Abstract. This study made use of the trophic state index method, the eutrophication index method, and the potential eutrophication evaluation method to analyze temporal and spatial changes of the nutrient content and the eutrophication level in waters of the Abandoned Yellow River Delta from 2010 to 2015. Findings of this study include the following: the average trophic state index in the study area remained above 3 over the years of investigation, so the study area was under eutrophication; the average eutrophication index each year was above 3, so the study area was in a medium-eutrophication state; both the average trophic state index and the average eutrophication index showed fluctuating trends and the indices were higher in each autumn than in each spring. Fourth, the study area showed a surplus of nitrogen and deficiency in phosphorus, but the N/P ratio declined from 176.68 to 32.234. The concentration of nutrients and the level of eutrophication declined from the coast to the sea and from north to south, with the estuaries marking the highest concentration and most severe eutrophication. Pollutants discharged from the rivers and development projects along the coastline are the main contributors to the high concentrations of nutrients and eutrophication.
Keywords: *trophic state index, eutrophication index, potential eutrophication evaluation, distribution, variation, cause*

Introduction

Coastal waters, which connect the continent with the sea, are among the most vibrant areas bustling with human activity and account for some of the world's most important economic belts. The ecology of coastal waters, subject to influence from both the continent and the sea, is susceptible to human interferences and is hence very sensitive and vulnerable. As costal development and ocean exploitation gather pace, and as land-sourced pollution exacerbates, the environment of coastal waters deteriorates and nutrients (especially nitrogen and phosphorus) and organic matter increase, which results in eutrophication in the waters (Pinckney et al., 2001; Peru's et al., 2004; Demit et al., 2018). Eutrophication will disturb the ecological balance of the waters, threatens marine ecosystems (Andersen et al., 2006; Cabrita et al., 2015), alters the original ecological system structure (Telesh et al., 1999; Capriulo et al., 2002), and leads to degradation of ecological functions (Diaz et al., 1995; Richardson et al., 1997). Eutrophication has become a major challenge that impedes the sustainable development of coastal areas.

Located in the north-central coast of Jiangsu province in China, the Abandoned Yellow River Delta features an erosion coast and deep waters, having all the ideal

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1406914085

conditions to build a large port. Additionally, backed by the rich resources of the adjacent continent, the local government plans to build a port with berths able to accommodate 300,000-tonnage vessels along the northern estuary of the Abandoned Yellow River to facilitate industrial transfer from the Yangtze River economic belt and boost the port economy. This area is expected to become a thriving economic engine along Jiangsu's coastline. Nevertheless, as the port develops and industries there take off, the waters of the delta face growing environmental threats. The major environmental problem now confronting the coastal areas of Jiangsu is eutrophication caused by excessive nutrients. Previous studies on eutrophication along coastal areas in Jiangsu focused on Haizhou Bay (Zhao, et al., 2015; Zhang, et al., 2014), but research on eutrophication in waters of the Abandoned Yellow River Delta is still limited. Using the waters of the Abandoned Yellow River Delta as the study area, this study examined water quality data obtained through investigations in 2010, 2012, 2013, and 2015 to analyze trend changes and distribution of nutrients in this area. Using such methods as the trophic state index method, the eutrophication index method, and the potential eutrophication evaluation method, this work probed the causes of pollution in hopes of providing a basis for environmental management and planning, protocols for pollution control, and policies to support environmental protection.

Materials and methods

Introduction to the study area

Located in the north-central coast of Jiangsu province in China, the study area stretches from the Zhongshan River estuary to the Northern Irrigation Canal of Jiangsu and extends 20 km into the sea (as shown in *Fig. 1*). The study area belongs to the waters of the Abandoned Yellow River Delta. With the headland on the north of the Abandoned Yellow River estuary as the point of inflexion, the coastline which meanders from northwest to southeast then runs from north to south. The coast is a plain erosion silt-muddy coast. The coast is broad and spacious, and the -15 m isobath and -10 m isobath on top of the delta are 3.95 km and 2.0 km away from the coastal baseline, respectively, which means the water is deep along the coast and this area offers ideal conditions to build a large port. Currently, a port with berths able to accommodate 100,000-tonnage vessels is under construction in the northern waters of the Abandoned Yellow River Delta. Rivers that join the sea through the study area include Zhongshan River, Fanshen River, the Abandoned Yellow River, and the Northern Irrigation Canal of Jiangsu. The major coastal development activities in the study area include open marine transportation, culture, and discharge of effluent. The port under construction now runs from the Fanshen River estuary to Erhong River estuary. Along the northern seawall of the study area are coastal industrial parks, the industrial effluent from which are discharged into the sea via outfalls 6 km away from the Zhongshan River estuary and the volume of discharge reaches 20,000 tons per day. The southern part of the industrial park specializes in aquiculture, the wastewater from which is discharged into the sea through the marine outfalls along the coast.

Sampling and sample processing

Sea water quality investigations were conducted from the waters of the Abandoned Yellow River Delta in May 2010, October 2012, May 2013, and October 2015. In

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1406914085

October 2010, there were 21 investigation sites in total. In May 2013, October 2012 and October 2015, there were 22 investigation sites. The sampling point coordinate range is 34°10′N-34°30′40.45″N, 120°6′E-120°32′41.33″E. The areas of investigation remained essentially the same, so data obtained from the investigations have good comparability in terms of space (*Fig. 1*).

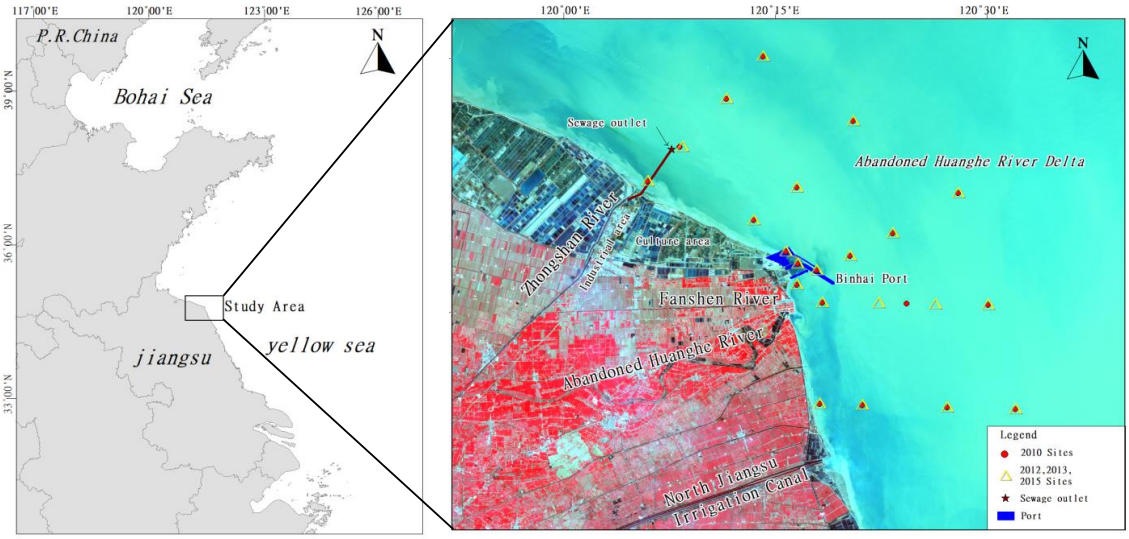

Figure 1. *Location of study area and sample sites*

Items monitored include chemical oxygen demand (COD), dissolved inorganic nitrogen (DIN, including NO_3-N, NO_2-N, NH_4-N), dissolved inorganic phosphorus (DIP), chlorophyll a, and salinity. Collection, storage, and transport of samples were performed according to the "Specifications for Marine Monitoring (GB17378-2007)," "Specifications for Oceanographic Survey (GB/T 12763-2007)," and other standards. The water samples were collected from a 50-cm depth where applicable using an Aqua trap water sampler and were then transported to the laboratory for the water quality investigations.

Methods

Single-factor pollution index method

The single-factor pollution index method (Jiang et al., 1991) uses the ratio of measured concentration of a given pollutant to the standard concentration to reflect how much pollution the pollutant has caused.

$$P_i = \frac{C_i}{L_i} \quad \text{(Eq.1)}$$

where P_i denotes the pollution index of the i-th pollutant, Ci denotes the measured concentration of the i-th pollutant, and Li denotes the concentration of the i-th pollutant in sea water of standard quality. The evaluation standard used in this study refers to Level-I Standard in "Sea Water Quality Standard (GB3097-1997)".

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1406914085

Trophic state index (TSI) method

The trophic state index (TSI) method (Chen et al., 1999; Bian et al., 2013) is one of most widely used methods to assess eutrophication and its calculation equation is as follows:

$$TSI = \frac{COD}{COD_S} + \frac{TN}{TN_S} + \frac{TP}{TP_S} + \frac{Chl.a}{Chl.a_S} \quad \text{(Eq.2)}$$

where COD, TN, TP, and Chl.a stand for the measured concentrations of the pollutants (mg/L), CODs, TNs, and Chl.as their corresponding standard concentrations (mg/L). According to the Level-II standard in the "Sea Water Quality Standard (GB3091-1997)" and the conditions of nutrients in the study area, the standard concentrations for COD, DIN, DIP, and Chl-a are 3 mg/L, 0.3 mg/L, 0.03 mg/L, and 3 mg/m^3, respectively. *Table 1* presents the levels of nutrition identified according to the TSI.

Table 1. *The levels of nutrition according to the trophic state index (TSI)*

Trophic state index (TSI)	Level of nutrition
Above 3	Eutrophic
2-3	Mesotrophic
Below 2	Oligotrophic

Eutrophication index (EI) method

The eutrophication index (EI) method, first proposed in Japan, was introduced to China by Zou (1983) and has been used according to the "Water Quality Standard for Fisheries" and the "Sea Water Quality Standard" issued by the Chinese government. Its calculation equation is:

$$EI = \frac{COD \times DIN \times DIP \times 10^6}{4500} \quad \text{(Eq.3)}$$

where *EI* denotes the eutrophication index, and COD (Chemical Oxygen Demand), DIN (dissolved inorganic nitrogen), and DIP (Dissolved Inorganic Phosphorus) refer to the measured concentrations of these pollutants (mg/L). If $EI < 1$, the water is considered as oligotrophic; if $EI \geq 1$, it is considered that eutrophication starts in the water, and the larger *EI* is, the more severe eutrophication is. If $EI \geq 1$, the water is identified as eutrophic. When $1 \leq EI \leq 3$, the water is identified as slightly eutrophic. When $3 < EI \leq 9$, the water is identified as moderately eutrophic. When $EI > 9$, the water is identified as severely eutrophic.

Potential eutrophication evaluation method

When pollution of nutrients occurs in sea water, the The concentration ratio of dissolved inorganic nitrogen and dissolved inorganic phosphorus (N/P ratio) does not equal the Redfield ratio of 16 (Redfield, 1963) and even deviates much from the latter. In such cases, there is a surplus of nitrogen (compared with phosphorus limitation) or phosphorus (compared with nitrogen limitation) and the surplus will not be absorbed by

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1406914085

marine plants. Excess of nutrients does not make a direct contribution to eutrophication, so it is considered a potential source that may induce eutrophication. In other words, only when a proper amount of phosphorus (compared with phosphorus limitation) or nitrogen (compared with nitrogen limitation) is supplemented do the excess of nutrients play a role in eutrophication (Guo et al., 1998). This is in fact a phenomenon of potential eutrophication. *Table 2* displays the division of nutrition levels in potential eutrophication.

Table 2. *Division of nutrition levels in potential eutrophication according to N/P ratio*

Level	Nutrition level	DIN (mg/L)	DIP (mg/L)	N/P
I	Oligotrophic	< 0.2	< 0.03	8-30
II	Mesotrophic	0.2-0.3	0.03-0.045	8-30
III	Eutrophic	> 0.3	> 0.045	8-30
IV_P	Phosphorus-limited mesotrophic	0.2-0.3	—	> 30
V_P	Medium-phosphorus-limited potential eutrophic	> 0.3	—	30-60
VI_P	Phosphorus-limited potential eutrophic	> 0.3	—	> 60
IV_N	Nitrogen-limited mesotrophic	—	0.03-0.045	< 8
V_N	Medium-nitrogen-limited potential eutrophic	—	> 0.045	4-8
VI_N	Nitrogen-limited potential eutrophic	—	> 0.045	< 4

Statistical methods

The DIN and DIP concentrations in water samples were statistically analyzed by SPSS25, the mean, standard deviation and coefficient of variation were calculated. Combining with the spatial information of station location, the data are processed by using Suffer11 software and Kristin interpolation method, and the spatial distribution maps of DIN, DIP, TSI, EI are drawn.

Results and discussion

Concentration changes of nutrients and spatial distribution

The statistical results of dissolved inorganic nitrogen (DIN) and dissolved inorganic phosphorus (DIP) from 2010 to 2015 are shown in *Table 3* and *Figure 2*. The DIN concentration in the delta measured in May 2010 ranged from 0.586 to 1.004 mg/L in May 2010, with a mean concentration of 0.793mg/L. In October 2012, the measured DIN concentration ranged from 0.512 to 1.615 mg/L, with a mean concentration of 0.851 mg/L. In May 2013, the measured range of DIN concentrations was from 0.306 to 1.520 mg/L, with a mean concentration of 0.590 mg/L. In November 2015, the DIN concentration ranged from 0.213 to 0.924 mg/L, with a mean concentration of 0.474 mg/L. From 2010 to 2012, the maximum concentration of inorganic nitrogen in the waters of the delta witnessed a considerable increase and the average concentration rose slightly. From 2012 to 2015, both the maximum concentration and average concentration of inorganic nitrogen in this area declined (*Fig. 2*), and this trend is significant. Data from estuaries (*Table 3; Fig. 3*) show that the DIN concentration of Zhongshan estuary over the years was obviously higher than the average value of the study area, the DIN concentration of Abandoned Yellow River estuary was slightly higher than the average value in 2010 and 2012, the DIN concentration of Northern Jiangsu Irrigation Canal estuary was slightly higher than the average value in 2010.

(a) Statistical charts of DIN (b) Statistical charts of DIP

Figure 2. *Statistical charts of DIN and DIP concentrations from 2010 to 2015*

(a) The DIN concentrations of estuaries (b) The DIP concentrations of estuaries

Figure 3. *The DIN and DIP Concentrations of estuaries from 2010 to 2015*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1406914085

The DIP concentration in this area ranged from 0.011 to 0.019 mg/L in May 2010, with a mean concentration of 0.016 mg/L; the DIP concentration monitored in October 2012 ranged from 0.018 to 0.040 mg/L, with a mean concentration of 0.029 mg/L; in May 2013, the DIP concentration range was from 0.014 to 0.041 mg/L, with a mean concentration of 0.021 mg/L; in November 2015, the DIP concentration range was from 0.012 to 0.106 mg/L, with a mean concentration of 0.035 mg/L. From 2010 to 2015, the maximum concentration of DIP in the study area kept rising (*Fig. 2*), and this trend is obvious. The average DIP concentration fluctuated, with the concentration higher in autumns than in springs obviously. Data from estuaries (*Table 3; Fig. 3*) show that the DIP concentration of Zhongshan estuary was obviously higher than the average value in2012, 2013 and 2015, the DIP concentration of Northern Jiangsu Irrigation Canal estuary was slightly higher than the average value in 2010 and 2012, the DIP concentration of Abandoned Yellow River estuary was slightly higher than the average value in 2010.

The coefficient of variation can reflect the dispersion degree of data distribution at different sampling points. The larger the coefficient of variation, the greater the degree of dispersion. It can also reflect the degree of influence of human factors on water, the larger the coefficient of variation, the greater the influence of human factors. The coefficient of variation of DIN from 2010 to 2015 ranged from 15.6 to 47.8%, with the largest coefficient of variation in 2013. From 2010 to 2015, the coefficient of variation of DIP ranged from 14.2 to 51.2%, and the coefficient of variation increased over the years. This data reflected the uneven spatial distribution of DIN and DIP concentration, which was obviously influenced by human factors.

Regarding spatial distribution (*Figs. 4* and *5*), the concentrations of DIN and DIP on the surface sea water in the study area declined from the shore outwards and from west to east. It presents a gradient of concentrations in spatial distribution and high concentrations occur near the estuary with the estuary recording the highest. The concentration isolines of DIN in the study area in 2010 are saddle-shaped, with the highest concentrations occurring both at the Zhongshan River estuary and at the Abandoned Yellow River estuary, and the level of pollution in these peak sites was essentially the same. In 2012, the concentration of DIN in these two estuaries remained high, but the concentration at the Zhongshan River estuary far exceeded that at the other estuary. In 2013 and 2015, high DIN concentrations only occurred at the Zhongshan River estuary and the Abandoned Yellow River estuary was no longer a high-concentration area. In 2010 and 2012, the highest concentrations of DIP occurred in areas radiating from the abandoned Yellow River estuary and from the estuary of Northern Irrigation Canal of Jiangsu, but in 2013 and 2015, high DIP concentrations only occurred at the Zhongshan River estuary.

Result of single-factor pollution index evaluation

Table 4 shows the Single-Factor Pollution Index of dissolved inorganic nitrogen and dissolved inorganic phosphorus (*Eq. 1*). According to the Level-I standards detailed in "Sea Water Quality Standard," the pollution index of DIN was between 2.931 and 5.021 in 2010, averaging 3.963. In 2012, this index ranged from 2.562 to 8.073, averaging 4.256. In 2013, the index ranged from 1.531 to 7.598, averaging 2.949. In 2015, the index ranged from 1.067 to 4.622, averaging 2.371. The index in all these years exceeded the standard index and, if calculated by the ratio of measured index to the standard, the index first presented an increase and then later a decline.

Table 4. *The single-factor pollution index of dissolved inorganic nitrogen (DIN) and dissolved inorganic phosphorus (DIP)*

Item			Time			
			2010.5	**2012.10**	**2013.5**	**2015.11**
DIN	Pollution index	Maximum	5.021	8.073	7.598	4.622
		Minimum	2.931	2.562	1.531	1.067
		Mean	3.963	4.256	2.949	2.371
		Rate of exceeding the standard	100%	100%	100%	100%
DIP	Pollution index	Maximum	1.267	2.687	2.687	7.067
		Minimum	0.707	1.207	0.907	0.793
		Mean	1.037	1.909	1.370	2.310
		Rate of exceeding the standard	61.9%	100%	86.3%	90.9%

According to the Level-I water quality standards detailed in the "Sea Water Quality Standard," the pollution index (*Eq. 1*) of DIP in 2010 ranged from 0.707 to 1.267, averaging 1.037, and the rate of exceeding the standard stood at 61.9%. In 2012, the pollution index ranged from 1.207 to 2.687, averaging 1.909, and the rate of exceeding the standard was 100%. In 2013, the index ranged from 0.907 to 2.760, averaging 1.439, and the rate of exceeding the standard was 87.5%. In 2015, the range of the index was from 0.793 to 7.067, averaging 2.310, and the rate of exceeding the standard was 90.9% (*Table 4*). The ratio of the measured index to the standard presented a fluctuating pattern, with the value in autumns higher than in springs.

Trophic state analysis

Table 5 and *Figure 6* show the analysis results of the trophic state index (TSI, *Eq. 2*) in the study area from 2010 to 2015. In May 2010, the TSI of the study area ranged from 3.314 to 5.015, with a mean index of 4.135, and the area was identified as eutrophic according to the division standard of nutrition levels. In October 2012, the index changed between 2.864 and 7.509, averaging 4.427, and the area was identified as being between mesotrophic and eutrophic, with an overall tendency towards the eutrophic level. In May 2013, the index ranged from 1.928 to 7.027, averaging 3.227, and the area was identified as being between oligotrophic and eutrophic, with an overall tendency towards the eutrophic level. In November 2015, the index ranged from 2.018 to 7.792, with the mean standing at 3.974, and the area was identified as being between the mesotrophic state and the eutrophic state, with an overall evaluation as eutrophic. From 2010 to 2015, the TSI value of Zhongshan estuary was significantly higher than the average value of the study sea area and other estuaries values (*Fig. 7*).

According to the analysis from the angle of time (*Table 5*), it can be seen that from 2010 to 2015, the average TSI fluctuated but remained above 3 and the area was identified as eutrophic. According to analysis from the angle of spatial distribution (*Fig. 8*), the TSI of areas near the shore were higher than those far away in the sea and presented a declining trend from the shore to the sea, with high TSIs occurring in waters close to the estuaries. In 2010, the TSI isolines resembled the shape of a saddle; the Zhongshan River estuary and the Abandoned Yellow River estuary had the highest and similar TSIs. In 2012, areas from the Zhongshan River estuary to the shore of the port had the highest TSIs and the index declined outwards from the estuary to the sea. High TSIs also occurred in the Abandoned Yellow River estuary, but the values were generally

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1406914085

smaller than those in the Zhongshan River estuary. In 2010 and 2012, the researched waters were essentially eutrophic. In 2013 and 2015, the TSI improved compared with 2012 and severe organic pollution only occurred in Zhongshan estuary and the Abandoned Yellow River estuary no longer showed high organic pollution. The area of eutrophic waters shrank and nearly half of the waters were in a mesotrophic state.

Analysis of eutrophication condition

According to the calculated eutrophication indices of the study area from 2010 and 2015 (as shown in *Table 5* and *Fig. 9*), the eutrophication index (*Eq. 3*) in this area ranged from 2.114 to 7.798, with a mean index of 4.419 in May 2010, and hence the area was identified as in a state between slight-eutrophic and moderate-eutrophic. In October 2012, the index fluctuated between 2.802 and 29.135, with the mean standing at 8.871, so the area as identified as being in a state between slight-eutrophic to severe-eutrophic. In May 2013, the range of the index was from 0.907 to 23.134, with the mean standing at 4.556, so the study area was identified as being in a state between oligotrophic to severe eutrophic. In November 2015, the index fluctuated from 0.717 to 29.229, with the mean standing at 7.252, so the study area was identified as being in a state between oligotrophic and severe eutrophic. From 2012 to 2015, the EI value of Zhongshan estuary was significantly higher than the average value of the study sea area and other estuaries values (*Fig. 7*).

Table 5. *Trophic state index (TSI) and eutrophication index (EI) over years*

Time	Category		TSI		EI	
			Scale	Nutrition level	Scale	Eutrophication level
2010.5	Study area	Maximum	5.015	Eutrophic	7.798	Moderate-eutrophic
		Minimum	3.314	Eutrophic	2.114	Slight-eutrophic
		Mean	4.135	Eutrophic	4.419	Moderate-eutrophic
	Zhongshan River estuary		4.954	Eutrophic	3.382	Moderate-eutrophic
	Abandoned Yellow River estuary		4.730	Eutrophic	6.558	Moderate-eutrophic
	Northern Jiangsu Irrigation Canal estuary		4.457	Eutrophic	7.798	Moderate-eutrophic
2012.10	Study area	Maximum	7.509	Eutrophic	29.135	Severe-eutrophic
		Minimum	2.864	Mesotrophic	2.802	Slight-eutrophic
		Mean	4.427	Eutrophic	8.871	Moderate-eutrophic
	Zhongshan River estuary		7.509	Eutrophic	29.135	Severe-eutrophic
	Abandoned Yellow River estuary		4.643	Eutrophic	11.063	Severe-eutrophic
	Northern Jiangsu Irrigation Canal estuary		3.514	Eutrophic	5.811	Moderate-eutrophic
2013.5	Study area	Maximum	7.027	Eutrophic	23.134	Severe-eutrophic
		Minimum	1.928	Oligotrophic	0.907	Oligotrophic
		Mean	3.227	Eutrophic	4.556	Moderate-eutrophic
	Zhongshan River estuary		7.027	Eutrophic	23.134	Severe-eutrophic
	Abandoned Yellow River estuary		2.733	Mesotrophic	2.868	Slight-eutrophic
	Northern Jiangsu Irrigation Canal estuary		3.159	Eutrophic	2.791	Slight-eutrophic
2015.11	Study area	Maximum	7.792	Eutrophic	29.229	Severe-eutrophic
		Minimum	2.018	Mesotrophic	0.717	Oligotrophic
		Mean	3.974	Eutrophic	7.252	Moderate-eutrophic
	Zhongshan River estuary		7.792	Eutrophic	29.229	Severe-eutrophic
	Abandoned Yellow River estuary		4.253	Eutrophic	9.787	Severe-eutrophic
	Northern Jiangsu Irrigation Canal estuary		4.855	Eutrophic	11.092	Severe-eutrophic

From 2010 to 2015, the mean of the eutrophication index indicated a moderate-eutrophic state of the study area, but the highest reading of the index witnessed a significant rise from 2010 to 2012, and the years from 2012 to 2015 marked the largest value of the maximum index, which reflected the fact that part of the researched waters suffered from severe eutrophication. The spatial distribution of the eutrophication index was in alignment with that of the trophic state index.

Potential eutrophication evaluation

The concentration and makeup of nutrients are of significant importance for the growth of phytoplankton and the N/P ratio is a vital indicator of the makeup of nutrients. When the N/P ratio equals 16:1, the waters provide the necessary conditions for the phytoplankton to growth; a smaller ratio will limit the growth of the phytoplankton and a larger ratio will make phosphorus the decisive factor for the phytoplankton's growth.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1406914085

According to the observed data regarding concentrations of DIN and DIP from 2010 to 2015, this study analyzed the potential eutrophication conditions of the study area, as shown in *Table 6*. In May 2010, the N/P ratio of the study area stayed between 108.818 and 318.031, with the mean standing at 176.680, so the whole area was in a state of phosphorus-limited potential eutrophication. In October 2012, the N/P ratio of the study area was between 30.654 and 97.282, with the mean standing at 65.433, and the waters was in a state between medium-phosphorus-limited potential eutrophication and phosphorus-limited potential eutrophication. In May 2013, the N/P ratio was between 45.893 to 83.433, with the mean standing at 60.639, so the researched waters were in a state between medium-phosphorus-limited potential eutrophication and phosphorus-limited potential eutrophication. In November 2015, the N/P ratio of the study area was between 18.636 and 54.377, with the mean standing at 32.234, so the study area was in a state of medium-phosphorus-limited potential eutrophication and medium-eutrophication.

Table 6. *Result of potential eutrophication evaluation over years*

Time	Category	DIN (mg/L)	DIP (mg/L)	N/P	Level	Nutrition level
2010.5	Maximum	1.0041	0.019	318.031	VI_P	Phosphorus-limited potential eutrophication
	Minimum	0.5862	0.0106	108.818	VI_P	Phosphorus-limited potential eutrophication
	Mean	0.7926	0.0156	176.680	VI_P	Phosphorus-limited potential eutrophication
2012.10	Maximum	1.6146	0.0403	97.282	VI_P	Phosphorus-limited potential eutrophication
	Minimum	0.5123	0.0181	30.654	V_P	Medium- phosphorus-limited potential eutrophication
	Mean	0.8513	0.0286	65.433	VI_P	Phosphorus-limited potential eutrophication
2013.5	Maximum	1.520	0.041	83.433	VI_P	Phosphorus-limited potential eutrophication
	Minimum	0.306	0.014	49.804	V_P	Medium- phosphorus-limited potential eutrophication
	Mean	0.602	0.022	61.712	VI_P	Phosphorus-limited potential eutrophication
2015.11	Maximum	0.924	0.106	54.377	V_P	Medium- phosphorus-limited potential eutrophication
	Minimum	0.213	0.012	18.636	II	Mesotrophic
	Mean	0.474	0.035	32.234	V_P	Medium- phosphorus-limited potential eutrophication

From 2010 to 2015, the N/P ratio of the researched waters presented a declining trend and the area shifted from phosphorus-limited potential eutrophication to medium-phosphorus-limited potential eutrophication. In the study area, there was excessive nitrogen and deficient phosphorus, but the gap between the content of these two nutrients was narrowing. Once the content of phosphorus rises due to an increased discharge of pollutants from outfalls or rivers, the area will be very likely to suffer from eutrophication.

Analysis of causes

According to the characteristics of the temporal distribution, the content of nutrients and the eutrophication level in the study area were higher in autumns than in springs,

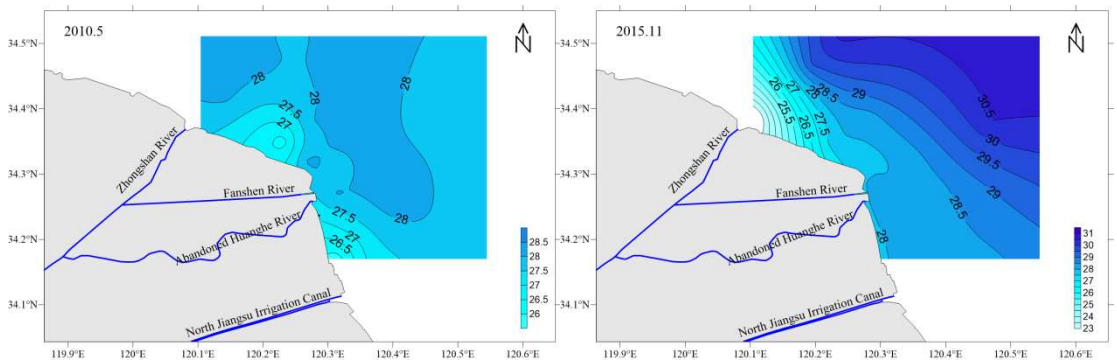
http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1406914085

which was largely because the phytoplankton begins reproduction and consumes nitrogen and phosphorus in springtime (Li et al., 2018; Sun et al., 2016).

According to the spatial distribution of nutrients and the conditions of eutrophication, the nutrient content declined from the shore to the sea and from north to south, with the estuary marking the highest content. Inside the northern seawall of the study area are coastal industrial parks and aquaculture plants, and outside the seawall are outfalls and berths. Effluents of these human activities discharged into the sea influence the water quality along the northern coastline. As for the southern part of the study area, inside the seawall are farmlands, which produce relatively less pollutants.

The eutrophication level of the study area is largely subject to the pollutants discharged to the sea from the rivers. Industrial effluents, urban sewage, and agricultural wastewater that are rich in such nutrients as nitrogen and phosphorus enter the sea from the Zhongshan River, the Abandoned Yellow River, and the Northern Irrigation Canal of Jiangsu, which increases the content of nutrients in the study area, exacerbates eutrophication, and gives rise to high-content areas that radiate from the estuaries.

The area and condition of high content of nutrients at the estuary vary with the conditions of discharge from the river. Channels of the Zhongshan River, the Abandoned Yellow River, and the Northern Irrigation Canal of Jiangsu are all gate-controlled channels, so the monitored content of pollutants in the waters near the estuaries was correlated to the status of the gate (i.e. whether the gate was open or not). The salinity of the sea near the estuary during investigations reflected the conditions of discharge of fresh water from the rivers. According to the result of the salinity investigation performed in 2010 (*Fig. 10*), a low-salinity area occurred in the waters close to the estuaries of these three rivers, which meant that the gates of these three rivers were open at that time. As a result, the estuaries marked the highest content of nutrients and highest level of eutrophication in the study area in 2010. According to the salinity map of 2015 (*Fig. 10*), waters surrounding the Zhongshan River estuary showed low salinity and waters surrounding the other two estuaries did not, which means the gates of the other two rivers were closed at the time of investigation and thus there was no discharge of freshwater into the sea from these two rivers. Consequently, the high content of nutrients only occurred around the Zhongshan River estuary in 2015. In short, pollutants from the rivers and effluents from production activities along the coastline and the nearby continent are major factors that determine the concentration of nutrients and the level of eutrophication in the study area (Hu et al., 2016; Zhang et al., 2018).



(a) Spatial distribution of salinity in May 2010 (b) Spatial distribution of salinity in November 2015

Figure 10. *Spatial distribution of salinity in the study area in May 2010 and November 2015 (unit: ‰)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1406914085

According to the China Marine Environmental Quality Bulletin of 2015, China's marine pollution areas were mainly distributed in Liaodong Bay, Bohai Bay, Laizhou Bay, Jiangsu coast, Yangtze Estuary, Hangzhou Bay, Zhejiang coast, Pearl River Estuary. The main pollution factors were inorganic nitrogen, active phosphate and petroleum. Inorganic nitrogen and active phosphate had become the main pollution factors in China's coastal areas, and the problem of seawater eutrophication was grim. Areas with serious eutrophication were mainly concentrated in estuaries, bays and coastal waters. Land-source pollutants from rivers entering the sea and coastal development activities were the main reasons for eutrophication (Chen et al., 2017; Dai et al., 2016; Li et al., 2018; Sun et al., 2016). Eutrophication had become a water environment problem in coastal waters of China.

Based on four-time water quality data of the Abandoned Yellow River Delta, this study analyzed the trend and distribution characteristics of nutrients in this area. For long-term eutrophication changes, distribution rules and characteristics, continuous monitoring and further analysis of the water quality are still needed in the abandoned Yellow River Delta. For the reasons of eutrophication, this paper makes a preliminary discussion. In the future, quantitative research should be strengthened on the extent and scope of impacts of human activities especially rivers, on eutrophication in coastal waters. In view of the eutrophication problem in coastal areas, it is necessary to reduce the amount of nutrients into the sea from the river and strengthen the regulation of sewage discharge from coastal development activities.

Conclusion

According to this study, the following conclusions are reached.

First, in 2010, 2012, 2013 and 2015, the average DIN concentration in the study area first increased and then declined, and the average DIP concentration followed a fluctuating trend, with the concentration higher in autumns than in springs. The DIN concentration in all the years of investigation exceeded the standard concentration for Level-I sea water and the rate that the DIP concentration exceeded the standard was between 61.9% and 100%.

Second, the mean of the trophic state index remained above 3 over the years of investigation and the study area was in a eutrophic state. The mean of TSI fluctuated, with the value higher in autumns than in springs.

Third, the mean of the eutrophication index over the years of investigation indicated that the researched waters were in the medium-eutrophic state; the maximum of the eutrophication index increased from 2010 to 2012, and from 2012 to 2015, it remained relatively high, which means that part of the researched waters were subject to severe eutrophication, with the estuaries marking the most eutrophic areas.

Fourth, there is an excess of nitrogen and a deficiency in phosphorus in the study area, but the N/P ratio declined from 176.680 in 2010 to 32.234 in 2015, which means the gap between the content of nitrogen and that of phosphorus narrowed and that the researched waters shifted from a state of phosphorus-limited eutrophication to medium-phosphorus-limited eutrophication. If the content of phosphorus rises due to the discharge of pollutants and effluents from rivers, the study area will in all likelihood suffer from eutrophication.

Lastly, according to the analysis from the perspective of time, the content of nutrients and the level of eutrophication in the study area is higher in autumns than in springs,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1406914085

which is largely because the phytoplankton begins reproduction and consumes such nutrients as nitrogen and phosphorus during this time. According to the analysis from the perspective of spatial distribution, the content of nutrients and level of eutrophication declines from the land outwards and from north to south, with the estuaries marking the highest values. Pollutants from rivers and effluents from human activities along the coastline and in the adjacent land to the sea are major factors that determine the temporal and spatial distribution of the content of nutrients and level of eutrophication in the waters of the Abandoned Yellow River Delta.

(Received 28th May 2019; accepted 31st Oct 2019)

Abstract. This study was conducted to determine the yield and some plant characters of different types of lavender (*Lavandula* spp.) at Harran University, Faculty of Agriculture, in Şanlıurfa, Turkey, during 2015, with Randomized Complete Block Design with three replications. In the study, 5 different types of lavender [*L. angustifolia* (Grosso Tina, English cv.) and *L. x intermedia* (Abriel, Dutch, Grosso cv.)] were used as plant material. This research was determined the plant height (29.30-31.15 and 25.47-30.10 cm), canopy diameter (47.72-56.86 and 44.33-47.60 cm), dry herb yield (91.32-111.80 and 66.17-103.31 g plant^{-1}), dry leaf yield (68.52-83.11 and 53.36-78.99 g plant^{-1}) and essential oil ratio (0.92-0.99% and 0.87-0.99%) of *L. angustifolia* and *L. x intermedia*, respectively. In addition, the major constituents of the essential oils of *L. angustifolia* and *L. intermedia* leaves were determined to be 1.8 cineol (33.11-36.19%), camphor (21.04-22.15%) and borneol (7.33-9.63%).
Keywords: *leaf yields, volatile oil constituents, herb yields, L. angustifolia, L. x intermedia*

Introduction

In recent years, the use and trade of medicinal and aromatic plants has increased significantly. This has made these crops sought after in domestic and foreign markets (Baydar and Erbas, 2007). The *Lavandula* genus belongs to the family of *Lamiaceae* (*Labiatae*) and has perennial species containing aromatic flowers and leaves. There are about 39 lavender species (*Lavandula* spp.), most of which originate from the Mediterranean region. There are three important species of lavender in the world with high commercial value. These are lavender (*Lavandula angustifolia* Mill), lavandin (*Lavandula x intermedia* Emeric ex Loisel) and spike lavender (*Lavandula spica* Medik.). More in the world, lavender and lavandin species are being cultivated (Baydar, 2009). Lavender essential oil quality is the best, while lavandin varieties have higher essential oil yield (Baydar and Erbas, 2007). Lavender and lavandin essential oils have a wide range of uses due to its many properties. It is used in perfumery and cosmetics industry because of its beautiful smell and is used in the pharmaceutical industry due to its sedative and pain-relieving properties (Baydar, 2009). Also, the herb essential oils of lavender and lavandin possible used be in fermentative or enzymatic processes involving various microorganisms, especially filamentous fungi, for the production of antimicrobials, antioxidants and other bio products with pharmaceutical and cosmetic activities, opening up new challenging perspectives in white biotechnology applications (Meessen et al., 2015).

It has been reported that the essential oil components of *Lavandula* species vary according to plant parts (Touati et al., 2011), genotype (Kara and Baydar, 2013), ecological conditions (Khalajee et al., 2017) and cultivation technique (Chrysargyris et al., 2017). The essential oils of *Lavandula* species show different chemotypes. The main

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1408714094

components of lavender essential oil are linalyl acetate (25.0-47.0%), linalool (25.0-45.0%) and camphor (0.5-1.5%) (ISO 3515), whereas the main components of lavandin essential oil are linalool (28.0-38.0%), linalyl acetate (19.0-29.0%) and camphor (7.0-11.0%) (ISO 3054). Lavender essential oil is included the lower camphor content than the essential oil of lavandin. Therefore, lavender essential oil is better than lavandin essential oil (Kara and Baydar, 2013). For these reasons, we can say that the most important indicator of lavender essential oil quality is the camphor ratio.

The leaves and stems of *Lavandula* plants are contain essential oil like flowers. In commercial lavender essential oil production, flowers are generally used, but contain a significant amount of essential oil of leaves and stems. For this reason, it is important to know the essential oil components of lavender and lavandin leaves.

The aim of this study is to determine the leaf yields, some plant characteristics and leaf essential oil components of lavender and lavandin varieties.

Materials and methods

In the study, *L. angustifolia* (Grosso Tina and English cv.) and *L. x intermedia* Emeric ex Loisel, (Abriel, Dutch and Grosso cv.) obtained from the Atatürk Horticultural Central Research Institute, Yalova, seedlings were used as plant materials.

The trial was carried out in the summer of 2015 in Harran University, Faculty of Agriculture, Eyyübiye Campus, Agricultural Research and Application Field, in Şanlıurfa, Turkey. The experimental field was located in South-eastern Anatolia region (in the Harran Plain) where semi-arid climate conditions are prevail, and some climatic data for the area are given in *Table 1*.

Table 1. *Monthly average some climate data in Şanlıurfa (Anonymous, 2016)*

Mounts	Temperature (°C)			Total Precipitation (mm)	Relative Humidity (%)	Sunshine Duration (h)
	Minimum	Maksimum	Mean

In the Sanliurfa province, where the typical continental climate prevails, the summers are hot and dry and the winters are cold and rainy. Throughout vegetation period, totally 389.8 mm precipitation were recorded.

The soils where the experiment was established are deep and flat soils with flat all sides. Typical red profiles have a clayy texture. The whole profile is very calcareous, low organic matter content, high cation exchange capacity (Dinç et al., 1988).

The trial area was plowed deeply before planting, then mixed by a cultivator and made ready for planting. In trail area, before the surface tillage, 150 cc da^{-1} herbicide

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1408714094

(*trifluralin*), 10 kg da^{-1} N, 10 kg da^{-1} $P_2 0_5$ and 10 kg da^{-1} K_2O composite fertilizer (15.15.15) was applied. The experiment was set up as four rows each was 5 m in length, for each cultivars. The seedlings were planted by hand, in the each plot with 70 x 50 cm distance on May 16, 2014. The trial was planned to the Randomised Block Design with three replicated. Immediately after planting, seedlings were given water. During the growing period, according to the needs of the plant irrigation and weed operation was performed according to the weed condition. The 10 plants were harvested, after the side effects were removed from the middle parts (3 repetitions), with 15 cm high from the ground on November 20, 2015 and the related observations were taken. After harvest *Lavandula* plant samples were separated in leaves and stems. Each samples were naturally dried in shadow and kept at 4°C until analysis. In the trial, plant height (cm), canopy diameter (cm), dry herba yield (g $plant^{-1}$), dry leaf yield (g $plant^{-1}$), volatile oil ratio in dry leaf (%) and volatile oil components (%) were determined to the method proposed by Balyemez (2014). Since the varieties did not bloom in the experimental year, there were no observations about the flowers.

Essential Oil isolation

Each dry *Lavandula* leaf sample (50 g) was hydrodistilled with 500 ml water in a Clevenger type apparatus during 3 h. The essential oil was stored in a dark glass bottle and kept at 4°C until GC-MS analysis.

Gas chromatography-mass spectrometry analysis

Lavandula essential oil was analysed by GC-MS using an Agilent 7890A equipped with an electron impact quadruple, Agilent 5975C mass spectrometer detector. The electron ionization energy was 70 eV, scan range 35-450 amu and scan rate 1 scans $second^{-1}$. The GC column was used an HP Innowax Capillary (A fused silica capillary column 5% phenyl-poly-dimethyl-siloxane), film thickness of 0.25 μm, a length of 60 m, and internal diameter 0.25 mm. The carrier gas was helium with a flow rate 0.8 ml $minute^{-1}$. Inlet temperature was 250°C. The GC oven temperature program was used as follows; 60°C initial temperature, hold for 10 min, raised at 4°C min^{-1} to 220°C and finally hold at 220°C for 10 min. A 1% (v/v) solution of the sample in n-Hexane was prepared and 1μl was injected using a 40:1 split ratio.

The identification of compounds was performed by comparing their mass spectra with data from Adams, US National Institute of Standards and Technology (NIST, USA) and WILEY 1996 Ed. mass spectra library. The identification of compounds was also based on the Kovats retention indices.

The data were subjected to analysis of variance (ANOVA) using Randomized Complete Block Design. The significance of differences among the different cultivars was determined using LSD with 5%.

Results and Discussion

Determined average the plant height, canopy diameter, dry herb yield, dry leaf yield and essential oil ratios of the varieties of different *Lavandula* species was given *Table 2*.

As shown in *Table 2*, the highest plant height, canopy diameter, dry herb yield and dry leaf yield were determined in Grosso Tina cultivar of the *L. angustifolia* and Grosso cultivar of the *L. x intermedia* type. In general, all properties were examined,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1408714094

L. angustifolia species was higher than *L. x intermedia*. This difference may be caused by genotypic difference.

As seen in *Table 2*, there was no statistically significant difference between the varieties in terms of essential oil ratio. The ratio of essential oils were varied between 0.91% and 1.01% depended on cultivars. The highst essential oil ratio was determined on the Grosso Tina and the Grosso cultivars.

According to *Lavandula* varieties, the ratio of the essential oil components detected in the leaves and the ratio of the chemical groups of the essential oil components are given in *Tables 3* and *4*, as percentage.

In total, between 51-52 components were quantified and characterized in the leaf essential oils of *L. angustifolia* and *L. x intermedia* cultivars, accounting for 97.31-99.55% (by GC peak area) of total oils. The main constituents in the essential oil of *Lavandula* leaves were 1.8 cineol 35.24% (33.11-36.19%), camphor 21.79% (21.04-22.15%), borneol 8.63% (7.33-9.63%), tau-cadinol 3.01% (2.46-3.35%), limonene 2.53% (2.11-2.86%), caryophyllene oxide 2.39% (2.12-2.63%), cumin aldehyde 1.91% (1.56-2.08%), carvone 1.45% (1.23-1.55%), *delta*-terpineol 1.43% (1.39-1.47%), *gamma*-cadinene 1.28% (1.05-1.44%), *trans*-verbenol 1.17% (1.13-1.24%), *trans*-carveol 1.12% (1.10-1.19%), *p*-cymene 1.11% (1.03-1.18%), *alpha*-terpineol 1.02% (0.90-1.11%) and terpinen-4-ol 1.01% (0.81-1.31%) (*Table 3*). However, the leaf essential oil was characterized by the presence of two dominating constituents (1.8 cineol and camphor with more than 54% composed of components). The other compounds detected in the range 0.05-1.00%. Essential oils of *Lavandula* species have been previously investigated by some researchers. In lavender, it was found the main components of the essential oil that in leaves 1,8-cineole 25.70% and borneol 11.32% (Meftahizade et al., 2011), borneol 15.21%, 1,8-cineole 8.50% and geraniol acetate 5.21% (Skwirzyńska et al., 2013), 1,8-cineole 31.9%, borneol 24% and camphor 16.1% (Hassanpouraghdam et al., 2011); in inflorescence β-linalool 18.74-34.43% and linalool acetate 20.68-30.57% (Zagorcheva et al., 2013), 1,8-cineole 64.99-71.08% and limonene 8.58-9.11% (Koleilat et al., 2017), linalool 28.5-43.9%, linalyl acetate 5.38-25.7% and cymene 1.14-11.30% (Kara and Baydar, 2013), linalool 33.7%, 1,8-cineole 17.1% and borneol 14.7% (Hassanpouraghdam et al., 2011).

In lavandin, it was found the main component of the inflorescence essential oil that 1,8-cineole 33.54% and camphor 18.89% (Koleilat et al., 2017), linalool 34.8-43.3%, linalyl acetate 3.76-44.46% and camphor 5.28-19.8% (Kara and Baydar, 2013). In *L. dentata*, it was found the main component of the leaf essential oil that 1,8-cineole 33.54% and camphor 18.89% (Touati et al., 2011). In *L. stoechas*, it was found the main component of the essential oil that fenchone 31.6%, camphor 22.4% and *p*-cymene 6.5% (Dob et al., 2006). Some researchers declared that the essential oil composition of lavender and lavandin varied depending on the genotype of the plant (Kara and Baydar, 2013), fertilization (Arabaci and Bayram, 2005; Chrysargyris et al., 2017), growth stage on the harvesting time (Baydar and Erbas, 2007), parts of the plant (Touati et al., 2011), harvest times at different on the day and year (Zheljazkov et al., 2012), drying conditions (Özgüven et al., 2007) and essential oil isolation technique (Skwirzyńska et al., 2013; Khalajee et al., 2017). Some similarities were recorded between our study and the previous reports. Investigation of our results revealed that the main component of leaves essential oils of lavender and lavandin cultivars were found 1.8 Cineol, like other researchers (Hassanpouraghdam et al., 2011; Meftahizade et al., 2011; Touati et al., 2011; Koleilat et al., 2017).

Baydar (2009) stated that better quality essential oil was included low camphor content and the camphor content in quality lavender oil must be between 0.5 and 1% in lavenders and between 5.0 and 10.0 in lavandins. Our result show that leaves essential oils of lavender and lavandin were included high camphor content (21.04-22.05% in lavender and 21.79-22.15% in lavandin). In this case, as the percentage of leaves in the plant during harvest increases, the amount of camphor in the volatile oil will also increase. In order to produce quality lavender essential oil, as few leaves as possible should be harvested.

GC/MS examinations of the essential oil indicated that monoterpens (88.95-89.85%) were characterized as the main class of components, followed by a minor rate of sesquiterpens (7.15-8.94%) in leaves of lavender and lavandin cultivars. It consists mainly of oxygenated monoterpenes (80.74-81.97%). Additionally, the leaves essential oil contained 7.49-8.79% monoterpene hydrocarbons, 5.93-7.26% oxygenated sesquiterpenes, 1.22-1.68% sesquiterpene hydrocarbons, and 0.63-2.24% other (*Table 4*). The concentrations of sesquiterpene hydrocarbons were lowest. Higher amounts of oxygen-containing monoterpenes in oils strongly support the dynamic pool of plastidal hydroxylases and dehydrogenases involved in the post-modification of the initial hydrocarbonic compounds (Hassanpouraghdam et al., 2011). Sesquiterpenes had a minor

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1408714094

share in the component classification, and the oxygenated compounds was higher than that of hydrocarbon sesquiterpenes. The lavender plant was potentiated in the biosynthesis and accumulation of monoterpenes rather than sesquiterpene ones. 1,8-Cineole was characterized as the most important oxidized compound and Camphor was the chief ketonic compounds of leaf essential oil.

Conclusion

Finally, the chemical profile of the leaf essential oil of lavender and lavandin cultivars were similar and showed a high content of 1,8-cineole, borneol and camphor. Camphor ratio was founded to be high in the essential oils of all cultivars leaves. If we are to produce high quality essential oil (low camphor), we must reduce the leaf content in the dry matter. The effect of lavender flower spike axis and stalk essential oil components on commercial lavender oil should be determined.

Abstract. The present study was conducted to assess the secondary metabolite profile differences of *Monsonia burkeana* populations naturally grown at Chuenespoort, Zebediela and Rietondale in South Africa. Three field surveys were conducted on 14 January 2015, 11 January 2016 and 4 May 2016 respectively in Chuenespoort, Zebediela and Rietondale and secondary metabolite profiles of the plants were determined using [1]H nuclear magnetic resonance (NMR) spectroscopy coupled with principal component analysis (PCA). Leaf samples from three plants per locality in the first survey and fourteen plants per site in subsequent samplings were included in the NMR analysis. Based on [1]H NMR spectroscopy and PCA of secondary metabolite profile data no major differences were detected between the populations except for the first survey where the Zebediela and the Chuenespoort populations were more closely related to each other than the Rietondale population. This study has for the first time determined differences between three plant populations of special tea with regards to secondary metabolite profiles.
Keywords: *plant population analysis, Monsonia burkeana, secondary metabolites, nuclear magnetic resonance, principal component analysis*

Introduction

Special tea (*Monsonia burkeana* Planch. ex Harv) (*Fig. 1*) is a prominent medicinal plant which is used to cure minor ailments (Venter, 1979) and it is native to Southern African countries such as Botswana, Lesotho, Mozambique, Namibia, Swaziland and South Africa (Wells et al., 1986; Gibbs Russel et al., 1987). This tea plant was recently reported in Madagascar (Schatz et al., 2011). Over and above indigenous knowledge various studies have uncovered the potential health benefits of special tea, among them, anti-diabetic and anticancer properties (Ngoepe et al., 2018; Mathivha, et al., 2019). Various biological and physical characteristics determine plant growth, plant traits and chemical composition, and therefore plant populations of various habitats are likely to differ in average plant height, average stem diameter, average number of leaves per plant, average dry biomass, leaf fat content, leaf protein content and secondary metabolite profiles (Khokhar and Magnusdottir, 2002; Clayton et al., 2006; Ohno et al., 2011; Von Staszewski et al., 2011; Sabhapondit et al., 2012; Lee et al., 2014a). For a wild tea plant which is harvested and traded it is important to determine if different populations are affected by their habitat characteristics so that productivity can be predicted and the harvested product quality can be standardized. Three populations of *M. burkeana* were selected for the assessment.

Figure 1. *Special tea (Monsonia burkeana Planch. ex Harv) plant growing in Rietondale, Gauteng Province, South Africa*

Nuclear magnetic resonance (NMR) spectroscopy coupled with principal component analysis (PCA) have been employed to evaluate the quality of foods and drugs and to evaluate drug toxicity (Khokhar and Magnusdottir, 2002; Ohno et al., 2011; Lee et al., 2014a; Martínez-Richa et al., 2003; Morita et al., 2004; Morita et al., 2008; Jiang et al., 2015). The use of this approach has been extended to plant population studies to assess differences as well as gauge various traits like plant population survival. Thus, in this study whose aim was to assess differences between three plant populations of special tea naturally grown in Chuenespoort, Zebediela and Rietondale and secondary metabolites profile differences of special tea populations were revealed using NMR coupled with PCA.

Materials and methods

Study area

Three sites, namely, Zebediela (Long: 24° 11′ 6″ S and Lat: 29° 27′ 42″ E), Chuenespoort (Long: 24° 10′ 56″ S and Lat: 29° 27′ 29″ E) and Riotendale (Long: 25° 43′ 43″ S and Lat: 28° 14′ 19″ E) were selected for the study. Zebediela and Chuenespoort are in the Limpopo province of South Africa about 20 km apart and Rietondale is in the Gauteng province about 300 km from the other two sites (*Figs. 2* and *3*).

These sites are isolated and natural except for Chuenespoort which was a maize field. However, no apparent disturbance took place at these sites, including Chuenespoort, during the survey period. Three field surveys were conducted on 14 January 2015, 11 January 2016 and 4 May 2016 as shown in *Table 1*. The climate data was included to show one of the aspects that vary between the sites but no aspect of climate is part of the investigation.

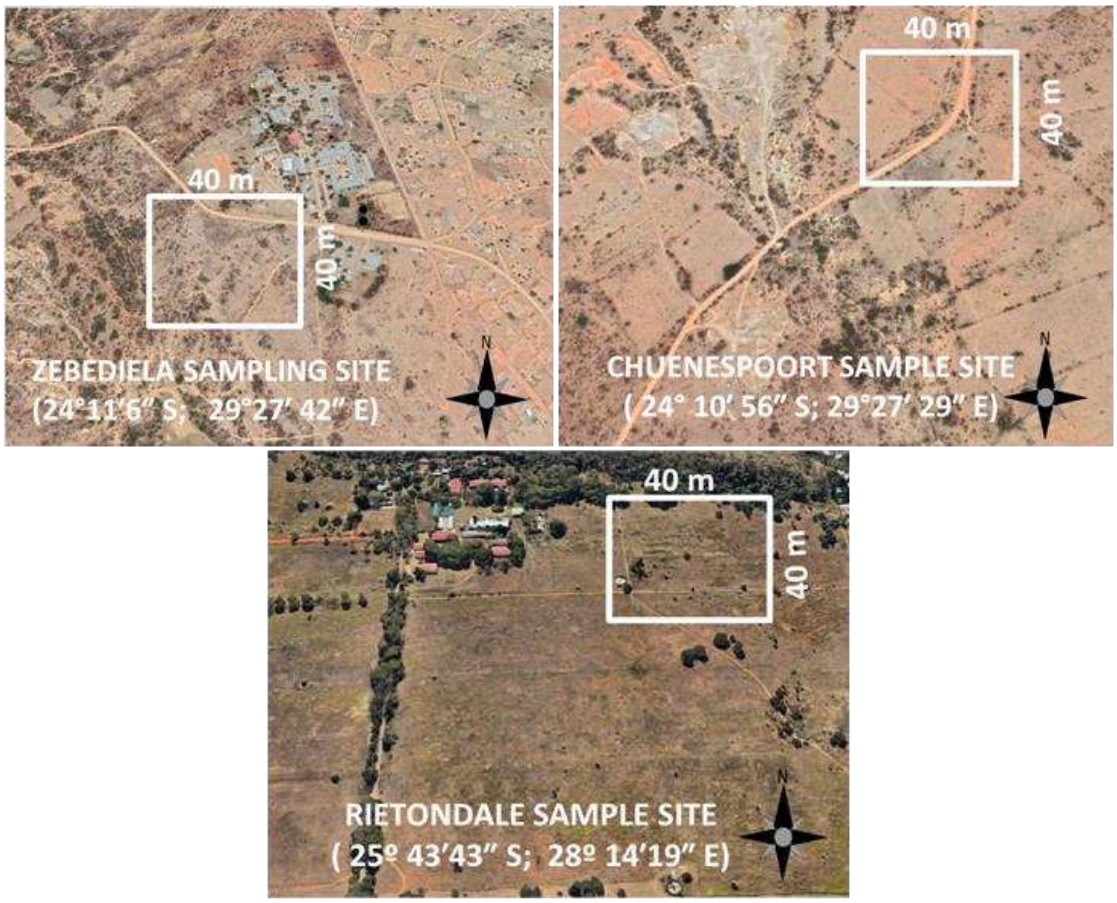

Figure 3. *Study sites Zebediela, Chuenespoort and Rietondale showing the demarcation of unitary quadrats in which leaf samples of Monsonia burkeana were collected for secondary metabolite profiling*

Secondary metabolite profiles of the plants were determined, three plants per locality in the first survey, fourteen plants per site in subsequent samplings. Secondary metabolite profiles were determined by ^{1}H NMR using a 600 MHz NMR Varian spectrometer to obtain magnetic spectra of the samples. Both phase and baseline corrections of the spectra were done using the ACD/NMR Processor. Only the most visibly discriminant range (assessed from spectra) was included in the bucketing for PCA. After processing the spectra, the intensity values represented by the spectra were exported as ASCII files and these intensity values were displayed on MS Excel to form a matrix which was used for PCA. PCA reduces dimensions of a dataset. It works by using an orthogonal transformation to convert a set of possible correlated variables into was is referred to as principal components. The principal components are designed in such a way as to explain as much of the possible variability. The first principal component has the largest possible variance and incrementally from the first principal component to successive principal components the possible variance decreases. For the dataset obtained in this study, the PCA was done using Multibase. Datapoints which represented NMR intensity values of the secondary metabolites extracted from the leaves of the plant samples from each of the localities were spread along PC 1 and PC 2. On the PCA scatterplot ellipses were drawn to show the discrimination between the localities.

Results

Secondary metabolite profiles which were determined by [1]H NMR spectroscopy, slightly varied or did not vary at all between the populations of Zebediela, Chuenespoort and Rietondale. Zebediela and the Chuenespoort populations were more closely related to each other than the Rietondale population in the first survey as shown by the PCA plot (*Fig. 4*) and the spectra shown in *Figure 5*.

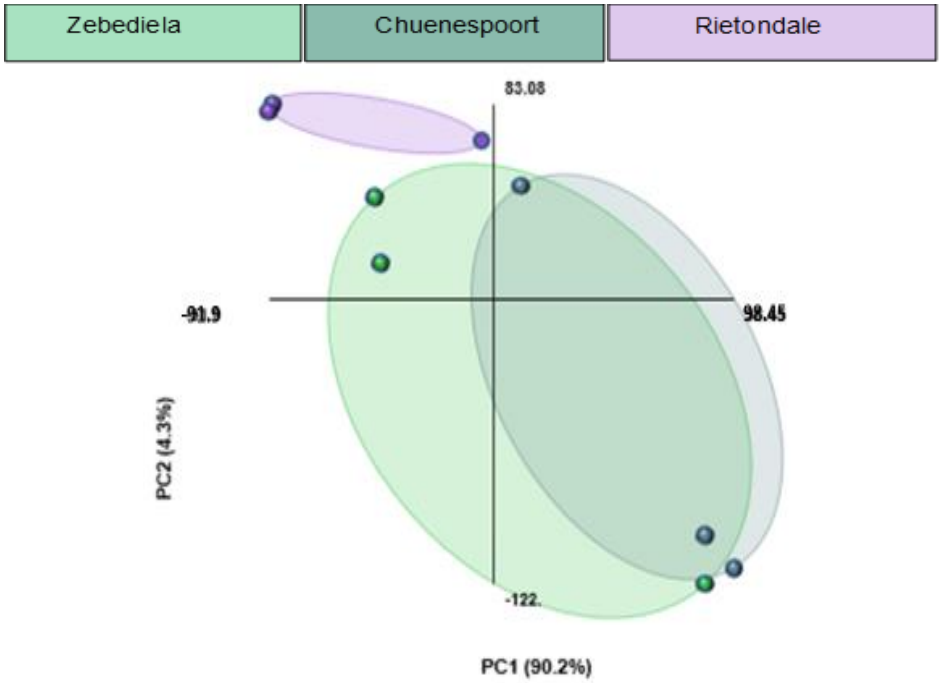

Figure 4. *Principal component analysis plot of [1]H NMR intensity values of secondary metabolites of Monsonia burkeana leaf samples from Zebediela, Rietondale and Chuenespoort. The sampling dates was 14 January 2015. The PCA plots show that the Rietondale site is slightly different from the other two sites which are similar*

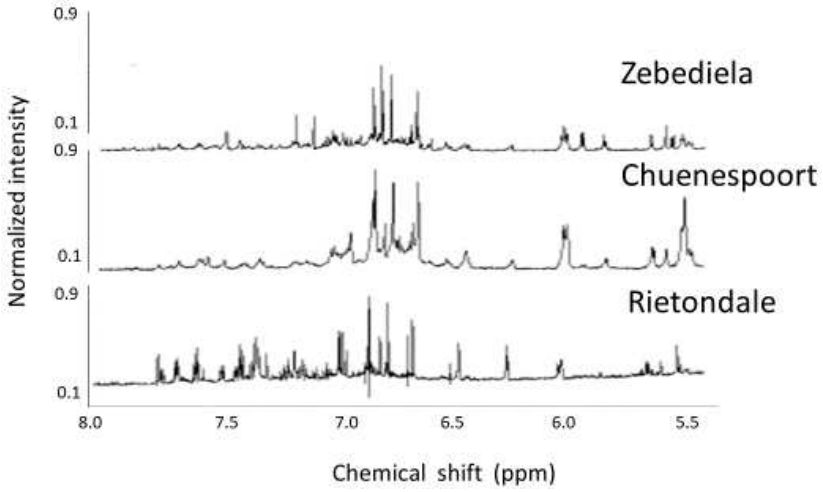

Figure 5. *[1]H NMR spectra of Monsonia burkeana leaf secondary metabolites in the 8.0–5.5 ppm range. Sampling was done in 14 January 2015. Notice that the spectrum of the Zebediela locality and Chuenespoort's are visible different from the Rietondale spectrum*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1409514103

In subsequent surveys, no difference in secondary metabolite profiles were detected in the different plant populations. The differences in the ^{1}H NMR spectra of special tea leaves from three plant populations shown in *Figure 5* was clearly as a result of differences in the 5.5–8.0 ppm range which was selected from the original shift scale which was from 0 ppm to 14 ppm. Within this discriminant region, it was obvious that the segregation was further determined by the region between 6.5 ppm and 7.8 ppm. The regions of sharp differences between the Rietondale spectra and either of the spectra, Zebediela and Chuenespoort must have caused the separation of the Zebediela ellipse from the other ellipses in the PCA plot in *Figure 4*.

Discussion

The current study revealed slight differences in the secondary metabolite profiles of three areas in one of three samplings conducted on 14 January 2015, 11 January 2016 and 4 May 2016. Studying natural plant populations is always challenging because of the inability to determine all interacting factors. The authors of this manuscript intended just to assess differences in the secondary metabolomic profiles of *M. burkeana* populations in Zebediela, Chuenespoort and Rietondale without investigating all underlying biophysical factors. However, it was found necessary to obtain rainfall and temperature data since rainfall and temperature are assumed to be major determinants of the growth and survival of the plant. The Rietondale site which is located about 300 km south of the other two sites received a little more rain and was also slightly warmer than the other sites. Despite these observable differences it was not possible to assume that these climatic differences were the main causes of the marked secondary metabolite profile differences observed in the samples collected on the 14 January 2015. A more comprehensive study would be necessary to assess this aspect. The scope of this work was only limited to assess if there are any differences in the secondary metabolomic fingerprint. However, it was unsurprising to find some differences in the secondary metabolite profiles of the study populations given the differences between plant populations caused by factors such as rainfall, temperature, soil type and altitude. The difference in secondary metabolites may be attributed to variation in rainfall received during the sampling periods. It was noted that in the first survey of the current study high rainfall was recorded as compared to the subsequent two surveys where low rainfall was received. A study conducted by Wedeking et al. (2018) indicated that drought stress triggers various physiological and biochemical responses in plants. The exposure of plants to various stress conditions results in modulations in metabolite contents and altered metabolic interactions, caused by alterations in environmental parameters, such as light, temperature and water (Mittler, 2006).

Secondary metabolism of plants may change considerably due to the influence of several biotic and abiotic stress signals (Pavarini et al., 2012). The finding of the current study is in agreement with Lee et al. (2014b) who found that secondary metabolites from the *Curcuma* spp. from different geographical locations using PCA was not different between the locations. However, this is in disagreement with Martin et al. (2016) who found that secondary metabolites from *Galium odoratum* showed clear differences between the plants from nature and those of controlled growth conditions as well as internal variation within the group. Lee et al. (2010) studied the effects of climatic conditions on *C. sinensis* metabolites in three different growing areas of Jeju Island, South Korea using ^{1}H NMR spectroscopy and found the revealed clear

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1409514103

discriminations of green teas from the three different growing areas. The ^{1}H NMR technique itself provides a solution for the identification and quantification of metabolites in plant cell, tissue, organ and extracts (Halabalaki et al., 2014; Zhou et al., 2017). Both PCA and orthogonal projections to latent structures discriminant analysis (OPLS-DA) revealed clear discriminations of green teas from the three different growing areas in terms of theanine, isoleucine, leucine, valine, alanine, threonine, glutamine, quinic acid, glucose, epicatechin (EC), epigallocatechin (EGC), epigallocatechin-3-gallate (EGCG), and caffeine levels. The PCA revealed a separation between the Longjing type and other Chinese teas in metabolites differences. Changes in seasonal climatic conditions affect flavanol and purine alkaloid contents of two leaves and a bud of tea (Wang et al., 2011). Lengthy period of precipitation decreases EGC, EC, ECG, EGCG and their total content but increases C content, whereas increased daily average temperature decreases the levels of EGC, EC, ECG, EGCG and C in green tea. The EGCG, CG and total catechins (TC) in *C. sinensis* grown at a high altitude are higher than those grown at a low altitude (Chen et al., 2010).

Nchabeleng et al. (2012) determined the chemical composition of wild bush (*Athrixia phylicoides* DC.) tea growing at locations differing in altitude, climate and edaphic factors. There was a positive correlation ($r^2 = 0.55$) between total polyphenol content of *A. phylicoides* and altitude. Samples of *Angelica gigas* collected from different geographical regions were distinguished by Kim et al. (2011) using ^{1}H NMR spectroscopy and ultraperformance liquid chromatography–mass spectrometry (UPLC-MS) followed by multivariate data analyses. The study concluded that ^{1}H NMR and UPLC-MS-based metabolic profiling coupled with chemometric analysis can be used to discriminate the geographical origins of various herbal tea. The variations of the total and individual catechin contents of tea were evaluated among three cultivars grown in 10 locations; the dynamic changes of chlorophyll and catechin contents in two cultivars during young leaf development were also analysed. This study highlights how metabolomics coupled with multivariate statistical analysis can illuminate the metabolic characteristics of *M. burkeana.* This application can be extended to do special tea quality studies.

Conclusion

In conclusion, based on ^{1}H NMR and principal component analysis of secondary metabolite profile data no major differences were detected between the populations except only in the first survey when the Zebediela and the Chuenespoort populations were more closely related to each other than the Rietondale population. Follow-up studies must focus on an in-depth understanding of the various causes of secondary metabolite profile differences between populations in various localities in South Africa. Discriminatory secondary metabolites must be identified using various applications from NMR to chromatography coupled with mass spectrometry. Moreover, future studies should determine the growth potential of *M. burkeana* under controlled conditions, and further metabolomic profiling of the special tea growing under controlled conditions.

Abstract. In order to assess the contamination, ecological and biotoxicity risk of heavy metals (Cd, Cr, Cu, Ni, Pb and Zn) in mariculture area of China, the total concentrations and speciation of metals were analysed in the sediments from a typical mariculture bay in 2011 and 2013. The results show that most heavy metal concentrations in 2013 were lower than those in 2011. The residual and sulfide-bound fractions were the primary fractions of heavy metals. The pollution can be described in all the sampling sites of heavy metals (except Cd) with moderate to a very high degree by geo-accumulation index (Igeo), enrichment factor (EF) and pollution load index (PLI). According to the risk assessment code (RAC), Cd, Ni and Pb posed a medium to very high ecological risk. The sampling sites that exhibited the biotoxicity risk in 2013 had higher biotoxicity levels than that in 2011. Based on statistical analysis and environmental investigation, four sites (S1, S2, S4 and S7) were highly affected by the environmental pollutants which primarily resulted from the combustion of gasoline and diesel fuel and the ships protective layer.
Keywords: *ecological risk, biotoxicity risk, Zhelin Bay, speciation, pollution load index, the risk assessment code*

Introduction

Heavy metals in ecosystems have received extensive attention because they are toxic, non-biodegradable, and easily bioaccumulate in organisms (Al-Othman et al., 2012; Dabney et al., 2018; Gao et al., 2012; Ghosh et al., 2018; Islam et al., 2014; Väänänen et al., 2016; Yang et al., 2012). With rapid industrialization and economic development in the coastal region of South China, heavy metals from industrial waste, sewage runoff, and agricultural discharges, are continuously introduced into the estuarine and bay environment through rivers, runoff, dust deposition and land-based point sources (El Nemr et al., 2016; Hyun et al., 2007; Wu et al., 2015; Yu et al., 2008). Due to the adsorption, hydrolysis, and co-precipitation of heavy metals, most of such pollutants deposit in the sediments and only a small part of free metal ions leave in water (Chaudhary et al., 2015; Hu et al., 1997; Nobi et al., 2010; Zwolsman et al., 2013.)

In recent decades, various assessment indices have been applied to assess the environmental pollution and risk of heavy metals in marine sediments. The heavy metal contamination in sediments is evaluated by the geo-accumulation index (Igeo), enrichment factor (EF) and pollution load index (PLI) (Gu et al., 2018; Liu et al., 2014; Varol et al., 2011; Wang et al., 2016;). In particular, the Hakanson risk index is prevalent in evaluating the ecological risk posed by heavy metals in sediments (Wu et al., 2014; Yi

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1410514120

et al., 2011; Zhuang et al., 2014.). However, the mobility and toxicity of heavy metals in sediment depend not only on their total concentrations, but also on their physicochemical fractions described as "speciation" (Yuan et al., 2004; Zhou et al., 2004.). The sequential extraction (SE) technique is often used to determine heavy metal speciation in sediments, defined operationally as acid soluble, reducible, oxidizable and residual fractions (Gao et al., 2010; Zhang et al., 2013.). Meanwhile, sediment quality guidelines (SQGs) and acid volatile sulfide (AVS)-simultaneous extracted metals (SEM) model are widely applied to analyze the bio-toxicity of heavy metals (Prica et al., 2008; Poot et al., 2009; Sundaray et al., 2011.). The exchangeable and carbonate fractions are usually used in the method of the risk assessment code (RAC) to assess the ecological risk.

Zhelin Bay, a semi-enclosed estuarial bay, which situated in the northeast part of Guangdong Province, is one of the most developed areas in China. Zhelin Bay is the largest cage mariculture areas and a vital culture fish zone in South China (Qiao et al., 2010) with many seaport container terminals for international seafood export. Due to the maritime activities, a lot of phosphorus, nitrogen, and organic wastes are discharged, and consequently result in water eutrophication (Cao et al., 2007; Liang et al., 2011; Wu et al., 2016; Xia et al., 2016). Meanwhile, the heavy metal pollution in the bay area is getting worse (Qiao et al., 2010; Xia et al., 2016). The high concentration of heavy metals in sediments can be directly or indirectly bio-accumulated in benthic invertebrates, as sediments provide the benthic fauna food sources and habitats. Therefore, the environmental hazards in the bay become increasingly severe (Kalantzi et al., 2013). The risk assessment of heavy metals in the sediment of the culture area has gained much attention because of the pollution characteristics and ecological hazards of heavy metals.

Our previous study suggested that the ecological risk level of heavy metals in this area is medium to high, especially at the northwest coastal area of the semi-closed bay (Wang et al., 2016). This study was conducted to consolidate and complement the previous results. PLI was used to assess the metal contamination compared with the EF and I_{geo} results. Based on heavy metal speciation, RAC was used to assess the ecological risk, and the results were compared with the Hakanson risk index. The AVS-SEM model was used to predict the bio-toxicity risk, and the results were compared with the SQGs. The study aims to analyze and evaluate the pollution and risk of heavy metals in this area, and identify the potential sources of high risk. The results could provide crucial information for the monitoring, management and conservation of coastal environments.

Materials and methods

Sampling

Samples of surface sediment from eleven sites were collected using a Petersen grab in September 2011 and August 2013 (*Fig. 1*) from Zhelin Bay in southern China. Temperature, salinity, pH and dissolved oxygen of the bottom water were measured by YSI water quality sensors on site (600R mode, YSI Inc., USA). Triplicate sediment samples were placed in the N_2 filled polypropylene bags rapidly after collection, immediately transported to the laboratory and freeze-dried before chemical analysis.

Chemical analysis

After drying at 70 °C for more than 24 h, the samples were re-weighted for the determination of moisture. Sediment total organic carbon (TOC) contents were estimated

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1410514120

by the wet oxidation method using $K_2Cr_2O_7$ -H_2SO_4 (Mingorance et al., 2007). The total concentration of heavy metal in sediment samples was analyzed following the EPA 3052 method (Wang et al., 2011). The concentrations of Al, Fe, Mn, Si, Cu, Ni, Pb, Zn, Cr and Cd in the final solutions were measured by microwave plasma-atomic emission spectroscopy (MP-AES, Agilent 4200) and atomic absorption spectrometry (AAS, Hitachi Z-2000). Analytical accuracy was achieved by the use of blanks and certified reference materials including GBW 07314 and GBW 07334, issued by the State Oceanographic Administration of China.

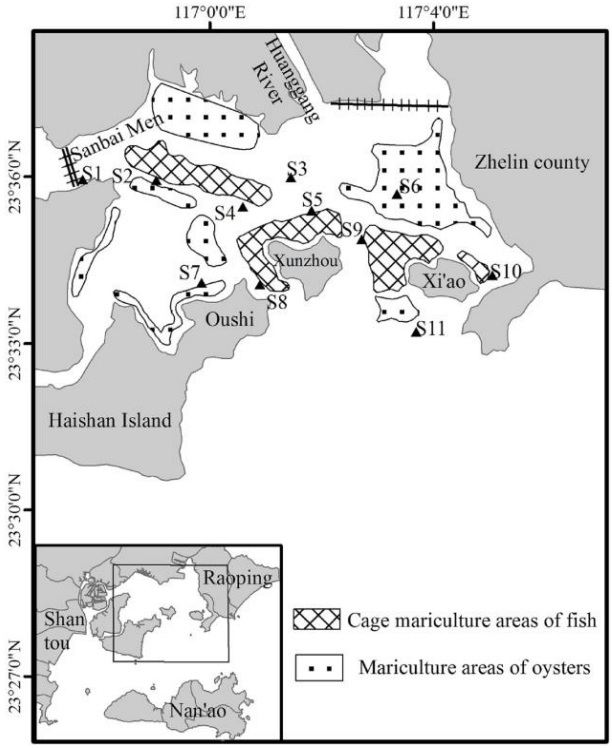

Figure 1. *The study area and sediment sampling sites in Zhelin Bay along the southern coast of China*

Extraction operations were performed by rotary shaking at 20 °C in dark environment with 100 ml of sealed centrifuge tubes. By centrifuging (4000 rpm, 10 min), the separation of the solid from solution was carried out for each step. The supernatant was then thrown away, and the residual was rinsed and centrifuged again. The centrifuge tubs were filled with N_2 in the experimental procedure. After acidifying the metal solutions with HNO_3, the metal concentration was determined by MP-AES and graphite furnace atomic absorption spectrometry (GFAAS, Thermo SOlAAR M6).

Five fractions from 4.5 g wet sediment were extracted using the proposal sequential extraction (PSE) procedure (Wang et al., 2011; Xia et al., 2016). Five fractions were weak acid soluble fraction (F1: pH 5.0, 1 M NaOAc, sample dry weight/extractant volume (SE) 1:15, 5 h), reducible fraction (F2: pH 2.0, 0.2 M NH_2OH•HCl + 0.2 mM EDTA-Na_2, SE 1:15, 5 h), organic matter bound fraction (F3: pH 9.8, 0.1 M $Na_4P_2O_7$, SE 1:10, 5 h), sulfide bound fraction (F4: 6 M HCl, SE 1:10, 1 h) and residual fraction (F5: estimated as the total metal content). F1 was the bioavailable fraction of heavy metals including the exchangeable and carbonates bound fractions.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1410514120

The procedure for AVS analyses was protected by N_2 and the same with that by Allen et al. (1993). The suspension in the acidified sediment was filtrated with a 0.45 μm membrane filter (Fang et al., 2005) and analyzed by MP-AES and GFAAS. Standard materials validated the results. By methylene blue method, the sulfide in the trapping solution was analyzed.

Ultra-pure, deionized water (Milli-Q) was boiled and purged with nitrogen to remove dissolved oxygen. All glassware and plastic containers were soaked in 2.7 M HNO_3 for at least 24 h and rinsed with deionized water before use. Standard solutions were prepared by dilution of 1000 μg/mL stock solutions with deionized water. All chemicals used in the experiment were at least of analytical reagent grade (p. A.) or superior purity. The concentrations of sediment components, including AVS, TOC, and metals were expressed as dry weight normalized concentrations.

Assessment of the metal contamination

The index of contamination factor (CF) and the pollution load index (PLI) were used to describe the sediment quality. PLI of the six metals were counted (Islam et al., 2015). The PLI was defined as the nth root of the multiplications of the CF of metals.

$$\mathrm{PLI} = (CF_1 \times CF_2 \times CF_3 \times \ldots \times CF_n)^{1/n} \quad \text{(Eq.1)}$$

where $CF_{metals} = C_{metal}/C_{background}$.

The background values of Cd, Cr, Cu, Ni, Pb and Zn in sediment were 0.15, 28.6, 15.8, 14.8, 32.2 and 57.8 ug/g, respectively (Qiao et al., 2009; Wang et al., 2010). PLI evaluated the overall contamination evaluation for all sites and a contribution consequence of the six metals. Therefore, the PLI value of zero indicated excellence, 1.0 represented only baseline level pollutants, and more than 1.0 indicated gradual deterioration of estuarine environment (Tomilson et al., 1980). The contamination factor (CF) of a given metal was calculated as the ratio of its measured concentration to natural abundance. The CF was then classified into four grades for monitoring the pollution from each metal over a period of time: low degree ($CF < 1$), moderate degree ($1 \leq CF < 3$), considerable degree ($3 \leq CF < 6$), and very high degree ($CF \geq 6$). Thus, the CF values indicated the enrichment of each metal in sediments over a period of time (Islam et al., 2015).

Assessment of risk

Assessment of ecological hazardous risk

In order to assess the risk to the ecological environment, the RAC was applied (Perin et al., 1985; Zhao et al., 2012), which was defined as *Equation 2:*

$$\mathrm{RAC} = \frac{[\mathrm{M}]_{Weak}}{[M]_{Total}} \times 100\% \quad \text{(Eq.2)}$$

where $[M]_{Weak}$ was the concentration of metals in weak acid soluble fraction, and $[M]_{Total}$ was the total concentration of metals. According to the RAC values, each sample falled into one of the five tiers: i) $RAC \leq 1\%$ (no risk); ii) $1\% < RAC \leq 10\%$ (low risk); iii) $10\% < RAC \leq 30\%$ (medium risk); iv) $30\% < RAC \leq 50\%$ (high risk); v) $50\% < RAC$ (very high risk).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1410514120

Assessment of biotoxicity risk

The concentrations of AVS, SEM and TOC were used to predict the toxicity (Di Toro et al., 2005). If $(\sum SEM\text{-}AVS)/f_{OC}$ was less than 150 μmol/g_{OC}, adverse effects due to SEM metals were not expected, and if $(\sum SEM\text{-}AVS)/f_{OC}$ was over than 3400 μmol/g_{OC}, suggested acute toxicity, and the range of uncertain effects was 150-3400 μmol/g_{OC} (McGrath et al., 2002).

Quality control and data analysis

The AVS, SEM and speciation analysis in replicates were measured to estimate the precision of the method. The relative standard deviation was less than 12% with the recoveries within 10% for the certified values. Total recoveries as the sum of individual metal fractions from SE compared to total contents were reasonable and ranged from 92.5-110% for Cd, 90.0-112% for Cu, 93.4-110% for Ni, 90.5-108% for Pb, and 96.9%-104% for Zn, respectively.

In this work, factor analysis and correlation analysis were used to elucidate the relationship between metals, parameters and risks, characterize the associated components of heavy metals, and identify the sources of heavy metal contamination. Correlation analysis was performed with two-tailed Pearson test, with $p < 0.05$ and $p < 0.01$ as the significant values. The descriptive statistics were used by SPSS 19.0.

Results and discussion

Distribution of heavy metals in the sediments

Among all sampling sites, no fluctuation was observed in the values of pH, dissolved oxygen (DO) and the moisture content of sediment (*Table 1*). However, the concentrations of TOC, Al, Mn, Fe, and Si show significant differences when comparing the values obtained in 2011 and 2013 ($p > 0.05$). For instance, the average value of TOC, Al, Mn, Fe, and Si was 1.11%, 9.86%, 0.104%, 5.09%, and 22.27%, respectively. In 2013, the average content of the above parameters reached 1.05%, 10.17%, 0.104%, 5.07% and 22.84%, respectively. The dissolved oxygen concentration was 2.88 ~4.72 mg/L in 2011 and 3.94~6.74 mg/L in 2013, indicating that the sampling point was an anoxic area.

The mean concentration of each metal in 2013 was lower than that in 2011 (*Fig. 2*). In 2011, the concentrations of Cd, Cr, Cu, Ni, Pb and Zn were in the ranges of 0.071–0.150, 27–35, 26–45, 31–204, 6–83 and 138–177 μg/g, with the averages of 0.108, 31, 32, 90, 76 and 156 μg/g. In 2013, the respective ranges were 0.057–0.110, 21–30, 23–35, 26–136, 51–64 and 116–196 μg/g, with the averages of 0.082, 26, 28, 55, 56 and 121 μg/g. The average values of Cu, Ni, Pb and Zn were higher than their background values, and close to their background for Cd and Cr. Heavy metal concentrations here generally exceeded the results from earlier studies (Qiao et al., 2010; Xia et al., 2016). There was a big difference on the distribution of Cd and Ni at those sampling sties. According to *Figure 2A* and *C,* Cd was mainly distributed close to the land area (S1, S2, S5, S7 and S11), and Ni near the cage mariculture areas (S2, S4, S5, S8 and S10).

The speciation distribution of heavy metals in the mariculture sediment is shown in *Figure 3.* Cr fractions were not investigated because the valence state is more important than that its bound fraction. Cd mainly was found in F1 33.6~63.8% in 2011 and 47.4~63.6% in 2013 and F4 16.9~43.4% in 2011 and 21.9~34.8% in 2013. The dominant

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1410514120

phase of Cu was in F5 53.6~69.2% in 2011 and 51.4~69.0% in 2013 and F4 20.0~32.7% in 2011 and 18.9~29.1% in 2013. Additionally, 5.3~12.2% in 2011 and 6.4~14.4% in 2013 of total Cu concentration existed in F3. The dominant proportion 64.0~74.1% in 2011 and 58.7~67.4% in 2011 of Pb was found in F5, and the proportions of other fractions were in the following order: F4 (12.8~19.5%, 2011), (17.1~26.7%, 2013); F1 (5.8~15.8%, 2011), (7.2~17.4%, 2013). The dominant phase of Zn was in F5, which accounted for 59.0~67.2% in 2011 and 53.0~69.6% in 2013. Ni was mostly retained in F5, representing 61.6~77.6% (in 2011), 58.6~72.5% (in 2013) of total concentration, and then F4 accounted for 8.9~23.6% (in 2011), 13.2~18.3% (in 2013) of total concentration. To sum up, Cu, Ni, Pb, Zn from the sediment were mainly present in the residual fractions, followed by the sulfide bound fractions, and then the content of organic matter bound fractions in Cu was higher than that of Cd, Pb, Ni, Zn. The Cd in the sediments was dominated by sulfide and weak acid fractions, followed by the residual fractions. On the whole, the reducing fractions of five heavy metals were low.

Assessment of the metal contamination

Figure 4 shows the CF values of each heavy metal in 2011 and 2013. It was shown that most of the CF values of the heavy metals in 2013 were lower than that in 2011, and the concentrations of heavy metals varied significantly at the eleven sampling sites. According to the CF values of heavy metals, all sites for Cd were in low degree in both years. The most sites for Cr in 2013 were in low degree, but in moderate degree in 2011. All sites for Cu and Pb were in moderate degree. Zn (at S6 in 2011 and at S8 in 2013) were in considerable degree. Half of the sites for Ni (mainly near the cage mariculture areas) were in very high degree, and heavy metal in this figure were arranged by their pollution degrees, Cd < Cr < Cu < Pb < Zn < Ni. The pollution degrees assessed by CF were higher for Zn, Cu, Cd, Pb, Ni than that by EF and Igeo in our previous studies (Wang et al., 2016.), furthermore, there were unpolluted at all sites for Cr by EF and Igeo. In general, based on CF, EF and I_{geo}, Cd at all sampling sites was unpolluted, and other heavy metals (except Cr) at all sampling sites were polluted, especially Ni near the cage mariculture areas was polluted in high degree. The PLI values of each sampling site are shown in *Figure 5*. It was shown that the PLI values in 2013 were lower than that in 2011 at all sites (except S8). At S8, the CF values of Cd, Cu, Zn and Ni in 2013 were higher than that in 2011. In both of 2011 and 2013, the PLI values were over 1.0 at all sites, which indicated that this area was polluted. In this case, despite the comprehensive pollution decreases, heavy metal pollution (especially Cd, Cu, Zn and Ni) at some site of this area should be considered for mariculture actions.

Assessment of risk

Assessment of ecological risk

The weak acid soluble fraction (F1) of Cd, Cu, Pb, Zn and Ni was analyzed, and the spatial distribution of calculated RAC values for those five metals in both two years was shown in *Figure 6* by ArcGIS. The order of ecological risk assessed by RAC was: Cd > Ni > Pb > Cu > Zn. The risk for heavy metals in 2013 was higher than that in 2011 (except Cu), the inconsistency of ecological risk and contamination shown that ecological hazardous risk was heavily affected by bound fractions of heavy metals than by their total concentrations.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1410514120

The range of RAC values for Cd was from 33.6% to 68.7%, which indicated high to very high risk. In 2011, very high risks for Cd were found at more than 50% of sites, especially at S5 and S9, where RAC values exceeded 60%. In 2013, very high risks for Cd were found in most of the sites (especially at S3 and S8) except S7. The range of RAC values for Ni and Pb was from 5.0% to 17.8%, from 5.80% to 17.4% respectively, which showed low to medium risk. For Ni, the medium risks existed in more than half site in 2011 and more than 70% sites in 2013, and a higher risk was found on S7 and S9 in 2011 and on S4 and S11 in 2013. For Pb, medium risks were contributed from less than half sites in both two years, and it presented higher risk at the S6 and S11 than other sites in 2011, S7 and S10 sites were higher in 2013. The range of RAC values for Cu and Zn were from 1.80% to 5.60%, from 1.80% to 6.30% respectively, which indicated low risk. For Cu, S9 and S10 showed higher risk than other sites in 2011, and S6 and S9 were higher in 2013. For Zn, S1 and S2 showed higher risk than other sites in 2011, and S1 and S10 were higher in 2013.

