia fish may be associated with a low resistance to pollution in this fish. To present, responses to oxidative stress in fish have been recorded differently according to habitat and feeding behavior of fish as well as concentrations and types of the pollutants (Giulio et al., 1993; Wilhelm, 1996; Hebert et al., 2008).

DNA

The 24 ISSR primers were successfully applied to generate 2,562 total bands with 375 characteristics, including 128 similar band profiles and 245 different band profiles. The dendrogram separated tilapia fish into two clusters corresponding to their studied areas. The genetic similarity values of the fish in the contaminated reservoir near municipal

The results from the dendrogram analyses separated the tilapia into two clusters corresponding to their studied areas. The genetic differentiation in tilapia fish revealed a positive correlation with Cd, Cr and Pb concentrations accumulated in the fish body. The genetic differentiation in the fish from the contaminated reservoir near the landfill was greater than that of the fish from the reference area. These findings suggested that the metal accumulations in the landfill fish could affect the genetic toxicity in term of the molecular nucleic acid profile. In contaminated environments, heavy metal exposure could demonstrate DNA damage in fish as single and double strand breakages, alterations in DNA repair processes, oxidation of nucleic bases and DNA-protein crosslinks (Wood et al., 2001; Monserrat et al., 2007; Vilela et al., 2018). When heavy metals enter the cell membrane, they generally induce diversified genotoxicity through several mechanisms. For example, Cd can induce oxidative stress, DNA damage, point mutations, mutagenesis, deletions, ploidy changes, substitutions and oxidization in gene bases (Waalkes, 2003; Castano and Becerril, 2004; Suhartono et al., 2013). Cr exposure demonstrated micronucleus appearance, Cr-DNA adducts, DNA strand breakage, protein-Cr-DNA adducts and modification of the DNA nitrogenous base, leading to neoplastic growth in fish (Teles et al., 2005; Wise et al., 2008; Arunachalam et al., 2013; Velma and Tchounwou, 2013). Pb can induce oxidative damage, mitogenesis, alteration in gene transcription, carcinogenic events involved in DNA damage and several other indirect genotoxic changes (Silbergeld, 2003). Furthermore, the loss of DNA structural or functional integrity in exposed organisms can initiate deleterious effects at both the individual and population levels, especially through impaired growth or reproduction (Bolognesi and Hayashi, 2011; Mustafa et al., 2012; Ngamniyom, 2012). Furthermore, experimental tilapia fish could be a potential bioindicator for genotoxicity in aquatic ecosystems. In addition, local communities around the municipal landfill should increase their awareness, and enhance environmental management to reduce the risks to human health from consuming the heavy metals accumulated in the fish from the landfill reservoir.

Conclusion

The concentrations of Cd, Cr and Pb in *O. niloticus* after chronic exposure to heavy metals in a reservoir near municipal landfill for 4 months were below Thailand food

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1289312907

quality standard for these metals. In comparison to the fish in the reference area, the fish in the landfill area demonstrated a significant increase in MDA and PC with a relatively greater genetic differentiation. The results of the study demonstrate that heavy metals potentially induce oxidative stress and genetic alteration in the tilapia fish in the reservoir near the municipal landfill. Future researches should be comparative study oxidative stress in the other aquatic animals in this area.

(Received 20th May 2019; accepted 28th Aug 2019)

Abstract. Climate change makes itself perceivable day by day. Therefore, the determination of the factors that cause climate change and the effects of these are studied increasingly nowadays. Considering the global scale, it is seen as an effective way for countries to reduce the impacts of climate change and to act together in adaptation efforts. Therefore, regional and non-regional collaborations are important in this struggle. The aim of this study is to reveal the relationships between livestock activity and Carbon Dioxide (CO_2) emissions in Developing-8 (D-8) countries, an economic co-operation organization, with panel data analysis. In this study, the effect of the cattle, sheep and poultry stock of D-8 countries between 1990 and 2017 on CO_2 emissions was investigated with the Autoregressive Distributed Lag (ARDL) model. As a result, there was a statistically significant positive correlation between the stock number of cattle and poultry and the CO_2 emissions in general, although there was no statistically significant relationship with the breeding of sheep. The effect of animal husbandry activities on climate change is important because of their contribution to CO_2 emissions. In the processes involving materials such as enteric fermentation, animal originated fertilizer, animal waste, it is thought that the political/regulatory arrangements that will eliminate such factors can be made for producers in the micro-scale and for the agricultural sector in the macro scale.
Keywords: *climate change, livestock production, D-8 countries, ARDL model, CO_2 emission*

Introduction

Global warming due to climate change is at the top of today's most important problems. A lot of research has been done on the future effects of global warming (FAO, 2015; Riphah, 2015; Seneviratne et al., 2016; Özdemir et al., 2017; Prasad et al., 2017; Chena et al., 2018; Doğan and Kan, 2018; Iddrisu and Peker, 2018; Doğan and Kan, 2019; Qadir et al., 2019) and its effects are felt day by day. Many scenarios have been developed for this. In this regard, there is a common consensus for many countries around the world: the countries with the highest greenhouse gas emissions should have more duties. Scientists point out that, by the first quarter of the 21st century, the carbon dioxide content in the atmosphere increased by 40% and the methane gas content by 150% compared to the years when the industrial revolution began (Euronews, 2015). China and the United States are the most prominent countries in terms of greenhouse gas emissions, while they are followed by countries such as AB-27, India, Russia, Japan and Brazil (The World Bank, 2019a).

There are also studies on the impact of the sectors on greenhouse gas emissions as the main factor of global warming (Bayar and Bahrend; 1994; Pekin, 2006; FAO, 2015; Riphah, 2015; Doğan and Kan, 2018; Kanat and Keskin, 2018; EPA, 2019;

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1290912919

Peker et al.; 2019; PSU, 2019), and the impact of each sector is different. Agriculture is an important sector that impacts climate change, also being affected by itself, because it affects the global flow of greenhouse gases. Greenhouse gases such as CO_2, CH_4, and N_2O are counted among the causes of climate change as a result of agricultural activities (energy consumption, plant and animal production, fertilization, pesticide use, etc.) (Houghton, 2003; Akalın, 2014). Agricultural activities are reported to be responsible for about 20% of the growing greenhouse gases in the world (Pathak and Wasmann, 2007). The activities of agriculture, such as the destruction of forests to transform the agricultural field, also greatly increase greenhouse gas emissions. The destruction of forest lands is considered to be responsible for 10% to 30% of the carbon dioxide released into the atmosphere. Therefore, it is the second biggest source of greenhouse gas emissions into the atmosphere after fossil fuel combustion (Harvey et al., 2010). The second important greenhouse gas originating from agricultural activities is methane. Rice cultivation is blamed for more than 40% of global methane emissions. Farm animals account for 15% of global methane emissions. Ruminants (cattle, sheep, goats, camels, and buffalo) digest grass and cellulose. In this way, they release methane into the air. The world's cattle number accounts for about 75% of the methane emissions of total farm animals (IPCC, 2007). However, since methane gas life is considerably lower than that of CO2 gas, CO2 emissions are generally emphasized in research.

The measures to prevent global climate change, as well as, the adaptation strategies for possible adverse effects constitute the main framework of this struggle. In the world, each country is creating its own strategy against adverse effects of climate change, and these strategies sometimes turn into a common struggle with regional integrations or national integrations. The provision of governance collaboration in the fight against climate change (mitigation, adaptation, and resilience) is one of the most important phases (Peker et al., 2019). Therefore, in regional integrations based on economic co-operation, the issues of combating climate change need to be more involved and the increase of collaborations is necessary.

The D-8 organization (Developing 8), which was established to act as a partner in the global system based on economic cooperation, consists of 8 countries (Bangladesh, Indonesia, Iran, Malaysia, Egypt, Nigeria, Pakistan, Turkey). Its foundations were laid in October 1996 at the invitation of Prof. Dr. Necmettin Erbakan, the former Prime Minister of the Republic of Turkey, at the "Cooperation in Development Conference" organized in Istanbul with the participation of representatives of those countries. After a series of preparatory meetings following the Cooperation in Development Conference on October 22, 1996, the establishment of the D-8 was formally announced at "the Summit of the Heads of State and Government" organized in Istanbul on June 15, 1997 (Istanbul Declaration). The purpose of the D-8 is to increase trade and co-operation between the Member States. The aim of launching the D-8 initiative is to create and diversify new opportunities in trade relations between 8 countries representing a large economic potential, various sources, a wide population and geographical area, and to increase participation in the decision making process at international level, to provide better life conditions, to improve economic co-operation around concrete joint projects and to strengthen the situation of developing countries in the world economy. Agriculture and food safety, renewable energy resources, industry, transportation, tourism are some of the main issues that are expected to be cooperated (D-8 OEC, 2019a).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1290912919

The D-8 has established a common platform for advocating the rights of developing countries against developed countries, especially in the World Trade Organization (WTO) decisions, with the goal of targeting more global partnerships than regional integration. In addition, this common platform has played an important role in protecting the rights of countries in determining the measures and responsibilities of the countries on the global CO_2 emissions causing climate change. For the first time, at the Malaysia-Kuala Lumpur Declaration in 2008, it was reported as follows: *"Recognizing the adverse impacts of global warming and climate change on development, we reaffirm our commitment to enhance cooperation in climate change negotiations following the Bali Roadmap to support the adaptation efforts of the developing countries, especially those of the least developed and the low-lying coastal countries and uphold the principle of common but differentiated responsibilities in mitigation of the emission of greenhouse gases"* (D-8 OEC, 2019b). In the 2012 Islamabad declaration, it was noted that the effects of climate change in sustainable and inclusive development should have also been considered (D-8 OEC, 2019c). The development of joint adaptation strategies against the impacts of climate change and need to be working to reduce the adverse effects, which may arise primarily from global warming, on the people of the D-8 countries were reported again in the 2017 Istanbul Declaration (D-8 OEC, 2019d).

It is clearly seen that climate change threatens human welfare and agricultural production, considering that nearly 2.5 billion people in developing countries earn their lives from agriculture. The D-8 countries constitute 13.94% of the world's agricultural production (465.7 billion $) (the World Bank, 2019b) according to 2017 data, and 6.20% of the world's CO_2 emissions according to 2014 data (The World Bank, 2019a). According to the data of 2016, the gross production value of beef is examined as $258,084,093 in Bangladesh, $2,636,059,545 in Egypt, $3,428,638,282 in Indonesia, $1,845,763,741 in Iran, $68,611,219 in Malaysia, $559,357,239 in Nigeria, $2,608,695,845, and also $6,217,254,585 in Turkey. The gross production value of mutton is $ 9,036,936 in Bangladesh, $490,525,023 in Egypt, $275,071,662 in Indonesia, $1,044,326,227 in Iran, $146,262 in Malaysia, $265,000,401 in Nigeria $328 274 105 in Pakistan and $2,173,555,064 in Turkey. Poultry gross production value is $228,811,476 in Bangladesh, $1,775,763,964 in Egypt, $ 6,918,959,386 in Indonesia, $8,275,937,537 in Iran, $280,193,375 in Malaysia, and $252,579,138 in Nigeria, $2,529,530,629 in Pakistan and also $3,943,021,371 in Turkey. Looking at the CO_2 emissions of the 8 countries that constitute the D-8, it is seen to be less than China, the United States, the EU-28 and India, which are countries and/or regional unions that are releasing the most CO_2 emissions in the world. Despite this, combating climate change continue to be a common share of global economic partnerships.

In this study, the effects of the animal stock numbers in D-8 countries on CO_2 emissions were investigated by using the panel data set, and for the D-8 meeting to be done thereafter, policy proposals have been attempted to develop measures for the prevention and adaptation of climate change.

Materials and methods

In the study, the relationship of CO_2 emission (kt) with cattle, sheep, and poultry stock numbers in D-8 countries was investigated. The variables and units are presented in *Table 1*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1290912919

Table 1. *Variables, abbreviations and units used in research*

Variable names	Symbols	Units	Data sources
Carbon dioxide emission	CO_2	kt	World Bank, FAO
Cattle stock	C	Head	World Bank, FAO
Sheep stock	S	Head	World Bank, FAO
Poultry stock	P	Head	World Bank, FAO

Some econometric models have been utilized with the help of panel data set in examining the variables and relations between countries. The research covers the years between 1990 and 2017. Eight countries, called D-8, constitute the research area. These countries are Bangladesh, Indonesia, Iran, Malaysia, Egypt, Nigeria, Pakistan, and Turkey. The research is based on two fundamental analyses. The data evaluated in full logarithmic form was analyzed by the unit root test and ARDL. Descriptive information for tests can be expressed as follows.

Unit root test (ADF)

The unit root tests have several fractions, which are proposed by researchers in the literature (Maddala and Wu, 1999; Kao and Chiang, 2000; Hadri, 2000; Choi, 2001; Levin et al., 2002; Im et al., 2003). This study uses Levin, Lin, Chu (LLC) and Im, Peseran, Shin (IPS) unit root tests based on the Augmented Dickey Fuller (ADF) test statistic. Basic equality for unit root tests based on ADF principles can be expressed as follows:

$$\Delta lnX_{it} = \beta_i lnX_{it-1} + \sum_{j=1}^{n} \theta_{ij} \Delta lnX_{it-j} + e_{it} \quad \text{(Eq.1)}$$

Autoregressive distributed lag (ARDL)

In the literature, the Engle-Granger (1987) models based on error term and Johansen (1988) and Johansen and Jesilius (1990) models based on the system approach (Altıntaş, 2013) are often used in cointegration tests. However, in order for these methods to be valid, all variables must be stationary at level I(1) and not stationary at the level I(0) (Peseran et al., 2001). The ARDL boundary test approach allows for co-integration testing with non-stationary series at the same level (Pesaran and Shin, 1995; Pesaran et al., 2001). The advantage of the ARDL approach is that it is possible to test the cointegration without considering the degree of integration of variables. There are three important points to be considered in the method. I- The boundary test procedure is easy and, unlike multivariate co-integration methods of Johansen and Juselius (1990), it is possible to verify co-integration after lag lengths are determined. II- Unlike the co-integration techniques of Johansen and Juselius (1990), the boundary test procedure does not require preliminary testing of the variables included in the unit root test model. The boundary test can be applied, regardless of whether I (0) and I (1) or all of them are mutually co-integrated at the same level except when the series in the model is at the level I (2), I (0) and I (1). III-Boundary testing is very effective for small or limited sample size.

ARDL notations adapted to the research were expressed in *Equations 2–5:*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1290912919

$$\Delta \ln CO2 = \beta_0 + \sum_{i=1}^{m} \beta_{1i} \Delta \ln CO2_{t-i} + \sum_{i=0}^{m} \beta_{2i} \Delta \ln C_{t-i} + \sum_{i=0}^{m} \beta_{3i} \Delta \ln S_{t-i} + \sum_{i=0}^{m} \beta_{4i} \Delta \ln P_{t-i} + a1 \ln CO2_{t-1} + a2 \ln C_{t-1} + a3 \ln S_{t-1} + a4 \ln P_{t-1} + u_t \quad \text{(Eq.2)}$$

$$\Delta \ln C = \beta_0 + \sum_{i=1}^{m} \beta_{1i} \Delta \ln C_{t-i} + \sum_{i=0}^{m} \beta_{2i} \Delta \ln CO2_{t-i} + \sum_{i=0}^{m} \beta_{3i} \Delta \ln S_{t-i} + \sum_{i=0}^{m} \beta_{4i} \Delta \ln P_{t-i} + a1 \ln CO2_{t-1} + a2 \ln C_{t-1} + a3 \ln S_{t-1} + a4 \ln P_{t-1} + u_t \quad \text{(Eq.3)}$$

$$\Delta \ln S = \beta_0 + \sum_{i=1}^{m} \beta_{1i} \Delta \ln S_{t-i} + \sum_{i=0}^{m} \beta_{2i} \Delta \ln CO2_{t-i} + \sum_{i=0}^{m} \beta_{3i} \Delta \ln C_{t-i} + \sum_{i=0}^{m} \beta_{4i} \Delta \ln P_{t-i} + a1 \ln CO2_{t-1} + a2 \ln C_{t-1} + a3 \ln S_{t-1} + a4 \ln P_{t-1} + u_t \quad \text{(Eq.4)}$$

$$\Delta \ln P = \beta_0 + \sum_{i=1}^{m} \beta_{1i} \Delta \ln P_{t-i} + \sum_{i=0}^{m} \beta_{2i} \Delta \ln CO2_{t-i} + \sum_{i=0}^{m} \beta_{3i} \Delta \ln S_{t-i} + \sum_{i=0}^{m} \beta_{4i} \Delta \ln C_{t-i} + a1 \ln CO2_{t-1} + a2 \ln C_{t-1} + a3 \ln S_{t-1} + a4 \ln P_{t-1} + u_t \quad \text{(Eq.5)}$$

In *Equations 2–5,* however, Δ refers to the difference processor, and m refers to the lag length. Information criteria such as AIC, SC, FPE, and HQ are utilized for determining the lag length. The lag length, which provides the smallest critical value, is determined as the model's lag length. Until reaching the model without autocorrelation, the process is resumed by passing the next lag value, for example, the first smallest value, the second smallest, etc. In Equations 2-3-4-5, H_0 hypothesis expressing that there is no co-integration between variables is formed as H_0: a1 = a2 = a3 = a4, the alternative hypothesis that mentions the existence of co-integration is formed as H_1: a1≠a2≠ a3≠ a4.

Results and discussion

Regional partnerships increase the capacity of countries to economically collaborate in the process of globalization, which is a great advantage for developing adaptability to global challenges. In these challenges, global climate change is the first of the most talked and debated issues nowadays. The factors that cause global climate change and the solution proposals against it require efforts to create an international policy outside of national policy creation. The struggle with this problem is only possible with collaboration (Peker et al., 2019).

The D-8 organization, which is an important step in regional, economic and social partnership, has an important potential in agriculture. In terms of total agricultural production, it produces 13.94% of the world's agricultural production according to 2017 data (465.7 billion $) (The World Bank, 2019b), constitutes the 8.75% of the world's bovine existence, 21.55% of chicken existence, 25.06% of goat existence, and 13.98% of sheep existence (FAOSTAT, 2019). As seen from *Figure 1,* Pakistan is the leading country for the cattle stock numbers between D-8 countries. Nigeria, Pakistan, Iran, and Bangladesh are the leading countries for the sheep stock numbers. Also, Indonesia and Iran are the leading countries for poultry stock numbers.

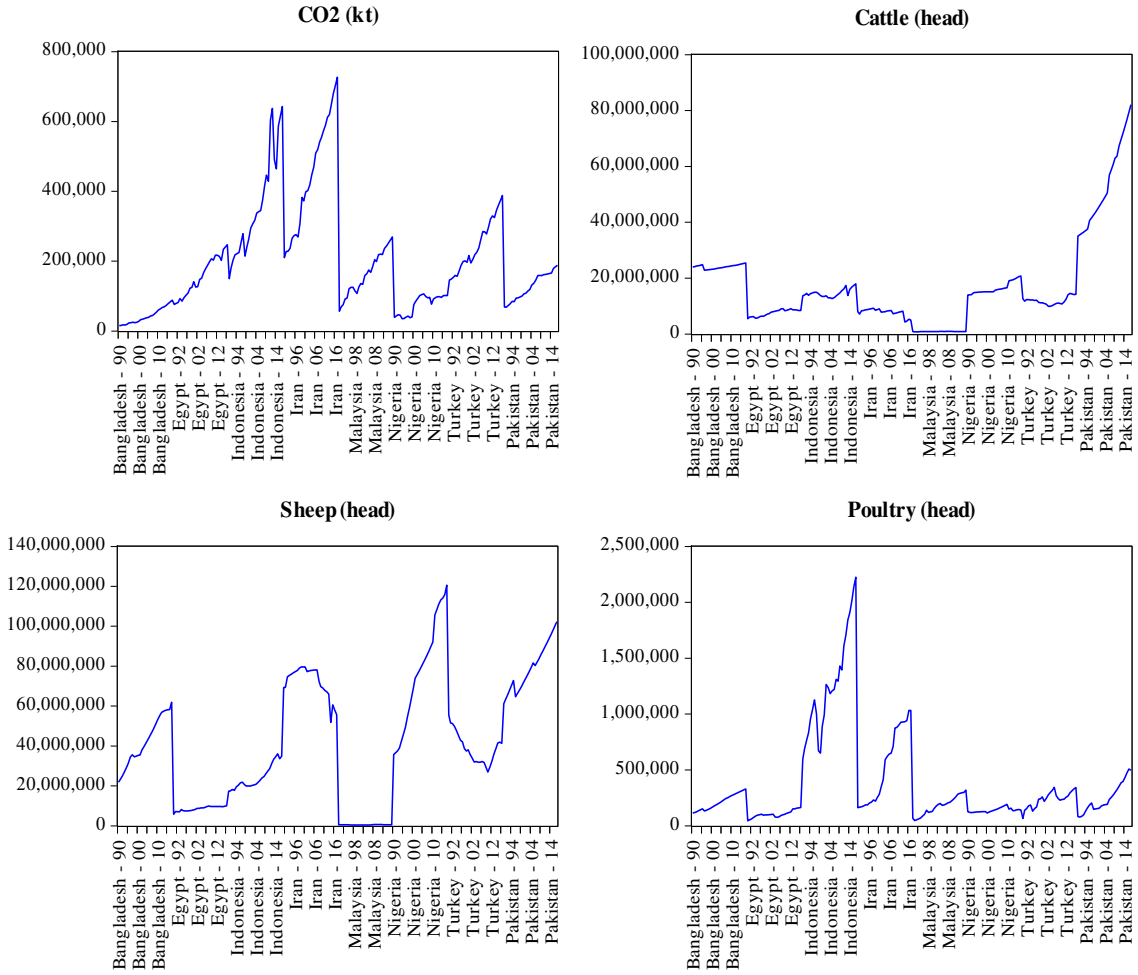

Figure 1. *CO_2 emission, cattle stock, sheep stock and poultry stock of D-8 countries by 1990-2017 years*

In econometric forecasts, the stationary of time series is important. Granger and Newbold (1974) showed that working with non-stationary time series might cause a false regression problem. In the study, if the results of the Levin, Lin, Chu, and Im, Peseran, Shin unit root test are examined, they can be seen as stationary in both Intercept and Intercept + Trend models. The unit root test results of the variables used in the study are given in *Table 2*.

In this study, the long run effects of bovine, sheep and poultry stock factors on CO_2 emissions were quantitatively determined, and they could be said to be in interaction with each other. However, in order to interpret the direction and severity of these interactions, ARDL analysis was performed and the results were shown in *Table 3*. *Table 3* shows that the contribution of cattle and poultry to CO_2 emissions in the long run in D-8 countries were positive and statistically significant, whereas the contribution of sheep stock was positive but statistically insignificant at 95% confidence level.

In evaluating the emergence of this situation, it is necessary to consider firstly the relationship between animals and global warming. When animal husbandry activities are evaluated in terms of global warming, two kinds of effects, direct and indirect, occur. Methane, one of the most important causes of global warming, primarily creates greenhouse gas effects, while the CO_2 effect is second-degree important. The heat-capture capacity of methane in the atmosphere is 21 times higher than CO_2, and its life

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1290912919

is shorter than other gases (Naqvi and Sejian, 2011). Methane gas is emerging as a result of the storage of fertilizers of animals, especially ruminant animals, and related activities (Sherlock et al., 2002). Ruminants are defined by their structures with a special digestive system. In this way, ruminants are an important methane producer with the greenhouse gases they produce as a result of their comfortable digestion of low-quality cellulose-rich materials. In fact, animals produce very small amounts of methane individually. For example, a cattle produces approximately 80-110 kg of methane per year. At this point, however, the main reason for the responsibility of ruminants is their numbers worldwide rather than the amount of gas they produce. This situation results in a significant contribution to emissions (Koyuncu and Akgün, 2017). From here, the presence of animals itself directly contributes to global warming as a factor.

The indirect effect of animal stock on global warming is sourced from the need for energy in the production of animal foods that are a need for human. The energy requirement used in the feeding chain produces 10% of total CO_2 emissions. The most important source of the resulting CO_2 emissions is animal production and it is said to be equivalent to 9% of total emissions (Clarke, 2001). The source of the resulting emission is not directly the animal itself, but the CO_2 generated by the energy used in feed production, fertilizer processing, product processing, and transport has a significant share (Anonymous, 2012). According to the 2017 data, per capita CO2 levels in D-8 countries were 553.74 kg in Bangladesh, 2564.37 kg in Egypt, 2428.09 kg in Indonesia, 9006.33 kg in Iran, 8651, 53 kg in Malaysia, 532, 98 kg in Nigeria, in Turkey, and 905.88 kg in Pakistan (World Bank, 2019).

In the D-8 countries, because of the fact that sheep breeding is mostly based on pasture, less energy is consumed for the production of feed plants required for these animals than for other animal groups. This could lead to no statistically significant contribution of the sheep stock to the CO_2 emissions in the analysis. In addition, corn production from feed plants, which has a significant share in cattle and poultry production, requires a significant amount of nitrogenous fertilizer (HSUS, 2008). In response to this imperative, the nitrogenous soil pollutes water and air at a significant level. According to FAOSTAT data of 2017, D-8 countries are among the major corn producing countries in the world, especially Indonesian is sixth in corn production worldwide. Indonesia, Nigeria, Egypt, Turkey, and Pakistan, respectively, are among the first 22 countries in the production of corn. D-8 countries have 7.75% (15.3 million ha) of the world corn production area and realize 5.41% of production (61.4 million tons) (FAOSTAT, 2019).

Conclusion

The contribution of direct agricultural production to climate change is lower compared to other sectors, and it plays an important role to meet the basic needs of humanity. In the process of adaptation to climate change, it will be wrong to consider both the vegetable and animal part of the agricultural production separately and to make the planning in direction to that. The result of the study reveals that the indirect effects of livestock activity can be effective in CO_2 emissions as much as livestock numbers. Although the animal husbandry has a direct share in global warming, the role of unconscious input use in the production of feed crops, and the role of animal products processing industry, especially corn for animal feeding, are more important for climate change. Nowadays, it is emphasized that national country policies are not sufficient

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1290912919

alone and that it is more effective to act together in the struggle and adaptation of climate change. It is important that the D-8 countries, which have an important agricultural share in the world, should meet and act on common denominators in economic cooperation as well as climate change. In this context, working together not only in livestock but in all aspects of agriculture will have an impact on the development of more effective policies in terms of mitigation and adaptation of climate change impacts. Global climate change can be directly and indirectly influenced by the quality and quantity of feed given to animals, feeding strategies, seasonal availability of pastures, genetic studies, number of animals and animal health. Accordingly, some recommendations such as the correct setting of the sowing dates of the feed sources, the right practices for shelter air conditioning, the right approaches to pest and disease control (monitoring, crop rotation, diversity, etc.), the more efficient use of water, soil management and the selection of animals from the right breeds according to the region/conditions could be evaluated.

ASSESSMENT OF VALUE FOR CULTIVATION AND USE (VCU) TRIAL DATA BY GGE-BIPLOT ANALYSIS IN BREAD WHEAT (*TRITICUM AESTIVUM* L.)

AKTAS, B.

Variety Registration and Seed Certification Center, Ankara, Turkey
(e-mail: bekir_aktas@yahoo.com; phone: +90-538-433-6374; fax: +90-312-315-0901)

(Received 21st May 2019; accepted 10th Sep 2019)

Abstract. The study was carried out with 17 bread wheat (*Triticum aestivum* L.) genotypes in 7 different environments under rain-fed conditions of the Thrace region in Turkey during 2014-2015 and 2015-2016 growing seasons. Value for cultivation and use (VCU) trial data on yield and quality traits (1000-kernel weight, test weight, protein content, Zeleny sedimentation and alveograph energy value) of bread wheat genotypes were assessed through GGE-biplot analysis. Variance analysis revealed significant genotype (G) × environment (E) interaction (GEI). GGE-biplot analysis explained 79.18% of total variation. Environment-focused assessments revealed 3 mega-environments (ME). E7 (Luleburgaz-2016) was identified as the best representative of all environments and had the greatest separation power among the genotypes. According to the average environment coordinate (AEC), of the genotypes with high PC1 (Principal component) scores, the ones with a PC2 score close to 0.0 were identified as the most stable genotypes. G15, G14, G10 and G13 were the closest genotypes to AEC apsis and they had high PC1 scores. Biplot graphs were generated for 5 quality traits and stabilities of genotypes were put forth based on their positions with respect to AEC. In VCU trials, 5 control cultivars were also used and the average of control cultivars (AC) was generated. AC-focused comparisons of the genotypes were performed. It was concluded based on the present findings that GGE-biplot analysis facilitated the assessments of VCU trial data on yield and quality traits.
Keywords: *genotype × environment interaction, grain yield, quality, stability, multi-environment trials*

Introduction

Wheat is among the leading agricultural products of Turkey with optimal available ecological conditions for its culture. Since the country is composed of different agro-ecological zones, breeders are directed to select appropriate genotypes for these zones or regions. Therefore, variety registration trials for wheat are conducted regionally. In the variety breeding efforts, selection criteria vary based on climate, soil, diseases and pests of the region. In other words, varieties developed by breeders in accordance with their regional adaptation capacities are tested in official registration trials.

In VCU trials, Thrace and Southern Marmara constituting the Marmara region are taken into consideration under different categories due to the different environmental conditions of these two zones. The Thrace region has the second greatest annual precipitation after the Black Sea region according to long-term climate data (TSMS, 2018).

In VCU trials, candidate varieties are compared to control cultivars. The registration committee assesses the candidate varieties for yield, quality, resistance to diseases and economic value and then the ones equivalent to or better than the control cultivars are registered (RTMAF, 2008). Widely cultivated and accepted varieties by both the farmers and the industry are used as the control varieties in VCU trials. The VCU trials are conducted during at least two growing seasons and in at least 3 locations in each growing season. The varieties are grouped according to their performance using several statistical analyses. However, genotypes may have different responses to varying

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1292112936

environmental conditions. Genotype by environment interaction (GEI) is a phenotypic outcome of interaction between genotype and environment (Gebru et al., 2011). The phenotypic effects manifest themselves in yield, quality, diseases or the other attributes. Plant breeders consider phenotypic characteristics of the genotypes in different environments while selecting genotypes under the existence of GEI. In VCU trials, variety register experts assess the performance of candidate varieties in different environments. Although regional adaptation is taken into consideration in wheat VCU trials of Turkey, each region is divided into sub-regions or zones with different ecologies.

The significance of GEI is attempted to be revealed through variance analysis and different statistical parameters have been developed to elucidate response of genotypes to different environmental conditions. In the present study, GGE-Biplot method developed by Gabriel (1971) to assess G and GEI in multi-environment and multi-genotype trials was used. Biplot analysis facilitates a visual presentation of data. The method separates environments into mega environments based on genotype performances and points out which genotype is better in which environment (Yan et al., 2000). Biplot analysis also allows the user to compare the genotypes and environments and to estimate ideal genotypes for each environment, thus facilitate the assessment of VCU trials. For bread wheat, previous researchers used biplot analysis to assess yield (Kaya et al., 2006; Tulu and Wondimu, 2019), quality (Aktas et al., 2017) and disease data (Akcura et al., 2017). Xu et al. (2017) pointed out the significance of superior cultivars in cultivar registration system and indicated that quality should also be taken into consideration besides the yield levels in cotton. Researchers convert environment into a trait in GGE-biplot analysis and assessed candidate cultivars through GT-Biplot (Genotype by trait) by scaling all traits. GGE-Biplot analysis was used to assess cotton genotypes (Farias et al., 2016), maize genotypes (Oyekunle et al., 2017), barley genotypes (Solonechnyi et al., 2015) and potato genotypes (Flis et al., 2014).

The supports provided for certified seeds have brought about significant developments in the seed industry of Turkey. The number of varieties brought from abroad and applied for registration increased significantly. The majority of these varieties are Europe-originated ones and applied for registration in irrigated or rain-fed conditions of Thrace and Central Anatolia regions. It is quite significant to test candidate varieties together with control cultivars in different environments and to assess the trial outcomes together. Recent climate extremities increased the significance of variety stability. Put forth of response of candidate varieties to poor and ideal environmental conditions through VCU trials will facilitate the decision of the registration committee.

This study was conducted with 17 bread wheat genotypes at 7 different environments under rain-fed conditions of Thrace region in 2014-2015 and 2015-2016 growing seasons to assess genotype-environment interactions for grain yield and some quality traits through variety registration trials.

Materials and methods

Present experiments were conducted with 17 bread wheat genotypes at 7 different environments of the Thrace region in 2014-2015 and 2015-2016 growing seasons in randomized blocks design with 4 replications. Growing seasons and locations are provided in *Table 1* and locations are also shown on the map (*Fig. 1*). 12 bread wheat

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

genotypes (Energo, Yigit, Maya, Asli, Huseyinbey, Dunaviya, Pannonia, Misiia Odes'ka, Rebelde, Nomade, Os Jelena and Duru 17) and 5 control cultivars (Gelibolu, Kate A-1, Selimiye, Pehlivan, Krasunia odes'ka) were the plant material of the study. Experiments were set up on 9 m long plots with 6 rows in each plot spaced 17.0 cm apart. Sowing was performed with a 6-row grain drill as to have 500 seeds per m^2 arranged based on thousand-seed weight of the varieties. To each plot, 200 kg ha^{-1} composed fertilizer (20-20-0) was applied at sowing, 150 kg ha^{-1} urea (46%) was applied in February and 180 kg ha^{-1} ammonium nitrate (26%) was applied in April. Harvest was performed in the last week of June with a plot combine harvester. Side effects were omitted from the plots and harvest area 8 m^2 was used in assessments.

*Control cultivars

Figure 1. *The view of experimental locations on the map*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1292112936

Quality criteria such as 1000-kernel weight, test weight, protein content, Zeleny sedimentation and alveograph energy values were determined. For 1000-kernel weight, 4 × 100 kernels were randomly selected. They were then weighed to calculate 1000-kernel weight. Results were expressed in dry matter. Hectoliter or test weight was determined in accordance with Uluoz (1965). Protein content was determined in accordance with ICC 105/2 method and results were expressed in dry matter (ICC, 2002a). Zeleny sedimentation analysis was performed in accordance with ICC 116-1 method (ICC, 2002b) and alveograph analysis was performed in accordance with AACC 54.50 (AACC, 2000).

Monthly precipitation and average temperatures of the experimental locations for growing seasons are provided in *Table 2*. In the first growing season, total precipitations were greater than the long-term averages in Edirne, Luleburgaz and Tekirdag locations and lower than long-term averages in Kesan location. In the second growing season, all locations, except for Edirne, had total precipitations lower than the long-term averages. With regard to total monthly precipitations, deviations were observed from the long-term averages in both experimental years. In general, monthly average temperatures were greater than the long-term averages in all locations. Especially in the second growing season, average temperatures were quite greater than both the first growing season and the long-term averages.

Since the locations were not same to each growing season, statistical analyses for yield and quality parameters were performed through assuming each location as an environment. For grain yield, a combined variance analysis over the environments was performed. The GGE biplot method was used to identify genotype-environment interactions for yield and quality parameters. GenStat (Genstat, 2009) statistical analysis software was used for GGE-Biplot analysis.

Results and discussion

Grain yield

Results of combined variance analysis over the environments for grain yields are provided in *Table 3*. According to variance analysis, G, E and GEI were found to be significant ($p < 0.01$). The coefficient of variation was calculated as 8.96%.

The mean yields of bread wheat genotypes over 7 environments are given in *Table 4*. The highest yield was obtained from E1 (Kesan-2015) environment and the lowest yield was obtained from E4 (Edirne-2016) environment. Considering the results obtained from all environments, the genotype G15 (Nomade) had the greatest grain yield. G14, G10, G9 and G13 were in the same statistical group with G15. With regard to grain yield of G15 in different environments, it gave the highest yields in E4, E6 and E7 environments. However, for grain yield performance, G15 was ranked as 14^{th} in E1 and 13^{th} in E3 environment. Considering the grain yields of the other genotypes, they exhibited more or less different performances in different environments.

GGE-biplot analysis was able to explain 79.18% of GGE-induced variation in the grain yields of 17 bread wheat genotypes tested at 7 different environments. In the environment-focused model, GGE ratio was 62.50% over PC1 axis and 16.68% over PC2 axis. Also, in the environment-focused GGE-biplot graph, all of the environments had positive PC1 values and such a case indicate the existence of non-crossover GEI (*Fig. 2*). For PC2, environments had either negative or positive values. With regard to PC2, environments indicated the existence of crossover GEI. The vector lengths from

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1292112936

the biplot origin and the angles between the vectors of the environments were different. Vector lengths of the environments indicate the separation power among the genotypes (Yan and Kang, 2003). The angles between the vectors reveal significant information for comparison of the environments. Lower angles between the vectors indicate increasing similarity between the environments and closer response of genotypes in those environments (Yan, 2001). Obtuse angle between E1 (Kesan-2015) and E5 (Tekirdag-2015) vectors indicate that the performance of environments or genotypes was not similar. On the other hand, acute angles between E2, E3, E4, E6 and E7 vectors indicated that these environments were placed in the same mega-environment (*Fig. 3*). E1 and E5 constituted the other 2 mega-environments.

[1]Control cultivars
[2]Least Significant Difference (LSD) of genotypes: 0.312 (for alpha 0.05)
[3]Codes of environments are given in *Table 1*

For the assessment of multi-environment trials, initially mega-environments were determined to explain which-won-where model. Polygon view of GGE-biplot is an efficient means of data assessment (Yan and Kang, 2003; Yan, 2014). A polygon view is generated through connecting genotype pointers furthest located from the biplot origin and called as a vertex (*Fig. 3*). Eight orthogonal rays were drawn from the biplot origin to polygon sides or side extensions. In this way, 8 sectors were generated including environments and genotypes. Vertex genotypes are considered as the best genotype of that sector and the genotypes between the vertex genotype and the biplot

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1292112936

origin were considered as less sensitive. Despite 8 sectors were generated with the rays drawn, there were 3 mega-environments (ME) in the biplot graph. E1 (Kesan-2015) constituted ME-1; E2 (Kesan-2016), E3 (Edirne-2015), E4 (Edirne-2016), E6 (Tekirdag-2016) and E7 (Luleburgaz-2016) constituted ME-2 and E5 (Tekirdag-2015) constituted ME-3. G12 (Pannonia) and G8 (Maya) were identified as vertex genotypes of ME-1, G15 (Nomade) was the vertex genotype of ME-2 and G9 (Asli) was identified as the vertex genotype of ME-3.

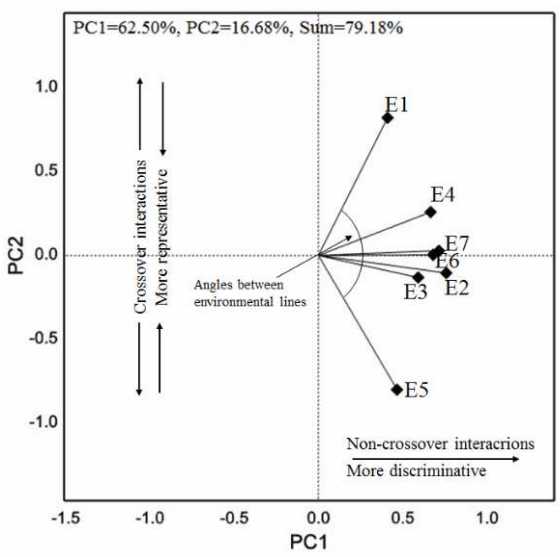

Figure 2. *The vector view of the GGE biplot among the trial environments. Abbreviations of environments are given in Table 1*

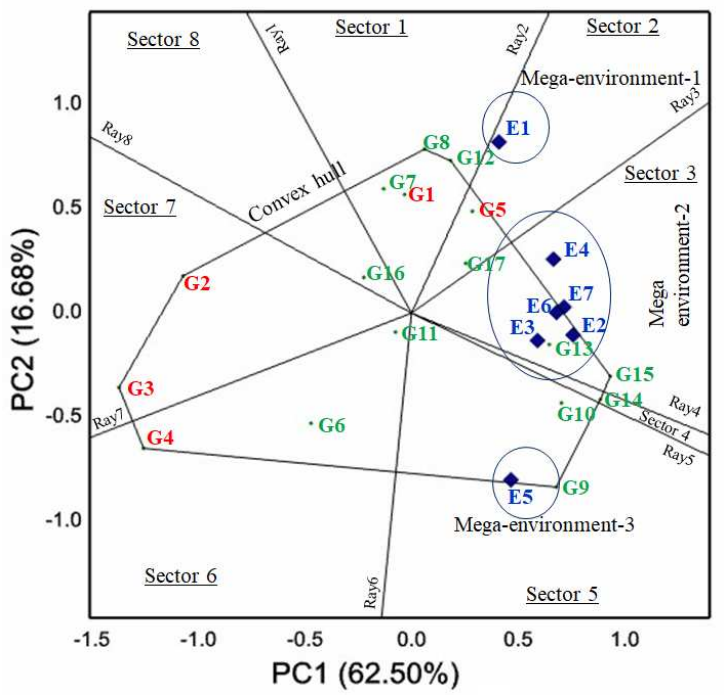

Figure 3. *The polygon view of the GGE biplot based on pattern for 17 bread wheat genotypes and trial environments. Codes of environments and genotypes are given in Table 1*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1292112936

In *Figure 4,* the average environment coordinate (AEC) connecting average environment point representing the entire environments to biplot origin was drawn. In this way, the apsis of AEC was formed. The ordinate of AEC passes through the biplot origin and is orthogonal to AEC apsis (Yan and Kang, 2003). The arrow on AEC apsis shows the direction from the lower genotype effect to the higher genotype effect. AEC ordinate expresses bi-directional effect and indicates decreasing stability as moved away from the AEC apsis (Yan, 2001; Yan, 2002). From the ordinate of AEC to high performance along the AEC apsis, genotypes were respectively ordered as G8, G12, G17, G5, G13, G9, G10, G14 and G15. The other genotypes were left below the average. Considering the distances of genotypes (vector lengths) between AEC ordinate and average from the AEC apsis, it was observed that G13 was the closest cultivar to AEC apsis. The genotypes of G15, G14, G10 and G13 with high PC1 values and relatively shorter vector lengths to AEC apsis were expressed as stable genotypes. Although G9, G12 and G8 were above the average, they placed furthest to AEC apsis. In other words, although these cultivars were above the average, they were not able to exhibit stable performance in changing environments, thus they were considered as less stable cultivars. G11 was the closest cultivar to biplot origin, thus exhibited the least reaction to changing environments.

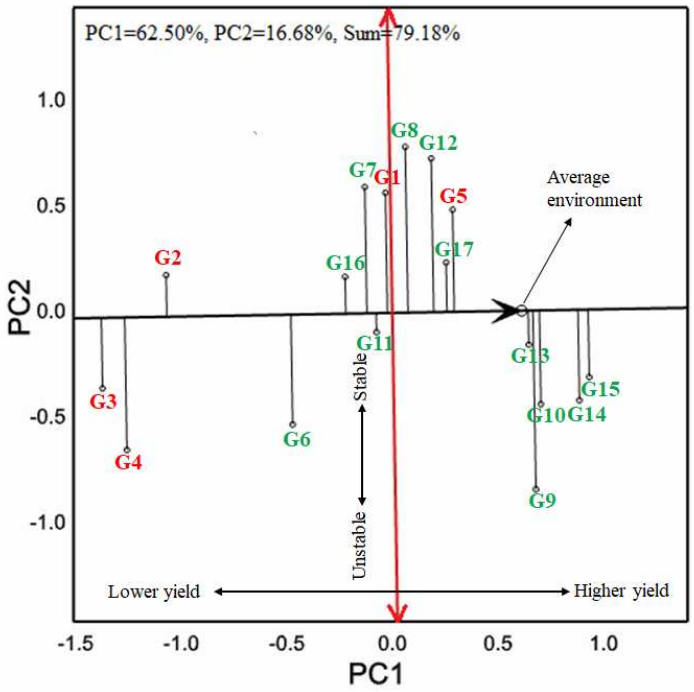

Figure 4. *The view of the distribution according to AEC of 17 bread wheat genotypes. Codes of genotypes are given in Table 1*

From a different perspective, assessments were made based on the ideal genotype in *Figure 5a*. The innermost circle represents the ideal genotype and the other circles represent the distance of other genotypes to the ideal genotype circle. G15 placed on the border of the innermost circle. G14, G10 and G13 were close to the ideal genotype region. Gradually increasing circle diameters indicate the way to undesirable genotypes region.

DOI: http://dx.doi.org/10.15666/aeer/1706_1292112936

As it was in ideal genotype-focused assessments in *Figure 5a,* the environment-focused assessments are presented in *Figure 5b*. The environment E7 (Luleburgaz-2016) placed closest to the ideal environment center. Thus, E7 was considered as the best representative of all environments and thus had the greatest power of separation for genotypes. E1 and E5 were placed furthest from the ideal environment circle. These two environments constituted separately the ME-1 and ME-3 as presented in *Figure 3*.

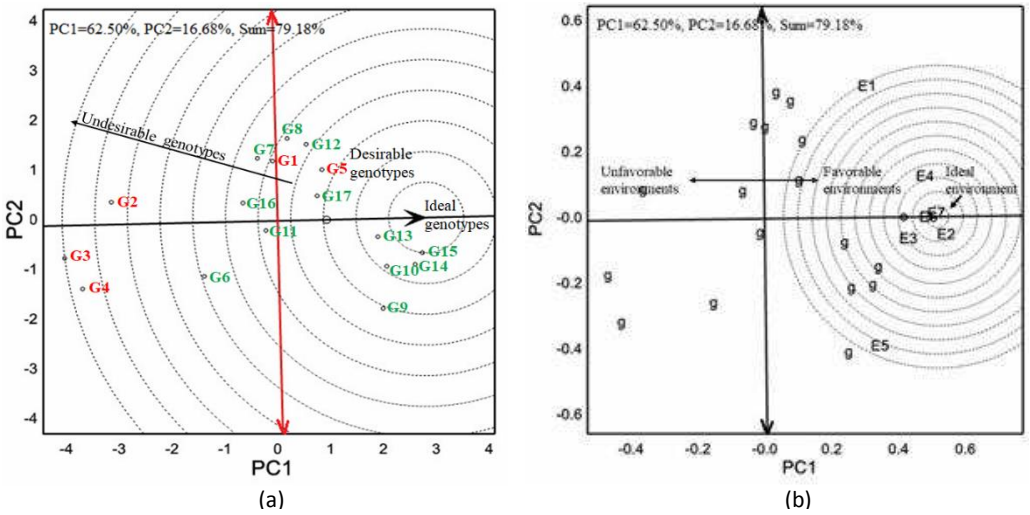

Figure 5. *(a) Comparison of 17 bread wheat genotypes with the ideal genotype. (b) Comparison of test environments with the ideal environment. Codes of environments and genotypes are given in Table 1*

Quality traits

The 1000-kernel weights, test weights, protein contents, Zeleny sedimentation and alveograph energy values of 17 bread wheat genotypes tested at 7 different environments are provided in *Table 5*. The variance analysis revealed significant differences ($p \leq 0.01$) in the quality traits between genotypes. The biplot graphs were generated separately for each quality trait. In VCU trials, candidate varieties are compared with the control varieties in terms of performance and adaptability. For quality criteria, the average of control cultivars (AC) was generated over the average of G1, G2, G3, G4 and G5 accepted as the control cultivars in each environment and candidate varieties were assessed on biplot over AC values.

Thousand-kernel weight

Regarding 1000-kernel weight, the genotypes G7, G10, G13, G11, G5, G1, G3, G6 and G4 gave PC1 values above the AEC ordinate (*Fig. 6a*). Among them, G4 had the greatest average 1000-kernel weight with the greatest vector length to AEC apsis. G7 and G8 were quite close to biplot origin, thus they were considered as the least sensitive to the environment. Of the genotypes with positive PC1 scores, except for G4 and G10, the others had close vector lengths to AEC. When the 1000-kernel weights were assessed over AC values, it was observed that G6 was the only genotype with a value greater than AC (*Fig. 6b*). Except for G6, all the other genotypes had values lower than AC. G14 had the lowest 1000-kernel weight, thus placed furthest to AEC and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1292112936

considered as the least stable variety (*Fig. 6a*). The 1000-kernel weight is a significant yield parameter and greatly influenced by the genotype and environment (Mut et al., 2005). Besides being a yield component, it also reveals significant information about the flour yield (Aydogan and Soylu, 2017). With the GGE-biplot analysis on 1000-kernel weights, 79.75% of GGE-induced variation was explained.

Table 5. *Mean and standard deviation of some quality characteristics of 17 bread wheat genotypes tested across 7 environments*[1]

[2]Control cultivars
**Significant at 0.01 probability level

Test weight

The genotypes of G2, G12, G11, G9, G14, G1, G4, G6, G3 and G16 had high PC1 values greater than the average on the test weight's biplot graph (*Fig. 7a*). Since G4 was placed over the AEC apsis indicates it was considered as the most stable genotype. Although G16, G3 and G6 had greater PC1 scores, they had the longest vector lengths to AEC apsis. The G15 with the greatest PC1 score for grain yield had the least PC1 score and a PC2 score of 0.0 for test weight. Besides having the least test weight, G15 proved such a trait in all environments. With regard to control cultivar-focused GGE-biplot, the AC axis had a greater PC1 score than the AEC axis (*Fig. 7b*). Such a case indicated that average of control cultivar was greater than the average of environments. Test weight is a physical analysis like 1000-kernel weight and reveals information about the shape, size and density of kernels (Bulut, 2012; Aktas et al., 2017).

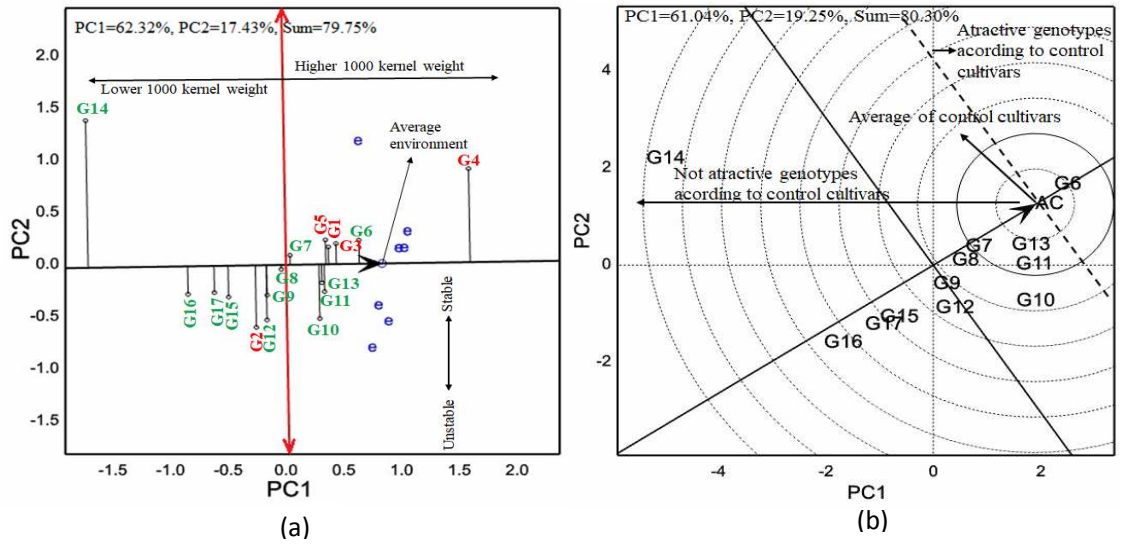

Figure 6. *(a) The view of the distribution of 1000 kernel weight of 17 bread wheat genotypes according to AEC. (b) Comparison of 12 bread wheat genotypes in terms of 1000 kernel weight with the average of control cultivars (AC). Codes of genotypes are given in Table 1*

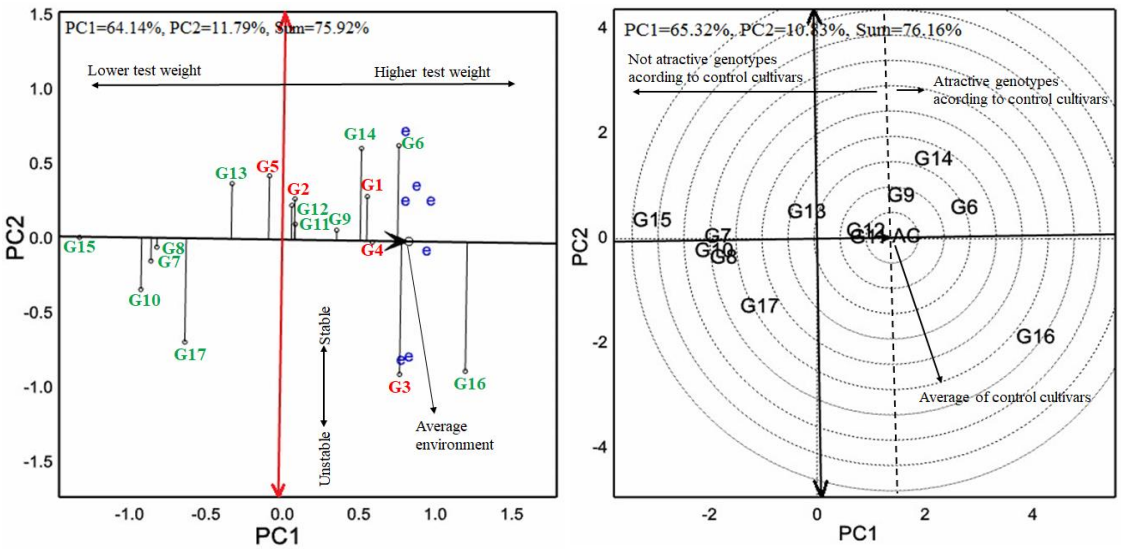

Figure 7. *(a) The view of the distribution of test weight of 17 bread wheat genotypes according to AEC. (b) Comparison of 12 bread wheat genotypes in terms of test weight with the average of control cultivars (AC). Codes of genotypes are given in Table 1*

Protein content

When evaluating genotypes from the aspect of protein content, G7, G12, G9, G2, G17, G14 and G6 had high PC1 scores over the averages (*Fig. 8a*). Since G9 was placed on AEC apsis, it was considered as the most stable genotype. The G6 was the most prominent genotype since it had the greatest PC1 score and was placed as the second closest genotype to the AEC axis after G9. The G14 had the second greatest PC1 score after G6, but it had a high vector length to AEC. In *Figure 8b,* biplot graphs were

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1292112936

generated through reversing PC1 and PC2 axes. When the assessments were done through comparisons with the control cultivars, it was observed that G10, G13 and G8 were placed behind the AC axis, in other words, they had lower protein contents than the control cultivars. The other genotypes had protein contents of above AC. Protein content is a significant quality trait for bread wheat and greatly influenced by the genotype and environment (Kahraman et al., 2017). Keceli et al. (2017) reported significant positive correlations between protein content and the other significant quality attributes.

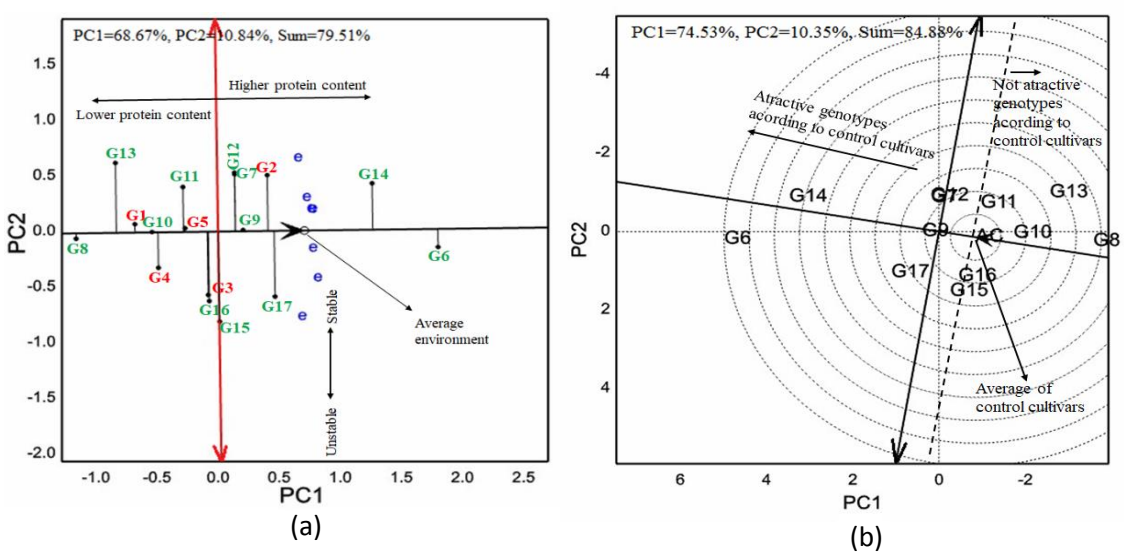

Figure 8. *(a) The view of the distribution of protein content of 17 bread wheat genotypes according to AEC. (b) Comparison of 12 bread wheat genotypes in terms of protein content with the average of control cultivars (AC). Codes of genotypes are given in Table 1*

Zeleny sedimentation and alveograph energy value

With regard to Zeleny sedimentation, G13, G15, G12, G16, G9, G11, G6, G5 and G14 were placed over the average (*Fig. 9a*). G13, G9, G11, G6 and G5 were the closest genotypes to the AEC axis. G14 had the greatest sedimentation score and a high vector length to AEC. G7, G8, G1, G2 and G3 with negative PC1 scores were placed furthest to AEC. These genotypes were behind the average of environments and quite sensitive to the environment. The G17 on biplot origin was considered as the least sensitive genotype to changing environments. When the Zeleny sedimentation values of the genotypes were compared with the values of control cultivars, it was observed that the majority of them had scores of above the AC (*Fig. 9b*). In *Figure 9b,* PC1 and PC2 axes were reversed. G10, G7 and G8 had scores of below AC. Zeleny sedimentation is considered as an indicator of protein quality and high values are desired in bread wheat (Sahin et al., 2017; Aydogan and Soylu, 2017).

Alveograph energy values yield significant information about the bread-making quality of the flour (Aydogan et al., 2012). The genotypes of G11, G16, G17, G12, G1, G5, G14, G9 and G6 had greater values than the average and thus had high PC1 scores, but their vector lengths to AEC were quite different (*Fig. 10a*). G6 had the greatest alveograph energy value. G14 had the greatest vector length to the AEC axis. As it was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1292112936

in protein content, the majority of the varieties had values over the AC axis (*Fig. 10b*). G7, G8, G10 and G15 had lower values than the control cultivars. The other genotypes were above the AC.

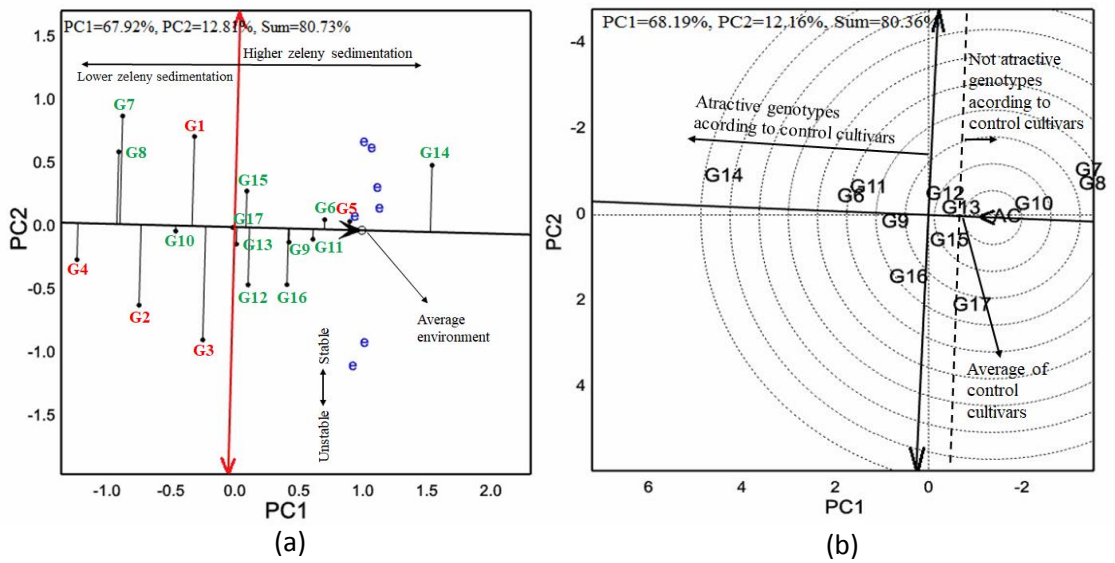

Figure 9. *(a) The view of the distribution of Zeleny sedimentation of 17 bread wheat genotypes according to AEC. (b) Comparison of 12 bread wheat genotypes in terms of Zeleny sedimentation with the AC. Codes of genotypes are given in Table 1*

Conclusion

A general assessment on grain yields revealed that control cultivars (Gelibolu, Kate A-1, Selimiye, Pehlivan, Krasunia odes'ka) had lower values than the average and the other genotypes had close to or greater values than the average. With regard to physical

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1292112936

quality traits (1000-kernel weight and test weight), control cultivars had greater values and genotypes exhibited different performances for the other quality traits. In this study, genotypes with quite high performance for both yield and quality traits were identified. Genotype responses to different environments and their stabilities in different environments were put forth.

The majority of Turkish agricultural lands are used in wheat culture. In recent years, several varieties were brought to Turkey from different countries and they were subjected to VCU trials. Although VCU trials are conducted for wheat based on regional adaptation capacities, climate parameters exhibited great variations from the long-term averages in recent years with the impacts of global warming. Wheat culture is practiced commonly under rain-fed conditions in Turkey, thus changes in environmental conditions play a significant role in the production. Genotype responses to changing environmental conditions with regard to yield, quality, diseases and other agricultural traits should be identified and registration reports should be prepared accordingly. Thrace region of Turkey is among the regions with the greatest number of varieties coming from abroad. Thus, the present study was conducted with 17 bread wheat varieties at 7 different environments of the Thrace region. Present findings revealed that GGE-biplot analysis could reliably be used in VCU trials for yield and quality traits. Grouping of experimental environments based on genotype responses, put forth of which-won-where model visually on graph and comparisons of environments and genotypes yielded quite significant assessments for the VCU trial reports.

Performance of registration experiments for new cultivars developed through long-term breeding programs is a significant issue for both breeders and growers. Grain yield is the most significant criterion for bread wheat in Turkey. Despite the satisfactory levels in grain yields, quality then became a dominant criterion in recent years. High stability in quality attributes besides high stability in grain yields will have great contributions to widespread of new cultivars.

(Received 22nd May 2019; accepted 28th Aug 2019)

Abstract. Microbial degradation is suggested to be the principal mechanism for removing Phthalate esters (PAEs) from the environment. PAEs esterase is one of key enzymes in the degradation pathway. In this study, a phthalate esters hydrolase gene, *pehA*, that displays good alkali stability, is cloned from *Arthrobacter* sp. ZJUTW and characterized. The enzyme showed a monomeric structure with a molecular mass of approximately 26.17 kDa and pI of 4.42. Its optimal pH and temperature were pH 10.0 and 50 °C, respectively. The enzyme was stable in a pH ranging from 8.0 to 10.0. In addition, the ester hydrolysis and transesterification catalytic ability of the esterase were compared through high performance liquid chromatography (HPLC) and Gas Chromatography-Mass Spectrometer (GC-MS). When performing the ester hydrolysis function, PehA has the catalytic ability to hydrolyze two ester bonds at the same time. The kinetic parameters of transesterification and ester hydrolysis conditions showed that the catalytic efficiency of transesterification is significantly higher than that of ester hydrolysis, and PehA preferentially catalyzed transesterification with PAEs and methanol as a substrate. This is the first report on the comparison of transesterification and ester hydrolysis ability of the PAEs esterase.
Keywords: *PehA, gene cloning, endocrine disrupting chemicals, degradation, purification*

Introduction

Phthalate esters (PAEs) are important synthetic organic compounds used as plasticizers in the industrial production of plastics. However, PAEs have become dangerous pollutants in environmental samples in recent years as endocrine disrupting chemicals which influence the genitals. Among rats and adult men, researches have shown that phthalate exposure increased DNA damage in sperm, induced hepatocellular tumors and in some cases reproductive toxicity (Fatoki and Ogunfowokan, 1993; Wang et al., 2004). Some of the PAEs including dimethyl phthalate (DMP), di-n-butyl phthalate (DBP), and di-n-octyl phthalate (DOP) have been listed as priority pollutants by the China National Environmental Monitoring Center (Fenner et al., 2013) and the US Environmental Protection Agency (Xu et al., 2005).

Since the photolysis and chemical hydrolysis rates of phthalate esters are very slow, microbial degradation is suggested to be the principal mechanism for removing PAEs from the environment. In recent years, some microorganisms have been reported to be capable of PAE degradation, these include *Gordonia* sp. (Jin et al., 2012), *Pseudomonas* sp. (Wang et al., 2003), *Arthrobacter* sp. (Wang et al., 2012), *Rhodococcus* sp. (Jin et al., 2010), *Camelimonas* sp. (Chen et al., 2014), *Pelotomaculum* and *Desulfotomaculum* species (Qiu et al., 2004). Numerous studies have demonstrated the microbial biodegradation pathways of phthalate esters. The metabolism of phthalate esters is initiated in bacteria by their hydrolysis converting them into mono-phthalate esters,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1293712949

which are further degraded by ester-hydrolysis to phthalate (PA). PA is further metabolized in aerobic bacteria by two different dioxygenase-initiated pathways through the common intermediate, protocatechuate (3,4-dihydroxybenzoate). Protocatechuate is further degraded into organic acids through either ortho- or meta-cleavage pathway by ring cleavage enzymes, which eventually converted them into CO_2 and H_2O through Krebs cycle (Eaton, 2001; Stingley et al., 2004; Ren et al., 2018).

Hydrolysis of the ester bond is a common key initial step in the microbial degradation of PAEs. PAEs esterase is one of key enzymes in the degradation pathway. However, only a few enzymes involved in this reaction have been reported. These enzymes include dimethyl terephthalate (DMT) esterase from *Fusarium* sp. DMT-5-3 (Luo et al., 2012), two distinct PAE hydrolases in *Micrococcus* sp. YGJ1 (Akita et al., 2001; Maruyama et al., 2005), mono-2-ethylhexyl phthalate hydrolase from *Gordonia* sp. P8219 (Nishioka et al., 2006; Iwata et al., 2016), ester hydrolase PatE from *Rhodococcus jostii* RHA1 (Hara et al.,2010), DBP hydrolase CarEW from *Bacillus* sp. K91 (Ding et al.,2015), DBP hydrolase from *Acinetobacter* sp. M673 (Wu et al., 2013), and Esterase EstB and EstG from *Sphingobium* sp. SM42 (Whangsuk et al., 2015). The esterase can either cleave the ester bond by ester hydrolysis or transesterify with alcohols. Previous studies have only reported the ester hydrolysis catalytic ability of PAEs esterase, but not explored its transesterification ability. Due to the complex composition of pollutants in the environment, it is possible that both alcohols and PAEs exist simultaneously. It is necessary to explore the transesterification of microorganisms and their esterases.

The PAEs esterase play important roles in the decontamination of PAEs. Studying the catalytic mechanism and recombinant expression of PAEs esterase can help improve the efficiency of PAEs pollutants treatment. In this paper, we described a basophilic enzyme from *Arthrobacter* sp. ZJUTW isolated from sludge of the river of Hangzhou city. This enzyme displayed specific hydrolase activity toward PAEs. The experimental data from HPLC and GC-MS led us to compare the ester hydrolysis and transesterification catalytic ability of the esterase.

Materials and methods

Strains and reagents

Arthrobacter sp. ZJUTW was isolated from sludge in Shangtang River of Hangzhou City, using dibutyl phthalate as sole carbon and energy source. The strain was deposited at the China Center for Type Culture Collection (CCTCC) under the accession number CCTCC M2012246.

DMP, diethyl phthalate (DEP), DBP, di (2-ethylhexyl) phthalate (DEHP) were purchased from Sinopharm Chemical Reagent Co., Ltd, all were > 98% pure. HPLC-grade methanol was purchased from Tianjin Siyou Fine Chemicals Co., Ltd. (Tianjin, China). Nickel-NTA agarose and pET28a expression kit were purchased from Shanghai Sangon Biological Engineering Technology Co., Ltd. (Shanghai, China). Other chemicals were analytical-reagent grade, and were purchased locally.

Genome sequencing and sequence analysis

Genomic DNA of *Arthrobacter* sp. ZJUTW was extracted using a genomic DNA isolation kit by Dalian Takara Biomedical Technology Co., Ltd (Dalian, China).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1293712949

Genome sequencing was performed by Zhejiang Tianke Biological Technology Co., Ltd. (Zhejiang, China) using Illumina Hiseq 2000 Sequencing platform, and a partial genomic sequence was obtained. Oligonucleotide primers were synthesized by Shanghai Sangon Biological Engineering Technology and Services Co., Ltd. (Shanghai, China). The full-length salicylate esterase gene *pehA* was revealed based on the prediction of ORFs from the partial genomic sequence by the Glimmer 3.02 (http://www.cbcb.umd.edu/software/glimmer/). Putative functions were inferred using the Basic Local Alignment Search Tool (BLAST) (http://blast.ncbi.nlm.nih.gov/Blast.cgi). Protein similarity search and alignment were performed using the data from CLUSTAL W (Thompson et al., 1994). The signal sequence for peptide cleavage in the amino acid sequences of *pehA* was predicted using SignalP 4.0 (www.cbs.dtu.dk/services/Signal P) (Petersen et al., 2011). ESPript output was used to render the analysis of multiple sequence alignment (Gouet et al., 1999). The neighbor-joining method in the molecular evolutionary genetic analysis software package MEGA (version 6.0) was used to construct a phylogenetic tree. The theoretical molecular mass and isoelectric point of the deduced *pehA* protein sequence was calculated using the Compute pI/Mw tool on the ExPASy proteomics server (available at http://ex pasy.org/tools/p itool.html).

Expression and purification of recombinant PehA

The *pehA* gene was amplified by primers P1 (forward): 5'-CGCGGATCCATGGAGATCGTACTGGTGCA-3' and P1 (reverse): 5'-CCCAAGCTTCCA GTCCTGTTAGGCAATGAC-3'. Initial activation of the *Taq* DNA polymerase was performed for 5 min at 94 °C, followed by 32 cycles as follows: 94 °C for 45 s, then 55 °C for 45 s, 72 °C for 90 s, followed by a final extension at 72 °C for 10 min. Then following the manufacturer's instructions, the expression of *pehA* gene was performed using the *pET*28a expression kit. The PCR product was ligated to the *pET*28a vector and introduced into *E. coli* BL21 (DE3) cells. Positive colonies were picked and grown in Luria-Bertani (LB) at 37 °C in the presence of 50 μg/ml of kanamycin to an OD600 of 0.6. The culture was then induced with 1.0 mM IPTG and grown at 22 °C with shaking at 180 rpm for 18 h. The cells were harvested, re- suspended in 20 mM potassium phosphate buffer (pH 8.0), and disrupted by sonication. After centrifugation at 12,000 × g at 4 °C for 15 min, the supernatant was collected and further purified by a 2 ml volume of NTA-Ni^{2+} agarose following the manufacturer's instructions. The following purification was then performed by size exclusion chromatography on a Q Sepharose XL 10/30 column (Amersham Bioscience) equilibrated with 20 mM sodium phosphate buffer (pH 8.0) at a flow rate of 1.0 ml min. The purified recombinant PehA was examined using sodium salt-polyacrylamide gel electrophoresis (SDS-PAGE). The protein concentration was quantified using the Bradford procedure with bovine serum albumin as a standard.

Assay of enzyme activity

Enzyme activity was quantified at 40°C, with 120 uL of 10 mM ρ-nitrophenyl butyrate (ρ-NPC4) substrates, 1.68ml of 50 mM phosphate buffer (pH 8.0), and 200 μl of the purified PehA. Blank reactions were performed with every measurement to subtract appropriate values for non-enzymatic hydrolysis of the substrate. The production of ρ-nitrophenol (ρ-NP) was monitored in triplicate every minute for 5 min

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1293712949

at 405 nm. One unit of esterase activity was defined as the amount of enzyme that produced 1 μmol ρ-NP in 1 min under the assay conditions

Properties of the PehA

The effect of pH and temperature on enzyme activity and stability was measured on ρ-NPC4 ester substrates for relative activity, which was expressed as a percentage of the initial activity. The optimum pH was determined by measuring the activity at 40 °C over the pH region 3.0-11.0. The stability at different pH (5.0-10.0) was determined after incubating the enzyme for 30 min and by measuring the relative activity at 40 °C and pH 8.0. The optimum temperature was determined by assaying the enzyme activity at various temperatures (30-70 °C) for 20 min in 0.02 mol/l potassium phosphate buffer (pH 8.0). The thermostability was determined by measuring the remaining activity at 30 °C and pH8.0, after incubation of the purified esterase between 30 and 70 °C and pH 8.0 for 30 min.

The effect of different potential inhibitors or activators (metal ions and organic solvents) on the enzyme activity was also determined by measuring the relative activity using a standard assay with ρ-NPC4 as the substrate. The reaction system was 120 μL of 10 mM ρ-NPC4 ester substrates, 1.68 ml of 50 mM phosphate buffer (pH 8.0), 200 μl of the purified PehA, and a final concentration of 1.0 mM of different metal or a final concentration of 1.0% (volume to volume ratio) of organic solvent. The enzyme was preincubated at 40 °C for 5 min. The remaining activity was assayed was described. The activity assayed in the absence of inhibitors or activators was defined as the control.

Comparison of transesterification and ester hydrolysis ability

For comparing the transesterification and ester hydrolysis ability of PehA, the enzyme kinetic constants were determined by measuring the initial rate of enzymic reaction for DBP, DEP and DMP, which were firstly dissolved in methanol and dimethyl sulfoxide (DMSO), respectively. Parametric identification of maximum velocity (V_{max}) and Michaelis-Menten constants (K_m) was used from the equation for initial reaction velocity. The recombinant PehA assays were performed in 50 mM Tris-HCl buffer (pH 8.0) with 10 mM of DBP, DEP or DMP (firstly dissolved in methanol and DMSO, respectively) at 40 °C for 10 min. The substrate amount was then determined by HPLC/MS analysis. The substrate-free assay system was also used as blank simultaneously. Kinetic values were calculated from nonlinear regression data analysis against various substrate concentrations.

HPLC and GC-MS analytical methods

The mixture of enzymatic degradation was extracted with equal volume dichloromethane, then the extract was evaporated, and the residue was dissolved in 1 ml methanol. The amount of remaining substrate was determined by HPLC (Agilent 1260 series, USA) equipped with a Diamonsil-C18 column (4.6 mm × 250 mm × 5 μm; Dikma Technologies Inc, China). A mixture of methanol and H_2O (90:10 by volume) was used as the mobile phase at a flow rate of 1.0 ml min^{-1}. The UV detector wavelength was 235 nm and the sampling quantity was 20 μl.

After collecting the HPLC peaks separately, enzymatic degradation products were identified using a Hewlett Packard 6890N gas chromatograph (Hewlett Packard, USA) equipped with an Agilent 5975C mass selective detector (Agilent, USA). The column

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1293712949

used was a HP-5MS (30 m × 250 m × 0.25 m) capillary column. The temperature program consisted of 1 min hold at 60 °C, an increase to 220 °C at 30 °C min^{-1}, and 2 min hold, an increase to 250 °C at 5 °C min^{-1}, and 2 min hold, an increase to 280 °C at 5 °C min^{-1}, and 3 min hold. The injection volume was 1 μl and the carrier gas was helium (1.0 ml min^{-1}). The mass spectrometer was operated at an electron ionization energy of 70 eV. Instrumental library searches, comparison with available authentic compounds, and mass fragmentation pattern were used to identify the degradation products.

Statistical analysis methodology

Each treatment in the experiment was performed in triplicates. Software Origin 8.0 was used to draw the figures with error bars. Data are expressed as the mean ± standard deviation (SD).

Results and discussion

Sequence analysis of PehA

A gene annotated as "salicylate esterase" with a 723-long ORF that encoded 240 amino acid proteins was found and we named it as *pehA*. No signal sequence was found. Sequence alignment revealed that amino acid sequence of *pehA* was 100% sequence identity to alpha/beta hydrolase from *Gordonia* QH-11 (*Fig. 1*), which was not reported about catalytic ability of PAEs. In addition, these sequences all contain the typical catalytic triad composed of Ser75-Glu194-His221 and the consensus motif (Gly-X-Ser-X-Gly) around the active-site serine (*Fig. 2*). Some PAEs esterases sequences were retrieved and compared with known representative esterases' sequences of eight families (Ren et al., 2018). The catalytic triad containing Ser, Glu (or Asp), and His was widely reported in families IV, V, and VII. Most enzymes in family V possess the typical α/β-hydrolase fold with a catalytic triad (Arpigny and Jaeger, 1999), and existed basic amino acid (H and R) in GX1SX2GG motif, suggesting PehA belongs to the family V. The sequence similarities and conservation of typical catalytic triads suggest that these enzymes may have a number of important common functions that were conserved during the course of evolution.

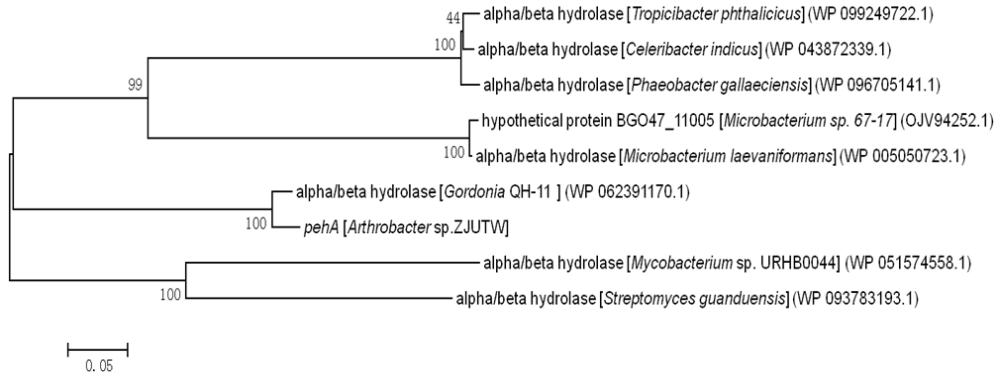

Figure 1. *Neighbor-joining tree of esterases. Protein sequences were aligned using the built-in CLUSTAL W (default parameters), the tree was built using the neighbor-joining method with default parameters and 1000 bootstrap replications*

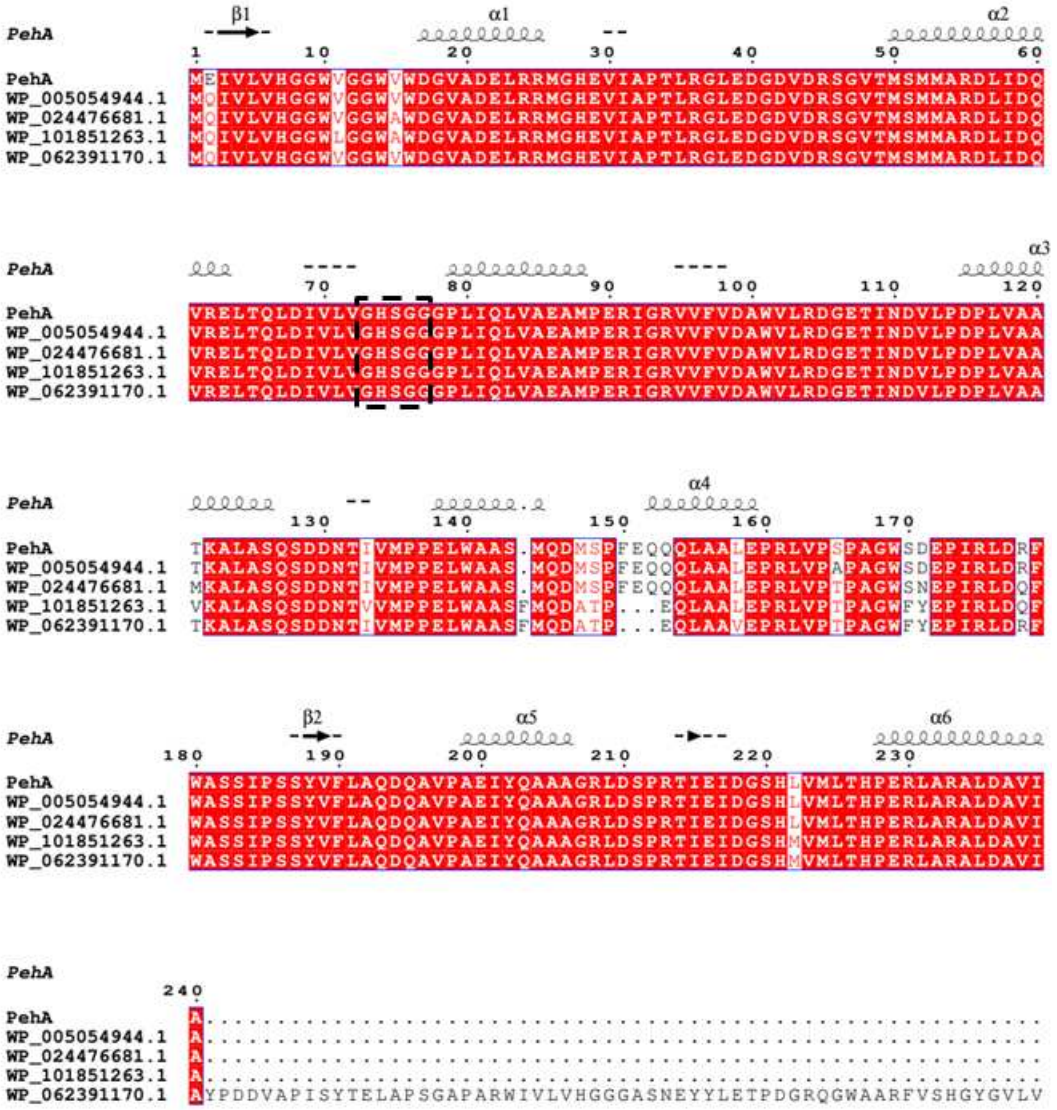

Figure 2. *Protein sequences alignment between PehA and homologs from the carboxylesterase family. ESPript outputs obtained with the sequences from the SWISSPROPT databank and alignment with CLUSTAL W. Sequences are grouped according to similarity. WP_005054944.1 from alpha/beta hydrolase of Microbacterium; WP_024476681.1 from alpha/beta hydrolase of Actinobacteria; WP_101851263.1 from alpha/beta hydrolase of Kocuria flava; WP_062391170.1 from alpha/beta hydrolase of Gordonia phthalatica. A conserved pentapeptide (GXSXG), containing the serine residue of the catalytic triad, was framed by a dotted box. Symbols above blocks of sequences represent the secondary structure, springs represent helices, and arrows represent β-strands*

Enzyme cloning, overexpression and purification

To investigate the biochemical properties of the enzyme, the *pehA* gene was expressed in the *pET*-28a vector as a 6 × His tagged fusion protein and induced with 1 mM IPTG or without IPTG at 20 °C for 18 h. The crude enzyme extracted from recombinant *E. coli* BL21 cells was purified using Ni^{2+}-NTA metal-chelating affinity chromatography and analyzed by SDS–PAGE. As shown in *Figure 3* (lane 3), one band corresponded in size to the calculated molecular mass of PehA was detected

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1293712949

(26.17 kDa). The band was absent in the control lane from the *E. coli* BL21 cells induced without IPTG (*Fig. 3,* lane 1). The isoelectric point (pI) was 4.42.

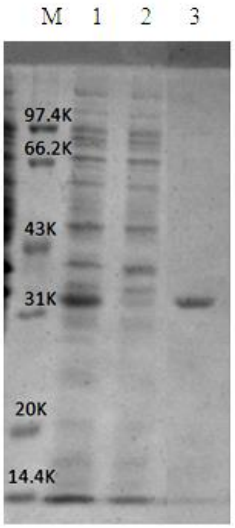

Figure 3. *Analysis of the protein expressed in E. coli BL21 cells following purification on a 12% SDS- PAGE. Lane M, protein molecular marker; Lane 1, after induction with 1 mM IPTG and grown at 20 °C for 18 h; Lane 2, before induction with IPTG; and Lane 3, purified recombinant PehA (molecular weight without histidine tag is 26.17 kDa)*

Effect of pH and temperature on enzyme activity and stability

The effect of pH on PehA activity was determined using ρ-NPC4 as the substrate at 40 °C with pH values ranging from 4.0 to 11.0. Optimum activity was observed at pH 10.0, with approximately no activity at pH 4.0 (*Fig. 4A*). The pH stability analysis revealed that the enzyme was very stable at pH 7.0- 10.0, retaining more than 70% of the original activity after pre-incubation at the given pH range for 60 min. However, PehA only maintained 41% and 32% of its activity at pH 6.0 and 11.0, respectively, after incubation for 60 min.

The effect of temperature on PehA activity was investigated using ρ-NPC4 as the substrate at pH 7.0 with the temperature ranging from 30 to 70 °C. Optimum activity was observed at 50 °C. When the temperature rises above 50 °C, the enzyme activity drops sharply. The temperature stability of PehA was examined by measuring its residual activity after incubating the purified enzyme for 0.5 h from 30 to 70 °C. PehA retained approximately 95%, 99%, 86% of its activity after incubation for 0.5 h at 30, 40 and 50 °C respectively. However, the enzyme was unstable above 70 °C, and retained approximately 33% of activity (*Fig. 4B*).

Effect of metal ions and organic solvents on enzyme activity

The effect of different metal ions on PehA activity was examined by addition of each metal ion into the reaction mixture at a final concentration of 1.0 mM. The results are presented in *Table 1*. Ni^{2+}, had a moderately inhibitory effect (86.2% residual activity); Mg^{2+}, K^{+}, Zn^{2+}, Ba^{2+}, Al^{3+} and Li^{+} had no apparent effect on enzyme activity; whereas Co^{2+}, Cu^{2+} and Mn^{2+} activated PehA, and Fe^{3+} strongly activated PehA with residual activities of 163%.

DOI: http://dx.doi.org/10.15666/aeer/1706_1293712949

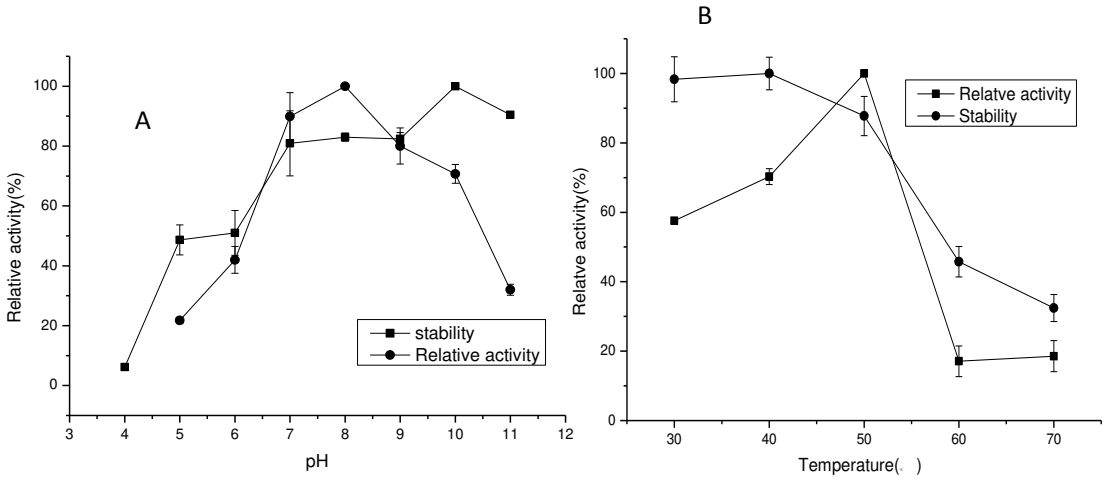

Figure 4. *Effect of temperature and pH on PehA activity and stability. Relative activity of purified PehA was determined at different pH (A) or temperatures (B) using ρ-NP butyrate (ρ-NPC4) as the substrate at 405 nm. Remaining enzyme activity was measured at 40 °C and pH 8.0 after incubating purified PehA at different temperatures (B) or pH for 60 min*

Table 1. *Effect of various metal ions and organic solvents on enzyme activity*

Metal ions/organic solvents	Concentration	Relative activity (%)
control	0 mmol/L	100
Ni^{2+}	1 mmol/L	86.2 ± 3.78
Mg^{2+}	1 mmol/L	98.0 ± 6.24
Co^{2+}	1 mmol/L	109.3 ± 3.21
Ba^{2+}	1 mmol/L	105.4 ± 2.61
Zn^{2+}	1 mmol/L	105.0 ± 7.43
Ca^{2+}	1 mmol/L	112.3 ± 6.37
Cu^{2+}	1 mmol/L	117.6 ± 4.45
Mn^{2+}	1 mmol/L	123.0 ± 3.54
Fe^{3+}	1 mmol/L	163.1 ± 4.59
K^{+}	1 mmol/L	107.3 ± 2.15
Al^{3+}	1 mmol/L	101.2 ± 2.07
Methanol	1%V/V	107.4 ± 7.74
Ethanol	1%V/V	109.9 ± 8.21
Acetone	1%V/V	105.5 ± 1.88
DMSO	1%V/V	97.4 ± 0.81
Formaldehyde	1%V/V	22.3 ± 1.33
Acetonitrile	1%V/V	93.8 ± 21.97
Trichloromethane	1%V/V	60.3 ± 2.87
Tween 80	1%V/V	80.5 ± 8.91

Organic solvents such as Formaldehyde (1%) strongly inhibited PehA (22.3% residual activity), and Trichloromethane (1%) and Tween 80 (1%) exhibited moderate

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1293712949

inhibitory effects (approximately 60.3% and 80.5%, respectively). Acetonitrile (1%) and DMSO (1%) had little inhibitory effect on the enzyme activity (97.4% and 93.8% residual activities, respectively), whereas methanol (1%), ethanol (1%), and acetone (1%) little activated PehA with residual activities of 107.4%, 109.9% and 105.5%, respectively.

Comparison of transesterification and ester hydrolysis ability of PehA

Break of the ester bond is a common key initial step in the microbial degradation of phthalate esters. Esterase has two kinds of catalytic reactions involved transesterification and Ester hydrolysis to execute the Initial degradation step. To explore the catalytic ability for transesterification and Ester hydrolysis of PehA, The products of the reaction catalyzed were identified by HPLC and GC-MS. In the reaction system containing methanol, butyl methyl phthalate (BMP) was detected (*Figs. 5A* and *6A, B*), indicating that in this system, PehA exchanged a methyl group on methanol with butyl group of DBP through a transesterification reaction. In the reaction system containing no methanol (DBP dissolved in DMSO), PA was detected (*Figs. 5B* and *6C*), and mono-butyl phthalate (MBP) was not detected, indicating that the esterase hydrolyzes two ester bonds simultaneously by ester hydrolysis to produce PA. However, in most of the previous reports, the initial step in the degradation of PAEs is that esterase hydrolyzes one ester bond to produce a monoester, then monoesterase hydrolyze another ester bond to form PA, suggesting that PehA has the catalytic ability to hydrolyze two ester bonds at the same time. Kcat/Km is one of the specificity constants of the enzyme, and can represent the specificity of the same enzyme for several substrates that compete with each other. The Kcat/Km ratio is a measure of the priority of different substrates, and the substrate with the larger Kcat/Km ratio is the preferred target for the enzyme. The kinetic parameters of different substrates were determined at pH 8.0 and 40 °C using the purified recombinant PehA (*Table 2*). After comparing the ester hydrolysis and transesterification catalytic kinetic constants of several PAEs, the results showed that the ester hydrolysis catalytic activity of esterase was significantly stronger than that of transesterification. In *Table 2,* the Kcat/Km values of DEP (containing methanol) and DEP (no methanol) as substrates are 41.02 and 0.47, respectively, and that of DBP (containing methanol) and DBP (no methanol) are 8.95 and 0.213, respectively, indicating that the catalytic efficiency of transesterification is significantly higher than that of ester hydrolysis in the presence of methanol, and PehA preferentially catalyzed transesterification with PAEs and methanol as a substrate. In addition, PehA exhibited strong catalytic ability for DBP and DEP, weak catalytic ability for DMP, and no catalytic ability for DEHP. This result suggested that PehA might have an ester chain length-dependence of PAEs. The kinetic parameters of some PAEs hydrolase are reported, the Kcat/Km values of DBP as substrates are 0.109 s^{-1} μM^{-1} (Ding et al., 2015), 0.07 s^{-1} μM^{-1} (Jiao et al., 2013) and 10.11 s^{-1} μM^{-1} (Wu et al., 2013), respectively, but all these data could only be measured at the condition of hydrolyzation. There is no report on the kinetic parameters of transesterification of these PAEs esterase. Some studies have reported that microorganisms can degrade PAEs through the ester conversion reaction process (Cartwright et al., 2000; Amir et al., 2005; Okamoto et al., 2011), but did not separate the esterases from these strains. To our knowledge, this is the first report on the comparison of transesterification and ester hydrolysis ability of PAEs esterase, and can help to further understand the degradation mechanism of PAEs by microbial.

DMP (dissolved in DMSO)	1.032 ± 0.02	1288 ± 20.07	3.56 ± 0.4	0.00276

Conclusions

In this study, the *pehA* gene efficiently degraded several PAEs such as DBP, DEP and DMP, was cloned from *Arthrobacter* sp. ZJUTW and heterologously expressed in *Escherichia coli* BL21 using the *pET28a* expression system. The enzyme showed a monomeric structure with a molecular mass of approximately 26.17 kDa and pI of 4.42. The enzyme exhibited maximal activity at pH 10.0 and 50 °C, The enzyme was better stable within the pH range from 8.0 to 10.0. HPLC and GC-MS were employed to detect the catalytic ability of PehA. The results showed that this enzyme has two catalytic functions: transesterification and Ester hydrolysis. When performing the ester hydrolysis function, it has the catalytic ability to hydrolyze two ester bonds at the same time. Through comparing the kinetic parameters of transesterification and ester hydrolysis conditions, we found that the catalytic efficiency of transesterification is significantly higher than that of ester hydrolysis, and PehA preferentially catalyzed transesterification with PAEs and methanol as a substrate. The PAEs esterase play important roles in the decontamination of PAEs, the production of such recombinant enzyme can probably provide efficient biocatalysts at low costs for environmental protection purposes.

Abstract. Activated sludge process is one of the most common methods in wastewater treatment, however, bulking sludge is nerve-wracking during the actual treatment. In this study, Polymerase chain reaction-denaturing gradient gel electrophoresis (PCR-DGGE) was employed to study the diversity of the micro-organisms of the untreated sludge and bulking sludge in the biological wastewater treatment. Simultaneously, microbe species and dominant microflora of the untreated sludge and the bulking sludge were analyzed. This paper provides a reliable theoretical basis to the prevention and control of the bulking of the activated sludge. The results indicate that the bulking of the activated sludge is mainly caused by the change of microbe population.
Keywords: *PCR-DGGE, the diversity of microbe, bulking sludge, filamentous, dominant microflora*

Introduction

The activated sludge treatment is an aerobic biological treatment. Under the aerobic condition, the organic matter in the wastewater is decomposed into inorganic materials, so as to purify the wastewater (Shao et al., 2005). Sludge bulking is a frequent and serious problem in plants using activated sludge, and the causes are fairly complex. Many researchers have studied this issue. The over-growth of many filamentous bacteria may cause the bulking problem (Henze et al., 2008). Simultaneously, theoretical studies on the overgrowth of the filamentous bacteria have also progressed (Eikelboom et al., 1975; Sezgin et al., 1980). The causes of sludge bulking can be divided into two types: the first is caused by the rapid multiplication of the filamentous bacteria in the activated sludge; and the other is caused by a large accumulation of highly viscous substances produced by bacterial colloid (Qin et al., 1989; Ma et al., 2012). In recent years, the metabolic diversity and genetic adaptability of microbes in sludge have been studied. Denaturing gradient gel electrophoresis (DGGE) fingerprint results indicated a shift in bacterial community composition during the granulation of aerobic granules, which was confirmed by 16SrRNA gene sequencing (Aqeel et al., 2015). Real-time quantitative polymerase chain reaction (qPCR) was used to study the abundance and community structure of ammonia-oxidizing bacteria in the activated sludge taken from different geographic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1295112958

regions in China (He et al., 2018). The abundance of filamentous morphotypes and floc-formers able to store biopolymers were analysed by PCR-DGGE and 16S amplicon sequencing (Meunier et al., 2016). With the development of modern molecular biotechnology such as DNA extraction, it is possible to analyze the diversity of microbial species and heredity (Li et al., 2015; Jiang et al., 2014).

In this study, PCR-DGGE was employed to study the micro-biodiversity of the untreated sludge and the bulking sludge. The species and dominant microflora of microbes in the two kinds of sludge were compared, and the causes of sludge bulking were found, which provides a reliable perspective for solving the problem.

Materials and methods

Materials

The experiment material was collected from the acclimated sludge and filamentous bulking sludge in a wastewater treatment plant Xi'an, China.

Methods

PCR-DGGE include preparation of sample DNA, PCR amplification and denaturing gradient gel electrophoresis (Sun et al., 2009).

(1) Preparation of sample DNA

Bacteria acquired through Centrifuge collection were dissolved in 5mL extraction buffer (100 mM Tris·Cl, 100 mM EDTA-Na2, 200 mM NaCl, 2% CTAB, pH 8.0) and were shaken at 37 °C for 30min. 0.75 mL 20% SDS was added in the solution above then water bathed it at 65 °C for 1 h. The supernatant was collected by centrifugation at 12000 rpm for 10 min. The volume (the same as the supernatant) of the mixture of phenol, Chloroform and Isoamyl alcohol, the ratio of which are 25:24:1, was extracted twice, 0.3 M of NaAC (pH 5.2) and ethyl alcohol which was twice as the volume as the extracted solution were added, and precipitated for 1 h at ambient temperature. After centrifugation (12000 rpm, 20 min) at 4 °C, the precipitate was collected and rinsed twice with 70% ethanol, then dried and dissolved in 50 μl TE.

(2) PCR amplification

PCR amplification primers used are F357(5'-CGCCCGCCGCGCCCCGCGCCCGGCCCGCCGCCCCCGCCCCCCTACGGGAGGCAGCAG -3') and R518(5'- ATT ACC GCGGCTGCT GG -3') from bacteria 16SrDNA V3 Highly variable region for the analysis of the diversity of the bacteria in the activated sludge. PCR amplification primers used fungus NS1(GTAGTCATATGCTTGTCTC) and Fung-GC(GC-ATTCCCCGTTACCCGTTG) for the analysis of the fungal diversity.

(3) Denaturing gradient gel electrophoresis (DGGE)

D-Code Universal Mutation Detection System (Bio-Rad) was used for the DGGE of the PCR products.

Results and discussion

Analysis of the bacteria diversity of the untreated activated and bulking sludge

After DGGE analysis and sequencing, the gene sequence was compared with the NCBI database, and the results of the main bacteria identification in the untreated sludge and bulking sludge were shown in *Tables 1,2* and *Figures 1,2*.

Table 1. *Identified bacteria species in the untreated sludge*

Most bacteria in the untreated sludge belong to proteobacteria (including *α-proteobacteria*、*β-proteobacteria* and *γ-proteobacteria*) (*Table 1*) and showed a close genetic relationship. Sequence 2, 1, 4, 5, 10, 7 stand for the dominant microfloras in the activated sludge. Moreover, the bacteria represented by sequence 3, 8, 6 were not artificially cultivated and classified, and they also showed a close genetic relationship. The microbe community of the activated sludge is formed together with the same 9 microbes (Wang et al., 2015).

Significant reduction in the total number of the dominant bacteria in the bulking sludge is showed from 10 species in the untreated sludge to 6 species (*Table 2*) after the treatment and the microbial community changed greatly.

The strains represented by sequence 2~5 (*Fig. 2*) are in accordance with the four strains represented by sequence 5, 6, 8, 10 in the untreated sludge. Two strains of bacteria represented by sequence 1 and sequence 6 are new in the bulking sludge. Strains represented by sequence 1 and sequence 6 highly similar to the *Anaerolineaceae* and *Collinsella aerofaciens*, respectively.

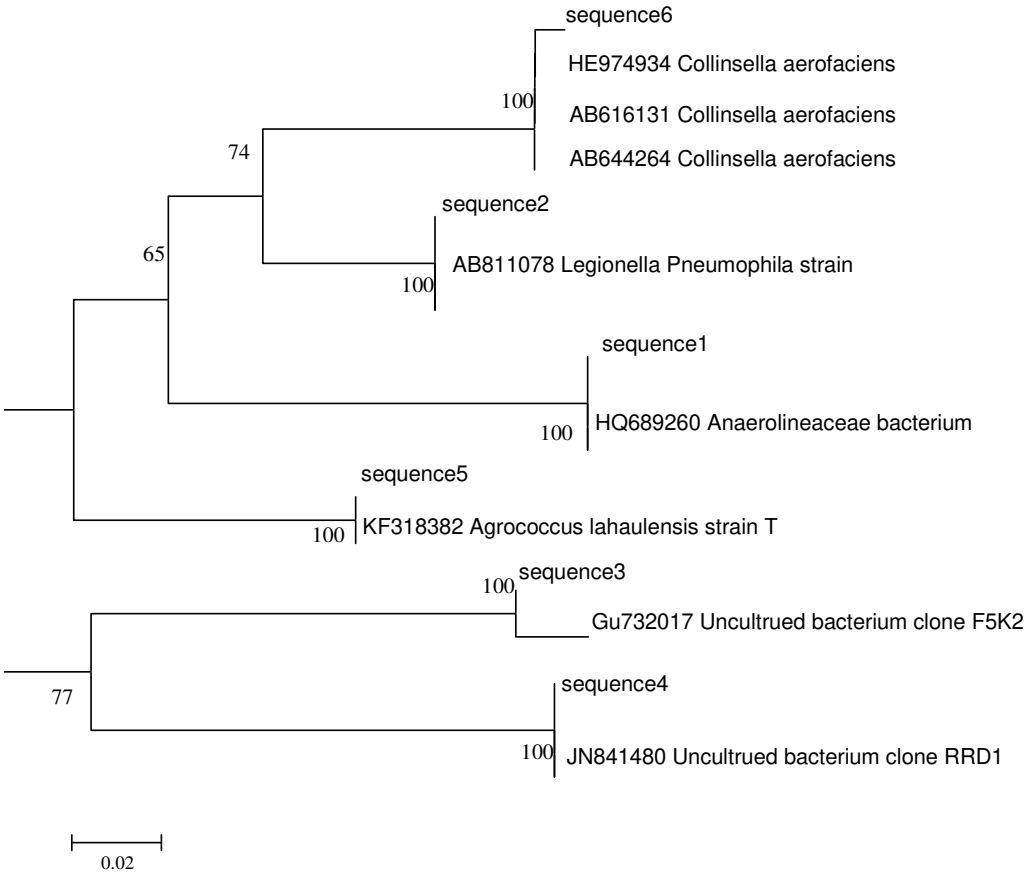

Figure 2. *Phylogenetic tree of the bacteria in the bulking sludge*

Analysis of fungus diversity of the bulking sludge

After DGGE analysis and sequencing, the gene sequences were compared with the sequences in the NCBI database, and the main funguses in the bulking sludge were shown in *Table 3*.

Table 3. *Identified funguses in the bulking sludge*

Stripe number	Clone number	V3 region	*Fungus* species
1	> 7.24XD1534-6(DG50-Z-2)M13-	349bp	*Uncultured eukaryote*
2	> 7.24XD1535-1(DG50-Z-3)M13-	349bp	*Saccharomyces cerevisiae*
3	> 8.16XD1631-2(DG50-Z-4)M13-	347bp	*Unculture alveolate*
4	> 8.16XD1632-1(DG50-Z-5)M13-	346bp	*Hanseniaspora guilliermondii*
5	> 8.16XD1633-1(DG50-Z-8)M13-	337bp	*Uncultured eukaryote*

The bulking sludge contains five kinds of funguses (*Table 3*), besides bacteria, they constitute the microbial community of the sludge, and are a part of the dominant microflora in the bulking sludge. The genus can be identified by cloning V3 conservative regions. The result is shown in *Figure 3*.

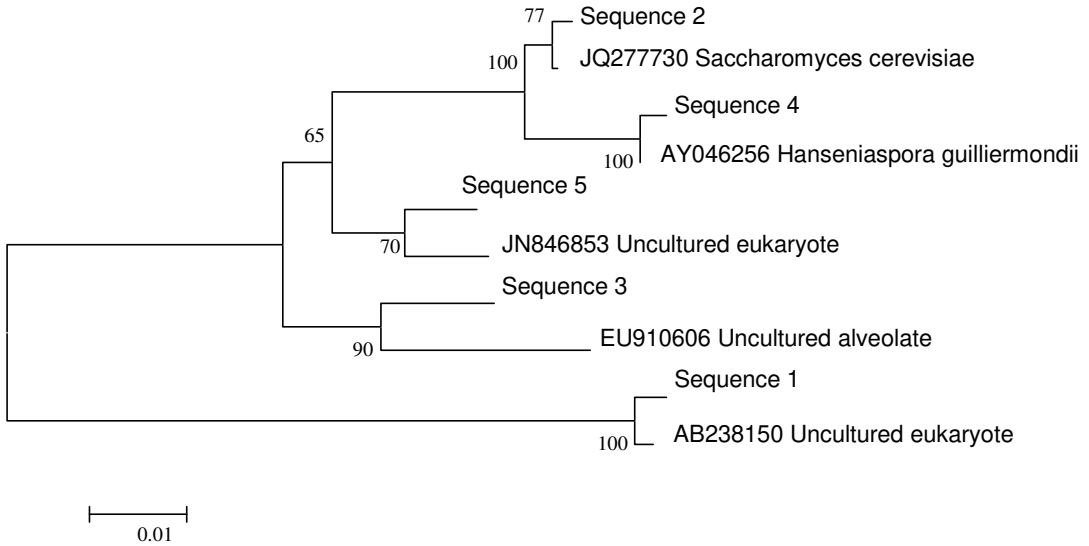

Figure 3. *Phylogenetic tree of the funguses of in the bulking sludge*

From *Figure 3,* the funguses represented by sequence 1, 3 and 5 are not artificially cultivated strains. The two fungus strains represented by sequence 2 and sequence 4 were closely related to *Saccharomyces cerevisiae* and *Hanseniaspora guilliermondii* in the evolutionary relations. So the two funguses were identified as *Saccharomyces cerevisiae* and *Hanseniaspora guilliermondii.*

Analysis of the root causes of sludge bulking

(1) Changes of bacterial composition of non-treated and bulking sludge

From the results of DGGE analysis in *Figure 4,* it can be seen that bacterial composition changed greatly after sludge bulking, showing a decrease of bacterial species and the change of the amount of the dominant microflora. The microflora represented by sequence1 in the untreated sludge are *Zoogloea sp*. Under natural conditions, the *Zoogloea sp*. produces capsule that not only directly affects the growth and reproduction of the bacteria but also the living environment of the bacteria. Bacteria can improve the poor living environment with its capsule property, and prevent the phagocytosis and utilization by some bad cell tissue. And on the surface of some specific bacteria cells, it showed a strong specificified of attack and defense capability (Wang, 2016). Microfloras which are commonly used microbes in sewage treatment cluster in the common bacteria colloid, so that the sludge has a good gel-flocculation structure and sedimentation property (Zhong et al., 2010). The disappearance of *Zoogloea sp*. in the sludge is the direct cause of sludge bulking.

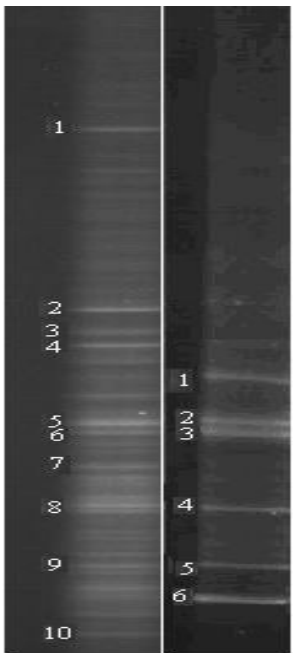

Figure 4. *Bacteria domains in the untreated sludge and bulking sludge*

(2) Changes of funguses composition of the untreated and bulking sludge

As can be seen from the DGGE bands in *Figure 5,* the fungus bands in the untreated sludge are few and unclear, indicating that the types and amounts of the funguses contained in the untreated sludge are small but the bulking sludge contains five kinds of fungi whose species and quantity are much more than the untreated sludge. Thus, the multiplication of fungi has changed the nutritional composition of the environment, absorbing a large number of nutrients, directly affect the growth of the bacteria such as *Zoogloea sp*. Thereby, the change of the composition of the microbe microfloras in the sludge, as well as the destruction of the flocs structure of the sludge lead to the sludge bulking.

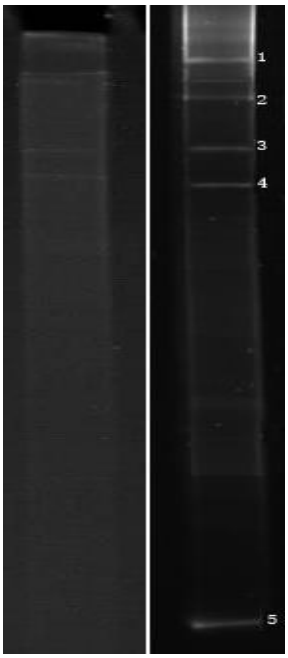

Figure 5. *Fungus domains in the untreated sludge and bulking sludge*

Conclusion

From the analysis of the diverse microbes of untreated sludge and bulking sludge, it is seen that sludge bulking is mainly caused by the change of microbe microfloras.

(1) The sludge bulks because the microfloras in it changed greatly, the main signs are the decrease of the bacterial species and the dominant flora changes. Under natural conditions, *Zoogloea sp*. in the untreated sludge flora has the property of producing capsule and the bacteria which are the common microbes in wastewater treatment cluster in the common bacteria colloid, so that the sludge has a good gel-flocculation structure and sedimentation property. The disappearance of *Zoogloea sp*. is one of the direct causes of sludge bulking.

(2) DGGE analysis of the untreated sludge showed that only a very small amount of fungi were present in the activated sludge, which indicates that the activated sludge mainly consisted of bacteria, but five kinds of filamentous fungi (most of which have hyphae) in the bulking sludge were detected with the same method. The mass growth of these filamentous fungi has replaced the predominant bacteria such as *Zoogloea sp*. in the activated sludge, therefore, the destruction of the gel-flocculation structure of the sludge eventually leads to the filamentous fungus sludge bulking.

In the future studies, the changes of carbon source, nitrogen source and inorganic salts in sludge before and after bulking should be systematically analyzed. Combined with the study of microfloras changes and strain metabolism, the mechanism of change would be deeply revealed, which would lay a theoretical foundation for controlling the sludge bulking.

Abstract. The construction of ecological civilization is an important part of the cause of socialism with Chinese characteristics. It concerns the well-being of the people, the future of the nation, the goal of "two hundred years" and the realization of the Chinese dream of great rejuvenation of the nation. County is the basic unit of ecological civilization construction in China. The construction of county ecological civilization is of great significance to that on the national scale. Therefore, how to accurately calculate the level of county ecological civilization construction has become a significant subject. Based on the general situation of Sichuan Province, this paper uses a large number of county data collected from Sichuan Province to calculate the county ecological footprint of Sichuan Province through the improved ecological footprint model. The ecological footprint model is revised based on NPP by GIS technology, which makes the calculation result more accurate and scientifically evaluates the level of County Ecological Civilization Construction in Sichuan Province.
Keywords: *net primary productivity, ecological deficit, NPP, equilibrium factor, yield factor*

Introduction

First of all, due to the characteristics of simple population composition and small area, county governments have a better understanding of the situation within the scope of management, which is more useful in the process of ecological civilization construction. Secondly, for the counties which are at the key position of implementing national policies, the task of ecological civilization construction is more specific, the space of play is broader, and it is easier to find problems in policy formulation and implementation and solve them timely and accurately. Thirdly, the county level is closer to the grassroots level and the masses, and promoting the construction of county ecological civilization will help making policies more precise to benefit the vast majority of the people. It can be seen that the county ecological civilization construction is the basic unit of the national ecological civilization construction, and is the key and foundation of the ecological civilization construction. Therefore, how to accurately calculate the level of county ecological civilization construction has become a significant subject. Based on the general situation of Sichuan Province, this study uses county data collected in here to measure the county ecological footprint of Sichuan Province through the improved ecological footprint model to measure the level of County Ecological Civilization Construction in Sichuan Province. In the process of

DOI: http://dx.doi.org/10.15666/aeer/1706_1295912971

using the ecological footprint model, the ecological footprint model is modified based on NPP by GIS technology, which makes the calculation result more accurate.

Literature review

Many studies have been made on the construction of ecological civilization at home and abroad, which mainly concentrates on the concept and connotation, evaluation methods and technical means of ecological civilization construction.

In terms of the concept and connotation of ecological civilization construction: The concepts in this regard have not been unified. Morrison (1995) put forward the concept of "ecological civilization" in 1995. Foreign researches on this concept are mainly based on the ecological study of civilization. Arnason (1998) studied the relationship between Japanese civilization and Marine ecology, and expounded the characteristics of Japanese civilization from the ecological perspective. Quinilley (2011) analyzed the spatial dimensions needed to ensure the development of ecological civilization based on the spatial attributes of ecological environment. Scholar Alakbarov (2015) started with the ecological civilization of Azerbaijani, and studied the impact of human resource development, increasing fixed assets, innovation strategy on ecological knowledge, as well as the relationship between these related issues. In 1987, the ecologist Ye (1987) first applied the concept of ecological civilization. He believed that ecological civilization means that human beings can benefit from nature and return to nature. After the 18th National Congress, both academia and government departments at all levels have expounded their understanding of ecological civilization from many perspectives. Qin et al. (2015) have subdivided the concept of ecological civilization into two dimensions, one is the history of human development, the other is the real social system, corresponding to the broad sense and narrow sense of ecological civilization.

As for the evaluation methods of ecological civilization construction, the main methods include ecological footprint method, real development index method and index system method. Mikuliqi et al. (2016) applied the ecological footprint method in the analysis of cement industry. The research results show that the industry has invested a lot of raw materials in time, but the level of energy utilization has not changed significantly. Bartocci et al. (2016) studied the environmental problems of Sagrantino and Grechetto by using carbon footprint, ecological footprint and water footprint methods respectively. Ferreira et al. (2016) introduced the life cycle assessment theory into the ecological footprint assessment system. Sziget et al. (2016) takes Hungary as the research object to analyze the changes of ecological footprint density in that country in recent years. The ISEW index proposed by scholar H. Daly, that is, the economic welfare index of sustainable development, can be used to replace GDP. Verhofstadt et al. (2016) studies the integration of personal welfare and ecological footprint. Qian et al. (1990) and others used the method of quantitative and qualitative integration to study the giant system. Because in the face of such a huge system, only by building a comprehensive index system, can it be more accurate quantitative research. After this method was put forward, Kong et al. (2016), Ma et al. (2017), Xing (2016) and other Tongdu all applied the index system method to give the corresponding evaluation to the construction of ecological civilization.