The order by Hakanson risk index was: Cd > Pb > Ni > Cu > Zn (Wang et al., 2016). The orders by both RAC and Hakanson risk index were approximately the same. However, assessed by Hakanson risk index, the risk degrees was a little lower than that by RAC, the higher risk occurred in 2011. Furthermore, the spatial distribution of ecological risk for each metal was different in two assessment methods.

Assessment of biotoxicity risk

The AVS and SEM concentrations of heavy metals in mariculture sediments were showed in *Table 2*. The AVS concentrations varied with sites, ranging from 0.005 to 2.012 μmol/g in 2011 and from 0.210 to 1.706 μmol/g in 2013. The average concentrations of Cd, Cu, Ni, Pb and Zn were 0.0002, 0.187, 0.861, 0.150, 0.898 μmol/g in 2011, and 0.0003, 0.166, 0.602, 0.130, 0.992 μmol/g in 2013 respectively. The sums of AVS-SEM, ∑SEM (SEM-Cd + SEM-Cu + SEM-Ni + SEM-Pb + SEM-Zn) at S2 and S8 in 2011 and at S2 and S5 in 2013 were higher than that on the other sampling sites.

∑SEM = SEM-Cd + SEM-Cu + SEM-Ni + SEM-Pb + SEM-Zn; $f$oc = organic carbon fraction

The ratios of (∑SEM-AVS)/f_{OC} obtained in our study sites were calculated to 113, 228, 145, 271, -2, 111, 66, 115, 81, 174, 116 μmol/gOC in 2011, and 48, 243, 100, 136, 170, 97, 10, 167, 115, 63, 77 μmol/g OC in 2013, respectively (*Fig. 7*). The results indicated that there were no adverse effects, except S2, S4, and S10 in 2011, and except S2, S5 and S8 in 2013.

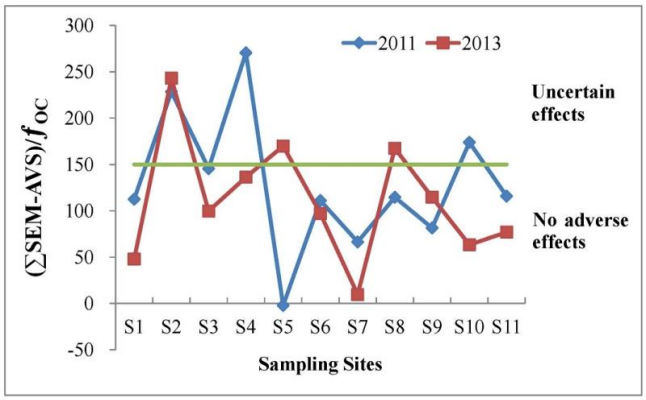

Figure 7. *The ratios of (∑SEM-AVS)/fOC*

The results of no adverse effects by AVS-SEM were in accord with the prediction results by the mean ERL quotients (Wang et al., 2016), which indicated that the ratios of (∑SEM-AVS)/f_{OC} could accurately be used to judge if there were no adverse effects and be of great help for environmental protection. Then, the uncertain risk part by AVS-SEM model could be compensated by other methods and would be discussed in the next step.

Statistical analysis

The average values of metal elements, characterization parameters and risk assessment values from 2011 to 2013 were analyzed by factor analysis and correlation

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1410514120

analysis. *Figure 8A* was factor loading plot to describe 20 features (six metals, seven characterization parameters and seven risk assessment indexes) from the different sampling sites. *Figure 8B* was factor loading plot for the different sampling sites, each of which was described by 20 features. The correlation analysis was mainly carried out by 15 features (seven risk assessment indexes, six metals, and two characterization parameters), and the results were showed in *Table 3*.

In *Figure 8A,* the first factor described 41.76% of the common variance, and the second factor described 15.44%. Rotation of the factor solution was necessary for better interpretation. The first factor was closely linked to Cu, Pb, As in Igeo, and the second factor was closely linked to Ni in AVS-SEM, SQGs, ER. These results indicated that 1) the ecological impacts of Ni were different from the impacts of Cu, Pb, As; 2) Cu and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1410514120

Pb were the major pollutants in the sediments; and 3) Ni was the main toxicity factor for ecological risk. From the correlation analysis, we concluded that: 1) the pollution factors (I_{geo} and PLI) were significantly and positively correlated with Fe and all heavy metals except Cr; 2) Ni was very significantly and positively correlated with SQGs, Hakanson risk index and AVS-SEM, followed by Fe; 3) Pb was significantly and positively correlated with SQGs and Hakanson risk index; 4) Si was negatively correlated with most of the heavy metals, which showed that the metal pollutants were mostly from human activities.

The factor scores were used to analyze the contamination sources. In *Figure 8B,* the first factor for the common variance was 96.39% with high contribution from S1 and S7. The second described 2.70% and highly loaded by S2 and S4. Near to Sanbai Men port that was occupied in fishery and trade, the locations of the four sites were concentrated in the northwest coastal area of the semi-closed bay. It is evident that the wasters from the fishery, trade, port construction and other urban activities resulted in the serious environmental pollution. On the other hand, in the cage area for the fish and maricultrure, vessel activities were frequent, which suggested that the primary pollution sources were from the combustion of gasoline and diesel fuel (Zhu et al., 2016; Yuan et al., 2015).

Conclusions

In this study area, all the sampling sites were polluted by heavy metals (Zn, Cu, Cr, Pb, Ni). The concentrations of heavy metals in 2013 were lower than that of 2011, and the residual fraction and sulfide bound fraction were the primary fractions of heavy metals. For each metal, Ni posed a moderate to very high risk; Zn and As posed a moderate to considerable risk; Cr, Cu and Pb were at a moderate degree; Cd was unpolluted at the sampling sites. From the aspects of ecological risk, a medium to very high risk came from Cd, Ni and Pb. Except for the cage mariculture area (S2, S5 and S8), all the sites would be expected no biotoxicity. Through analyzing the various factors about the heavy metals, four sites (S1, S2, S4 and S7) were profoundly affected by the environmental pollutants which primarily resulted from the combustion of gasoline and diesel fuel and the ship protective layer. The intensive mariculture activity is one of the main reasons for the heavy metal pollution and ecological risk of sediments in Zhalin bay. The exploration of effective strategies is quite necessary in the future for keeping a good quality of the coastal environment and sustainable mariculture development.

Acknowledgments. The project was supported by GDAS'Special Project of Science and Technology Development (No. 2017GDASCX-0104), National Nature Science Foundation of China (21777150, 21307120), Science and Technology Planning Projects of Guangdong Province (2016B02024006, 2017A05040), Science and Technology Planning Projects of Guangzhou (201803030042).Sincere appreciation is expressed to Professor Hong Du from Shantou University for their sampling work and Professor Jingwei Xu from Changchun Institute of Applied Chemistry for language improvement.

(Received 29th May 2019; accepted 16th Oct 2019)

Abstract. The paper investigates the causes, magnitude and damage caused by the flood as a result of the breaching of the east marginal embankment of the Taunsa Barrage. The flood frequency in the district of Muzaffar Garh located in south Punjab, Pakistan had serious impacts on human lives and their properties. To pursue this study, we used primary data, collected through questionnaire, formal interviews, field observations and secondary data, obtained through government departments and online open source databases. Furthermore, Landsat ETM+ imageries were used as input in the supervised classification in order to investigate the pre and post flooding land cover and land use. Hydrograph was used to analyze the flood limits and spatiotemporal change in river discharge for barrages. The results show an abnormal rainfall occurring in the month of July in the upper Indus Basin, which resulted in a massive discharge in the central Indus Basin. As a consequence, it exceeded the flood limits at the Taunsa Barrage, which resulted in the breaching of east marginal embankment. The flood caused a high number of human casualties and a total economic loss of 14.23 million US$ including a 6.8 million US$ agricultural loss. The study thus, gives insight on how authorities can devise a flood management plan in such a way to reduce the future impacts of riverine flood disasters in Muzaffar garh.
Keywords: *Indus Basin, east marginal embankment, flood disaster management, supervised classification, abnormal rainfall*

Introduction

Floods are the most frequent and destructive hydrological disasters in the world (Banerjee, 2010; Cann et al., 2013). In recent years, the severity and magnitude of excessive flooding has been experienced by many South Asian countries, including Pakistan, India and Bangladesh (Khan et al., 2009), which caused devastation to greater number of people as compared to other nature hazards(Zhou et al., 2000; Khan et al., 2009; Haq et al., 2012). Generally, floods have been widely caused by certain factors including unpreceded rainfall, melting of ice and snow, breaching of river embankment, improper structural measures and insufficient capacity of reservoirs (Howe and White, 2002; Shah and Gabriel, 2002; Ali, 2013). Similarly, population growth, land use change, deforestation, degradation of ecosystems, human encroachments in floodplains are some of the human escalation factors (Milly et al., 2002). Over the last few decades, the frequency and intensity of riverine flooding have been immensely boosted by various factors, including unusual climatic variability, abrupt sea level rise and extreme rainfall (Tariq and Giesen, 2012; Rehman and Khan, 2013; Dawood et al., 2017). In recent years, a large number of riverine floods have been triggered by the failure of dams, barrages and embankments, which rendered disastrous capacity to disrupt human

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1412114142

life and their property due to unpredictability and severity (Walder and O'connor, 1997). Moreover, riverine floods in the Indus Basin are induced by various factors, including flat topography, hydrology, climate, demographic and socio-economic catchment characteristic in the proximity of Indus river (Gaurav et al., 2011; Tariq and Giesen, 2012; Laghari et al., 2012). Riverine flooding is extremely destructive in terms of life loss with shattering economic developments to all sectors (Zhou et al., 2000).

Globally, floods produce severe damages to all socio-economic sectors. Every year, flood events have directly claim more than 20,000 lives and affect 1.4 million people (Howe and White, 2002; Messner et al., 2007). Categorically, management of flooding impacts involve three stages: the first stage is the estimation of flood inundation extent, the second stage is the estimation of damage to all socio-economic sectors and the last stage is flood recovery and rehabilitation (Zhou et al., 2000; Shah and Gabriel, 2002). These following marked flood impacts can be tackled down by applying certain structural and non-structural strategies (Rehman and Khan, 2011; Gaurav et al., 2011; Tariq and Giesen, 2012).

In Pakistan, flood is a frequent hydrological hazard (Khan, 2005; Syvitski and Brakenridge, 2013; Mahmood and Rani, 2018; Mahmood et al., 2019). Pakistan is considered as the most flood affected country in the world (Solheim et al., 2001; Natalia et al., 2008). In the last few decades, number of shattering floods of various magnitudes have recurrently been influenced by topographical and geological characteristics and climate change (Gaurav et al., 2011; Geis and Steeves, 1998). In addition, some human escalation factors have worsened the situation, which included urbanization, population growth in the proximity of floodplain, deforestation and ill equipped flood managers (Laghari et al., 2012; Khan, 2005; Ghosh et al., 2015). These factors have increased the risk of flooding in Pakistan and also increased the danger of loss of lives, damages to the infrastructure, standing agriculture crops and other vital properties (FFC, 2010; Hashmi et al., 2012). In this regard, an appropriate structural modifications and non-structural measures are required to efficiently cope with this menace (Khan et al., 2009).

In 2010, Pakistan was hit by the worst flood in the history of the Indo-Pak subcontinent, which was caused by widespread heavy rain spell of more than 250 mm. The rainfall occurred from the 27th to the 31st July with much intense in the catchment area of the upper Indus Basin (Rahman and Khan, 2011, 2013). As a consequence, flash flooding occurred in the upper Indus Basin and riverine flooding has occurred in the central Indus Basin. Over 2000 death tolls and massive acceleration in economic loss of ~43 billion US$ was recorded (PMD, 2010; Rahman and Khan, 2013 Mahmood et al., 2016a, b, 2019). Previous studies have studied the magnitude and intensity of flood damages, as a result of fluvial geomorphology, population density, land use change, structural river embankments, levees and irrigation systems (Syvitski and Brakenridge, 2013; Mahmood et al., 2016a, b). Nevertheless, the destructive effect in the whole Indus Basin was due to breaching of embankments, floodplains coupled with high population density, and economic growth (Ali, 2013; Chaudary and Sarwar, 2016; Mahmood et al., 2019). Furthermore, the flood's high peak runoff of 31149 m^3/s, exceeds the flood limits of various barrages and dams along the River Indus, including the Taunsa Barrage that falls within our study area (FFC, 2010; Chaudary and Sarwar, 2014, 2016; Mahmood et al., 2019).

Since 2010, a number of studies have been conducted to understand the causes and effects of flooding (e.g., Rahman and Khan, 2011, 2013; Syvitski and Brakenridge, 2013; Hashmi et al., 2012; Mahmood et al., 2016a, b, 2019; Khalid et al., 2018).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1412114142

However, these studies focused on the upper section of the River Indus with little or no emphasis on the middle section and the contribution caused by a number of series of barrages. The middle section of the river is of paramount importance as it has unique characteristics, one of which is the contribution to flooding pattern as the result of the Taunsa Barrage breach. Thus, this study focused on integrating the effect of the Taunsa Barrage and remote sensing results to better understand the causes, effects and damages caused by the flood in 2010. Remote sensing provides a framework to flood monitoring, depicts fluvial morphological changes, and extracts flood inundation and damages (Haq et al., 2012; El Bastawesy, 2015). We used supervised classification techniques, coupled with multispectral and temporal remote sensing data, to map the flood extent, damages to infrastructure and changes in river courses (e.g., Khalid et al., 2018). The land use and land cover change analysis of pre and post flooding in Muzaffar garh and in downstream areas of the Taunsa Barrage, which have not been done before, thus providing useful information for the implementation of flood protection measures along study area. We then explored the prevailing effects of the monsoon rainfall and the huge discharge over Upstream Indus Basin and the breaching of Taunsa Barrage. Thus, the present study provides a flood management plan framework to authorities on the management of future flood in relation to the control of Barrages and other flood barriers. This framework incorporates the flood generating factors and associated damages, the flood extent in relation to the land use/cover changed as the result of the flood in 2010, the water Inflow of the Taunsa and Chashma barrages to address how future managements of these barrages will reduce the effect of floods. The main objective of this present study is assessing the 2010 flood-causing factors, extent of inundation and associated socio-economic damages in one of the severely flood-affected areas in the south Punjab district Muzaffar garh, Pakistan. Further the study is focusing on filling the afore knowledge gap and introducing the use of combined techniques in Geographical Information System and climate data analysis as a monitoring tool in flood risk management in the future.

Materials and methods

Study area

The district Muzaffar garh is located in south Punjab, central Pakistan within 29.016°N to 30.765°N and 70.537°E to 71.726°E (*Fig. 1*). It is ~34 km away from Multan, which is regarding its population the 5th largest historical city of south Punjab, Pakistan. It is bounded by Layyah and Jhang districts in the north and Rahimyar Khan and Bahawalpur along River Chenab in the south. Dera Ghazi Khan and Rajaun pur along the mighty Indus are located in the west while Multan and Khanewal district lie in the East. Geographically, it is sandwiched between the mighty Indus and Chenab Rivers in the western and eastern borders, approximately 35 km and 8 km from district headquarter, respectively (*Fig. 1*). The total geographical area is 8,250 km², which is administratively divided into four tehsils; Muzaffar garh, Kot addu, Alipur, and Jatoi. Furthermore, it is subdivided into 93 smallest electoral units (Union Councils). In accordance with the latest 2017 census, the total population of the district was 4.32 million with 84% in rural areas and 16% urban population in comparison with the 1998 census with a total population of 2.64 million in 1998 with 88% rural and 12% urban population. The recorded average annual growth rate is 2.63 from 1998 to 2017 (Gop, 1999, 2017).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1412114142

Elevation varies from 42 m to 192 m above mean sea level from south to north, respectively (*Fig. 8*). The natural gradual slope in the district is toward the south, which made it possible to build an extensive irrigation canal system (Gop, 1999, 2017). District Muzaffar garh has desert type of climate, which is further classified as BWh, according to Koppen climate model (Mahmood et al., 2019). The highest maximum recorded temperature is 50 °C in the hottest month of June and the lowest is 2 °C recorded in the coldest month of January (PMD, 2010). The annual mean rainfall is 157 mm with a maximum of 45 mm monsoon rainfall in July a minimum of only 2 mm rainfall in October (PMD, 2010) The soil is fertile with the properties of sandy loam, which is suitable for widespread range of crops. In the study area, around 1,020,000 ha (60%) of land is characterized as barren land, which is not suitable for cultivation. The remaining 680,000 ha (40%) of land is cultivated with wide variety of crops including wheat, rice, sugarcane (Gop, 1999, 2017).

This paper emphasized the use of mixed research method approach to understand the flood causes, extent and evaluate the flood damages in the study area. To obtain the required objectives, primary and secondary data sources were used.

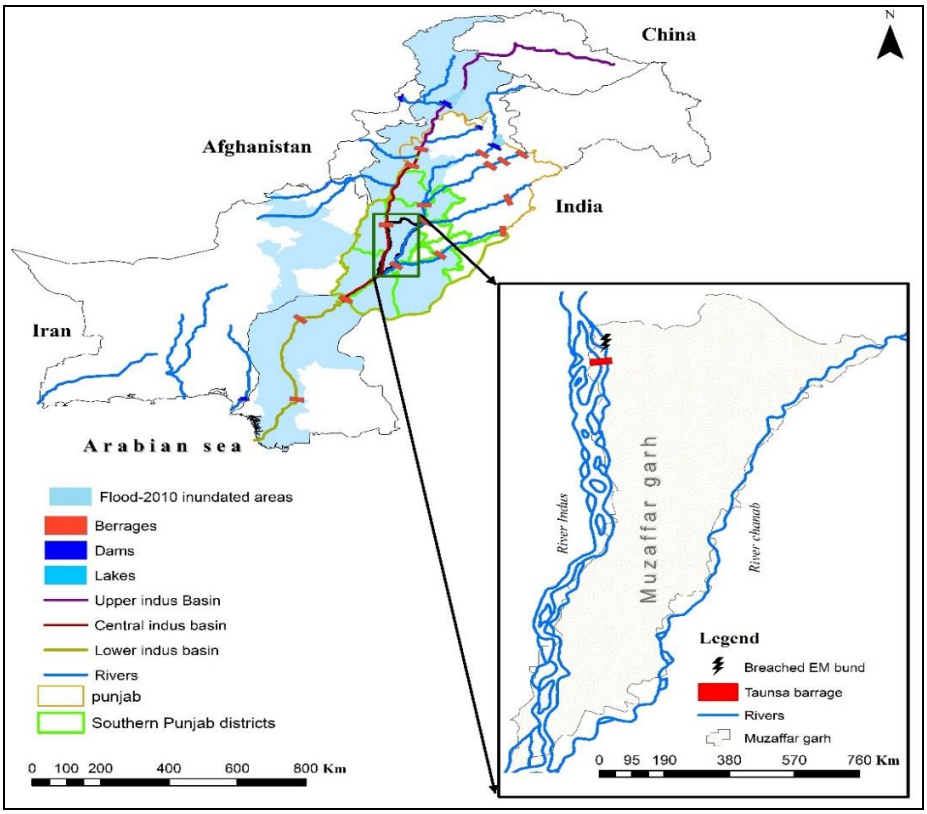

Figure 1. *Pakistan location of study area*

Primary data acquisition

Primary data was acquired through questionnaire-based survey, formal interviews and personal field observation and GPS. Prior to the survey, some frequent spatial field visits were conducted along with certain meetings arranged with different stakeholders, i.e. local communities, local irrigation department officials and farmers. The aim was to identify the most affected areas for conducting field survey. Based on prior field visits,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1412114142

comprehensive micro-level flood investigation and damage analysis of flood affected communities were examined. For this purpose, a semi-structured questionnaire was designed for the surveyed households to assess the flood genesis, magnitude and flood damages from three aspects. The first questionnaire was dealing with socio-economic condition of the household's while the second questionnaire was comprised of questions concerning flood causes, magnitude and damages to agricultural crops, livestock's, and houses with estimate loss in US$. Likewise, questionnaire for formal interviews with concerned government officials was designed to get the information of flood causes and damages and estimated rehabilitation cost of flood affected areas in million US$. A total of 500 households were selected on the basis of simple random technique. In the year of 2012, field survey was conducted by asking face to face afore mentioned questions in local language 'Saraiki'. Similarly, Global Positioning System (GPS) has been used to collect a total of 100 flood depth points in the study area, and sample training points of supervised classification classes e.g. water, built up, vegetation and barren land were examined to validate the result. On the other hand, the surveyed household locations were also taken along with infrastructure damages, and site locations were also noted. Field observation was also carried out in the study area to estimate flood extent, duration and depth. Similarly, correlation of flood duration and depth with Extent of damages to standing crops, livestock, housing structures were comprehensively investigated. Furthermore, identification of the most affected sites and the most vulnerable areas to flood in the study area were defined. Formal interviews were arranged with officials of government departments at provincial and district levels to get real time information of flood causes and estimated economic losses to all socio-economic sectors in US$.

Secondary data acquisition

Secondary data was acquired from different concerned government departments of Pakistan, and online open sources databases. In fact, there is no one single operating department to deal comprehensively with flood hazards in Pakistan. Further, flood hazard responsibilities are shared by various government departments. Topographic map of district Muzaffar garh was acquired from the Survey of Pakistan (SOP), Islamabad. Meteorological Rainfall data of 14 stations during 2010 were collected from the Pakistan Meteorology Department (PMD), Regional Office Lahore (PMD, 2010). Demographic statistics of Muzaffar garh district were acquired from the Population Census Organization, Islamabad (Gop, 2017). Economic loss to public roads infrastructures were collected from the Communication and Work Department, Muzaffar garh. Economic damages to electric power lines was collected from the Multan Electric Power Company (MEPCO) and river discharge data were collected from the Water and Power Development Authority (WAPDA), Pakistan.

Remote sensing Landsat 7 Enhanced Thematic mapper (ETM) images were downloaded from the United State Geological Survey (USGS) Landsat archive (https://earthexplorer.usgs.gov/). It was used to monitor pre and post-flood-2010 activities along the central Indus Basin, in district Muzaffar garh, south Punjab. Due to access of extensive spatio-temporal satellite imageries, it was easy to monitor flood extent and assess flood damages. Landsat ETM Image of 03 July, 2010 was used for pre-flood instance while ETM image of 20 August, 2010 was used for post-flood analysis. The effective spatial resolution and spectral sensitivity of Landsat ETM in visible and near infrared portion of electromagnetic spectrum have been useful for the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1412114142

extraction of flood inundation, flood damage assessment and monitoring (Chohan et al., 2015; Khalid et al., 2018). Shuttle Radar Topography Mission (SRTM) Digital Elevation Model (DEM) with 30 m resolution was downloaded from USGS open access archive. We have used for an understanding the spatial variations in the elevation in Muzaffar garh district.

Google Earth images of pre-flood 2009 and post-flood 2011 were acquired from Google earth Pro, which were used for observing the breaching points and their reconstruction.

Data methods and preparation

We used supervised classifications to separate different land cover and land use on the Landsat ETM images. The supervised image classification is widely used for the extraction of detailed invisible information from remote sensing data (Melgani and Bruzzone, 2004). It is a well-known automation technique that converts pixels into land use/cover change detection at a same location (Alphan et al., 2009). Maximum likelihood approach of supervised image classification was used for the mapping of pre- and post-flooding occasions in the study area. This technique has also been applied in a similar study by Khalid et al. (2018) and Chohan et al. (2015). Four classes were identified namely, water, built up, vegetation and barren land in the study area. Maximum likelihood approach is widely applied by various studies due to its results reliability and accuracy compared to other approaches. It provides a quantitative decision in which pixels are assigned based on their likelihood spectral signature classes by using sample training points (e.g. Chohan et al., 2015; Khalid et al., 2018). Global positioning system was also used to collect sample training points for the validation of spectral signatures of land use/cover classes (*Table 1*).

Table 1. *Training sites for image classification*

Sr. No	Class type	Latitude	Longitude
1	Water	30.5161	70.8486
2	Built up	30.4899	70.9386
3	Vegetation	30.3946	70.8997
4	Barren land	30.3747	71.3077

Moreover, we used change detection method, based on the classified classes for the pre and post flood images, to investigate the significant land use and land cover changes due to flooding phenomena in the study area. We have applied this change detection method on both images using Raster calculator tool in GIS environment. After that supervised classification of both pre and post images were presented in a map and change statistics results were compiled and presented in graphical form using MS Excel.

Meteorological rainfall data was collected from 14 meteorological stations located in all provinces of Pakistan from 27-31 July, 2010. Geo-database was prepared to store, manipulate, and geo-visualize spatiotemporal rainfall data in GIS environment. Moreover, Rainfall spatial distribution pattern was analyzed and interpolated using Inverse distance weightage (IDW) spatial analysis tool in Arc GIS. This technique (IDW) is ideal to interpolate scattered points, which employ deterministic methods to calculate the values of unknown points using weighed averages (Rehman and Khan, 2011, 2013). In this approach, it assumes that close points are related to each other that

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1412114142

diminish with distance, hence the inverse distance weighing. Similarly, this IDW technique was also applied to interpolate flood depth in the study area to geo-visualize the spatial pattern of flood depth.

Digital elevation model data files contain spatial terrain altitude at a defined grid interval over the bare Earth. ArcGIS 10.4.1 was used to analyze the spatial variance in terrain elevation in the study area.

Descriptive statistical analysis was applied on the collected socio-economic data and, and flood damages data using MS Excel. Arithmetic mean formula was applied to determine the average estimated economic loss of agriculture crops per ha. The estimated loss to all sectors were calculated in US$ and presented in graphical and tabular form. River Indus discharge data of Chashma and Taunsa stations from 29 July to 06 August, 2010 was collected from the Water and power development authority. Discharge data was prepared and organised in MS excel and presented in a hydrograph. Hydrograph is an ideal method to present any timeline series data. Additionally, the rainfall trends during monsoon rainfall from the years of 2001-2010 were also analyzed, compared and presented in line graph method.

Results and analysis

Socio-economic characteristics

A total of 500 households were surveyed from Kot addu, Muzaffar garh, Ali pur and Jatoi with a total population of 1617 persons. Out of which 915 were male and 702 were females. A total of 36.6% households were from Kot addu, 14% households were from Muzzafar garh, while 16.4% and 33% households were from Jatoi and Ali pur, respectively. The age structure of the respondents was classified into three main age groups; the 1st group (20-40 years) was 37.8% of total respondents, the 2nd group (41-60 years) was 54.2% and the 3rd group (46-60 years) made 8% of the total households. The family size was divided into four categories; Small family size of less than 4 members was 62%, medium size consist of 4 to 8 members was 28% and large family size of above 8 members made 10% of the total surveyed population. The flood in 2010 has induced direct implications on the well-being of these households. It damaged their limited assets and sources of earning, which consequently push them into extreme poverty level. The survey indicated that literacy ratio is 83% in the study area. Most of them were only literate at matric level and only few of them were at graduate and post-graduate level. The survey indicated that more than 60% respondents belong to daily wagers profession with less than 130 US$ earnings monthly.

Perceived causes of flood-2010

The 2010 flood in the central Indus Basin in south Punjab started in early August and continued till early September, following heavy prolong rainfall in the upstream of the Indus. Spatial Analysis of the rainfall data from 27-31 July was published by the Pakistan Metrological Department, which had experienced much higher rainfall in many stations in the monsoon season in 2010 in Khyber Pakhtunkhwa (KPK), Punjab, and Sindh provinces as shown in *Figure 2*. For example, abnormal heavy rainfall over 250 mm in 24 h had been recorded at Saidu sharif station located in KPK province. Similarly, northwestern part of the country had received high concentration of rainfall in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1412114142

comparison with the central and southern part of the country, which had received very low rainfall as depicted by rainfall spatial pattern analysis (*Fig. 2*).

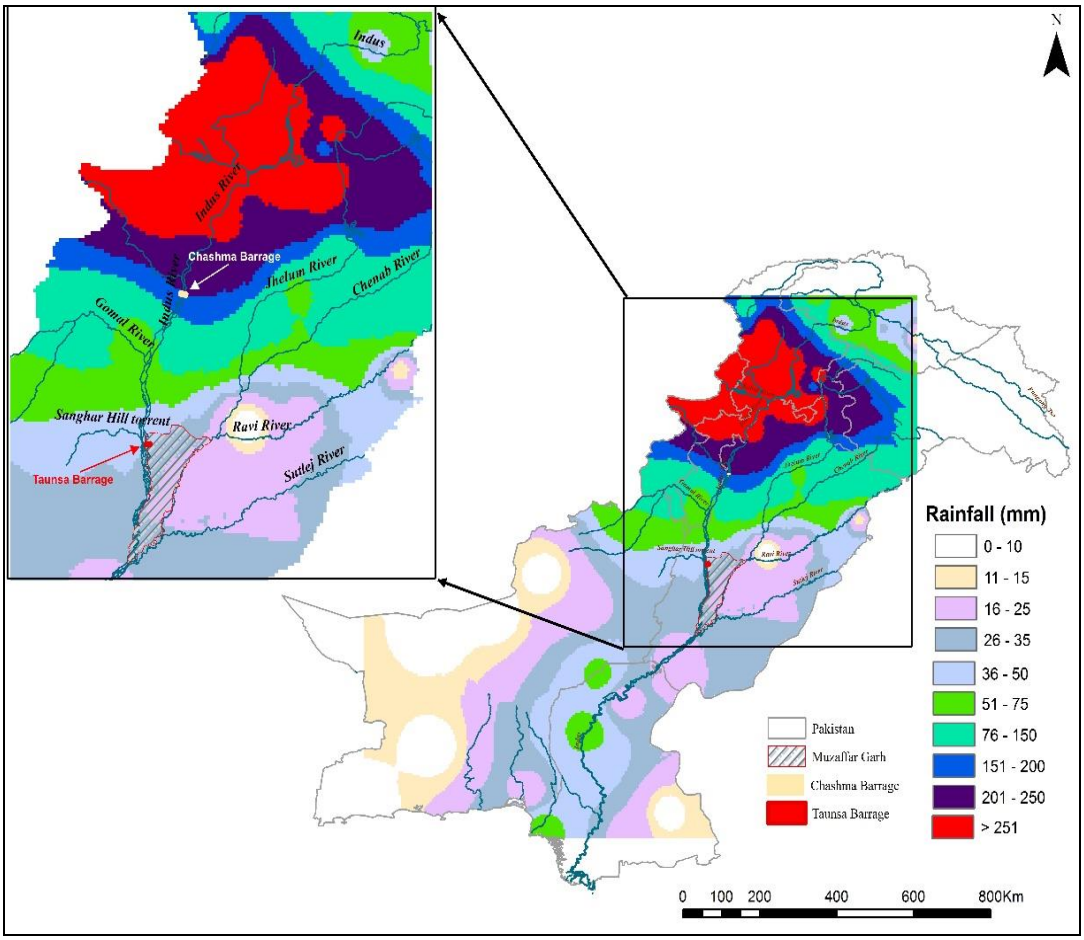

Figure 2. *Spatial pattern of rainfall from 27-30 July, 2010*

As a result of high intensity and continuous downpour in the upstream of the Indus river carried very high surface run off discharge and abnormal flow at several western tributaries of the Indus namely, Swat, Dir, Kabul, Panjkore, Gomal rivers, which caused an adverse flash flooding in KPK province, Pakistan. The hydrological data analysis shows that the unprecedented accumulated flood water recorded discharge of 26546 m^3/s on 30 July at Jinnah Barrage resulted in severe breaches at its left and right Guide Banks and inundated nearby low lying areas. Further, this extreme swollen water flow discharge generated high intense pressure at Chashma Barrage with an alarming level of recorded inflow 29354 m^3/s, and resulted inundation in the floodplain areas of districts Mianwali, Bhakhar and Layyah. The high flow of water with its disastrous consequences rushed down toward Taunsa Barrage and generated intense pressure on both sides of its embankments. Further, the recorded high flood peak of 27184 m^3/s on 2 August, 2010 at Taunsa Barrage not just exceeded the discharges at danger levels but it was also very close to its designed capacity of 28317 m^3/s. This recorded inflow water piled at the barrage and resulting the pressure of the East bank and the protective embankment. As a result, 12 km upstream of Taunsa Barrage, the east marginal embankment (EM) Abbas wala could not sustain the tremendous pressure and breached

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1412114142

at Rd 32-38 on the 2nd August with 1972 m length. Thereafter, three main secondary breaches of 140 m, 120 m, and 448 m have been formed subsequently to adjacent embankment as a consequence of EM embankment breach (*Fig. 6*). The approximate disastrous flow of more than, 3540 m^3/s roaring flood water through breached embankments, overtopped Taunsa Panjnad Link canal by breaching at Rd 10 and continued its disastrous flow followed by various breaches to Muzaffar garh canal in between Rd 13-14. As a result, the water gushing went on to flood the Muzaffargarh district and its adjoining areas. The hydrological analysis result shows the recorded 6 hourly discharge at Chashma-Taunsa barrages during flood instance that is closely matching with the breaching dates of the embankments (*Fig. 3*).

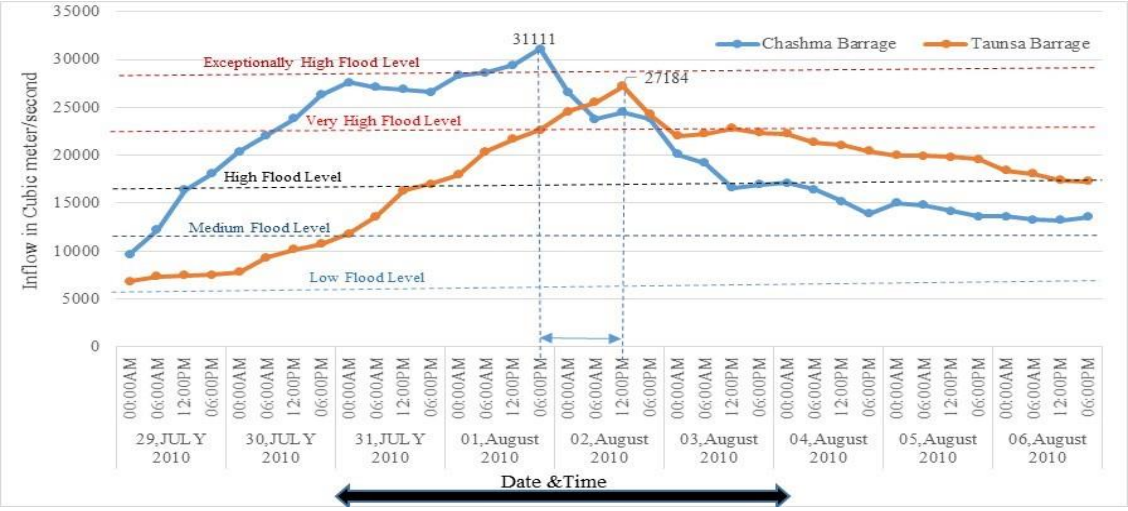

Figure 3. *Inflow m^3/s of Chashma Barrage and Taunsa Barrage from 29 July to 6 August 2010. Chashma–Taunsa reach is ~270 km*

Over the last decade, the analysis revealed that the trend of monsoon rainfall in Pakistan was not uniform, in the year 2003 has received maximum rainfall, which was exceeded in 2010 with an exceptional rainfall above 250 mm as shown in *Figure 4*.

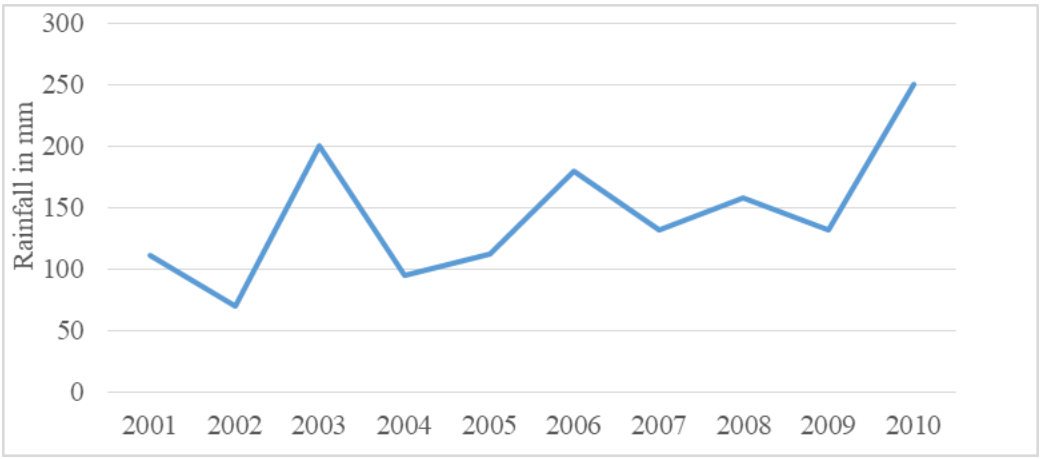

Figure 4. *Monsoon rainfall trend in Pakistan from 2001-2010*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1412114142

Taunsa Barrage is located in south Punjab district Muzaffar garh (*Fig. 2*). Taunsa Barrage is considered the most susceptible barrage structures built across the River Indus (Chaudary and Sarwar, 2016). As *Figure 5* shows in the year 2008, for the purpose of diversion structure re-modelling the construction of a sub-weir was completed at Taunsa Barrage which had about 2.5 m vertical and 274 m horizontal length. For this construction work, a massive coffer dam was used. Consequently, after completing the construction work, the coffer dam discarded material remained at the top of sub weir caused a minor blockage at the downstream of the Taunsa Barrage (Chaudary and Sarwar, 2014). As a result, flood-2010 water level remained the same in the upstream and downstream of the barrage. Similarly, the rising riverbed resulted in the deposition of large amount of sediments downstream in head up area that has reduced the discharge capacity of the Taunsa Barrage and triggered the high waves of flood water back to its embankment on the eastern side and breached the protection EM embankment (*Fig. 6*).

Figure 5. *Aerial view of the Taunsa Barrage, construction of sub-weir, sediments in head up during the flood in 2010. (Source URL: https://www.dawn.com/news/1195398)*

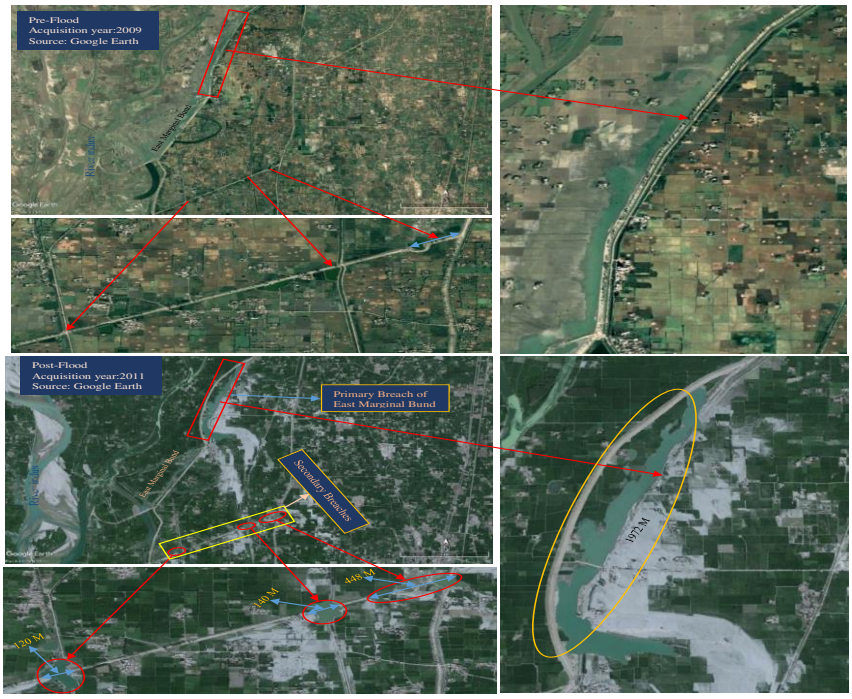

Figure 6. *Pre and post flood images of breached East Marginal Embankment at Rd 32-38*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1412114142

According to respondent perceptions regarding flood causing factors, 90% had indicated that breaching of the EM embankment at Rd (*32-38*) Abbas Wala at the Taunsa Barrage had caused this flood menace in the study area. A total of 10% reported heavy monsoon rainfall in upstream areas of the Indus River. Based on indigenous knowledge of this phenomenon and previous experiences forest and irrigation officials described that deforestation along the canal embankment for fuel and timber purposes has weakened the canal banks along with unpaved canal, as a contributing factor of breaching of canal banks, waterlogging and floods in the rainy season in the study area.

Extent of flood-2010

The extent of flood-2010 analysis comprises of supervised classification of flooded areas and depth of inundated surveyed areas. The supervised classification was performed using Landsat ETM Images. The Landsat ETM image of the 3rd July, 2010 was classified for pre-flooding situation whereas image of the 20th August, 2010 was classified for post-flood 2010 instance analysis. Further, we used change detection method, based on the classified classes for the pre and post flood images, to investigate the significance land use and land cover changes due to flooding phenomena as shown in *Figure 7*. The pre-flood image classification of the 3rd July, 2010 shows that only 7% of the area was covered by water, while vegetation, built up and barren land were covered by 39.9%, 30.03% and 22.8%, respectively. Similarly, Post flood image classification of the 20th August, shows that 24% of the area was covered by water while vegetation, built up and barren land were covered by 35%, 22% and 19%, respectively. Both pre and post flood instances classifications show significant clear demarcation of defined classes. Post flood change detection analysis shows dramatic change in water class, with an increase from 7% to about 21% while built up area has decreased by 8.03%, from 30.03% to 22% in post flood analysis. The vegetation decreased by 5%, from 40% in pre-flood instance to 35% in post flood situation and the barren land decreased by 3.8% from an area of 22.8% in pre-flood instance to 19% recorded in post-flood situation (*Fig. 7*). Overall, the significant change was shown in water class in comparison with other classes and inundated an area of around ~1732 km^2 in the study areas. A total number of 1,780,226 people were affected in the 2010 flood (NDMA, 2010; PPDMA, 2010). The resulted inundation depth was found very uneven in the study area measured by GPS and measuring tape. The flood inundation depth was found very high in Kot addu area, due to high proximity to breached EM embankment as shown in *Figure 1*. Similarly, in Ali pur area, moderate flood inundation depth was found, as located in the lower reach of the study area where the Indus and Chenab rivers meet as shown in *Figure 8*. Comparatively, most of the socio-economic damages were reported from these areas.

Damage assessment

Analysis revealed that the flood in 2010 was severely disastrous and devastating in nature, however, it has caused serious damages at large scale to agriculture, human settlements and physical infrastructure in the study area. Flood damage assessment was done through Geo-spatial analysis and statistical analysis.

Damage to agriculture

The study area is one of the fertile floodplains of the Indus. Agriculture is the main source of economic activity, hence local residents are actively engaged in crop

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1412114142

cultivations, in both Rabi and Kharif crop seasons. The analysis revealed that flood has badly affected the standing crops of Kharif season, including rice, sugarcane, cotton and fodder crop. A total of 4182.8 ha of agriculture standing crops were destroyed with an estimated economic loss of 8.68 million US$ as shown in *Figure 9*. It was further indicated that ~1499.9 ha of rice standing crop was submerged, which resulted in an estimated economic loss of 2.9 million US$. Likewise, sugarcane standing crop on ~1029.1 ha was destroyed, which incurred an estimated economic loss of 2.9 million US$. A total of 479.1 ha of cotton crop was completely destroyed, with an estimated economic loss of 1.1 million US$. Similarly, about 1174.7 ha of fodder crops were inundated with an estimated economic loss of 1.8 million US$ (*Fig. 9*).

According to community perception, an average estimated economic cost of rice crop on per ha was 1934 US$, sugar cane was 2906 US$, cotton was 2325 US$, fodder crop was 1611 US$.

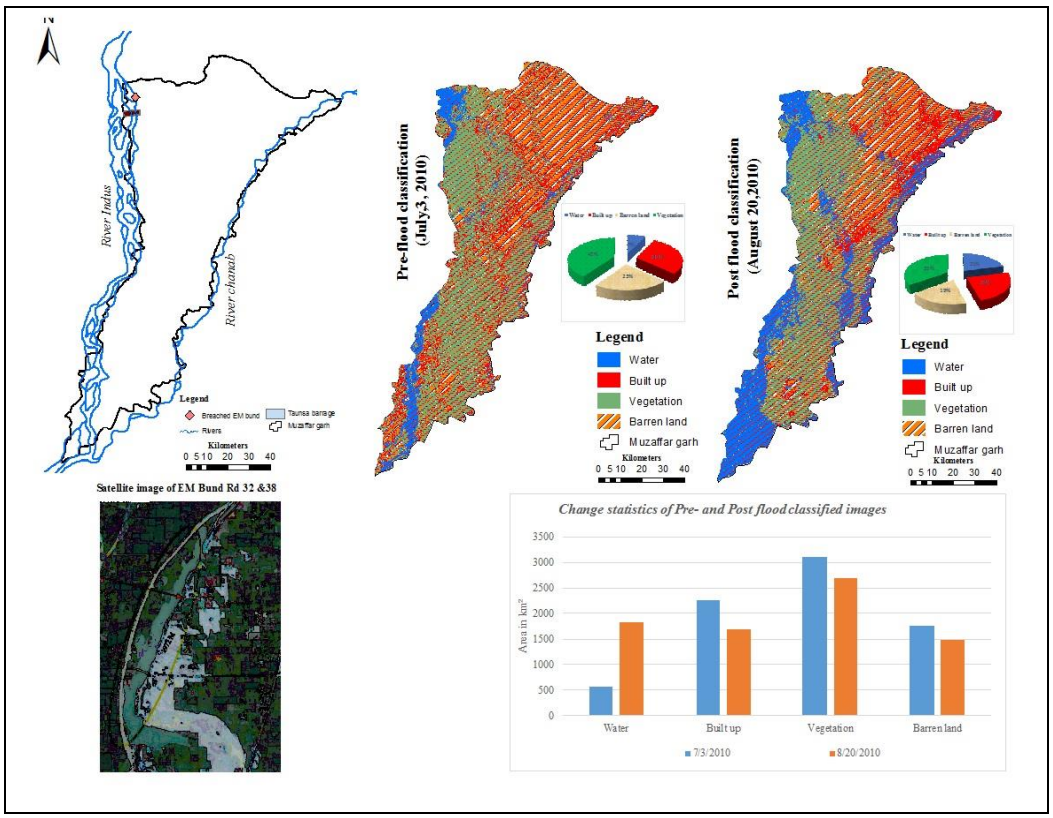

Figure 7. *Pre and post flood change detection statistics and classification*

Damage to livestock

Muzaffar garh is ranked as the 2nd largest district in livestock sector in Punjab province, Pakistan (GoP, 2017). People usually keep subsistence and commercial livestock for their source of earning, which include buffaloes, cows, sheep, goats, oxen, donkeys and camels in the study area. As *Figure 10* shows that a total number of 1172 livestock animals were found dead with an estimated economic loss of 0.761 million US$. The loss of buffaloes has incurred an estimated economic cost of 0.404 million US$ while an estimated economic cost by loss of cows was 0.28 million US$. Whereas

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1412114142

the loss of goats, sheep and donkeys has imposed a collective estimated economic loss of 0.077 million US$ (*Fig. 10*). The survey indicated that the maximum loss of animals was reported from the Kot addu surveyed area, where the flood depth was maximum revealed by the flood depth spatial analysis as shown in *Figure 8*. During field survey, the average estimated economic cost was determined as per community estimate, the average economic estimated cost of buffalo was 1176 US$, of cow was 823 US$, of goat and sheep was 176.4 US$ and of donkey was 94 US$ per community each.

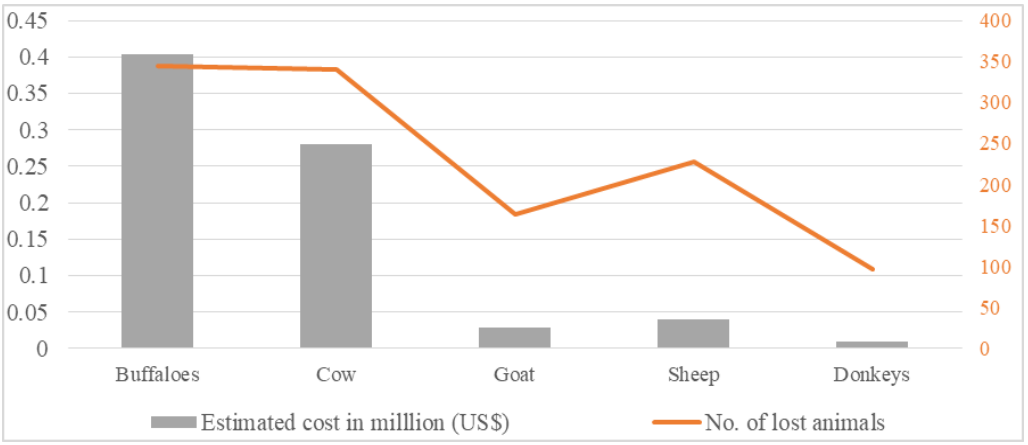

Figure 10. *Number of lost livestocks estimated loss in million US$*

Damages to houses

In the study area, housing structures were very dissimilar with respect to urban and rural areas. Brick houses and mud houses were found in the study area. Field observation and result revealed that the brick houses have more coping capacity in term of flood resilience and structural vulnerability, whereas mud houses have no such flood resilient coping capacity and have high vulnerability to flooding. As *Table 2* shows a total of 2673 houses were located in the study area with 1859 mud houses and 814 brick houses. A total of 776 mud houses were partially damaged with an estimated economic loss of 0.27 million US$, and about 768 mud houses were completely damaged with an estimated economic loss of 0.54 million US$ (*Table 3*). As a result, about 83% mud houses were found partially and completely damaged in the study area. In addition to this, a total of 360 brick houses were found partially damaged with an estimated economic loss of 0.25 million US$. Besides that, 188 brick houses were found fully damaged with an estimated economic loss of 0.26 million US$. The community estimated that the average cost per partially and fully damaged mud house was 353 US$ and 706 US$, respectively. Similarly, they had also indicated that the average rehabilitation cost of partially and fully damaged brick house were 706 US$ and 1412 US$, respectively (*Table 4*).

Damages to infrastructure

Road infrastructure is the main source of transportation link between the study area and the rest of the provinces of Pakistan, which in turn stimulate economic growth. In the flood 2010, major G.T. Roads and intra-district roads were severely damaged. According to Communication and Works Department (C&W) Punjab, a total of 150 km road network was fully damaged with an estimated economic loss of 3 million US$. For example, the road that connects G.T. Road in Taunsa Sharif to Multan via Muzaffar garh was seriously damaged from various places with the width of around 100 km. Further, Pak-Arab Oil Refinery Company (PARCO), which is located along this road, suspended oil supply in the whole country due to this flooding event. As a result, Kot addu power plant and Lalpir thermal power plant in Muzaffar garh, which depends on the oil supply from PARCO, were partially shut down, which meant that only 1600 MW was generated instead of the maximum capacity of 2400 MW.

Muzaffar garh	335	180	105	0.14
Jatoi	245	115	90	0.10

Table 4. *Study area: damages to brick houses*

Surveyed areas	Brick houses			
	Total number of houses	Partially damaged	Completely damaged	Loss in million US$
Kot addu	274	126	68	0.18
Ali pur	234	109	55	0.15
Muzaffar garh	175	70	35	0.09
Jatoi	131	55	30	0.08

The railway line is the other source of transportation in the study area. According to railway officials, around 4 km long railway track was burst in various locations. However, the most damaged tracks were in Kot addu due to the gushing water flow from nearby breached EM embankment. The devastated tracks of 1.5 km occurred in between Kot addu station to Taunsa Barrage station and around 2.5 km bursted track was reported in between Bud railway station to Memood kot railway station. The total estimated economic loss was 0.1 million US$.

The analysis revealed that following the collapse of EM embankment, the floodwater roared through Thal Panjnad (T-P) link canal and breached it due to the excessive spillover from the canal capacity. Further this torrent water drained into Muzaffar garh canal, which could not sustain the pressure of a destructive water and resulted in breaching at many points. According to the District Irrigation Department, collectively around 15 km irrigation channels were damaged by flood-2010 in the study area with a total estimated economic loss of 0.32 million US$.

In addition to this, flood had also seriously damaged bridges that were constructed over the irrigation channels for communication and transportation purposes. As *Table 5* shows a total of 15 bridges were completely damaged with an estimated loss of 0.151 million US$. Similarly, the flood has also disrupted electric power supply in the study area for almost two months by damaging more than 100 electric power poles and electric supply lines. According to Multan Electric Power Company (MEPCO), a total

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1412114142

of 0.15 million US$ economic loss was estimated for rehabilitation to recover the power supply.

The results of this study were supported by recent related research studies. Mahmood et al. (2019) concluded that 2010 flood in the central Indus Basin was devastating in term of agricultural damages and infrastructure. Gaurav et al. (2011) claimed that the Indus flood 2010 was triggered due to engineering structures of barrages and embankments along the Indus Basin. Hashmi et al. (2012) found that flood 2010 in Pakistan was very damaging in terms of infrastructure and agricultural losses. He further explained that the agricultural sector was badly affected by damaging of standing agriculture crops. Mahmood et al. (2016a) concluded that the 2010 flood in Pakistan was destructive in terms of damages to buildings, infrastructure, and huge economic losses to agriculture. Rehman and Khan (2013) found that 2010 flood disaster has triggered huge losses to infrastructure due to damaging of building, roads and canals. He further explained that infrastructure is the most flood affected sector in the upstream areas of the Indus.

Table 5. *Damaged bridges and estimated loss in million US$*

Kot addu	10	0.071
Ali pur	2	0.011
Muzaffar garh	2	0.011
Jatoi	1	0.058

Discussion

The flood 2010 occurred in the study area following the worst weather forecast ever recorded in history by Pakistan meteorological stations in the month of July 2010, with respect to cloud formation incorporated with spatial extent and duration of monsoon rainfall, as a result of the convergence of monsoon winds with upper air jet stream over the North-western regions of KPK province, Pakistan (PMD, 2010; Rehman and Khan, 2013; Mahmood et al., 2016a, b). As *Figure 4* shows the evidence of high rainfall of more than 250 mm recorded during 2010 in comparison with last decade rainfall data that triggered the high inflow of 27184 m^3/s at Taunsa Barrage. This high inflow was somehow equal to the designed capacity of the barrage as shown in *Figure 3*. Despite that the water flow was crossing at an alarming level, no action was timely taken to decide the breaching section at emergency purpose. In addition to this, as *Figure 5* shows that the influence of sub-weir construction and its upstream narrowing embankments certainly decreased the designed carrying capacity of the Taunsa Barrage. Furthermore, the Indus is famous for carrying a high sediment load from the Himalayas foothills and Taunsa Barrage structure has stuck huge sediments within the river belt thus causing the river bed raise in the last few years. Moreover, in the years 2004-2008, with the request of the Government of Pakistan (GOP), the World Bank took initiative and provided 144 Million US$ for the remodelling of a diversion structure at Taunsa Barrage (Chaudary and Sarwar, 2014). They did the remodelling of the structure in such a way that they had constructed a sub-weir of about 2.5 m vertical and 274 m horizontal length downstream of the Taunsa Barrage, as shown in *Figure 5*. The coffer dam material was used for construction work. The coffer dam discarded material remained at

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1412114142

the top of sub-weir resulted in a minor blockage and an increased sediment in the river bed eventually resulted in the breach of the EM embankment.

The findings regarding flood management at Taunsa Barrage revealed that there was no breaching outlet upstream on either side of the barrage. But in fact, the natural topographical slope and depression in the west side upstream, that can divert the emergency water to the depression areas is missing. As such, once flood peak wave passed to downstream, the emergency water can recede back to the river bed. Furthermore, the west bank is scarcely populated in terms of settlements, and economic developments. This resulted in less loss of life and properties since there was no such defined breaching outlet on the western side. In comparison with recent breached east embankment, there were dense human settlements with intensive agriculture crop cultivations and strong infrastructural developments (*Fig. 6*). The worst in fact is that the flood 2010 overbank water did not return to the river. Rather it was rushed and remained in the cities, towns and agriculture lands for about two months. Further, refilling process took 10 days, overbank bursted water remained destructive in nature with high intensity and destroyed everything that came in its way. Similarly, technical negligence and mismanagement of the Taunsa Barrage was also revealed. The heavy, prolonged rainfall in upstream of the Indus was forecasted by PMD, but there were no pre-flood measures taken to manage or even to reduce the impacts of flood by rapid structural maintenance of the embankments. In addition to this, they were also failed to operate the newly motorized hoisting system, as a result ten barrage gates were not totally opened (Chaudary and Sarwar, 2014, 2016). This led to the sudden pressure at the barrage and caused the collapse of EM embankment at Rd 32-38. Similarly, the Kosi flood 2008, in the eastern part of India also occurred due to a 1.2 km long breach in the eastern embankment at Kusaha, which was located almost 12 km upstream of the Kosi Barrage. Likewise, Indus, the Kosi River carries a very high sediment influx from upstream areas which caused the river bed level raise and a super elevated flowing in condition toward lower reaches in the Kusaha region. Further, negligence and improper maintenance of the embankments were also found which made this Kosi river more disastrous for the affected population in the Kusaha region (Sinha, 2010). In contrast, the Kosi flood disaster 2008 in India occurred due to a breach at eastern embankment with a very low discharge of 4078 m^3/s, whereas in southern Punjab 2010 flood occurred due to the breach of the EM embankment at Rd 32-38 near Taunsa Barrage with the discharge of 27184 m^3/s.

Depth of the flood 2010 in the study area was unevenly located in all surveyed areas with the help of GPS and measuring tape. The result shows the correlation between the flood depth and the nature of damages, which increased the flood magnitude of socio-economic infrastructure damages. During survey, we noticed that a total of 75% of the households indicated that flood depth varied from 1 to 2 m while the remaining 25% households indicated that flood depth varied from 2.1 to 3 m (*Fig. 8*). In addition, flood duration varied due to the slight geographical and topographical variability in the area and soil texture. The most consistent observation was that almost all the respondents indicated that flood water remained stagnant from 2 to 3 months in post flood situation. This increased the magnitude of damages as the mud houses and crop were subjected to adverse conditions.

Supervised classification was used for analyzing the landuse/cover change in the study area**.** Supervised classification result shows that built up areas has been decreased by 8.02% in post-flood situation. Further survey indicated that most of the respondents

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1412114142

belonged to very poor families and settled in mud houses. Flood had badly destroyed and even washed them away. Similarly, infrastructure and other built up areas were also destroyed in such a way that their materials were dispersed. In some areas, flooded water transported households' material in a different way, such as traction by rolling and suspension. Thus, survey evidences were found consistent with supervised classification result as decrease in built up area was shown in post flood classification (*Fig. 7*). Moreover, vegetation area had decreased by 5% in post flood classification and flood 2010 occurred in the month of July and August during the growing season of Kharif crops including rice, sugarcane, cotton and maize with other fodder crops. Thus, the visible green due to increase in chlorophyll was found in both pre and post flood instances and resulted in vegetation areas having the highest values in comparison with all other classes. Similarly, slight difference found in barren class during pre and post-flood classification (*Fig. 7*). Further, most of the barren land lies in the northern and north-eastern part of the study area characterized by high elevation and far away from the proximity of river which makes it the proposed area for safe evacuation places if flood occurs in future flood risk reduction.

We noticed that more damage and destruction was found in the agricultural sector in comparison with other sectors. Flood was not only very destructive in terms of agriculture standing crops damages, but also destroyed the district government wheat seed stocks. Further, disruption was observed in the forthcoming Rabi season crops, which were cultivated very late due to the presence of flood water for almost 8 weeks. Additionally, most of the damages to agriculture standing crops were found in Kot addu area as it was located very near to the breached EM embankment. Similarly, it was indicated that the maximum livestock damages were also reported from Kot addu, as this area had faced roaring disastrous unpredictable flood water with long duration and maximum depth.

Observations also revealed that an increase in duration and depth of flood is proportional to the increase of sensitivity of livestock. The depth difference influenced the loss numbers of different animals. For example, in areas with high flood depth of above 1.5 m experienced more buffaloes, cows, and donkeys were lost while areas having less than 1.5 m depth experienced the maximum losses of sheep and goat according to the records.

As far as housing structure is concerned, there were two types of houses that were found in the area namely, brick houses and mud houses. The brick houses were more resilient against flood vulnerability, whereas mud house had very little resilient capacity and had high flood vulnerability. In addition to this, a total of 1544 of mud houses were found completely and partially destroyed. We noticed that about 50% of the people have monthly income of less than 130 US$, which limited their capability to build brick houses. That is why, a large number of registered damaged houses were mud houses and mostly reported from the Kot addu survey area. Further, it is highly recommended that there is a need of appropriate financial aid to the vulnerable people to construct their flood resilient houses that can withstand future flooding events.

Conclusion

District Muzaffar garh is one of the unprivileged districts of South Punjab, Pakistan. It is located in a near juxtaposition to the river Indus and Chenab from its both sides which are exposing it to riverine flooding. Almost every year, riverine flooding occurs in the study area from the east bank of the mighty River Indus and the west bank of the River Chenab. In 2010, the worst riverine flooding of the century occurred in the study

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1412114142

area due to 4-days extra-ordinary amount of monsoon rainfall in the upstream of the Indus Basin that triggered a discharge of about 28317 m^3/s at Taunsa Barrage, which exceeded its capacity. The East Marginal (EM) embankment could not sustain the discharged water and it eventually collapsed. The collapse of the Taunsa Barrage caused inundation in the study area and consequently, agricultural standing crops, livestocks, infrastructure, human settlements were destroyed or damaged. This also led to a temporary shift for most of the local people to safe locations.

The leading majority of above 40% surveyed households were engaged directly and indirectly since the agricultural sector is considered as one of the main sources of earnings. Throughout the study area, flood has badly affected the standing crops of Kharif season with an estimated economic loss was 8.68 million US$ and it is largely one of the most exposed economic sectors to recurrent floods and poor mitigation approaches. Overall, total damages from flood 2010 were about 14.23 million US$. Agriculture and Infrastructure were seriously damaged sectors with an estimated economic losses of 8.68 and 3.48 million US$, respectively. Similarly, the economic damages to housing and livestock sectors were 1.31 and 0.761million US$. Furthermore, most of the surveyed respondents earned less than 130US$, which is not permitting them to build resilient brick houses. Therefore, the majority of them have been living in mud houses, which are highly vulnerable to floods. This circumstance had further intensified and exposed the physical and economic vulnerabilities of local communities to riverine floods. Out of all surveyed areas, the maximum damages to all economic sectors were reported from Kot addu which lies in the proximity of the breached EM embankment. Furthermore, most of the respondents were living in flood plain areas and that has further increased the intensity of massive flooding and imposed the huge economic losses to this vicinity.

The study concludes that, as many previous related studies and forums cited in the year of 2010, high rainfall in upstream Indus was the main cause of flooding in the entire Indus Basin. In comparison to this study, it is defined that the resulting discharge (27184 m^3/s) at Taunsa Barrage did not exceed its proposed designed capacity (28317 m^3/s). However, the obstacle of excessive volumes of water together with a large quantity of sediment deposition in the head up because of structural sub-weir construction in downstream and narrow river bed due to the construction of protective embankments in the upstream, has reduced the designed carrying capacity of the Taunsa Barrage. Moreover, the concerned authority and river management department did not take any measures corresponding to upraise the protective embankments with respect to flood management in 2010. This research study provides effective mixed method approaches to the local, regional and national disaster management authorities for devising the effective flood management plan with the identification of breaching points in any emergency situation to minimize future flood risk, human causalities and socio-economic damages. Moreover, this study will bring the attention of disaster management authorities to divert their obsolete strategy of river control to river management.

It can finally be concluded that this increase of population sprawl in floodplain for socio-economic development is expected to continue in the future in the study region. Similarly, there is an utmost need of effective flood-risk zonation and strategies to reduce the future impacts of riverine flood disasters in the study area. There is a need of effective studies on the human interventions in the river basins in term of cost-benefit approach, including impacts on human and environment. In addition to this, zone-specific flood-risk reduction strategies should be the next step.

(Received 30th May 2019; accepted 3rd Sep 2019)

Abstract. The Napahai plateau wetland, located in northwestern Yunnan province, China, is a unique seasonal plateau wetland of low-latitude and high-altitude, yet the microbial community is still unknown. To address this shortcoming, MiSeq high-throughput sequencing was used to analyze the composition and diversity of bacteria and archaea. The bacterial community comprised of 64 phyla, 164 classes and 484 genera, in which *Proteobacteria* was the most abundant, followed by *Actinobacteria*, *Chloroflexi* and *Acidobacteria*. Archaea comprised of 3 phyla, 5 classes, and 7 genera, in which *Thaumarchaeota* dominated. The results indicated that the composition and diversity of the bacterial community were more influenced by seasonal changes than by soil types, whereas the archaeal community was mostly resistant to these factors. Additionally, canonical correlation analysis (CCA) showed that the diversity of the bacterial community was closely correlated with nitrogen (N), total nitrogen (TN) and soil organic matter (SOM) in the dry season. However, no significant correlation of any of the factors was observed in the archaeal community. In conclusion, these results indicated that microbial communities in the soil of Napahai plateau wetland have unique diversity and composition, and Napahai plateau wetland as a microbial resource requires protection and restoration.
Keywords: *wetland ecosystem, high throughput sequencing, bacterial community diversity, archaeal community diversity, environmental factors*

Introduction

Wetlands are important links between terrestrial and aquatic systems. They are large reservoirs of biodiversity and ecologically powerful natural ecosystems. Ecological services of wetlands have high social and economic value. In wetland ecosystems, microbial community diversity is much better than vegetation species diversity to reflect environmental changes. The microbial community diversity and composition of wetland soils are more sensitive and comprehensive to reflect the wetland ecological conditions. Also they have a great significance for maintaining the balance of wetland ecosystems, repairing damaged wetlands and carrying out comprehensive environmental management.

Recently, the rapid development of high-throughput DNA sequencing has allowed the detailed study of the diversity of microbial communities in wetland soils, with fruitful results. For instance, soil samples were collected from six wetlands on the Qinghai-Tibetan plateau, and high-throughput 16S rRNA gene sequencing was used to assess the composition and localization of enriched microbial communities. Overall, microbial communities from the Qinghai-Tibetan plateau wetlands showed significant potential in converting cellulose and chitin to methane at low temperatures (Dai et al., 2016). In a subarctic wetland in Russia, the major bacterial groups identified in peat by high-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1414314158

throughput sequencing of the 16S rRNA genes were *Acidobacteria* (35.4-41.2%), *Alphaproteobacteria* (19.1-24.2%), and *Gammaproteobacteria* (7.9-11.1%). The distinctive feature of this community was a high proportion of two subdivisions of *Acidobacteria*, which are not characteristic for boreal sphagnum peat bogs (Danilova et al., 2016). In coastal mangrove wetlands, MiSeq high throughput sequencing was used to understand the microbial composition and diversity pattern. The five most abundant phyla within the bacterial and archaeal communities remained stable between two distinctive seasons, suggesting that the microbial community in the Mai Po wetland exhibits a mild seasonal dynamic (Zhou et al., 2017).

In a wetland ecosystem, geographic distance and environmental factors are two important drivers of the distribution of microorganisms (Widder et al., 2014; Savio et al., 2015). However, in the whole space, environmental factors are more important. Previous studies have demonstrated that soil microbial communities can be significantly influenced by mineral nutrients (Su et al., 2015). In Qinghai-Tibet plateau, soil organic matter and pH were the main factors affecting the soil macrofauna communities of composition and diversity. In addition to environmental factors, the sampling site can influence the microbial community. For instance, Cao studied soil samples across a regional scale in China (including Jiangxi, Hubei, and Henan provinces). Henan has the largest amount of bacterial and fungal phospholipid fatty acids (PLFAs), while Jiangxi shows the lowest amount of PLFAs (Cao et al., 2016). Moreover, the dominant microbial communities generally differ in different sites. For instance, the dominant bacterial phyla are *Proteobacteria*, *Bacteroidetes*, and *Actinobacteria* in Beijing (Tian et al., 2014), but they are *Proteobacteria*, *Acidobacteria*, and *Chloroflexi* in Jiangsu (Zhao et al., 2014).

The Napahai plateau wetland, an important water source for the upper reaches of the Yangtze River and located in northwestern of Yunnan Province, China, is a unique, seasonal plateau wetland in low latitude and at high altitude. The Napahai plateau wetland has been listed as an internationally important wetland, and has the significance of being a representative plateau wetland (Xiang et al., 2018). However, the microbial community composition and diversity of this region have not become the subjects of research. Soil microbes have ecological functions of central importance, playing crucial roles in nutrient cycling and soil fertility. Their diversity is a sensitive indicator of soil quality that can determine its ecological function (Anderson et al., 2009). Thus, research on microbial communities in the Napahai plateau wetland has become a fundamental need. To provide new insight into the Napahai plateau wetland microbial resources, six sets of samples from three different soil types were studied, with high-throughput 16S rRNA gene sequencing used to investigate the bacterial and archaeal community diversity in the soil. The major aims of this research were to address the following two key questions. (i) What are the characteristics of the bacterial and archaeal communities, with respect to diversity in the soil of Napahai plateau wetland? (ii) What are the influential factors and their contributions to the compositions of the two communities within the Napahai wetland environments?

Materials and methods

Soil sample sites and collection

Soil samples were collected from the Napahai plateau wetland, where the whole year split between the dry season (October to April) and the rainy season (May to September). According to the region's geomorphology, samples were collected from the areas of three

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1414314158

different soil types, including bog soil (YN), swamp meadow soil (SD) and peat soil (NT).

Soil samples were collected in November 2014 (dry season) and June 2015 (rainy season) from three sampling areas (YN, SD and NT). For each sampling areas, two samples were collected and for each sample, and eight mixed sample plot soils were selected ("S" distribution) at 10 cm soil layer. *Table 1* shows the general conditions of each sample, and *Figure 1* shows the sampling sites. YN samples were collected from the vicinity of Lalang from areas less disturbed by human activities. The work regarded as the environmental background area. NT soil sample area was overgrazed by livestock, belonging to a tourism hotspot. *Stellera chamaejasme* Linn., a plant that is a sign of wetland degradation, was also found. Therefore, this area was regarded to have significant disturbance by human activities. The soil from YN, SD and NT sampling areas represented the transition from native swamp soil and swamp meadow soil to meadow soil formed due to the degradation of the Napahai plateau wetland. The twelve soil samples were obtained and stored at 4 °C, and then transported to the lab for DNA extraction and property analysis.

Analysis of physical and chemical properties

Soil samples for property analysis were crushed and sifted using sieves with apertures of 1 mm. Physical and chemical factors, including soil organic matter (SOM), total nitrogen (TN), total phosphorus (TP), total potassium (TK) and nitrogen (N), were measured using ion chromatography (Dionex^{TM} ICS-6000, Thermo Scientific, USA) at the Ministry of Agriculture Agricultural Products Quality Supervision and Testing Center (Kunming, China).

DNA extraction and PCR amplification

Total soil DNA was extracted from 0.1 g of each soil sample, which had roots removed and was ground using the Power Soil DNA kit (MoBio Laboratories Inc., CA, USA) according to the manufacturer's instructions (Zhou et al., 2017). The DNA was confirmed using 1.0% agarose gel electrophoresis and a NanoDrop (ND2000, Thermo Fisher, USA), then stored at -80 °C.

For bacterial and archaeal communities, the primer pairs bac-515F 5'GTGCCAGCMGCCGCGGTAA3' and bac-806R 5'GGACTACHVGGGTWTCTAAT3'; arc-U515F 5'CAGYMGCCRCGGKAAHACC3' and arc-U806R 5'GGACTACNSGGGTMTCTAAT3' were used for amplifying the V4 region of the 16S rRNA genes of bacterial and archaeal, respectively, including barcodes and adapters (Peiffer et al., 2013; Shehab et al., 2013). The PCR mixtures (50 μl) contained 25 μl 2×MightyAmp Buffer Ver.2, 1 μl of each primer (10 μmol/L), 1.0 μl MightyAmp DNA Polymerase, and 2.0 μl template DNA (10-200 ng), with nuclease-free water added to 50 μl. The PCR amplifications used an initial denaturation step at 94 °C for 4 min, followed by 30 cycles of 30 s at 94 °C, 45 s at 56 °C and 35 s at 72 °C and were held at 72 °C for 10 min. The 16S rRNA gene PCR products were sequenced using the Illumina platform (Peiffer et al., 2013).

Sequence analysis

For each sample, three amplicons were pooled together and purified according to the Gene JET kit (Thermo Scientific, USA) instructions. Sequencing of the purified

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1414314158

amplicons was performed on an Illumina MiSeq platform (MiSeq PE300, Illumina, USA) at the Computer Center (Beijing, China). Sequence analysis was performed with Fast Length Adjustment of Short reads (FLASH), discarding the low-quality sequences. Using UPARSE v7.1, sequences were clustered into operational taxonomic units (OTUs) with a 97% similarity cutoff, and Usearch7.1 was used to filtered chimaeras (Edgar, 2013). The remaining sequences, including 530,418 bacterial and 561,217 archaeal, were assigned to OTUs at the 97% similarity level using Mothur v1.34.4 (Schloss et al., 2009). Each representative OUT sequence was assigned to a taxonomic level using the Quantitative Insights into Microbial Ecology (QIIME) pipeline and the RDP classification method (Caporaso et al., 2010).

Table 1. *The overview of Napahai plateau wetland sampling areas*

Soil samples	Sampling points	Longitude	Latitude	Average altitude (m)
YN1	NPH-YN1-YN8	E99°37’43.00”-41.26”	N27°54’26.00”-’24.38”	3290
YN2	NPH-YN1’-YN8’	E99°37’22.88”-20.75”	N27°53’41.21”-36.81”	3282

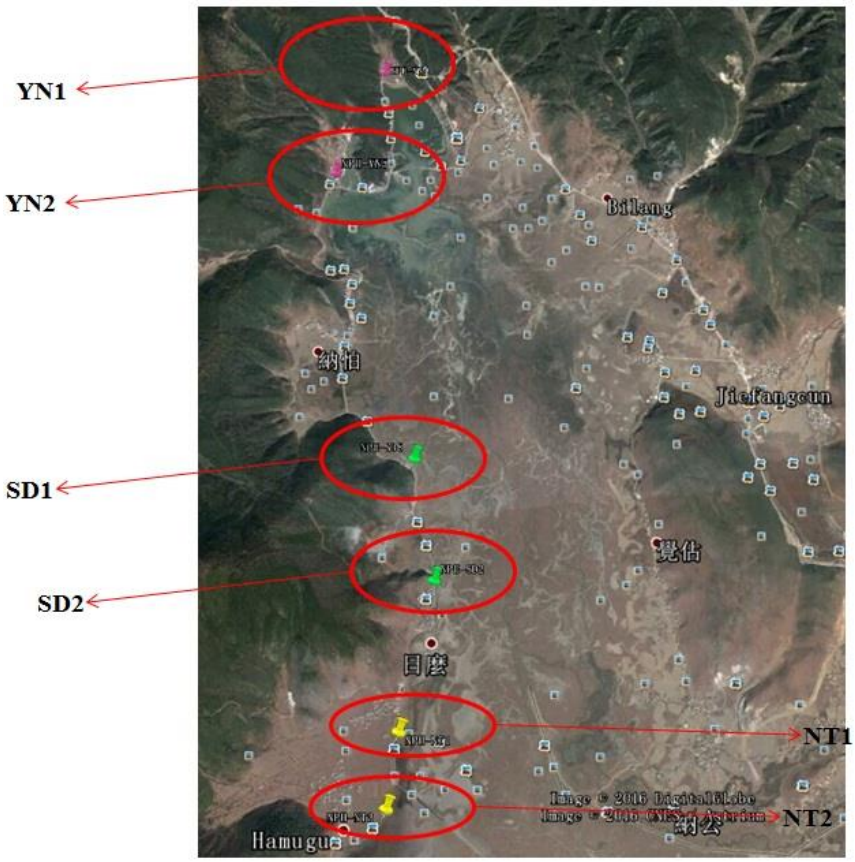

Figure 1. *Distribution of Napahai plateau wetland sampling areas. Each sampling area is composed of eight sampling points and eight sampling points distributed as “S”*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1414314158

Statistical analysis

A number of alpha diversity indices were assessed at the 97% similarity level using mothur 1.34.4 including the Shannon-Wiener and Simpson index, the abundance based coverage estimator (ACE), terminal richness estimation (Chao1), and Good's coverage estimator (Schloss et al., 2009). Beta diversity was measured using Bray-Curtis distances among samples, and community differences were assessed using complete-linkage clustering analysis. Based on Weighted_Unifrac, the Unweighted Pair-group Method with Arithmetic Means (UPGMA) was applied. The heatmap and Venn diagrams were generated using the Vegan Package for R v3.0.2 (Oksanen et al., 2013). Canonical correspondence analysis (CCA) was performed using Canoco v4.5.1 to reveal the relationships between microbial community diversity and soil environmental factors (Legendre et al., 2001).

Results

Physical and chemical properties of soil samples

Table 2 shows the physical and chemical properties of the soil. It can be concluded that soil nutrient contents (SOM, TN, TP, TK and N) show no significant differences in different seasons ($p > 0.05$), but are significantly different in different soil types ($p < 0.05$).

Table 2. *Determination of physical and chemical factors of soil samples*

Sample	SOM, g/kg	TN, g/kg	N, mg/kg	TP, g/kg	TK, g/kg
DS.YN1	105.8	0.568	393	0.032	0.416
DS.YN2	117.4	0.624	368	0.062	0.414

RS.NT2	51.2	0.358	227	0.142	0.908

Microbial community alpha-diversity analysis

To estimate the bacterial and archaeal community diversity and richness, the work applied the Shannon-Wiener index and Simpson's index, ACE, Chao1 and Good's coverage estimation (*Table 3*). In general, high OTU richness in both the bacterial and archaeal communities was found. Good's coverage estimator showed high coverage and reasonable sequencing depth. Regarding the seasons, the diversity (Shannon-Wiener and Simpson's) and richness (ACE, Chao1) indices for the bacterial community showed higher diversity in the rainy season than in the dry season, whereas there was no obvious change of index in the archaeal community. The soil type also influenced the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1414314158

diversity of the bacterial and archaeal communities. In the NT sampling area, both the bacterial and archaeal communities had higher diversity than in the other sampling areas.

Table 3. *The diversity analysis of bacterial and archaeal community at the 97% similarity level*

	Season	Sample	OTUs	Goods coverage	Alphya diversity

Taxonomic composition of the microbial community

Analysis of the bacterial community composition in the Napahai plateau revealed 64 phyla, 164 classes, 271 orders, 330 families and 484 genera. In addition, 3 archaeal phyla were detected to comprise 5 classes, 8 orders, 7 families and 7 genera. *Figure 2* shows the relative abundances of bacteria and archaea at the phylum and genus levels.

The dominant bacterial phyla across all samples were *Proteobacteria*, *Actinobacteria*, *Chloroflexi* and *Acidobacteria*, accounting for 72.4 to -81.8% of the bacterial sequences. It depended on the season and soil type (*Fig. 3*). The abundance of the phylum *Proteobacteria* was much higher ($p < 0.1$), and that of *Chloroflexi* and *Acidobacteria* was much lower ($p < 0.1$) in the dry season, while *Proteobacteria*, *Chloroflexi* and *Acidobacteria* showed the differences ($p < 0.1$) in soil type. The archaeal sequence information included approximately 40% unknown; the dominant archaeal phylum, *Thaumarchaeota* (*Cenarchaeum*), accounted for 50% without exhibiting differences in seasons and soil types.

DOI: http://dx.doi.org/10.15666/aeer/1706_1414314158

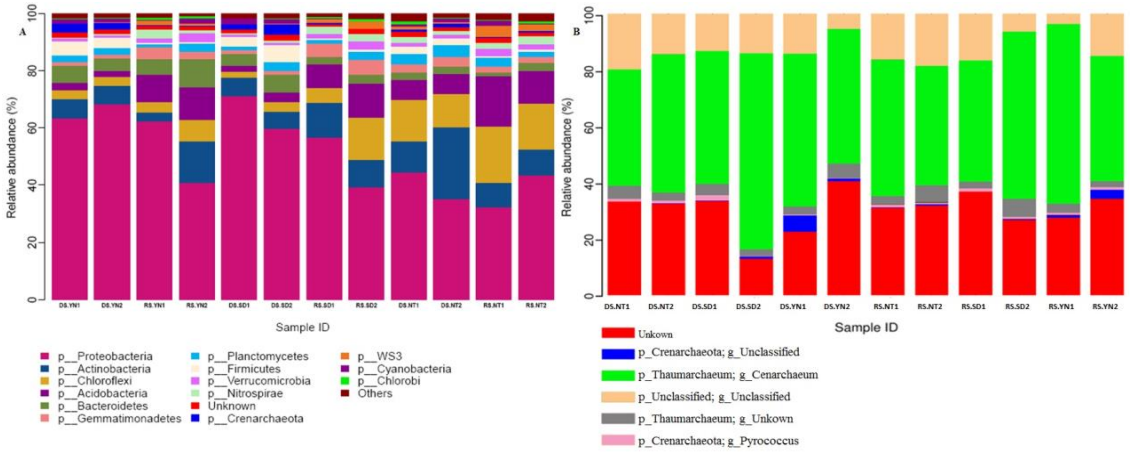

Figure 2. *Relative abundance of bacterial phyla (A) and archaeal phyla (B) detected in soil samples. At different taxonomic levels, the classification of microbial community structure in soil samples to the currently known taxonomic unit is defined as "unknown"; the definition of "others" in which the proportion of microbial community structure is less than 1%; although the microbial community information is aligned to sequences in the database, there is no definitive annotation for the data defined as "unclassified"*

Microbial community analysis of OTU distributions

Based on the statistics of the total OTUs, Venn diagrams were created to display the unique and OTUs were shared among samples (*Fig. 4*). Under a similarity threshold of 0.97, the numbers of overlapping bacterial and archaeal OTUs in the rainy season (2,634 and 828, respectively) were more than in the dry season (1,187 and 741, respectively) in the three soil types. For archaea, the YN sampling area contained more OTUs (1329) than the NT (1020), and SD (935) areas. Each sample contained specific OTUs. For bacteria, the NT sampling area contained more OTUs (2,547) than the SD (1,391) and YN (1,368) areas in the dry season, while the YN sampling area contained more OTUs (4,127) than the SD (3,344) and NT (2,919) areas in the rainy season.

The authors also performed heatmap cluster analysis to discern the community compositional differences (*Fig. 5*). The overall taxonomic diversity of the bacterial community was significantly higher than that of the archaeal community at the genus level. Bacterial and archaeal taxonomic diversity was considerably lower in the dry season compared to the rainy season. The heatmap of bacterial communities showed that *Proteobacteria*, *Actinobacteria* and *Bacteroidetes* were most differentiated between seasons. Additionally, bacterial communities differed slightly in the soil samples from the SD and YN sampling areas in the dry season, but were more irregular in the rainy season. In contrast, *Thaumarchaeota* (*Cenarchaeum*) was the predominant phylum in the archaeal communities. The abundance of archaeal was independent of seasons and soil types.

Microbial community beta-diversity analysis

Based on Weighted_Unifrac distances, the work assessed the similarities and differences in the composition of the microbial communities with respect to seasonal and spatial variations (*Fig. 6*). The UPGMA analysis showed that the diversity and composition of the bacterial community were more impacted by seasonal changes than

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1414314158

by soil types, the opposite of the low-abundance archaeal community. The archaeal community composition did not differ in soil samples from the SD and YN sampling areas, but dissimilar to the NT sampling area.

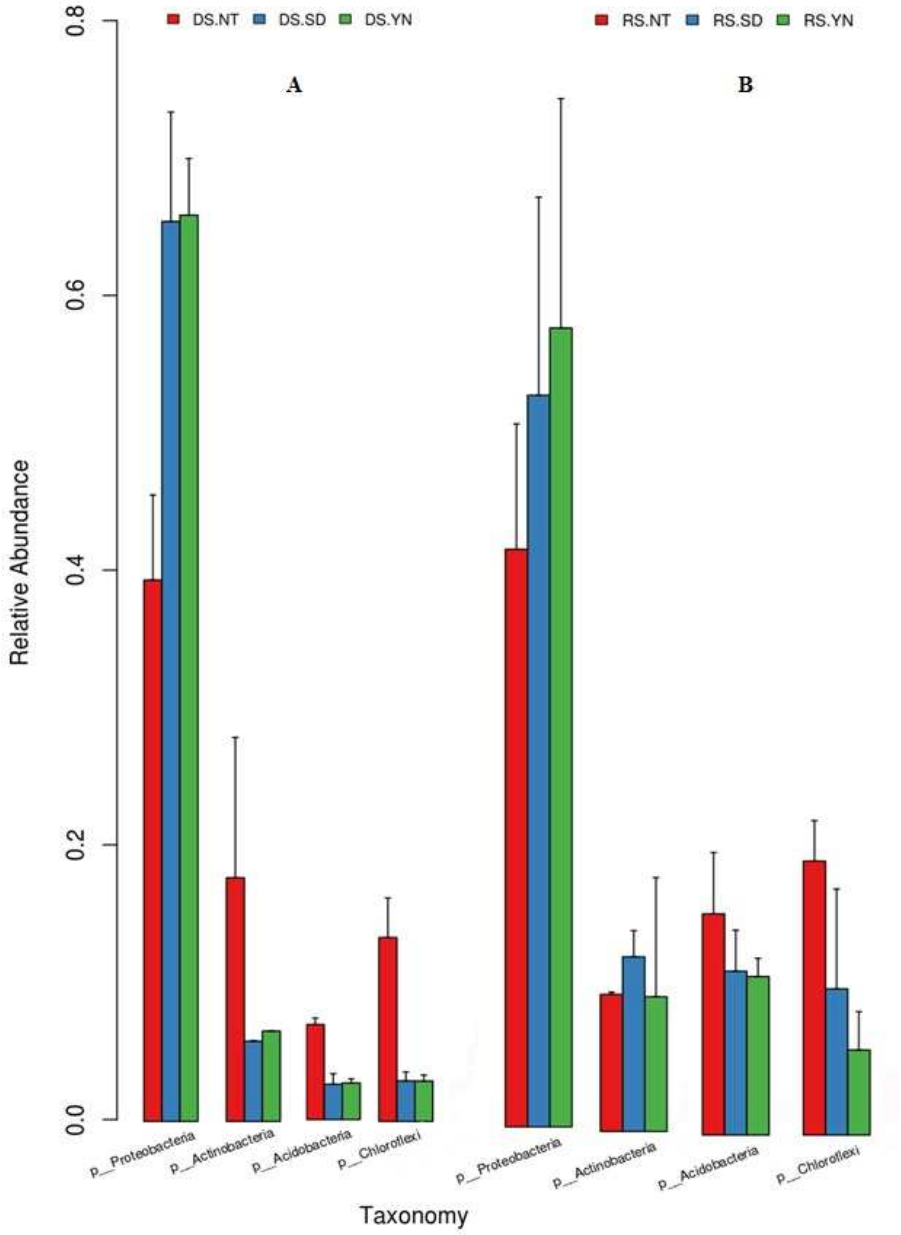

Figure 3. *Comparisons of the bacteria four mainly phyla taxonomy abundance of soil samples (YN, SD and NT) in dry and rainy seasons (DS and RS). The bacteria four mainly phyla taxonomy are Proteobacteria, Actinobacteria, Chloroflexi and Acidobacteria.* ***A*** *The soil samples are collected in dry season (DS).* ***B*** *The soil samples are collected in rainy season (RS)*

Effects of environmental factors on microbial community diversity

CCA was performed to identify the relationships between major environmental factors and microbial community diversity (*Fig. 7*). In the bacterial communities, the first two axes of the CCA plot explained 21.7 and 2.7% (in the dry season) and 77 and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1414314158

26.92% (in the rainy season), respectively, of the total variation in the data. These results indicate that the bacterial community is closely correlated with N, TN and SOM in the dry season. In the archaeal community, the first two axes of the CCA plot explained 34.38 and 27.05% (in the dry season) and 35.12 and 23.32% (in the rainy season), respectively, of the total variation in the data. However, no significant correlation of any of the factors was observed for the archaeal community.

Discussion

Plant and animal diversity have been studied over the past decade in the Napahai plateau wetland. The research has been complemented with microbial diversity information through the measurement of the bacterial and archaeal community composition and diversity, allowing for a better assessment of the whole area's ecosystem.

The composition and diversity of the microbial community in the Napahai plateau wetland were investigated using high-throughput sequencing of 16S rRNA V4 genes. *Proteobacteria*, *Actinobacteria*, *Chloroflexi* and *Acidobacteria* were the top four most abundant bacterial phyla (*Fig. 2A*). Similar results have been obtained in different land-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1414314158

use types of soils in North and South America (Lauber et al., 2009), agricultural and forest soils in Salta and Jujuy (Montecchia et al., 2015) and soils from Antarctic and Arctic (Teixeira et al., 2010; Yergeau et al., 2010). However, compared with those derived from cucumber rhizosphere soils, *Proteobacteria*, *Bacteroidetes* and *Actinobacteria* in the work were the most abundant phyla, accounting for over 70% (Tian et al., 2013). Nevertheless, *Proteobacteria* is the most common phylum in soils worldwide, consistent with our results (Janssen, 2006; Spain et al., 2009). *Actinobacteria* is not only the dominant phylum in low temperature environments but also the dominant phylum in freshwater ecosystems (Zwart et al., 2002; Johnson et al., 2007). The Napahai plateau wetland has an average temperature of approximate 5 °C with a freshwater lake, and its ecological environment is in line with *Actinobacteria* growth. Thus, *Actinobacteria* was also the most abundant phylum in the region. In contrast, the archaeal community compositions, especially the dominant phylum *Thaumarchaeota*, were clearly different from many other ecosystems, which tend to be dominated by *Crenarchaeota* and *Euryarchaeota*. The difference may be due to special geological features (Porat et al., 2010; Wang et al., 2010). *Thaumarchaeota* was the most abundant phylum accounting for almost 50%, which played an important role in the biochemical cycling of carbon, nitrogen and other elements (Cabello et al., 2004). In the *Thaumarchaeota*, most of the known sequences belong to the ammoxidation archaea, involved in the ammoxidation of soil and affect the nitrogen cycle. Therefore, it is speculated that archaea play a more important role than bacteria in the cycling of nitrogen in this area. How archaea and bacteria coordinate with each other to accomplish biogeochemical cycling in the wetland needs further study.

Moreover, greater biodiversity in soil can lead to a more stable system, providing the enhanced combinations of vital microbial functions and processes (Wagg et al., 2014; Regar et al., 2019). In the work, the difference in microbial community composition in different soil types revealed the feedback mechanism of ecological environmental degradation and microbial composition. *Acidobacteria* distribution in acidic environments is contaminated by heavy metal, belonging to non-original colonies (Diamond et al., 2019). Among the YN, SD and NT sampling areas, no significant differences in *Acidobacteria* abundance were observed (*Fig. 3B*). This may indicate that the whole area is affected by heavy metal pollution. In contrast, *Proteobacteria* and *Chloroflexi* showed differences ($p < 0.1$) in different soil types (*Fig. 3B*). One of the predominant classes of *Proteobacteria* was *Gammaproteobacteria*, which can degrade organic matter and were most abundant in the NT sampling area (Picazo et al., 2019). The authors also observed that the abundance of *Chloroflexi* was significantly higher in the NT sampling area, and these bacteria are known to live in environment with high organic matter content (Denef et al., 2015). These similar results could probably be due to the NT sampling area having more nitrogen oxides caused by serious disturbance of human activities. In the archaeal community, *Methanofollis* only present in the NT sampling area in the rainy season (*Fig. 5B*). *Methanofollis* lived in anaerobic environments such as oceans, lake sediments and the digestive tract of ruminants (Pazinato et al., 2010). In the NT sampling area, there are a large number of animals such as cattle and sheep grazing in the rainy season; therefore, *Methanogenus* has had an ecological balance with host ruminants for a long time. All the results illustrated that from the microbial perspective, the NT sampling area can be regarded as consisting of meadow soil formed due to disruption by human activities. Soil microbial composition is important for soil quality and health.

In this work, the effects of seasons and soil types on soil microbial community characteristics were observed. Based on the analysis of OTU distributions (Venn diagrams and heatmap cluster) and beta-diversity analysis, the differences in two factors impact the microbial community (*Figs. 4–6*). Seasonal differences clearly impacted bacterial diversity, consistent with most of the literature reported (Bissett et al., 2007; Kara et al., 2013; Wilhelm et al., 2014). Unlike our result for bacterial diversity, archaeal diversity was affected by neither seasons nor soil types, especially in terms of abundance. Our finding is consistent with the numerous studies on the homogeneous spatial distributions of the archaeal community in various habitats, including field soil (Yuan et al., 2009) and sediment (Keuter et al., 2016); however, in ocean ecosystems, the diversity of archaea was influenced by spatial and temporal differences (Vik et al., 2017). This difference is probably due to unpredictable movements in ocean ecosystems. The soil ecosystem is relatively stable. However, one major drawback of our study was that the small number of sampling sites was in different soils samples, so the changes of microbial community diversity was relatively less convincing.

Our analysis of the relationship between major environmental factors and microbial community diversity showed that TN had the largest effect on bacterial community diversity, but the archaeal community was not significantly affected by environmental factors. This conclusion was also supported by our finding that archaeal diversity was not affected by seasons or soil types (Keuter and Rinkevich, 2016).

Finally, a large number of unclassified microorganisms were detected in the Napahai plateau wetland, with the abundance of unclassified bacteria and archaea at the phylum level being approximate 10 and 25%, respectively. The unclassified bacteria consisted of the novel candidate divisions WPS-2, WS3, GN04, MVP-21 and MVS-104, whereas the archaeal candidate divisions included GA55, VAL11 and FRD15. Their ecological and biological interactions are unknown. Therefore, the isolation of soil microbes combined with traditional methods under laboratory conditions is ongoing, which will help us to identify critical resources in the Napahai plateau wetland.

Conclusions

The work examined the composition and diversity of the bacterial and archaeal communities with respect to spatial and temporal distribution and explored the relationships between environmental variables in the Napahai plateau wetland. For the bacterial community, *Proteobacteria* prevailed was the most abundant, followed by *Actinobacteria*, *Chloroflexi* and *Acidobacteria*. Meanwhile, they were more influenced by seasonal changes than by soil types and was closely correlated with N, TN and SOM in the dry season. For the archaea community, *Thaumarchaeota* dominated. Meanwhile, the archaeal community was neither associate with these factors nor significant correlation of physical and chemical factors. The microbial communities showed high and unique microbial diversity and composition, and influence with seasons and soil

DOI: http://dx.doi.org/10.15666/aeer/1706_1414314158

types, which lays a foundation for understanding the microbial and environmental response mechanism of the Napahai plateau wetland.

In the future, we will combine transcriptomics and proteomics to conduct research on microbial communities, and understand how the main bacteria or archaea conduct ecological functions in the particular ecological environment, and also for the discovery of unknown microorganism.

Acknowledgments. This research was funded by the Personnel Training Fund by the Kunming University of Science and Technology (KKSY201632059) and National Natural Science Foundation of China (No. 31700324).

Abstract. K-means clustering combined with genetic algorithm (GA) techniques are used to improve the accuracy of estimation process and to minimize computational effort for solving nonlinear optimization problems. The main purpose of K-means clustering is to exhibit faster convergence which turns into quick evolution. This paper focuses on newly proposed cluster based GA selection techniques for solving unconstrained optimization problems. The K-means cluster based genetic algorithm (GKA) selection techniques comprise of four major stages: clustering, membership probability indexing, fitness evaluation and selection. The hybridization of genetic algorithm and clustering will effectively cater the problem of population diversity and selection pressure. There are two types of GKA selection techniques that are examined, the first selection technique (GKA_F) includes two proposed selection operators which are linked with a fixed number of clusters while the second technique (GKA_{opt}) is based on the optimum number of clusters. The main focus of these new selection techniques is to preserve population diversity as well as to avoid local optima. The performance of each technique is evaluated through eleven well known benchmark functions. On the whole, the novel cluster based selection techniques are demonstrated to be extremely efficient and effective for achieving optimum solutions which are verified by simulated results.
Keywords: *cluster evaluation, selection operators, benchmarks, selection pressure, population diversity, comparisons*

Introduction

There has been a significant growth in the fields of artificial intelligence, computational analysis, data mining and optimization in recent years. Classical techniques are unable to solve complex problems efficiently in the fields of computational engineering, transportation, energy, and management (Zhang et al., 2014). Hence the edification of optimization algorithms can be classified into stochastic and deterministic approaches (Fister et al., 2013). Mostly, deterministic algorithms are gradient based algorithms that employ the function values with their derivatives. These algorithms are very much useful for smoothing unimodal problems, but in terms of some discontinuous functions, non-gradient algorithms will be preferred (Yang, 2014). Hooke–Jeeves pattern and Nelder–Mead downhill simplex (Rajan and Malakar, 2015) search techniques are some of the examples of non-gradient based algorithms. In regard of stochastic approach, heuristics and meta-heuristics are two types of stochastic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1415914177

algorithms. The major focus of stochastic techniques is to obtain feasible solutions at optimum scenario. There is no surety for finding absolute optimum solutions; however, it is presumed that mostly stochastic algorithms will achieve nearly optimal solutions.

Genetic algorithms (GAs) are stochastic based-heuristic search techniques that originated from biological evolution theory and applied in solving practical problems in the field of human developments. In the process of GAs, sometimes the optimal solution may not be feasible due to internal deficiencies such as less computational efficiency and premature convergence (Aibinu et al., 2016). GA does not have much mathematical requirements. Due to their developmental nature, GA will hunt down arrangements without looking to the particular internal working of the issue. It can deal with any sort of target capacities and imperatives (i.e. direct or nonlinear) characterized on discrete, non-stop or blended inquiry spaces. Hence the main focus of genetic algorithm (GA) is to find the best techniques through suitable adjustment between exploration (population diversity) and exploitation (selection pressure/premature convergences) (Haq et al., 2019a).

On the other hand, clustering is an algorithmic technique to organize the numeric information into meaningful groups. It can also be described as an unsupervised arrangement whereby the data values are clustered using specific information that is available in the dataset and also have prior knowledge about the number of clusters 'K'. This method is often used to discover the patterns of a given dataset (Li et al., 2015). The dataset contains information on variables and usually one attempt to reorganize the useful variables that have the same characteristics into the same group or cluster. However, the main challenge with the clustering is that different clustering algorithms may provide different clusters for the same dataset (Rehman and Islam, 2011). A good clustering algorithm is the algorithm that can reflect the natural clusters in a dataset and at the same time, attain the lowest validity index value (Islam et al., 2018). The clustering validity indices usually measure the compactness and the differentiability of the clusters. The detailed summary regarding strength and weakness of GA (Sivanandam and Deepa, 2008; Aibinu et al., 2016) and K means clustering (Islam et al., 2018) is presented in *Table 1*.

Genetic algorithm is one of the well-known optimization algorithms used to overcome K-means weakness. The major focus of GA based algorithm was to generate high quality clusters in minimum time. Some algorithms have also been designed in a multi-objective optimization form to understand and implement problems that are multifarious. In present study, we will focus on the cluster based selection techniques in genetic algorithm (GA), where clustering is used to organize the population of chromosomes/individuals for the process of reproduction and recombination. Hence, these newly proposed K-means cluster based genetic algorithm (GKA) selection techniques are effectively handle unconstraint optimization problems. The GKA method comprises of four major stages: clustering, membership probability indexing, fitness evaluation and selection. Hence the hybridization of genetic algorithm and clustering will effectively cater the problem of population diversity and selection pressure. A membership selection probability to each individual is followed by clustering. Fitness scaling modified the membership results in regard of selection function. Here two versions of (GKA) selection techniques are examined, the first selection technique (GKA_F) has two proposed selection operators which are linked with fixed number of clusters and the second technique (GKA_{opt}) is based on the optimum number of clusters. The performance of each technique is evaluated through eleven well-known benchmark

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1415914177

functions. The simulated results reveal that the proposed cluster based selection methods outperform as compared to others for achieving optimum solutions.

Table 1. *Detailed summary regarding strength and weakness of algorithms*

Type	Strength	Weakness
Genetic algorithm	• Conceptually easy to understand and execute • Efficiently perform for large scale complex optimization problems • Handle complex and noisy functions easily • Powerfully handle difficulties in evaluation process of the objective function • Require no prior knowledge or gradient information about the problem • Avoid to become stuck at local optima	• Difficulty in identifying fitness function and representation of optimization problems • Occurrence of premature convergence • Difficulty in selection of different parameters like population size, crossover and mutation rate etc. • Population diversity • Configuration is not so simple and straightforward
K-means clustering	• Relatively easy to implement • Computationally faster than other clustering methods with large population size • Clustering process is surely convergent • Easy adaptation for new examples • Easy generalization of clusters to different shapes and sizes	• Number of clusters must be determined before the iterative process begins • Clustering result is extremely sensitive to the initial seed-points • Noise, or outliers and empty clusters decline the superiority of the K-means clustering result • Neglects to recognize non-straight detachable groups in the input space

The remainder portion of this research is presented as: in "Literature review", we comprise of some relevant study for K-means clustering co-integrated with optimization algorithms. Defining problem along with working strategy of genetic algorithm is described in "Defining problem through hybridization of K-means clustering and genetic algorithm". The proposed selection strategy is comprehensively discussed in "Proposed K-means cluster based GA selection operators". A detailed description about the benchmark functions is presented after the proposed work, while simulated results and performance evaluation of proposed methods are demonstrated in "Statistical results and discussion". Finally, "Conclusions and future work" is provided at the end of the study.

Literature review

There are several algorithmic techniques like simulated annealing (Hatamlou et al., 2012) in the literature which are helpful to solve cluster problems. GA is one of the most promising algorithms that have consistently performed well in solving clustering problems. The capability of GA has proven to obtain efficient and effective results and provide appropriate clustering. In the past several years, GA has been extensively used as an optimization method in various domains such as image processing (Loai et al.,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1415914177

2008; Younus et al., 2015; Huang and Ma, 2019; Belahbib and Souami, 2011), and clustering (Lin et al., 2005; Maulik et al., 2011; Murty et al., 2008) to name a few examples. There are several literature reviews that focus on the application of GAs to cluster integer data. All of these methods showed good performance and better results when compared to other clustering methods. However, some of these methods have drawbacks and need to be improved to develop a better clustering algorithm.

Genetic K-means Algorithm, GKA is one of the examples of GAs that was proposed to improve the performance of K-means. The main objective of GKA is to find the global optimum of the given dataset and partition the data into a specified number of clusters. In GKA, instead of using a common crossover operator K-means are used (Zeebaree et al., 2017) as search operators. The problem of minimizing the total within cluster variation (TWCV) was also handled successfully by GKA.

Lu et al. (2004) proposed a Fast Genetic K-means Algorithm, FGKA, which was inspired by GKA, by incorporating several improvements over GKA. Both FGKA and GKA achieved the objective of their studies which converged to the global optima, and the study found that FGKA runs faster than GKA. Maulik et al. (2011) proposed a GAs based clustering where chromosomes were represented by the strings of the real numbers and encoded a fixed number of cluster centers in RN. This algorithm was then extended by Maulik et al. (2011) and named as Genetic Clustering for Unknown K (GCUK). To check the performance of the algorithm, Maulik et al. (2011) compared the minimum value of the objective function in the K-means algorithm with the same K, and showed that the GCUK outperform the K-means. In GCUK, Maulik et al. (2011) used the Davies Bouldin (DB) index to measure the validity of the clusters. These two algorithms used the Euclidean distance to calculate the distance from a point to a cluster center. GCUK became the most effective GAs clustering method but due to the real number representation, it took a longer time to converge (Lin et al., 2005).

In a paper by Lin et al. (2005), the cluster centers were selected directly from the data set and they constructed the look-up table to save the distances between all pairs of the data points. This process allowed the algorithm to speed up the evaluation of the fitness value. In GCUK, GAs clustering by Maulik et al. (2011), the string representation was used to encode the variable number of cluster centers, while Lin et al. (2005) used the binary representation. A cluster based genetic algorithm with polygamy and dynamic population control procedure have been suggested by Aibinu et al. (2016) with an application of route optimization problem. Islam et al. (2018) presented an effective genetic algorithm that combines the capacity of genetic operators to conglomerate different solutions of the search space with the exploitation of the hill-climber cycles of K-means.

Defining problem through hybridization of K-means clustering and genetic algorithm

It is very important for any clustering algorithmic to find approximate or global optima for complex nonlinear optimization problems (Maulik et al., 2011). The K-means clustering algorithm is quite likely to converge to a suboptimal position. The key benefit of stochastic optimization approach over deterministic techniques is that they are unable to converge to local optima. Hence, stochastic techniques are able to solve clustering related problems; such as genetic algorithms, ant colony optimization, simulated annealing and other evolutionary techniques.

DOI: http://dx.doi.org/10.15666/aeer/1706_1415914177

Genetic Algorithms (GAs) play with the idea of the evolutionary process where the chromosomes will have to compete with each other to have a place in the next generation. Strong chromosomes have more chance to survive and usually the weak chromosomes have limited chance. GAs are working with a search space that contains all feasible solution. It means that each of the points in the search space represents one feasible solution that will be marked according to its fitness through objective functions. The core processes of GAs are selection, crossover and mutation. All the processes of GAs make this algorithm more unique as compared to other conventional algorithms for the optimization. The selection process aims to select the good chromosomes which will be sent to the mating pool to combine with the other chromosomes where the features of parents are combined to form new offspring through crossover process (Haq et al., 2019b). Crossover process creates offspring with the help of those parents which are selected through the selection operator. Meanwhile the mutation process aims to encourage diversity in the new population with a very small probability.

Normally GA is a deliberately stochastic process, i.e. an ordered chain of well-defined states, whereby suitable solutions to given problems are determined by using a population of selected individuals. These individuals are examined by using some fitness criterion against the specific problem and using some predefined convergence or stopping procedure for the process to be terminated (Devooght, 2010). In Markov Chain, development of problem is based on modelling and analysis of GA (Eiben and Smit, 2011). Therefore, one of the most significant feature of GA is stochastic aspect which demonstrate the selection and formation of new chromosomes.

The conventional GA, may be characterized by the following schematic scheme:

1. Selection of all individuals as parents followed by a randomization approach (Zeebaree et al., 2018).
2. Genetic operators are used for a generation of offspring.
3. The new population of chromosomes are selected from the mixture of the old and newly generated offspring without changing the size of the string.
4. The main features including the fitness value of new chromosomes are examined against the termination criterion, the algorithm either stops or continue to the next step.

Genetic operators have the ability to maintain the genetic diversity throughout the generations. Variability in genetics or genetic diversity is necessary for the evolutionary process. The core intension of the genetic process is the creation of the fittest population which depends on the valuable cooperation between the genetic operators. The initiation of the idea regarding clustering in genetic algorithm is originated in the context to enhance the quality of solutions by avoiding excessive exploitation and restricting local optima instead of global optimum solution (local maximum or minimum solutions). The methodology of clustering is to enhance the selection probability for the convergence to the global optima by adequately covering the solution space, yet ensuring appropriate selection pressure to attain even better solutions from current population.

Moreover, there is not a rule of thumb for evaluating the performance of GA by choosing an appropriate optimization function. Therefore, the performance of the algorithm is based on the nature of the problem regarding variation rate in objective function and the number of local optima etc. (Hussain et al., 2017). A multimodal function has at least two local optima. The efficient search procedure must be proficient in eliminating the region around local optimum in context of the search for global

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1415914177

optima. The scenario becomes more complex in a situation of random distribution of local optima in search space. By hybridizing the strength of genetic algorithm and clustering of the fitness values, a detailed description of the proposed KGA methodology is revealed in the following section.

Proposed K-means cluster based GA selection operators

In this section, we briefly describe the process of proposed selection operators of genetic algorithm K-means clustering (GKA) for obtaining optimum solution of unconstraint optimization problems. Here, we use a standard genetic algorithm with objective function $f(\vec{x})$ to evaluate the performance of proposed GKA algorithm. These proposed techniques which cater the short comings associated the conventional section (selection) methods by minimizing the distance between centers and individuals by enhancing the search space.

GKA$_F$

The proposed methodology about selection operators of GKA is unique in such a way that the individuals of the population are divided into homogenous groups/clusters. These clusters are internally homogenous and externally heterogeneous as possible. These newly proposed selection techniques will resolve two important issues i.e. exploitation and exploration. Exploration means identifying potential areas of search space and discover new knowledge (Yang et al., 2009). It is also a process of attaining new information by visiting new states. Exploitation generates information and transmission of adaptation, which means optimizing within a promising region. Pure stochastic search is suitable at exploration while hill climbing is best at exploitation (Das et al., 2008). Recombination of the individuals within same cluster reduces population diversity and thus compromising scenario between the exploration and exploitation is mainly determined through clustering within individuals of the population.

The basic aim of the clustering is to explore a specific sequence among the data points that are exploratory in nature (Jain, 2010). The main focus is to organize datasets by using clustering technique which requires some divergence among the nature of the datasets and according to the purpose of analysis. Several types of clustering algorithmic techniques have been proposed (Jain, 2010; Belhaouari et al., 2014; Xu and Wunsch, 2005; Islam et al., 2018) i.e. taxonomy of clustering, discussions on primary short comings and major issues. One of the simplest and most popular clustering algorithmic technique is the K-means algorithm (KMA), and was originated by Steinhaus (1956). Although it was quite long ago, this technique is still the most widely used algorithm for clustering.

Our interest in this study was to cluster the fitness values to observe the same pattern for the selection of individuals. Illustratively, a set of '*n*' variables $X = \{x_1, x_2, x_3 \dots \dots x_n\}$ to be clustered with each of these $X_i \in R^p$is an attribute vector used to describe the variables. These variables will be clustered into a set of clusters, $C = \{C_1, C_2, C_3 \dots \dots C_k\}$ where K is the number of clusters.

The clusters are mutually exclusive $C, C_i \cap C_j = \emptyset \; for \; i \neq j$. The numbers of K may be priori known or not. Let $\bar{x}_k$ be the mean of the cluster C_k. The main objective of clustering is to find the minimum distance between x_i to the closest center $\bar{x}_k$ as follows in *Equation 1*.

$$\sum_{k=1}^{K} \sum_{x_i \in C_k} \| x_i - \bar{x}_k \|^2 \qquad \text{(Eq.1)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1415914177

The most familiar clustering technique is K-means (Islam et al., 2018) clustering which is an iterative procedure which is flexible to implement (Jain, 2010).

The procedure of K-means clustering along with inclusion of selection probabilities through GA can be described below:

1. Initially, the cluster centers $\{\bar{x}_1, \bar{x}_2, \bar{x}_3 \dots \dots \dots, \bar{x}_k\}$ are selected for each respective clusters $\{C_1, C_2, C_3 \dots \dots C_k\}$.
2. The new cluster membership is calculated by assigning each data value to the closest centers.
3. After allocation of data value to new cluster, cluster centers are re-computed.
4. If all cluster center stay in its position the algorithmic process is terminated. Otherwise, the procedure will be repeated from Step 2.
5. The selection probabilities are computed from proposed selection operators.
6. The parents are selected through recombination process.

To improve the performance of the GA process, a newly proposed cluster based selection operator through membership probability index that is assigned to each individual after clustering phase. Basically fitness evaluation will be transformed into membership probabilistic scores in range those are appropriate for selection. The membership probability score of an individual is a measurement of its affiliation with respect to both designated and external clusters. Hence proposed cluster based selection techniques create a balance between selection pressure and population diversity. In other words, these techniques are helpful for suitable adjustment between selection pressure and population diversity (Hussain and Muhammad, 2019). It has been also perceived that the mating pool may comprise of all higher proportionate individuals on absolute uniform scaling. These proposed selection techniques will be helpful in minimizing the selection pressure and improving the search space through clustering approach. The initiation of K-means clustering concept with new selection probability indices will definitely introduce greater diversity in the population thus offering better solution with sustainable convergence speed. In fact, new selection techniques create a balance between selection parameters. The mathematical ecology of the two newly proposed selection probability indices are shown in *Equations 2–7:*

Cluster based selection operator-1

$$P_{(i,j,l),1} = \frac{1}{N}\left[\frac{h_j}{N(h_j-1)}\left(\sum_{l=1}^{N} Z_l - NZ_l\right) + 1\right] \quad \text{(Eq.2)}$$

where

$$Z_l = \frac{f(x_i)}{h_j\left(e^{\sum_{i=1}^{h_j} \frac{\ln(f(x_i)}{h_j}}\right)} \quad \text{(Eq.3)}$$

and

$$N = \sum_{l=1}^{K} h_j \quad \text{(Eq.4)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1415914177

Cluster based selection operator-2

$$P_{(i,j,l),2} = \left[\frac{W_j}{(h_j - 1)}\left(\sum_{l=1}^{N} Z_l - NZ_l\right) + \frac{1}{N}\right] \quad \text{(Eq.5)}$$

where

$$Z_l = \frac{f(x_i)\left(\sum_{i=1}^{h_j} \frac{1}{f(x_i)}\right)}{h_j^2} \quad \text{(Eq.6)}$$

and

$$W_j = \frac{h_j}{N} \quad \text{(Eq.7)}$$

where N is the size of the population of individuals, K is the number of cluster along with cluster size h_j. W_j is the proportion of the cluster from individuals' population.

Here some theoretical findings associated with cluster based selection probability are given below.

1. The cumulative probabilities of j^{th} clusters with size h_j is equal to W_j, hence clusters with more individuals will be obtained larger probability sum of each cluster. Moreover, an individual with higher fitness value within the cluster allocated lower selection probability to control selection pressure and population diversity increased.
2. By reducing the recombination probability, the cluster will avoid premature convergence and lower selection probability will be awarded to each individuals in larger clusters.
3. The cumulative selection probability is equal to one i.e. $\sum_{i=1}^{N} P_{(i,j,l),1} = \sum_{i=1}^{N} P_{(i,j,l),2} = 1$.

In the process of fitness evaluation, fitness scaling transforms the membership scores in a range appropriate for the selection function which selects the parents for the next generation. The selection function assigns a higher selection probability to individuals with higher scaled values. The range of the scaled values can affect the GA performance. High variation in scaled values result in rapid reproduction and prevent the GA from searching other regions in the search space. On the other hand, lower scaled value variations give the same opportunity for reproduction resulting low search space progress. *Figure 1* depicted the proposed K-means cluster based GA selection scheme framework.

***GKA**$_{opt}$*

It is quite clear that the validation of clusters plays a vital role to improve the performance of cluster based GA. Validity of clusters is done to measure the quality of the clustering methods based on the compactness and separateness of the clusters. There are two major types of approaches for clusters validation:

External index is used to measure the extent to which cluster labels match externally supplied class labels, e.g. Rand and Adjusted Rand index.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1415914177

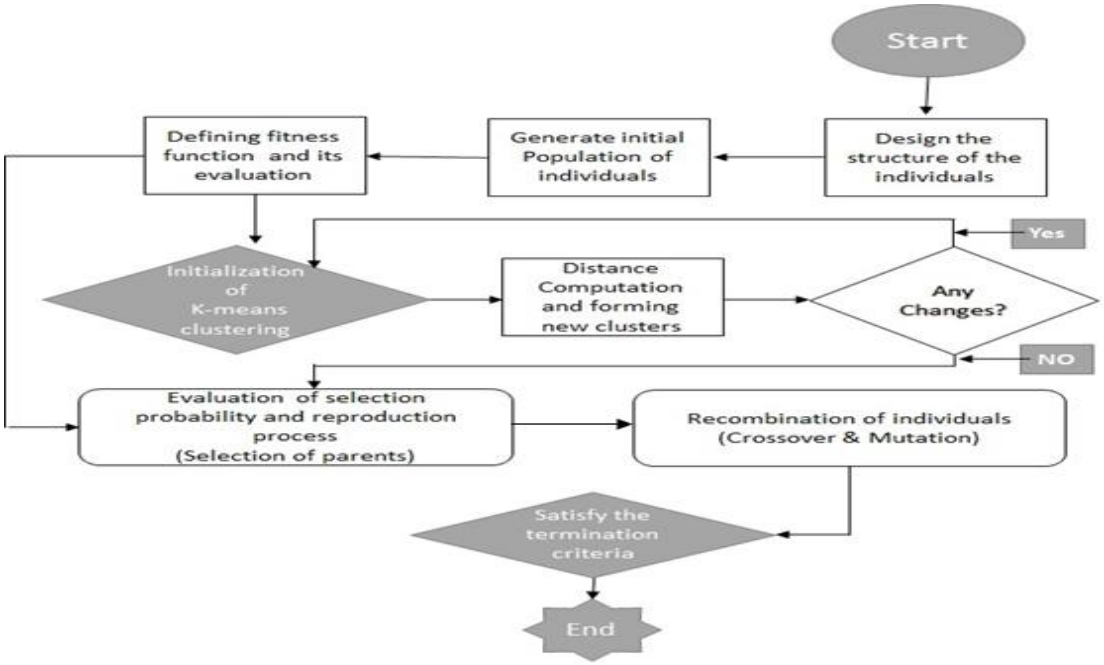

Figure 1. *Frame work of proposed cluster based selection process*

Internal index is used to measure the goodness of a clustering structure without respect to external information e.g. Davies-Bouldin index, Dunn's index, Xie-Beni index, Silhouette index.

The Silhouette index (Mahi, et al., 2018) is one of many cluster indices that can be used to find the number of clusters. The highest value of the average of the Silhouette index s_i indicates a suitable number of clusters. This index is an internal cluster index that can be used as a tool to find the suitable numbers of K with a graphical aid to show the performance of the clustering algorithm.

For each datum i, the Silhouette index can be defined as follows in *Equations 8* and *9:*

$$s_i = \frac{b_{(i)} - a_{(i)}}{max\,(a_{(i)}, b_{(i)})} \qquad \text{(Eq.8)}$$

which is

$$s_i = \begin{cases} 1 - a_{(i)}/b_{(i)}, & \text{if } a_{(i)} < b_{(i)} \\ 0, & \text{if } a_{(i)} = b_{(i)} \\ b_{(i)}/a_{(i)} - 1, & \text{if } a_{(i)} > b_{(i)} \end{cases} \qquad \text{(Eq.9)}$$

where $a_{(i)}$ the average dissimilarities of i with all data points in the same cluster and $b_{(i)}$ the average dissimilarity of i between the other neighbouring cluster. The smallest values of $a_{(i)}$ will indicate the better cluster while the largest values of $b_{(i)}$ will represent a cluster badly matched to its neighbour. If the value of (s_i) is close to 1, then we can say that it is well-clustered. However, if (s_i) is near to 0, then it is not clear in which cluster i belongs to. The larger the average value of the Silhouette index (s_i), the better the performance of the results.

GKA is a single objective optimization method that use only one fitness function. DB index (Mahi, et al., 2018) is used as their fitness function to measure the validity of the clustering algorithm. This index measured the similarity between the clusters (how separated and compact are the clusters). The lowest values of the index indicate the better clustering and how well the clusters are separated. For these reasons, this study uses the DB index.

The DB index measures the similarity of the clusters by calculating the function of the ratio of the sum within cluster scatter to the between cluster separation. The scatter within the C_i for the i^{th} can be computed as in *Equation 10:*

$$S_{i,q} = \left(\frac{1}{|C_i|}\sum_{x \in C_i} \|x - c_i\|_2^q\right)^{1/q} \quad \text{(Eq.10)}$$

where c_i is the center of the cluster C_i. Usually the choice of q is *2*, where a Euclidean distance measured between the center of the cluster and the individual data points. The $R_{i,qt}$ in *Equation 11* denotes the similarity of C_i to the other clusters. In this study, the Hamming distance is denoted in $d_{ij,t} = d(C_i;C_j)$.

$$R_{i,qt} = \mathrm{Max}_{j,j \neq i}\left\{\frac{S_{i,q}+S_{j,q}}{d_{ij,t}}\right\} \quad \text{(Eq.11)}$$

where $d_{ij,t} = d(C_i, C_j) = \|c_i - c_j\|t$.

Hence the fitness value can be evaluated by:

$$DB_i = \frac{1}{k_i}\sum_{i=1}^{k_i} R_{i,qt} \quad \text{(Eq.12)}$$

From *Equation 10,* the measure of dispersion of a cluster C_i; $i = 1,\ldots\ldots,K_i$ is represented by $S_{i,q}$. The evaluation of the DB index for the chromosome Ch_i is defined in *Equation 12* where the lowest value is indicated the better clustering. The whole process of GKA_{opt} technique focuses on finding optimum number of clusters within a range of clusters through evaluation of validity index functions. Hence the number of clusters K and the searching for k^{th} is constrained to a suitable interval $[K_{min}; K_{max}]$, where $K_{min} > 2$ and $K_{max} \leq n = 10$. The individual has a fixed length of K_{max}. While, the number of K is held to fixed then $K_{min} = K_{max}$. The reason to hold the K constant is to make sure that the best number of clusters has been pre-specified and its validity tested by the Silhouette index, whereas the minimum value of DB determines the optimization of clusters.

Benchmark functions

There are several optimization procedures claiming dominance over other procedures. Hence, to obtain an optimum solution, benchmark functions can be utilized as indicators to authenticate their effectiveness. Many benchmark functions along with their properties have been used to appraise the feasibility of optimization problems. Hence the efficiency of algorithm is based on the nature of the optimization problem regarding variation rate in objective function and the number of local optima etc. (Zhang et al., 2013). A multimodal benchmark function has a minimum of two local optima. The efficient search technique effectively eliminates the region around local optima for searching global optima. Furthermore, the dimensionality of search space is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1415914177

another significant factor which makes the problem more complicated. A comprehensive study regarding dimensionality problem and its characteristics were carried out by Friedman. During the search process, the value regarding global optimum needs to be obtained efficiently. Hence the areas close to local minima must be avoided as possible. If the local optima are randomly distributed in the search area, then that is considered to be a more difficult problem. The optimization process is focused on obtaining the global optimum point, consequently the regions nearby local optima should be circumvented because the optimization process might be stuck at local optima and then the local optima is considered as global optima (Deng et al., 2015).

To evaluate the performance and sustainability of the proposed selection operators, we will use eleven unimodal, multi-modal, non-separable, convex and continuous benchmark functions. *Table 2* presents the list of benchmark functions (Surjanovic and Bingham, 2016) utilized to appraise the efficiency of suggested evolutionary methods. Hence the benchmark function name, limit, properties and its fitness function are presented in *Table 2*. These benchmark functions have varying complexities that are most commonly applied in many comparative studies. The necessary detail regarding these benchmarks are given below:

Table 2. *Detail of benchmark functions for comparison*

Benchmark	Fitness function	Search limits	Optimum value	Properties
Axis parallel ellipsoid	$f(x) = \sum_{i=1}^{D} ix_i^2$	[-5.12, 5.12]	0	Continuous, convex, unimodal
Bohachevsky	$f(x) = \sum_{i=1}^{D} (x_i^2 + 2x_{i+1}^2 + 0.3 - 0.3\cos(3\pi x_i + 4\pi x_{i+1}))$	[-100, 100]	0	Multimodal, non-separable
Booth	$f(x) = \sum_{i=1}^{D} ((x_i + 2x_{i+1} - 7)^2 + (2x_i + x_{i+1} - 5)^2)$	[-10, 10]	0	Multimodal, separable
Easom	$f(x) = \sum_{i=1}^{D} \cos(x_i)\cos(x_{i+1})e^{(-(x_i-\pi)^2-(x_{i+1}-\pi)^2)}$	[-100, 100]	-1	Multimodal, non-separable
Ellipsoidal	$f(x) = \sum_{i=1}^{D} (100^{\frac{i-1}{k-1}}x_i)^2$	[-5.12, 5.12]	0	Multimodal, non-separable
Himmelblau	$f(x) = \sum_{i=1}^{D} ((x_i^2 + x_{i+1} - 11)^2 + (x_i + x_{i+1}^2 - 7)^2)$	[-6, 6]	0	Non-convex, multimodal
Six-hump camel	$f(x) = \sum_{i=1}^{D} \{(4 - 2.1x_i^2 + \frac{1}{3}x_i^4)x_i^2 + x_i x_{i+1} + 1 + (-4 + 4x_i^2 + 1)x_i^2\}$	[-3, 3]	(-0.0898, -0.7126, 0.0898, 0.7126)	Multimodal, non-separable
Matyas	$f(x) = \sum_{i=1}^{D} (0.26(x_i^2 + x_{i+1}^2) - 0.48x_i x_{i+1})$	[-10, 10]	0	Non-scalable, Unimodal
Maccormick	$f(x) = \sum_{i=1}^{D} (\sin(x_i + x_{i+1}) + (x_i + x_{i+1})^2 - 1.5x_i + 2.5x_{i+1} + 1)$	[-3,-1.5, 4,4]	-1.91333	Multimodal, Non-separable
Rastrigin	$f(x) = \sum_{i=1}^{D} [10n + \{(x_i^2 - x_{i+1})^2 + (1 - x_i)^2\}]$	[-5.12, 5.12]	0	Multimodal, Separable
Schwefel	$f(x) = \sum_{i=1}^{D} x_i \sin(\sqrt{\lvert x_i \rvert})$	[-500, 500]	0	Multimodal, Non-separable

Statistical results and discussion

The statistical results of GKA methods (**GKA$_{opt}$** (S-index), **GKA$_{opt}$** (DB-inbex), **GKA$_{P1}$** and **GKA$_{P2}$**) were evaluated at 10, 50 and 100 dimensions and compared with standard GA. In the present experimental study, the performance of optimization techniques is evaluated by fixed parameters such as population size, maximum number of generations, crossover fraction and scaling function. The population size for each experiment is 50 along with 0.8 two-point crossover fraction for 10, 50 and 100 dimensions. Each experiment is executed thirty times to determine the statistical results in terms of means, standard deviation (S.D) and t-test. An independent t-test is obtained to assess the significant difference between standard GA and proposed selection techniques. The performance of these selection methods are evaluated on eleven benchmark functions using MATLAB version R2015a.

The statistical results in *Tables 3–5* reveal that the proposed selection techniques (**GKA$_{P1}$** and **GKA$_{P2}$**) outperform under all benchmark functions from 10 to 100 dimensions. Additionally, the probability values of Bohachevsky, Easom and Schwefel benchmark functions at dimension 10 are ranging 0.0010 to 0.0093 which is significant to some extent but when we increase the dimension of the experiment from 50 to 100, the experimental results turned into highly significant with probability values are tend toward 0.0000. Most of the statistical results demonstrate that **GKA$_{P2}$** perform the best for achieving an optimal solution and **GKA$_{P1}$** is the second best technique because of its closeness to the theoretical optimum value. Overall cluster based selection techniques are broader and more comprehensive for achieving optimum solution and also restrict the individuals to premature convergence. More specifically, there are slight differences between optimum values of **GKA$_{P1}$** and **GKA$_{P2}$** at lower dimension but these differences become highly significant at 50 to 100 dimensions. Results of the above tables are also reveal that the proposed selection techniques perform distinctly better in unimodal and multimodal benchmark functions but rate of the change is slightly high in unimodal functions which turn into highly significant results.

In the context of the above results it is described that the cluster based GA techniques establish a realistic partitioning of the population. These techniques actually extend the population diversity by strengthening the search process and limiting the chance of less fitted individuals. The inclusion of the cluster is also more beneficial for reducing selection pressure, hence the proposed selection schemes authenticate the process of best fitted individuals' selection. Additionally, partitioning of the individuals in the form of clusters endorse that the adequate mixture of individuals is always carried forward to the next generation for obtaining optimum solutions. Above statistical results ensure that clustering is always helpful in exploration process and also minimizing the chance of permute convergence at local optima due to well-adjusted selection pressure.

In order to evaluate the pairwise comparison between the above selection techniques: a non-parametric statistical test is used known as Wilcoxon matched pair signed rank test. The test statistic (T_c) of this test is based on the ranking of absolute difference between two techniques. T^+ is the rank sum with positive signs and T^- is the rank sum with negative signs, the value of Tc depends on the fewer rank sum between T^+ and T^-. A sufficiently small value of T^+ and T^- will cause the rejection of the null hypothesis. The results in *Table 5* represent the pairwise comparison of the following cluster based selection techniques using Wilcoxon matched pair signed rank test at 5% level of significance.

According to the results indicated in *Table 6,* there is highly significant difference between most of the pairs of K-means cluster based techniques, when the dimension of the experiment increases from 10 to 100 the p-value turn into highly significant. However, there is also a non-significant difference between GKA$_{P1}$ and GKA$_{P2}$ at lower dimension but when dimension increases difference between them becomes highly significant.

Conclusions and future work

K-means cluster based genetic algorithm (GKA) selection techniques are proposed to solve optimization problems using unimodal and multimodal benchmark functions. Two distinct types of GKA techniques were proposed, one is using fixed number of clusters GKA_F and other is through optimum number of clusters GKA_{opt}. Hence, Davies-Bouldin and Silhouette index is used to determine optimum number of clusters in the population. The GKA method comprise of four major stages: clustering, membership probability indexing, fitness evaluation and selection. The hybridization of genetic algorithm and clustering of individuals will effectively cater the problem of population diversity and selection pressure. A selection probability is assigned to each individual after the process of K-means clustering. Fitness scaling changes the membership fitness scores in a limit that is suitable for selection function, which select the parents for future generation by the utilization of scaled fitness values. The comparative performance of each cluster based GA technique (GKA_{opt} (S-index), GKA_{opt} (DB-inbex), GKA_{P1} and GKA_{P2} are evaluated on eleven benchmark functions under 10, 50 and 100 dimensions. Usually, the performance of standard GA is good to solve unimodal problem but unable to handle multimodal problems. By the hybridization of GA and K-means clustering, the newly proposed selection techniques efficiently and effectively handle the multimodal problems by obtaining optimum value. The statistical results of present study represent that the performance of GKA_{P1} and GKA_{P2} selection operators are comparatively more superior to standard GA selection techniques. In addition, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1415914177

significance of proposed techniques is also improved by increasing the dimension of the experiment from 50 to 100. In-fact the cluster based selection techniques outperform in solving unimodal and multimodal problems with positive impact.

In the present research study, integrating the strengths of data mining and evolutionary computation were limited to single-objective optimization problems. Future research study could evaluate the performance of GKA in solving constrained optimization problems with multi-objective functions. The efficacy of novel selection procedure should be considered in future research study. It would be compelling to hybridize the K-means cluster with population based optimization schemes such as firefly algorithm (Rajan and Malakar, 2015), ant colony optimization (Gao et al., 2016) and particle swarm optimization (Pednekar, 2019). Finally, another potential avenue for future research is to examine the performance by making comparison of standard K-means clustering with the other clustering methods like Incremental K-means (IKM), Scalable K-means and Online K-means (Saharan et al., 2018) by considering presently proposed selection techniques.

Abstract. In order to overcome the difficulty in obtaining the initial shallow groundwater level of a small bedrock island and build a better geological body model, the assessment of groundwater potential by remote sense (RS) method was introduced into the shallow groundwater flow field modeling of bedrock islands. And the Wailingding Island in China was taken as the study area. The buried depth (h) of water level was fitted with the remote sensing assessment score of shallow groundwater potential, according to the actual water volume. As a result, the study obtained the formula of the fitting curve, which was $S=0.427e^{0.239h}$, $R^2=0.8462$ ($P<0.05$). Then, it used ENVI software to calculate $h=(1/0.239)\ln(S/0.427)$ and evaluate the initial water level of shallow groundwater: D= DEM-h. Moreover, the study introduced the value of D into the GMS software as the initial water level for the simulation of the shallow groundwater flow field, overcoming the difficulty in obtaining the water level of shallow groundwater in the bedrock islands. The GMS software was used to establish a simulation model of shallow groundwater flow field based on the hydrogeological data in this study area. Also, it used ENVI software to convert DEM data into TIF files and import them into the GMS software, improving the precision of island geological body simulation. Next, the study attempted to change the initial conditions of the simulation model of the shallow groundwater flow field, such as rainfall, evaporation capacity and so on, to predict the distribution of shallow groundwater flow field at different times. Finally, the actual water yield of springs and wells and the geophysical data were used to verify the results of the simulation, and the accuracy has met the requirement. Therefore, it is possible complete the simulation of the shallow groundwater flow field of a small bedrock island by RS technology and other techniques.

Introduction

Water is the source of life. Islands are short of water (McCartney and Houghton-Carr, 2018), and the protection of groundwater is an important factor for environment protection and an indispensable part of environmental assessment. Studying on the flow field distribution and pollutant migration and diffusion of island groundwater, which are helpful to the protection and development of groundwater resources. Due to the different geology, different landform and other factors, there are differences and similarities between the study of terrestrial groundwater and that of islands groundwater. As early as 1995, Li's team used the finite element method of water head and concentration dependence to calculate and simulate the water level, water flow and

DOI: http://dx.doi.org/10.15666/aeer/1706_1417914195

water quality of the pyroclastic pore aquifer of Weizhou island and the basalt pore and fracture aquifer (Li et al., 1995). Then, the basis of the groundwater exploitation planning and the control of seawater intrusion was obtained. In 1998, Person studied and predicted the distribution of groundwater in Nantui island (the United States) between 1977 and 2020, using the sharp-interface model, and discussed the intrusion of seawater (McCartney et al., 1998). Subsequently, with the development of computer software, some corresponding groundwater simulation programs and software came out. Liu's team used Modflow-96 to simulate the distribution of groundwater in China's Jinmen island in 2006 (Liu et al., 2006). The eastern part of the island is dominated by granite and gneiss, while the western part is dominated by laterite. Different parameters are set by the program to evaluate the variation level of the groundwater level and provide a scheme for groundwater utilization. In 2008, Barazzuoli et al. used field and experimental data from 1995-2013 in the coastal region of Tuscany, Italy, and used the FEFLOW numerical simulation software to model and analyze the impact of the natural inflow of groundwater into the sea, rivers and man-made wells, and considered the intrusion of seawater, and obtained the water budget. Wen's team studied the groundwater in Leizhou peninsula in 2013 (McCartney et al., 2018). The shallow aquifer in this area is composed of loose rocks and fissure water in volcanic rock cavities. In 2014, Kadi et al. used GMS software to simulate the flow field of Jeju island. And the island is a volcanic, basalts and pyroclastic rocks. For simulating the groundwater situation (Wen et al., 2013), they used the MODFLOW module simulation analysis of groundwater level and spring water, with the SEAWAT module simulating the analysis of seawater intrusion, according to the water level elevation, stream, salinity and other indicators, assessment of the island of groundwater sustainable ability (Alfaro et al., 2017; Mehdizadeh et al., 2017). Subsequently, Lathashri et al. (2016) also studied coastal areas by using the MODFLOW module and proceeds the module of GMS numerical simulation software. Yi et al. (2016) used GMS software to simulate the discharge and seawater intrusion of groundwater in Bohai Bay in Tianjin, China. He used the FEMWATER module to simulate variable density fluid to generalize groundwater and seawater. Li's team built a groundwater simulation model on the east island of Zhanjiang, China (Teng et al., 2015; Zhou et al., 2017). The island was turned into heterogeneous anisotropic, using the Visual MODFLOW software to simulate solution, combining the actual drilling data. The model can better reflect its groundwater hydrogeological situation, and put forward the following island in deep aquifers and deep aquifer groundwater hydraulic ties with China. They discussed the island's sustainability situation of groundwater, and guided the mining of groundwater. Before some integrated programs and software appear, bedrock island groundwater simulation takes analytical calculation as the mainstream, and its visualization effect is not good, and the simulator must have a high level of programming. With the advent of MODFLOW, Visual MODFLOW, GMS, FEFLOW and other software, it seems that the groundwater simulation becomes simple and process-based. It only needs to carry out a detailed investigation on the groundwater recharge and drainage of bedrock islands and seawater intrusion, as well as the experiment and investigation of geological parameters in the region. Then the study used the software to establish a model to simulate. The generalization of bedrock islands of pyroclastic rocks, basalt pore media, highly weathered granite or gneiss, and simulation of other loose rocks is no problem, in accordance with Darcy's law and the equation of motion of groundwater or two-dimensional flow. However, for some bedrock islands, there are mainly bedrock cracks,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1417914195

such as granite and gneiss. It should conform to the cubic law of groundwater movement. If the geological body is still to be generalized as a pore model, it is similar to the equivalent porous continuous medium model (Long et al., 1982), and it is necessary to modify the parameters such as lithology, water supply and permeability coefficient in local areas. If the geological body is directly considered as a fracture model, the discrete fracture network seepage model (Mao et al., 1984; Wang et al., 2012) is needed to simulate the fracture flow. If the upper strata of the island dominated by bedrock fissures are weathered to a high degree of loose rocks, and the middle and lower strata are still unweathered bedrock fissures, double or multiple media should be considered. If the geological body is still replaced by the pore model and the MODFLOW, Visual MODFLOW, GMS and FEFLOW are used, then the parameters of stratified strata need to be set, which should conform to the properties of each stratum. If the crack model is used, the crack can be simulated with the TOUGH2 software or GMS+TOUGH2 (Tan et al., 2017). At present, the Lawrence Berkeley laboratory in the United States has introduced TOUGH3 software, which is an upgraded version of TOUGH2, adding the function of coding modification and realizing a wider range of simulation. The MODFLOW-SURFACT module is also a program module that can simulate dual media and fracture well (Tan et al., 2017). The CONNETFLOW is a finite element groundwater simulation software for cracks, in which the NAMMU module is for porous media model and the NAPSAC module is for discrete fracture network seepage model. The software can be applied to dual media. Islands of volcanic islands, loose rocks and highly differentiated bedrock are pore type, whose seepage flow conforms to the movement equation of the groundwater of the heterogeneous anisotropy or transverse isotropy, which can be directly simulated by the MODFLOW program, Visual MODFLOW, GMS or FEFLOW software. Bedrock fissures are dominated or with a low degree of bedrock differentiation. They are fracture type. The movement law of groundwater conforms to the cubic law, which can be simulated by the TOUGH2 software, MODFLOW-SURFACT program module and CONNETFLOW finite element simulation software. If the geological body is a pore-crack type (dual medium or multiple medium), we need to simulate the flow geological model based on the MODFLOW, TOUGH2 software, or SURFACT program module. And the study used the CONNETFLOW finite element simulation software to carry out the coupling between pores and cracks. For the intrusion of the bedrock island seawater, its boundary can be directly delineated by combining geophysical and drilling data with its coastline, using SUTRA software, taking into account MODFLOW flow model combined with MT3DMS solute transport model, or using fault module for simulation.

In the past, researchers studied the groundwater flow field of islands in large scale sea areas or mostly studied the distribution of groundwater flow field of sandy islands. However, the simulation of the groundwater flow field in a small bedrock island has not been well studied. This study mainly aimed at the simulation of the shallow groundwater flow field in a small bedrock island. Groundwater in bedrock islands is mostly stored in the form of "freshwater mushroom" (Pang, 1987, 1988), and there are also "freshwater lens", which is different sand islands. The difficulty of shallow groundwater flow field simulation in bedrock islands lies in the acquisition of hydrogeological parameters, especially in small islands which are short of adequate wells or springs. Zhou et al. (2017) used the MODFOLW model to simulate the Donghai island of Zhanjiang, China. Currently, geophysical techniques were also used to detect groundwater throughout the islands (Rosemary et al., 2009). However, it will

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1417914195

cost a lot of work in this method. Therefore, the assessment of the shallow groundwater by remote sensing technology was introduced in this paper to solve the problem that it is difficult to obtain the initial water level of the shallow groundwater flow field in the small bedrock islands. And it combined with geophysical exploration technology and other hydrogeological means. Also, it combined with stratigraphic stratification data, and some hydrogeological parameters of the strata. Furthermore, the shallow groundwater flow field simulation of small bedrock islands was realized.

Material and Methods

Equation of groundwater movement in the bedrock islands

According to the lithologic characteristics of different bedrock islands, there are different theoretical expressions of groundwater movement. Its specific theory should be based on the island's specific bedrock lithology or stratigraphic lithology to choose different forms. If the bedrock island strata are loose strata, such as the east island of Zhenjiang city (Lu, 2007), and granite and gneiss affected by weathering, unloading, and topographic factors, it can be thought that the geological body can be generalized into non-homogeneous anisotropy or transversely isotropy in this paper. The groundwater motion equation (simplified anisotropic medium) or two-dimensional flow motion equation can be used as *(Eq. 1)*:

$$\frac{\partial}{\partial x}[\mathrm{K}_{xx}\frac{\partial H}{\partial x}+\mathrm{K}_{xy}\frac{\partial H}{\partial y}+\mathrm{K}_{xz}\frac{\partial H}{\partial z}]+\frac{\partial}{\partial y}[\mathrm{K}_{yx}\frac{\partial H}{\partial x}+\mathrm{K}_{yy}\frac{\partial H}{\partial y}+\mathrm{K}_{yz}\frac{\partial H}{\partial z}]+\frac{\partial}{\partial z}[\mathrm{K}_{zx}\frac{\partial H}{\partial x}+\mathrm{K}_{zy}\frac{\partial H}{\partial y}+\mathrm{K}_{zz}\frac{\partial H}{\partial z}]=\mathrm{S}_s\frac{\partial H}{\partial t} \quad \text{(Eq.1)}$$

Equation (1) is the general groundwater movement equation of anisotropic media (Wang, 2011). Assuming that x=y is substituted into *Equation (1)*, the groundwater movement equation of transverse isotropic media is obtained, that is *(Eq. 2)*:

$$2\frac{\partial}{\partial x}[2\mathrm{K}_{xx}\frac{\partial H}{\partial x}+\mathrm{K}_{xz}\frac{\partial H}{\partial z}]+\frac{\partial}{\partial z}[2\mathrm{K}_{zx}\frac{\partial H}{\partial x}+\mathrm{K}_{zz}\frac{\partial H}{\partial z}]=\mathrm{S}_s\frac{\partial H}{\partial t} \quad \text{(Eq.2)}$$

Assuming that K_x is the permeability coefficient in the horizontal direction and K_z is the permeability coefficient in the vertical direction, the two-dimensional flow motion equation is shown as follows (*Eq. 3*):

$$\frac{\partial}{\partial x}[\mathrm{K}_x\frac{\partial H}{\partial x}]+\frac{\partial}{\partial z}[\mathrm{K}_z\frac{\partial H}{\partial z}]=\mathrm{S}_s\frac{\partial H}{\partial t} \quad \text{(Eq.3)}$$

In fact, the principle of three-dimensional flow and two-dimensional flow is essentially consistent, as shown in *Figure 1*.

In *Figure 1*, profile 1 is the y-z profile of the geological body, and profile 2 is the x-z profile of the geological body. The permeability coefficients are K_y and K_z, K_x and K_z,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1417914195

respectively. $K_y=K_x$ indicates that the penetration coefficient of the y-z profile is consistent with that of the x-z profile, indicating that the permeability coefficient of 3 dimension form is consistent with that of 2 dimension, that is, the essence of 3 dimension flow is consistent with that of 2 dimension flow, but only means that the form is different.

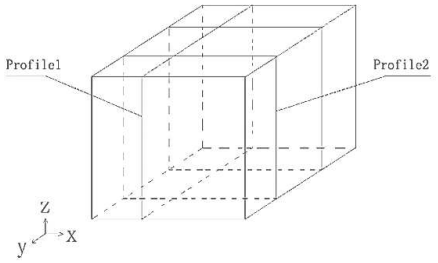

Figure 1. *Two - dimensional, three - dimensional seepage model of the geological body*

The theory of shallow groundwater level based on remote sense groundwater assessment

In this paper, the concept of "shallow layer" in the shallow groundwater is the first aquifer, most of which is the diving layer that is the first stable aquifer below the surface, sometimes the upper stagnant water, sometimes the pressure water, in short, the first aquifer below the surface. In order to obtain the initial groundwater level of bedrock islands, the study used the assessment of groundwater potential by RS method (GRSFAI method) to obtain the initial water level. And lithology index, slope index, relief index, soil humility index, land temperature index, vegetation fraction index and other indexes were selected to establish the model. The equation of score, S, is shown as follows (*Eq. 4*) (Deepesh et al., 2010; Lee et al., 2012; Deng et al., 2013):

$$S = \sum_{i}^{n} W_i \bullet Y_i \qquad \text{(Eq.4)}$$

where S is the score of assessment of groundwater potential, the Y_i values are different kinds of indexes. And the W_i values are the weights of indexes.

The assessment score, S, of shallow groundwater enrichment grade and the water volume, V, in the measured well can be obtained by applying the improved GRSFAI method based on RS-image grayscale statistics and cluster analysis method, and the fitting curve of the two can be finally obtained. And the general formula is $S = a \cdot e^{bV}$. The average the amount of water in a well or spring in terms of its area, the study can get the formula (*Eq. 5*):

$$h = \frac{1}{\Delta s \cdot b} \ln \frac{S}{a} \qquad \text{(Eq.5)}$$

where h is the buried depth per unit water level, as shown in *Figure 2*, and is the elevation from the level groundwater to 2 meters above the groundwater surface. Then, the study can obtain a water level of groundwater: D=DEM-h. The average V water

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1417914195

flow is directly represented by the actual unit water level buried depth h at this point, and the formula (*Eq. 6*) is

$$S = a_1 \cdot e^{b_1 h} \quad \text{(Eq.6)}$$

Next, by fitting the evaluated score, S, with the buried depth, h, of unit water level, the coefficients a_1 and b_1 are obtained. Then, using ENVI software (Duan, 2016), MATLAB software or EXCEL software to calculate the value of h in the entire research area, or the key points of the research area. And the water level of groundwater: DEM-h is used as the initial water level data matrix of the first aquifer in this area. The initial digital, D, is introduced into the GMS software or TOUGH software to simulate and predict the shallow groundwater flow. Thus, the difficulty of obtaining the initial water level elevation of the bedrock islands is overcome.

The specific research route of this paper is shown in *Figure 3*.

Hydrogeological parameters of the study area

Waiilingding island is located in the northeast of Zhuhai city, Guangdong province, China, extending between 22°5′17.16″N and 22°6′57.54″N latitude and 114°1′11.19″E and 114°3′15.40″E longitude, shown as *Figure 4*. Rainfall situation of the island is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1417914195

following, the rainfall can be divided into high and dry seasons. The rainfall during the period from April to September takes up more than 80% of the annual rainfall. The average monthly rainfall is between 200 and 350 mm. In addition, the whole island is about 3,200 meters long, about 2,400 meters wide, and the narrowest place is only 1,070 meters, with an area of 4.33 km^2. The coastline around the island is 12.3 km. And the coastline is changeable, the geomorphology changes is rich, the island landscape coexists, has many kinds of bay and beach. Wailingding island is very rocky outcrop. In the valley, there are a lot of granite eggs with diameter of 2 to 4 meters.

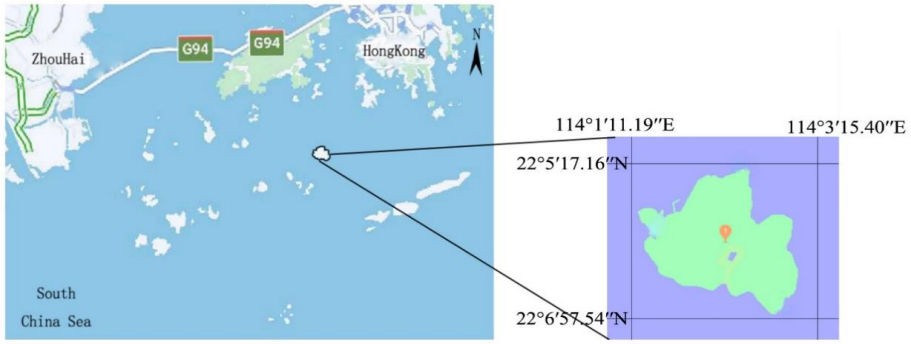

Figure 4. *The map of the study area*

The island's geological structure is simple, mostly granite. From the top to the bottom of the island, it can be divided into three layers, namely the weathered layer soil, vegetation cover, and bare rock, semi-weathered layer and granite bedrock bottom layer. Moreover, the joints of rocks are relatively developed, but the density is not uniform, and there are large faults. The discovery of groundwater in the large sump pit and the wells and springs previously used by people on the island has indicated the existence of groundwater, but the capacity is limited. The islands are surrounded by seawater, and the only source and supply of groundwater is rainwater. Underground cave or fissure, that is, a closed can accumulate a certain amount of water, and also known as island freshwater mushroom body or freshwater lens, forming the groundwater in this island for many years.

Software simulation of shallow groundwater flow field based on remote sense

Setting hydrogeological parameters in GMS software

According to the test values of hydrogeological parameters given in the Hydrogeological handbook (Wang, 2012), the Dam project handbook (Mao, 2009) and the Simulation of pollutant migration in groundwater (Zheng, 2009), The parameters such as horizontal permeability coefficient, vertical permeability coefficient, water availability, water storage coefficient and anisotropic parameters were input into the groundwater simulation software, as shown in *Figure 5*. And the *Figure 6* was a lithological sample of the study area.

Then, the study used the Wailingding island area of Google map as the base of software simulation. Large areas of groundwater on the island were delineated and potholes (or small lakes) were formed, and there were wells and springs in the study area. The recharge in this region is 0.000493 m/d. Due to the particularity of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1417914195

bedrock island, the coastal edge of bedrock is in the form of the freshwater mushroom body, which can set the bedrock coastline as the fixed head boundary by the SEAWATER module of GMS software (Pang and Gao, 1988). And the coastline of the island is used as the boundary of bedrock islands.

Figure 5. *Various lithologic hydrogeological parameters*

Figure 6. *A lithological sample of the study area*

Water level distribution parameters based on remote sense

Based on the assessment score value, S, of the results of shallow groundwater potential in the study area (Xu et al., 2018) which was shown as *Figure 7* (Xu et al., 2018). And the basal remote sensing data (DEM, GF-1 data, Landsat8 data and so on) can be download from http://www.rscloudmart.com or http://www.gscloud.cn/sources. The actual unit water level depth h of this point is directly expressed according to the average V water volume, that is, $S=a_1 \cdot e^{b1h}$. Subsequently, the evaluated score S was fitted with the buried depth h of unit water level, and the coefficients a_1 and b_1 were obtained. Then, using ENVI software or MATLAB to get the level of groundwater of the first layer, D=DEM-h.

According to *Table 1*, the study can obtain the formula (*Eq. 7*) of fitting curve of h and S (Zheng et al., 2009; Deng et al., 2013):

$$S=0.427E^{0.239H} \quad \text{(Eq.7)}$$

And $R^2=0.8472$. It showed that the fitting degree of h of water level per unit area per unit time in wells or springs and the S of assessment of shallow groundwater potential by remote sensing was good. Next, the formula for calculating h of the evaluated score value S of each point can be deduced reversely according to the formula (*Eq. 8*):

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1417914195

$$h = \frac{1}{0.239} \ln(\frac{S}{0.427}) \quad \text{(Eq.8)}$$

In addition, the water level of shallow groundwater was D, and the surface elevation valued DEM and h were (*Eq. 9*):

$$D=DEM-H \quad \text{(Eq.9)}$$

Then, the study introduced the initial level D of the simulation of the shallow subsurface flow field of the bedrock island into the GMS software. And the study set the parameters of layers and starting heads which were shown in *Figure 8*.

Establishment of shallow groundwater model by using GMS software (Liu and Zhang, 2015)

[STEP1]: Setting the basic hydrogeological parameters of the study area as shown in *Figure 5* and setting the parameters of layers and staring heads. Then, setting the supply item and discharge item according to the water level geological data and actual survey data. And the recharge is 0.000493 L/d. The recharge was 0.00603 L/d at the location of puddles and small lakes. And setting up the corresponding well-pumping water. The supply area was shown in *Figure 9*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1417914195

[STEP2]: Inputing reproduction, and then inputing the region of the DEM (Dong et al., 2008) which can download freely http://www.gdem.aster.ersdac.or.jp/index.jsp. TIF file was shown in *Figure 10*. And drawing the corresponding CAD reproduction, convenient area of the surface waters in the region, islands area, block partition and edge boundaries.

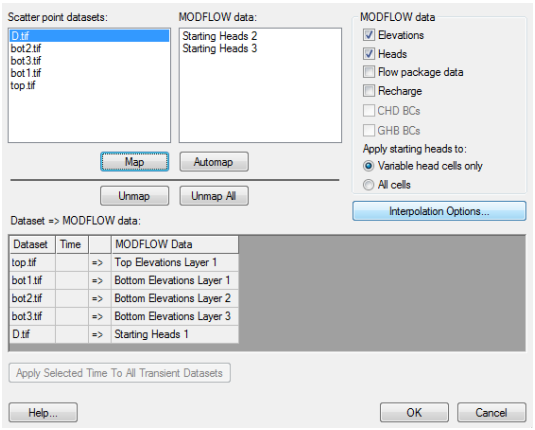

Figure 8. *Setting parameters of layers and starting heads*

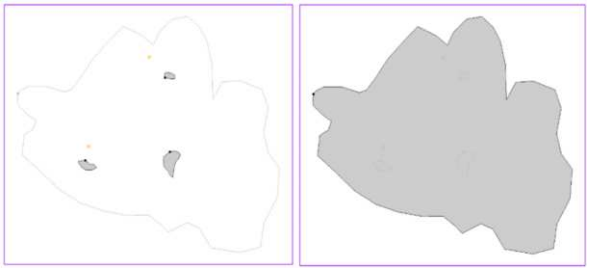

Figure 9. *Setting of the supply area*

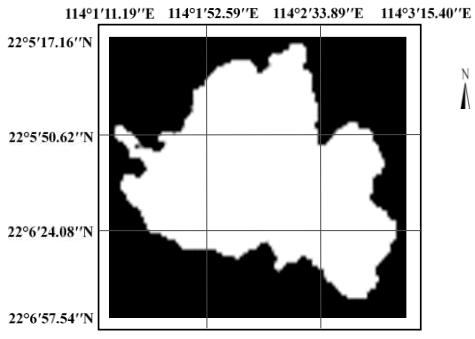

Figure 10. *TIF file of DEM in the study area*

[STEP3]: The mesh generation and model calculation.

The study imported the TIF file of the initial water level, D, into the GMS software and converted it into a scatter in the GMS software, as shown in *Figure 11*. And the study used the direct current method to detect the stratigraphic stratification of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1417914195

island, as shown in *Figure 11*. The results showed that the thickness of the blue region with low apparent resistivity was about 1~2 m. The thickness of the medium apparent resistivity area in *Figure 12* was about 2~5 m, that was, 5~7 m underground. It's green and yellow parts that were shown on the *Figure 12*. Moreover, the high apparent resistivity area below, combined with the actual survey data, should correspond to the underlying granite bedrock, and the orange and red parts were shown in *Figure 12*. The ground penetrating radar (GPR) was used to study the stratigraphic stratification results of the direct current method. The results were shown in *Figure 13*. According to the difference in the dielectric constant of the plastid, the thickness range of the surface layer is about 1~2 m, as shown in *Figure 13*.

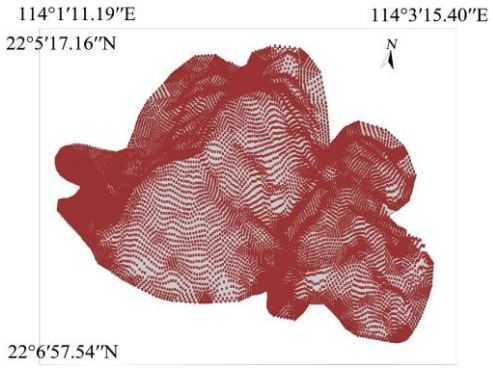

Figure 11. *A scatter diagram of D*

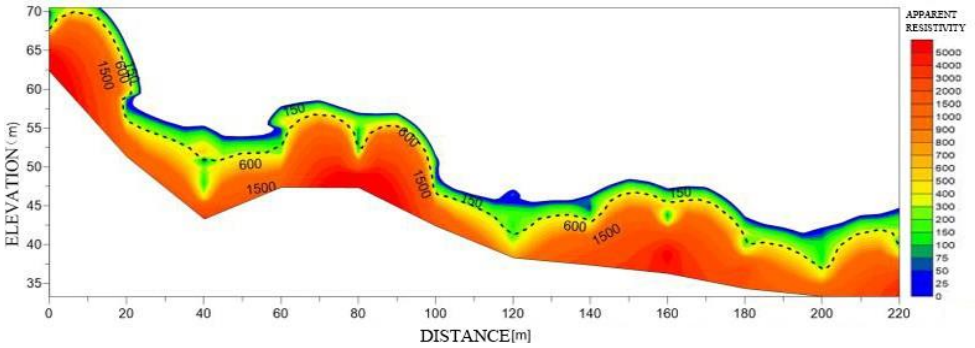

Figure 12. *The result of detection by DC method*

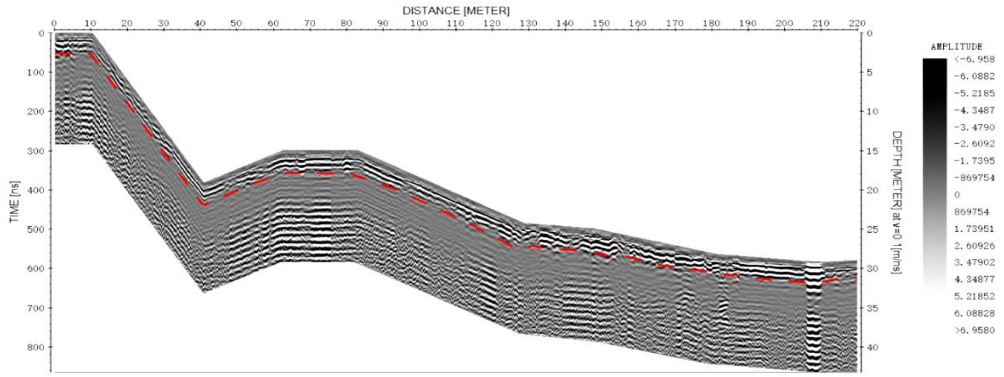

Figure 13. *The result of detection by GPR method*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1417914195

It is the completely weathering granite layer in the ground. Next, another 5-7 metre underground stratum can be clearly shown in the diagram, combined with the actual survey data, can correspond to partly weathering granite layer. Then, the part below 5~7 m underground is obviously different from the above stratum. Combined with the actual survey data, it can be corresponding to the bottom of the granite bedrock. Thus, the study can set the formation parameters according to the results of *Figure 5*, *Figure 12* and *Figure 13*. Then, the mesh was segmented, as shown in *Figure 14*. Next, the study used the MODFLOW program to calculate the flow field distribution in the study area.

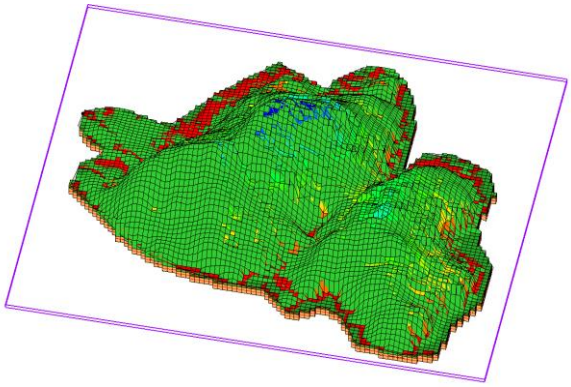

Figure 14. *Schematic diagram of mesh subdivision*

Results and Analysis

Simulation results of shallow groundwater flow field based on remote sense

The results of simulation by using GMS were shown the *Figure 15* and *Figure 16*. They showed that the level of groundwater in this island. The water level around the island was low.

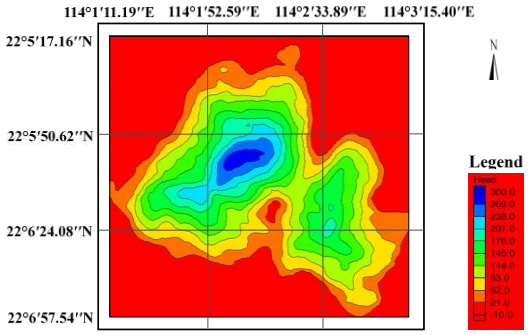

Figure 15. *Simulation results of island shallow groundwater by using GMS software*

High water levels in the middle and southeast of the island indicated a water-storage structure. And the study can see the shallow groundwater flow field that flows outward from the middle of the island, outward from the southeast, and surrounding flow towards the middle of the island. The lower water level in the south-central part of the island and combined with its analysis of water yield showed that the area was easy to fetch water.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1417914195

Figure 15 can clearly reflect the water level distribution of shallow groundwater. Moreover, *Figure 16* can clearly reflect the simulation results of the shallow groundwater flow field. From the perspective of water level, the water level of this island tends to be high in the middle and southeast and low in the periphery. *Figure 17* can reflect the water level distribution of the whole island in 3 dimensions. *Figure 16* can reflect the flow field trend of shallow groundwater of the island, which flowed from the middle to the outside, from the southeast to the outside, and from the surrounding to the inside of the island. The reason for the trend of the underground flow field to the island should be the existence of seawater. Four points, the first line, about 12 m in length, was located in the puddle above the road next to the first point coordinates: N22.096674°, E114.038623°, H33.2 m. The result is shown as *Figure 18*, which can show there should be bedrock fissure water storage in the underground 5~13 m range by analyzing the different apparent resistivity of this area. Also, spring water emerged about 10 m below this area, N22.097272°, E114.038793°, H21.4 m. It was shown as *Figure 19*.

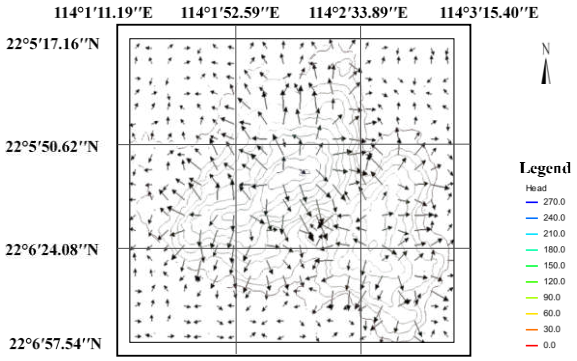

Figure 16. *Simulation results of island shallow groundwater flow*

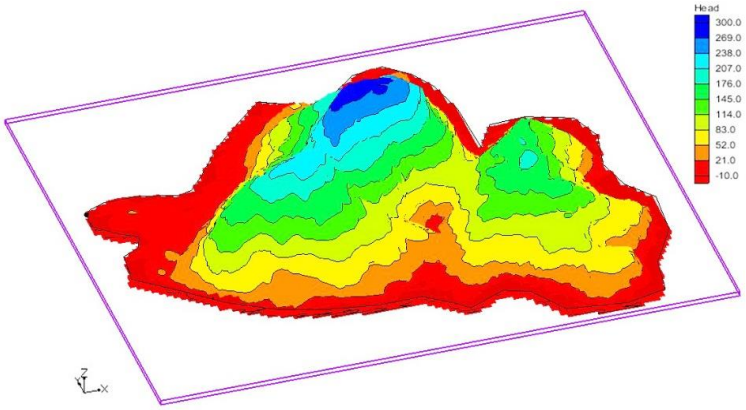

Figure 17. *3D results of simulation groundwater level of the island*

According to the data of springs and wells on the island, and the field survey and the evidence results of DC detection, the unit water level value of the corresponding point can be obtained, and the corresponding relationship between the simulated value and the actual value can be reflected in *Table 2*.

Correlation analysis of simulation data and the measured water level value

The study analyzed the results of simulation and D more carefully by using a correlation analysis chart between the D and D of simulation that was shown as *Figure 20*. And it was easy to see the two values were positively correlated.

The correlation between the simulated value and the actual water level of unit time and unit area D was positive and linear, and R^2=0.862 (P<0.05), as shown in *Figure 20*, indicating that the simulation results were consistent with the actual water level results and the error accuracy was also good. Therefore, the initial water level obtained based on remote sensing assessment of shallow groundwater was imported into GMS software, and corresponding hydrogeological parameters of islands were added. The model of flow field simulation can reflect the distribution of real shallow groundwater flow field within a certain precision range. Therefore, the difficulty of obtaining the initial water level of bedrock islands was solved based on an assessment of shallow groundwater by RS technology and groundwater simulation technology.

Discussion

This study used ENVI software to convert remote sensing satellite DEM data into TIF files and imported them into GMS software, which improved the accuracy of island geological body model. Using the DEM data to model the geological model of island was more accurate than the traditional method which based on use of some well data. And this paper combined high-precision remote sensing data with shallow groundwater simulation, which was an innovation in methods.

In addition, the score, S, of assessment groundwater potential was fitted to the depth, h, of the unit water level, which was used to obtain the initial water level, D, of shallow groundwater. Then, D was introduced into the GMS software. And using the meteorological and hydrogeological data, geological data and geophysical data of the study area, the simulation of shallow groundwater flow field was carried out, which solved well the difficulty of obtaining the initial water level of shallow groundwater in a small bedrock island and simulated well the shallow groundwater flow of a small bedrock island. Also, the results of the shallow groundwater simulation based on RS are correlated with the actual water level of wells or springs and the geophysical data.

Conclusions

This paper studied the related theories of groundwater in a bedrock island, which proposed to use remote sensing assessment technology of shallow groundwater to get the initial water level of groundwater in the bedrock island so that the study can simulate the flow of groundwater in this island. Finally, the following conclusions can be drawn:

(1) It was concluded that the form of fresh water on the bedrock islands is mainly in the form of "mushroom body", which is accompanied by the form of "lens body". If the groundwater flow field can be simulated, the movement equation of bedrock islands can be expressed as transverse isotropy (isotropy in horizontal direction), and the main recharge of island groundwater is rainfall.

(2) By combining remote sensing data with groundwater simulation, DEM data was transformed into TIF files by ENVI software, which was then introduced into GMS software, and the stratification of island strata determined by geophysical exploration technology combined with actual survey data improved the accuracy of geological body simulation.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1417914195

(3) The results of assessment shallow groundwater based on remote sensing was fitted with the water level of the area to get the initial water level. This method can solve the problem that the initial water level of the bedrock islands is difficult to obtain, and results the simulation flow groundwater of the island have good accuracy.

(Received 1st Jun 2019; accepted 2nd Sep 2019)

Abstract. In response to characteristics of the natural climate in extremely arid areas and the physiological characteristics of grapes in Shanshan County, China, and by relying on micro-spray atomizing regulation technology to change micro-climate environments in vineyards and using methods of contrastive analysis of test data and model calculation analysis, this paper studies changes in grape physiological ecology, photosynthetic characteristics, quality and yield under atomizing regulation action and proposes an optimal technical scheme for atomizing regulation: the atomizing regulation treatment can lower average temperatures by 1.6 °C during grape expansion periods, increase average humidity by 6.6%, and improve grape branch length, internode length, leaf number, leaf area, mid-rib length and oven-dry weight better than conventional drip irrigation (CK) treatment. Fitting calculation analysis of the photosynthetic rate, CO_2 concentration response curve, and light response curve through a mathematical model shows that the atomizing regulation treatment has less influence on photosynthetic characteristics of grapes but helps improve grape quality and provides higher yield than conventional drip irrigation (CK) treatment. Spray water for 1 h a day (WP2) treatment creates optimal quality and the highest yield, 24.0% higher than that of conventional drip irrigation (CK) treatment. All research data indicate that spray water for 1 h a day (WP2) treatment is an optimal technical scheme for atomizing regulation treatment of vineyards in extremely arid areas and creates strong benefits, including a high water resource utilization ratio, enhancement of micro-climates, obvious quality improvement, and yield increase effects.
Keywords: *vineyard, micro-spray atomization, micro-climate physiological ecology, photosynthesis, yield, quality*

Introduction

The Turpan-Hami and Rim-Tarim Basins in Xinjiang enjoy light, heat, water and soil conditions suitable for grape growing, with a wide variety of grapes and high grape quality, thus serving as the main sources of grapes in China (Liu et al., 2019). However, the region is characterized by sparse precipitation, strong evaporation, heavy sandstorms, high temperatures and hot weather during the summer, with the highest temperature in daylight at over 40 °C. Such extreme natural climate conditions heavily influence grape quality and yields. At present, traditional irrigation technology can only address basic water demands for grape growth but cannot fundamentally change climate factors that influence grape quality and yield. For this reason, this research proposes micro-spray

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1419714215

atomizing regulation technology for vineyards in extremely arid areas to address the issue of micro-climates using the following principle: keeping traditional modes of irrigation, arrange micro-spray heads at different positions in the grape trellis and control the length of spraying time and cycle for each water head, to form new artificial microclimates in the vineyard and research changes in physiological ecology, photosynthetic characteristics, and quality and yield of grapes under the effects of artificial microclimate-influencing factors.

Currently, more attention has been paid to micro-spray atomizing regulation technology by researchers, and some technical studies have been carried out both in China and abroad. For example, a study by Zhang et al. (2000) found that the conditions of active, accumulated temperatures ≥ 10 °C are highly related to grape characteristics during the mature period. Chen et al. (1996) has analyzed the agricultural, meteorological effect of mulberry field spray irrigation and drew the conclusion that micro-spray irrigation makes daylight average water vapor pressure increase by 1.33-1.73 hPa, makes humidity increase by 4-8%, and enhances moisture production efficiency by 10-49%. Liu et al. (2000) researched the influence of micro-spray on wheat field microclimates and found that micro-spray irrigation can influence canopy air temperature and humidity during irrigation and that there are phenomena of increasing inversion times, drops in temperature, and increases in humidity over the canopy. Bai et al. (2016a) researched the influence of micro-spray atomizing regulation irrigation technology on grape physiology and yield and found that this technology can produce high grape yields when the irrigation norm is 9,150 m^3/hm^2 and water is sprayed 1-2 h once a day at a spraying capacity of 105-120 m^3/hm^2 per spray. Koblet addressed the influence of light and temperature on vine performance in cool climates and its application to vineyard management in proceedings of an international symposium on cool climate vatic and enol (Koblet, 1986). Jackson examined aspects of light conditions in apple orchards (Jackson, 1970). Kohl et al. assessed the measurement of low pressure sprinkler poration (Kohl et al., 1987). Srinivas et al. (2000) carried out studies on grape growth and development, as well as moisture utilization efficiency, under different irrigation modes, such as drip irrigation and alternative root area irrigation. Studies by Hui et al. (2007) on main grape physiological indicators of water stress show that under water stress, grape leaf compositions of free proline and malondialdehyde increase with a rise in stress level. Under the influence of high-temperature stress, grape seedlings have a mechanism for quick heat resistance in a short period of time. Temperature has a clear influence on group photosynthesis of Kyoho grapes; high temperatures reduce the initial photochemistry efficiency, but increases maximize photosynthetic rates in Kyoho grapes under low CO_2 concentrations (Xie et al., 1998, 2007; Tang et al., 2006). However, studies on how climate factors in extremely arid areas influence grape physiological ecology, photosynthetic characteristics, quality and quantity are still insufficient. Some key problems remain unsolved, and field management still lacks effective technical support. Therefore, it is of great practical significance to promote comprehensive, harmonious and sustainable development of both society and the economy; research and propose a technical scheme of micro-spray atomizing regulation for grape growth; monitor various grape physiological, ecological indicators under different micro-climate conditions; analyze the relationship between different micro-climate environments and their influences on photosynthetic characteristics, quality, and yield of grapes in extremely arid areas; and explore an optimal technical scheme for atomizing regulation to improve moisture production efficiency, solve problems associated with grape quality improvement, and increase grape yields in extremely arid areas.

Study area

The study area is in the test base of Xinjiang Shanshan Grape, Fruit and Melon Development and Research Center, 42.91°N, 90.30°E, 419 m above sea level, a soil type of gravel sandy loam, an average annual rainfall of 25.3 mm, an average annual evaporation-pan evaporation of 2,751 mm, yearly sunshine time of 3,122.8 h, a higher-than-10 °C effective accumulated temperature more than 4,525 °C, and a frost-free period of up to 192 d, all features belonging to a typical, extremely arid climate. In the study area, the variety of seedless white grapes is ideal for relevant research. The vine was planted in 1981 in trenches along the east-west run, which is 54 m long, 1.0-1.2 m wide, and 0.5 m deep; the row spacing is approximately 1.2-1.5 m with a row pitch of 3.5 m; the cultivation mode is small-trellis cultivation, with the trellis front end at 1.5 m high and the rear end at 0.8 m high. The experiment was conducted from May 2016 to September 2016.

Data and research methodology

Atomization treatment design

The atomizing regulation test is designed with 7 treatments in total, each of which is arranged with 2 repeats. Each test block has an area of approximately 207 m^2. Micro-spray heads are arranged at 50 cm over the trellis (WP1), 50 cm under the trellis (WP2), and 30 cm above the ground (WP3). In addition, at 50 cm under the trellis, there are three additional treatments with different water spraying time lengths and cycles, namely, WP4, WP5 and WP6. Micro sprinkler working pressure 0.3 mpa (30 m water head), all treatments have a spray diameter of 200 cm, the sprinkler spacing is 200 cm, a flow of 40 L/h, It opens at 12:00 a.m. during the period of grape expansion (May 29, 2016 - July 4, 2016). CK treatment is a traditional treatment lacking micro-spray facilities. The irrigation norm is the total water consumption of grapes within a single mist-spraying growth cycle. The experiment scheme is shown in *Table 1*.

Table 1. *Micro-spray treatment design parameters*

Test treatment	Irrigation water volume (m^3)	Irrigation norm (m^3)	Mist spraying time length (h)	Mist spraying cycle (day)	Micro-spray arrangement mode	Micro-spray head parameters	
						Spray head flow (L/h)	Spray diameter (cm)
WP1	30	610	1	Every day	50 cm over the trellis	40	200
WP2	30	610	1	Every day	50 cm under the trellis		
WP3	30	610	1	Every day	30 cm above the ground		
WP4	60	1220	2	Every day	50 cm under the trellis

Data measurement

Photosynthetic data measurement

On July 1, 2016 (early stage of fruit development), three leaves were selected from each treated vine and vine. From 8:00 a.m. to 20:00 p.m., a portable photosynthetic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1419714215

system CIRAS-3 (PP SYSTEMS, USA) was used to measure photosynthetic data of selected leaves of sample trees every 2 h. A total of 7 groups of data were measured in one day. Mean values of photosynthetic data of three leaves were measured at the same time as photosynthetic data at that time.

Measurement of temperature and humidity under 2.2.2 rattan

Under each scaffold, a set of louvers were installed at 10, 20, 30, 40 and 50 cm above the surface, totaling 5 groups. Three groups of HC-2 automatic temperature and humidity recorders were built into each louver to monitor the air temperature and humidity under the scaffold, and the recording interval was 30 min.