As far as the technical means of evaluating the construction of ecological civilization are concerned, in foreign countries, the work of evaluating the construction of ecological civilization can be traced back to the 1960s at the earliest, but only in the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1295912971

1970s did it enter the stage of development. Based on this, Remote Sensing (RS), Geographic Information System (GIS) and landscape ecology were developed, and the corresponding ecological evaluation was carried out through them. Lee and Wong (2001) believe that landscape quality and ecological value are closely related. Through GIS and land use data, he evaluated the landscape and ecological value of the analysis area. Based on these results, corresponding management policies are formulated. Smith et al. (1999) used remote sensing, mapping and statistical techniques to analyze the level of land use in the region. Based on remote sensing monitoring data, Espejel (1987), analyzed the ecological status and sustainability of the monitoring area, and constructed different land use conditions in the analysis process. Scholar Reid et al. (2000), based on GIS technology, evaluates the effects of land use and land cover on ecosystem. Tang (2014) took Pengshan County as the research object, and analyzed its defects in the construction of ecological civilization. Lu et al. (2015) based on the space-time comprehensive measurement model and sustainable development evaluation index system, and then according to the technology of gravity center displacement, AHP and GIS, take many districts and counties in Liaoning Province as the research object, and adopt the comprehensive measurement model to study their sustainable development. Liu et al. (2017) are evaluating the sustainable development of Jiangxi Province. Wang and Ren (2018) took Yulin area as the research object, and made a comprehensive evaluation and analysis of the ecological security of the area through remote sensing and GIS technology, and compiled an evaluation index system for the area.

There are many methods to measure the level of regional ecological civilization construction, but the evaluation of the level of regional ecological civilization construction from the county perspective is relatively less. There are many studies on the evaluation of ecological footprint method, but most of them can not improve their inherent defects. The improvement of Ecological Footprint Based on NPP method is relatively rare. This paper studies the integration of improved ecological footprint model and GIS technology, and effectively improves the accuracy of evaluation.

Method selection and data source

Method selection

In 1992, W. Rees from Canada first proposed the ecological footprint model, which was improved by M. Wackemagel. The model is an important research tool. It introduces the concept of ecological space size and maps the natural capital consumption and the ecological services supported by natural systems to evaluate the sustainability of human activities. The core of the theory is “bio-production area”. With the help of ecological footprint analysis tools, the overall calculation results can be simplified, and the natural capital supply and demand information of the calculated area can be more vividly mapped. However, the ecological footprint model also has some shortcomings, mainly in the following aspects: firstly, the lack of dynamic. Only real-time ecological information can be analyzed, which belongs to a typical static analysis. When calculating the related ecological land area, a definite time is needed. Secondly, the assumption of spatial mutuality is flawed. In this footprint theory, the hypothesis of land spatial exclusion is put forward. However, this hypothesis obviously has defects, that is, land itself has various and replaceable attributes, which divides the whole system. Thirdly, the comparability and reality of equilibrium factors and yield factors

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1295912971

are difficult to coordinate. Based on the concept of global hectare ecological footprint, it is difficult to get close to the actual situation of the study area, and when calculating the ecological carrying capacity of cultivated land, construction land is usually equated with cultivated land, which invisibly increases the cultivated land area, and the corresponding calculation results will naturally become larger. Because the ecological footprint model has some defects and shortcomings, this study introduced the concept of time series to analyze the economic, natural and social changes of different time nodes. In addition, the parameters used in the traditional footprint model are based on the global perspective, which is lack of accuracy for the study of Sichuan. Therefore, the concept of Net Primary Productivity (NPP) is introduced to make the footprint model play a greater role.

Data sources

This study focuses on the county-level administrative regions of Sichuan Province. However, due to the sparse land, weak industrial, forestry, fishery and agricultural foundations, the calculation results of ecological footprint in Western Sichuan alpine Tibetan area and Liangshan Yi area are significantly lower than those in other areas, considering the availability of statistical data in some years. This study does not include 48 districts and counties under the jurisdiction of Ganzi Tibetan Autonomous Prefecture, Aba Qiang Autonomous Prefecture and Liangshan Yi Autonomous Prefecture. Therefore, this study selected 135 districts and counties in Sichuan Province (excluding alpine Tibetan areas in Western Sichuan and Liangshan Yi areas in large and small). The data are from Sichuan Yearbook, Sichuan Statistical Yearbook, Sichuan Statistical Bulletin of National Economic and Social Development and statistical yearbooks of cities at all levels in Sichuan Province from 2007 to 2016.

In this study, the ecological footprint of Sichuan counties mainly includes the consumption of bio-resources and fossil energy. According to the consumption of bio-resources in Sichuan Province, it mainly includes grain, oil, raw hemp, sugar, tobacco leaves, beef, mutton, rabbit meat, aquatic products, tea, garden fruits, etc. Energy consumption mainly includes Coal, gasoline, kerosene, diesel and natural gas, as shown in *Table 1*.

Table 1. *The indicator of county ecological footprint accounts*

Ecosystem consumption types	Land type	Account index
Biological resources account	Cultivated land	Food, oil crops, raw hemp, sugar, tobacco leaves, vegetables, medicinal materials
	Woodland	Garden fruits and tea
	Grassland	Pork, beef, mutton, rabbit, milk, eggs, honey, cocoon
	Waters	Aquatic product
Fossil energy account	Fossil fuel	Coal, gasoline, kerosene, diesel and natural gas
	Building land	Electric power

In addition, this study uses MOD17A3 data provided by the National Aeronautics and Space Administration (NASA). The fitting model is BIOME-BGC with a spatial resolution of 1 km. Modis Reprojection Tool (MRT) software provided by NASA is used to process the image mosaic and re-projection. Then ALBERS isoproduct projection is selected to remove outliers and other operations to process the MODIS data, and then NPP value is obtained. ArcGIS 10.2 software is used to clip global

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1295912971

MODIS data with the help of Sichuan geographic information vector map. The result is shown in *Figure 1.* In *Figure 1,* the data of 2006, 2009, 2012 and 2015 are shown respectively. Through the analysis of the above chart can find that the NPP value from east to West shows a decreasing trend, mostly 500-750 gC M 2 a 1. In a word, the low altitude is higher than the high altitude. The land in this province is classified according to the types of resources on the way, and overlapped with the map after cutting. Then the corresponding NPP mean values and corresponding areas of six types of land in Sichuan Province are calculated.

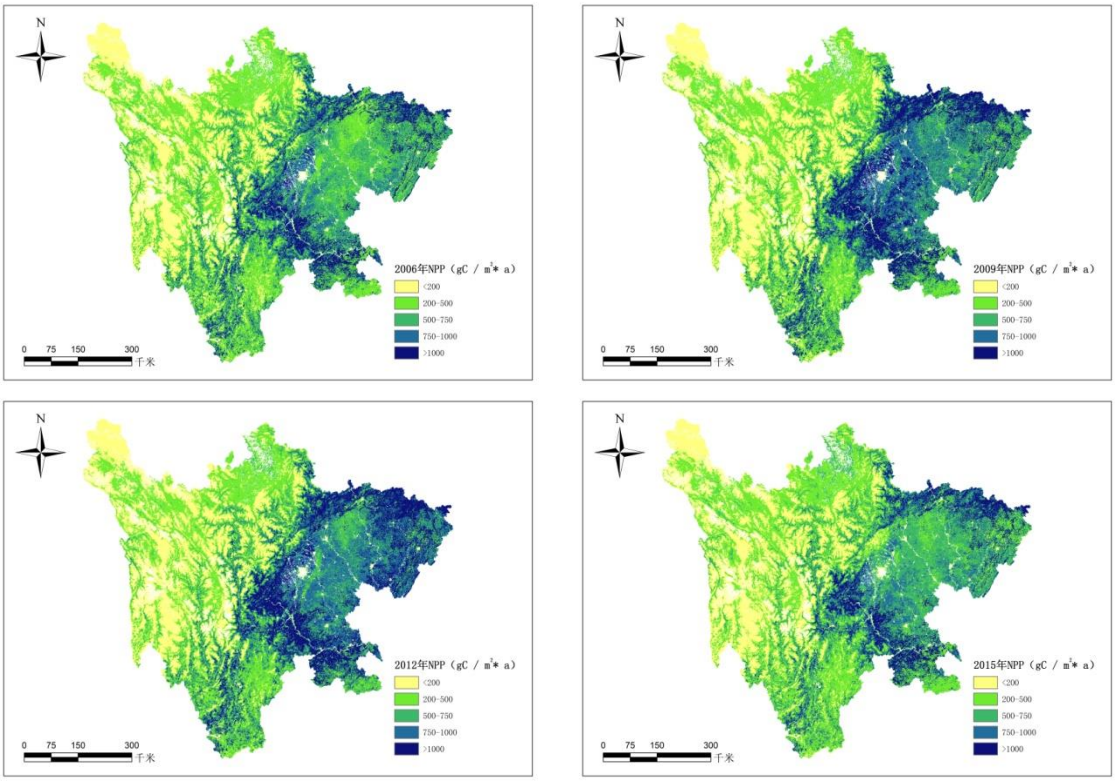

Figure 1. *Vegetation NPP spatial distribution of Sichuan Province on 2006, 2009, 2012 and 2015*

Adjustment of yield factor and equilibrium factor

This study applied the concept of "provincial hectare" to study the county ecological footprint of Sichuan Province. The basis of this province's hectare model is still the ecological footprint model. When calculating the output and equilibrium factors of Sichuan Province, the average productivity of the province is used. Equilibrium factors of related types of land are the ratio of their average productivity to other types of average productivity. The so-called yield factor is the ratio of the average productivity of the related types of land in a region to that of the same kind of land in a province. Bio productivity can be expressed by NPP. After removing self-consuming oxygen, green plants produce organic matter per unit time and area, which is called NPP. Therefore, it can be used to express the productivity of plants, and also to show the productivity of different land types, and then more accurately obtain the development level of the study area. NPP in this region needs to calculate NPP value of water area, woodland,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1295912971

grassland and cultivated land, and the corresponding area, then weighted sum, the corresponding formula is as follows:

$$\overline{NPP} = \frac{\sum_j \left(A_j \times NPP_j\right)}{\sum_j A_j} \quad \text{(Eq.1)}$$

In *Equation 1:* the area of various land types (m2).

The formulas for calculating the four types of land equilibrium factors of cultivated land, woodland, grassland and water area in China are as follows:

$$r_j = \frac{NPP_j}{\overline{NPP}} \quad \text{(Eq.2)}$$

In *Equation 2:* It is the average NPP of the land type j (gC/m2.a) and the average NPP of the land type (gC/m2.a).

The formulas for calculating the yield factors of cultivated land, woodland, grassland and water area in Sichuan Province are as follows:

$$y_i = \frac{NPP_j^{'}}{\overline{NPP_j}} \quad \text{(Eq.3)}$$

In *Equation 3:* NPP' is the average NPP (gC/m2.a) of all kinds of land types in Sichuan Province and the average NPP (gC/m2.a) of all kinds of land types in China.

Model calculation

Measuring ecological footprint

There are six main types of bio-productive area: fossil energy land, construction land, grassland, cultivated forest land, cultivated land and water area. Different types of bio-productive land have different ecological productivity, so it is necessary to introduce the equilibrium factor to calculate the bio-productive area with the world average productivity, so that different types of bio-productive land can be transformed into equivalent ecological productivity and the total ecological footprint can be calculated. Similarly, when calculating the ecological carrying capacity, it is necessary to introduce yield factors to convert the land area of the same ecological productivity in different countries or regions into comparable area. The calculation formula is as follows:

$$EF = N \times ef = N \times \sum \left(r_j \times A_j\right) = N \times \sum \left(r_j \times \left(c_j / p_j\right)\right) \quad \text{(Eq.4)}$$

In *Equation 4, EF* represents the total ecological footprint of a region. *N* is the total population. *ef* represents the per capita ecological footprint. r_j is the equilibrium factor. A_j is the ecological productive land area per capita converted from type j. c_j is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1295912971

the type i per capita consumption. p_j is the average production capacity of species j. j is productive land.

Estimation of ecological carrying capacity

Eco-carrying capacity, also known as biological carrying capacity, refers to the maximum amount of resources and wastes that can be supplied and digested without harming the ecosystem and on the basis of complete productivity and function.

$$EC = N \times ec = N \times \sum a_j \times r_j \times y_j \quad \text{(Eq.5)}$$

In *Equation 5,* EC is the total ecological carrying capacity of the region. N is the total population. ec is the per capita ecological carrying capacity. a_j is per capita Eco-productive land area. r_j is the equilibrium factor. y_j is the yield factor.

Estimating the ecological deficit

The ecological surplus/deficit is determined by comparing the size of EF and EC. When $EF - EC > 0$, there will be an ecological deficit; on the contrary, when $EF - EC < 0$, there will be an ecological surplus. By comparing the size of EF and EC, the sustainability of social development can be judged. Shengzhi deficit indicates that the human load in the region exceeds its ecological capacity. To meet the consumption demand under the existing living standard, the region either consumes its own natural capital to make up for the shortage of energy supply, or imports the lack of resources from outside the region to make up for the shortage of supply. Its development mode is in an unsustainable state. On the contrary, the ecological surplus indicates that the production and consumption patterns in the region are sustainable, and the human load in the region is within its ecological capacity, and its development pattern is in a sustainable state. The calculation formula is as follows:

$$ed = ec - ef \quad \text{(Eq.6)}$$

In *Equation 6:* ed is the per capita ecological deficit, when $ed < 0$, it is the ecological deficit, when $ed > 0$, it is the ecological surplus, ef is the per capita ecological footprint, ec is the per capita ecological carrying capacity.

Empirical results

Calculations of equilibrium factor and yield factor

By calculating *Equations 1–3,* the equilibrium factors and yield factors of various land types in Sichuan Province from 2006 to 2015 are obtained, as shown in *Tables 2* and *3*. *Tables 2* and *3* show only the land equilibrium factors and yield factors in 2006, 2009, 2012 and 2015 as follows.

The values of yield factor and equilibrium factor in the improved ecological footprint model are taken from the values in *Tables 2* and *3*.

Calculation results of ecological footprint

The average ecological footprint, ecological carrying capacity and ecological deficit per capita of 135 county-level administrative units in Sichuan Province were calculated by improved ecological footprint model. Calculate the ecological footprint according to *Equation 4*. Limited to the length of the article, only selected in 2006, 2000, 2009, 2012 and 2015 to show the ecological footprint per capita, ecological carrying capacity per capita and total ecological deficit per capita of 135 counties and districts in Sichuan Province in the main years. The counties and districts with the first-fifth and 131-135 indicators are shown in *Tables 4* and *5,* respectively.

Table 4. *Counties Ranking 1-5 on per capita ecological footprint of major years in Sichuan*

Ranking	1		2		3		4		5

Tables 4 and *5* show the per capita ecological footprint of counties in Sichuan Province in the main years. From the table, it can be seen intuitively that the top five and the last five counties in the per capita ecological footprint have great differences in numerical value. Especially in 2012, the per capita ecological footprint of Renshou County ranked first reached 30.86, 20.65 times that of Wusheng County ranked 135. Secondly, from the perspective of trend, from 2006 to 2015, the per capita ecological footprint of counties in Sichuan Province shows an increasing trend year by year. Especially in the period of 2012-2015, the growth rate accelerated significantly. Thirdly, by analyzing the counties with large per capita ecological footprint can find that most of the counties with high ranking, such as Renshou County, Anyue County, Santai County, Luxian County and Zhongjiang County, are the main producing areas of agricultural products in the province and have a large population base.

Calculation results of ecological carrying capacity

According to *Equation 5,* the ecological carrying capacity is calculated. The results are shown in *Tables 6* and *7*.

Tables 6 and *7* show the main years in Sichuan province county per capita ecological carrying case, can be seen from the table, the per capita ecological carrying capacity in 2006-2015, there is no significant change, but in the top five and five districts after from the numerical difference is bigger, especially in 2012, the number one cause of Mabian County per capita ecological carrying capacity is 1.21, 23.8 times is ranked 135th in Weiyuan. Secondly, in terms of trend, unlike the per capita ecological footprint, the per capita ecological carrying capacity of counties in Sichuan Province does not generally show a decreasing trend year by year, and the per capita ecological carrying capacity of some districts and counties has increased. Thirdly, by analyzing the counties with larger per capita ecological carrying capacity in Sichuan Province will find that Mabian County, Pingwu County, Qingchuan County, Wancang County, Wanyuan County, Baoxing County and Ebian County are the key ecological functional counties in

Sichuan Province, with the distribution of national-level nature reserves such as Dafeng Ding, Xuebaoding, Wang Lang, Tangjiahe, Micang Mountain, Huacalyx Mountain, Beepupa Village, Heizhugou Valley, Jiajinshan and so on. Domestic forest park, under the improved ecological footprint algorithm based on NPP, has a certain role in improving the ecological carrying capacity of the region.

Calculation results of ecological deficit

According to *Equation 6,* the ecological deficit is calculated. The results are shown in *Tables 8* and *9.*

Table 8. *Counties ranking 1-5 on per capita ecological deficit of major years in Sichuan*

Ranking	1		2		3		4		5	
Year	County	Value	County	Value	County	Value	County	Value	County	Value
2006	Renshou	27.56	Anyue	27.20	Santai	21.50	Yuechi	19.18	Zhong jiang	18.38
2009	Anyue	30.21	Renshou	29.46	Santai	24.55	Zhong jiang	22.72	Rong	19.67
2012	Renshou	34.01	Anyue	32.70	Yuechi	30.33	Zhong jiang	27.89	Santai	27.12
2015	Renshou	35.56	Anyue	35.27	Yuechi	34.73	Santai	34.24	Lu	32.58

Table 9. *Counties ranking 131-135 on per capita ecological deficit of major years in Sichuan*

Ranking	131		132		133		134		135	
Year	County	Value	County	Value	County	Value	County	Value	County	Value
2006	Cangxi	2.27	Yilong	1.88	Luo jiang	1.77	Qionglai	1.35	Wusheng	1.01
2009	Yucheng	2.33	Cangxi	2.16	Yilong	1.70	Wan yuan	1.60	Wusheng	1.10
2012	Ming shan	2.71	Wan yuan	1.90	Qionglai	1.66	Yilong	1.31	Wusheng	0.98
2015	Yucheng	3.23	Cuiping	3.18	Wan yuan	2.17	Yilong	1.33	Wusheng	1.06

Tables 8 and *9* show the per capita ecological deficit of counties in Sichuan Province in the main years. As mentioned above, the per capita ecological deficit is the difference between the per capita ecological footprint and the per capita ecological carrying capacity. However, from the calculation results, the difference between the per capita ecological carrying capacity and the per capita ecological footprint in Sichuan Province is very large. The ranking of the per capita ecological deficit is basically the same as that of the per capita ecological footprint. The ecological footprint of each county in Sichuan Province is far greater than that of the ecological carrying capacity.

The result of comprehensive evaluation shows that the per capita standard can reduce the error caused by population differences and make the calculation more reliable. It is feasible to evaluate the ecological footprint, ecological carrying capacity and ecological deficit based on the improved ecological footprint model. The evaluation shows that the ecological environment carrying capacity of the districts and counties in Sichuan Province is generally good, but there are great differences among the districts and counties, which are different from Shi et al. (2013). Agriculture, industrialization and fishery, represented by arable land, construction land and water area, are the core elements to evaluate the ecological carrying capacity. Industrialization is the root cause of the increase in energy and consumption, which is partly consistent with the conclusions of Zhao et al. (2008). The development of construction industry promotes

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1295912971

the transfer of rural surplus labor force, but also provides convenient conditions for industrial transformation and upgrading.

Conclusion

Because of the traditional ecological footprint model has certain defects, this article through the use of software and the MRT ArcGIS10.2 software of 1:100000 in Sichuan in 2006-2015 data of land use (geographic conditions monitoring cloud platform) and MOD17A3 data for Mosaic and projection, eliminate outliers, multiplied by the scale factor, the MODIS data into NPP actual value, represented the biological productivity of land with a NPP, improve the ecological footprint model of production factor and the equilibrium factor in order to closer to the actual of Sichuan province. Through the improvement of the ecological footprint model 135 counties of Sichuan province county per capita ecological footprint in 2006-2015, the per capita ecological carrying capacity and ecological deficit per capita, the results can be seen that all present in the study area of ecological deficit and increased year by year, the overall ecological environment extremely safe state for a long time, the development of sustainability. But at the same time, after 2012 because many counties began to emphasize the importance of ecological civilization construction in the development of county economy, the trend of high-speed growth of ecological footprint in some counties has not only been curbed, but also a trend of decreasing ecological footprint. For regions with too large ecological footprint, it is necessary to establish and improve the evaluation mechanism reflecting the requirements of ecological civilization, incorporate the construction of ecological civilization into the evaluation index system of county-level government's economic and social development performance objectives, increase the weight of assessment, and strengthen the constraints of indicators. a differentiated performance appraisal system will be implemented, explore the preparation of balance sheets for natural resources, and conduct outgoing audits of natural resources assets and environmental responsibilities for leading cadres. This also requires that Sichuan counties and districts in the formulation of county economic development strategy can not blindly compare, like great success, but need to take full account of their ecological conditions, in accordance with their own county conditions, so as to adapt to local conditions.

In future research, we should make full use of remote sensing technology, strengthen early warning of regional ecological carrying capacity, and provide scientific guarantee services for national county development policies to ensure sustainable development of regional ecology.

Abstract. Photocatalytic degradation of chlorophenols (CPs) has been attracting an increasing attention lately. In the paper, $TiO_2/H_3PW_{12}O_{40}$/Ag composite film was prepared by sol-gel method with programmed heating hydrothermal technology and spin coating technique to treat CPs. Direct photolysis of five CPs was performed according to the pseudo-first-order kinetics model, in which the photolysis rate of PCP was faster than that of the others under the simulated solar light. The results of mineralization indicated that the aromatic ring in PCP was difficult to be broken down via direct photolysis. By $TiO_2/H_3PW_{12}O_{40}$/Ag composite film, photocatalytic degradation efficiency elevated due to the enhancement of the quantum efficiency and visible-light absorption in comparison with direct photolysis as well as other reaction systems ($TiO_2/H_3PW_{12}O_{40}$ film and TiO_2 film), and the mineralization of PCP increased to 75.70%. The initial degradation rate (r_0) was in the following order as PCP (0.158 $mg \cdot L^{-1} \cdot min^{-1}$) > 4-CP (0.144 $mg \cdot L^{-1} \cdot min^{-1}$) > 2,4-DCP (0.014 $mg \cdot L^{-1} \cdot min^{-1}$) > 2,4,6-TCP (0.047 $mg \cdot L^{-1} \cdot min^{-1}$) > 2-CP (0.038 $mg \cdot L^{-1} \cdot min^{-1}$), confirming $TiO_2/H_3PW_{12}O_{40}$/Ag composite film as new catalyst to be more effective at removing for CPs.
Keywords: *direct photolysis, kinetics model, chlorine substituent, mineralization degree, degradation path*

Introduction

Chlorophenols (CPs) possess 19 homologues including mono-, di-, tri-, tetra-, and penta-chlorinated phenols, which have been widely used as pesticides, herbicides, fungicides, acaricides, and mold inhibitors (Olaniran et al., 2011; Garba et al., 2019; Yang et al., 2018; Guo et al., 2016). The position and quantity of chlorine substituent in CPs are closely correlated to their toxicity, e.g. ortho-substituted homologues are generally of lower toxicity than meta- and para-ones, and polychlorinated CPs are ascribed to increase hazardous effect for the organisms (Devillers et al., 1986; Du et al., 2016; Yu et al., 2019; Ge et al., 2017). CPs have been listed as priority pollutants by US EPA because of their adverse environmental effects, consequently, the disposal is currently one of the most serious environmental issues (Descorme et al., 2017). Photocatalytic degradation of CPs has been attracting an increasing attention lately, and numerous semiconductors have been investigated (Ku et al., 1996; Li et al., 2011; Gaya et al., 2009; Han et al., 2018; Al-Fahdi et al., 2019). TiO_2 is the most studied photocatalyst, however, the disadvantages including low quantum yield (approximately 0.14 at 365 nm) (Emeline et al., 2006), the limited solar light utilization (Meng et al., 2018), hindered its practical application.

In our previous work, an efficient plasmonic $TiO_2/H_3PW_{12}O_{40}$/Ag composite film was fabricated with an enhanced solar light photocatalytic activity due to the combined actions

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1297312983

of electrons-trapping via $H_3PW_{12}O_{40}$, visible-response induced by Ag, and Schottky-junction formed between TiO_2 and Ag (Lu et al., 2017). It has been documented that the chlorine positions in chlorophenol homologues act an important role in its photo-degradation kinetics (Hugül et al., 2000; Czaplicka et al., 2006). It is well known that ·OH is a very strong activator as well as ortho- and para-directing in electrophilic aromatic substitution (Antonaraki et al., 2002). Therefore, ·OH radical that was confirmed as the main role in $TiO_2/H_3PW_{12}O_{40}$/Ag reaction system (Lu et al., 2017) can directly attack the electron-rich positions in CPs molecules with a rapid degradation rate.

The current study is aimed to compare the removal efficiency and rate between direct photolysis and photocatalytic degradation of mono-, di-, tri- and penta-chlorophenols in TiO_2, $TiO_2/H_3PW_{12}O_{40}$, and $TiO_2/H_3PW_{12}O_{40}$/Ag systems. Moreover, the influence of chlorine substituent position and quantity on photocatalytic degradation in $TiO_2/H_3PW_{12}O_{40}$/Ag system was intensively investigated. The speculation of degradation path accompanied by mineralization degree analysis was discussed. This work would provide necessary information on the development of photocatalysis technique in practical application towards CPs wastewater treatment.

Material and methods

Reagents

The titanium tetraisopropoxide (TTIP, 98%) was purchased from Sigma-Aldrich Corporation. $H_3PW_{12}O_{40}$ (guaranteed reagent, GR), isopropanol (analytical purity, AR), $AgNO_3$ (AR), 2-CP (AR), 4-CP (AR), 2,4-CP (AR), 2,4,6-CP (AR) and PCP (AR) were purchased from China Pharmaceutical Group. Other chemicals were of reagent grade and applied without further purification. Double distilled water was utilized throughout the experimental procedures.

Catalyst preparation

The combining process of sol-gel-hydrothermal route and temperature programming was employed to fabricate $TiO_2/H_3PW_{12}O_{40}$/Ag composite film, which has been described in our previous study (Lu et al., 2017). The as-prepared film was confirmed with anatase phase TiO_2, the intact saturation Keggin structure, and metallic Ag inserted into the pore structures of $TiO_2/H_3PW_{12}O_{40}$, which enhanced the quantum efficiency, visible-light absorption and further improving in the photocatalytic performance.

Direct photolysis and photocatalytic experiment

2-chlorophenol (CP), 4-chlorophenol (4-CP), 2,4-dichlorophenol (2,4-DCP), 2,4,6-trichlorophenol (2,4,6-TCP), and pentachlorophenol (PCP) were selected as the targets, the corresponding molecular structures and detection conditions were listed in *Table 1*. The photocatalytic degradation of CPs was conducted in a home-made quartz photoreactor (*Fig. 1*) under the simulated solar light provided by a PLS-SXE300 Xe lamp (300 W, Beijing Trustech Co. Ltd., China) placing *ca.* 15 cm above the reactor. The lamp was equipped with cut filters to match solar light with wavelength of 320-780 nm, as well as light intensity of 200 mW/cm^2 measured by a radiometer (OPHIR, Newport, USA) (Lu et al., 2012). In the photocatalytic system, 2 pieces of coated films (Ag-$TiO_2/H_3PW_{12}O_{40}$ composite film, $TiO_2/H_3PW_{12}O_{40}$ composite film, or TiO_2 film) with a weight of *ca.* 5.0 mg were submerged in CPs solution (100 ml; 5 $mg \cdot L^{-1}$). Prior to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1297312983

irradiation, the films were maintained in dark for 30 min to reach adsorption-desorption equilibrium of CPs. After irradiation, 2 mL CPs solution was sampled and analyzed at 30 min intervals. The experiments were carried out in triplicate. Direct photolysis were conducted in the same conditions without catalyst.

Table 1. *Molecular structures and detection conditions of CPs*

CPs	Molecular structures	Detection conditions HPLC equipped with Waters 2489 UV/visible detector and symmetry C18 (4.6 × 250 mm, particle size 5 μm)
2-CP		Mobile phase of acetonitrile (40%) and H_2O (60%, containing 0.1% acetic acid) at a flow rate of 0.7 ml·min^{-1} with a detection wavelength of 254 nm
4-CP		Mobile phase of acetonitrile (50%) and H_2O (50%, containing 1% acetic acid) at a flow rate of 1.0 ml·min^{-1} with a detection wavelength of 254 nm
2,4-DCP		Mobile phase of methyl alcohol (80%) and H_2O (20%) at a flow rate of 1.0 ml·min^{-1} with a detection wavelength of 284 nm
2,4,6-TCP		Mobile phase of methyl alcohol (80%) and H_2O (20%, containing 0.3% phosphoric acid) at a flow rate of 1.0 ml·min^{-1} with a detection wavelength of 210 nm
PCP		Mobile phase of methyl alcohol (90%) and H_2O (10%, containing 2.0% acetic acid) at a flow rate of 0.7 ml·min^{-1} with a detection wavelength of 254 nm

Kinetics

Direct photolysis and photocatalytic degradation kinetics was accorded to simplified pseudo-first-order kinetics (Eq. 1) when the initial concentration of target compound was low.

$$ln\ (C_0/C_t) = K_{app} \cdot t + b \quad \text{(Eq.1)}$$

$$r_0 = K_{app} \cdot C_0 \quad \text{(Eq.2)}$$

in which K_{app} is the apparent constant; C_0 and C are initial and process concentration of the target compound, respectively; t is the reaction time; b is the intercept, R value was obtained by fitting with the least square method.

Statistical analysis

Statistical analysis and linear regression were conducted using SPSS 23.0 statistical software (SPSS Inc., Chicago, USA). The differences of K_{app} and r_0 were tested by one-way ANOVA, in which the comparisons were considered statistically significant, when $P < 0.05$.

Results

Direct photolysis and photocatalytic degradation

The direct photolysis of CPs under UV light was usually studied in many previous reports (Pandiyan et al., 2002; Hong et al., 2000); however, UV light only was around 4-5 percent in sunlight. In the current study, solar simulating irradiation was selected as light source, which was more similar to that of the practical proceeded under the natural sunlight. The results (*Fig. 2*) showed that PCP represented the highest direct photolysis rate as 90.95% after 240 min irradiation, followed by 4-CP (66.05%), 2,4-DCP (50.41%), 2,4,6-TCP (43.02%), and 2-CP (5.11%), which concluded most CPs could be direct photodegraded quickly except 2-CP.

In photocatalytic degradation system, the removal efficiency of CPs was increased obviously after adding the catalysts relative to direct photolysis (*Fig. 3*). By $TiO_2/H_3PW_{12}O_{40}$/Ag film, after 120 min irradiation, the photocatalytic degradation efficiency of 2-CP, 4-CP, 2,4-CP, 2,4,6-TCP, and PCP was 48.49%, 89.89%, 94.57%, 75.15%, and 90.50%, respectively. The degradation efficiency integrally elevated when irradiation time extended to 240 min, 4-CP, 2,4-CP and PCP was hardly completely degraded, while 90.22% of 2,4,6-TCP and 82.40% of 2-CP was degraded. All the values were higher than the attained degradation efficiency in $TiO_2/H_3PW_{12}O_{40}$ or TiO_2 film reaction systems.

Kinetics

By direct photolysis (*Fig. 4* and *Table 2*), the values of initial react rate (r_0) were in order as PCP (0.051 $mg \cdot L^{-1} \cdot min^{-1}$) > 4-CP (0.021 $mg \cdot L^{-1} \cdot min^{-1}$) > 2,4-DCP (0.014 $mg \cdot L^{-1} \cdot min^{-1}$) > 2,4,6-TCP (0.011 $mg \cdot L^{-1} \cdot min^{-1}$) > 2-CP (0.001 $mg \cdot L^{-1} \cdot min^{-1}$).

By photocatalytic degradation (*Fig. 5* and *Table 3*), kinetic study was conducted by selecting TiO_2 film, $TiO_2/H_3PW_{12}O_{40}$ film and $TiO_2/H_3PW_{12}O_{40}$/Ag film as the catalyst.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1297312983

In $TiO_2/H_3PW_{12}O_{40}$/Ag composite film system, the values of initial react rate (r_0) were in order as PCP (0.158 $mg \cdot L^{-1} \cdot min^{-1}$) > 4-CP (0.144 $mg \cdot L^{-1} \cdot min^{-1}$) > 2,4-DCP (0.014 $mg \cdot L^{-1} \cdot min^{-1}$) > 2,4,6-TCP (0.047 $mg \cdot L^{-1} \cdot min^{-1}$) > 2-CP (0.038 $mg \cdot L^{-1} \cdot min^{-1}$), which was faster than that of $TiO_2/H_3PW_{12}O_{40}$ or TiO_2 film.

Mineralization degree

The mineralization of PCP (20 $mg \cdot L^{-1}$) was evaluated by monitoring the changes of TOC in both direct photolysis and $TiO_2/H_3PW_{12}O_{40}$/Ag photocatalytic degradation system. Even though degradation rate of PCP was faster than that of other CPs in the two reaction systems, the mineralization degree of PCP was approximately 25.70% in direct photolysis, whereas it reached 75.70% in the photocatalytic reaction after 720 min (*Fig. 6*).

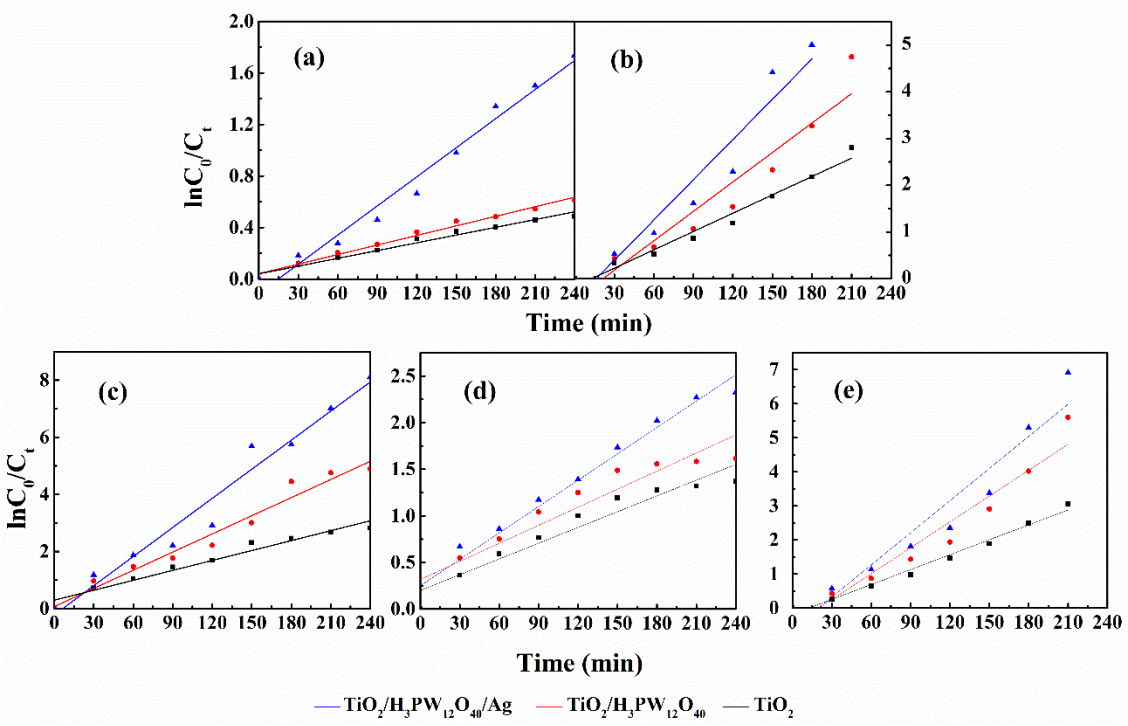

Figure 5. *Photocatalytic degradation kinetics*

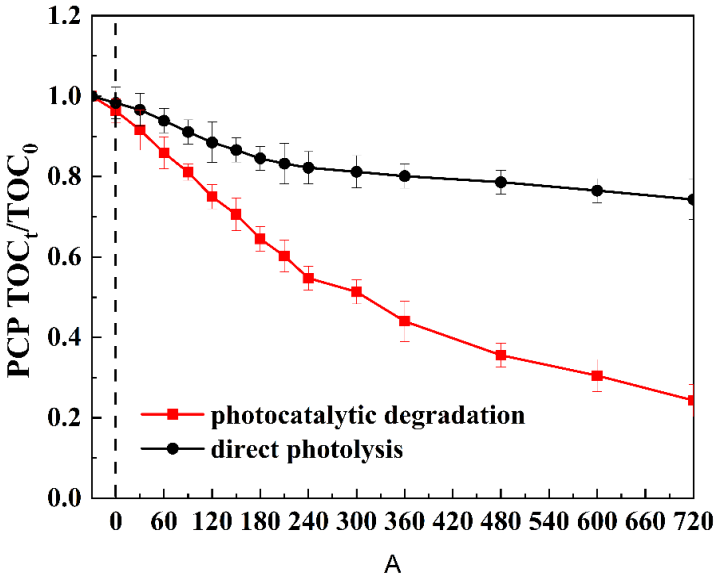

Figure 6. *TOC evolution of CPs*

DOI: http://dx.doi.org/10.15666/aeer/1706_1297312983

Discussion

Based on the results of direct photolysis and photocatalytic degradation, it could be concluded as follow: firstly, all position was full by chlorine atoms in PCP molecule resulting in electron density decreased on the ring due to the electron withdrawing properties of Cl atoms, making the ring less favorable to electrophilic attack, so increased degradation rate (Kim et al., 2003); secondly, degradation of 2-CP was retarded due to the formation of intramolecular hydrogen bonding between OH and Cl (Yang et al., 2014); thirdly, the degradation rate order of 4-CP > 2,4-DCP > 2,4,6-TCP was attributed to the fact that the more chlorine substituent in *meta-* position, the stronger passivation generated among them (Sundstrom et al., 1989). Therefore, the direct photolysis and photocatalytic degradation was mainly controlled by the position and quantity of substituted chlorine atoms in CPs, which were in agreement with other reports (Ko et al., 2007; Yuan et al., 2005).

As-prepared $TiO_2/H_3PW_{12}O_{40}$/Ag film showed the excellent photocatalytic property, the results showed that K_{app} of as-prepared $TiO_2/H_3PW_{12}O_{40}$/Ag reaction system increased significantly in comparison with TiO_2 system ($P < 0.05$). Because $TiO_2/H_3PW_{12}O_{40}$/Ag reaction system delayed the recombination of holes and electrons pairs efficiently owing to the synergistic effects between the Keggin unit and TiO_2 and the generation of Schottky junction at the interface between Ag and TiO_2, meanwhile expanded the absorption of visible-light due to SPR effect (Lu et al., 2017). It is worth noting that only a limited amount of *ca.* 5.0 mg $TiO_2/H_3PW_{12}O_{40}$/Ag was used in the current system, the degradation rate under simulated solar light was considerable in comparison with that in other studies (*Table 4*) even if their experimental conditions showed more advantages including of strong ultraviolet as light source or large catalyst amount.

Table 4. *Photocatalytic degradation dynamics in other reports*

CPs	Co ($mg \cdot L^{-1}$)	Catalyst	Lamp	Initial rate r_0 ($mg \cdot L^{-1} \cdot min^{-1}$)	Reference
2-CP	10	TiO_2 ($2\ g \cdot L^{-1}$)	15 W black flue fluorescent	0.047	Ku et al., 1996
4-CP	20	TiO_2/AC-PC ($2.5\ g \cdot L^{-1}$)	125 W Hg lamp	6.733	Herrmann et al., 2002
2,4-DCP	20	TiO_2 ($0.1\ g \cdot L^{-1}$)	125 W Hg lamp	0.569	Jardim et al., 1997
2,4,6-TCP	100	α-Fe_2O_3 ($1.5\ g \cdot L^{-1}$)	Solar simulator	0.231	Bandara et al., 2001
PCP	170	TiO_2 ($0.1\ g \cdot L^{-1}$)	125 W Hg lamp	0.789	Jardim et al., 1997

In the mineralization study, the photon energy of simulated solar light can only destroy Cl-C of PCP molecule successively till producing the mono-chlorinated phenol but not powerful enough to break down the aromatic ring (Skurlatov et al., 1997). In photocatalytic degradation system, the complex effect of dichlorination, hydroxylation and ring-cleavage functioned in the removal of chlorophenols (Tang et al., 1996). The specific degradation path was shown in *Figure 7*.

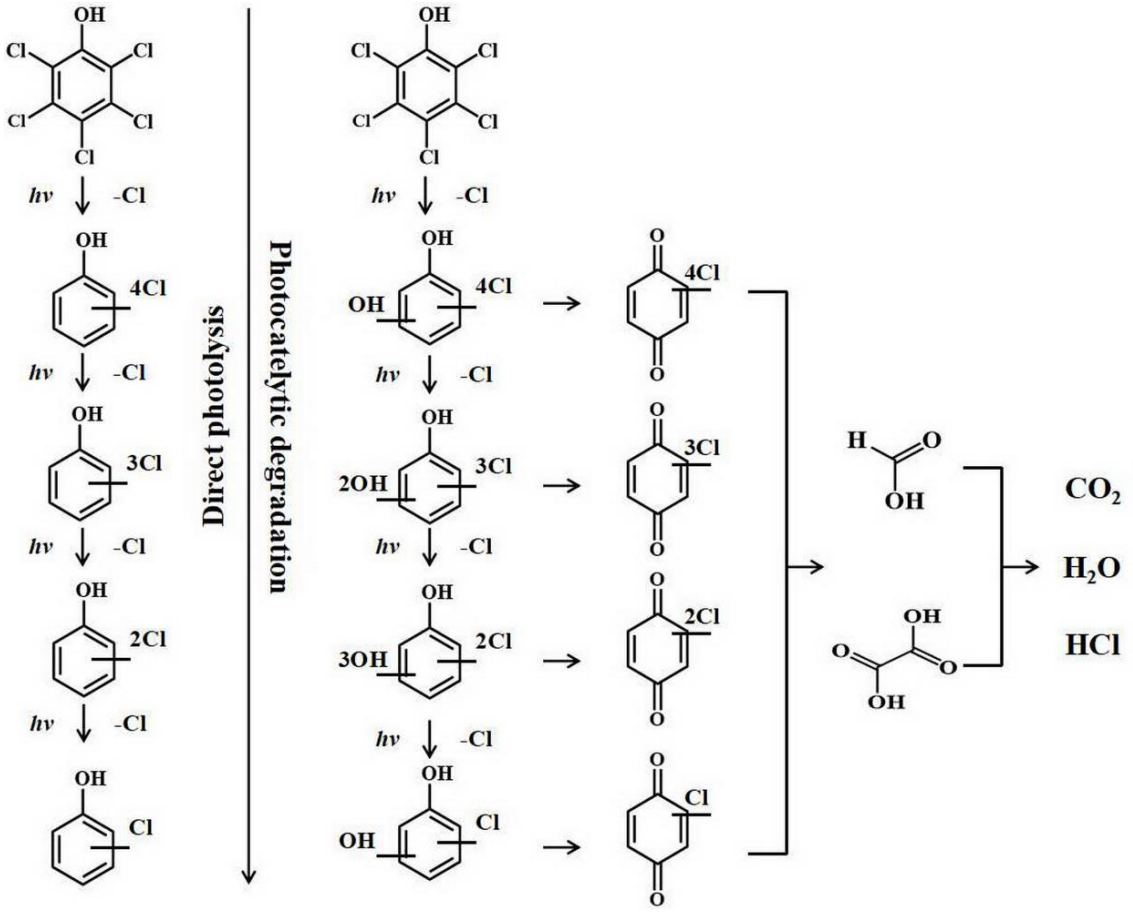

Figure 7. *Possible reaction pathway during photocatalytic degradation of PCP*

Conclusion

$TiO_2/H_3PW_{12}O_{40}$/Ag composite film as new photocatalyst represented an excellent removal efficiency towards CPs under the simulated sunlight relative to others photocatalytic system. The values of initial react rate (r_0) were in the order as PCP (0.158 $mg \cdot L^{-1} \cdot min^{-1}$) > 4-CP (0.144 $mg \cdot L^{-1} \cdot min^{-1}$) > 2,4-DCP (0.014 $mg \cdot L^{-1} \cdot min^{-1}$) > 2,4,6-TCP (0.047 $mg \cdot L^{-1} \cdot min^{-1}$) > 2-CP (0.038 $mg \cdot L^{-1} \cdot min^{-1}$) in the current system, which was related with chlorine substituent position and quantity in CPs molecules. Therein, PCP was highest degradation rate due to the decreased electron cloud density by full chlorine substituents in the phenolic ring, and 75.70% PCP (20 $mg \cdot L^{-1}$) could be mineralized after 720 min irradiation due to ·OH attack. This work will provide necessary information on the development of photocatalysis technique for chlorophenols wastewater treatment in practical application. Moreover, it can be predicted that other noble metal (Pt, Cu, et al) modified $TiO_2/H_3PW_{12}O_{40}$ will also show excellent photocatalytic performance, and the photoelectrocatalytic study of $TiO_2/H_3PW_{12}O_{40}$/Ag composite film is expected.

Abstract. Heavy metal contaminated wastewater is difficult to treat, and trace amounts of heavy metals can produce toxic effects. In order to provide a more reliable basis for controlling heavy metal pollution, modified carbonized straw was used to adsorb Cr^{6+} in this study, and the optimal adsorption conditions and adsorption effects of Cr^{6+} were studied. Finally, the adsorption kinetics and adsorption activation thermodynamics were analyzed and studied. The results showed that the iodine adsorption value of carbonized wheat straw modified using $FeCl_2$ activation method was the highest at 1161.15 mg/g. The response surface method can be used to optimize the adsorption conditions of Cr^{6+} adsorbed by modified carbonized straw and predict the optimal conditions for Cr^{6+} adsorption. Experiments showed that the actual value was in agreement with the predicted value, indicating that the response surface methodology was feasible to optimize the adsorption of Cr^{6+} by modified carbonized straw. In the kinetic analysis, the Elovich equation could better describe the adsorption of Cr^{6+} by modified carbonized wheat straw, and its fitting degree exceeded 0.91. In the analysis of thermodynamic parameters, $\Delta H > 0$, $\Delta G < 0$, indicating that the adsorption of Cr^{6+} by modified wheat straw was a spontaneous endothermic process. During the adsorption process, $\Delta S > 0$, indicating that the adsorption of Cr^{6+} by modified carbonized wheat straw increased the disorder of the system.

Introduction

With the development of industry in China, heavy metal pollution has seriously endangered human health. In fact, heavy metal pollution is difficult to be degraded and removed by simple methods, and it tends to accumulate in organisms and produce toxic effects (Zhao, 2016). At present, the aggravation of heavy metal pollution poses a great threat to the healthy development of human beings and other organisms, and the treatment of heavy metal wastewater has become an urgent problem to be solved. Therefore, it is of great significance to analyze and study the treatment and disposal of heavy metal wastewater (Zeng, 2014a; Zeng and Li, 2014b).

China is a country of traditional agricultural production (Cao et al., 2012). At present, China's agricultural straw production is high. However, with the improvement of people's living standards, straw is no longer needed in daily life. Nowadays, most of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1298512999

the straw is treated by incineration and disposal, and has not been reused (Sud et al., 2008), which not only wastes resources, but also brings more and more serious air pollution problems. Therefore, a large number of agricultural straws have not been properly utilized, and the conventional disposal methods have been unable to meet the current straw disposal requirements. In response to the call for building a resource-conserving and environment-friendly society, reusing these residues to dispose of waste is a good way to deal with agricultural waste (Ngah and Hanafiah, 2008). Straw is a biomass waste with high crude fiber content and low protein content (Zhu et al., 2010), which is difficult to be corroded, and it is not good to be directly returned to the field. However, the carbonized product of straw has good physicochemical properties, such as good combustibility, adsorption and low electrical resistance (Sun and Jiang, 2009), which can be used as fuels, soil conditioners and filling materials for electromagnetic shielding screen. Therefore, it is a feasible path to improve the comprehensive utilization rate of straw and carry out biochar utilization of straw and other biomass.

On the basis of the previous studies (Zeng et al., 2018), wheat, corn and paddy straw from farmland around Chengdu, Sichuan Province were carbonized to produce carbonized straw, which is used as activated carbon to study the best adsorption conditions and effects for Cr^{6+}, and the adsorption kinetics and thermodynamics of adsorption activation state were studied finally. In addition, this study evaluated the treatment of Cr^{6+} by modified carbonized straw, which is expected to provide some technical and theoretical support for the practical application of this method.

Materials and methods

Materials, reagents and instruments

The materials used in this experiment were waste wheat, corn, and rice straw produced by agriculture. Corn stalks were taken from Xihe Town, Longquanyi, Chengdu. Wheat straw and rice straw were taken from Huayang Town, Shuangliu, Chengdu.

The object of this experiment was a solution containing Cr^{6+}. The reagents used in the experiment were $ZnCl_2$, KOH, HCl, HNO_3, H_2SO_4, $K_2Cr_2O_7$, $FeCl_2$, I_2, KI, $Na_2S_2O_3$, soluble starch. All reagents were analytical pure. The equipments of the experiment include electrothermal constant temperature blast drying oven (DHG-9140A), visible light spectrophotometer (V-1200), water bath oscillator (HH-4), electronic analytical balance (ESJ120-4), pH meter (PHS-3C), constant temperature oscillator (THZ-032), electric stirrer (JJ-1), ultrasound instrument (KQ-50), high speed centrifuge (H1650R), universal electric furnace (BDW1-6), mesh screen (40 to 200 mesh).

Preparation of modified carbonized straw

In this paper, wheat, corn and rice straw were used as raw materials to prepare activated carbon by using chemical activation method, and the activator were zinc chloride, potassium hydroxide, concentrated sulfuric acid and ferrous chloride, the experimental scheme is shown in *Table 1* (Nu et al., 2017). First, distilled water was applied to clean three kinds of straws. Then straws were dried under the condition of 100 °C in the electrothermal constant temperature blast drying oven and cut into long strips of 3-4 cm. Next, the dried material was sealed with a foil paper and placed on a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1298512999

universal electric furnace for 30 min (the temperature of wheat straw was 800 °C (Xiao et al., 2010), the temperature of corn straw was 600 °C (Chen et al., 2010), and the temperature of rice straw was 300 °C (Pinto et al., 2005), then the outer wrapped tin foil paper was removed, and the crude carbonized straw obtained after activation was ground and sieved (40 to 60 mesh). Next, the three sieved carbonized straws were mixed with $ZnCl_2$ (3 mol/L), KOH (3 mol/L), H_2SO_4 (37%) and $FeCl_2$ (2 mol/L) in a mass ratio of 1:3 in a 100 mL stoppered conical flask and closed it immediately, and then it was oscillated in the constant temperature oscillator (temperature: 25 °C, oscillation speed: 150 r/min, oscillation time: 120 min). At the end of the oscillation, solid modified carbonized straw was obtained by filtering the mixed liquor. Firstly, it was washed by 1:9 dilute hydrochloric acid solution (1 mol/L). Secondly, it was washed repeatedly with distilled water to neutral. Thirdly, it was dried to constant weight. After grinding, the activated carbon in 200-mesh was selected for use.

Table 1. *Experimental design of carbonized straw modification*

Number	Straw	Activator	Mass ratio (g:mL)	Temperature (°C)	Oscillation speed (r/min)	Oscillation time (min)
1	Wheat	$ZnCl_2$	1:3	25	150	120
2	Wheat	KOH	1:3	25	150	120
3	Wheat	H_2SO_4	1:3	25	150	120

11	Rice	H_2SO_4	1:3	25	150	120
12	Rice	$FeCl_2$	1:3	25	150	120

Method for determining iodine value of modified carbonized straw

The iodine level is related to the adsorption capacity of activated carbon. It is generally believed that the higher the iodine value, the higher the porosity of activated carbon, which means the high adsorption capacity. In this experiment, the iodine value of modified carbonized straw was determined by national standard GB/T12496.8-2015 "Determination of iodine adsorption value by wood activated carbon experimental method" (Chen et al., 2007).

Drawing method of standard curve of Cr^{6+}

A certain concentration of Cr^{6+}-containing solution was configured with distilled water as a reference, and absorbance was measured at its maximum absorption wavelength (each sample was measured three times, averaged and recorded, n = 3). Taking 540 nm as the maximum absorption wavelength of Cr^{6+}, the concentration of the Cr^{6+}-containing solution respectively was 0 mg/L, 0.02 mg/L, 0.1 mg/L, 0.4 mg/L, and 0.8 mg/L. Then, the experiment was performed, the measured absorbance was taken as the ordinate, the concentration was taken as the abscissa, and the standard curve was drawn.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1298512999

Configuration of Cr^{6+}-containing solution

First, the best grade pure potassium dichromate was weighed 1.4135 g and dissolved in water, and then the volume of solution reached at 500 mL by adding water. Therefore, the standard reserve solution containing Cr^{6+} 1.0 mg/mL was obtained. When the solution needs to be used, the standard reserve solution is absorbed with 1.0 mL nitric acid, and then a standard solution containing 100 mg/mL Cr^{6+} was obtained (Chen et al., 2010).

Response surface experiment of Cr^{6+}

The experiment used the Box-Behnken design to predict the optimal adsorption conditions and explore the interaction between the factors through Design Expert software (Hadjmohammadi et al., 2016). In this experiment, temperature (A), adsorption time (B), and adsorbent dosage (C) were used as independent variables, the removal rate of Cr^{6+} by activated carbon modified under different conditions as a response value, and then the adsorption performance of modified carbonized straw for adsorption of Cr^{6+} was optimized. The experimental design was shown in *Table 4*.

Adsorption kinetics

In this study, the first-order kinetic equation, the double-constant equation, and the Elovich equation were used to analyze the adsorption kinetics of the Cr^{6+}-containing solution by modified carbonized straw.

The linear expression of the first-order kinetic equation is as follows *Equation 1* (Takeshi et al., 2004). In the formula, C_t is the mass concentration at time t (mg/L), a and k are the kinetic constants, t is the adsorption time.

$$\ln C_t = \mathrm{a} - \mathrm{kt} \quad \text{(Eq.1)}$$

The double-constant equation is suitable for complex non-homogeneous diffusion processes, and the linear expression of which is as follows (*Eq. 2*) (Wu, 2015). In the formula, X is adsorption capacity (mg/g), a and k are the kinetic constants, t is the adsorption time.

$$\ln X = a + k\ln\mathrm{t} \quad \text{(Eq.2)}$$

The linear expression of the Elovich equation (Shi and Li, 2014) is as follows (Eq. 3). In the formula, X is adsorption capacity (mg/g), a and k are the kinetic constants, t is the adsorption time.

$$X = a + k\ln\mathrm{t} \quad \text{(Eq.3)}$$

Adsorption thermodynamics

Calculating the change of standard thermodynamic function based on experimental data of adsorption thermodynamics is an important part of adsorption thermodynamics research, which has theoretical and practical significance (McKay, 1984). In the adsorption process, the relationships between the thermodynamic functions ΔG, ΔH, ΔS and the adsorption partition coefficient K are as follows (*Eqs. 4–7*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1298512999

$$K = \frac{q_e}{C_e} \quad \text{(Eq.4)}$$

$$\Delta G = -RT \ln K \quad \text{(Eq.5)}$$

$$\Delta G = \Delta H - \mathrm{T}\Delta S \quad \text{(Eq.6)}$$

From the above formulas:

$$\ln K = \frac{\Delta S}{R} - \frac{\Delta H}{RT} \quad \text{(Eq.7)}$$

In the formulas, q_e is the equilibrium adsorption amount (mg/g), C_e is the mass concentration of adsorbate in solution during adsorption equilibrium (mg/L), T is the thermodynamic temperature (K), R is the gas constant (8.314 J/(mol·k)), K is the adsorption partition coefficient, ΔH is the change of adsorption enthalpy (kJ/mol), ΔS is the change of adsorption entropy (J/(mol K)), ΔG is adsorption free energy (kJ/mol).

Experimental results and analysis

Results of modified carbonized straw

The straw obtained after carbonization was dark black, and it had a brittle texture and was lighter in weight than raw materials. The activated carbonized straw was black powder after drying and grinding, and the straw components were shown in *Table 2*.

Table 2. *Component of straw*

Straw	Lignin	Crude fiber	Crude ash	Crude protein
Rice	6.3%	35.1%	19.4%	3.2%
Corn	4.6%	29.3%	7.0%	9.3%
Wheat	9.5%	43.6%	2.6%	2.6%

It could be seen from *Table 2* that the lignin content and crude fiber content of wheat straw were higher than those of rice straw and corn straw, and the pore structure of cellulose directly affected subsequent adsorption properties.

In the process of carbonization and modification, the average pore size of straw decreased, which made the total pore volume increase. At the same time, the non-microcrystalline carbon of the carbon structure was oxidized, which made the specific surface area larger, and the microcrystalline carbon was rearranged to make pores more stable. Therefore, the specific surface area of the modified carbonized straw was much higher than the specific surface area of the original straw. In fact, the increase in specific surface area increased the adsorption area of the adsorbent for heavy metals, and then the adsorption rate was increased (Zhong, 2011).

During the adsorption process, with the increase of temperature, raw materials were rapidly decomposed by heat, so C—OH, C—O—C, C—H and other groups in cellulose molecular structure were decomposed at 280~380 °C, and small amount of molecule fragments or groups were decomposed continuously when the temperature more than

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1298512999

380 °C. At the same time, carbon element was rearranged to form graphite microcrystalline (Zhu and Zhou, 2014).

Determination and analysis of iodine value of modified carbonized straw

Through the measurement experiment of iodine value, the iodine values of the experimental samples were shown in *Table 3*.

Table 3. *Iodine value of different modified carbonized straw*

Number	Carbonized straw	Modifier	Iodine value (mg/g)
1	Wheat	$ZnCl_2$	1005.32
2	Wheat	KOH	993.84
3	Wheat	H_2SO_4	994.86
4	Wheat	$FeCl_2$	1161.15
5	Corn	$ZnCl_2$	1072.23
6	Corn	KOH	1135.19
7	Corn	H_2SO_4	1101.27
8	Corn	$FeCl_2$	962.80
9	Rice	$ZnCl_2$	1021.13
10	Rice	KOH	993.87
11	Rice	H_2SO_4	937.04
12	Rice	$FeCl_2$	1007.25

In this study, different carbonized straws were modified by different modifiers, and the iodine adsorption value was used as an indicator to compare the adsorption capacity of different modified carbonized straws. After the four modifiers were applied separately, the adsorption capacity of the modified wheat straw was greater than that of corn and rice straw, which might be closely related to the content of crude fiber and lignin in wheat straw. In the experiment, the modified carbonized wheat straw with 2 mol/L $FeCl_2$ as modifier had the highest iodine adsorption value 1161.15 mg/g. Therefore, the subsequent adsorption experiments selected modified carbonized wheat straw as the main research object, which used 2 mol/L $FeCl_2$ as modifier.

Response surface analysis of Cr^{6+}

Based on single factor experiments and orthogonal experiments, this study used Design Expert software to design a response surface experimental scheme in Box-Behnken mode, and then used model analysis to predict the optimal adsorption conditions and the interaction between the factors. In the experiments, temperature (A), adsorption time (B), and dosage of adsorbent (C) were used as independent variables, and the removal rate of Cr^{6+} by activated carbon was used as the response value, and then the adsorption conditions for the adsorption of Cr^{6+} by modified carbonized straw were optimized. The experimental results were shown in *Table 4*.

The results of the *Table 4* were analyzed and modeled, and then the quadratic polynomial regression equations of temperature (A), adsorption time (B), adsorbent dosage (C), and Cr^{6+} adsorption rate R were obtained as follows (*Eq. 8*):

$$R = 98.20 + 1.66A + 0.57B + 0.51C - 0.010AB + 0.23AC + 0.22BC - 1.81A^2 - 0.69B^2 - 0.42C^2 \quad \text{(Eq.8)}$$

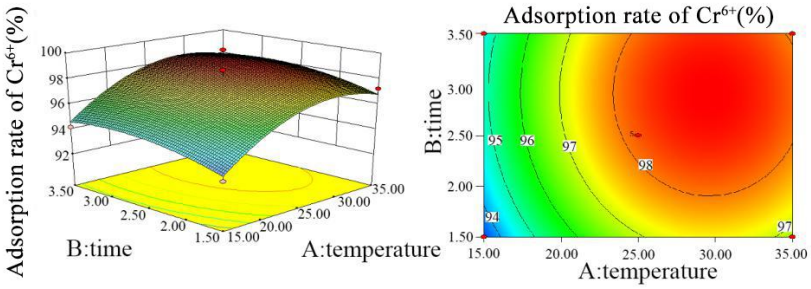
*Significant (P < 0.05), **highly significant (P < 0.01)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1298512999

According to the *Table 5*, the P value of the model was 0.0004, and the unfitting term was 0.0577, which indicated that the model was not significant, but the regression was significant. The correlation coefficient (R2) was 0.9596, indicated that the fitting effect was better; the variation coefficient was 0.54%, indicated that the model had good reliability and accuracy. The precision indicated the ratio of signal to noise, which should normally be greater than 4. The precision of this experiment was 12.354, indicated that the model could appropriately reflect the experimental results (Han et al., 2018). In addition, correlation coefficient (R^2) and correction correlation coefficient (Adj R^2) showed that the fitting degree and correlation of the model were high, which indicated that the model could be used to predict the optimal adsorption conditions of Cr^{6+} on modified carbonized straw.

Effect of temperature and time on the adsorption rate of Cr^{6+}

In *Figure 1,* the left graph was a three-dimensional model of temperature, time, and chromium ion adsorption rate, and the right graph was the equal adsorption rate line for adsorption time and temperature. The shape of the equal adsorption rate line could reflect the strength of the interaction of the investigation factors. If it was circular, it meant that the interaction effect was not significant. However, if it was elliptical, it meant that the interaction effect was significant (Pang et al., 2017).



Figrue1. *Effect of temperature and time on the adsorption rate of Cr^{6+}*

As shown in *Figure 1,* the adsorption rate increased with the increase of temperature, indicated that heating was beneficial to the adsorption reaction. In addition, when the treatment time increased from 1.5 to 3.5 h, the adsorption rate increased first and then tended to be slow, indicated that the modified carbonized straw adsorbed Cr^{6+} rapidly first and then gradually reached adsorption equilibrium. According to *Table 5*, the P value of temperature (A) was < 0.0001, the P value of time (B) was 0.0174, and the P value of AB was 0.9704 > 0.05, indicated that the influence of factors A and B on the adsorption rate of Cr^{6+} had no interaction. According to the multiple quadratic regression equation obtained from the response surface, the coefficient of AB was -0.010, indicated that the interaction of the two factors had a negative effect on the result.

Effect of temperature and dosage on the adsorption rate of Cr^{6+}

As shown in *Figure 2,* the adsorption rate increased with increasing temperature, and a high adsorption rate could be achieved at 25 °C. And then the temperature continued to increase, but the adsorption rate increased slowly. Under the condition of constant temperature, the adsorption rate increased with the increase of dosage. However, when

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1298512999

the dosage reached 2.4 g, the adsorption rate increased very slowly. According to *Table 5*, the P value of temperature (A) was < 0.0001, the P value of dosage (C) was 0.0286, and the P value of AB was 0.4103 > 0.05, indicated that the influence of factors A and C on the adsorption rate of Cr^{6+} had no interaction. According to the multiple quadratic regression equation obtained from the response surface, the coefficient of AC was + 0.23, indicated that the interaction of the two factors had a positive effect on the result.

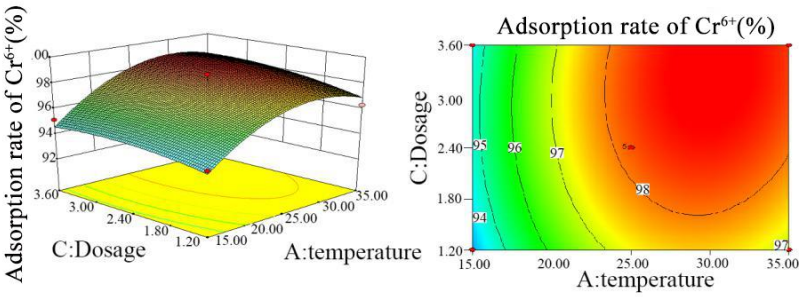


Figure 2. *Effect of temperature and dosage on the adsorption rate of* Cr^{6+}

The effect of time and dosage on the adsorption rate of Cr^{6+}

It could be seen from *Figure 3* that when the time was constant, the adsorption rate increased with the increase of the dosage, but when the dosage exceeded 2.4 g/L, the increase rate of the adsorption rate gradually decreased. At the same time, when the dosage was constant, the adsorption rate also increased with the time, and the growth rate was low. Theoretically, that was because the adsorbent rapidly adsorbed Cr^{6+} in the initial stage and had reached saturation in the later stage, so the adsorption rate did not increase significantly in the later stage. According to *Table 5*, the P value of time (B) was 0.0174, the P value of dosage (C) was 0.0286, and the P value of BC was 0.4201 > 0.05, indicated that the influence of factors B and C on the adsorption rate of Cr^{6+} had no interaction. According to the multiple quadratic regression equation obtained from the response surface, the coefficient of BC was + 0.22, indicated that the interaction of the two factors had a positive effect on the result.

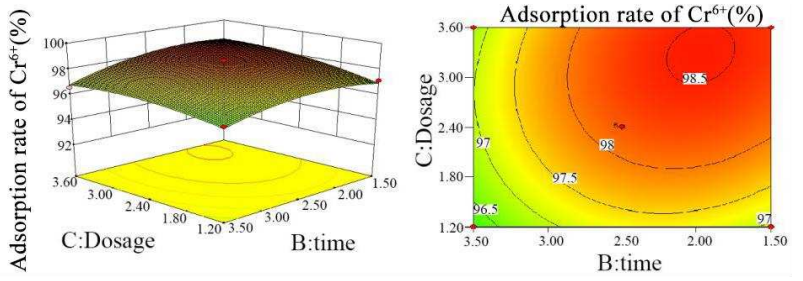

Figure 3. *Effect of time and dosage on the adsorption rate of* Cr^{6+}

The optimal solution was selected by response surface analysis

Further analysis was performed using the fitted multiple quadratic regression equation and Design-Expert 8.0.6 software. And the predicted values of the optimal values and optimal processing conditions were obtained within the experimental design

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1298512999

conditions. The optimal conditions for prediction were as follows: when the temperature was 30.12 °C, time was 3.05 h, the dosage was 3.45 g, the modified carbonized straw had the best adsorption effect on Cr^{6+}. And then it was proved that the actual and predicted values were well fitted, which indicated that it was feasible to optimize the modified carbonized straw to absorb Cr^{6+} by response surface method.

Adsorption kinetics of Cr^{6+} adsorbed by modified carbonized straw

The adsorption kinetics curves of different dosages (1.2 g/L, 2.4 g/L, 3.6 g/L) of carbonized wheat straw to 200 ml for 100 mg/L Cr^{6+} were shown in *Figure 4,* and the reaction conditions were as follows: temperature was 25 °C, pH was 9, oscillation speed was 250 r/min. The results showed that the larger the dosage of adsorbent, the smaller the adsorption capacity at equilibrium, and the time needed to reach adsorption equilibrium was close, which might be related to the concentration of Cr^{6+}. In addition, under different adsorbent dosages, the adsorbent exhibits similar adsorption kinetic behavior, and each curve could be divided into the following three stages: the dosage of 1.2 g/L was taken as an example. The slope of the first stage was very large, and the adsorption amount increased from 3.13 mg/g to 15.21 mg/g within 1.5 h, which might be caused by the Van der Waals' force between the adsorbent and the adsorbate, indicated that the adsorption process was a fast physical process (Gong, 2011). In the second stage, the adsorption amount increased from 15.21 mg/g to 16.34 mg/g within 0.5 h, which was slow. In the third stage, when the adsorption time was longer than 2 h, the adsorption amount reached equilibrium.

The data of *Figure 4* were fitted using the first-order kinetic equation, the double-constant equation, and the Elovich equation. The fitting results are presented in *Figures 5–7* and *Table 6*.

Table 6. *Fitting results of reaction rate equations under different dosages*

m (g/L)	First-order kinetic equation			Double-constant equation			Elovich equation		
	k_1	a	R^2	k_2	a	R^2	k_3	a	R^2
1.2	1.0457	4.5353	0.868	0.4701	2.2424	0.8732	5.4529	9.7438	0.9192
2.4	1.0877	4.390	0.8642	0.915	1.2643	0.9399	3.1211	4.4071	0.9123
3.6	1.0367	4.0728	0.8608	0.7668	0.8036	0.8946	2.2832	2.7421	0.9277

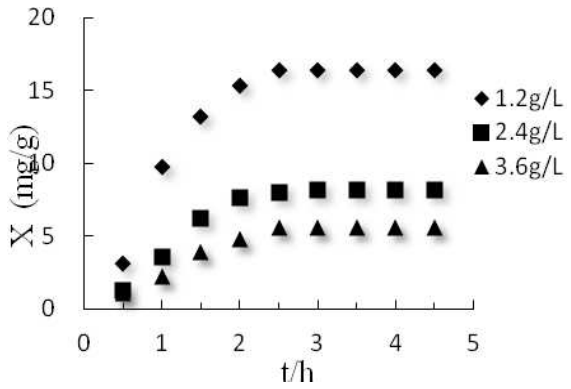

Figure 4. *Adsorption kinetic curves of different adsorbent dosages*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1298512999

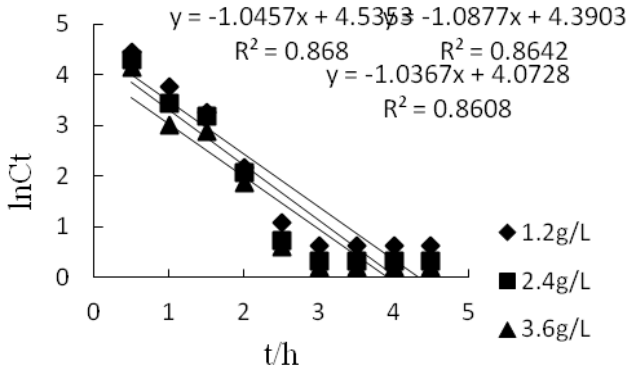

Figure 5. *First-order kinetic equation*

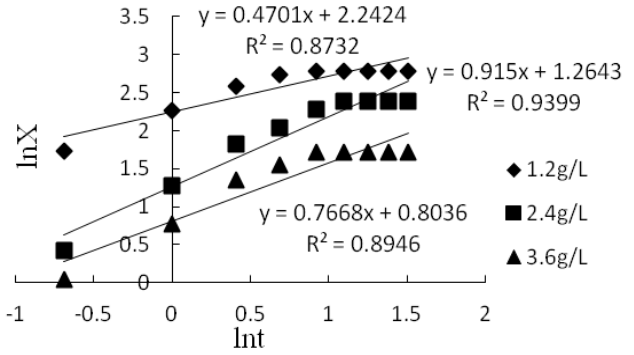

Figure 6. *Double-constant equation*

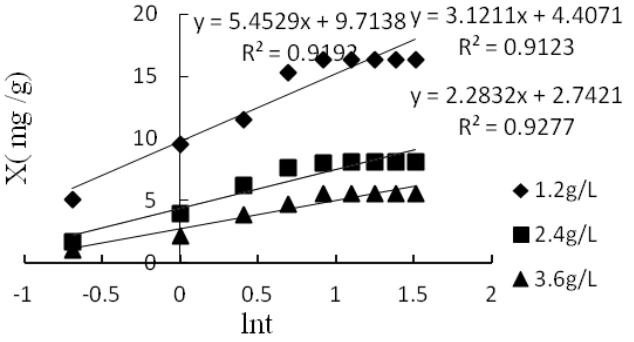

Figure 7. *Elovich equation*

It could be seen from *Table 6* that R^2 values of the first-order kinetic equation, the two-constant equation and the Elovich equation increase in turn, and R^2 values exceed 0.86. Therefore, the three kinetic equations could better fit the process of adsorbing Cr^{6+} by modified carbonized straw before the adsorption reaches equilibrium. However, Elovich equation had the highest fitting degree, and its R^2 was > 0.91, which indicated that the fitting effect of Elovich equation was the best, indicated that the fitting range of the first-order kinetic equation could not meet the process of adsorbing Cr^{6+} by modified carbonized straw. This might be due to the multiple effects of the modified carbonized straw on the adsorption of Cr^{6+}, rather than being limited to the first-order

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1298512999

kinetic range. In addition, the adsorption process was not a single adsorption mechanism, but a combination of interlayer cation exchange and surface complex adsorption, and it was also related to changes in structure and functional groups after straw modification (Li, 2015).

Thermodynamic analysis of Cr^{6+}

According to the thermodynamic experimental results of adsorption of Cr^{6+} by modified carbonized straw at different temperatures, the equilibrium partition coefficient K was obtained. lnK was used as the ordinate and 1/T was used as the abscissa to get a straight line, as shown in *Figure 8*. ΔS and ΔH could be calculated from the intercept and slope of the line respectively, and then ΔG was calculated. The calculation results were shown in *Table 7*.

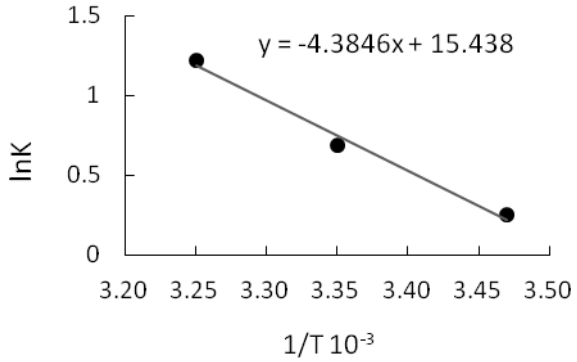

Figure 8. *lnK-1/T curve*

Table 7. *Thermodynamic parameters*

ΔS (J/mol·k)	ΔH (kJ/mol)	T (K)	ΔG (kJ/mol)
128.35	36.45	288	-0.51 kJ/mol
		298	-1.80 kJ/mol
		308	-3.08 kJ/mol

It could be seen from *Table 7* that ΔH > 0 in the adsorption process, indicated that the reaction process was an endothermic reaction, so the temperature rise was favorable for the adsorption process. ΔG could reflect the driving force of a reaction. It could be known from the above data that ΔG < 0 under the temperature conditions of 288 K, 298 K and 308 K, indicated that the adsorption of Cr^{6+} by modified carbonized straw was a spontaneous process. Therefore, chromium ions tended to spontaneously adsorb from the liquid body to the surface of the modified carbonized straw, and the spontaneity increased with the increase of temperature. In addition, ΔS > 0 indicated that the adsorption of Cr^{6+} by the modified carbonized straw increased the disorder of the system. According to the adsorption exchange theory, the adsorption of ions in the solution by the adsorbent was a process of entropy reduction. At the same time, the adsorbent would shrink and release part of the water molecules, which would increase the entropy of the system, and the combination of the two would increase the entropy of the system (Li, 2013).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1298512999

Conclusions

In the experiment, different carbonized straws were modified by different modifiers, and the iodine adsorption value was used as an indicator to compare the adsorption capacity of different modified carbonized straws. It was found that the modified carbonized wheat straw with 2 mol/L $FeCl_2$ as modifier had the highest iodine adsorption value 1161.15 mg/g.

Response surface analysis showed that adsorption rate was taken as the response value, temperature, pH and dosage were taken as the factors, and the quadratic response surface regression model of chromium ion adsorption on modified carbonized straw was obtained. The model was significant, the unfitting term was not significant, and the fitting degree of the equation was high. Therefore, it was feasible to optimize the adsorption conditions of Cr^{6+} on modified carbonized straw by response surface methodology.

Using wheat straw as raw material, the modified carbonized straw prepared by $FeCl_2$ activation method could effectively absorb chromium ions. The Elovich equation, the double constant equation and the first-order kinetic equation could be well fitted to the process of adsorbing chromium ions by modified carbonized straw. However, Elovich equation had the highest fitting degree, and its R^2 was > 0.91, indicated that the fitting range of the first-order kinetic equation could not meet the process of adsorbing Cr^{6+} by modified carbonized straw. This might be due to the fact that the main form of adsorption of chromium ions by modified carbonized wheat straw was interlayer cation exchange and surface complex adsorption, rather than a single adsorption mechanism, and it was also related to changes in structure and functional groups after straw modification.

The adsorption of chromium ions by modified wheat straw was a spontaneous endothermic process, and the temperature rise was beneficial to the reaction. Moreover, in the adsorption process, $\Delta S > 0$ indicated that the adsorption of Cr^{6+} by the modified carbonized straw increased the disorder of the system. This might be due to the change in the surface structure of the modified carbonized straw after the adsorption of chromium ions by the modified carbonized straw, resulting in the increase of the disorder of adsorption system.

The results of this research could raise concerns over possible the comprehensive utilization of agricultural wastes and the treatment of heavy metal wastewater. The authors plan to further study the treatment of different types of heavy metal wastewater by other types of activated carbon under different conditions in the future.

(Received 22nd May 2019; accepted 28th Aug 2019)

Abstract. China has grown rapidly to be Asian maximum cruise economic market (Green Book of Cruise Industry, 2018). To facilitate cruise economic growth and harmonious coexistence with ecological environment, this paper proposes a new perspective of the ecological efficiency and computes carbon footprint of the cruise tourism in China from 2009 to 2017. The results show a relatively low level of ecological efficiency in nearly nine years, the average ecological efficiency of cruise tourism is CNY 67.99/kg. In these nine years, ecological efficiency of cruise tourism within four years from 2011 to 2012 and from 2016 to 2017 is lower than the average and ecological efficiency within two years from 2009 to 2010 and from 2013 to 2015 is higher than the average, ecological efficiency within four years from 2013 to 2015 and 2017 is close to the average. Ecological efficiency has dropped continuously in 2011, but the overall carbon emissions and related carbon footprint of cruise tourism show the trend of rapid growth. It is necessary to explore a new way to develop cruise tourism, change the development mode of cruise tourism, rebuild a balance between industry booming and ecosystem by reducing resource consumption and pollution discharge, and further enhance ecological efficiency of cruise tourism.
Keywords: *cruise travel, ecological efficiency, carbon footprints, temporal evolution, China*

Introduction

As one of the fastest growing aspects of tourism, cruise tourism has become an industry power which cannot be ignored in driving the development of cruise ports and surrounding areas. Cruise tourism refers to trans-regional and transnational tourism activities, propelling industries relevant to ports with expansion of the cruise product market, logistics of cruise supplies, or even repair and maintenance of cruise ships. Cruise tourists and related spending can balance regional economic differences, even international balance of payments, and promote the prosperity of the local market. In 2006, international cruise lines began to enter Chinese market and start home port operation in China. It strongly boosts China cruise tourism market and constantly increases acceptance and engagement of tourists towards cruise tourism. China has become the largest Asian cruise tourist market and one of the fastest-growing cruise areas in the world. CCYIA's data shows 11 Chinese cruise terminals, including Shanghai and Tianjin, received totally 1,181 cruise ships in 2017, suggesting a year-on-year growth of 17%. In terms of cruise visitor reception, China received totally 4.954 million inbound and outbound tourists at 11 cruise terminals, suggesting a year-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1300113013

on-year growth of 18%. China's cruise revenue in 2017 is CNY (Chinese Yuan) 8.92 billion, which is increased by 32.5%. As domestic coastal port cities have speeded up the development and investment on cruise industry, cruise development and construction and tourism activities will inevitably bring plenty of ecological and environmental challenges and problems, including coastal landscapes changes, loss of original ecological habitats, air pollution and environmental congestion when cruise ships are reaching and berthing at ports. Hence, how to reduce impacts of cruise ships on the ecological environment and realize sustainable development of cruise industry has become a high-profile issue in the industry and academic world. In this context, in order to protect ecological environment and achieve sustainable development of economy, this paper chooses the green and sustainable development of cruise economy as the aim and introduces the ecological efficiency index to evaluate the sustainable development status of cruise tourism by comparing ecological environmental loads with economic benefits, to explore a green development path for China cruise tourism, to propel the transformation and upgrading of the cruise tourism industrial structure and mode suitable for the marine ecosystem, and to improve ecological efficiency of cruise tourism.

Literature review

Despite considerable economic income brought by cruise development (Vina and Ford, 1999), the practical effect is affected by local economic development level and degree of integration in the global industrial chain, and thus cruise tourism's positive effect on local areas will be limited by local industrial structure, variety of products and reception capacity (Chase and Mckee, 2003; Chang et al., 2016; Sun and Hou, 2017). The areas where cruise ships pass through will be effected and suffer negative ecological impacts due to a great deal of waste coming from fuel consumption, energy use, food consumption, etc., which increases the ecological cost of local cruise tourism development and results in potential loss of cruise economic benefits (Chase and Mckee, 2003).

Scholar Erize (1987) showed concern over cruise ecological problems as early as 1980s, and Ritter and Schafer (1998) proposed that importance must be attached to marine pollution control with the rapid development of cruise tourism (Ritter and Schafer, 1998). On a basis of the life cycle theory, Johnson (2002) believes ecological problems and environmental pollution of cruise tourism is mainly caused by resource consumption and utilization, discharge of waste, infrastructure construction, passenger transport and logistics distribution (Johnson, 2002). In his point of view, cruise waste's impacts on environment include poor water quality (Lincoln et al., 2006), sea area pollution (Gibson et al., 2012), damage to coral reefs (Jones, 2007, 2011) and so forth. Along with global changes and climate warming in recent years, low-carbon emission reduction in cruise industry becomes a hot research topic. More empirical researches have been done on the sustainable development of cruise economy, including researches on economic, social and ecological impacts of cruise pollution (Miller et al., 2013; Murena et al., 2018), cruise energy efficiency (Lepistö et al., 2016), ecological cost (Carić, 2016), cruise's carbon emission (Howitt et al., 2010) and cruise ships' effects on public health and social costs, etc. (Chatzinikolaou et al., 2015; Mölders et al., 2013). Moreover, scholars also discuss the cruise ecological protection system and sustainable development mode in many ways. In spite of an increasing number of Chinese cruise

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1300113013

references, fewer references concern impacts of cruise tourism, especially in regard to negative environment impacts of cruise economy, sustainable development and green treatment (Sun and Hou, 2017). Therefore, the academic study in China tends to "take foreign documents for references" and be led by policies. In the context of outdated cruise environment monitoring and a lack of relevant data, domestic scholars focus on the review and reference (Xie, et al., 2010; Qiu, 2007; Sun and Hou, 2017) of foreign documents which concern practical experience and researches on ecological pollution of foreign cruise ships and foreign ecological protection, such as shore power experience (Wu and Shen, 2012), green port construction (Ye et al., 2017), construction of a port ecological protection system (Ren, et al., 2017), etc. On the other hand, domestic scholars conduct researches on the measurement of carbon emission in cruise industry (Li and Lv, 2016), pollution prevention and control for cruise ships (Wang and Huang, 2015) and so on.

In view of all mentioned above, the academic world agrees that cruise tourism must follow the principle of sustainable development, and carbon emission and energy consumption of cruise ships must be strictly limited under the threshold (Yao and Chen, 2016). Tourism refers to an energy intensive industry (Becken, 2008). As an index giving consideration to both ecology and economy, ecological efficiency can indicate how to balance economic development and ecological impacts. The tourism ecological efficiency theory provides an access to bi-effect (Dobers and Wolff, 1999), that is, when job opportunities are created in the new market, costs and tourism's negative effects on the environment are reduced at the same time (Holleran, 2008). In a word, the essence of ecological efficiency is to create the maximum economic value with the minimum ecological impact. As the ecological efficiency analysis is a kind of typical quantitative analysis, it has been taken seriously and applied (Holleran and Lehto, 2008; Su, 2014; Gössling et al., 2005) by scholars in evaluation and quantitative analysis of tourism and sustainable development of cruise ships, including ecological efficiency research based on emission inventory (Su, 2014) and research on ecological cost and ecological efficiency of cruise carbon footprint (Tichavska and Tovar, 2015). Though there are a great many Chinese and foreign researches on economic development and ecological pollution of cruise tourism at home and abroad, there are not sufficient ecological efficiency studies of how to balance economic development and ecological impacts of cruise tourism. The introduction of ecological efficiency to this paper helps analyze a balanced relationship between cruise tourism development and its ecological impact in a more profound way, discuss a coexistence mode of cruise economy and ecological environment, explore a harmonious and unified development mode for economy and ecology, seek for a way to promote ecological efficiency of cruise economy, and work out a cruise ecological pollution control system putting prevention first, paying attention to comprehensive treatment, and preventing and controlling pollution from the source.

Research method and design

Evaluation method for ecological efficiency

Evaluation methods of ecological efficiency mainly include the ratio method, index system method and model method (Yao and Chen, 2015; Peng et al., 2017). The ratio method makes sense by giving simple ratio values. The index system method, based on weight to express the relationship between environment and economy, may involve too much subjectivity. The model method mainly refers to the data envelopment analysis

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1300113013

model, ecological topological method and so forth. In use of this kind of method, it is necessary to define weight of different indexes for integrating them to a single numerical value. In this case, the weight may lose objectivity. For studies into ecological efficiency, ecological risks and energy consumption caused by tourism become the focus at the present time. According to Gössling, ecological efficiency of tourism indicates a ratio between the carbon dioxide emission equivalent and tourism revenue (Gössling et al., 2005, 2007). In view of this, this paper applies the ratio method to compute ecological efficiency of cruise tourism in China.

When referring to the ratio method, a generally accepted ecological efficiency calculation formula is the calculation model proposed by World Business Council for Sustainable Development (WBCSD):

$$EE = TR/CFT \quad \text{(Eq.1)}$$

In this formula, EE stands for ecological efficiency, which can be described as the result that the revenue of cruise industry removes its ecological impacts. TR stands for the revenue of cruise industry, here uses the cruise tourism revenue to demonstrate, and CFT stands for the ecological impact of cruise industry, here uses its carbon footprint to present. All variable values shall be assigned to the increment of a product or service or ecological impacts according to the nature of industry. The total amount of carbon footprint from cruise travel is selected as the index of ecological impacts of cruise tourism, while cruise tourism revenue is selected as the index to measure economic value of tourism.

Calculation formula for cruise carbon footprint and coefficient determination

a. Calculation of total carbon footprint from cruise travel

Caron footprint originates from the concept of "ecological footprint", refers to the land needed to absorb the carbon emission. But with the development of the carbon footprint theory, now it has almost been expressed as carbon dioxide equivalent. In this paper, carbon footprint from cruise travel is decided by the carbon emission from fuel consumption, solid waste and sewage discharge of cruise ships. The designed formula is as follows:

$$GCF = \sum_i G_i * CE_i \quad \text{(Eq.2)}$$

In *Equation 2,* GCF stands for total carbon footprint from cruise ships, "i" stands for energy and different types of waste and they are marine fuel oil, solid waste and sewage, G stands for amount of energy consumption or generated waste, and CE stands for response carbon emission coefficient.

b. Calculation of carbon emission of cruise fuel oil

In this paper, Wang (2015) is mainly used to calculate the carbon emissions of cruise ships. At the same time, according to the trend of large-scale cruise ships and the extension of berthing time in recent years, the specific values of the correlation coefficient are improved to make the calculation more scientific and reasonable. Based on the theme of low-carbon green development of Shanghai cruise port, Wang Bowen used this model to quantitatively and intuitively calculate specific carbon dioxide

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1300113013

emission data, quantitatively analyze the carbon emissions of cruise port, and provide guidance for the development of low-carbon green operation of cruise port. In addition, Li and Lu (2016) used the bottom-up dynamic method to calculate the emission of sulfur oxides and particulates from cruise ships, and the principle of the dynamic method is similar to the formula used in this paper.

The topic of this paper lies in carbon emission from cruise travel in China and thus the carbon footprint defined in this paper must be within Chinese territory. The main focus is carbon emission of cruise fuel oil consumed during the period from the moment when a cruise enters the sea of China to its docking to the moment when a cruise leaves the port to arrival of an open sea, namely, the carbon footprint during cruise ships' berthing. This paper believes carbon footprint during cruise ships' berthing is mainly related to the number of cruise ships moored to the port (see *Table 1*), the duration of berthing, etc. The calculation thought is to transfer the electrical load during cruise berthing to the amount of fuel consumed during berthing via engine fuel efficiency; and then calculate carbon footprint by using the carbon emission coefficient of fuel oil. The correlation values in the formula (e.g. W = 10.5 megawatt, Y = 200 g/kWh) are borrowed from the data in previous studies (Dong, 2017; Yang, 2013; Gui et al., 2017). The calculation formula for CO_2 pollutants generated from cruise ship is:

$$S = N \cdot W \cdot t \cdot Y \cdot \beta \cdot \eta \quad \text{(Eq.3)}$$

S is the total amount of CO_2 emission; N is the number of cruise ships moored to the port annually; N is electrical load for berthing, and W = 10.5 megawatt; t is the duration of cruise berthing, and t = 11.95 h (average value); Y is power consumed by diesel engine, and fuel consumption power of oil engine on the cruise is 200 g/kWh; β is the combustion carbon emission coefficient; HFO carbon emission factor is 3.114 kg CO_2/KG; η is the electrical grid power factor of cruise and η = 7.5.

Table 1. *Recommended discharge coefficient of cruise solid wastes. (Source: IPCC2006, General Principles for Calculation of the Comprehensive Energy Consumption (GBT 2589-2008))*

Fuel type	A		B		C = A×B	
	CO_2 emission original coefficient from *IPCC2006*		Heating value of China		Recommended emission coefficient	
	Original coefficient	Unit	Heating value	Unit of heating value	Numerical value	Unit
Solid waste	3.84E-04	Kg CO_2/Kcal	2,955	kcal/kg	1.13	KgCO_2/kg

The carbon emission coefficient of cruise fuel oil in this paper is in accordance with relevant Chinese regulations on marine fuel oil. In *Notice on Issuing the Implementation Plan for the Marine Air Pollutant Emission Control Area,* issued by Ministry of Transport of the People's Republic of China in 2018, it is specified that sea ships should consume marine fuel oil whose Sulphur content does not exceed 0.5%m/m since January 1, 2019 when they enter the emission control area. This means cruise ships consumed heavy oil before 2019. In this paper, the carbon emission coefficient of HFO and MGO are 3.114 kgCO_2/kg and 3.205 kgCO_2/kg, respectively.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1300113013

c. Calculation of carbon footprint from solid waste of cruise ships

This paper borrows carbon emission original coefficients of different emission sources and different fuels from *IPCC2006*. The carbon emission original coefficient multiplied by the heating value equals to the recommended carbon emission coefficient of this type of fuel in China. For the heating value of solid waste, see the heating value of municipal solid waste, as shown in *Table 1*.

d. Calculation of carbon footprint of cruise solid waste

There is a lack of exact data about sewage carbon discharge domestically. For this reason, the sewage carbon discharge in this paper is replaced by the indirect carbon discharge of power consumption and use of PAM during sewage treatment. Power consumption and PAM consumption are two major indirect discharge sources from the sewage treatment plant. The carbon emission coefficient of power consumption varies greatly from 0.6 to 1.2 $kgCO_2/(kWh)$ with types of fuels used for local electricity generation. This paper cites the data of power supply emission intensity based on the national carbon market base value in 2015: 0.8066 $kgCO_2/kWh$. As the discharge coefficient of carbon consumed by PAM ranges from 20 to 30 $kgCO_2/kg$, this paper adopts the average value of 25 $kgCO_2/kg$. The statistical data in 2010 shows sewage per cubic meter consumes 0.24 kW electricity and 0.00076 kg PAM. The sewage carbon discharge coefficient formula in this paper is:

$$CE_{PW} = E_{PW} * CE_E + PAM_{PW} * CE_{PAW} \quad \text{(Eq.4)}$$

In *Equation 4*, PWCE stands for the sewage carbon discharge coefficient, Epw stands for electricity consumption for sewage treatment, CEE stands for power carbon discharge coefficient; PAMpw stands for the amount of PAM used for sewage treatment, and CEPAM stands for the carbon discharge coefficient of PAM. Upon calculation, the sewage carbon discharge coefficient is 0.212584 $kgCO_2/m^3$.

e. Discussion of uncertainty of the discharge coefficient

The carbon discharge original coefficient of energy in this paper are quoted from *IPCC2006*. For the combustion heating values of energy and waste, refer to national standard *General Principles for Calculation of the Comprehensive Energy Consumption* (GBT 2589-2008) released in 2008; average carbon emission per kilowatt hour in China (kg/kWh) is selected as the power carbon discharge coefficient used in the sewage carbon discharge calculation formula. Therefore, the coefficient uncertainty in this paper mainly comes from the regional differences domestically and there is a deviation from the actual carbon discharge coefficient.

Data collection

This paper collects data mainly from Annual Report on China's Cruise Industry (2016), Annual Report on China's Cruise Industry (2017), Annual Report on China's Cruise Industry (2018) and other relevant materials. Relevant coefficient values involved in carbon discharge calculation and the quantity of pollutants from tourists per day come from related studies as mentioned above. The quantity of pollutants per tourist is: 4 kg solid waste; 40 L black water; 340 L gray water; 10 L bilgy oily water;

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1300113013

0.16 kg toxic waste. The data on annual revenue in cruise tourism market from 2009 to 2017 comes from Annual Report on China's Cruise Industry (CCYIA, 2016), and the data on annul tourist reception in China cruise tourism industry and the data on the annual number of received cruise ships from 2009 to 2017 come from Annual Report on China's Cruise Industry (Wang, Ye, 2018), as shown in *Table 2*. The average value of cruise berthing durations in 2015, 2016 and 2017 is taken as the berthing duration.

Table 2. *Total number of cruise ships received by China, scale of the cruise tourism market and trading volume from 2009 to 2017. (Data source: Annual Report on China's Cruise Industry (2018), CCYIA)*

Year	2009	2010	2011	2012	2013	2014	2015	2016	2017
Cruise ships received by China (total number)	259	294	272	275	406	466	629	1,010	1,181
Trading volume of the cruise tourism market (100 million yuan)	19.7	23.8	7.1	11.8	26.2	33.5	45.3	60.8	82.3
Number of received cruise tourists (unit: 10,000 persons)	34.38	48.08	47.85	65.69	120.15	172.37	248	456.66	495.42

Research process and result analysis

Time evolution and characteristics of cruise carbon footprint

According to the data in *Table 2*, the carbon footprint of cruise ships received by China from 2009 to 2017 it obtained from *Equations 1* and *2*. *Table 3* shows values of annual and total carbon footprint of fuel oil, sewage and solid waste released by Chinese cruise ships from 2009 to 2017. Among three types of carbon footprint, solid waste, which is the most important source of carbon footprint, produces the largest carbon footprint load; fuel oil plays a secondary role, and carbon footprint from sewage occupies the smallest part.

Table 3. *Carbon footprints generated by cruise ships received in China from 2009 to 2017*

Carbon emission	2009	2010	2011	2012	2013	2014	2015	2016	2017
Cruise fuel oil	1516.03	1723.12	1594.17	1611.76	2379.54	2731.2	3686.53	5919.55	6921.77
Cruise sewage	7.04	9.84	9.80	13.43	24.60	35.3	50.78	93.5	101.4
Solid waste	404.03	565.04	562.33	771.99	1412	2025.69	2914.5	5366.67	5822.18
Total amount	1927.11	2298	2166.31	2379.20	3816.14	4792.18	6651.8	11379.72	12845.38

Table 3 lists carbon footprints from different sources and total amount of carbon emission. On this basis, this paper analyzes carbon emission composition and growth

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1300113013

change of China cruise tourism from 2009 to 2017, finds that cruise carbon emission shows a growing momentum when the number of cruise ships berthing in China increases (*Fig. 1*). The carbon emission from the fuel oil contributes the largest part to total emission. In respect to the growth rate of cruise carbon emission, the rate of fuel emission, solid waste carbon emission and overall carbon emission fluctuates greatly, and the fluctuation trend is similar.

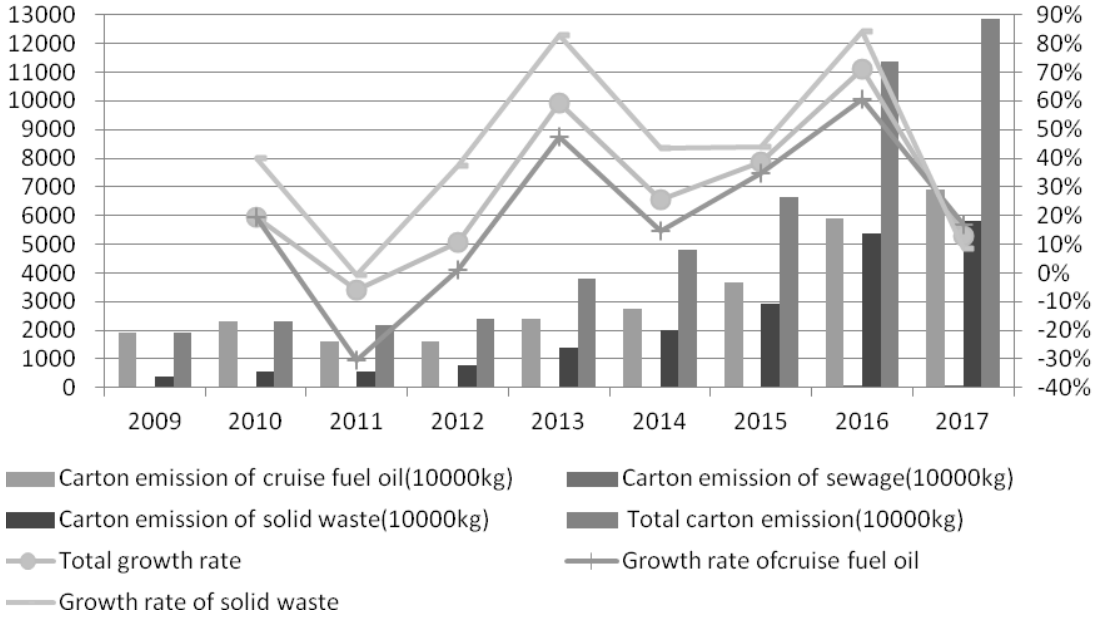

Figure 1. *Carbon footprints composition and growth change of China cruise tourism from 2009 to 2017*

Calculation of ecological efficiency of China cruise tourism

Table 4 shows the values of China's annual cruise revenue, total cruise carbon emission and ecological efficiency of cruise tourism from 2009 to 2017. These values are got by calculation according to the ratio of annual cruise travel revenue and total cruise carbon emission annually in *Equation 1*.

Table 4. *Ecological efficiency of China cruise tourism from 2009 to 2017*

	2009	**2010**	**2011**	**2012**	**2013**	**2014**	**2015**	**2016**	**2017**
Total carbon emission of cruise ships (10000 kg)	1927.11	2298.00	2166.31	2397.20	3816.14	4792.18	6651.80	11379.72	12845.38

Figure 2 mainly reflects the ecological efficiency tendency of China cruise tourism over time from 2009 to 2017 and its average level. In these nine years, ecological

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1300113013

efficiency of China cruise tourism has generally declined, its numerical value is still low and the average value is merely CNY 67.99/kg. Hence, ecological efficiency of China cruise tourism needs to be improved essentially. In 2011, China's cruise tourist ecological efficiency was at a record low of CNY 32.77/kg. This is because Chinese tourist revenue in 2011 fell as historically low as CNY 710 million but cruise carbon emission of cruise ships did not decrease. From 2009 to 2017, the maximum value of cruise tourist ecological efficiency in China is CNY 103.57/kg.

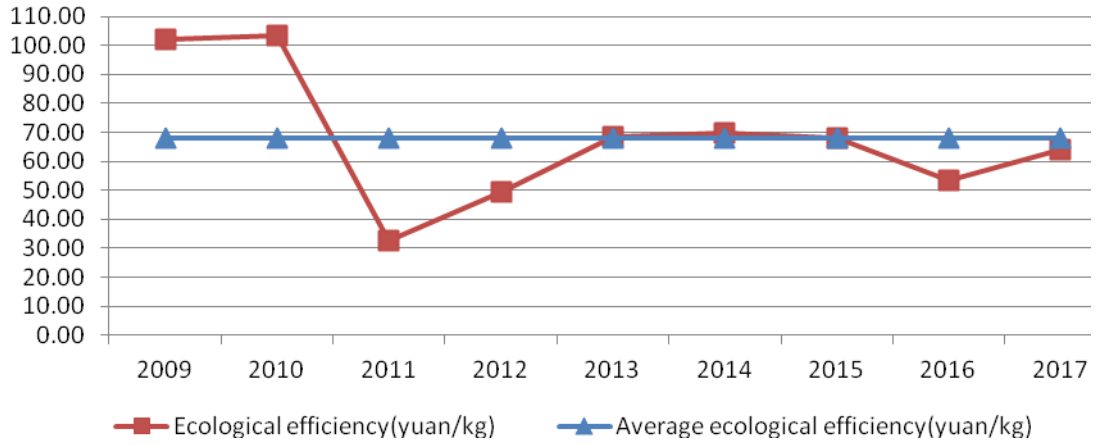

Figure 2. *Time evolution of China's cruise tourist ecological efficiency from 2009 to 2017*

Result analysis

Analysis on the time evolution characteristics of China cruise tourist ecological efficiency from 2009 to 2017

According to *Figure 2,* ecological efficiency of China cruise tourism shows an overall downtrend momentum from 2009 to 2017. The average tourist ecological efficiency is CNY 67.99/kg, namely, 1 kg pollutants are generated as soon as China cruise tourism earns CNY 67.99. In these nine years, the values of cruise tourist ecological efficiency from 2011 to 2012 and from 2016 to 2017 are lower than the average value and the values from 2009 to 2010 are higher than the average value and the values from 2015 to 2015 and 2017 are close to the average value. In 2011, China's cruise tourist ecological efficiency was at a record low of CNY 32.77/kg. This is because Chinese tourist revenue in 2011 fell as historically low as CNY 710 million, but cruise carbon emission of cruise ships did not decrease. In 2009-2017, cruise tourist ecological efficiency in China reached a record high of CNY 103.57/kg.

The overall ecological efficiency of China cruise tourism, which is still relatively low, does not benefit much from the continuously expansion of China's cruise tourist market. There are two root causes. The first one lies in low contribution of China cruise tourism to economy. International cruise lines play a leading role in global cruise industry and thus most economic benefit of cruise industry drains away. In this case, China benefits a little from the international cruise tourism. The second reason is a waste of resources and tourist spending. This is because China is still in the early stage of development to attract investment and expand size when the cruise market is moving eastward and the numbers of cruise tourists, cruise ships received in Chinese ports are growing; most cruise ships are used for outbound travel, featuring high mobility and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1300113013

hidden environment pollution; due to a lack of relevant legal norms and backward maritime control, ecological problems caused by cruise travel have not been taken seriously and treated, and the ecological cost of cruise economy for development has not been taken into account.

Carbon footprint change of cruise tourism in China from 2009 to 2017

With the rapid development of China cruise tourism, the ever-growing numbers of cruise ships and cruise tourists lead to constant growth of cruise fuel consumption, solid waste, sewage discharge and tourist food consumption etc. In view of this, the total carbon footprint of cruise ships also rises. According to *Figure 1* and *Table 2*, carbon footprint of cruise solid waste shows a fast-growing momentum with the tourist development in China and this momentum becomes more obvious especially from 2011 to 2013. Furthermore, among the total carbon footprint of cruise ships, cruise fuel oils accounts for the largest proportion.

Conclusions and suggestions

On the basis of analysis above, the following points can be concluded: firstly, ecological efficiency of China's cruise tourism is still low and generally show a downward trend from 2009 to 2017 and the value of average ecological efficiency is merely CNY 67.99/kg. There's a lot of room for improvement. Secondly, accompanied by vigorous growth of tourists' reception and cruise ships' visits, cruise ships' impact on the environment from 2009 to 2017 becomes more serious. In particular, carbon emission of solid waste occupies the largest proportion and exerts the greatest impact on environment.

Owing to rapid expansion of China cruise tourism, the numbers of cruise ships berthing in ports and tourists are increasing quickly. Accordingly, resource occupancy and consumption, waste discharge and pollution brought by industrial expansion also become serious. All of this is challenging the sustainable development of areas around ports and sea areas. As a result, importance must be attached to ecological problems caused by cruise tourism and seek solutions. Firstly, it is suggested to re-examine China's cruise tourism development structure and industrial layout, promote the continuous upgrading and transformation of the cruise industry towards low-carbon, high efficiency and ecological protection, and build an ecologically-efficient cruise economic development model. Secondly, it is suggested to raise tourists' and the public's concerns over cruise lines, green ecology of ports and enterprises' ecological behaviors, and encourage tourists to convert consumption concept and use green products. In this way, it is available to reduce tourism consumption waste, control uncivilized ecological behaviors, and form a responsible consumption pattern of green tourism. Thirdly, it is suggested to promote intelligent transformation of cruise economy with the help of new technological revolution, and advocate construction of smart cruise, smart port and smart tourism; on the other hand, it is suggested to propel the use of shore power at ports, clean energy cruise ships, air filtration and sewage treatment to build a market-oriented green technology innovation system; finally, the national government and departments concerned should formulate specific and detailed legal rules of cruise travel to restrict behaviors of cruise passengers, cruise lines, cruise ships and support the green development of China cruise ships.

DOI: http://dx.doi.org/10.15666/aeer/1706_1300113013

In future, China should explore actively the institutional assurance and operation mechanism. The first step is to make and perfect energy, ecological protection, economy, ocean, science and technology policies which can drive the green development of cruise ships, increase fiscal subsidies and policy support for clean energy, shore power technologies, energy conservation and ecological protection technologies, and perfect systems for coastal and marine ecological management and ecological management to build a policy system and a guidance mechanism for advocating clean production, low carbon emission and green development of cruise industry; the second step is to bring into full play the synergistic effect among climate change, energy conservation and ecological protection, new energy development, and ecological improvement, seek a stable and sustainable long-term capital investment operation mechanism, an efficient mechanism for transferring international low carbon ecological protection technologies and a public information platform to provide public mechanism guarantee for green development in terms of capital and technological information; the third step is to improve functions of maritime and coast guard departments for regulating marine ecosystem, clarify the supervision subject and personnel agency for coping with ecological environment problems caused by cruise ships, solidify cruise waste discharge and the sea area regulatory process, coordinate with relevant departments to take joint actions, and provide institutional safeguards for green regulators.

Abstract. Penetration of the landfill leachate during a tunnel excavation process has a certain impact on the properties of surrounding rocks, including their permeability. The present study was envisaged to analyze such changes by performing a comparative test on the rock specimens with or without being soaked in the landfill leachate. Furthermore, the groundwater flow and solute transport model were established. Tunnel drainage was conceptualized as a pumping well in the confined formation and the weighting factor for hydraulic conductivity coefficient was taken into consideration for specific regions in the model. Subsequently, the water level and the pollutant concentration distribution in these regions were analyzed. The results showed that the simulated groundwater levels on the south and north sides of the tunnel were higher than the original level. Fluctuation in the groundwater level caused by the tunnel drainage was significantly greater due to pumping well PW-1. Because of the soaking of the surrounding rocks in the landfill leachate, the hydraulic conductivity coefficients of these regions increased, which aggravated the downward penetration of the pollutants in the regions between the two tunnels.
Keywords: *groundwater flow simulation, solute transport simulation, surrounding rocks, hydraulic conductivity coefficient, tunnel excavation*

Introduction

Most municipal waste is disposed in the landfills in China (Zhan et al., 2014). Among these landfills, approximately 40% are devoid of a bottom liner system and leachate collection system (Du et al., 2009). Many scholars have studied the migration of the landfill leachate by simulation or experimental methods. In one such experiment a solute transport model was established with MT3D software, which simulated the migration process of Cr6 + leakage in the landfills and addressed the effects of different pollution control measures (Zhou et al., 2014). Han used the Visual MODFLOW software to study the longest distance travelled during the leakage of chloride ions from the landfill in the vertical direction (Han et al., 2014). A DRASTIC model and an MT3D model were further adopted to construct a vulnerability map of the groundwater of the Kinmen landfill (Liu et al., 2011). A three-dimensional solute transport model was established to study the changes in concentrations that found an increase of the sulfate concentrations due to the leaching of sulfate-rich waters from a landfill (Molinero and Samper, 2006)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1301513033

Lin and Lee (2009) proposed that the process of constructing a tunnel caused huge disturbances in the surrounding rock, including its hydraulic conductivity coefficient and the distribution of the stress field. Currently, numerous analytical and semi-analytical models have been developed to predict the discharge rate per unit length of a tunnel. Tunnel discharge was estimated by simulating the rock as a statistically homogeneous stochastic continuum in two dimensions (Ando et al., 2003). The hydraulic conductivity coefficient and the vertical anisotropy of the studied area, including the tunnel disturbance zone, were incorporated into a simplified expression according to the empirical formula proposed by Ersoy (2013). However, the spatial distribution of the hydraulic conductivity is complex and was difficult to fully characterize (Jiang et al., 2010). Very few studies have focused on the effects on a tunnel below the landfill or on the erosion of the geological media by landfill leachate, which affects the hydraulic conductivity coefficient.

Penetration of the landfill leachate during the tunnel excavation process has a certain impact on the properties of the surrounding rocks, including the permeability of the surrounding rocks. In order to precisely capture the change in permeability of the surrounding rocks under excavation, a simulation is usually needed. Rock specimens obtained from tunnel excavation were processed into standard specimens, which were subsequently soaked in the landfill leachate. Finally, a comparative test was performed on the permeability of rock specimens among the soaked and not-soaked in the landfill leachate. The changes in the permeability of the surrounding rocks soaked in the prepared landfill leachate were characterized. Then, GMS software was used to establish the groundwater flow and solute transport model. Changes in hydraulic conductivity coefficients in the characteristic regions of the model were considered and the groundwater level and pollutant concentration distribution in these regions were analyzed.

Materials and methods

Working principles

Rock permeability test was divided into the *in-situ* test and the laboratory test. In-situ test was performed on site that accurately determined the permeability of the rock and soil mass. However, the in-situ test is time and money-consuming. Laboratory test is easily operable, controllable and reliable, and requires less investment in terms of money or labor resources. There are mainly two methods to test the soil permeability in laboratory, *viz.* the transient test and the static test.

In the static test, a certain level of penetration pressure is imposed on the two ends of the test specimen. The volume of the fluid penetrating into the rock specimen within a certain period of time is recorded. Then the permeability under this working condition is calculated according to the Darcy's law (Zimmerman et al., 2000; Brace et al., 1968). Static test is easier and more stable than the transient test and requires less time. Therefore, static test was performed in this study. *Equations 1* and *2* represent the working principle of the static test, where q is the flow rate (m^3/s); k is the permeability (m^2); A is the cross-sectional area of the specimen (m^2); dh is the pressure head (m); L is the length of the penetration path (m); γ_f is the fluid density, which is 1000 kg/m^3 for water; μ is the coefficient of dynamic viscosity of fluid (Pastoules et al., 1982).

DOI: http://dx.doi.org/10.15666/aeer/1706_1301513033

$$q = -k\frac{\gamma_f}{\mu} \cdot \frac{dh}{dx} \cdot A \quad \text{(Eq.1)}$$

$$k = \frac{\mu LV}{A\Delta P\Delta t} \quad \text{(Eq.2)}$$

Test preparations

The purpose of the landfill leachate concentration test was to determine the pollutant concentration in the leachate that was used to immerse the rock specimens as well as the original landfill leachate concentration. *Figure 1* shows the picture of the sampling points at the No. 1 landfill BH-1. Samples were collected once per month from each of the landfills BH-1, BH-2 and BH-3. The GPS coordinates of BH-1, BH-2 and BH-3 were (30.644927, 104.359351), (30.648471, 104.362012) and (30.654969, 104.363600), respectively. The total number of sampling was 12, and the overall sampling duration was 1 year. The total nitrogen (TN) of the samples was determined by semi-micro Kjeldahl method. The oxidizing agent potassium permanganate ($KMnO_4$) was used for measuring chemical oxygen demand (COD). Ammonia nitrogen, chloride and sulfate ions were tested by titration. Subsequently, the pollutant concentrations were measured and processed statistically. *Table 1* shows the statistics of the field test results of landfill leachate for the concentrations of Cl^-, SO_4^{2-}, COD, TN, NH^{4+}-N and Ph at BH-1, BH-2 and BH-3, where Nu is the number of samples collected; Av is the mean and *Va* is the standard deviation of concentration. The unit of concentrations was *mg/L.*

During tunnel excavation, the penetration of landfill leachate causes a certain impact on the surrounding rocks, and the influence on permeability of the surrounding rocks needs to be given a major consideration. In order to determine the changes in the permeability of the surrounding rocks after tunnel excavation, it is important to conduct the experiment by soaking the excavated and processed rock specimens in the landfill leachate. The measured concentration of landfill leachate used was used to prepare the experimental leachate. The mean of pollutant concentration at the sampling points of BH-1, BH-2 and BH-3 were taken and the leachate samples were prepared by mixing together the different ions in an appropriate proportion. Total nitrogen was defined as the sum of all inorganic and organic nitrogen, including the inorganic $NO^{3-,}$ NO^{2-} and NH_4^+ and organic proteins, amino acids and amines. However, the preparation of nitrogen-containing leachate was difficult, and the resulting solution exhibited a low stability. Therefore, nitrogen-containing leachate was not prepared. The prepared landfill leachate was mainly composed of COD, SO_4^{2-}, Cl^-, OH^- and NH_4^+, and the volume of the prepared solution was 2000 mL with Ph value of 8. Concentrations of each pollutant in the leachate are shown in *Table 2,* and the soaking time was 60 days (*Fig. 2*).

Table 2. *Concentrations of different pollutants in the prepared leachate*

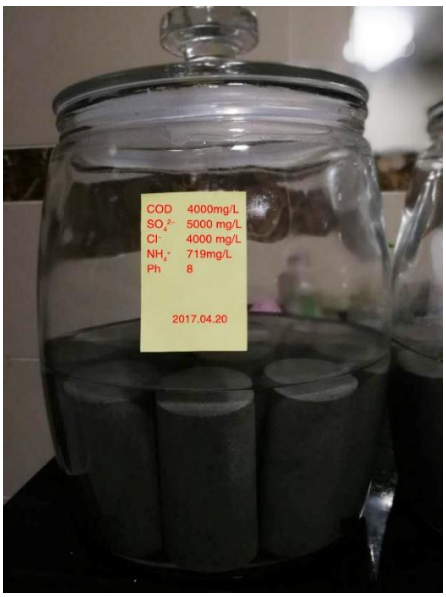

Figure 2. *Rock samples after soaking*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1301513033

The rock specimens were taken out from the leachate and all specimens, with or without soaking, were numbered. Before the permeability test, all the specimens were first soaked in water. The specimens were subjected to vacuum pumping in a pressure vessel for 4 h, followed by dehumidification for another 4 h. Then the specimens were placed into distilled water for 16 h, so that the pores of the rock specimens were filled with water. Moreover, by soaking in water, the external leachate would not stay inside the rock specimens because the pores of the rock specimens were not completely filled with water, thus, impairing accuracy of the test. The permeability test was undertaken by using the TRIAXIAL CELL V 4.0 system, as shown in *Figure 3*. This system was composed of automatic confining pressure, axial pressure and interstitial fluid pressure servos. The system was suitable for temperature-hydraulic pressure-mechanic-chemistry multi-field coupling test for the geological materials such as rocks.

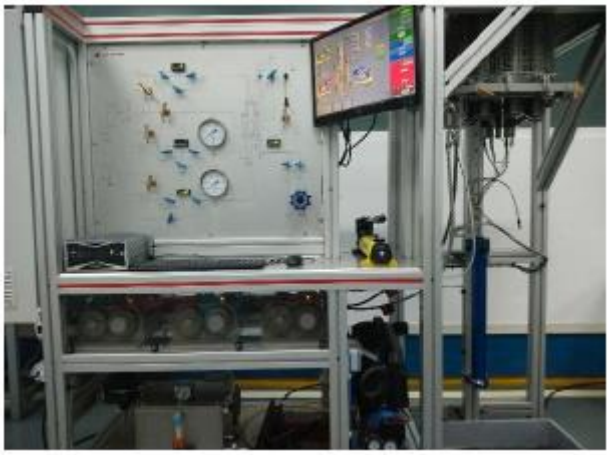

Figure 3. *Picture of TRIAXIAL CELL V 4.0*

Analysis of test results

The penetration pressure was set to 2 MPa in the test and the confining pressure test was 4 MPa and 10 M. In the meantime, two control groups were set up in order to analyze the influence of the landfill leachate on the permeability of the rock, *viz.* a group of test specimen not soaked in the leachate and a group of test specimen soaked in the leachate. The test results are displayed in *Figures 4* and *5*. Two types of curves are shown in the figure, the axial strain-deviatoric stress curve and axial-strain-permeability curve.