Determination of yield and quality

Determination of grape quality: 20 clusters of ears were randomly selected from each treatment, 3 grains were randomly selected from the selected ears, and the content of soluble solids was determined by hand-held refractometer; the content of soluble sugar was determined by anthrone colorimetry; the total acid content was determined by NaOH titration. Tartaric acid, 2,6-dichloroindophenol titration for reducing Vc, sugar-acid ratio: soluble sugar content/total acid content.

During grape harvesting, all the ears in the same treatment were weighed and the total yield was calculated: the total fruit quality in this treatment/the area occupied by the treatment experimental field (hectare).

Determination of physiological indicators in vineyards

During the period of grape germination and leaf development, three sample trees with good growth were selected from each treatment, three branches were selected from each sample tree and marked. From May 6 to June 15, the branch growth was measured once every 7 days with a tape measure of 1 mm accuracy. The length of each node, the number of leaves per branch were recorded, and one branch was selected from the selected branches. A vernier caliper with an accuracy of 0.01 mm was used to measure and record the length of the marker veins. The formula for calculating the leaf area of grape branches is as follows: leaf area = 1.183*X0.456*N, where X is the midrib length of leaves and N is the number of leaves.

During the germination period, a fixed number of new branches of grapevine were selected and marked to avoid pruning of the marked branches. Starting from May 11, 2016, three branches were selected from each treatment every 10 days or so, and then cut from the new parts and put into the corresponding breathable paper bags, using the one set at 85 °C. The oven is baked for 24 h. After natural cooling, the electronic balance with accuracy of 0.1 g is weighed and recorded.

Mathematical model

This research adopts fitted values and actual, measured values of four mathematical models for contrastive analysis, namely, “rectangular hyperbola model (Society et al., 1935), non-rectangular hyperbola model (Thornley et al., 1976), exponential function model (Ye, 2010) and corrected rectangular hyperbola model (Liao et al., 2012)”, with Four kinds of mathematical models simulate the changes of photosynthetic characteristics of CK treatment in vineyard, and compare the simulated values with the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1419714215

measured values. The purpose is to screen out more suitable models for simulating the photosynthetic characteristics of the region from many different models. On this basis, the selected models are used to simulate the changes of photosynthetic characteristics under different conditions. It can reduce some repetitive tests and improve work efficiency.

CO2 response curve calculation method

Set effective light radiation intensity (PAR) at 1,200 μmol·m^{-2}·s^{-1} and set reference lab CO_2 concentrations at 50, 100, 150, 200, 400, 600, 800, 1000, 1200, 1400, 1600 and 1800 μmol/mol to carry out two repetitive determinations. The CO_2 response curve fitting equation is the same as the light response curve, and the rectangular hyperbola model is adopted for fitting, namely:

$$A = \frac{\alpha A_{\max} C_i}{\alpha C_i + A_{\max}} - R_p \quad \text{(Eq.1)}$$

where α is the initial carboxylation efficiency, C_i is the intercellular CO_2 concentration, and R_p is the light respiration rate.

The fitting formula of the CO_2 concentration saturation point (CSP) and CO_2 concentration compensation point (CCP) is:

$$A = aC_i - R_p (C_i \leq 200\ umol \cdot mol/mol) \quad \text{(Eq.2)}$$

where, when $A = 0$, C_i is the CO_2 concentration compensation point (CCP); when $A = A_{\max}$, C_i is the CO_2 concentration saturation point (CSP); and the initial carboxylation efficiency (α) is expressed as the slope at the initial, straight-line section when CO_2 concentration is under 200 μmol/mol in the CO_2 response curve.

Light response curve calculation method

Set the temperature at (25 ± 1) °C and the relative air humidity (RH) at 60-70%; use the Model CIRAS-3 portable photosynthesis meter to determine the light response curve and CO_2 response curve by controlling light and CO_2 concentrations. In determining the light response curve, diurnal variation of photosynthesis was selected for the measured leaves. the CO_2 concentration is set at 400 μmol/mol, and the intensity of illumination is set at 0, 50, 100, 150, 200, 300, 400, 600, 800, 1000, 1200, 1400, 1600, 1800 and 2000 μmol·m^{-2}·s^{-1}.

Results

Influence of atomizing regulation technology on vineyard microclimate changes

Temperature change under the trellis

(1) Monthly temperature change: The monthly average temperature is obtained from the daily temperature of the same month. The temperature of micro-spraying treatment is the average temperature of all micro-spraying treatments. The control treatment is the monthly average temperature of CK treatment. As shown in *Figure 1,* during the grape

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1419714215

expansion period (June - Aug.), atomizing regulation technology can significantly lower the temperature under the vineyard trellis and improve vineyard microclimates compared with CK treatment, with drops in temperature of 1.5, 1.7 and 1.5 °C in June, July and August, respectively, an average drop in temperature of 1.6 °C, and a drop range of 5.6%.

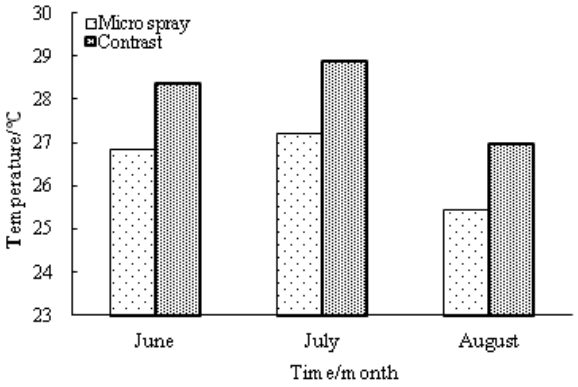

Figure 1. *Monthly temperature change*

(2) Daily temperature change: Daily temperature is obtained from every 30 min recorded by air thermometer and hygrometer during the period of micro-spraying during fruit swelling. As shown in *Table 2,* atomizing regulation treatment produces a daily highest temperature and daily lowest temperature 1.4 °C and 0.4 °C lower than those of CK treatment, respectively, during the grape expansion period. WP1, WP2, WP3, WP4, WP5, WP6, and WP7 daily average temperatures are 27.4, 27.6, 27.3, 27.6, 27.2, 27.4, and 27.4 °C respectively, which, on average, are 0.9 °C lower than the CK treatment average of 28.3 °C.

Table 2. *Temperature change*

Treatment	Temperature (°C)	
	Max value	Min value
WP1	33.1	21.6
WP2	33.7	21.5
WP3	33.0	21.6
WP4	33.3	21.8
WP5	32.7	21.8
WP6	33.1	21.7
WP7	33.2	21.6
CK	34.6	22.0

Humidity change under the trellis

(1) Monthly humidity change: The monthly average humidity is obtained from the daily humidity of that month. The humidity of micro-spraying treatment is the average humidity of all micro-spraying treatments. The control treatment is the monthly average

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1419714215

humidity of CK treatment. As shown in *Figure 2,* atomizing regulation treatment produces humidity increases by 5, 7.4 and 7.3% in June, July and August, respectively, with an average humidity increase of 6.6% and a range of increase of 13.8%.

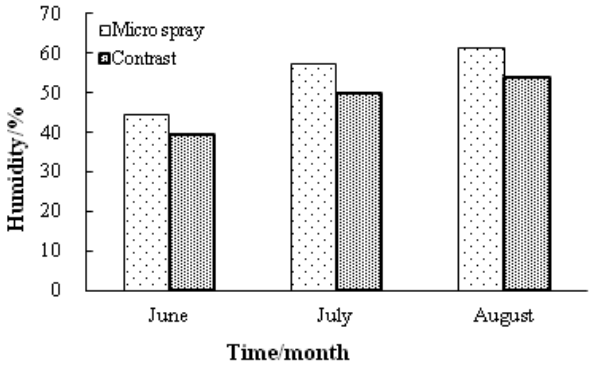

Figure 2. *Monthly humidity change*

(2) Daily humidity change: Daily humidity is the value of humidity every 30 min recorded by air thermometer and hygrometer during fruit expanding period. As shown in *Table 3,* atomizing regulation treatment produces a daily highest humidity and daily lowest humidity 3.0% and 1.0% higher than those of CK treatment, respectively, in June – August. Average daily humidity levels of WP1, WP2, WP3, WP4, WP5, WP6, and WP7 are 57.0, 60.4, 59.6, 57.4, 58.0, 58.3, and 59.6%, respectively, which, on average, are 15.9% higher than the CK treatment average of 56.6 °C.

Table 3. *Daily humidity change*

Treatment	Humidity (%)	
	Max. value	Min. value
WP1	84.9	29.1
WP2	91.5	29.3
WP3	89.7	29.5
WP4	85.0	29.8
WP5	86.3	29.8
WP6	86.2	30.5
WP7	88.3	30.9
CK	84.4	28.9

Influence of atomizing regulation treatment on changes in grape physiological ecology

Change in vine branch length

Length of vine branch under various atomization treatments is shown in *Figure 3,* which shows that the vine branch length continued to increase from May 6 to June 15 and that by Sept. 1, the grape harvesting time, the average vine branch lengths under WP1, WP2, WP3, WP4, WP5, WP6, WP7 and CK treatments were 58.3, 79.7, 79.7, 58.9, 55.5, 60.3, 79.8 and 58.0 cm, respectively.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1419714215

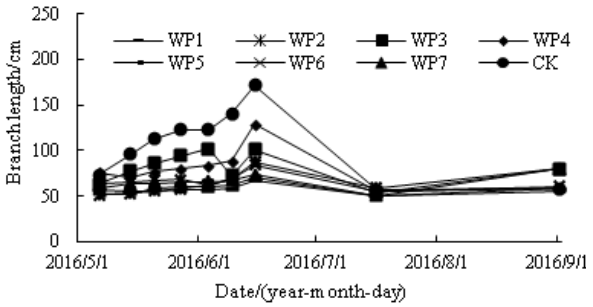

Figure 3. *Change in branch length*

Change in vine internode length

Changes in vine internode length under atomization treatment are shown in *Figure 4,* which shows that vine internode length continued to increase from May 6 to June 15 and that by Sept. 1, the average internode lengths under WP1, WP2, WP3, WP4, WP5, WP6, WP7 and CK treatments were 5.4, 5.4, 5.3, 4.8, 5.0, 5.4, 5.7 and 5.4 cm, respectively.

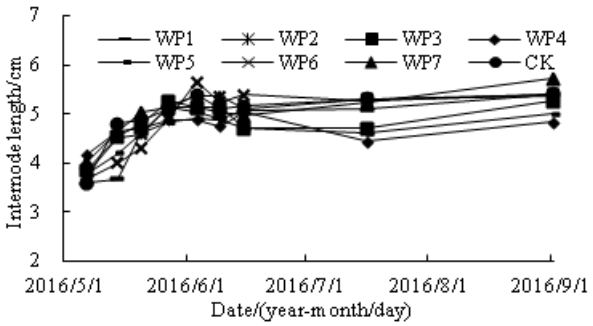

Figure 4. *Change in internode length*

Change in vine leaves

Changes in the number of vine leaves under the atomization treatment are shown in *Figure 5,* which shows that from May 6 to June 15, the number of grape leaves continued to increase and that by Sept. 1, the numbers of leaves under WP1, WP2, WP3, WP4, WP5, WP6, WP7 and CK treatments were 11.0, 15.3, 9.7, 9.5, 8.5, 12.5, 14.0 and 9.5 leaves, respectively.

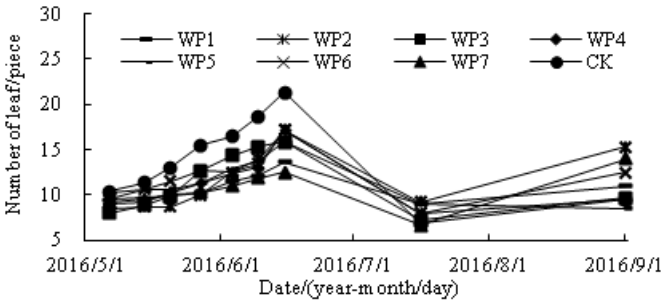

Figure 5. *Change in the number of leaves*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1419714215

Change in the length of vine leaf mid-rib

Changes in the length of vine leaf mid-ribs under atomization treatment are shown in *Figure 6,* which shows that from May 6 to May 14, vine leaf mid-ribs grew faster; from May 14 to May 27, vine leaf mid-ribs grew slowly; starting in June, leaves grew rapidly with widely varying changes under different treatments; and by Sept. 1, leaf mid-ribs under various treatments grew relatively slowly and with little variation in growth rates. By Sept. 1, the average lengths of leaf mid-ribs under WP1, WP2, WP3, WP4, WP5, WP6, WP7 and CK treatments were 12.6, 12.8, 13.2, 12.7, 11.7, 12.9, 12.5 and 12.3 cm, respectively.

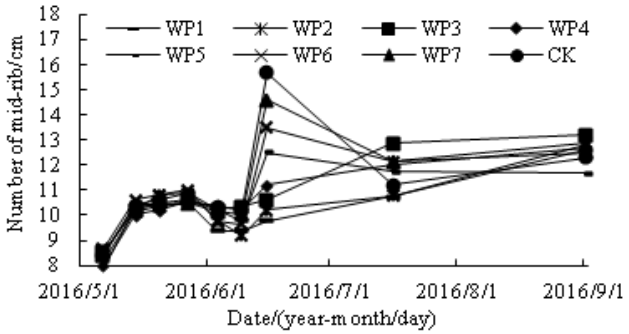

Figure 6. *Change in the length of leaf mid-rib*

Change in vine branch leaf area

Changes in vine branch leaf area under atomization treatment are shown in *Figure 7.* The formula for calculating vine branch leaf area is: leaf area = $1.183 \times X^{0.456} \times N$, where X is the leaf mid-rib length and N is the number of leaves. By Sept. 1, the average leaf areas under WP1, WP2, WP3, WP4, WP5, WP6, WP7 and CK treatments were 41.1, 58.0, 37.1, 35.8, 30.8, 47.5, 52.4 and 32.3 cm^2, respectively.

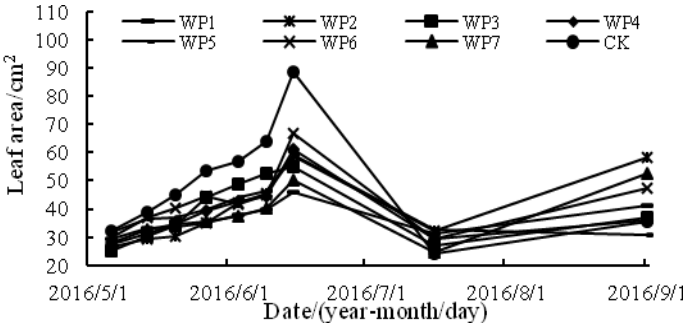

Figure 7. *Change in leaf area*

Changes in the oven-dry weights of new vine branches

Oven-dry weights of new vine branches are shown in *Figure 8*. From the date of initial monitoring, all new vine branches present consistent changes in growth. By Aug. 1, the average oven-dry weights of new branches under WP1, WP2, WP3, WP4, WP5, WP6, WP7 and CK treatments were 17.0, 17.0, 18.5, 17.0, 17.8, 15.8, 17.2 and 15.3 g, respectively.

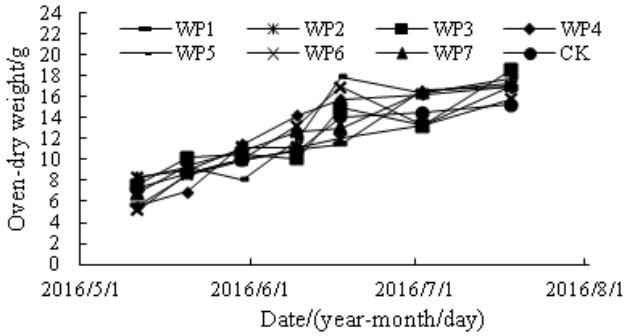

Figure 8. *Change in oven-dry weight*

Influence of atomizing regulation treatment on changes to grape photosynthesis

Change in vine leaf photosynthetic rate

The process of daily changes in vine leaf photosynthetic rate under atomization treatment is shown in *Figure 9,* which shows a consistent law of daily change in photosynthetic rate. Starting at 8:00 am, with a stronger solar radiation intensity and a rising temperature, air holes gradually open, and photosynthetic rates gradually increase until reaching a maximum daily value at 10:00 am. Later in the day, when temperatures continue rising toward the peak daily value, air holes gradually close until they shut off, and photosynthetic rates rapidly drop toward the minimum. At 4:00 pm, when the temperature gradually drops, leaf air holes start to open again, and photosynthetic rates increase once again to reach the second peak daily value. Later in the day, with poorer solar radiation and lower temperatures, photosynthetic rates decrease once again. The law of change under all treatments is consistent, but photosynthetic rates alternate at different time nodes. The average photosynthetic rates under WP1, WP2, WP3, WP4, WP5, WP6, WP7 and CK treatments reach their peak value at 10:00 am, namely, 6.2, 7.2, 7.0, 8.9, 9.2, 6.6, 6.4 and 7.2 μmol m^2s^{-1}, respectively, and the average daily photosynthetic rates of the treatments are 5.4, 6.2, 5.7, 6.4, 6.0, 5.5, 5.6, and 6.1 μmol m^2s^{-1}, respectively.

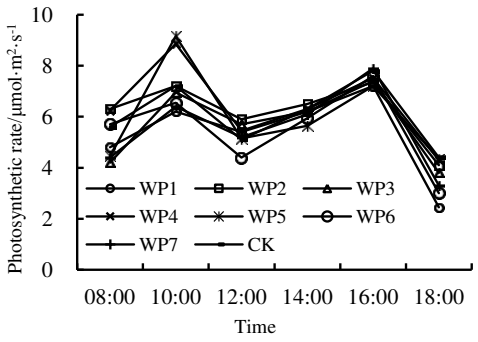

Figure 9. *Daily change of leaf's net photosynthetic rate*

Change in vine leaf transpiration rate

Daily changes in leaf transpiration rate under atomization treatment are shown in *Figure 10,* which demonstrates adherence to the distinctive law of transpiration rate,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1419714215

namely, reaching the peak value at approximately 4:00 pm and exhibits a high-low order of WP4 > WP5 > WP3 > WP6 > CK > WP7 > WP2 > WP1.

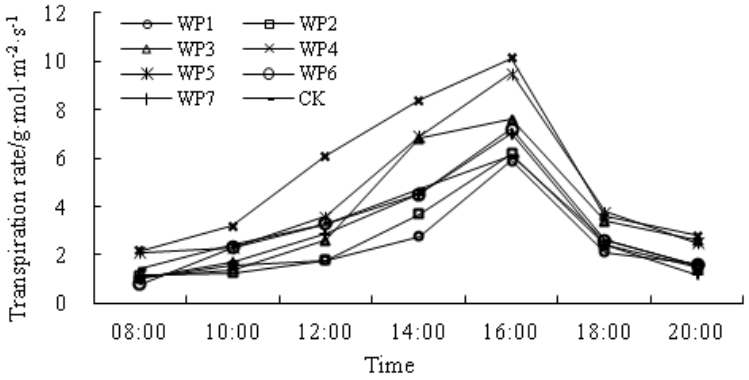

Figure 10. *Daily change in leaf transpiration rate*

Change in vine leaf air hole conductivity

Daily changes in leaf air holes under atomization treatment are shown in *Figure 11,* and basic relationships between air hole conductivity are P2 > WP4 > WP3 > WP7 > CK > WP5 > WP1 > WP6. Starting from 8:00 am, vine leaf air hole conductivity continues to increase until reaching the peak value at approximately 12:00 pm as solar radiation intensity becomes stronger and the temperature rises. After that, the conductivity curve of vine leaf air holes continuously drops.

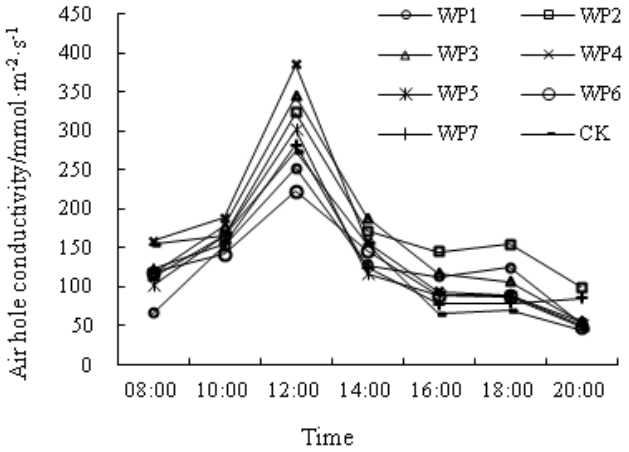

Figure 11. *Daily change of leaf air hole conductivity*

Influence of atomizing regulation technology on changes in grape photosynthesis characteristics

Response of grape photosynthetic rate to CO_2 concentration

The curve representing grape response to low CO_2 concentrations is shown in *Figure 12*. When CO_2 concentrations are under 200 μmol·mol^{-1}, the linear equation fits very well, and the coefficient of determination (R^2) is 0.9773.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1419714215

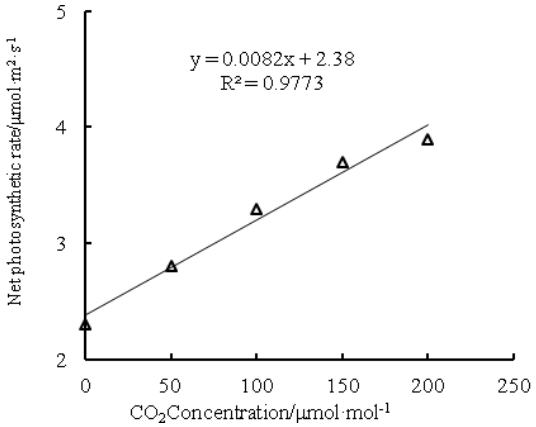

Figure 12. *Curve of response to low CO_2 concentrations*

The curve representing grape response to high CO_2 concentrations is shown in *Figure 13,* which indicates that before CO_2 concentrations reach 800 μmol·mol^{-1}, photosynthetic rates increase rapidly; after 800 μmol/mol, photosynthetic rates increase slowly.

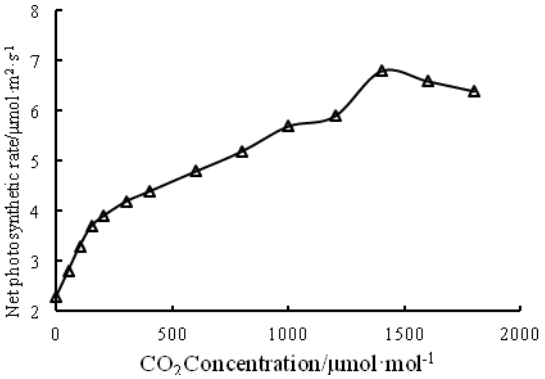

Figure 13. *Curve of response to high CO_2 concentrations*

Using the rectangular hyperbola to fit the curve representing grape response to CO_2, we calculate the maximum net photosynthetic rate, the CO_2 concentration compensation point and the CO_2 concentration saturation point, which are 5.935 μmol·mol^{-1}, 351.67 μmol·mol^{-1} and 1175.97 μmol·mol^{-1}, respectively. The coefficient of determination is 0.967, as shown in *Table 4*.

Table 4. *Characteristics of grape CO_2 response curve*

Characteristic parameters of light response	Fitting value
Max. photosynthetic rate (A_{max})/μmol•m^2•s^{-1}	5.935
CO_2 saturation point (CSP)/μmol·mol^{-1}	1175.97
CO_2 compensation point (CCP)/μmol·mol^{-1}	351.67
Light respiration rate (R_p)/μmol•m^2•s^{-1}	2.532
Carboxylation efficiency (a)	0.0072
R^2	0.967

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1419714215

Response of grape photosynthesis to light intensity

The curve representing grape photosynthetic response to low light intensity is shown in *Figure 14,* which indicates that when photosynthetic-effective radiation is under 200 μmol·m^{-2}·s^{-1}, the linear equation fits very well, and the coefficient of determination (R^2) is 0.9537.

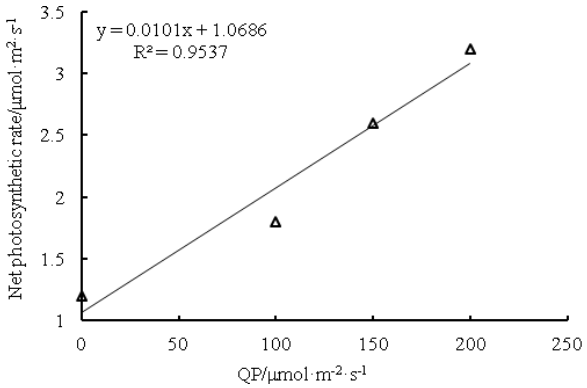

Figure 14. *Curve of photosynthetic response to low light intensity*

The curve representing grape photosynthetic response to high light intensity is shown in *Figure 15,* which indicates that when light intensity is 0-600 μmol·m^{-2}·s^{-1}, net photosynthetic rates rise rapidly, increasing with an increase in intensity of illumination. When the intensity of illumination is 600-1500 μmol·m^{-2}·s^{-1}, the rise in net photosynthetic rate is low. When the intensity of illumination is 1500-2000 μmol·m^{-2}·s^{-1}, net photosynthetic rates decrease with an increase in intensity of illumination, demonstrating the light inhibition phenomenon during which the light energy received by a plant leaf exceeds the light quantity that the leaf can utilize. Long time exposure to strong light can lower leaf photosynthetic activity.

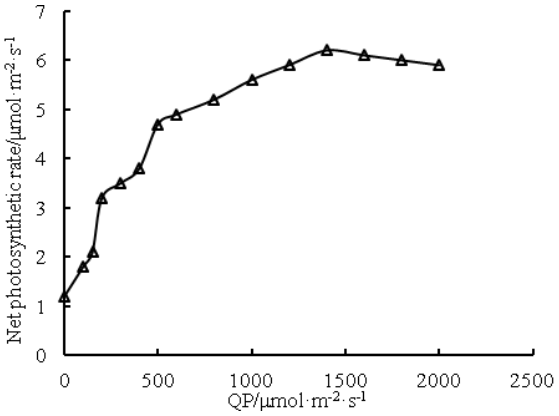

Figure 15. *Light intensity response curve*

Contrastive analysis of fitted values of grape light response curve models

The fitted values of the rectangular hyperbola model, as shown in *Table 5*, show the largest difference from actual measured values, and the net photosynthetic rates of the

other three models are similar under effective photosynthetic radiation. The fitted values of the corrected rectangular hyperbola model are closest to the actual measured values.

Table 5. *Actual measured value and fitted value of light response curve*

2000	5.9	6.32	6.11	6.13	5.92

Photosynthetic parameters of the grape light response curve through the fitting of four models are shown in *Table 6*. The fitted values of the four light response models are highly correlated with the grape light response curve, of which the non-rectangular hyperbola model and the corrected rectangular hyperbola model have the highest coefficients of determination at 0.988 and 0.989, respectively. In the rectangular hyperbola model and the non-rectangular hyperbola model, due to their non-convergence, the light saturation points cannot be obtained but can only be estimated through the linear regression equation under an effective photosynthetic radiation of 200 μmol·m^{-2}·s^{-1} and a maximum net photosynthetic rate (A_{max}). The light saturation points gained in the two models are 544.380 μmol·m^{-2}·s^{-1} and 501.100 μmol·m^{-2}·s^{-1}, respectively, showing a large difference from the actual measured value of 1400 μmol·m^{-2}·s^{-1}. The exponential function model cannot be obtained because the photosynthetic rate is assumed to be 0.9 A_{max}, and the light intensity to which it responds is the saturated light intensity, but the fitted value of 696.80 μmol·m^{-2}·s^{-1} is far lower than the actual measured value; it is assumed that the light intensity to which the photosynthetic rate responds is 0.99 A_{max}. The corrected rectangular hyperbola model can simulate gaining of the light saturation point, with a value of 1557.20 μmol·m^{-2}·s^{-1}, better dealing with the problem of decrease of grape photosynthetic rate in the section of high light intensity, which is closest to the actual measured value. The four models have light compensation points, which is the apparent quantum efficiency and dark respiration rate's simulation value free from significant difference, and the exponential function model's fitted value is closer to the actual measured value; at the highest

DOI: http://dx.doi.org/10.15666/aeer/1706_1419714215

photosynthetic rate, the corrected rectangular hyperbola model's fitted value is 6.072 μmol·m^{-2}·s^{-1}, which is closest to the actual-measured value of 6.1 μmol·m^{-2}·s^{-1}.

Table 6. *Photosynthetic parameters of grape light response curve*

Characteristic parameters of light response	Rectangular hyperbola	Non-rectangular hyperbola	Exponential function	Corrected rectangular hyperbola	Actual measured value

Influence of atomizing regulation technology on changes in grape quality and yield

Grape quality change

Grape quality indicators are shown in *Table 7*. CK treatment features a total acid content higher than that under all atomization treatments, but the soluble solid content, soluble sugar content, Vc content and sugar acid ratio are all lower than those under the atomization treatments, showing that atomizing regulation technology can effectively improve grape quality.

Table 7. *Contrast of grape quality indicators under different treatments*

Treatment	Soluble solid content (%)	Soluble sugar content (%)	Total acid content (%)	Reduction Vc content (mg/100 g)	Sugar acid ratio (%)
WP1	23.80	21.20	0.45	6.43	52.89
WP2	24.20	22.30	0.45	6.43	53.78
WP3	23.00	21.00	0.45	4.29	51.11
WP4	23.60	21.40	0.41	5.71	57.21
WP5	22.10	20.00	0.49	2.89	45.33
WP6	20.20	18.10	0.45	3.86	44.89
WP7	21.00	19.20	0.45	3.57	46.67
WP8	19.80	17.50	0.49	2.86	40.62
CK	19.50	16.50	0.49	2.88	39.63

Yield change

Grape yields under atomization treatment are shown in *Figure 16,* and the average yields under WP1, WP2, WP3, WP4, WP5, WP6, WP7 and CK treatments are 2,829.0, 3,432.7, 2,283.0, 2,155.5, 2,880.8, 2,195.8, 3,303.9 and 2767.5 kg/hm^2, respectively.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1419714215

Compared with that of CK treatment, yields of the atomization treatments are greater by up to 24.0%, indicating that the atomizing regulation technology plays a clear role in promoting higher yield.

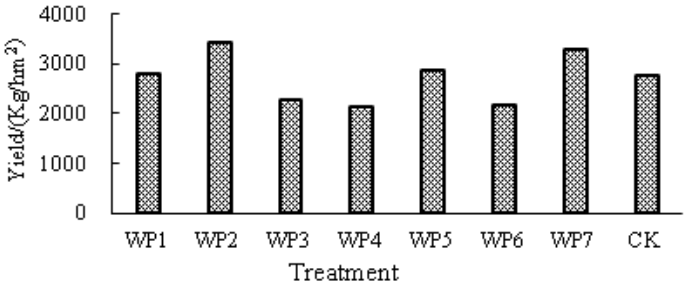

Figure 16. *Yield contrast*

Discussion

This study found that sprinkler treatment had lower temperature and higher humidity than control treatment, which was consistent with the results of Hong, et al. (2016). WP5 treatment should have the shortest spraying period and the longest spraying time, the highest air humidity, but the lowest air humidity. This is because the spraying time of WP5 treatment is longer and its physiological development is relatively inhibited, resulting in shorter branch length, shorter internode length, shorter leaf vein length and relatively fewer branches and leaves. The total leaf area of the branches was smaller and the canopy was sparse compared with other treatments, which increased the air exchange between the air and the atmosphere in the canopy, and eventually resulted in the lowest humidity.

The study also found that the net photosynthetic rate of all treatments in the field decreased at 12:00, that is, the phenomenon of "noon break" of crops, which is consistent with the conclusions of Sun et al. (2017), Wang et al. (2015), but the noon break time is earlier than other studies, the reason may be that the temperature in the experimental area is higher than that in other areas. Comparing the fitting models of photosynthetic response curves of different grapes, the fitting values of the right hyperbola model and the measured values have the greatest error, and the fitting values of the modified right hyperbola model are the closest to the measured values. The net photosynthetic rate decreased with the increase of illumination intensity when the illumination intensity ranged from 1500 to 2000 micromol m^{-2} s^{-1}, which showed the phenomenon of photoinhibition, which was consistent with the results of Bai et al. (2016b).

This study also found that micro-spraying could effectively reduce air temperature and increase humidity in vineyards. The results showed that suitable sprinkler irrigation (WP1, WP2, WP5 and WP7) could improve physiological indexes, photosynthetic characteristics, yield and quality of grapes. Excessive sprinkler irrigation (WP3, WP4 and WP6) could also easily lead to grape yield. Quantity and quality declined. Considering that WP2 treatment is the best treatment among many treatments, but this experiment can only qualitatively screen the best treatment. It is not known how long the spray time (or the amount of spray water) can correspondingly reduce the daily temperature and increase the humidity for grape trees to reach the maximum production capacity under the conditions of temperature and humidity. The numerical value is not clear, so the gradient of sprinkler duration can be set more intensively in future

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1419714215

experiments. The sprinkler duration is based on the reference crop evapotranspiration on the same day, and is compared with the difference of temperature and humidity in the control group. The yield and quality of each treatment are observed, and the sprinkler duration, temperature and humidity and yield products are discussed. The relationship between quality and yield is to find out the optimal micro-spraying time for maximum yield and quality of grapes.

Conclusions

Field test research during a growth cycle of grapes under different atomizing regulation treatments indicates that atomizing regulation technology leads to various influences on temperature, humidity, physiological ecology, photosynthetic characteristics, and product quality and quantity. The main conclusions are as follows:

(1) Atomizing regulation technology changes vineyard micro-climates. Research data show that atomizing regulation treatment can lower temperatures by an average of 1.6 °C during the entire grape expansion period, with a range in temperature drops of up to 5.6%. Average humidity can increase by 6.6%, with the increase range at up to 13.8%, of which WP2 treatment presents the widest range of change. This is very favorable for grape growth and development.

(2) Atomizing regulation technology changes the physiological ecology of grape plants. In terms of branch length, internode length, leaf number and leaf area under all atomization treatments, WP2 and WP7 treatments are most favorable; in terms of mid-rib length, WP3 and WP6 treatments are most favorable; and in terms of oven-dry weight, WP3 and WP5 treatments are most favorable. All indicators were better than those of CK treatment, demonstrating that regulation technology plays an active role in the physiological ecology of grape plants. In terms of the comprehensive indicator, WP2 treatment presents optimal results.

(3) Atomizing regulation technology slightly influences the photosynthetic characteristics of grapes. Through contrastive analysis of the photosynthetic rate monitoring data, transpiration rates and leaf air hole conductivities of grape plants under various treatments, and fitted calculation analysis of photosynthetic rates, CO_2 concentration response curves and light response curves with the “rectangular hyperbola model, non-rectangular hyperbola model, exponential function model and corrected rectangular hyperbola model”, it is found that atomizing regulation technology has less influence on the abovementioned items.

(4) Atomizing regulation technology influences grape quality and yield. According to contrastive analysis of grape indicators under various treatments, such as soluble solid content, soluble sugar content, Vc content and sugar acid, those under the atomization treatment are all higher than those under CK treatment. Grapes under WP2 treatment showed optimal quality, indicating that atomizing regulation technology effectively improves grape quality. The atomization treatment that produces the highest yield is WP2 treatment, with a yield of up to 3,432.7 kg/hm^2, 24.0% higher than that from CK treatment.

To summarize the abovementioned research conclusions, WP2 treatment is the optimal technical scheme for atomizing regulation treatment of grapes in extremely arid environments, namely, by erecting micro-spray equipment at 50 cm under the trellis, with a water spraying diameter of 200 cm and a spraying cycle of 1 h/day. In addition, WP2 treatment also shows significant benefits, including water resource conservation,

DOI: http://dx.doi.org/10.15666/aeer/1706_1419714215

creation of a more suitable micro-climate for grape growth, improvements to grape quality and significant yield increase effects.

(Received 1st Jun 2019; accepted 2nd Sep 2019)

Abstract. In order to strengthen the advantages of resin matrix composites such as light weight, high strength, fatigue resistance, corrosion resistance and electrical insulation, glass fiber shows great application potential in the field of Marine engineering. Composite profiles were prepared by pull-extrusion process, and the retention rate of mechanical properties was higher after 1000 h test in the neutral salt spray test chamber. The extruded composite profile was used as the frame of the solar module for the Marine environmental test. After a long time of marine environmental testing, the appearance of the component had no obvious defects. The strength retention rate of the composite profile was high, and the maximum power attenuation of the component was less than 5%. The results show that the composite profile can be used as a solar panel frame in marine environment.
Keywords: *vinyl ester resin, resin matrix composites, glass fiber, ocean, solar energy*

Introduction

With the development of science and technology, single material properties cannot meet the needs of production and social development. It has become a trend to combine things with different properties and exert the excellent comprehensive properties of materials by compound effect, and to make such materials become the mainstream of the material industry (Zhang et al., 2017). Composites have emerged at the right moment, and the most widely used composites are glass fiber reinforced resin matrix composites, namely glass fiber reinforced plastics (Huang et al., 2018). Glass fiber reinforced resin matrix composite has the advantages of light weight, high strength, fatigue resistance, corrosion resistance and electrical insulation, etc. Pultrusion preparation process is an important method for the preparation of high performance, high fiber content, fast and low-cost composite profiles (Chen et al., 2017). Marine environmental factors must be considered when pultrusion profiles are used in Marine engineering.

Composite material is a new type of structural material, because of its light weight, high strength, corrosion resistance and other characteristics, and has excellent performance in the long-term use in marine environment. Therefore, composite materials have greater application in ocean engineering, in the mid-1940s, the United States used composites in shipbuilding for the first time, composite materials in our country were first used of military purposes, and then gradually extended to the civilian life, although after rapid development, but the marine environment application still needs more development. Nowadays, the application of composite materials in the marine environment is mainly used in the construction of ships and the production of supporting products, including fishing boats, yachts and lifeboats. At the same time, glass fiber reinforced composite material is used as seawater pipeline, fire and waterproof pipeline in offshore oil and gas development.

The marine environment is complex, mainly including Marine hydrological environment, overhead meteorological conditions, geological environment and other

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1421714229

environmental factors, which have many influencing factors on the material. In order to apply composite materials more efficiently in the marine environment, research on the performance change of composite materials in the marine environment is a hot topic at present. The main factors of corrosion of materials in marine environment include salt content, temperature, sunshine and pH value. The study of the weather resistance of composite materials mainly refers to the assessment and evaluation of the weather resistance of composite materials by placing them in the outdoor natural environment and making them subject to the comprehensive effect of various factors.

Solar composite material is a new kind of material which is made by using advanced material preparation technology to optimize the composition of materials with different properties. Due to its many advantages, the application of solar composite materials in the Marine environment is increasingly valued. The Marine environment is extremely complex, and multi-traditional metal materials such as air humidity, high salinity and corrosive substances adhesion are a great challenge. Therefore, solar composite materials are of great significance in the application field of Marine engineering. Solar composites in the field of ocean engineering application is of great significance. However, due to the limitations of science and technology and materials, more research efforts are needed. Nachtane et al. (2018) explored and analyzed the properties of glass fiber reinforced composites applied to steel structures. Sutherland et al. (2018) summarized the application of composite riser pipe, coil-able composite pipe, composite mooring cable, underwater weapon shell, propeller and other components, and looked forward to the main technical development direction of composite materials for offshore drilling platforms in the future. Javier et al. (2017) summarized the research progress on accelerated aging of yacht fiber reinforced composites in Marine environment, and analyzed the influence of solar ultraviolet light, thermal oxygen, salt spray, seawater and other factors on their corrosion aging mechanism, material properties and variation rules.

In this paper, based on the research and experiment on the profile of solar composite material, a new material was developed for better marine operation and to provide technical support for the construction of marine engineering.

Experimental materials and methods

Experimental materials and equipment

The grades, models and manufacturers of raw materials required in the experiment are shown in *Table 1*, and the experimental equipment is shown in *Table 2*.

Sample preparation

A certain amount of vinyl vinegar resin liquid (0.5g) should be weighed into a mixing vessel, then according to the proportion of the corresponding mass (according to 1:100 mass ratio) of the additive should be added to the resin, which should be stirred to mix well with a glass rod.Then it should be let stand for deaeration, then mixing liquid should be added into the mould, after curing under 100 °C and a half hours, the samples are bagged for use. Fiberglass reinforced vinyl cool resin composite was prepared by pull-extrusion process. The resin, initiator and flame retardant were mixed according to the weight ratio of 100:1.3 ~1.5:15. The mixture was evenly stirred and injected into the soaking tank. Considering that the composite material surface needs to be protected in practical application, after processing the sample, the surface part of the sample was

Vinyl composite profiles pultrusion speed is 0.1 m/min commonly, it is 0.2 m/min, pultrusion speed when the production efficiency is higher, but too fast pultrusion speed is easy to make the product out of the mold has not fully solidified,in order to guarantee the quality of the products, this study used the pultrusion speed of 0.1 m/min, the traction of 50 kn, and three temperature ranges: 100 ~ 110 °C, 120 ~ 130 °C, 130 ~ 140 °C. In the actual production process, only by adjusting the temperature of the three zones according to the technological conditions a composite with excellent extruded profile properties can be prepared. The pultrusion profile was prepared and then the material was cut into the required size according to the size of the solar module.

Mechanical performance test

Tensile performance test was performed according to GB/T 3354-1999 “test method for tensile properties of oriented fiber reinforced plastics”. GFRP (Glass Fiber Reinforced Polymer) profile tensile performance test sample size was 230 mm × 15 mm × 2mm, the test was carried out on universal testing machine (Zhao et al., 2018). As the material is easy to be destroyed in the clamping position during the tensile process, aluminum alloy reinforcing sheets should be pasted at both ends of the tensile sample, with the thickness of the reinforcing sheets being 1.5 mm. The adhesive agent used to bond the reinforcing sheets is a mixture of 618 resin and polyphthalein, so as to ensure that the reinforcing sheets do not fall off during the test (Jiao et al., 2018). Tensile properties were tested at room temperature with a loading speed of 2 mm/min (*Fig. 1*).

Figure 1. *Tensile test*

The bending performance test was carried out on the same universal test machine. The bending sample size was 100 mm × 15 mm × 4 mm, and the three-point bending mode is adopted for testing. The loading head radius was R = 5 mm 0.2 mrn, the bearing fillet radius was R = 2 mm 0.2 mrn, and the loading speed was 2 mm/min. The experimental results show that its tensile and bending properties are good and not easily damaged (*Fig. 2*).

Figure 2. *Bending test*

Corrosion resistance test

According to the provisions of GB/T 10125-2012 "salt fog test for corrosion test of artificial atmosphere", the test of GFRP profile's resistance to neutral salt fog corrosion was conducted in the neutral salt fog test box. See *Figure 3* for the test box. In the neutral salt spray test, the FRP composites were divided into two groups. One group was sprayed with fluorine polyurethane semi-gloss enamel, while the other group was not treated. The two groups were processed according to the tensile sample size and the bending sample size, and tested in the neutral salt spray test chamber (Vimalathithan et al., 2018). Neutral salt spray test for 1000 h was divided into 7 sections in time regarding sampling observations, sampling time were 24 h, 48 h, 72 h, 168 h, 336 h, 672 h, and 1000 h from the test start time, take 3 samples for performance test at each age, including appearance evaluation, the weight test, the tensile strength test, the bending strength test and calculate its strength retention (Lopresto et al., 2018).

Figure 3. *Neutral salt spray test box*

After the test, to reduce the sample on the adhesive and to reduce corrosion,dry the sample in the room for 0.5 h ~ 1 h before cleaning, and then surface should be gently cleaned with flowing water with a temperature below 40 °C, to remove salt on the surface of the sample, then with an air pressure from the sample of about 300 mm less than 200 kpa samples should be blow dried immediately (Alia et al., 2018). The experimental results show that this kind of material has strong corrosion resistance and meets the selection conditions of marine engineering equipment materials.

Marine environmental test of composite profiles

The composite extruded profile was installed on the YGE 145 series solar photovoltaic panels as the frame and applied in the marine environment. The test was conducted at the sanya marine environment test station in China (Barkanov et al., 2017; Tucci et al., 2018). The size of the solar panel is 1470 mm × 680 mm × 25 mm, and the composite frame is prepared according to the size of the solar panel (Barkanov et al., 2018). The test was carried out in three areas: (1) splash platform test area, which can simulate the waves on the deck; (2) offshore platform test area, which can simulate the navigation environment of ships; (3) the atmospheric insolation test area, which is an offshore and coastal area, simulates the ship docking environment. 10 composite frame components and 10 aluminum alloy frame components were installed in each test area.

DOI: http://dx.doi.org/10.15666/aeer/1706_1421714229

During the test, the test environment conditions and the working status of solar photovoltaic modules were monitored in real time. Marine environment test period of 9 months, sampling at different time points, test after test the working characteristic of solar photovoltaic components and mechanical properties of the composite frame, through three areas of the test after the marine environment, the photovoltaic components and the borders of corrosion resistance, prevent ageing, impact resistance, wind resistance, waterproof performance can be evaluated (Barkanov et al., 2018).

Experimental results and analysis

Analysis of mechanical properties

In this paper, the mechanical properties of composite profiles prepared by pultrusion process were tested in accordance with relevant standards. The basic properties of composite profiles are listed in *Table 3*.

Table 3. *Mechanical properties of composite profiles*

The serial number	A pilot project	Test results	Execution standard	Sample size mm
1	The tensile strength MPa	786	GB/T3354-2014	230 × 15 × 2.3
2	The tensile modulus GPa	53.6		
3	The compression strength MPa	312	GB/T 1448-2005	12 × 10 × 4
4	The compression modulus GPa	11.6		
5	The bending strength MPa	1.01×10^3	GB/T3356-2014	100 ×15 × 2.3
6	Bending modulus GPa	40.2		
7	Impact toughness KJ/m2	442	GB/T 1451-2005	120 × 10 × 4
8	The density of kg/m3	2.03×10^3	GB/T 1463-2005	50 × 10 × 2.3

Corrosion resistance analysis

Figure 4 is the change curve of weight gain rate of composite profile after salt spray test. It can be seen from the figure that the quality of the two samples increased gradually from the beginning to 336 h. From 336 h to 1000 h, the weight gain rate of the samples gradually decreased, which was slower than the earlier trend. Because with the extension of the salt spray corrosion time, the absorption of water molecules in the samples was gradually saturated, and the weight gain rate of the two samples was between 0.12% and 0.14%. The reasons for weight gain of composite materials during salt spray test are as follows. First, water molecules in salt spray environment penetrate into the sample through the surface or resin and fiber sections; Another reason is that salt mist is attached to the sample (Baran, 2017).

The maximum stress that the material bears before tensile fracture is the tensile strength of the material， salt fog corrosion test before and after the change of the tensile strength of the sample values to represent composite material corrosion resistance calculation of salt spray test after tensile strength retention rate, neutral salt spray test after surface spraying fluorine polyamine vinegar semifinished enamel the tensile properties of the composite material test results are shown in *Table 4*.

Analysis of the influence of marine environment on mechanical properties and photovoltaic characteristics

Will the solar energy components used in ocean environment, respectively in atmospheric exposure test, offshore platform test area and splash experimental zone (*Fig. 5*) experiment platform, and set the aluminum alloy frame component as the control group, the Marine environment test for 9 months, study the mechanical properties of composite frame and through the comparison and analysis of composite frame with aluminium alloy frame's influence on the photovoltaic cell characteristics.

Table 6 shows the results of marine environment test of composite bending performance of solar module frame, after a period of time of test in three experimental areas in Sanya, the bending strength of the composite was increased, the strength retention rate increased, within the scope of the marine environment test time, as the sea trial was the longer the higher bending strength test values were observed (Chadel et al., 2017). This is because in the process of sea trials, composite material solar energy components border were mainly affected by sunlight and salt fog environment, ultraviolet ray is contained in sunlight, Ultraviolet irradiation can cause post-curing of composite material frame and also cause aging damage to the material. According to the test results, during the Marine environment test, the post-curing rate of composite material is higher than the rate of destruction by ultraviolet light, which is manifested as the increase of bending strength.

Table 6. *Component frame bending performance after marine environmental test*

Test area	Trial period of age	The bending strength (MPa)	Strength retention (%)
Splash platform test area	The initial value	1013	100
	Three months	1076	106

Discussion

From tensile results, after salt spray test, the tensile strength of the composites decreased, but with the extension of time, the salt fog corrosion did not cause faster strength degradation rate, but in a certain range fluctuations occurred. The reason is that early test of composite profiles in the salt fog environment water absorption, moisture absorption quantity are the important factors influencing the mechanical properties of composite materials, composite materials absorb moisture makes fiber easy to fall off from the substrate, causing internal clearance, and clearance have accelerated the absorption of moisture causing the loss of the performance of composite materials (Safonov et al., 2017). With the extension of time, the moisture absorption quantity saturated. The mechanical properties of the composite material decreased slowly. After 1000 h of neutral salt spray corrosion, the tensile strength retention rate of the composite profile is 86.12%, with a high tensile strength retention rate (Afanasyev et al., 2018).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1421714229

The tensile strength of the composite solar panel frame in the splash platform test area decreased slightly after a period of ocean test, but the degree of reduction was not obvious. The tensile strength of the composite solar panel frame in the offshore platform test area decreased at the initial stage, but increased with the extension of the test time. The tensile strength of the frame of the composite solar module in the atmospheric exposure test area increased with the extension of the test time. Similarly, the ultraviolet radiation from the sun may lead to post-curing of the composite frame during the test. When the curing degree is greater than the corrosion degree, the tensile strength of the material increases, which is roughly the same as the change trend of bending strength.

When solar photovoltaic module is used in marine environment, it is easy to accumulate more salinity on the surface of the module because of the large amount of salt fog in the marine environment. When the accumulated particulate matter is mixed with rainwater, sea water or other liquid substances, and then irradiated by sunlight for a long time, it will form a strong spot which is not easy to fall off. If this spot just blocked a series branch of the module, the blocked part could not perform photovoltaic effect and became a load consuming current, forming a “hot spot”. When the temperature of this part rises to a certain extent, it may cause damage to the whole battery assembly. The existence of hot spot will cause the attenuation of the maximum power of the module, and the smaller the size of the hot spot is, the more severe the hot spot effect will be, the more the number of hot spot, the more attenuation of the module will occur. After the marine environment test, the maximum power of the solar module has been attenuated. After nine months test, the maximum power attenuation of the solar module is less than 5%. The module can work normally, which shows that the module with composite frame can be used in the marine environment.

Conclusion

In the research of marine composite materials, it is necessary to pay attention to the coordinated development with marine ecosystem and avoid environmental pollution. On this basis, professional research structures should be established for the research of various materials to provide strong financial and technical support for the innovation of materials. The test results of the mechanical properties of the composite profiles show that the composite insulation has the advantages of light weight and high strength. The corrosion resistance of the composite material was evaluated through the neutral salt spray corrosion test. It can be seen that with the extension of the test time, the quality of the sample increased due to the hygroscopicity of the sample, and its tensile strength and bending strength retention rate were higher, indicating that the composite material had better performance in the salt spray environment. After the marine environment test, the bending and tensile properties of the composite frame were tested. The test results showed that the bending strength of the composite profile increased with the extension of the test time, and the retention rate of its tensile strength was higher, indicating that the composite was suitable for the marine environment. After the Marine environment test, the electrical performance of the solar module was tested. The test results showed that the maximum power of the solar module decreased after the Marine environment test,nine months after the test, the maximum power attenuation is less than 5%, the component can work normally, equipped with composite frame component it can be used in the marine environment.

Abstract. The air pollution problem which has arisen in developed countries, becoming evident by high levels of smoke from industries or traffic, has forced authorities to search for mechanisms to control the air quality by the real-time monitoring system. For this purpose, in this paper we develop a new procedure able to analyze this real-time data. More precisely, we use the recent development on mathematical Statistics to analyze the relationship between the maximum ozone concentration and the other palling gases such as the Nitric Oxides (NO), Nitrogen Dioxide (NO_2) and Sulphur Dioxide (SO_2). Specifically, we propose three models which are, Functional Nonparametric Regression, Functional Robust Regression and Functional Relative Error Regression. Considering the daily- curve of the concentration of the previous gases collected by the Marylebone road monitoring site in London, we provide statistical models allowing the prediction of the maximum ozone concentration 4 h ahead. We show that the accuracy of our prediction approaches is closely linked to the choice of the regression model and the input variables or the covariates. In particular, the nonparametric regression is more performant than the other models when the regressors are NO_2 and SO_2.
Keywords: *ozone forecasting, air quality data, functional regression, the nitric oxide, nitrogen dioxide, sulphur dioxide, nonparametric statistics, time series analysis, neural network model, Bayesian network models, principal component regression*

Introduction

Analyzing the levels of air pollution is nowadays of primary importance. Indeed the air quality has a great impact on human health as well as natural resources. In the last decades, air pollution is among the leading causes of death. Thus, pollution forecasting allows decision-makers to plan the prevention strategy. For this issue, several mathematical models are used to provide some software to control air quality (see, e.g., Ryan et al., 1995; Slini et al., 2002; Nghiem et al., 2009). Specifically, there exist two kinds of approaches: deterministic and statistical algorithms. The literature on the deterministic models treat the pollutant-formation processes by studying their chemical and physical properties (see Zhang et al., 2012). While the statistical models are based on the historical measurements of air pollution and/or meteorological data. In this context, most statistical models are constructed by using the classical regression method. We cite for instance the neural network models by Yi and Prybutok (1996), Bayesian network models by Gavrila (2013, 2016). We refer the readers to Gong and Ordieres-Meré (2016), Taylan (2017) and Ding et al. (2016) for some recent contributions on the prediction of ozone concentrations by the empirical methods. All the statistical models of these cited works are performed over the observed data in some discrete grid which allows at most making the daily prediction. However, because of the ozone concentration has a faster dynamics the daily prediction is not very important. Furthermore, the recent technological development of the measuring instruments and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1423114239

the informatics tools allow the recovery of increasingly bulky data being recorded densely over a thinner discretization grid what make them intrinsically a continuous curve. The manipulation of this kind of data permits the real-time forecasting of the ozone concentration. This is the main purpose of this paper. To do that, we use some new statistical models recently developed of big data analysis. The main advantage of these new models, so-called functional models, is the fact that they take into account the daily- curves in its continuous path, unlike the old models which take only the values of some few hours. Of course, with the functional models, we keep all the information in the sampled data and we predict different horizons. It should be noted that the functional statistics has encountered a strong infatuation in these last years, as evidenced the several special issues dedicated to this topic (see, e.g., Aneiros et al., 2019; Ferraty, 2010). For more discussion on this topic, we refer the reader to Hsing and Eubank (2015), Ling and Vieu (2018) and the references therein.

The present contribution deals with the assessment of functional statistics models for modelling ozone concentrations. More precisely, our main goal is to search accurate prediction methods of the ozone concentration with respect to the other polluting gases. We use for this study a sample of data recorded in the Marylebone road monitoring site in London. It contains the hourly measurements during the 2018-year for the following four variables: Nitric Oxide, Nitrogen Dioxide, Sulphur Dioxide and Ozone. This data is used to predict the maximum ozone concentration 4 h ahead. Let us point out that the considered models come from the recent development of the modern statistics that allow analyzing the big data without reduction of the dimension. These new approaches constitute alternative statistical models to the artificial neural network regression and the principal component regression which are usually employed in this prediction setting. The main feature of our functional models is the possibility to model the environmental date recorded by real-time monitoring. More precisely, we test three regression models that are Functional Nonparametric Regression (FNR), Functional Robust Regression (FRR) and the Functional Relative Regression (FRER) to forecast the maximum ozone concentration given four functional covariates such that the daily curves (one day before) of NO, NO_2, SO_2 and O_3. These models provide predictions, robust, fast and of higher accuracy.

The paper is organized as follows. In the next section, we introduce the functional methodology in the continuous-time prediction problem. The statistical models used are described in the section intituled "Some recent regression models". The predictions results of the three proposed methods are gathered in result's section. The last section is devoted to some conclusions.

Materials and methods

As mentioned in the previous section, the data of this contribution are acquired from real-time measurement by Marylebone road monitoring site. Marylebone Road is an important thoroughfare in central London, within the City of Westminster. It runs north-east to the south-west from the Euston Road at Regent's park to the A40 Westway at Paddington. This road is frequently heavily congested. It carries about 90,000 vehicles a day. The Marylebone Road monitoring site is funded by the Department for Environment, Food and Rural Affairs (Defra) in June 1997. The monitoring cabin is located one meter from the kerb on the southern side of the road. Its geographical

DOI: http://dx.doi.org/10.15666/aeer/1706_1423114239

location are 51.522530 (latitude), -0.154611 (longitude). *Figure 1* shows the location of the site.

Figure 1. *The location of the Marylebone Road*

The data used in this paper are provided by the website https://www.airqualityengland.co.uk/site/data?site_id = MY1. It contains the hourly measurements during the period from January 1st to the 31st December for the year 2018, for the variables NO, NO_2, SO_2 and O_3 (*Fig. 2*).

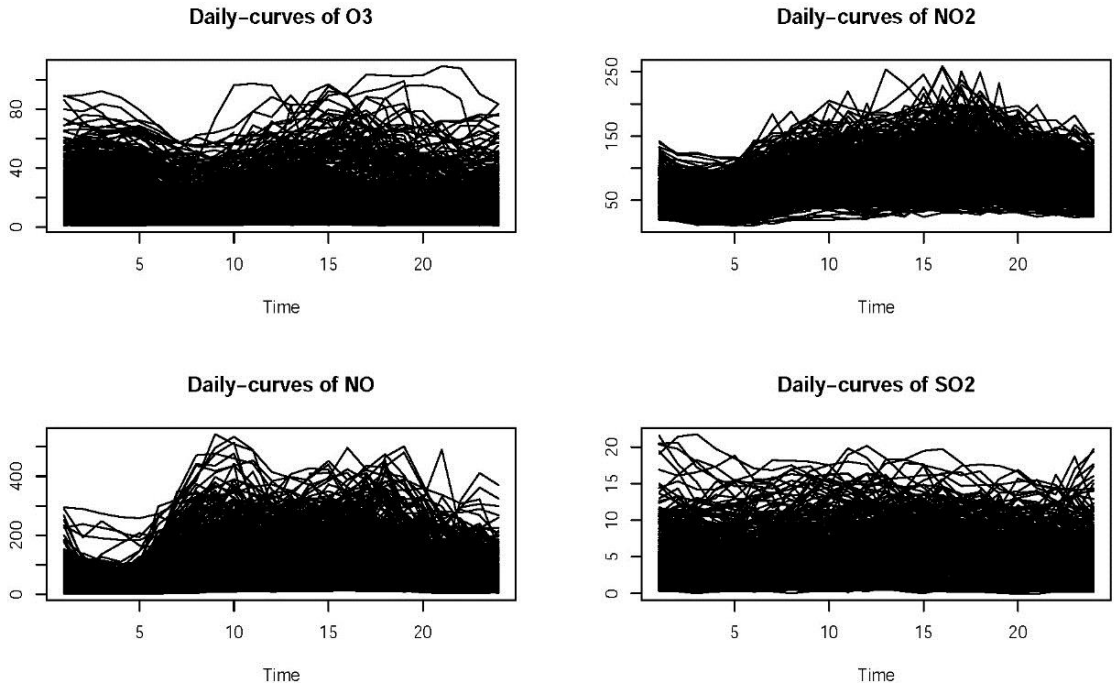

Figure 2. *The curves of the daily emission of the four gases NO, NO_2, SO_2 and O_3 in $\mu g/m^3$*

To fix the ideas, let us present the mathematical formulation of our prediction problem. Indeed, assume that we aim to predict the k-h-ahead prediction of the maximum ozone concentration at hour h_0, denoted by Y, using the curve of the daily emission of the gases observed the day before until $h_0 - k$. Formally, we assume that the output variable Y and the input variables $Z = (X_{NO}, X_{NO_2}, X_{SO_2}, X_{O_3})$ are linked by the following regression formula:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1423114239

$$Y = r(Z) + error. \quad \text{(Eq.1)}$$

So, the prediction of Y is based on the determination of the function $r(.)$ in *Equation 1*. Many models are recently developed in mathematical statistics to resolve this kind of big data problem where the data are continuous curves. In this paper, we employ three regression procedures which are described in detail in the next section.

Some recent regression models

Functional nonparametric regression (FNR)

The nonparametric estimation of the functional regression was initially studied by Ferraty and Vieu (2006) and Ferraty et al. (2010). They used the Nadaraya Watson method to estimate this statistical model. Precisely, the function $r(.)$ is explicitly expressed using the least square error criterion by

$$r(x) = argmin_f E[(Y - f)^2 | Z = z]. \quad \text{(Eq.2)}$$

It follows that $r(x) = E[Y|X = z]$.

So, for all fixed curves $x_{NO}, x_{NO_2}, x_{SO_2}, x_{O_3}$ we predict the maximum ozone concentration with respect to the criterion (*Eq. 2*) by

$$\hat{Y} = \hat{r}(z), \text{ where } z = (x_{NO}, x_{NO_2}, x_{SO_2}, x_{O_3})$$

where $\hat{r}(z)$ is the kernel estimator of $r(z)$ defined by

$$\hat{r}(x_{NO}, x_{NO_2}, x_{SO_2}, x_{O_3}) = \frac{\sum_{i=1}^{n} Y_i K\left(\frac{\|x_{NO} - x_{NOi}\| + \|x_{NO_2} - x_{NO2i}\| + \|x_{SO_2} - x_{SO2i}\| + \|x_{O_3} - x_{O3i}\|}{h_n}\right)}{\sum_{i=1}^{n} K\left(\frac{\|x_{NO} - x_{NOi}\| + \|x_{NO_2} - x_{NO2i}\| + \|x_{SO_2} - x_{SO2i}\| + \|x_{O_3} - x_{O3i}\|}{h_n}\right)}$$

with K is a kernel function and h_n is a nonnegative real sequence.

Functional ρ- regression (FRR)

This regression model is obtained by resolving the following optimization problem

$$min_f E[\rho(Y, f)|Z = z], \quad \text{(Eq.3)}$$

ρ is a real-valued Borel function chosen by the user according to the studied data.

The model (*Eq. 3*) has been introduced in functional statistics by Azzedine et al. (2008) independent case and Attouch et al. (2012) for dependent case. The robustness is the main advantage of this model. It permits to analyze the data even in the presence of the outliers. Its functional estimation is expressed by

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1423114239

$$\bar{\bar{r}}(x_{NO}, x_{NO_2}, x_{SO_2}, x_{O_3}) = argmin_f \frac{\sum_{i=1}^{n} \rho(Y_i f) K\left(\frac{\|x_{NO}-x_{NOi}\|+\|x_{NO_2}-x_{NO2i}\|+\|x_{SO_2}-x_{SO2i}\|+\|x_{O_3}-x_{O3i}\|}{h_n}\right)}{\sum_{i=1}^{n} K\left(\frac{\|x_{NO}-x_{NOi}\|+\|x_{NO_2}-x_{NO2i}\|+\|x_{SO_2}-x_{SO2i}\|+\|x_{O_3}-x_{O3i}\|}{h_n}\right)}.$$

Functional relative error regression (FRER)

This last regression is an alternative nonparametric regression to the least square regression model. It is recently considered in functional statistics by Demongeot et al. (2016) for independent case and Bassoudi and Kaid (2019) for dependent case. It is defined by the following rule

$$min_f E\left[\frac{(Y-f)^2}{Y^2} | Z = x\right]. \quad \text{(Eq.4)}$$

The expression of this regression is explicitly given by

$$\frac{E[Y^{-1}|Z=x]}{E[Y^{-2}|Z=x]}.$$

Its estimator is defined by

$$\ddot{r}(x_{NO}, x_{NO_2}, x_{SO_2}, x_{O_3}) = \frac{\sum_{i=1}^{n} Y_i^{-1} K\left(\frac{\|x_{NO}-x_{NOi}\|+\|x_{NO_2}-x_{NO2i}\|+\|x_{SO_2}-x_{SO2i}\|+\|x_{O_3}-x_{O3i}\|}{h_n}\right)}{\sum_{i=1}^{n} Y_i^{-2} K\left(\frac{\|x_{NO}-x_{NOi}\|+\|x_{NO_2}-x_{NO2i}\|+\|x_{SO_2}-x_{SO2i}\|+\|x_{O_3}-x_{O3i}\|}{h_n}\right)}.$$

Results

Undoubtedly, the accuracy of the three proposed regression models is closely related to the choice of the different parameters involved in these models. Specifically, the leading parameters in this prediction issue are kernel K, the smoothing parameter h_n, and the norm $\| \|$. The letter is equal to the distance between the smoothed curves obtained by interpolation. For basic materials on this notion, we refer the readers to Ferraty and Vieu (2006). Notice that the previous estimators are computed by using a sample of 364 obviations $(Y_i, X_{NOi}, X_{NO_{2i}}, X_{SO_{2i}}, X_{O_{3i}})$. The observations are determined with respect to the aimed prediction horizon. Generally speaking, for k-h-ahead prediction of O_3 at hour h_0 in a day i we denote by $(X_{NOi}, X_{NO_{2i}}, X_{SO_{2i}}, X_{O_{3i}})$ the daily curve of the emission of the gases observed the day before $(i.e.\ (i-1))$ until $h_0 - k$, and we put $Y_i = X_{O_{3\,(i+1)}}(h_0)$. Now, to test the performance of the proposed models, we randomly split the 364 observations into two sub-samples: 200 in learning sample (indexed by i) and 164 in the testing sample (indexed by j). The observations of the learning sample are used to compute the estimators. While the observations of the test sample are employed to evaluate the quality of the models $(\hat{r}, \bar{\bar{r}}, \ddot{r})$. To the end, let us point out that we have used the leave-one-out cross-validation technique to determine the bandwidth parameter h_n. The rule of the used cross-validation procedure is defined by

$$\frac{1}{200}\sum_{i=1}^{200}\left(Y_i - \theta(X_i)\right)^2 \quad \text{(Eq.5)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1423114239

where $\theta(.)$ means one of the previous regression models ($\check{r}, \bar{\bar{r}}, \breve{r}$). For the sake of shortness, we fixe $k = 4$ and we give the prediction results for $h_0 = 11\,am$. This hour corresponds to four hours after peak-hour road traffic. For the computational purpose, we use the same kernel and the score function as in Demongeot et al. (2016). To examine the sensitivity of this prediction problem to the input variables we have proceeded with several cases with different covariates. The obtained results are shown in *Figures 3–5*.

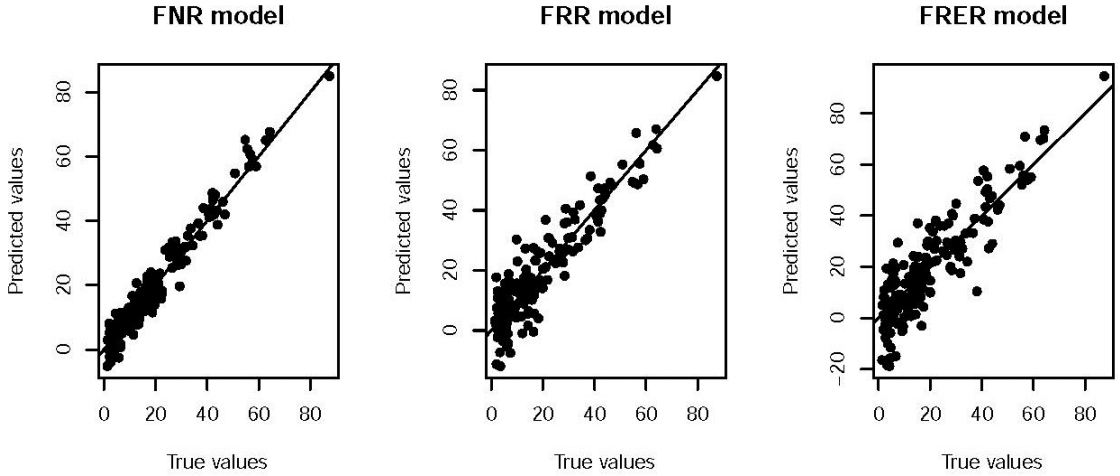

Figure 3. *4-h prediction of the maximum ozone concentration at $h_0 = 11\,am$ using the covariates $X_{NO}, X_{NO_2}, X_{O_3}$*

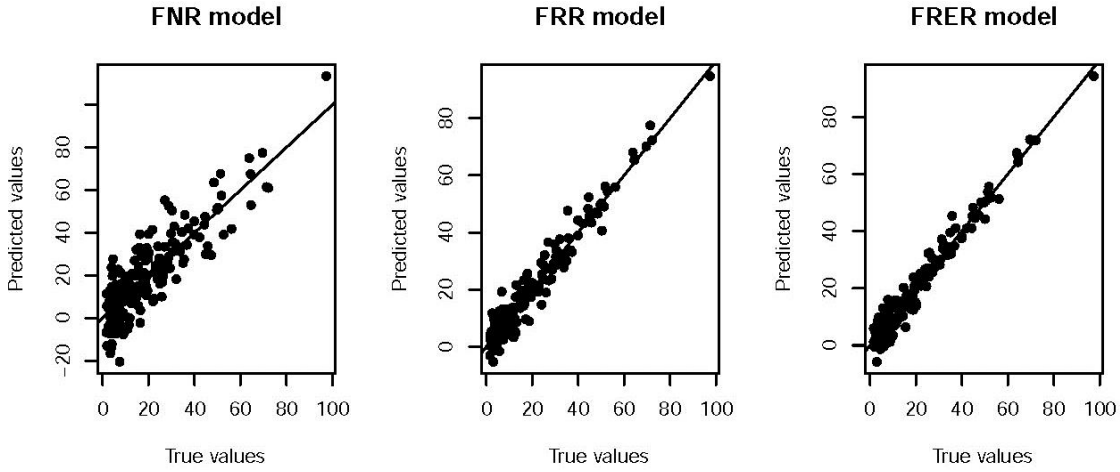

Figure 4. *4-h prediction of the maximum ozone concentration at $h_0 = 11\,am$ using the covariates X_{SO_2}, X_{O_3}*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1423114239

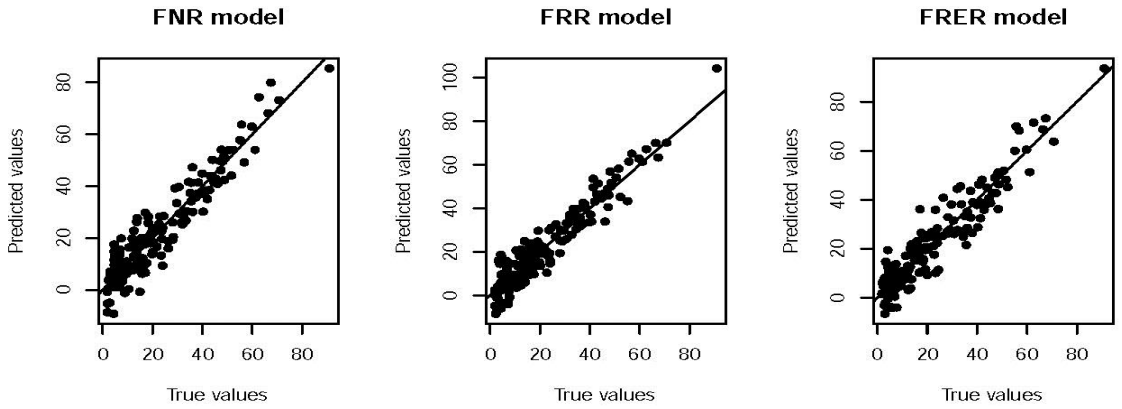

Figure 5. *4-h prediction of the maximum ozone concentration at* $h_0 = 11\ am$ *using the covariates* $X_{NO}, X_{NO_2}, X_{SO_2}, X_{O_3}$

It appears clearly that these new regression models performed well for this prediction problem and they have a fair accuracy. However, the performance of the considered models is varied with respect to the input variables. For instance, the FNR is more accurate when the regressors are $X_{NO}, X_{NO_2}, X_{O_3}$. On the other hand, the FRR and FRER provide better results for the covariates X_{SO_2}, X_{O_3}. All the models have a satisfactory result when the four regressors are considered. Such a conclusion is justified by the mean squared prediction error (MSPE) defined by

$$MSPE = \frac{1}{164}\sum_{j=1}^{164}\left(Y_j - \hat{Y}_j\right)^2. \qquad \text{(Eq.6)}$$

The MSPE errors are summarized in *Table 1*.

Table 1. *The MSPE of the three models*

Covariates	FNR model	FRR model	FRER
$X_{NO}, X_{NO_2}, X_{O_3}$ Case	**2.32**	3.12	2.98
X_{SO_2}, X_{O_3} Case	4.53	**3.09**	3.22
$X_{NO}, X_{NO_2}, X_{SO_2}, X_{O_3}$ Case	3.28	**3.19**	3.53

Discussion

The real time air quality in Marylebone road was analyzed by using the functional statistical models. A sample of 364 observations was used to analyze the impact of the other pollutant gases on the ozone concentration. The results of this statistical analysis are displayed in *Figures 3–5* and the prediction errors are summarized in *Table 1*. According to these prediction results, it appears clearly that the efficiency of this prediction issue is related to two important parameters which are the predictor model and the regressor variables. Precisely, using the three covariates $X_{NO}, X_{NO_2}, X_{O_3}$, Figure 3 shows that the best model is FNR; it gives an MSPE equal to 2.32. However, if we consider as covariates the two variables X_{SO_2}, X_{O_3} or $X_{NO}, X_{NO_2}, X_{SO_2}, X_{O_3}$ the best results were obtained by FRR model. Its prediction error is 3.09 and 3.19, respectively. Overall, it is clear that this functional regression models have satisfactorily performance. The prediction errors evaluated by the rule $MSPE$ is varied between 2.32-3.28 for the FNR, in the interval (3.12, 3.19) and is between 2.98-3.53 for the FRR and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1423114239

FRER, respectively. All these predictor models are performed with fixed horizon equal to 4 h. Of course the choice of the prediction horizon is crucial. It should be enough for alarm purposes. Conceptually, our approach can be used for any horizon, but, we focused, here in 4 h ahead prediction, only, to show the easy implementation of the proposed algorithms. Furth more, the prediction results show that the three proposed functional models are fast, robust and accurate in this prediction issue. Moreover, the main feature of these functional models is the modelling of the daily curves of the pollutant gases in theirs continuous path allowing to explore the whole existing information of this time series data. Of course this consideration permits to avoid several drawbacks of the multivariate regression models, such as the curse of dimensionality or the calibration problem. On the other hand, the prediction in advance of the future values of the ozone concentration has a great importance for the decision-makers. They permit to plan the prevention strategy in order to combat the principal cause of the pollution. The present study contribute in this fundamental issue with these flexible models which can be used for various covariates variables and several pollutant factors, such as temperatures, wind (speed and directions), radiations, etc. Thus, the integration of these additional factors in our functional model is one of the natural prospects of this work. In addition, we can, also, predict the ozone concentration using other recent statistical models such as the partial functional linear model or the functional local linear models.

Conclusion

In this work, we have developed a new approach to predict the maximum ozone concentration using other air quality factors. These models are based on real-time measurement of the input data. The main feature of these models is the fact that they allow exploring all the information of these continuous-time observations viewed as curves. They are easily implementable, and their efficiency is related to the choice of the exogenous variables. In the sense that in the function of the considered covariates we can choose the adapted model. Moreover, the proposed models permit to avoid the core drawback of the classical models that is the loss of information after the prediction transformation. Indeed, the classical models induced by the multivariate regression are obtained by discretization of the daily curve in some finite grid or by projection into a finite-dimensional space. All these transformations on the input data are performed independently to the output variables. But, the ozone prediction is very sensitive to the input data. So the classical models are failed in these situations of real-time measured data. Thus, the originality of the functional approach comes from the fact that the prediction problem is performed without any transformation of the data. In conclusion, we can say that the accuracy of air quality prediction is based on both: the choice of the appropriate statistical models and the determination of the covariates. Moreover, the performance of the proposed models can be improved by using other covariates such as the metrological data wind direction, wind speed, humidity, solar radiation, air temperature.

Acknowledgments. Authors greatly thank the Editor in chief, the Associate Editor and the anonymous referees for a careful reading of the paper and for their valuable comments and suggestions which improved the quality of this paper substantially. They also extend their appreciation to the Deanship of Scientific Research at King Khalid University for funding this work through General Research Project under grant number (G.R.P-125-40).

(Received 3rd Jun 2019; accepted 11th Oct 2019)

Abstract. A novel integrated approach was used to assess water quality in Taihu Lake in real-time using a radial basis function (RBF) network, structure index (SI) and principal component analysis (PCA). A total of eight sampling points covering an area of 2,338 km^2 were sampled once weekly from 2000 to 2005, except for 2003 and 2004. An RBF network was developed with 23 water quality parameters used as inputs. Then SI was applied to investigate main parameters. Parameters affecting water quality were also determined using PCA. The water quality of Taihu Lake was estimated by synthesizing the results of SI and PCA. Total nitrogen, with a weight of 0.34 for the first component, had the greatest negative effect on Taihu Lake water quality, being slighter than that of ammonia nitrogen, which had a weight of 0.324 for the first component. Conductivity, total phosphorus and alkalinity had weights of 0.322 0.292 and 0.267 for the first component, respectively. It is possible to identify potential sources of water pollution and the results indicated that the water quality of Taihu Lake in the study period was generally graded as Class V according to Environmental quality standards for surface water (GB 3838-2002).
Keywords: *PCA, RBF neural network, SI, water quality assessment, Taihu*

Introduction

Environmental sustainability is among the most serious global issues being addressed by planners, policy analysts, political scientists and others (Gleeson, 2001). Water pollution is an increasing concern, threatening the ecological integrity and sustainability of some of the world's largest water bodies (Havens et al., 2001). Lake water pollution is of particular concern because of its impact on fish habitats (Scavia et al., 2014) and human and animal health (Utah, 2016), and the fact that these are areas where there are complex interconnections between anthropogenic and climatic factors (Richards, 2010; Brooks, 2016). Harmful cyanobacterial blooms are one of the most significant markers of impaired lake water quality, especially in eastern China, a region with a rapidly growing economy (Paerl, 2011).

Taihu Lake (*Fig. 1*), situated in the Yangtze delta with an area of 2,338 km^2, is the most industrialized area in China, having a high population density and significant urbanization and economic development (Qin et al., 2002). The lake supports 10 million people working in tourism, fisheries, shipping and other industries. Taihu Lake also collects waste from urban, agricultural and industrial areas of surrounding cities, helping rapid growth in local economies (Qin et al., 1999; Qin, 2008). However, the increase of nutrients coming from urban and agricultural development in the watershed, has accelerated eutrophication (James et al., 2009; Duan et al., 2009). Cyanobacterial blooms, indicators of advanced eutrophication, in freshwater lakes impact fish,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1424114258

recreational lake users, and the drinking water supply (Fogg, 1969; Paeral,1988). The water quality of the lake is closely related to public health in the local area.

Prior to the 1970s, average water quality of Taihu Lake was classified as Grade II according to GB3838-88 (Groundwater Environmental Quality Standard. China: GB. 2003). Since the 1980s, discharge of industrial waste water and domestic sewage has increased yearly while the water quality of Taihu Lake has dropped, on average, by one grade every 10 years. In the 1980s, the water quality was graded between the second and third levels; in the 1990s, the water quality decreased to the fifth level, and eutrophication had increased. Since the late 1990s, water quality deterioration has slowed and some key indicators, including TP, ammonia nitrogen and chemical oxygen demand of permanganate (Permanganate index), have improved (China Taihu Ecosystem Positioning Observation Data Query System. Taihu Lake Water Quality Inquiry System. Accessed 1990-2018, http://lake.data.ac.cn/taihu).

Figure 1. *Location of the study area*

Statistical techniques, visual modeling, prediction algorithms, and time-series analyses have been used to evaluate and monitor water quality, and inform policy-makers (Junli et al., 2019; Jun et al.,2019; Taufiq et al., 2019; Dutta et al., 2018; Jabbar et al., 2018; Meng et al.,2018; Tong et al.,2018; Drakard et al., 2018; Shengli et al., 2018; Omar et al., 2018; Putri et al., 2018; Kellner et al., 2018; Islam et al., 2018; Skowron et al., 2018; Masindi et al., 2018; Meifang et al., 2018; Guilin et al., 2018; Zhi-Qiang et al., 2018; Ju et al., 2018; Cecconello et al., 2018). Methods that have been proposed to assess water quality include Roveda's water quality index (Roveda et al., 2013), EFER (Aminravan et al., 2013) and use of ships with deliberative control architecture (Halal et al., 2014). A RBF network algorithm is commonly used because of its ability to learn, generalize, and adapt (Garrett, 1994). The RBF network algorithm used in this study combines several lake water quality parameters, enabling the most important parameters to be identified based on analysis of the neighboring nodes. It can efficiently describe the non-linear relationships among complex water quality datasets (Adel et al., 2018; Zheng et al., 2017; Alizamir et al., 2017; Asadollahfardi et al., 2017; Wu et al., 2016; Zounemat-Kermani et al., 2016; Shiau et al., 2016; Bagheri et al., 2016).

Combining RBF with SI and PCA (Dutta et al., 2018; Prusty, 2018; Sun et al., 2018; Xiaohu et al., 2018; Wang et al., 2019; Xiao et al., 2019; Zhaoxue et al., 2018) yields more accurate results and provides sufficient evidence to characterize lake water

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1424114258

quality. In this study, RBF, SI and PCA were applied to identify the main parameters affecting water quality. The primary objectives of this study were to assess water quality in Taihu Lake, identify the main parameters that damage the water quality, and investigate possible sources of pollution.

Material and methods

This study focused on Taihu Lake, which is located in the southern border of the Yangtze River Delta (*Fig. 1*). Taihu Lake is the third largest freshwater lake in China, covering an area of 2,338 km^2. It has a length of 68.5 km from north to south, an average length of 34 km from east to west, and a coastline of 405 km.

Taihu Lake has a complicated river and channel network, with a mean depth of 1.9 m and a maximum depth of 2.6 m. Pen fish is the main form of aquaculture in Taihu Lake. Marsh development occurs primarily along the eastern shoreline. Taihu Lake has many functions, including supplying drinking water, supporting fisheries, tourism and shipping, and retaining flood water.

To evaluate the water quality of Taihu Lake, monthly data from eight sampling points in Taihu Lake were collected for the period 2000 to 2005, except for 2003 and 2004. The data used in this study are from "Lake-Watershed Science Data Center, National Earth System Science Data Sharing Infrastructure, National Science & Technology Infrastructure of China" (http://lake.geodata.cn). Parameters evaluated included pH, total nitrogen, total phosphorus, Chlorophyll a, Demagnesium chlorophyl, permanganate index, dissolved oxygen, ammonia nitrogen, nitrite nitrogen, nitrate, phosphate, alkalinity, potassium, sodium ion, calcium ion, magnesium ion, fluorine ion, chloride, sulfate, silicate, Dissolved total nitrogen, Dissolved total phosphorus, and conductivity. The abbreviations of words used in this paper are shown in *Table 1*.

This study combined RBF, SI and PCA to derive accurate results. Many parameters were included in our assessment of Taihu Lake water quality. Changes in parameter values were captured and analyzed in the MATLAB environment (MathWorks, Natick, MA, USA) using RBF algorithms to derive an accurate results. A novel three-layer RBF network was developed for this study. A confusion matrix was used to assess the performance of the RBF algorithm.

After the RBF network was built, the weights of and links between nodes were ascertained. SI was used to determine the parameters contributing most significantly to the output neurons. SI shows a high value when a parameter makes a great contribution to the RBF network, even if it has a less weight.

Following the above steps, the main parameters affecting each output neuron were determined. SPSS software (ver. 21.0; IBM Corp., Armonk, NY, USA) was used to compute the principal components, that is to seek projection directions with maximal variances which occupy bigger quantity (Flury, 1990; Joliffe, 2011). By investigating the principal components, the most important parameters affecting water quality can be identified using the RBF algorithm. A flow diagram illustrating the analysis process is shown in *Figure 2*.

Assessment model of water quality based on RBF algorithm was used to estimate the percentage amounts of each measured parameter in the lake. All data were pre-processed and separated into three data sets: training, test and verification sets. MATLAB was used for construction and analysis of the RBF network. There were 23 input layer neurons and 1 neuron in the output layer was used to represent the actual

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1424114258

water quality shown in *Figure 3*. There can be up to 71 hidden layers in this network. The nodes in the input and output layers are arranged in one line. A confusion matrix was used to assess the performance of the network and indicated that most of the predicted data fit, or nearly fit, the actual results.

The SI for the whole network was calculated as

$$\sum_{j}^{n} \sum_{k=1}^{j=1} \frac{|Wij - Wik|}{Djk} \quad \text{(Eq.1)}$$

where W_{ij} and W_{ik} are the connection weights of input variable i in neurons, and j and k of the RBF network, respectively; $\|D_{jk}\|$ is the topological distance between neurons j and k; and N is the total number of output neurons in the RBF network.

Table 1. *The abbreviations of words used in this paper*

Words	Abbreviation	Unit
pH	pH	/
Total nitrogen	TN	mg/L
Total phosphorus	TP	mg/L
Chlorophyll a	CHLA	μg/L
Demagnesium chlorophyl	DC	μg/L
Permanganate index	PI	mg/L
Dissolved oxygen	DO	mg/L
Ammonia nitrogen	NH3-N	mg/L
Nitrite nitrogen	NN	mg/L
Nitrate	NNA	mg/L
Phosphate	PO	mg/L
Alkalinity	ALKY	mmol/L
Potassium ion	K	mg/L
Sodium ion	Na	mg/L
Calcium ion	Ca	mg/L
Magnesium ion	Mg	mg/L
Fluorine ion	F	mg/L
Chloride	Cl-	mg/L
Sulfate	SO4	mg/L
Silicate	SiO	μmol/L
Dissolved total nitrogen	Dissolved TN	mg/L
Dissolved total phosphorus	Dissolved TP	mg/L
Conductivity	EC	μS/cm

The SI of each input node is presented in *Table 2*. Input layer 14, which represents Na, was the parameter most critical to the performance of the whole network. Dissolved TP and F were the second and third most important parameters, respectively. Ca, with an SI of 21.437 was next, followed by TN, PI and DO. Dissolved TN, Mg, NH3-N,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1424114258

NNA, NN, pH, EC, ALKY, and TP had SIs above 5; SiO, Cl-, CHLA, PO, DC, K, and SO4 had SIs below 5. Garson's Algorithm (Garson, 1991) and Connection weights approach (Olden, 2002b) are also presented as methods to study the relative importance of inputs on the output. The results are displayed in *Table 2*. Seven factors affecting water quality were identified by developing the network and analyzing the weight of each node by SI as well as synthesizing the results of Garson and Connection weights which was in the order of: TP, SiO, Ca, SO4, Na, K, and F.