It can be seen that the rock permeability was closely related to the confining pressure. Under the penetration pressure of 2 MPa, the rock permeability decreased as with an increase in the confining pressure. Under a higher confining pressure, the micropores and microcracks inside the rock specimens were compressed or closed, leading to a reduction in the size of seepage radius and channels. As a result the permeability of the specimens decreased. For specimens with or without soaking, under the penetration pressure of 2 MPa, the maximum permeability occurred when the axial strain was 0.8101, before which the deviatoric stress decreased suddenly. When the confining pressure was 10 MPa and the penetration pressure was 2 MPa, a maximum permeability occurred where the axial strain was 0.9954 and 1.2788, before which the deviatoric stress decreased dramatically. The maximum permeability of the rock

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1301513033

specimens occurred after the peak strength, that is, after the fracture of specimens. When a macroscopic fracture plane was formed inside the specimen, this plane would become the preferential seepage channel, leading to a sudden increase in permeability. Mean values were taken of the difference in permeability in all specimens with or without being soaked. It was found that the permeability of the specimens soaked in leachate increased by 21% on average.

Numerical simulation

Numerical simulation

Feng et al. (2019) found that if no pollution sources or acid precipitation were identified in the study area, the peak concentration of sulfate ions in water samples collected from tunnels was 438 times that of the background concentration in January 2017. This indicated that the high concentration of sulfate ions in the tunnel was attributed to No. 1 landfill. Han et al. (2016) surveyed 32 scientific research papers on the pollution environment of landfills, and found that sulfate ions leaking from landfills not only pollute the groundwater but also corrode concrete. Chloride ions are relatively stable in the migration process. However, the migration distance is generally short and the sulfate ions will cause severe corrosion of the concrete in the tunnel. So sulfate ions were taken as the object of simulation in the model. Jamrah et al. (2008) proposed that the simulation results without considering the hydrochemical behaviors were very helpful for groundwater governance. Therefore, the hydrochemical behaviors were not considered in the model.

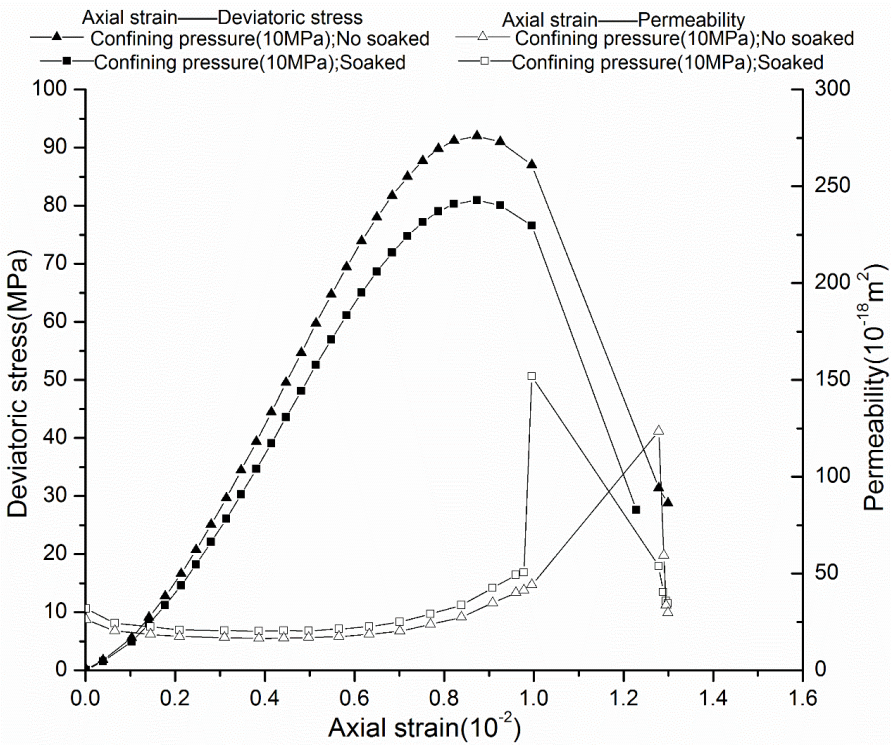

Figure 5. *Comparison of the axial strain-deviatoric stress curves and axial-strain-permeability curves in rock specimens soaked or not soaked under the confining pressure of 10 MPa and penetration pressure of 2 MPa*

The solute transport model (MT3D model) and groundwater flow model (MODFLOW model) in the study were established to simulate the solute transport and the groundwater flow, respectively (McDonald and Harbaugh, 1988; Zheng and Wang, 1999). Both the solute transport model and groundwater flow model were of the transient type. The time duration under simulation was from January 2015 to December 2030, for a total of stress periods. Configuration of the stress period was consistent with the changes in groundwater recharge, wherein, each month represented one stress period. Multiplier and time step were respectively set to 1.1 and 5. The boundary conditions, stress period and original conditions in MT3D model were consistent with those in MODFLOW model.

Original water level and boundary conditions

Feng et al. (2019) established a groundwater model in the study area, the boundary 4 in southwest and the boundary 2 in northeast were both conceptualized as the fixed head boundaries according to the measurements of the monitoring wells along the boundary 4 and boundary 2. Boundary 2 is set along the Shi fan Mountain and the head varied from 669.6 m to 672.0 m. The head on boundary 4 varied from 666.1 m to 667.3 m. Due to the presence of the impervious rocks, boundary 3 was set to the zero-flow boundary. Boundary 1 was set along a highway with roadbed, so it was also set as the zero-flow boundary. There were 4 intersections between the boundary 4 and the original water level, indicating that the head on the boundary 4 is reduced from ends to the middle. The boundary view is shown in *Figure 6*. The original water head is shown in *Figure 6*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1301513033

and the groundwater generally flows from northeast to southwest. In addition, the values of the original head and the elevations of the layers were input in the MODFLOW and MT3D model and then interpolated to get a value for each cell of the models.

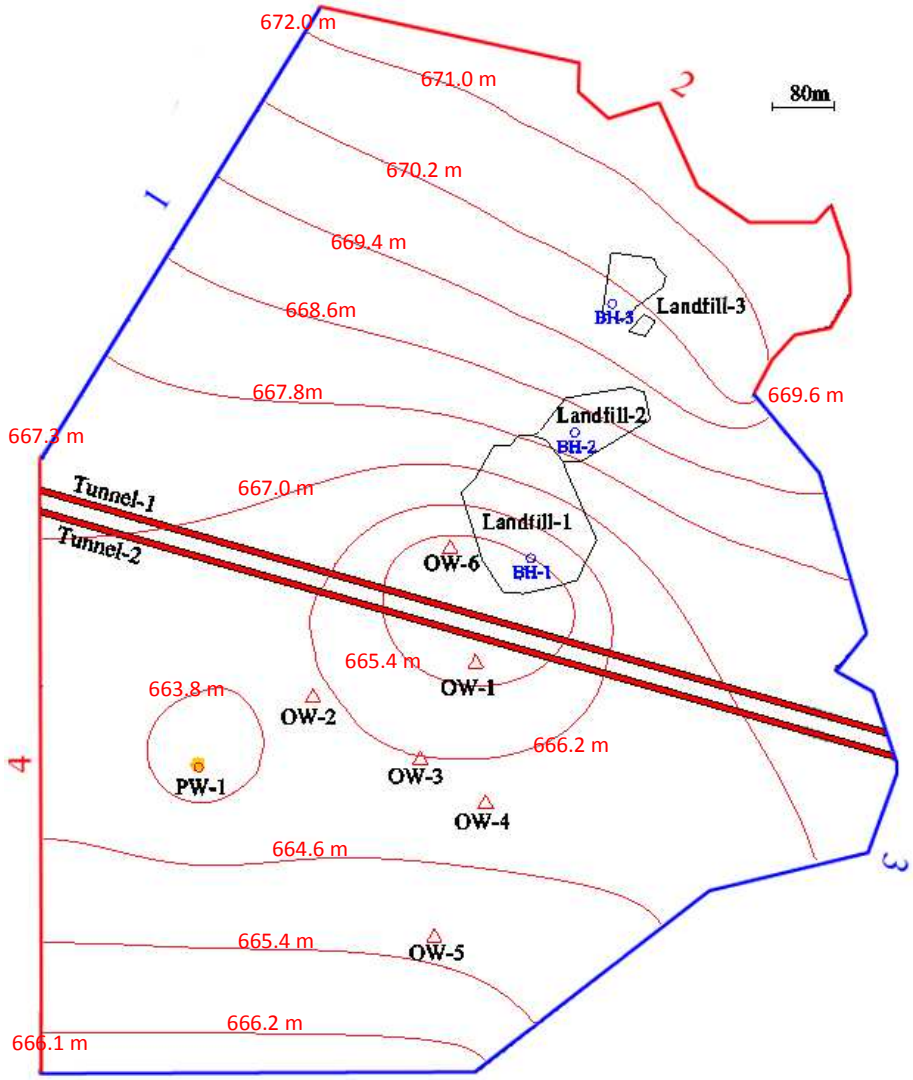

Figure 6. *Original water level in January 2014. Red circle and red triangles stand for the pumping well (PW-1) and six monitoring wells (OW-1, 2, 3, 4, 5, and 6), respectively. BH-3, 2, and 1 stand for the sampling points for Landfill-3, 2, and 1, respectively. Red boundary 4, 2 and the blue boundary 3, 1 stand for the fixed head boundary and zero-flow boundary, respectively*

Conceptualization of model

There was a very thin aquitard composed of silt in the stratum of the study area. The tunnel in the study area could be assumed to be inlaid in the thin aquitard, therefore the area of the location of the tunnels and the silt aquitard were conceptualized into the second layer. In addition, the layers from the bottom to the top were set to confined, convertible and unconfined, respectively. The layer 3 and layer 1 are composed of sandstone and argillaceous sandstone, respectively. The MODFLOW and MT3D model

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1301513033

for the studied area covered nearly 1.24 km^2 and consisted of 199 columns and 199 rows. The thickness of the first layer ranged from 24.5 m in the northeast to 10.8 m in the south. The thickness of the second layer was 0.1 m, beside that the tunnel area was 4.3 m to 4.6 m. The thickness of the third layer was 19 m. The drainage after tunnel excavation was generalized to the pumping well that was limited to the layer 2. The displacement of the four drainage points was 1700-2000 m^3/d. A spatial view of the MODFLOW and MT3D model is shown in *Figure 7*.

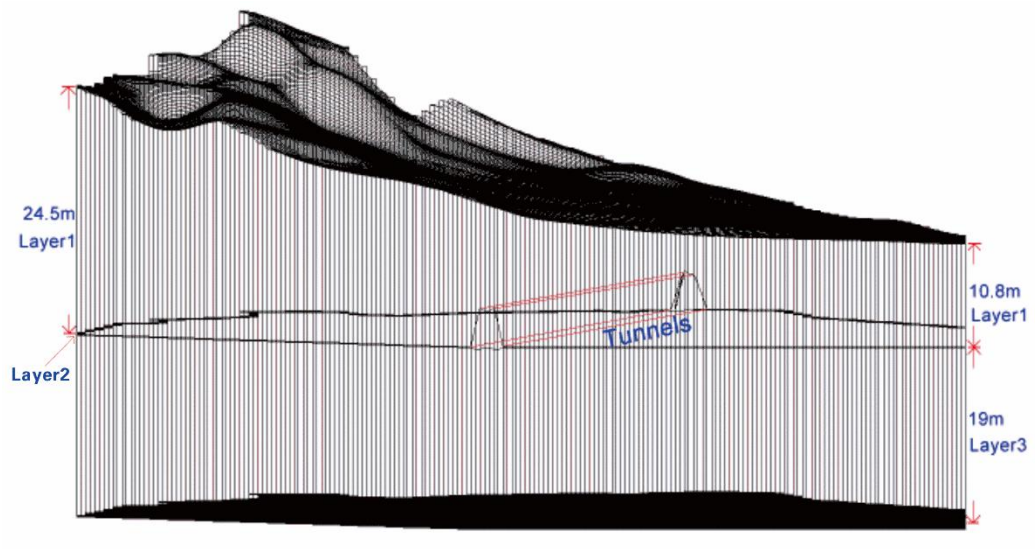

Figure 7. *Spatial view of the MODFLOW and MT3D model*

Parameter configuration

Groundwater recharge

The recharge values in the MODFLOW model were configured based on the monthly mean rainfall in Chengdu from 1970 to 2010. The recharge values and the amount of precipitation were represented by *Equation 3* (Huan et al., 2015).

$$Q_r = \lambda S_r \quad \text{(Eq.3)}$$

where the coefficient of recharge (λ) was consistently set to 0.19 from the precipitation (Feng et al., 2019); Q_r is the groundwater recharge (m/d) and S_r is the amount of precipitation. The recharge values and the average monthly precipitation are shown in *Table 3*.

Table 3. *Average monthly precipitation from 1970 to 2010 and recharge values. (Source: http://www.weather.com.cn/cityintro/101270101.shtml)*

Month	1	2	3	4	5	6	7	8	9	10	11	12
Precipitation (mm)	7.8	12.2	20.2	44.4	78.7	106.8	224.5	201.3	118.8	35.4	15.9	5.2
Recharge values (0.00001 m/d)	5.0	8.0	13.0	28.0	50.0	67.0	142.0	127.0	75.0	22.0	10.0	3.0

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1301513033

Hydrological parameters

The penetration coefficients in the first layer of the groundwater flow model were configured to vary in the range of 1.2~18.1 m/d. During model calibration for this layer, the range of parameter adjustment was directly set to 1.2~18.1 m/d. After correction, the horizontal penetration coefficient was 1.3 m/d. Following the general practice in the processing of penetration coefficients in hydrogeology, the vertical penetration coefficient was generally taken as one tenth of the horizontal penetration coefficient. Therefore, the vertical penetration coefficient was set to 0.13 m/d. After tunnel excavation began, the specific storage and specific yield of the first layer in the groundwater flow model were set to 0.00002 m^{-1} and 0.21, respectively. The configuration of the penetration coefficients in the second layer was more complex. The settings are displayed in *Figure 8,* where blue color represents the regions between the two tunnels, red color represents the tunnel under excavation, and white shows the ordinary region.

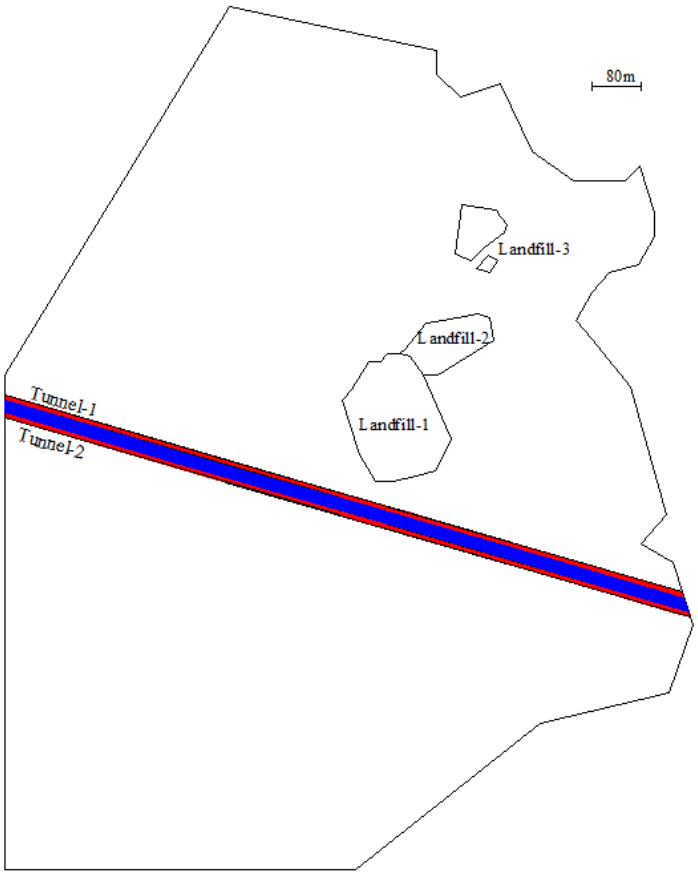

Figure 8. *Distribution of hydraulic conductivity coefficients of the second layer of model after tunnel excavation began*

The white region was silt, where the horizontal and vertical hydraulic conductivity coefficients were 0.005 m/d and 0.0005 m/d, respectively. Blue region was the argillaceous sandstone soaked in the leachate. For this region, the hydraulic conductivity coefficient was multiplied by the weighting factor of 1.21 that was obtained from the test. The horizontal and vertical hydraulic conductivity coefficients

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1301513033

were set to 1.5 m/d and 0.16 m/d, respectively. The specific storage and specific yield of the second layer in the groundwater flow model were set to 0.00002 m^{-1} and 0.08, respectively. The specific storage and specific yield of the third layer in the groundwater flow model were set to 3.6 m/d and 0.36 m/d, respectively. For the geological medium in this layer, the specific yield and specific storage were set to 0.21 and 0.00002 m^{-1}, respectively. *Table 4* shows the hydraulic conductivity coefficients, specific yield, specific storage and formation thickness of each layer in the groundwater flow model after the beginning of the tunnel excavation. According to the results of the field test, the original concentrations of sulfate ions at Landfill-1, Landfill-2 and Landfill-3 were all set to 5000 mg/L; the original concentrations of other grids were set to 0. The longitudinal dispersivity (m), transverse dispersivity (m), and vertical dispersivity (m) were set to 10 m, 1 m and 0.1 m, respectively. All the values were assigned using the earlier study done by Feng et al. (2019)

Table 4. *Hydraulic parameters of the three layers*

Layer number	Aquifer type	Specific yield	Specific storage (m^{-1})	K_x, K_y (m/d)	K_z (m/d)	Thickness (m)

Calibration and validation of groundwater flow model

After the beginning of the tunnel excavation, the measured groundwater levels of observation wells in the study area in 2014 and 2015 were collected. The year of calibration and validation was 2014 and 2015, respectively. For calibration of the simulated and measured groundwater level, the hydraulic conductivity coefficients were varied. The simulated groundwater level was calibrated against the measured water levels of six observation wells from January 2014 to December 2015, until the simulation agreed well with the observation (Panagopoulos, 2012). Changes in the measured groundwater levels in the observation wells OW-1, OW-2, OW-3, OW-4, OW-5 and OW-6 and simulated values from the groundwater flow model during calibration (2014) and validation (2015) after the excavation began are shown in *Figure 9*. At the end of the calibration period of the groundwater flow model (December 2014), the maximum difference between simulated and measured groundwater level simultaneously occurred at OW-1, OW-2 and OW-3, the difference being 0.15 m; difference was 0.06 m at OW-4, 0.03 m at OW-5 and 0.01 m at OW-6. None of the difference at the end of the calibration period exceeded 0.2 m. At the end of the validation period of the groundwater flow model after the excavation began (December 2015), the maximum difference between the simulated and the measured groundwater level occurred at OW-1 was 0.14 m; the difference was 0.05 m at OW-2, 0.03 m at OW-3, 0.02 m at OW-4, 0.03 m at OW-5 and 0.02 m at OW-6. None of the difference at the end of the calibration period exceeded 0.15 m. On the whole, the difference at the end of the validation period of the model (December 2015) was smaller than that at the end of the calibration period of the model (December 2014), indicating that the parameter adjustment achieved a certain effect.

Simulation results

Groundwater flow simulation results

The simulated groundwater level in the first stress period after the validation of the groundwater flow model under tunnel excavation is shown in *Figure 10,* and the time was January 2016.

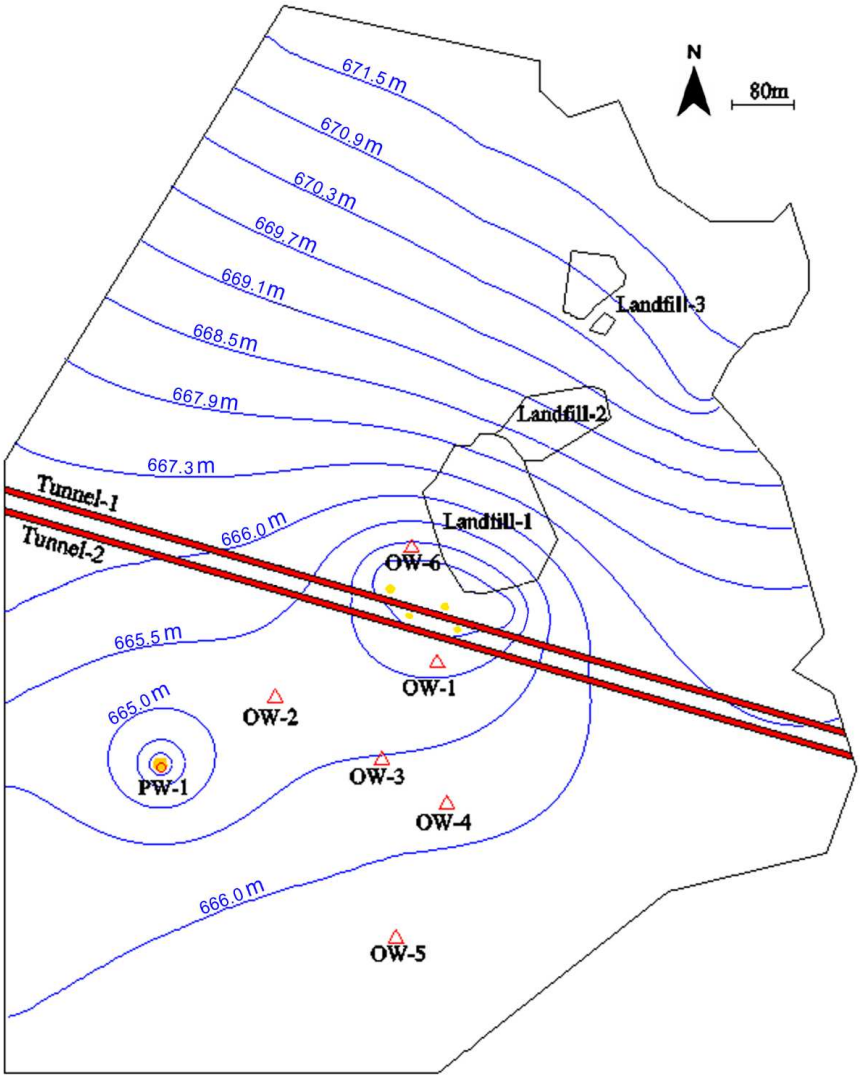

Figure 10. *Simulated groundwater level from the groundwater flow model in January 2016 after tunnel excavation began*

A precipitation funnel was formed near the middle section of the tunnel and PW-1. After the beginning of the tunnel excavation, four drainage sites were represented by small yellow circles. The amount of tunnel drainage varied within the range of 1700~2000 m^3/d. Tunnel drainage was conceptualized as a pumping well in a confined formation, which was the second layer. All the groundwater levels at the north and south sides of the tunnel in *Figure 10* were higher than the original groundwater level in *Figure 6,* and the water lines were denser. This indicated that the tunnel impeded the groundwater flow. Moreover, there was a large fluctuation in the simulated groundwater

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1301513033

level after the beginning of the tunnel excavation, which was attributed to the tunnel drainage. It was also found that the groundwater level showed greater fluctuations due to tunnel drainage than due to the pumping wells. Barrier to the groundwater flow and drainage due to the presence of tunnel decreased the pumping rate of PW-1.

Results of solute transport simulation

In the simulation of the solution transport under the tunnel excavation, it was necessary to import the results of groundwater flow simulation under excavation in advance. The solute transport model conceptualized three formations. However, while presenting the results of the transport of the pollutants, only the pollution plumes of the aquifer (first layer) and the convertible formation (second layer) are shown. *Figures 11* and *12* show the pollution plumes of the sulfate ions in the first layer (aquifer) of the solute transport model in December 2020 and December 2030, respectively.

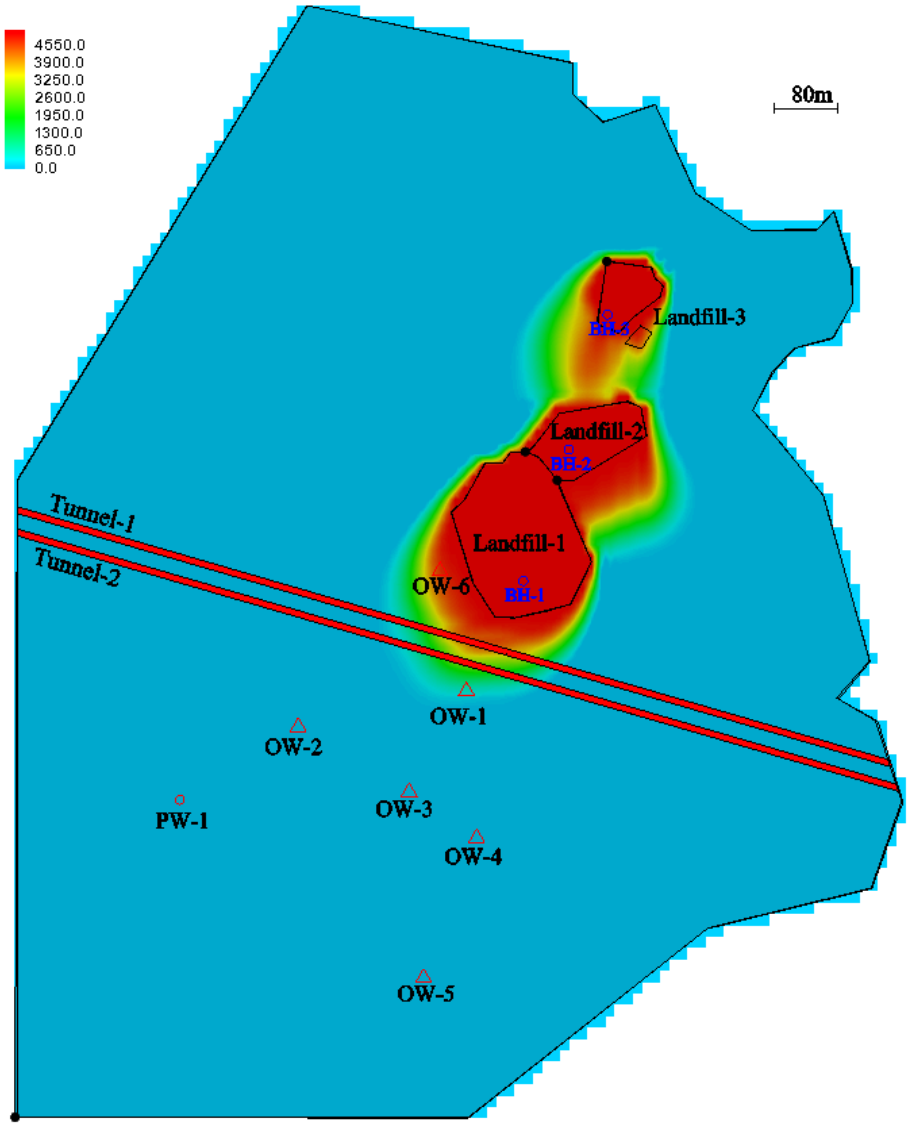

Figure 11. *Pollution plumes of sulfate ions in the aquifer (first layer) of the solute transport model under excavation in December 2020*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1301513033

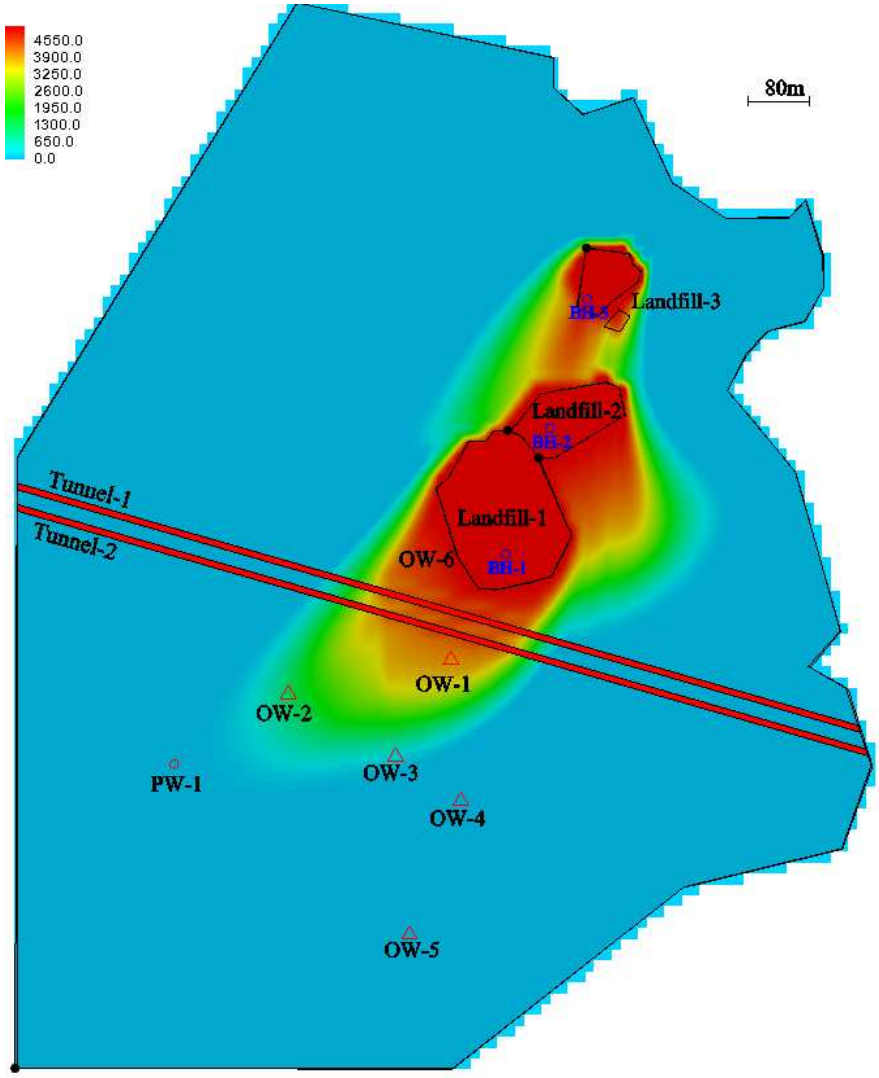

Figure 12. *Pollution plumes of sulfate ions in the aquifer (first layer) of the solute transport model under excavation in December 2030*

For the first layer, the pollution plumes just reached the OW-1 in December 2020. The concentrations of sulfate ions at OW-1 and OW-6 were 559 mg/L and 4115 mg/L, respectively. In December 2030, the plumes in the first layer completely covered OW-1, OW-2 and OW-6 and the transverse plumes just arrived at OW-3, while the vertical plumes had not yet arrived at PW-1. Observations at OW-1, OW-2, OW-3 and OW-6 indicated that the concentrations of sulfate ions were 3338 mg/L, 1872 mg/L, 440 mg/L and 4542 mg/L, respectively. *Table 5* shows the observed concentrations of the sulfate ions in the observation/pumping wells in the aquifer (first layer) of the solute transport model under tunnel excavation in December 2020 and December 2030, respectively.

Figures 13 and *14* show the pollution plumes of the sulfate ions in the second layer (convertible formation) of the solute transport model in December 2020 and December 2030, respectively. In practice, the shape of pollution plumes depends on several factors, including the groundwater flow rate, pressure head, distribution of hydraulic conductivity coefficients, and shape of the pollution source. A continuous leakage of landfill leachate represented a stable pollution source in the model. However, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1301513033

distribution features of the sulfate ions in the convertible formation were very different from those of the ordinary pollutants, and the reason was the irregular penetration path formed between the two tunnels. The hydraulic conductivity coefficients between the two tunnels increased due to the soaking of the surrounding rocks in the landfill leachate. As a result, the downward penetration of the sulfate ions from the first layer via the regions between the two tunnels was enhanced. In other words, the migration path of some the sulfate ions was indeed altered by the tunnel excavation. *Table 6* shows the observed concentrations of sulfate ions at the observation/pumping wells in the convertible formation (second layer) of the solute transport model under tunnel excavation in December 2020 and December 2030.

Discussion and conclusion

(1) By comparing the test results, it was found that the confining pressure exhibited a greater impact on the overall trend of the permeability curve. This was also indicated by the shape of the permeability curve, since, the rate of variation at the increasing permeability stage decreased with the increase in the confining pressure. The maximum permeability of rock specimens occurred after the peak strength, that is, after the fracture of specimens. When a macroscopic fracture plane was formed inside the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1301513033

specimen, this plane would become the preferential seepage channel, leading to a sudden increase in permeability. The mean values of the differences in the permeability between rock specimens with or without soaking were taken into consideration, after the beginning of the tunnel excavation under the same confining pressure and penetration pressure. On an average, it was found that the permeability of the specimens soaked in leachate was increased by 21%.

(2) Tunnel drainage in the model was conceptualized as a pumping well confined in the second layer. According to groundwater level simulation in January 2016, a precipitation funnel was formed near the middle segment of the tunnel and PW-1. Tunnel drainage in the model was conceptualized as a pumping well confined in the second layer. All the simulated groundwater levels in the north and south sides of the tunnel were higher than the original groundwater level, and the water lines were also denser. This indicated the barrier to the flow of the groundwater due to the presence of the tunnel. Moreover, there was large fluctuation in the simulated groundwater level after the beginning of the tunnel excavation, which was attributed to the tunnel drainage. It was also found that the groundwater level fluctuated more prominently due to the tunnel drainage, than due to the pumping wells. Furthermore, the presence of tunnel acts as a barrier to the groundwater flow and the drainage, thereby decreasing the pumping rate of PW-1.

(3) The distribution of the sulfate ion concentration in the second layer of model between the two tunnels showed an irregular pattern. The hydraulic conductivity coefficients between the two tunnels increased due to the soaking of surrounding rocks in the landfill leachate. As a result, the downward penetration of sulfate ions from the first layer via the regions between the two tunnels was enhanced. As the tunnel excavation accelerated the downward penetration of pollutants, this would lead to the pollution of deep groundwater. Therefore, the tunnel excavation area should not only pay attention to surface pollution, but also pay attention to underground pollution. In addition, it was necessary for the study area to conduct drilling sampling studies to support concentration simulation results.

Abstract. Under-nutrition is a serious health problem of developing countries, including Pakistan. Despite the implementation of a number of health strategies for the vulnerable population (especially children), the issue is still emerging and needs further investigation. The aim of this study was to investigate the role of various ecological and maternal factors responsible of children's nutritional health variations. By using Pakistan Demographic and Health Survey (PDHS) data, maternal factors were assessed as important factors of child under-nutrition. Multinomial nested logit regression and classification tree analysis were performed. A total of 1870 children of age < 5 years were included in the analysis and out of these 50.1% fall in the composite index of anthropometric failure (CIAF). Maternal education, mother's body mass index (BMI) and working status were among the significant factors while decision making autonomy remain insignificant. Maternal factors have significant impact on child health and use of CIAF as a measure of nutritional status is recommended for policy makers because of its capability to estimate the overall burden of under-nutrition.
Keywords: *child health, demographic and health survey, nested logit regression, wealth status, classification tree*

Introduction

Role of population's nutritional status is important in socio-economic development of a country. Adequate nutrition level for children's growth and development is imperative. Early years of life are of huge significance for mental as well as physical growth of a child. However, this age is regularly set apart by micronutrient inadequacies that meddle with ideal development. Moreover, children's of this age are powerless against the irresistible sicknesses such as diarrhea and acute respiratory infections (Final Report PDHS, 2012-2013). It is, therefore, considered as one of the important components of Sustainable Development Goals (SDGs) adopted by UN in 2015. A malnourished child is more likely to die from common illnesses such as malaria, measles, diarrhea and pneumonia (Chowdhury et al., 2016). Poor nutritional status increases the risk of infection, morbidity and mortality along with decline of mental development during the early years of child-hood (Endris et al., 2017). Hence, children are more vulnerable to under-nutrition. United Nations statistics show that 155 million children were stunted, 41 million were overweight and 52 million were wasted in 2016 (WHO, 2017). About 50% of these children live in the three south Asian countries, i.e.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1303513055

Pakistan, India and Bangladesh (Achadi et al., 2016), and under-nutrition is one of the major challenges in these countries. Best nutritional status of the children is one of best indicators of their well-being (Poda et al., 2017). A bunch of factors, which can affect child under-nutrition, are considered by various studies. These factors comprise of health care services, maternal literacy, wealth status, maternal decision making autonomy etc. (Amugsi et al., 2014; Debnath and Bhattacharjee, 2016).

Maternal factors are considered as the most important factors for children's health (Vikram et al., 2012). Existing literature reveals that improved maternal education can positively affect child's health (Arooj et al., 2013). Numerous studies considered the role of maternal factors as well as other socio-economic and demographic factors for improvement of child under-nutrition in middle and low income countries (Poda et al., 2017; Debnath and Bhattacharjee, 2016; Krishna et al., 2017; Sarma et al., 2017; Rakotomanana et al., 2017; Altare et al., 2016; Alemayeha et al., 2015; Senbanjo et al., 2013; Anekwe and Kumar, 2012; Pradhan, 2010). Gender of the child, child, size at birth, maternal education, mother's BMI, wealth status, dietary diversity, mother's decision making autonomy and vaccination were among the most important factors affecting child under-nutrition in the above mention studies. However, some studies showed insignificant relationship between child under-nutrition and mother's BMI, mother's education, fathers educations as well as wealth status of household (Rahman, 2016; Sharma and Kader, 2013; Maïga, 2013).

Pakistan, with sixth largest country by population, is ranked at 124 out of 132 countries with 45% stunted children and 106 out of 130 countries with 11% prevalence of wasting among children (Raju and D'Souza, 2017). According to global nutritin report, only 0.7% of government expenditure is allocated for nutrition-sensitive interventions, which is less than other countries in the region such as Nepal and Bangladesh, with 3.1% and 2.1% allocations respectively (Achadi et al., 2016). It reveals worst conditions of child under-nutrition in Pakistan and government negligence. A number of studies have considered these issues and discuss various causes of child under-nutrition. For example Tariq et al. (2018) identified that mother's BMI, rural residence, parental education, poverty and type of toilet facility were the associated factors of child under-nutrition. A study explored that maternal health and child health were among the most significant factors associated with stunting and wasting (Achakzai and Khan, 2016). Wealth status was considered as important factor of child under-nutrition while maternal education was declared insignificant by a study (Khan and Raza, 2014). However, Mahmood et al. (2016) revealed that maternal education was a significant factor to improve child under-nutrition in Pakistan.

Most of the aforementioned studies applied logistic framework and child under-nutrition was measured through commonly used anthropometric indices named stunting, wasting and underweight. These measures however, describe different dimensions of under-nutrition and are overlapping. For instance, underweight is the composition of both wasting and stunting, but does not make a separation between them (Fentahun et al., 2016). Moreover, none of the conventional indices has capability to provide a comprehensive measure of under-nutrition in the population (Khan and Raza, 2014). Therefore, the use of single indicator, that must be able to capture the magnitude of nutritional status and identify the susceptible part in the population, is needed. Peter Svedberg, a development economist, proposed an important measure of child nutrition, known as composite index of anthropometric failure (CIAF) (Svedberg, 2000). A number of recent studies in the literature has used this proposed indicator for different

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1303513055

countries (Endris et al., 2017; Khan and Raza, 2014; Fentahun et al., 2016; Sen and Mondal, 2012; Ejaz and Azid, 2011; Das and Bose, 2011) and they have recommended this indicator as an alternative measure of under-nutrition.

Conventional measures of under-nutrition (stunting, wasting and underweight) are commonly used in the existing studies for Pakistan (Tariq et al., 2018; Arif et al., 2011; Mushtaq et al., 2011). Moreover, neither of these studies focused on ecological and maternal factors, solely, nor the exposure variables as well as control variables were selected under UNICEF conceptual framework to analyze child under-nutrition. Keeping in view these gaps the specific objectives of this study were: first, to check the role/importance of maternal factors, selected under UNICEF conceptual framework, on child under-nutrition. Second, to consider CIAF as an alternative measure of child under-nutrition instead of conventional measures using nationwide community health survey data.

Materials and methods

UNICEF conceptual framework and model specification

The analysis is performed under UNICEF conceptual framework that constitutes three levels of causes of under-nutrition; immediate, underlying and basic levels (UNICEF, 1990). This framework presents the general relationship between a set of variables and child nutritional level. The immediate level causes comprise of dietary intake and illness which are interlinked. If a child could not take nutritious food he/she may be attacked by infectious diseases due to illness. On the other hand, if a child falls ill then he/she may not be able to consume desired diet which in turn results into malnourishment. Whether a child is in danger of infectious disease or whether he/she gets insufficient food to consume, is the consequence of the underlying factors that are consider as the household causes of under-nutrition. According to the framework of household food security, maternal and child care and environmental factors are the main causes under this level. The causes at the third level of the framework are the basic causes which comprise of political, economic, genetic and socio-cultural factors.

Following the example of Akin et al. (1986) the specified econometric model of this study is based on discrete choice models. Derivation of discrete choice models is based on the hypothesis that the choice of an individual follows the maximization behavior of the random utility (Anye and Yene, 2016). The utility U_{ij} that ith child falling in the jth category of CIAF is given by:

$$U_{ij} = z_i'\alpha + x_{ij}'\beta_i + \varepsilon_{ij} \quad \text{(Eq.1)}$$

where U_{ij} stands for nutritional outcome of the ith child falling in the *j*th category of CIAF, z_i varies over upper nest alternatives and x_{ij}varies over both upper and lower nest alternatives.

Data source and construction of variables

Pakistan Demographic and Health Survey (PDHS) data, version 2012-13, is used for the analysis. Two stage sampling technique was used for the survey. At first stage 500 primary sampling units (248 urban and 252 rural) were selected by using probability proportional to size. At second stage systematic sampling technique was used to select

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1303513055

fixed no of household (28) from primary sampling units selected at first stage. A sample of 14,000 household was selected. Out of 14,569 eligible women, 13,558 were successfully interviewed from these selected households. These women contributed a total of 11,763 live born children within five years before the survey. However, the analysis in this study was limited to 1870 live born children of age 0-59 months (< 5 years) who have valid information about the anthropometric measures. Complete details about sampling procedure and data collection can be found elsewhere (Final Report PDHS 2012-2013).

Response variable

The response variable in this study is the new policy-relevant anthropometric indicator of under-nutrition known as CIAF. The proposed CIAF comprises seven anthropometric failure groups. A Child with height-for-age Z-score (HAZ), weight-for-height Z-score (WHZ) and weight-for-age Z-score (WAZ), below -2 standard deviations from the median of the WHO reference population, are considered to be stunted, wasted and underweight respectively (PDHS report, 2012-13). All these children were distributed into seven groups following Nandy et al., 2005. The details of groups are given in *Table 1*.

Table 1. *Different groups used for construction of response variable (CIAF)*

Group	Description	Wasting	Stunting	Underweight	N (%)
A	No failure	No	No	No	933(49.9)
B	Wasting only	Yes	No	No	70(3.7)
C	Wasting & Underweight	Yes	No	Yes	67(3.6)
D	Wasting, Stunting & Underweight	Yes	Yes	Yes	93(5.0)
E	Stunting & Underweight	No	Yes	Yes	305(16.3)
F	Stunting only	No	Yes	No	374(20.0)
Y	Underweight only	No	No	Yes	28(1.5)

Wasted children = 70 + 67 + 93 = 230 (12.3%); Stunted children = 93 + 305 + 374 = 772 (41.3%)
Underweight = 67 + 93 + 305 + 28 = 493 (26.4%); No of children fall in CIAF = 937 (50.1%)

Explanatory variables

A range of indicators were included in the analysis under different layers of UNICEF's conceptual framework. The data were extracted from the PDHS data and re-categorized (where necessary). These indicators include vaccination status (categorized as non-vaccinated, who did not receive a single dose of any of the prescribed vaccines, partially-vaccinated, who has receive at least one of the vaccine but not complete doses and fully-vaccinated, who received the complete dose of all vaccines), household wealth status was used as proxy for wealth index, given in the survey data, generated by applying principal component analysis on the factors of household ownership of assets (such as bicycle, motorcycle, car, radio, television, etc.) and characteristics of dwellings (such as roof material, main floor material, etc). The index was subsequently cut into quintiles as poorest, poorer, middle, richer and richest and we have re-categorize by merging poorest and poor to only poor and similarly by merging rich and riches and consider as rich only. In this way we have three categories for wealth status as poor, middle and rich. Type of toilet facility was categorized as poor quality, intermediate

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1303513055

quality and high quality following the method of (Fink et al., 2011). Maternal nutritional level was measured using the BMI (calculated as mother's weight in kilograms (kg) divided by her height in meters squared) and categorized as overweight (if $BMI \geq 25.0$), normal ($18.5 \leq BMI \leq 25.0$) and underweight (if $BMI \leq 18.5$). Mother's autonomy was based on four questions asked to the respondent regarding who take the decisions in the household about her own health care, large purchase, visit to family/relatives and the consumption of husband earnings. The possible answers were as follows: (i) Respondent alone, (ii) Respondent and husband/partner, (iii) Husband/partner alone, (iv) family elders and (v) others. A value of 1 was assigned if the answer was (i) or (ii) and 0 for (iii), (iv) or (v), for each question. These recoded values were then added to get a score ranging from 0 to 4. These scores were then categorized into three categories as: no-autonomy if the score value is 0, partial autonomy if the score value is 1, 2 or 3 and the full autonomy if she got a score 4. Different regions are presented in *Figure A1* and different categories of considered factors can be seen in *Table A1* in the *Appendix.*

Methodology of analysis

Analysis is conducted in three stages i.e. descriptive analysis, classification tree analysis and regression analysis based on multinomial nested logit modeling. Percentage distribution of explanatory variables and CIAF categories were explained at first stage. In order to find most effecting maternal factors and their inherent associations with CIAF, we consider a non-parametric techniques, known as classification tree (CT) formalized by (Breiman et al., 1984). It works as an exploratory procedure and select the exposure variables that are most important for analyzing the behaviour of response variable. The CT has tree like structure, where terminal nodes represent the CIAF categories. The initial node split the data into two subsets which are further split to second level partition. By default, Gini index is the splitting criteria used in CT (Pawloski and Kitsantas, 2008). An indicator split is known as best split if it observes relatively high value of homogeneity, measured through Gini impurity function, in the node. The impurity got maximized if all observations are equally distributed among different categories of the variable, which implies that at these nodes provides least interesting information. Gini index got minimized if all the observations belong to only one category of the variable which implies that this node provides most interesting information. The tree stops growing if the terminal nodes approach either of these two conditions (Jung et al., 2014).

For regression analysis *Equation 1* can be summarized by:

$$U_{ij} = V_{ij} + \varepsilon_{ij} \quad \text{(Eq.2)}$$

Here the term V_{ij} is the observable component of child under-nutrition (comprising of immediate, underlying and basic factors) and ε_{ij} is the unobservable random part. The probability of a child falling in category j is equal to the probability of such a category that yield a maximum level of utility for him, that is

$$P_{ij} = \Pr(U_{ij} > U_{ik}) \; ; \forall j \neq k \quad \text{(Eq.3)}$$

$$P_{ij} = \Pr(V_{ij} + \varepsilon_{ij} > V_{ik} + \varepsilon_{ik}) \; ; \forall j \neq k \quad \text{(Eq.4)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1303513055

$$P_{ij} = \Pr\left(V_{ij} - V_{ik} > \varepsilon_{ik} - \varepsilon_{ij}\right) ; \forall j \neq k \quad \text{(Eq.5)}$$

Since the econometric specification depends upon the hypothesis regarding the distributional form of the error term of *Equation 5*. If the error term is assumed to follow normal distribution, then the estimated model would be a probit model. Though a probit model relax the IIA property and is attractive; however, probit models are infeasible due to their computational difficulties (Ben-Akiva et al., 1985; Adhikari, 2011). An alternative way to model this type of phenomenon is that ε_{ij} is assumed to follow generalized extreme value (GEV) distribution. By assuming the GEV distribution, a closed form model can be estimated using maximum likelihood method. According to (McFadden, 1981) it produces multinomial logit model $P_{ij} = \exp\left(V_{ij}\right) / \sum_j \exp\left(V_{ij}\right)$. However, this specification may create a severe problem. Since multinomial logit model assumes that unobservable terms (ε_{ij}'s) are identically and independently distributed (IID) and the assumption of independence of irrelevant alternatives (IIA) is not violated. In our case, some of the categories of CIAF are likely to share the error terms and thus be correlated that may violate the IIA property. To circumvent this situation, a more generalized form of multinomial logit model is referred to as multinomial nested logit (MNL) model (McFadden, 1981) which relax IIA assumption (Anya and Yene, 2016). The use of MNL procedure implies that the under-nutrition categories can be organized into an understandable nesting structure. Consider that the nesting structure of the j alternatives can be seen in *Figure 1*.

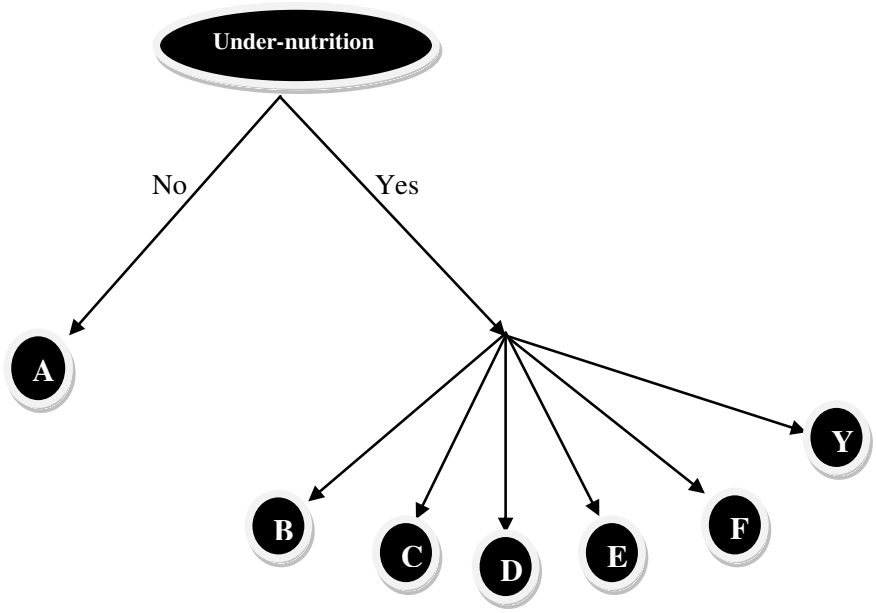

Figure 1. *Two-level nested structure of groups of CIAF*

A child may fall into one of the two categories (i. e. nourished or not-nourished) and if he/she fall in not-nourished category then he/she fall in one of the six categories of CIAF (i.e. B, C, D, E, F, Y). The probability that a child fall in category j given that he/she is malnourished is given by the equation:

$$P_{ij} = P_i * P_{j/i} \quad \text{(Eq.6)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1303513055

where $P_{j/i}$ is the conditional probability of falling in the jth category being in ith category of under-nutrition (i.e. at lower-nest) and P_i is the marginal probability of falling in ith alternative at upper-nest. Moreover,

$$P_i = \frac{\exp\,[z_i\alpha + \tau_i I_i]}{\sum_{i=1}^{I} \exp\,[z_i'\alpha + \tau_i I_i]} \quad \text{(Eq.7)}$$

$$P_{j/i} = \frac{\exp\,[x_{ij}\beta_{j/i}]}{\sum_{j=1}^{J} \exp\,[x_{ij}\beta_{j/i}]} \quad \text{(Eq.8)}$$

with $I_i = \ln\left(\sum_{j=1}^{J} \exp\left[x_{ij}\beta_{j/i}\right]\right)$. Here I_i is the inclusive value representing the maximum value of the attributes that determine the probability of a child falling in category$i$. $\tau_i$is the coefficient and its value must ranges from zero to one to be consistent with the NL derivation (McFadden, 1981). The NL model is estimated using full information maximum likelihood procedure. This method estimates the parameters in all stages simultaneously and produces consistent and efficient results (Hu and Donnell, 2010). Stata version 14 and Party-package of R were used for the regression analysis and classification trees respectively.

Results

Descriptive analysis

A total of 1870, children of age < 5 yrs were included in the analysis. Out of these children, about half (934 out of 1870) were female. According to the conventional indices of under-nutrition, 41.3% (772 out of 1870) were stunted, 12.3% (230 out of 1870) were wasted and 26.4% (493 out of 1870) were underweight among the studied sample. However, according to the CIAF, about 51% (937 out of 1870) of the children suffer from at least one of the groups (Group B-Y) and overall 49.9%(933 out of 1870) of the children fall in Group-A (i.e. without any failure). The highest prevalence of malnourishment was found to be in Group-F (20%: 374 out of 1870) followed by Group-E (16.3%: 305 out of 1870) while, Group-Y it was observed to be lowest with respect to malnourishment (1.5%: 28 out of 1870). Moreover, it was found to be approximately same in Group-B (3.7%: 70 out of 1870) and Group-C (3.6%: 67 out of 1870).

Majority of the mothers were uneducated (51.44%; 962 out of 1870) and have no autonomy (45.7%: 855 out of 1870) while, least of the women were underweight (12%: 225 out of 1870) among the studied sample. Prevalence of malnourished children among the poor and non-educated mothers remained high in failure groups E and F (23.3% & 25% for poor and 21.3% & 237% for non-educated mothers respectively). Moreover, percentage of undernourished children was lower in case of working mother (34.6%; 120 out of 347). Underweight mothers have high ratio of underweight and stunted children (i.e. Group-E: 29.3%; 66 out of 225). Six hundred and thirty six (34%: 636 out of 1870) children were resident of Punjab region followed by region Sindh (24%: 450 out of 1870). Percentage of nourished children stood high for Islamabad region (70.6%). About 40% (755 out of 1870) of the children belong to poor families (*Table 2*).

Classification tree analysis

Two classification trees were constructed in our study. *Figure A2* (*Appendix*) demonstrates the first tree where mother's related variables (mother's education, mother's autonomy, mother's BMI, household wealth status and working status of mother) were considered. At the primary split the nutritional status of child is divided into two groups according to the mother's education (*one* is secondary and higher and the *other* is non-educated and primary). Subsequently node 2 is further divided according to the mother's BMI (underweight; normal and overweight) while, node 5 split into two groups according to wealth status (poor, middle and rich) while, node 6 and 9 are also split according to the mother's BMI (underweight; normal and overweight). There are total 11 nodes. There is higher percentage (about 20%; terminal node 3) of malnourished child with stunting and underweight (Group-F) whose mother has higher or secondary education with low BMI (underweight) while, about 70% of children are well nourished (Group-A) if the mother's nutritional level is better (i.e. she is normal or overweigh). Moreover, about 40% children (terminal node 8) belongs to mothers who either have primary education or non-educated, with lower BMI, are stunted and underweight (Group-E). Middle class or rich mothers with lower nutritional status have about 25% of the children with failure groups E and F (terminal node, 10). In the second tree (*Fig. A3* in the *Appendix*), impact of interactions of mother's schooling and working status on her child's nutritional level was presented. At the top, mother's education is divided into two groups (*one* is secondary and higher and the *other* is non-educated and primary). If the mother has secondary or higher education, about 70% of the children are with Group-A (i.e. well nourished; terminal node, 2) while, we move to node 3 if the mother has either primary- or no-education which further split mother's working status in two groups (yes and no). Node 4 showed that about 25% of the children prone to failure Groups E and F who belongs to working mothers with primary or no-education. However, if their mother is not working, the nutritional status of children of mothers having primary education is better than that of non-educated mothers (about 55% vs. 40%: terminal node 6 and 7).

Multinomial nested logit analysis

Associations of different groups of CIAF (Group B-Y) and various demographic and socio-economic factors, based on nested logit model, are shown in *Table 3* (Odd ratios and estimates with standard errors for upper nest) and *Table 4* (Odd ratios and estimates with standard errors for lower nest). The results at lower nest suggested that children, observed to have group C, D and E, were found a higher significant association with various exposure variables at that level. *Table 3* shows that inclusive value at lower nest was found to be 0.38 with p-value < 0.05, which suggests that shared unobservable are significantly present between different categories of CAIF (Group B-Y). According to the Wald-test the nesting structure is appropriate (Wald chi2 = 230.13, p-value < 0.001) while, likelihood ratio test for IIA property indicates that nested logit, is in fact, probably more convenient (chi2 (1) = 15.43, p-value < 0.001). The results and interpretations of variables at lower nest are briefly given below.

Effect of mother education: Mother education was found to be a highly significant factor of CIAF groups (Groups B-Y). Children of mothers with secondary education as compared to non-educated mothers were at about 50% lower risk to be lying in groups C, D, E and F (*Table 4*). However, this percentage fall down to 40% (OR = 0.61) for

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1303513055

group-B. If mother's education improved (higher and above), the nutritional level of children also improved. The results stated significantly lower odds for those children whose mothers have higher or above education. OR = 0.34, for group-D and OR = 0.40, for group-E). Moreover, mother's primary education does not show a significant association, implying that there exist no relative difference among the children of non educated mothers and those with primary education, regarding under-nutrition.

Effect of vaccination: The association of CIAF groups showed that vaccinated children were less likely to be malnourished as compared to non-vaccinated children. The odd values were significantly lower for the children of failure Group-B (OR = 0.55), Group-C (OR = 0.53), Group-D (OR = 0.57) and Group-Y (OR = 0.51). Those who were completely vaccinated have about 50% lower risk to fall in failure group-B (OR = 0.52) and Group-Y (OR = 0.50). However, the association of fully vaccinated children remained insignificant.

Effect of mother's Working Status: The impact of mother's working status was found to have higher effect on child under-nutrition. There were 36 percent more chances of falling in Group-F (OR = 1.36) and 31% more chance of lying in Group-F for the children of working mothers (OR = 1.31).

Effect of Diarrhea: Child who had diarrhea within two weeks prior to survey were found to have significantly higher odds for those suffering from wasting and underweight group (Group-C: OR = 1.48) and multiple failure group (Group-D: OR = 1.38).

Effect of Mother's BMI: Children of under-weight mother's were found to have significantly higher odds of falling in Group-C (OR = 1.57), Group-D (OR = 1.73) and Group-E (OR = 1.64). While, the children of overweight mother were less likely to be malnourished (OR = 0.74 for Group-D and OR = 0.74 for Group-E).

Mother's autonomy as well as toilet facility is among the important factors of UNICEF framework but their association could not found to be significant. We turn to the results and interpretation of variables at upper nest. A brief description is given below:

Effect of Gender: There were 17% lower chance of falling in under-nutrition for female child (OR = 0.87) as compared to the male child.

Effect of Wealth Status: Wealth status is among the important factors affecting child's nutritional status at upper nest. The children of middle class families were 30% (OR = 0.70) less likely to be malnourished while, rich children were at 49% at lower risk of under-nutrition as compared to poor children (OR = 0.51).

Regional Effects: Geographic location affects the health status of child. There were 80% (OR = 1.79) more chances of falling in under-nutrition for Sindhi child. However, the children of Baluchistan were three times more likely to fall in the anthropometric failure (OR = 3.17) as compared to the children of Punjab. There is no significant difference between KPK, GB and Islamabad regions as compared to Punjab with respect to child under-nutrition.

Type of Place of Residence: there exist no significant association between type of place of residence and child under-nutrition.

Sex of Household Head: children of female headed household were 42% more likely to be malnourished as compared to children of male headed households (OR = 1.42).

Discussion

Assessment of the nutritional status of children (of age < 5 yrs) plays an important role in developing countries, such as Pakistan, where the major part of population is malnourished (Sen and Mondal, 2012). According to the conventional measures, the prevalence of stunting, wasting and underweight remained 41.3%, 12.3% and 26.4% respectively among the studied sample, while the prevalence of under-nutrition was 51.1% using the CIAF. Based on the CIAF, the results of this study are higher as compared to other countries such as Ethiopia (Fentahun et al., 2016), while the position is little bit better than India (Dasgupta et al., 2015).

Classification trees may work as a useful alternative to the traditional statistical techniques such as logistic regression (Pawloski and Kitsantas, 2008). It is one of the data mining techniques that can identify subgroups in the data that share similar characteristics (Marshall, 2001) and display the results graphically which helps in understanding their interpretations. This display of classification tree can help in understanding how maternal factors interact to define and understand the importance of each variable examined. Moreover, some studies provide the comparison of classification trees with logistic regression models (Pawloski and Kitsantas, 2008; Kitsantas et al., 2007) and found that both methodologies provide comparable predictive performance. In this study, the classification trees revealed that mother's schooling is the most important factor among the maternal factor. The data also show that the children of educated (even primary) and healthy mothers living in household with middle or rich wealth status, were more likely to bear better nutritional status while, if

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1303513055

the mother's education is secondary or above the wealth status does not matter. Furthermore if mother has secondary or higher education then her work status does not affect her child's nutritional health. However, if she has either primary education or no-education then work status influence her child's nutritional level. Interestingly, mother's autonomy did not appear in the classification tree display (*Fig. B1*), suggesting that maternal autonomy may not play an important role for the prediction of poor nutritional status in our case. The results suggested by the tree structure also support the findings of nested logit model as well.

There exist a significant association between regions of residence and the nutritional status of children. Children of Balochistan region are at high risk of falling under-nutrition followed by region Sindh. Similar results were found in some other studies for Pakistan (Tariq et al., 2018). This may be due the cultural norms, seasonal food insecurity, poor health, and sanitation conditions. There are various aspects of gender discrimination in the literature. Some studies revealed that girls are at greater risk as compared to boys (Khan and Raza, 2014; Petrou and Kupek, 2010), while others demonstrated that male child is more likely to be undernourished (Alemayehu et al., 2015; Kandala et al., 2011). However, some studies showed no discrimination (Arif et al., 2011; Mushtaq et al., 2011). Our results showed that female children are less likely to be malnourished, which are in the line with different examinations on the planet (Poda et al., 2017; Altare et al., 2016; Hazarika, 2000). It may be due to the reason as female are less active and stay at home near food preparation. Another explanation may be that the economies like Pakistan, where women's role is important especially as agriculture labour; women's health is preferred (Akombi et al., 2017). A number of studies addressed that children of urban areas have better nutritional status than rural areas (Ejaz and Azid, 2011; Kandala et al., 2011; Hazarika, 2000). The results of this study uncovered no critical relationship amongst categories of CIAF and sort of place of home. Other studies have also showed the similar result (Poda et al., 2017; Rahman et al., 2015). The findings of this study also demonstrate that children of female headed households were more likely to prone in under nutrition. Commonly female headed households, in middle and low income countries, are those where child's mother is a widow or divorced. These households are generally poorer, own less and have lower access to good jobs which ultimately impact the health status of their residents. Similar results can be found elsewhere (Haidar and Kogi-Makau, 2009).

We examined how mothers 'decision making autonomy was associated with the likelihood of childhood under-nutrition. The finding suggests that mothers' sole decision-making as well as partial decision making was not associated with the likelihood of childhood under-nutrition. This result may suggest that child's nutritional status is not affected by who makes decisions in the household. There exist mixed results regarding mother's autonomy in empirical studies conducted in other countries. For example Deasi and Jhnson (2005) conducted a cross-country study for 12 developing countries, using DHS datasets, found that impact of mother's autonomy on height-for-age was positive for Mali and India however, negative association was found between child's nutrition and height for age in Haiti and Malawi. Non-significant results were also found in some studies (Kamiya et al., 2018).

Maternal education is one of the important factors of child health (Asif et al., 2017). There is an extensive literature supported the consequence that improved maternal education to be one of the protective measures of child's poor nutritional status (Alemayehu et al., 2015; Khan and Raza, 2014; Asena and Teni, 2015; Solanki et al.,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1303513055

2014; Frongillo et al., 1997). Our study also showed that children of educated mothers (at least secondary) are less likely to fall in CIAF (in Categories B-Y). These results are consistent with other studies (Endris et al., 2017; Poda et al., 2017). An improvement in women's educational status may consider as a proxy for the increment in the household decision making autonomy which further act as a mediator for the relation between child's nutrition and mother's decision making autonomy (Akombi et al., 2017). Another way of explanation may be that an educated mother may get well pay jobs and more empowered in developing countries (Kandala et al., 2011) which positively affect the child's health ultimately. Thus, we may conclude that improved educational status of mother may consider as a protective measure of childhood under-nutrition.

In the present study we have evaluated the association between child's nutrition and mother's anthropometrics characteristic. Results indicated that maternal BMI was significantly associated with children nutritional status. Different Studies round the world showed that underweight mothers were more likely to have malnourished children as compared to normal or overweight mothers (Poda et al., 2017; Debnath and Bhattacharjee, 2016; Rahman et al., 2015; Tigga and Son, 2016; Ajslev et al., 2014; Fleten et al., 2012). This relationship also indicate and intergenerational transfer of socio-economic adversity and poor maternal health to child. Poverty may be another cause of low maternal BMI because poor mother are nutritionally deprived during early age which may not improve even after marriage. Moreover, social causes such early marriage, lack of birth spacing, and discrimination of food distribution in male dominant families may increase under-nutrition among mothers. The results of this study revealed that children of working mothers were more likely to prone under-nutrition. This may be due to the reasons: first, is that the working mothers have less time for care and feeding of their offspring. Second, generally the mothers of low-income families are less educated and engaged in informal work to earn a little money for the survival of their family. Moreover, such families lived in an unclear environment which adversely affects their health. Similar result can be found in the studies conducted for other countries (Toyama et al., 2001). Diarrhea is one of the important factors of child's death and illness in developing countries (Checkley et al., 2008) which may affect the child's health instantly. The findings of this study demonstrated that children with diarrhea were more likely to fall in Group-C and Group-D of CIAF. The reason behind might be that, diarrhea impact the child nutritional status indirectly as a child with diarrhea could not consume food properly and ultimately fall in undernourishment. Childhood vaccination may strengthen children's nutritional level and lead to a better childhood development in low and middle income countries, where 20% of children fewer than 5 years of age have low weight for age (underweight) and about 32% have low height for age (stunted). Childhood under-nutrition accounts for 35% of deaths worldwide among children of fewer than 5 years because it increases the risk of mortality due to infectious diseases (Anekwe and Kumar, 2012). The findings of our study showed that nutritional level can improve even if the child is partially immunized. Though the results for fully vaccinated children has been reported to be insignificant however this finding does not deny the importance of full vaccination for child's better nutritional status (Debnath and Bhattacharjee, 2016).

An association between household wealth status and child nutrition has been shown in several studies (Chowdhury et al., 2016; Poda et al., 2017). It is found that the children of middle class and rich families were less likely to fall in the CIAF. Other studies also demonstrated similar results (Chowdhury et al., 2016; Kandala et al., 2011;

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1303513055

Petrou and Kupek, 2010; Darteh et al., 2014). This is perhaps due to the reason that well off households may have better access to basic facilities such as good and nutritious food. On the other hand, children of poor SES are more likely to prone anthropometric failure due to insufficient intake, greater exposure to infection as well as lack of access to the basic needs (Hazarika, 2000). A study in Bangladesh has shown that parents of richer families are more likely to be educated than those from poor families, and thus have better access to food, allocate higher proportion of resources for children's welfare and improved standard of living (Sarma et al., 2017), which in turn gives better healthcare to the child. Another study investigating the interaction between SES and the mother's education in connection to child health, found that the impact of improved maternal education turned to be more protective for the children of rich families, while father's education works independently of SES and considered as protective element (Hatt and Waters, 2006).

Conclusion

A significant association among child under-nutrition and maternal factors in Pakistan underscore the requirement for sustained investment to highlight social factors and reproductive health. Our analysis has identified the most vital determinants influencing the child under-nutrition which may play a crucial role in the literature on the association of CIAF with socio-economic and demographic variables. There is need of interventions by the government in collaboration with non-governmental organizations, like USAID, for the improvement of children's nutritional level, especially in under-developed regions such as Blochistan and Sindh. The local governments representatives (Such as UC chairman, councilors etc.) in cooperation with civil society should work to frame child's nutritional level as a national development agenda. Steps should be taken to improve the maternal status in the society, especially the mother's education and her nutritional level. Such programmes should be launched that focus on increase in the women's role in the society, such as skilled education, well paid job opportunities and better health facilities. Moreover, the interventions for the improvement of household wealth status and the effective nutritional strategies (such as Benazir Income Support Programme (unconditional cash transfer for poverty reduction) and Health/Sehat cards (used for free or reduced-rate medical treatment issued by the government), over the long period, should be considered. However, for short run, maternal and child health programs as well as the provision of supplement food on subsidized rate may be useful for eradication of under-nutrition. The progress in preventive measures for infectious diseases, such as diarrhea, need attention of policy-makers to reduce child under-nutrition. Moreover, Lower maternal BMI needs attention in order to break the inter-generational existence of under-nutrition.

The use of CIAF as a measure nutritional status will serve to access more precise identification of nutritionally more vulnerable segments of population since, it has enough potential to improve the efficacy of different nutritional interventions by recognizing different failure groups (single, double and multiple) and also it gives an estimate of overall burden of under-nutrition. Therefore, further research on causes of malnutrition, taking CIAF as measure of malnutrition, is needed. Moreover, reproductive health care, maternal dietary pattern, access to information might be associated with children's nutritional status, therefore further studies should consider such maternal factors also, while investigating the causes of child under-nutrition.

DOI: http://dx.doi.org/10.15666/aeer/1706_1303513055

Moreover, child's dietary pattern should be considered while exploring the causes of child under-nutrition.

Abstract. Ecological wisdom in traditional nomadic societies is formed in the process of production, life and spiritual belief. Nomadic settlements are multidimensional cultural heritage and cultural landscape types in post-modern society. This research takes Qiongkushitai village as the research object, and referring to the research methods and achievements of human geography and temporal geography, this paper discusses the spatiotemporal features and evolution of the traditional nomadic settlements under the process of rapid urbanisation. Taking local wisdom as the breakthrough point, two characteristics of the traditional nomadic spatiotemporal picture are condensed: ① self-adaptability of nomadic spatiotemporal picture restricted by alpine resources, ② multi-level nesting law of nomadic spatiotemporal picture. By extracting the typical fragments on the spatiotemporal axis, this paper attempts to propose a periodic activity model on the multi-level spatiotemporal scale in the nomadic space and time trajectory. This paper explores the evolution mechanism of traditional nomadic settlements driven by national policies, individual demands, technology, and market. The results of this study can provide information for the study of resilience construction in the construction of ecological civilisations in alpine pastoral areas in Western China.
Keywords: *transhumance, adaptability of behavior, laws of nesting in multi-level space, ecological carrying capacity, conflict and acculturation*

Introduction

Ecological wisdom is a positive part of tradition in life and production,which shows recessive and dominant characteristics. It shows the recessive temporal and spatial order in time, but in form, it reflects the physical form or lifestyle reflected by the skills and values of regional cultural genes (Hills, 2009). The production and life patterns of the Kazakh settlements living in the high mountains can provide basic living security on the premise that nomadic data can be provided, although other dynamic factors restrict the strength and depth of their inheritance or continuation. However, this kind of livelihood method, which is rooted in the natural pastoral environment, will also show the trend that the one aspect wanes, the other waxes in the grassland ecosystem chain.

Xinjiang alpine nomadic settlement, as one of the important carriers of grassland man-land interaction, been concerned by the academic community and accumulated a wealth of academic achievements because of its special form. Through reviewing related research findings in recent years, reviewing, it mainly focuses on three aspects: (1) nomadic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1305713073

settlement and its related Noumenon Research: study on the Ecological View, Environmental behavior of Nomadic settlement; (Cui, 2002; Chen, 2017), Archaeological Observation of Prehistoric Nomadic Industry of the Western Tianshan Mountains in Xinjiang (Jia, 2018), Climate change and the local environment affected human activities in Heihe River basin (Shi et al., 2019), the characteristics of temporal and spatial, and its formation Mechanism (Meng, 2017), focus on recently implemented projects in the sequence of sedentarisation programs, the so-called Nomadic settlement (Ptackova, 2011); (2) Diversification of research perspectives: the study of the historical evolution of nomadic settlements on archaeological perspective, the tourism resources development such as tourism management and other nomadic settlements (Han, 2013; Li and Yu, 2019), The production and lifestyle after settlement under cultural anthropology (Doumani et al., 2015), the change and evolution mechanism of national belief, etc. (Felr, 1994); (3) Study on Nested Scale of Nomadic Social Organizations: Grassland ecological restoration based on regional scale, regional mountain nomadic villages, etc. (Honeychurch, 2014; Chen, 2014), The Economy and Politics of Mountain Nomadism. Based on the above analysis, the research results of the nomadic spatio-temporal picture from the perspective of the ecological wisdoms are relatively few. The authors draw lessons from the research results of spatio-temporal behaviour of production and life in human geography and time geography. Taking Qiongkushitai village as an example, this paper makes a case study of Kazakh Alpine Nomadic Settlements in the Turks River Basin of Yili Prefecture and explores the ecological wisdom commonly found in traditional nomadic behaviour.

Based on a long-term field survey in the alpine pastoral areas of Yili Prefecture, Xinjiang, China, this paper explores the temporal and spatial characteristics of production, life and ecology of Kazakh herdsmen, who are the main body of traditional Alpine nomadic settlements. This paper attempts to explore the practical significance, cultural connotation, and the relationship between Kazakh traditional survival prospect and grassland ecology from the perspective of evolution mechanism driven by national policy, individual needs, technology, and market. The author hopes that other scholars will further explore the traditional nomadic society transformation period, herdsmen's modern living needs, and balance between human and natural ecology in pastoral areas, and provide some reference for the resilience building in the construction of ecological civilisations in pastoral areas in Western China.

Materials and Methods

In the process of rapid urbanisation, we should reflect on the practical value of ecological culture construction in traditional local wisdom. Each region is a local national badge (Crown, 2005). Ecological wisdom is one of the best symbols of regional cultural identification. Ecological wisdom is a stable structure and type inherited by a fixed group or region in the process of continuous reconstruction. It has the characteristics of self-discipline, local creation with the help of foreign knowledge, technology, formulation, and so on. The traditional Kazakh nomadic production, living in the exchange of material and energy with a grassland ecosystem, can achieve efficient coordination between resource utilisation and environmental conservation. Nomadic production is not only the result of adapting to nature but also the means of protecting nature to ensure the balanced utilisation of grassland and avoid the risk of natural disasters for herdsmen. The compensatory grassland ecological cycle mechanism, such as the roof-covering grassland model, compensation base ecological

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1305713073

mechanism, moderate migration and nomadism, is rooted in the ecological view and environmental behaviour in nomadic activities, which condenses their ecological wisdom to live with the grassland (Chen, 2019). Ecological wisdom in traditional nomadic society is formed in the process of production, life and spiritual belief. It is also a multi-dimensional cultural heritage and landscape type for post-nomadic society. Therefore, the protection and development of cultural memory and cultural sites in post-nomadic settlements have important theoretical and practical significance.

Constraint and adaptability of nomadic landscape

The spatial and temporal characteristics of alpine grassland are important factors for restricting and encouraging nomads' access to resources (energy or information) and the way of using them regionally. Spatio-temporal differences are the response of human beings to the optimal use of time, which is believed to eventually lead to the growth of reproduction. In the new Darwinian theory, "adaptation"should be attributed to "moderate exchange" of energy (Torrens et al., 2010), information and technology or "Spatio-temporal threshold mechanism" (Meng, 2017). Time in the nomadic society is like an invisible bond, through the nomadic production and life of different time scales, through the visible and invisible space mapping and connected in the same system, namely, the nomadic grassland system. High-quality grassland resources appear seasonally in nomadic alpine settlements, so the survival strategy of effective utilisation of time is determined by the limited time of obtaining resources, and the time segment or seasonal length of each year. In the one-year periodic-cycle of nomadism, the core variables, such as the duration of effective utilisation of resources, the seasonal differences in the spatial and temporal distribution of available resources, the concentration and dispersion of resources, etc. The seasonal transition of nomadic production must be carefully planned and organised to reflect the adaptability to space-time constraints.

Spatio-temporal trajectory, space-time picture

Spatio-temporal trajectory is the record sequence of the position and time of a moving object. As an important data type and information source (Yang, 2004; Gong et al., 2017) of spatio-temporal mapping, the spatio-temporal trajectory is the spatial appearance after different time overlaps in order in space. The spatial and temporal trajectory of grassland nomadism records Kazakh nomad stability, periodicity, regularity, the flexibility of nomadic behaviour, traffic logistics, and other information. The similarity and differences in characteristics of nomadic spatio-temporal trajectory data (nomadic time, linear space, behaviour node) were extracted under the typical space-time dimension, and the local ecological order in traditional nomadic behaviour was revealed. The recognition of typical regional characteristics was first reflected through a space and time picture.

The space and time picture is composed of recessive and explicit spatio-temporal order, behavioural pattern, materialised structure. The space-time picture is the sum of the material cultural landscape and the non-material cultural landscape formed under the same cultural or multi-cultural background. It is constructed by strong recognition symbols and is recognised and inherited. Local wisdom is transmitted to future generations through a concrete or visual form, and can also be regarded as the superposition and reproduction of spatio-temporal images through different historical periods.

Materials

The typical Nomadic Settlements in the Turks River Basin of Yili Prefecture in Xinjiang, China (*Figure 1*), were selected as the research subjects. The research area is located in western Xinjiang, and there are a large number of traditional nomadic settlements in the high mountain areas. The region has features of typical landforms: undulating mountains, river streams with vertical and horizontal water sources, open and flat terrace grasslands, and other features to provide a natural place for nomadic activities. The Qiongkushitai village is located in southern Tianshan on the western part of the Tianshan Mountains. Two sides around the Wusun mountain, the two sides of the peak mountain stretch, adjacent barriers. The region has a long history of nomads, it is rich in cultural relics, less affected by the urbanisation process, and the traditional nomadic production behaviour remains relatively intact.

Figure 1. *Sample Research Location Map . Drawn by author according to the official map of Xinjiang, China*

Historical evolution and general situation of Qiongkushitai Village

(1) Location factors of nomadic settlements. The Qiongkushitai Village is located in the town of Karadara, Tex County, Yili Kazakh Autonomous Prefecture (locally known as “Five townships”), 90 km from the town government. It is a typical traditional pastoral village. The village’s nomadic settlements are located within about 20 km of the Qiongkushitai River. Its territory is endowed with unique nomadic conditions: wide and flat terrain, warm climate, broad grassland, and suitable for farming and grazing.The village of Qiongkushitai has been a nomadic land for many ethnic groups since ancient times. Since the Western Han Dynasty, Wusun Ancient Road has been an important passageway connecting the north and south of Tianshan Mountains. A flat plateau between two streams provided a good place for business tours to stop here, hoard materials, and convert materials. It makes it possible to get together with the road.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1305713073

(2) Livelihood elements of nomadic settlements. The total area of the village is 136 km², of which the total area of pastures is 84.7 km², of which 18.0 km² is winter pastures, 27.9 km² is summer pastures, 31.6 km² is spring pastures, and 7.2 km² is clipping pastures. There is a total of 303 households with a total population of 1737. At present, animal husbandry and tourism are dominated by 967 people engaged in animal husbandry and 770 part-time workers in the tourism service industry, accounting for 44.3% of the total population. The development and utilisation of tourism resources in famous historical and cultural villages at the national level have promoted a major adjustment of the economic structure of traditional animal husbandry in this village. At the same time, the living standard of herdsmen has greatly improved, with the average annual income of herdsmen reaching 12,700 Yuan (Economic Income Statistics of Qionkushitai Village, 2017), which is currently higher than that of other pastoral villages in the same region. The development of tourism resources in pastoral areas has become a hot pursuit in the past five years. Traditional nomadic settlement resources have become scarce and precious. Local cultural heritages in the nomadic landscape of Qiongkushitai village, such as log settlements, inhabited grasslands, Wusun Pastoral Road, and the three revolutionary historical sites, reflect the evolution of nomadic cultural landscape and the results of local wisdom in the process of development (*Figure 2*).

Research method

The main methods used in this study are historical literature analysis, and settlement landscape theory and method. Based on the field survey data of alpine pastoral areas and data such as Xinjiang Urban-Rural Construction Yearbook, Yili Pastoral Area Industry Long-term Development Planning Platform, Xinjiang Pastoral Area Urban-Rural Development Planning Implementation Guidelines. This study aimed at qualitative interviews with local nomads in a one-year nomadic cycle to obtain field data.The author analysed the space-time trajectory, internal characteristics, external expression and inheritance characteristics of nomadic cultural landscapes. The development of alpine nomadic settlements is a dynamic process. It is necessary to evaluate the regional characteristics and social structure in geography. The characteristics of nomadic cultural landscapes are identified and summarised by using ecological geography and economic research methods.

Results

Typical characteristics of traditional nomadic space-time landscape

The characteristics of nomadic production and life, such as social unit self-organisation, individual adaptability, time order, and nomadic spatial hierarchy , are the main factors that drive the dynamic space-time picture of nomadic life. Time factors, space factors, and social organisation factors determine the behaviour of the individual nomadic family as a unit and is restricted by nomadic ability (technical conditions, family labour force). The grass-roots organisation “Awule” provides the restriction effect and comprehensive guarantee of social authority, and optimises the combination of nomadic production activities of individual families and the conversion behaviour under the restriction of grassland resources under different seasonal elevation gradients. In the space-time, a social organisation unit shows a multi-layer nested human landscape picture.

Adaptability of nomadic space-time picture under the restriction of resources

Mixed model of migration and fixed residence in nomadic space-time scene. The traditional nomadic settlement form is the minimum spatial scale and unit for nomads to engage in group production and life, and it is also the iconic element of nomadic space-time picture. The pasture and settlements show two spatial patterns of aggregation and dispersion in the nomadic complex space.The other is that pastures and residential space are very close. The main factors of the seasonal and elevation differences in the distribution of grassland resources, determine the aggregation and fragmentation of the spatial form of settlements. In the nomadic cycle of one year, the living space has obvious vertical zonality. The spatial characteristics of settlements reflect the interaction between human activities and the natural environment in the process of nomadic migration from the micro-scale. The living characteristics of QiongkuShitai Village are typical in the alpine pastoral areas of northern Xinjiang. The second-order flat area of the valley between the Wusun Ancient Road and the Qiongkushitai River is the first choice for the settlement. Its overall form is banded, local concentration, the courtyard is patchy, the building along the river and contour parallel to the horizontal expansion, but also perpendicular to the longitudinal continuation of the contour. The scattered distribution of residential groups corresponds with the characteristics of nomadic production.

Mobile residence under the adaptation of livelihood resources. In the process of periodic nomadic space-time picture, there are complete identifiable or identifiable nodes in nomadic adjacent time-space, and the residential space changes with the behaviour of the nomadic stage, which is the most typical. For example, when spring and autumn pastures migrate to winter pastures, the form of residence changes from “Haita” (temporary portable type of residential space) to “winter nest” (winter residence), and summer pastures-assembled felt houses for spring and autumn pastures. Portable features are suitable for long-distance transitional residences. Based on the period and frequency of building use, construction type and the degree of expenditure, residential forms can be divided into permanent type, stage type, and transition type.

The first choice of settlement location and the hierarchical selection mode of secondary dependency. Based on the analysis of the settlement layout and the shape of Qiongkushitai village, the relationship between settlement, grassland, and water source, the hierarchical selection model of nomadic settlement environment selection was put forward, which exists the first choice and the secondary dependency. The preferred land is usually flat valley, leeward, and riverside for water needs, especially in spring and autumn pastures, the attachment of water resources is stronger than summer pastures. Because of the high spatial distribution density of water resources in summer pastures and the short rainfall cycle in mountain areas, settlements are not necessarily built near the river, and usually have convenient commuting distance, which is also closely related to the quality of grassland resources.

Linear spatio-temporal presentation of nomadic spatio-temporal trajectory: transition track and pastoral space

Periodic transition is one of the core elements of the nomadic landscape, and it is also one of the symbols that nomadic space-time picture is strongly recognised. The track of nomadic space is jointly determined by three factors: the specific logic of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1305713073

spatial and temporal allocation of nomadic subjects and resources, the coherent time order, and the flexible nomadic behaviour.

(1) Stable and dynamic characteristics of nomadic spatio-temporal trajectory. The transitional pastoral path is the product of the nomadic spatio-temporal track. The migratory transition behaviour and the individual family each have the zonation and verticality of the spatial distribution of grassland resources, which determines the dynamics and stability of the nomadic spatio-temporal trajectory in which the nomadic herdsmen complete the periodic migration. Dynamics refers to a local strategy for nomads to deal with natural disasters in a short period of time. Stability refers to the maintenance of long-term effectiveness of high-quality grassland resources and the long-term stability of the selected and optimised linear space. The village of Qiongkushitai belongs to the alpine transition settlement, and the herdsmen have a certain time, order and route, so they have formed a transitional pastoral road with spatio-temporal order (Huang, 2013). Qiongkushitai pastoral road and the linear spatial scale is 110 km≤150 km. The characteristics of long transition route and strong stability; River valley meadow, Zhongshan grassland and alpine grassland are distributed at an average altitude of 1020 m≤2680 m. The long-span characteristics of grassland resources at elevation determine the dynamics of nomadic trajectory (*Figure 3*).

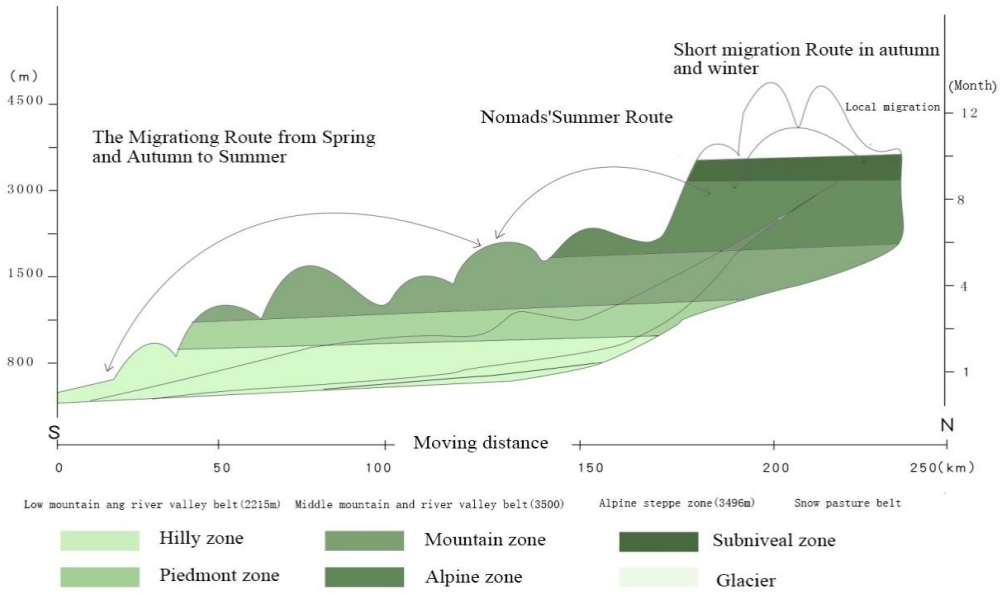

Figure 3. *The temporal and spatial trajectories of migration in the one year period of Nomadic settlement. Author redraws according to the illustration of "Transition and Modernity of Nomadic Society: Mountain Volume" (Center for Rural Environmentsocial studies, 2015)*

(2) Long-term "life path" and short-term "daily path" of nomadic spatio-temporal track.The construction of a nomadic path over long period is the representation of nomadic ecological strategy in time-space coordinates. The long-term migration strategy of alpine nomads has opened up a long-term "Life path" for their seasonal migration to summer pastures. It embodies the ecological values of the sustainable development of nomadic behaviour and ensures the possibility of the existence of nomadic picture for a long time.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1305713073

To a large extent, nomadic individuals can flexibly adjust their nomadic behaviour and make strategic decisions on the basis of following their natural laws, which is specifically reflected in the dynamic characteristics of the“daily path”in a short period of time. The nomadic "daily path" with one year as the cycle, constitutes a long period of “life path” of nomadic production in alpine grasslands. The short period of "daily path" is the basic element of the inheritance of grassland production mode, which ensures the continuation of the long period of "life path". The short-term “daily path” promotes the existence of the long-term “life path”of nomadic activities. Each type of nomadic behaviour can find its place on the timeline of the "daily path" for a short period of time, and the nomadic activity per unit time presents a typical spatial or behavioural reflection on the “fragment order” (*Table 1*).The short-term nomadic track depicts the seasonal movement trends of nomads in the daily periods, such as the change of space place in spring, summer, autumn, and winter, the change of living space, and daily nomadic behaviour such as lambing, fattening, grabbing, captivity, stocking.

Table 1. *Space-time order of “daily track” in a short period. Self drawn by author*

Time order / Spatial order	1	2	3	4	5	6	7	8	9	10	11	12

Everyday behaviour Node	Lambing Captivity.		Preliminary Transfer, Disease		Build houses, Catch fat, Shear wool, Repair horseshoe, etc.			Transition period Dismantling, Rransportation, etc.			Lambing Captivity	

Multi-level nesting law of nomadic space-time picture

Nomadic production and life are subject to regional resource conditions (the types of grassland resources and their advantages and disadvantages are distributed in time and space). The self-characteristics of nomadic production and life (the family is the unit + the group mutual aid mode of work) and other factors determine that the nomadic space-time picture shows the law of nesting at different levels. It is embodied in the nesting of the local order of the social unit and the nesting of the multi-level “centre-periphery” on the spatio-temporal scale of the relationship between man and land.

Local order nesting of social units: the organic combination of individual family and “awule” organization. “Local order nesting of activities” emphasises the relationship between human activities and the allocation of space-time resources needed for their

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1305713073

occurrence, implying the temporal arrangement and spatial combination of the resources needed behind human behaviour. Drawing lessons from its achievements, the interpretation of the grass-roots organisational order of nomadic society is helpful to explore the wisdom of building resilience in the construction of nomadic ecological civilisations. The grass-roots organisation of "Awule" is the builder of the grass-roots order in the traditional nomadic society. The stability of grass-roots social organisations depends on the ownership of the means of production, so each basic nomadic unit has its own territory, tribes have their own transfer routes, and customary law has a strong binding effect on life and production, to ensure the order of social organisations on a large scale.

The relationship between the nomadic family unit and "Awule" organisational behaviour is often inclusive and restricted. A series of activities of nomadic families aim at achieving individual goals: survival and nomadic activities are necessary to maintain survival on an individual scale. The goal of "Awule" organisational behaviour to maintain the basic order of nomadic society is to continue the fundamental activities of the existence and inheritance of such organisations and solidified into a symbolic organisational model. Nomadic individuals and organisations depend on each other and are reflected in the combination of nomadic behaviours. The nomadic space-time picture carries the activities of family, society, and nature. The temporal and spatial allocation of grassland resources and space is relatively regular in nomadic behaviour. It profoundly depicts the ecological process of the utilisation of regional resources by nomadic subjects under the influence of internal order.

Multi-level "center-sub-core-boundary" nested model of man-earth relationship on the spatio-temporal scale. The traditional settlement is not only the material support of human survival, but also the symbol of living space. The location of settlement integrates the basic elements of human survival mode and environmental choice (Han, 2008). Under the alpine nomadic production and lifestyle, the settlement environment follows the upward order of the vertical space of alpine grassland,medium alpine grassland, valley grassland, secondary grassland, and the diffusion law of successive circles in horizontal space. Nested model shows the relationship between human and land in Alpine nomadic ecological environment. This paper summarises the basic model of traditional man-land relationship in nomadic alpine settlements: horizontal multi-layer spatial nesting, and vertical upward "centre-sub-core-boundary" nesting model with grass migration. Through the settlement environment selection of Qiongkushitai village, the human-land relationship of nomads in the small watershed of Qiongkushitai River is re-examined. The multi-layer spatio-temporal nesting model of nomadic circle is a dynamic model which is used to deal with the complex nomadic ecosystem in balance and sustainability. For example, the location relationship between a family's multiple places of residence and grassland determines the man-land relationship model of settlement location.

Discussion

Conflict and Integration: the evolution of traditional nomadic space-time picture

The nomadic space-time picture is rooted in the space-time accumulation of specific natural conditions and human activities. It is reproduced through a series of time and space chain continuity such as a series of forms and activities in a specific alpine grassland space. Nomadic resources determine the type of production and mode of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1305713073

production, while the nomadic mode of production determines the way of life and social organisation of nomads; lifestyle and social organisation form condense into grassland culture and art. The spatial layout of traditional nomadic production and life and the timing arrangement of production and life are deeply affected by industrial economic structure, family type, and technological innovation. When the traditional material space disappears (or the function is replaced), the nomadic picture may be presented in another way: the appearance of exhibition, fragmentation, and symbolization, then the grassland nomadic picture loses the vitality of expression and the path of inheritance.

The drive of national policy of settlement and pastoral settlement

Spatial compression and linear fracture of traditional nomadic spatio-temporal trajectory.

Functional displacement of the pastoral resources. "For nomadic animal husbandry, the key factor in its development lies not in possession of grassland, but more in the right of migration, only in the process of migration with the sun" (Han, 2003). Stable and continuous transition is the most essential feature of nomadic culture. When grassland resources are replaced by conversion paths are separated, conflicts between pastoral roads and modern roads overlap, nomadic production becomes settled captivity. As a result, the seasonal and spatial continuity of grassland nomadic space-time track is broken, the nomadic chain is fragmented, and the traditional nomadic picture shows fragmentation. The spatial evolution and utilisation pursuit of the production behaviour of the micro-subject is the main internal driving force for the emergence of the above situation.

Under the background of rapid urbanization, the traditional nomadic space is compressed, the nomadic trajectory is discontinuous. There are problems in the process of redistribution and use of grassland resources. Breaking the traditional model of resource allocation, the traditional model of life and production has been gradually dispelled, and the living form has moved to a fixed-point residence with the adjustment of production structure. The grassland boundary is fenced, the grassland resource type is single, the grassland space radius becomes smaller, and the controllable transition path is shortened. The people and cycles who undertake the transition are compressed (domestic work is replaced by employment, mechanised transfer, shortening the transition period), the surplus labour force begins to shift to other livelihoods, and grassland resources no longer carry the current multi-level demand. Captive cultivation, the replacement of resources in different places, and animal husbandry production have broken the barriers to the distribution of spatial resources, cross-regional grassland artificial planting and anti-ecological farmland grass which is one of the ways to solve forage resources.

Individual needs drive the elimination of local intelligence system in traditional pastoral society

The settlement of nomads is a profound process of social and cultural change. The settlement of nomads is a process of re-socialisation which differs greatly from their traditional social culture. Nomads will face, and inevitably experience, the problem of re-socialisation in the process of settlement. The traditional form of "Awule" and "family unit co-production", which exists in nomadic social organisations, has been replaced by "individual family type, modern employment production". Standardisation

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1305713073

and accuracy of time cost. The mechanised, long-distance, cross-regional fragmented transfer behaviour model promotes the local wisdom spread in the traditional transition field to be concentrated and dispelled, and the compression of time and space promotes the acceleration of the rhythm of time and the overcoming of the hindrance of time to space caused by it. The temporal and spatial constraints and incentives of nomadic daily life trajectory have been reduced. In order to better control the time cost, animal husbandry production promotes the standardisation of time cost: the quantification and accuracy of time in the nomadic process, but with the change of phenology, the time cost is controlled within a certain range. The precision of the cost of production and living commute is reflected in the evolution of residence: from a nomadic lifestyle to settlement, felt house, semi-settlement wooden house, settlement log building, mobile residence mode and semi-settlement residence that changes with the season, the ownership of grassland changes, evolution from mobile and semi-settled to permanent residence. In order to meet the current needs of life, herdsmen build so-called high-end living environments, but it destroys the balance of the grassland water system, vegetation, and biology. The grasslands with slopes were filled with raw soil foundations, and modern buildings were built on them. These buildings are incompatible with the original grassland environment (*Figure 4*).

Figure 4. *Driven by information, technology, and materials, it is possible to expand the living space. Photographed by author*

Qiongkushitai's settlement began construction in 2012. It was originally a traditional settlement and reserved feed land in the spring and winter seasons of the pastoral village. The scale of the settlement is larger than that in other areas. Apart from the first and second group of displaced herdsmen, some land (originally pasture) for other later settled herdsmen has been reserved. There are 87 settled herdsmen. The land composition of settlements is composed of public grassland and pasture of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1305713073

herdsmen. In order to apply for settlements, the herdsmen need to take out three acre of land use rights to solve the land problem occupied by settlements. The settlement is facing the river, has convenient transportation, relatively open terrain, and good natural scenery. The water construction of the settlement is one of the projects of combining agriculture and animal husbandry, and developing pastoralists by settling down. The government hopes to develop tourism resources to solve the livelihood problems of some pastoralists after settling down. At present, it has attracted local herdsmen and some people from surrounding counties to settle and run tourism. In early 2017, the settler, Karze, transferred 56 acres of summer pasture and 15 acres of reserve pasture from his home. There is a steady income every year. At the same time, a Herdsman's Folk Tourist Inn has been built in the original settlements (not planned into the new settlements). Kalze has three children; two younger sons are in high school in Turks County. He and his daughter usually run their own camps together, and they are relatively wealthy. In the new settlement, Kalze has its own housing (herdsmen put out 60,000 yuan of construction funds, local government provides planning and other supporting facilities for the construction). When applying for settlement, the property rights of the housing belong to herdsmen, but no real estate certificate has been issued yet. For example, to protect herdsmen and social stability, settlements cannot be rented and sold out in principle, but there will be individual herdsmen to rent settlements to other people. The settled herdsmen have adapted to the present life, and the family economic structure has increased the additional income of the tertiary industry (pastoral transportation, tourism services, special breeding.) from the original pure income of animal husbandry production.

As a typical case, Qiongkushitai village is demonstrated in this area. Under the advocacy of governments at all levels, nomadic villages with tourism resources and convenient transportation conditions have begun a new round of “symbolic economy” rising, which repeats the upsurge of the urban symbolic economy. As famous villages and towns of history and culture, and as the main body of official protection law, their names will attract a large number of tourists. With the improvement of other factors, nomadic cultural resources, as an economic resource, enhance the income of local residents and also become a sign of local cultural tourism. The rise of symbolic economy is due to two reasons: one is the economic decline within the city relative to the suburbs. Cultural symbols play an important role in the process of the revival of the urban centre area. The other reason is the expansion of the investment field, and culture has become a new investment field. It has become a scarce resource for internal demand and external pursuit of dividends. Through the investigation of production and life in Qiongkushitai Village, it is concluded that the mode of production has changed after settlement.The traditional local wisdom heritage, agglomeration and decomposition, and the new life and production mode have become popular in pastoral areas (*Figure 5*).

Conflict and fusion: dynamic adjustment of nomadic picture induced by new technology

Technological change is a traditional factor of production for the sustainable and rapid development of settlements. Through the author's field investigation in the Tex River Basin, it is found that the application and popularisation of the new technology in the traditional pastoral areas is the main driving factor for the renewal or integration

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1305713073

of the traditional nomadic space-time picture, and it is also the inevitable result of social development. Extract t Three types of typical case descriptions:

(1) The innovation of production tools. The changes of transit vehicles: traditional horses, camels, flat cars vs horses and motor vehicles; innovation of weeding tools: traditional long handle sickle vs weeding mechanisation;

(2) Innovations of living facilities. The change of communication tools: horseback riding to transmit information vs modern mobile communication tools. The location of water resources and access to the reduced constraints: water-by-water living vs now long-distance across the space-time construction of water facilities. Comprehensive strategies to deal with disasters: local wisdom word of mouth vs rapid emergency system, mechanised long-distance commuting support.

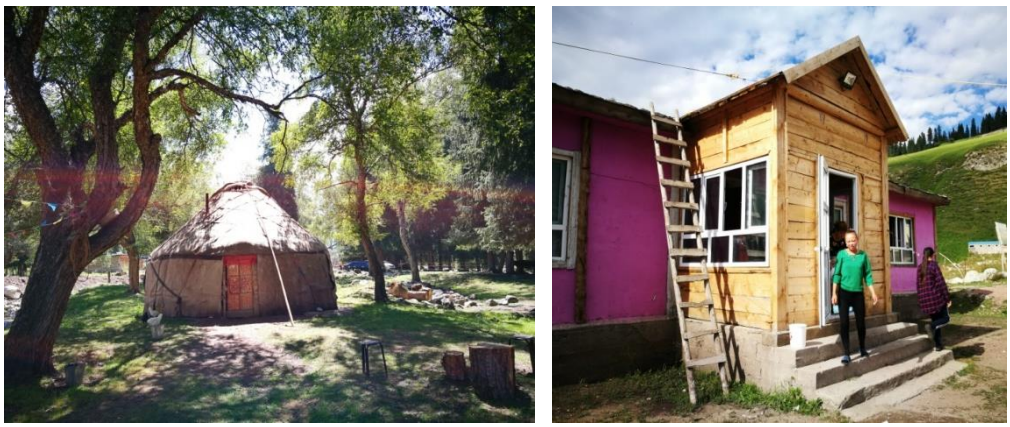

Figure 5. *Forms of Residence before and after Settlement. Photographed by author*

(3) Technology and Market Drive. Adjustment of nomadic landscape in the post-industrial era dynamic adjustment of nomadic space-time picture (cultural landscape). When the frequency of new technological innovation is accelerated, and the popularisation of application is high, the process of material production reflects the compression of space-time picture and the rapid change of spatio-temporal feeling. For example, the multi-level coverage of vehicles and roads has made it possible to explore potential sites for the spatial expansion of nomadic production. At that time, the boundary of space was broken through, and the cost of time was reduced to the lowest in geography and space. The acceleration of capital flow and exchange speed reconstructed the spatial picture of nomadic production and consumption. Post-modernist grassland nomadic cultural landscape, time and space experience is the result of the combination of various social resources. The traditional nomadic time and space picture has three possibilities: collage, reconstruction, and disintegration. Driven by external and internal forces, it has completely broken the rank, stability, and continuity of traditional time and nomadic space, and only the fragmentation of sporadic temporal and spatial characteristics has been retained and reconstructed in a single way. The segmented nomadic space-time picture is used as a display label and developed as a selling point (Harvey, 2003). The cultural tourism brand promotes the experience of this nomadic cultural landscape of a pastoral village by saying: return to the most primitive nomadic settlement: experience nomadic slow life here. It is not a real experience of grassland nomadic time and space, but an illusory experience

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1305713073

created by the collusion of capital and media to satisfy the strange experiences of tourists. We should understand the unique cultural landscape characteristics contained in different agricultural and cultural heritage and provide method support for the rational utilisation and protection of important agricultural, and cultural heritage in our country (Hu et al., 2018).

Conclusion

Based on the case study of Nomadic Settlements in the Turks River Basin, this paper puts forward two characteristics in the space-time landscape of nomadic alpine settlements: (1) the adaptability of nomadic space and time landscapes under the constraints of alpine grassland resources, and (2) multi-level nesting rule of nomadic space-time landscape. Nomads are passively adapted to regional resources in the process of nomadic production and life. However, the nomadic subjects dynamically adjust their nomadic behaviour according to their own conditions (population, technology, grassland resources), and form a multi-layer organic combination of mutual social organisations, periodic stability of nomadic space and time landscape, living scale and multi-point migration of space.

Driven by national policy, individual demand, technology, and market guidance, nomadic settlements in the process of urbanisation are out of order in production and life of traditional nomadic society, and their ecological carrying capacity is weakened due to the combined effects of external and internal forces such as policy implementation, modern technology, and market guidance. The short-term “daily path” of nomadic production and life characteristics will be decomposed or split, the long-term “life path” will disappear or be replaced by another form, and the “modern" nomadic landscape will be reconstructed. The reconstructed nomadic landscape is embodied in two aspects: (1) nomadic economy under the change of economic structure is no longer the core of family income. Herdsmen need to manage other economic types on the basis of traditional nomadic production to meet the needs of grassland resources, ecological deterioration, and improvement of living standards. For example, they are engaged in settled agricultural production, tourism, and non-agricultural production in cities, and (2) technology and market incentives, traditional natural nomadism to fixed-point non-organic pasture change. The practice of fixed-point industrialised captive farming production mode in traditional alpine pastoral areas has reduced the frequency and distance of transfer, weakened the constraints of grassland space-time resource allocation, weakened the original intimate relationship between nomads and livestock, water and grass, and gradually diluted or replaced the traditional alpine nomadic culture.

This article serves as a starting point for further research concerning the development and change of lifestyle for the nomads after settlement life and fixed grazing production. We should select samples with universality to ensure the validity of the universality of the research results. Due to the highly dispersed spatial pattern of nomadic alpine settlements and the constraints of researchers' energy and academic levels, it is hoped that comparative studies can be carried out in the latter part of the study to select sufficient samples within the geographical units of small watersheds to make up for the deficiencies in this study. Suggestions for future research would be to pay attention to the integration and adjustment of the old and new nomadic scenery in nomadic alpine settlements, retain the essence of the traditional, nomadic, and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1305713073

humanistic landscape or the reconstruction of the new cultural landscape of the main components to meet the needs of the new era. The assessment of regional ecological environment carrying capacity of nomadic settlements should be paid attention to by scholars, and the research on the coordinated development of nomadic livelihood needs and ecological protection should be deepened to explore the theoretical and practical path suitable for the protection and development of traditional nomadic settlements.

Abstract. The invasive nature of *Eichhornia crassipes, Pistia stratiotes*, and *Nymphaea lotus* is worrisome because they tend to dominate the economic and ecological region of the aquatic environment, hence the need for their eco-friendly utilization. This research is aimed at assessing the efficacy of *Eichhornia crassipes, Pistia stratiotes* and *Nymphaea lotus* as a low-cost absorbent for the biosorption of Nickel (Ni^{2+}) from refinery wastewater. Refinery wastewater was collected from the effluent point of Kaduna Refining and Petrochemical Company (KRPC). The selected macrophytes were characterized using Fourier transform infrared (FTIR) spectroscopy. Biosorption of Ni^{2+} from the wastewater and aqueous Ni^{2+} solution was performed under factors such as contact time, particle size, absorbent dosage, pH and Ni^{2+} concentration. The Langmuir equation and Freundlich isothermal were used in determining absorption equilibrium while pseudo-first and pseudo-second-order were used to determined adsorption kinetics. The result obtained shows that Ni^{2+} absorption by the selected macrophytes is greatly influenced by contact time, particle size, absorbent dosage, pH and Ni^{2+} concentration with high efficiency recorded in the removal of Ni^{2+} from refinery wastewater. Both Langmuir equation and Freundlich isothermal gives a nearly perfect fitting for adsorption of Ni^{2+} for all the selected macrophytes signifying favorable Ni^{2+} absorption. Pseudo-second-order kinetic model gives nearly perfect fitting than the pseudo second-order kinetic model signifying that adsorption of Ni^{2+} by the selected macrophytes is due to the physical and chemical reaction. The selected macrophyte can be effectively utilized as low-cost biosorbents for the removal of Ni^{2+} from Refinery wastewater.
Keywords: *Langmuir equation, adsorption kinetics, macrophytes, heavy metals, invasive species*

Introduction

Aquatic macrophytes are plants that can survive in or around water bodies (Osti et al., 2018). They are classified into four major groups namely emergent macrophyte, floating leaves macrophyte, submerged macrophyte and free-floating macrophyte (Bordoloi et al., 2015; Galal and Farahat, 2015; Pulzatto et al., 2018). The ability of *Eichhornia crassipes, Pistia stratiotes* and *Nymphaea lotus* to overtop ecological and economic zones of aquatic ecosystem is alarming due to the negative impact it causes on economic yield, human health and aquatic organisms (Lamb et al., 2016). These macrophytes hindered the penetration and flow of sunlight due to their ability to extend over water bodies (Ugya, 2015; Ma et al., 2019).

The control of *Eichhornia crassipes, Pistia stratiote* and *Nymphaea lotus* is necessary because of the macrophytes to interfere with water flow and sunlight penetration which is detrimental to flora and fauna inhabiting the habitat (Ugya et al., 2019a). Different control method has been used against these plants in the past but

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1307513087

recent research has focused on how to utilize the benefit associated with these plants (Lareo, 1981; Chen et al., 2012; Hanks et al., 2015).

The incessant discharge of heavy metal polluted water into the environment is worrisome due to their persistence nature and ability to accumulate in the food chain (Dudgeon et al., 2006; Lintern et al., 2016; Ugya and Imam, 2017; Liu et al., 2018). The menace associated with heavy metal pollution is endemic in developing countries where industries channel wastewater into nearby water bodies either untreated or not properly treated due to their proximity to these water bodies (Ugya et al., 2015; Desrosiers et al., 2019). The wastewater produced by oil refinery industries is rich in heavy metals particularly Ni^{2+} which pose serious toxicity at low-level exposure (Hughes et al., 2015; Ugya et al., 2019b). These heavy metal have been shown by many researchers to be associated with chronic and acute toxicological effects to man and detrimental to organisms such as algae, plants, micro-organisms and other vertebrate and invertebrate animals (Costa-Boeddeker et al., 2018; Wang et al., 2018; Xun et al., 2018; Ugya et al., 2019c). It is thereby paramount to treat wastewater before discharge (Zhang and Anadon, 2013; Tong and Elimelech, 2016).

A variety of techniques are available for the treatment of wastewater before discharging into water bodies, many of which have contributed in minimizing pollution resulting from chemical industries, but biosorption is gaining acceptance owing to the fact that most researchers have revealed the potentiality of some bio sorbents to effectively remediate wastewater with high heavy metal pollutants (Nahar et al., 2018; Ugya et al., 2019d). Biosorption is a remediation technology that depends on the mechanism of heavy metal accumulation by agricultural or biological adsorbents from an aqueous solution as a result of the binding site present on this bio sorbents (He and Chen, 2014; Ileri et al., 2014; Abdic et al., 2018). *Eichhornia crassipes, Pistia stratiote*, and *Nymphaea lotus* have been utilized by researchers such as in the biosorption of Cd, Pb, Cr, etc but little or no literature exists for the biosorption of Ni^{2+} from refinery wastewater. This study is aimed at assessing the efficacy of *Eichhornia crassipes, Pistia stratiote* and *Nymphaea lotus* as a low-cost absorbent for the biosorption of Ni^{2+} from refinery wastewater.

Materials and methods

Sample collection, authentication, and preparation

Eichhornia crassipes, Pistia stratiote, and *Nymphaea lotus* were collected at three different abandon pond of proximity located at Kinkinau, Ungwar Ma'azu, Kaduna South Local Government, Kaduna State, Nigeria. The macrophytes were handpicked with the aid of hand gloves, identified using relevant guides (Gusain and Suthar, 2017; Hanafiah et al., 2018) and authenticated in the herbarium of the Department of Botany, Ahmadu Bello University Zaria, Kaduna State, Nigeria and Department of Plant Biology, Bayero University Kano, Kano State, Nigeria (*Table 1*) (Ugya et al., 2019e). The macrophytes were cut into small pieces, washed twices with borehole water and once using distilled water and were dried in sunlight for 48 h. The macrophytes were grounded using a mechanical blender (Greenis, FGR-8840) and sieved accordingly to obtain Large (60 mm) and small (30 mm) particle sizes of *Eichhornia crassipes, Pistia stratiote*, and *Nymphaea lotus*. The macrophytes powders were stored separately in an airtight container before use. Refinery wastewater sample was collected from the effluent point of Kaduna Refining and Petrochemical Company (KRPC), which is in

DOI: http://dx.doi.org/10.15666/aeer/1706_1307513087

Chikun Local Government, Kaduna State, Nigeria around latitude 10° 24' 36.18" N and longitude 7° 29' 17.37" E. The physicochemical and heavy metal characteristic of the wastewater was determined using standard method.

Table 1. *Test plants used for biosorption*

SN	Plants	Common name	Accession number
1	*Eichhornia crassipes*	Water Hyacinth	3268
2	*Pistia stratiotes*	Water Lettuce	1977
3	*Nymphaea lotus*	Water lily	BUKHAN0356

Sorbent characterization

The functional groups present in the treated and untreated *Eichhornia crassipes, Pistia stratiote* and *Nymphaea lotus* were determined using Fourier transform infrared (FTIR) spectroscopy (Rosales et al., 2016).

Effect of particle size and contact time on Ni^{2+} adsorption

The effect of contact time and particle size was determined by placing 2 g of *Eichhornia crassipes,* 0.5 g *Pistia stratiote* and 1 g *Nymphaea lotus* of two different particle sizes (30 mm (small size) and 60 mm (large size)) in separately in 250 ml containing 4.5 mg/l of Ni^{2+}. The mixture was shaken at 150 rpm using a magnetic shaker at a constant temperature of 25 °C. Each set of flasks were agitated for 20, 30, 40, 50 and 60 min, respectively (*Fig. 1*). The sample was then filtered and Ni^{2+} concentrations of the solution were determined using AAS techniques. Biosorption capacity was thus calculated using the mass balance formula below (Amer et al., 2015):

$$q = \frac{v(C_i - C_e)}{m} \quad \text{(Eq.1)}$$

where q (mg/g) is the adsorption capacity, C_i and Ce are the initial and final concentrations (mg/l) of Ni^{2+}, respectively, v (l) is the volume of aqueous and m is the weight (mass) of adsorbent (g).

Percentage removal was calculated using the formula:

$$q\%\ uptake\ = \frac{(C_0 - C_e)}{C_0} \cdot 100 \quad \text{(Eq.2)}$$

where C_0 and C_e are the initial and final concentrations (mg/l) of Ni^{2+} ions in the sample before and after shaking, respectively.

Effect of Ni^{2+} concentration on adsorption process

To 250 m/l of solution containing 10 mg/l, 20 mg/l, 30 mg/l, 40 mg/l, and 50 mg/l of Ni, 1 g of dried *Eichhornia crassipes,* 0.5 g *Pistia stratiote*, and 1 g *Nymphaea lotus* were added separately and the mixture was shaken at 150 rpm using a magnetic shaker at a temperature of 25 °C for 1 h. The sample was then filtered and Ni^{2+} concentrations of the solution were measured using AAS techniques. Ni^{2+} percentage reduction of Ni^{2+} was thus calculated using *Equation 2* (Kumar et al., 2018).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1307513087

Figure 1. *Experimental setup during culture*

Effect of pH on Ni^{2+} adsorption process

The absorption ability of the macrophytes was compared at a pH of 2, 4, 6, 7, and 8 by placing 1 g of dried *Eichhornia crassipes,* 0.5 g *Pistia stratiote* and 1 g *Nymphaea lotus* in 250 ml each of the solution of Ni^{2+} at 4.5 mg/l and shaken at 150 rpm for 1 h using a magnetic stirrer at a constant temperature of 25 °C. The samples were filtered and the Ni^{2+} concentrations of the solution were determined using AAS technique. Ni^{2+} percentage removal was calculated using *Equation 2* (Kumar et al., 2018). The pH of the solution was adjusted using 0.01 N NaOH and HNO_3 (Salim et al., 2016).

Effect of absorbent dosage

The effect of adsorbent dosage was studied by placing 1 g, 2 g, 3 g, 4 g, and 5 g each of *Eichhornia crassipes,* 1 g, 2 g, 3 g, 4 g, and 5 g each *Nymphaea lotus* and 0.2 g, 0.4 g, 0.6 g, 0.8 g and 1 g of *Pistia stratiotes* where placed in to a solution 250 ml of solution containing 4.5 mg/l of Ni^{2+} and shaken at 150 rpm using a magnetic stirrer for 1 h at a constant temperature of 25 °C. The samples were filtered and the Ni^{2+} concentrations of the solution were determined using AAS technique. Ni^{2+} Percentage removal was calculated using *Equation 2* (Kumar et al., 2018).

Adsorption equilibrium study

Adsorption equilibrium study for Ni^{2+} using *Eichhornia crassipes, Pistia stratiote* and *Nymphaea lotus* was performed by placing 1g, 2g, 3g, 4g, and 5g of *Eichhornia crassipes,* 1 g, 2 g, 3 g, 4 g, and 5 g *Nymphaea lotus* and 0.2g, 0.4g, 0.6g, 0.8g and 1g of *Pistia stratiotes* in 5 mg/l, 10 mg/l, 15 mg/l, 20 mg/l and 25mg/l of Ni^{2+} and shake at using a magnetic stirrer at 150 rpm for 24 h at a constant temperature of 25 °C. The samples were filtered and the Ni^{2+} concentrations of the solution were determined using AAS technique. Langmuir and Freundlich isotherm models were thus determined using *Equations 3* and *5* (Manikandan et al., 2016).

Langmuir equation is represented below:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1307513087

$$\frac{1}{q_x} = \frac{1}{b_i q_f} \cdot T_e + \frac{1}{q_f} \quad \text{(Eq.3)}$$

The equation above was adopted from Kumar et al. (2018), where T_e is equilibrium Ni^{2+} concentration in solution, q_f is maximum Ni^{2+} absorbed per unit weight of *Eichhornia crassipes, Pistia stratiote*, and *Nymphaea lotus*, b_i is affinity adsorbate. The value of q_f and b_i is determined from the slope and intercept. Z_l is the separation factor and is calculated using the formula below:

$$Z_l = \frac{1}{1 + b_i T_g} \quad \text{(Eq.4)}$$

where T_g is the initial concentration of Cr^{3+} and Pb^{2+} in the solution.

Freundlich Isotherm is represented below:

$$log(q_x) = log(K_f) + \frac{1}{r\ log\ T_e} \quad \text{(Eq.5)}$$

The equation was adopted from Wang et al. (2010), where K_f is *Freundlich* constant r is *Freundlich* coefficient, and K_f and r are determined by plotting a graph of q_x against T (Wang et al., 2010).

Adsorption kinetics

Adsorption kinetics is fundamental in describing the character of an absorbent. To ascertain the mechanism involved in the adsorption of Ni^{2+} by *Eichhornia crassipes, Pistia stratiote*, and *Nymphaea lotus*. Pseudo first-order and the pseudo second-order reaction was used (Ho and McKay, 1998).

The pseudo first-order is represented below:

$$log(q_i - q_t) = log\ (q_i) - \frac{K_i T}{2.303} \quad \text{(Eq.6)}$$

The pseudo second order is represented below:

$$\frac{T}{q_t} = \frac{1}{K_2 q_2} + \frac{T}{q_2} \quad \text{(Eq.7)}$$

Data treatment

Experiments were conducted in triplicate and data were analyzed statistically and presented as mean ± standard deviation as represented by error bar on figures. The Residual Sum of Squares (RSS) was determined for both adsorption kinetic and isotherm models to check error in model fittings. All analysis was done using BM SPSS statistics version 23

Results and discussion

Physicochemical and heavy metal characteristic of KRPC wastewater

The result represented in *Table 2* shows the heavy metal and physicochemical status of KRPC wastewater. Most of the parameters determine such as total suspended solid (TSS), electrical conductivity (EC) and hardness were within the permissible limit for

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1307513087

wastewater except for total dissolve solid (TDS), alkalinity and turbidity which were above the permissible limit as such indicate pollution resulting from organic and inorganic pollutants. Cu^{2+} and Ni^{2+} were within the permissible limit whereas Cd^{2+} was above the permissible limit and could pose a threat to aquatic organisms. Although, it has been reported that Ni^{2+} is an essential element needed for different biochemical and physiological pathways in biological systems, excess amount of Ni^{2+} could lead to cellular and tissue damage leading to a variety of disease. The detectable amount of Ni^{2+} in the wastewater was within the permissible limit of wastewater by WHO but this could still pose a treat to man and other aquatic organisms because of the persistence's nature of Ni^{2+} and subsequent bioaccumulation in the food chain (Tchounwou et al., 2012).

Table 2. *The physicochemical and heavy metal characteristic of KRPC wastewater*

SN	Parameter	Mean ± SD	WHO limit (2004)
1	pH	7.2 ± 0.75	6-9
2	Turbidity	15.4 ± 5.02	5
3	EC	65.5 ± 13.42	50-500
4	TDS	1219.50 ± 680.70	500
5	TSS	8.40 ± 6.40	30
6	Alkalinity	98.95 ± 43.57	50
7	Hardness	30.96 ± 17.23	500
8	Nitrate	2.07 ± 0.50	-
9	Chloride	33.28 ± 7.94	-
10	Ni^{2+}	0.54 ± 0.08	3.0
11	Cd^{2+}	0.09 ± 0.06	0.003
12	Cu^{2+}	1.77 ± 0.27	2.0

Mean ± SD are expressed in mg/l except for pH (no unit)

Characterization of biosorbent

The result obtains for the surface characterization of biosorbent using FTIR spectrum analysis (*Fig. 2*) shows that the functional group changes occur in the profile of *Eichhornia crassipes, Pistia stratiotes and Nymphaea lotus* following the absorption of Ni^{2+}. The peak at nearly 3500 cm^{-1} for untreated *Eichhornia crassipes, Pistia stratiotes, and Nymphaea lotus* represent the presence of OH^-group, this OH^-group has been stretched to Ni-OH bond in treated *Eichhornia crassipes, Pistia stratiotes, and Nymphaea lotus* as shown in *Figure 2*. The peak at nearly 1500 cm^{-1} shows the presence of CH_2 functional group in untreated *Eichhornia crassipes, Pistia stratiotes and Nymphaea lotus,* the stretching seen in the same peak for treated *Eichhornia crassipes, Pistia stratiotes and Nymphaea lotus* is attributed to the absorption of Ni^{2+}. The peak at nearly 3000 cm^{-1} for untreated *Eichhornia crassipes, Pistia stratiotes, and Nymphaea lotus* shows the presences of C-H functional group which stretches in the treated *Eichhornia crassipes, Pistia stratiotes and Nymphaea lotus* due to absorption of Ni^{2+} (Sujatha et al., 2013).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1307513087

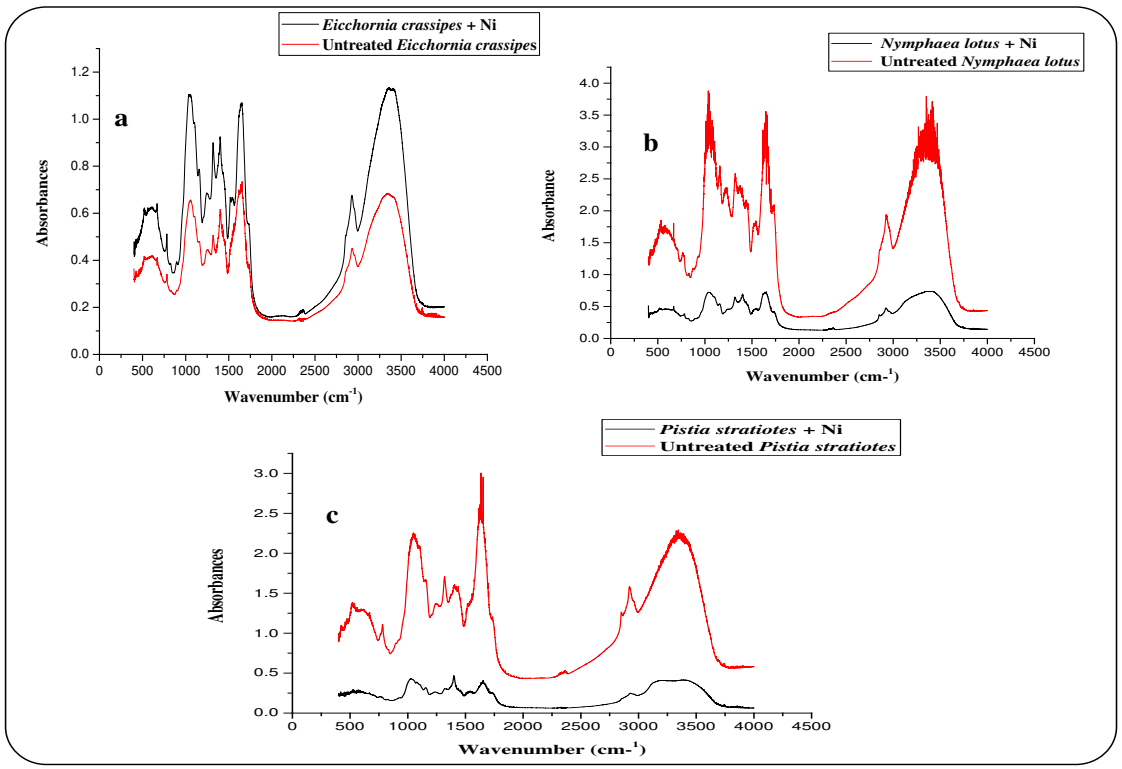

Figure 2. *FTIR of (a) Eichhornia crassipes (b) Nymphaea lotus and (c) Pistia stratiotes before and after treatment*

Effect of Ni^{2+} concentration and absorbent dosage on adsorption process

The result in *Figure 3a* shows that Ni^{2+} absorption by the macrophytes is strongly influenced by the change in Ni^{2+} concentration because significant difference exists between the absorption of Ni^{2+} by *Eichhornia crassipes, Pistia stratiotes and Nymphaea lotus* at Ni^{2+} concentration of 10 mg/l if compared to 20 mg/l, 30 mg/l, 40 mg/l, and 50 mg/l. This enhanced absorption of Ni ion at a concentration of 10 mg/l by the 3 absorbents is attributed to the fact that at the concentration of 10 mg/l the 3 absorbents have available binding sites to bind Ni^{2+} but these binding sites become saturated as metal ion increase (Feng et al., 2011). The result in *Figure 3b* shows that a significant difference exists in Ni^{2+} absorption for various dosages of *Eichhornia crassipes, Pistia stratiotes, and Nymphaea lotus.* These increasing trend of Ni^{2+} absorption with increasing dosage could be attributed to favorable pH of the solution and the fact that an increase in dosage of absorbent lead to increase of the maximum Ni^{2+} uptake due to availability of more binding site.

Effect of particle size, contact time and pH on Ni absorption

The result obtained shows higher reduction efficacy of Ni^{2+} from aqueous solution by biosorbent of larger size (60 mm) if compared to smaller sizes (30 mm) (*Fig. 4*). This significant differences could be attributed to the fact that the 60 mm biosorbent is porous as such have larger surfaces which permit increase Ni^{2+} absorption while 30 nm biosorbent is less porous as such have fewer surfaces whereas the absorption potential of a biosorbent depends on the number of surfaces of the biosorbent (Migahed et al.,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1307513087

2017). The highest reduction efficacy of Ni^{2+} was recorded at a pH of 4 (*Fig. 5a*) this result could be attributed to the fact that the solubility of Ni is at pH 4 or the binding site of *Eichhornia crassipes, Pistia stratiotes and Nymphaea lotus* were activated at pH of 4. The result obtained in (*Fig. 5b*) shows that Ni^{2+} was effectively adsorbed by *Eichhornia crassipes, Pistia stratiotes, and Nymphaea lotus* at all the contact time when exposed to refinery wastewater, this could be attributed to the fact that binding is available via out the period of adsorbent exposure to Ni^{2+}. The availability of binding site via out the period of adsorbent exposure could be due to the fact that the competition of binding sites by Ni^{2+} is minimal even though other metals such as Cd^{2+}, Pb^{2+}, Cr^{3+}, etc were presences but the concentration is too low to cause competition for binding by the co-ions present (Nor, 1994).

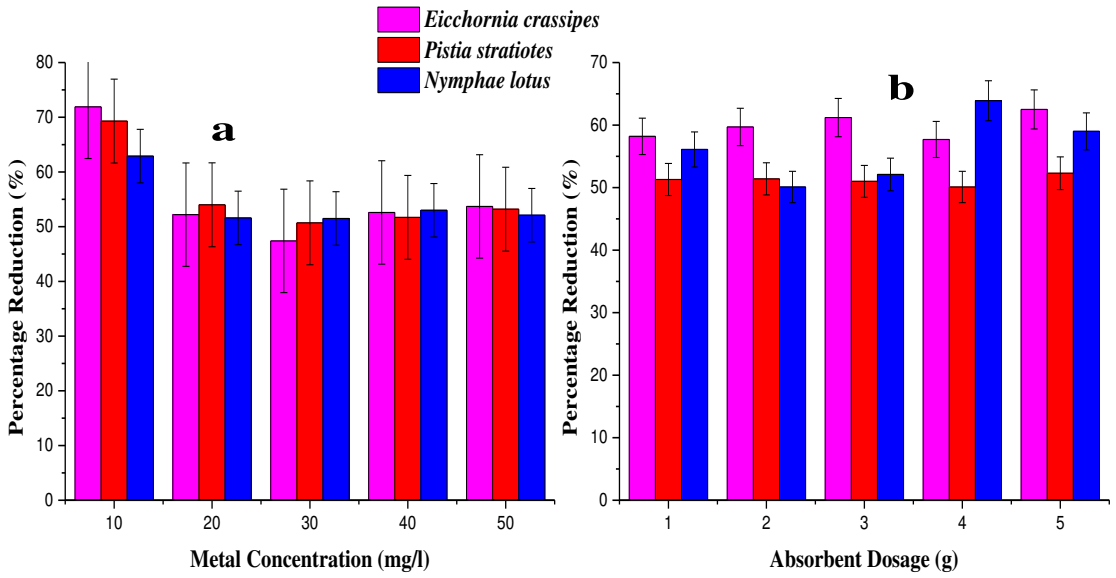

Figure 3. *Effect of absorbent dosage (a), metal concentration (b) on Ni biosorption*

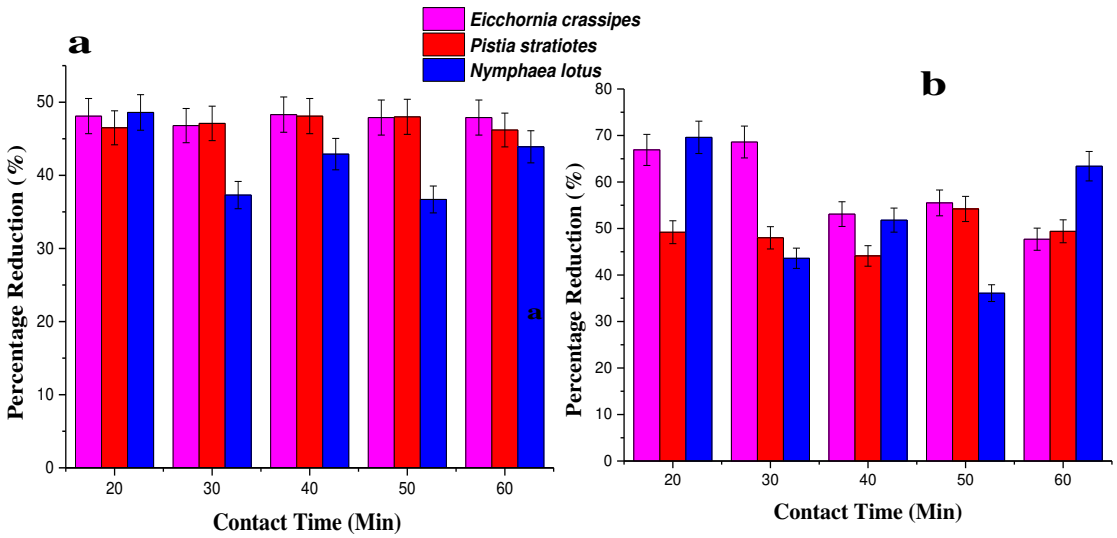

Figure 4. *Effect of contact time and particle size (a) small size (b) large size on the absorption of Ni*

DOI: http://dx.doi.org/10.15666/aeer/1706_1307513087

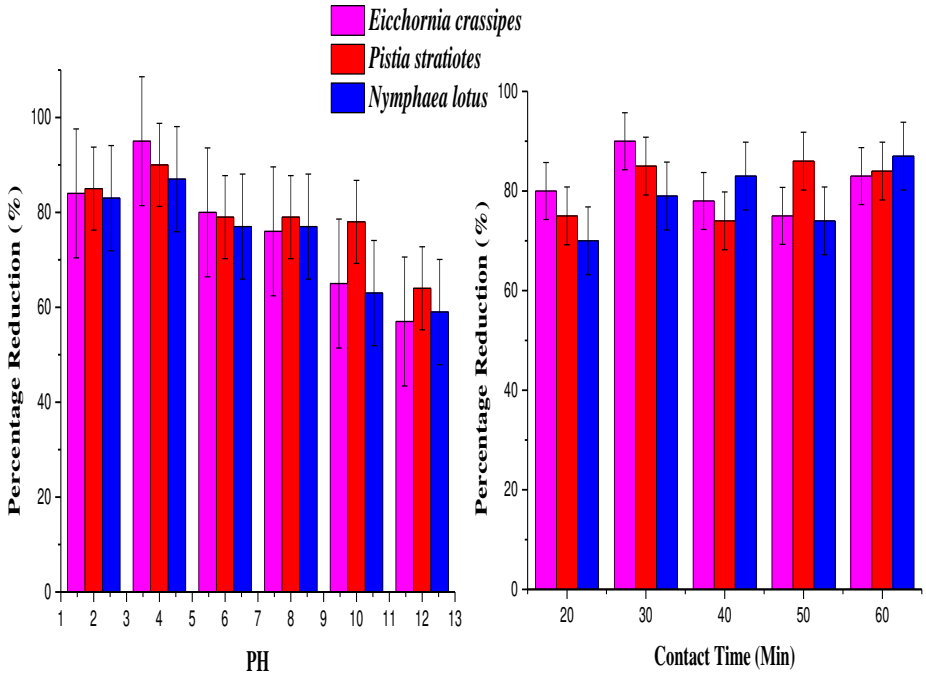

Figure 5. *(a) Effect of PH on Ni absorption from aqueous solution. (b) Effect of contact time on the Ni absorption from refinery wastewater*

Adsorption isotherms

The Langmuir model obtained gives a nearly perfect fitting for adsorption of Ni^{2+} for *Eichhornia crassipes* (0.9933) and *Pistia stratiotes* (0.9898) while poor-fitting was recorded for *Nymphaea lotus* (0.9311). Although it can be concluded that the adsorption of Ni^{2+} onto *Eichhornia crassipes, Pistia stratiotes, and Nymphaea lotus* correlated well with Langmuir equation with the relationship becoming more linear with R^2 value closer to 1 (Amer et al., 2015; Ugya et al., 2019c). The Freundlich model shows a nearly perfect fitting for absorption of Ni^{2+} for *Eichhornia crassipes* (0.9978), *Pistia stratiotes* (0.9885) and *Nymphaea lotus* (0.9753) with a high n value of (3.1) *Eichhornia crassipes*, (2.7) *Pistia stratiotes* and (2.3) *Nymphaea lotus* which are all within the range of 1-10 signifying favourable absorption of Ni^{2+} for *Eichhornia crassipes*, *Pistia stratiotes* and *Nymphaea lotus* (Rosales et al., 2016; Poonam et al., 2018).

Adsorption kinetics

The biosorption of Ni^{2+} by *Eichhornia crassipes, Pistia stratiotes*, and *Nymphaea lotus* was determined at various initial concentration and time interval for the understanding of biosorption mechanism (Manikandan et al., 2016). The result obtained shows that the Pseudo Second-order kinetic model gives nearly perfect fitting for *Eichhornia crassipes* (0.9194) and *Pistia stratiotes* (0.9645) but poor fitting for *Nymphaea lotus* (0.7329). The correlation coefficient shows that the absorption of Ni by *Eichhornia crassipes, Pistia stratiotes*, and *Nymphaea lotus* follows the pseudo second-order kinetic model because poor fittings of (0.7501) *Eichhornia crassipes,* (0.5678) *Pistia stratiotes* and (0.5404) *Nymphaea lotus* was obtained for pseudo-first order model. This result obtained signifies that that the absorption of Ni^{2+} to *Eichhornia crassipes, Pistia stratiotes* and *Nymphaea lotus* is due to chemical and physical reaction

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1307513087

of Ni^{2+} and the surface of *Eichhornia crassipes, Pistia stratiotes* and *Nymphaea lotus* which leads to the formation of bond between the valence electron and the negative surface charge of *Eichhornia crassipes, Pistia stratiotes* and *Nymphaea lotus* to attain an equilibrium state (Low et al., 1994).

Conclusion

The petrochemical refining industry is the world largest contributor of Ni^{2+} particularly in developing countries like Nigeria where wastewater containing Ni^{2+} is discharged into nearby water bodies without proper treatment due to low technologic know-how. It is thereby paramount for petrochemical refineries to utilize the availability of aquatic macrophytes as low-cost absorbents for further treatment of its wastewater before discharge since most industries are unwilling to establish a costly convectional treatment plant.

The comparison of the present study and other research as shown in *Table 3*, shows that although *Eicchornia crassipes* have the highest Ni^{2+} reduction efficiency both *Pistia stratiotes* and *Nymphaea lotus* can also be used effectively as biosorbents for the removal of Ni^{2+} from refinery wastewater.

Table 3. *Comparison of biosorption efficiency of Ni^{2+} by different macrophytes*

SN	Macrophytes	Heavy metal	Percentage reduction (%)	References
1	*Eichhornia crassipes*	Ni^{2+}	90	Present study
2	*Pistia stratiotes*	Ni^{2+}	87	Present study
3	*Nymphaea lotus*	Ni^{2+}	86	Present study
4	*Lemna minor*	Ni^{2+}	82	Axtell et al. (2003)
5	*Hydrilla verticillata*	Ni^{2+}	92	Mishra et al. (2016)
6	*Salvinia sp*	Ni^{2+}	71.4	Dhir and Kumar (2010)

Further investigation is needed on how to increase the efficiency of these macrophytes for the uptake of Ni^{2+}**.** More research needs to be done using more macrophytes such as *Salvinia sp, Azolla sp, Ludwigia sp,* etc to discover more novel eco-friendly cheap biosorbent for Ni^{2+} removal from wastewater.

Acknowledgments. The first author appreciates Petroleum Technology Development Fund (PTDF) Nigeria for providing the fund and enabling environment to carry out the research.

(Received 25th May 2019; accepted 9th Sep 2019)

Abstract. In the study, it was aimed to determine the optimum irrigation issue by examining the anatomical features of *Lycopersicon esculentum* Mill. cv. Ceren cultivated in perlite by different irrigation treatments. Irrigation strategies were created based on the amount of drainage water and different irrigation applications were performed by using the drip irrigation system. For anatomical examination, cross sections were taken from the samples of the root, stem and leaf by microtome and examined by light microscopy. Some tissues in the root, stem, and leaf under over-irrigation and limited irrigation conditions changed significantly. As a result, the condition created by reducing 25% of irrigation water was determined as the optimum irrigation issue in four different irrigation applications. The amount of drainage under optimum condition was 10% of the amount of irrigation water applied. The study will contribute to the researchers to optimize the ecological condition in terms of irrigation in greenhouse.
Keywords: *costs, plant histology, stress, tomato, water management*

Introduction

Soil and freshwater resources are within the guarantee of economic and social order in society. Limited land and freshwater resources in the world and in Turkey have been freely used by mankind for many years without any problems. However, later it was negatively affected by climate change and abuse of agricultural land. On the other hand, requirement for the crop product increased due to rapid increase of population. Greenhouse improvement has been developed in order to reduce or eliminate these negative effects (Tuylu et al., 2018).

Today vegetable production in Turkey is 28.4 10^6 ton and ranks 4th in the world (Yanmaz et al., 2015). Approximately 87% of vegetable production is open and 13% is under cover (61,000 ha). Tomato which is one of the vegetables cultivated in Turkey ranks 1st with the amount of 11.8 10^6 ton (Anonymous, 2015).

Today soil and soilless agriculture can be performed depending on the irrigation and crop production technologies developed in the greenhouse. Soilless agriculture is more productive than soil agriculture and its production cost is half of soil agriculture (Özkan, 2014). On the other hand, as a result of using geothermal water resources to heat greenhouse, the concept of geothermal greenhouse has started to develop in Turkey and greenhouse areas have increased where geothermal resources are available. Karaali, Şanlıurfa is a province where geothermal water is used for greenhouse heating and plant

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1308913104

production is performed by using high technology in modern greenhouse (Deliboran et al., 2013).

In the studies carried out in plant cultivation in greenhouses, 30-35% free drainage condition has been commonly used for the irrigation applications mentioned in Winsor and Shwarz (1990), Lieth (1996), and Öztekin et al. (2017). Irrigation applications are effective on anatomical, morphological, physiological, etc. features of plants. Plants try to survive by developing many reversible or irreversible responses to all biotic or abiotic environmental factors they perceive as stress effect (Korkmaz and Durmaz, 2017).

In this way the plants become compatible with the factors of their habitat by developing stress responses. The responses developed by the plants to adapt to stress conditions can be due to changes in physiological, morphological, anatomical, etc. features. In cultivation, irrigation is one of the important abiotic factor for creation of ecological request of plants. If the accurate irrigation strategy can not be determined, water stress or drought stress condition occurs when over-irrigation or limited irrigation is applied. It causes anatomical changes in the plant. The changes can occur in various tissues. For this reason, it was aimed to determine the optimum irrigation issue for the variety studied by examining anatomical features of the plants cultivated by applying different irrigation issues. The study will contribute to the producers to determine accurate irrigation strategy in greenhouse and also support the researchers for literature to optimize the ecological condition in terms of irrigation in greenhouse in the World.

Materials and methods

The workout was carried out in polycarbonate covered greenhouse in Harran University, Şanlıurfa, Turkey during the spring of 2016. Tomato (*Lycopersicon esculentum* Mill. cv. Ceren) was cultivated in perlite by using drip irrigation system (*Fig. 1*). Anatomical studies were performed in the laboratories at the Department of Biology in Ankara University, Ankara, Turkey.

Figure 1. *An appearance of cultivation area in the greenhouse*

Şanlıurfa is situated in the south eastern Anatolia, Turkey. The workout area is 465 above sea level and located between 37°08’ N latitude and 38° 46’ E longitude (Demirok and Tuylu, 2017).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1308913104

Şanlıurfa has a climate feature that is hot and dry in summers and warm in winters. Some climate values measured in and outside the greenhouse for the year 2016 when the workout was carried out are presented in *Tables 1* and *2*, respectively.

Table 1. *Some climate parameters measured in greenhouse in 2016*

Months	Decades	Temperature* (°C)	Relative humidity* (%)
April	2	23.4	30.6
	3	24.3	28.0
May	1	23.8	33.1
	2	27.9	30.0
	3	26.1	31.6
June	1	29.9	28.7
	2	31.0	26.8
	3	35.3	28.3
July	1	35.4	27.1
	2	35.8	28.7
	3	35.4	28.3

*Measured at 14:00 pm

Table 2. *Average climate values of 2016 and 1985-2016 long years (LY) in research area (Anonymous, 2016)*

Climate parameters		Max. temperature (°C)	Min. temperature (°C)	Ort. Temperature (°C)	Relative humidity (%)	Wind speed (2 m s^{-1})	Hours of sunshine (h)
Months	Year						
April	2016	32.7	7.4	20.6	36.1	1.4	8.90
	LY	22.5	10.8	16.2	53.4	1.5	7.55
May	2016	35.0	10.7	23.2	38.3	1.9	10.20
	LY	29.7	19.7	21.9	39.4	1.7	9.70
June	2016	42.0	18.9	29.8	28.0	1.9	11.90
	LY	34.9	21.0	28.3	35.2	2.0	11.95
July	2016	43.0	20.9	33.0	25.4	1.9	12.40
	LY	37.4	25.7	33.4	29.1	1.9	12.00

The workout was created as with 3 replications according to the random parcels plant pattern. 8 plants were cultivated in each pot. 2 of 8 plants cultivated were separated as edge effect. The samples were randomly taken from the remaining 6 plants and were examined.

Perlite cultivation condition was created by filling perlite in white styrofoam pots with sizes of 100 × 20 × 20 cm and drainage holes at the bottom. The seedlings were planted as 135 × 25 cm or more row spacing (2.9 plants m^{-2}) (*Fig. 1*). The nutrient solution used were passed through the filter and water meter by taking from the 1 ton-reservoir with centrifugal pump and was given to the plants by means of four-outlet drip irrigation system set up on pressure-regulated dripper in the 8 L h^{-1} flow on lateral pipe

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1308913104

(Ø16). The workout design was performed according to the open feed system and the nutrient solution that was drained was not used again.

In the study, the irrigation issues were planned according to free drainage condition (Winsor and Shwarz, 1990; Lieth, 1996; Öztekin et al., 2017). The issues were created according to four different irrigation levels which were I_1, I_2, I_3, and I_4. I_1 was the issue allowed 20% drainage of irrigation water. I_2, I_3, and I_4 were planned by proportionally reducing the amount of irrigation water used in I_1 issue (25, 50, 75%, respectively).

Nutrient solution was modified by using Arnon and Hogland (Tuylu et al., 2018). Stock A and Stock B solutions were separately prepared (*Table 3*). Electrical conductivity (EC) of nutrient solution was measured as 2. 5 dS m^{-1} by EC meter and pH of nutrient solution was fixed at 5.8-6.5 by using nitric acid. In soilless agriculture EC of nutrient solution has to be kept at optimum level. While high electrical conductivity (EC) reduces the yield affecting number of fruit, the diameter of fruit and the thickness of pericarp negatively, it causes increase of parameters of quality such as titratable acidity and the amount of dry substance which is easily soluble in water reducing glucose and lycopene (Söylemez and Pakyürek, 2017).

Table 3. *The content of element in nutrient solution (mg l^{-1})*

Stock A										**Stock B**	
N	P	K	S	Mg	Mn	B	Cu	Zn	Mo	Ca	Fe
210	31	234	64	48	0.5	0.5	0.02	0.05	0.01	200	2.8

The samples of plants vegetatively and generatively grown were kept in alcohol 70% for anatomical studies (*Figs. 2* and *3*). Dehydration was applied to small pieces taken from the lower, middle, and upper parts of the root, stem and, leaf by means of different ethyl alcohol series. Then, they were saturated with paraffin. The samples were embedded in paraffin blocks to take cross sections. 8-10 µm thick cross sections from the root and the leaf and 20-30 µm thick cross sections from the stem were taken by microtome Leica SM 2000 R. The cross sections were stained by safranin-fast green (Tuylu et al., 2017; Tuylu, 2018a). They were examined by light microscope Leica 1000 and the results were photographed by digital camera Leica EC3.

Figure 2. *Morphological appearance of the roots grown in different irrigation areas. A: I_1, B: I_2, C: I_3, D: I_4*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1308913104

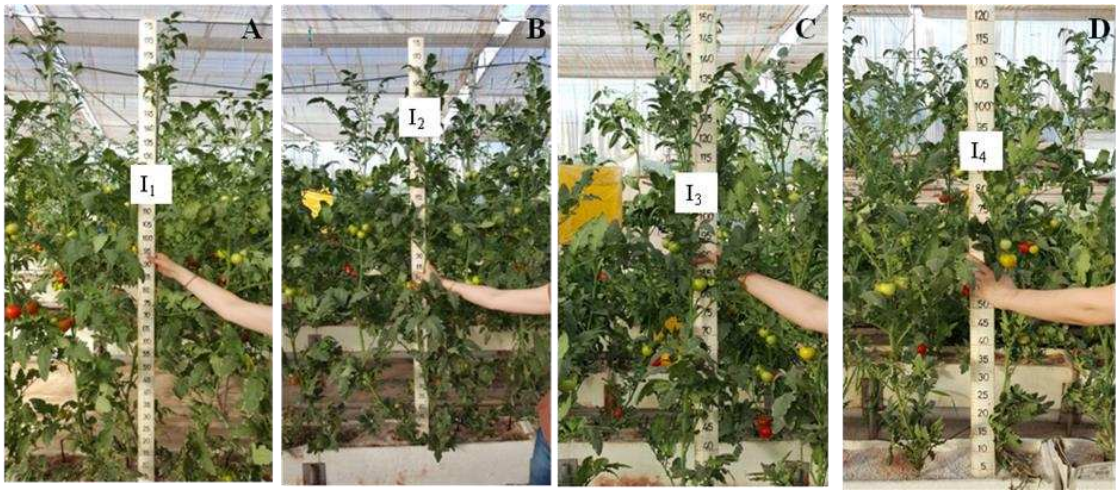

Figure 3. *Morphological appearance of the stems and leaves grown in different irrigation areas. A: I_1, B: I_2, C: I_3, D: I_4*

The photos are completely original. Biometric measurements were performed in some tissues by using Las v4.3 program. 3 groups in itself for each replication were created in the workout. The total number of cross sections taken from the plants and examined is 90 on 9 preparats for each replication and total 270 values of measurement were obtained by taking 3 from each section. The arithmetic mean of the values of measurements and mean standard error were calculated by using Microsoft Excel computer software and the results were anatomically expressed.

Results

Results for some anatomical features of the root, stem and leaf under different irrigation applications

Roots

The roots under all the conditions were formed by the cortex composed of wavy-walled cells surrounded by one-layered epidermis, one-layered endodermis, and one-layered pericycle. Prismatic crystals were observed (*Fig. 4*). Endodermis and pericycle were seen in some sections under I_2 and I_4 (*Figs. 5* and *6*). Both prismatic crystals and druz crystals were also seen under I_2. Prismatic crystals were regularly observed in parenchymatic cells around endodermis under I_3 (*Fig. 7*). Parenchymatic cells like a large air space in cortex were seen in some sections under I_4.

According to the biometric measurements performed in some tissues of the roots under four conditions; the thickness of cortex under I_3 and I_4 increased more than the one under I_2 ($p < 0.01$; $p < 0.05$; *respectively*). There was no significant change in the thickness of cortex under I_1 ($p > 0.05$). The diameter of xylem vessels narrowed under I_1, I_3, and I_4 ($p < 0.05$; $p < 0.01$; $p < 0.01$, *respectively*) more than the one under I_2 (*Fig. 8*). According to the results of the biometric measurements, the roots under the other issues underwent anatomical changes comparing to the ones under I_2 statistically and the I_2 condition was determined as optimum issue ($p < 0.01$: *highly significant,* $p < 0.05$: *significant,* $p > 0.05$: *no significant*).

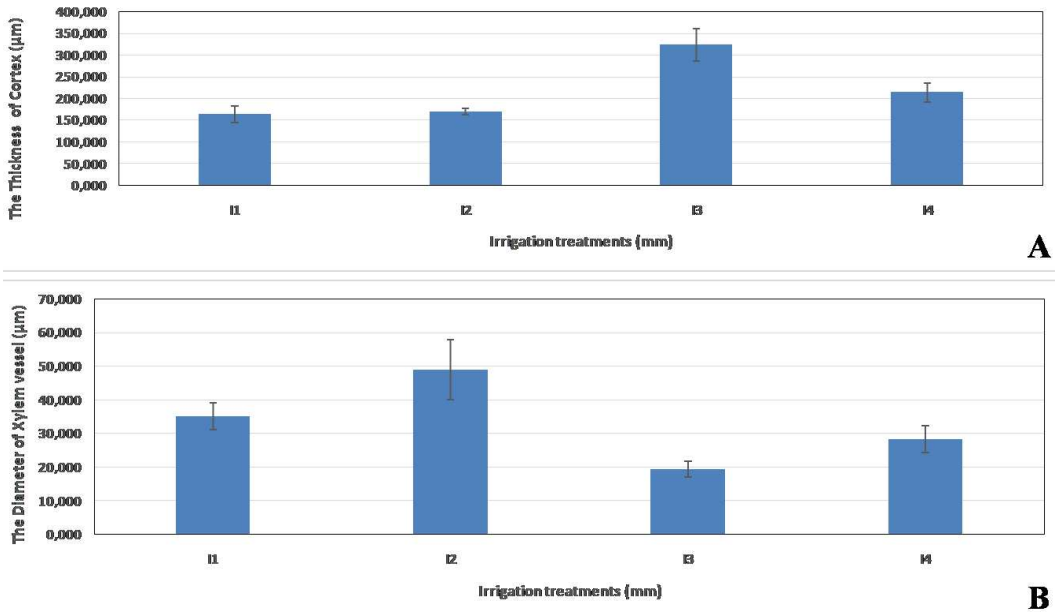

Figure 8. *Measurements of some tissues in roots of Ceren cv. under different irrigation treatment conditions. A. The relationship between irrigation treatments and thickness of cortex. B. The relationship between irrigation treatments and diameter of xylem vessel*

Stems

The stems under all the conditions were formed by one- layered epidermis, 1-2 layered chlorenchyma with large spaces between the cells, 4-5 layered collenchyma, 4-5 or 5-6 layered cortex. The pith was parenchymatic surrounded by bicollateral vascular bundles. 3-4 layered cambium and seconder xylem rays under I_1 and I_3 were observed (*Figs. 9* and *11*). The cambium was 4-5 layered under I_4 (*Fig. 12*). Sclerenchyma cells supported vascular bundles on both sides around phloems. All the stems had stomata, epidermal and glandular hairs. While prismatic crystals were generally observed, druz crystals were seen among prismatic crystals in some sections. Prismatic crystals in chlorenchyma under I_2, air spaces in chlorenchyma in some sections under I_4 and starch molecules under I_2, I_3, and I_4 were observed (*Figs. 10, 11* and *12*). Starch molecules were rarely seen under I_1.

According to the biometric measurements performed in some tissues of the stems under four conditions, cuticle thickened under I_1 and I_4 ($p < 0.01$; $p < 0.05$, *respectively*). It was not affected clearly under I_3 ($p > 0.05$). Epidermis did not change clearly under I_1 ($p > 0.05$), but it significantly thickened under I_3 and I_4 ($p < 0.05$). Cortex did not change clearly under I_1 and I_3 ($p > 0.05$), but it significantly thickened under I_4 ($p < 0.05$). Xylem vessel narrowed under I_1, I_3, and I_4 comparing to I_2 ($p < 0.05$; $p < 0.05$; $p < 0.01$, *respectively*) (*Fig. 13*). According to the results of the biometric measurements, the stems under the other issues underwent anatomical changes comparing to the ones under I_2 statistically and the I_2 condition was determined as optimum issue.

Leaves

The leaves under all the conditions were bifacial and amphistomatic. Mesophyll was formed by one-layered palisade parenchyma with large spaces between the cells and 4-5 layered spongy parenchyma with large spaces between the cells under I_1 (*Fig. 14*). Palisade parenchyma was one-layered and spongy parenchyma was 2-3 layered under I_2 (*Fig. 15*). Mesophyll was formed by 2-3 layered palisade parenchyma generally rarely arranged by small cells and 3-4 layered spongy parenchyma with large spaces between

DOI: http://dx.doi.org/10.15666/aeer/1706_1308913104

small cells under I_3 (*Fig. 16*). One-layered palisade parenchyma formed by long cylindirical cells and 3-4 layered spongy parenchyma with large spaces between the cells in mesophyll under I_4 were observed (*Fig. 17*). Druz crystals were observed among prismatic cyristals in mesophyll in some sections. Big vascular bundle was bicollateral. Small vascular bundles surrounded by bundle sheath were collateral and embedded in mesophyll. Epidermal and glandular hairs were observed under all the conditions. Glandular hairs were rarely seen under I_4.

Discussion

According to the results the anatomical features in the roots, stems and leaves in the issues analyzed are similar to the general anatomical features of Solanaceae family and *Lycopersicon esculentum* Mill. mentioned in Metcalfe and Chalk (1950), Rost (1996), Tuylu et al. (2018) and Tuylu (2018a). Abnormal changes in the development of basic tissues were not observed in the roots, stems and leaves in all the issues studied $I_{1\text{-}4}$. Structure and functions of all plant organs are affected by water stress (Sam et al., 2000). The tissues affected when the plant is applied by limited irrigation can be also affected by over-irrigation. The adaptation reactions of the tissues under over-irrigation or limited irrigation condition can be opposite or parallel to each other. In the study the I_1 issue was determined as over-irrigation. The comparison of the biometric measurements between the issues in the study and the results of the measurements of the tomato, Ceren cv. cultivated under hydroponic system and anatomically examined in Tuylu (2018a) contributed to determine I_1 issue as over-irrigation. The study mentioned was carried out in the same greenhouse, period and climate parameters. The stress- related anatomical changes were observed in the roots, stems and leaves of the plants cultivated under I_3 and I_4 issues determined as limited irrigation conditions comparing with the ones under I_2 issue determined as optimum condition.

When the results were evaluated for the root, the diameter of xylem vessels in the root in Ceren cv. narrowed in all the issues more than the one under optimum issue. It means that the diameter of xylem vessels anatomically reacted to water and drought stress conditions in the same way. The xylem vessels under I_1 condition in the study and the ones in Ceren cv. cultivated under hydrophonic culture in Tuylu (2018a) gave the same reactions. Similarly, Tuylu et al. (2018) figured out in the study on Malatya Kurucaova cv. that the xylem vessels in the root narrowed as a result of water stress under hydrophonic culture more than the ones under perlite condition well- irrigated. The xylem vessels in Malatya Kurucaova cv. and Ceren cv. gave reactions in parallel anatomically to stress resulting in over- irrigation.

When the results were evaluated for the stem, it was observed that cuticle and cortex thickened and the diameter of xylem vessel narrowed under I_1, I_3, and I_4 conditions comparing with I_2 condition. In the stem of Ceren cv. mentioned in Tuylu (2018a) the thickness of cuticle increased and the diameter of xylem vessel narrowed comparing with I_2 in the study. In the stem of Malatya Kurucaova cv. in Tuylu et al. (2018) it was stated that cuticle and epidermis thickened while cortex and xylem vessel narrowed under hydrophonic condition. It was clear that the thickness of cuticle and the diameter of xylem vessel anatomically changed in parallel in Ceren cv. and Malatya Kurucaova cultivated under hydrophonic condition and under over- irrigation and limited irrigation conditions in the present study.

When the results were evaluated for the leaf, it was obvious that upper and lower epidermis thickened under I_1, I_3, and I_4 conditions comparing to I_2 condition. Sam et al. (2000) studied the effects of water deficit on epidermis of leaf at preflowering stage in *Lycopersicon esculentum* Mill. cv. INCA9 and stated that water stress have slight effects on the width and the length of epidermis cells. Thus, it is understood that the plant also shows epidermal change under water stress as it shows under water deficit. In addition, in the present study, the width of mesophyll increased, the diameter of xylem vessel narrowed and the length of big vascular bundle increased. While the width of big vascular bundle increased under I_1 and I_4, it decreased under I_3. The thickness of bundle sheath wall increased as long as the amount of irrigation water reduced. Tuylu et al. (2018) introduced that midrib region widened and the width and the length of big vascular bundle increased in the leaf of Malatya Kurucaova cv. cultivated under hydrophonic condition as a result of water stress comparing to the ones under perlite condition. They stated that no clear change was observed in the other tissues measured. It was similar to the change observed in midrib region of the plant cultivated and exposed to over- irrigation under I_1 in the present study. A similar change in big vascular bundle was observed under particularly I_4 which was one of the limited irrigation issues. However; the fact that in the study the leaf under I_1 also showed anatomical changes in the other tissues comparing to the one under I_2 differed from Tuylu et al. (2018).

The fact that the thickness of upper epidermis and mesophyll increased and xylem narrowed in the leaf of Ceren cv. exposed to over- irrigation in Tuylu (2018a) was similar to the leaf under I_1 in the present study.

Tuylu (2018b) figured out that the thickness of cortex and the diameter of xylem vessel in the root, the diameter of xylem vessel in the stem and the thickness of cuticle, the thickness of upper epidermis, the number of stomate in the upper and the lower epidermis, the length and the width of bullate cell, the width of mesophyll, the diameter of xylem vessel, the distance of bundles, the thickness of midrib region, and the width of big vascular bundle in the leaf significantly changed under over- irrigation and limited irrigation in the study on the maize cultivar.

Conclusion

As a result, some tissues of Ceren cv. cultivated under perlite condition by applying different irrigation issues were anatomically examined and compared. When all the issues were compared according to the measurements performed in the root, stem and leaf, the tissues under I_1, I_3 and I_4 conditions showed anatomical changes due to drought and water stress comparing to I_2 condition.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1308913104

Thus, the anatomical features analyzed pointed out that I_2 issue was optimum irrigation condition for the plant. It was the issue that 10% of irrigation solution was drained. The plants cultivated under over- irrigation (I_1) and limited irrigation (I_3, I_4) did not have a clear anatomical anomaly comparing to the ones cultivated under I_2. They underwent changes such as thickening or narrowing due to water and drought stress and they adapted to the conditions.

To determine the accurate irrigation strategy for the plant under irrigation applications some tissues of the root, stem and leaf can anatomically present if the plant was exposed to water stress or drought stress. In the study, it was figured out that the thickness of cortex under limited irrigation, and the diameter of xylem vessels under over- irrigation and limited irrigation in the root, the thickness of cuticle, and the diameter of xylem vessel under over- irrigation, and the thickness of cuticle, epidermis and cortex, and the diameter of xylem vessel under limited irrigation in the stem, the thickness of cuticle, the width of mesophyll, and upper and lower epidermis, the length and width of big vascular bundle under over- irrigation, and the thickness of upper epidermis, the width of mesophyll, the diameter of xylem vessel, the length and width of big vascular bundle, the thickness of bundle sheath wall under limited irrigation in the leaf significantly reacted anatomically. The optimum issue can be determined statistically in terms of importance levels by evaluating the measurements of these tissues.

According to the results of the study, it is suggested that the amount of drainage should be 10% in the irrigation applications in contrast to 30-35% drainage mentioned in Winsor and Shwarz (1990), Lieth (1996) and Öztekin et al. (2017). In other words, irrigation application should be performed by reducing 25% of irrigation water. It is suitable for the anatomical characteristics of the root, stem and leaf of tomato. In cultivation, not only saving up the cost of the nutrient solution in terms of its total cost but also supplying energy savings by reducing irrigation time will contribute considerably to the producer. In addition, researchers in the field should consider irrigation parameter to optimize the ecological condition in further studies.

Acknowledgements. This research did not receive any specific financially funding, but we thank to Harran University for equipments in greenhouse, and Ankara University for biology laboratories in Turkey for providing materials mentioned in the Materials and Methods to support the study.

Abstract. To explore the signal transduction pathway that *TaRHA2b* gene is involved in regulating, yeast two-hybrid system was used to screen and identify proteins interacting with TaRHA2b. The homogenized cDNA library was constructed from the embryo of mixed barley. The decoy protein vector pGBKT7-*TaRHA2b* was constructed and transformed into yeast AH109 cells for self-activation detection. Candidate positive clones were screened by one to one yeast co-transfection, SD/-Leu/-Trp and SD/-Leu/-Trp/-Ade/-His medium screening and β-galactosidase chromogenic reaction. The in vitro co-transfection and GST-pull down experiments were used for further verification. The homogenized cDNA library of the barley embryos with titer of 1.2 10^6 cfu/ml and storage capacity of 1.1 10^6 was successfully constructed. The inserted fragment size was between 1000-3000 bp. The plasmids of the cDNA library were extracted and sequenced on a large scale, and 5000 plasmids were obtained. The decoy vector without self-activation function was successfully constructed. The x-gal filter paper of eighty-four hybrid clones showed strong blue color and forty-nine pieces of effective sequence information were obtained. Eight of them were selected for co-transfection verification. YTH2450 was selected for GST-pull down verification. The results showed that they were positive hybrid clones. TaRHA2b interacted with YTH2450 and other proteins. The information of above genes could be used for genetic improvement of crops, further improving the adaptability of crops to the environment.
Keywords: *preharvest sprouting, abscisic acid, cDNA library, self-activation, pull down assay*

Introduction

Preharvest sprouting (PHS) refers to the phenomenon of direct germination of grains on the ear in wet environment at the mature stage of wheat (*Triticum aestivum* L.). The negative effects of spike germination on wheat production are mainly reflected in decreasing yield, deteriorating quality and lower seed value. At present, the resistance of most wheat varieties to spike germination is not strong. The shortage of wheat resistance gene resources severely restricted the breeding and application of wheat varieties resistant to heading germination.

Cys-rich RING domain was identified for the first time in proteins encoded by *Really Interesting New Gene*. In *Arabidopsis thaliana* proteome, more than 5% of the predicted proteins (more than 1400 genes) are involved in ubiquitination/26S proteasome pathway (Smalle and Vierstra, 2004). Among these proteins, only a few encode E1 enzymes (two isoforms), 37 predicted proteasome components of E2, 26S, and other factors (such as deubiquitinase), while more than 1400 genes encode E3 ubiquitin ligases to participate in ubiquitination-dependent proteasome degradation pathways (Smalle and Vierstra,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1310513124

2004). A variety of E3 ubiquitin ligases involve them in specific proteasome degradation pathways. Different binding of E2 and E3 can also increase the specificity of E3 in recognizing target proteins. Therefore, the diversity of E3 and the diversity of E3 binding with E2 can not only regulate different types of ubiquitination modification, but also specifically regulate target proteins.

The *AtRHA2b* gene of *Arabidopsis thaliana* encodes E3 ubiquitinated ligase. It plays an important role in ABA (abscisic acid) signal transduction and stress. Overexpression of *AtRHA2b* gene results in ABA-related phenotypes, such as ABA sensitivity at the stage of seed germination and seedlings (Li et al., 2011).

The *TaRHA2b* (Genbank: AEQ67396.1) gene, a Ring finger protein gene, was isolated from wheat by our team (Li et al., 2019). In previous studies, much work has been done on the *TaRHA2b* and *RsRHA2b* genes. The results showed that *TaRHA2b* gene may play an important role in seed dormancy during germination, which could be used to improve the PHS resistance of wheat. The genetic distance between radish and *Arabidopsis thaliana* is very small, so the function of radish *RsRHA2b* gene should be similar to that of *Arabidopsis thaliana AtRHA2b* gene. Compared to Zhengmai 9023, wheat lines transfected with *RsRHA2b* gene showed higher dormancy, PHS resistance and sensitivity to exogenous ABA. Meanwhile, under the treatment of 0.5 μM ABA and 5 μM ABA, the expression of ABA-related genes in transgenic lines was significantly higher than that in control Zhengmai 9023. The differences in nucleotide polymorphism sites of *RsRHA2b* gene resulted in differences in the three cleavage sites of *BstD102I, Cfr10I, and HpaII/MspI*. These results facilitate the exploration of the correlation between the *TaRHA2b* gene and wheat's increased PHS resistance ability and the development of molecular markers for PHS resistance.

The protein interaction network of RHA2b can be predicted by string software. This protein interaction network includes KIN1 (AT5G15960.1), ATDI8 (AT5G66400.1), AT5G12110 (AT5G12110.1), KUOX1 (AT5G07480.1), KUF1 (AT1G31350.1), AIRP1 (AT4G23450.2), SDIR1 (AT3G550.1), KEG (AT5G13530.1), AT5G58410.1 (AT5G58410.1) and ATC019 (AT1G52890.1). RHA2b is involved in the process of protein ubiquitination, cell protein metabolism and response to acid compounds. The regulatory network of a series of proteins interacting with RHA2b involves the processes of protein ubiquitination, cell protein metabolism, low temperature tolerance, and response to water loss, ABA, acidic compounds, oxygen-containing compounds and abiotic stress (Kurkela and Franck, 1990; Haynes et al., 2002; Sajan et al., 2007; Usadel et al., 2008; Jiang et al., 2009; Nelson et al., 2010; Robinson et al., 2010; Cho et al., 2011; Zheng et al., 2012; Stone, 2014).

The complexity of transcription factors determines the diversity of their functions. However, the specific signaling pathways and mechanisms involved in RHA2b are not very clear. What proteins can interact with it? Using TaRHA2b as bait and yeast two-hybrid technique to study the proteins interacting with TaRHA2b can lay a foundation for solving the above problems. Yeast two-hybrid technology has been widely used as an effective means to study protein interaction, providing a mature technology platform for the study of protein interaction and unknown proteins.

Fields and Song's yeast two-hybrid technique is a sensitive method for analyzing protein-protein interactions (Fields and Song, 1989). Although the system is closer to the natural conformation and function of the protein, but can not avoid the "false positive" problem. The self-activation detection of decoy protein is necessary for yeast two-hybrid experiment. If the decoy itself has self-activation function, then the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1310513124

downstream reporter gene can be directly expressed, which makes no sense to use the decoy protein vector to screen the library.

In order to further understand the function of *TaRHA2b* and its mechanism of PHS resistance, some genes related to TaRHA2b were screened by yeast two-hybrid method. The present study can not only screen new stress-resistant genes, but also provide a theoretical basis for elucidating the mechanism of TaRHA2b-mediated PHS resistance.

Materials and methods

Construction and identification of homogeneous cDNA library

Wheat is hexaploid and its genome structure is too complex. Barley and wheat are both gramineous plants. The genetic distance between them is very small. Therefore, the interaction of TaRHA2b protein in barley can be studied first, and then the function of TaRHA2b in common wheat can be studied.

Preparation and purity detection of total RNA from barley (Hordeum vulgare L.) embryo

Barley seeds were treated with 5 μM ABA and distilled water, respectively. The seeds amount of each treatment was 50, and the sampling time was 0 h, 6 h, 12 h and 24 h. After the obtained materials were degerminated, mixed samples were prepared and total RNA was extracted using the RNAiso Plus Kit (Takara, Japan). Total RNA was determined by spectrophotometer at OD260/OD280 values. 1-2 μg RNA was treated with thermal denaturation (65 °C, 10 min). Then Agarose gel electrophoresis was used to detect the purity of RNA.

Synthesis of 1st strand and 2nd strand cDNA

The total RNA was taken as the template and the experimental steps were followed in the Creator Smart cDNA Library Construction Kit (Clontech, the United States). The electrophoresis on agarose gel was determined with 5 μL.

Homogenization

The obtained double-strand cDNA PCR was purified using the QIAquick PCR Purification Kit (Cat.No.28104, QIAGEN, Duesseldorf, Germany). Homogenization is performed according to trimmer-director kit (Cat#NK002, Evrogen, Moscow, Russia).

Purification, enzyme digestion, binding and library transformation of dscDNA

The dscDNA was purified using the QIAquick PCR Purification Kit. The purification of the ds cDNA was treated with *Sfi I* enzyme, 65 °C warm bath 2 h. The products were purified by CHROMA SPINTMTE-400 Column. Purified product was connected with pGADT7-Rec carrier, 16 °C, for the night. Connect the product to *E. coli* DH10B transformation, which was placed in the resistance of ammoniac benzyl LB tablet (15 cm in diameter) on 37 °C training for the night.

Identification of library

Observe and record the number of colony, then calculate its storage capacity. Thirty clones were randomly selected for PCR. The product was detected by agarose

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1310513124

gel electrophoresis, the recombination rate was calculated and the size of the inserted fragment was predicted.

Extraction, sequencing and bioinformatics analysis of cDNA library plasmids

2*96 monoclonal extraction templates were selected and sequenced with ABI3730. Positive sequencing was used. The sequence was analysed by BLAST. The NCBI and Swiss-Prot databases were used for bioinformatics.

Cloning of the wheat TaRHA2b gene

The seeds of wheat variety "Zhengmai 9023" were used for total RNA extraction. Total RNA was extracted with the Plus plant total RNA extraction kit (Tiangen Biotech (Beijing) Co., Ltd., Beijing, China). Fast Quant RT Kit (With gDNase) (Tiangen Biotech (Beijing) Co., Ltd., Beijing, China) was used to synthesize the first strand of DNA. The reverse transcription of wheat embryo DNA was used as template. Primers (*TaRHA2b*-F1 (Bait): 5'-GAATTCATGGGGTTCCCTGG-3', *TaRHA2b*-R1 (Bait): 5'-CTGCAGTCACCAAACGCGCGGGGGGGTGAG-3') were used for PCR amplification: 94 °C, 4min; 94 °C, 40s; 61 °C, 40s; 72 °C, 50s; 72 °C, 10min; 34 cycles. The length of the target fragment was 477 bp, and the target fragment was recovered by the gel recovery kit (Tiangen Biotech (Beijing) Co., Ltd., Beijing, China). The recovered product was linked to pMD-19T, transformed into *E. coli* DH5a and cultured overnight on ampicillin resistant LB plate 37 °C. Monoclones were selected and cultured in shaking bacteria. Plasmid DNA was extracted and identified by PCR.

Construction and self-activation detection of decoy protein vector

Screening of interacting proteins is done in accordance with Matchmaker™ Gold Yeast Two-Hybrid System User Manual (PT4084-1).

Construction of bait protein vector

Both pMD19-TaRHA2b and pGBKT7 vectors were digested by *EcoR I* and *PST I* at the same time, and the corresponding target fragments and linear pGBKT7 vectors were recovered. The recombinant vector pGBKT7-TaRHA2b was finally obtained and transformed into E. coli. Monoclones were selected and plasmids were extracted after shaking bacteria culture. The obtained plasmids were identified by enzyme digestion, and the rest were stored in a refrigerator at -80 °C with 50% glycerol.

Self-activation detection of bait carrier

Yeast strain AH109 was inverted cultured on YPDA plate at 30 °C. Yeast with diameters of 2-3 mm were selected and streaked on SD/-Trp, SD/-Leu, SD/-His and SD/-Ade media, respectively. The growth of yeast was recorded by inverted culture at 30 °C for 3-5 days. The bait vectors $pGBKT_7$-TaRHA2b and $pGADT_7$ were co-transfected into yeast AH109 competent state, and were separately delineated on SD/-Trp-Leu, SD/-Trp-Leu-His-Ade medium. The positive control group was co-transformed with $pGBKT_7$-53 and $pGADT_7$-T, while the negative control group was co-transformed with $pGBKT_7$-lam and $pGADT_7$-T. The growth of yeast was recorded after 3-4 days of inverted culture at 30 °C on all co-rotating plates.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1310513124

Systematic high-throughput yeast two-hybrid assay

One-to-one transfection of bait plasmids and library plasmids into yeast competence

The bait vector pGBKT$_7$-TaRHA2b was transfected into yeast AH109 cells together with the library plasmid. The lines were drawn on SD/-Trp-Leu and SD/-Trp-Leu-His-Ade medium, respectively. At the same time, the yeasts transformed with pGBKT$_7$-53 and pGADT$_7$-T, pGBKT$_7$-lam and pGADT$_7$-T were used as positive control and negative control, respectively. The growth of yeast was observed and recorded after 3-4 days incubation at 30 °C.

Identification of yeast positive clones

The large-scale library plasmid and bait protein vector were co-transformed into yeast AH109 cells. The activity of beta-galactosidase co-transforming yeast colonies on SD/-Trp-Leu-His-Ade culture plate was detected by X-gal filter paper colorimetry. The colour reaction of yeast colonies was observed within 8 h.

Sequencing and analyzing the AD-ORF of positive candidates.

The plasmids corresponding to the yeast positive clones were sequenced. The obtained sequences were analyzed by bioinformatics. The NCBI and Swiss-Prot databases were used for bioinformatics.

The co-transfection verification

The barley DNA stored in laboratory was used as template and amplified with primers (*Table 1*). The amplification procedures were as follows: 94 °C, 5 min; 94 °C, 30 s; 57 °C, 30 s; 72 °C, 1 min 20 s; 72 °C, 10 min; 30 cycles. The size of the target fragment was 933 bp. After gel recovery, it was connected with pGEM-T and transformed into DH5a to extract plasmid. The above plasmids were digested by EcoRI/BamHI and pGADT$_7$-T by EcoRI/BamHI. The target fragment was linked with the digested pGADT$_7$-T vector by T4 ligase and transformed into DH5a. The plasmid was extracted and identified by PCR, and the corresponding candidate protein prey was finally obtained. The bait vector and prey vector co-transformed yeast were applied to SD/-Trp-Leu and SD/-Trp-Leu-His-Ade solid medium plates. Colony growth was observed after incubation for 2-4 day.

The GST-pull down verification

Cloning of YTH2450 gene and TaRHA2b gene

PGADT7-*YTH2450* was used as the template, and 59/60 primers were used for amplification. The amplification procedure was as follows: 94 °C, 5 min; 94 °C, 30 s; 60 °C, 30 s; 72 °C, 1 min 20 s; 72 °C, 10 min; 30 cycles. The size of the target fragment was 933 bp. It was linked with pGEM-T for *E. coli* transformation and plasmid extraction. Take pGBKT7-TaRHA2b as the template, The primers TaRHA2b-F1/R1 were used for amplification. Amplification procedure is as follows: 94 °C, 5 min; 94 °C, 30 s; 60 °C, 30 s; 72 °C, 45 s; 72 °C, 10 min; 30 cycles. The size of the target fragment was 477 bp. It was linked with pGEM-T for *E. coli* transformation and plasmid extraction. The primers used in the experiment are shown in *Table 2*. The design of all

Construction of prokaryotic expression vector

BamHI/SalI double enzyme digestion was performed on the plasmid pGEM-T-YTH2450. At the same time, *BamHI/SalI* double enzyme digestion was performed on the pMAL vector, and the target products were recovered after electrophoresis. The target fragment and the target vector were linked with T4 ligase, and the linked product was transformed into *E. coli*. The plasmid pMAL-YTH2450 was extracted. *BamH I/Xho I* double enzyme digestion was performed on the plasmid pGEMT-T-TaRHA2b. At the same time, the pLEICS vector was subjected to *BamH I/Xho I* double enzyme digestion, and the target products were recovered after electrophoresis detection. The target fragment and the target vector were linked with T4 ligase, and the linked product was transformed into *E. coli*. The plasmid pLEICS-TaRHA2b was extracted.

Induced expression and purification of fusion protein

Transfer 500 μL positive bacteria fluid to 10 ml LB liquid medium containing 50 μg/ml ampicillin, 37 °C for the night. Transfer 2 ml bacteria liquid to 50 ml LB

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1310513124

liquid medium containing 50 μg/ml ampicillin, 37 °C for the night. Take 1 ml bacteria liquid as a control, to add IPTG residual cultures to the final concentration of 0.3 mM, 37 °C to continue to develop. 1 ml of bacterial fluid was collected at different induction stages (1 h, 2 h, 3 h, 5 h). Centrifuge for 2 min, discard the supernatant, and suspend the cells with 100 L buffer solution. The samples were boiled in boiling water for 5 min, centrifuged for 1 min, and the cells were suspended with buffer solution. PAGE electrophoresis was performed on the obtained samples. Freeze thawing at room temperature, place on ice immediately, add 10-20 ml of bacterial lysate (PBS + l%Triton-100 + PMSF) for every 500 ml of medium, and mix well. Ultrasonic crushing on ice, open 2 s, stop 9 s, total 40-60 min. Until the lysate is sufficiently cool. 11000 rpm, 15 min, 4 °C on the centrifugal separation, -80 °C saved for later use.

GST (glutathione S-transferase) pull down

Three purified columns containing Glutathione sepharose 4B were balanced by adding a binding buffer (50 mM Tris-HCl, pH 7.4, 100 mM NaCl). The bacterial lysate was added by ultrasonic crushing and centrifugal filtration. Two of them were added with pLEICS-TaRHA2b to induce GST-TaRHA2b lysates in large quantities, while the other one was added with pLEICS to induce GST lysates in large quantities. Placed in 4 °C, horizontal oscillation apparatus, slow upside down with rights and cracking liquid contact with column material, promote the combination. After 2-4 h, discard the lysate and rinse 5-8 times with pre-cooled combined buffer. A large amount of pMAL-YTH2450 induced bacterial lysate (ultrasonic crushing, centrifugal filtration) was added to the GST-TaRHA2b column and the GST-bound column respectively. Also 4 °C, fluctuation slow oscillation 4 h, abandon cracking fluid, clean with combined buffer after 5-8 times, with the elution buffer (50 mM Tris HCl, pH 7.4, 10 mM NaCl, 10 mM reducing GSH) elution 3 purification column, collect samples for SDS-PAGE analysis.

Statistical analysis

The GraphPad Prism 8 was used for statistical analysis and drawing. For comparing results of different treatments, Variance analysis is followed by a post-hoc test in order to determine pairwise differences. Differences were considered significant for $P < 0.05$.

Results

Construction and identification of homogeneous cDNA library of barley embryos

When the prepared RNA was detected by spectrophotometer, the OD260/OD280 value was 2.03, which indicated that the purity of the RNA was very high. When RNA agarose gel electrophoresis, the brightness of the two bands of 28S and 18S is close to 2:1 (*Fig. 1A*). Normal proportion indicates that the integrity of the RNA is good. In summary, the prepared RNA can be further tested. The size of double-stranded DNA fragments was uniformly distributed in the range of 300-5000 bp by LD-PCR (*Fig. 1B*), with slightly high abundance gene bands.

The storage capacity of the plate is about 1200. The titer of the library was 1.2 10^6 cfu/ml and the storage capacity was 1.1 10^6. The results of colony PCR identification of randomly selected clones in the library showed that the size of inserted fragments in the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1310513124

library ranged from 1000 to 3000 bp (*Fig. 1C*). The results showed that the library was of high quality and could be used in the follow-up yeast two-hybrid screening library.

Large-scale extraction, sequencing and bioinformatics analysis of library plasmids

The bacterial solution of barley cDNA library was amplified by PCR, and 5000 plasmids were finally extracted. Most of the amplified fragments are over 1000bp in size (*Fig. 2*). Considering the integrity of the DNA fragments, 120 plasmids with longer amplified fragments were selected and sequenced. Sequence data of 80 plasmids were obtained. A total of 71 genes were obtained after the duplication was removed (*Table 3*). The information about the sequences includes query coverage, percentage of identity, accession number, species and domain description. Information about 51 of these genes is known. Domain functions of some genes are related to Aldo/keto reductase family, EPSIN1, Zinc finger B-box type profile, Serine/Threonine, protein kinases active-site signature, AGD5, TPR repeat profile, NAF domain profile, AP2/ERF domain profile, Myb-type HTH DNA-binding domain profile, BARE-2, SAC9, Leucine-rich repeat profile, HEAT repeat profile, UBX domain profile, GRAS family profile, autophagy-related protein 7c (ATG7c), delta-1-pyrroline-5-carboxylate synthase, MO25-like protein and so on (*Table 3*). Information about 20 of these genes is unknown.

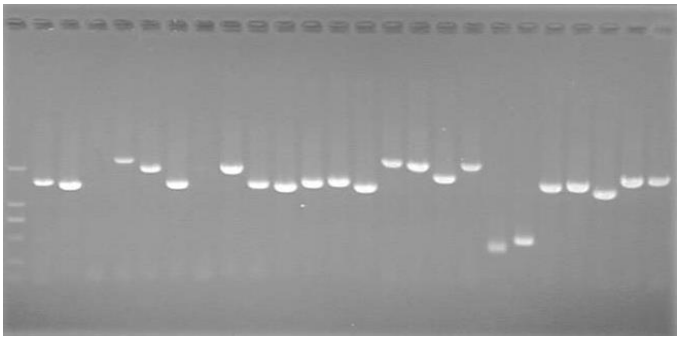

Figure 2. *The PCR results of liquid bacterial germ in the cDNA library*

Construction and self-activation detection of recombinant vector of decoy protein

RT-PCR was used to obtain a fragment size close to 500 bp, which was consistent with the expected fragment size (*Fig. 3A*). After sequencing, the size was confirmed to be 477 bp, which was found to be consistent with *TaRHA2b* gene sequence of wheat by sequence blast. The enzyme digestion results of decoy vector pGBKT7-*TaRHA2b* were shown in *Figure 3B*. After plasmid sequencing, sequence blast was compared and found to be consistent with the *TaRHA2b* gene sequence of wheat, indicating that *TaRHA2b* fragment was correctly integrated into the polyclonal site of pGBKT7 vector.

Yeast strains AH109 on SD/-Leu/-Trp/-Ade/-His medium did not grow after 3-5 d (*Fig. 3C*). This indicated that the yeast strain AH109 had no phenotypic mutation in the secondary culture. The experimental group, positive control group and negative control group grew on the SD/-Leu/-Trp medium (*Fig. 3D*). The positive control grew on the SD/-Leu/-Trp/-His/-Ade medium, but neither the experimental group nor the negative control grew on the SD/-Leu/-Trp/-His/-Ade medium (*Fig. 3E*). The results show that the decoy carrier pGBKT7-*TaRHA2b* has no self-activation function.

cDNA library was screened by decoy protein pGBKT7-RsRHA2b

A total of 1000 plasmids of a pair of transgenic yeast AH109 cells were tested (*Fig. 4A–C*), and the preliminary positive plasmids were 84 and 49 were effectively sequenced, all of which were analyzed by bioinformatics (*Table 4*). The information about the sequences includes query coverage, percentage of identity, accession number, species and domain description. The RHA2b interacting proteins include RGA, MYB, SF2, USP1, Lks2, Rp120, SBE starch branching enzyme, RPR44, TUDOR1, TEF1, auxin response factor 12, Hox-1, CBF9, TIP1, AP2/EREBP, MYB and ARF GTPase activator (*Table 4*).

The focus of the present research was plasmids in the following codes: 311, 611, 1065, 2433, 2437, 2438, 2443, 2449, 2450, 2456, 2457, 2475, 2476, 2496, 2708, 3019. In the process of in vitro and in vitro verification of yeast two-hybrid candidate proteins, 8 of them were finally selected, with codes 2449, 2450, 2456, 2457, 2475, 2476, 2496, 2708.

A pair of positive plasmids were co-transformation for in vitro validation

pGADT$_7$-*YTH2450* and pGBKT$_7$-*TaRHA2b* were co-transformed into yeast AH109 cells and then cultured on SD/–Trp–Leu–His–Ade medium for 3d (*Fig. 5*). The results showed that YTH2450 and RHA2b had a strong interaction.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1310513124

The primers were designed according to the homologous sequences obtained by bioinformatics analysis of *YTH2450*. The obtained plasmid pMAL-*YTH2450* was sequenced. After bioinformatics analysis has determined that the fragment is correct, subsequent operations can be carried out. The final pMAL-*YTH2450* recombinant plasmid and its enzyme digestion identification results showed that it was correct (*Fig. 6A*). PCR was performed on the bacterial solution containing *pLEICS-TaRHA2b* plasmid, and the results were shown in *Figure 6B*. The size of the target fragment was consistent with the expectation. Sequencing was performed, bioinformatics analysis was performed to determine the correct fragment, and subsequent operations were carried out.

The size of the expressed protein was about 75.0 KDa, which was consistent with the expected size of 75.0 KDa, indicating the successful expression of prokaryotic protein (*Fig. 6C*). The size of the expressed protein was about 63.0 KDa, which was consistent with the expected size of 63.0 KDa, indicating the successful expression of prokaryotic protein (*Fig. 6D*).

GST-*TaRHA2b* was fixed to Glutathione-Sepharose4B column and GST (inducing expression of empty vector pLEICS-14) was fixed as negative control. After repeated washing, SDS-PAGE analysis was performed. YTH2450 can bind specifically to GST-TaRHA2b (swim lane 1), but not to negative control GST (swim lane 2) (*Fig. 6E*). It indicates that there is an interaction between TaRHA2b and YTH2450 in vitro.

Discussion

The development of cDNA library technology provides an important tool for functional genome research (Shao et al., 2009). At present, cDNA libraries are widely used in the research of model organisms and important crops, including tobacco, peanut and soybean (Ke et al., 2011; Cai et al., 2007). cDNA libraries provide information that reflects the level of gene expression at the RNA level. There are not many studies on the cDNA library of barley, and the construction of the cDNA library based on the embryo of barley treated by ABA treatment has not been studied. This project aims to explore the specific regulatory network of *TaRHA2b* gene in ABA signal transduction pathway and study the interaction between proteins. The yeast two-hybrid technique is the first choice. The construction of high-quality homogeneous cDNA library is the basis of subsequent experiments. Homogenization can ensure the existence of low-abundance mRNA as far as possible, which is necessary for the successful construction of cDNA library. In SMART technology, LD PCR method is adopted to obtain dscDNA, which

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1310513124

can obtain longer fragments as far as possible, fully reflecting the integrity of mRNA (Schuler, 1997; Wellenreuther et al., 2004). In this experiment, the homogeneous cDNA library was constructed with a capacity of 1.1 10^6. Random clone sequencing results showed that the fragment size was within the range of 1000-3000 bp. The storage capacity requirement of cDNA library is above 1.7 10^5 (Thanh et al., 2011). Only when this standard is reached, the low abundance mRNA can be well processed and the constructed library can be used for the yeast two-hybrid screening library experiment.

In the present study, the yeast AH109 was deficient in the synthesis ability of Leu, Trp, His and Ade. The synthesis of Leu and Trp was remedied when the plasmid was transformed into yeast. As for His, there is a possibility of background expression in yeast. However, it was found that AH109 could not grow in the SD/-His medium without 3-AT in the defect validation experiment on yeast. Therefore, 3-AT was not added in this experiment. In this experiment, the decoy vector pGBKT$_7$-TaRHA2b for yeast two-hybrid system was successfully constructed. The decoy vector can be expressed normally in yeast without toxicity. It is proved that it has no self-activation in the system.

Yeast two-hybrid screening consists of two methods. The first method was to screen AH109 by co-transposing decoy protein granules with ds cDNAs. Although this method is simple, the library can only be used once and it is difficult to screen the interacting proteins. The second was screened by conjugation of two inverters, including Y187 yeast inverter containing decoy protein and AH109 yeast inverter containing pGADT$_7$-Rec and ds-cDNAs. The operation of this method is complex. In this experiment, a pair of total transformed yeast AH109 was used. If positive interaction was confirmed, specific plasmids could be directly corresponding. The follow-up operation is more efficient.

Using the protein expressed by the limited PHS resistance gene *RHA2b* as bait, we screened some corresponding fragments of TaRHA2b-related proteins by yeast two-hybrid technology, which not only has important significance in searching for new PHS resistance genes, but also provides new information for studying the mechanism of TaRHA2b-mediated PHS resistance.

The interaction between TaRHA2b and interacting proteins was fully demonstrated by positive clones identification, sequencing, verification of the pair of repeated co-transformation and GST-pull down.

These conclusions lay a foundation for studying the interaction and mechanism of TaRHA2b/YTH2450, TaRHA2b/YTH2456 and TaRHA2b/YTH2476 in the stress tolerance pathway of wheat. The complex formed by yeast hybrid candidate proteins and TaRHA2b may act on different signal transduction pathways. Bioinformatics analysis showed that the function of YTH2450 may be malate/ketoglutarate transporter, the function of YTH2456 may be RACD protein, and the function of YTH2476 may be TIP1 protein.

TaRHA2b is a protein of the type of transcription factor positively regulated by ABA signal transduction, which is essentially an ubiquitinated ligase and mainly participates in the process of protein degradation in cells. RHA2b targeted MYB30 degradation to regulate ABA signal transduction (Zheng et al., 2018).

Ketoglutaric acid/malate transporter was involved in the tricarboxylic acid cycle. The present study showed a strong interaction between ketoglutarate/malate transporter and TaRHA2b. The process of ubiquitination involves the formation of multiple complexes and changes in energy metabolism. α-ketoglutarate carrier protein (OGCP), located on

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1310513124

mitochondria, encodes 314 amino acids and has the following important functions: scavenging endogenous oxygen free radicals in mitochondria and participating in cellular energy metabolism (De Palma et al., 2010; Regalado et al., 2013). These results indicated that the complex formed by ketoglutarate transporters and TaRHA2b could be involved in ABA signal transduction.

RAC/ROP involved in plant (ROP) family is related to small molecule G protein, which is a molecular switch of signal transduction in many cells, regulating the development process of cells and the response to the environment. RAC/ROP has three conformations, including an active GTP binding state, a transient free state, and a GDP bound state. In the active GTP binding state, RAC/ROP interacts with effector proteins to initiate downstream signaling (Haitina et al., 2006). These results indicate that the complex formed by RAC/ROP and TaRHA2b can activate the downstream signal and then play a role in a specific pathway.

TIP1 protein is a water channel protein, which can theoretically be expressed in all tissues, but the expression amount is not the same (Wudick et al., 2009). Therefore, in response to ABA, an abiotic stress, or in the climate where spikelet germination occurs, it is very likely that the complex formed by TIP1 and RHA2b participates in these regulatory pathways. These results lay a foundation for further study on the interaction and mechanism of TaRHA2b and protein-protein interaction in wheat stress resistance pathway.

Conclusion

The information of cDNA library lays a foundation for the discovery of stress resistance genes. TaRHA2b interact with YTH2450 and other proteins. The TaRHA2b interacting proteins could be used for genetic improvement of crops, further improving the adaptability of crops to the environment. The detailed regulatory mechanism mediated by TaRHA2b and interacting proteins needs to be further studied.

Abstract. Tobacco (*Nicotiana tabacum* L.) can accumulate higher concentrations of cadmium (Cd). However, genotypic differences of tobacco cultivars in Cd uptake and their responses to Cd toxicity have not been thoroughly investigated. This study was conducted to determine the resistance of four tobacco cultivars to Cd toxicity under greenhouse conditions. Four doses of Cd (0, 5, 10 and 20 mg kg^{-1} soil) were used to test the resistance of tobacco cultivars. Increasing the Cd applications significantly ($P < 0.01$) decreased the shoot dry matter yields of genotypes, while shoot Cd concentration and content significantly ($P < 0.01$) increased. The highest decrease in dry matter under the highest Cd (Cd20) treatment was in Özbaş (58.5% reduction), Birlik/124 (52.4% reduction) and Canik190/5 (51.1% reduction) cultivars, while the lowest decrease was in Xanthi/81 (44.6% reduction) cultivar. The amount of Cd removed from soil was significantly different among the tobacco cultivars. The highest Cd uptake was obtained in Cd20, while the lowest was in Xanthi/81 (395.2 µg Cd $plant^{-1}$) and Canik190/5 (232.6 µg Cd $plant^{-1}$) cultivars, respectively. The results revealed that Canik190/5 cultivar removes lower Cd compared to the other cultivars, whereas Cd uptake of Xanthi/81 cultivar is higher, thus is considered more resistant to Cd toxicity than other cultivars.

Introduction

Cadmium (Cd), having a toxic effect on all living organisms, is one of the most dangerous heavy metal pollutants in the ecosystem (Mishra et al., 2019). The major sources of Cd in soils are geological parent material and inputs from human activities. Extraneous sources of cadmium are phosphorus fertilizers (54 to 58%), atmospheric storage (39 to 41%) and sewage sludge and farm manure applications (2 to 5%) (Cheng et al., 2014). The Cd uptake ratio of plants is high, due to its high-water solubility and mobility in soil compared to the other metals. Therefore, Cd is considered to be the most dangerous heavy metal accumulated in soils. The Cd causes many physiological changes due to changes in nitrogen and carbohydrate metabolism in plants. Cadmium inactivates the enzymes in -SH groups of proteins, closes stomata, causes water loss by transpiration and deterioration of chlorophyll biosynthesis (Sharma et al., 2019). The severity of heavy metal stress of plants varies depending on the environmental factors and the growth stage of plants (Stolt et al., 2003). The Cd resistance, uptake and transport of Cd in plant significantly vary among plant species. Grant et al. (1998) indicated that Cd concentrations of wheat, pea, maize and tobacco grown in the same solution culture were considerably different, and wheat contained lower Cd

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1312513134

concentration than the others. The magnitude of Cd accumulation and location of Cd in plants are major determinants of the plant resistance to Cd toxicity (Obata and Umebayashi, 1993; Quezada-Hinojosa et al., 2015). The responses of plant species and even between cultivars of a particular species to Cd toxicity considerably differ due to the prominent genetic variability among the different cultivars. The results reported by Erdem et al. (2012, 2017) for tobacco, Socha et al. (2015) for soybean, Wang et al. (2016) for maize, Zhang et al. (2002) for wheat and Zorrig et al. (2019) for lettuce clearly point out the effects of genetic variation in Cd uptake of plants. Several metal-tolerance mechanisms were introduced to explain the responses minimizing the adverse effects of heavy metal exposure. The Cd immobilization at the cell wall is the first prevention mechanism to prevent from excess Cd effect (Rizwan et al., 2016). Preventing the penetration of Cd into the cytosol, complexation of Cd with peptides or proteins to form phytochelatins and metallothioneins, compartmentalizing of Cd within vacuoles, and improving the antioxidative defense systems are major causes defined to explain the Cd detoxification in plants (Kirkham, 2006). Tobacco is one of the most common substances consumed for pleasure in the world. However, smoke of tobacco products is the most prevalent means of Cd reception of human, especially for smokers (Willers et al., 2005). Tobacco is known as an efficient Cd accumulator (Lugon-Moulin et al., 2004). Therefore, studies on investigating the effects of different Cd concentrations on Cd uptake of the commonly grown tobacco cultivars are needed. Determining the genetic variation of tobacco cultivars in Cd accumulation and uptake mechanisms are also important for the plant breeders. Research, particularly, focusing on metal uptake of international and local commercial tobacco cultivars used for tobacco products is missing.

This study was carried out to investigate the effects of different Cd concentrations on the growth of various tobacco cultivars, to determine the responses of tobacco cultivars in terms of Cd concentration and uptake, and to comprehend the interactions between Cd and Fe, Zn, Cu and Mn in tobacco plants.

Materials and methods

Materials

A pot experiment using Özbas, Canik190/5, Xanthi/81 and Birlik/124 tobacco cultivars was carried out at the greenhouse in Gaziosmanpasa University, Tokat, Turkey. Some characteristics of the genotypes used in the experiment are given in *Table 1.* The soil, used in the pot experiment was sandy loam, high in $CaCO_3$ content (11.8%), slightly alkaline in pH (8.01), low in organic matter content (0.89%) and Zn concentration (0.38 mg kg^{-1}), sufficient in Fe, Mn and Cu concentrations (6.65, 3.97 and 1.98 mg kg^{-1}), respectively), and low in Cd concentration (0.004 mg kg^{-1}).

Table 1. *Some characteristics of tobacco genotypes used in the experiment (Peksüslü, 1998)*

Genotypes	Flowering	Plant height (cm)	Number of leaves	Quality degree
Özbaş	Medium late	60-85	35-40	Medium
Canik190/5	Early	75-95	32-35	Medium
Xanthi/81	Medium late	65-105	30-32	High
Birlik/124	Medium late	85-125	40-44	High

Methods

Experiment

Greenhouse experiment was carried out in Field Research Centre of Tokat Gaziosmanpasa University located at 40°20'02.19"N latitude and 36°28'30.11"E longitude and 623 m above sea level, Tokat Province in middle Black Sea region of Turkey. The pot experiment was laid in a randomized plot design with three replications. Tobacco seedlings in a 4-leaf stage were transferred to the plastic pots filled with 2.75 kg sandy loam soil. Air-dried soil, prior to filling the pots, was homogeneously mixed with a fertilizer solution containing 250 mg N kg^{-1} soil as $Ca(NO_3)_2.4H_2O$, 100 mg P kg^{-1} soil as KH_2PO_4, 2.0 mg Fe kg^{-1} soil as Fe-EDTA and 2.0 mg Zn kg^{-1} soil as $ZnSO_4.7H_2O$. The treatments were control (Cd0), 5.0 (Cd5), 10 (Cd10) and 20 (Cd20) mg Cd kg^{-1}, and each treatment was replicated three times. The Cd was applied as a solution containing $3(CdSO_4).8H_2O$. Pots were watered as needed using deionized water. At 42 days after the transplanting of seedlings, leaves were harvested when the Cd toxicity symptoms (decline in growth and chlorosis in leaves) were observed (*Fig. 1*). The leaves were dried in an oven at 70 °C till constant weight. Dry weights (DW) of leaves were expressed as g DW of plants. Dried plant materials were powdered and then digested in a microwave oven using 2 ml of 35% H_2O_2 and 5 ml of 65% HNO_3. The Cd, Fe, Zn, Cu, and Mn concentrations were determined by inductively coupled plasma atomic emission spectroscopy (Varian Vista) (Bataglia et al., 1978). The Cd content of plant material was calculated by multiplying the dry weight of shoot by the concentration of Cd. The measurements of the metal concentrations were cross-checked by using the reference leaf samples of the National Institute of Standards and Technology (Gaithersburg, MD, USA).

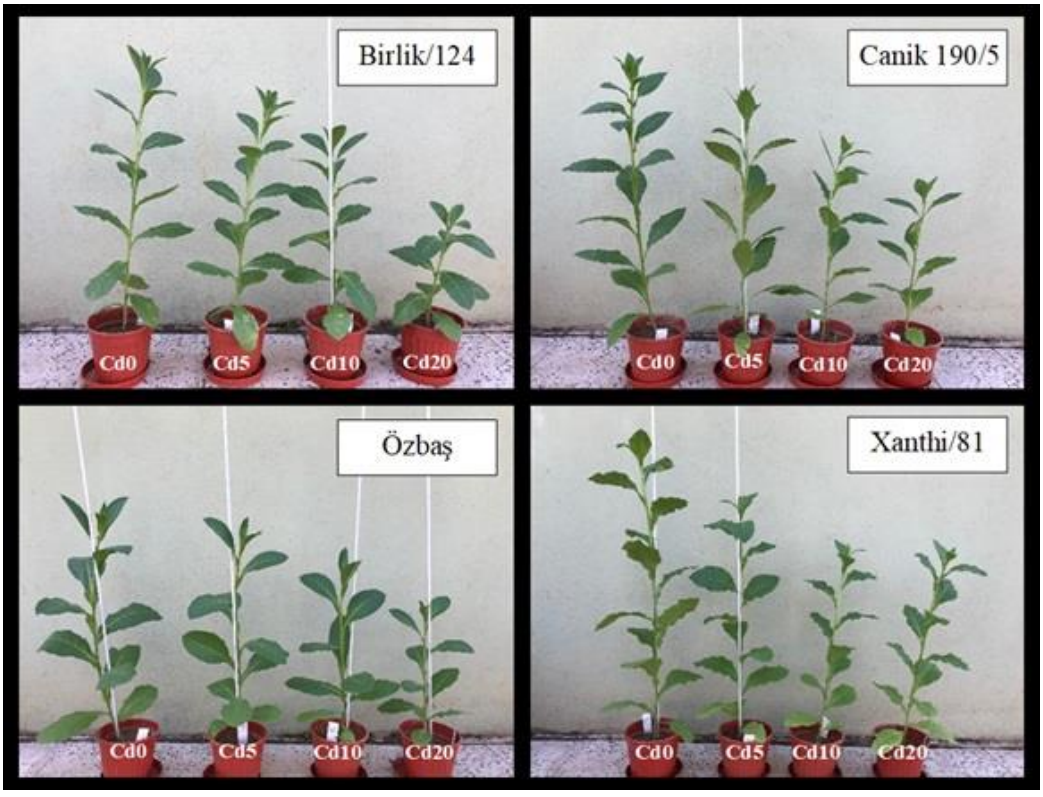

Figure 1. *Effects of increasing doses of cadmium on tobacco genotypes*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1312513134

Statistical analyses

Analyses of variance (ANOVA) were performed to test the Cd dose effects on element concentrations and content of four different tobacco cultivars and on dry matter yield. The means were compared with Duncan's homogeneity test to determine whether the average concentrations and content of tobacco grown in the treated pots differed from those of tobacco grown in the control pots. The dose effect was considered significant when the P-value lower than 0.05. The statistical analyses were performed using the MSTAT-C statistical software.

Results and discussion

Effect of cadmium on shoot dry matter yield, Cd concentration and Cd content

The increasing Cd doses significantly ($P < 0.01$) reduced the shoot dry matter yield of four tobacco cultivars (*Table 2*). The highest decrease in dry matter yield with increasing Cd dose was observed in Özbaş, Birlik/124, and Canik190/5 cultivars respectively, and the lowest was in Xanthi/81 cultivar. The dry matter yield of Özbaş cultivar in control treatment (0 mg Cd kg^{-1}, Cd0) was 6.90 g $plant^{-1}$ which reduced to 2.87 g $plant^{-1}$ (58.5% reduction) with Cd20 application, whereas dry matter yield of Xanthi/81 cultivar was 7.63 g $plant^{-1}$ under Cd0 and decreased to 4.23 g of $plant^{-1}$ (44.6%) with Cd20 treatment (*Table 2*). The results of dry matter yield revealed that the Xanthi/81 is the least affected genotype from Cd toxicity. In a similar study conducted under greenhouse conditions testing five Cd doses (0, 100, 200 and 300 ppm) using 17 different tobacco cultivars, dry matter yields of cultivars significantly decreased with increasing Cd doses. However, the decrease in dry matter yield was significantly different among genotypes. The highest decrease in dry matter yield was reported in Connecticut (21% reduction), Drama (19% reduction), Myrodata Agryniou (18% reduction) and Katerini 53 (5% reduction) genotypes respectively, while the lowest decrease was obtained in Katerini 53 (5% reduction) and Argyroudis genotypes (Vasiliadou and Dordas, 2009).

Erdem et al. (2017) reported a significant decrease in dry matter yield of Xhanti 2A tobacco cultivar with increasing Cd doses (0, 10 and 20 mg Cd kg^{-1}). Dry matter yield in Cd20 (1.48 g of $plant^{-1}$) treatment was 47.5% lower compared to the control (2.82 g $plant^{-1}$). In another study conducted with maize, a significant decrease in shoot dry matter yield was reported with increasing Cd doses. The reduction in shoot dry matter yield was 11.9% with 10 mg Cd kg^{-1} and 23.5% with 20 mg Cd kg^{-1} treatment (Khurana and Jhanji, 2014). The decrease in dry matter yield with Cd treatment was attributed to the phytotoxic effect of Cd (Pereira et al., 2011). Cadmium toxicity negatively affects the photosynthesis of plants by inhibiting the activities of photosynthetic enzymes involved in Kalvin cycle and chlorophyll biosynthesis and consequently results in a decrease in dry matter yield (Sun et al., 2017).

Cadmium can be easily transferred to the green parts of plants following the taken up by roots. The mobility of Cd in soils is higher than other heavy metals (Mn, Zn, Mo and Se), thus can be easily taken up by many plant species (Moral et al., 2002). Therefore, a positive relationship was often reported between the increasing doses of Cd application and shoot Cd concentration and content. Shoot Cd concentrations and content of four tobacco cultivars were significantly ($P < 0.01$) increased with increasing Cd application to the soil (*Table 2*). The lowest shoot Cd concentration under Cd20 treatment was obtained for Canik190/5 (79.8 mg kg^{-1}) and the highest Cd concentration was for Özbaş (117.5 mg kg^{-1}) cultivars (*Table 2*).

**p < 0.01, *p < 0.05, ns: non significant; small letters: differences in genotypes in terms of cadmium doses; capital letters: differences between genotypes

The Cd uptake and accumulation considerably differ between plant species and genotypes of the same species (Grant et al., 1998). The differences in Cd uptake and accumulation among plant species are considered as the main factors in determining plant tolerance to Cd toxicity (Obata and Umebayashi, 1993). The results indicated that the Cd uptake of plants significantly different between the cultivars used in the experiment. The highest Cd uptake (395.2 µg plant^{-1}) at Cd20 dose was in Xanthi/81 cultivar and the lowest was in Canik190/5 (232.6 µg plant^{-1}) (*Table 2*).

The results of shoot Cd concentration and content revealed that Cd uptake of Canik cultivar is lower than the other tobacco cultivars. On the other hand, the resistance level of Xanthi/81 cultivar to Cd toxicity is considered higher compared to the other three tobacco cultivars due to the lower decrease in dry matter yield and higher Cd uptake under the increased Cd application doses *(Table 2; Fig. 2)*. The Cd resistance of Xanthi/81 cultivar could be related to the detoxification of heavy metals. Similar to the finding of the current study, many studies have indicated that most of the plant species are capable of tolerating high Cd concentrations in soil (Mench et al., 1989; Cieśliński et al., 1998; Rizwan et al., 2016). Plants can build up tissue tolerance at different levels when exposed to high Cd concentration. Khan et al. (1984) reported that Cd accumulates in the cell wall, whereas Vazquez et al. (1992) reported that Cd accumulates in the vacuole in a study conducted with bean plants.

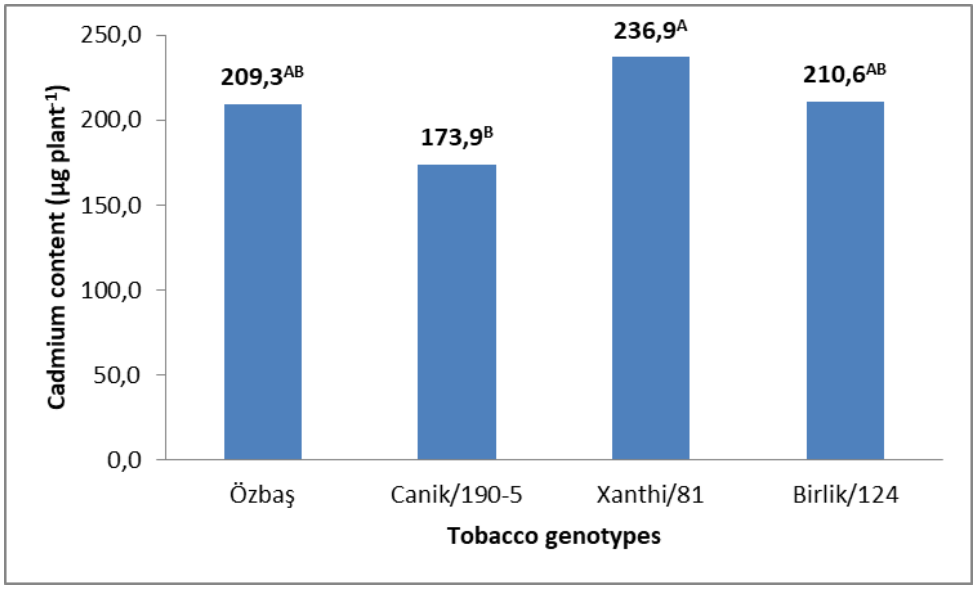

Figure 2. *Average cadmium content (µg Cd plant^{-1}) of tobacco genotypes*

Effect of cadmium on shoot Zn, Fe, Mn and Cu concentrations

Interaction of Cd with mineral nutrients (especially microelements) is an important effect of Cd toxicity in plants. The increasing Cd application dose to soil caused a decrease in the shoot Zn concentrations of 4 different tobacco varieties (*Table 3*). The decreases in shoot Zn concentration were insignificant for Canik190/5 and Birlik/124 cultivars, while it was significant ($P < 0.01$) for Özbaş and Xanthi/81 cultivars. The Zn concentration of Xanthi/81 cultivar under Cd0 dose was 108.2 mg kg^{-1}, which decreased to 74.5, 68.7 and 66.8 mg kg^{-1} at Cd5, Cd10, Cd20 doses, respectively. Vasiliadou and Dordas (2009) reported that increasing Cd application doses resulted in statistically significant reductions in shoot Zn concentrations (-0.542 ***) of 17 different tobacco cultivars. The decrease in Zn concentrations under increasing Cd doses may be linked to the antagonistic relationship between Cd and Zn. Higher Cd uptake of plants grown under Zn deficiency can be attributed to the competition of Cd and Zn, which have similar chemical properties, for absorption points on the membrane (Cakmak et al., 2000) and, increase in the membrane permeability (Cakmak and Marschner, 1988).

The shoot Fe concentrations of 4 different tobacco cultivars decreased with increasing Cd doses. The decrease was statistically significant in Canik190/5 while it was insignificant in the other three cultivars (*Table 3*). The Fe concentration of Canik190/5 cultivar was 64.8 mg kg^{-1} under control treatment, which decreased to 55.3, 54.8, and 57.4 mg kg^{-1} with Cd5, Cd10, and Cd20 treatments, respectively. Significant increases and decreases occurred in shoot Mn concentrations of the cultivars with Cd application. However, shoot Cu concentrations of all cultivars, particularly in the Cd10 and Cd20 treatments, decreased with Cd application (*Table 3*).

For example, shoot Cu concentration in Cd0 dose was 6.71 mg kg^{-1}, which decreased to 6.56 in Cd5, while increased to 28.7 and 25.9 mg kg^{-1} in Cd10 and Cd20 doses, respectively (*Table 3*). Erdem et al. (2012) reported that the increasing doses of Cd resulted in a statistically significant ($P < 0.05$) increase in shoot Cu concentration of tobacco plants. The results pointed out the importance of Cu absorption and/or translocation to the shoots, in contrast to the other essential micronutrients, under the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1312513134

high concentration of Cd in the root zone. In addition, shoot Cu concentrations of all tobacco cultivars used in the experiment were not affected by Cd5 treatments, whereas Cd10 and Cd20 treatments significantly affected the shoot Cu concentrations. Ramos et al. (2002) reported that increasing doses of Cd caused a decrease in shoot Fe, Zn and Cu concentrations of lettuce plants grown under the water culture conditions, while an increase in Mn concentration. The results indicated a general decrease in the Zn, Fe and Mn concentrations of tobacco plants with increasing the doses Cd application to soils. This situation reveals that the most important cause of the decrease in ion uptake of plants grown under Cd stress is the prevention of root growth and development due to damage of plant roots under Cd toxicity (Rizvan et al., 2016).

Conclusions

Cadmium pollution in soils is a worldwide serious problem for sustainable agriculture and human health (Dumat et al., 2019). This study presents novel information about the effects of toxic Cd doses on the growth of tobacco cultivars, the amount of Cd uptake from the soil, and uptake of microelements. Shoot dry matter yields of tobacco cultivars significant (P < 0.01) reduced with the increasing doses of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1312513134

Cd application to soil. The greatest reduction has occurred in Özbaş, Birlik/124 and Canik190/5 cultivars, while the lowest was in Xanthi/81 cultivar. The Cd concentration and content of shoots significantly ($P < 0.01$) increased with the increase in Cd doses. The Xanthi/81 taken up the highest Cd concentration from soil under the highest Cd treatment (Cd20), while Canik190/5 cultivar removed lower Cd from soil compared to the other cultivars. The Cd treatments resulted in a decrease in shoot Zn and Fe concentrations of tobacco cultivars, while increases and decreases occurred for Mn concentrations. The Cu concentration of shoots significantly increased in Cd10 and Cd20 treatments. The results revealed that Canik190/5 cultivar uptakes lower Cd from the soil compared to the other three tobacco cultivars. In contrast, Xanthi/81 cultivar uptakes higher Cd from the soil, thus considered more resistant to Cd toxicity than other tobacco cultivars. The data obtained will contribute to the basic knowledge needed for further research on the genetic and biochemical basis of cadmium uptake of tobacco genotypes.

Conflict of interests. The authors have not declared any conflict of interests.

Abstract. Bacteria that are not identified by utilizing automated and manual systems can be identified precisely using 16S rRNA gene sequencing. It can also be used to characterize previously undescribed species. In the present study, the experiment entailed 16S rRNA sequencing of bacteria isolated from thalassemia patients in Erbil, Iraq. Samples were obtained from thalassemia patients from different sources. The bacteria were first identified by biochemical and Vitek method, and finally, the 16S rRNA of 78 clinical bacteria were amplified by PCR and sequenced. The results of the sequencing methods performed on the clinical bacteria identified the isolates as 5 genera and 7 species: *E. coli*, *P. aeruginosa*, *K. oxytoca*, *K. pneumoniae*, *M. morganii*, *E. fergusonii,* and *Pantoea sp*. The results show that the most common causative organism was *E. coli*, and the most common site of infection was found to be the urinary tract. The results demonstrated the significance of 16S rRNA sequencing in accurate identification bacteria and understanding the bacterial diversity. Given the advantages of 16S rRNA sequencing method including cost-effectiveness, availability, and convenience, and it would be worthwhile to integrate it into clinical practice in developing countries.
Keywords: *E. coli, microbial identification, VITEK 2, 16S rRNA gene, phylogenetic analysis*

Introduction

As a severe genetic blood disorder that results from a mutation in the globin gene, thalassemia causes excessive destruction of red blood cells. Its prevalence has been reported to be high among populations in Southeast Asia, Africa, and the Mediterranean region. Given the severity of its clinical presentation, thalassemia syndrome has been classified into 3 subgroups: thalassemia minor, thalassemia intermediate, and thalassemia major. Patients with thalassemia major have been the focus of most studies of bacterial infections (Vichinsky, 2005; Weatherall, 2012). According to the estimations, Beta-thalassemia afflicts more than 42000 newborns every year all over the world. If the patients are not treated, for example through blood transfusion, Beta-thalassemia major (TM) causes the infected children to die before they are 3 years old (Modell and Darlison, 2008).

As major complications and the second most frequently reported cause of mortality, infections have been referred to as the main cause of death in patients with thalassemia. A range of immune abnormalities, splenectomy, iron overload, and severe anaemia are the predisposing factors for infection in patients with thalassemia. *Yersinia enterocolitica* in western countries and *Klebsiella* spp in Asia have been introduced as the major causative organisms of bacterial infections in thalassaemic patients (Vento et al., 2006). The most common bacterial infections in thalassaemic patients are liver abscesses, septicaemia, soft tissue infection, biliary tract infection, and pneumonia, while the most frequently isolated bacteria are reported to be *Yersinia enterocolitica*, *Salmonella typhi*, *Streptococcus*

DOI: http://dx.doi.org/10.15666/aeer/1706_1313513146

pneumoniae, *Escherichia coli*, *Klebsiella pneumoniae*, and other gram-negative bacteria (Aswapokee, 1988; Issaragrisil, 1988; Peng et al., 2000; Wanachiwanawin, 2000; Li et al., 2001; Chung et al., 2003; Wang et al., 2003). Yet, no studies have been carried out on bacterial infections in patients with thalassemia in the Kurdistan Region of Iraq.

Biochemical techniques and traditional culture are still the major methods in clinical microbiology laboratories to identify most pathogens. However, as technology has developed more than ever, many laboratories have adopted automated microbiology systems for the purpose of identifying pathogens. In recent years, there have been more reports on severe infections among patients. In most laboratories, the automated biochemical text platforms can be utilized to identify a number of clinical isolates from such patients. However, identifying some isolates is difficult through those platforms (Cheng et al., 2014). Currently, precise and fast identification of infectious agents is referred to as one of the main challenges for public health surveillance and clinical practice. Even the presence of a pathogen is usually vague in the setting of clinical syndromes like sepsis because causative agents are cultured in less than half of these cases (Martin et al., 2003), which leads to treating a large number of patients empirically. In addition, as indicated by several studies, patient outcomes, especially in the intensive care unit setting, can be significantly improved by appropriate, rapid, and adequate antibiotic treatments, moreover, it has been stated that patient mortality increases by 2 folds in the absence of such treatments (Iregui et al., 2002; Shorr et al., 2011). Therefore, molecular methods for bacterial identification are highly recommended.

Complete sequencing of the genome of some bacteria has been performed since automated DNA sequencing and polymerase chain reaction (PCR) were invented. As revealed by comparing the genomic sequences of bacterial species, the 16S ribosomal RNA (rRNA) gene is strongly conserved within a species and among species of the same genus; therefore, it can be utilized as a novel gold standard for specifying bacteria (Woo et al., 2000). The 16S rRNA gene sequences are very useful to study bacterial taxonomy and phylogeny. Over time, the function of the 16S rRNA gene has not changed despite the presence of the gene in almost all bacteria, often existing as a multigene family or operons, which suggests the fact that time is more accurately measured through random sequence changes, and the 16S rRNA gene (1500 bp) is large enough for informatic purposes (Patel, 2001). It has been stated that applying molecular approaches for clinical diagnosis has numerous advantages, including ease of specimen processing, speed, and sensitivity, over standard microbiological techniques. This has been proved to be useful to identify both fastidious, unusual and slow-growing bacteria and rare bacteria that have ambiguous profiles, which cannot be differentiated correctly by conventional methods (Sun et al., 2005; El Bakkali et al., 2013).

The present study was carried out in order to identify gram-negative bacteria in patients with thalassemia by employing 16S-rRNA gene sequencing and to compare 16S rRNA gene sequencing and non-16S based clinical methods (automated and phenotypic identification methods) regarding their identification accuracy.

Materials and methods

Clinical isolates

Specimens were retrieved form 160 thalassemia patients (85 females and 75 males) who referred to thalassemia center in Erbil province, Iraq. The records of total patients were reviewed, and bacterial infections were observed in 78 patients (48.75%). The 78

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1313513146

isolates were collected in various sources: urine cultures, buccal cavity specimens, ear specimens, and blood cultures over two years period from June 2016 to September 2018. In general, the isolates were represented the most common Gram-negative bacterial pathogens.

Culture-based and automated identification of clinical isolates

The isolates that were obtained from the thalassemia center had undergone culture and sub-culture on relevant selective media, which include MacConkey agar, Eosin methylene blue agar, Cetrimide agar and Xylose lysine deoxycholate. Afterwards, in order to provide a final culture-based identification, clinical microbiology laboratory protocols were utilized to test their biochemical profile (Collee et al., 1996; Atlas, 2010). Then, the isolates identified by automated microbiology system using the VITEK2 compact system (BioMerieux, France).

16S rRNA-based molecular identification of clinical isolates

The full length of 16S rRNA of all 78 bacterial strains was sequenced. From those 78 isolates, some bacteria had not been identified clearly by VITEK2 method or phenotypic methods. Therefore, 16S rRNA sequencing was utilized to identify the bacterial isolates with high confidence.

Genomic DNA preparation

Presto^{TM} Mini gDNA bacterial kit was used to isolate genomic DNA. The samples were stained with safe stain and run on 0.8% agarose gel. The presence of genomic bands in the gel was examined under UV light (*Fig. 1*). The DNA was stored at -20 °C until it was used for the PCR amplification.

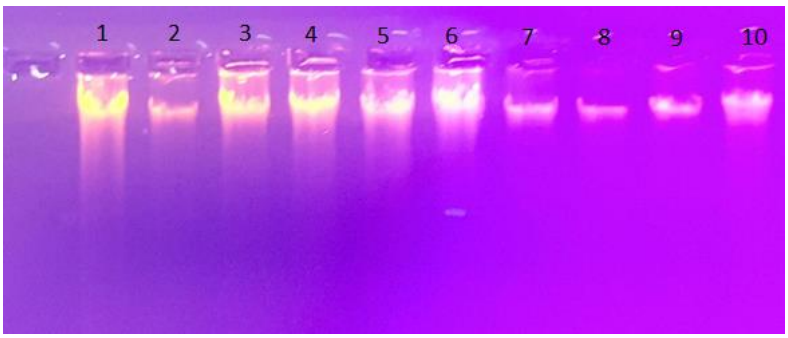

Figure 1. *Bacterial genome of 10 isolates in agarose gel electrophoresis*

Amplification of 16S gene

Universal primers 1492R (1) (5′- GGTTACCTTGTTACGACTT -3′) as reverse primer and 8F (5′- AGAGTTTGATCCTGGCTCAG -3′) as forward were used to carry out PCR for the amplification of the 16S rRNA gene (Turner et al., 1999). All reactions of PCR were conducted by utilizing 2 µl DNA template (density of 10 ng/µl), the Master Mix consisting of 3 mM $MgCl_2$, 0.2% Tween® 20, 20 mM Tris-HCl pH 8.5, $(NH_4)2S0_4$, 0.2 units/µl Ampliqon Taq DNA polymerase, 0.4 µM of each primer, and 0.4 mM of each dNTP. The conditions of PCR included primary denaturation at 95 °C

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1313513146

for 5 min, followed by 35 cycles at 95 °C for 45 s, at 55 °C for 45 s, and at 72 °C for 90 s, and a last extension at 72 °C for 6 min. After safe staining, the product of the reaction was visualized under UV light on a 1% agarose gel (Sambrook et al., 2001; *Fig. 2*). The PCR products were used for sequencing the 16S rRNA of all 78 bacterial isolates.

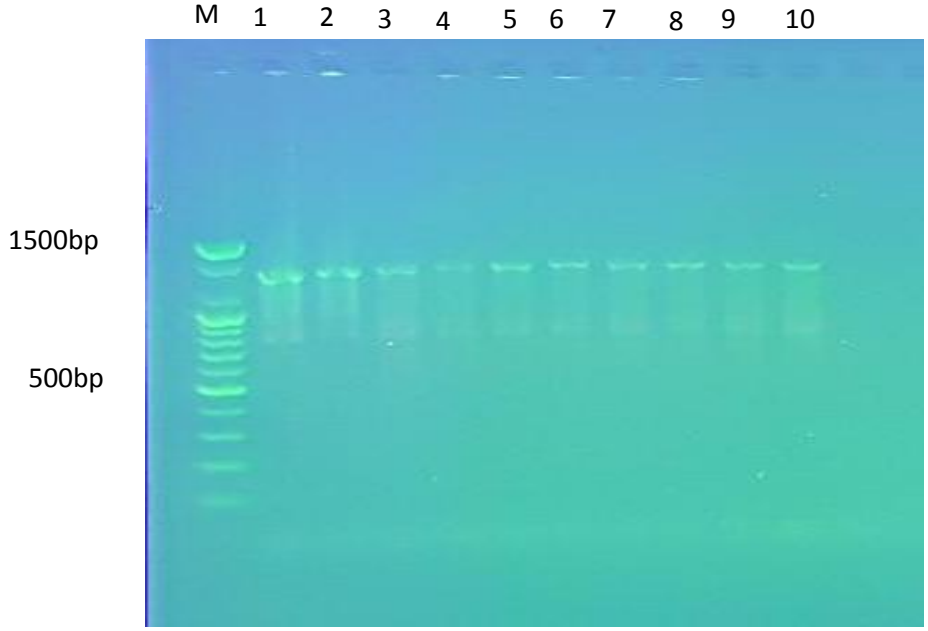

Figure 2. *Bacterial 16S rRNA PCR products in agarose gel electrophoresis*

Phylogenetic analysis and sequencing of 16S rRNA gene

The automated sequencer ABI 3100 with Big Dye Terminator Kit v. 3.1 was utilized to purify and sequence the amplified PCR products of microbial gene fragments at MACROGEN, Seoul, Korea. Primers 1391R (5'- GACGGGCGGTGTGTRCA -3') was used for sequencing (Turner et al., 1999). Sequencing was performed in only one direction since this is easy and inexpensive and phylogenic analysis is reported to be insensitive to quality of sequencing. As a result, the obtained sequences were compared with the database of NCBI via BLAST searches (http://blast.ncbi.nlm.nih.gov/Blast.cgi). In this comparison, sequences of type strains most closely related to the sequences of the isolates were searched. The sequences in the present study were only blasted against full genome sequences in NCBI database. For the phylogenetic analysis, the obtained sequences were aligned with Clustal W, and method based on the Jukes-Cantor model using the software MEGA and by the Maximum Likelihood, evolutionary distances were used to construct a phylogenetic tree (Kumar et al., 2016; Jukes and Cantor, 1969).

Results

In the current study, a total of 160 patients (85 females, 75 males) who referred to thalassemia center in Erbil, Iraq were examined, and 78 patients (48.75%) were found to suffer from bacterial infections. From these patients, 78 isolates were collected from

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1313513146

various sources: urine cultures, buccal cavity specimens, ear specimens, and blood cultures over a over two years period from June 2016 to September 2018. The isolates were initially been identified using either conventional (which is depend on cultural, morphological, and biochemical tests) or by automated microbiology system using the VITEK 2 compact system. These initial identities span 5 genera and 2 families, including a wide range of gram-negative rods. Among the 78 gram-negative isolates, 77 (98.7%) were members of Enterobacteriaceae and 1 (1.3%) members of Pseudomonadaceae.

Out of those 78 patients with infections, the most common causative organism was found to be *E. coli* (n = 48, 61.53%), followed by *K. pneumoniae* (n = 14, 17.94%), *M. morganii* (n = 11, 14.10%), *K. oxytoca* (n = 3, 3.84%), and *P. aeruginosa* and *Pantoea* sp. (n = 1, %1.28). Moreover, urinary tract infection was the most common site of infection (n = 61, 78.20%), followed by oral cavity infection (n = 10, 12.82%), ear otitis media (n = 5, 6.41%), and blood bacteremia (n = 2, 2.56%). *Tables 1* and *2* summarize the causative organisms, number of isolates, clinical identification method, and sites of infection in the 78 infected patients.

Table 1. *Clinical identity and techniques of identifying the isolates*

Clinical identity	Identification technique	Number of isolates (%)
Escherichia coli	Culture-based + VITEK 2 compact system	48 (61.53)
Klebsiella pneumonia	Culture-based + VITEK 2 compact system	14 (17.94)
Morganella morganii	VITEK 2 compact system	11 (14.10)
Klebsiella oxytoca	Culture-based + VITEK 2 compact system	3 (3.84)
Pseudomonas aeruginosa	Culture-based + VITEK 2 compact system	1 (1.28)
Pantoea species	VITEK 2 compact system	1 (1.28)

Table 2. *Sites of infection*

Site of infection, n (%)	Patients (n = 78)
Urine urinary tract infection	61 (78.20)
Oral cavity	10 (12.82)
Ear Otitis media	5 (6.41)
Blood Bacteremia	2 (2.56)

After isolates had initially been identified using either conventional or by automated microbiology system using the VITEK 2 compact system, the molecular method was used for isolate identification based on the sequence of 16S ribosomal RNA. The 16S rRNA gene was amplified and sequenced for each strain to confidently identify bacteria. Out of the 77 members of Enterobacteriaceae, 48 (62.3%) were confirmed as *E. coli* by conventional and automated microbiology system using the VITEK 2 compact system, whereas 16S rRNA sequencing method confirmed only 41 isolates as *E. coli*. Regarding the other Escherichia isolates, 5 out of the 48 tested isolates were sequenced successfully, but their sequences did not match with high similarity to any known bacterial deposited in NCBI database; therefore, they were called as unidentified bacteria since they had similarity with unknown cultured bacteria in the database.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1313513146

Interestingly, the 2 *Escherichia* isolates without species ID were identified as *E. fergusonii* and *M. morganii* by 16S rRNA sequencing.

In general, the 16S rRNA gene is universal in bacteria, and so relationships can be measured among all bacteria. The comparison of the 16S rRNA gene sequences allows differentiation between organisms at the genus level across all major phyla of bacteria, in addition to classifying strains at multiple levels, including what we now call the species and subspecies level. The occasional exceptions to the usefulness of 16S rRNA gene sequencing usually relate to more than one well-known species having the same or very similar sequences.

Regarding *Klebsiella* species, among the 17 isolates, 14 isolates were confirmed as *Klebsiella pneumoniae* and 3 as *Klebsiella oxytoca* by conventional and automated microbiology system using the VITEK 2 compact system, while 16S rRNA sequencing method revealed 11 *K. pneumoniae* isolates and 4 *K. oxytoca* 4 isolates. Moreover, 11 member of non-lactose fermenter that identified by conventional and automated method as *Morganella morganii*, this ratio rose to 14 *M. morganii* by 16S rRNA sequencing method. One isolate that was identified by automated method as *Pantoea* species was confirmed by molecular method too. On the other hand, one members of Pseudomonadaceae was *Pseudomonas aeruginosa* that was identified by conventional and automated methods and confirmed by molecular methods.

Table 3 presents the results of comparing conventional and automated identification methods with the molecular approach is shown in. As shown in the table, 58 (74.35) out of 78 isolates were correctly identified.

Table 3. *Comparison between conventional and automated methods with the molecular approach*

Isolates	Clinical identification	
	Conventional and automated	**16S rRNA**
E. coli	48	41
K. pneumoniae	14	11
M. morganii	11	14
K. oxytoca	3	4
P. aeruginosa	1	1
Pantoea species	1	1
E. fergusonii	0	1
Unidentified	0	5
Total	78	78

Furthermore, the Neighbour-joining method was utilized to draw phylogenetic trees for 16S rRNA region. Moreover, MEGA (Molecular Evolutionary Genetics analysis) version 7.0 was employed to perform the molecular and phylogenetic evolutionary analyses. In addition, nucleotide BLAST was utilized to compare different sets of sequence databases and the 16S rRNA gene sequence of isolate. Bacterial identification was conducted using the annotated information for the sequence in the database of whole-genome sequences to which 16S rRNA aligns.