Table 2. *The weight of each input node by different methods*

Input layer(s)	Parameter(s)	Weight(s) by SI algorithm	Weight(s) by Garson's algorithm	Weight(s) by connection weights approach

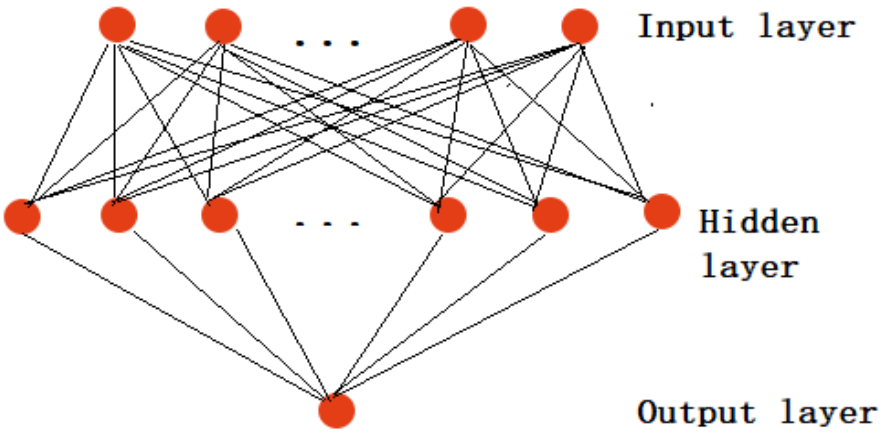

Figure 3. *Basic network structure*

Some criteria were used to evaluate the performance of the RBF model. The sum-squared error which can be calculated in *Equation 2* show the total epochs (iterations) required for the function to converge on parameters. Fitness value, indicators used to measure the quality of individuals in a population, can be calculated in *Equation 3*. Mean square error calculated in *Equation 4* was used to assess performance of each model.

$$\text{Sum - squared - error} = \sum (\text{actual value} - \text{predicted value})^2 \quad \text{(Eq.2)}$$

$$\text{Fittting} = \frac{1}{\text{Sum - squared - error}} \quad \text{(Eq.3)}$$

$$\text{mean square error} = \frac{\text{Sum - squared - error}}{n} \quad \text{(Eq.4)}$$

Results

Analysis of the main parameters affecting water quality

During the study period, TP concentrations in the samples ranged from 0.013 to 2.133 mg/L, with an average of 0.145 mg/L (*Table 5*). The peak concentrations in the third quarter of 2000 and 2002 may be due to the construction of new factories and the associated increase in the quantity of polluted water entering Taihu Lake during this period.

Increasing temperatures in spring promote the release of TP and increase its concentration in water. Throughout the summer, the concentration of TP in water may decrease because aquatic plants consume nutrients (*Fig. 4-1a*). TP peaks in 2000 and 2005 occurred in February, while the peaks in 2001 and 2002 occurred in July.

The dissolution of SiO was relatively stable, ranging from 0 to 157 mg/L and with an average of 77.27 mg/L (*Fig. 4-1b*). The low SiO concentration observed in the fourth quarter of 2000 may have been related to diatom activity. However, the variation in SiO concentrations seen in 2002 and 2005 indicates that diatom activity is likely not the

DOI: http://dx.doi.org/10.15666/aeer/1706_1424114258

main factor affecting SiO concentrations; values were high all year round, particularly in the autumn and winter. Organic pollution of the water body is another possible factor influencing SiO concentrations, which were at an acceptable level for drinking water.

Table 5. *Statistical analysis of the main parameters affecting water quality in Taihu Lake*

Parameter	Max	Min	Avg	Var

Dissolved TP	0.245	0.003	0.035744792	0.0015636
EC	1100	195	195	121.74

Ca concentrations ranged from 14.3 to 125.4 mg/L; Na concentrations ranged from 4.4 to 210 mg/L; K concentrations ranged from 1.73 to 10.33 mg/L; and Flu concentrations ranged from 0 to 10.73 mg/L.

Ca concentrations are expected to show opposite trends to SiO concentrations; this was observed in 2000 and 2001 in *Figure 4-1c*. The decrease in Ca concentration in 2003 may have been caused by polluted water emanating from factories and a nearby residential development. By 2005, the effect of human and diatom activity had reached a balance, and minimal variation Ca concentrations was observed.

SO4 is toxic to human health even at low concentrations. Over the study period, the SO4 concentration in Taihu Lake ranged from 24.1 to 174.6 mg/L, with an average value of 58.12 mg/L. SO4 concentrations declined through the middle part of the year, except in 2005 (*Fig. 4-1d*). The high SO4 concentration during the winter and spring from 2000 to 2002 may have been due to coal mine emissions. The peak SO4 concentration was observed from 2000 to 2002, with the appearance of the peak varied from January to April. SO4 concentrations were consistent with SiO concentrations (*Fig. 4-1b* and *d*, respectively).

DOI: http://dx.doi.org/10.15666/aeer/1706_1424114258

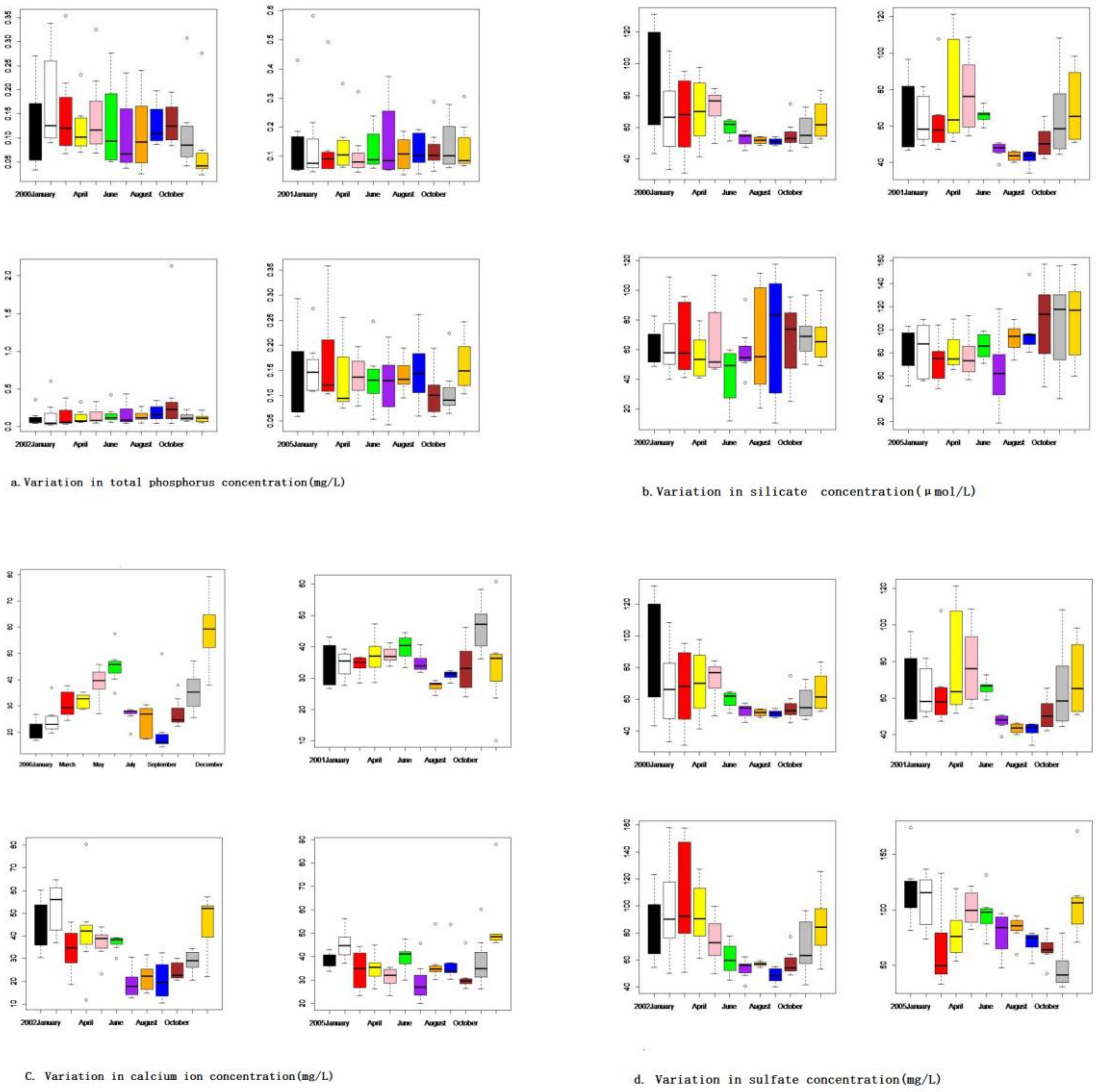

Figure 4-1. *Variation in different parameters' values by study year*

Nas are a common component of natural waterways. The most important characteristic of Nas in natural waterways is the wide variation in concentration under different conditions. *Figure 4-2e* shows that Na concentrations were low during the wet seasons. In the Earth's crust, K and Na are similarly abundant (2.60% and 2.64%, respectively). Although they have similar chemical properties, K concentrations are generally much lower than Na concentrations in natural waterways. K and Na concentrations decreased from 10% to 4% from 2000 to 2005 (*Fig. 4-2e* and *f*, respectively). The K to Na quality ratio was 0.1028 in 2005, while the ratio was 0.118, 0.120, 0.128 in 2003, 2001 and 2000 respectively. Ks are more mobile than Nas due to soil colloid adsorption, but are absorbed by plants. Increases in Na concentrations were mainly due to the drainage of sewage into the basin.

An acceptable F concentration in drinking water is 0.5 - 1.0 mg/L; the F concentration in Taihu Lake was within this range (*Fig. 4-2g*). The peak high and low points in 2000 and 2001 were similar, although the peak occurred later in 2001. The F concentration trend in 2002 was opposite to that in 2001.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1424114258

TN and SO4 concentration trends were opposite which are illustrated in *Figures 4-2h* and *4-1d*. TN concentration was highest in the middle part of 2000, while in the following years there were low TN concentrations in the middle of the year.

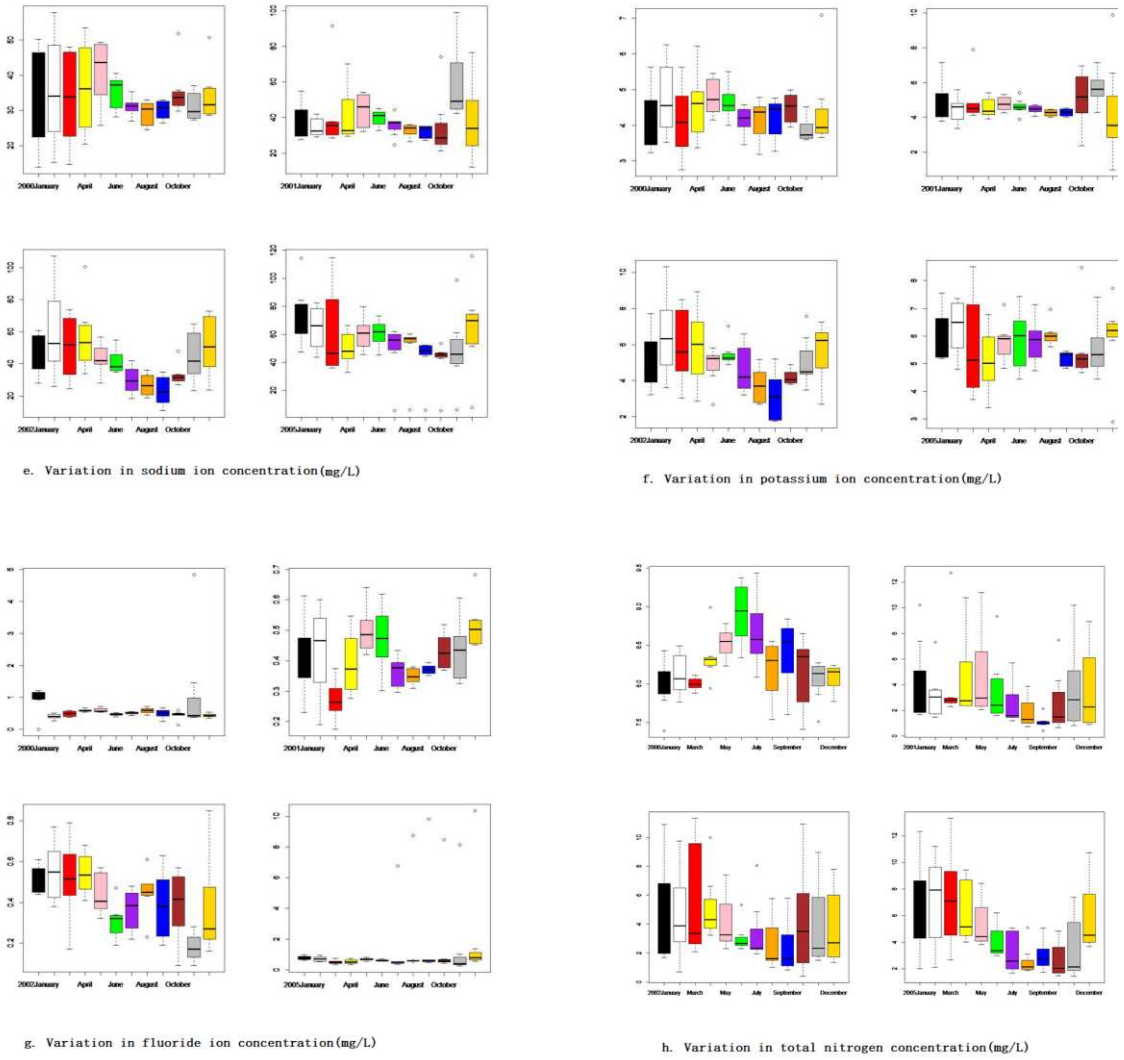

Figure 4-2. *Variation in different parameters' values by study year*

Formation of NH3-N is due to a lack of oxygen during the conversion of ammonia to nitrate. Over the study period, the NH3-N concentration varied from 0.001 mg/L to 6.95 mg/L, with an average of 0.10 mg/L. The NH3-N concentration was high during autumn and winter (*Fig. 4-3i*) and has increased in recent years in Taihu Lake; this is directly related to the lack of oxygen in the water caused by eutrophication of the water body.

PI is commonly used as a comprehensive indicator of the degree of contamination of surface water by organic and inorganic matter. The PI values ranged from 2.69 to 13.6 over the study period. In 2000, the PI concentration was low but exhibited relatively large variation in the following years (*Fig. 4-3j*). In addition, in 2005, the PI concentrations were relatively high.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1424114258

ALKY indicates that a water body contains a substance that can accept hydrogen ions. The ALKY of Lake Taihu in summer and autumn was lower than in winter and spring (*Fig. 4-3k*). Over the study period, the minimum value was 0.147, with an overall upward trend in recent years and a peak value of 3.35. The temperature in the Taihu Lake basin is relatively high in summer and autumn. When there are large numbers of plants, microorganisms will produce acidic substances that neutralize some alkaline substances. Additionally, the use of coal for heating in the winter and spring seasons has greatly increased.

EC trends were consistent from 2000 to 2005 (*Fig. 4-3l*). In the spring and summer, as temperature increased, so too did EC. During the wet season, EC decreased due to density loss.

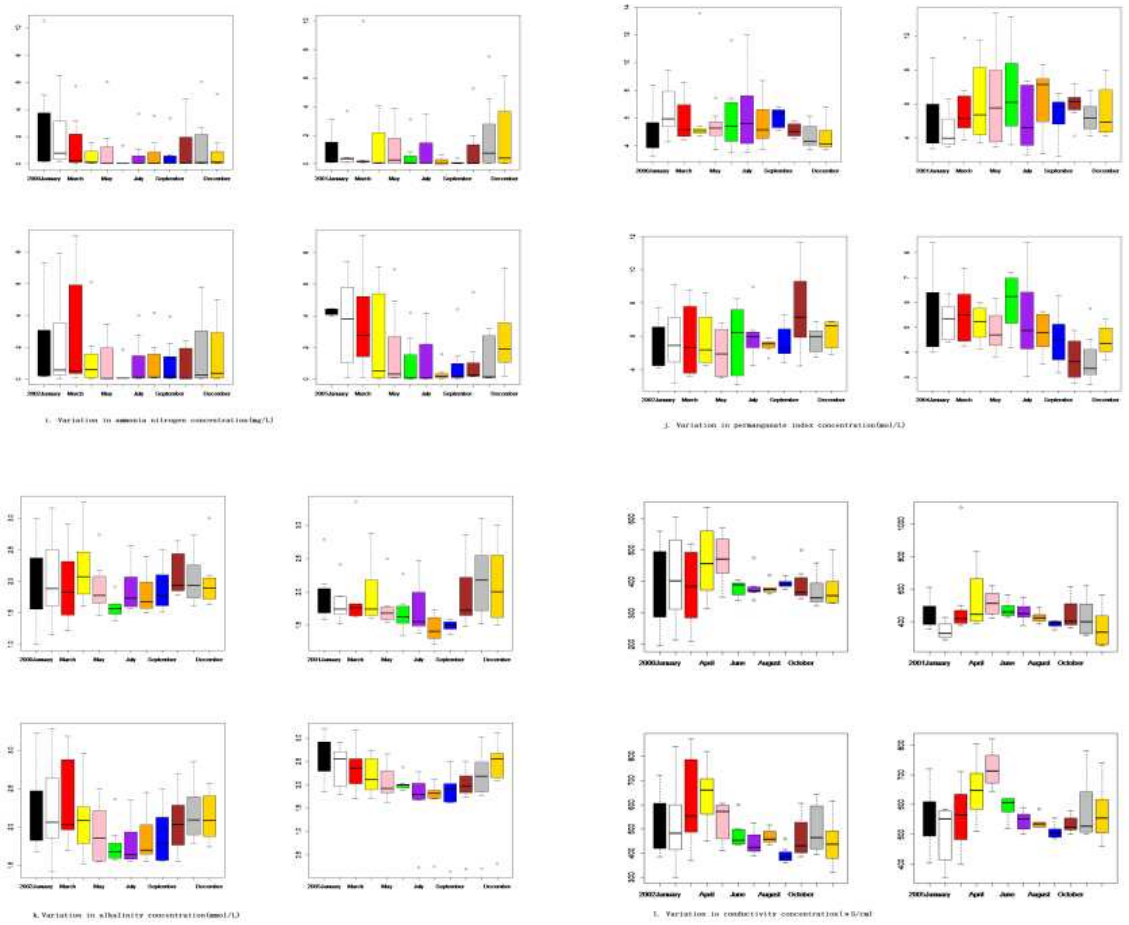

Figure 4-3. *Variation in different parameters' values by study year*

Difference in the water quality index over time

Differences in water quality parameters in Taihu Lake from 2000 to 2005, except for 2003 and 2004

Of the 23 chosen water quality indicators, 4 exhibited little variation over the study period, while 4 exhibited significant variation (*Table 5*). The factors affecting water quality showed similarities as well as differences; the difficulty of assessing water quality can be reduced by focusing only on the factors exhibiting significant changes.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1424114258

Water quality index

The main factors influencing water quality, as calculated by the RBF network algorithm, PCA and SI algorithm, were included in the water quality index formula. This yielded a simple water quality index based on single water quality parameters, and a comprehensive index - water quality identification index of water samples which is the worst water quality index (*Table 6*).

Table 6. *Water quality index*

Model number	Feature(s)	Evaluation result
1	Single index – TP	IV
2	Single index – K	V
3	Single index – SO4	V
4	Single index – SiO	V
5	Single index – TN	V
6	Single index NN	IV
7	Single index – PI	II
8	Comprehensive index - water quality identification index	V

Discussion

The sum-squared error graphs (*Fig. 5*) show the total epochs (iterations) required for the function to converge on TP, SO4, SiO and Ca. The red line indicates the ideal objective function evolution curve, and the blue line represents the objective function curve. Graphs of TP, total SO4, SiO and K were produced using BP-GA. 40 epochs (iterations) were required for TP, SO4, SiO and Ca to converge (*Fig. 5*). In *Figure 6,* the blue line indicates the ideal fitness evolution curve, and the other line indicates the actual fitness evolution curve. The fitness of individuals tends to plateau after 70 generations, indicating that they have reached fitness. *Figure 7* shows the performance of each model. The goal is set to 1e-028. All parameters reach their goals at 5 epochs (iterations).

The error rate of the RBF algorithm used to assess the water quality of Taihu Lake in this study was compared to those of other prediction methods (Random Forest and LASSO) applied to the same data sets. The RBF network data were more accurate than those of the other methods. Under identical conditions and using the same data sets, the error rate was 0.032 for the RBF network, 0.093 for Random Forest, and 0.352 for LASSO. Random Forest is commonly used to make predictions and its results are generally accurate; however, the RBF method used in this study was significantly more accurate (*Table 7*).

Table 7. *RBF model error rate compared with other methods*

Method	RBF network	Random forest	LASSO
Error rate	0.032	0.093	0.352

Conclusions

This study proposed a lake water quality assessment method based on an RBF network, SI and PCA. The method is suitable for water quality assessment of large areas over a long period and can identify the most important factors damaging water quality via a comprehensive evaluation. Water quality can be evaluated over time and space and evaluation indexes comprising single and multiple factors can be generated, which avoids over-generalization and better reflects the overall water quality.

The water quality of Taihu Lake for the period 2000 to 2005, except for 2003 and 2004 was between Grade 4 and Grade 5. Thus, water quality satisfied established standards based on our evaluation results. Future water quality control and protection efforts directed toward Taihu Lake should focus on improving management and supervision, as well as water treatment technology; such treatments are expected to improve the water quality of Taihu Lake.

The major environmental issue affecting Taihu Lake concerns control of pollution sources, particularly of Cl-, sulfides, etc. Control of pollution sources is a prerequisite for managing eutrophication in the lake. Ensuring safe drinking water requires point and non-point source pollution control, including a reduction in pollution from sewage. And adjustment of industrial practices and environmental management policies are necessary.

In this study, we investigated the factors affecting the quality of Taihu Lake in the view of data miner. But it is really important to find the very pollution sources, the process in which pollution sources affect the water quality and the cause of pollution sources.

SUPER-RESOLUTION RECONSTRUCTION OF CROP DISEASE IMAGES BASED ON DEPTH LEARNING

WANG, X.

College of Teacher Education, Pingdingshan University, Pingdingshan 467000, China
(e-mail: aaabbbw211@126.com)

(Received 3rd Jun 2019; accepted 11th Oct 2019)

Abstract. Current image reconstruction has some problems, such as low image segmentation and denoising precision, slow convergence speed, and poor image integrity after reconstruction. In this regard, this study proposed a super-resolution reconstruction of crop disease images based on deep learning. The improved neighborhood averaging method is used to denoise the low frequency subband image, and the enhanced wavelet coefficients are replaced by the wavelet inverse transform to realize the high frequency subband image denoising. The image enhancement results are introduced, and the image initial segmentation area is obtained by using the color roughness concept and the incremental region growth method. When the stop condition is satisfied, the best result is presented. The small feature extraction of image segmentation results is carried out, and the feature vectors are transformed from low resolution space to high resolution space by nonlinear mapping. Feature extraction, nonlinear mapping and image reconstruction are fused into a deep convolution neural network, and the final reconstruction results are obtained. The experiment showed that the method improves the image segmentation and denoising precision, and that the integrity coefficient of the image reconstruction is high and the reliability is strong.
Keywords: *reconstruction, wavelet inverse transform, image denoising, nonlinear mapping*

Introduction

The determination and control of crop diseases and insect pests play an important role in the development of agriculture in China. In actual production, most farmers only rely on experience and their own senses to diagnose crop diseases. Although it has achieved some results, it also has harmed the growth status of crops (Burgess et al., 2017). Therefore, early diagnosis is the key to accurately identify disease. It is not scientific to achieve the accurate recognition of all kinds of diseases only by human visual observation and experience (Gao et al., 2017; Fu and Liu, 2017). The symptoms of common crop diseases are mainly expressed by the color and texture of leaves (Mo et al., 2018; Kniat, 2017; Sanchez et al., 2017). At present, the treatment of agricultural diseases is mainly through expert diagnosis, and then taking corresponding measures (Wei, 2017). The symptoms of some diseases are not obvious at the initial stage, their symptoms become more pronounced with time, enabling precise diagnosis. This delays prevention and the time treatment can begin. The symptoms of some diseases are similar to those of other diseases. At this time, the experts have difficulties confirming the diagnosis, and other auxiliary methods should be used. Based on the research situation of crop diseases and insect pests, the following outstanding research results have appeared (Roy et al., 2018; Nongqwenga and Modi, 2017).

Mao et al. reconstruct the SEM (Sitemap) image by using the image edge gradient information. It used Kirsch operator to analyze the gradient information of the image, and then classified each region by using the feature that the gradient of the outer edge of the image is greater than the gradient of the inner edge, and filled the final image according to the statistical information. Experimental results showed that this method has high stability and high automation in high-resolution images, but the accuracy of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1425914275

image segmentation is not enough, resulting in image reconstruction effect is not very ideal (Mao and Shi, 2016). Song proposed the 3D (3 Dimensions) reconstruction of images based on compressed sensing. By establishing the mathematical model of the image reconstruction of the SRM section, the principle of the algebraic reconstruction is analyzed. Based on the analysis of ART (Algebra Reconstruction Technique), SART (Simultaneous Algebraic Reconstruction Technique) and SIRT (simultaneous iterative reconstruction technique) method and its iterative formula, the CSART (compressive sensing Algebra Reconstruction Technique) algorithm combining the compressed sensing theory with ART is put forward to test the SRM (Switched Reluctance Moto) structure simulation model. According to the obtained projection data, several algorithms are analyzed and compared. The results showed that the CSART algorithm has the fastest convergence rate, but the reconstructed image integrity is not guaranteed (Song, 2016). Yu proposed a Tabu search based image reconstruction of capacitance tomography. The Tabu algorithm is referenced to the ECT (Emission Computed Tomography) image reconstruction. By constructing the target function, the neighborhood and Tabu table are set to constrain the image reconstruction. The image reconstruction problem is converted to the global optimal solution based on the contempt criteria and the ad hoc criteria and used termination criteria to jump out of Tabu Search. The simulation results showed that the reconstructed image is more fidelity, but the speed of reconstruction is slower (Yu et al., 2016). Li proposed the super-resolution image reconstruction based on support vector machine. The sparse characteristic of the image block is calculated, and the sparse representation coefficient is obtained. Then the sparse representation coefficient is used to train the support vector machine, and the super-resolution image reconstruction model is established. Finally, the simulation is used to analyze its performance. The results showed that the method can effectively maintain the speed of reconstruction, but the noise in the image is larger (Li, 2016). Guo proposed the super-resolution image reconstruction based on wavelet denoising and neural network. The wavelet transform is used to remove the noise in the image, improve the image quality, and obtain the learning samples needed for the network training. The learning samples are trained by neural network, and the artificial fish swarm algorithm is used to determine the key parameters of the neural network. Finally, the effectiveness of the super-resolution image reconstruction algorithm is tested, and its superiority is analyzed by comparison experiment. The experimental results showed that the proposed method can achieve an ideal image denoising effect, but there is also a low segmentation precision (Guo and Cen, 2016).

At present, there are various problems in image reconstruction methods of crop diseases, so we proposed to use deep learning to reconstruct super-resolution images of crop diseases. It can solve the problem that the traditional method does not accurately classify images. The detailed structure is as follows:

1. Using the improved neighborhood averaging method and the wavelet inverse transform respectively, the low frequency subband image and the high frequency subband image are de-noised to improve the image quality.
2. The initial segmentation area of the image is obtained by using the concept of color roughness and the incremental region growth method. Then the initial segmentation region is classified and merged to achieve high precision segmentation.
3. According to the application process of deep learning, we combine small feature extraction, nonlinear mapping and image reconstruction into a deep

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1425914275

convolution neural network system, and get the final disease image super-resolution reconstruction results.
4. Experimental results and analysis to verify the effectiveness of the reconstruction.
5. Discussion.
6. Summarize the content of the full text and look forward to the future.

According to the above method, the problem that the human eye cannot distinguish the pests and diseases of similar crops can be avoided, the accuracy of the identification of pests and diseases is effectively improved, and the economic benefit is improved.

Materials and methods

Image enhancement of crop disease

In order to effectively remove impulse noise in crop disease image, wavelet transform can be used to decompose the noisy image into low frequency subband and high frequency subband image, and then process them separately.

In the low frequency subband image denoising, the improved neighborhood averaging method is used to filter the low frequency subband image after the wavelet transform. Assuming that the gray value of pixels of crop disease pixels is $w(i,j)$, then the fuzzy distortion can be reduced as far as possible in the denoising process, so that the gray mean value of the original pixel in the window is as follows:

$$\overline{w(i,j)} = \begin{cases} w'(i,j) \left| w(i,j) - w'(i,j) \right| > T \\ w(i,j) \quad else \end{cases} \tag{Eq.1}$$

Among them,

$$w'(i,j) = \frac{1}{MN} \sum_{i=1}^{M} \sum_{j=1}^{N} w(i,j) \tag{Eq.2}$$

where $w'(i,j)$ representative is centered on the pixel $w(i,j)$, the size is the average value of pixels in a window of $M*N$, and T represents the adaptive threshold. M and N represent the length and width of the window, respectively.

According to the calculation of *Equations 1* and *2,* the improved neighborhood averaging method is used to filter the low frequency subband image after the wavelet transform, and the denoised image is obtained as follows:

$$f(x,y) = \frac{1}{M*N} * \frac{\overline{w(i,j)} * T}{w'(i,j) * \kappa} \tag{Eq.3}$$

Among them, $f(x,y)$ represents the image of crop disease after the low-frequency subband image denoising, and κ represents the image enhancement parameters.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1425914275

In the high frequency subband image denoising, considering each subband image in a certain direction, so the horizontal high frequency subband image is filtered by the horizontal window, vertical high frequency subband image is filtered by vertical window, high frequency subband images is filtered by using a shaped window (Giuliani et al., 2016). The local energy method of pixel neighborhood is used to judge the pulse noise point, and the point which is larger than the local energy is regarded as the impulse noise point.

Taking the 3*3 window as an example, the pixel $w(i,j)$ neighborhood of the crop disease image is shown in the following case, as shown in *Figure 1*.

	$(i-1,j)$	
$(i,j-1)$	(i,j)	$(i,j+1)$
	$(i+1,j)$	

(a)

$(i-1,j-1)$		$(i-1,j+1)$
	(i,j)	
$(i+1,j-1)$		$(i+1,j+1)$

(b)

Figure 1. *Pixel* $w(i,j)$ *neighborhood of crop disease image*

When the image pixel $w(i,j)$ neighborhood of the crop disease image pixel in the case of *Figure 1a,* the local energy in the neighborhood of the pixel $w(i,j)$ is:

$$E_1(i,j)=\left|\begin{Bmatrix}2[w(i,j)-w'(i,j)]^2-[w(i-1,j)-w'(i,j)][w(i+1,j)-w'(i,j)]-\\[w(i,j-1)-w'(i,j)][w(i,j+1)-w'(i,j)]\end{Bmatrix}\right| \quad \text{(Eq.4)}$$

When the image pixel $w(i,j)$ neighborhood of the crop disease image pixel is in the case of *Figure 1b,* the local energy in the neighborhood of the pixel $w(i,j)$ is:

$$E_2(i,j)=\left|\begin{Bmatrix}2[w(i,j)-w'(i,j)]^2-[w(i-1,j+1)-w'(i,j)][w(i+1,j-1)-w'(i,j)]-\\[w(i-1,j-1)-w'(i,j)][w(i+1,j+1)-w'(i,j)]\end{Bmatrix}\right| \quad \text{(Eq.5)}$$

According to *Equations 4* and *5,* the local energy $E(i,j)$ of the center pixel of the crop disease image center in the neighborhood window is to select the maximum value of $E_1(i,j)$ and $E_2(i,j)$ as follows:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1425914275

$$E(i,j)=\max\left[E_1(i,j),E_2(i,j)\right] \quad \text{(Eq.6)}$$

It is assumed that the local energy threshold in the neighborhood window is as follows:

$$TH=\frac{k}{M*N}\sum_{i}^{M}\sum_{j}^{N}E(i,j) \quad \text{(Eq.7)}$$

The k in *Equation 7* represents the empirical constant. Then it is possible to judge whether a point is a pulse noise point.

$$E(i,j)>TH \quad \text{(Eq.8)}$$

The pulse noise of the satisfying *Equation 8* is filtered out by a median filter. An adaptive wavelet threshold is set as follows:

$$TH_l=C_h\sigma_l\sqrt{\frac{2\log l+1}{l}}*2^{\frac{l+1}{2}} \quad \text{(Eq.9)}$$

Among them, l represents the decomposition scale, C_h represents the constant, h value is 1, 2, 3, respectively, which indicates that the horizontal and vertical directions are all high frequency sub-band images, the horizontal direction is the high frequency subband image and the vertical direction is the low frequency subband image, and the horizontal direction is the low frequency subband image and the vertical direction is the high frequency subband image. σ_l represents the standard deviation of the image noise of crop diseases at various scales, and the wavelet coefficients within each sub window of each scale are as follows:

$$\sigma_l=\left\{\frac{TH_l}{M*N}*\sum_{i}^{M}\sum_{j}^{N}w'(i,j)-E\left[w_l'(i,j)\right]\right\}^{\frac{1}{2}} \quad \text{(Eq.10)}$$

Among them, $E\left[w_l'(i,j)\right]$ represents the mean value of the medium and small wave coefficients of each sub window.

Based on the above content, the wavelet coefficients are obtained by using the wavelet soft threshold function to get the enhanced wavelet coefficients.

$$\eta\left[w(i,j)\right]=\operatorname{sgn}\left[w(i,j)\right]\left[\left|w(i,j)\right|\right]*\sigma_l*\left|TH_k\right| \quad \text{(Eq.11)}$$

Among them, η represents the enhanced wavelet coefficients. The setting of the coefficient can effectively improve the effect of image enhancement.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1425914275

According to the enhanced wavelet coefficients obtained by *Equation 11,* the image $f'(x,y)$ of high frequency sub-band crop disease after de-noising is obtained by using the inverse wavelet transform *Equation 11.*

$$f'(x,y) = E(i,j) * TH_k * \frac{\eta[w(i,j)]}{TH} \quad \text{(Eq.12)}$$

Image segmentation of crop disease

According to the image enhancement results of crop disease, the image segmentation algorithm of crop disease is realized by using the image segmentation algorithm of color and image spatial information. The image used in the segmentation is color image, and the whole process is divided into initial segmentation and hierarchical region merging.

The initial segmentation of the image is done by color quantization and incremental regional growth, which will be described in detail below. In order to make the algorithm for the definition of color distance conforms to the human visual characteristics, we choose LUV color space, and the color distance is measured by Euclidean distance (Lal et al., 2016).

For color quantization, it is assumed that a crop disease image contains M windows of $w_1 * w_2$, and each window contains n pixels. S_m represents the roughness of the image color, which is used to represent the intensity of the color change in the current window. The color quantization series of the current image is determined by the average color roughness S_{avg} of the entire image. There are:

$$S_m = \left(\frac{1}{n} \sum_{i=0}^{n-1} \left\| \vec{x_i} - \vec{x}_{mean}^{(m)} \right\| \right)^{\frac{1}{2}} * f'(x,y) \quad \text{(Eq.13)}$$

$$S_{avg} = \frac{1}{M} \sum_{i=0}^{M-1} S_m \quad \text{(Eq.14)}$$

where $\vec{x_i}$ represents the color of the i pixel in the $w_1 * w_2$ window, $\vec{x}_{mean}^{(m)}$ represents the mean color in a window, and $\|\cdot\|$ represents the Euclidean distance. Based on *Equation 14,* the quantity of the color quantization of a crop disease image is calculated by using *Equation 15.*

$$N_{Quan} = \beta * S_{avg} + 1 \quad \text{(Eq.15)}$$

Among them, β represents the image color quantization threshold, depending on the accuracy of image segmentation, it can be divided into high, medium and low grades, respectively, and is set to 2, 1, and 0.5, respectively.

After determining the number of color quantization, we use vector quantization to divide the crop disease image pixels into color space, and get the image $\gamma(x,y)$ after color quantization. The formula is as follows:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1425914275

$$\gamma(x, y) = VQ * \sqrt{\frac{N_{Quan}}{w_1 * w_2}} \quad \text{(Eq.16)}$$

Among them, VQ represents vector quantization.

Being divided into the same class of pixels in the color space does not necessarily belong to the same region (Olafsson et al., 2017). These color-classified pixels also need to combine space information to form meaningful segmentation areas. An incremental regional growth algorithm is used to discover the spatial connectivity between pixels. The pixels that conform to the following conditions to form the seed region are defined as:

1. The color is the same after the color is quantified.
2. Four neighborhoods are connected in space.
3. Connected pixels reach a certain area (according to the segmentation precision (that is, high, medium, low), set the original image area of 0.001%, 0.01% and 0.1% respectively).

The pixels in the image that are not in the seed region will be allocated by a regional growth method to the region that is adjacent to the color and is the closest to the color. For a seed area, if the newly grown pixels meet the following conditions, the algorithm divides the newly growing connected pixels into an independent new seed area. A new region growing method, which can generate new seed regions in growth process is defined as incremental region growing. This growth algorithm is more conducive to some details in the process of growth.

1. The newly grown pixels are connected in the four neighborhoods in space.
2. The average distance between the newly grown pixels is less than the average distance between the pixels and the current region.
3. The newly grown connected pixels reach the requirement of the seed area. (According to the segmentation accuracy (high, middle and low), they are set to 0.001%, 0.01% and 0.1% of the original image area, respectively).

Through the above calculation and analysis, regional merger is carried out. After the initial segmentation, there are still a lot of similarities between the regions (Katsevich and Katsevich, 2017). The ensemble is combined by a hierarchical region merging algorithm to merge the divided area, and an automatic stop region merging rule is proposed.

For region merging, region distance measurement is an important criterion for region merging. Distance metric determines the result of region merging and the final segmentation result of image. This study considers that the necessary conditions for merging two regions are: two regions are similar in color and adjacent in space, and there is no significant edge on their adjacent areas (Pagnanelli and Borgesneto, 2016). Then the edge, color and adjacency information are fused, and *Equation 17* gives the distance definition of the two regions.

$$D_{ij}^{r} = \left(D_{ij}^{c}\right)^{p} * \left(D_{ij}^{e}\right)^{q} * \Delta_{ij} * \gamma(x, y) \quad \text{(Eq.17)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1425914275

Among them, p and q are used to adjust the color distance and the distance from the edge of the effect size threshold, Δ_{ij} represents the adjacency relation, that is, the existence of adjacency relation between representatives of r_i and r_j, there is relationship between adjacent assumptions, the Δ_{ij} value is 1, whereas the value is $+\infty$, and the region distance is $+\infty$. D_{ij}^c and D_{ij}^c represent the color distance and edge distance of two regions, defined as *Equations 18* and *19*.

$$D_{ij}^c = \frac{|r_i| * |r_j|}{|r_i| + |r_j|} * \|\mu_i - \mu_j\| * \sqrt{D_{ij}^r} \quad \text{(Eq.18)}$$

$$D_{ij}^e = \frac{1}{|E_{ij}|} \sum \|x_a - x_b\| * \sqrt{D_{ij}^c} \quad \text{(Eq.19)}$$

Among them, $|r_i|$ and $|r_j|$ represent the number of pixels contained in the i region and the j region, μ_i and μ_j represent the two regional color mean, and the $\|\mu_i - \mu_j\|$ represents the Euclidean distance. The product of the molecular part $|r_i|$ and $|r_j|$ in *Equation 18* is beneficial to the priority merging of the cell domain, making the segmentation results more consistent with the visual characteristics of the masses. E_{ij} represents the pixels on the edge of two regions, and $|E_{ij}|$ represents the number of pixels on the edge. x_a and x_b represent the color values of the a and b points on both sides of the edge, respectively.

For the initial segmentation area, the classification region merging algorithm is used to complete the final segmentation. That is, each time we merge the two regions with the closest distance in the image, form a new area, and the adjacency and distance between the new area and other regions will also be adjusted.

In the process of regional merger, it is a very critical question when to stop the regional merger to get a reasonable combination result, and directly decide the result of image segmentation (Wu et al., 2016). The threshold method is used to terminate the region merging, and the merging is affected by the distance between the local regions. The threshold selection also needs to be adjusted according to different images. It is necessary to manually adjust the number of regions according to different requirements, using the method of specifying the number of areas to terminate the merger. Considering the relationship between the information loss in the process of image merging and the number of areas retained in the image, a new automatic stopping region merging criterion is proposed. The detailed process is as follows:

A function that represents the color divergence of the image region is defined to indicate the degree of disunity of the total color in each region of the image. When the area of the image is merged to K, the color divergence can be defined as:

$$J = \frac{\sum_{r=0}^{K} J_w^r}{J_t} = \frac{\sum_{r=0}^{K} \sum_{i=0}^{N_r} \left\| x_i^r - x_{mean}^r \right\|}{\left\| x_i^r - x_{mean}^r \right\|} \quad \text{(Eq.20)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1425914275

where J_w^r represents the color divergence within a region, and J_t represents the total color divergence in the image. N_r represents the number of pixels in the r region, and x_i^r represents the color value of the i pixel in the r region, and x_{mean}^r represents the color mean of the r region.

Each initial region that defines an image contains only one color, and the color value of all the pixels in each region is equal to the mean color of the region. At this point, the region color of the image is 0, that is, $J=0$. With the continuous consolidation of the region, that is, the K continues to decrease, and the region color dispersion of the image is increasing in J. When all areas in the image are merged into one area, J is 1. Assuming that k_l represents the number of remaining regions in the merging process, the relationship curve between J and k_l is shown as shown in *Figure 2.*

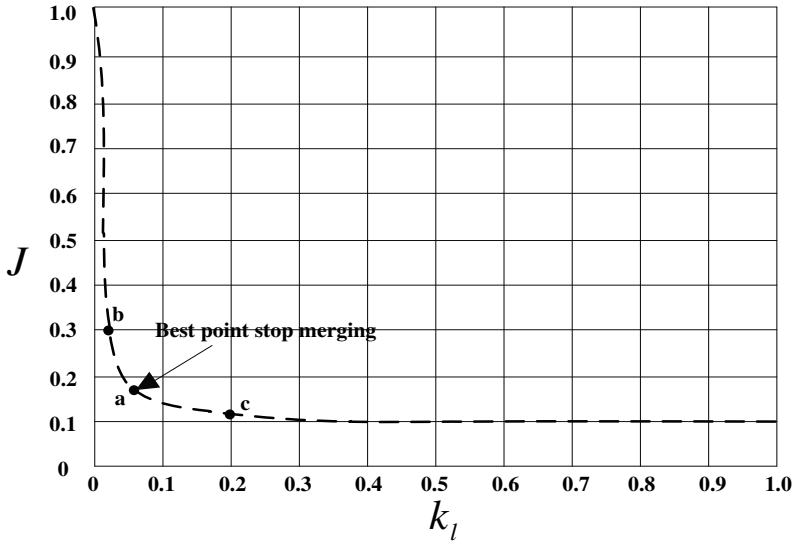

Figure 2. *Relation curve between* J *and* k_l

As shown in *Figure 2,* from the point of view, it is hoped that the least area can be used to represent the information in an image, that is, the smaller the better the k_l. From the point of view of the segmentation, the smaller the better the information loss in each region after the segmentation, that is, the smaller the area of the image is, the smaller the J, the better. The two values cannot be minimized at the same time, because each area merge will cause the increase of J. In order to get the most reasonable segmentation results, the minimum value of $J+k_l$ is obtained, that is, the ratio of reserved regions and the color dispersion J of the image area to achieve the best compromise when the k_l is terminated. According to the above analysis, the best combination point in *Figure 2* is a.

According to the above calculation and analysis, the optimal segmentation results are as follows:

$$F(x,y)=\min\left(k_l+J\right) \quad \text{(Eq.21)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1425914275

Super-resolution reconstruction of crop disease images

Deep learning is a new field in machine learning research. Its motive is to establish and simulate the human brain's analysis and learning neural network. It simulates the mechanism of human brain to interpret data, such as image, voice and text (Zhou et al., 2016). Based on the image enhancement of 2.1 and the image segmentation of 2.2, the high resolution reconstruction of the crop disease image is realized by the depth learning method. The concrete process of reconstruction is as follows.

Small feature extraction and representation: it is the first layer of network. The operation will input low resolution image Y to extract small blocks densely, and use high-dimensional feature vectors to represent small blocks. The equivalent is to convolution the image through a set of filters. Assuming that the first layer, the small block feature extraction result is set to F_1, by using the image segmentation of 2.2, F_1 can be expressed as:

$$F_1(Y) = \max(0, W_1 \partial Y + B) \quad \text{(Eq.22)}$$

Among them, W_1 and B represent the bias vector of the filter combination neuron, and ∂ represents the convolution operation. Suppose that d represents the number of channels to enter crop disease image. f_1 represents the spatial size of a single filter, and n_1 represents the number of filters. The size of W_1 is $d * f_1 * n_1$.

Through the calculation of *Equation 22,* n_1 dimensional feature vector were extracted from each image block, in the second layer nonlinear mapping, each high dimensional vector is mapped to a vector of another dimension n_2, that is, to transform feature vectors from low resolution space to high resolution space, the output characteristics is $F_2(Y)$. Then the mapping results of the second layers can be expressed as:

$$F_2(Y) = \max(0, W_2 \partial F_1(Y) + B_1) \quad \text{(Eq.23)}$$

Among them, W_2 represents convolution kernel, B_1 represents a n_2 bias vector, and each output n_2 dimension vector represents the reconstructed high resolution block.

Using the above calculation, the image block reconstruction layer is reconstructed to form the output image after the mapping. The average can be considered as a predefined filter on a set of feature images, thereby defining the following reconstruction layer to produce high resolution images:

$$F(Y) = W_3 \partial F_2(Y) + B_2 \quad \text{(Eq.24)}$$

where W_3 contains d linear filters, and B_2 represents a bias vector with a dimension of d.

Convolution neural network is essentially a mapping from input to output. It can learn a lot of mapping relationships between input and output without any precise mathematical expression between input and output (Salehi et al., 2017). Therefore, as

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1425914275

long as the convolution network is trained with a known pattern, the network has the ability to map the input and output. The purpose of the convolution neural network is to estimate and optimize the parameters in essence. From the above, the parameters that need to be trained can be expressed as $\theta = \{W_1, W_2, W_3, B, B_1, B_2\}$. When the error between the reconstructed image $F(Y;\theta)$ and the real image X is small, the optimal solution of the parameters can be obtained.

A set of original crop disease image $\{X_i\}$ and its corresponding low resolution image set $\{Y_i\}$ are given, and the loss function is used to indicate the error between them. The mean square error (MSE) is considered to represent the loss function $L(\theta)$. As shown in *Equation 25:*

$$L(\theta) = \frac{1}{n}\sum \left\| F(Y;\theta) - X_i \right\|^2 \quad \text{(Eq.25)}$$

According to the calculation by *Equation 25,* we can see that the error between original crop disease image $\{X_i\}$ and its corresponding low resolution image set $\{Y_i\}$ is the smallest, that is, when the loss function is minimum $\min L(\theta)$, the image reconstruction accuracy of crop disease is the highest. The result of the final image super-resolution reconstruction using the minimum loss function is as follows:

$$Best(X,Y) = \min L(\theta) * \left(\{X_i\} \Leftrightarrow \{Y_i\} \right) * \varpi * \vartheta \quad \text{(Eq.26)}$$

Among them, ϖ represents the threshold of super resolution reconstruction for crop disease image, which is controlled between 0.4-0.5. After image reconstruction, integrity is kept the best and the reconstruction result is the best. ϑ represents the speed factor of the image reconstruction convergence speed, which can improve the speed of image reconstruction efficiently.

Results

In order to verify the effect of reconstruction, the experiment was completed by the contrast of different image reconstruction methods. Taking into account the fairness of comparison, the experiment used a data set of a domestic agricultural production base on crop disease image as a training sample, and the experimental platform was built on Matlab7.0. After training the samples, the experimental objects were tested with the trained parameters, this result is obtained from a real agricultural planting shed and *Figure 3* is the test sample.

According to the experimental platform and the experimental data, the experiment is carried out under the following experimental indexes.

1. Image enhancement effect of crop disease, that is, image clarity.
2. The accuracy of image segmentation.
3. The integrity of the reconstructed image.
4. The convergence rate of image reconstruction.

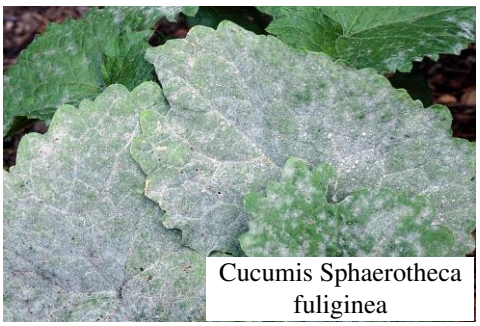
http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1425914275

Figure 3. *Test examples*

The experimental results are as follows:

Figure 4 showed that image reconstruction based on support vector machine has low clarity and low color division, and texture area is poor. The image reconstruction method based on depth learning is very effective, the texture is clear and the color is distinct. The overall definition of the image is better than the image reconstruction method based on support vector machine.

(a) Image enhancement effect based on support vector machine image reconstruction



(b) Image enhancement effect based on deep learning image reconstruction

Figure 4. *Enhancement of image reconstruction with different image reconstruction methods*

According to the analysis of *Figure 5,* the image segmentation accuracy of image reconstruction based on edge gradient information is gradually low with the increase of image number. The maximum segmentation precision is 56% and the lowest is 33%, which indicates that the reliability of the method is low. The image segmentation accuracy based on wavelet denoising and neural network image reconstruction has a downward trend, the maximum segmentation precision is 63%, and the lowest is 50%.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1425914275

The image segmentation precision curve of the image reconstruction method based on depth learning is increasing gradually, the maximum segmentation precision is 96% and the minimum segmentation precision is 75%, which is more reliable compared with image reconstruction method based on the edge gradient information.

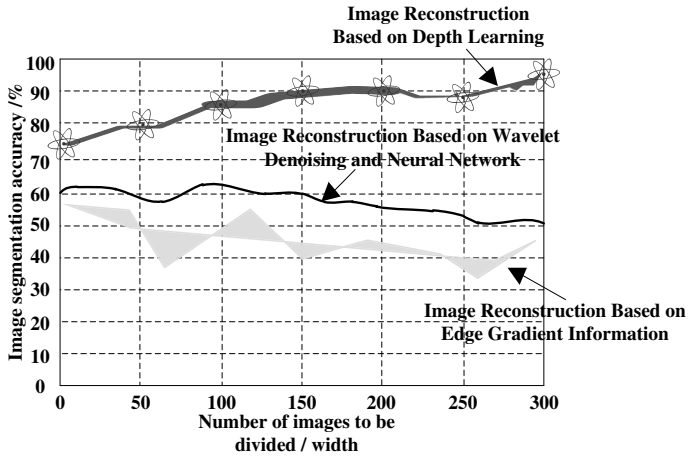


Figure 5. *Image segmentation precision comparison of different image reconstruction methods*

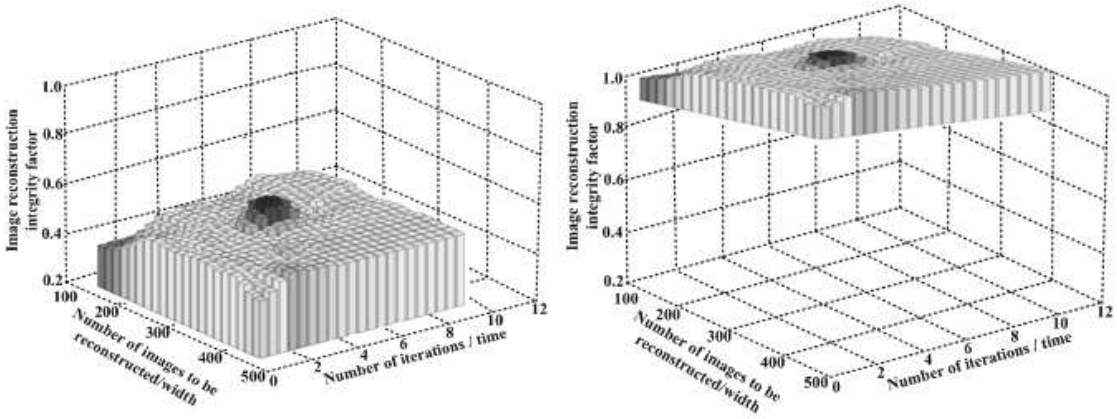
From the contrast result of *Figure 6,* we can see that the integrity coefficient of image reconstruction based on compressed sensing is low, the highest is 0.48. This data indicates that the integrity of image reconstruction is not guaranteed. The integrity coefficient of the reconstruction method based on depth learning is 0.98 and the lowest is 0.7. According to the data comparison, it is obvious that the image reconstruction based on depth learning can be practicable and useful for reference.



(a) Integrity of image reconstruction based on compressed sensing

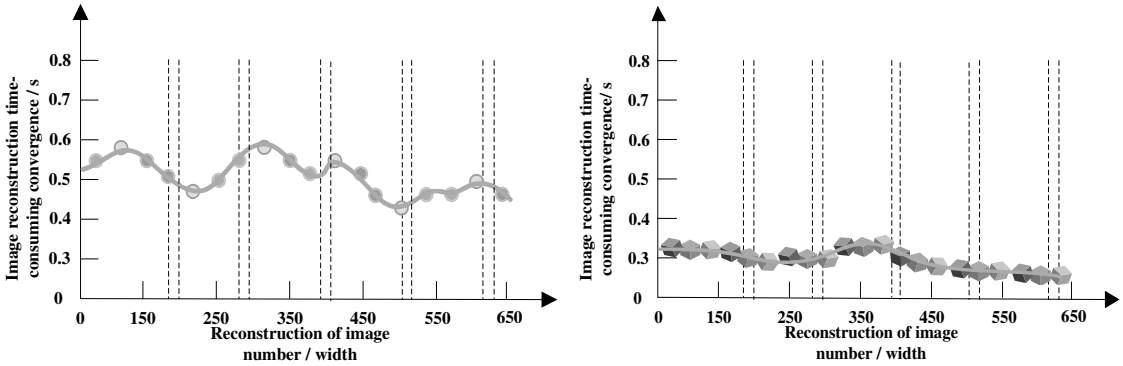
(b) Integrity of image reconstruction based on deep learning

Figure 6. *Reconstruction integrity comparison of different image reconstruction methods*

In *Figure 7,* the time-consuming curve of the image reconstruction convergence based on Tabu search showed an unstable state, which is fluctuate up and down, and the average convergence time is about 0.5 s. The time-consuming curve stability of the image reconstruction based on depth learning is better, the maximum time of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1425914275

convergence is 0.35 s, and the time of average convergence is 0.3 s. Compared with the two image reconstruction methods, the time dependent data is convergent, and the image reconstruction method based on depth learning occupies a significant advantage and is reliable.



(a) Time consuming of image reconstruction based on Tabu Search

(b) Time consuming of image reconstruction based on deep learning

Figure 7. *Time consuming comparison of reconstruction of different image reconstruction methods*

The identification of crop diseases is accurately compared, and the results are as follows:

Analysis of *Figure 8* shows that the accuracy of the identification of disease and insect information in three different methods is different. The accuracy of this method is significantly higher than the other two methods, and has a high promotion value.

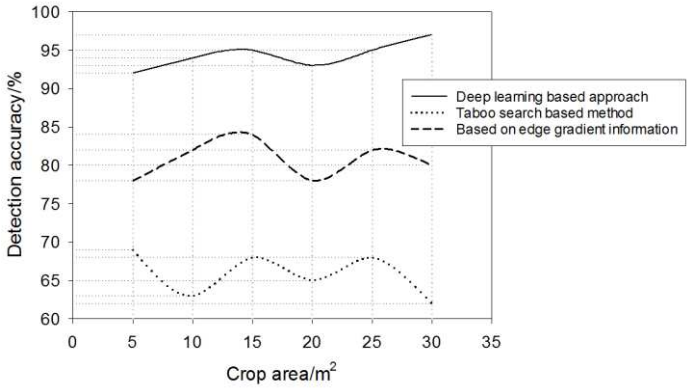


Figure 8. *Comparison of information recognition accuracy under different methods*

Discussion

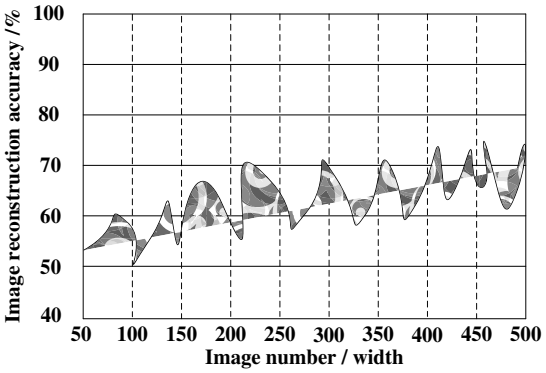
In the discussion part, the ϖ threshold of super resolution reconstruction of crop disease image is used to observe and verify the influence of the value range on the super resolution reconstruction of crop image.

In order to make the results of the discussion more comprehensive, the ϖ values of 0.3, 0.4 and 0.45 are considered as the scope of discussion, respectively. The discussion environment is selected as follows: Intel (R) Core (TM) i5-3210M CPU@2.50 GHz;

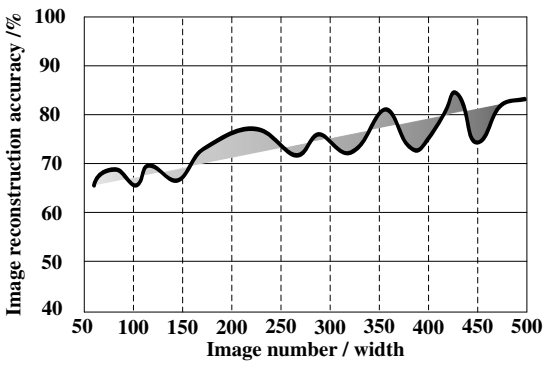
http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1425914275

6.00 GB memory; Win7x64; Matlab; Caffe. And the Matlab interface of Caffe is used to achieve image super resolution reconstruction.

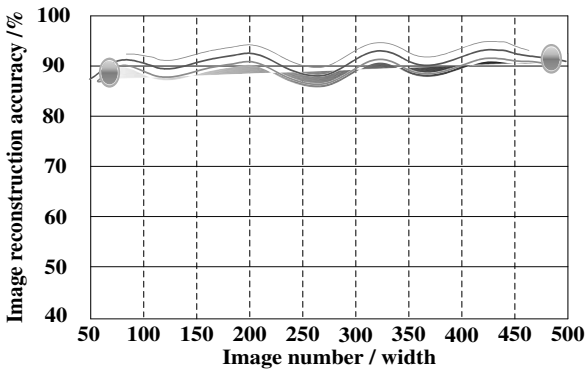
The graphs in *Figure 9* represent the effects on image reconstruction when the ϖ values are 0.3, 0.4, and 0.45.



(a) Image reconstruction accuracy when ϖ is 0.3



(b) Image reconstruction accuracy when ϖ is 0.4



(c) Image reconstruction accuracy when ϖ is 0.45

Figure 9. *The impact of different values of* ϖ *on image reconstruction results*

According to the results of *Figure 9,* we can see that when ϖ is 0.3, the accuracy of image reconstruction is 73%, and the accuracy of reconstruction accuracy is not good, but it shows a rising trend. When the ϖ is 0.4, the accuracy of image reconstruction is obviously superior to that of when ϖ is 0.3, the precision of the reconstruction is 83%, and the whole fluctuation of the precision curve is stable. When the ϖ is 0.45, the accuracy of the image reconstruction is the highest and the transformation of the precision curve is the smallest. When the reconstructed image is 425, the reconstruction precision is 95%. The above data show that when ϖ is 0.45, the image reconstruction results are most significant.

Conclusions

At present, there are many problems in the algorithms and methods of image reconstruction. In order to solve these problems, an image super-resolution reconstruction based on deep learning is proposed. Image reconstruction is completed by three links of image enhancement, image segmentation and image reconstruction. In the process of image reconstruction, the speed of reconstruction and the accuracy of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1425914275

reconstruction are the difficult problems. In order to solve such problems, the threshold of image super-resolution reconstruction and the speed factor of image reconstruction convergence are set up respectively. Two parameters are used to control the accuracy and speed of the reconstruction. The effectiveness of the proposed image reconstruction method is verified by experiments and discussions. It is also proved that the threshold of reconstruction and the speed of convergence play a very important role in the whole process of image reconstruction, which effectively solves the problems of image reconstruction.

In the future, the efficiency of image reconstruction will be further studied while compressing reconstruction costs.

Abstract. Landscape sensitivity is one of the ways that give us the opportunity to exhibit ecology-based approaches to the world we live in. Landscape sensitivity refers to areas where landscape is sensitive to natural or human-based pressures. This study aims to develop a model for revealing and mapping the landscape sensitivity of Duzce province in Turkey. The model was developed by evaluating four parameters (ecologic process). These are erosion risk, landslide susceptibility, water infiltration and habitat fragmentation. Within the scope of the study, sensitivity data related to each parameter has first been formed within the framework of expert opinions and then all data has been analyzed by ArcGIS 9.3 software and a Duzce Province Landscape Sensitivity Map has been produced. When the landscape sensitivity map obtained within the scope of the model is evaluated, it is seen that the sensitivity in 38.6% of the area is low while it is medium with 30.6%, very low with 21.7%, high with 8.2% and very high with 8.2%. These findings are easily visualized on the map. As a result, the landscape sensitivity map produced is a data that is compatible with ecological principles, produced by scientific methods, compatible with technological tools and can be integrated with similar analyses. In addition it is an important element to develop ecological based decisions related to the space. Therefore, its usage as a basis map for spatial planning is a need beyond desire.
Keywords: *ecological sensitivity, vulnerability, risk analysis, suitability analysis, land use decision, landscape planning*

Introduction

The coexistence of nature and man is an existential necessity. Indeed, there is no other space in the known universe where human beings can survive. On the other hand, nature has no such obligation. For nature can realize its cycle on its own. Such that, the quite short history of mankind in the world is the clearest indication of our need for nature and not its need for us. In the simplest sense, man is born and raised within nature; he grows up and builds his culture and civilization there. However, human beings' disposition on nature varies according to historical periods (İlboğa and Aygül, 2015). This differentiation has been rapidly moving towards a humanistic approach that sees nature as an object exploitable for its own interests and commodifies it. Scientists who realized this strived to reveal the discomforts caused by this commoditization process and to identify its sensitivity to solve the problems. Landscape sensitivity is one of the studies conducted in this context.

The landscapes arose from the unity of man and nature. The landscape is a combination of rocks, surface deposits, soils, plants, animals, people, etc. together with the earth itself, and each of these is a component of the landscape. The landscapes do not only contain objects, they also include dynamic earth surface systems. In this context, they are energy and material stores maintained with growth, decay, flow and transformation processes. The landscapes exhibit spatial mosaics forming a "complex

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1427714296

combination" at different characters and scales on the earth's surface (Thomas, 2001). In this context, the landscape is a heterogeneous land area consisting of similarly replicated and interrelated ecosystem clusters, i.e. habitat patches (Forman and Godron, 1986; Dunning et al., 1992; Turner et al., 2001; Boström et al., 2011). While maintaining growth, decay, flow and transformation processes of landscaping, the landscape is also dynamical earth surface systems containing not only objects but also energy and material stores (Thomas, 2001). The landscape which consists of many superimposed environments or components is the semiotic interface between sources and organisms, and it is shaped by ecological processes (Farina, 2001, 2008; Farina and Pieretti, 2012). In fact, landscaping refers to two natural systems (physical and biological) and processes that constitute this system. Physical systems are composed of landform, surface deposits, rock components and are formed as a result of processes such as rock erosion and sediment transportation etc. Biological systems are composed of plants, animals and people, and have many ecological processes. Soil is the other component of landscape which these two systems closely interact with. In short, landscaping is an area on which action, interaction and various relationships between natural and/or cultural resources take place (Demir, 2019). Therefore, it is a dynamic and multidimensional concept.

With its components and ecological processes, the landscape has become key to defining the relationship between nature and human beings, and the common evolution between natural and human processes (Mazzino and Burlando, 2010). For, the landscape is the product of a long history of evolution that reflects the interactions of landscape, geology, topography, climate, geomorphologic processes and their transformations over time (Gordon and Sutherland, 1993). All aspects of landscaping (ecological, economic, social) also arise with historical processes (Turner, 2018). This process is in fact related to the history of Quaternary. The history of the Quaternary has evidence related to the occurrence rate of natural processes (especially geomorphologic processes) and plant communities' response to both climatic changes and improvements. Furthermore, this evidence provides information on the development of the natural environment before and after the human impact (Gordon and Sutherland, 1993). This information provides important clues to the understanding landscape formation and change. These clues can contribute to the identification of red lines related to human life in the landscape. As Usher (2001) argues, human is also a part of this landscape and as natural as plants, but due to its non-conscientious nature, it is necessary to determine its boundaries of movement in the landscape, to provide the nature with an opportunity to renew the nature and to ensure its sustainability. In this context, it is very important to determine the landscape sensitivity, in other words to determine the sensitive areas in the landscape. The result is an open system; any interference from outside may affect this structure. These effects on the landscape can be realized in such a way as to contribute to the sustainability of the landscape or change its very structure (Steffen et al., 2011; Lewis and Maslin, 2015).

Landscape sensitivity is not easy to define. It requires considering the main natural systems that determine the landscape, its structure and the processes that change these natural systems (Usher, 2001). Based on this idea, the concept comes from geomorphology (Miles, 2001). Biostasisve and rexistasis concepts used by Erhart in 1955 to define the transition from biogeochemical equilibrium to the conditions of erosion and clastic sedimentation that refer to the basic idea of landscape sensitivity concept. However, the "landscape sensitivity" concept was first used in 1979 by

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1427714296

Brunsden and Thornes to help think about geomorphological systems and understand especially episodes of erosion and sedimentation (Thomas, 2001). The first definition of the concept of landscape sensitivity was as "landscape's capacity to absorb the effects of changes and disturbances." Since then, the meanings of landscape sensitivity have been constantly explored and developed (Chia et al., 2019). For example, landscape sensitivity is expressed as the ratio of change in a system in a landscape component. The higher the ratio is, the greater is the sensitivity (Usher, 2001). Due to perturbations in controlling environmental processes, landscape sensitivity is defined as conditional instability in the system with the possibility of a rapid and irreversible change. It has also been used to describe the response of landscape systems to perturbations at different time and spatial scales (Thomas, 2001). Landscape sensitivity was also defined as landscape's exposure to external stressors of the natural components of the landscape and thus, their capacity to change or to be affected or harmed (Aretano et al., 2015; Kesoretskikh et al., 2015).

Usually, there is a need for landscape sensitivity for three reasons. These include: (i) determining which environmental conditions require a major change in the landscape; (ii) identifying which parts of the landscape are affected in what proportions; (iii) demonstrating how long the transition of landscape features will be before the semi-equilibrium state is reached (Knox, 2001). For, the landscape can give different responses to anthropogenic pressures or ecological processes. As stated by Brunsden, when a landscape is in a state of stability with respect to controlling environment and its minor perturbations, the change will be incremental and at rates that allow mutual readjustment between all the components of the landscape complex. But when instability results from increases in the magnitude and rate of stress applied to landscape components, a period of readjustment will take place, as the various subsystems respond by attempting to establish new equilibria. These equilibria will not be attained if the frequency of high magnitude events, enough to cause further disturbance, is greater than the 'relaxation time' of the system. The stability of ecosystems has been considered both in terms of their resistance to displacement by disturbing forces, and their ability to recover after disturbance (Thomas, 2001). At this point, it is important to distinguish between concepts of sustainability/adaptive capacity, resilience and vulnerability in understanding landscape sensitivity. Sustainability or adaptation capacity is the capacity of a system to withstand external influences/pressures, to manage the risks and effects, to respond to the challenges by developing effective approaches, and to adapt (Turner et al., 2003; Damiano et al., 2014; Kesoretskikh et al., 2015). Resilience is defined as the ability of a system to improve, reorganize and develop against stresses and disturbances (Aretano et al., 2015). Resilience can also be expressed as the capacity to adapt (Vaillant et al., 2016). Vulnerability is generally referred to as sensitive landscapes' exposure to the stressor and their inability to absorb the change and failure to adapt. In this context, vulnerability has three primary components: exposure to the stressor, sensitivity to a range of stressor variability, and resilience following exposure (Adger, 2006; Birkmann and Wisner, 2006; Golobič and Žaucer, 2010; Damiano et al., 2014; Aretano et al., 2015; Campbell et al., 2016; Vaillant et al., 2016; Menezes et al., 2018). In this context, low adaptation capacity and resilience increase the landscape sensitivity. High sensitivity and these areas' failure to adapt due to constant pressure causes vulnerability. Therefore, the relationship between sensitivity and vulnerability is very important in understanding the process.

The aim of this study is to reveal the landscape sensitivity based on ecological processes and to identify the sensitive areas. In addition, the properties and importance of sensitivity maps are revealed.

Materials and methods

Study case

The study was conducted in Duzce province in the Black Sea region located in 64685.081-613754.468 and 572602.468-766623.408 UTM coordinates (ED-1950-utm-zone 36N) (*Fig. 1*). The study area covers approximately 2487 km^2 area, and this area constitutes 0.3% of Turkey (Tatar, 2003; Anonymous, 2019a). Water resources, vegetation cover, rich biodiversity and ecologically sensitive qualities were effective in determining the study area.

Figure 1. *The location of the study area*

The study area has a landscape view surrounded by the plain of Duzce near the south-west border and mountains in the north, south and east. Approximately 14.5% of the area is Duzce plain and its 85.5% is mountainous areas surrounding this plain. The mountain heights are 1388-1380 in the south and east, and they reach to the Black Sea as the heights reduce northward. The mountains are generally divided into deep valleys (Tatar, 2003). 64.2% of the area has more than 20% slopes. Urbanization and settlements are concentrated in Duzce plain and other plains due to high slopes. The flat areas are located in the plateaus in the mountains, Duzce plain and Black Sea coasts (Anonymous, 2000). The area is located in North Anatolian Fault line, 1st-degree seismic zone. It has 22 various rock formations with different names such as sandstone, shale, conglomerate, siltstone, limestone, ophiolitic rocks, granite, gabbro, tuff,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1427714296

andesite, basalt, agglomerate, gneiss, metagranite, amphibolite, migmatite, marble, phyllite etc. Duzce plain is covered with thick and loose alluvium (Anonymous, 2002; Tatar, 2003). The hydrological structure of the area consists of 6 large streams, ranging in length from 4.5 km to 17 km; 7 natural lakes, reservoirs, groundwater and geothermal resources (Anonymous, 2019a). 79.8% of the area is in VI., VII. and VIII. degree land use capability class which have limited agricultural potential. Most of the fertile agricultural land is located in Duzce plain (Anonymous, 2010). The study area is located in the flora of Euxine and Xsero-Euxine transition zone and the vegetation cover is very rich. In the area, there are 14 taxon rare plants located under 11 families. There are also 66 endemic species. 5 of them are in critically endangered (CR), 2 in endangered (EN), 3 in vulnerable (VU), 12 in near threat (NT) and 44 in the least concern (LC) category. The area is ranked 15th in terms of its forest density. In addition, there is one protection area (430 ha), four nature parks (340.71 ha), 4 natural monuments (10 ha) and 3 wildlife development areas in the study area. The wildlife in the area is also very rich (Anonymous, 2019a). According to the climatic parameters of the area, the average annual temperature is 13.2 °C, the average humidity is 77.5% and the rainfall is 87.7 mm/month (Anonymous, 2019b). 50% of the area is forest and heathland, 30% is agricultural area, 9% is other areas (settlement, industry, etc.) and 1% is meadows and pastures (Anonymous, 2019a).

Duzce province has 7 districts, 279 villages and 2 towns. The population of the area in 2018 is 387844. Its population has increased by 65.4% from the day it became a province in 2000 (130632). The number of people per square kilometer in Duzce is 156 (Anonymous, 2019c-d). The economic structure the area is based on tourism, agriculture and industry. Due to the widespread forests, the study area is rich in the forestry industry and has also developed rapidly in other industrial areas as well thanks to industrial incentives to support development in the aftermath of 1999 earthquake. In 2017, in order to protect agricultural areas against urbanization and industry, Duzce Plain and its vicinity were declared agricultural protection sites. The most important issue to be mentioned about the agricultural activities in Duzce is the transformation of forest areas into hazelnut agricultural area for years (Anonymous, 2019a). Furthermore, the Büyük Melen Dam still under construction is planned to cover 75% of the water demand of Istanbul, which is 170 km away. The project was prepared in 1997 and construction started in 2001, the first phase was completed in 2007 and the work is still in progress (Anonymous, 2019e). The project is significant since it is the largest water supply project in Turkey. In this context, the study area is a very important drinking water basin.

The study area has an ecologically sensitive structure. The earthquake, landslide, erosion, flood and habitat fragmentation clearly reveal this fact. One of the most important examples is 17 August and 12 November 1999 earthquakes in 7.4 and 7.2 density according to the Richter scale. In these earthquakes, approximately 18 thousand 374 people were killed, and 48 thousand 901 people were injured (Anonymous, 2019d). There are also natural disaster risks such as mass movements, landslides, and floods along with earthquakes. Mass movement around the Duzce basin is widespread due to its abundant rainy climatic characteristics and geological and geomorphologic structure. In 1998, various mass movements occurred due to excessive precipitation. In this context, Duzce-Akçakoca Highway in Yazlık Dere, Melen River basin in the north of Cumayeri and Almacık Mount slopes are areas with landslide risks (Özaslan et al., 2001). In this context, it is stated that 12.8% of the area has high risk, 21.7% has high,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1427714296

23.6% has medium, 16.8% has low, and 15.6% has very low landslide susceptibility. Furthermore, data on 9.5% of the area has not been produced (Anonymous, 2016). There is no significant difference between the north and south of Duzce in terms of landslide susceptibility. In the central part, landslide sensitivity is quite low. The main reason for this is the increase in height and slope as progressed north and south from the middle section. The landslide susceptibility is increased along the Çilimli Fault and the Duzce Fault in the East-West direction along the North Anatolian Fault. The landslide sensitivity is high on the slopes facing the north, northwest and northeast. A little more rainfall on the north-facing slopes makes the sensitivity higher. The landslide sensitivity is high on slopes with 10-30% inclination. Vegetation is often forest depending on climate and recently transformed into hazelnut areas; thus, the natural balance of the slopes deteriorates and the landslide sensitivity increases (Kocabaş, et al., 2016). The rivers in the study area are mainly in the form of meanders and are quite twisted and the stream beds are very shallow. This situation constitutes the flood risk for Duzce basin (Özaslan et al., 2001). As a matter of fact, flood incidents that caused considerable loss of property occurred in 1995, 1997 and 1998, and similar cases are experienced every year (Tatar, 2005). Also, 21.4% of the area has very severe, 18.2% has severe, 11.4% has medium; 19.5% has mild and 29.5% has very mild erosion risk (Anonymous, 2018). The human spread in the area (urbanization, industrialization, transportation, etc.) ignoring the habitats causes habitat fragmentation (Aydın et al., 2016), threatening both forest areas and biodiversity.

Materials

The main material of the study is composed of the maps, which are evaluated in order to reveal the natural and cultural characteristics of Duzce province, and which are used to create the sensitivity map. The other study materials consist of institutional reports on Duzce province and the scientific literature on landscape sensitivity. Maps used in the study are:

- 1/25000 scale digital Duzce Topographic Map produced by The Ministry of Defense, the General Directorate of Maps in 2000 (Anonymous, 2000) and updated road network map based on this map.
- 1/25000 scale digital Duzce Geological Map produced by Ministry of Energy and Natural Resources, General Directorate of Mineral Research and Exploration in 2002 (Anonymous, 2002).
- 1/25000 scale Digital Duzce Soil Map produced by the Ministry of Agriculture and Forestry, General Directorate of Agricultural Research and Policies in 2008-2010 (Anonymous, 2010).
- 1/25000 scale digital Duzce Forest Management Map produced by the Ministry of Agriculture and Forestry, General Directorate of Forestry in 2008 (Anonymous, 2008).
- 1/25000 scale digital Duzce Landslide Susceptibility Map produced by the Ministry of Internal Affairs Disaster and Emergency Management in 2016 (Anonymous, 2016).
- 1/125000 scale Duzce Erosion Risk Map produced by the Ministry of Agriculture and Forestry in 2018 (Anonymous, 2018).
- In the study, ArcGIS 9.3 software was utilized to create some thematic maps and sensitivity maps.

The theoretical basis of methods

As Brunsden states, landscape sensitivity should be sought in landscapes resistance against and their responses to the forces of change (Thomas, 2001). Barabas et al. (2014) defined the sensitivity analysis as the examination of how ecological variables of interest respond to changes in external conditions. Usher (2001) emphasized that starting to think primarily about the landscape; the main natural systems that determine the structure of the landscape; and then about actions that change the natural systems are the best ways to determine sensitivity. In addition, it was also emphasized that changes and their magnitudes have both spatial and temporal components and that these components are an integral part of the sensitivity (Usher, 2001). In this context, to determine the sensitivity of landscape, some researchers are interested in related landscape components (inclination, aspect, proximity to water resources, etc.); some researchers consider ecological processes (erosion, landslide, desertation, climate change, habitat fragmentation, etc.); some others consider both as a combination parameter (Gordon and Sutherland, 1993; Thomas, 2001; Penghua et al., 2007; Mingwu, 2010; Wang and Bian, 2011; Aretano et al., 2015; Kesoretskikh et al., 2015; Bede-Fazekas et al., 2017; Haara et al., 2017; Hussain et al., 2018; Shi et al., 2018; Chia et al., 2019). The reason for the holistic evaluation of the parameters is that "anyone or more landscape components/ecological processes may be sensitive to change in certain situations and that the change in a component may trigger instability in any part of the system." For, the landscape is an intrinsically complex system, and the sub-systems can exhibit concurrent but opposite behaviours (Phillips, 1999; Usher, 2001; Thomas, 2001).

In the study, it was decided to conduct a sensitivity analysis based on the landscape processes including the components of the landscape. Landscape processes indicate a process depending on landscape components. Therefore, the analysis of processes will also allow the components to be analyzed at the same time. In addition, the spatial heterogeneity will be ensured, and excessive data will be avoided, and landscape systems will be evaluated with a reductionist approach.

Erosion risk, landslide susceptibility, water infiltration and habitat fragmentation processes were evaluated as parameters within the scope of the study. The efficiency of these processes and the existence of reliable spatial data related to these processes or the possibility of being produced were effective in the selection of the parameters and the landscape of the study area

The erosion sensitivity evaluated in the study is a parameter that has been evaluated since the first studies on landscape sensitivity (Thomas, 2001; Penghua et al., 2007; Mingwu, 2010; Wang and Bian, 2011). Erosion refers to the movement of upper soil due to various factors. Erosion is also important in terms of exploring the relationship between landscape pattern and ecological process. Landscape pattern, type of vegetation, soil properties, precipitation, etc. are some of the factors for erosion (Fu and Bruce Jones, 2013). In addition, as Thomas (2001) states, the soil has the clearest expression of landscape complexity, and it is sensitive to many landscape components such as rocks, precipitation, slope, aspect etc.

The landslide is another parameter that affects the landscape and is important for landscape sensitivity (Thomas, 2001). The landslide is a sudden mass movement of soil and substrate in the sloping areas. Landslides can cause many changes in landscape hydrology, vegetation cover, habitat, sediment load, biodiversity, organism movement, etc. Landslides, especially in mountainous landscapes, are one of the common problems

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1427714296

along with precipitation and steep slope and should be accordingly evaluated in sensitivity process (Walker and Shiels, 2013).

Water is an important component of life and hence, landscape. In this context, the hydrologic cycle is one of the important processes in the landscape. The water is in continuous motion inside atmosphere, hydrosphere and lithosphere layers. Precipitation water's passing through vegetation cover, soil and rock layers to reach the impermeable layers thanks to gravity and slope effects is called the water process in the landscape or landscape's water function (Karadağ, 2019). This infiltration of water is important for landscape sensitivity and is considered as a parameter (Aydın et al., 2018).

Habitat fragmentation is one of the other important sensitivity criteria in the landscape (Thomas, 2001; Penghua et al., 2007; Mingwu, 2010; Wang and Bian, 2011; Aretano et al., 2015; Bede-Fazekas et al., 2017; Chiet et al., 2019). For, habitat loss and/or fragmentation have been identified as perhaps the most important driving force of the global biodiversity crisis. Landscape connectivity is critical to the viability of many types of species (Forman and Godron, 1986; Cushman et al., 2010). Habitat fragmentation decreases disintegration, increases mortality and decreases genetic diversity (Cushman et al., 2010; Kosydar, 2014). In addition, the vegetation cover destroyed by habitat fragmentation ceases its duty to protect soil and water resources, (Babalık et al., 2019) and changes the landscape pattern. Landscape pattern is a concrete reflection of the spatial heterogeneity of the landscape (Penghua et al., 2007). It is also the result of ecological processes affecting different spatial and temporal scales (Bolliger, 2005).

Earthquake risk zones are not taken into consideration in the study. For, the whole area is within the 1st-degree earthquake zone.

Methods (data acquisition and analyses)

The study consists of three stages. These are; determination of parameters to be evaluated in sensitivity analysis; obtaining the parameter data and making the necessary analysis in this process; holistic analysis of selected parameters on the basis of sensitivity analysis (*Fig. 2*).

Düzce Erosion Risk map was obtained from the relevant unit of the Ministry of Agriculture and Forestry. The map was created by Revised Universal Soil Loss Equation (RUSLE) method. The average soil loss per year hectare with RUSLE method is generally determined by the holistic evaluation of six different parameters. These parameters are; rainfall-runoff erosivity, soil erosion erodibility, slope length, slope steepness and support practice. Erosion risk status in the map is classified as very severe, severe moderate, mild and very mild (Erpul et al., 2018). Also, erosion risk map has been considered as an erosion sensitivity map within the scope of this study. Because risk maps are produced in order to reveal the loss of life and property to be affected by the change in landscape. Therefore, in this study, erosion risk maps were used to determine areas sensitive to erosion. This classification was evaluated using a scale between 1 and 5 according to expert opinions. According to the evaluation, the areas with very severe erosion risk had 5 points (too high sensitivity) followed by severe with 4 points (high sensitivity); moderate with 3 points (medium sensitivity); mild with 2 points (low sensitivity) and very mild with 1 point (too low sensitivity). Later, these scores were added to the database of erosion risk maps with ArcGIS 9.3 software and an erosion sensitivity map was created.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1427714296

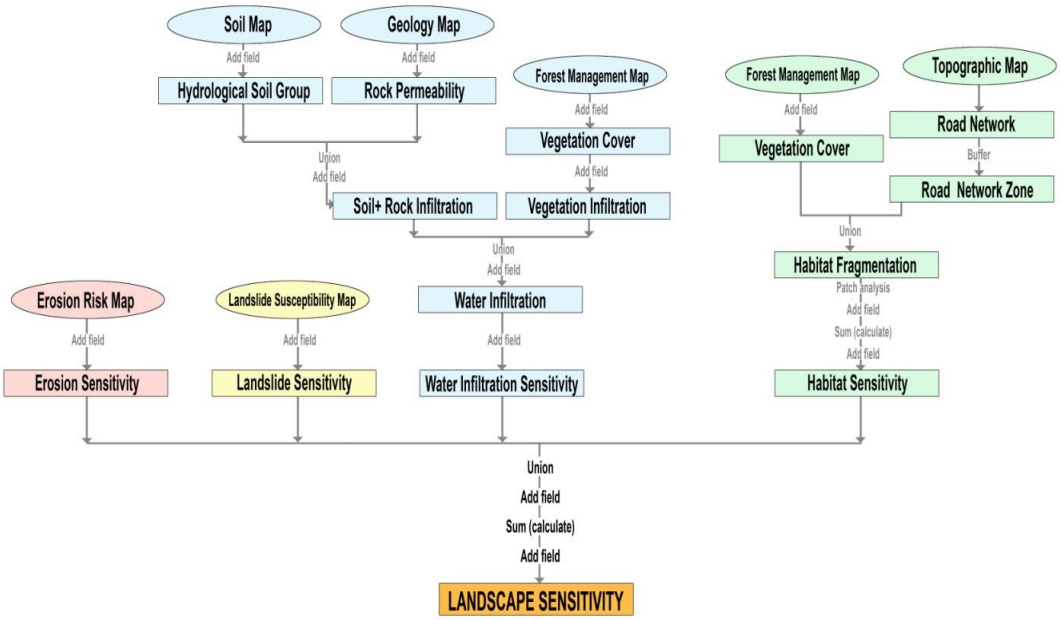

Figure 2. *Landscape sensitivity analysis model (parameters, data, and analysis process)*

Düzce Landslide Susceptibility Map was obtained from the relevant unit of the Ministry of Internal Affairs. The map was generated by the Frequency Ratio method. In this method, after the determination of the parameters which come out as a result of the field observations, the parameter maps and the landslide polygons are coupled. It provides the proportional landslide possibility in other areas based on the characteristics of the corresponding parameters. In determining landslide sensitivity, lithology, height, curvilinearity, aspect and slope were considered holistically. Landslide susceptibility status is classified as very high, high, medium, low, very low on the map (Kocabaş et al., 2016). This classification was evaluated by using a scale between 1 and 5 according to 3 expert opinions. According to the evaluation, the areas with very high landslide susceptibility have 5 points (very high sensitivity); high areas have 4 points (high sensitivity); medium areas have 3 points (medium sensitivity), low areas have 2 points (low sensitivity) and very low areas have 1 point (very low sensitivity). These points were then added to the database of the landslide susceptibility map with the ArcGIS 9.3 software and a landslide sensitivity map was created.

Water infiltration map was created within the scope of the study. Water process analysis method was used to create the water infiltration map of the study area. Within the scope of the method, 1/25000 scaled digital soil map, geology map and forest management map were used (Anonymous, 2002; Anonymous, 2008; Anonymous, 2010). Hydrological soil groups from the soil map; the rock permeability from the geology map, vegetation cover from the forest management map, and then vegetation infiltration data were produced. These data are then were analyzed according to the water process analysis method used by Uzun et al. (2015) and Karadağ (2019), and water infiltration data were generated (*Table 1*). Then, hydrological soil groups and rock permeability data were evaluated by union analysis and soil + rock infiltration data were obtained in the first stage. In the second stage, this data was subjected to union analysis with vegetation infiltration, and water infiltration data consisting of five classes were formed. This map was then evaluated by using a scale between 1 and 5 according

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1427714296

to 3 expert opinions. According to the evaluation, areas with very high water infiltration have 5 points (very high sensitivity); high areas have 4 points (high sensitivity); medium areas have 3 points (medium sensitivity); low areas have 2 points (low sensitivity) and very low areas have 1 point (too low sensitivity). These points were later added to water infiltration map database with ArcGIS 9.3 software and a water infiltration sensitivity map was created.