Phylogenetic tree of *E. coli* is presented in *Figure 3A,* which was drawn based on 1,548 conserved core gene clusters of 41 *E. coli* genomes. The phylogenetic trees

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1313513146

clearly indicate that there was an intra-species genetic distance of 0.010 between the individual isolates. As shown in *Figure 3B;* however, there was an intra-species genetic distance of 0.0020 between the individual isolates of the 11 *Klebsiella pneumoniae*. Moreover, in *Figure 3C,* an intra-species genetic distance of up to 0.020 was observed between the individual isolates of the *Morganella morganii*. Based on these findings, compared to *E. coli* and *Klebsiella pneumoniae*, *Morganella morganii* had a higher rate of evolution and the genetic variation.

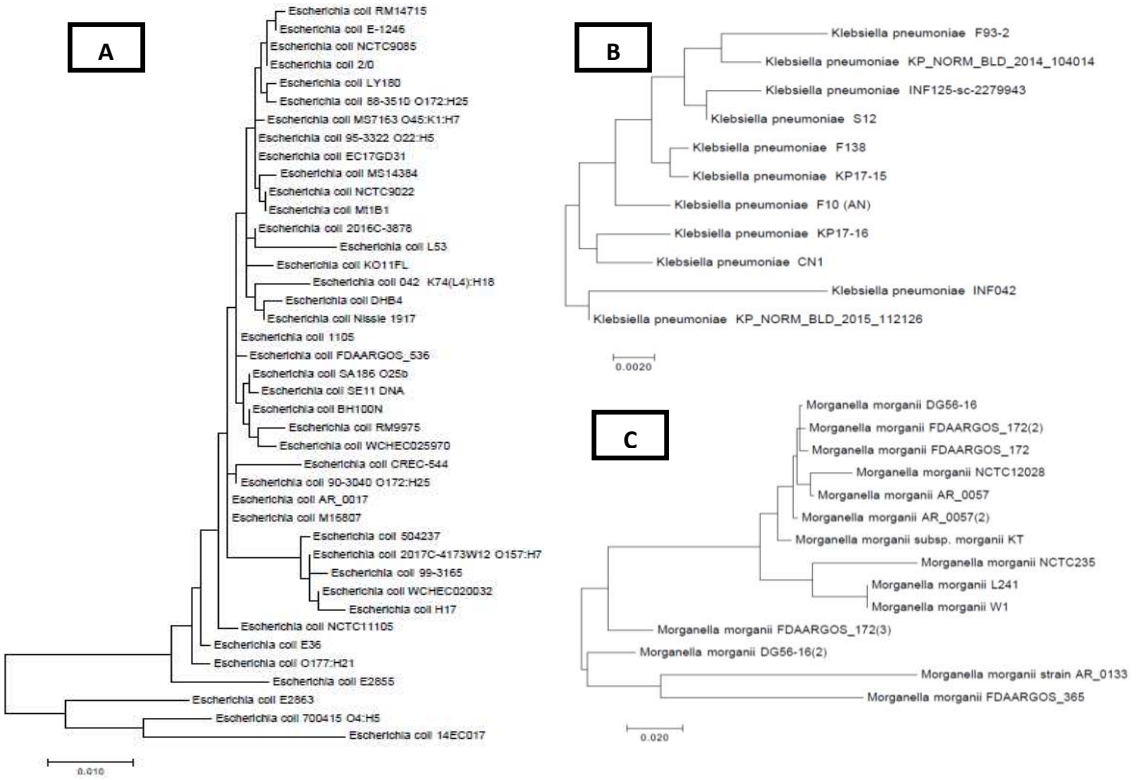

Figure 1. *Phylogenetic neighbor-joining trees of 16S rRNA amplified from the tested isolates of E coli (A), K. pneumoniae (B), and M. morganii (C)*

Discussion

Most of the isolates in the present study were identified by an automated microbiology system (i.e. BioMerieux VITEK 2 Compact) and conventional phenotypic method. However, the 16S rRNA gene was sequenced and amplified for each strain in order to identify the bacteria confidently. In scientific investigations and clinical practice, identification of bacterial species is frequently performed through sequence analysis of conserved "housekeeping" genes like the bacterial 16S rRNA (Clarridge, 2004; Petti et al., 2005). In fact, Bacterial identification traditionally achieved by carrying out labor-intensive and time-consuming, and the interests of identification genotypically are many including shorter time for results, higher reliability, sensitivity, and specificity (Jesumirhewe et al., 2016). To specify the phylogenetic characterization of prokaryotes such as archaea and bacteria, the16S rRNA gene sequence is utilized as the template in the latest bacteria identification manuals such as Bergey's Manual of Systematic Bacteriology which is widely used by microbiologists to identify and characterize bacteria (Werner et al., 2012).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1313513146

In order to identify previous bacteria in clinical settings and amplify 16S rRNA, a set of universal reference primers were chosen based on previous clinical work and key reports. Moreover, previously conducted taxonomic studies have utilized sequence analysis of the 16S ribosomal RNA (rRNA) gene in order to identify bacterial species (Chakravorty et al., 2007).

Identifying typical clinical isolates through PCR and sequencing in the present study revealed the fact the consistency of this method with conventional laboratory methods. The desirable characteristics of this molecular identification method include: (1) cost-effectiveness: Given the low cost of developing the technology and information, the procedure is quite cost-effective; (2) accessibility: this procedure has a high level of accessibility because it is developed based on well-established methods and theories such as amplicon preparation through PCR, commercial sequencing, and Gene Bank verification); and (3) convenience: This procedure is quite convenient because it utilizes common techniques and methods of molecular biology including sequence analysis, commercial sequencing, electrophoresisand, PCR, and efficient one-step DNA extraction. Identifying microbes that are difficult to identify is conducted using molecular methods if laboratories do not have the required expertise to use other phenotypic identification methods (Cheng et al., 2014). Although 16S rRNA gene sequencing is frequently utilized in reference laboratories, the difficulty of interpreting 16S rRNA gene sequence results is one of the main limitations to its broader use. Marginal intra-species differences and significant inter-species differences in 16S rRNA gene sequences have a remarkable effect on utilizing 16S rRNA gene sequencing to identify bacteria. As a result, identifying the bacteria cannot be done with sufficient confidence through this technique when the same 16S rRNA gene sequence is share by two different bacterial species (Woo et al., 2009).

In the present study, sequencing was used to identify different bacteria. It was observed that sequence analysis had an excellent overall performance in distinguishing the bacterial isolates that were difficult to identify. Therefore, bacteria identification in clinical settings can be aided by the 16S rRNA sequencing as a supplement, particularly for organisms that are biochemically fastidious or deficient or poorly described. *Pantoea* is a difficult-to-identify bacterium. This bacterium can lead to development of infections in humans. It is also pathogenic to plants. However, different strains of Pantoea and their probable association with disease and hosts are poorly known, and it is difficult to identify Pantoea species. The biochemical heterogeneity of *Pantoea* makes it to be identified difficulty and due to similarities in phenotypic characteristics between *Pantoea* species and related Enterobacteriaceae. Currently, confident identification is not achieved routinely (Delétoile et al., 2009; Brady, 2013).

The advantage of 16S rRNA gene sequencing in clinical microbiology has been focused on in several studies. For example, Drancourt et al. (2000) carried out a study to compare 16S rRNA and phenotypic based identification techniques. For this purpose, they obtained 177 isolates, 81 of which were collected from medical clinical samples. Also, Bosshard et al. (2003) assessed the appropriateness of 16S rRNA for the identifying the clinical strains of aerobic gram-positive rods. Moreover, Spilker et al. (2004) examined 66 cystic fibrosis sputum isolates in order to check the agreement between the results identification of Pseudomonas species using phenotypic and 16S rRNA sequencing methods.

The present investigation, 78 infected patients were studied to figure out the causative organisms and sites of infection. It was observed that the most common

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1313513146

causative organism was *E. coli* that was identified in 41 cases, followed by *Morganella morganii* with 14 cases and *K. pneumoniae* with 11 cases. Moreover, the most common site of infection was identified to be urinary tract infection with 61 cases, followed by oral cavity infection with 10 cases.

The profile of pathogens in the series of the present study differed from those that were previously described for thalassaemia, such that *Escherichia coli* was the most common causative organism, followed by *Morganella morganii* in the second place and *Klebsiella* species in the third place. This finding is in line with those two studies that were conducted on Asian patients with thalassemia (Wang et al., 2003; Yapp et al., 2009). However, this finding is not in agreement with those of the studies conducted in Western countries, where the most common causative organism in thalassemia patients was found to be *Yersinia* species (Robins-Browne and Prpic, 1985; Abcarian and Demas, 1991).

In the present study, Escherichia coli species were found to be the most frequent organisms that cause infection in thalassemia, which can probably be contributed to the fact that there were a larger number of female patients than the males and that women develop urinary tract infections four times more frequently than males, and it is well known that *Escherichia coli* bacteria are responsible for most cases of urinary tract infection (UTI) (Sakamoto et al., 2018; Alperin et al., 2019).

In the present study, excess iron presence might be the reason for different spectrum of infections among the patients. Moreover, since iron plays a role in the growth of *Klebsiella* spp., high levels of ferritin seem to be a risk factor (Chung et al., 2003). Dissemination and replication of bacterial pathogens in which iron is used as a growth factor can be promoted by high levels of serum iron. Saturation of transferrin in iron overload makes labile iron available to bacteria. Iron overload changes the phagocytic and chemotactic properties of neutrophils, in turn leading to a decrease in their capability of killing invading pathogens. It also seems to change the function of T-cell. Moreover, immune effector mechanisms like immune cell proliferation iron, nitric oxide (NO) formation, or cytokine activities (interferon-c effector pathways towards macrophages) are also modulated by iron (Hoen, 1999; Weiss, 2002; Wiener, 2003). *Pseudomonas aeruginosa*, *Klebsiella* species (e.g., pneumoniae), and *Escherichia coli*, which are gram-negative, rod-shaped bacteria, frequently lead to infections and mortality in a splenic patients (Cappellini et al., 2014).

Conclusion

The results of the current study indicated that using DNA sequencing techniques to identify bacteria isolates, especially biochemically aberrant, rarely isolated, or poorly described strains, in clinical settings can lead to remarkable improvement in clinical microbiology. It was found that accurate identification and understanding of bacterial diversity across and within the group were fulfilled through 16S-rRNA gene sequencing. In addition, low cost and high accuracy are guaranteed by sequencing technologies which are effective and appropriate for small- and medium-sized microbiological laboratories. Furthermore, the results of the present study revealed that identification of all cases is possible through single-strand sequencing. By studying the isolates obtained from thalassemia patients in the present study, it was concluded that genetic methods can help to identify the pathogenic isolates, which will be further helpful in administering appropriate antibiotics and understanding the trend of

DOI: http://dx.doi.org/10.15666/aeer/1706_1313513146

pathogens in various clinical samples. As figured out in the present study, the most common causative organisms were found to be *Escherichia coli*, followed by *Morganella morganii* While *Klebsiella pneumoniae* as the second and third most frequent causative organisms. It is recommended to depend on Multilocus Gene Sequencing for more rapid and accurate identification, especially for *Pantoea* typing in clinical samples due to its difficulty identification.

Abstract. Lack of historical land cover and urban growth governance structure makes spatial planning within the economic capitals of developing countries difficult. Monitoring urban built-up growth with in-situ methods is complicated. In this paper, long-term Landsat archive is utilised to map the built-up areas of Accra, the economic capital of Ghana, in Africa. Simple two band ratio and band combination is coupled with historic Google Earth imagery to monitor built-up dynamics from 1980-2017. A 10-year period was sub-divided into three parts each; early period, mid period and late period – for analysis. Maximum Likelihood classifier was used for the classification within the ENVI environment. The results show 11.90% as the highest and 4.63% as the lowest built-up growth rates between 2001-2005 and 1996-2000 respectively. Annual loss of non-built-up areas was 1.31%, and 48.57% over the entire study period. Water bodies lost 0.08% annually but 3.1% over the 37-year period. Highest and lowest overall accuracy were 87.18% and 81.31% respectively, with an average kappa coefficient of 0.7618. Gain in the built-up area was 1676.69 km^2 but non-built up areas lost 1576.10 km^2 while water bodies lost 100.60 km^2. Results will be of interest to spatial planners, policy makers and land administrators.
Keywords: *long term images, urbanization, band index, band combination, urban change rate, urban growth rate*

Introduction

Rapid urbanisation poses challenges to the United Nations sustainable goals (Giles-Corti et al., 2017), because challenges still exists in finding both temporal and spatial change information over a long period (Li et al., 2018). Ghana, like other developing countries face these challenges as well (The World Bank Group, 2015). However, there are very few studies done on the economic capitals, where most of the urbanisation takes place. These challenges are further worsened by low and sometimes non-availability of readily available long-term, urban growth governance structures, land cover maps, census data and high population projection ambiguity (Satterthwaite, 2010). Sometimes the data used is erroneous due to lack of size estimates and growth (Potts, 2012; Songsore, 2010). Gathering in-situ datasets to monitor urban growth in these countries is difficult, hence most developing countries like Ghana have turned to remote sensing for urban expansion studies and densification analysis (Potts, 2012). The use of long-term remote sensing datasets offers a full analysis which is believed to provide decision makers information for informed commitments on economic policy

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1314713168

drafting and spatial planning, to realise a translated impact of government economic policies, as there is a direct relation between population growth, urbanisation, infrastructure deficits and Gross Dometic Product (GDP).

A tentative attempt by (Osei et al., 2013) used only two-year imagery for the study on Accra, which is inadequate for an in-depth analysis. Previous studies have mapped the urban expansion extent and its monitoring for various applications using varied approaches; urbanisation and urban growth (Li and Yeh, 2000; Li, et al., 2015; Mohammady et al., 2013; Cobbinah and Niminga-Beka, 2017; Mu et al., 2006), urban expansion and urban sprawl (Angel et al., 2011; Yin et al., 2011; Ghosh et al., 2017), urban landcover change (Seto et al., 2000; Defries et al., 2010; Yang et al., 2014), all have used impervious surface extraction as a part for their study and analysis (Chester and Gibbons, 1996). A few have scrutinised spatial patterns of urban distribution and expansion with buffer zones in different directions (Li et al., 2016). Impervious Surface Areas (ISA) extraction, has mostly been done with high resolution imagery (HRI) due to accuracy issues. Spatial resolution becomes very important depending on the impervious characteristic under study (Sobrino et al., 2012).

Various studies (Guo et al., 2015; Yao et al., 2018; Sharma et al., 2016) and (Kuang et al., 2014), have proposed ISA extraction improvements using datasets such as Defense Meteorological Satellite Program-Operational Linescan System (DMSP-OLS), Quick Bird, Landsat, Visible Infrared Imaging Radiometer Suite-Day/Night Band (VIIRS-DNB), Moderate Resolution Imaging Spectroradiometer (MODIS), IKONOS and Advanced Spaceborne Thermal Emission and Reflection Radiometer (ASTER). In their proposed methods of multiresolution segmentation and canny algorithms, object layers were created first before extraction by spectrum, shape, size, texture, topology and context characteristics of the object. Noises were removed and the local singularity issue as well as the pepper and salt phenomenon were solved. However, the use of HRI and other data that are costly makes it difficult to replicate their methods especially over large regions in developing countries due to lack of research funds.

Again, the cost of HRI is a great challenge in Ghana which hinders urban studies research. These HRI also do not have the long-term advantage of more than two decades of data. This is a challenge for those involved in historical urban studies. As such urban feature extraction for analysis and planning sustainability is difficult. Landsat Thematic Mapper/Enhanced Thematic Mapper Plus/Operational Land Imager (TM/ETM + /OLI) data archive provide a solution to this hurdle, and are currently freely available with a global coverage. Most of these previous studies applied complex mathematical equations (Varshney and Rajesh, 2014) of spectral indices, sometimes combining two or more of these indices (Xiang et al., 2016), which are sometimes difficult to replicate. Also these applications were done on quite smaller areas and the effect of these methods is not fully appreciated over very large areas. Band ratios and band combinations can be useful in any scale of area for classification. Most important is the validating of the classification results or the algorithm. Long-term ground truth data is difficult to come by or in most cases impossible to acquire if it did not exist already. In this discussion we used the historical Google Earth (GE) map facility to obtain the ground truth. Landsat (4, 5, 7, and 8) imagery is used to extract the built-up areas for change dynamics analysis.

The main aims of this paper are; to do a built up analysis of the growth rate, growth change and the spatial area coverage of Greater Accra Region, the economic capital of Ghana, and, to provide a long-term base data for analysis in a long period spatial planning

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1314713168

for the Accra city planners. These examinations will be done using a two band ratio and Maximum Likelihood (ML) classifier. Most band ratio applications are coupled with multisource data, especially for lithological applications. In this study two band ratios solely applied to a single source data. Study is important because, analyses presented here can give an indication of the future impacts associated with urban built-up dynamics. Lessons drawn from happenings and the implemented solutions to them. For instance, most developed countries have turned to high rise buildings to solve the accommodation problem of the ever increasing urban population. These high rise buildings have caused an increase in surface temperatures at the heart of the cities (Giridharan, et al., 2004; J. Lu et al., 2007). Solutions to this problem have been suggested by (Kolokotroni et al., 2018). These lessons can inform the Ghana government not to commit the same mistakes of the advanced countries. This study is also vital for the development of sustainable policies to improve the adverse consequences of urbanization for sustainable urban development (Estoque and Murayama, 2015; Arsanjani et al., 2013).

Materials and methods

Study setting

The economic capital of most developing countries has similar traits. Most buildings within the Metropolitan are high rising and concentrated within the heart of the metropolis. This quick urban advancement comes with a constant congregation of population and an intense industrialisation (Senanayake et al., 2013) which has created its own environmental problems (Hettiarachchi et al., 2014). Most roads are paved, except some residential roads for newly developing estates. These characteristics are also observed in the study area. Accra had a population of 1.7 million as of 2010 (Ghana Statistical Service, 2014) and estimated to be 2.27 million by 2018. The total size area of Greater Accra Region is 3245 km^2, map of which is shown in *Figure 1*.

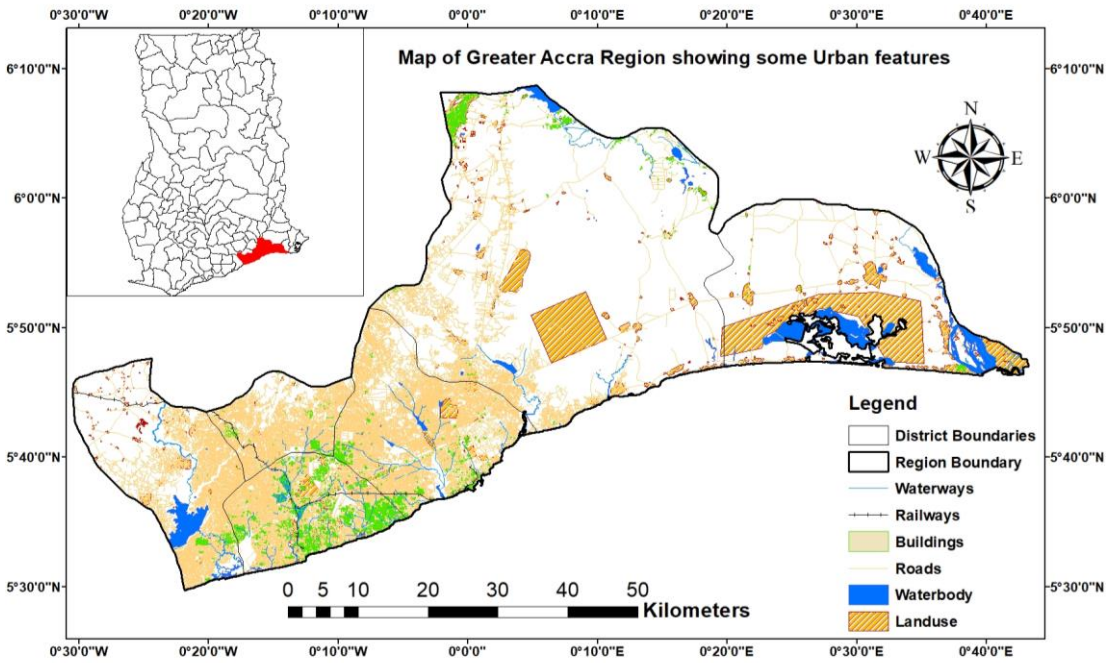

Figure 1. *Map of Greater Accra Region (insert: Ghana, study area shown in red)*

Dataset

We used Landsat imagery over a period of thirty-seven (37) years (1980–2017). However, one imagery before 1980 was obtained to provide a before-baseline comparison. The structure of Landsat Level-1 products ensures the provision of a steady annal of data quality to support time-series analyses and data "stacking", while controlling incessant improvement of the documentation and access to data as they are acquired. The images were obtained from the United States Geological Survey (USGS) website (https://earthexplorer.usgs.gov). Description of the Landsat imagery is given in *Table 1*. Although images were non-available for some years, it did not affect the objective since the study was not strictly an annual comparison. Those years with too much cloud cover were not used. Some excellent images were obtained though for these sensors, despite the scan line corrector failure of ETM+. The focal analysis tool was used to correct this. Although some spectral property may have been lost, it had insignificant influence on the quality of the work since mostly the combined bands were for visual interpretation and identification of the built-up areas. Image of 1972 has a size 170 km × 185 km and on path 207 and row 56. The rest all have size 170 km × 183 km and on path 93 and row 56.

Table 1. *Spectral descriptions of Landsat imagery and scenes*

Band name	**LS 1-5 MSS**	**LS 4-5 TM**	**LS 7 ETM +**	**LS 8 OLI**	**Pixel size (m)**

In all cases the chosen bands (*Table 1*) were stacked together to provide a composite of all the good usable bands. Corresponding bands were chosen for the respective sensors. One key advantage for using this type of data is the possibility to detect a complete historical profile of urban growth, which is not easily discernible from stacked images with sparse satellite observations (Roy et al., 2014). We also used Google Earth (GE) from (https://earth.google.com) obtained around the same time of the acquisition date of the Landsat imagery for collecting ground truth to serve as training data. Google Earth provided historical records feature samples locations for five classes (i.e. vegetation, open bare land, roads, buildings and water). Bands were combined to visualise where these features are. Using visual interpretation these areas were digitised in GE and saved to shape-file in ArcGIS. For each digitised polygon, a point around the centre was taken and recorded in excel. These served as the ground truth and training

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1314713168

data for the classification. After the maximum likelihood supervised classification of five classes, a post-classification was done to regrouped into built-up areas (BUP), non-built up areas (NBUP) and water bodies (WB). Here, residential areas, commercial and industrial area are all classified as BUP. Agriculture, Plantation, Recreational Parks, Orchards and Forest are all classified as NBUP. Dams/Reservoirs, Ponds, River, Lakes, Stream are all classified as WB.

Procedure and approach

We used two band ratio and band combination to extract and classify features from the Landsat imagery. Developed indices serve as an indicator to analyse a particular type of land class during feature extraction and classification processes. In principle, indexing determines a ratio between the strongest (maximum) reflectance band and weakest (minimum) reflectance bands for the target feature. Then the normalised ratio of these two bands gives the highest contrast for the particular land type with minimum background noise. Landsat imagery that showed a significant presence of clouds was avoided. Conversely, Landsat images with less cloud cover outside the area of interest were included, which were subsequently imported into ERDAS Imagine for layer stacking. The focal analysis tool in ERDAS was applied to gap-fill the images that had stripes. The stacked images were later subsetted using shape-files of the study area. All the subset images were then moved to the ENVI environment for classification. The general procedure used is shown in *Figure 2*.

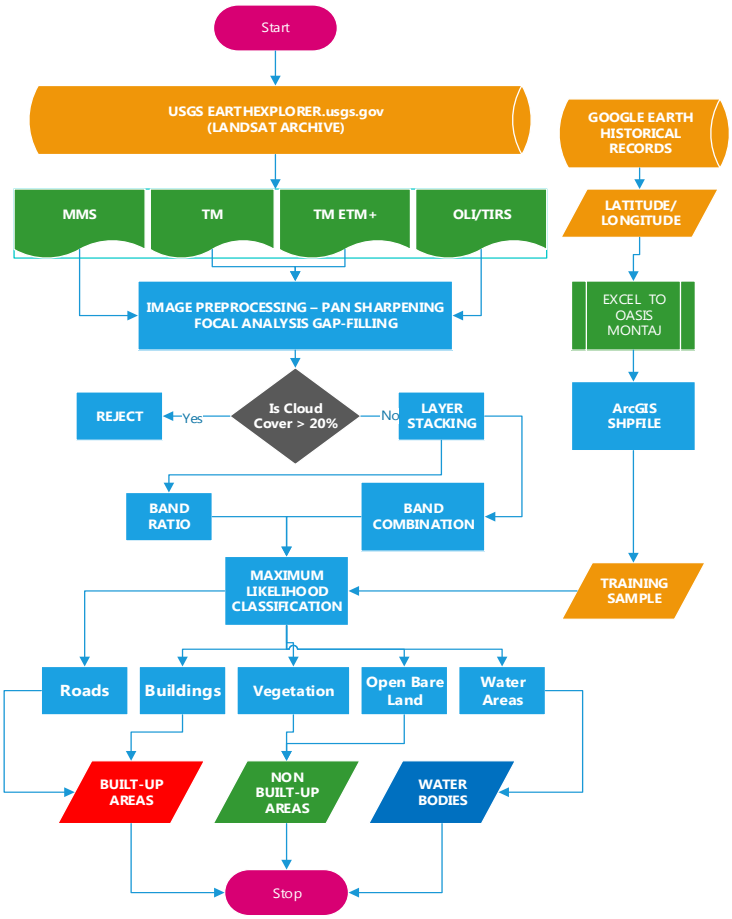

Figure 2. *Workflow procedure diagram*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1314713168

Band combination

Band combination is an RGB composite that enhances the visual interpretation of the potential information content as shown in *Figure 3*. RGB composites for Landsat 8 differ from RGB composite obtained from Landsat 7 and Landsat 5 due to the difference in wavelength information for similar band in these images. For instance, a band combination of band 4, band 3 and band 2 create colour infrared (CIR) in Landsat 7 or Landsat 5, whereas the same resulting colour infrared in Landsat 8 is created using band 5, band 4 and band 3. Thus, it is imperative to choose a particular band combination dependent on the visual depiction of the preferred feature or phenomena. In this study, we created the following band combination to extract and classify features as described (*Fig. 3*):

- **Bands 7, 4, 2:** Urban areas appear in shades of magenta while vegetation appears light green. Light-green spots in the city specify grass-land cover like parks, golf courses, cemeteries**.**
- **Bands 4, 3, 2:** Deep red hues designate healthy vegetation while lighter reds show sparsely vegetated areas. Light blue shows densely populated urban areas.
- **Bands 4, 5, 3:** This blend offers further description of land-water boundaries and highlights subtle details not distinctively apparent in the visible bands**.** This combination exhibits moisture differences which are useful for soil and vegetation analysis.
- **Bands 5, 4, 3:** Healthy vegetation is bright green with soils as light purple, and mostly used for agricultural studies. It can also be applied in timber logging management.

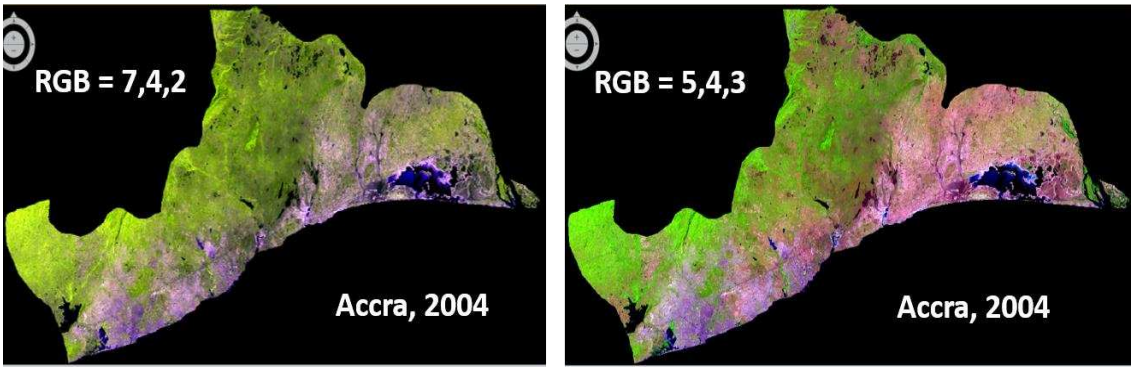

Figure 3. *Sample of some band combinations*

Band ratio

The Band Ratio (BR) technique has been applied before for geological interpretation as in (Inzana et al., 2003) and, for detecting mangrove forests as in (Rahman et al., 2013) among others. In these previous studies, band ratio images are evaluated based on their ability to discriminate the target feature (i.e. geologic units and structure; mangrove species). Generally, the illumination effect is removed in the spectral difference for any two-band ratio, in which the difference is the ratio. The illumination defines the magnitude of the DN received by satellite (Muniz et al., 2003). The principle is applied here to detect urban areas. In this study, the stacked images were loaded with

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1314713168

all the bands, however only the applicable RGB composites are loaded into the viewer for visual interpretation. The whole idea behind this method is to be able to confidently identify the targeted features (vegetation, open bare land, water areas, roads and buildings), on the displayed image to collect appropriate training sample features. Unique information with subtle spectral reflectance is provided by ratios for surface materials often difficult to detect in a standard image (Inzana et al., 2003). The following band ratios were applied to the respective targeted features.

- **Roads and buildings – (*Band 3/Band 5 and Band 3/Band 4*):** These sharply defined the urban area and barren land. They enhance barren lands, street patterns, highways in the urban areas and urban built-up or paved areas. Urban and built-up areas appear as brighter tone and forests, water body and croplands appear darker.
- **Open bare land – (*Band 5/Band 7 and Band 3/Band 5*):** Land and water are distinctively separated because soils exhibit strong absorption in the band 7 and high reflectance in band 5. Land appears as lighter tone and water appear darker.
- **Vegetation – (*Band 4/Band 3 and Band 4/Band 5*):** This discriminate between vegetation, water and croplands which is due to the moisture content. Vegetation reflects higher in near IR region and strong absorption in the red region. The lighter the tone, means more vegetation present.
- **Water areas – (*Band 4/Band 3, Band 4/Band 5 and Band 5/Band 7*):** Easily discriminates water bodies from the land. Water absorbs strongly in near IR region and reflects much in band 5. Water body appears darker than vegetation and land which appear lighter.

The mathematical expression of the band ratio function is displayed in *Equation 1*.

$$BandRatio = BR_{i,j,r} = \frac{BN_{i,j,k}}{BN_{i,j,1}} \quad \text{(Eq.1)}$$

where $BR_{i,j,r}$ is the output ratio value for the pixel, at row *i*, column *j*, and $BN_{i,j,k}$ and $BN_{i,j,l}$ is the brightness value at the same location in band *k* and *l*. Both the numerator and the denomerator factors belong to the same image scene.

Classification method

We used Maximum Likelihood (ML) algorithm to classify the images (Rawat and Kumar, 2015; Dewan and Yamaguchi, 2009). Maximum Likelihood was preferred over other classification algorithms due to the robust nature of the Gaussian probability distribution in assigning classes (Mather and Tso, 2010). It has successfully been applied in urban and peri-urban areas to monitor land cover changes (Schneider, 2012). We used training sample features that were extracted (digitised) from GE for each of the defined class. Then the band ratio (as described above) was applied for the respective features. We subjected the single band result to a ML supervised classification using the extracted training sample as ground truth. The classification was done for five classes (bare land, vegetation, water, roads, and buildings), which were later aggregated to three classes of built-up areas (roads and buildings), non-built up areas and water bodies, during the post-classification. A kennel smooth size 3 was used to smoothen the result.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1314713168

The advantage of this approach is that it can be applied to various Landsat sensors for this purpose, whereas the established indexes are limited to specific sensors because the bands used are not present in all the array of sensors. This approach is also simple as it involves very little mathematics and does not necessarily need an in-depth understanding for implementation.

Change rate and growth rate calculations

Change and growth rates have been used by (Li et al., 2016; Xu et al., 2011) to examine urban impervious surface distribution and change dynamics where the surface area coverage was determined for various years for Hangzhou and Xiamne cities. Change rate is this paper was calculated using *Equations 2* and *3*.

$$ChangeRate = (CR) = A(x) = \frac{f(x_2) - f(x_1)}{x_2 - x_1} = \frac{y_2 - y_1}{x_2 - x_1} \quad \text{(Eq.2)}$$

where x_2 is the final year, and x_1 is the initial year; the functions are defined as in *Equation 3:*

$$\begin{aligned} f(x_2) &= x_2^{\,2} - (2 \times x_2) \\ f(x_1) &= x_1^{\,2} - (2 \times x_1) \end{aligned} \quad \text{(Eq.3)}$$

Different formulas exist for the calculation of growth rates, however in this study the formula of *Equation 4* (Feeney, 2014) was adopted.

$$GrowthRate = (GR) = T(x) = \left[\frac{present}{past} \right]^{\frac{1}{n}} - 1 \quad \text{(Eq.4)}$$

where *present* and *past* represent the figures for the current and past years respectively. *n* is the interval over which the growth is computed - 10 years for this study (*Fig. 7*).

To assess the spatial distribution of built-up expansion intensity, an annual urban expansion intensity index (AUEII) by (Liu et al., 2000) was adopted and modified to Built-Up Expansion Intensity Index (BUEII) for use as an indicator of the urbanization rate of the study area. BUEII is expressed as in *Equation 5*.

$$BUEII = \frac{A_{n+i} - A_i}{nTA_{n+i}} \times 100\% \quad \text{(Eq.5)}$$

where TA_{n+i} is the total area of the target unit at time $n + i$; A_{n+i} and A_i the built-up area within the target unit at time $n + i$ and i, respectively, and n the interval period (in years).

Accuracy assessment calculation (kappa coefficient)

The *kappa coefficient* measures classification and truth values agreement. With a kappa value of 1 there is a perfect agreement, while a value of 0 means no agreement.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1314713168

The kappa coefficient mathematically follows *Equation 6* but can be simply reduced to *Equation 7:*

$$K = \frac{N\sum_{i=1}^{n} m_{i,1} - \sum_{i=1}^{n}(G_i G_i)}{N^2 - \sum_{i=1}^{n}(G_i G_i)} \quad \text{(Eq.6)}$$

where i is the class number; N is the total number of classified values compared to truth values; $m_{i,i}$ is the number of values within class i that have also been classified as class i which values are along the diagonal of the confusion matrix; C_i is the total number of predicted values within class I; G_i is the total number of truth values within class i.

$$Kappa = \frac{(Nb - g)}{N^2 - g} \quad \text{(Eq.7)}$$

where N is the total number of points; b is the sum of correctly mapped points; g is the sum of the products of classes between the ground truth points used and the predicted points digitised.

Results and analysis

Accuracy assessment

We generated the confusion matrix to assess the accuracy of the results. The highest overall accuracy obtained is 87.18% and a lowest of 81.31% with a mean accuracy assessment of 84.25%. The Kappa coefficient was used to evaluate the quality of agreement, either positive or negative. The average kappa coefficient for Accra was 0.7618 using *Equation 6,* which is a simplified rendition for its calculation. The producer accuracy and user accuracy are calculated for each image for each class and are shown in *Table 2*. It was possible to obtain a producer accuracy of 90.91% for built-up area in 1987. The user accuracy for the same year is 84.96%. For built-up areas the producer accuracy ranged between 75.36 and 90.91%, non-built up areas range from 75.00 to 93.27%, and between 81.08 and 92.31% for water bodies. Figures for water bodies seem high because it was easy to identify them within the chosen band combinations, thus reducing the chances of error. Water can even attain a high accuracy of 100% (Elhag, 2017).

Analysis on built-up area coverage

In total, thirteen comparable years were analysed. The entire timeline was divided into five epochs; (i) before 1980, (ii) 1981-1990, (iii) 1991-2000, (iv) 2001-2010 and (v) 2011-2017. These were further grouped into three periods of the *early period (first 3 years)*, *mid period (second 3 years)* and *late period (last 4 years),* of each epoch. This approach made the comparison easier and visually comprehensible. A graph of the gains is shown in *Figure 4*.

BUP = Built Up Areas; NBUP = Non-Built Up areas; WB = Water Bodies; PA = Producer Accuracy; UA = User Accuracy; OVA = Overall Accuracy; K = Kappa

Non-built up areas generally lost to built-up areas steadily with some anomalies in 2011 and 2008. These anomalies, we think, may be due to the migration from rural-urban into the urban centres which may have contributed to a drastic increase in built-up areas. Constant urban development picked up around these times, and it is fully represented in the graph (*Fig. 4*). Information presented in *Figure 5* compliments that of *Figure 4*. Gaps within the graph indicate years with no data (images). Either images were avoided entirely due to cloud cover or it was missing (sensor failure). The complete mapped area coverages are shown in *Table 3*. It shows the corresponding area coverage of the land covers for respective years.

Analysis on built-up change rate

This rate gives an indication of when much built up occurred which can be a measure of the economic status of the region. With an argument, it is assumed that the citizens and not the government do the built-up activities. The change rate is shown in *Figure 6*. It was calculated using *Equations 2* and *3* (Phiri and Nyirenda, 2015). In the second epoch (1991-2000), Accra added 3.83% more to its built-up environment but there was a slight increase of 2.12% during the third epoch (2001-2010). Notwithstanding this small increase it did an increase of 11.04% over the period (2011-2017). By 1980, the built-up areas had increased from 15.65% in 1972 to 21.87% representing a land surface area of 507.84 km^2 and 709.68 km^2, respectively, an increase of only 0.19%. However, by 1989, over 15-17 years, the built-up areas occupied 55.94% of surface area. The highest change occurred between 2001 and 2005 and the lowest occurred between 1996 and 2000 against the previous years, over the last 35 years. The last column of *Table 3* gives annual percentage increase in built-up areas depicting the annual change in size.

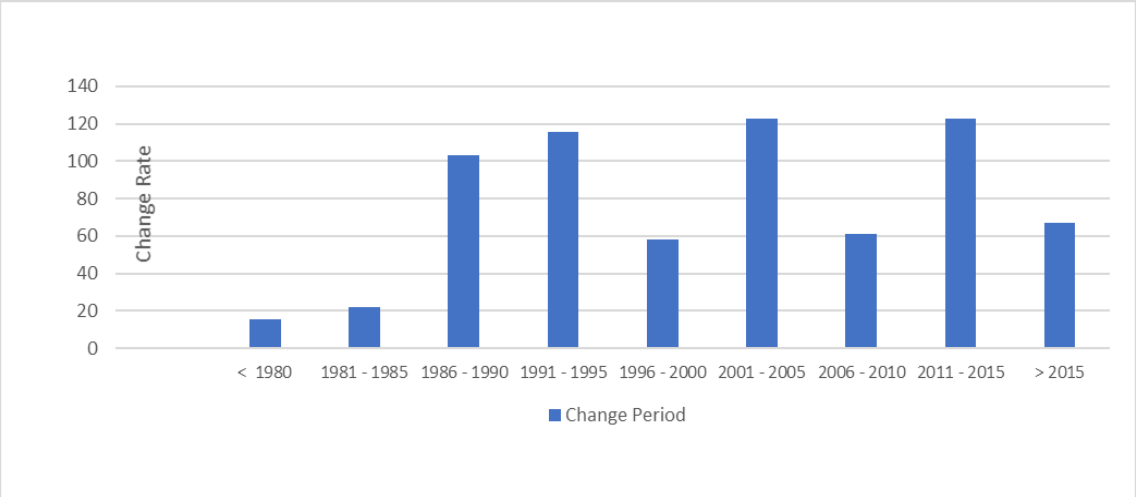

Figure 6. *Graph of annual built-up change rate*

Analysis on built-up growth rate

The GR over the period 1984-1994, 1995-2005 and 2006-2016 were 10.19%, 0.32%, and 0.34% respectively. Over the entire period of 1984-2017, Accra had a built-up growth rate of 11.9%. This figure, a graph of which is in *Figure 7,* does not necessarily mean lack of development (urbanisation) but rather it tells the spatial coverage of development or urbanisation within the region. The high growth rate of Accra in the first decade from 1984 is attributed to stable political environment after various coup d'états from 1966 until 1979. Although it was a military regime for almost the entire period, the country had a stable environment for growth.

There was coup d'état around this time, the economy of the country was very bad and this resulted in a lot of people leaving the country for greener pastures. Built-up areas within the capital were just very low as the economic status of the citizenry was not encouraging. The 1972 urban built-up scenario is depicted in *Figure 8*.

By 1984, the country had a stable government and economic activities had picked up. The country was implementing the Structural Adjustment Programme (SAP) as the

DOI: http://dx.doi.org/10.15666/aeer/1706_1314713168

building foundation of the economy which was destroyed over the 15-year coup d'état period. Physical infrastructure was pursued vigorously by government which resulted in a constant growth by the year 1992 when the country returned to constitutional governance. *Figure 9* shows the change between 1984 and 1992.

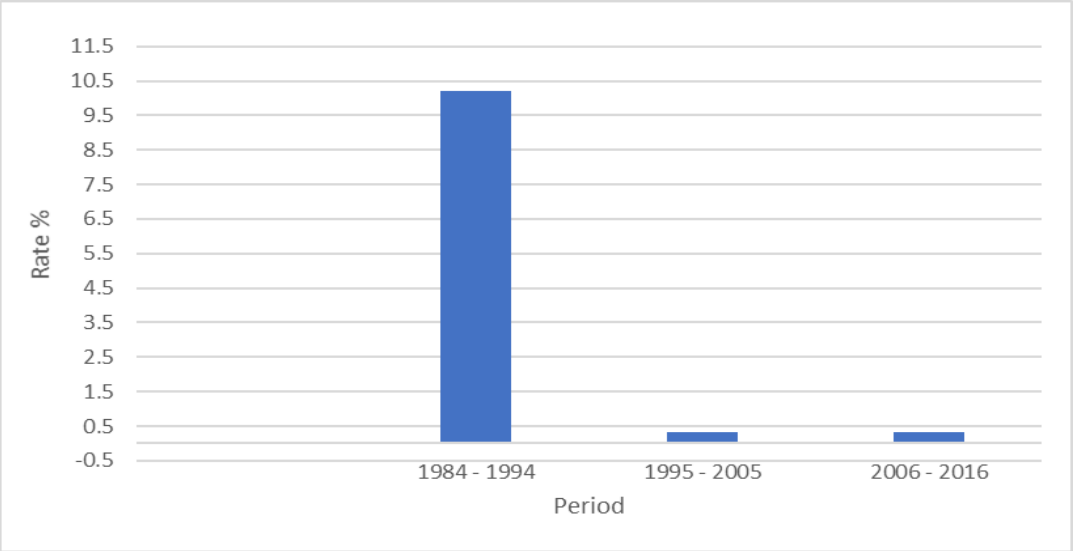

Figure 7. *Decade analysis of built up growth rate*

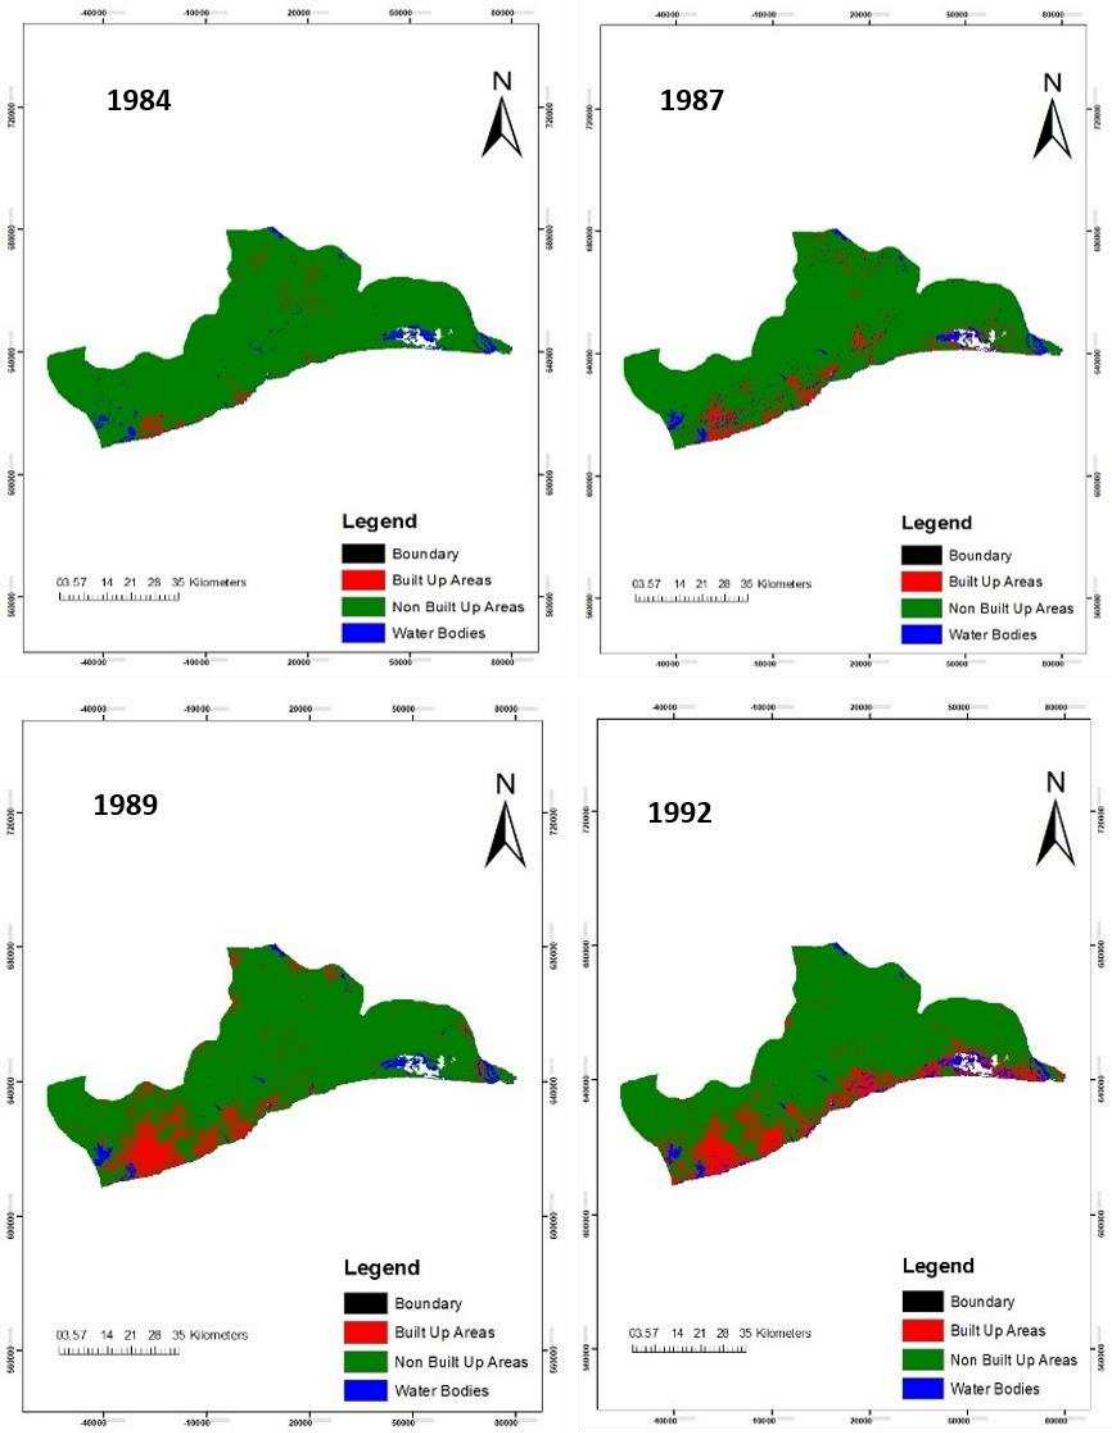

Figure 9. *Map of land cover classification – selected years*

Between 1993 and 1999, there was less development because greater portion of resources was channelled in expanding the country through electrification projects and building of feeder roads. Much of the built up activities was experienced mostly outside the economic capital. After the debt cancellation in 2001, the government had economic space to accelerate infrastructure once more and this increased the built up areas. The gradual increase is adequately shown in *Figure 10*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1314713168

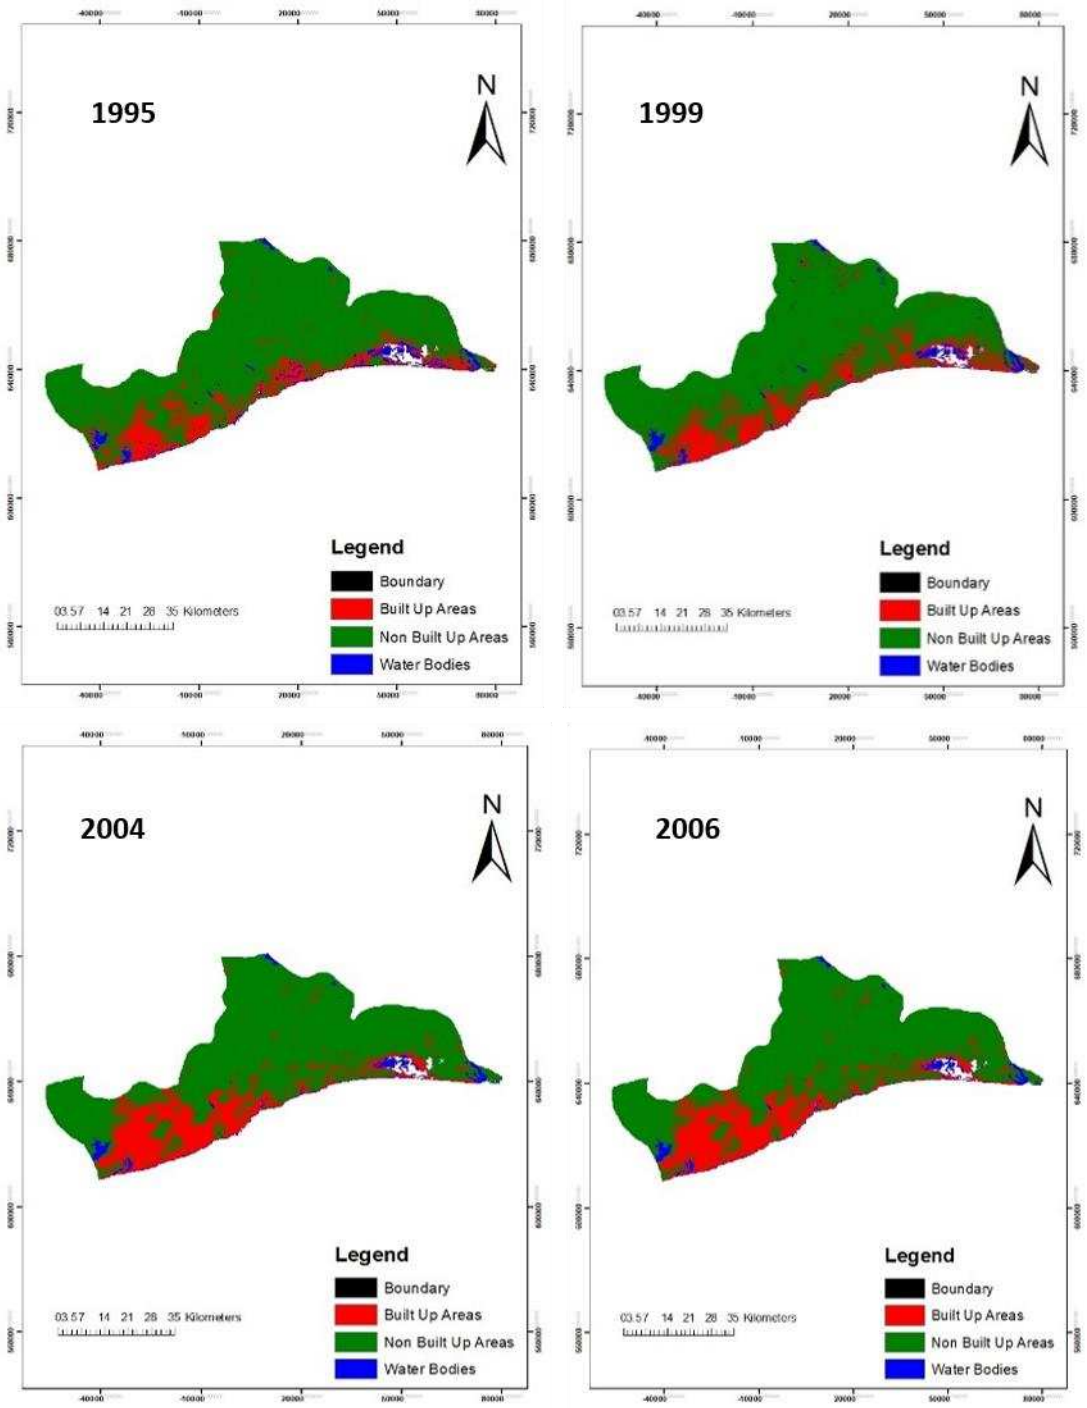

Figure 10. *Map of land cover classification – selected years*

There was a setback in 2007 and 2009 following flooding disaster which resulted in a massive demolishing of structures put up on water ways (dried up streams). The rapid increase in population and massive migration to the economic capital between 2010 and 2014 resulted in rapid housing projects to accommodate the influx. These have their own associated problems as demolishing of houses continues whenever there is flooding. This has seemingly slowed the rapid built up of infrastructure expansion. *Figure 11* shows the apparent scenarios explained above.

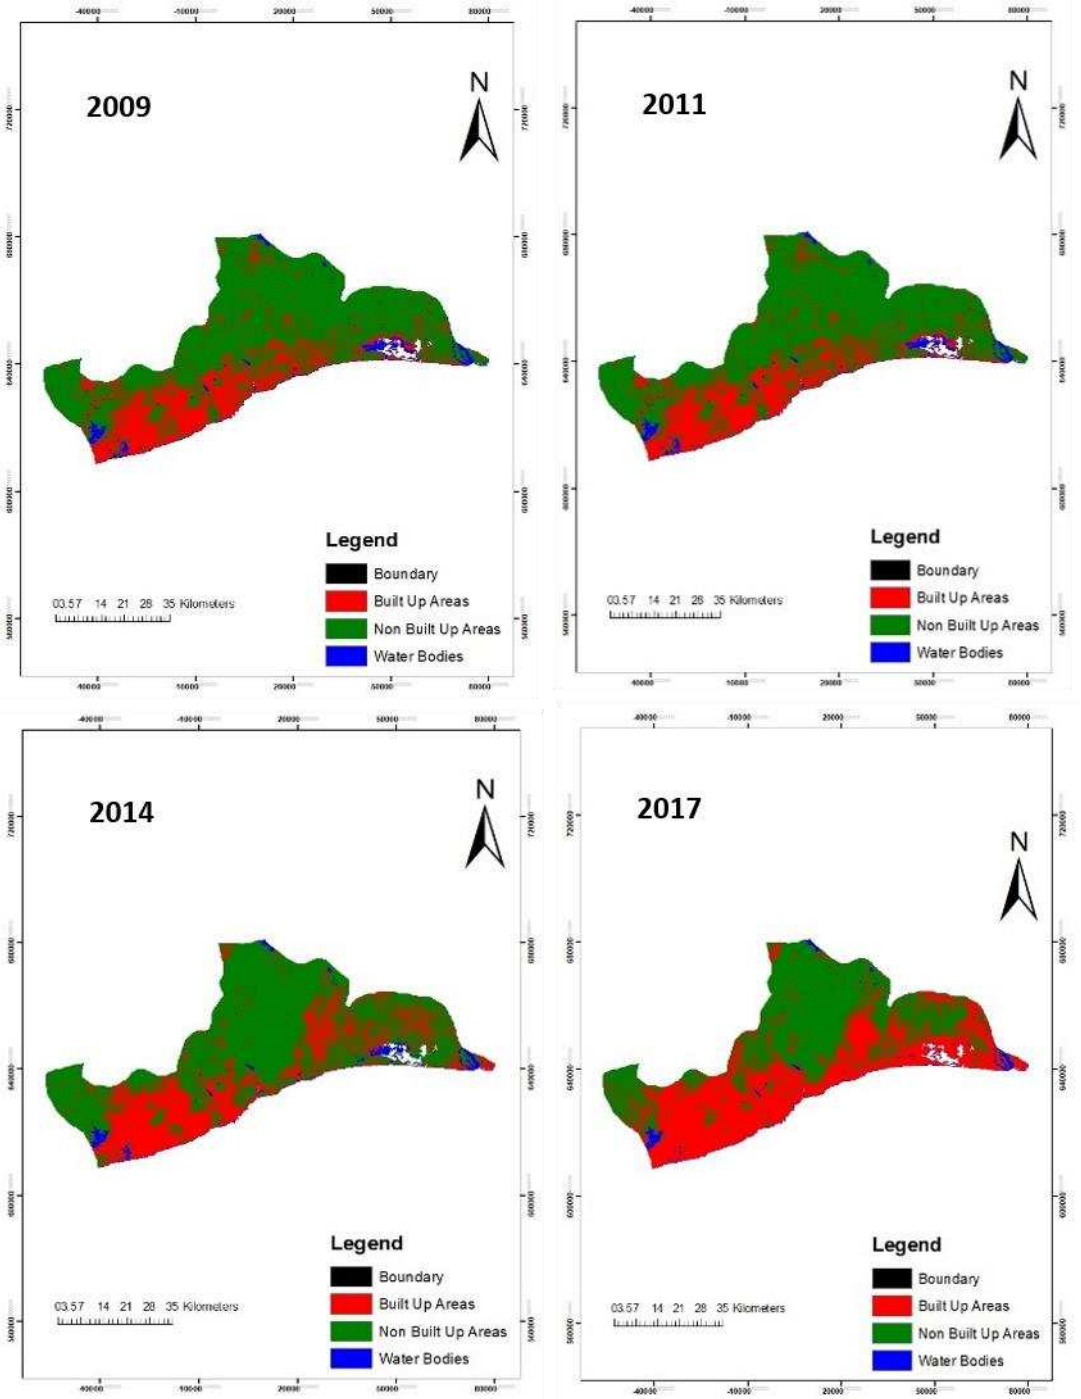

Figure 11. *Map of land cover classification – selected years*

Analysis on non built-up and water bodies performance

Results of the Area coverage percentage indicate a sharp loss of non-built up areas between 1981 and 1987. The 26.52% loss between 1984 and 1987 matches with the 26.82% gain in built up for the same time period. Water bodies lost 3.1% within 37 years translating into an annual loss of 0.08%. The highest loss value for water body

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1314713168

areas is only 1.58% between 1972 and 1984. In between comparable years, water body areas did not decline by even 1%.

Discussion

Band ratios and band combination

This is a very important image processing technique. The DN value of each pixel of one band is divided by the corresponding pixel value of another band. This yielded new number sets from zero (0/1) to 255 (255/1) which highlight more the specific target feature while suppressing the others. When necessary a rescaling can be done to provide a gray tone image resulting in a truer image because effect of shadows (or topographic) are dealt with (Zhouyu et al., 2006). This is an important advantage because eliminating shadows is still a challenge in a mixed urban environment during classification. Rescaling was not done in this study. Two distinct advantages result from band ratios; the differences in spectral reflectance curves of surface types are highlighted, and then illumination and radiance differ. Band rationing has the effect of removing shadows.

Another important property of two band ratios is that some features can be recognized by simply observing a single ratio. Many band ratios exist but involve the use of more than two bands. A few two band ratios exist but are mostly related to lithological discrimination and mapping and applications in hyperspectral image analysis (Simon et al., 2016; Mohammad et al., 2001).

The spectral reflectance curves, of ground targets provide great insight for information extraction. Usually ratio results of 1 or more is expected since pixels of ratios less than unity is characterized by dark signatures. Hence, ratio bands calculations were chosen to give values more than unity or close to unity. Between any two bands, which will be the numerator and which will be the denominator is carefully adjusted.

Maximum likelihood classification

As a parametric statistical classifier, the analyst training samples are numerically presented to the classifier algorithm by assuming that the distribution of the training sample is normally distributed. All unclassified pixels are assigned classes within the probability density function (Lillesand et al., 2015). The greatest advantage with ML is the quality of training samples. Training samples were collected in a homogeneous cover types as much as possible, since Google Earth provide a high resolution visually for good collection. The classifier develops signatures by taking advantage of the spectra of training set pixels which includes the contributions of all the materials in the training set. It is robust for most topographic and climatic variations which were tested in this study due to the stretch of time period over which topography had been affected due to urbanization. During evaluation in the accuracy assessment, it was manifest that while ML provide higher rates of correct recognition, it also yielded some false alarms. Maximum Likelihood classifier over the years has supported by many remote sensing and geographic information system based software such as ERDAS, with a straight forward in implementation.

Google Earth data

Digitizing training samples for ground truth from this platform gives geometrically-corrected high-resolution image. This serves as a great free source of validating data

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1314713168

because Google Earth can go back in time to give a real time training data. Google Earth provide high-resolution image that is coupled with other datasets for effective detection and classification (Xu et al., 2016). The class of water bodies like rivers and lakes is featured by their fairly better pixel uniformity and good spectral discrimination. The classification results using a combination of GE imagery and object-based classification techniques can attain an overall accuracy above 70.00% (Hu et al., 2013), which seem to be the situation in this paper.

Statistical analysis on delineated features

As of 2017 the total urban built-up land occupied in Accra was 2184.53 km^2. Total coverage of built up in Accra before 1972 was 507.84 km^2 but gained as much as 597.73 km^2 (34.07%) between 1981 and 1990 to reach 1815.25 km^2. During the second epoch of 1991-2000, the total coverage moved from 1876.26-1950.89 km^2. It increased only from 2004.76 to 2048.24 km^2 within the third epoch of 2001-2010. From 2011-2017 it added up to 241.10 km^2 in coverage. These figures are different from the results obtained by (Osei et al., 2013). According to their findings, urban areas covered 534.2279 km^2 in 2014 but our results indicate 2103.08 km^2 for the same year. We are inclined to say, their analysis might be off since the total land size of Accra as indicated by them is 3693.69 km^2 in 1985 and 3694.70 km^2 in 2014. This is problematic since Greater Accra region was not demarcated again in 2014. The total size since 1960 has remained 3245 km^2 and not what was obtained by them. Again areas covered by water have declined since 1985 due to buildings springing up on waterways which eventually dries the streams. It lost from 15.86% in 1972 to 2.88% by 2014. What is left now are the big rivers and big drains. However, their results showed very little change, 11.80% in 1985 to 11% in 2014. Over the period of 1984-1994, Accra increased its built up areas 7.2%. Over the 37-year study period, non-built up areas lost almost 49% to built-up areas because it gained by almost the same margin by 2017. Water bodies remained fairly stable with only 3.1% decrease over 37 years which means it lost 0.084% annually.

Conclusions

Remote sensing has the exclusive capability to support the extraction of urban features to detect urban growth with associated by-problems as, rise in surface temperatures, high traffic volume or population assessment. Change is very regular with all cities. These changes have both temporal and spatial characteristics which transformations can be temporally measured. Multi-year remote sensing information offers an essential source for monitoring and evaluating these endless changes with sufficient information for spatial urban growth investigation at regional level and at varied spatial and temporal scales. Understanding dynamic interaction between diverse aspects of urban expansion as expansion of built-up area and construction activities is very important as it is a very essential indicator of economic growth of a country. Again, the extraction of urban land-cover and land-use studies help to answer questions associated with these interrelations and its endless changes.

Band ratios have been used for many years in the field of remote sensing to classify terrain cover types. In this paper, we have shown the potential of spectral band ratio features for accurate pixel classification. Two band ratio combinations created in this study exhibit a better discrimination of urban features and patterns of urban growth. It

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1314713168

looked at the growth rate, growth change and the spatial area coverage of the economic capital of Ghana. This paper utilised the entire archive of Landsat data and does a 10-year varied-year analysis unlike other depiction of only two years, which is inadequate for in-depth analysis. Every algorithm has its own strengths and flaws. To effectively detect built-up areas based on a chosen algorithm, the nature of the input data is important. Depending on the output of this study, we can primarily say that, the quality of the training data required in supervised classification added to the success of the classification stage.

There were some inconsistencies in the built-up rate but this may be attributed to an uncoordinated land tenure system in the city which resulted in settlements springing up at hitherto odd inhabited places. This occurrence add-up positively because they all contribute to the built-up areas. Also, it can negatively impact because during digitising such sparse small areas might not be classified at all, or could be wrongly classified. The study provided here gives information that can be used by decision makers to make informed decisions on spatial planning, economic policy drafting and a real realisation of the translated impact of government economic policies as there is a direct relation between population growth, urbanisation, infrastructure deficits and GDP. Outputs present readers a guide on spectral diversity, band combination and accuracy assessment for urban areas detection.

Finally, the freely obtainable and accessible Google Earth data coupled with the high spatial resolution can serve as a reliable and effective source of data in urban land-use and land-cover mapping and change detection analysis. Another benefit of Google Earth is that it offers images at different time period which is very useful for urban engineers for land-use change detection studies. Although GE has more advantages, few studies have been done on the use of this data source for land-use mapping. Except for its spectral characteristics, it can make full use of the spatial features of objects, which can, to some degrees, strengthen the advantages of GE based data for its high spatial resolution and compensate its limitation of poor spectral information. This paper contributes to the search for simple use of basic classification techniques to classify urban areas over large geographical areas. It was able to adequately classify the targeted features.

(Received 31st May 2019; accepted 2nd Sep 2019)

Abstract. This study presents the application of Artificial Neural Network (ANN) techniques to estimate the total energy use of broiler farms. Chicken meat is shown as one of the important parameters in the modeling of energy use efficiency of broiler farms. However, the measurement of this extremely important parameter is difficult and takes a long time to obtain the desired results. In order to overcome such difficulties, scientists have tried to develop alternative methods. The farm-scale data used in the study was obtained from 30 broiler farms in Mersin (Turkey) province in 2018. In the application of ANN model, consumed feeds, electricity, fuel, water, broiler farms, chicks, human labor and machinery parameters used in the farm are used as input; broiler poultry meat and fertilizer parameter are used as output. In addition, the total energy equivalent estimates of chicken meat were made using various input combinations to investigate the best results model. The highest coefficient of determination (R^2) (0.936) and the lowest root mean square error (RMSE) and the mean absolute error (MAE) values were found to be 0.232 and 0.019, respectively. The results showed that the ANN model is a very promising approach for the estimation of total energy equivalent of chicken meat in broiler farms.

Introduction

The need to provide adequate food for the increasing population of the world has increased energy consumption in agriculture. Increased population and energy demands have forced governments to work on the efficiency of energy use. This issue makes agriculture vulnerable to oil prices (Taki and Yildizhan, 2018). Agriculture, as an efficient part of the economy, plays an important part in national production. With the reduction of energy resources, people will be forced to produce more food with less energy consumption in the future (Rohani et al., 2018). Agriculture is not only an energy consumer but also an important energy supplier (Almasi et al., 2008). Poultry meat offers significant potential to meet human nutritional needs (Folorunsho and Onibi, 2005). 35 g protein of animal origin is recommended for daily intake by FAO (FAO, 2011). In human nutrition, one third of the meat consumed in the world is obtained from broilers (Atilgan and Koknaroglu, 2006). Efficient use of energy in agriculture reduces environmental problems, prevents the destruction of natural resources and develops sustainable agriculture as an economic production system (Hatirli et al., 2005). In animal production systems, energy and feed are the main components of production costs (Rivera-Torres et al., 2010). Energy efficiency relates to the reduction of inputs purchased in agricultural production. The modeling capability

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1316913183

of ANN has made them the most popular tool for modeling the biological processes of complex systems with nonlinear properties (Kologirou, 1999). Artificial neural networks have a high approach and have a great advantage in a short time such as problem solving (Bechtler et al., 2001). ANN is applied in a wide area such as energy, mathematics, engineering, medicine, economy, environment and agriculture (Safa and Samarasinghe, 2001). ANN is one of the smartest techniques that are flexible and do not require too much physical complex operation (Yazdani et al., 2009). ANN is an optimization algorithm in which the learning process is tried to be modelled mathematically. ANN is a simple approach to a complex process, but uses the basic concepts inherent in the learning processes of people and animals. The ANN imitates the human brain's ability to learn by experimenting to produce solutions to problems that require a person's thinking and observing abilities. Learning in humans occurs by adjusting the synaptic connections between nerve cells (neurons). Since one birth, because of the process of learning by experience, the brain shows a continuous improvement. As the number of experience increases, synaptic connections are adjusted and new connections are created. In this way, learning takes place. This also applies to ANN. Learning is through training, using examples. By processing the input and output data, the training algorithm using this data, it is possible to re-adjust the connection weights until a convergence is achieved (Keskin and Taylan, 2007). ANNs are universal function estimators that work better than traditional function approach methods (Farjam et al., 2014). Classical regression analysis does not give any good results due to the nonlinear complex relations resulting from the nature of the problem. There are other methods that can be used more appropriately in cases of uncertainty. There are various methodologies in the literature, such as artificial neural networks (ANN), fuzzy logic, adaptive neuro-fuzzy systems which can be expressed as flexible methods. ANN models can be used to estimate the performance of the energy efficiency of broiler farms (Yurtoglu, 2005). In efficient energy use in agriculture, mathematical models have been used to find the relationships between the inputs and outputs of a production process (Pahlavan et al., 2012). Mathematical functions are of great importance in finding the relationship between inputs and yield by various methods (Hatirli et al., 2006). In study conducted in Iran using artificial neural networks; total equivalent input and output energy in broiler production was calculated as 153.79 and 27.45 GJ per 1000 birds, respectively (Amid and Gundoshmian, 2016). Rahman and Bala used artificial neural networks to estimate the dry matter of the cannabis plant in Bangladesh using parameters dependent on climatic conditions. They concluded that the best model had two hidden layers, the 6-9-5-1 structure (Rahman and Bala, 2010). Houshyar et al. in the wheat production in Iran, ANN was used. The best model for this study was the GFFN model with a hidden layer and the LM training algorithm with $R^2 = 0.95$ and RMSE = 0.071 (Houshyar et al., 2010). Using artificial neural network, Taki et al. have concluded that the optimal network for the estimated output energy of wheat production has two secret layers, each containing 8 neurons and which can be well predicted (Taki et al., 2012). In another study, Zangeneh et al. have compared the results of the implementation of two different approaches, namely, parametric model (PM) and ANN models, to evaluate the economic indices that benefit economic efficiency, total production costs and the cost ratio of the potato crop (Zangeneh et al., 2011). A study was carried out on the estimation of the energy demand of greenhouses by artificial neural network. In this study R^2, RMSE and MAE were found to be 0.93, 0.187 and 0.058, respectively (Trejo-Perea et al., 2009). Some other non-linear models such as

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1316913183

artificial neural networks, adaptive neuro-fuzzy inference system and nonlinear similar studies have been used in regression technique (Ekici and Aksoy, 2011; Mellit and Kalogirou, 2011; Talebizadeh and Moridnejad, 2011; Nefeslioglu et al., 2008; Yagiz et al., 2009; Dagdelenler et al., 2011). A multi-layered ANFIS has been used to estimate the yield of agricultural products (Naderloo et al., 2012; Khoshnevisan et al., 2014a, 2014b). In Iran, Heidari et al., in a study done in Yezd province measured energy efficiency of five-input and two-output parameters and broiler units, 16 were found to be fully efficient from 44 poultry farms (Heidari et al., 2011a). Heidari et al. using the Artificial Neural Network models estimated the Benefit Cost Ratio (BCR) of chicken farms in the tropical regions of Iran (Heidari et al., 2011b). The neural network used a multilayered feed network with five neurons (bird cost, labor cost, food cost, fuel cost and electricity cost) in the input layer and a neuron (benefit-cost ratio) in the output layer (Layer structure 5-20-1). Statistical indicators were estimated in R^2, RMSE, MAE and to verify the model. The indicators were calculated at 0.978, 0.002, 0.037 and 2.695 (Heidari et al., 2011b). Sefeedpari et al., in order to estimate the energy consumption of egg production farms in Iran, they used a three-entry ANN model to estimate variables such as fuel energy, electricity and feed energy (Sefeedpari et al., 2012). Atilgan and Koknaroglu according to the results of energy analysis used in broiler production units, showed that larger production units had higher energy efficiency compared to smaller production units (Atilgan and Koknaroglu, 2006). The electricity, fuel and manpower used in the 60,000-capacity brolier farm are reported in the winter 2395.8, 38563.88 and 94.85 MJ, respectively, and in the summer were 3359.5, 66.124, and 94.58 MJ, respectively (Sedaghat Hoseyni et al., 2008). Risse et al., who studied poultry farms as an energy source (Risse et al., 2007). reported that poultry manure saved 283 million gallons of fuel in the United States. In this study, Artificial Neural Network (ANN) models are applied for efficient use of Broiler Farms and estimation of total energy use.

Artificial neural networks (ANN)

ANN is a sub-branch of artificial intelligence. The artificial working principle of the human brain is the artificial systems that have adopted the model. ANN is one of the most popular subjects of modern science with its ability to learn, adapt, ability to work with little information, fast work and identification. ANNs work with the principle of increasing knowledge and experience through learning and producing results by benefiting from the learning (Oztemel, 2003). Environment, agriculture, engineering, medicine, such as employees working in various areas of the sphere of their own areas of expertise, began to develop applications in their own fields. This interest is further strengthened by the theoretical and practical successes. It has been seen that some areas that seem to be unique to human intelligence can be expressed numerically, and thus machines can perform learning and recalling in a surprisingly similar way to human intelligence. Artificial neural networks are a powerful computational system inspired by the structure and learning characteristics of biological neuron cells and are very powerful classifiers in pattern recognition. Artificial neural networks, especially with the development of computer technology, have found a wide range of applications in the field of engineering (Kalogirou, 1999). Artificial neural networks are parallel information processing structures with the following characteristics:

- Inspired by a biological neuron, a mathematical model was introduced.
- It consists of a large number of processing elements connected to each other.
- Connection holds information with weights.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1316913183

- A processing element can react dynamically to the input warnings and the response is entirely dependent on local information (the input signal through the connections and link weights that affect the respective processing element).
- It has learning, recalling and generalizing skills thanks to the connection weights set by the training data.

These outstanding features provide the ability to solve complex problems in artificial neural networks. It has found wide application areas in the fields of modeling and control. ANNs are first trained using the available data and then tested with unused data during training. Although training takes quite a long time; they decide very quickly during use. They found a wide range of applications in modeling both linear and nonlinear systems because of their ability to tolerate learning, generalization and errors and to take advantage of faulty samples (Haykin, 1994). ANN is looking at the examples of events and making generalizations about these events, collecting information and using the information they have learned when they have never seen them before and can decide on those examples (Ozcalik and Kucuktufekci, 2003). The concept of artificial neural networks (ANN) emerged with the idea of mimicking the working principles of the human brain on digital computers and the first studies focused on the mathematical modeling of neurons. Studies have shown that neurons exchange information with neighboring neurons. The so-called artificial neural networks are composed of neurons coming together in certain forms. ANN models differ from conventional models with non-algorithmic parallel and distributed information processing capabilities. Thanks to these different features, ANN can easily and quickly perform complex and non-linear accounts. Non-algorithmic and very intense parallel operations can be performed in parallel with the ability to learn and parallel distributed memory has led to new perspectives in the calculation. Input layer neurons transmit values to the next information processing layer elements through links that retrieve input information. This process continues until the output layer is reached. This type of information flow is known as the network feed forward network, which occurs in one direction. A typical ANN model is given in *Figure 1*. ANN models are configured as single or multiple inputs, and single or multiple outputs.

Feed forward back propagation artificial neural network (FFBPANN) model

In this study, ANN (i, j, k) model is created to show input, hidden and output layers of icons i, j and k, respectively. Each layer is composed of many neurons and is bound by weight clusters between layers. The way of attachment and the number of neurons in each part may vary. Communication between neurons in the same section is not allowed. At the beginning of this training process, connection forces are assigned as random values. The learning algorithm changes the force until each iteration is completed with success. When the iteration process reaches a conclusion, the coupling forces obtain and store the available information in the samples used in the training process. When a new input group is presented, an output group is obtained by means of the learned and stored information in the connection forces of the artificial neural network with forward feed. Here, i and k values are 1 and j values are taken as 2, 3, 5, 7, 9, 10, 12 and ANN models are created. In this study, sigmoid function is used as transfer function, and back propagation algorithm based on generalized delta rule is used for ANN training (ASCE, 2000). The article aimed to use Artificial Neural Network (ANN) techniques to assess broiler farm energy consumption as a method that can sufficiently calculate the energy equivalent of chicken meat.

Materials and methods

In this study, data were collected from 30 producers of broiler farms in Mersin. In the Mediterranean region city of Mersin, located south of Turkey. It is located between 36° 48' N and 34° 38' E (*Fig. 2*). The average annual temperature is approximately 19.2 °C and the total annual rainfall is 592.1 mm. Approximately 94% fall from October to May (GDM, 2017).

Figure 2. *The location of the Mersin province involved in the presented study*

Data on the production of broiler farms were collected with face-to-face surveys from the producer in 2018. Samples were selected using randomly selected random sampling method. Using the random sampling method of the producers who are producing in Broyler Farms in Mersin province where the production was made in 2018, the sample size was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1316913183

calculated using the following equation (Newbold, 1994): The total number of registered farmers in Mersin in 2018 year was 35039 (GDAE, 2018). The Neyman method was applied to determine of number the farmer(Yamane, 1967).

$$n = \frac{N \times S^2}{(N-1)S^2_x + S^2} \quad \text{(Eq.1)}$$

where n is the required sample size, N population volume, S standard deviation, S_X sample is the standard deviation of the mean (S_X = d / z), z is a reliability coefficient, d is based on the allowable error equation of the sample size (*Eq. 1*) In the Broiler Farms, the number of samples examined for production systems was 414. The permissible error (d) was defined as 5%, and for 95% reliability (z), the sampling size of 414 was calculated. First, the most common production systems for each Broiler Farm were identified, and then all inputs and outputs from the systems were identified and digitized, and then converted to energy units. With the addition of partial energies to the total energies per production unit, the energy inputs of each input were: chicks, human labor, fuel, electricity, feeds, water and machine. In order to estimate the energy in the MJ unit equivalents were used to find the input quantities as presented in *Table 1*.

Implementation of feed forward back propagation artificial neural network model

Analysis of 414 data from 30 broiler farms consisting of chicken meat and manure from seven input vectors (feeds, electricity, fuel, chicks, machinery, human labor and water) and two output vectors was considered. The data is divided into two groups to form the training and test sets. While constitute 276 data training sets, the remaining 138 data sets, were used as the test set in evaluating the performance of the program to the real values. The estimated network structure in Artificial Neural Networks model for broiler farms is given in *Figure 4*. In this study, for the evaluation of errors, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1316913183

coefficient of determination (R^2), the square root of the mean square error (RMSE) and the mean absolute error (MAE) functions were used.

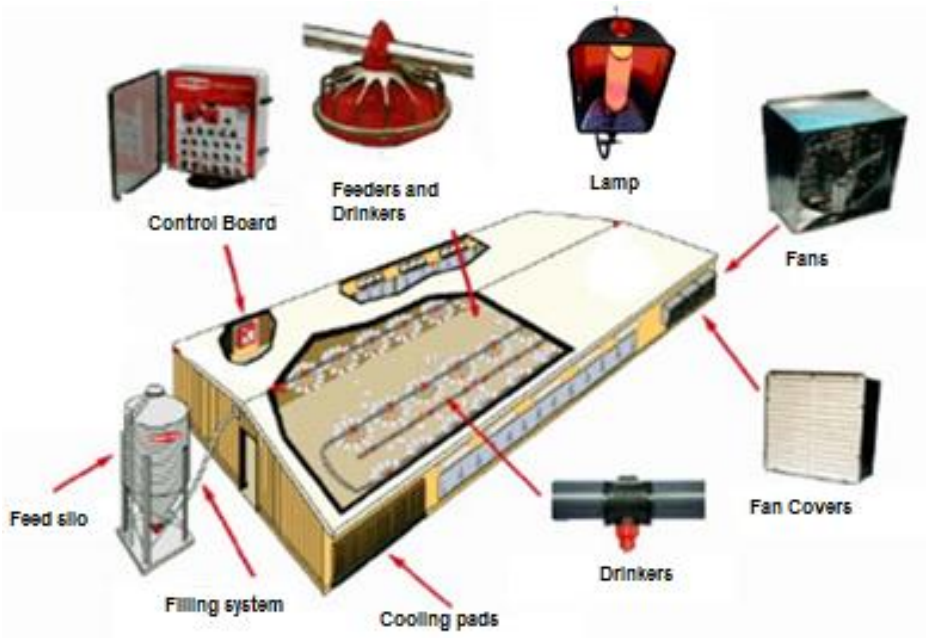

Figure 3. *Poultry equipment used on broiler farms*

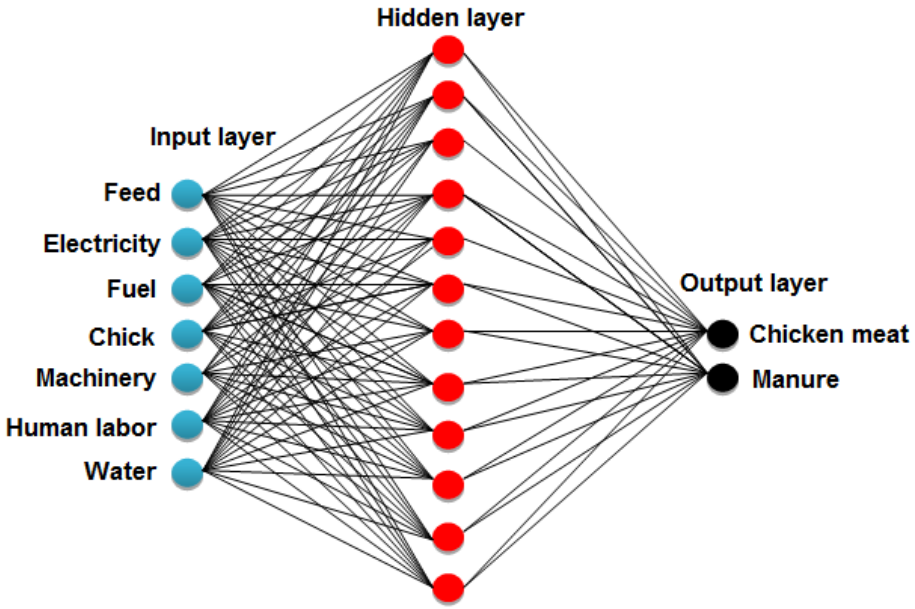

Figure 4. *Network structure estimated in the neural networks model for broiler farms*

In this study, each model was tested with the test data set by training the training data set and the root of the square root mean square (RMSE) was calculated by using *Equation 2* (Landeras et al., 2008). One of the best evaluations used for statistical indices, the root of the mean square error (RMSE), as well as R^2 estimation value were found with *Equation 3*. The related equations are:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1316913183

$$RMSE = \sqrt{\frac{\sum_{i=1}^{N}\left(yi - yi^{'}\right)^2}{N}} \quad \text{(Eq.2)}$$

According to the R^2 equation; m is the number of data tested, the estimated data on the Oi neural network, *yi* is the amount of data calculated (Traore et al., 2010).

$$R^2 = \frac{\left[\sum_{i}^{m}(yi - \overline{y})(Oi - \overline{O})\right]}{\sum_{i=1}^{m}(yi - \overline{y})^2 \sum(Oi - \overline{O})^2} \quad \text{(Eq.3)}$$

where $\overline{y}$ is the average of the calculated data amount (yi) and the mean values of the estimated data amounts (Oi) in the $\overline{0}$ artificial neural network. In addition, mean absolute error (MAE) values were calculated (*Eq. 4*) (Trejo-Perea et al., 2009).

$$MAE = \frac{1}{N}\sum_{i=1}^{N}\left|y_i - y_i^{'}\right| \quad \text{(Eq.4)}$$

Sensitivity analysis using feed forward back propagation artificial neural network model

The choice of input parameters to be used in the FFBPANN model is important for the performance of the model (Khoshnevisan et al., 2014b). The effectiveness of the inputs in the model can be determined by sensitivity analysis. For the estimation of chicken meat, each input parameter was used individually and the most sensitive parameter was found with FFBPANN. The results are shown in *Figure 5a-g*. In addition, it was found that which combinations of inputs would give the most effective model by using sensitivity analysis (*Table 4*). As a result of sensitivity analysis, it was observed that all input parameters were important in estimating chicken meat. The feed input parameter is the most effective parameter for poultry meat prediction; Water as the least effective parameter is determined by the sensitivity analysis as shown in *Figure 5a* and *g,* respectively.

DOI: http://dx.doi.org/10.15666/aeer/1706_1316913183

Determination of the most appropriate FFBPANN model

FFBPANN model, which gives the best result, was obtained after various trial errors. The determination of the FFBPANN model is shown in *Table 5*. RMSE and R^2 performance functions are used to find the most effective FFBPANN model. In this study, the number of secret layer neurons is determined as 12 as seen in *Table 5* after various experiments. The highest performance is the ANN (7.12.2) model. It is also understood from *Table 5* that the maximum number of iterances is 1000 for the training of the model.

Table 5. *Determination of the most effective IBGYYSA model*

ANN (number of neurons in layers)	Number of iterations	Determination factor (R^2)	Root of the mean square error (RMSE)
ANN(7,2,2)	1000	0.885	0.197
ANN(7,3,2)	1000	0.889	0.201
ANN(7,5,2)	1000	0.892	0.207
ANN(7,7,2)	1000	0.896	0.209
ANN(7,9,2	1000	0.852	0.152
ANN(7,10,2)	1000	0.911	0.217
ANN(7,12,2)	1000	0.936	0.232
ANN(7,2,2)	2000	0.861	0.159
ANN(7,3,2)	2000	0.865	0.167
ANN(7,5,2)	2000	0.868	0.171
ANN(7,7,2)	2000	0.872	0.175
ANN(7,9,2	2000	0.843	0.149
ANN(7,10,2)	2000	0.877	0.178
ANN(7,12,2)	2000	0.882	0.186

The model was tested after the training of the FFBPANN model. When the test set chicken meat predictions were compared with the measured chicken meat, it was observed that the estimates of FFBPANN were very close to the observed ones. *Figure 6* shows that the predicted values are very close to the observed values and their tendency is almost equal.

Results

In this study, the data obtained from 30 broiler farms in Mersin province by using feed forward, back diffusion artificial neural networks FFBPANN model the energy consumption of poultry was tried to be estimated. In the network structures where the best results for the test and training data are obtained; R^2, MAE and RMSE etc. statistical analyses were performed. Training and test R^2 values showed that the ANN used in this study gave high accuracy results. Each input parameter was used as an input in a separate model and the efficiency levels of each parameter in the estimation of chicken meat were found. As a result of this, the most effective parameter is that feed supply energy. Then the energy of electricity, fuel, chicks, machine and human labor are effective, respectively; water supply energy has been determined as the least effective parameter. Furthermore, sensitivity analysis was performed for the determination of the most effective model due to the fact that an effective Forward Feed Back Artificial Neural Networks FFBPANN model was dependent on the input parameters. As a result of sensitivity analysis, it has been observed that all input supply energy parameters have an influence on the model of Feed, Electricity, Fuel, Chicks, Machines, Human labor and Water, ANN model. As a result, for the broiler farm process, the Advanced Feed Back Flow Artificial Neural Networks model proved that using ANN in the estimation of chicken meat supply energy is a better technique than traditional mathematical modeling. It can be said that Broiler Farms can be used as a very effective model in the evaluation of energy use estimation due to the fact that they provide realistic and reliable estimates thanks to well-trained ANN parameters. The model developed in this study has an acceptable generalization ability. Since it is an effective analysis and identification method to simulate the nonlinear behavior of the Broiler Farms of ANN, it is concluded that it is used as a good performance evaluation method. The highest coefficient of determination (R^2) 0.936 and the lowest root of the mean square error (RMSE) and the mean absolute error (MAE) values were found as 0.232 and 0.019, respectively. Sensitivity analysis showed that all input parameters (Chicken Meat) were important in estimating chicken meat. (Feed) Feed input parameter (Chicken Meat) is the most effective parameter for estimating chicken meat, Water was determined as the least effective parameter by sensitivity analysis.

Based on the findings of this study, ANN topologies are recommended. In the study conducted in the province of Mersin it has been found efficient in the estimation of energy usage of seven inputs, two output parameters and broiler farms by using ANN techniques.

QUERCETIN REDUCES OXIDATIVE STRESS DAMAGE TO REPRODUCTIVE PROFILE INDUCED BY 2,3,7,8-TETRACHLORODIBENZO-*P*-DIOXIN IN MALE ALBINO RATS (*RATTUS NORVEGICUS* L.)

ABDULKAREEM, S. M.* – NANAKALI, N. M.

(Received 1st Jun 2019; accepted 2nd Sep 2019)

Abstract. The article aimed to investigate the effect of the antioxidant quercetin (QCT) on male Wistar albino rats under oxidative stress caused by 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), focusing on their reproductive system, in order to find a way to combat declining male productivity. Thirty adult male Wistar rats of body weight ranged from 230 to 250 g were randomly divided into five equal groups (6 per group), designated as normal control (corn oil) and treatments: 10 µg/kg TCDD; 20 mg/kg QCT; 20 mg/kg QCT + 10 µg/kg TCDD (pretreatment of QCT); 10 µg/kg TCDD + 20 mg/kg QCT (post-treatment of QCT), and the treatments were administered intragastrically by gavage for twelve weeks and the study was conducted in Salahaddin University-Erbil, Iraq. In each group, three males were mated with untreated fertile females, and the reproductive and biochemical parameters were evaluated for each group. TCDD significantly reduced the values of sperm quality (motility, viability, and count), serum testosterone, sex ratio, body weight, gonads weight, and testicular antioxidant enzymes (superoxide dismutase, catalase, and glutathione reductase). However, increased sperm abnormality and oxidant biomarker (malondialdehyde) were observed. Concomitant treatment with QCT ameliorated these affected values, especially when QCT treatment was administered 30 min before TCDD dosing.
Keywords: *TCDD, QCT, sperm quality, male fertility, antioxidants*

Introduction

It is believed that biological factors such as contamination of the environment have a considerable impact on male fertility. Various environmental contaminants responsible for the global decline in male reproductive health have been suggested (Erthal et al., 2018). One of these environmental polluters is dioxins, and dioxin-like compounds that are known as endocrine-disrupting and reprotoxic pollutants (Dhanabalan et al., 2011). These substances exerted their cellular and metabolic effects through interactions with the aryl hydrocarbon receptor (AhR) associated with the xenobiotic- (XRE) and antioxidant responsive (ARE) DNA elements (Nguyen et al., 2009). Upstream genes such as the promoter of the cytochrome P450 1A1 (CYP1A1) and another Ah-responsive gene that organizes the expression of the genes participating in the metabolism and detoxification of polycyclic aromatic hydrocarbons such as dioxins and dioxin like-compounds in experimental animals and humans (Mandal, 2005).

Dioxins suchlike 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) are leaked as unwanted by-products to the environment from several industrial processes such as the production of certain herbicides, pesticides and plastics, and combustion of plastics and medical waste (Anderson and Fisher, 2002; Hewitt et al., 2006; Lin et al., 2006). Home heating systems, cars exhaust, and cigarette smoke have been found to contain trace

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1318513197

quantities of dioxin (Fiedler et al., 1990). TCDD is a toxic chemical compound and a widespread potent environmental contaminant, and because of its lipophilicity and long biological half-lives, it bioaccumulates in organisms and biomagnifies in the food web. They enter to human body primarily by eating food rich in animal fat and accumulating in human fatty tissues (Jackson et al., 2017). TCDD can affect male fertility by reducing the number of sperm (Pilsner et al., 2017), changes in motility and in sperm transit time (Sanabria et al., 2016), serum testosterone (Karman et al., 2012), lowering reproductive organs weight (Jin et al., 2010), delayed sexual maturation (Takeda et al., 2012), and can also change the "male/female" sexual ratio of offspring (You et al., 2018).

Quercetin (3,5,7,3',4'-pentahydroxyflavone, QCT), a compound of yellow powder extracted from natural sources and have a potent antioxidant, due to the existence of two pharmacophores, the catechol group in the B-ring and the OH group at situation 3 within the molecule scavenging the free radicals (Nabavi et al., 2015). It is found in several daily foods such as onion, grape, nuts, tea, berries, cabbage, and cauliflower (Azzi et al., 2018). Inal and Kahraman (2000) reported the following biological effects of QCT: anti-cancerous, antiviral, anti-ischemic, anti-inflammatory, and anti-allergenic, in addition to the protective power against atherosclerosis and coronary heart disease.

In animal studies, TCDD exposure has been shown to induce testicular damage and QCT may reduce the male reproductive toxicity of TCDD due to its antagonistic activity against AhR which is activated by TCDD (Ciftci et al., 2012). Melekoglu et al. (2016) reported that TCDD and related substances promote the production of reactive oxygen species (ROS) in the reproductive system. Additionally, several studies have shown that TCDD exposure results in oxidative damage to many tissues, such as the kidney, liver, and testis (Palaniswamy et al., 2014; Slezak et al., 2000).

Though to our knowledge, there are some literary works on the mitigating role of QCT in testicular damage caused by TCDD. Therefore, the purpose of this study was to assess the role of QCT in alleviating the testicular damage caused by TCDD in rats by estimating serum testosterone, sperm qualities, and determining the levels of the oxidant-antioxidant biomarkers activity in the testis.

Materials and methods

Chemicals

2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD; purity > 99%) and quercetin (QCT; purity > 99%) were purchased from Beijing Solarbio Science & Technology Company, Ltd. (Beijing, China), and corn oil (Afia, Saudi Arabia) was obtained from local markets. TCDD was dissolved in corn oil at a dose of 10 μg/kg body weight, and QCT at a dose of 20 mg/kg body weight was also dissolved in corn oil.

Experimental animals

Thirty adult male Wistar rats, *Rattus norvegicus*, used for this study were procured from the Laboratory Animal Center (College of Science, University of Zakho, Duhok Province, Iraq). The rats were acclimated to the animal housing for two weeks before the start of dosing. They were preserved in plastic cages with wire mesh coverings and kept in an air-conditioned and well-ventilated room in a controlled light environment (12-h light/dark cycle) and temperature (22 ± 2 °C). Rats were fed on a balanced rat chow, and water (tap water) provided ad libitum. The local Committees approved the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1318513197

experimental protocols for using animals of the Salahaddin University-Erbil, Erbil city, Kurdistan Region of Iraq. The care and handling of the experimental animals were performed according to the precepts of the National Institutes of Health Guide for the Care and Use of Laboratory Animals (NRC, 2011).

Experimental design

The body weight (BW) of the animals ranged between 230 to 250 g. After weighing, the animals randomly divided into five equal groups (n = 6), and the treatment was given intragastrically by gavage for twelve weeks: The 1st group was kept as a normal group and was given corn oil (vehicle). The 2nd group (TCDD group) was orally administered TCDD at a dose of 10 µg/kg BW/day. A dose of 20 mg/kg BW/day of QCT was treated to rats in group 3 (QCT group). In group 4 (QCT-TCDD), rats were treated with TCDD (10 µg/kg BW/day) and QCT (20 mg/kg BW/day) 30 min before TCDD treatment (pre-treatment group), while in group 5 (TCDD-QCT), after 30 min of TCDD administration (10 µg/kg BW/day), animals were treated with 20 mg/kg BW/day of QCT (post-treatment group).

Body weight and gonadosomatic index (GSI)

The rats weighed once per week throughout the experiment and the weight gain determined at the end of the study. The testes and cauda epididymis were removed and weighed to measure the gonado-somatic index (GSI) and epididymal-somatic index (ESI) by the following equation:

$$GSI = \frac{Gonad\ weight\ \times\ 100}{Body\ weight}$$

$$ESI = \frac{Weight\ of\ epididymis\ \times\ 100}{Body\ weight}$$

Serum testosterone concentration

Serum testosterone concentration was measured by the enzyme-linked immunosorbent assay (ELISA) method using DRG ELISA testosterone kit (ELISA EIA-1559, 96 wells; DRG Instruments, GmbH, Marburg, Germany), as directed by the manufacturer's instructions.

Preparation of tissue homogenates

The testis tissue samples were homogenized in extraction solution specialized for each test, using an Ultra-Turrax (Janke and Kunkel IKA, Labortechnik, Germany) homogenizer at 20000 rpm/min. The resulting homogenate was centrifuged at 8000 rpm for 10 min at 4 °C using a cooling centrifuge (Biobase, China). The resulting cell-free supernatant was used for the biochemical analysis. The product was assessed spectrophotometrically according to the manufacturer's protocol.

Lipid peroxidation and anti-oxidant assay

The level of lipid peroxidation of testis tissue was measured spectrophotometrically (EMC^2 GmbH, Germany) by determining the malondialdehyde (MDA) production and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1318513197

the antioxidant profiles such as superoxide dismutase (SOD), catalase (CAT), and glutathione reductase (GSH-R) levels were assayed using the kit method supplied by Beijing Solarbio Science & Technology Company, Ltd, (Beijing, China). The results are expressed per unit weight of tissue.

Sperm quality analysis

Spermatozoa were obtained from the right cauda epididymis, which was carefully removed, cleaned, and immediately placed into a pre-warmed container with 1 ml of phosphate-buffered saline (PBS, pH 7.2) at 37 °C and minced with scissors (Narayana et al., 2005). Subsequently, sliced tissue was incubated at 37 °C for 10 min. All epididymal samples were examined for the following parameters:

Sperm motility analysis

Sperm motility was evaluated by counting 200 sperms per rat counted throughout at least 10 fields of view of the sample on a pre-warmed slide (37 °C) under prewarmed coverslip (37 °C) using binocular microscope (Nikon, Japan) with a warmed stage (400× magnification).

Total sperm count

The sperm counting was carried out by diluting the sperm suspension with PBS (1:20) in the pipette with white bead, then mixed gently, after that a drop of the suspension was delivered into the Neubauer hemocytometer in each side of the counting chamber. The hemocytometer was allowed to stand for 5 min for sedimentation, and then sperms were counted under binocular microscope (Nikon, Japan) in large eight squares of 1 mm^2 each area with the exception of the central area for erythrocyte counting of Neubauer's chamber was performed and multiplied by a 5 × 10^4 factor to calculate the total count of spermatozoa in a million/epididymis (Narayana et al., 2005). Counting was only done for those sperms with sperm head located in squared areas.

Sperm viability

In order to determine live-dead spermatozoa, 10 µL of pre-heated eosin-nigrosin stain was placed on a pre-warmed slide (37 °C) then 10 µL of sample suspension was added and mixed gently. A smear of the sample-stain mixture was prepared and dried at room temperature. Samples were analyzed at 1000-fold magnification under a binocular microscope (Nikon, Japan). Two hundred sperms per rat were used for the determination of sperm viability. Unstained (white) sperms are viable, while stained (pink) sperms are dead sperms (Kledmanee et al., 2013).

Sperm abnormality

Sperm morphology was evaluated following smear staining with eosin-nigrosin stain. Slides were viewed with an oil immersion (100× magnification) under a microscope (Nikon, Japan). On each slide, a total of two hundred sperms were examined for each animal, and the total sperm abnormality rates were expressed as percentages (Ciftci et al., 2012).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1318513197

Fertility test

At the end of the experiment, fertility and sex ratio was estimated in adult male rats of treated groups and the control of male counterparts. In each group, three males were randomly selected, and each one was mated with three untreated fertile females in separated plastic cages. Detection of sperm in the vaginal smear supposes an early indicator of successful mating. After five days of mixing, every three days, female rats were checked for pregnancy in three days intervals (by checking abdominal size) with calculating the pregnancy percentage for each group. Also, the number and sex ratio (male/female ratio) of newborns in each group was calculated.

Statistical analysis

Data were expressed as mean ± standard deviation (SD) for this experiment. Analyzing of results performed by one-way analysis of variance (ANOVA) followed by Tukey's post hoc test to determine significant differences between the experimental groups using GraphPad Prism 6 version 6.01 for Windows (GraphPad Software 2012). Accepting a conventional 5% level of significance ($P \leq 0.05$), hence, all tests are statistically significant. Significant differences between treatment groups (or comparison of mean values) and appropriate vehicle control were denoted by superscript asterisks symbols *, **, ***; significant differences between TCDD group and the rest treatment groups were denoted by superscript hash symbols #, ##, ###; significant differences between QCT group and the treatment groups were denoted by superscript symbols $, $$, $$$ which represent significance at $p < 0.05$, $p < 0.01$ and $p < 0.001$, respectively.

Results

Metabolic results

Body weight and GSI

Results of mean (±SD) body weight (g), the GSI (%), and the ESI (%) are given in *Table 1*. There was a statistically significant decrease in body weight after twelve weeks of TCDD administration in TCDD group rats in comparison to control and QCT group rats (TCDD: 244.16 ± 13.92 g; Control: 294.83 ± 7.60 g; 286.83 ± 8.18 g, $p < 0.001$). However, co-treatment of QCT with TCDD in both QCT-TCDD and TCDD-QCT group rats reversed this effect of TCDD, but administration of QCT 30 min after TCDD administration was more effective than administration of QCT 30 min before TCDD administration (QCT-TCDD: 303.66 ± 8.71 g; TCDD-QCT: 320.66 ± 10.48 g; TCDD: 244.16 ± 13.92 g, $p < 0.001$).

The GSI and ESI of the TCDD treated rat were significantly lower than that of the control rat (TCDD: 0.387 ± 0.012%, 0.056 ± 0.01%; Control: 0.419 ± 0.021%, 0.075 ± 0.01, $p < 0.05$). The GSI and ESI of the QCT group rats were insignificantly higher than that of the control rats ($p > 0.05$) and significantly greater than that of the TCDD group ($p < 0.001$, $p < 0.01$). Rats received QCT in combination with TCDD (QCT-TCDD) significantly ($p < 0.001$) reduced the adverse effects of TCDD in rats received TCDD alone, which demonstrate increasing of GSIs in comparison to TCDD group. While QCT administration in combination with TCDD (TCDD-QCT) showed a reduction in the adverse effects of TCDD compared to rats received TCDD alone, but the values did not meet any statistical significance ($p > 0.05$).

Testosterone concentration

Relative to the rats of the control group, the plasma testosterone level is significantly reduced in rats administrated with TCDD, whereas the testosterone levels in rats in QCT group were not markedly changed in comparison to control rats (Control: 1.83 ± 0.26; TCDD: 0.31 ± 0.19; QCT: 2.25 ± 0.38, $p < 0.001$, $p > 0.05$).

The results obtained in this study exhibit a significant ($p < 0.001$) decrease of plasma testosterone levels in rats treated with TCDD, but in the QCT-TCDD and TCDD-QCT rats, the value of hormone testosterone is significantly reversed in the blood plasma compared to the TCDD treated group (TCDD: 0.31 ± 0.19; QCT-TCDD: 1.18 ± 0.24; TCDD-QCT: 1.01 ± 0.18, $p < 0.001$, $p > 0.01$). This increase was grown, but it was still lower than the corresponding value in the blood plasma of control group. Plasma testosterone started to increase again after subsiding to approximately 1/6 of the corresponding control value. In rats with QCT administered alone, the testosterone concentration was insignificantly ($p > 0.05$) increased when compared with the corresponding control (*Table 2*).

Lipid peroxidation and anti-oxidant assay

Values of the antioxidant enzymes (SOD, CAT, and GSH) and the oxidative biomarker (MDA) in the testis are shown in *Table 3*. A significant elevation in MDA levels was observed in the rats exposed to TCDD, whereas GSH levels, SOD, and CAT activities were meaningfully declined in testis tissues in opposition to the control group rats. Also, there were statistically insignificant changes between the QCT and control groups regarding MDA, SOD, CAT, and GSH levels. Otherwise, the decline in MDA levels and rises in SOD and CAT activities and GSH levels in the group pretreated with QCT (QCT-TCDD) were observed in comparison to the rats exposed to only TCDD. Administration of QCT 30 min after TCDD administration (post-treatment group) improved SOD, CAT, GSH, and MDA levels but these improvements (except MDA level) did not reach the statistical significance when compared with the rats of TCDD group.

Sperm analysis

TCDD-treated rats exhibited a significant reduction in sperm count, motility, and viability percentage, while increased morphologically abnormal sperms in the TCDD group compared with the control and other experimental groups. The sperm numbers, motility, viability, and abnormality were 58.25 × 10^6 ± 5.53, 61.33 ± 8.93%, 51.33 ± 6.47%, and 12.83 ± 1.94%, respectively, in the TCDD group. The corresponding values in the control group were 71.33 × 10^6 ± 6.96, 86.33 ± 7.28%, 84.50 ± 8.33%, and 6.50 ± 1.87%. However, QCT consumption by rats treated with TCDD resulted in significant (QCT-TCDD: $p < 0.001$, TCDD-QCT: $p < 0.01$) ameliorations in all sperm parameters when compared with the TCDD group rats. The corresponding values in the QCT-TCDD group were 67.66 × 10^6 ± 5.90, 78.33 ± 8.16%, 69.83 ± 5.23%, and 7.16 ± 1.47%, and similar amounts in the TCDD-QCT group were 64.25 × 10^6 ± 5.98, 71.67 ± 7.11%, 66.67 ± 4.50%, and 8.66 ± 1.03%, but the results showed that administration of QCT 30 min before TCDD administration was more effective than QCT administration 30 min after TCDD administration. On the other hand, the sperm number, sperm motility, sperm viability, and sperm abnormality were not significantly changed in rats orally received QCT when compared with the rats of the control group, while a considerable change was observed in comparison to TCDD group rats (*Table 4*).

Table 4. *Sperm analysis of control and treated groups (n = 6)*

Groups	Sperm count (million/epididymis)	Sperm motility %	Sperm viability %	Sperm abnormality %
Control	71.33 ± 6.96	86.33 ± 7.28	84.50 ± 8.33	6.50 ± 1.87
TCDD	58.25 ± 5.53*	61.33 ± 8.93***	51.33 ± 6.47***	12.83 ± 1.94***
QCT	71.91 ± 7.76$^{\#\#}$	88.50 ± 7.03$^{\#\#\#}$	86.17 ± 7.19$^{\#\#\#}$	5.16 ± 1.60$^{\#\#\#}$
QCT-TCDD	67.66 ± 5.90	78.33 ± 8.16$^{\#\#}$	69.83 ± 5.23$^{**\#\#\#\$\$}$	7.16 ± 1.47$^{\#\#\#}$
TCDD-QCT	64.25 ± 5.98	71.67 ± 7.11$^{*\$}$	66.67 ± 4.5$^{***\#\#\$\$\$}$	8.66 ± 1.03$^{\#\#\$\$}$

Fertility test

The percentage of pregnant female rats in the group received TCDD was significantly lower than that of the control and QCT group (TCDD: 66.66%; Control: 100%; QCT: 100%, $p < 0.05$). Whereas in the QCT-TCDD and TCDD-QCT group, the pregnancy rate was reversed compared to the TCDD group, but the difference did not attend any statistical significance, and this increase grew but was remain lower than the corresponding value in the control group (QCT-TCDD: 88.88%; TCDD-QCT: 88.88%, $p > 0.05$).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1318513197

The sex ratio of the control group's 9 litters (89 embryos), 6 litters of the TCDD group (51 embryos), 9 litters of the QCT group (92 embryos), 8 litters of the QCT-TCDD group (77 embryos) and 8 litters of the TCDD-QCT group (74 embryos) was linked to the visual examination of anogenital distance away and the presence of male genitals (*Table 5*). Our results showed a statistically significant decrease in the sex ratio of embryos in the TCDD group against the control and QCT group rats (TCDD: 27.62 ± 21.14%; Control: 52.01 ± 8.58%; QCT: 53.98 ± 10.26%, $P < 0.05$). In general, QCT treatment significantly increased pregnancy percentage, mean litter size, and sex ratio (male/female ratio) in comparison to TCDD treatment. Additionally, the results exhibited that QCT administration along with TCDD in both QCT-TCDD and TCDD-QCT groups in contrast to TCDD group insignificantly increased pregnancy percentage, mean litter size, and sex ratio percentage. Also, there were no significant changes between QCT-TCDD and TCDD-QCT groups in means of pregnancy percentage, mean litter size, and sex ratio percentage. The QCT substance when given together with TCDD, especially in a group when pre-treated with QCT, brought pregnancy percentage, mean litter size, and sex ratio percentage closer to the control level.

Table 5. *Fertility test of control and treated groups (n = 6)*

Groups	Pregnant female rats (%)	Total No. of male newborns	Total No. of female newborns	Mean litter size	Total sex ratio (%)
Control	100 ± 0.00	46 ± 0.78	43 ± 1.09	9.88 ± 1.05	52.01 ± 8.58
TCDD	66.66 ± 0.50*	21 ± 1.80*	30 ± 2.64	5.66 ± 4.38*	27.62 ± 21.14*
QCT	100 ± 0.00$^{\#}$	50 ± 1.50$^{\#\#}$	42 ± 1.00	10.22 ± 1.64$^{\#}$	53.98 ± 10.26$^{\#}$
QCT-TCDD	88.88 ± 0.33	42 ± 2.12$^{\#}$	35 ± 1.69	8.55 ± 3.46	48.27 ± 19.83
TCDD-QCT	88.88 ± 0.33	38 ± 1.92	36 ± 1.65	8.22 ± 3.30	40.47 ± 24.15

Discussion

Male reproductive disorders, such as a diminution in sperm quality and quantity, have shown an increasing trend in recent years. Several environmental/lifestyle factors (like exposure to dioxins, traffic exhaust fumes, smoking, and obesity) appear to negatively affect both the perinatal and adult testes (Sharpe, 2010; Wang et al., 2017). TCDD was found to increase oxidative stress and inhibit the activity of the antioxidant enzymes in testis and influences the serum level of testosterone hormone. It has also been reported that TCDD decelerates the progressive motility of epididymal sperm (Dhanabalan et al., 2015).

The current data showed the beneficial properties of QCT on TCDD induced reproductive impairment in male rats. We found a reduction in the sperm characteristics of TCDD treated rats compared to control rats. TCDD induced significant oxidative disorders in the testis tissue. Administration of QCT to rats received TCDD markedly decreased the reproductive damage and its oxidative stress induced by TCDD. Similarly, other researchers (Ciftci et al., 2012) found that TCDD produced oxidative stress in rat testes tissue. In addition to significantly decreasing serum testosterone levels, sperm count with its motility as well as increasing abnormal sperm percentage and testicular damages with TCDD dosing. It was thought that spermatological effects of TCDD might be due to its oxidative and histopathological effects.

The results of the study showed that body weight in TCDD group less gained in comparison to control rats and also GSI and ESI in the rats treated with TCDD decreased. The results of the study are in agreement with previous findings obtained by Seefeld et al. (1984) and Ciftci et al. (2010). They showed that oral TCDD administration decreased body weight compared to control rats. However, Awal et al. (2001) reported that in male rats, exposure to TCDD during adulthood resulted in a reduction in the weights of testes and accessory sex organs, but it still remains unclear which cells of the testis are particularly affected by TCDD. This adverse effects of TCDD, including those related to the endocrine-disrupting activities (Le Magueresse-Battistoni et al., 2017; Decherf and Demeneix, 2011). While, pre and post-treatment with QCT could improve the gonad and body weight in the rats treated with TCDD.

Furthermore, antioxidant defence systems consist of SOD, glutathione peroxidase (GPx), CAT (enzymatic), and GSH (non-enzymatic) protects the cell against oxidative damage in normal physiological conditions. TCDD treatment caused a significant increase in testicular MDA levels in the present study with a decrease in testicular SOD, GSH, and CAT activity compared to the control group. An increased MDA concentration is maybe a consequence of the reduced production of antioxidants in the TCDD treated rats' tissues thereby shifting the accurate balance in favour of ROS, thus leading to an excess of pathologic damage to sperm cells and coincident loss of function (Oyeyipo et al., 2014). The antioxidant superoxide dismutase enzyme dramatically speeds up the dismutation of the superoxide anion to hydrogen peroxide (H_2O_2). Catalase breaks down H_2O_2 to H_2O and O_2, and the glutathione peroxidase/reductase system catalyzes H_2O_2 and lipid hydroperoxide degradation by reduced glutathione. Reducing the activity of SOD, CAT, GSH-R, and GPx could reflect the negative effect of TCDD on antioxidant enzymes in epididymal sperm (Latchoumycandane et al., 2003). Due to the direct damaging effect of TCDD, reduced activity of one or more antioxidant systems leads to increased lipid peroxidation and oxidative stress, resulting in testicular and sperm toxicity.

As pointed out in the introduction that TCDD binds to an AhR in the cytoplasm, the receptor complex (AhR-TCDD) translocates into the nucleus, where AhR heterodimerizes with the Ah receptor nuclear translocator (ARNT), connects to dioxin-responsive enhancer elements and regulates the transcription of target genes (Baba et al., 2005). The mechanisms of TCDD-induced disorders in the reproductive system of mammals have been shown to be multiple, including impairment of spermatogenesis (Foster et al., 2010), steroidogenesis (Adamsson et al., 2009), dropping in the number of testicular cells (Johnson et al., 1994), and induction of cytochrome P450 (CYP) 1 family enzymes, leading to inactivation of steroid hormones (Badawi et al., 2000). The treatment of QCT ameliorated these detrimental effects. These results corroborate the previous findings of Ciftci et al. (2012) and El-Gerbed et al. (2015). Ciftci et al. (2012) reported that QCT could reduce testicular damage caused by TCDD in rats. El-Gerbed et al. (2015) said that exposure to TCDD triggered semen quality to deteriorate, a reduction in fertility indexes, decreased the activity of serum enzymes, and decreased testosterone, in addition to histological changes in the tests. The team also highlighted the effect of QCT in reducing the adverse impact generated by TCDD.

Our results showed decreased male/female ratio in TCDD group rats compared with control group rats. Several studies have shown that exposure to TCDD in humans and animal reduces the male sex ratio of offspring (You et al., 2018; Mocarelli et al., 2000; Rowlands et al., 2006; Ishihara et al., 2007). James (2006) supposes that before

DOI: http://dx.doi.org/10.15666/aeer/1706_1318513197

conception, elevated gonadotropin and low levels of testosterone would have injured and distorted Y- bearing gametes. Song et al. (2018) found that Y chromosome-bearing human spermatozoa were more susceptible to EDCs than spermatozoa with the X chromosome. Ishihara et al. (2010) investigated the effects on sex ratio, sperm concentration, and motility of TCDD exposure. They found that TCDD leads to decreasing Y-bearing/X-bearing sperm ratio. Although it is still unclear why Y spermatozoa are more susceptible to high TCDD levels than X spermatozoa, You et al. (2018) proposed that after exposure to stressful conditions such as endocrine-disrupting chemicals (EDCs), the fertilization capacity according to their chromosome constitution may differ. Interestingly, Y spermatozoa survived at high TCDD concentrations for a shorter time than X spermatozoa. Furthermore, the reduced male sex ratio of births was related to the limited lifespan of Y spermatozoa and they attributed that to the antiandrogenic properties in utero or during lactation in adult rats that might be exposed to dioxin-like compounds and polychlorinated biphenyls (PCBs), leading to permanently changed sperm-transit time through the epididymis and the extra-testicular excurrent duct system (Jongbloet et al., 2002).

Conclusion

In summary, that we really found that rats subjected to TCDD showed reduced sexual activity, low motility with sperm count inhibition, viability, decreased antioxidant enzymes activity, additionally increased sperm abnormality and oxidative biomarker (MDA) in testis tissue. QCT treatment could minimize the effects of TCDD in rats, in part by improving sexual performance and eliminating oxidative damage. Thus, these results suggested that QCT could be used as protective agents against reproductive toxicity induced by TCDD in male rats. Further studies are required to clarify the mechanism of QCT as a therapeutic agent against the toxic effects of TCDD.

Acknowledgements. This study was supported as a PhD plan by Salahaddin University-Erbil, Erbil, Kurdistan Region-Iraq (Administrative order No. 1/1/15738. Signed on December 1, 2015). The authors wish to gratefully thank Rêbwar M. Hama Salih, Sarwar N. Jafar, and Younis M. Saleh for excellent technical support performed for spermatological and biochemical tests.

(Received 3rd Jun 2019; accepted 2nd Sep 2019)

Abstract. The field experiment was conducted at two locations, Qlyasan and Kanipanka in Sulaimani governorate, Iraq. The main aim of this research is, to evaluate the impact of adding various levels of Humic Acid and Sulfur rates on maize yield and yield components. Experimental treatments have been organized and a factorial experiment was laid out in a complete randomized block design with three replicates. The treatments included four levels of humic acid, and four levels of sulfur incorporated into the soil. The results showed that the effect was significant at ($P < 0.05$) on the reproductive growth criteria of a maize plant. The number of kernels per ear, the weight of 100 kernels (g), kernel yield (ton ha^{-1}), biological yield (ton ha^{-1}), harvest index and relative yield maize plant from both of locations. While the results showed that the humic acid and sulfur application significantly affected of the number of kernels per raw from Kanipanka and of the ear diameter (cm) from Qlyasan, it did not affect the number of kernels per raw from Qlyasan location and by the ear diameter (cm) from Kanipanka location.
Keywords: *kernels, biological yield, relative yield*

Introduction

Maize (*Zea mays* L.) is the third most important cereal crop in the world after wheat and rice. Maize is a miracle crop called "Queen of Cereals", is grown in more than 130 countries and it belongs to the family of Gramineae (Poaceae), (Shah et al., 2009) and tribe Maydeae, all varieties of the maize belong to a single species which is Zea mays (Sikandar et al., 2007). Iraqi Kurdistan region as a semi-arid region, there is an increasing interest for field crop production and recommended farmers to grow grain crops and vegetables.

An increasing the number of human population continuously increases their demands for food and energy, which require to incorporate the new areas in agricultural as well as increase the crop yield-per unit of area with healthy quality with good nutritional or healthy quality. Generally, the average yield of maize is greater than (4 ton ha^{-1}) (Farnhamet al., 2003). The maize cultivation in Iraq in the last decade increased, because of its importance as previously mentioned, its cultivation focused in the south of Iraq in Wasit, Meesan and AL-Qadeseya governorates, with only (3500 ha) during 1998. In 2014, the cultivated area with maize in Iraq increased to (299500 ha) with average production (4166.5 kg ha^{-1}), Central Statistical Organization of Iraq (2014). The maize cultivation in the Kurdistan region–Iraq has got more attention in last year's. The cultivated area in Kurdistan region roughly is about (1824 ha) with average production about (5138 kg ha^{-1}), (KRG, 2014). In the last decade, the maize production increased about (40%) reaching (840) million tons in the world in 2011 (FAO, 2009).

In terms of nutrient acquisition efficiency by the plant, Maize may have different strategies in response to nutrient deficiency. In addition to that the strategy of Maize cultivation is recently had been introduced to the Kurdistan Iraqi region, and every year

DOI: http://dx.doi.org/10.15666/aeer/1706_1319913217

new high-yielding maize varieties are continually being evolved and introduced by the breeder to be grown by farmers in the area. However, the properties such as economic, quality and grain yield potential of this new Maize not fully aware by the farmers (Hogir, 2016).

Therefore, intensive efforts of the researchers were focused on how to maximize the productivity of this crop through highly nutrient efficient, especially for humic acids and sulfur fertilizers.

Humic acid (HA) is a naturally occurring polymericheterocyclic organic compound with carboxylic ($COOH^-$), phenolic (OH^-), alcoholic and carbonyl fractions extracted from various sources such as lignite, peat, coal, farmyard manure, coirpith besides natural persistence in soil (Sharif et al., 2002). Humic acids is not only found in soil, plants, peat, natural water, rivers, sea sediments, and other chemically and biologically transformed materials but also extracted from lignite, oxidized bituminous coal, leonardite and gyttja (Karaca et al., 2006).

The mechanism of humic acid activity in promoting plant growth is not completely known, but several explanations have been proposed by some researchers such as increasing cell membrane permeability, oxygen uptake, respiration and photosynthesis, phosphate uptake, and root cell elongation (Turkmen et al., 2004). Addition of HA to soil increases the rate of absorption of ions on root surfaces and their penetration into the cells of the plant tissue. Plants show more active metabolism and increased respiratory activity, which are attributed to the intervention of the quinine groups of HA (Atefe and Ali, 2012). The physicochemical and molecular structure and the mechanism of its stimulating effect on various crops and soil conditions have been envisaged by various workers (Singh and Agrawal, 2010; Cordeiro et al., 2011).

The sulfur (S) dynamics and its availability are less studied than other nutrients, even though S is an essential nutrient for crops production (Rheinheimer et al., 2007). Most soil sources of sulfur are in organic matter and are therefore concentrated in the topsoil or plow layer. Elemental sulfur and other forms as found in soil organic matter and some fertilizers are not available to crops. They must be converted to sulfate (SO_4^{2-}) form to become available to crops. This SO_4^{2-} is available to crops when the roots reach this area of the soil. Sulfur is a part of the amino acids cystine, cysteine and methionine and is therefore required for protein formation and hence plant growth. Sulfur is also present in plant oils and is involved in enzyme activation. Many common crop plants contain approximately the same amount of sulfur as they do of phosphorus (Scherer, 2001). Sulfur is a by-product of the oil industries, despite this, it is found in a comparatively large amount in Iraq in the fields of Mashraq, which has a production capacity of one million tons annually, so the addition of sulfur has become a standard method for a number of researchers as a means of managing nutrients in the soil.

This study aims to investigate the influence of humic acids and sulfur individually or mixing on yield characteristics of maize growing under calcareous soil condition.

Review of literature

Humic acid (HA) is a naturally occurring polymericheterocyclic organic compound with carboxylic ($COOH^-$), phenolic (OH^-), alcoholic and carbonyl fractions extracted from various sources such as lignite, peat, coal, farmyard manure, coirpith besides natural persistence in soil (Sharif et al., 2002). Humic acids are not only found in soil, plants, peat, natural water, rivers, sea sediments, and other chemically and biologically

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1319913217

transformed materials but also extracted from lignite, oxidized bituminous coal, leonardite and gyttja (Karaca et al., 2006). The humic substances are distributed in soil, peat, coal, many upland streams, dystrophic lakes, and ocean water (Stevenson, 1994).

Humic acids are technically not a fertilizer, although in some walks people do consider it. Humic acids are an effective agent to use as a complement to synthetic or organic fertilizers. In many instances, regular humic acids use will reduce the need for fertilization due to the soil and plant ability to make better use of it. In some instances, fertilization can be eliminated entirely if sufficient organic material is present and the soil can become self-sustaining through microbial processes and humus production.

To promote efficient plant absorption of nutrients and reduce environmental pollution, some chemical molecules have been studied (Ertani et al., 2011) these compounds are defined as bio-stimulants such as humic substances.

In many studies, humic and fulvic acids preparations were reported to increase the uptake of mineral elements (Mackowiak et al., 2001), to promote the root length (Canellas et al., 2002), and to increase the fresh and dry weights of crop plants (Chen et al., 2004).

The use of humic acids has been on the increased in last year's. Improvement of soil conditions and establishing equilibrium among plant nutrients are also important for soil productivity and plant production. Humic acids and organically improvement of soil increased the yields of some field crops in several studies (Ulukan, 2008).

The sulfur (S) dynamics and its availability are less studied than other nutrients, even though S is an essential nutrient for crops production (Rheinheimer et al., 2007). In a general overview of the element we can at first, describe sulfur as a solid. It is a pale yellow non-metallic, brittle element and is widely distributed in close proximity to hot springs and volcanoes and is also found in many minerals and ores. Sulfur is one of (16) essential elements for crop growth. Although sulfur is considered as a secondary nutrient, it is often called the fourth major nutrient ranking just below nitrogen, phosphorus, and potassium. It is also an essential nutrient for plant growth and development as it is a part of major metabolic compounds such as amino acids (methionine and cysteine), glutathione, proteins, and sulpho-lipids (Duke and Reisenauer, 1986). Most soil sources of sulfur are in organic matter and are therefore concentrated in the topsoil or plow layer. Elemental sulfur and other forms as found in soil organic matter and some fertilizers are not available to crops. They must be converted to sulfate (SO_4^{2-}) form to become available to crops. This SO_4^{2-} is available to crops when the roots reach this area of the soil. Sulfur is a part of the amino acids cysteine, cysteine and methionine and is therefore required for protein formation and hence plant growth. Sulfur is also present in plant oils and is involved in enzyme activation. Many common crop plants contain approximately the same amount of sulfur as they do of phosphorus (Scherer, 2001).

Maize dry weight increased as elemental sulfur rate increased, after which there was a sharp decrease in dry maize weight. This was mainly due to the significant increase in soil Mn and Zn availability (Karimizarchi and Aminuddin, 2015) and uptake by maize as demonstrated by Karimizarchi et al. (2014). Scherer (2001) provides an overview of soil sulfur transformations describes the diverse forms of organic sulfur in soil and outlines the processes linked to sulfur mineralization that release SO_4^{2-}. Most studies on sulfur mineralization have involved laboratory experimentation. There is limited information on the rates of sulfur mineralization in field soils.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

The maize is the major source of starch in the worldwide. It can be fed to stock as green chop, dry forage, silage or grain. Various fractions of milling processes, also it can be used as animal feed. Furthermore, maize uses in nonfood making products such as drugs, paper goods, paints, textiles (cloths) and ceramics (Jones, 2003).

An increasing the number of human population continuously increases their demands for food and energy, which require to incorporate the new areas in agricultural as well as increase the crop yieldper unit of area with healthy quality with good nutritional or healthy quality. Among all grain crops, the maize has the highest yield per hectare (Du Plessis, 2003). Generally, the average yield of maize is greater than (4 ton ha^{-1}) (Farnham et al., 2003).

The maize cultivation in Iraq in the last decade increased, because of its importance as previously mentioned, its cultivation focused in the south of Iraq in Wasit, Meesan and AL-Qadeseya governorates, with only (3500 ha) during 1998. In 2014, the cultivated area with maize in Iraq increased to (299500 ha) with average production (4166.5 kg ha^{-1}), Central Statistical Organization of Iraq (2014). The maize cultivation in the Kurdistan region–Iraq has got more attention in last year's. The cultivated area in Kurdistan region roughly is about (1824 ha) with average production about (5138 kg ha^{-1}), (Ministry of Agriculture and Irrigation, Kurdistan regional government, Iraq, 2014). In the last decade maize production increased about (40%) reaching (840) million tons in the world in 2011 (FAOSTAT, 2013).

Therefore, intensive efforts of the researchers were focused on how to maximize the productivity of this crop through highly nutrient efficient, especially for humic acids and sulfur fertilizers.

Calcareous soil is a soil that has high levels of both calcium carbonate and magnesium that reduce acidity in the soil and covers more than one-third of the cultivable surface land in the world. Calcareous soil can have differing levels of sand, silt or clay as well as coarse to fine texture. This soil type typically maintains a moderate to high alkalinity (Pasricha et al., 2001).

Calcareous soils are common and widely spreader not only in arid and semiarid regions but also is formed in humid and per humid regions, due to the relatively low leaching and the nature of the weathered parent material such as limestone, shells (Sandstone) or calcareous glacial tills (Brady and Weil, 2002) and relatively young parent material which subjected to slight weathering process (Pal et al., 2000).

Lalljee and Facknath (2001) and Alloway (2008) found that micronutrients solubility in calcareous soils is extremely low because the pH value of these soils is high, which reduces nutrient absorption by plants, finally increases plant requirements to these nutrients. In addition to this, high rate of fertilization with P-fertilizers prompts micronutrients deficiencies in plants. Therefore, micronutrients content in plant dry matter and crops yield will reduce (Salimpour et al., 2010).

Materials and methods

To assess the impact of humic acid and sulfur incorporated into the soil on yield and yield constituents of maize (*Zea mays* L.) cv. Gloria, grown under calcareous soil, the experiment was conducted at two different locations. The first one at Qlyasan Agricultural Research Farm (45.3581 E, 35.5767 N 757 m above sea level) and the second one at Kanipanka Agricultural Research Farm (45.7161 E, 35.3822 N 578 m above sea level) in Sulaimani governorate, Iraq as shown in (*Fig. 1*) during spring

growing season of (10th and 11th April 2017 to 29th and 27th July 2017) respectively. The experiment includes four levels of humic acid as humate potassium (Humic 85%), obtained from AFICO factory in Jordan, ($H_0 = 0$, $H_1 = 25$, $H_2 = 50$ and $H_3 = 100$ kg HA ha^{-1}) and four levels of sulfur, obtained from LAWA factory in Sulaimani–Iraq, as agricultural sulfur, which contained 99% S ($S_0 = 0$, $S_1 = 500$, $S_2 = 1000$ and $S_3 = 2000$ kg S ha^{-1}) were incorporated into the soil in deep by 5 cm at sowing time. Average of the rainfall and air temperature climatic data of the experiment field locations (Kanipanka and Qlyasan) in 2017 showing in *Tables 1* and *2*.

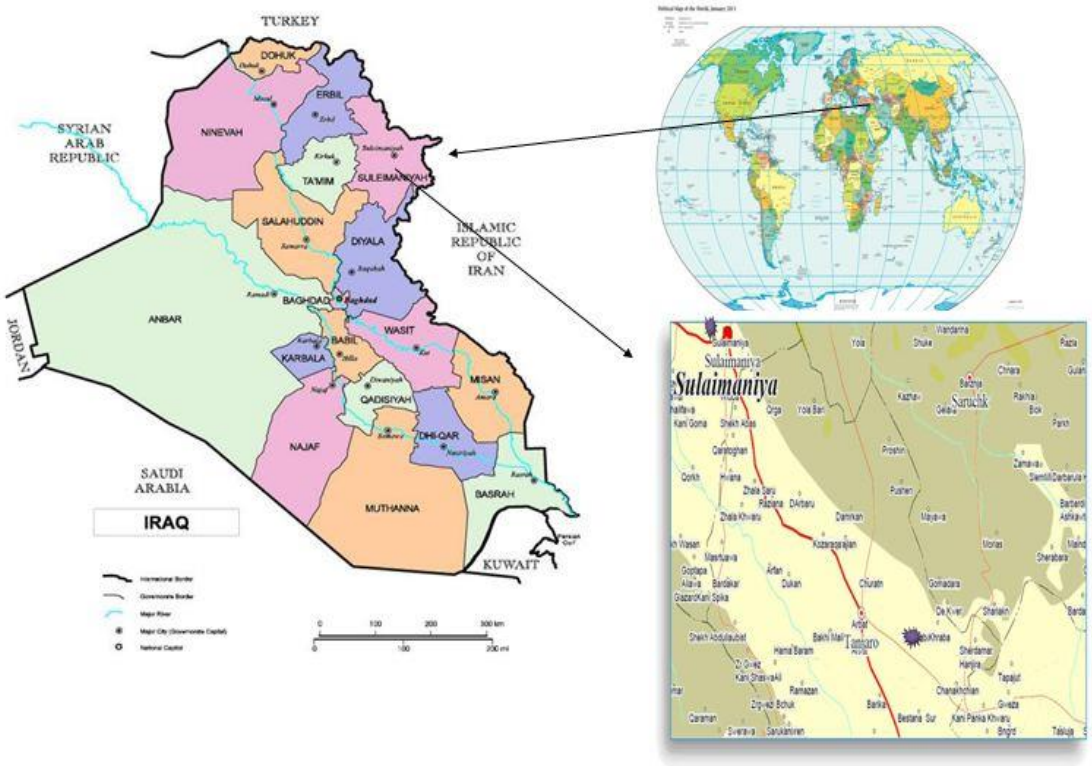

Figure 1. *The location of testing site*

The experiment was conducted on the 622.5 m^2 area (15 m × 41.5 m), in 16 experimental units with three replicates, the area of each experimental unit was 6 m^2 (2 × 3) m, each experimental plot included 3 rows in 3 m length, and the distance between these three was 0.70 m while it was 0.30 m within the rows of the individual plants, to obtain a mean density of 50,000 plants ha^{-1}, and the distance between the experimental units was 0.5 m while the distance between the blocks was 2 m. Experimental treatments have been organized in a factorial experiment by using the complete randomized block design (CRBD) by having three replicates. Treatments were as follows:

T1 = (control)
T2 = 500 kg S ha^{-1}
T3 = 1000 kg S ha^{-1}
T4 = 200 kg S ha^{-1}
T5 = 25 kg HA ha^{-1}
T6 = 25 kg HA ha^{-1} + 500 kg S ha^{-1}
T7 = 25 kg HA ha^{-1} + 1000 kg S ha^{-1}
T8 = 25 kg HA ha^{-1} + 2000 kg S ha^{-1}
T9 = 50 kg HA ha^{-1}
T10 = 50 kg HA ha^{-1} + 500 kg S ha^{-1}
T11 = 50 kg HA ha^{-1} + 1000 kg S ha^{-1}
T12 = 50 kg HA ha^{-1} + 2000 kg S ha^{-1}
T13 = 100 kg HA ha^{-1}
T14 = 100 kg HA ha^{-1} + 500 kg S ha^{-1}
T15 = 100 kg HA ha^{-1} + 1000 kg S ha^{-1}
T16 = 100 kg HA ha^{-1} + 2000 kg S ha^{-1}

All required management practices were done at proper times, and the standard practices were used for weed control. Soil samples were taken before planting from a depth of 0-40 cm of the soil used in the field experiments. The soil samples were air-dried, filtered by a 2 mm sieve, and kept in plastic bottles until analyzed. (*Table 3*) illustrates the main physical and chemical properties of the soils.

Table 3. *Some physical and chemical properties of soil used in field experiments*

		Location	
		Qlyasan	Kanipanka
Particle size distribution (PSD) g kg^{-1}	Sand	59.68	37.40

$CaCO_3$ equivalent g kg^{-1}	Total	215.68	215.50

Physiological parameters were measured as follows: Three plants of each plot were tagged, and all the reproductive growth and vegetative growth parameters were recorded, leaf area per plant, all available leaves of five plants per net plot were collected at 50% milking stage, and leaf length and width were measured. The leaf area was determined by multiplying leaf length and maximum leaf width adjusted by a correction factor of 0.75 (i.e., 0.75 X leaf length X maximum leaf width) as suggested by Francis et al. (1969).

$$\text{Leaf area (LA)} = \text{Length (cm)} \times \text{Maximum width of leaf (cm)} \times 0.75 \quad \text{(Eq.1)}$$

The diameter of the ear of maize was measured at harvest and expressed in centimeter. The randomly selected ears were cleaned, and a number of rows in each ear were counted manually. Then, the average number of rows of selected ears was taken as the number of rows per Ear. The number of Kernel was obtained by manual counting after separation of Kernels from the ear and the row.

At maturity, the crop was harvested on 27/7/2017 for Kanipanka location and 29/7/2017 for Qlyasan location, after reaching the mature physiological stage (when maturity symptoms occur on plants). Six plants were harvested from each treatment which signed previously, the ears were separated from plants, for removing the dust

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1319913217

from plants, plants washed by tap water, then rinsed three times by distilled water, air dried in dry cabinets chamber at 70 °C till the weight fixed at constant weight, and the plants total dry matter weight were recorded. Then, the plants were chopped into small pieces to enable complete drying and then oven-dried at 70 °C till a constant weight was obtained. The oven-dry weight of dry matter was recorded and expressed in grams per plant. Maize ears were dried, then shelled and the maize grain dried to 15% moisture content. The dry maize grains were weighed from each harvested area. The weight of grain for each experimental unit (6 m^2) was determined, and the yield was expressed in (Mg ha^{-1}). Other yield parameters were also collected.

A small sample of the seeds selected randomly from the grain yield of each experimental unit, and 100 seeds were counted and weighted, to obtain the net weight of 100 seeds (g). Kernel yield (ton ha^{-1}) was obtained in ton per hector according to Wasonga et al. (2008) using the following equation:

$$\text{Kernel yield (ton ha}^{-1}\text{)} = \text{Plant density ha}^{-1} \times \text{Grain yield kg plant}^{-1} \quad \text{(Eq.2)}$$

Higher harvest index indicates a superior conversion of dry matter to grain yield. Many workers currently (Sharma et al., 1987) calculate harvest index for grain crops as a percentage, thus:

$$\text{Harvest index (\%)} = (\text{Kernel yield} / \text{Biological yield}) \times 100 \quad \text{(Eq.3)}$$

The relative yield was calculated by the following equation according to Tisdale et al. (1995):

$$\text{Relative yield} = (\text{yield of the control/ yield of fertilized treatment}) \times 100 \quad \text{(Eq.4)}$$

Data were subjected to analysis of variance (ANOVA) performed by XLSTAT (2016) Package and the differences were compared by Duncan Multiple Range Test (DMRT) at the 5% significance level.

Results

The attained results will be presented as follows:

Vegetative growth criteria

Leaf area (cm^2)

The results in (*Figs. 2* and 3) refer to the significant effect of humic acid and sulfur rate fertilizer on the leaf area (cm^2) of a maize plant. The results showed that the increasing humic acid and sulfur fertilizer application increased the leaf area significantly. The maximum leaf area of maize (78.50 and 77.50 cm^2) was produced by T_{16} from both of locations Qlyasan and Kanipanka, while the minimum leaf area of maize (66.75 cm^2) was produced by T_3 and T_1 from Qlyasan and Kanipanka locations respectively. Similar results were obtained by Erdal et al. (2000) and Abdullah et al. (2016) for humic acid. While the results were obtained by Nader and Nadia (2011) and Habtamu (2015) for sulfur rates, they found that the application of humic acid and sulfur rate fertilizer were affected significantly in the leaf area (cm^2) of maize.

DOI: http://dx.doi.org/10.15666/aeer/1706_1319913217

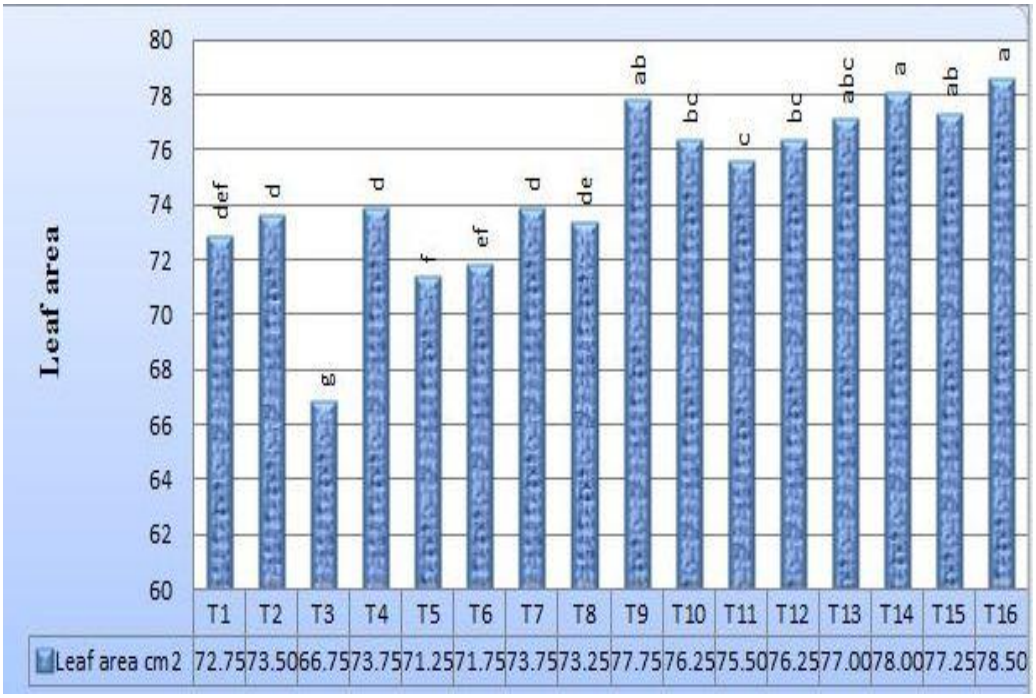

Figure 2. *Influence of humic acid and sulfur on the leaf area of maize from Qlyasan location*

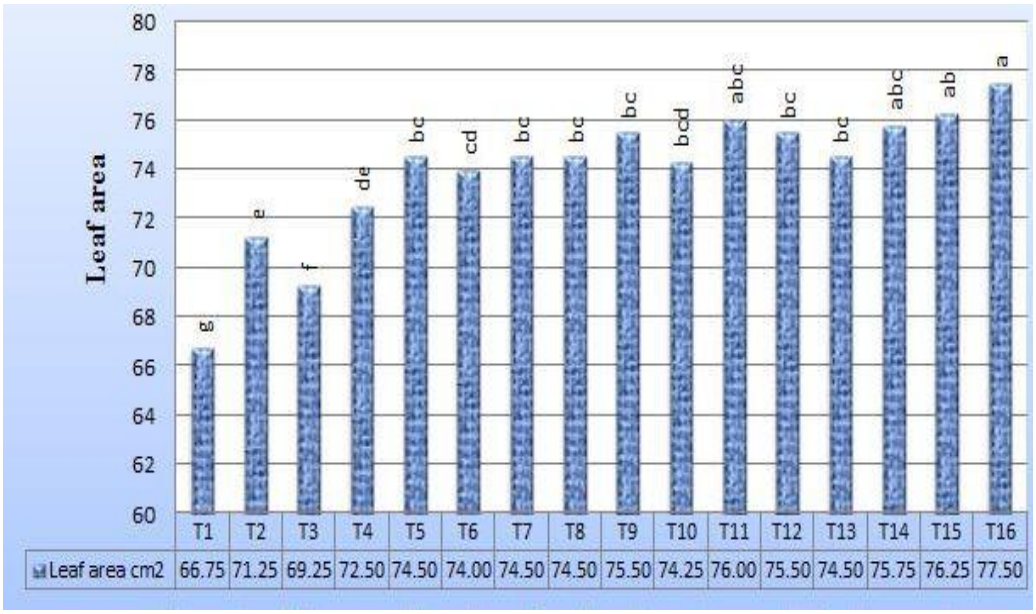

Figure 3. *Influence of humic acid and sulfur on the leaf area of maize from Kanipanka location*

Reproductive growth criteria

Ear diameter (cm)

The data presented in (*Table 4*) shows that the application of humic acid and sulfur rates were affected significantly at ($P < 0.05$ level) on the ear diameter (cm) from the Qlyasan location, the highest value (4.67 cm) was recorded from (T_{16}), while the lowest

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1319913217

value (4.26 cm) was obtained from (T_{11}). The positive effect of humic acid confirmed with the finding of Ebtisam et al. (2012) and Daur and Ahmed (2013) and similar results obtained by Makary (2002) and Nader and Nadia (2011) for the sulfur rate fertilizer application they referred that the application of humic acid and sulfur are essential to increase the ear characters of the corn plant. While the data present in (*Table 5*) revealed that, the application of different rates of humic acid and sulfur have not significant effects on the ear diameter (cm) from Kanipanka location.

Number of rows per ear

Results from a meaningful comparison of data (*Tables 4* and 5) of study treatments indicate that humic acid and sulfur rate application to the soil were affected significantly on the number of rows per ear of maize. The highest value of the number of rows per ear (16.67) was recorded from (T_{12}), while the lowest value (14.00) was obtained from (T_2) for Qlyasan location, but for Kanipanka location the highest value of the number of rows per ear (17.67) was recorded from (T_{16}), while the lowest value (15.33) was obtained from (T_1). Similar results were obtained by Attia et al. (2013) and Muhammad et al. (2015) for humic acid, and were obtained by Khan et al. (2006) and Habtamu (2015) for sulfur rates application, they found that the application of humic acid and sulfur rate affected significantly on the number of rows per ear of maize.

Treat. = Treatments, No. = Number, HI = Harvest index

Number of kernels per row and ear

The application of humic acid and sulfur rate fertilizer significantly increased the kernel per row of maize. The highest mean value of kernel per ear (754.67) was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1319913217

recorded from (T12), while the lowest mean value of kernel per ear (598.67) was obtained from (T1) for Qlyasan location (*Table 4*), but for Kanipanka location the highest value of kernel per ear (768.00) was recorded from (T16), while the lowest value of kernel per ear (648.33) was obtained from (T2) (*Table 5*). Similar results were obtained by Celiket al. (2010) for humic acid, and the results are in agreement with those obtained by Choudhary et al. (2013) for sulfur rate application, they found that the application of humic acid and sulfur rates affected significantly of the kernel per ear of maize. From the results in (*Tables 4* and *5*) it has been observed that the application of humic acid and sulfur rates have not a significant effect on a number of kernels per row in Qlyasan location but have a significant effect in Kanipanka location.

The weight of 100 kernels (g)

According to the analysis of variance, the mean comparison showed that the application rates of humic acid and sulfur revealed that the weight of 100 kernels (g) of maize was affected significantly at ($P < 0.05$). The results show that significantly increased the weight of 100 kernels (g) of maize from 22.26 g was recorded from (T2) to 27.02 g was recorded from (T16) for Qlyasan location (*Table 4*) and from 27.33 g was recorded from (T1) to 33.92 g was recorded from (T16) for Kanipanka location (*Table 5*). These findings are in coincidence with those recorded by Navigehet al. (2012) and Balbaaet al. (2013) about humic acid, and the results are in agreement with those obtained by Srinivasraoet al. (2010) about the sulfur rate application, they found that the application of humic acid and sulfur rates affected the weight of 100 kernels (g) of maize significantly.

Kernel yield (ton ha^{-1})

The data relating to kernel yield (ton ha^{-1}) are presented in (*Tables 4* and 5), revealed that kernel yield was affected significantly at ($P < 0.05$ level) by the application of humic acid and sulfur rate to the soil. The maximum of kernel yield (9.93 and 9.20 ton ha^{-1}) was produced by T15 and T13, while the minimum kernel yield (6.26 and 7.22 ton ha^{-1}) was produced by T2 and T1 from Qlyasan and Kanipanka locations respectively. Similar results were obtained by Turanet al. (2011), and Awwadet al. (2015) about humic acid and the results are in a harmonic with the finding by Khan et al. (2006) about sulfur rates application, they found that the application of humic acid and sulfur rate affected significantly of the kernel yield (ton ha^{-1}) of maize.

Biological yield (ton ha^{-1})

The result regarding biological yield (ton ha^{-1}) of maize plant showed that the application of humic acid and sulfur rates to the soil was affected significantly at ($P < 0.05$) on biological yield from both locations Qlyasan and Kanipanka. The maximum biological yield (26.15 and 26.54 ton ha^{-1}) was obtained from T16 and T15, while the minimum biological yield (22.68 and 22.6 ton ha^{-1}) was obtained from T2 and T1 for both locations Qlyasan and Kanipanka respectively (*Tables 4* and 5). These results are in a harmonic with those recorded by Gomaa et al. (2014) and Daur and Ahmed (2013) for humic acid, and the results are in agreement with the finding by Khan et al. (2006); Choudhary et al. (2013) and Habtamu (2015) for sulfur rate application, they found that the application of humic acid and sulfur rates affected significantly of the biological yield (ton ha^{-1}) of maize.

Treat. = Treatments, No. = Number, HI = Harvest index

Harvest index %

The statistical analysis of the variance in (*Tables 4* and 5) showed that applying humic acid and sulfur rate for the soil was affected significantly at ($P < 0.05$ level) on harvest index. The highest value of harvest index percentage (38.20% and 35.93%) was recorded from T15 and T13, while the lowest value of harvest index percentage (27.59% and 29.06%) was observed in T2 from Qlyasan and Kanipanka locations respectively. These results for humic acid were in agreement with the results of Celiketal (2010) and Awwadet al. (2015) who found that the harvest index increased owing to the increase of humic acid rates. About the effect of sulfur rates, the results in a harmonic with the results of Szulcet al. (2012), reported that the different levels of a sulfur application significantly affected the grain yield and harvest index of maize plans.

Relative yield percentage

The results regarding the relative yield percentage of maize plant are shown in (*Figs. 4* and *5*) which showed that the humic acid and sulfur rates incorporated into the soil were affected significantly on relative yield from both locations Qlyasan and Kanipanka. The highest value of relative yield percentage (108.96% and 100.05%) was observed in T5 and T8, while the lowest value of relative yield percentage (64.95% and 78.40%) was recorded from T15 and T13 for Qlyasan and Kanipanka locations respectively. These results are in a harmonic with those recorded by Hakanet al. (2011) and Balbaaet al. (2013) for humic acid, and the results are in agreement with the results of Dwivedi et al. (2002) for sulfur rates, they found that applying humic acid and sulfur rates affected significantly and decreased of the relative yield percentage of maize.

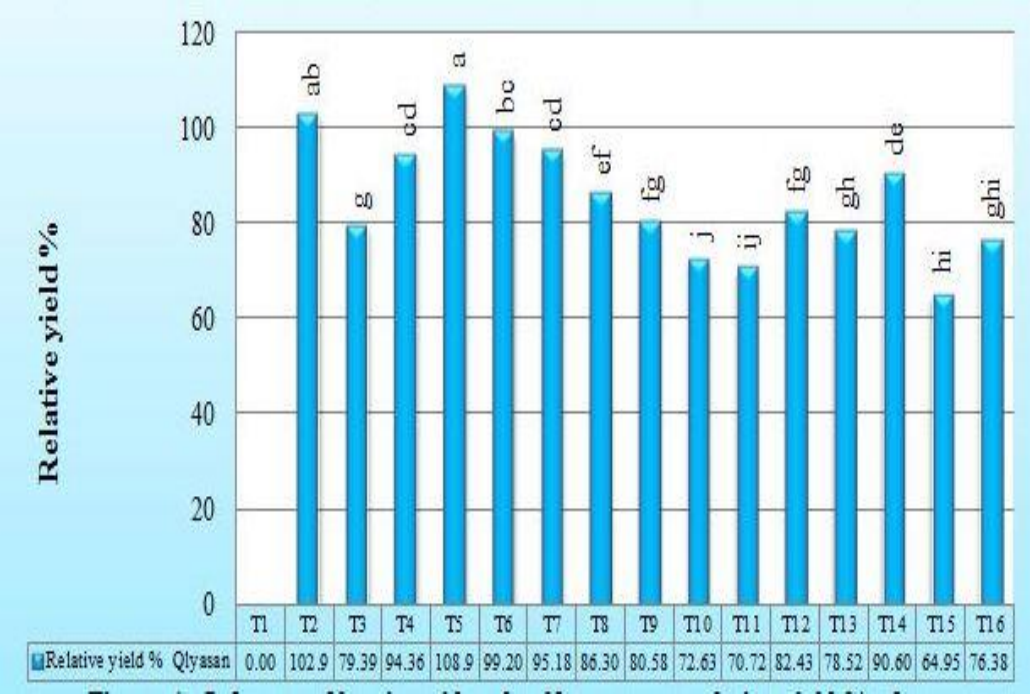

Figure 4. *Influence of humic acid and sulfur on the relative yield % of maize from Qlyasan location*

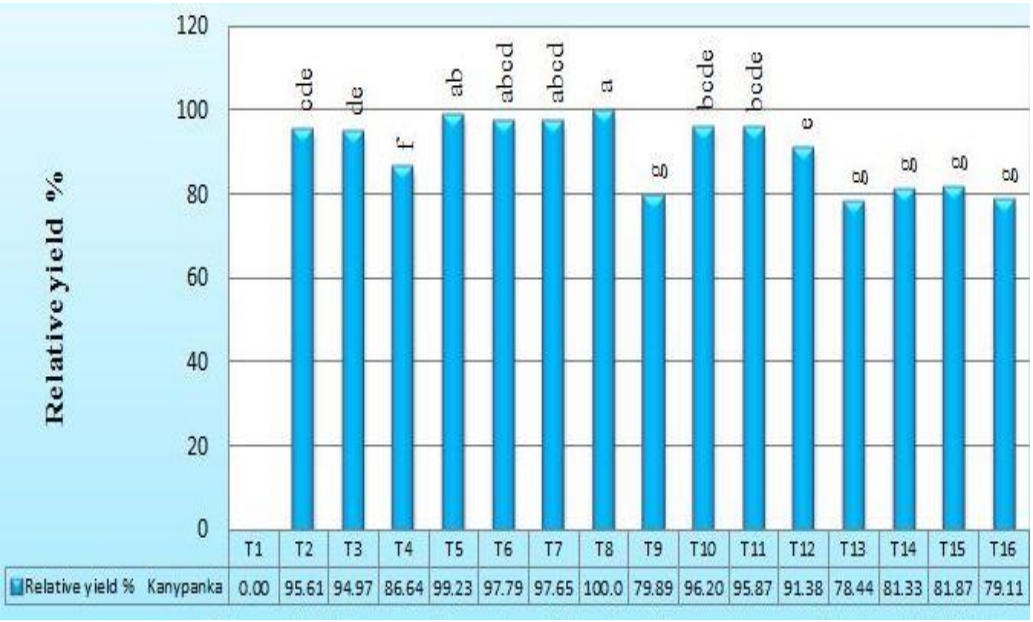

Figure 5. *Influence of humic acid and sulfur on the relative yield % of maize from Kanipanka location*

Discussion

From the above results it has been observed that applying humic acid and sulfur rates in the higher levels (T16 and T15 treatments) have a significant effect on yield and yield constituents of maize in both locations, because the humic acids improve the soil

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

structure (Ali et al., 2011) and through various mechanisms which were indicated to plant growth and development, enhance nutrient abundance and absorption (Berbara and Garcia, 2014). Humic acid is crucial for enhancing the abundance of nutrients through the chelation of metallic nutrients, promoting the chelation of various elements and turning them obtainable by the plant and improve the plant growth and nutrient uptake.

This process may be attributed to the distinctive structural properties of humic acid as it has so many oxygen-containing functional groups (CO_2H_2, OH, phenols, and C = O).

Humic acid is vital for modified soil physical properties. Humic acid is essential to increased plant yield through physiological effects such as the impact on the metabolism of plant cells and increasing the leaves area (Nardi et al., 2009). Increased root growth has been attributed to improved soil structure, stimulation of the soil microflora and plant growth regulator effects. For comprehensive reviews of humic acid effects on plants and because sulfur is essential in the structural and enzymatic components in plants, sulfur is a fundamental constituent of some basic amino acids that comprise proteins, and it contributes in chlorophyll synthesis. Moreover, Sulfur optimizes utilization of supplementary nutrients in plants, which are crucial for growth, development of root nodule in legumes in addition to plant protection mechanism since soil pH drops when sulfur is added to the soil.

Many previous studies have indicated that applying humic acid optimizes soil physical configuration, supports preserving soil moisture, raises root absorptivity of water and nutrients, promotes the production of nucleic and amino acids, promotes the action of enzymes and metabolic rate, and subsequently, optimizes yield (Dursunet al., 2002). All these pathway alterations may be attributed to humic acid since it elevates membranes absorbency and enhances the uptake of nutrients Furthermore; humic acid intensifies soil sponginess and enhances root development which in turn contributes to a larger shoot (Garcia et al., 2008). Humic acid optimizes the fresh and dry weight of shoot and root in corn (Cordeiro et al., 2011). Using sulfur fertilizers promotes growth through promoting the absorbency of soil micronutrients which eventually leads to more significant yield quantities (Fayed, 2005). Due to the significance of sulfur in root development, chlorophyll production, and metabolism, heavier fresh and dry weights of plants treated with sulfur-containing humic acid might be attributed to sulfur (Atoosa et al., 2017).

Conclusion

The results of the current work indicate that humic acid has a positive impact on the yield and its components in corn. Using humic acid may decrease the demand for other chemical and biological fertilizers to a reasonable extent. These wanted outcomes might be attributable to its impact on corn growth and physiology. Besides raising yield quantities of corn, humic acid may also contribute to realizing the objectives of agricultural sustainability. Sulfur is a central micronutrient needed for plant growth and development. Because sulfur and humic acid are involved in affecting physiological and biochemical pathways, they have to be studied thoroughly and profoundly In order to grasp better the nutritional mechanisms of sulfur about humic acid and in order to serve as a guideline for developing balanced fertilizer formulas to optimize yield quality and quantity. According to the results obtained from the present research, we guide the

related directions to farmers in Sulaimani Governorate, Kurdistan Region – Iraq to cultivate the cv. Gloria of maize. It is necessary to implement more studies on other levels of humic substances in maize plant at different dose along with the sulfur and other methods of application for reaping higher yield and quality apart from sustaining the soil health. Evaluation of soil fertility status to other potential maize growing areas should be done to understand the deficiency situation of the nutrients

(Received 3rd Jun 2019; accepted 2nd Sep 2019)

Abstract. The effect of foliar application of seaweed extracts Bio-algeen S90 (*Ascophyllun nodosum*) and Kelpak SL (*Ecklonia maxina*) and humic and fulvic acids from leonardite HumiPlant on plant growth and marketable tuber yield of early potato crop was investigated. The application of seaweed extracts resulted in a faster rate of plant growth. Bio-algeen S90 affected potato growth more than Kelpak SL. The plants grew taller and produced a greater above-ground biomass. With the use of HumiPlant, stems were shorter but had a similar weight to plants in the cultivation without biostimulant. Biostimulants caused enlargement of the assimilation leaf area, but had no effect on the weight of leaves, leaf weight ratio (LWR) or leaf area ratio (LAR). The yield-increasing effect of biostimulants depended on hydrothermal conditions during potato growth. Seaweed extracts produced better results in a warm and a very wet growing season, whereas humic and fulvic acids produced better results in a cool growing season with drought during the tuber growth period.
Keywords: *biostimulant, plant height, above-ground biomass, assimilation leaf area, leaf area ratio (LAR), leaf weight ratio (LWR)*

Introduction

Potato (*Solanum tuberosum* L.) growth and, as a result, tuber yield depends on the site-specific interaction between cultivar and environment, and on the agronomic practices. Potato growth is influenced by many biotic and abiotic stress factors. In sustainable agriculture, biostimulants have been gaining increasing importance. Biostimulants contain a wide range of bioactive compounds that increase plant stress resistance, which allows better use of the cultivar production potential under the environmental conditions of the cultivar area (Calvo et al., 2014; Bulgari et al., 2015). In field crop production, the most commonly used are seaweed extracts and humic acids (Battacharyya et al., 2015; Canellas et al., 2015).

Many plant growth-stimulating compounds such as auxins, cytokinins, gibberellins, betaines, polyamines, abscisic acid, brassinosteroids and minerals were identified from seaweed. These compounds affect cellular metabolism in treated plants, leading to increased tolerance to abiotic stresses, improved plant growth and crop yield (Craige, 2011; Sharma et al., 2014). Most commercial seaweed products are manufactured from red (*Lithothamnium calcareum*) and brown (*Ascophyllum nodosum*, *Ecklonia maxima*, *Sargassum* spp., and *Durvillaea* spp.) microalgae (Craige, 2011). The plant growth-promoting effects of seaweed extracts have been documented in several agricultural and horticultural crops such as tomato, onion, pepper, carrot, potato, wheat, barley and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1321913230

maize. Seaweed extract applied via roots or leaves stimulates plant growth in a species-specific manner. The effect of seaweed extract on plant growth depends on the date and dose of application (Haider et al., 2012; Sharma et al., 2014; Begum et al., 2018).

A study carried out in Finland showed that in long-day conditions characterized by a cool and short growing season, the foliar application of the first seaweed extract SM3 (originally called Sea Magic) had a remarkable effect on potato growth and tuber yield (Kuisma, 1989), whereas a later study carried out in Iraq showed that the foliar application of extracts from brown seaweed *Sargassum* Alga 600 and Sea force 2 promoted potato growth and increased tuber yield (Sarhan, 2011). A positive response of potato plant growth and yield to the foliar application of the extracts from *Ascophyllum nodosum* (Primo, Bio-algeen S90) and *Ecklonia maxima* (Keplak SL) was shown in studies carried out in Pakistan and Poland (Haider et al., 2012; Wierzbowska et al., 2015) and the extracts from *Kappaphycus alvarezii* (K sap) and *Gracilaria edulis* (G sap) in a study carried out in India (Prajapati et al., 2016).

Humic substances are able to produce positive effect on the growth, yield and quality of potato (Verlinden et al., 2009). The biostimulant effects of humic substances extracted from naturally humified organic matter, from composts, or from mineral deposition are characterized by both structural and physiological changes in plants. The activity of humic substances is related to their chemical structure (Calvo et al., 2014; Canellas et al., 2015). Humic acids have been reported to stimulate the growth of such crops as wheat, rice, maize, tomato, cucumber, pepper and potato. The effect of humic acids on plant growth depends on their source and concentration and on the date and method (foliar or soil) of application, as well as the plant species (Calvo et al., 2014; Canellas et al., 2015; Alenazi et al., 2016; Zhang et al., 2017). A strong potato response to the application of humic substances originating from leonardite formations in Canada has been reported (Verlinden et al., 2009). Later studies carried out in Poland, Saudi Arabia and China confirmed the positive effect of humic and fulvic acids on potato growth and on tuber yield and quality (Matysiak and Adamczewski, 2010; Alenazi et al., 2016; Zhang et al., 2017). The results of a study carried out in Korea showed that foliar or soil application of fulvic and humic acids had no clear promotional effects on tuber growth or potato yield (Suh et al., 2014).

The application of humic substances (soluble humic and fulvic acids fractions) and seaweed extracts shows inconsistent, yet a generally positive, effect on plant growth. To date, few studies have been focused on the effects of seaweed extracts and humic acids application on early crop potato culture. In our study it was hypothesised that the stimulation of potato plant growth by seaweed extracts and humic acid application would contribute to increase early potato crops. The assumption was also made that the potato response to foliar application of seaweed extracts and humic acids depends on the potato cultivar and environmental conditions. The aim of the study was to determine the effect of seaweed extracts and humic acid application on plant growth and marketable tuber yield of very early potato cultivars.

Materials and methods

Experimental site and season

The field experiment was carried out in central-eastern Poland - 52°03'N, 22°33'E (*Fig. 1*) during three growing season of the 2012-2014 period, on loamy soil (Luvisol) with an acidic-to-slightly-acid reaction (pH in 1 M KCl from 4.7 to 6.3). The content of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1321913230

available phosphorus in the soil ranged from 118 to 144 mg P kg^{-1}, potassium from 124 to 208 mg K ha^{-1} and magnesium from 22 to 51 mg Mg kg^{-1} of soil. In each year of the study, spring triticale was grown as a potato forecrop. Farmyard manure was applied in autumn, at rate of 25 t ha^{-1}, and mineral fertilizers were applied in rates 80 kg N (ammonium nitrate), 35 kg P (superphosphate) and 100 kg K (potassium sulphate) per hectare in spring. Potato cultivation was carried out according to common agronomical practice. Colorado potato beetle (*Leptinotarsa decemlineata*) was controlled using Actara 25 WG (thiametoksam) and Apacz 50 WG (chlotianidine).

Figure 1. *Location of experimental site (http://freeworldmaps.net)*

Plant material and experimental design

The field experiment was established in the split-plot design with three replications. The experimental factors were as follows: (i) – type of biostimulant: control treatment without biostimulant, Bio-algeen S90 – 2 L ha^{-1} at the beginning of leaf development stage BBCH 10-11 and 2 L ha^{-1} after two weeks from first treatment, Kelpak SL – 2 L ha^{-1} at the leaf development stage BBCH 14-16 and 2 L ha^{-1} after two weeks from first treatment, HumiPlant – 2 L ha^{-1} at the leaf development stage BBCH 14-16 and 2 L ha^{-1} after one week from first treatment (*Table 1*); (ii) – potato cultivar: 'Denar', 'Lord', 'Miłek' (Polish cultivars registered on the Common Catalogue of Varieties of Agricultural Plant Species CCV).

Table 1. *Characteristics of biostimulants used in the experiment*

Trade name	Source of biologically active compounds	Plant growth-stimulating compounds
Bio-algeen S90	Seaweed extract *Ascophyllum nodosum*	90 groups of chemical compounds including: amino acids, vitamins, alginic acid and other active components of seaweeds, N - 0.02%, P - 0,006%, K - 0,096%, Ca - 0,31%, Mg - 0,021%, B - 16 mg kg^{-1}, Fe - 6,3 mg kg^{-1}, Cu - 0,2 mg kg^{-1}, Mn - 0,6 mg kg^{-1}, Zn - 1,0 mg kg^{-1}, Mo, Se, Co
Kelpak SL	Seaweed extract *Ecklonia maxima*	Auxin - 11 mg L, cytokinin - 0.031 mg L
HumiPlant	Leonardite extract	Humic acid - 12%, fulvic acid - 6%, K_2O - 3%, Fe, Ca, Mn, S, Mg, B, Mo, Zn, Cu

DOI: http://dx.doi.org/10.15666/aeer/1706_1321913230

In successive years, 6-weeks pre-sprouted seed potatoes were planted on the 12th, 18th and 7th and 4 April, with an in-row spacing of 25 cm and 67.5 cm between rows. The average length of sprouts at the time of planting was 15-20 mm. The plots were six rows wide and 4 m long (96 plants per plot). At the tuber formation stage (BBCH 41-43), the length and weight of stems and weight of leaves and assimilation leaf area were determined. The measurements were made on four successive plants per plot. The assimilation leaf area was measured by the weight method based on the weight of pieces with a known diameter and total weight of leaves per plant (Wadas and Kalinowski, 2017). The leaf weight ratio (LWR) and leaf area ratio (LAR) were calculated. LWR and LAR were calculated as the ratio of the weight of leaves/weight of the whole plant and the ratio of assimilation leaf area/weight of the whole plant, respectively (Pietkiewicz, 1985). Potatoes were harvested 75 days after planting (the end of June). The marketable tuber yield (diameter above 30 mm) was determined.

Statistical analysis

The results of a two-way field experiment were analysed statistically by means of analysis of variance (ANOVA) for the split-plot design. The significance of differences was verified using Tukey's test at $p \leq 0.05$ (*Table 2*).

Table 2. *Effect of experimental factors on potato growth and tuber yield*

Weather conditions

The mean air temperatures in the period of potato growth were above or similar to the long-term average (*Table 3*). In 2012 total precipitation in April-June was similar and in 2013 and 2014 above the long-term average and unevenly distributed during potato growth period.

Table 3. *Mean air temperature and precipitation total in potato growing period*

Years	Temperature (°C)			Rainfalls (mm)		
	April	May	June	April	May	June
2012	8.9	14.6	16.3	29.9	53.4	76.2
2013	7.4	15.3	18.0	36.0	105.9	98.8

DOI: http://dx.doi.org/10.15666/aeer/1706_1321913230

The most favourable thermal and moisture conditions for early crop potato culture were in the warm and moderately wet growing season of 2012. 2013 was warm and with a heavy rainfall, whereas 2014 was cool with a heavy rainfall after the plant emergence and a drought in the period of tuber growth.

Results

Length and weight of stems

The type of biostimulant had a significant effect on potato growth (*Table 4*). Following the application of Bio-algeen S90, the stems were longer by 2.3 cm, on average, and the average weight of stems was 40 g higher compared with the control object without the growth stimulant. With the application of Kelpak SL the stem lengths were similar and with the application of HumiPlant they were shorter by 3.3 cm, on average, in comparison with the control object, although the stem weights were not significantly different. The effect of tested biostimulants on plant growth depended on weather conditions during the potato growing season. The type of biostimulant had the greatest effect on plant growth in 2014 with a low air temperature and a heavy rainfall after the plant emergence. In that year, after the application of Bio-algeen S90 the weight of stems was higher by 81 g than the plants from the control object without biostimulant, with a comparable length of stems. Following the application of Keplak SL and HumiPlant, stems were shorter by 3.9 cm and 5.0 cm, respectively, compared with the plants from the control object with comparable stem weights.

Table 4. *Length and weight of stems*

Type of biostimulant	Years			Cultivar			Mean
	2012	2013	2014	Denar	Lord	Miłek	
Length of stems (cm)							
Without biostimulant	63.6 b	59.0 ab	82.5 a	72.1	71.8	61.2	68.4 b
Bio-algeen S90	67.6 a	59.7 a	84.8 a	76.5	77.0	58.7	70.7 a

The type of biostimulant and cultivar interaction effect on the length of stems was not statistically confirmed. Bio-algeen S90 had a greater effect on the weight of stems of ‘Denar’ and ‘Lord’ than ‘Miłek’ (*Table 4*). The differences were highest in 2014 with a low air temperature and a heavy rainfall after plant emergence.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1321913230

The rate of plant growth depended on the cultivar and weather conditions (*Table 4*). Regardless of the treatment (with or without biostimulant), the length and weight of stems were higher for 'Denar' and 'Lord' than for 'Miłek'. The stems were longest and they had the greatest weight in 2014, with the highest air temperature and moderate rainfall in the second half of May.

Weight of leaves and assimilation leaf area

The biostimulants used in the experiment had no significant effect on the weight of leaves, but caused enlargement of the assimilation leaf area, on average, by 366 cm^2 to 664 cm^2 (*Table 5*). The type of biostimulant and year interaction effect on the assimilation leaf area was statistically confirmed. In 2013 with the highest air temperature and a heavy rainfall after plant emergence, the greatest enlargement of assimilation leaf area, on average by 624 cm^2, was caused by Kelpak SL. In 2014 with the lowest air temperature and a heavy rainfall after plant emergence, following the application of Bio-algeen S90, the assimilation leaf area was larger, on average, by 941 cm^2 than the plants from the control object without a biostimulant, with a comparable weight of leaves.

Table 5. *Weight of leaves and assimilation leaf area*

Type of biostimulant	Years			Cultivar			Mean
	2012	2013	2014	Denar	Lord	Miłek	
Weight of leaves (g)							
Without biostimulant	250	171	282	221 a	204 b	279 a	234 a

Means within columns/rows followed by the same lowercase/uppercase letters do not differ significantly at $p \leq 0.05$

The type of biostimulant applied had a greater effect on the weight and assimilation leaf area of 'Lord' than 'Denar' and 'Miłek' (*Table 5*). Following the application of Bio-algeen S90, the weight of 'Lord' leaves was higher by 46 g, on average, and the assimilation leaf area was larger by 1583 cm^2 as compared with the plants from the control object without biostimulant. The differences were highest in 2014 with a low air temperature and a heavy rainfall after the plant emergence.

Regardless of the biostimulant applied, the weight and the assimilation leaf area were higher for 'Miłek' than for 'Denar' and 'Lord'. The plant growth indices were highest in 2014 with the highest air temperature and a moderate rainfall at the end of May (*Table 5*).

DOI: http://dx.doi.org/10.15666/aeer/1706_1321913230

Leaf weight ratio (LWR) and leaf area ratio (LAR)

The biostimulants used in the experiment had no significant effect on the LWR or LAR (*Table 6*). Following the application of biostimulants, the plant growth indices were similar to the control object without biostimulant.

Table 6. *Leaf weight ratio (LWR) and leaf area ratio (LAR)*

Type of biostimulant	Years			Cultivar			Mean
	2012	2013	2014	Denar	Lord	Miłek	
Leaf weight ratio (g g^{-1})							
Without biostimulant	0.446	0.455	0.380	0.388	0.413	0.480	0.427 a
Bio-algeen S90	0.434	0.449	0.366	0.381	0.398	0.471	0.416 a
Kelpak SL	0.435	0.480	0.403	0.409	0.407	0.503	0.440 a
HumiPlant	0.450	0.469	0.387	0.407	0.405	0.494	0.435 a
Mean	0.441 A	0.463 A	0.384 B	0.396 B	0.406 B	0.487 A	
Leaf area ratio (cm^2 g^{-1})							
Without biostimulant	13.50	16.47	12.60	13.10	13.46	16.01	14.19 a

Kelpak SL	12.72	17.51	13.41	13.63	13.16	16.85	14.55 a
HumiPlant	13.36	16.60	12.89	12.99	12.82	17.04	14.28 a
Mean	13.24 B	16.61 A	12.85 C	13.06 B	13.18 B	16.46 A	

Means within columns/rows followed by the same lowercase/uppercase letters do not differ significantly at $p \leq 0.05$

The LWR and LAR depended on the cultivar and weather conditions during potato growth (*Table* 6). Regardless of the treatment (with or without biostimulant), the LWR and LAR were higher for 'Miłek' than for 'Denar' and 'Lord'. The plant growth indices were lowest in 2014 with the highest air temperature and a moderate rainfall in the second half of May.

Marketable tuber yield

The productive effects of biostimulants used in the experiment were comparable, which was reflected in an increase in the marketable tuber yield in comparison with the cultivation without biostimulant (*Table 7*). In the three years of the study, the marketable tuber yield was higher by 2.15 t ha^{-1}, on average. The yield-increasing effect of biostimulants depended on weather conditions during the potato growing season.

Table 7. *Marketable tuber yield (t ha^{-1})*

Type of biostimulant	Years			Cultivar			Mean
	2012	2013	2014	Denar	Lord	Miłek	
Without biostimulant	39.49 a	29.75 b	29.34 b	31.84	33.10	33.64	32.86 b
Bio-algeen S90	38.96 a	34.64 a	30.62 b	34.49	35.47	34.26	34.74 ab
Kelpak SL	40.22 a	34.12 a	30.62 b	33.50	35.46	36.00	34.99 a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1321913230

Bio-algeen S90 and Kelpak SL caused the highest increase in marketable tuber yield in the warm and very wet growing season of 2013. With the use of those biostimulants, the marketable tuber yield was higher by 4.63 t ha^{-1}, on average, in comparison with the cultivation without biostimulant. HumiPlant caused the highest increase in marketable tuber yield in 2014 with a low air temperature and, at the same time, insufficient water supply for plants in the period of tuber growth. In that year, following the application of HumiPlant the marketable tuber yield was higher by 3.49 t ha^{-1}. The type of biostimulant and cultivar interaction effect on marketable tuber yield was not statistically confirmed.

The marketable tuber yields of the tested potato cultivars were similar (*Table 7*). The yield of early potato was highest in the warm and moderately wet growing season of 2012.

Discussion

An analysis of plant growth is important to determine the effect of biostimulants on the crop yielding. In the present study, the type of biostimulant applied significantly affected the growth of very early potato cultivars. A faster rate of plant growth was observed with the use of seaweed extracts, than with the use of humic and fulvic acids. Seaweed extracts have more biostimulant potential due to the presence of phytohormones and a number of other compounds promoting plant growth and strengthening stress resistance (Begum et al., 2018). Among the tested seaweed extracts, Bio-algeen S90 (*Ascophyllum nodosum*) had a greater effect on the rate of plant growth than Keplak SL (*Ecklonia maxima*). Bio-algen S90 have more bioactive compounds than Kelpak SL. Following the Bio-algeen S90 application, the plants were higher and produced a greater above-ground biomass. The positive effect of the foliar application of *Ascophyllum nodosum* extract on the growth of medium-early potato cultivar was also shown in a study carried out in Pakistan (Haider et al., 2012). Following the application of HumiPlant, plants were lower but had a similar weight of stems as in the cultivation without biostimulant, which suggests that the stems were thicker. To date studies showed a generally positive effect of humic acids on potato growth. A study carried out in Iraq and Saudi Arabia showed that the application of humic acid promoted the growth of medium-early potato cultivars (Sarhan, 2011; Alenazi et al., 2016), whereas the results of a study carried out in Korea showed that foliar or soil application of humic and fulvic acids had no clear effect on the growth of medium-early potato cultivar (Suh et al., 2014). A study carried out in China showed that foliar application of fulvic acid increased the stem length and diameter of early potato cultivar and prolonged the plant growth period (Zhang et al., 2017), which was no clear confirmed in the present study. Plant response to exogenously applied humic substances depends on the plant species and its ontogeny and environment conditions. Plant growth response to humic substances obtained from leonardite are less than the response to humic substances obtained from peat, composts or vermicomposts (Canellas and Olivares, 2014). Biostimulants had no effect on the weight of leaves, but caused enlargement of the assimilation leaf area under abiotic stress conditions. In the year with the highest air temperature and a heavy rainfall after plant emergence, the assimilation leaf area was the largest after the application of Kelpak SL, whereas in the year with a lowest air temperature and with a heavy rainfall after plant emergence, the assimilation leaf area was the largest after the application of Bio-algeen S90.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1321913230

Biostimulants caused enlargement of the assimilation leaf area, but had no significant effect on the share of assimilation organs in the whole plant weight (LWR) or on the weight per unit leaf area (LAR). These indices are determined by the cultivar and plant growth stage, and by the interaction effect between the cultivar and environment (Pietkiewicz, 1985; Lahlou et al., 2003; Wadas and Kalinowski, 2017), which was confirmed in the present study. The LWR and LAR varied with plant growth, due to potato response to weather changes by falling or new growth of leaves (Pietkiewicz, 1985; Camargo et al., 2015).

The yield-increasing effect of biostomulants depended on the hydrothermal conditions during potato growth. The seaweed extracts Bio-algeen S90 and Kelpak SL produced better results in a warm and a very wet growing season. With the use of those biostimulants, the marketable tuber yield (with diameter above 30 mm) was higher by 15.5% in comparison with the cultivation without biostimulant. Seaweed extracts improve the thermal tolerance of plants (Battacharyya et al., 2015), which was confirmed in the present study. Humic and fulvic acids from leonardite produced better results in a cool growing season and with insufficient water supply for plants in a period of tuber growth. With the use of HumiPlant the marketable tuber yield was higher by 12%. Very early potato cultivars showed a differential response to seaweed extracts. Kelpak SL did not have a significant effect on the marketable tuber yield of very early potato cultivar 'Felka', but caused an increase in the yield of very early cultivar 'Volumia'. In a year with a lower air temperature and less rainfall, Bio-algeen S90 caused a higher increase in the total yield of the very early potato cultivar 'Volumia' than Kelpak SL (Erlichowski and Pawińska, 2003; Wierzbowska et al., 2015). Kelpak SL caused an increase in the total tuber yield of medium-early potato cultivars (Matysiak and Adamczewski, 2010). Kelpak SL contains auxins and cytokinins at the level of 350/1. Exogenous auxin plays an important role in tuber formation and plant stress resistance; however, the action of exogenous auxin depends on its concentration and light conditions. The potato growth response to exogenous auxin depends on the plant genotype and carbohydrate status (Kolachevskaya et al., 2019). Cytokinins also have an important effect of plant adaptation to environmental stresses. Under drought conditions, exogenous cytokinins can increase stomatal apertures and transpiration in plant, and have a positive effect on photosynthetic activity (Ha et al., 2012). In the present study, the type of biostimulant and cultivar interaction effect of early crop potato yield was not statistically confirmed. Positive potato response to humic substances originating from leonardite applied to soil or foliar was confirmed in studies carried out by other authors (Verlinden et al., 2009; Matysiak and Adamczewski, 2010). Under water stress, foliar application of humic acids increased leaf water retention and photosynthetic and antioxidant metabolism (Fahramand et al., 2014). Periods of high temperature and drought are becoming more frequent in Central Europe. In east-central Poland, the shortage of rainfall in the growing season of early potato cultivars occurs more often than their excess (Radzka et al., 2015).

A positive correlation was found between the tuber yield and the number of main stems per plant, stem length and diameter (Arslan, 2007; Darabad, 2014). A significant relationship was also found between the tuber yield and LWR and LAR (Zrůst and Čepl, 1991; Wadas and Kalinowski, 2017). In the present study, following the application of Bio-algeen S90, the plants were higher and produced a greater above-ground biomass than in the cultivation without biostimulant, whereas following the application of HumiPlant the stems were shorter at a similar weight as the control

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1321913230

plants, which suggests that the stems were thicker. Biostimulants caused enlargement of the assimilation leaf area, but had no effect on the weight of leaves. This suggests that the leaves were thinner following the application of biostimulants. As the result, the biostimulants had no significant effect on the LWR or LAR. It often happens that the enlargement of the assimilation leaf area does not result in an increase in the tuber yield, because the rate of photosynthesis per unit of leaf area decreases with an increase in the leaf area (Pietkiewicz, 1985).

Conclusions

This study showed the possibility of improving plant growth in an early crop potato culture with the foliar application of seaweed extracts *Ascophyllum nodosum* (Bio-algeen S90) and *Ecklonia maxima* (Kelpak SL) and humic and fulvic acids from leonardite (HumiPlant). Seaweed extracts caused a faster rate of potato growth. Bio-algeen S90 had a greater effect on plant growth than Kelpak SL. Following the application of Bio-algeen S90, the plants were higher and produced a greater above-ground biomass than in the cultivation without biostimulant. Following the application of HumiPlant, plants were lower but had a similar weight of stems as plants in the cultivation without biostimulant. This suggests that the stems were thicker. Biostimulants caused enlargement of assimilation leaf area, but had no effect on the weight of leaves, which suggests that the leaves were thinner. As a results, the biostimulants had no effect on the leaf weight ratio (LWR) or leaf area ratio (LAR). The biostimulants caused an increase in the marketable tuber yield of early crop potato. The yield-increasing effect of biostimulants depended on the hydrothermal conditions during potato growth. Seaweed extracts produced better results in a warm and a very wet growing season, whereas humic and fulvic acids produced better results in a cool growing season and with a drought in the period of tuber growth. To use humic substances and seaweed extract for promoting plant growth in early crop potato culture, it is necessary to optimize their source and concentration for environmental conditions to achieve the expected outputs.

(Received 4th Jun 2019; accepted 2nd Sep 2019)

Abstract. The work presents results of a research conducted in 2009-2011 to assess the yield and sugar content of selected maize (*Zea mays* L.) cultivars included in the Common Catalogue of Varieties of Agricultural Plant Species (CCA), harvested at various development stages, which affects the quality of animal feed produced, and select cultivars suitable for cultivation under the soil and climatic conditions of Poland. Two factors were examined in the study: A − the harvest date of maize green matter (I − tasseling stage (75% of plants at this stage), II − milk maturity stage (after three weeks), III − wax maturity stage (after another three weeks)); B − cultivars with different earliness of maturity: Pyroxenia – very early, FAO 130, Codimi – early FAO 200, Moschus – early, FAO 220, Alombo – medium early, FAO 230, and Celive – medium early, FAO 245. Total protein yield, dry matter and starch content, soluble sugars and reducing sugars were determined in maize plants. The obtained study results demonstrated that the highest total protein yield was produced by the following maize cultivars: Codimi, Moschus, Alombo and Celive harvested at the wax maturity stage. The highest starch content was determined in the plants of cv. Pyroxenia, Codimi, Alombo and Celive also harvested at the wax maturity stage. Maize plants of all the examined cultivars harvested at the milk maturity stage and cv. Pyroxeni harvested at the tasseling stage had the highest soluble sugars and reducing sugars.
Keywords: *FAO, harvest date, total protein yield, dry matter, starch*

Introduction

As the cultivation area of maize and the crop's economic importance are increasing, there is also an increase in the demand for better cultivars − hybrids. Nowadays, breeding new maize cultivars makes use of heterosis or hybrid vigour which is displayed in the F_1 generation obtained as a result of crossing maternal and paternal inbred lines (Adamczyk, 2001; Sulewska et al., 2011). According to Jha et al. (1998) and Michalski et al. (2002), the role new cultivars play in modern agriculture is of great importance. In the cultivation of maize, breeding of new cultivars is developing dynamically, so it is advisable to study new cultivars recommended for cultivation in Poland, as well as from the CCA Community Catalog with neighboring countries. Thus, it is could prove beneficial to examine new cultivars originating from neighbouring countries and grown under the soil and climatic conditions of Poland. Both yielding and chemical composition of maize green feed are cultivar-related (Korniewicz et al., 2000; Ptaszyńska and Sulewska, 2008; Lynch et al., 2012). In their experiments, Filya (2004) and Komainda et al. (2018) observed that the greatest changes in organic matter chemical composition are associated with maize development stages. The more the harvest date is delayed, the higher increase in soluble sugars and starch content, and the lower the protein content of maize plants. Their contents are the highest when maize plants are at the milk maturity stage. The paucity of Polish literature on the subject

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1323113238

provided an incentive to conduct this research. Its objective was to assess yielding and sugar content in maize plants of selected cultivars included in the Common Catalogue of Varieties of Agricultural Plant Species (CCA), harvested at various development stages which affect the quality of animal feed produced, and select cultivars suitable for cultivation under the soil and climatic conditions of Poland.

Materials and methods

Field studies were conducted in 2009-2011 on a private holding located in Kowiesy near Siedlce (52° 03' 39" N, 22° 33' 80" E). The field trial was set up on the soil classified as Albic Luvisol (Arenic) characterised by a slight acidity and average available phosphorus, potassium and magnesium contents. The soil's humus content was 1.28%. The experiment was arranged as a split-plot design with three replicates. The area of one plot was 30 m^2. The following two factors were investigated: A − maize green matter harvest date (I − tasseling stage (75% of plants at this stage), II − milk maturity stage (after three weeks), III − wax maturity stage (after another three weeks)); B − cultivars with different earliness of maturity (Pyroxenia – very early FAO 130, Codimi – early FAO 200, Moschus – early FAO 220, Alombo – medium early FAO 230, Celive – medium early FAO 245; *Table 1*). The number of plants per 1 m was 10, and the sowing rate was established based on previous research by Sulewska (2001). Inter-row widths were 0.8 m. Maize was grown in monoculture. In the autumn, cattle manure was applied at the rate of 30 t ha^{-1}.

Table 1. *Characteristics of studied cultivars*

Cultivar	Earliness of maturity	Number FAO
Pyroxenia	Very early	130
Codimi	Early	200
Moschus	Early	220
Alombo	Medium early	230
Celive	Medium early	245

In spring, phosphorus and potassium fertilisers were applied at rates matching soil contents of available elements, that is 60 kg P ha^{-1} and 90 kg K ha^{-1}. Nitrogen fertiliser was applied pre-plant at the rate of 92 kg N ha^{-1} in the spring and followed by maize, the nitrogen rate being increased due to an application of Polifoska 6. Seeds of the examined cultivars were planted in late April. Cv. Pyroxenia (bred by Trnava s.r.o. Slovakia, three-way cross (Tc)) is a hybrid characterised by extreme earliness, a high share of cobs in the yield structure, resistance to increased stand density and rapid increase in cob dry matter. Cv. Codimi (bred by Codimes, France, Tc) is an early maturing variety with a classical stay-green trait, rapid initial growth and a high share of grain dry matter in silage. Its plants are of medium height developing an abundance of wide leaves. Cv. Moschus (bred by Freiherr von Moreau Saatzucht GmbH, Germany, modified three-way cross (MTc)) is an early maturing multiple-use variety displaying the stay-green trait. It produces high yields of grain which easily releases water. Cv. Alombo (bred by Freiherr von Moreau Saatzucht GmbH, Germany, single cross (Sc)) is a multiple-use variety suitable for both grain and silage production even under poorer soil conditions. It has a high yield-production potential and good healthiness. Cv. Celive

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1323113238

(bred by Cezea a.s., Czech Republic, Sc) is an early maturing hybrid suitable for grain production, cold-tolerant, producing high grain yields, which is indicative of high quality of silage produced from its green matter. The green matter of maize crop was harvested at three dates as set in the methodology. The plant matter was sampled to determine dry matter content, total protein content, starch content, soluble sugars and reducing sugars by means of near infrared spectroscopy (NIRS) using the spectrometer NIR Flex N-500. The analyses were performed at the certified laboratory of the Institute of Technology and Life Sciences in Falenty.

The results of the research were statistically analysed; ANOVA following the linear model for a two factor split-plot design was performed for each characteristic examined, and separation of means was obtained by means of Tukey test at the significance level of 0.05. All the calculations were performed in STATISTICA®, version 12.0 and MS Excel.

The studies were carried out on lessive soil. Maize was grown in monoculture. Nitrogen at a dose of 92 N kg ha $^{-1}$ was applied in spring before sowing maize in the form of urea for the tilling set, the additional nitrogen dose was increased by the use of mineral fertilizer in the form of Polifoska 6. Phosphorus at a dose of 60 P kg ha $^{-1}$ and potassium at a dose of 90 K kg ha $^{-1}$ was applied in the form of multi-component mineral fertilizer-Polifoska 6 in spring.

Weather conditions in the 2009 growing season were moderately favorable for the proper vegetation of corn plants. During the growing season of 2010, weather conditions favored the growth, development and yielding of maize. The vegetation season of 2011 was varied in terms of both rainfall and temperature.

Results

The total protein yield of maize plants

Total protein yield of maize plants varied significantly due to the impact of the experimental factors and their interaction (*Table 2*).

Table 2. *Total protein yield of maize plants (means across 2009-2011), kg ha^{-1}*

Cultivars (B)	**Harvest date (A)**			**Means**

The highest total protein yield was produced by maize plants harvested at the wax maturity stage, it being significantly lower at the milk maturity stage and the lowest at the tasseling stage. Cultivars had a significant influence on total protein yield. The yield produced by cv. Codimi, Moschus, Alombo and Celive was the highest and differed insignificantly between the cultivars, it being significantly lower for cv. Pyroxenia only. An interaction between the experimental factors was determined which indicated that the highest total protein content was produced by cv. Codimi, Moschus, Alombo and Celive harvested at the wax maturity stage, it being the lowest for all the examined cultivars harvested at the tasseling stage.

The dry matter content in maize plants

Statistical analysis revealed a significant influence of the experimental factors and their interaction on dry matter content in maize plants (*Table 3*).

Table 3. *Dry matter content in maize plants (means across 2009-2011), g kg^{-1}*

Cultivars (B)	**Harvest date (A)**			**Means**

Interaction (AxB)	< 0.001		23.0	

Values in columns followed by the same small letter and values in rows followed by the same capital letter do not differ significantly at P < 0.05

The highest dry matter content was recorded for maize plants harvested at the wax maturity stage, it being significantly lower at the milk maturity stage and the lowest at the tasseling stage. Cultivars significantly affected dry matter content in maize plants, as well. The highest dry matter content was determined in maize cv. Pyroxenia, Codimi, Moschus and Alombo, it being the lowest in the green matter of maize cv. Celive. An interaction between the experimental factors was confirmed indicating that the highest dry matter content was found in maize plants of cv. Pyroxenia, Codimi, Moschus and Alombo harvested at the wax maturity stage, it being the lowest for all the cultivars harvested at the tasseling stage.

The starch content in maize plants

Starch content in maize plants was significantly affected by harvest date, cultivars and their interaction (*Table 4*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1323113238

Interaction (AxB)	< 0.001		48.0	

Values in columns followed by the same small letter and values in rows followed by the same capital letter do not differ significantly at P < 0.05

The highest starch content was recorded in maize plants harvested at the wax maturity stage, it being significantly lower at the milk maturity stage and the lowest at the tasseling stage. Cultivars had a significant influence on starch content in maize plants. The highest starch content was determined in the maize plants of cv. Pyroxenia and Codimi, it being significantly lower in cv. Moschus, Alombo and Celive. An interaction between the experimental factors was confirmed: the highest starch content was recorded in maize plants of cv. Pyroxenia, Codimi, Alombo and Celive harvested at the wax maturity stage, and the lowest for all the examined cultivars harvested at the tasseling stage.

The soluble sugars in maize plants and reducing sugars in maize plants

Statistical analysis demonstrated a significant effect of harvest date and an interaction between harvest dates and cultivars on soluble sugars and reducing sugars in maize plants (*Tables 5* and *6*).

Table 5. *Soluble sugars in maize plants (means across 2009-2011), g kg^{-1} d.m.*

Values in columns followed by the same small letter and values in rows followed by the same capital letter do not differ significantly at P < 0.05

The largest amounts of soluble sugars and reducing sugars were found in maize plants harvested at the milk maturity stage, them being significantly lower at the tasseling stage and the lowest at the wax maturity stage. An interaction between the experimental factors was confirmed which indicated that the highest amounts of soluble and reducing sugars were characteristic of all the experimental maize cultivars harvested at the milk maturity stage and cv. Pyroxenia plants harvested at the tasseling stage. The lowest soluble sugar contents were determined for maize plants of cv. Pyroxenia, Codimi, Moschus and Celive harvested at the wax maturity stage whereas reducing sugars were the lowest for cv. Pyroxenia and Codimi harvested at the same maturity stage.

Discussion

Maize is a crop plant which provides bulky feed produced in ploughed fields and characterised by many beneficial characteristics, Animal feed produced from the whole plants has a high energy value but a low protein content (Brzóska, 2001; Schittenhelm, 2008). In the present study, the highest total protein yield was obtained from maize plants harvested at the wax maturity stage, which was due to the highest dry matter yield. Similar findings were reported by Stejskalove et al. (2013), Magalhães et al. (2015) and Nowab et al. (2017) who demonstrated that a delay in the harvest of maize plants contributed to an increase in total protein yield. In the study discussed here, cultivars affected the total protein yield, too. Cv. Codimi, Moschus, Alombo and Celive were superlative in terms of total protein yield. Similar relationships were observed by Verbic et al. (1997). In the present work, cv. Pyroxenia produced the lowest total protein yield because it is flint type which has the shortest growing season.

Similarly to Magalhães et al. (2015) and Podkówka et al. (2015), in the experiment presented here a delay in maize harvest was followed by an increase in dry matter. Cultivars had a significant effect on dry matter content in maize plants. The highest concentration of this component was recorded in maize plants of cv. Pyroxenia, Codimi, Moschus and Alombo. Celive was the cultivar with the lowest dry matter content. Also

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1323113238

Magalhães et al. (2015) found the lowest dry matter content in maize plants of cv. Celive characterised by the longest growing season.

In the present work, the highest starch content was recorded in maize plants harvested at the wax maturity stage. The results are similar to those reported by other authors (Tolera et al., 1998; Yuxiang et al. (2007). When harvest was delayed, there was observed an increase in starch content in the dry matter of green feed, which is closely correlated with maize maturity stage. In the experiment discussed here, significant differences were found between starch content in the dry matter of maize plants representing the experimental cultivars. The concentration of starch was higher in the dry matter of two early maize cultivars, that is Pyroxenia and Codimi. Also Tolera et al. (1999), Strzetelski et al. (2001) and Szempliński et al. (2009) mentioned that starch content was higher in the dry matter of earlier maturing maize cultivars.

In the current work, there was confirmed a significant effect of maize harvest date on soluble sugars and reducing sugars in the plants. The highest concentration of the sugars in the dry matter of maize green matter was recorded when plants had been harvested at the milk maturity stage. A delay in harvest until plants reached the wax maturity stage contributed to a decline in soluble sugars and reducing sugars, and an increase in starch content. The above relationship was also reported by Lynch et al. (2012) and Magalhães et al. (2015). Maize harvest at the wax maturity stage is associated with the highest starch content, which contributes to the production of the best quality silage. Of the examined cultivars, early representatives, that is Pyroxenia adn Codimi, had the most beneficial chemical composition of green matter.

A new approach to the problem to examine cultivars from neighboring international countries in Poland's soil and climate conditions. New cultivars such as Pyroxenia and Codimi are available for cultivation in Poland and provide the best feed.

Conclusions

(1) The highest total protein content was produced by maize cv. Codimi, Moschus, Alombo and Celive harvested at the wax maturity stage. Maize cv. Pyroxenia, Codimi, Moschus and Alombo harvested at the wax maturity stage had the highest dry matter content.

(2) The highest starch content was recorded in maize cv. Pyroxenia, Codimi, Alombo and Celive harvested at the wax maturity stage.

(3) All the examined maize cultivars harvested at the milk maturity stage, and cv. Pyroxenia harvested at the tasseling stage produced the highest amounts of soluble sugars and reducing sugars.

(4) It is necessary to continue research on the cultivation of new cultivars from the CCA community catalogue in Polish soil and climate conditions.

Abstract. The test adopted the OECD (Organisation for Economic Co-operation and Development) guideine106 equilibrium adsorption method (Bian et al., 2016), to explore the Ni adsorption behavior of the bottom sediment and black soil of the lake. The isothermal adsorption curve of Ni on sediment and black soil retained an "S" shape, and the Freundlich model and D-R model could sufficiently fit the adsorption of Ni by sediment and soil, and the correlation coefficient r was 0.9859~0.9963; Within 120 min, the adsorption amount of nickel in the sediment and soil reached 99.57% and 99.84% of the total adsorption amount, respectively, and reached equilibrium after 720 min. The final desorption amounts of Ni in sediments and soil accounting for 1.26% and 1.35% of the adsorption amounts, respectively. The amount of Ni adsorbed in the sediment increases with rising temperature, and the adsorption coefficient changes in the following manner: K_f 15 °C < K_f 25 °C < K_f 35 °C, Δ G < 0. The adsorption process of nickel on sediment and soil is spontaneous and high temperature is beneficial to this process. The removal of organic matter from sediment and soil weakened the adsorption of nickel, indicating that organic matter could improve the interception of nickel.
Keywords: *sediment, soil, Ni, adsorption, desorption*

Introduction

The content of nickel (Ni) on the earth ranks the fifth, and it generally exists in the form of ore in nature, and the Ni in the natural water body is basically in the form of sulfide and nitrate (Prithviraj et al., 2014). On October 27, 2017, the World Health Organization's International Agency for Research on Cancer announced that Ni is a class of carcinogen, which can lead to a variety of cancer lesions, such as rectal cancer, oral cancer (De Brouwere et al., 2012). Ni is non-biodegradable and persistent, and is easily enriched in soil and organisms, posing a serious threat to human health. In recent years, with the development of economy and society and the acceleration of industrialization, heavy metal pollution has become a global environmental pollution problem, especially the pollution of heavy metals to the soil environment (Kashulina et al., 2018; Abdelwaheb et al., 2017). A large amount of Ni is released into the environment through mining, atmospheric deposition, fertilizer and pesticide application, and sludge and sewage are irrigated into the soil. The Ni accumulated in the soil may remain in the soil and enter crops through planting and other agricultural activities, or enter water bodies through leaching. Part of the pollutants in the water will enter the sediment of the lake through the action of particle adsorption and sedimentation, which makes the sediment become the important "source" and "sink" of the pollutants, which will produce endogenous pollution. The sediment is an important part of the aquatic ecosystem. Heavy metal pollution can cause great harm to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1323913251

aquatic organisms, and thus cause harm to human body and ecosystem (Vukosav et al., 2014). Adsorption of soil and sediment can affect Ni mobility and bioavailability, thus playing a key role in reducing further risks to the environment and humans.

Riparian belt is a transition zone between land and river, and it is an important hub connecting aquatic ecosystem and terrestrial ecosystem. Human agricultural activities are the main source of sediment input to rivers. During rainstorms, a large amount of soil, silt and other materials are transported into rivers through surface runoff, so the sediment and the shore soil have a certain correlation on the components (Zhang et al., 2018). Therefore, it is necessary to study the adsorption characteristics of nickel in sediment and shore soil, and to understand the distribution law of metal nickel between solid and liquid phases. At present, there has been some research on the adsorption of Ni in soil, Sangiumsak (2014) investigates the adsorption of Ni and Zn on different kinds of soils found in the Northeastern Thailand as silty soil and sandy soil. Peng (2017) studied the adsorption and desorption characteristics of heavy metals in soil by soil organic matter and mineral composition, and found that SOM seems to play the most important role in soil adsorption of metal Ni. At present, there are many researches on soil adsorption of heavy metals, but few researches on the comparison between soil and sediment. This paper focuses on the evaluation of the adsorption potential of heavy metal nickel in sediments and soil, and provides theoretical guidance for the prevention of heavy metal contamination of groundwater in soil and sediment.

Materials and methods

Samples for test

Sample collection and basic physical and chemical properties

The tested sediment was taken from Xinlicheng reservoir, Changchun city, Jilin Province, China. The Xinlicheng Reservoir (125°42’57”E, 43°42’57”N) is located in the middle and upper reaches of the Yitong River, 16 km from the center of Changchun. On May 24, 2017, grab dredger was used to collect the surface layer (0-10 cm) sediments of Xinlicheng reservoir. A sampling point was set at the upstream, middle and downstream of the reservoir, and repeated collection was made for three times. After the collected samples were mixed, and after air drying in the room, impurities such as animal and plant residues and stones were removed, and then ground through a 100 mesh sieve and stored for use (Duan et al., 2016). The tested soil was taken from the soil around the entrance of Xinlicheng reservoir. After removing the plants and rocks on the soil surface, five-point sampling method was used to collect the surface soil of 0~20 cm (Wu et al., 2017). The collected samples were naturally dried, removed animal and plant residues, stones and other impurities, and ground through a 100-mesh sieve for preservation. Sampling points are shown in *Figure 1*. The basic physical and chemical properties of samples were shown in *Table 1*.

Test design

Ni isotherm adsorption-desorption

The experiment was conducted with reference to the OECD guideline106 equilibrium adsorption test (OECD). The 1.000 ± 0.0005 g soil samples were taken in 50 ml polyethylene centrifuge tubes, according to the water-soil ratio of 20:1, added 20 ml solution containing different concentrations of Ni background, make the concentration of Ni respectively, 50, 100, 200, 300, 400, 500 $mg \cdot L^{-1}$, after shaking at a constant temperature at 25 °C until adsorption equilibrium, it was centrifuged at 4000 $r \cdot min^{-1}$ for 10 min, filtered, and the concentration of Ni in the supernatant was measured. Immediately after the adsorption, the desorption test was carried out, after removing all the supernatant, added 20 ml deionized water at 25 °C under constant temperature oscillation to desorption balance, and the concentration of Ni in the supernatant was determined.

Adsorption kinetics of Ni

According to the test method in Ni isothermal adsorption-desorption. Added 100 $mg \cdot L^{-1}$ Ni background solution 20 ml for constant temperature oscillation at 25 °C. Samples were taken at the time of 1, 5, 10, 20, 30, 60, 120, 240, 360, 480, 720 and 1440 min, respectively, and centrifuged at 4000 $r \cdot min^{-1}$ for 10 min, then filtered and determined the Ni concentration in the supernatant.

Ni adsorption thermodynamics

According to the test method in Ni isothermal adsorption-desorption. Five Groups of 20 ml solution with Ni concentration of 50, 100, 200, 300, 400 and 500 $mg \cdot L^{-1}$ were prepared, which were placed at 15 °C, 25 °C, 35 °C constant temperature to oscillate to adsorption equilibrium, centrifuged at 4000 $r \cdot min^{-1}$ for 10 min, and filtered to determine the concentration of Ni in the supernatant.

Effects of different organic matter contents on Ni adsorption behavior

The organic matter in the sample was removed by H_2O_2 digestion method, and the experiment was conducted with reference to Ni adsorption thermodynamics.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1323913251

All tests were performed in triplicate.

Data processing

Freundlich equation:

$$lg\ q_\varepsilon = lg\ K_f + lg\ C_\varepsilon^{\frac{1}{n}} \quad \text{(Eq.1)}$$

D – R equation:

$$ln\ q_\varepsilon = ln\ q_m - k\varepsilon^2 \quad \text{(Eq.2)}$$

Elovich equation:

$$C = a + b\ ln\ t \quad \text{(Eq.3)}$$

Parabolic diffusion equation:

$$\frac{C}{C_{Ni}} = a + bt^{\frac{1}{2}} \quad \text{(Eq.4)}$$

In *Equation 1,* lgK_f and 1/n respectively represent the adsorption capacity and adsorption strength of the sample to Ni; In *Equation 2,* q_m is the maximum adsorption capacity, K is a constant for the adsorption energy, ε is the adsorption potential of Polanyi. In *Equations 3* and *4:* C_{Ni} and C are the equilibrium adsorption capacity and the adsorption capacity at time t, respectively $mg \cdot kg^{-1}$; a is the adsorption constant related to the maximum adsorption amount, and b is the adsorption rate coefficient, which is a measure of how fast the reaction rate decreases with time. R value represents the correlation coefficient between variables in the sample, and the magnitude of correlation; P value is the test value, which is to test whether the two variables have the same correlation with the samples in the population from which the samples come, and $p < 0.01$ means extremely significant correlation.

Results and discussion

Adsorption-desorption isothermal behavior of Ni in sediment and black soil and its discussion

Adsorption isotherm of Ni in sediment and black soil

Adsorption isotherms of sediment and black soil on Ni are shown in *Figure 2*. It can be seen from *Figure 2* that in the experimental concentration range, when the initial concentration of Ni changes from 50 $mg \cdot L^{-1}$ to 500 $mg \cdot L^{-1}$, the isothermal adsorption line of Ni in sediment and soil showed a tendency of increasing slope, but the adsorption amount did not reach saturation, When the concentration of Ni is 500 $mg \cdot L^{-1}$, the equilibrium adsorption concentration of sediment and soil on Ni were 17.86 and 20.71 $mg \cdot L^{-1}$, respectively, and the equilibrium adsorption amount were 9642.88 and 9585.84 $mg \cdot kg^{-1}$ respectively. According to the classification of isothermal adsorption curves by Giles (1974), it can be seen that the isothermal adsorption curve of the sediment and soil to Ni is “S” type. For this “S” type isothermal adsorption line, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1323913251

data can be analyzed and fitted with Freundlich and D-R models to explain the adsorption mechanism of Ni in sediment and soil, and the fitting parameters are shown in *Table 2*.

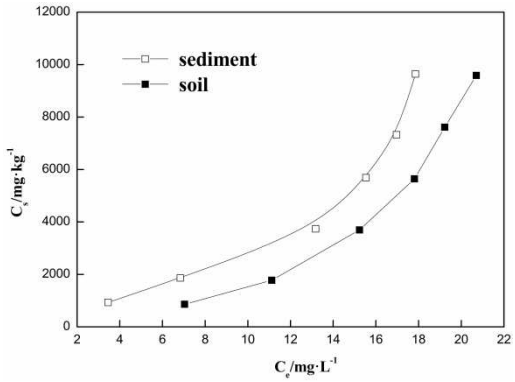

Figure 2. *Adsorption isotherm of Ni in sediment and soil*

Table 2. *The isothermal adsorption fitting parameters of Ni in sediment and soil*

Sample type	Freundlich equation			D-R equation		
	K_f	1/n	r	q_m	k	r
Sediment	3.1906	2.761	0.9891**	31898.2507	68.8476	0.9859**
Soil	1.2562	2.938	0.9963**	26562.0806	78.3844	0.9866**

n = 6, $r_{0.05}$ = 0.811, $r_{0.01}$ = 0.917. **indicate statistical significance at P < 0.01. The same below

It can be seen from *Table 2,* Freundlich equation and D-R equation were used to fit the adsorption isotherms of nickel on sediment and soil, and the correlation coefficients were above 0.98, the fitting results were all significantly correlated ($p < 0.01$). The Freundlich equation has the best fitting effect, the adsorption constant K_f represents the adsorption capacity of Ni on the sediment and the soil. The larger of the K_f, the stronger the adsorption capacity was. The adsorption coefficient K_f of Ni in the sediment was greater than that in the soil, indicating that the adsorption effect of the sediment on nickel was greater than that on the soil. When the concentration of nickel was lower than 500 mg·L^{-1}, the adsorption of Ni on sediments and soil did not reach the saturation state, which may be due to the modification effect of nickel on the bottom sediment and soil surface, forming a new adsorption field, thus promoting the adsorption of nickel in the bottom sediment and soil (Rinklebe et al., 2017). Since the D-R equation describes an ideal adsorption state in which the pores of an adsorbent are completely filled with solutes, the calculated equilibrium adsorption q_m is an ideal state.

The desorption of Ni in sediment and black soil

The desorption amount was often used as an index to indicate the adsorption strength, and can generally be used to illustrate the bonding degree of the colloidal surface active adsorption position with heavy metal ions (Tahervand et al., 2016, 2017). The desorption isotherm and desorption rate of Ni on bottom sediment and soil are shown in *Figure 3*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1323913251

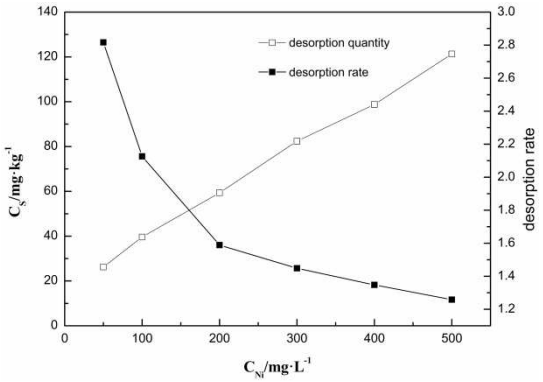

Figure 3. *The desorption amount and desorption rate of Ni in sediment*

As can be seen from *Figure 4*, the desorption of Ni by sediments and soil has a similar trend to that of adsorption, and the desorption of soil and sediment gradually increases with the increase of the initial Ni concentration. The final desorption of Ni by sediments and soil was 121.34 mg·kg^{-1} and 129.78 mg·kg^{-1}, respectively, accounting for 1.26% and 1.35% of the adsorption capacity, respectively.

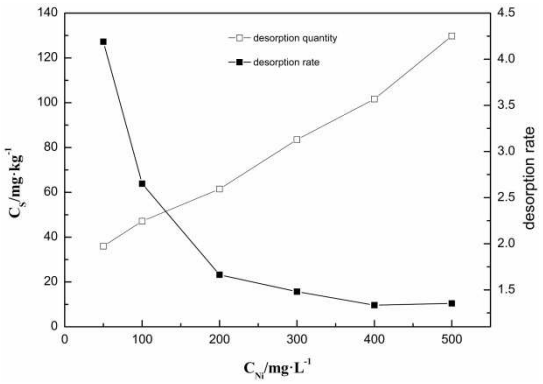

Figure 4. *The desorption amount and desorption rate of Ni in soil*

It can be seen that the adsorption capacity of sediments and soil to Ni was strong, while the desorption capacity was weak. The desorption amount of Ni in sediments was slightly less than that in soil. When the adsorption capacity was low, Ni occupies a high energy adsorption point, and the adsorption was mainly specific adsorption, so the desorption of Ni was difficult. When certain saturation was reached, specific adsorption points gradually decrease, and adsorption of heavy metals in stable sediments and soil was reduced, making it easier to desorption, so desorption also increased (Arancibia et al., 2015). The sediment contains more organic matter than the soil, so it has a stronger adsorption ability to nickel and a stronger fixation ability, leading to less desorption. Low Ni desorption may be the buffer of sediment and soil against heavy metal pollution (Davari et al., 2015). The desorption process can be regarded as the reverse process of soil adsorption process, and all factors affecting adsorption affect the desorption. The desorption data of Ni in sediment and soil are fitted with the Freundlich equation and the D-R equation, and the results are shown in *Table 3*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1323913251

Table 3. *Isothermal desorption fitting parameters of Ni in sediment and soil*

Sample type	Freundlich equation			D-R equation		
	K_f	n	r	q_m	k	r
Sediment	0.7218	0.5727	0.9706**	197.7315	82.1164	0.9338**
Soil	1.1054	0.6496	0.9724**	151.2162	61.7417	0.9052**

n = 6, $r_{0.05}$ = 0.811, $r_{0.01}$ = 0.917

As can be seen from *Table 3,* the correlation coefficient of desorption isotherm of nickel in sediment and soil of Freundlich equation was 0.9937~0.9937, $K_{f\ (sediment)} < K_{f\ (soil)}$. The adsorption capacity of sediment on Ni was strong, but its desorption capacity was weak. Ni adsorbed on sediments and soil is not easy to desorption. Kaur (2018) proposed to use hysteretic coefficient (HI) as a quantitative indicator of the irreversible adsorption degree of the compound in soil.

$$HI = (q^d - q^s)/q^s$$

In the formula, q_d and q_s respectively refer to the adsorption concentration of Ni in the soil during adsorption and desorption at a certain temperature mg·kg^{-1}. When 0.7 < HI < 1.0, the desorption rate was similar to the adsorption rate, and the adsorption isotherm coincides with the desorption isotherm. When HI < 0.7, the desorption rate was lower than the adsorption rate, and the desorption process was positive hysteresis. When HI > 1.0, the desorption process was negative hysteresis (Mosqueravivas et al., 2018). It can be seen from *Table 4* that as the Ni concentration of the background solution increases, the desorption hysteresis coefficient gradually decreases and was much smaller than 0.7, indicating that the desorption rate was much smaller than the adsorption rate. When the initial concentration was the same, $HI_{\ sediment} < HI_{\ soil}$, indicating that the Ni adsorbed on the sediment was more difficult to desorption than the soil.

Table 4. *Ni desorption hysteresis coefficient HI at different concentrations*

Initial concentration (mg/L)	50	100	200	300	400	500
Sediment	0.0290	0.0217	0.0161	0.0147	0.0131	0.0127
Soil	0.0437	0.0273	0.0169	0.015	0.0135	0.0137

Adsorption kinetics of Ni in sediment and black soil

The change of Ni adsorption amount with sediment and black soil with time is shown in *Figure 5*. As can be seen from *Figure 5*, the whole adsorption process can be divided into two stages, namely, rapid adsorption stage and slow equilibrium stage. The concentration of Ni in the solution decreased rapidly in 0-120 min, and the concentration of Ni in the solution was gradually balanced in the 120-1440 min solution. In the 0-120 min, the adsorption amount of Ni to the sediment and soil accounted for 99.57% and 99.84% of the total adsorption, respectively. At the adsorption equilibrium, the maximum adsorption capacity of sediment and soil to Ni was 1881.60 and 1804.58 mg·kg^{-1}. Because there are more adsorption sites on the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1323913251

surface of the sediment and soil, Ni can be quickly adsorbed. When more and more adsorption sites are occupied, the reaction rate decreases until the adsorption reaches equilibrium. Ni may form a complex when adsorbed in the sediment and soil, so that the heavy metals adsorbed on its appearance are transferred to the inside of the particles and precipitate on the sediment and soil surface, so that the adsorption of the sediment and soil to the Ni was getting smaller, and finally until it tended to balance (Peng et al., 2018). And the reduction agent in the sediment and soil dissolves from the solid phase to the water phase is a slow dissolution process (Huang et al., 2018).

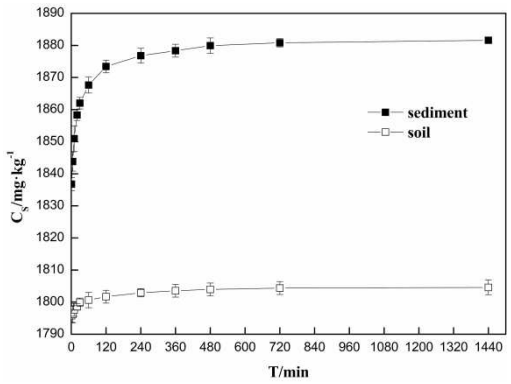

Figure 5. *The adsorption kinetic curve of Ni*

In this experiment, Elovich equation and parabolic diffusion equation were used to fit the adsorption kinetics of Ni in sediment and black soil. The relevant parameters of the fitting are shown in *Table 5*. It can be seen from *Table 5* that Elovich equation has a good fitting effect on the adsorption kinetics of Ni in sediments and black soil, indicating that the adsorption kinetics process is non-uniform diffusion process, and the reaction process is controlled by multiple mechanisms such as diffusion, dissolution and mineralization. The adsorption fitting coefficient r of Ni in lake bottom sediment and soil was 0.9827 and 0.9895, respectively. The greater the constant a value in the Elovich equation, the greater the adsorption rate, so the adsorption amount of the sediment is greater than the adsorption amount of the soil. The fitting of adsorption by parabolic diffusion equation is relatively poor, and the correlation coefficients r were 0.7905 and 0.8813, respectively. In the above model fitting, it can be inferred that the diffusion of particles is not the only mechanism controlling the adsorption process, which is also adsorbed by other adsorbents (Zhu et al., 2015).

Adsorption thermodynamics of Ni in sediment and black soil

The adsorption of Ni by sediment and black soil over time are shown in *Figures 6* and *7*. As can be seen from *Figures 6* and *7*, in the test temperature range, with the increase of temperature, the adsorption amount of sediment and soil to Ni increases gradually, and the adsorption does not reach saturation. The increase of temperature was beneficial to the adsorption of Ni by sediment and soil, and the reaction can be determined to be an endothermic reaction. Heavy metal Ni has good hydration in the test temperature range. When the metal Ni was adsorbed by sediment and soil, it lost its hydrating shell. The process of nickel losing hydrated shell requires some energy, and the process of removing water molecules is endothermic. The higher the temperature is,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1323913251

the more favorable it is for the Ni adsorbed on the bottom sediment and soil surface to diffuse into the particles. It is also a benefit for external complexity and internal complexity. It also facilitates the combination of thermodynamic unstable state to stable state transition. Therefore, the adsorption of nickel in sediments and soil increases with temperature.

DOI: http://dx.doi.org/10.15666/aeer/1706_1323913251

that the higher the temperature, the stronger the adsorption capacity of sediment and soil nickel. The adsorption reaction can be determined as endothermic reaction.

Table 6. *The isotherm adsorption parameters of Ni at different temperatures*

Sample type	Temperature (°C)	Freundlich equation			D-R equation		
		K_f	n	r	q_m	k	r
Sediment	15	1.9583	0.3554	0.9923**	24814.9828	70.5966	0.9786**

n = 6, $r_{0.05}$ = 0.811, $r_{0.01}$ = 0.917

According to the K_f in the Freundlich equation at different temperatures, the enthalpy change and entropy change are calculated by lnK_f and 1/T, $\Delta G = \Delta H - T\Delta S$. It can be seen from *Table 7* that the ΔG at different temperatures were less than zero, as the rise of environmental temperature, ΔG gradually reduced. It was indicated that the adsorption process of Ni on sediment and soil is spontaneous, and the high temperature is favorable for the spontaneity of adsorption, which is consistent with the fitting results of Langmuir equation and Freundlich equation (Wu et al., 2013; Turp, 2018). It can be seen from the table that $\Delta H > 0$ of Ni in the sediment and soil is indicated as an endothermic reaction. ΔG and ΔH indicated that sediment and soil buffer capacity of Ni, and may have a seasonal migration and activity (Guo et al., 2012).

Effect of organic matter content on adsorption characteristics of Ni

The Ni adsorption by sediment and soil before and after the removal of organic matter are shown in *Figures 8* and *9*. As can be seen from the figure, when organic matter was removed from sediments and soil, and the Ni concentration in the solution was 500 mg·L^{-1}, the adsorption capacity of sediments and soil on Ni decreased by 2.17% and 1.7%, respectively. The above phenomenon indicates that the presence of organic matter can increase the adsorption of Ni by sediment and soil. In the experiment, according to the formula of: contribution rate = ($Q_{original}$-$Q_{removal}$) / $Q_{removal}$. According to this formula, the contribution rate of organic matter in sediment and soil to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1323913251

Ni was 2.06% and 1.73% respectively. The higher the content of organic matter is, the greater the contribution rate of organic matter to Ni was, and the adsorption point of sediment to Ni after removing organic matter is greater than that of soil.

There was a significant correlation between the adsorption amount and the content of organic matter. The reason may be that the organic matter entered the sediments and soil to form humus after microbial action. Humus contains carboxyl, phenol hydroxyl and alcohol hydroxyl. These groups can easily complex or chelate with heavy metal elements to form stable compounds, thus improving their adsorption capacity. In addition, polar groups in sediment and soil organic matter, such as hydroxyl group and carboxyl group, can make sediment and soil surface have a large amount of negative charge, thus enhancing the electrostatic adsorption of nickel (Refaey et al., 2014; Yin et al., 2016).

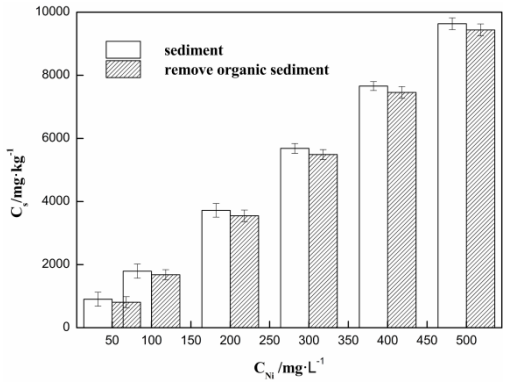

Figure 8. *Adsorption isotherm of Ni under removal of sediment organic before and after*

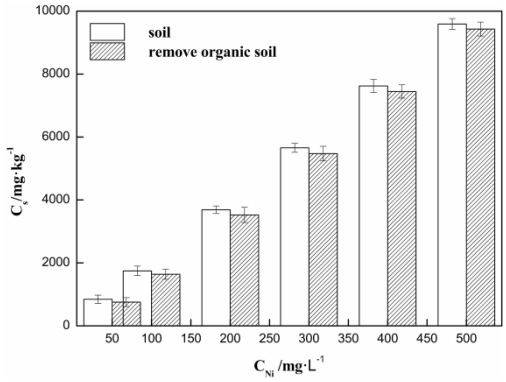

Figure 9. *Adsorption isotherm of Ni under removal of soil organic before and after*

Conclusion

The adsorption characteristics of Ni on the sediment of the lake and the black soil on the shore show that the adsorption of Ni on the sediment was larger than that in the soil, and the adsorption process can be fitted with the Freundlich model and the D-R model. The Freundlich model can better fit the adsorption of Ni by sediment and soil. The correlation coefficient r were 0.9891 and 0.9963, the final desorption amount of sediment and soil to Ni are 121.34 and 129.78 mg·kg^{-1}, which accounts for 1.26% and 1.35% of adsorption, respectively. The initial concentration was the same,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1323913251

$HI_{sediment} < HI_{soil}$, indicated that the sediment had a stronger retention capacity to Ni than the soil. The adsorption kinetics of nickel in sediments and black soil can be well fitted by Elovich equation. In the experimental temperature range, the adsorption amount of Ni on the sediment and soil gradually increased with the increase of temperature, and the ΔG value of adsorption thermodynamic parameters is less than 0, which indicates that Ni adsorption process on sediment and shore soil is spontaneous. After removing organic matter, the adsorption capacity of bottom sediment and soil on Ni was weakened, and the adsorption capacity was reduced by 2.02% and 1.70%, respectively, indicating that organic matter could enhance the retention capacity of Ni. These factors may limit or enhance the transport or absorption of metal Ni in soil. This work provides a theoretical framework for the prediction of metal adsorption characteristics and provides a potential help for the prediction of bioavailability, fate and transport of heavy metals in newly contaminated areas. Meanwhile, the interaction between Ni and other heavy metals is expected to be considered in future studies.

Abstract. Selecting drought-tolerant alfalfa cultivars is conducive to improve the forage yield in arid and semi-arid areas. In this study, drought resistance of five alfalfa (*Medicago sativa* L.) cultivars at the seedling stage was analyzed by using agronomic and physiological indicators. After withholding water for 6 days and then re-watering for 4 days, shoot dry weights of "Longdong" and "Daye" were significantly higher than that of the other cultivars. Under drought stress, "Daye" had healthier plasma membrane with the minimum leaf membrane permeability, while the leaf osmotic potential of "Longdong" and "Gannong No. 3" were significantly lower than that of the other three cultivars. Moreover, "Longdong" showed the highest leaf relative water content. According to the combination of above indicators, the relative drought resistance of the five cultivars decreased in order: "Longdong", "Daye", "Gannong No. 3", "Sandili", and "Rambler". This study suggested that "Longdong" and "Daye" might be more suitable for planting in arid and semi-arid regions.
Keywords: *forages, arid environment, physiological mechanism, agronomic indicators*

Introduction

Drought is one of the most adverse environmental factors causing the reduction of agricultural productivity worldwide (Hassine et al., 2010; Ghaderi et al., 2011). In order to face this challenge, we need to identify suitable crops adapting to drought. Alfalfa (*Medicago sativa* L.) is the most important legume forage, which is rich in vitamins, minerals and phytonutrients (Xiao et al., 2015; Kumar et al., 2018). Establishing alfalfa pastures has played a more and more important role in ecological environment and livestock production of China (Shi et al., 2017). Alfalfa planting areas in China were significantly extended by 74% from 2001 to 2013, and about 70% of them are distributed in northern China, an arid or semi-arid region with water resource shortage (Lu, 2013). Planting alfalfa cultivars with strong drought resistance is one of the fundamental ways for promoting forage productivity and saving the limited water resources in northern China. However, there is a considerable variation of drought tolerance among existing alfalfa cultivars (Guo et al., 2004). Alfalfa is very sensitive to drought during the seedling stage (Kumar, 2011). Therefore, to evaluate the drought tolerance in the seedling stage is necessary for selecting drought-tolerant alfalfa cultivars.

Drought stress can directly disrupt the water balance, decrease the leaf turgor potential, and damage the cell membrane (Ma et al., 2012). On a physiological level, the most important strategy for plants survival in arid environment is osmotic adjustment,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1325313261

by which plants can retain the water and maintain the stability of cell membrane (Quan et al., 2016). Therefore, the physiological indicators such as osmotic potential (Ψs), leaf relative water content (RWC) and relative membrane permeability (RMP), were frequently used to evaluate drought resistance of plants (Foster et al., 2012; Cui et al., 2019). However, it is difficult to determine by single physiological indicator and the result tends to unilateralism, since the mechanism of drought resistance in plants is extremely complex (Cattivelli et al., 2008; Wu et al., 2014). On the other hand, the agronomic indicators (such as yield, survival rate, plant height and biomass) are the phenotypes that integrate the various physiological mechanisms in response to stress, but are readily affected by other factors instead of the concerned factor (Noble and Rogers, 1992; Singh et al., 2019). The objective of this study was thus to assess and compare the drought resistance among five alfalfa cultivars at the seedling stage by combining one agronomic indicator (shoot dry weight) and three physiological indicators (leaf RMP, Leaf Ψs and leaf RWC).

Materials and methods

Plant materials, growth conditions and treatments

Seeds of five alfalfa cultivars, "Longdong", "Gannong No.3", "Daye", "Rambler" and "Sandili" collected from the Chinese commercial market were surface sterilized and germinated as described by Bao et al. (2009). The seedlings were transplanted in plastic pots filled with artificial soil with a mixture of perlite, vermiculite and peat moss (v/v, 1:1:1). Each cultivar was transplanted in 60 pots. All the seedlings were grown in the greenhouse in Lanzhou University (36.03°N, 103.40°E; elevation 1520 m) under a 16-h photoperiod (the light flux density was approximately 600 μmol/m^2/s) at 24 ± 2°C and 60 ± 5% of relative humidity, watered with 1/8 Hoagland nutrient solution every 2 days, and seedlings in each pot were thinned to 3 plants after 5 days. The pots were continuously watered with 1/8 Hoagland nutrient solution to maximum field water-holding capacity for 15 days, then nutrient solution was withheld for 6 days and re-watered for 4 days. The seedlings in the control group were watered with 1/8 Hoagland nutrient solution normally. Each treatment was repeated three times, and each repetition contained 10 pots (3 plants/pot). Physiological indicators including leaf relative membrane permeability (RMP), leaf osmotic potential (Ψs) and leaf relative water content (RWC) were measured after water withholding, and shoot dry weight was determined after re-watered.

Measurement of shoot dry weight

After being re-watered for 4 days, the shoots were cut from stem base of seedlings and rinsed with distilled water, then were dried in an oven at 80°C for 48 h and the dry weights of shoots were weighed.

Measurement of leaf RMP, Ψs and RWC

After water withholding for 6 days, the leaves were excised from seedlings. Leaf RMP was determined according to the method reported by Bao et al. (2009) using a conductivity meter (EC215, HANNA, Italy). Leaf Ψs was measured according to the method as described by Wu et al. (2014) using a cryoscopic osmometer (Osmomat-030,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1325313261

Gonotec GmbH, Germany). Leaf RWC was calculated through the method mentioned by Ma et al. (2012).

Assessment of drought resistance in five alfalfa cultivars

According to the method as described by Bao et al. (2009), the data of shoot dry weight, leaf RMP, leaf *Ψs* and leaf RWC were converted into relative values (the ratio of value from drought stress to value from control), respectively. Then the relative value of each indicator from each cultivar was standardized by the subordinate function method (Wu et al., 2014). Finally, the relative drought resistance of each cultivars was scored according to standardized values of each indicator by the following formula: [*I* (1) + *I* (2) + *I* (3) + *I* (4)]/4. Where *I* (1-4) refer to the standardized value of shoot dry weight, leaf RMP, leaf *Ψs* and leaf RWC, respectively.

Statistical analysis

All data in this study were analyzed by one-way analysis of variance (ANOVA) using SPSS 13.0 (SPSS inc. USA) and Duncan's Multiple Range test was used to detect significant differences among the means ($P < 0.05$).

Results

Shoot dry weight

After withholding water for 6 days and then re-watering for 4 days, shoot biomass of each cultivar was significantly reduced. The shoot dry weight of "Rambler" showed the largest decline by 35.8% and was significantly lower than that of the other cultivars. Shoot dry weights of "Longdong" and "Xinjiang Daye" only decreased by 9.8% and 12.9%, respectively, and were significantly higher than other three cultivars (*Fig. 1*).

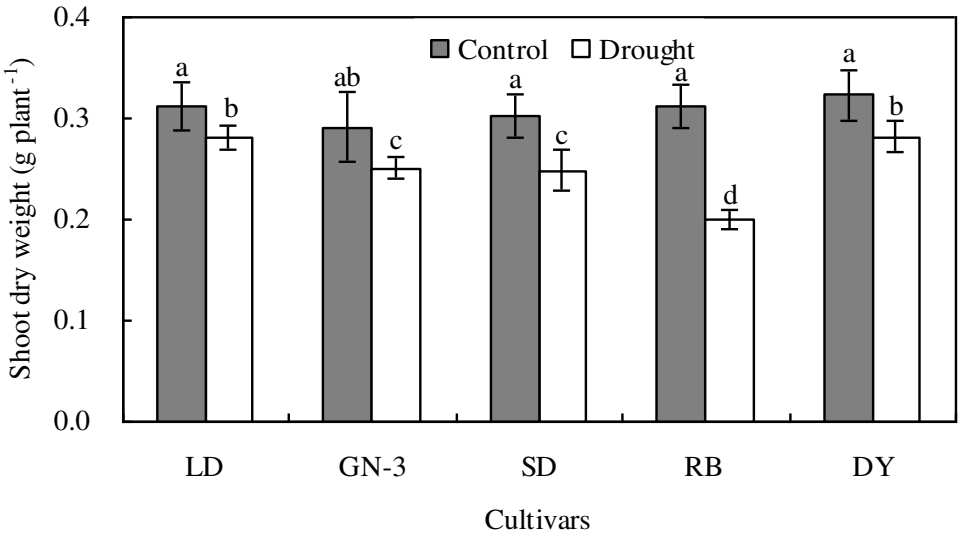

Figure 1. *Shoot dry weights of alfalfa seedlings under control and drought conditions for 6 days, and then re-watering for 4 days. Values are means ± SD (n = 6) and bars indicate SD. Different letters on columns indicate significant difference at P < 0.05 (Duncan's test). LD: "Longdong"; GN-3: "Gannong No. 3"; SD: "Sandili"; RB: "Rambler"; DY: "Xinjiang Daye"*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1325313261

Leaf relative membrane permeability (RMP)

After being treated with drought for 6 days, leaf RMP of all cultivars increased sharply. However, the leaf RMP of "Longdong" and "Gannong No. 3" were significantly higher than those of the other cultivars, while "Xinjiang Daye" showed the lowest leaf RMP value, under drought stress (*Fig. 2*).