A habitat fragmentation map was created within the scope of the study. The data obtained by using the patch-corridor-matrix model in the creation of the habitat fragmentation map of the study area were analyzed and interpreted by the Patch Analysis 4 software, an interface of ArcGI9.3 developed by Rempel (2010). In this context, Düzce Forest Management Map was used, and vegetation cover data were prepared from this map. In this data, the forest cover was examined and four spots (coniferous forest, leafy forest, mixed forest and pasture) were defined. The data were subjected to union analysis with the road map in order to reveal the fragmentation. The road map was prepared from 1/25000 scaled digital topographic map. However, before the analysis, 4 m effect zones were formed on the roads by way of proximity (buffer) analysis in order to involve the effects of the roads on the environment. The data obtained from the Union analysis were accepted as the base data of the habitat fragmentation. These data were then analyzed at class level with the Patch Analysis module, which was developed by Rempel (2010) as an interface to ArcGIS 9.3. The analysis was carried out in two stages. In the first stage, patch size and number, patch shape and edge properties of patches were determined by spatial statistics based on patch analysis. As a result of the analysis, No of Patches (NumP) Related to patch size and number, Class Area (CA) and Mean Patch Size (MPS), Mean Shape Index (MSI) related to patch shape, Mean Perimeter-area Ratio (MPR), Mean Patch Fractal (MPFD) values, and Edge Density (ED) values were obtained. In the second stage, core areas related to patches were determined on the basis of patch analysis. During the analysis, a 100 m edge zone was identified in order to assess fragmented forest edges and their effects on the living creatures in the inner habitats. Then, total core area (TCA), total core area index (TCAI) and Core Area Density (CAD) values were obtained by spatial statistics on the basis of patch analysis. All obtained spatial values were evaluated on the basis of the studies by Forman and Godron (1986), Rempel (2010) and Uzun (2012). In this context, the result was that "NumP increased, MPS and CA decreased, fragmentation decreased; MPAR and MSI values decreased, MPFD value closed to 1 and fragmentation decreased; ED increased, fragmentation increased; TCAI and CAD increased, fragmentation decreased." Decreased of that fragmentation was evaluated as an increase in sensitivity. For, in larger patches, biodiversity and forest cover is high and these areas should be considered a priority in conservation. In order to map this condition, first, the sensitivity status of each patch was scored between 1 and 5. Then, the scores obtained from these four parameters were totalized, and the habitat total sensitivity score was determined and reclassified. In this context, the total score for each patch from four parameters is maximum 20 and minimum 4. These scores are divided into five classes (very high, high, medium, low, very low) according to the sensitivity status. The range of points used in the formation of the classes was found to be about 3, calculated by "subtracting the lowest score from the highest, and dividing the sum into six." According to this assessment, areas with very high sensitivity have 20-19 points; high sensitivity have 19-16 points; moderate sensitivity have 15-12 points; low sensitivity have 11-8, and too low sensitivity has 4-7 points. Finally, by calculating the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1427714296

total scores obtained from four parameters of each patch, sensitivity scores according to the class range were determined. Then, the total habitat sensitivity score was calculated with ArcGIS 9.3, which was processed in a new field in the patch map database and a habitat vulnerability map was created. Uzun's (2012) study was used in the analysis and evaluation process.

The final analysis within the scope of the study is the union analysis performed to ensure a holistic assessment of all data, after the creation of the four data sensitivity parameters to be evaluated in the sensitivity analysis. Four data are subjected to union analysis. A new field is added to the database of the resulting map. Later, calculation of landscape sensitivity total score of each polygon is done with the following formula:

$$\text{Landscape sensitivity total score} = \text{Erosion sensitivity score} + \text{Landslide sensitivity score} + \text{Water infiltration sensitivity score} + \text{Habitat sensitivity score} \quad \text{(Eq.1)}$$

The total score of each polygon was written to the new field. Then the maximum and minimum scores are determined, and the difference is divided into six so that the sensitivity can be defined by a scale of 5 (sensitivity is very high, sensitivity is high, sensitivity is medium, sensitivity is low, sensitivity is very low). The score interval of these 5 classes is defined with the number obtained. Finally, the total sensitivity score received by each polygon is determined based on specific sensitivity state, and this detection is processed in the new data added to the database of the data obtained from the union analysis and a total sensitivity map is generated.

Results

In this study, firstly, data sensitivity parameter maps in *Figure 3* are produced. When the database of the maps was examined, the data given in *Table 1* was obtained.

When the erosion sensitivity map was examined, it was seen that the erosion sensitivity increases in the mountainous areas to the north of the area. In the southern and inner parts of the area, erosion sensitivity decreases (*Fig. 3*). When the erosion sensitivity map database was evaluated, it was seen that the sensitivity in 21.4% of the area was very high while it was high in 18.2%, medium in 11.4%, low in 19.5% and very low in 29.5% (*Table 1*).

Table 1. *Sensitivity (sen.) parameter areas in the study area, (%)*

Sensitivity degree	Sensitivity parameters			
	Erosion sen. area (%)	**Landslide sen. area (%)**	**Water infiltration sen. area (%)**	**Habitat sen. area (%)**
Very high	*21.4*	12.8	0.4	-
High	*18.2*	21.7	11.6	*33.1*
Medium	*11.4*	23.6	80.6	*3.4*
Low	*19.5*	16.8	4.2	*16.8*
Very low	*29.5*	15.6	3.2	-

When the landslide sensitivity map was examined, it was seen that the landslide sensitivity increases in the mountainous areas to the north of the area. This is due to the high slope, elevation, fault lines and habitat fragmentation in these areas. In the inner

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1427714296

parts of the area, landslide sensitivity is low (*Fig. 3*). When the landslide sensitivity map database was evaluated, it was seen that the sensitivity in 12.8% of the area was very high while it was high in 21.7%, medium in 23.6%, low in 16.8% and very low in 15.6% (*Table 1*). Data for 9.5% of the area was not produced

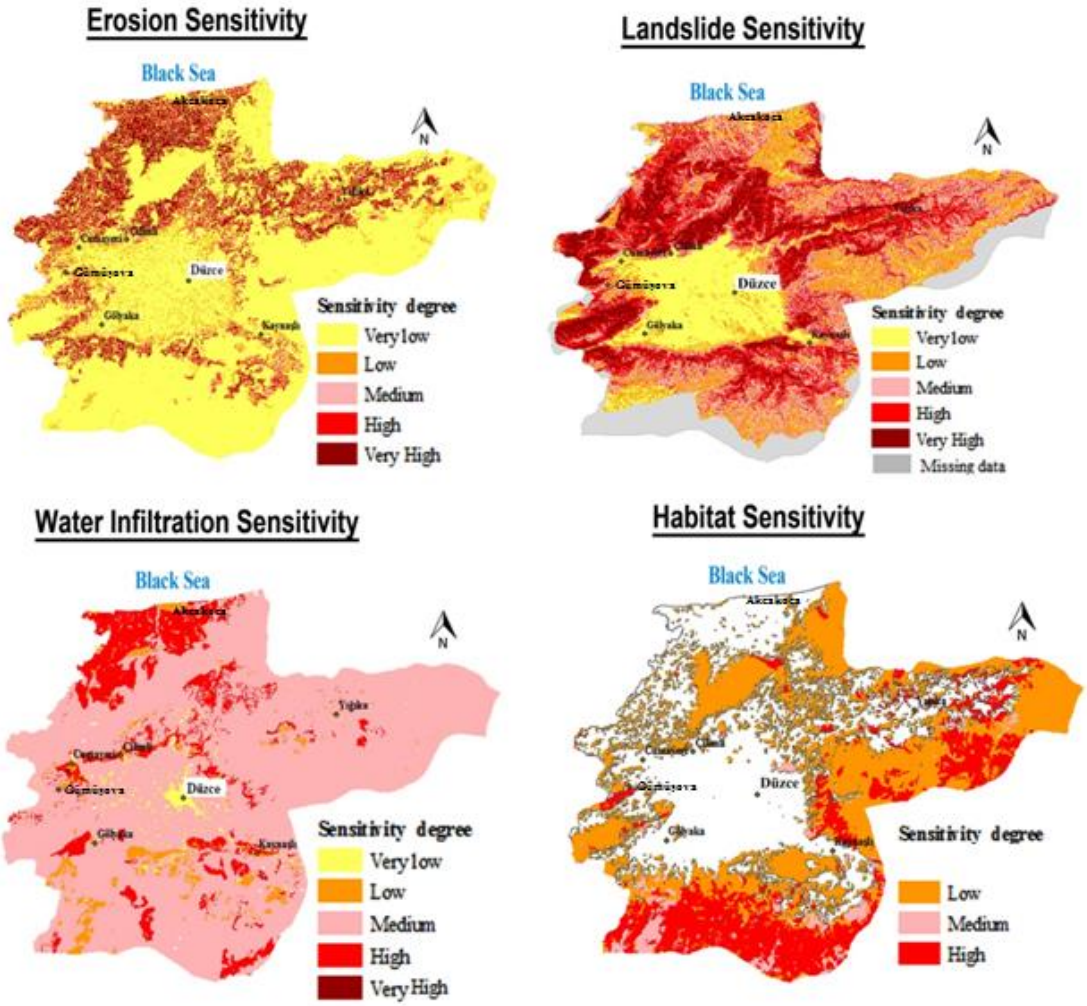

Figure 3. *Maps of landscape sensitivity parameters*

When the water infiltration sensitivity map was examined, it was seen that the water infiltration sensitivity in the area is generally moderate (except for residential areas/artificial surfaces). Only the Black Sea coast and from the coast to the inland increase sensitivity (*Fig. 3*). When the water infiltration sensitivity map database is evaluated, it was seen that the sensitivity in 0.1% of the area was very high while it was high in 11.6%, moderate in 80.6%, low in 4.5% and very low in 3.2% (*Table 1*).

The habitat sensitivity map of the area was produced based on vegetation cover. The habitat patches in the area were evaluated as "coniferous forest, leafy forest, mixed forest, pastures" and the breaks in these spots were analyzed based on conservation priority. In order to reveal the fragmentation in the patches, the destructive power of the roads was evaluated and a total of 3158 patches were detected in the area by union analysis. Patch size and number, patch shape, patch edge and core area parameters

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1427714296

related sub-criteria values were determined. These values were scored based on the studies by Forman and Godron (1986), Rempel (2010) and Long (2012) and expert opinions as the increase of fragmentation is accepted as a sensitivity-lowering effect; and mixed forests received 16 points, pastures 14 points, coniferous forests 12 points and leafy forests 10 points. When these scores were evaluated according to the sensitivity classification in the area, it was determined that mixed forests had high sensitivity while coniferous forests and pastures had moderate, and leafy forests had low sensitivity. When the habitat sensitivity map was examined, it was seen that the sensitivity decreased in the eastern and southern parts of the area. This situation shows that habitat fragmentation occurs in this area (*Fig. 3*). When the habitat sensitivity map database was evaluated, it was seen that the sensitivity in 33.1% of the area was high while it was low in 16.8% and moderate in 3.4% (*Table 1*). 46.7% of the area has not been evaluated as patch.

As a result of overlay analysis of four sensitivity parameter data related to the study area, Duzce Province landscape Sensitivity Map in *Figure 4* was obtained. When the sensitivity map database was examined, it showed that the maximum landscape sensitivity total score in the field was 18 and the min total score was 4. When scores are ranked according to their sensitivity, 16-18 points were considered very high sensitivity, 13-15 points were considered high, 10-12 points was considered moderate, 7-9 points was considered low and 4-6 points was considered very low. When the landscape sensitivity map database was evaluated, it was seen that the sensitivity in 38.6% of the area is low while it is medium with 30.6%, very low with 21.7%, high with 8.2% and very high with 8.2%. These findings indicate that 39.7% of the area is sensitive (medium, high and very high) (*Fig. 4*).

When the landscape sensitivity map is examined, it is seen that very low sensitivity areas are located in Duzce plain. In these areas, especially water infiltration has affected sensitivity. There are intense land uses like settlements, agriculture, and industry in these areas. Low sensitivity areas are located in the south and southeast of the area. In these areas, habitat fragmentation and water infiltration have affected sensitivity and the settlement is not dense. Medium sensitivity areas are spread throughout the study area. Erosion, landslide and water infiltration are effective in sensitivity in these areas. There are especially rural settlements and forests in these areas. High sensitivity areas are concentrated, especially located in the northwest of the area. In these areas, erosion, landslide and water infiltration sensitivity is high. Very high precision areas are located in the north of the area. These areas take up very little space in the area. Erosion, landslides, water infiltration and habitat sensitivity are high in these areas (*Fig. 4*).

Discussion

The deterioration of the ecological balance has been a common problem in the world since the industrial revolution. Many researchers in different disciplines have done various researches on this concept (Shi and Tong, 2019). Landscape sensitivity analysis is one of these studies.

Landscape studies has a significant public interest in cultural, ecological, environmental and social areas and is a resource that is conducive to economic activity and that can contribute to job creation, conservation, management and planning. In this context, it is one of the key elements of individual and social welfare (Anonymous, 2017). Therefore, understanding and recognizing the landscape is very important. In the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1427714296

process of recognizing and understanding the landscape, sensitive landscapes are very important. This is because sensitive landscapes are the most intensively associated with ecological-environmental changes and tend to be most prone to ecological problems (Forman, 1995; Hong et al., 2017). In this context, it is aimed to reveal areas which are sensitive to natural/anthropogenic factors, have a high potential for change under external factors and have priority in spatial development (Thomas, 2001; Shi et al., 2018; Chia et al., 2019). In this study, mapping of landscape sensitivity areas is the main objective. In this study, an ecology based sensitivity map has been created for spatial planning. This map is practical data for many occupational disciplines. Uzun et al. (2015), Demiroğlu (2016), Cengiz et al. (2017) and Karadağ (2019) emphasize that such practical data is necessary for ecology-based planning.

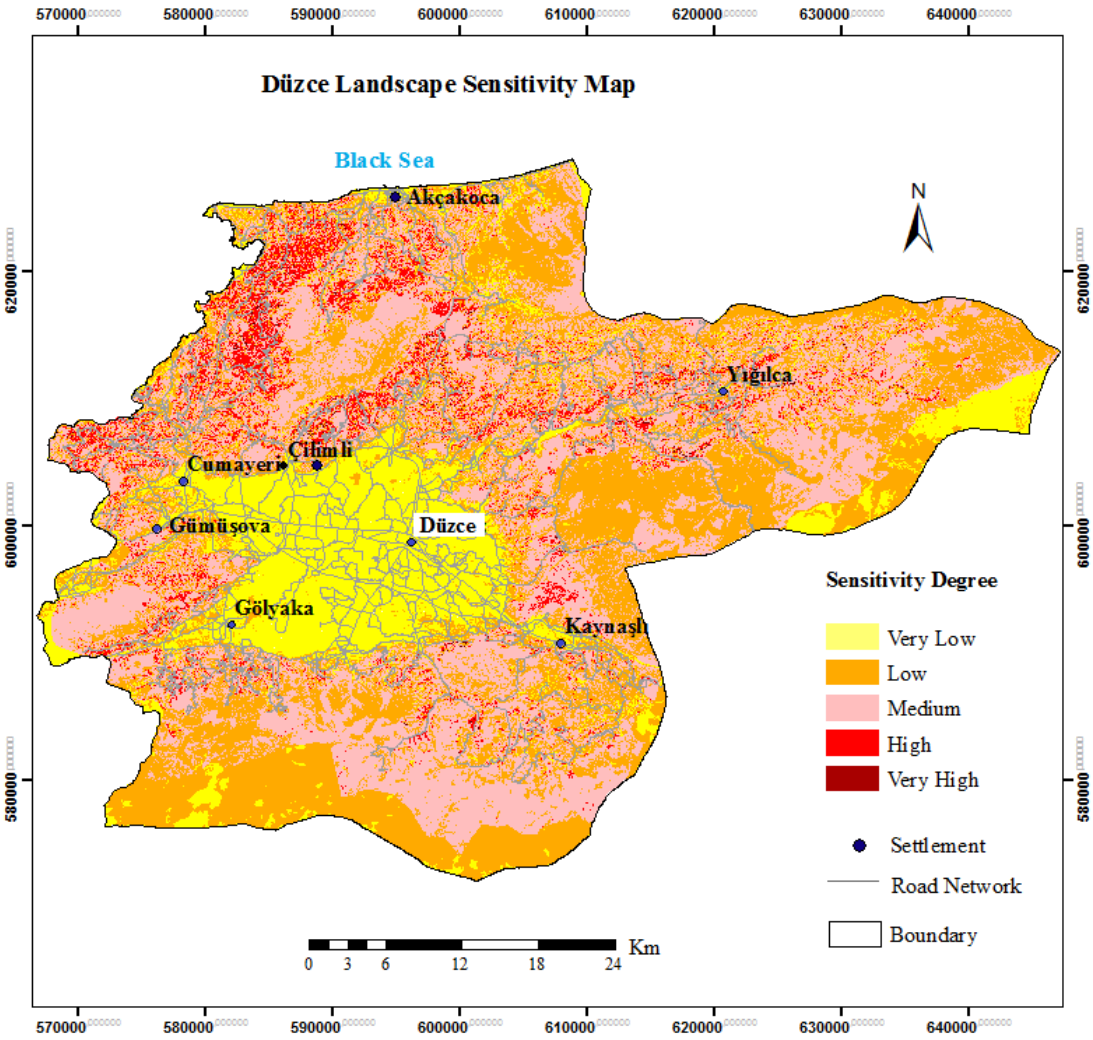

Figure 4. *Duzce landscape sensitivity map*

In this study, landscape sensitivity map is presented as a result of sensitivity analysis. In the sensitivity analysis, like many researchers (e.g., Thomas, 2001; Penghua et al., 2007; Mingwu, 2010; Wang and Bian, 2011; Fu and Bruce Jones, 2013; Walker and Shiels, 2013; Aretano et al., 2015; Bede-Fazekas et al., 2017; Aydın et al., 2018; Chia et

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1427714296

et al., 2019) ecological processes were evaluated holistically. Ecological processes to be included in the analysis are shaped according to the purpose of the study. In this study, four different ecological processes (erosion sensitivity, water infiltration sensitivity, habitat fragmentation sensitivity) were considered as parameters. The processes were selected on the basis of the basic processes that have an impact on the landscape character of the study area. In addition, these parameters and natural and cultural landscape components could be evaluated together.

Sensitivity parameter maps and landscape sensitivity map obtained in the study showed that the sensitivity structure of the study area has a complex structure. Mapping of this complex structure is very important in terms of spatial planing and land use. Aydın et al. (2018) have reached similar results and map regarding the landscape sensitivity of the study area. They also emphasized the importance of landscape sensitivity map for spatial planning.

The study area has significant ecological sensitivities. However, the land uses in the study area were not developed with ecology-based plan decisions. The creation of the sensitivity map is necessary in order to determine the sensitive areas/ecosystems in the area and to determine the protection priority compared to others. For, areas with high landscape sensitivity are areas that need to be protected. The exposure to human uses and their severity may cause vulnerability issues and may pose risk situations. In this context, sensitivity maps can be considered as a basis for suitable analysis used in the development of land-use decisions. For, space use should be considered on the basis of sensitivity due to its effects on the loss of ecosystems as stated by Saran et al. (2019).

In this study, the reduction of the data to be analyzed with the evaluation of ecological processes and a reductionist approach was exhibited. However, many researchers like Gordon and Sutherland (1993), Penghua et al. (2007), Wang Mingwu (2011), and Bian (2011), Aretano (2015), Haara et al. (2017) Hussain et al. (2018), Shi et al. (2018), Chia et al. (2019) evaluated ecological process and landscape components together. As Thomas (2001) points out, landscape sensitivity is more easily analyzed with reductionist approaches. In addition, the performance of the ArcGIS program was not forced by the reduction of data.

Conclusion

In this study, a model for the development of landscape sensitivity areas is presented and the reasons for this approach are explained. The most important result of the study is to produce a map describing the landscape sensitivity of the study area. The landscape sensitivity map of the study area is a data that is compatible with ecological principles, produced by scientific methods, compatible with technological tools and can be integrated with similar analyzes. It is an ecological guide for various spatial plans (landscape planning, construction planning, open and green space planning, green infrastructure planning, etc.). It may contribute to the development of policies for ecology-based protection, usage, planning, management, etc. They can be legally defended due to their scientific and transparent nature during production/preparation. In addition, sensitivity maps are base data that provide the exposure of field uses, vulnerability and risk analysis.

In the study, only four parameters were evaluated in determining landscape sensitivity. However, a wide range of parameters (habitat sensitivity, earthquake sensitivity, etc.) can be included in the analysis to further enhance landscape sensitivity.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1427714296

Increasing parameters will change the total landscape sensitivity in the area. Thus, a more accurate result will be achieved. The landscape sensitivity map in spatial planning processes is an impressive guide. However, it should be noted that each parameter map should be included in the decision-making process and evaluated.

Determination of parameters is very important in sensitivity analysis. The selection of sensitivity parameters should take into account the ecological processes that direct the formation of the area or ecological sensitivities in the area.

The spatial data used in the study are digital maps with a scale of 1/25000. These data are of a higher scale and might be more directives for planning decisions. For decisions on a local scale, sensitivity maps developed using smaller-scale maps should be used. For this reason, further sub-scale data should be used to make decisions on local scale (cities, rural settlements, etc.).

In the assessment of the sensitivity of the maps used in the production of the sensitivity map, a scale of sensitivity (1-5) was created and scoring was made by applying 3 expert opinions. In order to increase objectivity, the number of experts can be increased, and the scores can be analyzed by statistical methods (e.g. analytic hierarchy process, Delphi technique) and transferred to the mapping process. Thus, objectivity is further increased.

Intensive land use in the study area has developed in very low sensitivity area. These areas are not sensitive in terms of erosion and landslides. There is also no vegetation cover. However, they are sensitive areas for water infiltration. But these plans were not developed on the basis of landscape sensitivity and the necessary measures were not taken. Because there is no such legal justification in the spatial planning processes of the study area. Therefore spatial planning related to the study area should be developed on the basis of landscape sensitivity maps. For example, in areas with high sensitivity, necessary protection decisions should be made and appropriate planning made. The rationale for these decisions should be clearly demonstrated on the basis of scientific and technological data.

As a result, landscape sensitivity map is one of the important keys in order to develop ecologically-based decisions related to space. Therefore, its usage as a basis map for spatial planning is a need beyond desire. In addition, the preparation and use of these maps as a base should be made legally mandatory.

(Received 4th Jun 2019; accepted 16th Oct 2019)

Abstract. The analysis of the Transcriptome of different jujube, and the mining of their functional genes was performed. And the genes were annotated and analyzed, and the difference gene was screened out to provide the theoretical basis for the fresh jujube. The sequencing of the cDNA library was performed using synthesis technology and the Illumina HiSeq platform. The sequencing results of splicing and functional annotation. A total of 29402 Unigenes were annotated, while in the Nr, Swiss-Prot, GO, COG, KEGG and Pfam databases 29330, 24358, 21771, 11028, 6962 and 28940 Unigenes, respectively. At the same time, 355 new genes were annotated. The 50 functional groups in the Go database gene function annotation, 14608 metabolic processes in biological processes, accounting for 67.1%; reference KEGG database, 110 metabolic pathways, the number of annotations, gene function ribosomes, amino acid biosynthesis. Human embryonic stem cells, carbon metabolism, and plant hormone signaling are more abundant; it is noted that COD in 11028 single-gene distribution families has general function prediction, transcription, replication, recombination and repair, and secondary metabolites in 25 genes. Biosynthesis, transport and catabolism. This study is the first time to use RNA-seq high-throughput sequencing technology to perform transcriptome sequencing and functional analysis of transcriptome results in fresh-eating jujube leaves, to explore genes for biological processes, cell components and molecular functions, and to study different functional genes, effective biosynthetic pathways and regulatory mechanisms.

Keywords: *fresh jujube, Bearing branch, RNA-seq, differential gene expression, gene ontology, transcriptomics*

Introduction

Ziziphus jujuba Mill is a plant belonging to the Rhamnaceae family. It's the main cultivated species in China. Cultivation and distribution all over the country. The species has recently been introduced to Asia, Europe, America, Africa and Oceania, but is generally not cultivated economically (Qu et al., 1993). *Jujube* are different from other fruits. Its branches can be divided into once branch of jujube, jujube stock and bearing branch. The Bearing branch is the basic unit of the result of the jujube tree. It is also known as the result branch, the exfoliative branch, the falling branch, and the two type

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1429714313

branch (Tang et al., 2012). Bearing branch can be divided into lignification jujube hoists and shedding jujube cranes (Yang et al., 2007, 2014). Recently, many studies have been made on the lignification of jujube cranes. Scholars believe that lignification jujube is better in result performance. Study on the cultivation of fresh Chinese jujube in the South. Study on the performance, photosynthetic efficiency, nutrient transport and nutrient accumulation of lignification jujube hoist (Yan et al., 2013; Wang et al., 2014). The majority of jujube stock is formed by the accessory bud. In practice, callus or pruning of jujube head is easy to form jujube crane. The jujube cranes can also be lifted on the base of the jujube head and the two branches of the year. Most jujube cranes are able to blossom, and the small part of the jujube is suspended from the top of the jujube head (Shi et al., 1999; Tang et al., 2012; Wang et al., 2014). In fact, jujube crane can be divided into fruit jujube crane and non-fruiting jujube crane from its form, bear fruit Jujube cranes are divided into lignification jujube cranes and non-lignification jujube cranes. The study of jujube crane is directly related to the value of the breeding and breeding of jujube trees. It is also related to the economic and production value of jujube trees. Study the development rule of jujube crane to provide basic theory for production management (Sun et al., 1996; Chen et al., 2015).

RNA-Seq can respond to the expression of genes at the transcriptional level (Reich et al., 2018). High energy sequencing can be used to better study the expression of different genes in different jujube cranes. Thus, the molecular formation mechanism of the flower bud differentiation and results of jujube crane is described better.

Materials and methods

Experimental materials

Sample from Jiangxi Xianlv modern agricultural demonstration garden Magu jujube No. 1, Take 3 different jujube cranes: first is Lignification jujube hanging leaf (A1, A2, A3), Non lignification jujube hanging leaf (B1, B2, B3). Non lignification jujube leaves without flower bud differentiation (C1, C2, C3). Lignification leaves of jujube leaves on 3 jujube trees (A1, A2, A3), B1 and C1 are the same trees, B2 and C2 are the same trees, B3 and C3 are the same trees. A total of 9 samples (3 Biological duplicates). Rapid freezing of liquid nitrogen after sampling. Put in the -80℃ refrigerator and spare.

Construction of cDNA library and sequencing of Transcriptome

RNA sequencing is commissioned by Hangzhou Jing Jie Biological Technology Co., Ltd. After testing the sample. Magnetic beads with Oligo (dT). Complementary pairing through A-T and use The combination of mRNA's ployA tail enriching the mRNA of eukaryotes. Then add fragmentation buffer to break mRNA into short segments. Take mRNA as a template. Synthesis of a chain cDNA with six base random primers. And then add the buffer, *dNTPs* and *DNA* polymerase I. Synthesis of two chain cDNA. Then using

AMPure XP beads to purify double stranded cDNA. Purification of double stranded cDNA for terminal repair. Adding A tail and connecting sequenced joint. Then AMPure XP beads is used to select the size of the fragment. Finally, the final PCR library is enriched and the final cDNA library is obtained (Qi et al., 2011; Ding et al., 2017).

Statistics and comparison of sequencing

The original data reads of the machine. Clean Data was filtered after removing the reads containing the joint, repeated and low quality of the sequencing. Sequence alignment with the specified reference genome. The obtained Mapped Data. Quality evaluation of insert fragment length test, randomness test and so on. This project uses the specified genome as a reference for sequence alignment and subsequent analysis. Using *TopHat2* (Kim et al., 2013) Alignment of Clean Reads with the reference genome. Obtaining location information on the reference genome or gene. And sequence characteristic information of sequence samples. *TopHat2* is based on the comparison of software *Bowtie2* (Langmead et al., 2012). Comparison of the transcriptome sequence Reads to the genome, Recognition of splice points between exons by analyzing comparison results (Splicing Junction).

Discovery of new genes

Based on the selected reference genome sequence. Using Cufflinks software to splice Mapped Reads. And compare with the original genome annotation information. Looking for the original unnoted transcriptional area. Discovery of the new transcript and new genes of the species. So as to supplement and improve the original genome annotation information. Filtering the encoded peptide chain is too short or contains only a single exon sequence (less than 50 amino acid residues). Using BLAST software to compare the new genes that are excavated with the *NR, Swiss-Prot, GO, COG, KOG, Pfam, KEGG* database, KEGG Orthology results of new genes were obtained by using KOBAS2.0, Using HMMER software compared with Pfam database after predicting the amino acid sequence of the new gene. Annotated information of new genes (Zhu et al., 2018).

Functional annotation and analysis of the Transcriptome

Filtering and assembly of Unigenes. Based on the selected reference genome sequence. Using *Cufflinks* software to splice Mapped Reads. And compare with the original genome annotation information. the amino acid sequence of the new gene, Obtain annotated information of the measured genes (Liu et al., 2017; Niu et al., 2018; Zhang et al., 2018; Chen et al., 2018).

Results and analysis

Sequencing data output statistics

Repeat sequencing of 3 material samples with high energy sequencing technology. The total number of pair-end Reads of clean Data in the ReadSum of A2 is maximum. Up to 28708241. The total base number of Clean Data in BaseSum is 8612472300. The minimum of A3's ReadSum in all the samples is 21709049. The BaseSum 6512714700 of A3. The percentage of two bases of G and C in Clean DataGC is more than 44%. The percentage of Clean Data with a mass greater than or equal to 30 of a base is greater than 88%. The percentage of Clean Data with a mass greater than or equal to 20 of a base is greater than 94%. The above analysis indicates that the quality of sequencing is good, and the data can be used for subsequent All-Unigenes database establishment, gene function annotation, classification and same-sex analysis. The output statistics of the sample data in this project are shown in *Table 1*.

Table 1. *Sequencing data statistics table*

SampleID	ReadSum	BaseSum	GC(%)	Q20(%)	Q30(%)
A1	24, 974, 459	7, 492, 337, 700	45. 18%	95. 07%	88. 88%
A2	28, 708, 241	8, 612, 472, 300	44. 78%	95. 25%	89. 25%
A3	21, 709, 049	6, 512, 714, 700	44. 34%	94. 81%	88. 42%
B1	26, 961, 553	8, 088, 465, 900	44. 44%	95. 25%	89. 25%
B2	26, 875, 609	8, 062, 682, 700	45. 00%	95. 27%	89. 26%
B3	27, 843, 858	8, 353, 157, 400	44. 96%	95. 28%	89. 30%
C1	22, 799, 545	6, 839, 863, 500	44. 79%	95. 25%	89. 24%
C2	24, 859, 991	7, 457, 997, 300	45. 08%	95. 34%	89. 41%
C3	24, 962, 466	7, 488, 739, 800	45. 00%	95. 32%	89. 35%

Ratio of transcriptional data to reference genome sequence

This not only provides a data base for variable splicing analysis, but also enables more Reads to be compared to the reference genome, and improves the utilization of sequencing data.

Comparison efficiency refers to the percentage of Mapped Reads that accounts for Clean Reads, which is the most direct manifestation of the data utilization of the transcriptional group. The efficiency of comparison is not only affected by the quality of data sequencing, but also related to the advantages and disadvantages of the reference genome assembly, and the biological classification relationship between reference genome and sequencing samples. By comparing efficiency, it is possible to assess whether the selected reference genome assembly can meet the needs of information analysis (*Table 2*).

C3	49924932	34395909 (68. 90)	478825 (1. 39)	33917084 (98. 61)	37594222 (63. 12)	21969233 (36. 88)

More than 67% samples in total percentage of Reads compared to the reference genome Reads number in Clean Reads accounted for the percentage of the number of Reads, compared to the reference genome at various locations in the Clean Reads accounted for less than 2%, the number of Reads percentage compared to the reference genome location in Clean Reads only accounted for more than 98%, the percentage ratio the number of Reads positive reference genome chains in Clean Reads accounted for more than 62% (including more than reads), compared to the number of Reads and percentage of negative strand genome reference in Clean Reads accounted for less than 38% (including more than reads).

Discovery of new genes

The total number of newly discovered genes obtained from corresponding database annotation information was 355, of which 196 were 300-1000bp in length and 155 in length 1000bp. COG notes to 37, of which there are 19 300-1000bp in length, length of more than 1000bp 18; GO notes to 205, of which there are 123 300-1000bp in length, length of more than 1000bp 79; KEGG notes to 65, of which there are 38 300-1000bp in length, length of more than 1000bp there are 27; KOG notes to 155, of which there are 77 300-1000bp in length, length of more than 1000bp 77; Pfame notes to 138, of which there are 68 300-1000bp in length, length of more than 1000bp 68; Swissprot notes to 196, of which there are 100 300-1000bp in length a length of more than 1000bp, 95; NR notes to 344, of which there are 188 300-1000bp in length, length of more than 1000bp 152. The specific distribution of the genes for each data annotation is shown in *Table 3* and *Figure 1*.

Gene GO classification

GO database is a structured standard biological annotation system built by GO Organization (Gene Ontology Consortium) in 2000, aiming at establishing standard vocabulary system of genes and their product knowledge, which is suitable for all kinds of species. The GO annotation system is a directed acyclic graph, which contains three main branches, namely Biological Process, Molecular Function and Cellular Component. In this study, the Unigene obtained from three samples of fresh jujube was compared in the GO functional database. A total of 21771 annotations were selected in 50 functional groups of GO biology. The metabolic processes involved in biological processes (14608, 67.1%), cell processes (12146, 55.79%), and single biological processes (10464, 48.06%). The main components related to annotation of cell components were cells (9818, 45.09%), membrane (8930, 41.02%), cell components (9760, 44.83%), and membrane (6609, 30.36%). The main parts of the molecular functional annotations are catalytic activity (11882, 54.57%), and binding (9688, 44.5%). This result also shows the main distribution of the annotation function. See *Table 5*.

Classification of KEGG metabolic pathways

To KEGG database as a reference, there are 6962 notes to the KEGG database, can be classified into 110 groups of gene transcription in the metabolic pathways (*Table 6*), which notes to the biosynthesis of ribosomes, amino acid biosynthesis, carbon metabolism, plant hormone signaling, plant pathogen interaction, splicing, RNA transport, and starch sucrose metabolism, endoplasmic reticulum protein processing, phenylpropanoid is relatively high. Glucosinolate biosynthesis and degradation of aromatic compounds, sulfur relay systems, non-homologous termination, glycosphingolipid biosynthesis - ganglion series, beet red pigment biosynthesis, lipoic acid metabolism, other types of O-glycan biosynthesis and Vancomycin resistance, caffeine metabolic pathways is to compare notes low.

ribosome structure and biosynthesis of secondary metabolites biosynthesis, transport and catabolism and other functions (Allen et al., 2018; Astaneh et al., 2018; Li et al., 2018; Nisavic et al., 2018; Wang et al., 2018; Wu et al., 2018).

Conclusion

The sequence of cDNA library using Using Illumina HiSeq platform, the sequencing results were linked and functional annotations were analyzed to reveal the overall functional expression pattern of transcripts from different leaves of jujube. In recent years, there have been many studies based on high-energy sequencing, including Daphne *odora Thunb* (Yang et al., 2017), *Michelia macclurei Dandy* (Li et al., 2017), Rhododendron calvescens Balf.f. (Li et al., 2017), *Carthamus tinctorius L.* (Dong et al., 2017), *Penthorum chinense Pursh* (Yuan et al., 2017) and other plants. Transcriptome genes are classified into 110 metabolic pathways, including ribosome, amino acid biosynthesis, carbon metabolism, plant hormone signal transduction, plant pathogen interaction, splicer, RNA transport, starch and sucrose metabolism, endoplasmic reticulum protein processing, phenylpropanoid biosynthesis and so on. This study is the first time to use RNA-seq high-throughput sequencing technology to perform transcriptome sequencing and functional analysis of transcriptome results in fresh-eating jujube leaves, to explore genes for biological processes, cell components and molecular functions, and to study different functional genes, effective biosynthetic pathways and regulatory mechanisms.

Analysis of lignin-related genes in lignified jujube suspension

The results showed that the expression of lignin-related genes was more active in comparison with non-lignified jujube suspension, all of which were up-regulated genes. There were 11 up-regulated genes: *gene 29690, gene 4518, gene 30089, gene 1272, gene 21988, gene 16475, gene 16475, gene 14268, gene 14269, gene 10082 and gene 29495.*

The main functional genes in *gene 29690* family are monooxygenase activity and lignin metabolism. In *gene 14269* gene family, it includes the functions to be expressed in almost other gene families. Meristem growth regulation, chitin decomposition, glycolysis, cytokinin response, abscisic acid response, lignin biosynthesis, polar transport of auxin, cell tip growth.

The up-regulation of gene expression related to Lignin Metabolism in lignified jujube suspension also confirms that the cause of lignified jujube suspension is related to the synergy of gene expression mentioned above. Jiang et al. (2018) found that 16 lignin genes, including *2 PAL*, *5 CCR*, *3 4CL*, *2 CADH2* and *4 LAC*, were up-regulated with shoot development, suggesting that they may be related to developmental lignin accumulation. Lin et al. (2018) studied the characteristics and rules of Lignin Metabolism in okra fruits and found that the significant increase of lignin and cellulose content was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1429714313

related to phenylalanine ammonia lyase (*PAL*), cinnamyl alcohol 4-hydroxylase (*C4H*), 4 coumarin acyl-CoA ligase, protopectin and flavonoid enzymes.

PRX52 is a major lignin and secondary cell wall biosynthetic gene, especially in xylem vessel. The mutant of Arabidopsis thaliana showed a 70-80% decrease in lignin content, which was syringyl lignin (Fernandez-Perez et al., 2015). Previous studies have investigated its possible role in ABA-mediated plant defense against bacterial and fungal responses (Mohr et al., 2007). *TCP3* and *MYB12* were found to be involved in the regulation of *PRX52* (Arro et al., 2017) in grape tendril transcriptome studies. During lignification, *PRX52* interacts with TCP3 more extensively than it responds to adversity. *PRX52* also shares the phenylpropane metabolic pathway in lignin biosynthesis with *MYB12* (response switch gene for flavonol metabolism) (Czemmel et al., 2012). Phenylalanine aminolytic enzyme (*PAL*) is a rate-limiting enzyme in the metabolic pathway of lignin phenylpropane, which catalyzes the conversion of phenylalanine to cinnamic acid and coenzyme lipids, and is one of the most important enzymes in lignin synthesis (Matus et al., 2008). In this experiment, homologous genes were expressed in the transcripts of lignified jujube suspension.

Differential gene expression analysis of lignified jujube suspension related to photosynthesis

The results showed that the genes annotated in GO were up-regulated in *gene 4228*, *gene 10305* and *gene 42934*, down-regulated in *gene 6204*, *gene 29074*, *gene 24178*, *gene 15775*, *gene 2674*, *gene 4496* and *gene 296156*. In the annotation of metabolic pathway in KEGG database, three genes participated in photosynthesis expression, of which *gene 4496*, *gene 24178* were down-regulated and *gene 4293* was up-regulated.

In the *gene 4496* gene family, there are reactive oxygen species, photosynthesis and redox processes involved in biological processes. Molecular function is involved in iron oxidase activity and iron binding. Chloroplasts are involved in cell components. In gene 24178 expression, serine cysteine biosynthesis, photosynthetic adaptation, regulation of hydrogen peroxide metabolism, regulation of superoxide metabolism, photosynthesis and so on. The molecular functions include transferase activity, pyridoxal phosphate binding activity and cysteine synthetase activity. The thylakoid cavity is involved in the up-regulation of cell composition. *Gene 4293* family genes are up-regulated, including sulfur amino acid metabolism, glycine metabolism, vitamin metabolism, cell amino acid biosynthesis, aromatic amino acid metabolism, lipid metabolism, coenzyme biosynthesis, cold reaction, biological stimulation detection, blue light response. High light intensity response, red light response, far red light response, PSII related light capture complex II catabolism process, regulation of hydrogen peroxide metabolism process, chlorophyll biosynthesis process, starch biosynthesis process. Only the chloroplast envelope is involved in the expression.

Liu (2008) studied the temporal and spatial expression of *cab-PhE3, cab-PhE1, cab-PhE5, cab-PhE8, cab-PhE10* and *cab-PhE11* genes in Phyllostachys heterocycla (Carr.)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1429714313

Mitford cv. Pubescens under photosynthesis (Zhang et al., 2009). Through proteomics, bioinformatics and *VIGS* analysis, it was found that *TYLCCNV/TYLCCNB* invasion was involved in stress and defense, energy production, photosynthesis, protein homeostasis, metabolism, cell structure, signal transduction, transcription, transport and cell growth/division. Effective methylation of N-methyl was promoted through N-adenosine-L-methionine cycle II pathway (Zhang, 2014). Molecular mechanism of carbon flux regulation is fixed carbon expression in photosynthesis in different wild-type algae and Arabidopsis thaliana. Arabidopsis thaliana is used as a model to study the transformation of genetic regulation from vegetative growth to reproductive growth (Khan et al., 2014; Carrieri et al., 2018). The study also proved that both lignified and non-lignified jujube suspension had gene expression, and more up-regulated genes were expressed in lignified jujube suspension.

Summary

By comparing lignified jujube suspension with non-lignified jujube suspension, using GO and KEGG database annotations, the differential functional genes were analyzed from three database systems.

For lignified jujube suspension analysis, 11 genes were up-regulated with lignin gene expression, and there was no up-regulated with non-lignified jujube suspension. The results showed that lignified jujube suspension was related to lignin synthesis. There are 42 genes involved in lignin biosynthesis. They have synergistic effects on Chitinase activity, polysaccharide binding, cell wall tissue, root hair elongation, regulation of carbohydrate biosynthesis, cellulose biosynthesis and meristem growth. The formation of lignified jujube suspension is related to the co-regulation of photosynthesis and endogenous hormones.

(Received 5th Jun 2019; accepted 25th Oct 2019)

Abstract. This study is a first attempt to evaluate the toxic effects of prominent aquatic pollutants (nutrients and toxic metals) on the brown seaweed *Bushy Rainbow Wrack (Cystoseira tamariscifolia)* physiology along the Atlantic coast of Morocco. The physicochemistry (nutrients) of seawater, toxic metals (Chromium, Lead, Copper and Cadmium) and physiological parameters (Chlorophyll contents, Proline, Glycinebetaine and Total Phenolic Compounds) of the brown macroalgae *Bushy Rainbow Wrack* were studied in order to assess the pollution degree of 8 coastal areas. The results show that the toxic metal contents of *Bushy Rainbow Wrack* (especially Cadmium) and the concentration of phosphorus are correlated with stress physiological parameters, and inversely correlated with pigment contents. It shows that while these brown algae exist in the less polluted areas, their physiology is significantly affected. However, in the highly polluted areas, this brown seaweed disappears. Thus, this specie could be used for monitoring the pollution degree in coastal areas.
Keywords: *environmental pollution, heavy metals, physicochemical parameters, algal physiology*

Introduction

Cystoseira is a genus of brown macroalgae. Most of the species of this genus are very sensitive to pollution and to other anthropogenic pressures, and their numbers have diminished considerably during the last decades (Cormaci et al., 1999; Thibaut et al., 2005). With the rapid industrialization and economic development of coastal regions, heavy metals continue to be introduced into coastal zones, our country's coast must be in such a state that local organisms can live, develop and reproduce without hindrance. To achieve this goal, it is essential that pollutant inputs to water be reduced or even avoided, regardless of their origin: domestic, artisanal, industrial, agricultural or other sources (Blinda et al., 2013). Seaweeds are widely recognized as autogenic "ecosystem

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1431514331

engineers" (Jones et al., 1994) or "foundation species" (Dayton, 1975). In general, the direct causes of change in marine biodiversity loss and coastal ecosystems, are: pollution, habitat destruction, increases in sedimentation, overexploitation of resources, climate change, and invasive species (Walker and Kendrick, 1998; Claudet and Fraschetti, 2010; Munday et al., 2013). The aim of this study is to portray the decrease of *Bushy Rainbow Wrack* (*Cystoseira tamariscifolia* (Hudson) Papenfuss) and to clarify the source and the conceivable reasons of its decrease in the Atlantic coast of Morocco.

Materials and Methods

Location

Eight (8) stations located on rocky substrates along the Atlantic coast of Morocco were chosen:

- Eljadida city with 2 stations: Sidi Bouzid coast: 33°13'N-8°55'W as a control area (S1). According to Moroccan beaches position, this station is ranked each year among the beaches called "Blue Flag". The Mohammed VI Foundation for the Protection of the Environment awards this distinction each year to beaches that fit the international standard norms of cleanliness (F.M.6, 2018). Jorf Lasfar: 33°07'N -8°37'W (S2) known as a polluted one. This area is characterized by the presence of multiple industrial units including a phosphate complex and a power thermal plant (Essedaoui et al., 2001; Kaimoussi et al., 2001; Ferssiwi et al., 2004).
- Safi city with 3 stations: Beddouza: 32°54'N-9°27'W (S3), less polluted station located 34 km from the industrial city of Safi (Goumri et al., 2018); Industrial Area: 32°28'N-9°24'W (S4) and Phosphate Area: 32°18'N-9°26'W (S5).
- Essaouira city where 3 stations were selected: Moulay Bouzerktoun (31°63'N-9°67'W) (S6); located approximately 15 km from the enclosure of the city, it is less affected by anthropogenic activities, just an ephemeral tourism activity during the summer. Bab Doukala: 31°51'N-9°76'W (S7) and the port: 31°51'N-9°77'W (S8), receive domestic and some industrial releases (Sabri et al., 2017; Cherifi et al., 2018). Among them, 3 stations less polluted and 5 more polluted near to industrial factories (*Fig. 1*).

Sampling

Algal Samples were collected during Autumn 2017 to Summer 2018 at 0-5 meter depth depending on the geomorphology of the stations (*Fig. 2*) and following the principle of the quadrats. Then, washed in seawater, put in plastic packs and transported to the research center in a cooler for metal analysis. The samples expected for identification are preserved into alcohol at 10% while samples for physiology analysis are kept dry. Those of ocean water were collected during the same period, placed in a cooler and were conveyed fresh to the research center.

Physicochemical parameters

Concentration of inorganic nutrients of seawater (Phosphorus and Nitrogenous compounds) was measured according to AFNOR norms: T90-012 for Nitrate, T90-015 for Ammonium, T90-061 for Total nitrogen, T90-022 for Orthophosphate and T90-023 for Total phosphorus. Metal Concentrations of Cd, Cu, Pb and Cr were measured in seawater and the dried *Bushy Rainbow Wrack* according to Blinda et al (2013) and

DOI: http://dx.doi.org/10.15666/aeer/1706_1431514331

Topcuoglu et al (2003) methods, respectively. The samples were digested with concentrated nitric acid and analyzed using Atomic Absorption Spectrophotometer.

Biochemical and physiological parameters

Chlorophyll

The contents of chlorophyll a, c were estimated using the method of Jeffrey and Humphrey (1975). Pigment concentrations are expressed as µg/g FW (Fresh Weight) and calculated according to the following equations:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1431514331

$$\text{Chlorophyll a} = 11.47 \times \text{O.D.}664 - 0.40 \times \text{O.D.}630 \quad \text{(Eq.1)}$$

$$\text{Chlorophyll c} = 24.36 \times \text{O.D.}630 - 3.73 \times \text{O.D.}664 \quad \text{(Eq.2)}$$

The pigments were extracted from 1 g seaweed *Bushy Rainbow Wrack* with 10 mL of acetone in the presence of calcium carbonate. Then put in 4°C for 24 hours in the dark. The chlorophyll content was determined in triplicate.

Total carotenoids were calculated according to the equation of Lichtenthaler (1987):

$$\text{Carotenoid} = \frac{1000 \times \text{O.D.}470 - 1.9 \times \text{Cha} - 63.14\,\text{Chb}}{214} \quad \text{(Eq.3)}$$

Glycinebetaine (GB)

Analysis of GB was performed according to the method of Grieve and Grattan (1986). 0.5 g DW (dry weight) of the seaweed *Bushy Rainbow Wrack* prepared in 20 mL test tubes was mechanically shaken with 20 mL of deionized H_2O at 25°C for 24 h. The extracts then were diluted 1:1 with 2N H_2SO_4. 0.5 ml of this solution were measured into heavy walled glass centrifuge tubes and cooled in ice water for about 1 hour. A preparation of 0.2 ml KI-I2 was made by dissolving 20 g of KI and 15.7 g of iodine in 100 ml. Then, water was added and the reactants were gently stirred with a vortex mixer. The tubes were stored for 16h at 0-4°C and then centrifuged at 10000 rpm at 0°C for 15 min. The supernatant was aspirated and dissolved in 9 ml of 1,2-dichloroethane. Vortex mixing was made to effect complete solution in the developing solvent. The absorbance was measured after 2 h at 365 nm. The concentration was estimated by using a standard curve developed with different concentration of GB in triplicate.

Proline

The method used is the one of Monneveux and Nemmar (1986). 100 mg of the seaweed *Bushy Rainbow Wrack* are directly weighed and then placed in a test tube. 2 ml of methanol 40% is added to the tubes and placed in a water bath at 85°C for about 1 hour. 1 ml of the solution is added to 25 mg ninhydrin after cooling, 1 ml of acetic acid and 1 ml of the mixture distilled water-acetic, acid-acetic, acid-acid orthophosphoric, of density 1.7 (120, 300, 80: v / v / v). The solution is brought again for 30 minutes in a water bath at 100°C, then cooled and added to 5 ml of toluene. After agitation, a pinch of Na_2SO_4 is added to each tube. Absorbance was measured at 528 nm.

Total phenolic compounds (TPC)

TPC of the extract was estimated by the method of Taga et al. (1984). Dry weight samples of the seaweed *Bushy Rainbow Wrack* were prepared in 60:40 (0.3% HCl) acidified methanol/water. Solutions of 100 µL were added to 2 mL of Na_2CO_3 (2%). 100 µL of Folin-Ciocalteau (50%) reagent were added after 2 min. Absorbance was measured after 2 hours at 750 nm. Gallic acid standards was prepared with a range of concentrations of 10 mg/mL to 200 mg/mL. The phenolic concentrations were determined by comparison with the standard calibration curve. Phenolic content was expressed as gallic acid equivalent (GAE).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1431514331

Statistical analysis

All the analyzed parameters were established in triplicate and gave mean values and standard deviation. The values were tested for normality and homogeneity of variance, as well as for significance between parameters using a one-way and two-way analysis of variance with Excel 2016 and SPSS (IBM, USA), version 22. Correlation matrix was used to determine the relation between the physiological parameters, Heavy metals and the physicochemical compounds studied. Principal Component Analysis (PCA) was performed using SPSS (IBM, USA), version 22.

Results

Distribution of Bushy Rainbow Wrack

The preliminary study shows that there is a first presence of Bushy Rainbow Wrack in the control station (S1) at Eljadida coast during the 4 seasons. Essaouira city comes in the second range where this specie is more present in (S5). Safi coast comes in the thirth place where the Bushy Rainbow Wrack is abondant in unpolluted station (S3) (*Table 1*).

Table 1. *Bushy Rainbow Wrack inventory in the studied areas during autumn-summer 2018*

City	Station	Autumn	Winter	Spring	Summer
Eljadida	**S1**	A	A	A	A
	S2	-	-	-	-

Physicochemical parameters: nitrogenous and phosphorus compounds

Statistical analysis of nitrogenous compounds didn't show significant difference between control and polluted stations ($F= 11.29$; $p<0.01$). Thus, it could not explain the degradation of the species studied. Total nitrogenous concentrations are ranged between 2.52±0.30 and 4.70±0.16 mg/L and those of nitrate between 1.30±0.56 and 2.56±0.46 mg/L (*Table 2*).

Statistical analyses of phosphorus compounds, however, have showed a highly significant difference between the areas studied ($F= 1.65$; $p<<0.01$). The maximum total phosphate concentration was recorded in the Phosphate industrial area (S5), at Safi coast with 2.00±0.13 mg/L and the minimum in the control station (S1), in Sidi Bouzid coast with only 0.04±0.01 mg/L (*Table 2*).

Heavy metals analysis

Heavy metals analysis in seawater

The analysis of metals shows that the mean metal levels in seawater decreased in the following order: Pb > Cd > Cr > Cu (*Table 3*). The results obtained are discussed on the basis of the Moroccan standards for direct discharges of heavy metals into aquatic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1431514331

environments (surface water). The maximum concentrations required by the above standard are: 0.5 mg/l for Pb, 2 mg/l for Cr, 0.5 mg/l for Cu and 0.2 mg/l for Cd (FAO, 2006). The highest concentrations of toxic metals were recorded in two polluted stations near to Safi coast: a fish industrial discharges (Cd: 1.12±0.15 µg/L; Pb: 2.563±0.73 µg/L) and phosphate discharge area (Cd: 1.15±0.88 µg/L; Pb: 1.53±0.55 µg/L).

Heavy metals analysis in Bushy Rainbow Wrack

The analysis of heavy metals shows that the mean levels in seaweed *Bushy Rainbow Wrack* decreased in the following order: Cu > Pb > Cr > Cd. The results obtained are discussed on the basis of comparaison of these heavy metals levels in seaweed *Cystoseira* sp. from other different locations in the world. The highest concentrations of all heavy metal were recorded in the polluted area (S8), the port station at Essaouira coast (Cd: 2.60±0.15 µg/g during spring; Pb: 4.43±0.73 µg/g during autumn, Cu: 10.60±1.14 µg/g during summer and Cr: 2.90±0.23 µg/g during autumn) (*Table 4*).

Biochemical and physiological parameters

Chlorophyll contents

Maximum value of chlorophyll a were recorded at (S1) Sidi Bouzid coast near Eljadida city with 586±167 µg/g FW during spring season, and reached its minimum at (S8) The port station in Essaouira city with 59±14 µg/g FW during autumn season. Values of chlorophyll c has its maximum as well at (S1) Sidi Bouzid coast near Eljadida city with 387±93 µg/g FW during spring and summer season, and its minimum also at (S8) The port station in Essaouira city with 34±13 µg/g FW during spring season. The same thing for carotenoid that shown a maximum value at (S1) Sidi Bouzid coast near Eljadida city with 399±175 µg/g FW during summer season and a minimum likewise at (S8) The port station in Essaouira city with 34±0.9 µg/g FW during summer season (*Table 5*).

Glycinebetaine (GB), proline and total phenolic compounds (TPC)

GB parameter reaches a high value of 19.35±14.97 mg/g DW at (S8) The port station in Essaouira city during summer season, and achieved its minimum at (S3) Beddouza station near Safi city with 1.72±0.12 mg/g DW during autumn season. In the same way, the proline parameter has the same result as GB. The maximum value is recorded at (S8) The port station in Essaouira city with 647.48±198 µg/g DW during summer season, and a minimum value of 57.55±15.11 µg/g DW at (S3) Beddouza station near Safi city during autumn season. Moreover, TPC parameter has given the same result as GB and proline parameters which we have found a maximum value of 1.54±0.28 mg/g DW during autumn season at (S8) The port station in Essaouira city, as well as a minimum value of 0.52±0.12 mg/g DW at (S1) Sidi Bouzid coast near Eljadida city during winter season (*Table 5*).

Statistical analysis

A tow-way mixed ANOVA was conducted to investigate the impact of seasons, the sampling sites and Heavy metals concentrations in sea water. There was a significant main effect of sampling sites and seasons, $F(1, 66) = 183.397$, $p<0.001$ (*Table 6*). Moreover, there was a significant interaction between Heavy metals, Sampling sites and seasons, $F(1, 66) = 2.197$, $p<0.001$ (*Table 7*).

By performing the Principal Component Analysis (PCA) on the physiological parameters (Chlorophyll a, Chlorophyll c, Carotenoid, Proline, Glycinebetaine (GB) and Total Phenolic Compounds (TPC)) combined with the physicochemical parameters (Phosphorus and Nitrogenous compounds) and heavy metals (Cu, Cd, Pb and Cr) under study, two principal components have been extracted by covering 74.085 % of the cumulative variance (*Table 8*).

Discussion

Based on the online Algaebase data which includes marine algal species, Guiry and Guiry (2019) provided information about *Cystoseira* species diversity and discussed the description of new taxa and distribution. In Morocco, some authors have discussed the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1431514331

geographic distribution of *Bushy Rainbow Wrack* in the Mediterranean sea of Morocco (Ribera et al., 1992; Báez et al., 2005; Taskin et al., 2012; Bermejo et al., 2018; Moussa et al., 2018). However, no studies have been made in the Atlantic coast of Morocco concerning these species. Some authors have mentioned their sensitivity (Ballesteros et al., 1984; Thibaut et al., 2005). In contrast, the situation is more critical at Safi coast where only *Bushy Rainbow Wrack* seems to be more tolerant but all *Cystoseira* species have disappeared in 3 polluted stations (S2, S4 and S5). Many authors have showed the sensitivity of these brown seaweeds in polluted coasts (Cormaci et al., 1999; Thibout et al., 2005; Sales and Ballesteros, 2009). Furthermore, *Cystoseira* species are used as indicators of good water quality (Ballesteros et al., 2007).

The values of nitrogenous compounds are higher in comparison with the other ocean areas (Sverdrup et al., 1943). It is widely accepted that nitrogen may be an important factor in limiting marine algal productivity. Although the need to examine macroalgal-nitrogen relationships has long been recognized (Haas and Hill, 1933). Efforts with benthic marine algae have not paralleled those with phytoplankton.

The highly concentration of phosphorus was due to the huge amount of phosphogypsum used by the industrial factory. Inorganic nutrients are present in natural environments but their concentration near urban areas is usually enhanced (Nixon, 1995; Scavia and Bricker, 2006). The overloading of inorganic nutrients stimulates algal production and increases turbidity leading to changes in the species composition and the structure of littoral communities (Mcglathery et al., 2007). In addition, increased nutrient concentration in seawater favors opportunistic species, while long-lived species such as seagrasses and perennial macroalgae gradually decline (Munda, 1982; Schramm et al., 1999). Thus. the high phosphorus concentration in (S5) could explain the disappearance

DOI: http://dx.doi.org/10.15666/aeer/1706_1431514331

of *Cystoseira* species. It is known according to Celis-Plá et al. (2014) that nitrate and phosphate represent important macronutrients for macroalgae development and can protect the algae against stress. Moreover, highly concentrations of nutrients in seaweeds can reduce photoinhibition, as it has been observed in *Bushy Rainbow Wrack*. Other observations showed that nutrient enrichment could also have effects on photosynthesis, photo-protection and biochemical responses (Celis-Plá et al., 2016). Nonetheless, stress biology studies on heavy metal in brown seaweeds has demonstrate different results of molecular, biochemical and physiological effects, as it has been studied in *Ascophyllum nodosum* (Connan and Stengel, 2011a,b), *Fucus vesiculosus* (Nielsen and Nielsen, 2010) and *Ectocarpus siliculosus* (Roncarati et al., 2015; Sáez et al., 2015).

The comparison of our data with those previously studied by some authors (*Table 9*) shows that the concentrations of heavy metals: Cd, Pb, Cu and Cr for *Bushy Rainbow Wrack* in the present study recorded higher values in *Cystoseira* sp obtained by Akcali and Kucuksezgin (2011) of the Aegean Sea in Turkey, Al-Masri et al. (2003) at the Syrian Coast, Schintu et al. (2010) at Sardinia coast in Italy and Caliceti et al. (2001) at the Venice lagoon in Italy. Nonetheless, lower level of Pb and Cu than those reported by Schintu et al. (2010) and Caliceti et al. (2001), respectively.

Table 9. *Comparison of heavy metal levels (µg/g dry weight) in seaweed Cystoseira sp. from other different locations in the world*

	Cd	Pb	Cu	Cr	Location	References
***Cystoseira* sp.**	0.18	0.003	6.00	-	Aegean Sea, Turkey	(Akcali and Kucuksezgin, 2011)
	1.72	10.3	1.80	-	Sardinia, Italy	(Schintu et al., 2010)
	0.1-0.5	1.31	7.21	-	Syrian Coast	(Al-Masri et al., 2003)
	0.2	5.6	21	1.5	Venice lagoon, Italy	(Caliceti et al., 2001)
	2.6	4.43	10.6	2.9	Atlantic coast of Morocco	Present study

The relatively high levels of Lead in seawater could be attributed to discharges from industries near the study sites that could increase directly this element (leaching from gas stations), as well as leaching at the dump, traffic and leaching of farmlands, can contribute to the highly lead concentration at these stations. However, the lead concentrations at all stations are below the Moroccan standard 500 µg/l (FAO, 2006). For Cadmium detected in polluted waters, concentrations indicate a non-contamination by this element. Indeed, they are all below the limit value of 200 µg/l (FAO, 2006) (*Table 10*). The concentrations found at these sites, lead us to assume the presence of one or several sources of pollution near the stations above.

Table 10. *Comparison of heavy metal levels in seawater (µg/l) for the studied stations with the Moroccan standards for seawater (FAO, 2006)*

Heavy metals	Sea water	Moroccan norm FAO, 2006
Cd	1.151	200
Pb	2.563	500
Cu	0.604	500
Cr	0.987	2000

The resultant PCA (*Fig. 3*) presenting the loading of the variables on the two principal components demonstrate that Cd, Pb, Cu, Cr, DP, PO_4^{3-}, Proline, TPC and GB were the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1431514331

dominant correlated positive variables on the PC1 (0.951; 0.645; 0.735; 0.961; 0.912; 0.905; 0.967; 0.915; 0.967, respectively) while Chla, Chlc and Carotenoid the negatif correlated ones (-0.940; -0.824; -0.753, respectively), in addition to TN, DN and NO_3^-, the dominant variables on the PC2 (0.569; 0.965; 0.528, respectively). Indeed, according to PCA results, an important positive correlation and proportionate augmentation in proline, GB and TPC contents was recorded with increase in concentration of heavy metals and excessive Phosphorus in polluted stations mentioned, in addition to a negative correlation with pigments. It is proved by Alia et al. (1999) that Cadmium is the strongest inducer for proline and GB accumulation. Moreover, TPC can be released in stressful conditions from algal thalli and could react rapidly with carbohydrates and proteins to form UV-absorbing exudates (Koivikko et al., 2005). It has also been shown that proline, GB and TPC are the stress-induced substances in plants and algae under different kind of stress (Anbazhangan et al., 1988; Fadma et al., 2007; Abdel Latef and Sallam, 2015). Proline and GB concentrations in *Bushy Rainbow Wrack* in polluted areas are much higher than those found in other green, brown and red seaweeds (Fleurence, 2004). Furthermore, the maximum value of TPC in this study (1.54 mg/g dry weight during autumn season at (S8) The port station in Essaouira city) is higher than that found by Pereira and Yoneshigue (1999) in brown seaweed *Sargassum furcatum* (0.2-0.5 mg/g DW). According to this author, TPC may also be present in brown seaweed for reasons other than defense, as they have been considered to have a number of physiological and ecological functions.

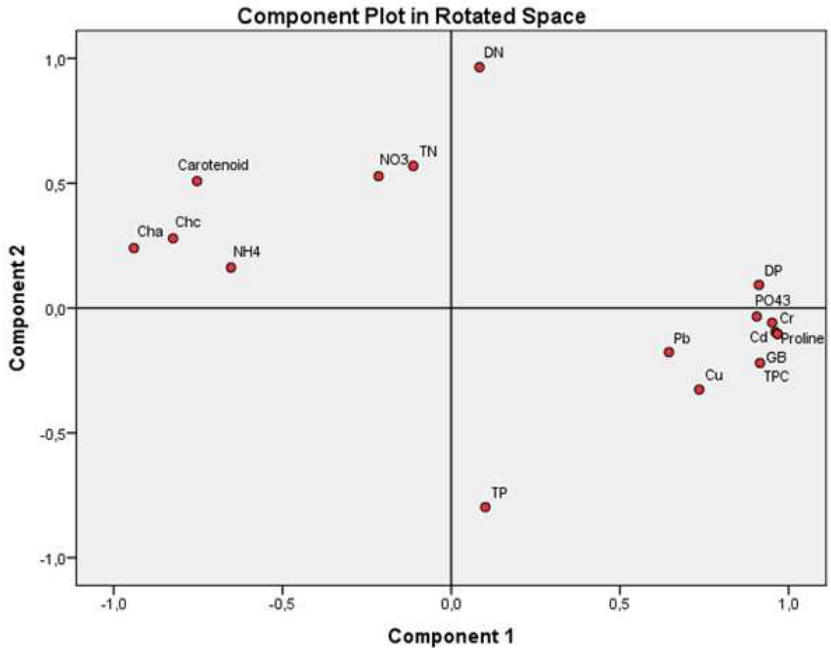

Figure 3. *Component Plot in Rotated Space for the parameters studied*

In the basis of the Conceptual framework of Mineur et al. (2014), anthropogenic local stressors create additional disruption often altering dramatically assemblage's structure. Global stressors are not manageable locally, but have local impacts and may indirectly affect local stressors. All stressors are affecting seaweed diversity (populations and communities), and directly impacting coastal ecosystems (*Fig. 4*) (Mineur et al., 2014).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1431514331

At the Industrial area (S4) and Phosphate area (S5) in Safi city and Jorf Lasfar area (S2) near Eljadida city, these stressors are due to increased nutrient inputs, heavy metal pollution and mostly derived from the industrial activity out there. According to Ferreira et al. (2011), marine biota living in coastal waters are under constant threat from exposure to elevated concentrations of pollutants, such as metals and nutrients, mostly derived from domestic, industrial and farming activities.

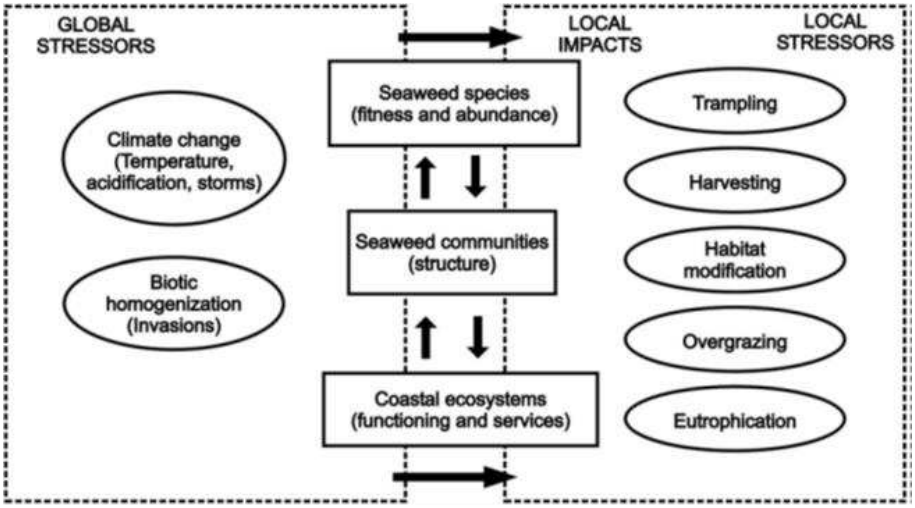

Figure 4. *Conceptual framework of Mineur et al. (2014)*

Changes in the composition of *Bushy Rainbow Wrack* through these stressors in polluted stations (S2, S4 and S5) has resonated through entire coastal ecosystems in this area. Furthermore, anthropogenic activities on these coastal areas, such as industrialization and urbanization create increasing anthropogenic stress. *Cystoseira* and seaweed biodiversity in general of the Moroccan coastlines need more attention to predict how they are affected by human activities.

Conclusion

To conclude, we have found a regular element variety in species lavishness with least qualities in winter and an auxiliary least top in spring, and most extreme qualities in summer. The regularity is for the most part because of the adjustment in biomass of the overwhelming species. Just *Bushy Rainbow Wrack* is by all accounts progressively tolerant to the contamination in polluted stations. Nitrogenous compounds did not clarify the decay of the species around there, yet the highly phosphorus concentration in the phosphate station and highly values of heavy metal concentrations could affect the physiology and clarify the vanishing of *Bushy Rainbow Wrack*, notwithstanding the nearness of dangerous components like Pb, Cd, Cu and Cr.

Thus, the investigation on the combined effects of nutrients, metals and biochemical parameters studied in this brown seaweed would provide relevant information about their capacity to withstand the future pollution scenarios. The interaction between metals and nutrients excess is still not well understood for macroalgae. Further examinations ought to be done to characterize different parameters that lead to *Bushy Rainbow Wrack* debasement.

DOI: http://dx.doi.org/10.15666/aeer/1706_1431514331

For future research, we aim to develop the culture experiments under controlled laboratory conditions on *Bushy Rainbow Wrack* as well as the genetic characterization of this brown seaweed based upon DNA barcoding of the cytochrome oxidase subunit 1 (COI), 23S rDNA (23S), and 23S-tRNAVal intergenic spacer (mt-spacer).

Abstract. Recently, the statisticians have developed a new approach called functional Statistics to treat the data as curves or images. In parallel, the Near-Infrared Reflectance (NIR) spectroscopy approach has been used in modern Chemistry being a fast, inexpensive and accurate procedure to characterize chemical properties for an object. In this paper, we study the forage quality by analysing the spectroscopy procedure with some modern statistical models. Our contribution leads to the prediction of chemical components of Chinese ryegrass forage by analysing its spectral data using some functional models. Precisely, the functional linear quantile regression (FLQR), the functional nonparametric quantile regression (FNQR), the functional local linear quantile regression (FLLQR) and the functional local linear model regression (FLLMR) are implemented to predict the quantities of acid detergent fiber (ADF), neutral detergent fiber (NDF), and crude protein (CP) contents. The choice of these functional models is motivated by the fact that they can construct a predictive region with a given confidence level. We show that the considered models improve the prediction results significantly as compared to conventional models such as the classical partial least squares regression (PLSR) and the principal component regression (PCR). Moreover, we also show that the proposed models are more robust than their competitive models like PLSR and PCR in the sense that their efficiency is not much affected by non-homogeneity of the data.

Keywords: *Leymus chinensis, functional quantile regression, principal component regression (PCR), neutral detergent fiber, predictive regions, crude protein, neutral detergent fiber, acid detergent fiber*

Introduction

The analysis of the forage quality is crucial for livestock producers. It usually measured by its ability to provide livestock high amounts of nutrients and all kinds of livestock feeds. The forage quality depends on the composition of different chemical and biological components present in it. Precisely, the amounts of crude protein (CP), acid detergent fiber (ADF) and neutral detergent fiber (NDF) are the most critical parameters to determine the forage quality (see Mott and Moore, 1970). While the CP content increases the quantity of protein in milk and meat which is essential for dairy producers. On the other hand, NDF and ADF are also crucial for the digestibility of livestock animals (see Agnihotri et al., 2003 or Suksombat, 2004). Accurate prediction of the nutrients present in forage permits the producers to harvest, store and inventory the feed resource optimally way for both grazing and confinement fed ruminants. To get ideal results before

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1433314346

selling, it is highly needed to apply rapid and accurate methods to evaluate the chemical properties of forage without its destruction. In literature, two methods are commonly used to analyze the quality of forage samples in a laboratory. First, one is the traditional wet chemistry analysis, and the other one is near-infrared reflectance Spectroscopy (NIRS) analysis. First, one is based upon well-established chemical principles, with the help of chemicals and drying agents to find the quality of different components present in the forage.

On the other hand, NIRS analysis is a computerized method to determine the quality of the forage using near-infrared light. However, the traditional approaches are costly, non-ecological and require a great number of samples (Yu et al., 2010; Yu et al., 2011; Albrecht et al., 2008). Alternatively, the NIRS is precise technology, rapid, inexpensive and nondestructive nature of the analysis (see for example Kamruzzaman et al., 2012; De Marchi et al., 2012; Stuth et al., 2003; Foley et al., 1998). The NIR spectroscopy assessment of the forage quality is widespread in the last few years. It was introduced by Norris et al. (1976). This approach has significant advantages over the classical chemical analyses in the form of minimal sample in the laboratory, short time for analysis, less cost in case of a single sample or large batches of samples, many constituents can be found simultaneously, non-destruction of the samples during analysis, no need of skilled operator during analysis, elimination of use of hazardous chemical reagents, and the results are usually more precise and accurate as compared with the methods usually employed. Being the responsibility of the analyst, it is utmost important not only to choose the most appropriate analytical technique but also to follow standard procedures for accurate and precise results. In the last decade this technology has received a growing interest in forage quality assessment (see Bai et al., 2004; Nie et al., 2007; Chen et al., 2007; En et al., 2009 for previous studies and Asekova et al., 2016; Monrroy et al., 2017; Yang et al., 2017 for recent advances). In all these previous studies, the spectral data are analyzed by some classical statistical methods such as the partial least regression (PLSR) or the Principal Component Regression (PCR). However, these old approaches have some drawbacks, which affect their efficiency. Indeed, in these two models the spectral data is not taken into account. The users are required to reduce the dimension of the data by transforming it over some directions. But this transformation can lead inaccurate prediction and results because the direction is chosen independently of the prediction problem. In particular, the variable of interest does not intervene in the choice of the optimal direction reduction. In order to avoid this drawback, we implemented some alternatives models recently developed in modern Statistics. Such models allow analyzing the big data without dimension reduction. These new models are based on the notion of functional Statistics that allows to model the data as curves instead of some numerical numbers which permit to explore the total information of the data. For an overview on recent developments in this topic, we cite, some special issues dedicated to this topic by various statistical journals such as Gonzalez-Manteiga and Vieu (2007), Valderrama (2007), Goia and Vieu (2016) and Aneiros et al. (2019).

More precisely, the main aim of this paper is to combine the Near Infrared Spectroscopy (NIRs) methodology (as modern Chemistry tools) with the recent development of big-data analysis in order to provide a new prediction approaches for the forage quality to circumvent the drawbacks of the previous model. For this study, we consider a sample of 151 size of Chinese ryegrass (Leymus Chinensis) forage and we examine the performance of NIR spectroscopy in estimating the CP, ADF and NDF quantities present in this sample. For this purpose, we use four statistical models the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1433314346

functional linear quantile regression (FLQR), the functional nonparametric quantile regression (FNQR), the functional local linear quantile regression (FLLQR) and the functional local linear model regression (FLLMR). The main feature of these models is to make two kinds of prediction namely, pointwise prediction and predictive regions. Moreover, it is well known in statistics that these predictors are more robust than the classical regression models.

Materials and methods

Sample collection and chemical analysis

The samples for this study were taken of the sites ranging from the west to east across the grassland situated in Heilongjiang Province of Northeast China. To accomplish the task 151 samples of sheepgrass hay were chosen at random from different sheepgrass fields of hay factories in 2013 with longitudes from 123.209°E to 132.944°E and latitudes from 44.475°N to 51.728°N. These sampling sites are rich in production of sheepgrass fields and also comprise of wide range of soils and climate. All of the samples were taken at the stage of blooming, recognized and collected before being cutting and packaging. Total of 151 samples from 21 different sites were distributed over 8 regions in Heilongjiang province and tested in the lab and stored at 4 °C for further process. For good quality, every sample consisted of one quarter square meter trimmed at 4 cm, oven dried (65 °C, for 48 h), ground (1 mm sieve), and finally mixed. The chemical and microbiological properties of this data set have been described in Chen et al. (2015). They state that the CP was being measured using the Kjeldahl method for nitrogen (N) determination such as (%CP = %N × 6.25) with the help of methods recommended by Association of Official Analytical Chemists-AOAC (AOAC, 1990). Similarly, the ADF and NDF were treated with the help of the methods proposed by Van Soest et al. (1991). As discussed in the introduction the core feature of the prosed models is their insensitivity to the outliers. To highlight this point, we compare their resistances to outliers to the classical models (PLS and PCR). For this aim, we have used the MAD-Median rule (Wilcox, 2005) to detect the outliers in the endogenous variables CP, ADF and ANF. Thus we observe that there is wide variability in the ADF variable compared to the others variables. This variable is ranged between 23.81% and 47.86% and MAD-test detect 11 outliers. The CP and the NDF values are more homogenous than the CP concentration. Specifically, the CP is ranged from 5.59% to 15.76%, and the MAD-test report 3 outliers in this variable. While the NDF values are between 62.96% and 81.41% and have 5 outliers from the MAD-test.

Spectroscopic analysis

NIR spectrometer Model (DA7200, Perten Corporation, Hagersten, Sweden) was used to collect the spectra of the given sample. The NIR spectra were taken at 5 nm intervals in a range from 950 to 1,650 nm. A dried sample with a weight of 50 g was scanned in a sample cell with a diameter of 7.5 cm, with a quartz window maintained at room temperature of 25 °C. Further, using DA7200 software with reflectance mode (R mode) the samples were scanned from 950 to 1,650 nm. The obtained measurements were transformed into the logarithms of the reflectance reciprocal (absorbance). To minimize or eliminate an error caused by loading the sample, each sample was repeated to scan three times. Then the average of three spectral scanning recordings was considered as the final value, which was further treated to final calculation with the help of Grams32

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1433314346

software (Perten Corporation, Hagersten, Sweden). Because of the fineness of the grid, we can consider each subject of the spectral data as a continuous curve (see *Fig. 1*).

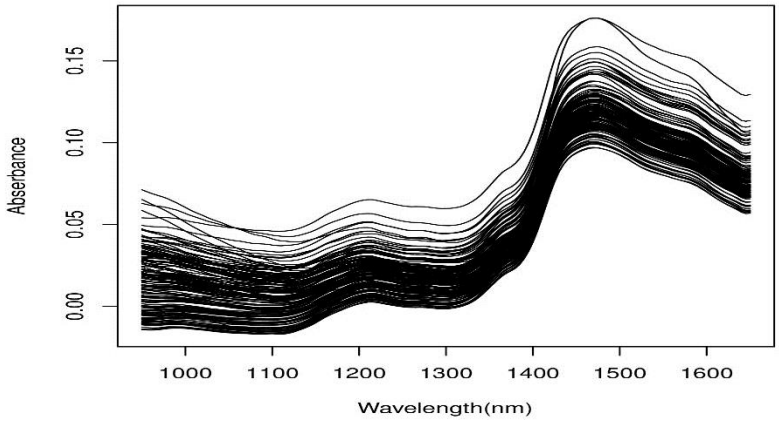

Figure 1. *The NIR spectroscopy curves of the data*

A first preliminary study with the multivariate factorial analysis shows that there is no visible structure of the data (see *Fig. 2*). This fact confirms that the spectral data cannot be summarized by a discretization on small number of grides. In sense that for this prediction issue, it would be more interesting if we incorporate the whole curve of the spectral data.

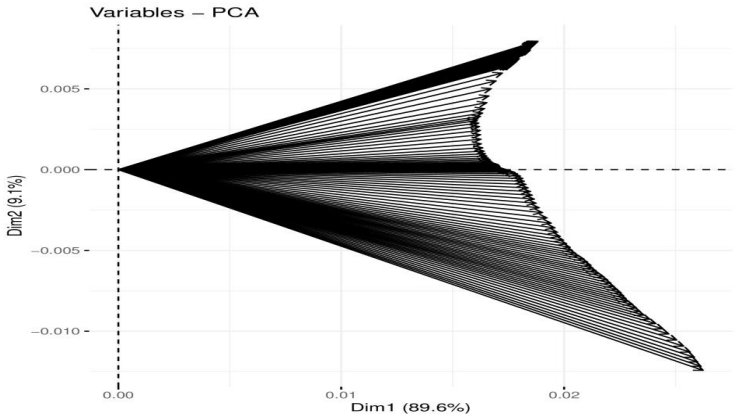

Figure 2. *Factorial analysis of the data*

Notice that the shape of the spectra contains some peaks and valleys which indicated the different chemical component characteristics of Chinese ryegrass samples.

Using this NIR sample, Chen et al. (2015) have considered three standard models (MLR, PCR and PLSR) to predict the chemical quality of this sheepgrass. However, the implementation of these models requires some pretreatment of the spectral data such as dimension reduction, linearity correlation, outliers removing, calibration etc. Such pretreatment modifies the structure of the spectral data independently to the chemical parameters CP, ADF or NDF, which ultimately influence the prediction results negatively. Alternatively, in this paper, we use some new statistical models in order to investigate the forage quality without any transformation. The main advantage of this approach is the fact

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1433314346

that it takes into account the whole curve in its continuous path. Of course, with this consideration, we keep all the information in the sampled data and we accelerate the prediction process by avoiding the initial pretreatment and related drawbacks.

Statistical analysis

Recall that, in the previous works (see, for instance, Chen et al., 2015; Asekova et al., 2016; Monrroy et al., 2017; Yong et al., 2017) the correlation between the NIR spectroscopy and the chemical components of the forage is assumed to be linear. In this contribution, we consider the general case that covers not only the linear and nonlinear models but also the parametric and nonparametric situations. Indeed, to fix the ideas, let us present the mathematical formulation of the equation describing the relationship between the spectral data and the chemical properties of the sheepgrass:

$$Y = r(X) + error, \quad \text{(Eq.1)}$$

where Y is a real variable means either the CP, ADF or NDF. The functional variable X is the curve of the NIR spectroscopy (950-1,650 wavelength). Therefore, the prediction of Y given $X = x$ is based on the determination of the function $r(.)$. The latter is obtained by minimizing the following criterion

$$r(x) = argmin_f E[\rho(Y, f)|X = x] \quad \text{(Eq.2)}$$

Where ρ is a given loss function.

In the modern statistics, there exist various approaches which can be used to model this prediction issue. In this paper, we focus on some models related to the conditional distribution of Y given X which is constructed from the quantile regression and the modal regression. Of course, the conditional distribution of Y given X has the advantage of completely characterizing the relationship between Y and X. Thus, the two used regression models are more informative than the standard regression for analyzing the link between the spectral data and the chemical components of the hay. Furthermore, to provide to NIR spectroscopy users, we present in the rest of this section a varied collection of statistical predictors with mathematical formalism which is recently developed in functional statistics.

The functional linear quantile regression (FLQR)

The FLQR was first introduced in functional Statistics by Cardot et al. (2005). Since this pioneer work, this model had been widely studied in the context of functional Statistics (see, for instance, Qingguo and Linglong, 2017). Mathematically, the quantile regression of order α is the quantity t_α such that$P(Y \leq t_\alpha|X = x) = \alpha$. It is well known that the quantile regression can be also expressed by *Equation 2* using loss function $\rho_\alpha(z) = (2\alpha - 1)z + |z|$ (see the proof in Laksaci et al., 2009). Based on the linear formulation of the quantile regression obtained by Koenker et al. (1978) and Cardot et al. (2005) constructed an conditional quantile estimator of order α for a given sample $(X_i, Y_i)_{i=1,...,n}$ as below

$$\widehat{t_\alpha} = argmin_f \sum_{i=1}^{n}[(2\alpha - 1)(Y_i - < f, X_i >) + |Y_i - < f, X_i >| \quad \text{(Eq.3)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1433314346

It is well established that the conditional median which corresponds to $\alpha = \frac{1}{2}$ constitutes an alternative predictor than the classical regression. Thus, for all given spectra curves x, we can predict CP, ADF and NDF contents by

$$\hat{Y} = \hat{r}(x) = argmin_f \sum_{i=1}^{n} |Y_i - < f, X_i >| \quad \text{(Eq.4)}$$

Notice that one of the main advantage of the quantile regression is to make prediction with predictive region being informative than a single-point prediction, It allows the predictions for thorough contingency planning. Indeed, for a fixed confidence level, for example $\gamma = 0.95$ the theoretical confidence interval is expressed $(t_{0.025}, t_{0.975})$. From the estimator given in *Equation 3,* we can write the interval of predictive region as

$$(\widehat{t_{0.025}}, \widehat{t_{0.975}}) \quad \text{(Eq.5)}$$

The functional nonparametric quantile regression (FNQR)

The nonparametric version of the quantile regression is defined by

$$\tilde{t_\alpha} = argmin_f \sum_{i=1}^{n} [(2\alpha - 1)(Y_i - f) + |Y_i - f|] K\left(\frac{\|x - x_i\|}{h_n}\right) \quad \text{(Eq.6)}$$

This estimator was constructed by Laksaci et al. (2009). In fact, there exist several versions of the FNQR, the natural one is the inverse of the cumulative distribution function estimator. This last estimator was studied by Ferraty et al. (2006) and Dabo-Niang and Laksaci (2012). In this work, we have opted the estimator presented in *Equation 6* being more fast and robust. Similar to the previous case, for single-point prediction, we use the conditional median to predict the CP, ADF or NDF contents denoted by Y. So for all given spectra curves x, Y is approximated by

$$\tilde{Y} = \tilde{r}(x) = argmin_f \sum_{i=1}^{n} |Y_i - f|] K\left(\frac{\|x - x_i\|}{h_n}\right) \quad \text{(Eq.7)}$$

while for the predictive region we use the following nonparametric confidence interval

$$(\widetilde{t_{0.025}}, \widetilde{t_{0.975}}) \quad \text{(Eq.8)}$$

The functional local linear quantile regression (FLLQR)

The study of the local linear estimation of the quantile regression is more recent than the other models. It was introduced by Al-Awadhi et al. (2018). This version of the quantile regression inherits the advantages of the both of the previous models. In particular, from the linear property of this model, we reduce the convergence rate and from the nonparametric one we explore the local structure of the curves. Recall that as a local linear approach, the FLLQR is obtained by assuming that the function $t_\alpha(x)$ has a linear form in the neighbourhood of a given spectra curve x. Mathematically, this assumption is expressed by

$$\forall\, x_0 \; in \; neigborhood \; of \; x \;\; t_\alpha(x) \approx a + b\beta(x, x_0) \quad \text{(Eq.9)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1433314346

Where the quantities a *and* b are obtained by minimizing

$$min_{f,g} \sum_{i=1}^{n} [(2\alpha - 1)(Y_i - f - g\beta(X_i, x)) + |Y_i - f - g\beta(X_i, x)|] K\left(\frac{\|x - X_i\|}{h_n}\right) \quad \text{(Eq.10)}$$

with $\beta(x,x)$ is known function used to measure the proximity among the curves. Thus, for fixed spectra curve x, FLLQR is estimated by $\widehat{t_\alpha}(x) = a$ (where a is solution of *Eq. 4*). Furthermore, for the pointwise prediction, we approximate the contents of CP, ADF and NDF by the conditional median $\bar{r}(x) = \bar{a}$ as solution of *Equation 11*

$$min_{f,g} \sum_{i=1}^{n} |Y_i - f - g\beta(X_i, x)| K\left(\frac{\|x - X_i\|}{h_n}\right) \quad \text{(Eq.11)}$$

Once again this estimator can be used to construct the 95% confidence interval that is

$$(\widehat{t_{0.025}}(x), \widehat{t_{0.975}}(x)) \quad \text{(Eq.12)}$$

The functional local linear modal regression (FLLMR)

The modal regression or the conditional mode is an old alternative model introduced by Collomb (1986). It is well established that this model is more pertinent than the classical regression where the white noise has a Chi-squared distribution. In functional Statistics there exist several nonparametric estimators for conditional mode. In this work we consider more recent one that is proposed by Almanjahie et al. (2018). This estimator is attractive and more robust and fast. With this model, the response variable CP, ADF and NSDF is approximated for a given spectral curve x as in *Equation 13*

$$\ddot{Y} = \ddot{r}(x) = argmin_y \hat{f}(y|X = x) \quad \text{(Eq.13)}$$

where $\hat{f}(.|X = x)$ is the local linear estimator of the conditional density of Y given $X = x$ (see Almanjahie et al., 2018 for more details on this topic). From this estimator, we construct a predictive region so-called the maximum conditional density predictive region introduced by Hyndman (1995). It is defined for a given spectral curve x as in *Equation 14*

$$R = \{y \quad such\ that \quad \hat{f}(y|X = x) > l_{0.95}\} \quad \text{(Eq.14)}$$

with

$$l_{0.95} = max\{l > 0\ such\ that \int_{f(y|X=x)>l} \hat{f}(y|X = x)dy > 0.95\}. \quad \text{(Eq.15)}$$

Results

The performance of all above mentioned models is closely linked with the use of different parameters involved in the estimation of $\hat{r}, \tilde{r}, \bar{r}$ *and* $\ddot{r}$. In fact, the distance between the curves $\|.\|$ and the smoothing parameter h_n are the most influencing parameters in this prediction issue. Concerning the norm $\|.\|$, it is observed that the most of the metrics are obtained by expanding the curve on some basis functions such as

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1433314346

spline basis, trigonometric basis or the interpolation by wavelet basis functions see for example, Ferraty and Vieu (2006). Formally, we write

$$x(t) \approx \sum_{i=1}^{k} c_i B_i(t) \quad \text{(Eq.16)}$$

where $(B_i(.))_i$ is a given orthonormal basis function. Thereafter, the distance between the curves is computed between their interpolation functions. We refer the readers to Ferraty and Vieu (2006) for more details on the mathematical formulation for the functional metric. Meanwhile, we use the leave-one-out Cross-Validation (CV) technique to select the parameter k and the bandwidth parameter h_n. We point out that the CV procedure is implemented with respect to the Mean Square Error (MSE) defined by *Equation 17*

$$MSE = \frac{1}{n}\sum_{i=1}^{n}\left(Y_i - \theta(X_i)\right)^2 \quad \text{(Eq.17)}$$

where $\theta(.)$ Refers to one of the previous models $\hat{r}, \tilde{r}, \bar{r}$ *and* $\ddot{r}$. On the other hand, we choose the same locative function β and the same kernel K as Rachedi et al. (2014). To evaluate the efficiency of the proposed model in this prediction issue, we divide random sample of 151 into two parts as learning sample (size = 100) and testing sample (size = 51). Further, in *Figures 3–5* we draw the box-cox plots of the absolute errors of the testing sample curves of CP, ADF and NDF respectively for four proposed regression models along with previous classical models namely PLS and PCR. The prediction results are shown in *Figures 3–5*.