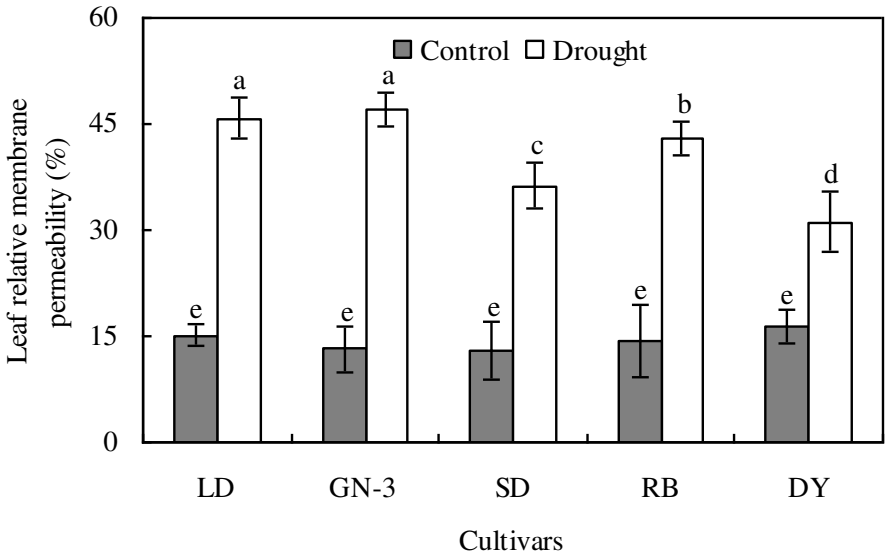

Figure 2. *Leaf relative membrane permeabilities of alfalfa seedlings under control and drought conditions for 6 days. Values are means ± SD (n = 6) and bars indicate SD. Different letters on columns indicate significant difference at P < 0.05 (Duncan's test). LD: "Longdong"; GN-3: "Gannong No. 3"; SD: "Sandili"; RB: "Rambler"; DY: "Xinjiang Daye"*

Leaf osmotic potential (Ψs)

It is observed that leaf *Ψs* of "Longdong" and "Xinjiang Daye" were significantly lower than that of the other three cultivars under the control condition. Under drought stress, leaf *Ψs* of each cultivar significantly decreased, but there were significantly differences among five cultivars, in which "Longdong" and "Gannong No. 3" had the lowest leaf *Ψs* compared to other three cultivars (*Fig. 3*).

Leaf relative water content (RWC)

Under well-watering condition, there was no significant difference in leaf RWC between the five alfalfa cultivars. After withholding water for 6 days, leaf RWC of each cultivar was significantly reduced. Moreover, there were significant differences among five cultivars, of which "Rambler" showed the lowest RWC (decreased by 53.0%), while "Longdong" exhibited the highest RWC (decreased by 35.8%), under drought stress, suggesting that "Longdong" showed stronger water retention ability than other cultivars (*Fig. 4*).

Comprehensive assessment on drought resistance among five cultivars

The relative values of shoot dry weight, leaf RMP, leaf *Ψs* and leaf RWC, were used to evaluate and compare the relative drought resistance of five alfalfa cultivars. From

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1325313261

the comprehensive assessment, the relative drought resistance of the five cultivars decreased in order: "Longdong", "Xinjiang Daye", "Gannong No. 3", "Sandili" and "Rambler". The result of comprehensive evaluation indicated that "Longdong" and "Xinjiang Daye" had relatively higher drought resistance among five cultivars (*Table 1*).

Discussion

As a major abiotic factor, drought can reduce the growth of plants by directly leading to the decrease of shoot yield (Yamaguchi and Sharp, 2010). Therefore, shoot biomass is an important indicator for identifying the stress resistance of higher plants, not only for its ease of measurement, but also due to the fact that it is a direct reaction to the interaction of a variety of physiological mechanisms in plants and external environment (Noble and Rogers, 1992; Wu et al., 2014). Numerous studies have been performed on the effects of drought stress on the seedling growth of alfalfa by focusing on the relationship between water deficit and shoot biomass (Liu et al., 2005; Pang et al., 2011). In the present study, shoot dry weight of five alfalfa cultivars were significantly reduced by water deficit and showed significant difference between cultivars. The similar results were also observed in previous studies on drought response of alfalfa (Kang et al., 2011; Quan et al., 2016). Foliage yield is the primary determinant of plant productivity and economic performance and thus is a momentous criterion for pasture managers to screen cultivars with high-yielding (Liu et al., 2005). Our study demonstrated again that shoot biomass completely can be used as a reliable indicator for evaluating drought resistance in alfalfa cultivars. In addition, this study indicated that other important physiological indicators can also be used as a better basis for assessing the drought resistance of alfalfa cultivars.

Abiotic stresses (including drought) can cause the accumulation of high concentrations of reactive oxygen species (ROS) in plants, which can result in the cell membrane lipid peroxidation, membrane permeability increase and finally inhibit the growth of plants (Wang et al., 2009; Zhang et al., 2018). The ability to maintain stability of membrane structure is closely related to stress resistance of plants, and relative membrane permeability (RMP) is an important indicator reflecting cell membrane stability (Guimarães et al., 2011; Quan et al., 2016). In this study, leaf RMP of five alfalfa cultivars were significantly increased under drought stress, but the increment differed widely among different cultivars. “Xinjiang Daye” showed a significantly lower leaf RMP in comparison to other four cultivars under drought stress, suggesting that it has the relatively higher ability to maintain the stability of membrane structure than other cultivars. This might be resulted from increased antioxidants contents as well as higher antioxidant enzymes activities in drought-tolerant cultivars under drought stress (Kang et al., 2011; Quan et al., 2016).

One of the strategies for plants adapting to arid environment is the accumulation of osmotic adjustment substances, which reduces osmotic potential and thus slows down the water loss of plants (Ma et al., 2012; He et al., 2019). Therefore, the osmotic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1325313261

potential (Ψs) is an important physiological indicator for measuring the drought tolerance of plants. In this study, "Longdong" and "Gannong No. 3" showed lowest leaf Ψs under water deficit condition. Interestingly, it was found that leaf Ψs of "Longdong" and "Xinjiang Daye" were significantly lower than that of the other three cultivars under the normal condition, indicating that their adaptability to drought may be stronger than the other cultivars, since the lower initial leaf Ψs means the stronger water retention capacity (Mohamed and Tawfik, 2006; Ma et al., 2012). The data of leaf relative water content (RWC) in this study support this point. Under drought stress, "Longdong" had the highest leaf RWC, followed by "Xinjiang Daye", suggesting that these two cultivars have better water status, which may be due to their lower initial osmotic potential. Previous studies have demonstrated that drought-tolerant alfalfa cultivars showed less water loss and higher water use efficiency in drought conditions (Kang et al., 2011; Quan et al., 2016).

Drought resistance of higher plants is a combination of morphological variations, physiological changes, biochemical metabolisms and gene expression regulation, and there are diverse mechanisms and environmental variables involved in drought responses of plants (Wang et al., 2009), thus it actually hard to be accurately clarified by single indicator (Wu et al., 2014; Yan et al., 2015). In the present study, this point was confirmed again. Generally, there are various results presented by different indicators. Therefore, we developed a comprehensive assessment approach through combining one agronomic indicator and three physiological indicators, which are closely related to drought resistance, and especially, can be easily measured at seedling stage of plants. The results of this assessment clearly showed that the performance of "Longdong" and "Xinjiang Daye" were better than the other three alfalfa cultivars under drought stress, suggesting that these two cultivars may be more suitable for planting in arid and semi-arid regions of northern China.

Conclusion

In this study, we developed a comprehensive assessment procedure for drought resistance of alfalfa seedlings through combining one agronomic indicator and three physiological indicators. The results indicated that there existed great differences in drought resistance among five commercial alfalfa cultivars, in which "Longdong" and "Xinjiang Daye" were more suitable for planting in arid and semi-arid regions of northwestern China, and could be generalized as excellent cultivars with strong resistance. The next step will be to determine the overall adaptability by comprehensively assessing the drought resistance of the different alfalfa cultivars at different growth stages under field conditions, including yield and quality evaluations.

Abstract. The aim of this study was to determine the effects of different mixture rates and harvest periods on the herbage quality of triticale (*xTriticosecale* Wittmack) and forage pea (*Pisum sativum* L.) intercrops. The research was carried out in Diyarbakir province of Turkey during the winter vegetation period of 2016-2017. The research was carried out in randomized block design in split parcels in which the harvest periods and mixture ratios formed the main parcels and sub-parcels, respectively. In the study, all harvests were conducted at spike and milking period of triticale. The mixing ratios were 100% forage peas (FP), 100% triticale (T), 75% FP + 25% T, 50% FP + 50% T, 25% FP + 75% T. As the harvest periods delayed, crude ash, crude protein, digestible dry matter, dry matter consumption and relative feed value decreased where Acid Detergent Fiber (ADF) and Neutral Detergent Fiber (NDF) rates increased. As the proportion of forage pea in the mixture increased, the ratio of crude protein and ADF increased, while the rate of digestible dry matter decreased. The spiking period of triticale was found to be the suitable harvest period. Sowing mixture at 25% FP + 75% T was superior obtaining good ADF, digestible dry matter and relative feed value. In the case of favorable NDF and crude protein ratios, 75% FP + 25% T proved to be superior to other mixture combinations.
Keywords: *cereal, legume, mixed cropping, feed quality*

Introduction

Intercropping is co-cultivation of two or more plant species in same period in same field. Triticale (× *Triticosecale* Wittmack), as a cereal, is more tolerant to biotic and abiotic stress conditions than wheat. Therefore, it is more suitable for marginal areas (Villegas et al., 2010). Triticale has high adaptability, better nutrient content and higher yield compared to other cereals (Oettler, 2005).

Forage pea is an important and nutritious fodder plant. It is reported that harvesting and weed control is a problem due to the significant lodging when this species is grown sole (Kadziuliene et al., 2011). Intercropping has many advantages. The presence of at least one legume species in the intercrop results with higher quality herbage production. Protein content and feed value increase with this method. In addition, wheat improves resistance to soil erosion where legumes reduce or prevent frost damage. The danger of swelling in animals due to some legumes may be reduced by feeding with these mixtures. Existence of cereals in mixtures also prevents lodging and decay of some legume fodder crops. In mixtures, the herbage gets dry better and more successful results are obtained in case of silage making. In case of existence of legumes in the intercrop; organic matter and nitrogen in the soil also increase. Generally in plants, as the development progressed, the weight increases, but the feed value decreases, which is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1326313271

more rapid since cartilage is more rapid in wheat. Therefore, harvest times should be determined based on the development periods of cereals in intercrops (Asik, 2006).

In a study in Spain, Pereira-Crespo et al. (2010), used forage peas and triticale in mixtures where they reported that ADF and NDF content of triticale alone was higher compared to the mixture and sole forage pea. Lithourgidis et al. (2006) reported that they obtained highest crude protein yield from common vetch-triticale mixture containing 65% common vetch and 35% triticale. Karadag and Büyükburç (2004) reported that, with the Hungarian vetch and triticale mixtures, the ratio of crude protein increased when triticale ratio decreased in the mixture.

The ratio of the species in the mixture is very important in terms of yield and quality. In legume and cereal mixtures, with the increase in the ratio of leguminous, dry grass yield generally decreases but in order to obtain the desired quality feeds, the ratio of cereals should not be more than 20% (Yucel and Avci, 2009). In a study conducted in Mediterranean conditions of Turkey, it is reported that with triticale-berseem clover mixtures, 60% berseem clover + 40% triticale rate, and 100% flowering period of berseem clover was best for high yield and good silage quality values (Yucel et al., 2018a). In another study carried out in Mediterranean conditions of Turkey, it is reported that 60% berseem clovers with 40% Italian ryegrass harvested at 100% flowering period of the berseem clover were suitable for high yield and good silage quality values (Yucel et al., 2018b).

The aim of this study was to investigate the effects of mixture ratio and harvest periods on forage quality of triticale and forage pea mixtures cropped in winter season in Diyarbakır condition which is a very important zone for feed and animal production in Turkey.

Materials and methods

Forage pea (*Pisum sativum* L. cv. Gap Pink) and triticale (× *Triticosecale* Wittmack cv. Karma 2000) were used as material in the research. The research was carried out in 2016-2017 winter (November-May) conditions in research fields of "GAP International Agricultural Research and Training Center" in Diyarbakir province of Turkey. Some climate data for the research period from the trial area are presented in *Table 1*.

Table 1. *Some climate data of Diyarbakir province of Turkey*

Month	Average temperature (°C)		Precipitation (mm)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1326313271

Climatic data of trial year shows low deviation compared to long-term averages. The study was carried out with 3 replications based on divided parcels in randomized complete blocks design. Harvest times were at main parcels and mixture ratios were at sub-parcels. Harvest times were at two different times; spiking and milking period of triticale in the mixtures. Mixture ratios were 100% forage pea (FP), 100% triticale (T), 75% FP + 25%T, 50%FP + 50%T, and 25%FP + 75%T.

Each parcel was 6 m long containing 10 rows at 20 cm row spacings where both species were mixed before planting. 100 kg/ha forage pea and 220 kg/ha triticale seed applied at planting. Before planting, diammonium phosphate fertilizer (18.46.0) was applied to the parcels in order to provide 40 kg/ha pure nitrogen and 100 kg/ha pure phosphorus (Kir, 2014). Parcel border rows and 0.5 m of row end tails of parcels were eliminated before harvest and 8 m^2 areas of each parcel were harvested. 500 g of harvested green herbage materials were used for the determination of both species in each parcel. These samples were separated into two species (triticale and forage pea) to calculate the ratios of both species in each parcel. Green herbage samples were dried in a drying cabinet for 48 h at 70 °C before determining dry herbage ratios. Then botanical composition rates of dry herbage were determined and each sample was milled for quality analysis. Crude ash, crude protein, ADF and NDF analysis were performed on these milled herbage samples of forage peas and triticale separately and parcel values were calculated according to their ratio in botanical composition in accordance with Yucel et al. (2015). According to this method, during the harvests, 500 grams of green herbage samples taken from the mixture parcels were divided into pea and triticale species and green herbage weights were determined. Then, the proportional weights of the forage pea and triticale plants were calculated and assigned as botanical composition rate. Weende method for raw ash (AOAC, 1990), Kjeldahl method for raw protein (AOAC, 1990) and ANKOM method for ADF and NDF (Van Soest, 1967) were applied for quality analysis. Digestible dry matter (DDM), dry matter consumption (DMC) and relative feed value (RFV) of dry herbage were calculated by using *Equations 1–3* in accordance with Morrison (2003).

$$DDM = 88.9 - (0.779 \times ADF\%) \quad \text{(Eq.1)}$$

$$DMC = \frac{120}{NDF\%} \quad \text{(Eq.2)}$$

$$RFV = \frac{DDM \times DMC}{1.29} \quad \text{(Eq.3)}$$

Variance analysis of the data obtained from the study was conducted by using JUMP statistical package program and the significant averages were grouped into LSD, 5% (Kalayci, 2005).

Results and discussion

Harvest period, mixture rate and harvest period x mixture rate interaction were found statistically significant for crude ash (CA) and crude protein (CP) ratios (*Table 2*). The CA ratio, which was 8.70% at the spike period, decreased to 7.34% at the milking

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1326313271

period, meaning that the effect of the harvest period was significant on CA ratio. The average lowest CA ratio (7.67%) was obtained from the 75%FP + 25% T mixture and no statistically significant difference was observed between other mixtures. When the CA ratio is examined for the harvest period x mixture interaction; the highest CA ratio was found to be obtained from spiking period at 100% T, 25% FP + 75% T and 50% FP + 50% T mixtures. The lowest CA ratio was obtained from milking period at all applications except 100% FP (*Table 2*).

Table 2. *Rates of crude ash and crude protein examined in the dry herbage (%)*

Mixture rate (MR)		Crude ash ratio (%)			Crude protein ratio (%)		
		Harvest period (HP)			Harvest period (HP)		
		Spiking	Milking	Average	Spiking	Milking	Average
100% FP		8.35c[1]	8.03c	8.19A*	16.42a	15.66a	16.04A
100% T		8.93a	7.30d	8.12A	10.22c	5.50e	7.86E
25% FP + 75% T		8.87ab	7.15d	8.01A	10.27c	8.35d	9.31D
50% FP + 50% T		8.96a	7.28d	8.12A	12.90b	11.21c	12.06C

	MR	0.32*			0.44**		
	HP × MR	0.47**			1.15**		

*The means with the same capital letter in the same column are not statistically significant different from each other according to the LSD test at $P \leq 0.05$

+The means with the same capital letter in the same row are not statistically significant different from each other according to the LSD test at $P \leq 0.05$

[1]The means of different treatment-harvest stage combinations with the same lower case are not statistically significant different from each other according to the LSD test at $P \leq 0.05$

The effect of harvest period on the CP ratio was found significant. The CP ratio was decreased from 12.67% to 10.69% after the transition from the spike to the milking period. Kim et al. (1990) reported that the CP ratio decreased rapidly due to the reduction in photosynthetic leaf area during the post-spike period. Other investigators also reported decreases in CP ratio following delays in harvest period. For example, Asik (2006) reported a CP ratio decrease from 13.36% to 5.77% at barley-pea mixtures when barley harvest period was delayed from stem elongation stage to yellow dough stage. Kir et al. (2018) also reported CP ratio decrease from 16.3% to 14.0% at Hungarian vetch-cereal mixtures when cereal was progressed transition from booting stage to milk dough stage.

Table 2 shows that the effect of average CP on mixtures is significant. The highest and lowest CP ratio was obtained from sole forage pea with 16.04% and sole triticale with 7.86%, respectively. CP ratio of all mixtures was higher than sole triticale. The high CP ratio of sole pea sources probably from the high ratio of both pods number and leaves/stalk rate. Many investigators was reported an increase in the CP ratio in case of existence of higher proportion of legumes in the mixtures (Kavut et al., 2014; Yildirim and Ozaslan-Parlak, 2016; Kir et al., 2018).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1326313271

When *Table 2* is examined; the effect of HP x MR interaction on CP probably was found to be significant. The highest CP ratio was obtained from sole forage pea at milk period while the lowest CP ratio was obtained from sole triticale at milking stage.

The effect of harvest period on ADF and NDF ratios was found significant. There was a statistically significant increase in ADF ratio as the harvest period was delayed (*Table 2*). The mean ADF ratio was increased from 31.29% to 36.20% and the rate of NDF from 44.15% to 48.91% after transition from spiking period to milking period. Many investigators also reported an increase in ADF and NDF ratio with delayed harvest time. For example, Aksoy and Nursoy (2010) reported that, in Hungarian vetch-wheat mixture, the ratio of ADF and NDF ratio varied between 25.94-38.24% and 36.47-57.61%, respectively. Guzelogullari (2012) reported that, in different vetch species at different harvest time, the ADF and NDF ratio was varied between 25.53-34.58% and 33.21-38.68%, respectively. Turgut et al. (2006) observed that, at Hungarian vetch, common vetch and hairy vetch, delays in harvest time was increased NDF ratio. Kir et al. (2018) reported the ADF ratio in Hungarian vetch-cereal mixtures as between 29.5-32.1% and NDF ratio as between 49.7-52.3%. These results are supporting our findings.

When *Table 3* is examined, it can be noticed that averages ADF and NDF values of mixtures were statistically significant. The highest and the lowest ADF ratio was obtained from sole triticale with 37.89% and sole forage pea with 29.95%, respectively. The lowest NDF ratio was also obtained from sole forage pea. Yildirim and Ozaslan-Parlak (2016) found ratio of ADF as 29.59%, NDF as 55.53% for triticale, and ADF as 23.10% and NDF as 46.34% for forage pea. Gocmen and Ozaslan-Parlak (2017), reported the ADF ratio of triticale as 45.16% and NDF ratio as 63.22% and forage pea ADF ratio as 41.23% and NDF ratio as 50.31%. These results are in accordance with our results.

When *Table 4* is examined, it is noticed that the effect of harvest period on the DDM rate is significant. Significant reductions was realised in the ratio of DDM as the harvest period was delayed. The rate of DDM was 64.52% and 60.70% at the spike period and milking period, respectively. Prolonged vegetation period probably resulted with structural changes in plant tissues with increased ADF ratios and finally these changes decreased DDM rate. One of the most important factors affecting the quality of feed is harvest time. Because the differences in the ADF value due to developmental periods significantly affect the digestibility of the feed (Caddel and Allen, 1997; Cinar, 2012).

The effect of mixtures on DDM ratios was found significant. The highest and lowest DDM ratios were obtained from sole forage pea and sole triticale, respectively (*Table 4*).

In studies conducted by different researchers, the ratio of DDM was between 59.1-68.7% at Hungarian vetch-wheat mixture (Aksoy and Nursoy, 2010), 65.5% at barley, 65.8% at triticale (Canpolat, 2012), 60.7-64.4% at Hungarian vetch-barley (Yilmaz et al. (2014) and average 63.9% at different Hungarian vetch-cereal mixtures (Kir et al., 2018). Our findings were similar to these results.

When the effect of harvest periods on DMC ratio was examined (*Table 4*), statistically significant differences were observed. The rate of DMC was 2.73% at spiking period, and 2.46% at the milking period. DMC rate was significantly decreased when harvest period was delayed. The effect of mixtures on DMC ratios was also found significant (*Table 4*). The highest DMC ratio was obtained from sole forage pea (2.77%), where the lowest was obtained from sole triticale and 50% YB + 50% T mixture.

DOI: http://dx.doi.org/10.15666/aeer/1706_1326313271

The effect of harvest periods on RFV was found significant. A statistically significant decrease was observed in the RFV as the harvest period was delayed (*Table 5*). RFV was 136.69 and 115.64 at the spiking period and milking period, respectively. It was determined that the effect of the different mixtures on the RFV was significant, where the highest and lowest RFV was obtained from sole forage pea and sole triticale, respectively.

When quality classification of Rohweder et al. (1978) was considered as reference, which is based on the 100% flowering period of clover, where RFV > 151 = premium quality, 151-125 = 1st quality (very good), 124-103 = 2nd quality (good), 102-87 = 3rd quality (medium), 86-75 = 4th quality (bad), < 75 = 5th quality (unacceptable), quality scores ranged between 1st and 2nd quality at different harvest periods and mixture combinations in our study.

In different studies, relative feed value in different harvest periods was between 98-114 for pure triticale (Yucel et al., 2018a), 106-108 for wheat-Hungarian vetch mixture (Aksoy and Nursoy, 2010), 96.2-118.8 for Hungarian vetch-barley (Yilmaz et al., 2014) and 109 for Hungarian vetch-lolium mixture (Kusvuran et al., 2014). Our findings were similar to these results.

Conclusions

Main aim of inclusion of forage pea in triticale is to increase its protein content. Shifting forage pea rate in the mixture from 25% to 50% increases the CP approximately 33% whereas shifting forage pea rate from 50% to 75% increases CP approximately 8%. But in the same time, RFV is 6 points and DMC is 0.2% higher when shifted forage pea rate from 50% to 75%. Milking period of triticale was found the most appropriate harvest period. So, when these important quality parameters

DOI: http://dx.doi.org/10.15666/aeer/1706_1326313271

considered together, it is found appropriate to propose 75% FP + 25%T mixture under arid climate conditions similar to East Anatolia according to this study. Testing morphologically different forage pea and triticale cultivars may produce different information related to the subject which is proposed to future researchers.

Abstract. The *RHA2b* gene from radish encodes a transcription factor that is involved in abscisic acid (ABA) signal transduction and is associated with seed dormancy and preharvest sprouting. *RsRHA2b* gene may have the function to improve dormancy and tolerance to PHS in transgenic wheat. The *RsRHA2b* gene was cloned and transferred into Zhengmai 9023 via *Agrobacterium*-mediated stem apex transformation. The results of RT-PCR and southern blot indicated that the *RsRHA2b* gene was integrated into the genomes of the wheat transformants. Seed dormancy and PHS tolerance was significantly enhanced in transgenic plants that stably expressed *RsRHA2b*. In addition, in the presence of 0.5 μmol/L ABA and 5 μmol/L ABA, a significant reduction in weight was found between the transgenic wheat plants and the non-transgenic Zhengmai 9023 plants. Furthermore, the expression of genes involved in *RHA2b*-mediated ABA signal transduction, such as *ABI5, FUS3* and *MAL,* significantly increased at the second leaf stage in ABA-treated transgenic wheat plants. These results show that *RsRHA2b* improves dormancy and preharvest sprouting tolerance in transgenic wheat.
Keywords: *agrobacterium-mediated stem apex transformation, southern blot, abscisic acid, signal transduction, reverse transcription-polymerase chain reaction*

Introduction

Preharvest sprouting (PHS) in wheat (*Triticum aestivum* L.) is the germination of grains in the ears when long-range rainfall or damp conditions occur prior to harvest (Li et al., 2004). PHS is an important issue, which is is not conducive to the stability of wheat production worldwide (Xiao et al., 2002). Seed viability and the hydrolysis of starch and protein in the endosperm are always reduced after PHS (Mohan, 2008). Moreover, PHS creates a favorable environment for serious infections by saprophyte fungi and thus causes heavy losses to grain yield (Castor and Frederiken, 1977). Therefore, there is a need to breed for increased resistance to PHS. Molecular breeding may be an effective method to reduce PHS susceptibility. Wheat is an important cereal crop worldwide, and it is a staple food for many populations. Genetically modified (GM) crops can act as powerful complement to the crops produced by laborious and time consuming conventional breeding methods to meet the worldwide demand for quality foods and help fight malnutrition by enhanced yield, nutritional quality and increased resistance to various biotic and abiotic stresses (Kamthan et al., 2016). PHS and dormancy in wheat have been focuses of numerous researches. *TaRHA2b* and *RsRHA2b* gene may play an important role in seed

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1327313288

dormancy during germination, which could be used to improve the PHS resistance of wheat. Because of homologous co-suppression in transgenic plants, exogenous genes are usually used for genetic manipulation.

To date, most researchers have agreed that PHS is the result of interactions between genotypes and the environment. Seed dormancy is an adaptive trait that inhibits seed germination and is positively correlated with resistance to PHS (Derera et al., 1977; Gerjets et al., 2010; Gubler et al., 2005; Chen et al., 2008b). The resistance of a seed to PHS is partially influenced by the external environment, but seed dormancy is the most critical determinant (Kucera et al., 2005; Holdsworth et al., 2008). As has been confirmed in many species, seed dormancy is influenced by the internal abscisic acid (ABA) content and the sensitivity to ABA (Groot and Karssen, 1992; Tan et al., 1997). ABA plays a critical role in plant development. Therefore, ABA, including its metabolism and signaling, has long been a focus of research (Grill and Himmelbach, 1998; Raghavendra et al., 2010; Zhu, 2002). ABA is important for plant growth and developmental processes, such as seed maturation, germination and seedling growth. ABA also regulates plant adaptation to various environmental challenges, including drought, salt, cold and other abiotic stresses (Nambara and Marion-Poll, 2003; Yamaguchi Shinozaki and Shinozaki, 2006; Lopez-Molina et al., 2001). During seed maturation, the ABA content in the seed increases significantly, resulting in strong dormancy. After the mature seed absorbs water, it quickly changes from a state of dormancy to a state of germination.

Many regulatory factors and response regulators in ABA signaling act in the signal transduction cascade during seed maturation and in young seedlings. These factors include ABA receptors, regulators and really interesting new gene (RING) finger transcription factors, which regulate the regulatory factors via ubiquitination and via the expression of ABA downstream response regulators (Koornneef et al., 1984). The genes related to ABA include ABI5, FUS3, MAL, and so on (Chiu et al., 2012; Huang et al., 2012; Li et al., 2011). The ubiquitin-proteasome pathway comprises two major components, the ubiquitination machinery, which attaches a ubiquitin or a poly-ubiquitin chain to a substrate, and the 26S proteasome, which degrades poly-ubiquitin-tagged protein substrates (Dreher and Callis, 2007; Moon et al., 2004; Schwechheimer and Schwager, 2004; Smalle and Vierstra, 2004). The ubiquitination of substrate proteins requires three types of enzymes, including E1 enzymes, which are ubiquitin-activating enzymes; E2 enzymes, which are ubiquitin-conjugating enzymes; and E3 enzymes, which are ubiquitin ligases. These three enzyme types act sequentially to catalyze the covalent attachment of the 76-amino-acid ubiquitin to the target protein. The E3 ligases recruit specific substrates and are the key determinants of the specificity of ubiquitination (Smalle and Vierstra, 2004).

RING finger proteins have motifs containing conserved cysteines and histidines. The RING motifs can be classified into three subgroups, including C3HC4 (RING-HC), C3H2C3 (RING-H2) and modified RING domain proteins. RING finger proteins always mediate protein-protein interactions and the formation of multi-protein complexes (Borden, 2000; Stone et al., 2005). At least 477 RING motif-containing proteins that play a critical role in plant developmental processes have been found in *Arabidopsis* (Vierstra, 2009). Some evidence has indicated that RING class E3 enzymes are critical for regulating ABA signaling and are associated with abiotic stress responses in plants (Ko et al., 2006; Zhang et al., 2005, 2007). RHA2a and RHA2b, which are RING finger E3 ligases, can positively regulate the ABA-mediated

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1327313288

inhibition of germination and act in the early seedling stage. RHA2a can activate positive regulators by mono-ubiquitinating and stabilizing certain key regulators of the ABA signaling pathway (Bu et al., 2009). ANAC019 and ANAC055, two closely related NAC family proteins, were identified as RHA2a-interacting proteins (Bu et al., 2008; Jiang et al., 2009). RHA2b acts additively with RHA2a in regulating ABA signaling. Seeds over-expressing *RHA2a* and *RHA2b* showed increased sensitivity to exogenous ABA, increased dormancy and a significant reduction in germination capacity. RHA2b targets MYB30 degradation to regulate ABA signal transduction (Zheng et al., 2018). Although some progress has been made in understanding the molecular and biological functions of *RHA2b* in *Arabidopsis*, the molecular mechanism of *RHA2b*-mediated ABA signaling is largely unknown. The *AtRHA2b* gene encodes an active E3 ubiquitin ligase that plays a positive regulatory role in ABA signaling and stress responses. The over-expression of *AtRHA2b* leads to ABA-associated phenotypes, such as ABA hyper-sensitivity in seed germination and seedling growth (Li et al., 2011).

In our previous studies, *TaRHA2b* and *RsRHA2b* genes were cloned from wheat and radish (*Raphanus sativus* L.), respectively. The results showed that the proteins encoded by *TaRHA2b* and *RsRHA2b* were consisted of Zinc finger RING-type profiles. Blast and phylogenetic analysis showed that the protein encoded by *TaRHA2b* and *RsRHA2b* shared the identity with *AtRHA2b* from the Arabidopsis. The expression of *TaRHA2b* and *RsRHA2b* genes was significantly tissue-specific. The sensitivity of the *TaRHA2b* and *RsRHA2b* genes to ABA was significantly increased (Li et al., 2019a). The differences in nucleotide polymorphism sites of *RsRHA2b* gene resulted in differences in the three cleavage sites of *BstD102I*, *Cfr10I*, and *HpaII/MspI* (Li et al., 2019b). These results facilitate the exploration of the correlation between the *TaRHA2b* gene and wheat's enhanced resistance to PHS and the development of molecular markers for resistance to PHS.

In the present study, the *RsRHA2b* gene from radish was cloned and then transferred into wheat using *Agrobacterium tumefaciens*. Seed dormancy and ABA sensitivity were significantly enhanced in transgenic wheat lines. These results displayed that *RsRHA2b* gene has the function to improve dormancy and tolerance to PHS in transgenic wheat.

Materials and methods

To clone the *RsRHA2b* gene, mRNA was isolated from the embryos of a local radish variety, "New generation 791". The elite Chinese bread wheat cultivar Zhengmai 9023, a hexaploid wheat cultivar with weak resistance to PHS, which is widely cultivated in Henan Province, was used for transformation.

Construction of a binary vector

The coding sequence and 3'-untranslated region (3'-UTR) of the *RsRHA2b* gene were amplified from radish cDNA via PCR with primers *RsRHA2b*-F2/*RsRHA2b*-R2 (*Table 1*). The PCR-amplified products were cloned into TA vectors (Takara, Dalian, China) and sequenced. A binary vector was constructed based on pCAMBIA3301. The TA vectors including the *RsRHA2b* gene and the pCAMBIA3301 vector were digested with *Bgl*II and *BstE*II. The two digested fragments were ligated together using T4 ligase. The resulting binary vector carried the *phosphinothricin* gene (*bar*) for selection.

Agrobacterium-mediated stem apex transformation of wheat

Wheat seeds were sterilized with 0.1% $HgCl_2$ for 10 min, then washed five times with sterilized distilled water. The sterilized seeds were germinated at 25 °C in the dark for 2–3 days on filter-containing plates. When the coleoptiles of the seeds reached a certain height (2–4 cm), the shoots were cut using a clean knife. Then, the stem apexes were exposed. Finally, 2–4 μL of resuspended *Agrobacterium* harboring the *RsRHA2b* gene and that had been induced with 100 μmol/L acetosyringone was dropped onto the stem apex for inoculation.

The inoculated seedlings were maintained on medium-containing plates until new leaves grew out, and then the seedlings were transferred into pots. Selection for resistance was performed by spraying the seedlings with a solution containing 160 mg/L basta when the seedlings had 3–4 leaves. The resistant plants were planted in the field.

Propagation of the transgenic lines

The seeds were harvested from the field in 2011. Then, they were grown in a digital biochemical incubator after rigorous screening. When the seedlings had 3–4 leaves, selection for resistance was performed by spraying the seedlings with a solution containing 160 mg/L basta. Genomic DNA and RNA were extracted from young wheat leaves. Then, PCR, reverse transcription-polymerase chain reaction (RT-PCR) and quantitative real-time polymerase chain reaction (qRT-PCR) analyses were conducted on the resistant plants. The seeds of *RsRHA2b* transgenic plants were harvested while the plants were in the digital biochemical incubator. Then, they were grown in the field. They were then grown and screened as in prior years.

DNA and RNA extraction

Genomic DNA was extracted from young wheat leaves. Total RNA was isolated from seeds and leaves using TRIzon reagent (CoWin Biotech Co., China) according to the manufacturer's instructions and treated with RNase-free DNase I (Tiangen, China) before final precipitation with ethanol.

PCR, RT-PCR analysis and southern blot

For the PCR analysis of transgenic plants, a 565 bp *RsRHA2b* product was amplified using PCR with the primers *RsRHA2b*-F1/*RsRHA2b*-R1 (*Table 1*), which were designed based on pCAMBIA3301-*RsRHA2b*. The primers were specific for radish.

For RT-PCR analyses of transgenic plants, approximately 5 μg of total RNA from the shoots of transgenic plants was reverse-transcribed into cDNA using reverse transcriptase (Tiangen, China) and oligo-dT_{18} primers. PCR amplifications were performed using the primers *RsRHA2b*-F2/*RsRHA2b*-R2.

Southern blot analysis was performed using standard procedures. Genomic DNA samples (30 μg) from PCR-positive transgenic wheat plants were digested with *Hind*III overnight at 37 °C. The DNA fragments were separated on 1.0% (w/v) agarose gels and transferred to Hybond N^+ nylon membranes. The PCR-amplified fragment to be used as a probe was further purified and labeled with digoxigenin (DIG)-dUTP using a DIG-High Prime Kit (Roche, Manheim, Germany). Hybridization was conducted at 68 °C. Hybridization and detection were performed using a DIG Nucleic Acid Detection Kit (Roche) according to the manufacturer's instructions.

qRT-PCR analysis of transgenic wheat plants

For qRT-PCR, the RNA from wheat leaves at 12 h, 24 h, 48 h after treatment with 0 μmol/L, 0.5 μmol/L, or 5 μmol/L ABA was used for reverse transcription (Toyobo, Osaka, Japan). qRT-PCR was performed in a volume of 20 μL containing SYBR Green I PCR Master Mix (Promega, Madison, USA) 10 pmol each of forward and reverse gene-specific primers (*Table 1*), and cDNA (0.2 μmol/L). Gene-specific primers were designed using Primer Premier 5 software. The wheat *ACTIN* gene was co-amplified as an internal control to normalize the total amount of cDNA present in each reaction and to eliminate the differences among the samples. PCR amplification was performed in an iQ5 Cycler (Bio-Rad) under the following conditions: 95 °C for 3 min, followed by 39 cycles of 94 °C for 10 s, 60 °C for 20 s, and 72 °C for 30 s. The plate was read at 72 °C for 30 s. To determine the specificity of each PCR primer pair, a melt curve was generated by incubating the reaction at 95 °C for 10 s, cooling to 65 °C for 10 s and increasing to 95 °C at a rate of 0.5 °C/10 s.

Seed germination test

Intact spikes were harvested at physiological maturity. Grains from the wheat spikes were hand-threshed. The dormant seeds were used for further analysis. Thirty sound grains of each plant were placed crease down on moist filter paper in Petri dishes at 20 °C in the dark for 7 d. The germinated grains were counted every day and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1327313288

calculated in terms of the germination index (GI). $GI = (7n1 + 6n2 + \ldots + 1n7)/7N$, where n1, n2, n3, …n7 are the number of grains that had germinated on the 1st day, 2nd day, …7th day, and N is the total number of grains in the assay. The grains from each plant composed a replication, and the experiments were performed in three replicates. Additionally, 30 sound grains of each plant were placed crease down on moist filter paper in Petri dishes at 20 °C in normal conditions (16 h, light:8 h, dark; 20 °C). The germination capacity on the 39th day after sowing was recorded.

Spike sprouting test

Ten spikes of each T5-generation transgenic line harvested from the experimental field were inserted into floral foam (floral foam can retain water to prevent the detached wheat spikes from wilting) at approximately 20-25 °C in a greenhouse. Misting was controlled by a humidifier and checked automatically for 4 d. Under these conditions, a high relative humidity (> 98%) was maintained.

ABA sensitivity assay

Wheat seeds from the transgenic lines and from the non-transgenic Zhengmai 9023 whose dormancy had been broken were tested for ABA sensitivity. Seeds were germinated at 20 °C. At the second leaf stage, they were treated with different concentrations of ABA, including 0 μmol/L, 0.5 μmol/L and 5 μmol/L ABA. Fourteen seedlings from each transgenic line and from non-transgenic Zhengmai 9023 were assayed after being treated for13 d (Saad et al., 2013). The initial fresh weight and final fresh weight of the plants were measured. Then, the difference in weight was calculated. The experiments were performed on three replicates.

Statistical analysis

The GIs, germination capacity and average weight difference of each line were analyzed using Excel software, and Student's *t* test was calculated for relevant data using SPSS software. The figures were created using Origin8 software and Adobe Photoshop CS5 software.

Results

Cloning and analysis of the RsRHA2b gene

The EST database was BLASTed based on the amino acid sequence encoded by the *Arabidopsis* RING finger gene *AtRHA2b* (Gene ID: 814644). Many highly homologous ESTs were found. A cDNA sequence including the entire ORF of the radish RING finger gene *RHA2b* was found using artificial splicing and software analysis based on the radish database. The length of the entire sequence was 697 bp (*Fig. 1*). The ID of the *RsRHA2b* gene was KR349970. The entire coding sequence, plus a 93 bp sequence in the 3'-UTR, was amplified from radish cDNA and was 565 bp in length. The sequence was then used to construct the binary vector pCAMBIA3301-*RsRHA2b* (*Fig. 2*). The constructed vector was further confirmed by sequence analysis (*Fig. 1*) and was then transferred into *Agrobacterium tumefaciens* EHA105. Transgenic wheat plants were obtained to investigate the function of *RsRHA2b*.

Identification of transgenic wheat plants

The transgenic plants were identified using PCR and RT-PCR. As shown in *Figure 3*, the *RsRHA2b* gene fragment was found in the genome of transgenic wheat, and *RsRHA2b* transcripts were also detected. These results showed that the *RsRHA2b* gene was stable in the wheat genome and was stably expressed. Each of the five lines (L1, L2, L3, L4 and L5) showed a single band, indicating independent transformation events (*Fig. 4*). As expected, there was no significant hybridization signal from WT DNA. These results indicated that the *RsRHA2b* gene was integrated into the genomes of the wheat transformants in the selected lines and was inherited by the progeny as a single copy. However, the segregation was not consistent with heredity of a single-copy gene. Ultimately, four transgenic lines, 1471 (100 wheat heads), 1477 (102 wheat heads), 1492 (105 wheat heads) and 1569 (103 wheat heads), were selected for further characterization. Their morphology was similar to that of the non-transgenic Zhengmai 9023.

RsRHA2b has an important role in the regulation of RsRHA2b-mediated seed dormancy

To assay the seed dormancy of transgenic wheat, GIs were investigated using the seeds from the T5 generation. The GIs were significantly lower in the transgenic wheat lines than in the non-transgenic Zhengmai 9023 (*Table 2*). The GIs of the seeds of the transgenic lines ranged from 0.098 to 0.387, a significant reduction, up to 89.9%. In particular, the GI of transgenic line 1477 was 0.098. The germination capacity of the transgenic lines ranged from 0.367 to 0.724, a significant reduction of up to 63.3%. In particular, the germination capacity of the transgenic line 1477 was 0.367. GI value (less than 0.4) was defined as resistance to spike germination. GI value (0.4-0.8) is medium resistance. GI value (more than 0.8) is prone to spike germination (Ma et al., 2014). The GI values of the seeds of the four transgenic lines in this study were all less than 0.4, while the average GI values of the control group were 0.973. Therefore, the retarded seed germination in the transgenic wheat with *RsRHA2b* gene is stably inherited, and *RsRHA2b* can increase seed dormancy.

RsRHA2b effectively regulates RsRHA2b-mediated tolerance to PHS in spikes

To ascertain whether the *RsRHA2b* gene mediates the PHS response, 10 T5-generation plants from each of four transgenic lines, as well as non-transgenic Zhengmai 9023, were assayed for their PHS tolerance. The GI of the transgenic wheat line 1477 was significantly lower than that of the non-transgenic Zhengmai 9023 (*Table 2; Fig. 5*). Seeds from 1477 had just started to germinate while Zhengmai 9023 had a long first leaf. Spikes of 1477 maintained dormancy while Zhengmai 9023 displayed substantial leaves after 4 d of misting. The results showed that the *RsRHA2b* gene can improve PHS tolerance in transgenic wheat plants.

Higher sensitivity to exogenous ABA in transgenic plants

The ABA sensitivity of the *RsRHA2b* transgenic wheat plants was assayed. At the second leaf stage, the plants were transferred to Hoagland's liquid medium containing different concentrations of ABA (0 μmol/L, 0.5 μmol/L or 5 μmol/L). In the absence of ABA, the weights of transgenic wheat plants and non-transgenic Zhengmai 9023 were 0.701 g and 0.743 g, respectively (*Table 3*); there was no significant difference between them. However, in the presence of 0.5 μmol/L ABA, the weights of the transgenic wheat plants and non-transgenic Zhengmai 9023 were 0.417 g and 0.597 g, respectively (*Table 3*), and the difference was significant. The inhibitory effect was more apparent when 5 μmol/L ABA was applied. As shown in *Table 3*, with 5 μmol/L ABA, the weights of transgenic wheat plants and of non-transgenic Zhengmai 9023 were 0.274 g and 0.448 g, respectively. Taken together, the ABA sensitivity was significantly improved in transgenic wheat lines containing the *RsRHA2b* gene.

RsRHA2b affects the expression of genes associated with ABA signal transduction

To investigate whether the expression of the *RsRHA2b* gene affected the ABA signal transduction pathways, the expression levels of several genes associated with ABA were analyzed in the T5 transgenic plants and non-transgenic Zhengmai 9023. Three genes, *ABI5* (accession no. AB362818.1), *FUS3* (accession no. AM418838.1, homologous cloning) and *MAL* (accession no. AK334873.1), were found to be closely associated with *RsRHA2b*. As shown in *Figure 6A-C*, the expression of three genes showed an obvious steady increase in transgenic wheat plants after ABA treatment. In the presence of 0.5 μmol/L ABA, the expression levels of *ABI5*, *FUS3*, and *MAL* increased 2.6-fold (48 h, highest level), 25.7-fold (24 h, highest level) and 7.2-fold (48 h, highest level), respectively, in the transgenic wheat plants relative to non-transgenic Zhengmai 9023; in the presence of 5 μmol/L ABA, the expression of the three genes increased 3.8-fold (48 h, highest level), 6.8-fold (24 h, highest level) and 43.5-fold (24 h, highest level), respectively, in the transgenic wheat plants. Taken together, these results indicate that the *RsRHA2b* gene up-regulated the expression of several genes related to seed germination in transgenic wheat.

Discussion

To solve the problem of PHS in wheat, scholars have conducted much research to explore the mechanism of PHS resistance. The conclusions are as follows. First, studies have focused on the apparent physical and physiological characteristics of wheat seeds, such as spike morphology (Zanetti et al., 2000), the color of the seed coat (Torada and Amano, 2002; Bassoi and Flintham, 2005), seed structure and water absorption (King

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1327313288

and Von Wettstein-Knowles, 2000), seed dormancy (Andreoli et al., 2006; Hughes et al., 2010), ABA content (Gerjets et al., 2010) and α-amylase activity (Major et al., 2001). In the breeding process, grain color, spikelet density, 1000-grain weight and grain width can be used as important reference indexes for wheat varieties resistant to spike germination (Ma et al., 2016). Second, research has focused on the characteristics of genes related to PHS or seed dormancy and the positional cloning of QTLs (Anderson et al., 1993; Chen et al., 2008a; Somers et al., 2007). Third, research has focused on the screening of molecular markers, the mapping of resistance genes and the generation of transgenic lines using genetic engineering methods. PHS resistance in wheat is a quantitative trait, and relevant quantitative trait locuses linked to PHS have been reported on almost all chromosomes (Munkvold et al., 2009; Ogbonnaya et al., 2008). However, PHS-resistant wheat germplasm resources are scarce. Therefore, the use of genetic engineering provides good choices for the improvement of PHS resistance in wheat. The *VP1* and *Trx* genes have been used to improve the PHS resistance of wheat (Li et al., 2009; Huang et al., 2012). Although these attempts have yielded some progress in controlling seed dormancy and PHS, more work is required.

The objective of this study was to determine whether the *RHA2b* gene from radish could improve the PHS tolerance of wheat. The *RsRHA2b* gene was used to improve seed dormancy and PHS tolerance in wheat.

The success of the *Agrobacterium*-mediated transformation method used here provides a new technique for wheat genetic breeding (Zhao et al., 2006). In this study, the stem apex was used to improve *Agrobacterium*-mediated transformation. Basta was used to select the transgenic lines. The optimum half lethal concentration of basta had not been reported previously. Prior to this study, the concentration was analyzed using concentration gradient experiments. The phenotypes of plants treated with basta solutions of 80 mg/L, 100 mg/L, 120 mg/L, 140 mg/L, 160 mg/L, 180 mg/L, 200 mg/L, 220 mg/L, 240 mg/L, and 260 mg/L were recorded. The results showed that the optimum half lethal concentration of basta was 160 mg/L. This method can provide genetically stable material for further application. As shown in *Figure 3*, the transgenic lines were rigorously screened using basta, PCR and RT-PCR. The seeds from pure transgenic lines, identified based on the segregation ratio of the integrated *RsRHA2b* gene, were used for propagation.

Seed dormancy was stably inherited in transgenic wheat lines carrying the *RHA2b* gene from radish (*Figs. 3* and *4*). GIs and germination capacities were stably reduced in the T5 generation of transgenic wheat lines (*Table 2*). The transgenic lines in the present study had significantly increased tolerance to PHS, indicating that *RsRHA2b* has an important role in regulating seed dormancy and PHS tolerance.

The resistance to dormancy and PHS is regulated by ABA anabolism and ABA signal transduction (Gubler et al., 2005). Additionally, studies on wheat mutants have shown that ABA sensitivity is directly associated with seed dormancy (Kawakami et al., 1997; Noda et al., 2002). Research on the physiological characteristics of wheat has shown that ABA synthesis is important for embryos to remain dormant. However, embryo dormancy is closely associated with the internal ABA content and the sensitivity of embryos to ABA (King, 1993; Morris et al., 1989; Walker-Simmons, 1987). Cultivars with strong dormancy have strong sensitivity to ABA (Morris et al., 1989; Walker-Simmons, 1987; Corbineau et al., 2000). These results demonstrate that both ABA signal transduction and ABA cascade effectors are important for maintaining dormancy and resisting PHS. Increased ABA sensitivity in transgenic wheat may increase survival rates.

In this study, the *RsRHA2b*-regulated ABA sensitivity apparently failed to impair the growth of transgenic wheat plants without exogenous ABA, but with exogenous ABA, smaller weight increases were observed (*Table 3*). Therefore, the exogenous *RsRHA2b* gene may regulate the ABA signaling pathway in transgenic wheat.

Although the *AtRHA2b* gene plays a positive role in regulating ABA signaling and stress responses, the regulatory factors and response regulators associated with *AtRHA2b* are not known. Previous qRT-PCR assays have indicated that ABA treatment increased the expression of several ABA-inducible marker genes, including *RAB18, RD29A, KIN1, AtADH1, RD22* and *RD29B* in wild-type *Arabidopsis* (Li et al., 2011). The regulators associated with ABA and ABA-inducible marker genes were chosen for analysis in transgenic wheat containing the *RsRHA2b* gene. In the present work, three genes, i.e., *ABI5, FUS3* and *MAL,* were found to be significantly associated with *RHA2b*. *ABI5*, a bZIP transcription factor, is a positive regulator of ABA signaling, and its expression can be activated by exogenous ABA treatment (Suzuki et al., 2003; Kobayashi et al., 2008). *FUS3* (FUSCA3) promotes dormancy and prevents the precocious germination of immature seeds by stimulating ABA synthesis (Chiu et al., 2012). MAL is involved in the metabolic pathways of ABA signaling (Huang et al., 2012). The expression of *ABI5, FUS3* and *MAL* significantly increased in the presence

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1327313288

of 0.5 μmol/L ABA and 5 μmol/L ABA at the second leaf stage in transgenic wheat (*Fig. 6*). Thus, the *RsRHA2b* gene could positively regulate ABA signaling intermediates in transgenic wheat.

The grain germination rate of the over-expressed miR9678 wheat transgenic lines was significantly lower than that of the wild type, and the content of active gibberellin was reduced, leading to significantly increased resistance to spike germination (Guo et al., 2018). The miR9678 can mediate the splicing of long-segment non-coding RNA and produce a series of phasiRNA, which eventually leads to the change of gibberellin metabolism and its regulatory pathway by affecting the expression of gibberellin synthesis gene, thus controlling the germination rate of grain and spike germination (Guo et al., 2018). Based on transgenic wheat containing *RsRHA2b*, the reason for significantly increased tolerance to PHS can be explored by further work.

Conclusion

The *RsRHA2b* gene was integrated into the genomes of the wheat transformants. Transgenic wheat containing the *RsRHA2b* gene showed improved seed dormancy and PHS tolerance. *RsRHA2b* gene plays a significant role in regulating the genes associated with ABA signal transduction. This study provides a promising strategy for breeding wheat cultivars with improved seed dormancy and PHS tolerance using genetic engineering with the *RsRHA2b* gene. However, more work is needed to discover the mechanism of *RsRHA2b*-mediated PHS resistance.

(Received 9th Jun 2019; accepted 28th Aug 2019)

Abstract. The phenology of landscape plural can predict the urban environment and guide the development of the city. The aim of the study is to get the relationship between urban environment and plant phenology. The methods monitored the phenology of the environment and garden plants in the main urban area of Chongqing from 2016 to 2019. And it is concluded that artificial light of garden lighting is between 1000 to 4000 Lx in Chongqing, and the application of LED (Light Emitting Diode) is the highest number. At the same time, the flowering period of trees is more susceptible than that of the shrubs; the flowering period of plants is more susceptible than the evergreen plants; and the fruit period of trees is earlier; the flowering period is prolonged. The flowering stage and flowering period of pruning plants are longer than the plants under natural state. This data should prove useful for future research of the subject.
Keywords: *nightscape lighting, plant phenology, garden plants, environment and phenology*

Introduction

The urban environment has a great impact on plant phenology. Since 1950, the flowering period of urban garden plants has moved 1~3 days ahead in Europe (Menzel, 2002), and from 1902 to 2006, the flowing period for the shrub species in nearly 1/4 of North America also came much earlier (Neil, 2010). In China, the spring phenological period of most plants in urban areas has moved to an earlier date, and the autumn phenological period was delayed (Caruso, 2004). In particular, from 1963 to 2007, the early flowering period of 34 woody plants came 9 days ahead of time, and the full-bloom stage 12 days earlier (Bai et al., 2010). In recent years, nightscape lighting have been widely applied in urban areas above the county level in China, and so far spread to scenic tourist areas and some natural mountains. To celebrate Hangzhou G20 Summit, more than one billion RMB was invested in nightscape, which further triggered the construction of nightscapes in various cities. Now landscape plants have been illuminated at night everywhere in China (Yuan, 2014) The light environment is an important factor affecting plant growth. According to the biological rhythm, plants do not perform photosynthesis at night (Zhang et al, 2012). However, with the artificial lighting, the photosynthesis time of plants is prolonged, affecting their phenology. There is a close relationship between light and plant photosynthesis (Kendrick, 1986). Unlike daylight, the light source intensity, spectral energy distribution and illumination time of artificial light all affect plant phenology (Fukuda et al, 2008).

Chongqing is located in Class V light climate zone in China. It is in the southwestern part of China and the upper reaches of the Yangtze River, falling within the subtropical climate zone, with an average annual temperature of 16~18 °C, an annual rainfall of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1328913296

1017.5 mm and a sunshine duration of 1000~1400 h. This city has abundant garden plants, so a large amount of lighting facilities have been built. This paper attempts to study the phenology of garden plants in Chongqing, with a view to finding out the impacts of artificial lighting on the urban forestry ecosystem.

Materials and methods

Selection of materials

25 observation points with landscape lighting in the main urban area of Chongqing were selected for monitoring of landscape lighting and plant phenology. The research location is in *Figure 1*. The parameters recorded included artificial illumination, temperature, humidity and altitude. In each survey area, 20 sampling sites were randomly selected for measurement and each measurement was repeated 3 times. The criteria for material selection were that it had an ornamental value and that it was widely distributed in Chongqing. There were 36 species of woody garden plants, including 16 species of shrubs (8 evergreen and 8 deciduous shrubs) and 20 species of arbors (5 evergreen and 15 deciduous arbors). The selected plants fell within 14 families and 21 genera (see *Table 1*).

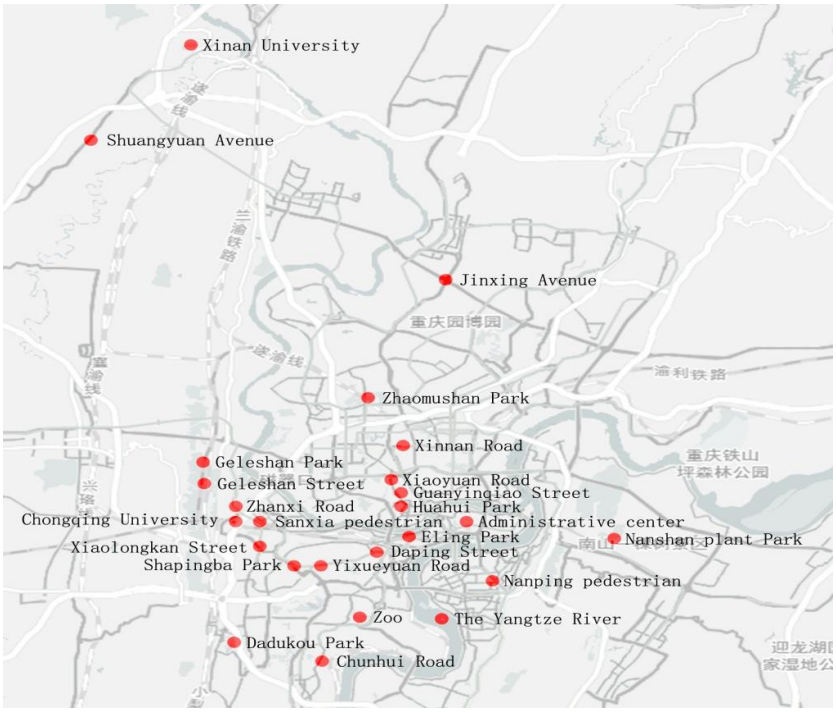

Figure 1. *Research location in Chongqing*

Research method

From January 2017 to December 2018, a total of 36 species of woody plants were monitored. The phenological observations were carried out on specific plants at fixed points in accordance with the Chinese Phenological Observation Method (Wan, 1979) every 4 to 7 days. Each time, the observation on all plants in a survey area must be completed within 3 days. The tree species selected were middle-age plants that were

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1328913296

robust and had been blossomed and fruited for more than 3 years. In each survey area, 3-5 plants were observed for each species, including at least 15 branches. During the phenological observation, records and pictures were taken. According to the Julian daily conversion method, the length of the corresponding flowering period and the growing season are calculated. In this study, the bud stage, the early flowering stage, the full-bloom stage and the late flowering stage were defined as the flowering phenology; the bud opening stage, the early leaf expansion and the leaf flourishing stage as the leafing phenology; and the bud opening period, the early leaf expansion, the leaf flourishing stage and the leaf fall stage as the leaf phenology. Artificial illumination is measured by professional illuminance meter.

Table 1. *Observation sample land environment factor data table (2016~2019)*

Site	Illumination (lx)	Temperature (°C)	Humidity	Altitude (m)	Architecture proportion (%)	Hard ratio (%)	Plant coverage (%)

Results

Artificial light source types in garden lighting

The types of artificial light sources in garden nightscape were analyzed with the survey data, through which, the utilization of these light sources were obtained, as shown in *Figure 1*. According to statistics, the garden nightscape sources mainly include metal halide lamps, high pressure sodium lamps and LEDs. Traditional light sources accounted for 20% of the total surveyed ones, followed by white LEDs (39%),

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1328913296

yellow LEDs (6.8%), red LEDs (5.4%), violet LED (2.7%) and green LED (2.5%). Due to the transient nature, long service life and high luminous efficiency, LED light is gradually replacing the traditional light source as the dominant light source in landscape lighting (Pousset et al, 2010).

Illumination of artificial light sources in garden lighting

At present, the illumination intensity of garden nightscape lighting is generally high, resulting in extremely serious light pollution. Statistics of the illumination intensity applied in garden lighting are shown in *Figure 2*. As can be seen, the illumination intensity of garden nightscape lighting ranges mainly between 1000~4000 lx, accounting for 74% of the quantity surveyed; the illumination intensity for key plants ranges between 5000~6000 lx, accounting for 14% of the total surveyed quantity; most fluorescent lighting has an intensity of 1000 lx or below, accounting for 12% of the total quantity. In the garden lighting practice, an illumination intensity of 1000~4000 lx can meet people's usage and aesthetic needs, and such intensity is also the most widely applied (Duan, 2015).

Phenological characteristics of plants in the urban environment

36 plants radiated by artificial light sources were observed, and the averages of the flowering period (early flowering, full blossom and late flowering) and the mature fruiting period were compared with those recorded in Flora of China, Flora of Chongqing Jinyun Mountain and Flora of Sichuan. According to *Table 2*, among the 36 observed plants, 18 showed obviously earlier flowering periods, and 5 experienced earlier fruiting periods. All other plants showed consistent phonological periods with those recorded (see *Table 2*).

Phenological sensitivity of plants in the urban environment

The plants experiencing earlier flowering periods included 2 species of evergreen shrubs, accounting for 25% of all evergreen shrubs; 5 species of deciduous shrubs, accounting for 63% of all deciduous shrubs; 3 species of evergreen arbors, accounting for 60% of all evergreen arbors; and 8 species of deciduous arbors, accounting for 53% of all deciduous arbors. In terms of the fruiting period, the evergreen shrubs, deciduous shrubs and evergreen arbors had consistent phenological periods with the historical records, and only 5 of the deciduous arbors experienced earlier fruiting, which accounted for 45% of all deciduous arbors (see *Fig. 2*).

Through comparative analysis, as shown in *Figure 2,* the flowering period of the arbors under artificial lighting changed more obviously than that of the shrubs, and that of the deciduous plants experienced more obvious changes than the evergreen ones. Of the species in life forms experiencing earlier flowing periods, most are deciduous shrubs and deciduous arbors, and their proportions were also high in terms of quantity. However, in terms of the fruiting period, only deciduous arbors experienced earlier fruiting, which was consistent with the results regarding the flowering period.

Plant phenology under the urban management mode

An independent sample T test was performed on the selected woody plants to analyze the phonological differences between different landscape management modes. The survey areas of Chinese Loropetalum herb included the Three Gorges Square, Xinnan Road, Southwest University, Chongqing University, Zoo, Eling Park, Shaping Park, Flower Garden, and Nanshan Botanical Garden; those of michelia figo included Eling Park and Nanshan Botanical Garden; and those of the sample plots of ligustrum sinense included Daping, Star Avenue and Flower Garden. The analysis results are shown in *Figure 3*.

Under landscape lighting, after being pruned, the bud stage, the early flowering stage and the full blossom stage of woody plants came significantly later than those in the natural state, but the difference between the two states was not significant in the late flowering stage, nor are those in the bud opening stage, the early leafing stage and the leaf flourishing stage. Data show that, under the natural state, woody plants would blossom earlier and longer, but that there is no difference in leafing, probably because woody plants in the natural state are older and have larger ground diameters, making the flowering period earlier; and also because pruned woody plants will preferentially undergo vegetative growth, which is a response to the environmental change.

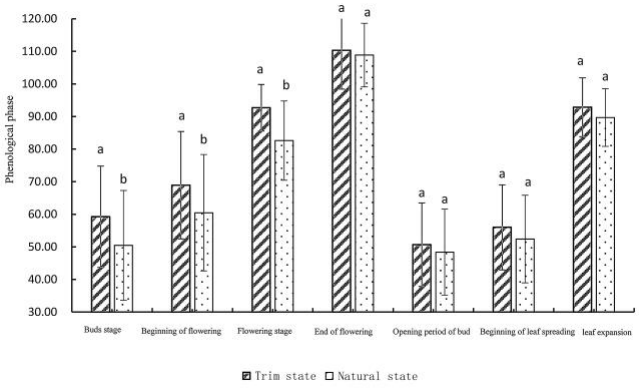

Figure 3. *Difference phenological period under different garden management modes*

Discussion

Artificial illumination has significant impacts on the phenology of woody landscape plants (Wang et al., 2012; Kulchin et al., 2018). The high-pressure sodium lamp has a discontinuous spectrum, with a peak value ranging between 570 and 600 mm; the metal halide lamp has a spectral peak ranging between 500 and 600 nm; the white and yellow LEDs contain much blue and red light; and the chromatic spectrum of LEDs has a narrow range. According to the absorption behaviour of the plant with respect to the light source spectrum, the spectra of low-light-intensity high-pressure sodium lamps and LED colour light sources have little effect on plant growth, while those of white and yellow LEDs and metal halide lamp have obvious impacts thereon. The results of the research verified this conclusion.

Artificial illumination is a direct factor affecting plant phenology and the paper-making plants. The flowering period is more sensitive to artificial light than the fruiting period, so it is more suitable as an indicator of the impact of artificial light on plant

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1328913296

phenology. Through analysis of the differences between the phenological periods of 5 arbors in urban and rural areas, it is found that the phenological period in urban areas is 4 days ahead of that in the rural one (Hu, 2013). This study also finds that artificial light, temperature, floor area ratio and proportion of rigid pavement can promote and extend the flowering and leafing of the plants and delay their defoliation; and that the increase of altitude and vegetation coverage has the opposite effect. For pruned woody plants, the bud, early flowering and full-blossom stages are all significantly later than those for plants in the natural state, but the difference between the two states is not so significant in the bud opening, early leafing and leaf flourishing stages (Jia et al., 2019). There is a certain relationship between the stem diameter of the plant and the flowering period, and after being pruned, woody plants would preferentially undergo vegetative growth under the artificial light (Chen, 2007), resulting in much earlier and longer flowering period of woody plants in the natural state.

Conclusion

The wide application of artificial nightscape lighting in the urban areas affects the phenology of garden plants and does harm to the forest growth, which is not conducive to the urban ecological environment. Through the monitoring on the phenology of garden plants in the artificial light environment in Chongqing, this study preliminarily obtains the current range of landscape illumination, applications of spectra and the phenological changes of garden plants, such as the flowering period and fruiting period, which provide information and data for the research on the phenology of landscape plants in Chongqing and also allow people to see the harm of artificial light environment to the landscape plants and the paper-making plants. Future research will focus on the effects of the illumination intensity, spectral energy distribution and illumination time of artificial light sources on plant phenology so as to provide basis for rational use of artificial lighting.

Abstract. In order to explore the mechanism of the microbial weathering of rock, study the covering green process on rocks and improve the ecological environment, the soil forming effect of weathering granite, gneiss and sandstone was studied. Using ICP–OES and SEM method, the species and capacity of metabolites produced by *Bacillus mucilaginosus* in the fermentation process, concentrations of various elements released from the granite, gneiss, and sandstone and rock surface morphology were assessed. Results showed that metabolites such as organic acids, amino acids and polysaccharides formed by the *B. mucilaginosus* had significant differences among three types of rocks, concerning their quantities, granite > gneiss > sandstone; metabolites mentioned above could destroy the structure of the rock, which released many oxides. According to the amount of oxides leached from the three kinds of rock fermentation liquid, more oxides such as SiO_2, Na_2O, P_2O_5, Fe_2O_3, Al_2O_3, CaO, K_2O, MgO, TiO_2 were dissolved from the fermentation liquid of the granite. MnO was dissolved in the highest quantities in the fermentation broth of gneiss, more than that of granite and sandstone. The result indicated that the *B. mucilaginosus* had an obvious weathering effect on three kinds of rocks, especially on the weathering ability of granite.
Keywords: *Bacillus mucilaginosus, weathering, granite, gneiss, sandstone*

Introduction

Silicate minerals are widely distributed in nature, about one-third of all the known minerals (Du, 1984). Because of the excessive exploitation of ore in the last century, bare rock was everywhere, which had led to land degradation and a sharp decline in biodiversity (Fang et al., 2016), and ecological environment needs to be repair. However, under the natural condition, relying on the physical and chemical weathering, changing bare rock to soil usually takes 20000 years to form 1 m thick soil (Yang, 2013). Therefore, in order to promote the restoration of degraded ecological environment, it is urgent to have good bacterial species resources of ecological restoration and effective vegetation restoration methods. The evolution of hard rock into a bioactive and porous soil requires an extremely complex process of weathering and soil formation. All kinds of organisms living in soil fundamentally change the physical, chemical and biochemical properties of soil parent material, and promote the formation and evolution of soil (Li, 2006). Hall believes that in the environment with biological existence, biological weathering rocks can play a leading role under certain conditions (Hall et al., 2005). Microorganisms are widely attached to the rock surface, which can

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1329713309

affect the weathering of rocks and minerals and promote the formation of soil through growth and reproduction and the formation of biofilms (Ehrlich, 1999). Researches showed that the main microorganisms weathering the rock minerals were *B. mucilaginosus* (Zeng, 2016), *Burkolderia solanacearum* (Barker, 1998), *Pseudomonas protegens* (Wu et al., 2017a; Wu, 2016), *Bacillus megatherium* (Wu et al., 2017b), *Aspergillus niger* (Wu, 2018, 2019), *Rhizobium tropici* (Wang et al., 2015), *Penicillium oxalicum* (Song et al., 2015) and so on. The weathering effects of these microorganisms on mineral rocks include direct dissolution and mechanical damage, and indirect chemical corrosion. By reducing pH value and producing organic acids or inorganic acids, these microorganisms dissolve rock components and accelerate the release of Si, Al, Ca, Mg, K and other elements from rocks (Welchm, 1993; Vandevivere et al., 1994; Sun et al., 2018; Zhang et al., 2018; Zhou et al., 2015; Li et al., 2017), which are directly supplied to plant growth and utilization (Ge and Li, 2017; Li et al., 2016).

B. mucilaginosus is an important functional bacterium widely used in microbial fertilizers. It decomposes rock minerals through mechanical damage, mineral complex, acidolysis, enzymatic hydrolysis, reduction and complexation (Zeng, 2018; Man, 2015). Štyriaková et al. studied the infection of *B. mucilaginosus* on basalt, granite and gneiss at different temperatures and leaching tests on potassium, calcium, magnesium, silicon, iron and aluminum, and found that the influence of temperature on microbial weathering of rocks and the change of element extraction was obvious (Štyriaková, 2012). Xiao Guoguang et al. studied the release of metabolites (organic acids, amino acids and polysaccharides) of *B. mucilaginosus* under laboratory conditions, and believed that all metabolites had a certain weathering effect on plagioclase (Xiao, 2013). To date, however, no one has discussed the effect of *B. mucilaginosus* on weathered soils of granite, gneiss, and sandstone.

In this experiment, the metabolites released by weathering of granite, gneiss and sandstone, and the ability of dissolution of Si, K and other elements were compared and studied by using the *B. mucilaginosus* under laboratory conditions, which aimed at a deeper understanding of the effects and mechanism of the *B. mucilaginosus* weathering mineral rocks, cleared the role of the microbial weathering of rock, and screened good strains of weathering rock minerals, thus to provide important clues for clarifying the soil generating process, the ecological restoration, the development of sustainable agriculture and a series of scientific problems.

Materials and method

Materials

Bacteria

A *B. mucilaginosus* was isolated, purified and screened from the soil in Key Laboratory of Soil and Water Conservation and Ecological Restoration in Jiangsu Province, Nanjing Forestry University, China. It was identified as a *B. mucilaginosus* by biochemical analysis and 16s rDNA. The strain formed a raised colorless transparent colony on the nitrogen-free silicate medium, and the colony was smooth in surface, neat in its edge, with viscous and elastic, and could be drawn into silk. Its form was rod, gram reaction was negative, the optimum growth temperature was 28 C, and it was cultured for 3 d on the N-containing medium.

Rock sample

The tested granite samplings were taken from the closed mine in Jinding mountain, Wuzhong district, Suzhou; the sandstone samplings from the Yuyang mountain in Suzhou, and the gneiss samplings from the Lingzhou mine in Lianyungang. According to the XRD analysis of the collected rock samples, the mineral composition of the granite: quartz 30-35%, plagioclase 20-25% and potassium feldspar 25-30%, mica 10-15%, chlorite or vermiculite < 5%, the collected rock was porphyritic granite; Main mineral composition of gneiss: quartz 30-35%, Plagioclase 45-50%, Mica 15-20%; Main mineral composition of sandstone: quartz > 95%; A small amount of feldspar; small amounts of iron, etc. The chemical compositions (%) by X-ray fluorescence analysis were shown in *Table 1*. The rock powder was sieved with a 100 mesh sieve for experiment.

Table 1. *Chemical compositions (%) of the tested rocks*

N-containing medium

Sucrose 10 g, KCl 0.1 g, (NH_4) SO_4 1.0 g, $CaCO_3$1.0 g, $Na_2HPO_4 \cdot 12H_2O$ 2.0 g, $MgSO_4 \cdot 7H_2O$ 1.0 g, distilled water 1.0 L.

The *B. mucilaginosus* were cultured on N-containing medium for 3 d to activate the bacteria. The pH value was adjusted by 0.1 mol• L^{-1} HCl and NaOH in the preparation of N-containing medium.

Experimental methods

The test of weathering rock by B. mucilaginosus

The *B. mucilaginosus* was inoculated in 250 mL culture solution for 56 h, centrifuged at 5000 rpm for 10 min, and then washed with sterile water for 3 times, and 600 mL of sterile water was added as the inoculation solution. 150 mL liquid medium was first added into a 500 mL triangular flask, and then 5 g granite powder or 5 g gneiss powder or 5 g sandstone powder was added. Sterile filter membrane was used for sealing. 121 C high pressure sterilization for 20 min, to add 5% *B. mucilaginosus* spore suspension (10^7/mL) at 28℃ (plus or minus 0.5 C) for static culture after cooling, and the contents of organic acids, polysaccharides, pH value, Si, Fe, Al, Ca, K and Mg in the fermentation broth were determined at 2 d, 5 d, 10 d, 15 d, 22 d and 30 d respectively. Compare with no bacteria, repeat three times. The experimental period was 30 d (Wu, 2018).

Observation of the surface morphology of weathering rock by B. mucilaginosus

The powders of granite, gneiss, and sand rock were collected respectively after experiment processing, and dried at 50 C. Then the samples were fixed, sprayed gold.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1329713309

The surface characteristics of rocks were observed using a Scanning Electron Microscopy (SEM) (Neo Scope JCM - 5000) after 30 d.

Method of measurement

Determination of organic acids

1 mL of filtered fermented liquid after cultured 10 d was sucked up and put into the centrifuge tube with 10 mL from the test samples treated by the spore suspension liquid of *B. mucilaginosus*, 200 μL of 50% H_2SO_4 were add into it, which was centrifuged with 10000 r/min for 5 min, 500 μL of supernatant were taken, and filtered with the 0.45 μm filter membrane, the contents of 6 kinds of organic acids (oxalic acid, tartaric acid, citric acid, acetic acid, malic acid and succinic acid) were determined by means of High Performance Liquid Chromatography (HPLC, 1260 Infinity, Agilent Technologies, USA) method (Wu, 2018).

Determination of amino acids

2 mL of filtered fermented liquid after cultured 10 d were sucked up and put into the centrifuge tube with 10 mL from the test samples treated by the spore suspension liquid of *B. mucilaginosus*, 2 mL of sulfosalicylic acid solution were accurately added into it, blended and vibrated overnight at 4 C; then 1 mL of EDTA-Na solution with 50 g/L and 1 mL of HCl solution with 0.06 mol/L were added into it, mixed, and centrifuged with 10,000 r/min for 5 min, their supernatant liquids were sucked up, and freeze-dried; then 1 mL of sodium citrate buffer solution was added to make the concentration of amino acid be in the best detection range, and the contents of different amino acids in the fermentation liquid were determined by the amino acid tester (Germany, sykam S-433D) (Wu, 2018).

Determination of polysaccharides

2 mL of filtered fermented liquid after cultured 10 d were sucked up and put into the centrifuge tube with 10 mL from the test samples treated by the spore suspension liquid of *B. mucilaginosus*, which was centrifuged with 8 000 r/min for 20 min, their supernatant liquids were taken, 60 mL of anhydrous ethanol were added, and put into refrigerator at 4 C for 1 h; then centrifuged with 6 000 r/min for 20 min, washed and precipitated with 95% of ethanol, anhydrous ethanol and ether precipitation respectively, the polysaccharide crude products were obtained after centrifugation, the removing protein processing were conducted by the Sevag reagent (chloroform: isoamyl alcohol = 4 : 1), and then dialyzed using deionized water, frozen at - 80 C after about 24 h, freeze-dried, a pure polysaccharide was gained and weighted, thus contents of polysaccharide in the fermented liquid of *B. mucilaginosus* were determined and compared in different rocks (Wu, 2018).

Determination of the elements in the fermentation fluid

5 mL fermented liquid of cultured 2 d, 5 d, 10 d, 15 d, 30 d were respectively taken to centrifuge with 5000 r/min for 10 min from the test samples treated by the spore suspension liquid of *B. mucilaginosus*, then their supernatants were fetched and put into the volumetric flask to be constant volume with 50 mL, 5 mL of measured liquids were taken, and added 1 drop of concentrated nitric acid into it, the contents of various

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1329713309

element of the processed samples were determined by inductively coupled plasma emission spectrometer Inductively Coupled Plasma Optical Emission Spectr (ICP-OES) (the Vista MXP type, USA).

Results

Changes of the metabolites formed by B. mucilaginosus in different rocks

Change trend of pH value of fermented liquids for B. mucilaginosus in different rock conditions

Figure 1 presented the change trend of pH value of fermented liquids for *B. mucilaginosus* with cultured time. It can be found that, with the extension of cultured time, pH value of the fermented liquids decreased first and then increased; within the cultivation of 1-10 d time, pH value declined rapidly, when cultivated 10 d, the pH value achieved minimum, subsequently, with the extension of cultured time, pH value had a rising trend gradually; Under different rock conditions, the variation trend of pH value was similar, the rangeability of pH value varied differently, with the highest pH value (4.59) in sandstone, secondly pH value (4.48) in gneiss, and lowest pH value (4.34) in granite, but three all were significantly lower than the control pH value (5.88, $p < 0.05$). In the experimental system containing *B. mucilaginosus*, the pH value first decreased and then increased, which may be because of *B. mucilaginosus* producing metabolites such as organic acids, polysaccharides and amino acids, which were gradually ionized as H+, resulting in a lower pH value of fermentation broth. The increase of pH value in the later stage of the experiment may be related to the autolysis of bacterial cells.

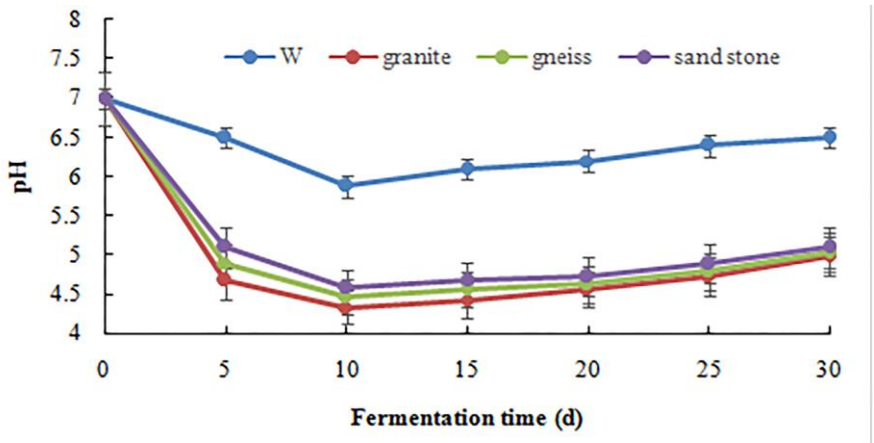

Figure 1. *Change of contents of pH values of the fermented liquids for B. mucilaginosus in different rocks*

Changes of types and contents of organic acids in the fermented liquids of B. mucilaginosus in different rocks

Organic acid is one of metabolites of *B. mucilaginosus*, reflects the ability of mineral leaching and silicon dissolving of *B. mucilaginosus* to a certain extent. The contents of 6 organic acids (oxalic acid, citric acid, malic acid, tartaric acid, acetic acid and succinic acid) in the fermentation broth of *B. mucilaginosus* at the 10th d were measured (at this

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1329713309

time, the pH value of the fermentation liquids was the smallest, as shown in *Fig. 1*). The contents of organic acids in the fermentation fluids in different rocks were found to be significantly different (*Fig. 2*). Among them, the contents of various organic acids in the fermentation fluids for granite were highest, followed by gneiss, and the lowest the sandstone, and three all were significantly higher than the control (without rock) ($p < 0.05$, *Table 2*). From the perspective of the types of organic acids, the three types of rocks all produced six organic acids, while the control produced only five organic acids, without citric acid; From the perspective of the contents of organic acid, among 6 kinds of organic acid, of tartaric acid were the most (1225.51), followed by glucose acid (1077.29), succinic acid (198.55), malic acid (116.61), and oxalic acid (76.11) and citric acid (55.78) the lower.

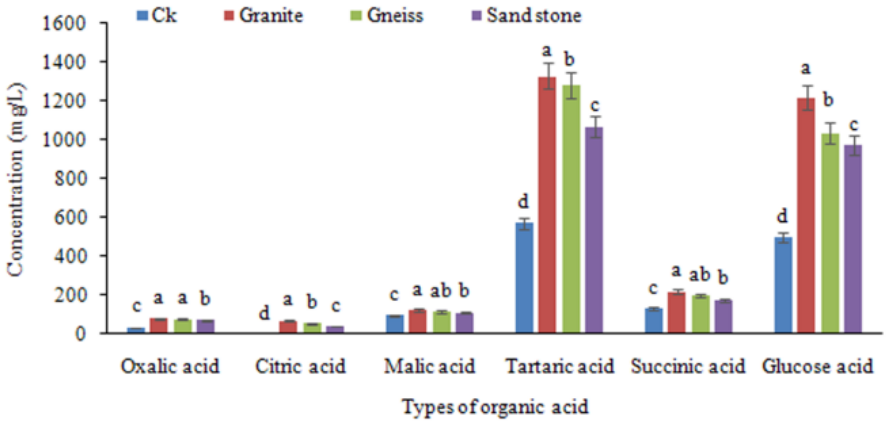

Figure 2. *Types and contents of organic acids in the fermented liquids of B. mucilaginosus for different rocks*

Changes of amino acid contents in the fermentation liquids of B. mucilaginosus for different rocks

Table 2 showed the types and contents of amino acids in the fermentation liquids at the cultured 10th d. It was obvious that the types and content of amino acids in the fermentation fluids between different rocks were different. 19 kinds of amino acids were detected out in fermented liquids for granite and gneiss, 18 kinds of amino acids for sandstone (methionine was not detected out), and just 8 kinds of amino acids for the control (without rock), which suggested that the types of amino acid produced in fermented liquids in added rock powder were more than in control (without rock powder). In other words, the rock powder to add in the fermented liquid stimulated *B. mucilaginosus* to produce more amino acids.

It can be seen from *Table 2* that the contents of amino acids in fermented liquids of *B. mucilaginosus* in different rocks were significant different, and its size sequence was granite > gneiss > sandstone > control, and the composition of amino acids was different obviously in different rock except control. Among them, the contents of alanine were the most, followed by cysteine, glutamic acid, glycine, leucine, isoleucine, methionine content in the least. This result further indicates that different rocks stimulate the fermentation broth of silicate bacteria to produce different metabolites, that is to say, microorganisms have certain selectivity to destroy the mineral rocks with different structures.

Changes of polysaccharide contents in the fermentation fluids of B. mucilaginosus for different rocks

The contents of polysaccharides in the fermentation liquid at cultured 10th d were shown in *Figure 3*. It can be seen that there were obvious differences in the contents of polysaccharides in the fermentation liquid of *B. mucilaginosus* for different rocks. The contents of polysaccharide in the fermentation liquids of *B. mucilaginosus* in the addition of rock powders were significantly higher than that of the control (without rock powder), indicating that the rock powder added in the medium stimulates the *B. mucilaginosus* to produce more polysaccharides. At the same time, we can see from *Figure 3* that the *B. mucilaginosus* have different effect of yielding sugars in different rocks. Among them, the contents of polysaccharide in the fermentation liquids in granite were the highest, which had no significant difference with gneiss, but was significantly higher than that of sandstone and control.

The weathering effect of the B. mucilaginosus on different rocks

The dissolution effect of the B. mucilaginosus on the elements in different rocks

Figure 4 showed the dissolution effect of *B. mucilaginosus* on different oxides in granite, gneiss and sandstone. The data in the figure were obtained from the content of oxide in the fermentation broth minus that of the control (without *B. mucilaginosus*). It was observed from the figure that with the increase of culture time, concentration of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1329713309

each oxide was significantly increased, a good growth effect of the *B. mucilaginosus* in the culture liquids added rock was showed, which indicated that the three kinds of rocks could promote the growth and reproduction of *B. mucilaginosus*, and further showed that *B. mucilaginosus* had a certain weathering effect on the three kinds of rocks. According to the amount of oxides leached from the three kinds of rock fermentation liquid, more oxides such as SiO_2, Na_2O, P_2O_5, Fe_2O_3, Al_2O_3, CaO, K_2O, MgO, TiO_2 were dissolved from fermentation liquid in the granite. Compared with sandstone, they increased by 17.28, 5.71, 2.27, 22.96, 5.99, 17.15. 16.80, 1.93 and 0.65 mg/L respectively; compared with gneiss, they increased by 14.24, 3.51, 1.48, 6.80, 1.55, 5.39, 1.93, 0.70 and 2.43 mg/L, respectively. MnO was dissolved in the highest quantities in the fermentation broth of gneiss, more than that of granite and sandstone, which was increased by 0.41 mg/L and .50 mg/L, respectively.

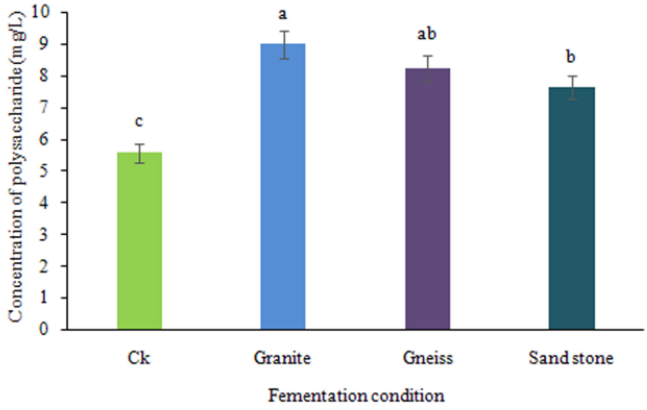

Figure 3. *Change of contents (mg/L) of polysaccharide in the fermentation liquids of B. Mucilaginosus for different rocks*

It can also be seen from *Figure 4* and *Table 1* that the weathering effect of *B. mucilaginosus* on rocks is closely related to the structural components of rocks. In addition to SiO_2, TiO_2 and Na_2O, in general, the higher the content of a certain chemical component in rocks, the more the chemical component dissolved by *B. mucilaginosus*. For example, granite and gneiss have similar structural components, mainly composed of quartz and feldspar, so the weathering effect of the two kinds of rock fermentation liquid is also similar. The main reason why the element dissolution of gneiss is lower than that of granite is that the content of this element in the rock component is slightly lower than that of granite. The main component of sandstone is quartz, the content of SiO_2 is greater than 95%, and the content of other element oxides is less, so the dissolution concentration of oxides of other nine elements in the three types of rocks is low. It should be pointed out that the content of SiO_2 in sandstone is extremely high, ranking the first among the three types of rocks, but its dissolution concentration is the lowest, and the reason remains to be further discussed.

Morphological changes and analysis of rock samples before and after dissolution

The observation results of fore-and-aft of granite, gneiss and sandstone weathered by B. mucilaginosus with the scanning electron microscope were shown in *Figure 5*.

DOI: http://dx.doi.org/10.15666/aeer/1706_1329713309

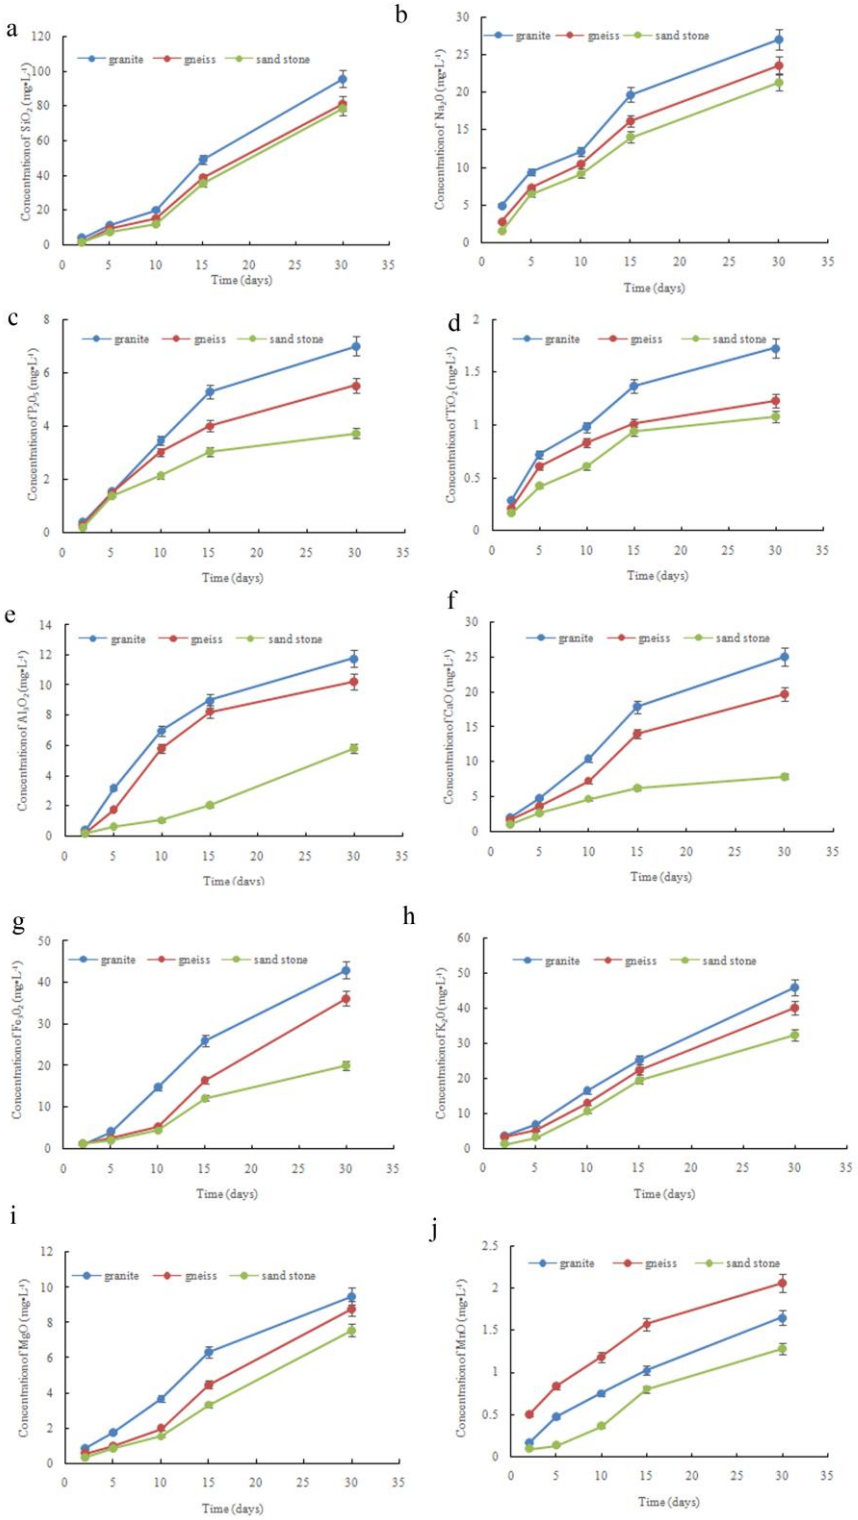

Figure 4. *The concentration of various oxides in the fermentation broth of B. mucilaginosus for different rocks*

Figure 5a, b, c were surface appearance of granite, gneiss, and sandstone rock that were not contacted with *B. mucilaginosus* respectively, it can be seen that the surface of rock particles was smooth, angular, obvious uneven shape, complete crystal structure;

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1329713309

Figure 5f was the surface topography of sandstone corroded by *B. mucilaginosus* at cultured 30 d, its surface structure was basically destroyed, blurred edges and corners, with some small caves and fractures; *Figure 5e* was the surface appearance of gneiss rock corroded by *B. mucilaginosus* at cultured 30 d, and its angular surface became smooth, the large corner angle and the bulge were broken up into smaller angular and smaller particles, with more corrosion holes and cracks. *Figure 5d* was the surface appearance of granite corroded by *B. mucilaginosus* at cultured 30 d. It can be seen from the *Figure 5d* that the surface structure of granite was completely destroyed, its raised edges and corners was completely blurred, and its surface became rough and uneven. These fully demonstrated that the *B. mucilaginosus* had obvious weathering effect on the surface of three kinds of rocks, and the weathering effect of granite was most distinct.

Discussion

Most researchers believe that acid hydrolysis is an important way for microorganisms to promote rock and mineral weathering. In this experiment, organic acids such as oxalic acid, citric acid and succinic acid produced in the fermentation broth had good dissolution effects on granite, gneiss and sandstone. It has been proved by studies that under the condition of mineral properties and the same pH value, organic acid solution is more likely to dissolve silicate minerals than inorganic acid solution (Bennett, 1996), because organic acid has both acid dissolution and complexation in the dissolution of silicate minerals, and complexation plays an important role in the dissolution of silicate minerals by organic acid.

Previous studies have shown that *B. mucilaginosus* can promote the weathering of potassium feldspar, illite, quartz, plagioclase and kaolin (Sun, 2006; Ren, 2015). The results showed that *B. mucilaginosus* also had obvious weathering effect on granite, gneiss and sandstone. This was basically consistent with the results of previous studies. However, compared with Sun Side's experiment of promoting silica, plagioclase and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1329713309

kaolinite to dissolve silicon and aluminum by using the JXF strain of *B. mucilaginosus* (Sun, 2008), two kinds of organic acids (acetic acid and succinic acid) and three kinds of amino acids (tryptophan, threonine and histidine) were detected in the fermentation broth. These metabolites undoubtedly play an important role in the weathering of rocks by *B. mucilaginosus*.

The fermentation broth of *B. mucilaginosus* could dissolve the elements contained in granite, gneiss and sandstone, such as phosphorus, potassium, silicon, sodium, magnesium, iron and calcium. With the extension of fermentation time, the content of released elements increased. Among them, the weathering effect of the granite was best, followed by gneiss, that of the sandstone was weak. The results of this study fully confirmed that *B. mucilaginosus* could promote weathering of granite, gneiss and sandstone, and elucidate its dissolution effect on phosphorus, potassium, silicon, sodium, magnesium, iron and calcium and other elements, but its dissolution effect had certain selectivity to rock types. Phosphorus and potassium are essential macroelements for plants. Sodium, magnesium, iron and calcium are essential microelements for plants. Although silicon is not a necessary element for plants, it is also a beneficial element. Once applied to the restoration of abandoned rock mining areas, *B. mucilaginosus* will promote the dissolution of available nitrogen, phosphorus, potassium, silicon, sodium, magnesium, iron and calcium in the soil, increase the contents in the soil, improve the status of soil nutrient poverty, so as to enable plants to obtain sufficient nutrients to promote the growth of plants (Zhang et al., 2016).

Granite, gneiss and sandstone are widely distributed in China, which are the three rock types in Jiangsu province. Their bare rock needs repairing. The experiment results showed that the *B. mucilaginosus* could effectively weather the three rocks. Its application in the restoration of bare rock will undoubtedly help to solve the problems of soil erosion and vegetation growth in Jiangsu province and even the whole country, and it is of great significance and value to accelerate the rock slope greenization project and realize the sustainable development of ecological environment. As for how *B. mucilaginosus* mixes with other microbial species, plant seeds, soil, etc. remains to be further studied.

Conclusion

In the fermentation broth of *B. mucilaginosus* added with granite, gneiss and sandstone respectively, their pH values showed a tendency of first decreasing and then increasing with the extension of culture time.

B. mucilaginosus can promote the dissolution effect of granite, gneisses and sandstone by secreting organic acids, amino acids, polysaccharides and other metabolites. Different rocks stimulate *B. mucilaginosus* to produce different metabolites. The contents of various organic acids, amino acids and polysaccharides in the fermentation liquid of granite were the highest, followed by gneiss, and sandstone was the lowest. More 9 kinds of oxides such as SiO_2, Na_2O, P_2O_5, Fe_2O_3, Al_2O_3, CaO, K_2O, MgO and TiO_2 were dissolved in fermentation broth added with granite.

B. mucilaginosus can significantly promote the weathering of granite, gneiss and sandstone, especially granite. SEM observation showed that after 30 days of dissolution by *B. mucilaginosus*, the edges and corners of sandstone rock became blurred, the edges and corners of gneiss rock smooth, and the convex edges and corners of granite surface rough, and obvious corrosion pits appeared in all three kinds of rocks.

DOI: http://dx.doi.org/10.15666/aeer/1706_1329713309

This paper provided a good seed resources for solving the problem of rapid soil formation of exposed rocks in abandoned mining areas and a new idea and solution for ecological restoration of degraded habitats. However, the effective combination of *B. mucilaginosus* with other microbial species, plant seeds and soil still needs to be further studied.

(Received 9th Jun 2019; accepted 28th Aug 2019)

Abstract. Eisenia fetida are commonly used for water and soil ecotoxicology tests. Here, we use Eisenia fetida as a model organism to investigate the effect of cartap and Cr^{6+} on the physiological and biochemical indicators, such as mortality, protein content, superoxide dismutase (SOD), catalase (CAT) and malondialdehyde (MDA). The results showed that with an increasing content of cartap, protein contents in Eisenia fetida increased in the beginning, then decreased, and finally stabilized after prolonged exposure. In the case of increasing Cr^{6+}, protein contents in Eisenia fetida decreased in the beginning, then increased, and finally decreased after prolonged exposure. The SOD activity in Eisenia fetida was simulated under low concentration and short durations of contaminations, while the SOD activity decreased after prolonged exposure. Meanwhile, under low contaminations, CAT contents were stimulated. The MDA contents in Eisenia fetida were significantly negatively correlated with SOD activity. This indicated that when the organisms are subjected to pollutant stress, the activity of SOD will be rapidly induced for removing excess oxygen free radicals and producing H_2O_2, accompanied by enhanced activity of CAT converting H_2O_2 to H_2O. With the prolonged exposure time, the SOD activity decreased, and the organisms were harmed by oxidative damage with enhanced MDA contents.
Keywords: *chlorpyrifos, ecotoxicity, superoxide dismutase, catalase, malondialdehyde*

Introduction

With the rapid development of China's industrialization, heavy metal content in farmland soils and water bodies severely exceeds the standard, seriously affecting the quality of agricultural products and endangering human health (Yu and Liu, 2011). This issue gained the attention of all countries. Heavy metal pollution does great harm to aquatic and soil ecosystems, affecting the physiological activities of aquatic plants such as respiration and photosynthesis, and inhibiting their growth (He et al., 2008). Affect the metabolism and growth of aquatic animals, such as cadmium affecting fish growth, interfering with fish endocrine (Wang et al., 2015). Heavy metals cause loss of activity in proteins and enzymes in the human body, accumulating in certain organs of the human body, causing chronic poisoning (Zhao et al., 2007). Among them, Cr^{6+} and Pb are more toxic, and they are more easily absorbed in the human body and are carcinogenic to the human body (Teng et al., 2014). When pesticides are applied, they are easy to remain on the surface of soil and agricultural products. Under the action of enzymes, metabolic processes such as hydrolysis, dechlorination and oxidation occur, and are transmitted to the human body through the food chain. In particular, some of the larger molecular weights are more soluble and easily absorbed by crops (Chen, 2014; Xia, 2008; Huang, 2002). When pesticides are applied, they are easy to remain on the surface of soil and agricultural products. Under the action of enzymes, metabolic processes such as hydrolysis, dechlorination and oxidation occur, and are transmitted to the human body

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1331113327

through the food chain. In particular, some of the larger molecular weights are more soluble and easily absorbed by crops (Xiao and Zhao, 2005). In addition, crops also absorb some residual pesticides from the soil and enter the crops through enrichment, which affects crop safety (Liu et al, 2002).

Traditional chemical analysis methods can accurately quantify the content of major components in pollutants, but can not directly reflect the environmental and biological toxicity of various toxic substances (Su et al, 2011). The biotoxicity method is a rapid monitoring method that reflects the overall toxicity of various toxic pollutants to the environment (Liao and Chen, 2007). Is a oligochaete terrestrial animal, one of the most biomass soil organisms, and a source of food for many birds and other organisms. It is located in the terrestrial ecosystem at the lowest level of the bio-chain and is easier in the food chain. The transfer of pollutants plays an important role in maintaining the stability of farmland ecosystems and the entire soil ecosystem, but it is likely to have more enrichment of heavy metals and pesticides in the body. In addition, alfalfa can improve the soil structure through feeding, excavation, etc., help the degradation of organic decay substances in the soil, maintain soil fertility, and affect soil physical and chemical properties. Because the soil moisture content, pH value and other changes can affect the cockroaches, cockroaches are highly sensitive to pollutants, and are highly susceptible to pollutants leading to changes in survival, genetics, etc. Therefore, cockroaches as ecotoxicology indicator organism for facilitating related research (Wang et al, 2012). Thus, our study aimed at (i) studying the toxic effects of Cr^{6+} on Eisenia fetida, and (ii) determining whether Eisenia fetida is suitable as an indicator of soil ecotoxicity.

Materials and methods

Acute toxicity test

Chlorpyrifos, with a purity of 98.8%, from Shanghai Institute of Pesticide; potassium dichromate（$K_2Cr_2O_7$, Purchased from Sinopharm Chemical Reagent Co., Ltd. Before the experiment, the chlordane and potassium dichromate were prepared and formulated into a 1000 $mg \cdot L^{-1}$ stock solution, which was sealed and stored at 4 °C for use. Eisenia fetida, Purchased from a professional carp farm in Jiangsu (*Fig. 1a*). Before the test, it was pre-cultured for a period of time in the laboratory. During the test, adult mature ticks with a body weight of about 0.3 g were selected.

Experiment method

Clean up the gut of the earthworm

Pick up the sexually mature adult cockroaches in the pre-cultivated red scorpion, wash them with ultrapure water and put them into a beaker. The bottom of the beaker is covered with filter paper and moistened with appropriate amount of water. Seal with plastic wrap and use the anatomical needle. Make holes in the cling film. Place the beaker in a constant temperature incubator at 20 ± 1 °C, humidity 80 to 85%, and clear the intestines for 1 day and night in the dark.

Contamination

The median expected toxicity was determined according to the literature. Pre-experiment was performed before the formal test to find the maximum lethal

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1331113327

concentration LD_{100} and the minimum lethal concentration of the pollutants, and the formal test concentration was set according to the preliminary experiment. The double-layer double-circle qualitative filter paper was placed in a glass culture dish, and 4 mL of the test concentration reagent was accurately absorbed on the filter paper, and 10 replicates with one test organism were set for each treatment, and a blank control group was set at the same time. Rinse the sputum after the intestines and blot the excess water on the surface and place one in each glass dish for the test. Seal with plastic wrap, place the glass culture dish in a constant temperature incubator at 20 ± 1 °C, adjust the humidity to 80% to 85%, culture in the dark for 72 h, and at 24 h, 48 h and 72 h recorded the survival of sputum.

Figure 1. *(a) The test organism Eisenia fetida; (b) sexually mature adult worms; and (c) toxicity test*

Data processing

The dose-effect model (DRC) of the toxicity of mixed pollutants was nonlinearly fitted by origin 8.5 software, and the LC_{50} values of the earthworms 24 h, 48 h and 72 h were calculated by nonlinear regression equation and passed SPSS software. Calculate a 95% confidence interval. The significance of different treatment was tested using Duncan's multiple-range test at $p < 0.05$ after one-way analysis of variance (ANOVA) in SPSS 20.2.

Experiment on earthworm physiological and biochemical indexes

Pollutant addition method

1. Blank control of experimental methods

In the blank test, 4 mL of deionized water was accurately absorbed and uniformly poured onto the glass culture dish with double layer and double coil qualitative filter paper.

2. Method of adding pyrrolidin

Accurately weigh the standard product of pyrrolide 1.02 g, dissolve with deionized water at a constant volume of 100 mL volumetric flask, configured into 10,000 $mg \cdot L^{-1}$ pyrrolide standard product mother liquid, is now used. Deionized water was used to dilute the mother solution of pyroridin with the concentration gradient of 0.5, 1.0, 1.5, 2.0 and 2.5 $mg \cdot L^{-1}$, respectively. Double layer and double coil qualitative filter paper was placed in a 9 cm diameter glass culture dish, and the diluted solution 4 mL was uniformly poured on the filter paper.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1331113327

3. Add methods of Cr^{6+}

Accurately weigh the dried potassium dichromate standard 0.565 g, dissolve it in water, use deionized water to fix the volume of 100 mL volumetric flask, and configure it into 1000 mg· L^{-1} potassium dichromate standard storage liquid. The mother solution of potassium dichromate was extracted and diluted with deionized water into 5 experimental solutions with concentration gradient of 1.0, 2.0, 3.0, 4.0 and 5.0 mg· L^{-1}. Double layer and double coil qualitative filter paper was placed in a 9 cm diameter glass culture dish, and the diluted solution 4 mL was uniformly poured on the filter paper.

Earthworm in vivo biochemical index test experiment

1. Test for determination of protein content

Earthworm samples from each treatment group at 24 h, 48 h and 72 h of exposure were collected, and the weight of the tissue to be measured was accurately weighed. 0.86% normal saline was added according to the proportion of weight (g): volume (mL) = 1:9. Mechanical homogenation was performed in ice water bath. The supernatant was diluted into 2% tissue homogenate with normal saline at 1:4, and was to be tested.

Blank tube, standard tube and measuring tube were set up in the experiment, in which double steaming water was added into the blank tube, protein standard substance 0.563 g/L was added into the standard tube, and homogenized earthworm tissues were placed in the measuring tube. In the test, the sample was first added with coomath bright blue color developing liquid, mixed and set for 10 min, then the absorbance value of each tube was measured at 595 nm by a colorimetric cup with a light diameter of 1 cm with ultraviolet spectrophotometer and double steaming water for zero adjustment. According to the measured absorbance, the protein content of the tissue homogenate with 2% concentration of earthworm sample was determined by the calculation formula shown below:

$$\text{Protein Concentration in the Sample(gprotj/L)} = \frac{\text{Measured value (OD)} - \text{Blank value (OD)}}{\text{standard value (OD)} - \text{Blank value (OD)}} \times \text{Standard concentration} \times \text{Dilution multiple before sample determination} \quad \text{(Eq.1)}$$

2. Determination of total superoxide dismutase activity

Respectively collected 24 h, 48 h and 72 h exposure when the earthworm samples of each treatment group accurately according to weight of the organization, by weight (g): the ratio of volume (mL) = 1:9 add 0.86% saline, ice water bath conditions, mechanical preparation of 10% homogenate and serum, use refrigerated centrifuge (Thermo Multifuge X1R) homogenate good earthworm tissue fluid under the condition of 2500 r/min centrifuge for 10 min. Remove the supernatant and test.

Test tube and set up the determination of the tube and the care, determination of the tube with samples, the care of the same volume of double steaming water, room temperature static 10 min, the use of ultraviolet spectrophotometer (Multiskan™ GO, Thermo Scientific), double steaming water zero, light diameter 1 cm colorimetric cup at the wavelength of 550 nm, determine the absorbance value of each tube. Because SOD has a specific inhibitory effect on superoxide anion radicals, resulting in the formation

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1331113327

of nitrite reduction, colorimetric determination of the tube absorbance value is lower than the care of the absorbance value, substituted into the formula to calculate SOD activity. The calculation formula is as follows:

$$\text{Total vitality (U/mgprot)} = \frac{\text{Control value (OD)} - \text{Measured value (OD)}}{\text{Control value (OD)}} \div 50\% \times \frac{\text{Total volume of reaction liquid}}{\text{Sampling quantity}} \div \text{Protein Concentration in the Sample to be Measured (mgprot/ml)} \quad \text{(Eq.2)}$$

3. Determination of catalase (CAT) activity

Respectively collected 24 h, 48 h and 72 h exposure when the earthworm samples of each treatment group accurately according to weight of the organization, by weight (g): the ratio of volume (mL) = 1:9 add 0.86% saline, ice water bath conditions, mechanical preparation of 10% homogenate and serum, use refrigerated centrifuge homogenate good earthworm tissue fluid under the condition of 2500 r/min centrifuge for 10 min. Take supernatant and normal saline (0.86%) and prepare 5% tissue homogenate according to 1:1 volume ratio.

The care and measurement tubes were operated according to the kit purchased by Nanjing Jiancheng Institute of Biological Engineering.

Ultraviolet spectrophotometer, double evaporation water zero, light diameter 0.5 cm colorimetric cup at the wavelength of 240 nm colorimetric, determine the absorbance value of each tube. The calculation formula is as follows:

$$\text{CAT vitality (U/mgprot)} = \frac{(\text{Control value (OD)} - \text{Measured value}) \times 271}{60 \times \text{Sampling quantity}} \times \text{Protein Concentration in the Sample to be Measured} \quad \text{(Eq.3)}$$

4. Determination of malondialdehyde (MDA)

Earthworm samples from each treatment group at 24 h, 48 h and 72 h of exposure were collected, and the weight of the tissue to be measured was accurately weighed. 0.86% normal saline was added according to the proportion of weight (g): volume (mL) = 1:9. Mechanical homogenation was performed in ice water bath. Take the supernatant and dilute it with normal saline at 1:4 to 2% tissue homogenate for testing.

The test set blank tube, standard tube, measuring tube and pair of care, according to the operation of the kit, the use of ultraviolet spectrophotometer, double steaming water zero, light diameter 0.5 cm colorimetric cup at the wavelength of 405 nm colorimetric, determine the absorbance value of each tube. The calculation company is as follows:

$$\text{MDA content (nmol/mgprot)} = \frac{\text{Measured value (OD)} - \text{Blank value (OD)}}{\text{standard value (OD)} - \text{Blank value (OD)}} \times \text{Standard concentration} \div \text{Protein Concentration in the Sample to be Measured} \quad \text{(Eq.4)}$$

Results

Toxicity test of chlorpyrifos and Cr^{6+} on earthworms

The toxicity test results of chlorpyrifos and Cr^{6+} on earthworms are shown in *Table 1*. The results show that both drugs have a certain degree of toxicity on earthworms, and the toxicity increases with the extension of exposure time. The experimental results showed that the survival rate of earthworms was 100%. When the poisoning time was 24 h, the single toxicity value of chlorpyrifos and Cr^{6+} on earthworms was significantly different, and the order of toxicity was > Cr^{6+} of chlorpyrifos. Among them, the most toxic was pyroridin, with a 24-h LC_{50} value of 14.30 (13.57-15.02) $mg \cdot L^{-1}$, followed by Cr^{6+}, and a 24-h LC_{50} value of 104.42 (99.20-109.64) $mg \cdot L^{-1}$. Two drugs are longer duration of canister and toxic, canister for 48 h, chlorpyrifos, Cr^{6+} 48 h-LC_{50} were 12.36 (11.74 12.98), 71.53 (67.95 75.11) $mg \cdot L^{-1}$, toxicity increased 1.16 and 1.46 times respectively, chlorpyrifos toxicity is still the strongest, is 5.79 times that of Cr^{6+} infected time for 72 h., chlorpyrifos, Cr^{6+} toxicity continue to strengthen, the strongest toxicity is still chlorpyrifos, 72-h LC_{50} value was 10.43 (9.91-10.95) mg· l-1, and the toxicity of cyanilon and Cr^{6+} was 1.19 times and 1.78 times stronger than that of cyanilon 48 h after exposure, respectively.

Table 1. *Single toxicity of cartap, Cr^{6} on earthworm*

Effects of pyroridin, Cr^{6+} and the biochemical indexes on earthworms

Effects of pyroridin and Cr^{6+} on the protein content of earthworms

Protein is composed of 20 kinds of amino acid, is an important part of the cell is the foundation of many life processes, is responsible for performing the life activities of the main functional molecules, easily happened due to the impact of certain factors in degeneration or other changes, thus could be obtained by using the studies of the changes of protein material toxicity mechanism of relevant information. Studies have shown that soil contaminated with pesticides and heavy metals can cause changes in the protein content of earthworms.

The experiment set up five treatment groups of 0.5, 1.0, 1.5, 2.0 and 2.5 $mg \cdot L^{-1}$. Earthworm samples were collected for pretreatment at 24 h, 48 h and 72 h respectively, and the protein content was determined. The results were shown in *Figure 2*.

As can be seen from *Figure 2,* the protein content of earthworms changed to different degrees after the exposure of pyroridin at different concentrations. The protein content of the infected earthworms was higher than that of the blank control group, which may be caused by the stimulation of pollutants and the stress proteins produced by the earthworm body, such as c-reactive protein (CRF) and fibrin connective protein (Fn), etc., which may lead to the increase of the protein content of earthworms (Ling, 2004). When the exposure time of 24 h, the earthworm body protein content increased with the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1331113327

increase of concentration of test presents a trend of reducing the rise, were relatively blank control group increased by 12.9%, 12.9%, 43.57%, 29.59% and 23.8%, the concentration of 1.5 $mg \cdot L^{-1}$ when the maximum, the protein content of 144% times as blank group, then gradually reduce the protein content, may be due to chlorpyrifos has strong tag and stomach poison, start acting on earthworm skin table, send the earthworm appear after stress reaction or worms infected body metabolic disorders cause the protein content is higher, With the increase of the concentration, the toxin ACTS on the stomach of earthworms and destroys the protein synthesis, resulting in the decrease of protein content (Xue and Pei, 2000).

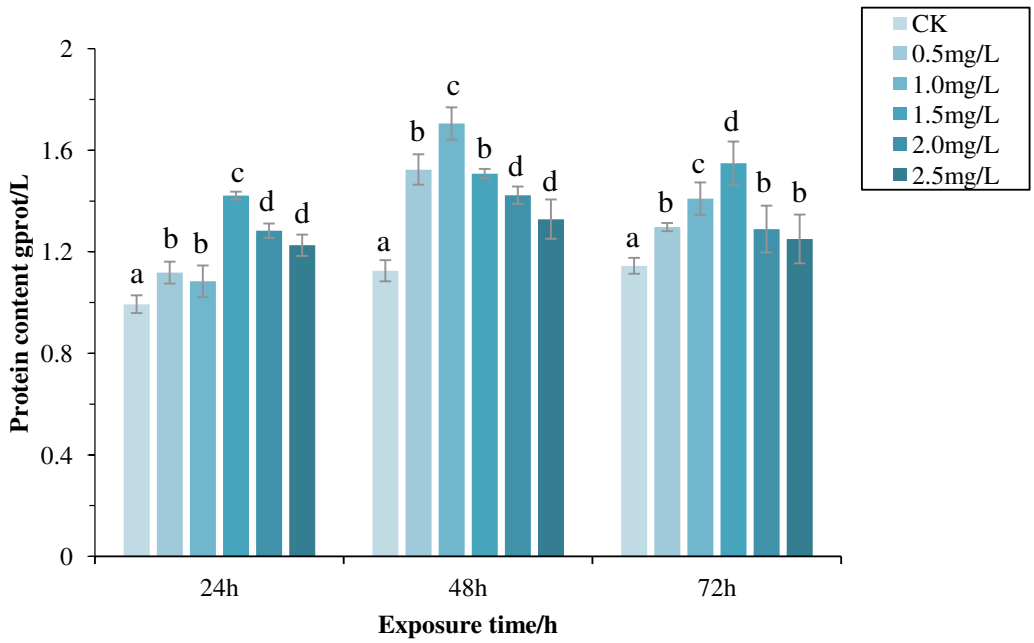

Figure 2. *Effect of cartap with different concentrations on protein contents of earthworm after single exposure 24, 48 and 72 h. Different lowercase letters indicate significant differences between treatments, as revealed by one-way ANOVA with Duncan's multiple-range test at* $p < 0.05$

Earthworms were treated with Cr^{6+} solution of 1, 2, 3, 4 and 5 $mg \cdot L^{-1}$, and earthworms were collected at 24, 48 and 72 h for protein content determination. The results are shown in *Figure 2*.

As can be seen from *Figure 3,* the protein content of blank treated earthworms decreased slightly with the exposure time and was lower than that of Cr^{6+} infected earthworms, which may be related to the stress protein produced by the body stress response of earthworms after being poisoned. When the exposure time was 24 h, with the increase of Cr^{6+} concentration, the protein content of earthworms presented an increasing trend, indicating that earthworms produced more stress proteins in the short term, which led to the increase of protein content in the body. When the exposure time was 48 h, the content of earthworm in vivo was first decreased, then increased and then decreased. When the Cr^{6+} concentration was 4 $mg \cdot L^{-1}$, the maximum value was 1.52 gprot/L, which was 1.30 times higher than that of the blank group. At 72 h of exposure, the change trend of protein content first decreased and then increased to a stable level, and it was lower than the blank value when the Cr^{6+} concentration was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1331113327

3 $mg \cdot L^{-1}$, which may be due to the fact that with the extension of exposure time, earthworms were stressed and the absorption of digestive tract cells was destroyed (Sun et al, 2011). This leads to decreased protein content.