It is depicted in *Figures 3–5* that there is a significant gain among the functional models as compared to the classical ones. The models FLQR, FNQR, FLLQR, and FLLMR are giving small absolute errors followed by PLS and PCR (*Table 1*).

Table 1. *Absolute error (AE) of crude protein (CP), acid detergent fiber (ADF) and neural detergent fiber (NDF) contents using proposed functional models and classical models*

Models	FLQR	FNQR	FLLQR	FLLMR	PCR	PLS
CP	0.73	1.11	0.73	0.62	2.95	1.45
ADF	0.82	1.24	0.81	1.12	7.08	2.03
NDF	0.67	1.17	0.77	0.71	5.24	1.78

The same fact is confirmed by *Table 2,* where we present the root mean squares error (RMSE) expressed by *Equation 18*

$$RMSE = \sqrt{\frac{1}{25}\sum_{j=1}^{25}\left(Y_i - \theta(X_i)\right)^2} \quad \text{(Eq.18)}$$

Table 2. *Root mean square errors (RMSE) of crude protein (CP), acid detergent fiber (ADF) and neural detergent fiber (NDF) contents using proposed functional models and classical models*

Models	FLQR	FNQR	FLLQR	FLLMR	PCR	PLS
CP	0.85	1.04	0.88	0.69	2.83	1.54
ADF	0.96	1.11	0.97	1.04	6.87	1.91

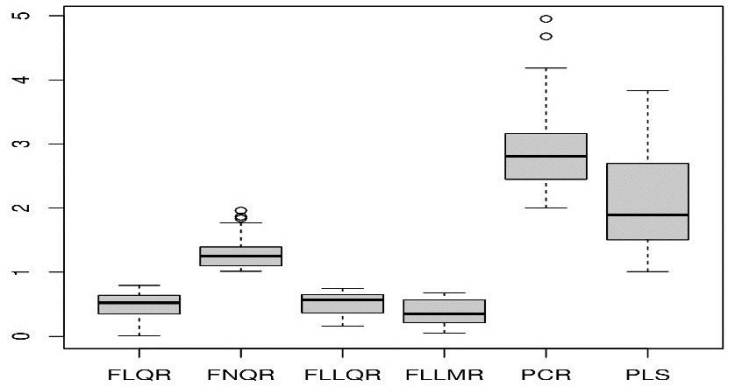

Figure 3. *Box-cox plots of absolute errors of crude protein (CP) contents using functional models and classical models*

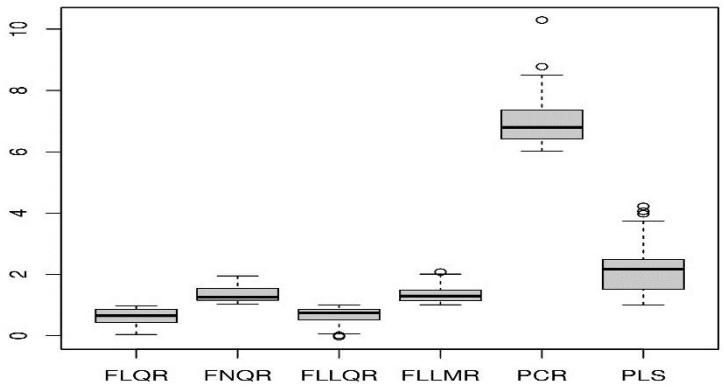

Figure 4. *Box-cox plots of absolute errors of acid detergent fiber (ADF) contents using functional and classical models*

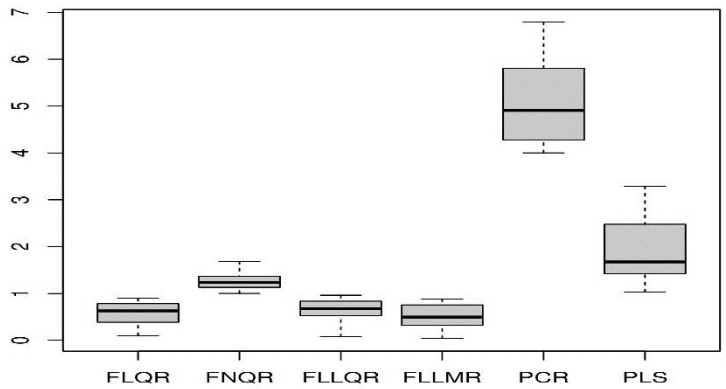

Figure 5. *Box-cox plots of absolute errors of neural detergent fiber (NDF) contents using functional models and classical models*

The values of RMSE is relatively stable and smaller for the four proposed functional models namely FLQR, FNQR, FLLQR and FLLMR as compared to the classical models namely PLS and PCR.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1433314346

Although the performance of the studied models is varied, the variability of the RMSE is relatively stable for the four proposed models FLQR, FNQR, FLLQR and FLLMR as compared to that of the classical models such as PLS and PCR (see *Table 3*).

Table 3. *The broader range of the RMSE*

Models	FLQR	FNQR	FLLQR	FLLMR	PCR	PLS
Range for CP	(0.7, 0.97)	(0.9, 1.93)	(0.35, 0.84)	(0.37, 0.76)	(2.21, 4.95)	(1.01, 3.82)
Range for ADF	(0.4, 0.98)	(1.15, 1.81)	(0.09, 0.99)	(0.97, 1.76)	(6.01, 10.25)	(1.15, 1.81)
Range for NDF	(0.5, 0.91)	(1.03, 1.68)	(0.11, 0.96)	(0.33, 0.88)	(4.11, 6.97)	(1.02, 3.29)

In addition, we also evaluate the performance of NIRS to determine the predictive region using four functional models. The accuracy of these predictive intervals is evaluated with the help of two statistical measures namely the coverage in probability (Co-P) and the mean length of the interval (ML).

In *Table 4,* we summarize the (Co.P) and the M.L of 95% confidence intervals as mentioned in *Equations 3, 6, 10* and *13*.

Table 4. *Accuracy measures in terms of coverage in probability (Co-P) and mean length (ML) for predictive intervals using functional models*

Models	FLQR	FNQR	FLLQR	FLLMR
Co.P-CP	0.97	0.94	0.97	0.98
Co.P-ADF	0.95	0.91	0.93	0.94
Co.P-NDF	0.96	0.94	0.95	0.97
M.L-CP	0.41	0.65	0.34	0.28
M. L.-ADF	0.49	0.75	0.47	0.34
M.L-NDF	0.38	0.69	0.42	0.30

Discussion

The principal forage quality parameters were evaluated using a sample of 151 observations and the results summarized in *Tables 1–3*. The analyzed parameters are CP, ADF and NDF which are ranged between 5.59%-15.76%, 23.81%-47.86% and 62.96%-81.41%, respectively. Such a data analysis was operated using four functional models: FLQR, FNQR, FLLQR and FLLMR.

Based on the results from *Tables 1–3,* it is clear that the best model (having a small AE and RMSE) is the FLQR; it has an absolute error between 0.85-0.96 and its RMSE is valued between 0.67-0.82. Overall, it appears clearly that efficiency of the NIR Spectroscopy to predict the chemical properties differs from one parameter to another and also from one model to another. In particular, the best result is obtained by the FLLMR model in the prediction of the CP quantities. The model FLLQR is more adequate for the ADF parameter as well as for the NDF. On the other hand, both RMSE and AE emphasize the superiority of the functional model against the multivariate models (represented by the PCR and PLS regressions). Furthermore, the best multivariate model is the PCR for which RMSEs are respectively 2.83, 6.87 and 5.08 of CP, ADF and NDF. Moreover, the prediction results confirm that the robustness of the proposed functional models over the multivariate ones have lower variability in the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1433314346

prediction error (RMSE and AE). Undoubtedly, the performance of the functional algorithms over that for the multivariate model is justified by the adequate exploration of the information based on the NIR data. Whilst the efficiency of the multivariate model is linked to several uncontrolled arguments such as the number of regressors, number of factors, the regression equation, etc. Furthermore, the functional approach has also satisfactorily performance for the prediction by the confidence interval as shown in *Table 4*. Precisely, the results of *Table 4* show that there is no substantial difference among the four models for the Co.P parameter as well as for ML. Nevertheless, by taking into account the ratio of Co.P and ML, we can say that the most suitable model in the sense of accuracy measure for the CP is FLLMR while for ADF and NDF is the FLQR model.

Conclusion

In this work, we have developed a new approach to predict the forage quality of Chinese ryegrass in term of its chemical components. We are interested to the prediction the CP, NDF and ADF contents. The proposed approaches combine the recent development in Chemistry and the modern Statistics. Specifically, from the Chemistry, we use the NIR spectroscopy technology which is inexpensive, rapid, reliable and accurate method. Moreover, it reduces the need for conventional wet Chemistry procedures. On the other hand, form the modern statistics we use some functional models which allow to explore all the information of the spectroscopy analysis where the spectral data are viewed as curves. These models are easily implementable and improve substantially of the prediction results. Moreover, the proposed models permit to avoid the core drawback of the PLS and PCR models that is the loss of information after the predictors transformation. Indeed, it is well known that the prediction by the PLS or the PCR regressions requires some transformation of the exogenous variable to reduce the dimension, get the linearity or remove the effect of the outliers. However, all these transformations are carried out through some directions chosen independently to the prediction problem. In particular, the endogenous variable does not intervene in the choice of the optimal direction which can affect the performance of the prediction. Thus, the originality of the functional approach comes from the fact that the prediction problem is performed without any transformation of the data. In conclusion, we can say that this combination of modern Chemistry and modern Statistics is very beneficial ecologically, economically and is more flexible, robust and fast. To the end, let us point out that in addition to pointwise, the proposed models offer the possibility to precise a predictive interval with a given confidence level which being more informative than a single-point prediction in certain situations.

We mention that the NIR analysis of the forage data is a promising analysis technique. It has been regarded as a new fast and reliable method compared to traditional analytical methods. In the last decade, this kind of technique is becoming more and more popular for the screening of forage quality parameters. See, for instance, Asekova et al. (2016) for a list of references). In this study, we combine this modern chemical technique together with the recent development of mathematical statistics in order to provide performance prediction procedures permits to use the whole spectroscopy curves as regressors.

Abstract. The land area of paddy has decreased every year. Karst as one of the most extensive dry land areas in Indonesia is used to raise paddy as well. This study aims to determine the role of land tenancy in rice farming efficiency and the determining factors of the efficiency of rice farming in the karst mountainous Gunungkidul. The research is located in karst mountainous area of Gunung Sewu, Gunungkidul. This study uses the stochastic frontier analysis with cost function approach. The result shows that the estimated parameter of land rent, price of urea fertilizer, labor wage, and production are significantly correlated with the cost production of rice farming. In addition, land tenancy plays an important role in increasing the efficiency of rice farming in the karst mountainous Gunungkidul. Farmers prefer to lease land in the long term between 1-4 years due to the fact that the price offered is cheaper. Other factors that improve the efficiency of rice farming are the number of household members and farm size, while the household head age decreases the efficiency of rice farming.
Keywords: *paddy, land tenancy, stochastic frontier analysis, cost function, farm size*

Introduction

Indonesia is classified as the third largest rice consumer in the world with an average of 38.41 million tons per year (Ministry of Agriculture, 2016). Rice as the primary food of the Indonesian people with a population of 258, 705 million in 2016 (Central Bureau of Statistics Republic of Indonesia, 2017). Compared to other food commodities, per capita rice consumption is the highest (Central Bureau of Statistics Republic of Indonesia, 2017) with an average of 98.01 kg/year (Ministry of Agriculture, 2016).

Due to high consumption of rice, Indonesian rice production is not able to meet the demand and the commodity must be imported. During the 1983-2016 period the value of trade's balance of rice became deficits every year (Ministry of Agriculture, 2016). Even though Indonesia is also the third largest paddy producing in the world (8.11%) reaching 77.29 million tons (FAO, 2018). The cultivated of rice in Indonesia are lowland paddy and dry paddy.

The increasing productivity of dry paddy is higher than lowland paddy. During the period of 2010-2013 dry paddies reached 3.43%/year (Irawan, 2015). The success of increasing productivity of paddy on dry land is not only because of increasing land area, but also caused by technological innovation and an intensification program approach. In fact, the land area has decreased every year. In the period of 2010-2016 the total area of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1434714357

agricultural land was decreased by more than 3,202,560.55 ha (Ministry of Agriculture, 2015a, 2017).

Rice farmers in Indonesia actually have economies of scale which is being able to enlarge their farmland (Antriyandarti and Fukui, 2016). However, the average land area is still stagnant around 0.3 hectares. This is due to several obstacles in the process of enlarging (Antriyandarti and Fukui, 2016; Antriyandarti, 2018). The recommended alternative policy to expand the land is by increasing land liquidation. According to Antriyandarti (2018) liquidation of agricultural land in Indonesia has not gone well, only a small percentage of farmers are renting out their land. Land liquidation is a condition of land market through rent (lease) or sale. In rural Java, land is part of social status and inheritance that must be maintained. Sale of farmland is very rare and in many cases when sale does happen, it is a difficult process.

The potential of availability agricultural land in Indonesia is quite large and has not been utilized optimally. There are 95.81 million hectares which are potential for agriculture, with 70.59 million hectares of which are located on dry land (Ministry of Agriculture, 2015b). Karst is one of the most extensive dry land areas in Indonesia. Indonesia classified as a country that uses the largest karst waters in the world (Margat and Gun, 2013; Younos et al., 2019). The karst region in Indonesia is also the largest karst region in Southeast Asia (Clements et al., 2006). Indonesian karst is estimated at ± 15.4 million hectares (National Development Planning Agency, 2016). One of the karstic areas that become a prototype of karst in tropical regions in Indonesia is karst Gunungsewu, Gunungkidul (Adji et al., 1999).

Gunung Sewu is one of two UNESCO Global Geoparks in Indonesia (UNESCO, 2017). Gunung Sewu as a karst terrain that is geologically, geomorphologically and hydrogeologically shows unique phenomena. It is a classic tropical karst landscape in the south central part of Java Island well-known in the world, and dominated by limestone. Typical formation of “conical hills” is the formation of a series of small hills which are estimated to be 40,000 hills it can be called “gunung sewu”. The Javanese word “sewu” translates into “thousand”.

Geology of Gunungsewu expresses tracks of tectonic, erosion, denudation, and deposition occurred since Miocene epoch. Gunungsewu displays a specific Tropical landform, characterized by the existence of hills, closed depressions, and caves (Kusumayudha et al., 2015). Groundwater systems in this area are dominated by gaps resulting from dissolution which cause dry conditions on the surface. So that for agricultural production is less optimal. This condition causes low crop productivity and causes high poverty (Retnowati et al., 2014; Central Bureau of Statistics of Yogyakarta Province, 2017).

According to (Liu et al., 2017) agricultural land rent increases productivity from households with low productivity to high productivity. The land leasing market to bring land to more productive uses while at the same time providing development of rural non-agricultural economies (Deininger and Jin, 2003; Deininger et al., 2006). According to Zhang (2008), the tenancy increases efficiency in agriculture, because households that acquire land use it more productively. On the other hand (Roger, 1998), productivity and efficiency have a relationship with each other, namely productivity growth includes changes in efficiency and increased efficiency can increase productivity. If technically the production process is carried out inefficiently, it will have an impact on the failure to realize maximum productivity. Therefore, the factors that cause the efficiency of rice farming need to be known. This paper has significant

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1434714357

contributions. This is the first study that aims to determine the role of land tenancy on the efficiency of rice farming in the Gunungkidul Karst Mountainous. Then, the recommendation of this study will be useful for Indonesian government to set the alternative policies and strategies to enlarge farmland in Java which has the largest contribution to the national rice production. Expanding farmland on Java Island would improve the national productivity of rice.

Materials and methods

This research was conducted in the karst mountainous, Gunungsewu area Gunungkidul district located in the coordinates 110°19'48"-110°50'24" BT and 7°52'48"- 8°12'36" LS (see *Fig. 1*). Gunungsewu karst region is a prototype of karst in the tropical region in Indonesia (Kusumayudha et al., 2015; Adji et al., 1999). The focus of the study was carried out in the Girusubo sub-district where the area is in the south which occupies a large part of the Gunungsewu karst region (Regional Development Planning Agency of Gunungkidul, 2013; Tjia, 2013; Retnowati et al., 2014).

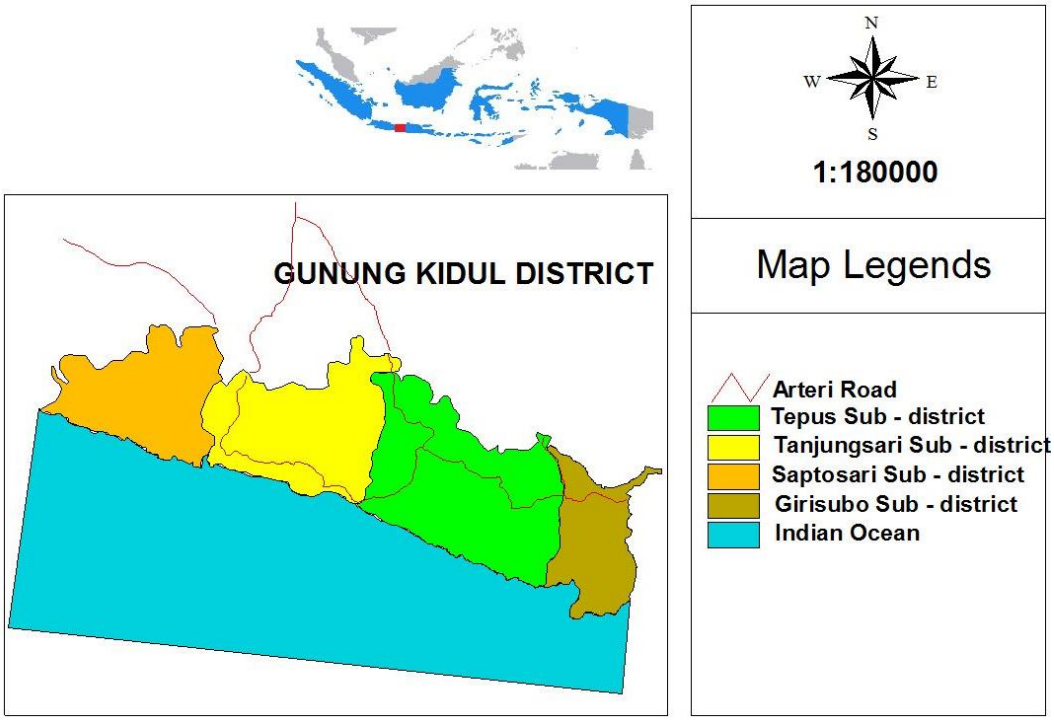

Figure 1. *The Gunung Sewu Karst Area in Gunungkidul District*

The farmers in the study area use karst groundwater as groundwater system. The characteristics of this karst region are influenced by secondary porosity (groundwater flow through dissolving gaps) which causes water to enter the underground flow system and cause dry conditions on the ground (Ford and William, 2007; Cahyadi et al., 2013). So that rice cultivation is not optimal. Because of that reason, the cultivation of rice uses rain to get water or can be called rainfed rice. Where it can only be planted once a year when the rainy season arrives. It cannot be planted for other planting seasons since rice requires a lot of water.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1434714357

The soil condition in this karst region is classified as dry. So it causes the condition of infertile land that has an impact on agricultural cultivation in this region is less optimal (Regional Development Planning Agency of Gunungkidul, 2013). The income of farmers in the Gunungkidul karst area is very small due to the land in this area is not fertile and only relies on rainwater. This condition causes low crop productivity and causes high poverty (Retnowati et al., 2014; Central Bureau of Statistics of Yogyakarta Province, 2017). The survey was conducted in July 2018. The research was collected from household farmers selected as samples using the in-depth interview method with a structured questionnaire prepared. The questionnaire contains characteristic of respondents, farming system, inputs and outputs of crops, farmland liquidation. The sample used was 60 households of rice farmers using the random sampling method.

One method for estimating a production frontier using such data is to envelop the data points using an arbitrarily-chosen function. This approach was used Cobb-Douglas production frontier of the form:

$$Ln\, q_i = x_i\, \alpha - u_i \; i = 1,\ldots,I \qquad \text{(Eq.1)}$$

where q_i represents the output of the i-th firm; x_i is a K x 1 vector containing the logarithms of inputs; α is a vector of unknown parameters; and w, is a non-negative random variable associated with technical inefficiency.

The production frontier (*Eq. 1*) is *deterministic* insofar as q_i is bounded from above by the non-stochastic (i.e., deterministic) quantity $\exp(x_i\alpha)$. A problem with frontiers of this type (and with the DEA frontier) is that no account is taken of measurement errors and other sources of statistical noise - all deviations from the frontier are assumed to be the result of technical inefficiency. An obvious solution to the problem is to introduce another random variable representing statistical noise. The resulting frontier is known as a stochastic production frontier. The stochastic frontier production function model of the form

$$Ln\, q_i = x_i\, \alpha + v_i - u_i \qquad \text{(Eq.2)}$$

Equation 2 is identical to the model *Equation 1* except we have added a symmetric random error, V/, to account for statistical noise. Statistical noise arises from the inadvertent omission of relevant variables from the vector x_i, as well as from measurement errors and approximation errors associated with the choice of functional form. The model defined by *Equation 2* is called a stochastic frontier production function because the output values are bounded from above by the stochastic (random) variable $\exp(x_i\alpha + v_i.)$. The random error v, can be positive or negative and so the stochastic frontier outputs vary about the deterministic part of the model, $\exp(x_i\alpha)$.

These important features of the stochastic frontier model can be illustrated graphically. To do so it is convenient to restrict attention to firms that produce the output qt using only one input, x. In this case, a Cobb-Douglas stochastic frontier model takes the form:

$$Ln\, q_i = \alpha_0 + \alpha\, ln\, x_i + v_i - u_i \qquad \text{(Eq. 3)}$$

This study uses a stochastic frontier analysis with cost function approach. The method of the stochastic frontier cost function which is a derivative of the Cobb-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1434714357

Douglas production function. The cost function of the stochastic frontier according to (Kumbhakar et al., 2015; Coelli et al., 2005) the equation is as follows:

$$Ln\, C = \alpha_0 + \alpha_1 lnPx_1 + \alpha_2 lnPx_2 + \alpha_3 lnPx_3 + \alpha_4 lnPx_4 + \alpha_5 lnPx_5 + (v_i - u_i) \quad \text{(Eq.4)}$$

C = Total cost production (USD)
Px_1 = Land rental (USD/ha)
Px_2 = Labor wage (USD/HOK)
Px_3 = Seed price (USD/kg)
Px_4 = Fertilizer price (USD/kg)
Px_5 = Production (kg)
U_i = Farmer specific characteristics related to cost inefficiency
V_i = Statistical disturbance term

Variable total cost production expresses cost as a function of input prices and outputs (Coelli et al., 2005). Examples of variable costs include the costs associated with the purchase of inputs such as seeds, fertilizers, wages of labor, land rent, herbicides, insecticides, and so on (Debertin, 2004). Land Rental is costs incurred by farmers to rent land during one crop rotation be counted in (USD/ha). Labor wages is costs incurred to pay labor used in the production process for various types of activities farming system, from land preparation to post-harvest during one crop rotation be counted in (USD/HOK). Price of seeds, fertilizers is costs incurred to buy seeds and fertilizers used in a crop rotation be counted in (USD/kg). According to Antriyandarti (2015) seed prices, labor costs, tractor fees, land rental, irrigation costs significantly correlated with total cost in some rice producing areas in Indonesia. Cost is the total cost including land cost, labor cost and material cost, materials include seed, water, fertilizer, chemicals, mulch and other agricultural production materials and services (Liu et al., 2017).

To identify the determinants of cost inefficiency, we estimate the following regression *Equation 2.*

$$U_i = \delta_0 + \delta_1 Z_1 + \delta_2 Z_2 + \delta_3 Z_3 + \delta_4 Z_4 + \delta_5 Z_5 + e \quad \text{(Eq. 5)}$$

U_i = Cost inefficiency effects
Z_1 = Land tenure (if rented land = 1; others = 0)
Z_2 = Number of household member (people)
Z_3 = Education of household head (years)
Z_4 = Age of household head (years)
Z_5 = Farm size (ha)
e = Error term

Efficiencies are observed among rice farmers to examine factors that explain why some farmers are more efficient than others. The source of inefficiency in rice farming concerns the characteristic of the farm and farmers (Villano and Fleming, 2004). Furthermore, efficiency will imply to raise the productivity (Okoruwa, et al., 2006). The base for determining this variable is because of that variable influencing technical inefficiency must be a farmer characteristic or socioeconomic. Variable of age, education, family member, kind of land, location of land, land tenure, off farm occupation, farm size plot significantly correlated with inefficiency in some rice producing areas in Indonesia (Antriyandarti, 2015). Fukui et al. (2002) that the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1434714357

production efficiency under tenancy land is not lower than that of the owned land. Variable of renting land, renting out land, head age, education, agricultural labor, block size, soil fertility, landform significantly correlated with cost inefficiency components in wheat and maize in Gansu, China (Liu et al., 2017). Variable of farmers' age, frequency of participation in counseling, frequency of participation in training, the role of institution, farming system management significantly correlated with inefficiency in organic rice farming in Boyolali Indonesia (Sudrajat et al., 2017). Variable of age, education, training, farm size has effect on inefficiency in rice farmers in Bangladesh (Rahman, 2013).

Results and discussion

Efficiency of cost is the possibility of the minimum cost ratio with the level of specific inefficiencies to the actual total cost (Coelli et al., 2005; Kumbhakar and Lovell Knox, 2000). Therefore, efficiency of cost is defined as the percentage of achieving production costs with best practices. Thus, estimation of the cost efficiency index is calculated from the frontier analysis function. *Table 1* presented the input prices, production and potential determinants of cost inefficiency in the study area.

Table 1. *Input prices, production and potential determinants of cost inefficiency*

Variable	Min	Max	Mean	Amount (percentage)
Total cost (USD)	150.697	545.494	309.926	
Land rent (USD/ha)	59.653	596.525	230.077	
Labor wage (USD/HOK)	3.190	4.052	3.686	
Seed (USD/kg)	0.522	0.969	0.699	
Fertilizer (USD/kg)	0.137	0.164	0.153	
Production (kg/ha)	200.000	2,700.000	967.000	
Family member (person)	1.000	7.000	3.183	
Education of household head (year)	0.000	16.000	7.066	
Age of household head (year)	23.000	85.000	53.500	
Farm size (ha)	0.250	1.000	0.450	
Land Tenure: % of land is HH's owned land				
- All owned (person)				28(47%)
- Mixed (owned and rent) (person)				0
- All rent (person)				32 (53%)

HOK = Workday of labor

This study uses the Cobb Douglas stochastic frontier cost function model. Cost function analysis is carried out to examine the factors that influence the total cost of rice farming in study area. In the initial cost function it is suspected that there are five variables, namely production, land rent, seed price, fertilizer price, and labor wage. The result can be shown by *Table 2.*

The estimation results illustrate the best performance of the respondent farmers at the level of existing technology. This study uses half model with heteroscedasticity, so the standard error is the white standard error (Baum, 2006). The coefficient of all variables is positively significant, except the seed price is negative but not significant. Thus, the results are mostly plausible and consistent with the theory. The estimated parameter of land rent, fertilizer price, production and labor wage are positively significant to the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1434714357

total production cost. While, the estimated parameter of seed price is not significant the total production cost. This is in line with the Rachmat (1985) variable of seed prices do not have a significant effect on total costs and coefficients are negative. Antriyandarti (2015) seed price variables had no effect on the total cost production and coefficient values were negative in rice farming in North Sumatra, West Java and Central Java.

Table 2. *Estimation of Cobb–Douglas frontier cost function*

Variable	Coefficient	S.E

*Significant at 10% level; **significant at 5% level; ***significant at 1% level, ^{ns}not significant

Variable of production is positively significant to total cost production at 1% level. An increase in rice production by 1% lead to increase the total cost production of rice farming by 0.25%. Variable of land rent has positive effect on the total cost production of rice farming at 10% level, with a coefficient of 0.102 it is mean that an increase in land rent by 1% lead to increase the total cost by 0.1%. In addition, the frontier cost elasticity of the variables of fertilizer and labor is 0.81 and 1.27, respectively. This result is consistent with Antriyandarti (2015).

The result of the determinants of cost inefficiency is presented in *Table 3*. The estimated parameter of land tenure as dummy variable is negatively significant to the inefficiency of rice production cost at 5% level. The status of 'tenant' land will decrease inefficiency compared to the status of non-tenant land. In other words, land tenancy will increase the efficiency of rice farming in the karst mountainous, Gunungkidul. This is highly related to the behavior of farmers. The farmer who rent land has higher motivation to take care for their land so that productivity is higher compared to the owned land farmers. The tenant farmers strive to manage production in a professional manner and are receptive to new technology; therefore, they can improve their production and increase their income. This result is in accordance with Antriyandarti (2015) that land rent has a positive effect on the efficiency of rice farming costs in most parts of Indonesia. This finding is also consistent with Mailena et al. (2014) and the result in Central Java by Fukui et al. (2002) that production efficiency on rented land is not lower than that of the owner's own land.

Tenancy of land in the karst mountainous Gunungkidul, originated from the farmers who rent land to other farmers, the land of the village treasury managed by village officials to fund the construction of infrastructure or village needs, and the land which is right of the village officials to compensate for their salary called "*tanah lungguh*". The contract of land tenancy term is ranging from 1-4 years. If the farmer rents in the long run the price offered is cheaper. This finding is the main highlight of this study. Land

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1434714357

tenancy plays an important role on improving the efficiency of rice farming in karst mountainous Gunungkidul which is an unproductive area with a high poverty rate. Poverty alleviation effort in this area is very urgent (Antriyandarti et al., 2018). The improvement of efficiency of rice farming would improve rice farm income. Thus, the poverty in karst mountainous Gunungkidul can be reduced.

Table 3. *Potential determinants of cost inefficiency*

Variable	Coefficient	Std. Err
Land tenure	-0.074**	0.031
Household member	-0.095**	0.041

Farm size	-0.110***	0.002
Constant	0.522*	0.276
F-stat	52.57***	
Number of observations	60	
R^2	0.792	

*Significant at 10% level; **significant at 5% level; ***significant at 1% level

The estimated parameter of number of household member is negatively significant to the inefficiency of rice farming at 5% level. The larger number of household members will reduce the inefficiency of rice farming in the karst mountainous Gunungkidul. This indicates that efficiency will increase if the number of households increases. This finding is contrast with Antriyandarti (2015) which states that the number of family members influences the increase in inefficiency of rice farming in West Java and North Sumatra, Indonesia. The rice farming in Gunungkidul is dominated by the use of family labor for land preparation, transplanting, fertilization, weeding, and harvesting.

The education of household head is also negatively significant to inefficiency of rice farming. It is suggested that the higher education can manage rice farming more efficiently. This is in line with the (Antriyandarti, 2015; Rahman, 2013; Sudrajat et al., 2017) that education has a positive effect on the cost efficiency of rice farming. The education is an important variable that can improve efficiency. Conditions in the field prove that farmer education is still low, so that it becomes a problem in efficiency. Therefore, this finding has policy implementation for government to improve education and managerial skills of farmers. Meanwhile, the variable of age is positively significant to inefficiency of rice farming. This indicates that the older the farmer, the greater inefficiency of rice farming or in other word, the younger farmer will produce more efficient farming. This finding is contrast with Antriyandarti (2015). The younger household head in the study area suggests more adaptable to accept and implement the new innovation technology of rice farming that can achieve high efficiency. Thus, farmer regeneration is strongly needed, particularly family member in the farm household. However, degeneration in agricultural sector is serious problems in most countries since young people are uninterested in farming or in rural futures.

The estimated coefficients of farm size are significantly negative to inefficiency of rice farming in karst mountainous Gunungkidul**.** This shows that the larger farm size will increase the efficiency of rice farming (Antriyandarti, 2015).

Conclusion

The results show that land tenancy and farm size increases the efficiency of rice farming in the karst mountainous, Gunungkidul. This is much related to the behavior of farmers where renting land have the motivation to care for their land so that productivity is higher compared to farmers who own their own land. Land tenancy has important role in increasing efficiency and improving farmland liquidation in dryland area. Farm size can be enlarged by improving land tenancy system. Farmers in the study area need to enlarge their farm size by leasing land from others because rice farmers in upland Gunungkidul are not willing to sell their land. This prompted the government to facilitate leasing of land in rural areas to increase rice production. Moreover, local government can facilitate transaction in rental market and promote farmland liquidation. Enlarging farm size not only increases efficiency but also increases farm household income. Therefore, the poverty in the karst mountain region in Gunungkidul can be reduced (Antriyandarti, 2018).

(Received 6th Jun 2019; accepted 24th Oct 2019)

Abstract. A performance auditing evaluation problem of governmental ecological environment belongs to a Multiple Criteria Decision Making (MCDM) problem. However, we must use quantitative data to avoid inconsistency as well as to ensure the science and correctness of the decision in an evaluation index system of performance auditing. In this paper, we present a comprehensive evaluation index system of performance auditing of governmental ecological environment based on fuzzy Analytic Hierarchy Process (AHP) and Technique for Order Preference by Similarity to Ideal Solution (TOPSIS). Firstly, a comprehensive evaluation index system of performance auditing is approved from the literature related to governmental ecological environment. Secondly, the relative weights of the chosen evaluation indexes of performance auditing are calculated by fuzzy AHP method. Furthermore, TOPSIS method is adopted to rank the performance auditing and improve the gaps with five local governments as an empirical example. As a new data analysis method, the results show that fuzzy AHP theoretical model and TOPSIS method has become suitable for use in the evaluation of performance auditing of governmental ecological environment.
Keywords: *performance auditing, evaluation index system, decision model, governmental ecological environment, TOPSIS, analytic hierarchy process*

Introduction

In response to accelerating global clean-energy race, governmental ecological environment has been heavily advocated over the past decade. Many different theories and methods of performance auditing of governmental ecological environment for conducting a scientific and reasonable valuation have been applied in various academic circles in the last several years (Paydar et al., 2017). Today organizations operate in an ecological environment where performance auditing is continuously changing and increasing in the process of incidental development (Ivanova et al., 2016). Thus, dealing with qualitative information is quite common in various fields such as decision making and prediction (Fero et al., 2013). The fact of the matter is that evaluation process of performance auditing of governmental ecological environment is costly and its adaptation takes too much time so the evaluation cost is too high in many countries (Zanardo et al., 2018). The performance auditing evaluation has become the certain tendency for the government ecological environment (Shi, 2017). With the development of economic reforms, remarkable progress has been made in the efficient use of resources and ecological environment by using performance auditing in the past years in China. Thus, an effective intelligent decision method which automates and integrates evaluation processes and allows information sharing in governmental ecological environment needs to be researched in in-depth (Minichilli et al., 2017; Manzoor et al., 2018). Moreover, making some research on performance auditing of the governmental ecological

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1435914374

environment is of great significance to find a way to evaluate performance auditing accurately.

On the other hand, it is necessary to supervise and improve the situation of performance auditing by government, and the evaluation of governmental ecological environment is becoming more and more important. The research of comprehensive evaluation index system of performance auditing has been theoretical and practical as the development of scientific technology and economic reform (Gutierrez, 2015). So a theoretical analysis of the objectiveness for evaluation of performance auditing was used to protect the whole governmental ecological environment. Although local governments can develop their own evaluation index system, other ones may prefer ready systems to shorten application cycle and reduce human resource cost (Johansen and Christoffersen, 2017). Therefore the evaluation index system of performance auditing is an important decision making problem of local governments and effects directly the governmental ecological environment (Mueller, 2011). The overall performance auditing must be verified by environmental checkers in the following aspects of implementation measures of governmental ecological environment, environmental monitoring and auditing arrangement and other environmental protection system (Nehme, 2017). Because governmental ecological environment entries propagate to performance auditing, the comprehensive evaluation index system would require more attention and time (Stephenson, 2015). This paper focuses on structuring a decision aid mechanism on the basis of fuzzy AHP and TOPSIS under fuzzy environment in order to route useful decisions with respect to the public satisfaction evaluation of governmental sectors. Furthermore, the fuzzy algorithms are integrated into the decision-making framework in order to involve quantitative information into the performance auditing evaluation.

The remainder of this paper is organized as follows. A comprehensive evaluation index system of performance auditing of governmental ecological environment is built in Section 2. And the concepts of fuzzy AHP and TOPSIS are introduced in this section. In Section 3, the performance auditing evaluation framework and the analytical methods are proposed. The detailed implementation of the evaluation model and process by using fuzzy AHP and TOPSIS method is also given in this section. An empirical example for performance auditing evaluation indexes and the result analyses is presented to illustrate the approved evaluation model and method with five local governments in Section 4. Lastly, concluding remarks and proposals for further research are given in Section 5.

Comprehensive evaluation index system of performance auditing

In this paper, a fuzzy theory and AHP method is adopted to implement the evaluation process. To use AHP model for the evaluation of performance auditing of governmental ecological environment for a new tool, a new group of expert's opinions are needed as input to the decisions process. The comprehensive evaluation index system of performance auditing is shown in *Fig. 1*.

At present, the research on a systematic and complete performance auditing evaluation system is not perfect in practice. This study has attempted to establish a decision mechanism towards the execution of shipping investment decisions based on customer satisfaction levels in different markets. The comprehensive evaluation index system of performance auditing is presented with the analysis of governmental ecological environment affecting factors. As an effective decision tool, the proposed comprehensive evaluation index system of performance auditing is expected to provide invaluable decision for governmental ecological environment. In addition, multi-level

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1435914374

comprehensive evaluation index system of performance auditing of governmental ecological environment was expounded from the model.

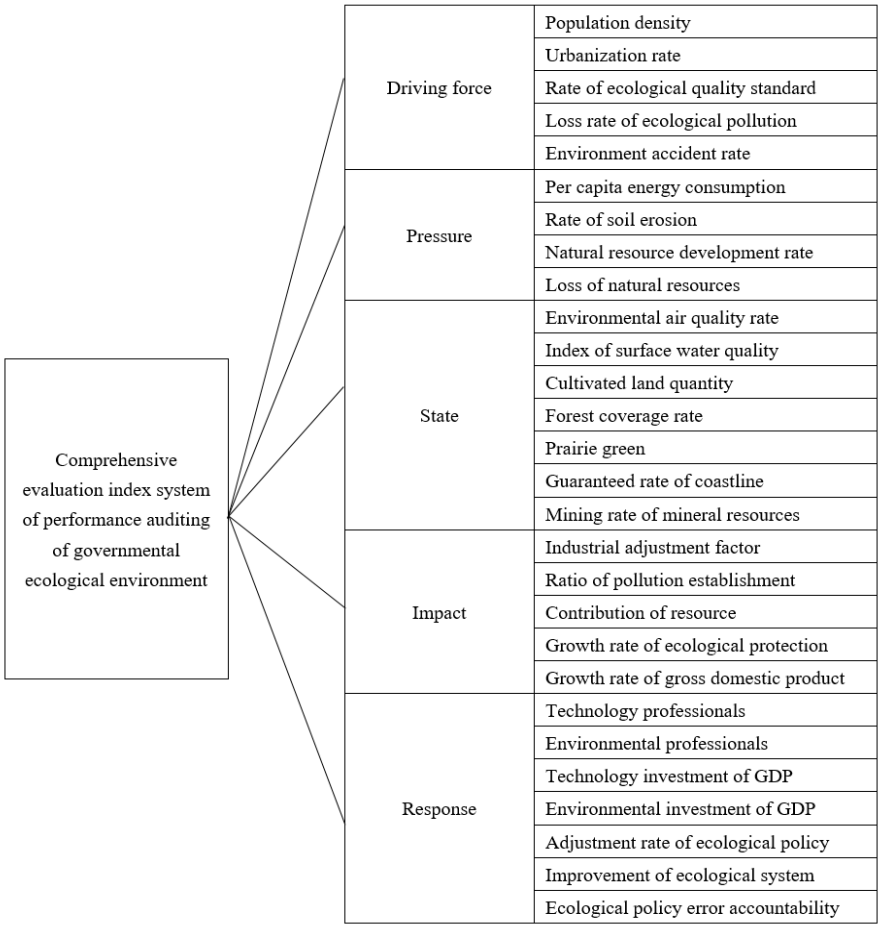

Figure 1. *The comprehensive evaluation index system of performance auditing*

Research methodology

Fuzzy analytic hierarchy process

In this paper, we propose a comprehensive evaluation method of performance auditing consists of integration of fuzzy AHP and TOPSIS. The Analytic Hierarchy Process (AHP) was firstly devised by Wind and Saaty in 1980. It is a useful tool to solve complex decision problems in many fields (Groselj and Stirn, 2018). The relative importance of a list of indexes was presented by using a pairwise comparison amongst the factors by relevant experts (Ahmadipari et al., 2018). In past years, the AHP method has been used often for decision problem, but recently years fuzzy AHP method has been preferred more than AHP method for MCDM problem (Kumar et al., 2017). Moreover, the fuzzy theory has become a useful tool for automating human activities in the decision-making process (Nazari et al., 2018). Fuzzy numbers are often convenient to work with triangular fuzzy numbers in promoting representation and information processing of system theory in a fuzzy environment (Hategekimana, 2018). For example, the decision makers cannot provide a satisfaction value precisely such as ‘quite satisfactory’ and ‘not very

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1435914374

satisfactory' (Tahri et al., 2017). In here, it is suggested that the decision makers use the different variables to evaluate the importance of the criteria combined with the actual condition.

The evaluation criteria and alternatives as regards the problems of performance auditing of governmental ecological environment presented in this paper have been modeled by using fuzzy AHP. Next, this paper describes the relevant elements of computational steps and the main method of calculating process.

Step 1. Structuring fuzzy judgment matrix

Triangular fuzzy number M is presented as (l, m, u), and $\mu_{\mathrm{M}}(x)$ is given as:

$$\mu_{\mathrm{M}}(x)=\begin{cases}\dfrac{1}{m-u}x-\dfrac{u}{m-u} & x\in[m,u]\\ \dfrac{1}{m-x}x-\dfrac{l}{m-l} & x\in[l,m]\\ 0 & other\end{cases} \quad \text{(Eq.1)}$$

where l≤ m ≤u, l and u is the lower and upper bound values of M respectively, which is shown in *Fig. 2*.

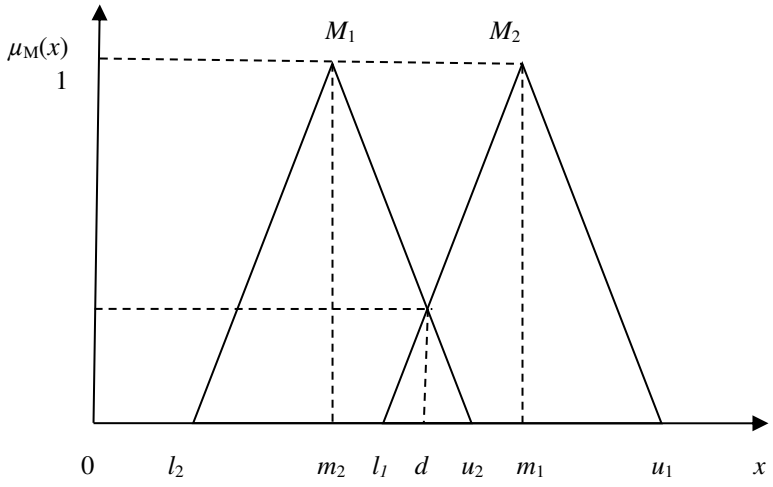

Figure 2. *Relationship between fuzzy number M1 and M2*

As $M_1=(l_1,m_1,u_1)$ and $M_2=(l_2,m_2,u_2)$ are two triangular fuzzy numbers, the operation methods of two trigonometric fuzzy numbers are presented in the following:

$$M_1+M_2=(l_1+l_2,m_1+m_2,u_1+u_2) \quad \text{(Eq.2)}$$

$$M_1\otimes M_2\approx(l_1l_2,m_1m_2,u_1u_2) \quad \text{(Eq.3)}$$

$$1/M\approx(1/u,1/m,1/l) \quad \text{(Eq.4)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1435914374

Step 2. Determining fuzzy number

In order to get the interval solution of the model, all the comparison matrix numbers would be turn into a fuzzy number. The formula to transform various kinds of fuzzy number into triangular ones are given as:

$$(\frac{l_1 + l_2 + \cdots + l_i}{i}, \frac{m_1 + m_2 + \cdots + m_i}{i}, \frac{u_1 + u_2 + \cdots + u_i}{i}) \quad \text{(Eq.5)}$$

With algorithms, a fuzzy variable will transform the fuzzy number into interval number by using the basic theory of fuzzy numbers.

Step 3. Calculating fuzzy value

In this paper, the definition of a fuzzy value is presented in the following:

$$\boldsymbol{D}_{\mathrm{i}}^{k} = \sum_{j=1}^{n} a_{ij}^{k} / (\sum_{i=1}^{n} \sum_{j=1}^{n} a_{ij}^{k}) \quad \text{(Eq.6)}$$

where $i = 1,2,...,n$.

Step 4. Definition of trigonometric fuzzy functions

As M1 ≥ M2, the probability of the triangular fuzzy function is defined as:

$$V(M_1 \geq M_2) = sup_{x \geq y}[\min(\mu_{M1}(x), \mu_{M2}(y))] \quad \text{(Eq.7)}$$

$$V(M_1 \geq M_2) = \mu(d) = \begin{cases} (l_2 - u_1) / ((m_1 - u_1) - (m_2 - l_2)) & m_1 \leq m_2, \ u_1 \geq l_2 \\ 1 & m_1 \geq m_2 \\ 0 & otherwise \end{cases} \quad \text{(Eq.8)}$$

Step 5. Determining weights of the level indicators

If a fuzzy number is greater than the probability of other fuzzy numbers, it is given in the following:

$$V(M \geq M_1, M_2, ..., M_n) = \min V(M \geq M_i) \quad \text{(Eq.9)}$$

Step 6. Calculating the weight vectors

Assume that d(Ai) = minV(Si≥ Sk), and k=1, 2, . . ., n. the fuzzy theory was used to determine the weight vector of each index, which can be defined by

$$W' = (d'(A_1), d'(A_2), \cdots, d'(A_n))^T \quad \text{(Eq.10)}$$

where Ai (i=1, 2, …, n) are n elements of a situation.

Next, the normalized weight vectors with different optimum indicators are expressed as follows:

$$W = (d(A_1), d(A_2), \cdots, d(A_n))^T \quad \text{(Eq.11)}$$

Thus, the calculation method obtained from above results can be used to accurately determine the comprehensive weight of each index.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1435914374

Technique for order preference by similarity to ideal solution

TOPSIS (Technique for Order Preference by Similarity to Ideal Solution) is one of the useful tools to solve real-world problems of quantitative and qualitative factors including economic and social factors (Deveci et al., 2018). TOPSIS makes it possible to appraise the distances of each indicators from the positive and negative ideal solutions by comparing the difference among many schemes (Wang et al., 2017; Korucu et al., 2018). The positive ideal solution is composed of all best values in the decision making process (Hussain and Yang, 2018). Furthermore, the sorting of schemes and weights are very straight forward and clear. In the process of TOPSIS method, the performance ratings and the weights of each criteria are given more verbose output (Kaur et al., 2018). The TOPSIS is an extensive and thorough decision tool to evaluate the performance auditing in different fields (Lourenzutti et al., 2017; Gupta, 2018). With respect to MCDM problem in which both the attribute weights and attribute values are fuzzy numbers, a new method of TOPSIS is presented in this paper.

Assume that a multiple criteria decision-making problem with m alternatives $A_1, A_2, \cdots, A_m$ and n decision attributes $D_1, D_2, \cdots, D_n$, and the decision matrix is defined in *Table 1*.

Table 1. *The decision matrix of multiple criteria decision-making problem*

No.	D_1	D_2	$\cdots$	D_n
A_1	x_{11}	x_{12}	$\cdots$	x_{1n}
A_2	x_{21}	x_{22}	$\cdots$	x_{2n}
$\cdots$	$\cdots$	$\cdots$	$\cdots$	$\cdots$
A_m	x_{m1}	x_{m2}	$\cdots$	x_{mn}

Step 1. Computing canonical decision matrix

The multilevel matrix is modeled and simulated in the following:

$$y_{ij}^{'} = \begin{cases} y_{ij} & income-type\,inde \\ -y_{ij} & cost-type\,ind \\ 1-y_{ij} & others \end{cases} \quad \text{(Eq.12)}$$

The indexes are evaluated by each decision maker, and are converted into proper variables, which can be defined by

$$Z_{ij} = x_{ij} / \sqrt{\sum_{i=1}^{m} x_{ij}^2} \quad \text{(Eq.13)}$$

Step 2. Calculating weighted canonical decision matrix

With the help of the object weight vector, the weighted canonical decision matrix of the alternatives is defined as

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1435914374

$$V_{ij} = W_j \cdot n_{ij} \quad \text{(Eq.14)}$$

where $\sum_{j=1}^{n} W_j = 1$, which can be determined by using fuzzy AHP method.

Step 3. Determining positive ideal solution (PIS) and negative ideal solution (NIS)

$$A^+ = \left\{V_1^+, V_2^+, \cdots, V_n^+\right\} = \left\{\left(\max V_{ij} \,|\, j \in I\right), \left(\min V_{ij} \,|\, j \in I\right)\right\} \quad \text{(Eq.15)}$$

$$A^- = \left\{V_1^-, V_2^-, \cdots, V_n^-\right\} = \left\{\left(\min V_{ij} \,|\, j \in I\right), \left(\max \upsilon_{ij} \,|\, j \in I\right)\right\} \quad \text{(Eq.16)}$$

where, I belongs to benefit attribute, j belongs to cost attribute.

Step 4. Calculating the distance of each alternative from PIS and NIS

The distance of each alternative from PIS and NIS are determined:

$$d_i^+ = \sqrt{\sum_{j=1}^{n} \left(V_{ij} - V_j^+\right)^2} \quad \text{(Eq.17)}$$

$$d_i^- = \sqrt{\sum_{j=1}^{n} \left(V_{ij} - V_j^-\right)^2} \quad \text{(Eq.18)}$$

Step 5. Calculating the closeness coefficient of each alternative

The closeness coefficient of each alternative is given by

$$C_i^* = \frac{d_i^-}{d_i^+ + d_i^-} \quad \text{(Eq.19)}$$

where $i = 1, 2, \cdots, m.$.

Then, the ranking of alternatives can be designed by comparing C*i values.

In this paper, we present TOPSIS method and fuzzy AHP to analyze decision objects, it would make the result to be more reasonable and accurate.

Results

The aim of this paper is to evaluate the performance auditing of governmental ecological environment of five local governments in Fujian Province of China. The comprehensive evaluation index system and method are applied to assessing performance auditing in part of the local government of Fujian province administrative cities as one example. Firstly, the comprehensive evaluation index system was set up in allusion to the ecological environment of the five local governments by using the method of multifactorial evaluation method of fuzzy mathematics. Based on analysis mode and characteristics of comprehensive evaluation index system, the hierarchy structure of comprehensive evaluation index system was established in a very powerful way. Then,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1435914374

many decision makers from different areas evaluate the importance of evaluation indexes with the help of questionnaires. Next, the performance auditing was built and the traditional method of AHP is improved with fuzzy theory, which was also utilized for determining the weights of main evaluation criteria. Finally, TOPSIS method was presented for evaluating the performance auditing of governmental ecological environment by considering ecological efficiency and weights of the criteria. According to above methods, the ranking of the performance auditing can be obtained by improvement of the given model and method in the numerical example.

Based on fuzzy AHP method, the hierarchical structure of performance auditing of model in application is shown in *Fig. 3*.

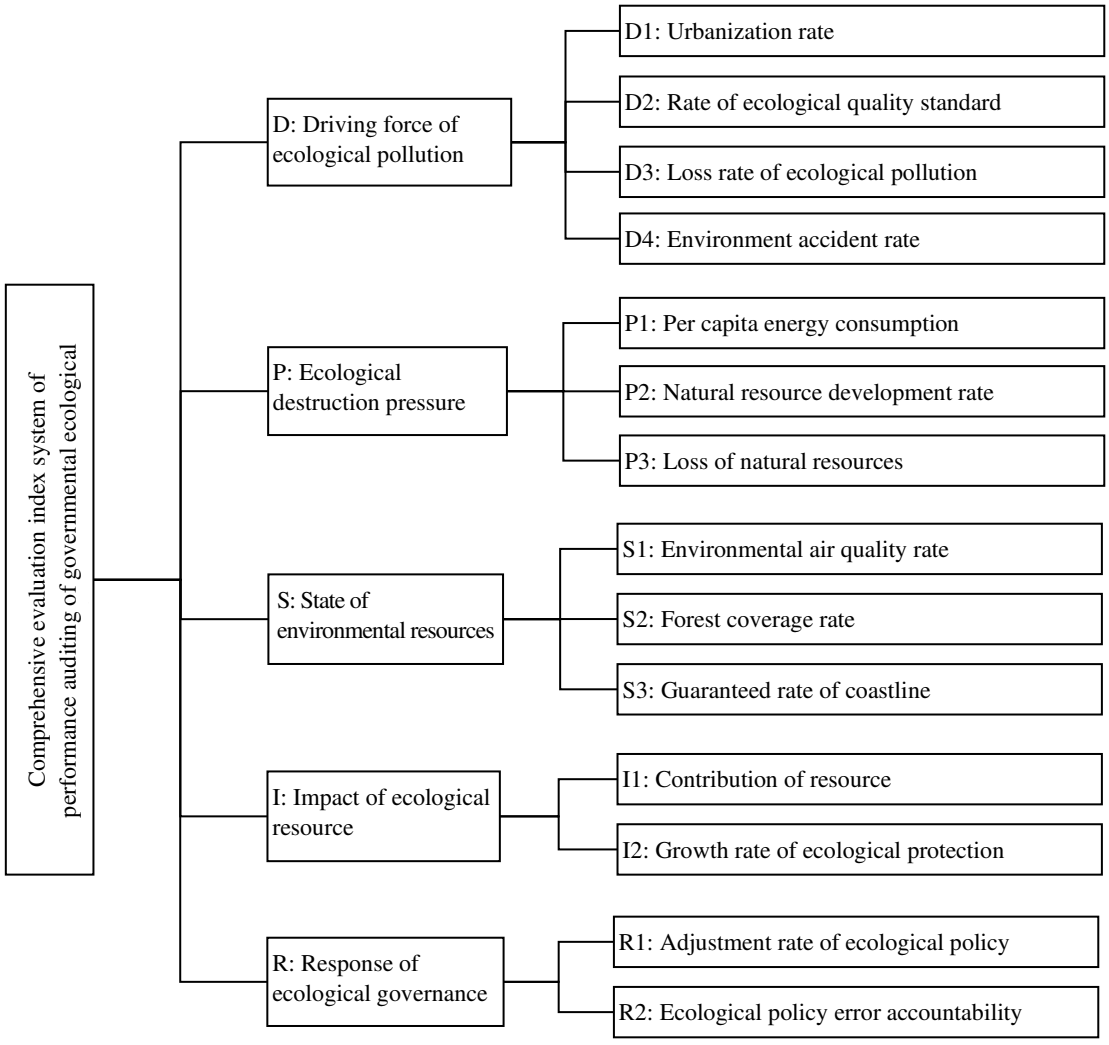

Figure 3. *Hierarchical structure of performance auditing of model in application*

The decision of fuzzy AHP is an interactive evaluation system intended to help decision makers from different backgrounds compile useful information from different weight vectors to make decisions. The data extraction process includes combinations of qualitative and quantitative data analysis, questionnaires, interviews, scoring by many experts from Fujian province administrative cities in China. For the purpose of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1435914374

determining the correlation between evaluation criterions more accurately and faster than ever before, we determine relative importance of each criteria over another based on pair-wise comparison by a group decision. Thus, each decision maker individually can make out pair-wise comparison by using 1–9 scale.

In this paper, we take the evaluation index of ecological destruction pressure (P) as example, the mathematical model and solution procedure for performance auditing of governmental ecological environment are briefly depicted, which includes sub-indicator of per capita energy consumption (P1), natural resource development rate (P2) and loss of natural resources (P3). The pair-wise comparison matrix is show by using *Eq. 1* in the following:

1	1	1	3	2	2	1	1	2
1	1	1	2	3	4	2	1	2
1	1	1	4	1	2	1	2	3
1/2	1/2	1/3	1	1	1	1	1	2
1/4	1/3	1/2	1	1	1	1	2	3
1/2	1	1/4	1	1	1	8	1	7
1/2	1	1	1/2	1	1	1	1	1
1/2	1	1/2	1/3	1/2	1	1	1	1
1/3	1/2	1	1/7	1	1/8	1	1	1

Based on triangular fuzzy number judgment matrix theory and priority method, the fuzzy pair-wise comparison matrix is transformed into triangular fuzzy numbers by using *Eq. 2*, *Eq. 3* and *Eq. 4*, which is given as

1.000	1.000	1.000	3.000	2.000	2.667	1.333	1.333	2.333
0.417	0.611	0.361	1.000	1.000	1.000	3.333	1.333	4.000
0.444	0.833	0.833	0.325	0.833	0.708	1.000	1.000	1.000

By using fuzzy pair-wise comparison matrix, the synthesis values of different evaluation indexes can be calculated in the following:

5.333	4.333	6.000
4.750	2.944	5.361
1.770	2.667	2.542

Next, the complementary index set is composed of the evaluation indexes, which is given as

0.384	0.436	0.506
0.342	0.296	0.452
0.127	0.268	0.214

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1435914374

Then, the synthesis values respect to main goal can be calculated using the system and load characteristics in the following:

V(S1≥S2)= 1.000, V(S1≥S3)= 1.000.

Then, d'(C1)=min(1.000, 1.000)=1.0000.

V(S2≥S1)= 0.330, V(S2≥S3)= 1.000.

Then, d'(C2)=min(0.330, 1.000)=0.3296.

V(S3≥S1)= 106.446, V(S3≥S2)= 1.281.

Then, d'(C3)=min (106.446, 1.281)=1.281.

Thus, we can obtaine the values priority weights respect to main goal, which is given as

W=(0.383,0.126,0.491).

In the same way, we can calculate other weights of evaluation index of performance auditing of governmental ecological environment with similarity calculation method. So weights of sub-criteria to illustrate the steps used to evaluate five local governments are shown in *Table 2*.

Table 2. *The weights of multiple evaluation criteria*

Evaluation criteria	Local weights	Over weights	Rank
(D) Driving force of ecological pollution	0.358	0.358	1
(D1) Urbanization rate	0.138	0.049	10
(D2) Rate of ecological quality standard	0.187	0.067	8
(D3) Loss rate of ecological pollution	0.372	0.133	1
(D4) Environment accident rate	0.303	0.108	2
(P) Ecological destruction pressure	0.217	0.217	2
(P1) Per capita energy consumption	0.383	0.083	5
(P2) Natural resource development rate	0.126	0.027	14
(P3) Loss of natural resources	0.491	0.107	4
(S) State of environmental	0.106	0.106	5
(S1) Environmental air quality rate	0.273	0.029	13
(S2) Forest coverage rate	0.321	0.034	12
(S3) Guaranteed rate of coastline	0.406	0.043	11
(I) Impact of ecological resource	0.173	0.173	3
(I1) Contribution of resource	0.384	0.066	9
(I2) Growth rate of ecological protection	0.616	0.107	3
(R) Response of ecological governance	0.146	0.146	4
(R1) Adjustment rate of ecological policy	0.473	0.069	7
(R2) Ecological policy error accountability	0.527	0.077	6

Thus, the weights of multiple criteria of the comprehensive evaluation index system of performance auditing of governmental ecological environment is shown in *Fig. 4*.

In subsequent sections, we discuss how TOPSIS method is used for comprehensive evaluation of performance auditing of governmental ecological environment. Based on the survey of five local governments in China, this paper sums up the document data and makes some summary statistics, which is shown in *Table 3*.

Based on TOPSIS method, the establishing process includes constructing the fuzzy judgment matrix and integrating the weight vector is given in the following.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1435914374

By using *Eq. 12*, we can get the index data after transformed and processed of five local governments, which is shown in *Table 4*.

Next, data normalization of index classification during system modeling has been given in *Table 5*.

I1	0.441	0.426	0.466	0.446	0.456
I2	0.437	0.475	0.421	0.459	0.443
R1	0.433	0.448	0.443	0.458	0.453
R2	0.441	0.456	0.465	0.427	0.446

Then, the distance of each local government from PIS and NIS with respect to each criterion are calculated with the help of basic principles and methods of TOPSIS.

The ranking of the five local governments is shown as

C*=(0.804, 0.475, 0.361, 0.197, 0.652).

Moreover, the ranking result of the five local governments is shown in *Fig. 5*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1435914374

Based on C* values, the ranking of the evaluation alternatives in descending order are A, E, B, C and D. Proposed model results indicate that A local government is the best alternative with C* value of 0.804. The result is a fundamental measure for raising the evaluation quality, which auditors can also put forward adequate audit findings and audit conclusions.

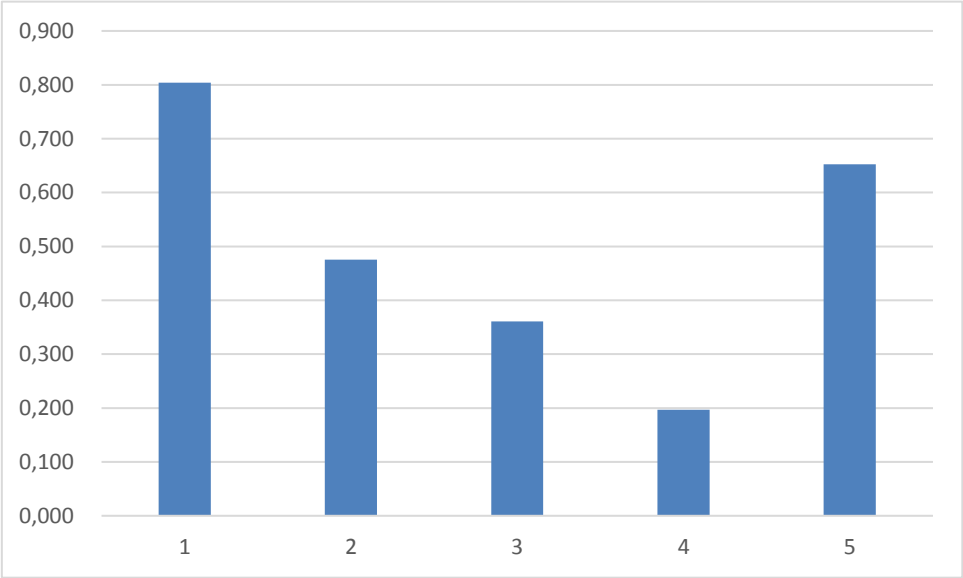

Figure 5. *The ranking results of the five local governments*

Discussion and implications

This Innovative Comprehensive Evaluation Index System is an Effective Means to the Performance Auditing of Governmental Ecological Environment in China

In this paper, we find that the comprehensive evaluation index system of performance auditing can better solve the dilemmas faced by China's governmental ecological environment. A comprehensive index system based on fuzzy AHP model is presented in this paper. AHP can be used to solve MCDM problem in many areas, so it has good applicability. Based on establishment of evaluation index system, AHP model is applied to realize the scientific computation on performance auditing of governmental ecological environment in china. This paper also based upon the comprehensive evaluation index system of fuzzy AHP model to come to a good conclusion, which corresponds to the actual case.

This Innovative Method Can Enrich the Evaluation Veracity and Efficiency of Performance Auditing

Based on fuzzy AHP and TOPSIS method to analyze and solve the evaluation problem is an innovative way to enrich the quality of performance auditing scientifically. The evaluation index system is put forward and the expert system based on AHP is established, so as to solve the evaluation problem of performance auditing combined with TOPSIS method effectively. And the evaluation process are divides into five levels and associates them with evaluating values to solve the problem of index standards for different policies governmental ecological environment. Finally, the result of the case in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1435914374

Fujian Province of China shows that the improved method, this innovative method with fuzzy AHP and TOPSIS method increases the evaluation's veracity and efficiency of the comprehensive evaluation system.

This New Model of Performance Auditing Contributes to the Sustainable Development of Governmental Ecological Environment in China

Through our investigations, we can see that government and people have indicated that it gains the great benefits to take action to solve the ecological environment in China. Constructed intelligent evaluation technology that combines together of performance auditing and governmental ecological environment, it has extensive application prospects in sustainable development status on the scales of the Fujian Province and the whole country. This paper explains the meaning of sustainable development, analyses the importance of evaluating performance auditing of governmental ecological environment, and proposed the corresponding countermeasure.

Conclusions

The performance auditing evaluation of governmental ecological environment has become the important part of government auditing in many developed countries. This study mainly focused on discussing the theory feasibility by using the comprehensive evaluation index system of governmental ecological environment in performance auditing evaluation process. The performance auditing evaluation of governmental ecological environment is a synthetic analysis process from the macro-point of view. This paper gives some useful suggestion in the application of performance auditing evaluation system. Moreover, the solution is performed by using decision-making algorithms under fuzzy evaluation environment. In this paper, we extended the concept of fuzzy AHP and TOPSIS to develop a new method for solving MCDM problems in fuzzy environment. The comprehensive evaluation index system is built by using the concept and trait of performance auditing. Therefore, the proposed evaluation framework overcomes the various difficulties during the decision process of decision-making. In this paper, the illustrative application of the approved model was performed on the base of complex classification and processing. Moreover, the research methodology of this paper is established on the basis of fuzzy theory, AHP theoretical model and TOPSIS method. The results show that the comprehensive approach of evaluation index system has better decision precision and adaptability. This research is of significance not only to performance auditing of the governmental ecological environment, but also to performance auditing of other government environment protection policy. For future work, if the approved methods combining with other intelligent decision making techniques can be successfully applied to the evaluation system, then the decision efficiency and accuracy will be effectively increased.

Abstract. This study uses the discrete-time optimal control models and numerical simulations of different scenarios to explore the impact of Genetically Modified (GM) Crop' value on the sustainability of an ecosystem's biomass. The results indicate that profit-maximizing farmers and a welfare-maximizing government would plant GM crops regardless of whether the biomass of the ecosystem remains sustainable (the ecological or evolutionary loss of GM crops) or not. However, the slightest loss of biomass (ecological loss) caused by the ecological mechanism of GM crops, due to their evolution mechanism, may become significant (evolutionary loss). Furthermore, the sustainability problem of biomass would become more severe due to the impact on identity preservation, improvement in planting technology and biotechnology, and climate change. However, conservation activities may help solve this problem.
Keywords: *genetically modified crop, bioeconomics, biodiversity, discrete-time optimal control model, the value of genetically modified crop*

Introduction

A genetically modified (GM) crop is the fastest developing crop, and it is governed by many regulatory systems dictated by international groups and countries. The focus of these regulatory systems should be the economic or ecological values of GM crops; however, the existing literature does not discuss all the value categories of GM crops. Thus, this paper proposes a numerical approach to evaluate GM crops, which combines economic value, ecological loss and evolutionary loss (Mutuc et al., 2013; Bradshaw, 2016). Many countries have discussed the values of GM crops and pronounced their regulations, as the regulation of GM crops in Belgium focuses on authorizing their production, use, and distribution (economic value), and limiting the potential release of GM crops into non-GM crop fields (ecological loss). Brazil has established rules for the production and marketing of GM crops and their release into the environment. The production and sale of GM crops are subject to very restrictive rules in France, and French legislation focuses on the potential release of GM crops into the environment and on labeling requirements (The Law Library of Congress, 2014).

The economic value of GM crops is defined as the additional profit of a crop-mix (with non-GM and GM crops) compared to a non-GM crop. Many studies have proved that profit from GM crops is higher than that from non-GM crops, as the former has larger yields. This is after considering its sustainability, health, and other related issues (James, 2005; Jacobsen et al., 2013; Mutuc et al., 2013; Blahova et al., 2014; Brookes and Barfoot, 2015; The International Service for the Acquisition of Agri-biotech Applications, 2016). As Qaim and Zilberman (2003) show that the pest-resistant GM crops substantially reduces pest damage and increases yields. Klümper and Qaim (2014) found the adoption of GM crops has reduced chemical pesticide use by 37%, increased crop yields and farmer profits by 22% and 68%.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1437514390

The ecological and evolutionary loss of GM crops are defined as the negative value from the reduced biomass in the present and last stages of an evolutionary ecosystem with a crop-mix compared to a scenario with a non-GM crop. A GM crop negatively affects the biomass of ecosystems because it may increase the mortality of other species. The impact on this biomass by GM crops could follow the competition or predation of the evolution mechanism and produce an uncertain result of this biomass. The evolution mechanism consists of elements such as monoculture, mutation, natural selection, genetic drift, recombination, and gene flow. The United Nations (2010) and Jesse and Obrycki (2000) show that the promotion of superior breeds (e.g., a GM crop) can have side effects (Brock and Xepapadeas, 2003; Noailly, 2008).

We argue that the value of a GM crop could be the sum of its economic value and ecological and evolutionary loss. Therefore, this study will discuss these three perspectives through numerical simulations of discrete-time optimal control models on the biomass of an ecosystem with crop-mix and pest interactions. Moreover, the impact of identity preservation, the improvement in planting technology and biotechnology, and climate change on the value of GM crops and the biomass of an ecosystem would be discussed (Weitzman, 1998; Kouser and Qaim, 2013).

In short, the goal of this study is to analyze and simulate the effect of a GM crop' value on biomass sustainability. The remainder of this paper is organized as follows. In Section 2, we develop the Materials and Methods. The points are Farmer's GM crop management (FGM) Model and Government's GM crop Management (GGM) Model. In Section 3, we develop their results, the points are to perform the numerical simulations of FGM and GGM numerical simulations. The last two sections contain our discussions and concluding remarks.

Materials and methods

To develop an integrated valuation model of farmer's GM crop management, this study considered an ecosystem with crop-pest interactions, and this theoretical model should be adapted to many countries. The crops could be divided into GM, and non-GM crops, i=1, 2, and there was only one type of pests (Ives and Andow, 2002).

At time t, let $Q_{i,t}$ denote the farmer' s harvest of crop i, $D_i(Q_{i,t})$ and $S_i(Q_{i,t})$ be the inverse demand and supply function of crop i, so that the farm's revenue and cost function would be $R(Q_{1,t}, Q_{2,t}) = D_1(Q_{1,t})Q_{1,t} + D_2(Q_{2,t})Q_{2,t}$, and $C(Q_{1,t}, Q_{2,t}) = S_1(Q_{1,t})Q_{1,t} + S_2(Q_{2,t})Q_{2,t}$, respectively.

The objective of a representative farmer is to choose time paths $Q_{i,t}$ to maximize the farmer's profit function:

$$\sum_{t=1}^{T} \rho^t [D_1(Q_{1,t})Q_{1,t} + D_2(Q_{2,t})Q_{2,t} - S_1(Q_{1,t})Q_{1,t} + S_2(Q_{2,t})Q_{2,t}] \quad \text{(Eq.1)}$$

The time [0, T] is assumed fixed, and the discount factor is $\rho = (1+\eta)^{-1}$, where $\eta>0$ is the discount rate.

The biomass of this ecosystem (B_t) is defined as the sum of the biomass of the crop and pest at time t ($B_{c,t}, B_{p,t}$). In the existing literature, B_t could be measured by its biodiversity from different hierarchical categories. World Resources Institute et al. (1992)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1437514390

divided biodiversity into three hierarchical categories: genetic diversity, species diversity, and ecosystem diversity (Vatn and Bromley, 1994; Mainwaring, 2001).

The amount of land for crop-mix is limited, and crops in the initial stage are all crop 2. The biomass of the ecosystem depends on the farmer's harvests of the crop-mix, and the growth and death rates of crop and pest. Biomass corresponds to the quantity of crop 2, based on the assumption that the genetic makeup of every individual in crop 1 is the same. Although GM crops can be planted in higher densities than conventional crops, for the sake of simplicity, this study does not consider this situation (Stanger and Lauer, 2006).

Based on the above assumptions, as in Brock and Xepapadeas (2003), the biomass evolution of the crop, pest, and ecosystem could be characterized as follow:

$$\begin{gathered} B_{c,t} - B_{c,t-1} = \left(B_{c,t-1} - Q^*_{1,t}\right)\left(g_c p_{c,t-1} - m_c p_{p,t-1}\right) - Q^*_{1,t} - Q^*_{2,t} \\ B_{c,t=0} = B_{c,0} \\ t=1, \ldots T \end{gathered} \tag{Eq.2}$$

$$\begin{gathered} B_{p,t} - B_{p,t-1} = B_{p,t-1}\left[g_p p_{p,t-1} - m_p \left(p_{c,t-1}\right)^{-1}\right] \\ B_{p,t=0} = B_{p,0} \\ t=1, \ldots T \end{gathered} \tag{Eq.3}$$

where:

$$\begin{gathered} p_{c,t} = B_{c,t}(B_{c,0})^{-1},\ p_{p,t} = B_{p,t}(B_{p,0})^{-1} \\ B_t = B_{c,t} + B_{p,t} \\ t=1, \ldots T \end{gathered} \tag{Eq.4}$$

$$\begin{aligned} B_t - B_{t-1} = {} & \left(B_{c,t-1} - Q^*_{1,t}\right)\left(g_c p_{c,t-1} - m_c p_{p,t-1}\right) \\ & + B_{p,t-1}\left[g_p p_{p,t-1} - m_p \left(p_{c,t-1}\right)^{-1}\right] - Q^*_{1,t} - Q^*_{2,t} \\ B_{t=0} = {} & B_{c,0} + B_{p,0} \end{aligned} \tag{Eq.5}$$

where g_c, g_p, m_c and m_p are the constant growth and death rates of the crop and pest. The pest biomass is exogenously assumed to be negatively related to the quantity of the GM crop.

For numerical simulations of the above model, this study assumes $D_1\left(Q_{1,t}\right) = P_1$, $D_2\left(Q_{2,t}\right) = P_2$, $S_1\left(Q_{1,t}\right) = \alpha + \beta Q_{1,t}$, $S_2\left(Q_{2,t}\right) = \alpha + \gamma Q_{2,t}$, and $\gamma > \beta > 0$. The optimal harvest quantity of crop 1 and crop 2 at time t ($Q^*_{1,t}$, $Q^*_{2,t}$) are derived from *Equation (1)*, which are $Q^*_{1,t} = (P_1 - \alpha)(2\beta)^{-1}$ and $Q^*_{2,t} = (P_2 - \alpha)(2\gamma)^{-1}$. These equations are used in combination with the growth *Equation (5)* of the ecosystem's biomass to obtain a measure of biomass in time [0, T].

Moreover, this study uses the GGM model which assess the value of biomass to discuss the economic, ecological, and evolutionary value of GM crops. In the GGM model, the welfare function on the biomass of an ecosystem is defined as $W(B_t) = W(B_{c,t}, B_{p,t})$. The social welfare function of the government is defined as follows:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1437514390

$$\sum_{t=1}^{T} \rho^{t-1}\Big[\int_0^{Q_{1,t}} D_1(x)dx + \int_0^{Q_{2,t}} D_2(x)dx + W(B_{t-1}) - \int_0^{Q_{1,t}} S_1(x)dx - \int_0^{Q_{2,t}} S_2(x)dx - D_1(Q_{1,t})Q_{1,t} - D_2(Q_{2,t})Q_{2,t} + S_1(Q_{1,t})Q_{1,t} + S_2(Q_{2,t})Q_{2,t} \quad \text{(Eq.6)}$$

This study uses the Bellman state valuation function as a welfare measure of biomass, and it assumes that the welfare function in t is affected by the ecosystem's biomass in t-1. Brock and Xepapadeas (2003) obtained an endogenous measure (Bellman state valuation function) of the biomass' value, which is linked to ecologically/biologically oriented biomass metrics. There are more than 100 empirical papers that positively evaluate the biodiversity of indigenous cattle, threatened mammals, native plants, forests, wetlands, marine sanctuaries, ecosystems (Martin-Lopez et al., 2007; Matero and Saastamoinen, 2007; Siikamaki and Layton, 2007; Baral et al., 2008; Garcia et al., 2009; Yi et al., 2014). Many studies argue that the value of biodiversity includes the market value (a source of new industrial, agricultural, or pharmaceutical products) and non-market value (option, existence, and bequest values, culture and spiritual), as in Weitzman (1998), Polasky and Solow (1995), Nehring and Puppe (2002), and Brock and Xepapadeas (2003).

The purpose of the government is to maximize social welfare function, and the present value of the social welfare function at time t is $V(BS_{t-1}, C_t)$. Let $BS_{t-1} = (B_{c,t-1}, B_{p,t-1})$, $C_t = (Q_{1,t}, Q_{2,t})$ be the state and control vector associated with the maximization of (6), and $f(BS_{t-1}, C_t)$ be the vector of (5). The Hamiltonian function is as follows:

$$H_c(BS_{t-1}, C_t) = V(BS_{t-1}, C_t) + \rho\lambda_{p,t+1} f_p(BS_{t-1}, C_t),$$

For the sake of simplicity and comparability, we follow the assumptions in Section 2: $W(B_t) = W(BS_t) = \delta(B_{c,t} + B_{p,t})$, and δ is a constant value for a unit of biomass.

As the optimality conditions of the Hamiltonian function derived from (2), (3), (4) and (6) are self-referred, ($B_{c,t}$, $B_{p,t}$) could not be simulated by repeating the process. Thus, the assumptions of (2) and (3) are modified as:

$$B_{c,t} - B_{c,t-1} = \left(B_{c,t-1} - Q^*_{1,t}\right) - Q^*_{1,t} - Q^*_{2,t},\ B_{c,t=0} = B_{c,0}, \qquad t=1, \ldots T,$$
$$B_{p,t} - B_{p,t-1} = B_{p,t-1}(g_p - m_p),\ \ B_{p,t=0} = B_{p,0}, \qquad t=1, \ldots T,$$

The Hamiltonian function is:

$$H_c(BS_{t-1}, C_t) = P_1 Q_{1,t} + P_2 Q_{2,t} + \delta\left(B_{c,t-1} + B_{p,t-1}\right) - \alpha Q_{1,t} - \beta Q_{1,t}^2 - \alpha Q_{2,t} - \gamma Q_{2,t}^2 + \rho\lambda_{c,t+1}\left[\left(B_{c,t-1} - Q_{1,t}\right)(g_c - m_c) - Q_{1,t} - Q_{2,t}\right] + \rho\lambda_{p,t+1} B_{p,t-1}\left(g_p - m_p\right),$$

with the optimality conditions:

$$\partial H_c/\partial Q_{1,t} = P_1 - \alpha - 2\beta Q_{1,t} - \rho\lambda_{c,t+1}(1 + g_c - m_c) = 0,\ t=1, \ldots T, \quad \text{(Eq.7)}$$

$$\partial H_c/\partial Q_{2,t} = P_2 - \alpha - 2\gamma Q_{2,t} - \rho\lambda_{c,t+1} = 0,\ t=1, \ldots T, \quad \text{(Eq.8)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1437514390

$$\rho(\lambda_{c,t+1} - \lambda_{c,t}) = -\partial H_c/\partial B_{c,t-1} = \rho\lambda_{c,t+1}(g_c - m_c) - \delta,\ t=1, \ldots T, \quad \text{(Eq.9)}$$

$$\rho(\lambda_{p,t+1} - \lambda_{p,t}) = -\partial H_c/\partial B_{p,t-1} = \rho\lambda_{p,t+1}(g_p - m_p) - \delta,\ t=1, \ldots T, \quad \text{(Eq.10)}$$

$$\lambda_{c,T+1} = \lambda_{p,T+1} = 0, \quad \text{(Eq.11)}$$

$$B_{c,t} - B_{c,t-1} = \rho^{-1}\,\partial H_c/\partial\lambda_{c,t-1} = (B_{c,t-1} - Q_{1,t})(g_c - m_c) - Q_{1,t} - Q_{2,t},\ t=1, \ldots T \quad \text{(Eq.12)}$$

$$B_{p,t} - B_{p,t-1} = \rho^{-1}\,\partial H_c/\partial\lambda_{p,t-1} = B_{p,t-1}(g_p - m_p),\ t=1, \ldots T, \quad \text{(Eq.13)}$$

$$g_c = g_p = G,\ m_c = 0.5m_p = M,\ B_{c,0} = B_{p,0} = 0.5B_0 \quad \text{(Eq.14)}$$

To derive all the necessary information, the process begins in the final period (T = 20, in this case) and proceeds backward. From (7) and (8), the optimal harvest quantity of the GM crop and non-GM crop at time t ($Q_{1,t}^{**}$, $Q_{2,t}^{**}$) are $[P_1 - \alpha - \rho\lambda_{c,t+1}(1 + g_c - m_c)]/(2\beta)$ and $(P_2 - \alpha - \rho\lambda_{c,t+1})/(2\gamma)$, respectively. Since $\lambda_{c,21} = \lambda_{p,21} = 0$, (9) is used to solve $\lambda_{c,20} = \lambda_{p,20} = \delta/\rho$. The process is repeated and ($B_{c,t}$, $B_{p,t}$) is derived.

Results

Table 1 reports the values of the parameters obtained through the FGM model. We consider six cases to study the value of GM crops and the biomass of the ecosystem in time [0, 20]. The parameters in *Tables 1 and 3* are set as the existing literature, and the minor modification of the assumptions in the FGM and GGM model does not affect the findings of this study as many simulation results have been obtained from various parameter values. Many studies have discussed the higher price of the non-GM crop in Case 2. Lusk et al. (2001) and Chern et al. (2003) discussed consumer acceptance and willingness to pay for the non-GM crop. Many studies have also discussed the lower fixed cost of the two crops in Case 3, such as Marra et al. (2003). Raymond Park et al. (2010) examine the lower variable cost of GM crops in Case 4. McDowell et al. (2011) discussed the lower growth rate and higher death rate of the two crops in Case 5 and Case 6.

Case 0 is the initial scenario with Crop 2, and Case 1 is used as the baseline for the crop-mix. In Case 2, the non-GM crop is segregated by identity preservation and has a higher price. Case 3 is characterized by a lower fixed cost of the two crops for the improvement of planting technology, and Case 4 by the lower variable cost of GM crops for the improvement of biotechnology. Case 5 and Case 6 are characterized by the lower growth rate and higher death rate of the two crops due to climate change. Crop 1 and Crop 2 sell at the same price in all cases (except Case 2, for identity preservation), as in most cases, it is hard to distinguish GM crops from non-GM crops.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1437514390

The solutions of Cases 0 ~ 6 are reported in *Table 2* and *Figure 1*. Our main conclusions on the value of the GM crop are as follows. First, the value of the GM crop is equal to its economic value in the FGM model, as farmers do not consider the value of biomass. Second, profit-maximizing farmers are likely to plant more GM crops than non-GM crops, as the value of GM crops is higher. Third, the improvement of planting technology and biotechnology increases the value of GM crops. Moreover, identity preservation and climate change do not affect the value of GM crops. These conclusions are in line with Brookes and Barfoot (2015), James (2005) and The International Service for the Acquisition of Agri-biotech Applications (2016).

Note: these results are based on simulated data

Furthermore, our main conclusions about the impact of the introduction of a GM crop on the biomass of an ecosystem are as follow. First, the biomass of an ecosystem is decreased by the introduction of a GM crop. Second, the impact on the biomass of an ecosystem caused by a GM crop in the initial stage might be negligible, but even the slightest change could follow the evolution mechanism and lead to a considerable loss of an ecosystem's biomass. Third, climate change and the improvement in planting technology and biotechnology would decrease the biomass of an ecosystem. Fourth, the biomass of an ecosystem would not be improved and may even be worsened by identity preservation. These conclusions mean the sustainability of an ecosystem's biomass might not exist by the impact of the GM crop's economic value and are in line with Gregory et al. (2009), and the United Nations (2010).

Table 3 reports the values of the parameters obtained through the GGM model. This study uses these cases to study the value of the GM crop, welfare, and the biomass in the GGM model. A non-GM crop characterizes Case 7, and Case 8 uses a crop-mix to discuss its effect of the increment of P_2 (Case 9), α (Case 10), β (Case 11), M (Case 13), δ (Case 14), and the decrement of G (Case 12). Case 14 can be explained by the growing recognition and activities of the public and private sector to conserve biomass (Bishop et al., 2008). A discount rate of 5 percent means that the discount factor (ρ) is about 0.95.

Table 3. *Values of the Parameters with the government's bit-crop management model*

Note: these results are based on simulated data

The value of biomass is set far below the price of GM crops. The reason for this is that people's willingness to pay for conserving the biomass is lower than its market value. The solutions of Cases 7~14 are reported in *Table 4*, *Table 5*, and *Figure 2*.

Table 4. *Simulation of welfare and biodiversity in the GGM model*

	The present value of Welfare	**The biodiversity of the ecosystem in T=20**
Case 7	2,791.33	13,671.94
Case 8	5,176.34	8820.74
Case 9	5,897.93	8,517.03
Case 10	6,197.10	8,359.09
Case 11	7,677.02	6,399.28
Case 12	4,987.48	5,409.29

conservation activities could improve the value of GM crops, but identity preservation and biomass conservation activities could not. Finally, the impact of climate change on the value of GM crops depends on the ability of species to migrate or cope with new scenarios.

Our conclusions about the impact of the introduction of a GM crop on the biomass of an ecosystem are as follows. First, the approaches of simulated biomass in each case of the GGM and FGM models are similar, the conclusions are in line with the solutions of the FGM model, and the modification of the assumptions in the GGM model does not affect the findings of this paper. Second, biomass conservation activities slow down the decline rate of biomass. These conclusions imply the sustainability of an ecosystem's biomass might not exist by the impact of the GM crop's economic value considering its ecological or evolutionary loss.