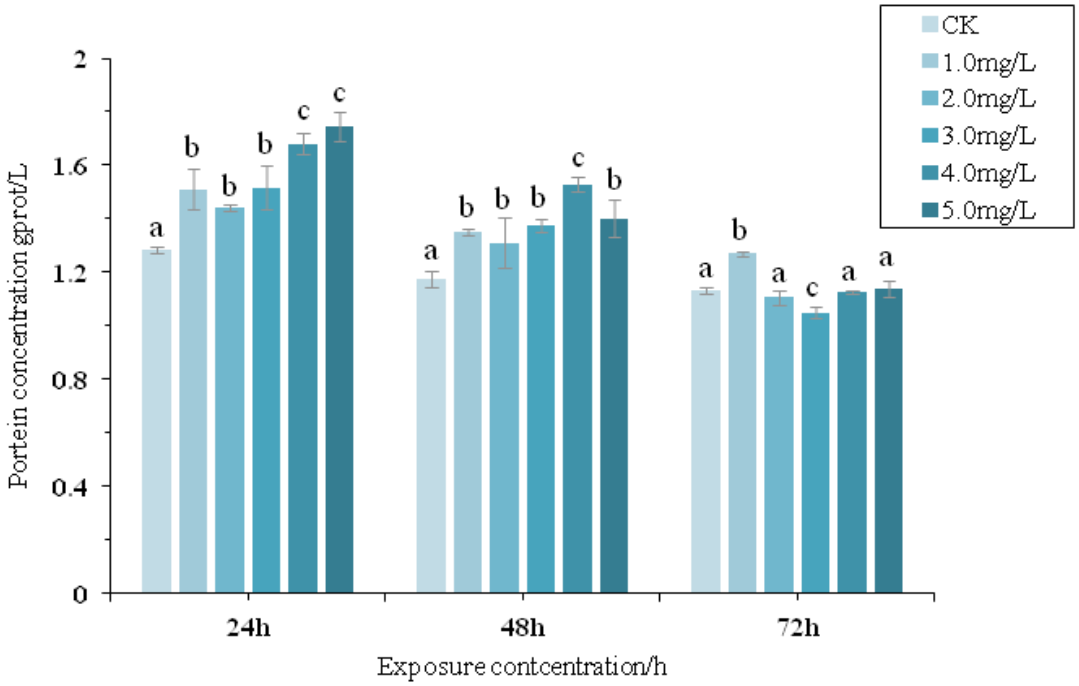

Figure 3. *Effect of Cr^{6+} with different concentrations on protein contents of earthworm. Different lowercase letters indicate significant differences between treatments, as revealed by one-way ANOVA with Duncan's multiple-range test at $p < 0.05$*

Effect of pyroridin and Cr^{6+} on SOD content in earthworms

The experiment set up five treatment groups of 0.5, 1.0, 1.5, 2.0 and 2.5 $mg \cdot L^{-1}$. Earthworm samples were collected for pretreatment at 24 h, 48 h and 72 h, respectively, to determine the content of SOD in vivo.

It can be seen from *Figure 4* that the SOD activity of earthworms infected with chlorpyrifos at different concentrations showed different trends in different poisoning time. SOD activity first decreased and then increased at 24 h after poisoning, then increased at 48 h and then decreased at 72 h after poisoning. Exposure time of 24 h, the low concentration of chlorpyrifos examination in the SOD activity of SOD vitality is higher than the blank group, were higher than that of blank control group 10.93%, 3.02%, 2.06%, 5.51% and 19.04%, obviously when the concentration of 1.5 $mg \cdot L^{-1}$ basic comparative with the SOD vitality of blank control group, with the increase of concentration, the higher SOD vigor, chlorpyrifos is mainly applied to earthworms in the stomach, in the early infected by epidermal cells after absorption, the body's antioxidant defense response, SOD activity was induced. Infected time 48 h, chlorpyrifos role in earthworms in the stomach, earthworms affects the body metabolism, inhibit SOD activity, lower overall than 24 h, and SOD activity in vivo in contrast to the 24 h trends, the concentration of 2.0 $mg \cdot L^{-1}$, reach the maximum, then the SOD activity decreased, but speculation is that as the extension of exposure time, SOD is consumed, and enzyme activity reduced. Exposure time of 72 h, the earthworm

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1331113327

body total SOD vigor decreasing trends, and much lower than the blank control group, who is probably the most prolonged and the increase of concentration, SOD activity significantly reduced, because the earthworm when suffer less stress, increased the amount of oxygen free radical, in order to remove excess oxygen free radicals and reduce the membrane lipid peroxidation, induction of SOD content increases, the stress levels increase, the body is not enough to resist oxidation, severely damage, enzyme activity is also reduced (Xue and Pei, 2000).

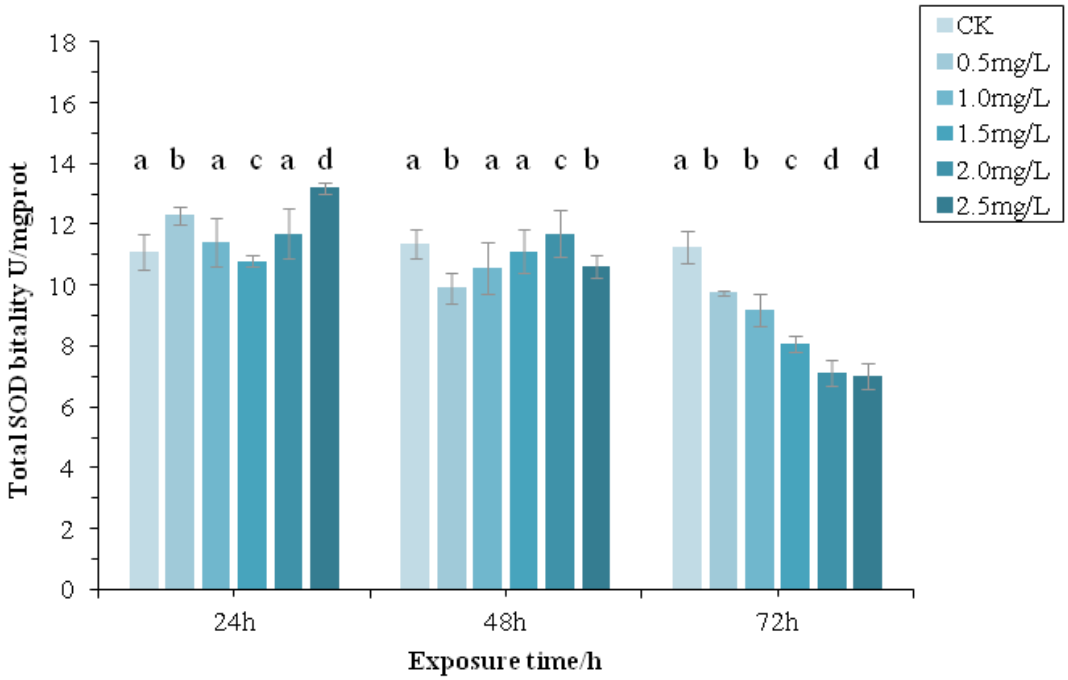

Figure 4. *Effect of cartap with different concentrations on SOD activity of earthworm after single exposure 24, 48 and 72 h. Different lowercase letters indicate significant differences between treatments, as revealed by one-way ANOVA with Duncan's multiple-range test at* $p < 0.05$

In the experiment, Cr^{6+} was set as the concentration of 1.0, 2.0, 3.0, 4.0 and 5.0 mg·L^{-1}. Earthworm samples were collected for pretreatment at 24 h, 48 h and 72 h, respectively, to determine the content of superoxide dismutase (SOD) in vivo.

By *Figure 5,* exposed to the Cr^{6+}, earthworms + pollution, the SOD activity in the body as the canister to the extension of time is reduced, the highest SOD activity in 24 h, may be due to the superoxide dismutase (SOD) is the first line of organism to resist oxidation, so under pollution stress the body to make quick oxidation reaction, induction of enhanced SOD activity, remove excess oxygen free radicals, avoid lipid oxidation reaction. Infected when the time for 24 h, according to the processing of SOD activity were blank control group 145%, 156%, 174%, 148% and 133%, with the increase of concentration of Cr^{6+} processing in earthworm body SOD activity showed a trend of lower after the first rise, the maximum SOD activity was in Cr^{6+} concentration of 3.0 mg·L^{-1}, compared with the blank control group, SOD activity increased by 74.12%. SOD activity decreased at 72 h after exposure compared with that at 24 h and 48 h after exposure, which may be because earthworms were severely affected by Cr^{6+}

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1331113327

stress, the body was seriously damaged, and SOD activity decreased. The above results showed that Cr^{6+} pollution could significantly induce SOD activity in earthworms at the early stage of infection. When the exposure time was more than 48 h, the SOD activity in earthworms decreased significantly. Under the stress of heavy metal pollution, earthworms produce a large number of oxygen free radicals in the body. In order to reduce the damage caused by oxygen free radicals to themselves, antioxidant enzyme activity increases. However, with the extension of the exposure time, the body is seriously damaged, and various internal balances are broken, and enzymes are gradually consumed to maintain the steady state, thereby reducing the SOD activity.

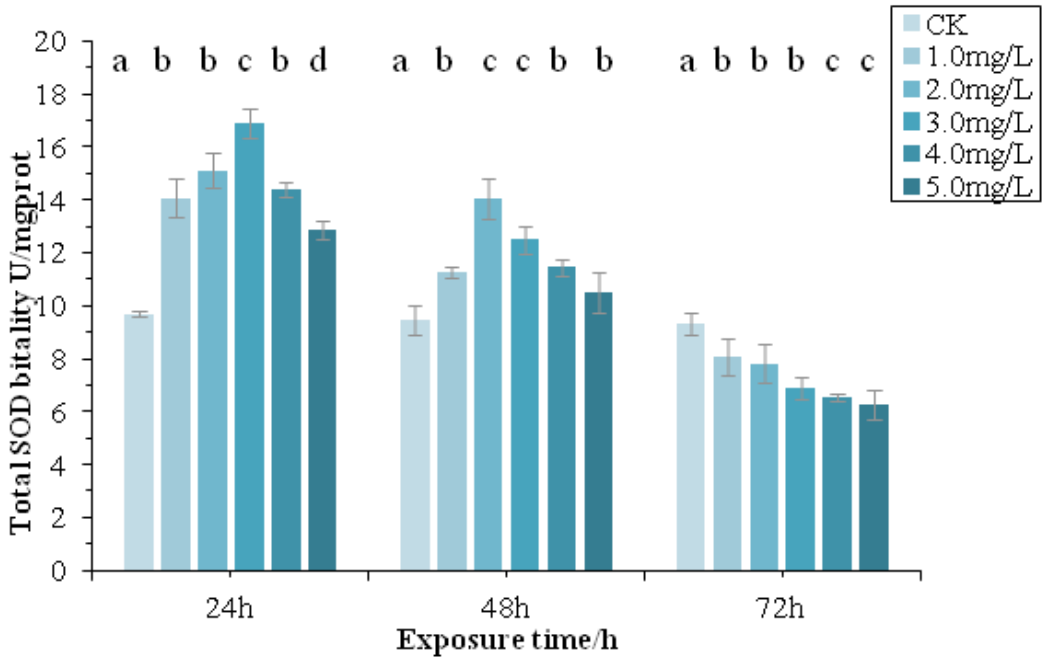

Figure 5. *Effect of Cr^{6+} with different concentrations on SOD activity of earthworm after single exposure 24, 48 and 72 h. Different lowercase letters indicate significant differences between treatments, as revealed by one-way ANOVA with Duncan's multiple-range test at $p < 0.05$*

Effect of pyroridin, Cr^{6+} and Pb on the content of CAT in earthworms

CAT as a biological enzyme systems is an important antioxidant defensive function, existence of red blood cells in most organisms, and some cells of oxygen in the body, usually with the GSH-Px synergy, the product of the free radicals SOD disproportionation H_2O_2 into harmless H_2O and O_2, eliminate free radical and lipid peroxide formation, pollutants stress can lead to the active content changes, so the test in earthworm body of CAT as a biomarker research.

The experiment set up five treatment groups of 0.5, 1.0, 1.5, 2.0 and 2.5 $mg \cdot L^{-1}$. Earthworm samples were collected for pretreatment at 24 h, 48 h and 72 h, respectively, to determine the catalase (CAT) content in vivo.

From *Figure 6,* you can see that when infected 24 h, the earthworm treated by chlorpyrifos induced rapidly rising, the CAT activity was obviously in the kill moth when chlorpyrifos is 0.5 $mg \cdot L^{-1}$ peak, with the increase of chlorpyrifos concentration, the CAT inside its body content is on the decline, probably because with the increased

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1331113327

concentration of cells in the body chlorpyrifos, nature is the CAT activity. When infected time for 48 h, earthworm body CAT activity increased with the increase of concentration of chlorpyrifos was reduced after the first rise trend, when chlorpyrifos is 2.0 mg · L $^{-1}$ peak, compared with 24 h, slash, CAT content decrease respectively 52.18%, 46.51%, 41.24%, 46.51% and 41.24%, may be due to the early infected cells absorb less chlorpyrifos, vicarious induced the CAT activity increased, with the extension of time, the activity of CAT back to normal levels. CAT activity increased first and then decreased with the increase of pyrrolidan concentration at 72 h, and reached the maximum when pyrrolidan concentration was 1 mg·L^{-1}. Compared with 48 h, CAT activity was more stable, which may be due to the adaptive reaction of earthworms to pyrrolidan, and the enzyme activity reached a stable state.

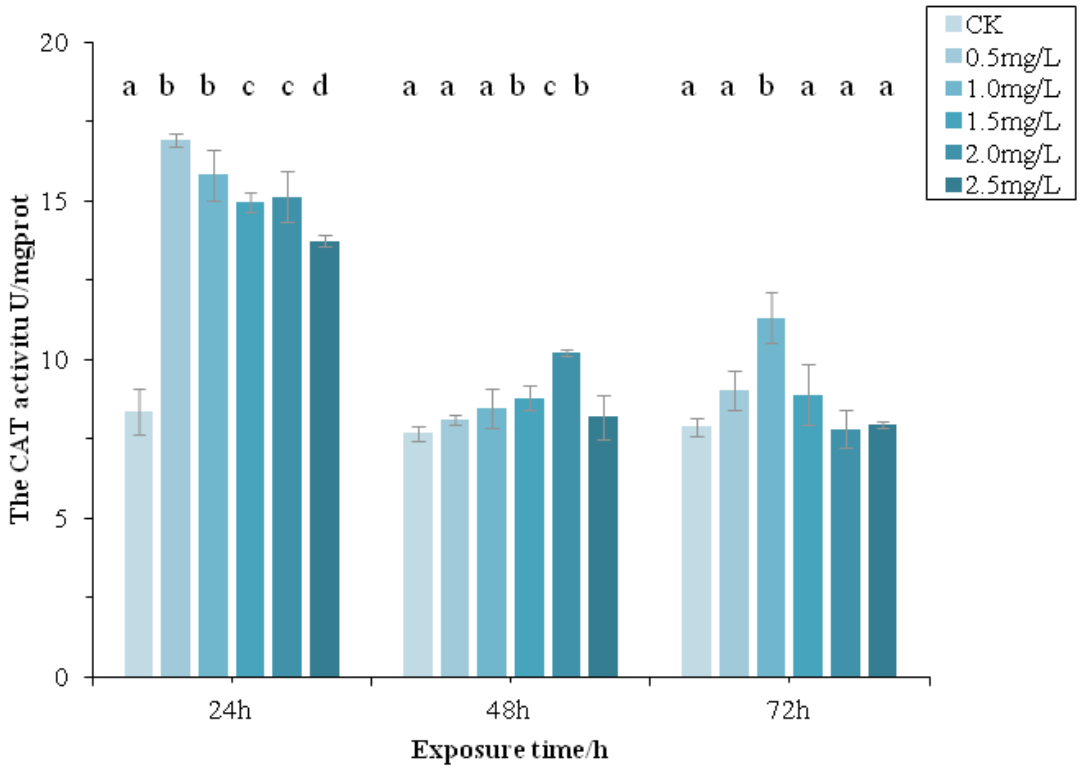

Figure 6. *Effect of cartap with different concentrations on CAT activity of earthworm after single exposure 24, 48 and 72 h. Different lowercase letters indicate significant differences between treatments, as revealed by one-way ANOVA with Duncan's multiple-range test at* $p < 0.05$

In the experiment, Cr^{6+} was set as the concentration of 1.0, 2.0, 3.0, 4.0 and 5.0 mg· l-^{1}. Earthworm samples were collected for pretreatment at 24 h, 48 h and 72 h, respectively, and the CAT content in vivo was determined, as shown in *Figure 7.*

By *Figure 7* you can see that when infected time for 24 h, the earthworm body CAT activity of Cr^{6+} treatment was obviously higher than that of blank control group, obviously with the increase of concentration of Cr^{6+} CAT activity is "S" shape change, Cr^{6+} concentration of 2 mg·L^{-1} peak, is at the beginning of the canister, the earthworm intimidation, induction of SOD and CAT activity, CAT is mainly used to produce the H_2O_2, consumption of SOD with elevated Cr^{6+} concentration, the cell absorption Cr^{6+}

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1331113327

increase, SOD activity continues to strengthen, to produce a large amount of H_2O_2, The activity of CAT was inhibited. With the increase of concentration, SOD activity decreased and CAT activity recovered. When the time of exposure was 48 h, the time of exposure was prolonged and the stress of the body was enhanced. The CAT activity of earthworms in each group was increased to reduce the oxidative damage of the body, and the change trend was first increased and then decreased. The maximum CAT activity also appeared when the Cr^{6+} concentration was $2mg \cdot L^{-1}$. When the time of exposure was 72 h, the change trend was similar to that of 48 h, and the overall decrease was relatively small compared with that of 48 h. With the extension of exposure time, the CAT activity of earthworm in the blank control group was relatively stable without obvious fluctuation. The exposure time of the group treated with Cr^{6+} at different concentrations was basically inverted u-shaped at 24 h, 48 h and 72 h.

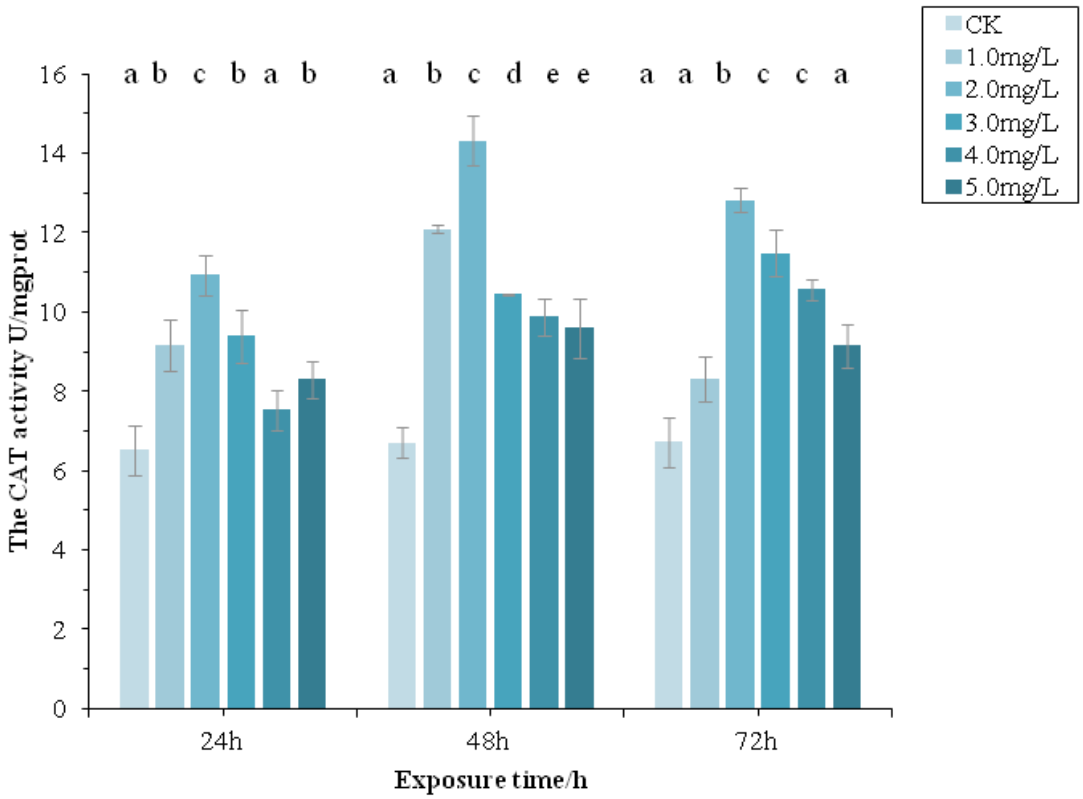

Figure 7. *Effect of Cr^{6+} with different concentrations on CAT activity of earthworm after single exposure 24, 48 and 72 h. Different lowercase letters indicate significant differences between treatments, as revealed by one-way ANOVA with Duncan's multiple-range test at $p < 0.05$*

Effects of chlorpyrifos and Cr^{6+} on MDA content in earthworms

Earthworm under environmental stresses can produce ROS metabolism, the body through a series of antioxidant way to eliminate, when the degree of oxidation than compensatory ability to eliminate the oxidation and anti-oxidation system will lose the original balance appear oxidative stress response, at this point, the antioxidant enzyme system (SOD, CAT, POD, GSH-Px) such as enzyme activity, enhance antioxidant capacity. Malondialdehyde (MDA) is an excess ROS oxidative lipid product that

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1331113327

directly reflects the degree of peroxidative injury. Therefore, malondialdehyde (MDA) in earthworm was used as an important indicator of peroxidation level in organism.

1. Effect of pyrrolidan on MDA content in earthworms

In the experiment, pyroridin was set as 0.5, 1.0, 1.5, 2.0 and 2.5 $mg \cdot L^{-1}$ concentrations. Earthworm samples were collected for pretreatment at 24 h, 48 h and 72 h respectively, and malondialdehyde (MDA) content in vivo was determined. The results were shown in *Figure 8*.

By *Figure 8* can be concluded that chlorpyrifos infected by different concentration of earthworms in infected time after 24 h, 48 h, 72 h, the overall trend of decrease the MDA content in the body, speculated that this phenomenon is because at the beginning of the virus, worm surface stress by chlorpyrifos, antioxidant defense system is not fully, the body by oxidative damage, leading to lipid oxidation product MDA content rise rapidly, as the antioxidant defense system open, all kinds of antioxidant enzyme activity, eliminates the excessive oxygen free radicals, reduce MDA content.

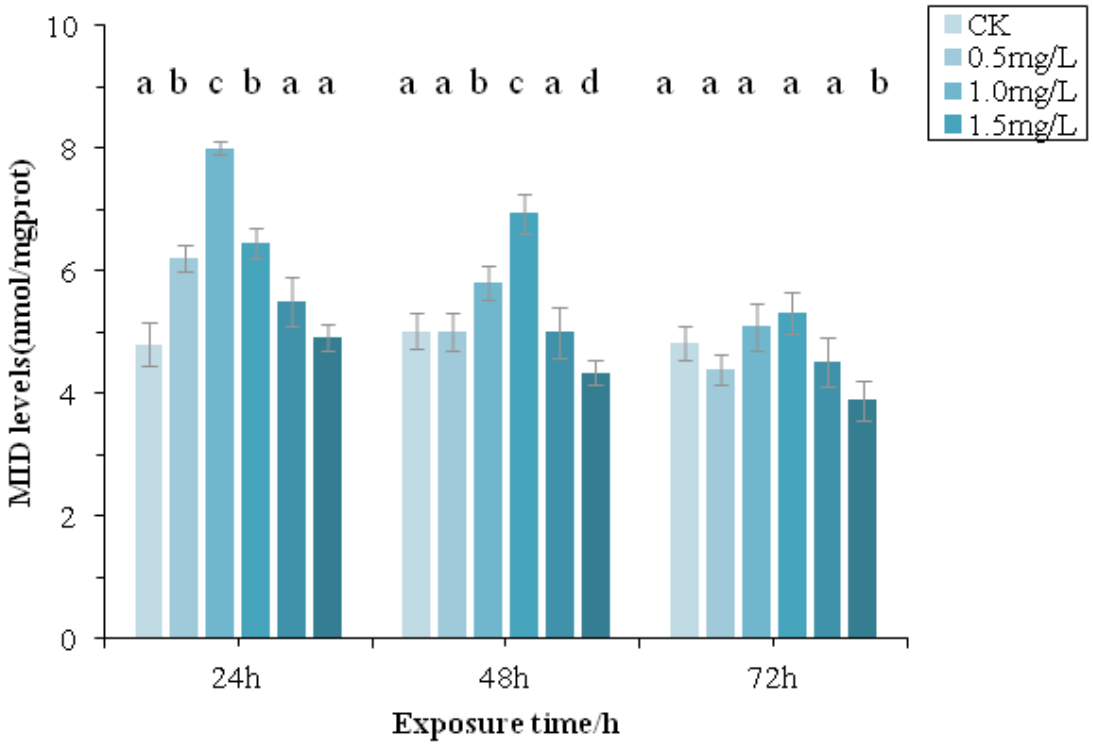

Figure 8. *Effect of cartap with different concentrations on MDA content of earthworm after single exposure 24, 48 and 72 h. Different lowercase letters indicate significant differences between treatments, as revealed by one-way ANOVA with Duncan's multiple-range test at* $p < 0.05$

2. Effects of Cr^{6+} on MDA content in earthworms

In the experiment, Cr^{6+} was set as the concentration of 1.0, 2.0, 3.0, 4.0 and 5.0 $mg \cdot L^{-1}$. Earthworm samples were collected for pretreatment at 24 h, 48 h and 72 h respectively, and malondialdehyde (MDA) content in vivo was determined, as shown in *Figure 9*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1331113327

It can be concluded from *Figure 8* that the content of malondialdehyde (MDA) in earthworms with different concentrations of Cr^{6+} varied in different poisoning time ranges after single exposure. Chlorpyrifos infected by different concentration of earthworms in infected time after 24 h, the MDA content in the body as a whole was reduced after the first rise trend, but with the blank control group, MDA content was not significantly change, is due to the earthworm itself is Cr^{6+} stress and oxidative stress response, antioxidant system effectively resist Cr^{6+} oxidative damage to the body. Infected time 72 h, with the canister to the extension of time, the earthworm body by oxidative damage degree aggravating, increased MDA content accumulation in the body, a trend of reducing the rise on the whole, were higher than the blank control group 48.23%, 69.88%, 77.12%, 47.23% and 43.21%, in Cr^{6+} concentration of 3.0 $mg \cdot L^{-1}$ MDA content is the highest, while the concentration of earthworms body oxidative damage is the most serious.

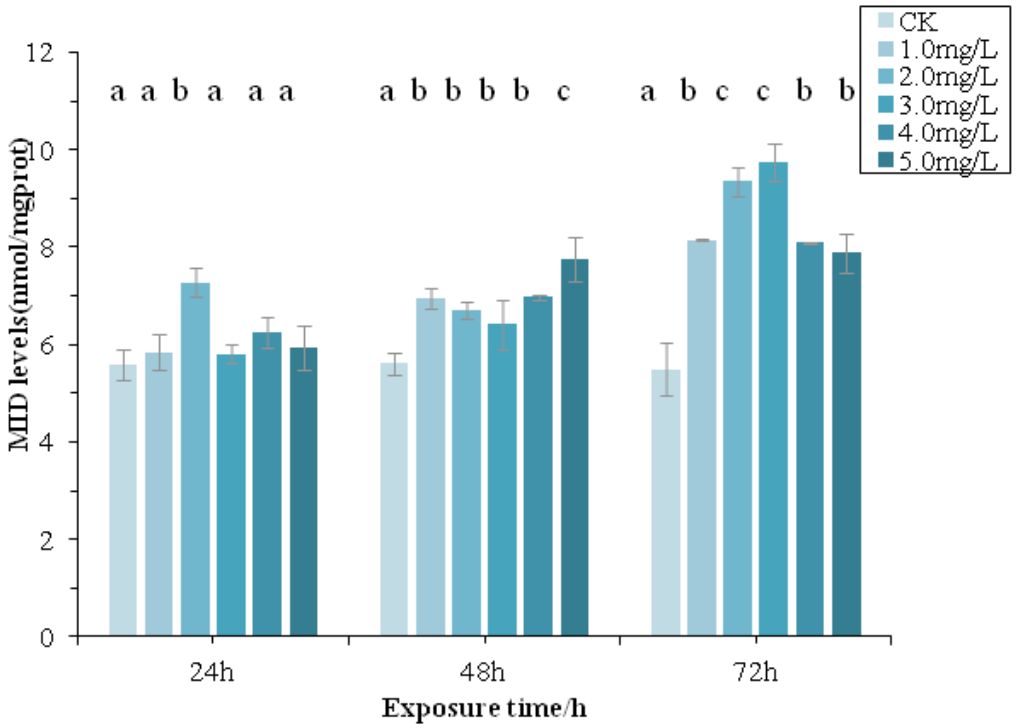

Figure 9. *Effect of Cr^{6+} with different concentrations on MDA content of earthworm after single exposure 24, 48 and 72 h. Different lowercase letters indicate significant differences between treatments, as revealed by one-way ANOVA with Duncan's multiple-range test at $p < 0.05$*

Discussion

Test to select chlorpyrifos, Cr^{6+} to the single toxicity test of earthworm, record the different influence on earthworm mortality after a single drug, and calculate the chlorpyrifos, Cr^{6+} in 24 h, 48 h and 72 h exposure when single LC_{50} value of earthworms, after two or three kinds of drug toxicity of earthworms size order: chlorpyrifos > Cr^{6+}, and with the extension of exposure time and enhance the toxic. Select chlorpyrifos, Cr^{6+} to the single toxicity test of earthworm, record the different influence on earthworm mortality after a single drug, and calculate the chlorpyrifos, Cr^{6+} in 24 h, 48 h and 72 h exposure when single LC_{50} value of earthworms, after two or

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1331113327

three kinds of drug toxicity of earthworms size order: chlorpyrifos > Cr^{6+}, and with the extension of exposure time

Total protein content reflects the sum of all types of enzymatic and non-enzymatic cellular proteins. When the chlorpyrifos single action, the earthworm body protein changes have the regularity, as the chlorpyrifos concentration increases the protein content first increases then decreases, as the time of infection extends the protein content first increases after tends to be stable. SOD in earthworms is sometimes induced and a dynamic balance is maintained to meet the needs of organisms to eliminate O^{2-} but the balance can be easily disrupted by the stress of pollutants (Ma et al., 2017). SOD activity in vivo was induced in a short period of time with low concentration, and decreased with the extension of the exposure time. The CAT activity of earthworm decreased with the increase of pyrrolidine concentration and decreased with the extension of time. MDA is the product of lipid peroxidation and has been used to assess oxidative stress in earthworms (Xue et al., 2009). The content of MDA in earthworms is regular. With the increase of the concentration of pyroridin, the content of MDA increases first and then decreases. With the extension of the poisoning time, the content of MDA decreases, possibly because the body is less damaged by oxidation. When Cr^{6+} acted alone, the protein content of earthworm decreased first and then increased with the increase of Cr^{6+} concentration, and the protein content of earthworm showed a trend of decrease with the extension of the duration of infection.

After single action of Cr^{6+}, the activity of SOD in earthworms first increased and then decreased, and the activity decreased with the extension of the poisoning time. CAT activity in vivo increased first and then decreased with the increase of Cr^{6+} concentration, and increased with the extension of exposure time. There was no obvious rule between the change of MDA content and the concentration of Cr^{6+} in vivo. As a whole, MDA content increased with the extension of the exposure time, indicating that the body was aggravated by oxidative damage.

Generally, single toxicity test of chlorpyrifos and Cr^{6+} on earthworms was carried out, and the effect of different drugs on the mortality of earthworms was recorded. Similar result was also reported before (Oliveira et al., 2018). The order of toxicity of two drugs on earthworms was obtained: chlorpyrifos > Cr^{6+}, and the toxicity increased with the extension of exposure time.

Potential synergistic effects of chemicals interactions were highlighted recently because of existence of complicated synergistic and antagonistic responses, which might cause serious ecological problems (Yang et al., 2017). Here, joint effects of chlorpyrifos and Cr^{6+} on earthworms were studied. The changes of SOD activity, CAT activity and MDA content in earthworms infected with chlorpyrifos and Cr^{6+} at sublethal dose were significant ($p < 0.05$). The results showed that when the body was under the stress of pollutants, the first antioxidant defense was activated, and the activity of SOD in the body was rapidly induced to remove excessive oxygen radicals in the body and generate H_2O_2 (Ma et al., 2017). Subsequently, the activity of CAT was enhanced and H_2O_2 was converted into H_2O. With the extension of poisoning time, SOD activity decreased and MDA content increased, indicating that the degree of oxidative damage to the body increased. Therefore, both SOD activity and MDA content can be used as indicators for earthworms to cope with oxidative stress and the degree of oxidative damage to the body.

Conclusion

In conclusion, distinctive toxicity effects on Eisenia fetida under different chlorpyrifos and Cr^{6+} stress levels were generally indicated by levels of enzyme activity/content impact, in terms of protein content, SOD, CAT and MDA activities. Generally, enzyme activity of Eisenia fetida may be sensitive indicators of chemical stress. However, in order to appropriately assess the ecological risk, more studies should be focused on long-term effects of chemical mixtures at different concentrations on earthworms.

Abstract. In order to ascertain the status quo and variation trend of arsenic pollution in Yangzonghai Lake, China, the water samples of Yangzonghai Lake, sediment and interstitial water were collected and the total amount and morphological composition of arsenic were determined. The spatial distribution of arsenic was analyzed and the variation trends of arsenic pollution was evaluated. The results showed that the arsenic content of lake water in December 2016 was between 0.029-0.036 mg/L. The arsenic content in interstitial water is generally lower than 0.005 mg/L. The average content of arsenic in 0-2, 2-4, 4-6, 6-8 cm sediments are 50.5 mg/kg, 40.1 mg/kg, 33.6 mg/kg and 32.5 mg/kg, respectively. The high arsenic area is mainly distributed in the north and south shores, and gradually decreases from the coastal areas to the lake center. As the depth increases, arsenic content in the sediment gradually decreases. The arsenic in the sediment is still mainly in residual fraction, followed by organic fraction and oxide fraction. With the passage of time, the arsenic in the sediment gradually transforms from oxide fraction and organic fraction to residual fraction. The release of arsenic in the sediment is limited and the ecological risk is minimal.
Keywords: *arsenic, morphology, interstitial water, sediment, variation trend*

Introduction

Arsenic is a serious pollutant with potentially harmful effects (Huang et al., 2018; Zhang et al., 2015). Due to its recalcitrance, strong biotoxicity, bioaccumulation and biomagnification effect, arsenic contamination has been attracting much attention (Barrett et al., 2019; Jakobsen et al., 2018; Romero-Freire et al., 2014). In 2008, a serious arsenic pollution incident occurred in Yangzonghai Lake, one of the nine highland lakes in Yunnan Province. From April to October 2008, the arsenic content of Yangzonghai Lake rose sharply from 5 $\mu g \cdot L^{-1}$ to 134 $\mu g \cdot L^{-1}$ (Bi et al., 2014), and the water quality decreased from class II to inferior class V. According to the investigation, the source of arsenic pollution derived from a chemical plant on the hill in the southwest corner of the lake. The area belongs to karst landform area. The underground of the chemical plant area is carbonate rock and caves, and the karst is strongly developed. The high-arsenic wastewater discharged by the chemical plant in violation of regulations enters the karst zone through the soil, and then enters the lake from the spring formed by the fracture of the karst zone. The pollution incident has brought a huge impact on the production and life of the surrounding residents, directly threatening drinking water safety of more than 20,000 people around, causing inconvenience to irrigation of crops around the lake. The livelihood of hundreds of fishermen on both

DOI: http://dx.doi.org/10.15666/aeer/1706_1332913340

sides of the river is worrying, and the surrounding tourism and holiday industry is also suffering from heavy losses, so it has aroused widespread concern in society (Wang et al., 2011). The team of Academician Chen Jing of Yunnan University has carried out arsenic pollution control in Yangzonghai Lake since 2009 (Chen et al., 2015) by adopting the process of atomization spray of $FeCl_3$ solution to remove arsenic from lake water. According to reports, the water quality of Yangzonghai Lake has been restored to Class III in November 2016. However, up to now, there is yet no detailed report on the status and variation trends of arsenic content in lakes and sediments after the treatment, and the stability of arsenic in sediments needs further investigation. Based on this, the author conducted systematic sampling and analysis of Yangzonghai Lake water and sediments in December 2016, found out the total amount and morphological composition of arsenic in lake water and sediment, and analyzed spatial distribution of arsenic in water bodies, sediments and sediment interstitial waters. Combining the sample analysis of 2008-2010 (Zhang et al., 2012), the variation trend and risk of arsenic were evaluated. This means important guiding significance for the further management of Yang Zonghai and the restoration of water environment.

Materials and methods

Study area

Yangzonghai lake (E102°59'-103°02', N24°51'-24°58') belongs to the Nanpanjiang water system of the Pearl River Basin. The lake surface is spindle-shaped, 2.5 km wide from east to west, 12.7 km long from north to south, and 32.3 km long on the lakeshore. The drainage area is 286 km^2, the lake area is 31.9 km^2 (at water level 1770 m), the deepest point is 29.1 m, the water storage capacity is 604 million m^3, and the water exchange period is 13 years (Chen, 2008). The nourishment source mainly comes from natural rainfall, Yangzong Great River and Qixing River catchment, artificial water of Baiyi River and underground water. The lake water flows into Nanpan River through the only outlet, Tangchi River.

Sampling and analysis

In December 2016, systematic sampling of lake water and sediment was carried out, as shown in *Figure 1* and *Table 1*. A total of 19 water samples were taken and 120 groups of sediment samples were collected. In order to analyze the arsenic content in the lake water, 7 sampling points were arranged along the north-south axis of the lake center, and the sampling numbers were S01-S07. Using the "MEGA-MONSOON sampling pump" produced in the United States, water samples of 0.5, 10 m depth were collected at S01 and S07, water samples of 0.5, 10, and 20 m depth were collected at S02-S06. The samples were stored in a 250 ml plastic bottle and a total of 19 samples were taken. To analyze the content and morphological characteristics of arsenic in the sediment, an average of 30 sampling points were arranged in the lake. Sample collection and stratification were performed using the "LENZ type sediment sampler" produced by HYDRO-BIOS, Germany. For each sampling point, 1-layer sample was taken from the top to the bottom at 2 cm intervals and 4 layers were taken. The samples were placed in a plastic ziplock bag and sealed for preservation, and 120 groups of samples were taken.

After the water samples were collected, the "Hash multi-parameter field test box" was used to quickly measure the indicators like pH value, conductivity, dissolved

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1332913340

oxygen on the site; the collected water sample was filtered by a 0.45 μm disposable pinhole filter, added with 1% volume of HNO_3 with a concentration of 1:1 for total arsenic analysis. The samples were sent to the Guangdong Province Material Testing Center for testing. After the sediment samples were collected, they were divided into 2 parts, one of which was dried in shade in the laboratory, removed with animal and plant residues and stones, ground, screened through a 200 mesh nylon sieve, and analyzed for arsenic and its seven binding fraction (including water soluble fraction, ion exchange fraction, carbonate fraction, oxide fraction, humic acids fraction, strong organic fraction, residual fraction) (Liu et al., 2018); for the other one, interstitial water was prepared using "centrifugation method", and the sample was placed in a plastic centrifuge cup, centrifuged at 5000 r/min for 20 min, with upper layer interstitial water taken for analysis of indicators like total arsenic. The test of sediment and interstitial water was completed by Guangdong Province Material Testing Center.

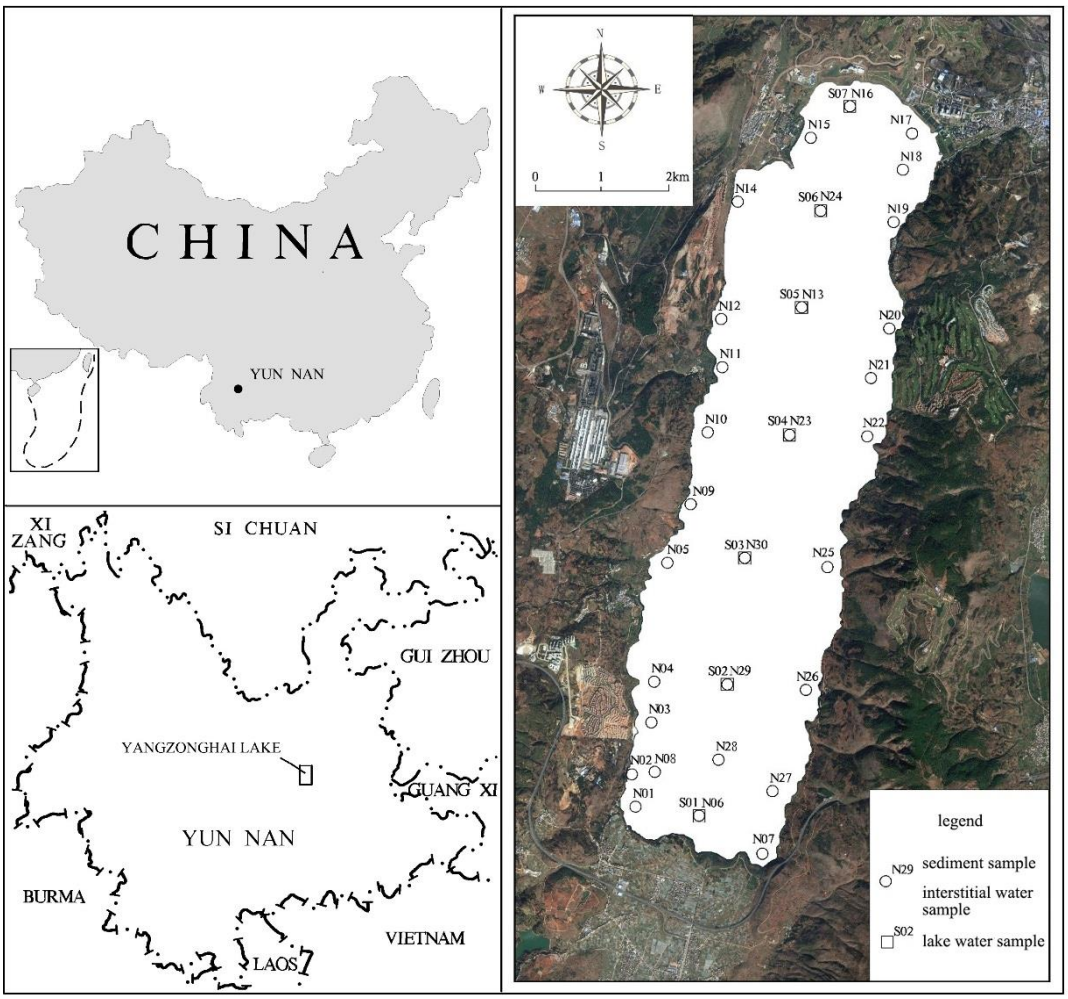

Figure 1. *Sampling points*

The descriptive statistical parameters were calculated with Microsoft Office Excel 2016. The positions of sample locations were recorded as a coordinate system using a GPS receiver. The kriging interpolations of the contaminant concentrations were computed with the MapGIS 6.7.

Results and analysis

Arsenic in lake water

The pH value of the lake water is between 7.95-9.01, with an average of 8.69, which is alkaline. There is no obvious regularity in the horizontal distribution. In the vertical distribution, the pH value decreases slightly as the water depth increases. The conductivity is between 442-524 μS/cm, the average value is 463 μS/cm, with relatively uniform distribution vertically. The dissolved oxygen is between 5.91-6.12 mg/L, with an average value of 6.07 mg/L, which decreases slightly as water depth increases. The results of the 2010 survey showed that the average pH value of the lake water was 8.66, which also decreased slightly with the increase of water depth; the average conductivity was 456 μS/cm, and the distribution was relatively uniform. It can be seen that in recent years, regardless of content or distribution characteristics, field indicator characteristics of the lake water show no significant changes and the overall characteristics of the lake water environment is relatively stable.

According to the results of this survey, the dissolved arsenic content in Yangzonghai Lake water ranges from 0.029 to 0.036 mg/L, with an average of 0.033 mg/L. According to the Surface Water Environmental Quality Standard (GB 3838-2002), it belongs to Class III water. In the vertical distribution, the arsenic content does not change much, but the arsenic content at the depth of 10 m is slightly higher than that of 0.5 m in the surface layer and 20 m in the bottom layer. The arsenic content at the depth of 10 m is more concentrated than that of 0.5 m and 20 m, and the distribution difference is relatively small. In the horizontal distribution, from south to north, the arsenic content in each lake depth is basically reduced gradually. Among them, the maximum difference of arsenic content in the depth of 0.5 m is 0.007 mg/L, the maximum difference of arsenic content in the depth of 10 m is 0.003 mg/L, and the maximum difference of arsenic content in the depth of 20 m is 0.005 mg/L, which also reflects that in the horizontal distribution, surface lake water and bottom lake water

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1332913340

have relatively obvious distribution differences, and the arsenic content of lake water is stable at 10 m depth.

Previous studies have shown that the As content in the lake water in October 2008 ranged from 0.130 to 0.190 mg/L (Qi et al., 2010). By September 2009, the average content of As in lake water and sediment was 0.161 mg/L (Wang et al., 2011). By April 2010, the total As content in Yangzonghai water was 0.083 mg/L (Zhang et al., 2012). It can be seen that the arsenic content of Yangzonghai Lake reached a peak value in 2009 and gradually decreased thereafter. As of 2016, the arsenic content of lake water decreased to an average of 0.033 mg/L, a decrease of about 78%. In 2010, there was a significant difference in the vertical distribution of arsenic in the lake. The arsenic content in the lower layer was significantly higher than that in the upper layer. However, there was no significant difference in the arsenic content of the lake in the vertical direction. This is due to the fact that the sampling in 2010 was during the control of spraying agents. In the flocculation and sedimentation process, the sedimentation of the lower layer of water is later than that of the upper layer of water, or the sedimentation effect is reduced as the action progresses. In this investigation, after the sedimentation process ended, the lake water was evenly mixed, which caused the phenomenon.

Arsenic in interstitial water

The arsenic content in 0-2 cm sediment interstitial water is between 0.0004-0.0629 mg/L and the average value is 0.0082 mg/L. The arsenic content in the 2-4 cm sediment interstitial water is between 0.0006-0.0227 mg/L and the average value is 0.0042 mg/L. The arsenic content in 4-6 cm sediment interstitial water is between 0.0004-0.0222 mg/L and the average value is 0.0038 mg/L. The arsenic content in 6-8 cm sediment interstitial water is between 0.0002 and 0.0170 mg/L, and the average value is 0.0031 mg/L.

The arsenic content in interstitial water is generally low. Except for the surface interstitial water of the N18 point, the arsenic content is less than 0.05 mg/L in all the samples, and the arsenic content of most samples is less than 0.005 mg/L. As the depth increases, the average arsenic content decreases sharply. The arsenic content in the 0-2 cm layer is nearly twice that of the 2-4 cm layer, while the average arsenic content in the three layers below 2 cm decreases, but the variation is small. In terms of the distribution ratio, the proportion of samples with arsenic content less than 0.005 mg/L gradually increases, and the proportion of other ranges gradually decreases. By 4-6 cm and 6-8 cm, the proportion of arsenic content in different ranges has become stable. Comparison of the interstitial water arsenic content in each sampling point reveals that the vertical distribution of arsenic generally decreases with the increase of sediment depth, but the local area is also more complicated. The arsenic content of 17 points increases linearly with depth, and that of 6 points shows fluctuation state of increasing first and then decreasing. The two accounts for 3/4 of the total number of samples. There are 6 points with wavelike rises, only arsenic at one point rises linearly, and the two accounts for about 1/4 of the number of samples, as shown in *Figure 2*.

In the 0-2 cm interstitial water, the relatively high arsenic area is concentrated in two areas. One is Tangchi Town and Shijiazui area on the north shore. The arsenic content of the four sampling points in this area, N15, N16, N17 and N18, is above 0.01 mg/L, and the number is the highest in point N18 (0.0629 mg/L). The other is located near the N30 point in the south of the lake center, where the relatively high arsenic distribution

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1332913340

is only caused by N30 (0.0219 mg/L), and the distribution range is small. Arsenic content in other areas is generally low, basically within 0.005 mg/L. In 2-4 cm pore water, the arsenic content is obviously lower than that of the upper layer, and the relatively high value points are concentrated in the north shore area. Here, the arsenic content of the four sampling points is still above 0.01 mg/L, and the highest value point is changed from N18 to N15 (0.0227 mg/L). However, high value area of the lake center has disappeared, the arsenic content in the whole lake area is basically less than 0.004 mg/L, and arsenic content in some areas is below 0.002 mg/L. In the 4-6 cm interstitial water, the relatively high value points are concentrated in two areas. One is still near the north shore, but the area with figure larger than 0.01 mg/L has been reduced. It is mainly concentrated around N15 and N18, and the highest value still appears in N15 (0.0222 mg/L). The other area appears in the 30-mu area of the West Bank, with a small distribution range concentrated around N11 point carrying arsenic content of 0.0154 mg/L. Except the two areas, the arsenic content in other areas is basically within 0.004 mg/L, and the area with a figure below 0.002 mg/L is further expanded. In the 6-8 cm interstitial water, the relatively high value points are concentrated only in the north shore area. The arsenic content of the three sampling points of N15, N16 and N18 is above 0.01 mg/L, and the highest value point is still N15 (0.0170 mg/L). The arsenic content of other areas drops to within 0.002 mg/L, as shown in *Figure 3*.

Arsenic in sediment

The determination of arsenic in the sediment shows that the arsenic content of the 0-2 cm sediment is between 16.2-230.0 mg/kg, with an average of 50.5 mg/kg and a coefficient of variation of 94%. The arsenic content in 2-4 cm sediment interstitial water is between 15.1-136.0 mg/kg, with an average of 40.1 mg/kg and a coefficient of variation of 76%. The arsenic content in 4-6 cm sediment interstitial water is between 11.7-96.4 mg/kg, with an average of 33.6 mg/kg and a coefficient of variation of 62%. The arsenic content in 6-8 cm sediment interstitial water is between 11.8-148.0 mg/kg, with an average of 32.5 mg/kg and a coefficient of variation of 79%. Samples with an arsenic content of less than 25 mg/kg are substantially uncontaminated, and the proportion of samples in each layer ranges from 37% to 60%, with the ratio from top to bottom significantly increased, as shown in *Figure 4*. The sample with arsenic content between 25-50 mg/kg is slightly polluted, and the proportion of samples in each layer is between 27% and 37%, with the proportion of 0-6 cm basically unchanged and that at 6-8 cm decreased to some extent. The samples with arsenic content between 50-100 mg/kg are moderately polluted, and the proportion of samples in each layer is between 10%-17%, showing wavelike decrease from top to bottom. The samples with arsenic content higher than 100 mg/kg is heavily polluted, and the proportion of samples in each layer is between 0%-10%, showing wavelike decrease of first decrease and then increase from top to bottom and the amplitude is big. It can be seen that as the sampling depth increases, arsenic content in the sediment gradually decreases on the whole, and the heavily polluted sediment is still mainly distributed in the surface layer.

Arsenic in the sediment has very obvious difference in horizontal distribution. The high arsenic area is mainly distributed in Tangeying, Xinjie of south shore and Sanying and Tangchi town of north shore. The arsenic content is generally above 50 mg/kg, and the arsenic content in the central area of the lake is relatively low. Generally, it is lower than 25 mg/kg, and characteristics of gradually spreading to the lake center along the

DOI: http://dx.doi.org/10.15666/aeer/1706_1332913340

pollution source on the shore are demonstrated in overall, and there is obvious pollution halo characteristic, as shown in *Figure 5*.

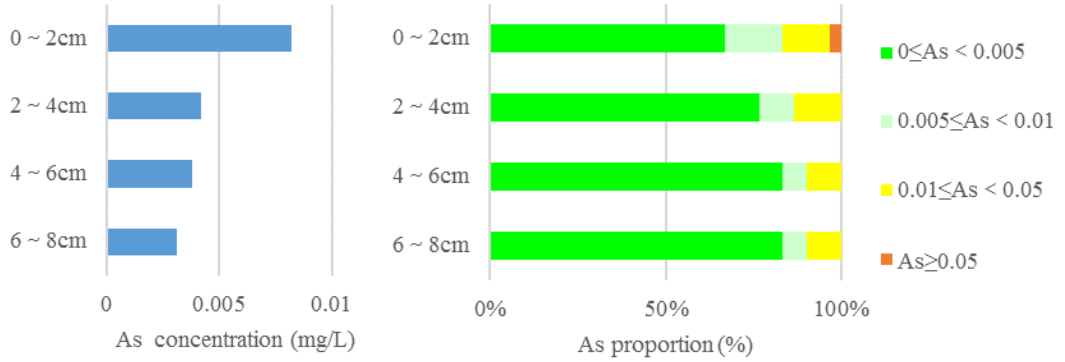

Figure 2. *Average content and proportion of arsenic in interstitial water*

DOI: http://dx.doi.org/10.15666/aeer/1706_1332913340

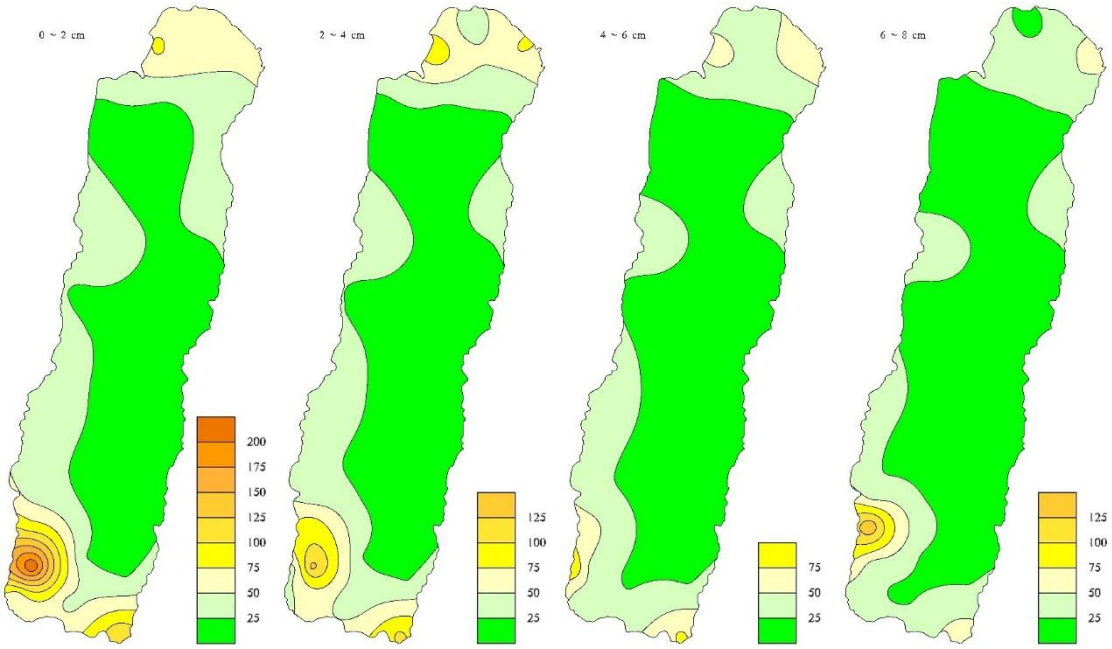

Figure 5. *Spatial distribution of arsenic content in sediments (mg/kg)*

Specifically, in the 0-2 cm sediment, the area with the highest arsenic content is located at N08, N02, N03 points near Tangeying and N07 point near Xinjie, and the arsenic content is 230 mg/kg and 164 mg/kg, 85.4 mg/kg and 121 mg/kg, respectively, followed by Tangchi Town of north shore where the arsenic content of N15, N16 and N17 points in the coastal areas is 77.9 mg/kg, 66.8 mg/kg and 74.3 mg/kg, respectively. In the 2-4 cm sediment, the high arsenic distribution area on both the north and south shores decreases to different extents. The arsenic content of N08 point in Tangeying is still the highest, being 136 mg/kg, followed by that of N07 point of Xinjie and the content is 104 mg/kg. The high arsenic area in north shore is reduced to the vicinity of Sanying N15 point and Tangchi N17 point, and the arsenic content is 92.9 mg/kg and 77.9 mg/kg, respectively. In the 4-6 cm sediment, the high arsenic zone is once again reduced and concentrated around Tangeying N02, Xinjie N07, Sanying N15 and Tangchi N17 points, with arsenic content being 96.4 mg/kg, 77.8 mg/kg, 62.9 mg/kg and 70.9 mg/kg, respectively. In the 6-8 cm sediment, the arsenic content in the vicinity of Tangeying increases, increasing to 148 mg/kg at N03 point, while area of other high arsenic zones continues to shrink, and the arsenic content in most of the lake area is maintained within 25 mg/kg.

Previous studies have shown that the arsenic content in the sediment at the end of October 2008 ranged from 54.86 to 193.29 mg/kg (Qi et al., 2010). By September 2009, the average content of arsenic in the sediment was 46.96 $mg \cdot kg^{-1}$ (Wang et al., 2011). The data in 2010 showed that the arsenic content in the sediment increased to 6.05-396.49 mg/kg, and the average content of As in the 0-2, 2-4, 4-6 and 6-8 cm sediments was 155.66. 52.01, 29.78, 19.22 mg/kg, respectively (Zhang et al., 2012). On the one hand, the arsenic content in the sediments of each layer in this sampling has dropped significantly, and the surface arsenic content has the largest decline, which is about 1/4 of the 2010 test data. Due to the implementation of arsenic treatment by sedimentation, the sedimentation process resulted in a higher arsenic content in the sediment at the end

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1332913340

of 2010. After 2014, the arsenic content of the sediment decreases quite obviously, and the arsenic content in the lake water does not rise, indicating that the arsenic in the sediment is less likely to be reversely dissolved into the lake water. On the other hand, the vertical distribution characteristics of the sediment are gradually complicated. At the end of 2010, the vertical distribution of sediment arsenic content decreased significantly with depth. The maximum value of arsenic appears in the surface sediment. Only the maximum arsenic content at 2 points appears in the lower sediment. The arsenic content of these two points is generally low, both lower than 20 mg/kg, and the difference in arsenic content between the layers is extremely small, which basically reflects the natural deposition state. In this sampling result, the maximum arsenic content of 11 points appears in the lower sediment, and the maximum arsenic content of 5 points appears in the 6-8 cm sediment.

The decrease in the total arsenic amount in the sediment and the abnormal distribution of arsenic in each layer found in this investigation may be caused by the following reasons: Affected by the arsenic removal and sedimentation process, as the arsenic content in the lake water decreases, the arsenic content in sedimentation particles is also reduced, then the low arsenic sediment covers the previous high arsenic sediment; The migration of sediment arsenic to the lower layer or surrounding sediment under the disturbance of lake water; Under the disturbance of the lake water, the sediment agitation phenomenon appears.

Arsenic exists in different binding states in the sediment and shows different mobility, bioavailability and ecotoxicity (Desbarats et al., 2017; Hossain et al., 2016). The mass fractions of water soluble fraction, ion exchange fraction and carbonate fraction are relatively low, and the sum of the three accounts for 0.55% of the total amount on average, and there is almost no change in the vertical distribution. Arsenic in water soluble fraction, ion exchange fraction and carbonate fraction is sensitive to environmental changes, which can be released under neutral conditions. Easy to migrate and transform, it can be absorbed by plants and carries high potential ecological risks (Zhou, 2017). The arsenic in oxide fraction accounts for 6.82% of the total amount on average, up to 27.20% at the highest, and the proportion decreases with increase of depth in the vertical distribution. This form is a wrapped or precipitated part of arsenic linked to iron-manganese oxide, which belongs to a strong ion bonding chemical form. It is not easily released under stable external conditions, but when the water body has a reduced redox potential or is in hypoxia, this bound arsenic may be reduced to a bioavailable state (Wang et al., 2015). The humic acid fraction and strong organic fraction are mainly chelated by organic matter such as animal and plant residues, humus and arsenic in the sediment. When the external conditions change little, the arsenic in this state is relatively stable, which has small environmental hazard. The sum of the two accounts for 8.97% on average, up to 23.25% at the highest, and the proportion also decreases with the increase of depth in the vertical distribution. The residual state is mainly present in the crystal lattice of primary minerals and secondary silicate minerals. It is very stable and does not participate in the rebalanced distribution of water-sediment systems (Huang et al., 2010, 2016a), which contributes little to migration and bioavailability of arsenic in sediments, so it is generally considered safe to the environment. The arsenic in the Yangzonghai sediment mainly exists in the form of residual fraction, with the average content accounting for 83.66% of the total, up to 93.79% at the highest, and the proportion increases with the increase of depth in the vertical distribution, as shown in *Figure 6*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1332913340

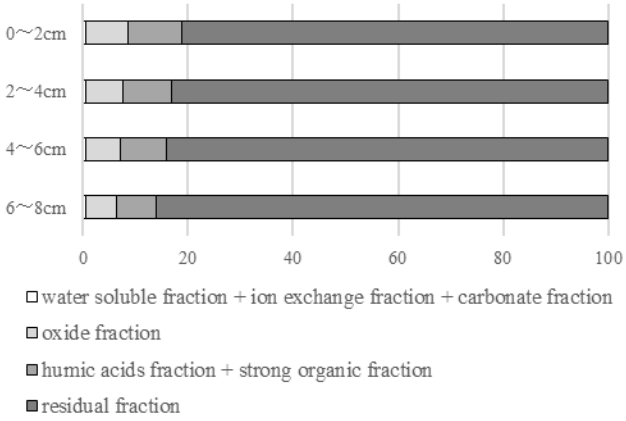

Figure 6. *Ratio of different fraction of arsenic in sediments (%)*

According to the study in 2010, the proportion of residual arsenic in the 0-2, 2-4, 4-6 and 6-8 cm sediments was 58%, 65%, 69% and 78%, respectively, which was increased to 81%, 83%, 84% and 86% respectively in this investigation. Meanwhile, content of arsenic in other forms decreased. It reflects that the form of arsenic in the sediment gradually changes to a more stable residual fraction over time. On the one hand, it is affected by the aging mechanism of arsenic in the soil (Huang et al., 2016b). On the other hand, flocculant used in the treatment work may also be one of the reasons for increased proportion of residual state arsenic in the sediment (Li et al., 2015).

In summary, the form of arsenic in the sediment is mainly in residual fraction, followed by the organic fraction and the oxide fraction, and the sum of the three accounts for more than 99% of the total amount. The content of water soluble fraction, ion exchange fraction and carbonate fraction is extremely low, and environmental influence is limited. The vertical distribution of various binding states of arsenic shows that with the continuous sedimentation process, the arsenic in the sediment gradually transforms from oxide fraction and organic fraction to the residual fraction. Therefore, in a more stable lake environment, the release of arsenic in the sediment is limited and the ecological risk is minimal.

Comparing the test results of interstitial water and sediment, it was found that there was no significant correlation between the two. The generation and direction of interstitial water are restricted and affected by various conditions, such as sediment pollution level, sedimentation physiochemical properties, redox conditions and hydrodynamic influence. The environment in Yangzonghai area is complex, and the total arsenic content in the sediment and arsenic content in various binding states do not determine the arsenic content in the interstitial water.

The vertical distribution characteristics of sediment interstitial water are often used to determine whether there is release of substance from the sediment to the lake (Wang et al., 2016). Generally speaking, if there is a phenomenon that substance in the sediment is released to the lake water, there is often a curve tendency that substance content increases first and then decreases as the depth increases. In this investigation, the arsenic content in the sediment interstitial water in most areas of Yangzonghai decreased significantly with the increase of sediment depth. Therefore, it can be inferred that there is no release of sediment arsenic into the lake water.

Conclusions

In December 2016, the arsenic content of Yangzonghai Lake was between 0.029-0.036 mg/L, with an average of 0.033 mg/L. It has reached the Class III water standard, and the arsenic content is evenly distributed in different depths of the lake. The sediment interstitial water is weakly alkaline. The arsenic content in the interstitial water in Tangchi of north shore is relatively high, up to 0.0629 mg/L at the highest, while arsenic content in other areas is generally lower than 0.005 mg/L, and the content is very small. Vertically, as the depth increases, the arsenic content mainly declines rapidly. The average content of arsenic in 0-2, 2-4, 4-6, 6-8 cm sediments was 50.5 mg/kg, 40.1 mg/kg, 33.6 mg/kg and 32.5 mg/kg, respectively. Horizontally, the high arsenic area is mainly distributed on both sides of the north and south shore, which gradually decreases from the coastal side toward the lake center. Vertically, as the depth increases, arsenic content in the sediment gradually decreases on the whole, and heavily polluted sediment is still mainly distributed in the surface layer. Morphological analysis shows that arsenic in the sediment is mainly in residual state, followed by organic matter binding state and iron-manganese oxide binding state, and the sum of the three accounts for more than 99% of the total amount. The water soluble fraction, ion exchange fraction and carbonate fraction are extremely low in content and has limited environmental impact. With the passage of time, the arsenic in the sediment gradually transforms from oxide fraction and organic fraction to residual fraction, tending to be more stable. That is to say, the lake treatment has achieved remarkable results, the release of arsenic in the sediment is limited, the possibility of reverse dissolution is small, and the ecological risk is minimal.

(Received 10th Jun 2019; accepted 28th Aug 2019)

Abstract. The effective heavy metal content of soil indicates ecological environmental risks. The study takes the typical watershed area in northwestern China as a research area. The real-time and rapid risk assessment of ecological environment can be achieved through the monitoring value of normalized difference vegetation index (NDVI) of remote sensing information and environmental factors, and a heavy metal ecological risk assessment model (HMER) for the evaluation of the watershed is built. The research results show that the change of the effective heavy metal content in different areas of the watershed is affected to some extent by the influence of geographical location and human activities. Among them NDVI and the content of heavy metals, precipitation and temperature, and a nonlinear relationship between the average heavy metal content and the ecological risk index HRI. The establishment of HMER research model is applied to different land use types to evaluate the ecological risk level of the watershed, explore the ecological risk level of different land use types in the same region, and in different regions. The results of the study emphasize that the risk assessment of the watershed can be carried out through remote sensing information and environmental factors.
Keywords: *soil, heavy metals, HMER, land use type, NDVI*

Introduction

Soil safety is closely related to agricultural production, food safety, human health and ecological health (Shi et al., 2019). At present, about 20% of China's land ecological environment is under high risk, with a total area of about 0.11 billion km^2 (Liu and Zhang, 2010). Among them, the effective pollution status of heavy metals in soil environment has received increasing attention (Yang et al., 2018). Studies have shown that heavy metals pose a high risk of environmental exposure by spreading and accumulating between plants (the main pathways includes crops and vegetables) and animals (Sawut et al., 2018). The heavy metal environmental hazard released by the ecological chain link process has a negative impact on the viability of urban trees (Yu et al., 2018). Frequent human activities accelerate the release of heavy metal activity, causing heavy metals in the soil to pose a public health threat (Doabi et al., 2018).

In different land use types, soil moisture content will change (Tang et al., 2018). Physical properties such as soil texture, porosity, structure, and chemical properties such as absorption and cushioning are also different (Liang et al., 2018). As the content of heavy metals in soil is related to these properties of soil, there are differences in the distribution and quantity accumulation of heavy metals in soil of different land use types (Su et al., 2013), which leads to the phenomenon that the content of heavy metals in soil of different land types is different (Wang et al., 2016). Some scholars have carried out ecological assessment studies on the production of heavy metals in different

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1334113354

land use types in the same area (Zhou et al., 2017). Some scholars have used different evaluation methods to study the status of heavy metal pollution (Liu et al., 2013). The reasons for these differences and the relationship between soil physical and chemical properties and heavy metals under different land use types need further verification (Wu et al., 2018). Traditional evaluation methods all require field sampling, but due to the weather, geographical location and other factors, the difficulty of sampling is increased, and the sample processing time is also relatively long. These factors cause great obstacles to further study and understanding of regional heavy metal ecological risk.

This paper studies the impact of human activities on environmental and ecological risks from the perspective of land use types and the correlation between climatic and environmental factors and heavy metals. The precipitation, temperature and NDVI of the study area are analyzed. The extraction and comparison of different land use types were carried out, and then the remote sensing data and environmental data and the ecological assessment model of the average content of heavy metals were established in the soil over a long period of time. The relationship between different land use types and ecological risk index was explored, and then the remote sensing data was used to estimate the distribution of heavy metals in the basin and construct an ecological risk assessment model. The research methods are applied to different land use types in the same area and the same land use types in different areas to determine their ecological risk levels. Because of the difficulty of sampling different land use types in the basin area, it is more accurate to carry out ecological risk assessment for the study basin area. The research results provide a theoretical reference for the assessment of soil heavy metal ecological risk in small and medium watersheds, the prevention and treatment of heavy metals in farmland and the methods of restoration.

Materials and methods

Research area overview

The research area is the Daxia River which flows through the southwestern part of Gansu Province in China. The study area is located between 102°02'~103°23' East longitudes and 34°51'~35°48' North latitude. There are two river sources in the Daxia River, namely Xiahe and Luohe (Yang, 2013). The Daxia River originates in the southern part of Tongren County and the west of Xiahe County in Qinghai Province, and flows through Qingshui Gorge in Xiahe County, passes through Tumen Gate and enters Maji Town of Linxia County, and passes through Yinji and Xinji Towns into Linxia City. From the estuary, the river enters the Liujiaxia Reservoir and merges into the Yellow River. It is called "the first-level tributary of the upper reaches of the Yellow River" (Wang, 2016). According to the water conservancy department in Linxia Prefecture, 45.5% of the river water resources in the area are affected by different levels of anthropogenic pollution, and 11.6% has water quality that is lower than the drinking standard. More than 90% of municipal water resources are threatened by water security (Chen, 2015). In terms of the geographical distribution of water pollution, the water quality of the main stream is higher than in the tributaries, and the upstream water quality is better than the downstream. A major source of water pollution is the mines (Luo, 2017). Water conservation in the Daxia River Basin is regarded as an important foundation for the sustainable social and economic development in the ethnic minority areas (Lin, 2015).

Source and processing of remote sensing data

Remote-sensing data are mainly provided by the Geospatial Data Cloud (http://www.gscloud.cn/) and the Landsat 8 OLI_Thermal Infrared Sensor (TIRS) remote sensing satellite data from the LANDSAT series of data provided by the United States Geological Survey (USGS) (https://earthexplorer.usgs.gov/). The applied remote sensing image is in the period from 2015 (January to December) to 2017 (January to December), and its spatial resolution is 30 m × 30 m. The ENVI software was used to calculate the corresponding NDVI values for radiometric calibration, image mosaic, image cropping, and atmospheric correction on the smoke image of the study area, and to remove the outliers and center standardization. The NDVI is defined as the ratio of the difference between near-infrared (NIR) and visible-red-red (R) bands and the sum of the two bands, NDVI = (NIR-R) / (NIR + R). In vegetation remote sensing, NDVI is the most widely used, as (1) NDVI can be applied to detect vegetation growth status, vegetation coverage, and to eliminate some radiation errors; (2) negative values indicate that the ground cover is cloud, water, snow, etc., with a high reflection for visible light; 0 means rock or bare soil, where NIR and R is approximately equal; positive values indicate vegetation coverage, and the positive value increases with increasing coverage (Yuan and Gu, 2018). The average monthly NDVI of the study area from 2015 (January to December) to 2017 (January to December) is shown in *Figure 1*.

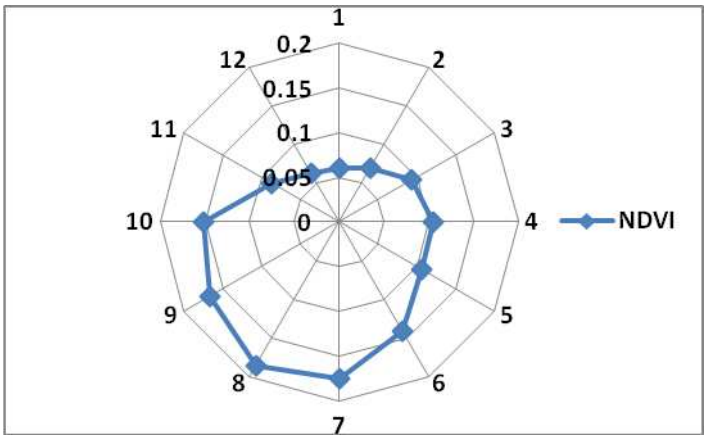

Figure 1. *NDVI monthly average*

Source and treatment of heavy metal data

In order to determine the number of samples more reasonably, this paper uses the Cochran method to estimate the optimal number of samples and sampling points for the construction constructed with pure random sampling of the study area. And there are 114 sampling points, including 24 fixed sampling points and 90 random sampling points. Among them, the fixed sampling point refers to the point to be collected every time, and the random sampling point is the point that is not necessarily collected every month, which can make the sample closer to the real situation. The main sampling time for this study is 2015 (January to December) to 2017 (January to December). Among them, the sample collection is performed once a month. The distribution of sampling points is shown in *Figure 2*. When collecting samples, a hand-held GPS device was used, and a plastic spoon was used to take 0-20 cm of the upper layer of the bottom

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1334113354

mud. The soil sample was dried and ground, after passing through a 200-mesh nylon sieve. In addition, the sample was processed by microwave digestion. Finally, the content of heavy metals was determined by inductively coupled plasma optical emission spectrometer (ICP-OES). By combining remote sensing images and combining field visits to study areas, we learn about the main sources of heavy metals in the study area, such as plant emissions, and the use of pesticides.

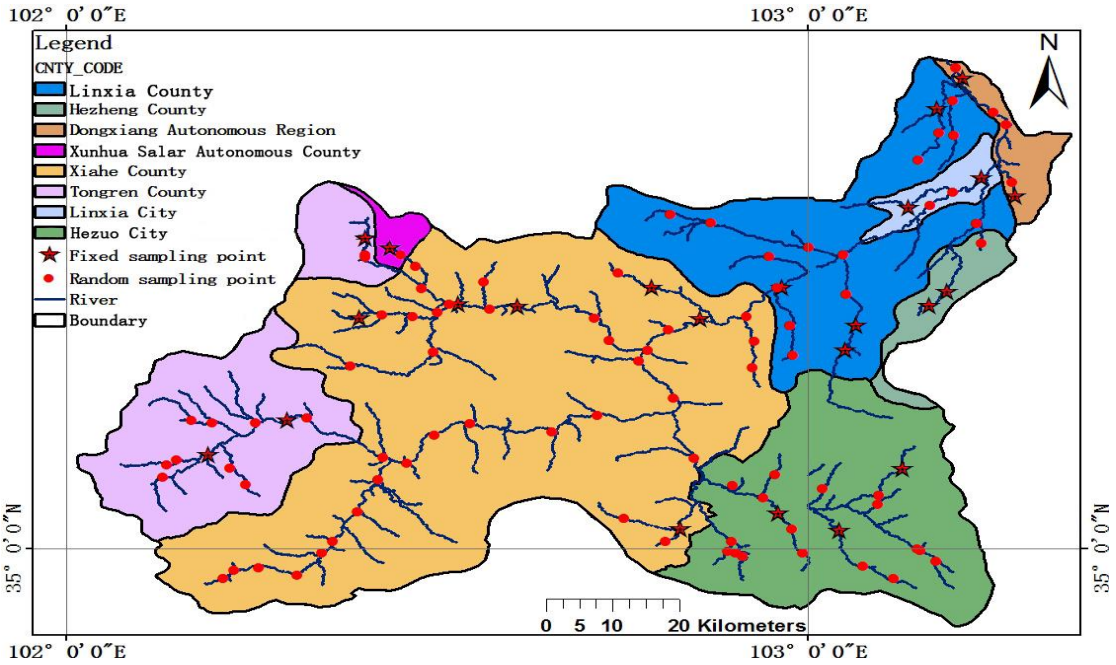

Figure 2. *Study area sampling point map*

Source and treatment of precipitation and temperature

Surface meteorological data from the China Meteorological Data Network (http://data.cma.cn/site/index.html) is typically used as the main source of precipitation and temperature data. Monthly average temperature and monthly average precipitation data from January 2015 to December 2017 was obtained for the study.

Results and discussion

Relationship between regional factors

Impact of climatic factors on NDVI

As the seasons change, the value of NDVI will change due to variations in moisture and temperature (Wang et al., 2018) Changes in vegetation cover are also affected by the combined or synergistic effects of hydrological conditions (such as temperature, precipitation, and humidity) (Liu et al., 2018). Due to little variation in pH and land use type in the study area, this paper focuses on the differences in precipitation and temperature. The amount of precipitation, temperature, and NDVI is affected to some extent by human activities. The monthly average NDVI values from January 2015 to December 2017, the monthly average precipitation and the monthly average temperature were used for correlation analysis.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1334113354

It can be observed that the correlation between monthly average NDVI value and monthly average precipitation is 0.807, and the correlation between monthly average NDVI value and monthly mean temperature is 0.808. The relationship between temperature and NDVI ($P = 0.01 < 0.05$), and precipitation and NDVI ($P = 0.02 < 0.05$) are statistically significant. Details are shown in *Figure 3a, b*.

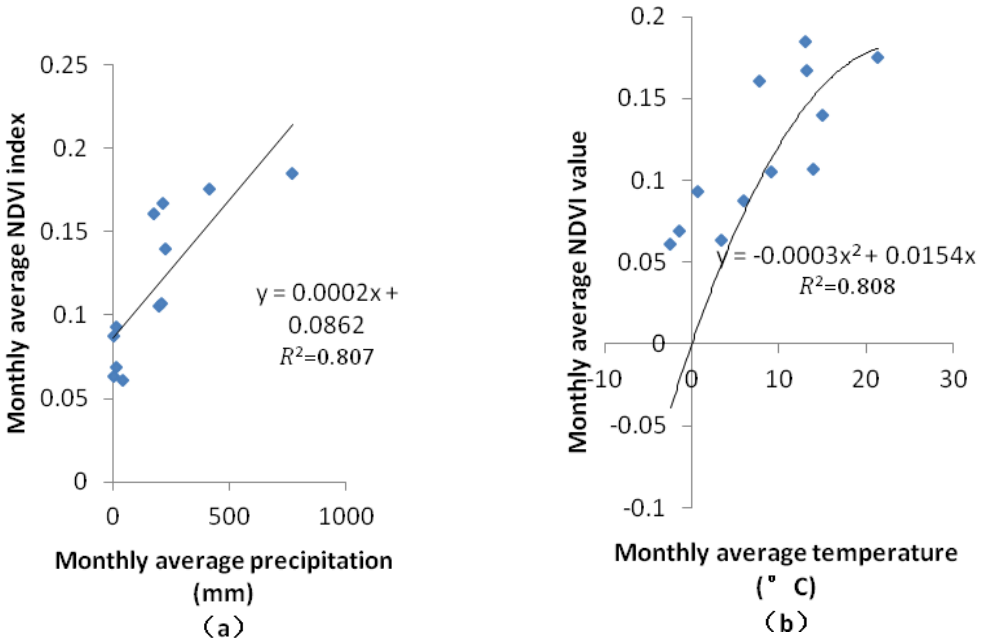

Figure 3. *Relationship between NDVI and precipitation temperature*

Influence of climatic factors on heavy metal content

Field measurements showed evidence of the presence of Cd, Cr, Cu, Pb, and as in the research area. The content of heavy metals is related to the migration of heavy metals. The speed of migration is linked to precipitation and temperature, and the cumulative effect of heavy metals in organisms is related to climatic factors (Ahonen et al., 2018). The soil heavy metal content is significantly correlated with the annual average precipitation and temperature at the sampling point (Zhou et al., 2018). Human activities indirectly affect the content of heavy metals by affecting climate change. The monthly average heavy metal content of the five elements was calculated, and a correlation analysis was undertaken for monthly precipitation and monthly average temperature. The correlation between monthly heavy metal content and precipitation was -0.79, and the correlation between monthly heavy metal content and temperature was -0.784, and the significance was sig. = 0.03, sig. = 0.02, respectively. The average heavy metal content in soil is negatively correlated with precipitation and temperature. Erosion and rainfall runoff will reduce the content of heavy metals (Li et al., 2011). An increase in temperature causes increased acidity and an increase in the activity of heavy metal ions, which means that the heavy metal content increases. However, the increase of heavy metal active ions means that the water solubility of heavy metal ions increases. Thus, heavy metal content can be seasonal, increasing with an increase in temperatures. The scouring effect is notable, and will reduce the heavy metal content of the soil. Details are shown in *Figure 4a, b*.

Ecological risk assessment model

Remote sensing data prediction of heavy metal average content model

The heavy metal content, the average monthly NDVI, the monthly average precipitation, and the monthly average temperature data from 2015 (January to December) to 2017 (January to December) in the Daxia River Basin were modeled using SPSS20 statistical software. The modeling result was $R^2 = 0.866$.

$$H = -0.002P - 54.2876N - 0.042T + 34.443 \quad \text{(Eq.1)}$$

where H is the average heavy metal content, P and T are the precipitation amount and temperature, respectively; N is the NDVI value.

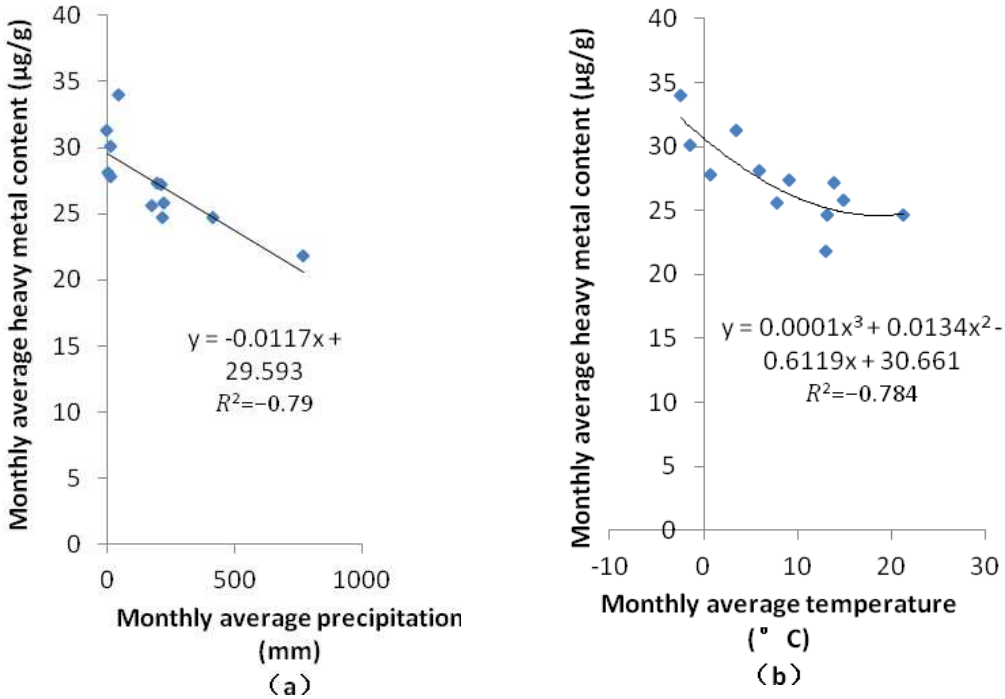

Figure 4. *Relationship between monthly heavy metal content and water purification temperature*

From 2015 (January to December) to 2017 (January to December), the fixed sampling points of the study area and the values of the random sampling points are measured. After treatment, the content of heavy metals was determined by inductively coupled plasma optical emission spectrometer (ICP-OES), and then the values were averaged. The comparison with the average heavy metal content of the soil predicted by *Equation 1* is as follows. *Equation 1* can be used to predict the average heavy metal content of the study area. From *Figure 5*, the average heavy metal content in August is the lowest. The vegetation in August is the lushest, and the vegetation has an inhibitory effect on the dissolution of heavy metal content in the soil.

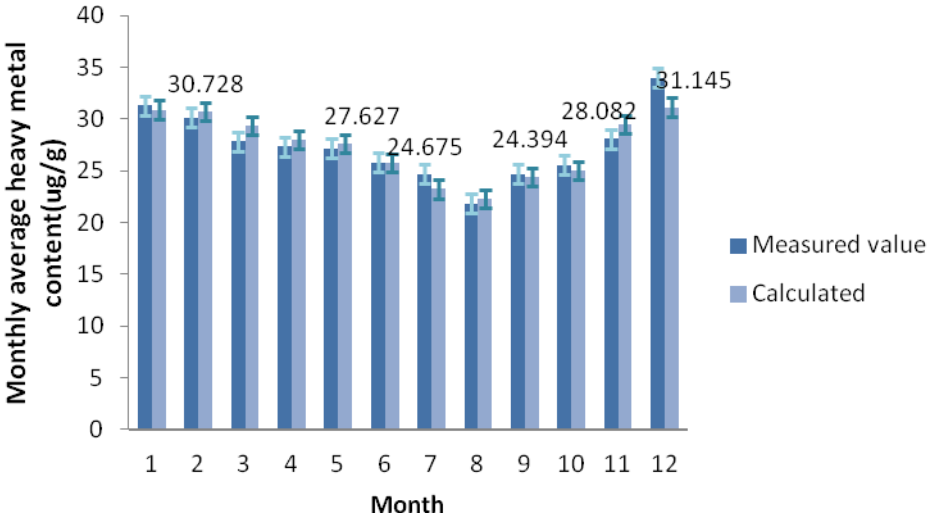

Figure 5. *Comparison of measured and calculated values of monthly heavy metal content*

Establishment of ecological risk assessment model

The Hakanson Ecological Risk Index is a commonly used potential ecological risk assessment index for heavy metals (Hakanson, 1980) which predicts the slow release processes and potential effects of heavy metals in the soil. In response to this potential hazard, the Swedish environmentalist Lars Hakanson introduced the potential ecological risk index (HRI) in 1980.

$$HRI = \sum_{i=1}^{n} E_r^i = \sum_{i=1}^{n} T_r^i \cdot C_r^i = \sum_{i=1}^{n} T_r^i \cdot \frac{C_f^i}{C_z^i} \quad \text{(Eq.2)}$$

where: HRI is the potential ecological risk index of n kinds of heavy metals in the sample. E_r^i is the single potential ecological risk index of the sample heavy metal I; T_r^i is the toxicity response coefficient of the T heavy metal I; C_r^i is the pollution coefficient of the heavy metal I; C_f^i is the measured value of the heavy metal i in the sample, and C_z^i is the specific gravity metal value of the uncontaminated sediment before industrialization. (This can also be replaced by the local sediment background value.) The geochemical background values of the heavy metals in the study area (Wang and Lian, 1993) are shown in *Table 1*, and the classification criteria for the potential ecological hazard index of heavy metals (Li et al., 2015) are shown in *Table 2*.

The size of HRI value is related to the content of heavy metal. Therefore, the average heavy metal content H calculated in *Equation 1* is the independent variable, and the HRI calculated by *Equation 2* is the dependent variable, and the linear fitting is performed. The fitting result is shown in *Table 3*.

Table 1. *Geochemical background values of soil heavy metals in the study area (Wang and Lian, 1993)*

Project	Copper	Lead	Arsenic	Cadmium	Chromium
Background values	28. 91	20.83	14.03	0.130	75.35

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1334113354

Table 2. *Classification criteria for potential ecological hazard index of heavy metals (Li et al., 2015)*

Risk level	E_r^i	*HRI*	Potential ecological risk
A	< = 40	< = 150	Low
B	40~80	150~300	Medium
C	80~160	300~600	Slightly serious
D	160~320	600~1200	Serious
E	> 320	> 1200	Extremely serious

E_r^i is the potential ecological hazard index of heavy metals I; HRI is the potential ecological risk index

Table 3. *Fitting results of HRI and average heavy metal content*

Model type	Linear function	Logarithmic function	Countdown function	Quadratic function	Cubic function	Composite function	Power function
Correlation	0.731	0.682	0.629	0.88	0.893	0.825	0.785

By comparing the fitting results, the cubic function fitting is ideal, the cubic formula is selected, and the specific fitting *Equation 3* is the remote heavy metal ecological risk assessment model (HMER) follows:

$$HMER = 0.02H^3 - 0.718H^2 + 228.034 \quad \text{(Eq.3)}$$

where H represents the average heavy metal content calculated in *Equation 1;* HMER represents the ecological risk assessment value, and its classification is referred to *Table 2*.

Using the data from 2018 (January to June) for verification, a comparison between the verification result and the sampling result in shown in *Figure 6* (Numbers 1-12 and Numbers 13 to 19 are the data of the sample area and verification area, respectively). The relationship between the watershed heavy metal ecological risk index, RRI, and the meteorological remote sensing information can be expressed by *Equation 3*.

Model application

Application of different land use type models in the same area

Due to the relatively large difficulty of different land use types in the whole study area, this method is used to evaluate the ecological risks of different land use types.

By using ENVI software to read, inlay, trim, and atmospheric correction of remote sensing images with less cloud cover, the unsupervised classification K-Means and the combination of on-site surveys are used to classify the land as shown in *Figure 7*. The map is processed by Majority/Minority analysis, and the clustering process is carried out to ensure the continuity of the space. The filtering problem is also used to solve the island problem in the picture, so the image is close to the real situation. In this study, land types are mainly divided into water area, grassland, town, cultivated land and woodland, as shown in *Figure 7*. Among them, the NDVI value is usually in the range

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1334113354

of [-1, 1]. The negative value of the waters is normal. When the waters are extracted, the water bodies may have positive values because some vegetation grows in the water and floats on the water surface. Similarly, when extracting land use types such as grassland, woodland, cultivated land, and towns, it may be affected by the background of the plant canopy, such as soil, wet ground, snow, dead leaves, roughness, etc., and will get negative values. NDVI values of each land use type were calculated by using mask and other operations, as shown in *Table 4.*

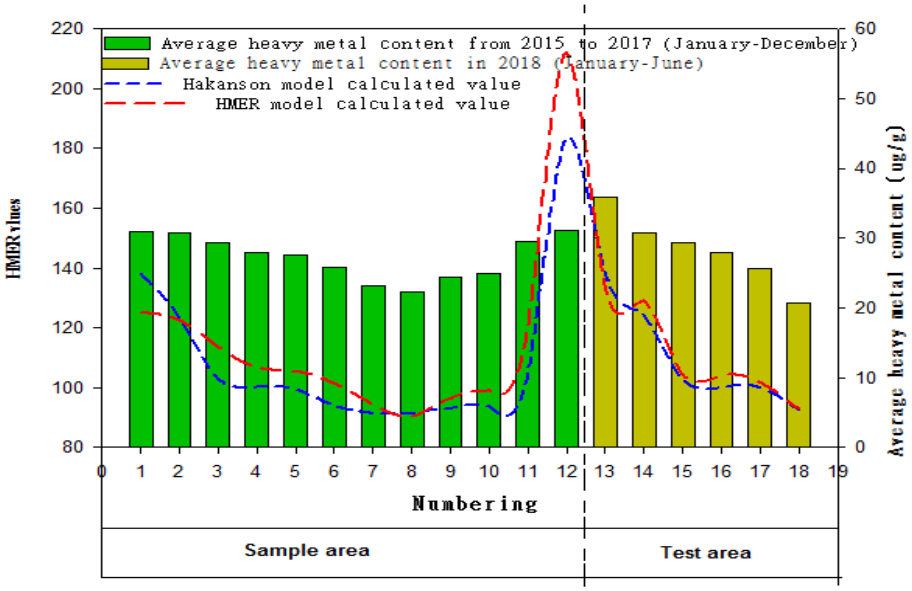

Figure 6. *Comparison of the HMER model and the Hakanson model*

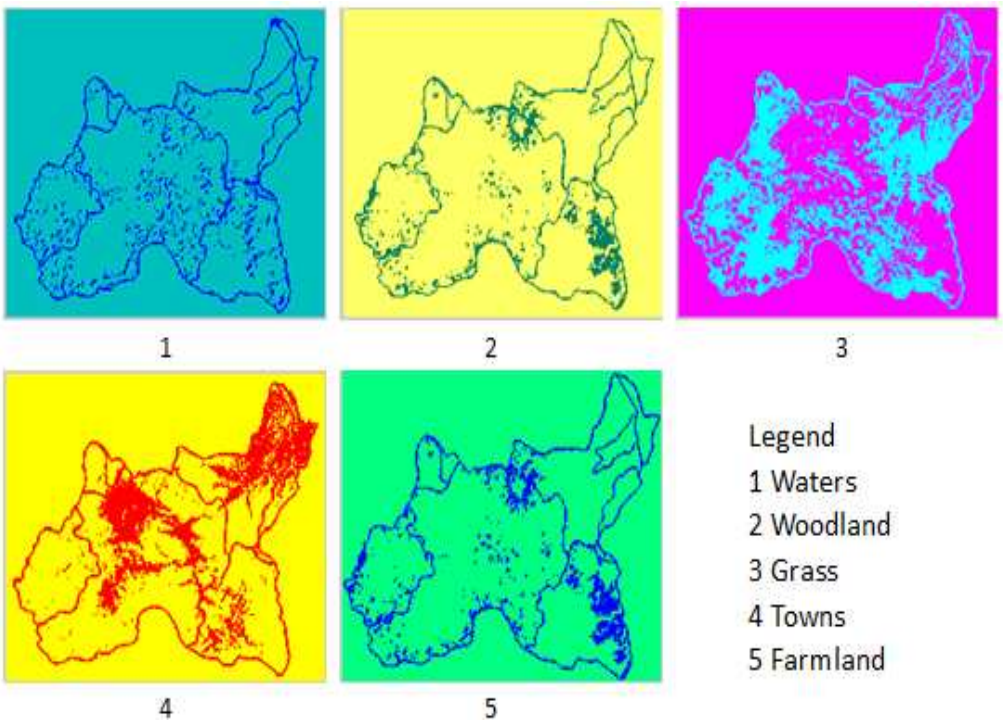

Figure 7. *Daxiahe land use type classification map*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1334113354

Table 4. *NDVI values for different land use types*

Types	Min	Max	Stdev	Total
Waters	-0.76625	0.59237	0.104546	7014712
Grassland	-0.4982	0.62051	0.198214	10064524
Town	-0.74373	0.600615	0.126054	8560026
farmland	-0.72819	0.624793	0.130765	542308
woodland	-0.70428	0.606539	0.362047	729353

According to *Equation 1,* the different land use types of average NDVI value of the heavy metal content in the research area, precipitation, temperature factors, in order to compare the influence of different land use types on heavy metal content, the average rainfall and temperature in different areas of the process, to get the precipitation and temperature in the whole area. The corresponding NDVI value, precipitation and temperature, etc. were substituted into the corresponding formula. The results are shown in *Table 5*.

Table 5. *Ecological risk levels of different land use types in the Daxia River Basin*

Types	HMER	Risk level	Potential ecological risk index
Waters	-21.5568	A	Low
Grassland	113.5366	A	Low
Town	168.7537	B	Medium
Farmland	144.7092	A	Low
Woodland	69.37197	A	Low

It can be seen from *Table 5* that the waters are negative and do not participate in the discussion. The potential risk index of grassland, farmland and forest land is low pollution, and the HMER index of woodland is the lowest. It can be inferred that the planting of woodland in this study area can help inhibit the heavy metals and reduce the ecological risk. The ecological risk level of the town is medium. Due to the large urban population, human activities are frequent. It can be seen that the impact of human activities on soil heavy metal content is positive, so the ecological risk level of towns is high.

Application of different land use types in different regions

Read, mosaic, crop, and atmospheric correction of remote sensing images with less cloud content by using ENVI software. The land is classified using unsupervised classification K-Means and combined with on-site surveys. Then, using mask technology, according to the administrative boundaries of each small area, it is divided and the NDVI value is calculated, as shown in *Figure 8* and use the average of the precipitation in each area from 2015 to 2017 and the temperature average to be substituted into *Equations 1* and *3,* as shown in *Table 6*.

It can be seen from *Table 6* that the ecological risk pollution levels of different land use types in small areas are low or medium, among which the ecological risk levels of grassland, farmland and forest land in Dongxiang County, Linxia City, Llinxia County,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1334113354

Hezuo City, Xiahe county, Hezheng county, Xunhua Salar Autonomous County and Tongren County are all low. The ecological risk levels of Dongxiang County, Linxia City, Linxia County, Hezuo city, Xiahe County, Hezheng County and Xunhua Salar Autonomous County were all medium, while the ecological risk levels of Tongren County were low.

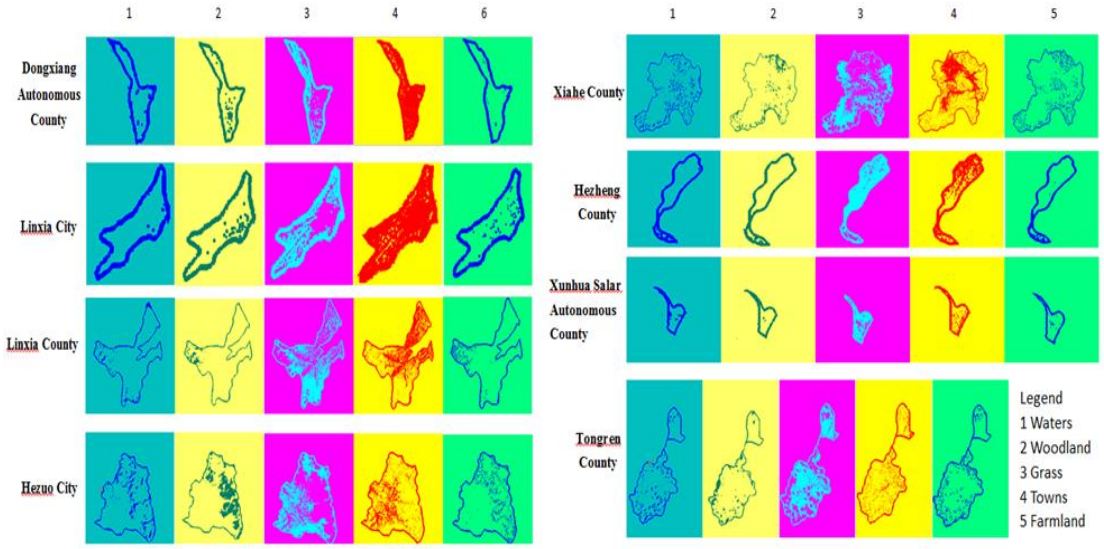

Figure 8. *Small area land use type*

Table 6. *Ecological risk levels of different land use types in small areas*

Region	Grass		Towns		Farmland		Woodland		Waters
	P-I	P-L	P-I	P-L	P-I	P-L	P-I	P-L	
Dongxiang County	85.365	A-L	243.455	B-M	143.4	A-L	70.365	A-L	No
Linxia City	83.215	A-L	270.532	B-M	148.653	A-L	68.447	A-L	No
Linxia County	97.117	A-L	184.663	B-M	146.637	A-L	72.256	A-L	No
Hezuo City	132.419	A-L	168.321	B-M	84.571	A-L	40.752	A-L	No
Xiahe County	140.327	A-L	179.988	B-M	79.634	A-L	56.766	A-L	No
Hezheng County	63.021	A-L	193.365	B-M	139.521	A-L	86.329	A-L	No
Xunhua Salar Autonomous County	86.130	A-L	153.654	B-M	136.774	A-L	12.114	A-L	No
Tongren County	74.557	A-L	68.776	A-L	66.521	A-L	38.123	A-L	No

A-L: A-low; B-M: B-medium; P-I: pollution index; P-L: pollution level

Combined with the remote sensing image map (*Fig. 5*) and the local interview survey, we can see that there are many towns in Dongxiang county, Linxia city and Linxia county. Human activities (factory emissions, transportation, etc.) cause high ecological risk assessment, and the ecological risk pollution index is close to 150 (close to c-heavy). Therefore, Dongxiang County, Linxia City and Linxia County can increase the planting of forest land to alleviate the ecological risk of this area.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1334113354

Conclusion

From Jan 2015 to Dec 2017, the NDVI of the study area increased, in areas where humans live in more areas, the NDVI value is lower. The NDVI is significantly affected by precipitation and temperature. The correlation coefficient between precipitation and NDVI is 0.807, and the correlation coefficient between temperature and NDVI is 0.808. It can be seen that the temperature has a greater influence on the NDVI. The heavy metal content was negatively correlated with temperature and precipitation, and the correlation coefficients were -0.79 and -0.784, respectively.

The ecological risk level of land use types in grassland, cultivated land and forest land in the Daxia River Basin is low. The town is medium. The overall ecological risk is better. The ecological risk pollution levels of different land use types in small areas are also low or medium, including the grasslands of Dongxiang County, Linxia City, Linxia County, HeZuo City, Xiahe County, Hezheng County, Xunhua Salar Autonomous County and Tongren County. The ecological risk grades of cultivated land and forest land are all low. The land use types are Dongxiang County, Linxia City, Linxia County, Hezuo City, Xiahe County, Hezheng County, Xunhua Salar Autonomous County, and the ecological risk level of Tongren County is low. The towns of Dongxiang County, Linxia City and Linxia County are more distributed, and their ecological risk pollution index is close to heavy pollution. Therefore, Dongxiang County, Linxia City and Linxia County can increase the planting of forest land to alleviate the ecological risk of the area. This paper establishes remote sensing data and average heavy metal content model in the Daxia River Basin. The ecological risk assessment HMER model and method, through data verification shows that the model has potential application value and certain degree of implementation. It laid the foundation for the subsequent heavy metal pollution of the soil in the study area.

The model under study has an intentional significance for the risk assessment of the Daxia River Basin. Whether the HMER model has a more accurate assessment effect on the basin area of other vegetation and industrial types remains to be studied by the researchers. The follow-up work of this paper is mainly to study the data monitoring through data sensors and establish intelligent data detection and analysis in order to increase the efficiency of the relevant staff.

(Received 12th Jun 2019; accepted 28th Aug 2019)

Abstract. Chrysanthemum is famous as the Queen of the East grown mainly in China and Japan. Chrysanthemum is the second most important plant in both the ornamental industry and traditional Chinese medicine. The most important chemical extracts of Chrysanthemum include flavonoids, betaine, choline and vitamin B1. Thirteen important compounds of chrysanthemum flowers are acacetin-7-0-beta-D-glucopyranoside, luteolin, luteolin-7-O-beta-D-glucopyranoside, acaciin, acacetin 7-0-(6$^{//}$-0-alpha-L-rhamnopyranosyl)-beta-sophoroside, 3-0-caffeoylquinic acid, syringaresinol 0-beta-D-glucopyranoside, 5,7-dihydroxychromone, uracil, p-gydroxybenzoic acid, 4-0-beta-D-glucopyranosyloxybenzoic acid, boscialin and blumenol A. The most outstanding health benefits of chrysanthemum tea are easing stress and anxiety, improving cardiovascular health, protect against oxidative damage, inhibit inflammation, support healthy immune function, improve eye health and lower risk for osteoporosis. In traditional Chinese medicine, chrysanthemum is a cold herb which helps dispel pathogenic heat, helps the liver, improves eyesight and aids detoxification. To conclude, treatment with natural Chinese herbal medicine especially chrysanthemum, non-synthetic drug is recommended for an organic life.
Keywords: *health benefits, Asian medicinal science, western pharmaceutical science, herbal medicine, silk road*

Introduction

Traditional Chinese medicine is a system of medicine based on acupuncture, acupressure, Chinese herbs, cupping, diet and moxibustion (Soleymani and Shahrajabian, 2012, 2018; Ogbaji et al., 2018; Shahrajabian et al., 2018, 2019a, b, c). Traditional medicine refers to health practices, knowledge, approaches and beliefs incorporating plants and herbs based on both ancient and modern pharmaceutical science (Sharajabian et al., 2019d, e, f, 2020). Chrysanthemum with high ornamental value is a one of the ten most popular traditional flowers in China and one of the most popular cut flowers in the world (Sun et al., 2011; Wang et al., 2014; Chung et al., 2018). Wang et al. (2014) stated that there are more than 20,000 chrysanthemum cultivars in the world and about 7,000 cultivars in China. The objective of this review is survey on some important modern and ancient pharmaceutical sciences of chrysanthemum.

Materials and methods

All relevant papers in the English language of researchers from different countries were collected. The keywords of chrysanthemum, traditional Chinese medicine, traditional Asian medicine, modern pharmaceutical science, health benefits and western medicine were searched in Google Scholar, Scopus, Research Gate and PubMed.

Results and discussion

Chrysanthemum occurrence and cultivation

In Chinese culture, ancient Chinese scholars consider chrysanthemum as a symbol of nobility and integrity and long prized by ordinary people for its medicinal properties. Teixeria (2003) mentioned that, chrysanthemum is the world's second most economically important floricultural crop, following rose. In China, it is found most often in Zhejiang, Anhui, Henan and Sichuan provinces. Imtiaz et al. (2019) also noted that chrysanthemum is native to China and was first cultivated as a flowering herb back in the 15th century BC, and it was believed that this plant had the power of life. Chrysanthemum is famous as Queen of the East, and also known as autumn flower (Saicharan et al., 2017). In traditional Chinese medicine, chrysanthemum provides mildly cold energy, and it has special affinity to the energy channels that lead to the lungs, liver, spleen and kidneys. Chrysanthemum tea is an herbal infusion made from the dried flowers of the chrysanthemum plant in ancient China, and it was used as an herbal remedy in traditional Chinese medicine (TCM) as early as 1500 B.C. Its petals consumed in the form of a salad has the perception of causing longevity. *Chrysanthemum* commonly called as gul-e-daudi or golden flower autumn queen has been cultivated for more than 2000 years ago in Iran. It belongs to the family of Asteraceae, and it behaves both as an annual as well as perennial flowering crop (Kalia, 2015). It is the world's second most important floricultural crop only after Rose (Kalia, 2015). The National Chrysanthemum Society of Britain lists over 600 cultivars of this plant (Datta, 2013). Klie et al. (2014) has shown that chrysanthemum is a segmental allohexaploid with an ambiguous pattern of inheritance. Chrysanthemums require well-drained soil and full sunlight to grow and successfully bloom. Plants grown with less light will become weak, spindly and produce few flowers. Chrysanthemums are shallow rooted and do best if planted high, which means that frequent watering may be necessary during times of high heat and little rainfall. The best defense against adverse weather conditions is to provide good drainage so that water does not accumulate around the plants and promote ice formation. Cicek Atikmen et al. (2014) found that 12.5% fresh mushroom compost and 25% exhausted mushroom compost were the best ratios for cultivation of chrysanthemum. Chrysanthemum white rust (CWR) is one of the primary diseases on chrysanthemum which has been considered as a quarantine disease in many countries (Dong et al., 2018). List of some chrysanthemum varieties is presented in *Table 1*. Qualitative characters of 20 genotypes of chrysanthemum is shown in *Table 2*. Genotypes of *C. morifolium* is shown in *Table 3*. Performance of chrysanthemum genotypes for vegetative characters is presented in *Table 4*. Length of flowering, diameter of flowering stem, diameter of flower bud, diameter of most open inflorescence, plant height, and number of inflorescences per pot of chrysanthemum is presented in *Table 5*. Phytochemical characteristics evaluated in chrysanthemum plants (average of three cultivars) with and without application Si is shown in *Table 6*. Chukki

et al. (2018) indicated that *Chrysanthemum indicum* flower has the potential for Congo red dye reduction from aqueous solution. A number of disease plague chrysanthemus, are Septoria Leaf Spot, Powdery Mildew and virus diseases such as mosaic and stunt or virus-like diseases such as aster yellows. A number of insects such as Aphids, Caterpillars, Leafhoppers, Leaminers, Plant Bugs and Spider Mites may hurt the crops. Chrysanthemums cultivars reveal amazing colours, shapes types of inflorescence and a varied growth (Carvalho-Zanao et al., 2012). Plants are generally raised through suckers and terminal cuttings. It has been said that micro propagation to be very efficient technique for the fast and disease free raising of *Chrysanthemum* plants (Kalia, 2015). Cojocariu et al. (2018) noted that knowing the particular architecture can improve the correct application of chrysanthemum culture technologies as properly positioning of the crops into the appropriate fertility plots, adequate application of fertilizers, and mechanical maintenance of chrysanthemum crops in order to protect the root system of the plants. Yasemin et al. (2017) reported that flower diameters, disc florets, number of flowers, shoot height, root collar thickness, root and shoot fresh weights were negatively affected in 150 and 200 mM NaCl treatments. Liu and Xiao (2018) reported that fourteen compounds were isolated and identified as stigmata-4-ene-3-one (1), calenduladiol-3β-O- palmitate (2), 16β,22α-dihydroxypseudotaraxasterol-3β-O-palmitate (3), α-amyrin (4), urs-12-ene-3β,16β-diol (5), 3β-hydroxyurs- 12-ene-11-one (6), arnidiol (7), maniladiol (8), 3β-hydroxyolean-12-ene-11-one (9), luteolin (10), apigenin (11), apigenin-7,4'- dimethyl ether (12), genkwanin (13), and 1-linoleic acid glycerate (14). Carvalho-Zanao et al. (2012) reported that silicon has promoted improvements both in quantitative and qualitative aspects when supplied to some ornamental species produced in these conditions. Lee and Van Iersel (2008) found that saline water may be more readily available and can have the added benefit of reduced plant height, which is an important quality characteristic for floriculture crops such as chrysanthemum. The effect of growth substrates over the nutrients of *chrysanthemum* plant is shown in *Table 7*. The effect of growth substrates over the nutrients of chrysanthemum plant is presented in *Table 8*. Germination rate of seeds is shown in *Table 9*. Kalia (2015) indicated that *Chrysanthemum* can be multiplied in large scale through micro propagation using right concentration of the auxins. She clearly indicates that the above problems can be minimized by micro propagation of *Chrysanthemum*.

Table 1. *List of some chrysanthemum varieties (Kumar et al., 2014)*

Cultivars	Cultivars
Kanchil	Pusa Anmol

Medicinal uses and potential health benefits in traditional and modern medicine industry

In traditional Chinese medicine (TCM), chrysanthemum flowers are plants that belong to the Cool/Acrid herbs that release the exterior category. Herbs which release the exterior aim to treat the early stages of diseases that affect the upper respiratory tract, the eyes, the ears, the nose, the throat or the skin. In some Eastern cultures, chrysanthemums are also a symbol of good luck, wealth, happiness, and longevity. In Chinese medicine, chrysanthemums are a versatile herb called Ju Hua. In Chinese traditional medicine, Ju Hua is considered to be a fragrant, cool, and light herb. Also, it is used for cooling heat in the liver channel, especially when it manifests as dry, red or painful eyes. Yang et al. (2019) discovered that the *Chrysanthemum morifolium* flower is widely used in China and Japan as a food, beverage, and medicine for many diseases. Chrysanthemum tea is naturally caffeine-free which makes it a great alternative to drinks containing caffeine like black tea and coffee. It has been reported that *Chrysanthemum morifolium* has many antioxidant activities including resisting fatigue, improving the function of cardiovascular system, and lowering the levels of serum lipid (Wang and Xiao, 2013; Yu et al., 2013). The healing benefits of *Chrysanthemum morifolium* are closely related to the composition and content of phenolic compounds (Liu et al., 2013), and apigenin-7-O-glucoside is one of the most active phenolic compounds in chrysanthemum flowers (Wang et al., 2018). Sassi et al. (2008) found that chrysanthemum acts as an antibiotic against a variety of pathogens. Marongiu et al. (2009) reported that the extract of a fresh plant can be applied to skin infections. Liang Yu et al. (2010) and Michalowska and Lema-Ruminska (2018) reported that chrysanthemums have many health-promoting properties used in medicine. Bose et al. (2003) found that chrysanthemum s boiled roots were used as a headache remedy, young sprouts and petals were eaten as salad and leaves were brewed for a festive drink. Chrysanthemum has aesthetic values, antigenotoxic, antioxidative and antimutagenic properties. 13 different types of Chrysanthemums are: Single blooms, Quilled blooms, Spider blooms, Anemone, Pompons, Decorative blooms, Reflex and Incurve blooms, Reflex mums, Brush or Thistle Chrysanthemums, Unclassified, Spoon mums, Cushion mums and Miscellaneous mums. Terpenes concentrations used for sensory analyses is shown in *Table 10*. Compounds identified from Chrysanthemum morifolium Huangju by UHPLC-Q-TOF-MS is presented in *Table 11*. Antioxidant activities of apigenin-7-

Table 15. *The health benefits of chrysanthemum*

1-	Increase the metabolism in the body, which can help people to lose weight, improve circulation, regulate hormone levels, and even improve neurotransmitter activity
2-	Prevent certain chronic illnesses, in part because it helps fight free radicals, prevents cellular mutations, and protects body against numerous illnesses which cause by free radicals
3-	Improve vision. Chrysanthemum tea can also improve eyesight, and also can protect against diseases such as cataracts, macular, degeneration, neuropathy and even blurry vision
4-	It may help to improve bone density and even prevent osteoporosis. This is due to its many naturally occurring minerals, including calcium and magnesium
5-	It may boost immune system because of its high levels of Vitamin C and A
6-	It may help unclog arteries and improve overall heart health
7-	It may help alleviate varicose veins
8-	Help ease digestive issues, eliminating a lot of digestive problems and keeping body in less pain with fewer stomach problems
9-	It may help alleviate dryness and itchiness in the eyes
10-	Rejuvenate the brain and alert the senses
11-	Detoxify the liver, making body healthier overall, as well as make the cholesterol numbers lower
12-	It may help alleviate pimples, acne, and other skin problems
13-	It may lower body temperature, and can help relieve the pain
14-	It may help feeling better without the nasty side effects that chemical medicines may have, particularly prescription

Conclusions

Chrysanthemum is the second most important plants in both ornamental industry and traditional Chinese medicine. Chrysanthemums, often called mums or chrysanths (family *Asteraceae*, genus *Chrysanthemum*), are one of the most important crops in the flower industry. Chrysanthemum is both a source of beautification and high medicinal characteristics. In some Eastern cultures, chrysanthemums are also a symbol of good luck, wealth, happiness, and longevity. In Chinese medicine, chrysanthemums are a versatile herb called Ju Hua. In Chinese traditional medicine, Ju Hua is considered to be a fragrant, cool, and light herb. Also, it is used for cooling heat in the liver channel, especially when it manifests as dry, red or painful eyes. It has tremendously diverse in morphologies including flower shapes, sizes, colors and plant architecture. Thirteen important compounds of chrysanthemum flowers are acacetin-7-0-beta-D-glucopyranoside, luteolin, luteolin-7-O-beta-D-glucopyranoside, acaciin, acacetin 7-0-($6^{//}$-0-alpha-L-rhamnopyranosyl)-beta-sophoroside, 3-0-caffeoylquinic acid, syringaresinol 0-beta-D-glucopyranoside, 5,7-dihydroxychromone, uracil, p-gydroxybenzoic acid, 4-0-beta-D-glucopyranosyloxybenzoic acid, boscialin and blumenol A. Some health benefits of chrysanthemums are for allergies, hypertension (high blood pressure0, tightening of the chest, anxiety, skin conditions such as boils, vertigo, eyes that are inflamed, headaches, sore throats, colds and tinnitus. In traditional Chinese medicine, chrysanthemum is a cold herb which helps dispel pathogenic heat, helps the liver, improves eyesight and aids detoxification. In TCM, chrysanthemum tea has been used for varicose veins, atherosclerosis, acne, influenza, sore throat, fever, angina (Chest pain), common cold symptoms, high blood pressure, inflammation, HIV/AIDS, dizziness and type 2 diabetes. Integrative use of modern agriculture and science of traditional Chinese herbs with new technologies will play an important role in sustainable agriculture and food systems. More clinical researches are necessary to uncover the numerous substances and their impacts on chrysanthemum that contribute to public health.

Conflict of interests. No potential conflict of interests was reported by the authors.

Abstract. Astragalus is a common Traditional Chinese Medicinal plant and is a widely used herbal product in China and other countries. Saponins, polysaccharides, amino acids, flavonoids, organic acid, glycosides, alkaloid, and trace elements, are the major classes of chemical compounds occurring in the species of Astragalus genus. In Traditional Chinese Medicine, Astragalus is considered to be effective in the treatment of diabetes, mellitus, nephritis, leukemia, uterine cancer, besides its tonic agent and diuretic effects. Some uses of Astragalus are in the treatment of kidney and urinary problems, digestion, liver problems, female reproductive system problems, muscular, skin problems, cardiovascular and blood related issues, immune and lymphatic system, nervous system, respiratory system, and for some specific diseases. It helps protect the body against various types of stress such as physical and emotional stress. Astragalus root has anti-aging properties, and also help in the prevention of bone loss. *Astragali radix*, the root of *Astragalus membranaceus* Bunge, has been reported to exert hepatoprotective effects, anti-oxidative effects, antiviral activity, anti-oxidative effects, anti-hypertensive effects, and immunostimulant properties; it has also been reported to strengthen superficial resistance, drainage action and new tissue growth. More clinical studies are necessary to discover the effects of Astraglaus.