Table 5. *Simulation of the Value of GM crop in the GGM Model*

	The economic value of GM crop (B)	**The ecological value of GM crop (C)**	**The evolutionary value of GM crop (D=A-B-C)**	**The value of GM crop (A)**
Case 7	0.00	0.00	0.00	0.00
Case 8	2,615.07	-12.76	-217.30	2,385.01
Case 9	2,615.07	-12.76	-217.30	2,385.01

Case 12	2,614.53	-12.72	-180.17	2,421.64
Case 13	2,614.53	-12.72	-255.30	2,346.51
Case 14	2,609.08	-24.87	-428.06	2,156.15
Mean	2,701.08	-14.47	-230.93	2,455.68

Note: these results are based on simulated data

The simulated value of GM crops in previous studies (e.g., FGM model solution) is more significant than that in this study (e.g., GGM model solution), as the ecological and evolutionary loss of GM crops would decrease the optimal planned harvest of the welfare-maximizing government. Thus, the legal restrictions should consider the ecological and evolutionary loss of GM crops. Owing to public hostility and legal restrictions, no GM crops are currently planted in France (The Law Library of Congress, 2014). Based on the findings of FGM model are in line with previous studies, the differences between the presented approach and the referred literature are: 1. Their methods are different: the method of this paper is to use the numerical calculus and derivation of the hypothetic theory model which is the optimal control models with crop-mix and pest interactions, and the methods of the referred literature are most the statistical analysis of the different empirical models. 2. Their influencing factors are different: their influencing factors which discussed by this paper are identity preservation, improvement in planting technology and biotechnology, and climate change; their influencing factors of the referred literature are most the developing degree of country. As Klümper and Qaim (2014) use meta-analysis to prove that yield and profit gains for farmers of GM crops are higher in developing countries than those in developed countries.

Discussion

The major contributions of this study are as follows. First, this paper discussed the economic value and ecological and evolutionary loss of GM crops in agricultural systems simultaneously. Most existing studies discuss the economic value of GM crops as Klümper and Quaim (2014). Some studies discuss the ecological loss of GM crops as in Sanvido et al. (2007). Moreover, the only study discussing the evolutionary loss of GM crops is Flynn et al. (2010).

Second, this paper employs a discrete-time optimal control model and its numerical simulations to discuss the value of GM crops. We have not seen much research discussing the value of GM crops by the economic model and its numerical simulations. Therefore, this paper could increase the completeness of the theory on the value of GM crops. Third, this paper found that ecological loss of GM crops would be due to the mortality of its natural enemies, its monoculture, and competition with non-GM crops. The ecological loss of GM crops, which is the mortality of its natural enemies affected by GM crops, has been discussed in many previous studies. This paper also develops the ecological effect of GM crops to its monoculture and competition with non-GM crops. For the value of biodiversity is underestimated, government subsidies and fines for bioconservation are far below the market value of biology. As Chan et al. (1995) reported, the fine for illegal hunting is USD 50 (Kalmykia) and USD 60 (Kazakhstan) for one male Saiga antelope. However, the antelope can be sold at USD 764 (Hong Kong), USD 885 (Mainland China) and USD 920 (Taiwan) per kilogram.

Jose et al. (2006) studied the economic impact of GM crop in the Philippines by a Cobb-Douglas production function and a two-step econometric procedure where the initial stage consists of GM crop adoption decision and the second stage estimates the impact of GM crop adoption on net returns. The results showed that the yields of GM crop farmers (4,850 kg/ha) were significantly higher than those of the non-GM crop farmers (3,610 kg/ha) and there was a significant welfare effect (PhP 43.48 million) of using GM crop among farmers. James (2010) stated that the first 500 million GM crop hectares in 2005 took 10 years to reach, but only 5 years were needed to plant the second 500 million GM crop hectares (a total of 1 billion GM crop hectares) in 2010.

Fourth, this paper found that the evolutionary loss of GM crops is an aggregated ecological loss through the evolutionary mechanism. Also, this paper is one of the first to establish models to prove the reason why its existence. Fifth, this paper found that small ecological loss would develop into substantial evolutionary loss and might result in crop species rapidly becoming purebred. So the sustainability of an ecosystem's biomass might not exist by the impact of the GM crop's economic value regardless of considering its ecological or evolutionary loss or not. Very few studies focus on the relationship between the ecological loss of GM crops and its evolutionary loss, and how the relationship affects crops. Hence, this paper builds models to fill this research gap. Craft and Simpson (2001) used two models of competition between differentiated products to derive the value of biodiversity for use in new product development, and found the private value of marginal species (as biodiversity) is small, and its social value could be very model-dependent and parameter-specific. However, these findings would undervalue biodiversity, due to the static models and negligible nonmarket value of biodiversity. The Secretariat of the Convention on Biological Diversity (2010) shows that the promotion of superior breeds (like GM crop) would reduce biodiversity.

Magg et al. (2001) found greater European corn borer larval mortality observed for GM maize (84.6% after 4 days) when compared to non-GM maize (50.4% after 4 days).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1437514390

Jesse and Obrycki (2000) proved that GM corn pollen naturally deposited on milkweed in a corn field (lethal effect) cause significantly higher mortality of monarch butterflies (20±3% at 48 h) than with no pollen (3±3% at 48 h) or with non-GM corn pollen (0%). Hilbeck et al. (1998) proved that the mortality rate for chrysopid larvae raised on GM corn-fed prey was 62.25±5.97% compared with 36.88±4.57% when raised on non-GM corn-fed prey.

Last but not least, this paper simulated the impact of the value of GM crops due to identity preservation, improvement in planting technology and biotechnology, climate change, and conservation activities. Therefore, this paper fills another significant research gap as there is a lack of studies on the impact of the value of GM crops by the change of external factors. Specifically, this paper selected and observed the changes in external factors to understand how that related to the value of GM crops. The impacts on the value of GM crops are also considered.

Conclusions

This paper introduces optimal control models and numerical analysis to analyze the value of GM crops, seen as the sum of economic value, and ecological, and evolutionary loss. In the FGM model, which does not consider the value of biomass, a profit-maximizing farmer plant more GM crops. However, even the slightest loss of biomass caused by GM crops in the initial stage may become significant following the evolution mechanism. Furthermore, the biomass of the crop, pest, and ecosystem worsens by identity preservation, improvement in planting technology and biotechnology, and climate change in the FGM and GGM model. In the GGM model, which takes into consideration the value of biomass, the welfare-maximizing government plants the GM crop. Moreover, the social welfare could be improved by identity preservation, the improvement in planting technology and biotechnology, and biodiversity conservation activities.

Based on the simulation results, our conclusions are as follow. First, a GM crop raises not only the mortality of its natural enemies and species on the same food chain or ecosystem, as reported by previous studies, but also causes the ecological loss resulting from monoculture of the GM crop and competition between GM and non-GM crops, as well as evolutionary loss, which is ecological loss determined by the evolutionary mechanism. Second, the biomass of the ecosystem has been over-damaged by the introduction of GM crops, and market mechanisms alone cannot determine the efficient use of GM crops. Third, using GM crops for profit maximization induces species to become purebred quickly (Noailly, 2008). Thus, the impact of Genetically Modified Crop' value on the sustainability of an ecosystem's biomass might be significantly negative.

The several limitations of this study may provide useful ideas for future researchers. The main limitation of this study is the simplification of the GGM model for the simulations. As this paper takes into consideration of the value of a GM crop is highly simplified for the GM crops are not homologous. The future study could take the discussion on the different transgene or the different type of genetic modification could have influenced the value of the GM crop. Or as the government's target for ecosystem biomass, which should be its sustainability, could be utilized for a discussion of its impact on the government's behavior. Moreover, the model can consider the risk of GM crops, as a single pathogen could wipe out entire species and their predators (Martin, 2000). Capellesso et al. (2016) proved that GM crops increase environmental impacts without

DOI: http://dx.doi.org/10.15666/aeer/1706_1437514390

changing economic performance. Researchers can also study the impact of GM crops on the biomass of other species (as non-target insects). For example, they can study farm size for managing conventional corn-soybean rotation in a larger area than organic rotation (Lu et al., 2012; Delbridge et al., 2013). Finally, the bifurcation theory could be employed to assess the ecological and evolutionary value of GM crops, as it involves a complicated evolution mechanism and cannot be represented by an optimal control model.

Abstract. The species and bio-availability of phosphorus (P) in primary, secondary and digested sludge were fractionated and further analyzed in this study. Results showed that inorganic P (IP) was the primary P fraction in the secondary sludge and digested sludge, in which non-apatite IP (NAIP) amounted to 91.6% and 69.3% of total IP, respectively. Organic P (OP), accounting for about 71.7% of total P (TP), was the dominant P composition in primary sludge. The content of bio-available P was about 9.7, 43.4, 29.8 mg-P/g-TS in primary sludge, secondary sludge and digested sludge, respectively, suggesting secondary sludge is the optimal choice when land application of sewage sludge is taken into consideration, followed by digested sludge and primary sludge. Polyphosphate and orthophosphate, comprising approximately 54.3% and 89.2% of TP, were the dominant P species in the secondary sludge and digested sludge, respectively. Monoester-P (54.6% of TP in extract) and diester- P (24.1%) were identified as OP species in primary sludge by Phosphorus-31 nuclear magnetic resonance (^{31}PNMR). The present results would be helpful for P recovery and recycling from sewage sludge in wastewater treatment plants.
Keywords: *sewage sludge, P bio-availability, P species, SMT protocol*

Introduction

Phosphorus (P) is one of the essential mineral elements for all living organisms, which accounts for around 2 - 4% of the dry weight of most cells (Karl, 2000). The extensive application of P fertilizers is one of the main reasons that the current crop production has been able to meet the food demand and security associated with an ever-expanding world population. It is estimated that approximately 90% of the P derived from phosphate rock is used in agriculture as fertiliser (Christen, 2007). However, on one hand, phosphate rock is a non-renewable resource which is estimated to be exhausted in 50 - 100 years with a peak in its production occurring in 2030s if the growth of demand for fertilizers remains at 3% per year (Cordell et al., 2009; Gilbert, 2009; Hao et al., 2013). On the other hand, according to the statistics of the US Geological Survey (USGS, 2014), eight countries or areas including United States, Algeria, China, Jordan, Morocco and Western Sahara, Russia, South Africa and Syria control 93.9% of global phosphate rock reserves. In order to secure domestic raw materials, some major producer countries have designated phosphorous as a strategic resource and restricted export of the P rock or in the form of processed

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1439114402

and chemical products with added value in recent years (Cordell et al., 2009). With these trends, the price of P rock has been increasing in the international trade market. Therefore, P resource protection and P recycling is prerequisite for a sustainable agriculture and society on a global scale, especially for the countries that lack P resources.

Sewage sludge, a by-product of biological wastewater treatment process, is regarded as a potential P reservoir due to its high production and P content (Xu et al., 2012). Various P recovery technologies from sewage sludge have been developed, including incineration, alkaline/acid extraction, thermal treatment, phosphorous crystallization as HAp (hydroxylapatite) and MAP (magnesium ammonium phosphate) (Arakane et al., 2006; Hao et al., 2013; Hosni et al., 2008). However, the costs of these projects are too high due to their complex processes for phosphorus recovery. Land application of sewage sludge as P fertilizer is now very attractive, because it not only solves the sludge disposal problem but also benefits crop production (Singh and Agrawal, 2008). In US and EU-15, land application of sludge now is the predominant choice for sludge management (41% in US and 53% in EU-15) (Catallo and Comeaux, 2008; He et al., 2018; Kelessidis and Stasinakis, 2012; Zhang et al., 2018). In China, about 45% and 3.5% of sludge is applied to agriculture and gardening, respectively. It is a well-known fact that Japan is a P resource- poor country. While the percentage of treated sewage sludge for farmland and green areas has been stable at around 14% for many years in Japan, it is much lower than those in other countries (UN-HABITAT, 2009). Thus land application of sewage sludge as P fertilizer has great development potential to alleviate P resource shortage to a certain extent in Japan.

Generally, P content in sewage sludge accounts for about 0.3-4.8% of total solid (Fytili and Zabaniotou, 2008). But it is well known that not all the forms of P exhibit similar mobility and bio-availability in the sludge, identification of the P fraction and species in the sludge is beneficial for both land application of sewage sludge as P fertilizer and understanding the characteristics and function of P in different sludge. Primary sludge, secondary sludge and digested sludge are the three main types of sludge produced from WWTP. Previous study mainly focus on investigate the bio-availability of P in secondary sludge and P species in secondary sludge and digested sludge. Xie et al. (2011) reported that 75%-88.7% of TP in secondary sludge possesses high mobility and bio-availability. Poly-P and ortho-P was the major P in enhanced P removal activated sludge and digested sludge, respectively (Hinedi et al., 1989; Uhlmann et al., 1990; Lalmi and Hadef, 2017). However, to date, little detailed and comprehensively information could be found about the P fractions and species in primary sludge, secondary and digested sludge.

This study aimed to investigate the P bio-availability and species in primary sludge, secondary and digested sludge. The Standards, Measurements and Testing (SMT) protocol was applied to analyze the fractionation of P in sewage sludge and to evaluate the mobility and bio-availability of P in various sludge. Solution 31P nuclear magnetic resonance (^{31}P NMR) spectroscopy is employed to characterize the inorganic and organic phosphorus species in sewage sludge. It is expected that this work will be useful for P utilization and recovery from sewage sludge, especially when agriculture utilization of sludge is taken into consideration.

Materials and methods

Sewage sludge sample

Sludge samples were collected from a WWTP treating domestic wastewater in Shimodate, Ibaraki Prefecture, Japan, on October, 2018. The process flow diagram of the WWTP is shown in *Figure 1*. 50 L sludge samples were collected from the primary tank, secondary sedimentation tank and digestion tank, respectively. The collected sludge was kept in a refrigerator at 4 °C and analyzed within 2 days.

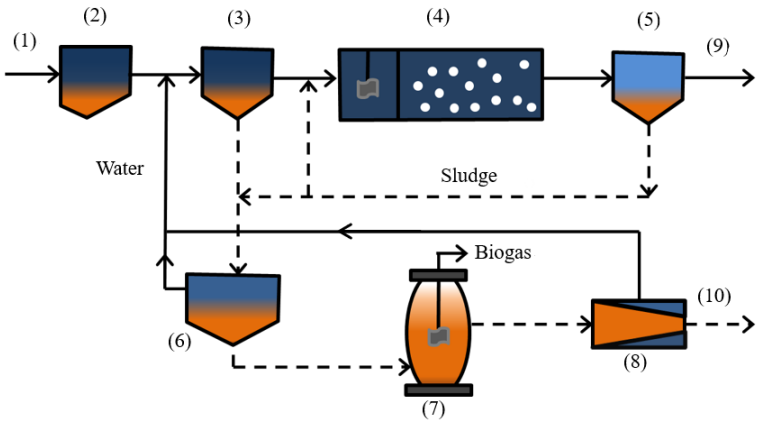

Figure 1. *Process flow diagram of wastewater treatment plant in Shimodate, Ibaraki Prefecture, Japan. (1) influent, (2) grid, (3) primary settling tank, (4) aeration tank, (5) secondary settling tank, (6) sludge concentration tank, (7) digestion tank, (8) sludge dewatering, (9) effluent, (10) sludge disposal*

Phosphorus fractionation in sludge

In this study, the SMT programme extraction protocol was applied to analyze P fractions in all sludge samples (*Fig. 2*), which has been widely used in soil, sediment and sewage sludge samples (Ruban et al., 1999; Medeiros et al., 2005; Zhao, 2012).

After sequential extraction based on the SMT method, P in sludge was fractionated into the following 5 categories: (1) concentrated HCl-extractable P, namely total P (TP), (2) organic P (OP), (3) inorganic P (IP), (4) non-apatite inorganic P (NAIP, the P fraction associated with oxides and hydroxides of Al, Fe and Mn), and (5) apatite P (AP, the P fraction associated with Ca). In order to avoid the transformation of P species in sludge during preparation, the samples centrifuged at 6000×g for 10 min at 4 °C, and then the residue were frozen immediately at -80 °C, lyophilized at -50 °C for 48 h and stored at -20 °C until analysis. The P concentration in the supernatant collected after extraction was determined with molybdenum blue method. All of the experiments were done in triplicate, and the average data was reported.

Extraction of P from sludge

PCA and NaOH extraction methods have been efficiently used for IP and OP extraction from sludge, soil and sediment samples (Ahlgren et al., 2005; Daumer et al., 2008; Vestergren et al., 2012; Saric et al., 2016). In this study, the PCA-NaOH extraction procedure was applied to fractionate and characterize P in the sludge samples according to the schematic diagram shown in *Figure 3*. Before extraction, a certain

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1439114402

amount of sludge was washed twice with 100 mM NaCl solution (4 °C) with the supernatant being discharged. After extraction, neutralization was conducted immediately to minimize P transformation. 2 ml of the resultant supernatant was taken for TP, IP and OP analysis. The remaining extracts were freeze-dried at -50 °C for 48 h, and the dried PCA-NaOH extracts were uniformly mixed and them stored at -20 °C till 31P NMR analysis.

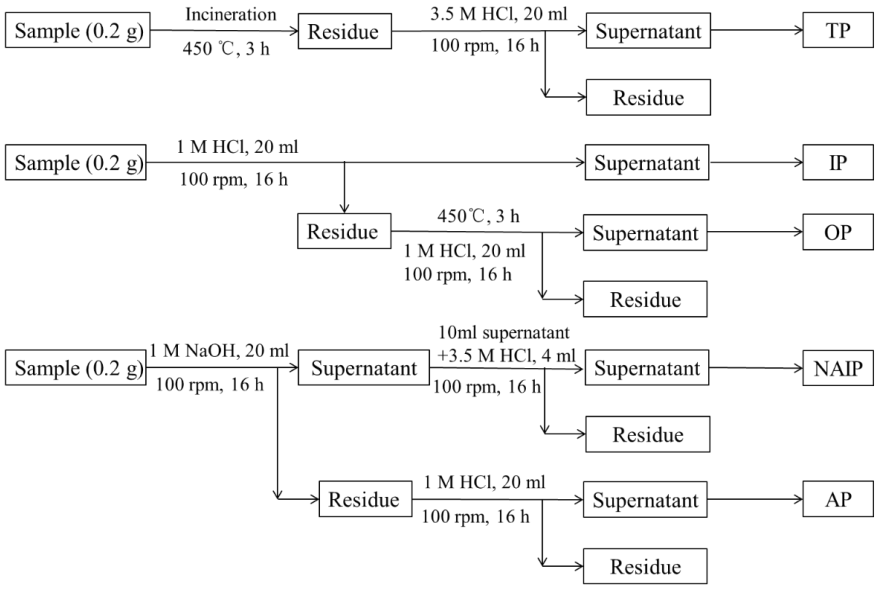

Figure 2. *The schematic diagram of the SMT protocol*

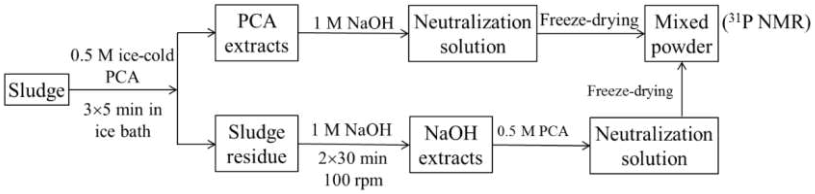

Figure 3. *Schematic diagrams for the fractionation and characterization of various forms of P in sewage sludge*

Chemical analysis

Mixed liquor (volatile) suspended solids (ML(V)SS), chemical oxygen demand (COD), ammonia nitrogen (NH_4-N), and phosphorus (PO_4-P) were measured in accordance with the standard methods (APHA, 2012). Total concentration of phosphorus in the liquid was determined with molybdenum blue method after digestion by potassium persulfate at 120 °C. Metal ions in sludge samples were quantified after the sludge samples being digested and filtered through 0.22 μm cellulose nitrate membrane filters (Nalgene). 0.1 g of dried sludge was digested in a mixture of 3 ml hydrochloric acid (37%, Wako), 1 ml nitric acid (70%, Wako), and 1 ml perchloric acid (60%, Wako) on an electric heating plate for 10 min. The concentration of each metal was measured by inductively coupled plasma mass spectrometry (ICP-MS, ELAN DRC-e, Perkin Elmer, USA).

DOI: http://dx.doi.org/10.15666/aeer/1706_1439114402

^{31}P NMR analysis

To obtain the ^{31}P NMR spectrum, 200 mg of freeze-dried sludge extracts were re-dissolved in 0.8 ml of 1 M NaOH and 0.2 ml D_2O and then 0.2 ml of 100 mM EDTA solution was added. The dose of EDTA and NaOH solutions was to minimize the interference of divalent/trivalent cations and to adjust pH above 12.0, respectively, to ensure consistent chemical shifts and optimal spectral resolution during the ^{31}P NMR measurement.

The ^{31}P NMR spectrum was obtained by using a Bruker Avance-600 MHz NMR Spectrometer at 242.94 MHz. 90 °C of pulse width, 25 °C of regulated temperature, and acquisition time of 0.67 s (with relaxation delay of 2 s) were applied in the experiments. To obtain accurate phosphorus forms, spectra were collected immediately after preparation and the process was finished within 2 h to minimize transformation of phosphorus species. Chemical shifts of signals were determined relatively to an external standard of 85% H_3PO_4 via signal lock. The peaks were assigned to P species according to the reports in literature with peak areas calculated by integration (Turner, 2003; Turner et al., 2004; Zhang et al., 2013; Reis et al., 2017).

Statistical analysis

All values presented are the means of independent triplicates ± standard deviation. One-way analysis of variance was used to compare the experimental results using SPSS statistics 19.0 (IBM, US). And statistical significance was declared when $p < 0.05$.

Results

Characterization of sludge

TS, TVS and TVS/TS ratio of sludge were shown in *Figure 4*.

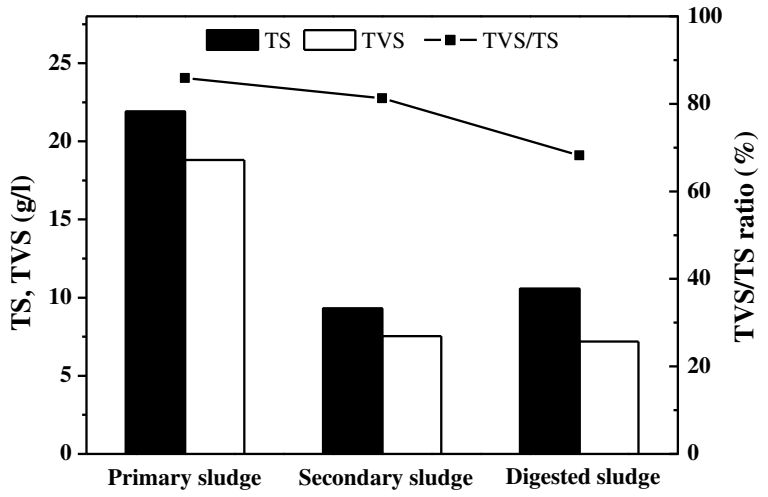

Figure 4. *Changed in TS, TVS and TVS/TS ratio of the sludge sample*

The concentration of TS in primary sludge is about 21.9 g/L, which is approximately 2 times of that in secondary and digested sludge. The TVS concentration is insignificant with TS concentration in the three kinds of sludge ($p = 0.362 > 0.05$). The TVS/TS ratio

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1439114402

of primary sludge, secondary sludge and digested sludge were 85.9%, 81.2% and 68.1%, respectively. In anaerobic digestion stage, biodegradable organic substances can be converted to biogas, leaving most inorganic and recalcitrant materials in the digested sludge. This can be explained the lower TVS/TS ratio of digested sludge than those of primary sludge and secondary sludge. Mineral element analysis showed that K, Mg, Fe and Ca were the major ions in all sludge samples (*Table 1*). In addition, the concentration of mineral elements in digested sludge was much higher than that in primary sludge and secondary sludge, proved previously explanation.

Table 1. *Average metal content in sewage sludge (unit: mg/g-TS)*

Sample	Na	K	Mg	Ca	Fe
Primary sludge	1.6	2.3	1.4	1.7	0.6
Secondary sludge	4.3	12.4	9.6	7.2	6.4
Digested sludge	6.2	22.7	17.1	13.1	11.5

P fractionation in sludge by SMT protocol

TS, total solids; TP, total P; OP, organic P; IP, inorganic P; NAIP, non-apatite P; AP, apatite P; Bio-availability, the percentage of OP + NAIP to TP. *Table 2* summarized the P fractions of primary sludge, secondary sludge and digested sludge, respectively. The concentration of different P fractions in primary sludge varied were significant with that in secondary sludge and digested sludge ($p = 0.010\text{-}0.015 < 0.05$), and the P contents between secondary sludge and digested sludge were insignificant ($p = 0.338 > 0.05$). The TP concentration in secondary sludge was about 46.1 mg/g-TS, which was around 4.3 times of that in primary sludge. This result may be brought about by the secondary sludge, which accumulated high concentration of P and responsible for P removal from wastewater. While the primary sludge directly settled from wastewater is mainly suspended solid contaminants. Compared to secondary sludge, lower concentration of TP in digested sludge was also detected, most probably due to parts of P in the secondary sludge was released to the effluent in digestion tank (*Table 3*). The percentage of OP to TP were 71.7%, 41.4% and 16.3% in primary sludge, secondary sludge and digested sludge, respectively, indicating OP is the dominant P in primary sludge. The concentration of OP varied similarly with TP content in the three types of sludge ($p = 0.166 > 0.05$). Ahlgren et al. (2011) claimed that OP can be released from sediments and utilized by algae. Moreover, OP in soil can be hydrolyzed by phosphatase and then used by the rhizosphere of plants (George et al., 2006; Mesmoudi et al., 2017). Thus high content of OP in sludge may play an important role in P recycle when land application of sludge as P fertilizer is taken into consideration.

Table 2. *Average contents of each P fraction in sludge by using the SMT extraction protocol*

Sludge	TP (mg-P/g-TS)	OP (mg-P/g-TS)	IP (mg-P/g-TS)	NAIP (mg-P/g-TS)	AP (mg-P/g-TS)	OP + NAIP (mg-P/g-TS)	Bio-availability (%)
Primary sludge	10.6±3.2	7.6±2.4	3.1±1.6	1.7±0.8	1.4±0.6	9.3	87.7
Secondary sludge	46.1±5.6	19.1±3.5	26.9±2.8	24.6±3.1	2.6±1.1	43.7	94.8
Digested sludge	31.9±5.1	5.2±2.9	26.7±3.4	19.1±2.3	8.2±2.7	24.3	76.2

Treatment units	COD (mg/l)	NH_4-N (mg/l)	TP (mg/l)	PO_4-P (mg/l)
Influent	205.3	28.3	3.0	2.3
Primary settling tank effluent	248.8	30.2	3.5	3.4
Digestion tank effluent	714.2	636.9	241.4	211.8
Effluent	19.3	1.3	0.2	0.1

COD: chemical oxygen demand; TP: total phosporus

On the other hand, IP was the major P fraction in secondary sludge and digested sludge, in which IP accounted for 58.4% and 77.5% of TP, respectively. Only about 3.1 mg/g IP (about 28.8% of TP) was detected in primary sludge (*Table 2; Fig. 5*). Statistical significances analysis indicated that the IP has a similar trend with TP in the three kinds of sludge ($p = 0.459 > 0.05$). NAIP was the dominant IP in primary sludge, secondary sludge and digested sludge, accounting for 55.8%, 91.6% and 69.3% of IP, respectively. In addition, NAIP was about 16.0%, 53.4% and 59.9% of TP in primary sludge, secondary sludge and digested sludge, respectively. Compared with OP and NAIP, AP content was relatively low, about 13.2% of TP in primary sludge and 5.6% of TP in secondary sludge. However, a high content and percentage of AP was founded in digested sludge (8.2 mg/g-TS and 25.7% of TP), most probably due to the formation of Ca-P precipitates in the digestion tank resulting from the saturation status of co-existing calcium phosphate. AP content was significant different with TP content in the three kinds of sludge ($p = 0.042 < 0.05$).

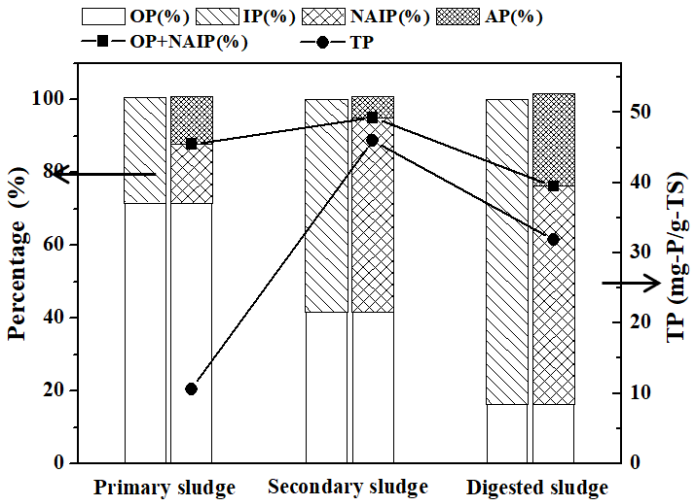

Figure 5. *TP concentrations and percentage of each P fraction to TP in the sludges by using the SMT extraction protocol. TS, total solids; TP, total phosphorus; OP, organic phosphorus; IP, inorganic phosphorus; NAIP, non-apatite inorganic phosphorus; AP, apatite phosphorus*

OP and NAIP were considered to be releasable and bio-available P. In this study, the concentration of NAIP + OP were 9.3, 43.7 and 24.3 mg/g-TS, accounting for about 87.7%, 94.8% and 76.2% of TP in primary sludge, secondary sludge and digested sludge, respectively. It was obviously that secondary sludge not only has the highest

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1439114402

NAIP + OP content but also has the highest percentage of NAIP + OP among the three sludge samples. Although digested sludge has the lowest percentage of NAIP + OP, its NAIP + OP contents are much higher than those in primary sludge. Thus digested sludge should be reused in preference to primary sludge when utilization of sewage as P fertilizer is taken into consideration. These indicated the content of bio-available P was a more intuitive and better parameter than TP concentration and proportion of bio-available P to assess the bio-availability of P in sewage sludge.

Identification of P species in sludge by ^{31}P NMR analysis

Quantification of various P fractions by integrating the peak areas in NMR spectra has been widely used to estimate the relative proportions of P fractions. All NMR-spectra show peaks in the areas for ortho-P, monoester-P, diester-P, pyro-P, poly-P (*Fig. 6*). *Table 4* summarizes the contents of these compounds and their relative proportions (% TP) in primary sludge, secondary sludge and digested sludge extracts identified by ^{31}P NMR. The average TP contents in the PCA + NaOH extracts from primary sludge, secondary sludge and digested sludge were 9.7, 43.4 and 29.8 mg-P/g-TS with average extraction rate of approximately 91.5-94.1% of TP, respectively, indicating the high efficiency of PCA + NaOH procedure for P extraction from sludge samples.

In primary sludge extracts, ortho-P, monoester-P and diester-P were identified as the major P species, accounting for approximately 21.3, 54.6 and 24.1% of TP, respectively. Obviously, the monoester-P and diester-P were the dominant OP species in primary sludge extracts. Generally, monoester-P and diester-P are regarded as potential bio-available P due to that they can be hydrolyzed and utilized by plants and algal in certain conditions. In the secondary sludge, poly-P was the major form of P species, comprising 54.2% of the extractable TP from sludge (*Table 4*). The high content of poly-P in secondary sludge signals the high amount and bioactivity of PAOs in activated sludge in the aeration tank during sampling period. Specifically, pyro-P was only identified in the secondary sludge, around 2.4% of extractable TP. The presence of pyro-P could reflect microbial activity in sludge due to it was directly related to adenosine triphosphate (ATP) hydrolysis in cells. Ortho-P, a main nutrient for living organisms, was about 89.2% of TP in the digested sludge and much higher than that in the primary sludge and the secondary sludge. These results indicated that most of poly-P, pyro-P, monoester-P and diester-P in primary sludge and secondary sludge were converted to ortho-P or reused by anaerobic bacteria during digestion process.

Discussion

The TP content in primary sludge, secondary sludge and digested sludge was about 10.6, 46.1 and 31.9 mg/g-TS, respectively. Obviously, secondary sludge has the highest concentration of P, followed by digested sludge and primary sludge. In primary sludge, OP was the dominant P fractions and accounting for about 71.7% of TP. IP was the major P fraction in secondary sludge and digested sludge, in which IP accounted for 58.4% and 77.5% of TP, respectively. Monoester-P, poly-P and ortho-P, accounting for 54.6%, 54.3% and 89.2% of TP, were the dominant P species in the primary sludge, secondary sludge and digested sludge, respectively. The concentrations of NAIP + OP were 9.3, 43.7 and 24.3 mg/g-TS, accounting for about 87.7%, 94.8% and 76.2% of TP in primary sludge, secondary sludge and digested sludge, respectively, indicating the high mobile and bio-available P stored in those sludge samples.

Some studies have been conducted to investigate the P in sewage sludge, but most have only focused on the concentration of TP and ignoring the bio-available P in sludge. The content of bio-available P may provide a more intuitive and convenient parameter

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1439114402

to evaluate the P in sewage sludge. The results of the present study indicated that secondary sludge not only contains the highest concentration and proportion of TP among different sludge samples, but also has the highest content of potential mobile and bio-available P. In this study, secondary sludge was the optimal choice for land application of sewage sludge as P fertilizer source. Although the proportion of bio-available P in primary sludge was slightly higher than that in digested sludge, digested sludge is more suitable for land application as it contains much more bio-available P content. This study proved that land application of sewage sludge as P fertilizer should be in the order secondary sludge > digested sludge > primary sludge.

Conclusions

In this study, the P species and bio-availability in primary sludge, secondary sludge and digested sludge were identified and evaluated. The following results can be obtained:

(1) IP was the primary P fraction in the secondary sludge and digested sludge, in which NAIP amounted to 91.6% and 69.3% of TP, respectively. OP content (about 7.6 mg/g-TS) was the dominant P in the primary sludge.

(2) Two OP fractions (monoester-P and diester-P) and three IP compounds (ortho-P, poly-P and pyro-P) were identified P species in the secondary sludge. Poly-P was the dominant P species in the secondary sludge, comprising approximately 54.3% of TP. Monoester-P and ortho-P, accounting for 54.6% and 89.2% of TP, were the major P species in the primary sludge and digested sludge, respectively.

(3) The content of bio-available P is a good parameter to evaluate the bio-availability of P in sewage sludge. About 9.3, 43.7 and 24.3 mg/g-TS bio-available P were stored in primary sludge, secondary and digested sludge, respectively.

These results revealed that P species and bio-availability were different in primary sludge, secondary sludge and digested sludge, which is much meaningful for P removal and recovery from wastewater and sludge in WWTPs. As secondary sludge has high P concentration and bio-available P, future researches should pay more attention to how to effectively utilize and recover P from secondary sludge.

(Received 7th Jun 2019; accepted 10th Oct 2019)

Abstract. Ethylene was reported to be important in the response to cadmium (Cd). It is generally agreed that ethylene could improve Cd resistance, but the specific mechanism is not yet clear. To make up for this gap, this paper explores the antioxidant capacity, malondialdehyde (MDA), hydrogen peroxide (H_2O_2) content, Cd content and the expression of relevant genes in *Arabidopsis thaliana* seedlings, and examines the effect of ethylene on the physiological performance of Cd-stressed seedlings. The results show that ethylene could greatly improve the Cd resistance of plants by suppressing the translocation of Cd ions. In addition, ethylene can ease the metal phytotoxicity of Cd by lowering the MDA content and H_2O_2 generation, and regulate the over-expression of AtATM3 and APDR8 to enhance Cd resistance. To sum up, ethylenecould enhance Cd resistance by enhancing antioxidant activity and inhibiting the translocation of Cd ions.
Keywords: *ethylene, cadmium (Cd), resistance, gene expression, translocation factor*

Introduction

Cadmium (Cd) is ubiquitously distributed in the environment, it is non-essential and toxic to the human body. Because of its high-water solubility, the element can easily be absorbed by plants from Cd-contaminated soil, and can interfere in nutrient absorption and translocation, leading to nutrient imbalance (Järup and Akesson, 2009). The uptake of Cd by plants is accelerated under Cd stress. A high content of Cd ions may inhibit plant growth, reduce biomass accumulation and even cause cell death. The Cd can also affect membrane function by inducing lipid peroxidation. In addition, the element tends to boost the production of oxygen free radicals and suppress that of enzymatic antioxidants, leading to oxidative stress (Gratão et al., 2012; Monteiro et al., 2011).

Many scholars have proved that Cd stress has the potential to cause the following issues: the accumulation of reactive oxygen species (ROS), the inactivation of antioxidant enzymes, damages protein and DNA and negatively influences lipid peroxidation (Mishra et al., 2006; Ranieri et al., 2005; Schützendübel et al., 2002). Focusing on the Cd-resistance of ethylene, Zhang et al. (2010) investigated the effect of ethylene on the Cd uptake and accumulation of plants at different Cd contents, and found that plants with high translocation factor are less tolerable to Wang et al. (2011) observed that Cd and Cd-containing toxic compounds were excluded from the cytoplasm of *Arabidopsis*, with the increase in the expression of AtPDR8, indicating that transport gene is contributing to Cd resistance. The studies of Chen et al. (2018) showed that exogenous application of Cu, Zn or Ca to plant medium could alleviated the Cd stress to *Catharanthus roseus*.

It has been reported that lipid peroxidation, a sensitive response to metal stress, is usually characterized by the contents of Malondialdehyde (MDA) and hydrogen peroxide (H_2O_2). Some scholars discovered immediate generation of H_2O_2 when plants were exposed to high Cd content, and thus considered H_2O_2 as the key molecule that stimulates signal transduction after metal exposure of plants (Mithöfer et al., 2004; Smeets et al., 2008, 2009). Some concluded that the roots of plants, especially the plasma membranes of root cells, are the primary targets of metal action under Cd stress (Cuypers et al., 2009; Vangronsveld and Clijsters, 1994). Because the toxicity of Cd^{2+} is exerted through membrane damage and inactivation of enzymes. The antioxidation power of cells mainly comes from antioxidants like catalases (CAT), glutathione reductase (GR) (Mittler et al., 2004). The CAT and the GR can detoxify H_2O_2 into H_2O (Gratao et al., 2005; Passardi et al., 2007), and control cellular redox homeostasis within certain limits (Mittler et al., 2004).

Ethylene is an endogenous regulator for plant growth. The hydrocarbon has a strong impact on ripening, abscission and senescence, as well as many other aspects of vegetative growth. The existing studies have shown that ethylene is involved in the plant's response to metal stress (Cao et al., 2007; Iakimova et al., 2005). Under metal stress, the plants will produce much more ethylene than that under normal conditions. This surge in ethylene production occurs when the Cd content exceeds 1 mM (Chen, 2017). Many scholars held that ethylene regulates cellular and developmental processes responding to abiotic stress, highlighting how ethylene is involved in stress responses of plants (Achard et al., 2006; Ahmadi et al., 2018; Ali et al., 2018; Cao et al., 2007; Jung et al., 2009; Wang et al., 2007). Furthermore, ethylene is considered as a stress hormone (Kende, 1993) and ethylene signalling regulates multiple stress responses (Cao et al., 2009). However, it is not clear what specific roles it plays in signalling of stress responses (Cao et al., 2008).

In light of the above, this paper probes deep into the relationship between ethylene and plant resistance to heavy metal stress, aiming to enhance crop yield, improve the crop resistance to heavy metal stress and remediate the soil polluted by heavy metals.

Materials and methods

Plant and Cd treatment

Arabidopsis thaliana (Columbia ecotype) (Col-0) seeds were surface sterilized by 10%(v/v) sodium hypochlorite (NaClO), then washed with water and dried under sterile conditions. The sterilized seeds were then placed on agar plates containing Murashige and Skoog (MS) basal salt mixture, 1% sucrose, pH 5.7, 0.8% Agar. Next, the plates were respectively added 0 μM, 10 μM, 20 μM, 40 μM, 50 μM, 60 μM and 100 μM $CdCl_2$. The plates were kept in the dark at 4 °C for a 4d-long synced germination, before being relocated to light (photosynthetically active radiation (PAR) = 160 μM photons m^{-2} s^{-1}) at 23 °C with a 16:8 h light: dark regime.

Assay of seedling growth

To measure the growth of *Arabidopsis thaliana*, the root lengths of at least 15 seedlings were measured daily after the seedlings were transferred to light. The measurements were carried out with an SMZ 1500 stereomicroscope (Nikon, Japan) and the measured data were analysed on NIS-Elements Basic Research (Nikon, Japan).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1440314414

Assay of antioxidative enzyme activity

To evaluate antioxidative enzyme activity, 0.3 g seedling were ground in liquid nitrogen and extracted in 5 mL phosphate-buffered saline (PBS) buffer (50 mM, pH7.0), containing 1mM ethylenediaminetetraacetic acid (EDTA), 1mM acetylsalicylic acid (ASA) and 1% (w/v) soluble polyvinylpyrrolidone (PVP). The homogenates were centrifuged (10,000g) for 30 min at 4 °C, and then the supernatant was collected for the assay of enzyme activities.

The CAT activity was measured by the method of Lin et al. (2013). The H_2O_2 (extinction coefficient: 0.04nM-1cm-1) was decomposed at 240nm for 3min in a quartz cuvette. The reaction mix consists of 2.7mL 0.1M PBS buffer (pH7.0), 0.1mL 300mM H_2O_2 solution and 0.2mL extract. All experiments were performed in triplicate for each treatment.

The GR activity was determined by the method of Kaya and Yigit (2012). The glutathione disulphide (GSSG) and reduced nicotinamide adenine dinucleotide phosphate (NADPH) were reduced into glutathione and nicotinamide adenine dinucleotide phosphate ($NADP^+$) in the presence of GR. The reaction mix consists of 0.5mL PBS buffer (pH7.8), 0.1mL 20mM EDTA-Na_2 solution, 0.1mL 5mM GSSG solution, 0.1mL 1.5mM NADPH solution and 0.2mL extract. The absorbance of the mixture was measured at 340nm. The reaction lasted for 3min. All experiments were performed in triplicate for each treatment.

Determination of H_2O_2

The content H_2O_2 was determined by the method of Satterfield and Bonnell (1955) with a little modification. Firstly, about 0.3g plant tissue was frozen in liquid nitrogen and then ground into powder. Then, 3mL precooled propanone was added and mixed with the powder. After centrifugation, the supernatant was collected for further use. Next, 2mL supernatant was taken, and added with 0.1mL 5% titanium sulphate and 0.2mL concentrated ammonia. After centrifugation, the precipitate was collected and washed with propanone, and then added with 5mL 2M sulfuric acid. The absorbance of the mixture was measured at 415nm. All experiments were performed in triplicate for each treatment.

Determination of lipid peroxidation

The lipid peroxidation was determined by the method of Ashraf et al. (2015). The thiobarbituric acid reactive substances (TBARS) were taken as the measure of lipid peroxidation. Firstly, 300 mg plant tissue was homogenized with 3 mL 10% precooled trichloroacetic acid (TCA) buffer. After centrifugation (8,000 g) for 10 min at 4 °C, 2 mL 0.5% TBA was added to 2 mL extract. Then, the mixture was heated for 30 min at 95 °C and centrifuged. Finally, the absorbance of the supernatant was measured at 532 nm and corrected for unspecific absorbance at 600 nm.

Analysis on gene expression

The total ribonucleic acid (RNA) was extracted from 100~200 mg samples (both leaves and roots), using TRIzol reagent, and quantified by a Nanodrop ND-1000 spectrophotometer (Thermo Fisher Scientific, US) with absorbance at 260 nm. Next, 2 μg RNA was adopted for reverse transcription with a Revert Aid Reverse Transcriptase

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1440314414

and Oligo (dT) primers (Takara, Japan). The quantitative reverse transcription-polymerase chain reaction (qRT-PCR) was analysed on a RealMasterMix Kit (TIANGEN Biotech, China). The initial denaturation lasted 30 s at 94 °C, 30 s at 60 °C and 30 s at 72 °C, followed by a 5 min-long process at 92 °C. All quantifications were normalized to the amplification of Actin2 gene. The primer sequences of all genes used for qRT-PCR are listed in *Table 1*. All experiments were performed in triplicate for each treatment.

Statistical analysis

In the present study, there were three replicates arranged in a randomized block design manner for each treatment including control. All the data were presented as mean ± standard error (SE) and comparison of means were performed using SPSS (SPSS 17.0, SPSS Inc., USA). The one-way ANOVA with the Duncan's post hoc test was performed to test the difference significance ($p < 0.05$) of means.

Experimental results

Ethylene synthesis and signal related gene expression

Figure 1 illustrates the expression of ACO2, ACS2 and EIN3 genes in *Arabidopsis thaliana* under elevated Cd content. Obvious changes were seen in the expression of all three genes from the figure. Specifically, ACO2 was expressed more strongly under Cd stress, except at the Cd content of 10 μM; ACS2 had a strong expression at the Cd content of 60 μM; EIN3 expression increased with Cd content. Overall, the strongest synthesis and signal of ethylene gene expressions were observed at the Cd content of 60 μM. This means ethylene is involved to maintain the normal growth of plants under Cd stress.

Altered element uptake in Arabidopsis thaliana under Cd stress

Several macro- and micro-nutrients were analysed to disclose the nutrient acquisition in *Arabidopsis thaliana* seedlings under Cd stress. The seedlings were placed in nutrient solutions with different Cd contents for 14 d. Then, the Cd contents in the shoot and the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1440314414

root of the seedlings were measured one by one. The results show that, under Cd stress, the Cd contents in both the shoot and the root are positively correlated with the Cd content in the solution, while the translocation factor of the shoot is negatively correlated with the Cd content in the solution.

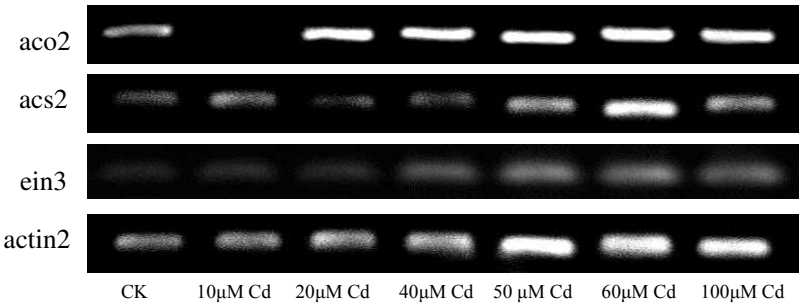

Figure 1. *Expression of ACO2, ACS2 and EIN3 in Arabidopsis thaliana under elevated Cd content*

Effect of ethylene on Cd content in Arabidopsis thaliana under Cd stress

The effect of ethylene on Cd content in *Arabidopsis thaliana* were explored at three Cd contents. The experimental results are displayed in *Figure 2*. Compared with the seedlings treated with Cd alone, the seedings treated with 30 μM aminocyclopropane-l-carboxylic acid (ACC) had a low Cd content in the shoots. The same trend was observed in the roots. The translocation factor of seedlings added with ethylene was lower than that of those treated with Cd alone. To sum up, the ethylene could reduce the Cd content and translocation factor in *Arabidopsis thaliana* seedlings under Cd stress.

Effect of ethylene on MDA content in Arabidopsis thaliana under Cd stress

Plasma membranes are the primary targets for metal stress in both roots and leaves. The membrane damage can be deduced through the TBA assay on lipid peroxidation products. Here, several *Arabidopsis thaliana* seedlings are treated with different contents of Cd. The results show that the Cd treatment consistently promoted the MDA contents in leaves of *Arabidopsis thaliana* seedlings. Hence, three Cd contents were selected to treat the seedlings, and used to detect the effect of ethylene on MDA contents in leaves. As shown in *Figure 3,* the seedlings added with ethylene contained fewer MDA than those treated by Cd alone. Under Cd stress, the application of ethylene suppressed the MDA content, easing the membrane damage caused by lipid peroxidation.

Effect of ethylene on H_2O_2 content in Arabidopsis thaliana under Cd stress

H_2O_2 is a common product under metal exposure. Thus, the H_2O_2 contents in leaves of *Arabidopsis thaliana* seedlings were measured at different Cd contents. The measured results in *Figure 4* show that the leaves of seedlings treated with Cd produced more H_2O_2 than the control. Thus, the Cd content can greatly impact the production of H_2O_2 in seedlings. With the increase of Cd content, the H_2O_2 content in leaves of *Arabidopsis thaliana* gradually increased (*Fig. 4*). Then, the effect of ethylene on H_2O_2 content in the leaves was determined at the Cd content of 60 μM. The results indicate that the ethylene inhibited the H_2O_2 content in *Arabidopsis thaliana* seedlings under Cd stress.

Antioxidative enzyme activities

The effects of Cd and ethylene on CAT and GR activities in leaves of *Arabidopsis thaliana* seedlings were tested, and the results were plotted in *Figure 5*. Obviously, the Cd content exhibited a great impact on the antioxidative enzyme activities. The CAT activities in seedlings treated with Cd were greatly affected. Compared with the control, the CAT activities in all seedlings treated with Cd were relatively low. Next, the Cd content of 60 μM was selected to detect how ethylene affects CAT activity. The detection results show that the ethylene significantly boosted the CAT activities in seedlings under Cd stress. In addition, the Cd content greatly promoted the GR activities in seedlings, while the growth in ethylene content led to a decline and then increase in the GR activities.

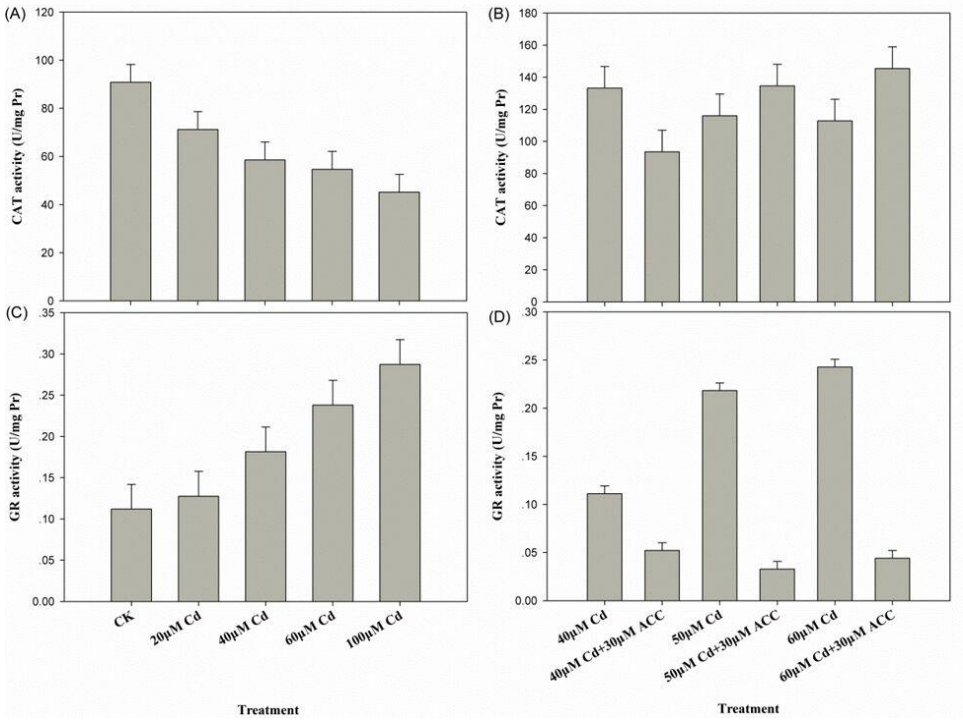

Figure 5. *Effect of Cd and ethylene on the activities of CAT (A and B) and GR (C and D) in leaves of Arabidopsis thaliana seedlings*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

Expression of AtATM3 and AtPDR8 in Arabidopsis thaliana seedlings under Cd stress

The AtATM3 gene is involved in Cd transporter proteins in the roots of *Arabidopsis thaliana* seedlings. If this gene is overexpressed, the plant will be more resistant to Cd. Meanwhile, the AtPDR8 gene has been identified as a transporter of ATP-binding cassette (ABC) that contributes to Cd resistance in *Arabidopsis thaliana*, as it excludes Cd or Cd-containing toxic compounds from the cytoplasm. The author tested the expression of AtATM3 and AtPDR8 in *Arabidopsis thaliana* seedlings treated with different Cd contents. The results (*Fig. 6*) show that both AtATM3 and AtPDR8 were expressed more stronger with the growth in Cd content, indicating that the two genes contribute to Cd resistance.

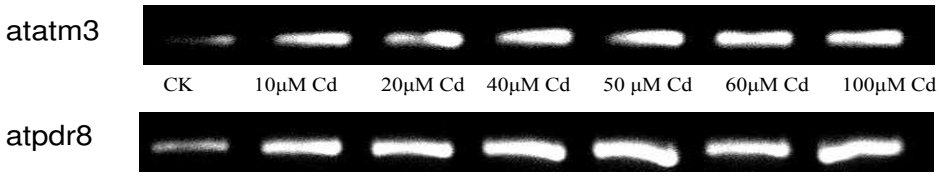

Figure 6. *Expression of AtATM3 and AtPDR8 in Arabidopsis thaliana seedlings under different Cd contents*

Figure 7 presents how ethylene content affects the expression of AtATM3 and AtPDR8 in *Arabidopsis thaliana* seedlings under Cd stress. It can be seen that the two genes were expressed more strongly with the Cd content and with the ethylene content. This means ethylene contributes to Cd resistance by enhancing the expression of AtATM3 and AtPDR8 (*Fig. 7*).

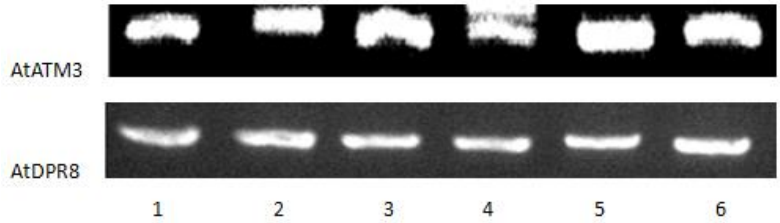

Figure 7. *The effect of ethylene content on expression of AtATM3 and AtPDR8 in Arabidopsis thaliana seedlings under Cd stress. Note: The treatments are 60 μM Cd(1), 60 μM Cd+ 2 μM ACC(2), 60 μM Cd+ μM ACC(3), 60 μM Cd+ 10 μM ACC(4), 60 μM Cd+ 30 μM ACC(5) and 60 μM Cd+ 50 μM ACC(6)*

Discussion

This research uses *Arabidopsis thaliana* seedlings to test the effect of ethylene on Cd resistance. Ethylene, an important regulator of plant physiology under stress, is deeply involved in the response to abiotic response. In recent years, several reports claim that ethylene could improve Cd resistance (Fuhrer, 1982). In these reports, it is confirmed that ethylene takes part in modulating the cadmium response, but the modulation mechanism is not explained. Therefore, our research attempts to verify the hypothesis that the modulation mechanism works thanks to the ability of ethylene to reduce Cd

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1440314414

translocation from roots to shoots in Cd-stressed *Arabidopsis thaliana*. The research results prove the validity of the hypothesis.

With the increase in metal content in the environment, plants worldwide are suffering from metal phytotoxicity (Chen, 2018). The roots, which are in direct contract with the nutrient solution, often accumulate lots of Cd. Under the stress, there is a cumulative effect on the inhibition and phytotoxicity of roots. Our research results also show that Cd stress could greatly boost the expression of ACO2, ACS2 and EIN3 genes in *Arabidopsis thaliana* seedlings. Hence, ethylene may play an important role in resistance to Cd.

Over the time, the heavy amount of Cd accumulated in roots under Cd stress will gradually move to the shoots. With the growth in Cd content, both shoots and roots will witness an increase in their Cd contents. In our research, the root-shoot Cd transport is measured by the translocation factor. Our results show that the translocation factor of shoots first decreased and then increased with the increase in Cd content. Under a high translocation factor, lots of heavy metals were transported from roots to shoots. Thus, a high translocation factor does not contribute to the Cd resistance. After adding ethylene to Cd-stressed seedlings, it is observed that the Cd content in the seedlings decreased. Besides, the addition of ethylene significantly suppressed the translocation factor under the 50 μM Cd stress.

The cellular redox state is an important determinant of metal phytotoxicity (Kranner et al., 2010). Lipid peroxidation could be the first indication of oxidative damage and was observed under Cd exposure. There is a mutual promotion relationship between lipid peroxidation and the production of hydroxyl radicals. In our experiment, when seedlings were treated with Cd alone, the MDAs in roots and leaves increased gradually with the Cd content. Comparatively, the roots had higher MDA than leaves, and thus suffered more injuries under Cd stress. When ethylene of different contents was applied to the Cd-stressed seedlings, the MDA contents dropped across the board. This means ethylene could ease the membrane injury caused by lipid peroxidation in Cd-stressed plants. During lipid catabolism, H_2O_2 is generated as a by-product of fatty acid oxidation (Sharma et al., 2012). However, excess H_2O_2 may bring oxidative damage to plants. In our experiment, the H_2O_2 content in the leaves of *Arabidopsis thaliana* seedlings gradually increased with the Cd content. The trend is the same with that of the MDA. Thus, the addition of ethylene could suppress the H_2O_2 content in Cd-stressed seedlings.

In leaves, the H_2O_2-scavenging enzymes are key weapons of the antioxidative defence system (Skulachev, 1997). Major H_2O_2-scavenging enzymes of plants include the CAT, the GR, the ascorbate peroxidase (APX), the superoxide dismutase (SOD), and the peroxidase (POD). Among them, the CAT and the GR were selected for our research. The experiment shows that the CAT ability in seedlings treated by Cd alone was poorer than that of the control, indicating that the Cd-exposure suppressed the activity of the H_2O_2-scavenging enzyme, and boosted the production of H_2O_2. However, the CAT ability improved after the addition of ethylene, revealing the promotional effect of ethylene on the CAT. With the growth in Cd content, the GR activity exhibited an increasing trend. This is because the GR can produce the GSH to eliminate H_2O_2 and combine with Cd to yield PC_S. As a result, heavy metals are combined with proteins, malic acid and other substances in the cells. However, the GR activity was weakened after ethylene was added, meaning ethylene could suppress GR ability.

DOI: http://dx.doi.org/10.15666/aeer/1706_1440314414

AtATM3 is a transporter protein involved in the root-shoot Cd transport in *Arabidopsis thaliana* (Kim et al., 2006). Our research shows that the AtATM3 was upregulated in the roots of seedlings with the increase of Cd content, and overexpression of the gene could enhance Cd resistance. Besides, it is learned that ethylene can enhance AtATM3 expression to resist the Cd. Specifically, the ethylene retains the Cd ions in roots, lowering the translocation factor. In some plants, about 90% of the Cd ions are combined with PC_S. In our experiment, about 60% absorbed in the roots existed as PC-Cd compounds. Meanwhile, AtPDR8 is an ABC transporter capable of excluding Cd or Cd-containing toxic compounds from the cytoplasm (Kim et al., 2010). Our research shows that the overexpression of this gene enhances Cd resistance, and that ethylene improves AtPDR8 gene expression to resist Cd.

Conclusions

Our research results demonstrate the key role of ethylene in alleviating the metal phytotoxicity of Cd stress. Ethylene is involved in plant responses to Cd stress, ensuring the normal growth of plants. The application of ethylene is an effective way to enhance the Cd resistance. Taking *Arabidopsis thaliana* for example, ethylene reduces the root-shoot translocation of Cd ions, leading to stronger Cd resistance. In addition, ethylene can ease the metal phytotoxicity of Cd by lowering the MDA content and H_2O_2 generation, and regulate the over-expression of AtATM3 and APDR8 to enhance Cd resistance. To sum up, the ethylene mainly bolsters Cd resistance of plants by enhancing antioxidant activity and suppressing the root-shoot translocation of Cd ions. It is worthing that related antioxidative substance should be further studied in the future.

Abstract. Drought prediction is the premise of effective response to the hazards of drought, a serious water-deficit phenomenon resulting from the complex interaction between climatic factors. Considering the high non-linearity of drought, this paper establishes a drought prediction model based on copula entropy and general regression neural network (GRNN). The climate indices that directly affect the formation of drought were selected as the inputs of the GRNN. The established model was applied to predict droughts for Lanzhou site of the middle reaches of the Yellow River. The results show that our model can effectively predict drought occurrence in the study area. With a strong predictive ability for drought, the proposed model is an ideal tool to forecast meteorological disasters based on climate factors.
Keywords: *Hampel, intelligence algorithms, SPI, neural network, prediction*

Introduction

Drought as one of the major natural disasters the human race faces directly threatening human life. It is now a serious factor that can restrict the sustainable development of community economy. Intensifying drought monitoring and prediction is significant for the relative authorities, in order to prevent drought and reduce losses caused by drought. However, the route that leads to drought is extremely complex, but it often develops and occurs as the result of a relatively slow process. Impacted by many factors, there has not been a relatively mature, accurate and universal model for drought prediction. The study is still in its infancy (Liu et al., 2019; Mossad and Alazba, 2018).

To predict drought, the regression model in time series is mostly used to construct future drought prediction model (Mokhtarzad et al., 2017) since it has a certain practicability. However, the meteorological forecast features significant nonlinearity. There is a highly complex nonlinear relationship between the predicted object and the predictor, but the regression model in the time series ignores this complex relationship.

By far, the Artificial Neural Network (ANN) model have been widely applied in the field of hydrology (Bello and Mamman, 2018; Garai et al., 2018; Isah et al., 2017; Mostefa et al., 2018; Qi et al., 2019; Sánchez-Escalona and Góngora-Leyva, 2018). When it is used to establish a drought prediction model, there is problem on how to select the predictors and the network models. To select predictive input factors, the practice is to consider the correlation between relevant drought predictors and drought indices, based on which to effectively predict the drought. As there is a highly complex nonlinear relationship between drought indices and prediction factors, it is considered the copula entropy can be used to determine the prediction factors; for the specific

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1441514424

network model, the Generalized Regression Neural Network (GRNN) with strong nonlinear mapping is used (Ladlani et al., 2012; McKee et al., 1993).

Based on all above, GRNN coupled with copula entropy (CE) is used to construct a drought prediction model based on CE-GRNN. The drought prediction correlation factor was selected by CE, and the GRNN was used for prediction to achieve drought prediction results.

This paper includes the following parts: Part 1 is the Introduction; Part 2 discusses the basic method and theory, including: the selection of predictors, the establishment of neural networks and the flow chart of the hybrid model. Part 3 is the Analysis of the results of the relevant sites; Part 4 gives the discussion, and the last part gives the Conclusion.

Materials and methods

Standard precipitation index

Standard Precipitation Index (SPI) (McKee et al., 1995; Shiau and Chiu, 2019) as one of drought indices was proposed by American scholar McKeed in 1993. It represents the standard deviation of the precipitation from the mean, similar to that in mathematical statistics.

SPI is defined as follows (Sharma, 2000):

Assume that the precipitation in an area is x, the probability density function is:

$$g(x) = \frac{1}{\beta^{\gamma}} x^{\gamma-1} e^{-x/\beta} \quad \text{(Eq.1)}$$

where: $\beta > 0$ is the scale, but $\gamma > 0$ is the shape parameter; β and γ can be obtained by the maximum likelihood estimation method:

$$\gamma = \frac{1 + \sqrt{1 + 4A/3}}{4A} \quad \text{(Eq.2)}$$

$$\beta = \frac{\bar{x}}{\gamma} \quad \text{(Eq.3)}$$

where:

$$A = \lg \bar{x} - \frac{1}{n} \sum_{i=1}^{n} \lg x_i \quad \text{(Eq.4)}$$

where: x_i represents the precipitation; $\bar{x}$ represents the mean of precipitation; n represents the length of the sequence.

After determining the parameters for the probability density function of the distribution, the cumulative probability function is expressed as

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1441514424

$$G(x) = \int_0^x g(x)dx = \int_0^x \frac{1}{\beta^\gamma} x^{\gamma-1} e^{-x/\beta} dx \quad \text{(Eq.5)}$$

Since the *Gamma* function is undefined when $x = 0$, the precipitation value 0 can be transformed by the following formula:

$$H(x) = q + (1-q)G(x) \quad \text{(Eq.6)}$$

where: q is the probability of occurrence of value 0 in the precipitation sequence, and then $H(X)$ is normalized by a Gaussian function. The normal normalization is performed on *Gamma* distribution probability, so that an approximated solution can be obtained:

$$SPI = S(t - \frac{2.52 + 0.8t + 0.01t^2}{1 + 1.43t + 0.19t^2 + 0.001t^3}) \quad \text{(Eq.7)}$$

where:, $t = \sqrt{ln\frac{1}{H(x)^2}}$, $H(x)$ is the probability obtained by the *Equation 6,* when $H(x) > 0.5$, $S = 1$; when $H(X) \leq 0.5$, $S = -1$.

Option of prediction factors based on copula entropy

Copula Entropy, as a new entropy concept defined by Ma and Sun (Chen et al., 2015; Chen and Guo, 2019; Fernando et al., 2009; Hao and Singh, 2012; Ma and Sun, 2011) in 2008, can be used to measure the full order correlation between random variables. Here, Copula entropy can describe the correlation between the target and the predictive factors. How to use the copula entropy to select predictive factors requires an effective and reliable standard. That is to say, at the time of what the copula entropy value is, relevant prediction factors can be used as the input set of the prediction model. Here, the Hampel test recommended by Fernando and May, et al. is used as the stopping criterion of the algorithm (May et al., 2008).

The Hampel test algorithm is expressed as:

$$H_j = \frac{d_j}{1.4826 d_j^{(50)}} \quad d_j = \left| C_{PMI} - C_{PMI}^{(50)} \right| \quad \text{(Eq.8)}$$

where: H_j- Hampel distance; 1.4826 - normalization factor such that H_j is equal to the standard deviation σ of the data sequence; $d_j^{(50)}$- median of d_j; $C_{PMI}^{(50)}$- median of the values C_{PMI} in a set of data; $C_{PMI}^{(50)}$- copula entropy.

According to the standard deviation 3σ criterion, when the Hampel distance is greater than 3, the input variable will be included into the set of input variables, that is, determined as the prediction factors of the model.

According to the selection criteria of copula entropy, the prediction factors of the neural network model are determined by the following procedure:

1. Filter out all possible input variables;.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1441514424

2. Construct a joint distribution of individual factors and the predicted target, and select the optimal Copula function.
3. Determine the Copula density function with the selected Copula function, calculate the Copula entropy value of each factor and the predicted target.
4. Calculate the Hampel distance between the predicted target and the factor with the Hampel algorithm.
5. According to the test criteria, the determined factors are included in the input variable set as the last input factor for the neural network.

Establishment of NN model

The neural network is a new type of intelligent algorithm that can imitate the animal's nervous system. It depends on the neurons to link each other. there are three layers: the input layer, the hidden layer, and the output layer, each of which has its own special functions: the input layer performs factor input and processing; since input data must not be linear in real world, and sometimes is multidimensional. It is required to allow data to be trained via the hidden layer to make data visible, in order to obtain data as required. The hidden layer is therefore the core of the neural network; after the training via the hidden layer, data basically is what we want to be. Then it is required to output data via the output layer. These three layers are independent of each other, and the state of neurons in each layer can only affects those in the next layer. In this paper, the input variables are various factors related to drought prediction, and the output variables is drought prediction result. The framework of neural network is shown in *Figure 1*.

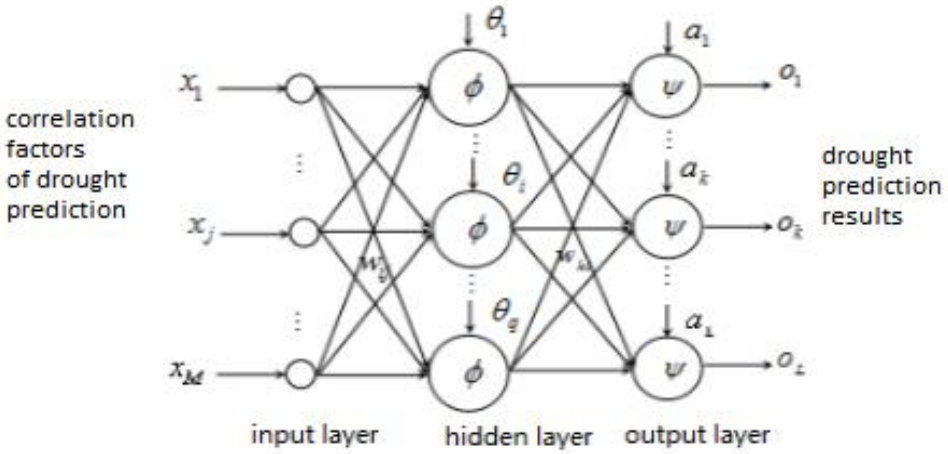

Figure 1. *Framework of neural network*

Hybrid prediction model based on Copula entropy and GRNN

When the GRNN is used to carry out the correlation prediction algorithm, the correlation between individual factors and drought object is first calculated based on the Copula entropy, and then the last input factor selected is chosen as the input layer of the neural network according to the Hampel distance. The drought prediction is also explored when appropriate. The relevant prediction process is shown in *Figure 2*.

In the process of establishing the GRNN model, more attention should be paid to the analysis of the physical meaning between prediction objects and the selection of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1441514424

predictors. Undoubtedly, precipitation and drought are the most closely related. The SPI drought index is calculated from precipitation. Therefore, when the predictor is considered, the correlation between the nine related factors other than precipitation is studied. Among these related factors, CE method is used to select four factors which are most closely related to drought as prediction factors according to HAMPLE criterion. This coincides with the prediction content of the climate dynamics model proposed by Zeng Qingcun, an academician at the Institute of Atmospheric Physics of Chinese Academy of Sciences (Zeng, 1998).

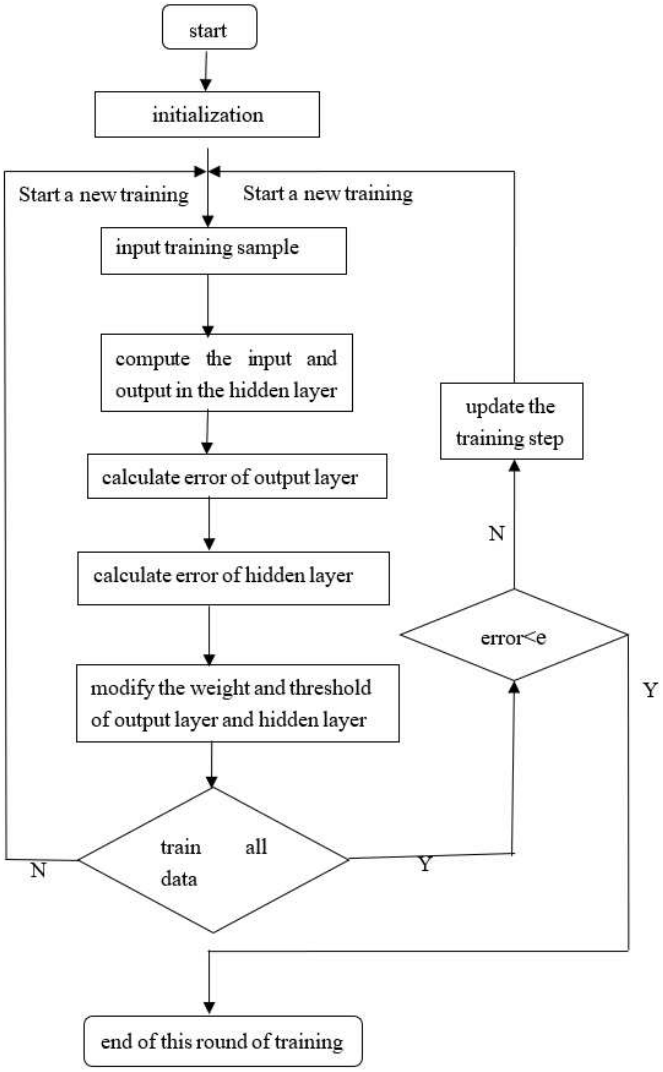

Figure 2. *Flow chart of prediction of neural network*

Results

Selection of input set

In order to verify the effectiveness of the algorithm of drought prediction in practice, the Lanzhou site in the middle reaches of the Yellow River basin of China is taken as study sample. The Lanzhou site is located at 34.29° north latitude and 110.05° east longitude. The distribution map of Lanzhou site and nearby sites is shown in *Figure 3*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1441514424

For some reasons, only some relevant data are obtained. Therefore, meteorological data from 1957 to 2010 are used for analysis. In order to eliminate the inconsistency of data, normalization processing for homogenize data is adopted, and at the same time, interpolation method is used to process the abnormal value.

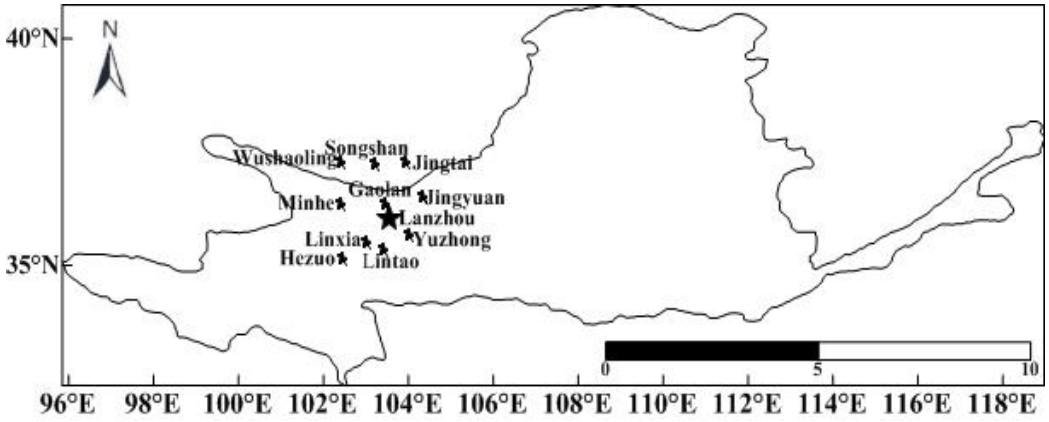

Figure 3. *Distribution map of Lanzhou site*

For selecting drought prediction factors, the following nine meteorological drought indices: wind speed, wind direction, air temperature, precipitation anomaly, temperature departure, vapor pressure, relative humidity, percentage of sunshine, sunshine hours, are used as initial factors and labeled as independent variables to calculate the Copula entropy, then n factors closely related to drought index of SPI were screened out based on the Hampel test which value is greater than 3 as the last set C. Finally, the variables of last set *C* are used as an input variable into the neural network for training. *Table 1* lists the copula value and the associated Hampel distance calculated by the above method from meteorological data of Lanzhou site.

Table 1. *Entropy value and Hampel list*

Factor (SPI)	Mutual entropy	Copula entropy	Hampel distance
Precipitation nomaly	0.29	-0.29	2.82
Wind speed	0.16	-0.16	3.05
Air temperature	0.39	-0.39	3.47
Temperature nomaly	0.09	-0.09	2.89
Vapor pressure	0.45	-0.45	3.31
Sunshine hours	0.07	-0.07	2.82
Relative humidity	0.29	-0.29	3.41
Percentage of sunshine	0.16	-0.16	2.77
Wind direction	0.01	-0.01	1.65

According to the Hampel test criteria, when the Hampel distance is greater than 3, the selected factors are used as the last input factors. As shown in *Table 1,* there are meteorological factors with Hampel distance greater than 3, including four factors: wind speed, air temperature, vapor pressure, and relative humidity. Therefore, these four factors are used as the last input set of variables of GRNN for drought prediction.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1441514424

Predicted results

The predictive analysis of drought is made with the Lanzhou site SPI as the prediction target, and the selected factors, i.e. wind speed, air temperature, vapor pressure and relative humidity, are input into the input layer of the neural network for correlation prediction. And in his paper, the error of the actual value and the predicted value is used to test the performance of the algorithms. The image of predicted results is shown in *Figure 4*. The error map for the actual and predicted values of the drought indices is shown in *Figure 5,* and the violin plot of the predicted results is shown in *Figure 6*.

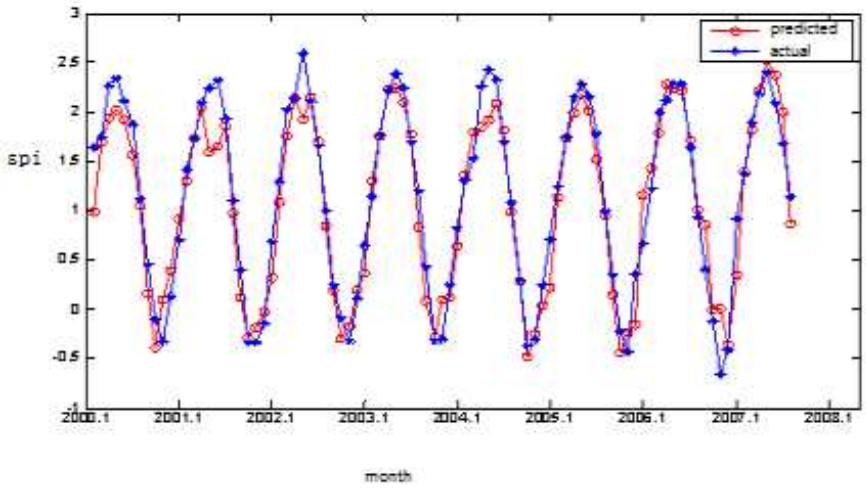

Figure 4. *Actual and predicted SPI value*

The red line in *Figure 4* represents the predicted value output, and the blue line represents the actual value. As shown in *Figure 4,* the fitting effect is better at most points, but the prediction effect at the critical values is relatively poor. In *Figure 5,* the value of the horizontal coordinate corresponds to the time coordinate in *Figure 4,* and it describes the error value of the corresponding time. As seen from the error results in *Figure 5,* the prediction effect is better.

Figure 5. *Error of actual drought and predicted values*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1441514424

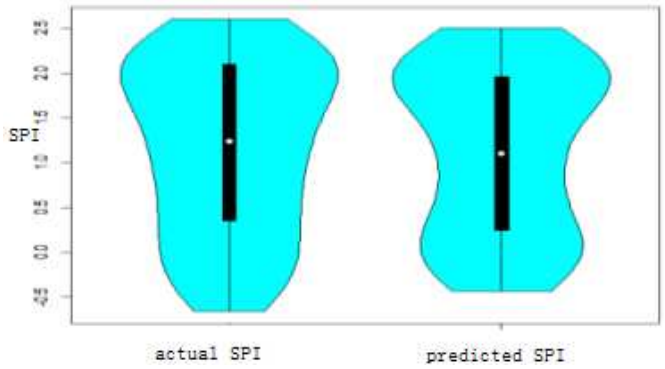

Figure 6. *Violin plot of actual and predicted results*

As shown in *Figure 6,* the simulated and actual values for the drought indices of Lanzhou site can well fit the nuclear density and box plot. The median of the simulated values is slightly lower than but substantially consistent with the actual value. It lies in half-way down the box, basically to be consistent with the actual situation. The maximum of the simulated values is substantially equal to that of the actual values, and the minimum value is relatively low.

As shown in *Figures 4, 5* and *6,* the results simulated for the drought prediction in Lanzhou site further show that the hybrid algorithm based on Copula entropy and GRNN has better prediction effect.

Discussion

Traditional prediction method is designed for linear sequences, while predicted results from methods for nonlinear drought sequences are often unsatisfactory. It is extremely important to improve the prediction accuracy of nonlinear time series. Copula entropy can well describe how well the correlation between nonlinear drought sequences and drought predictors, and the neural network is also proven to be effective in predicting nonlinear drought time series.

Conclusion

Since the drought presents a complex nonlinearity, the traditional drought prediction algorithm has a relatively wide error. In contrast, the GRNN has a good nonlinear approximation performance, so that it features high robustness and fault tolerance. With copula entropy, the nonlinear dependence between factors and objects can be depicted. Therefore, this paper predicts the meteorological drought indices by establishing a hybrid model based on Copula entropy and GRNN. The results reveal that the well-established drought prediction model can directly predict the drought time sequence at a high accuracy rate. This model has a favorable generalization performance.

Although GRNN improves the prediction accuracy to some extent, but it is easy to fall into the extreme value, and the mapping ability of the non-stationary sequence is insufficient, which affects the accuracy of prediction to a certain extent. Therefore, some relevant parameter optimization algorithm (for example, the fruit fly optimization algorithm) can be considered to optimize the parameters of the neural network to further improve the prediction accuracy.

Abstract. The excessive consumption of forest resources has severely challenged the sustainable development of society, economy and resources in state-owned forest areas, so it is urgent to explore the economic transformation of forest areas. In the process of economic transformation and development in forest areas, a large amount of social capital is needed to make up for the shortage of national financial investment. The implementation of an ecological compensation mechanism is of great significance to attract social capital to the economic transformation and development of forest areas and to realize the sustainable development of the ecological environment. However, ecological compensation involves the direct interests of many parties, and it is easy to form a game situation. The evolutionary game model between government's ecological compensation behavior and social capital's ecological protection behavior is constructed to study the selection strategies of ecological problems under different circumstances by both sides, obtaining stability strategy and evolution path of both sides within different range of parameters. The research shows that the necessary condition to realize the optimal and stable equilibrium strategy is that the project investment profit of social capital should be larger than speculative profit under the government's ecological non-compensation, and the supervision cost of government departments should be less than ecological profit.
Keywords: *ecological protection, ecological compensation, evolutionary strategy, evolutionary trend, ecological benefit*

Introduction

During the inspection of state-owned forest areas in China, some scholars have pointed out that new ways for industrial development should be explored after the commercial logging has been completely stopped in the state-owned forest areas. It is necessary to shift from the extensive strategy of resource development and economic development to the ecological development strategy of rational protection, intensive resource development and economic development. At this stage, the research achievements on the economic transformation of state-owned forest areas are as follows: the current situation of the transformation is analyzed, and the measures for the coordinated development of ecological construction and economic transformation are put forward (Li et al., 2019; Tong et al., 2018; Wen et al., 2017). Through the analysis of the interest game among the central government, local government and state-owned forestry enterprises in the process of the construction of the ecological function zones in the Daxiaoxingan Mountains, the strategies for improving the economic transformation in the state-owned forestry areas are put forward (Zhong et al., 2017). In the reform of the state-owned forest ownership, the game model of the stakeholders' responsibility of the government, forestry enterprises and workers is established, and the measures for the three parties to obtain reasonable interests according to their responsibilities are put

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1442514434

forward (Sun et al., 2018). To sum up, it is an arduous task to protect both ecology and the people's livelihoods in the transformation and development of forest areas. We should broaden our thinking and take multiple measures simultaneously. Therefore, finding a balance between ecological protection and economic transformation has become the key to the reform of state-owned forest areas in China. Introducing the mechanism of ecological compensation and adjusting the ecological interest relations among ecological stakeholders by economic means are of great significance for protecting the forest ecosystem and promoting the economic transformation and upgrading of forest areas.

The existing research on ecological compensation mainly includes two aspects: one is the construction of ecological compensation mechanism. On the basis of systematic analysis of the elements of ecological compensation for forest tourism, the specific mechanism of taking ecological protection and economic development into account simultaneously through ecological compensation is put forward (Fang et al., 2018; Liu et al., 2018). The other is that the evolutionary game theory is used to solve the problem of ecological compensation in many fields. In China's non-resident islands, the dynamic evolution process of the influence of various elements of the main stakeholders of ecological compensation on decision-making behavior is analyzed by using the evolutionary game theory (Liu et al., 2016). The strategic selection between ecological compensation of mineral resources development enterprises and government supervision is discussed from the perspective of evolutionary game theory (Zhang, 2016). The game behavior of upstream and downstream governments in the process of implementing ecological protection and compensation is analyzed, and the effective ways to protect the ecological environment of the basin is obtained (Zhou et al., 2018). The conflict of interest and game in ecological compensation for coal mining is analyzed, and some measures and suggestions for coordinating and balancing the interests of all parties in ecological compensation is put forward (Guo et al., 2018). In summary, no scholars have explored the ecological compensation problems for the economic transformation of the state-owned forest areas in China from the perspective of the Public-Private Partnership model and the evolutionary game. Therefore, this paper introduces evolutionary game theory to construct a game model between the social capital side's ecological protection behavior and government's ecological compensation behavior, which provides theoretical basis and decision support for the realization of high-quality coordinated development of ecological construction and economic transformation.

Materials and methods

Research subject

This paper takes Lutou forest farm in Pingjiang County, Yueyang City, Hunan Province, China, as a specific research object. The construction of Lutou forest farm needs a large amount of financial support. The Public-Private Partnership model should be adopted to encourage and guide the participation of social capital, which is conducive to promoting the economic transformation of the forest farm. However, in the process of cooperation, there is a certain conflict between the social capital's goal of maximizing economic benefits and the government's goal of pursuing environmental benefits, which leads to the game between them in the process of ecological protection implementation. In the process of game, when the investment income of the social

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1442514434

capital side decreases due to the protection of the ecological environment, they tend to prefer not to protect the ecological environment. For this kind of behavior of the social capital side, when the government takes incentive measures to compensate for the ecological expenditure of enterprises, they will restore the ecological environment; and when the government relaxes the incentive of their ecological protection behavior, the social capital side will produce acts of destroying the environment. In this way, the social capital side and governments play games according to their respective goals until they reach equilibrium.

Therefore, the main stakeholders involved in the evolutionary game model of the ecological compensation are the social capital side and government departments. The social capital side and government departments conduct strategy selection for ecological protection. The strategic space for social capital side is ecological protection and non-ecological protection, and the strategic space for government departments is ecological compensation and non-ecological compensation. During the whole process of cooperation, the two sides are bounded rationality and they constantly adjust their own decision-making according to their own benefits and strategies of the other side.

Basic assumptions

The following assumptions are made on the evolutionary game model of ecological compensation:

(1) Benefits and cost of social capital side: I is the project investment; R is the benchmark rate of return; b_s is the for the distribution rate of benefits; L_1 is the environmental benefits obtained by carrying out the ecological protection measures; e is the extra benefits by pursuing the pure economic interests but failing to implement the ecological protection measures, which is related to the degree of speculation of the social capital side. c_1 is the cost paid by social capital to achieve the project economic and environmental benefits; K is the ecological compensation given by government departments when social capital side performs ecological protection measures; S is the punishment imposed by government departments on the social capital side which does not perform ecological protection measures.

(2) P_1 ($0 \leq P_1 \leq 1$) is the ecological protection level of the social capital side. In the case of ecological protection measures in place, $P_1 = 1$; the smaller the value of P_1, the weaker the ecological protection, which is reflected in the decline in ecological protection costs, increase in the extra benefits and punishment cost.

(3) Benefits and cost of government departments: the benefits of government departments come from the distribution of the income of the social capital side and punishment imposed on the social capital side. The cost includes the cost c_2 of supervising whether the social capital side implement ecological protection measures and the incentive cost of ecological subsidy for the social capital side.

(4) P_2 ($0 \leq P_2 \leq 1$) is the ecological compensation level of government departments. The smaller the value of P_2, the less the compensation, which is reflected in the decline of supervision cost and punishment cost.

Establishment of evolutionary game model

The evolutionary game is based on bounded rationality, which assumes that due to the bounded rationality of the economic subjects, it is impossible for the economic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1442514434

subjects to clearly understand their own state and thus they will follow the most favorable strategy to imitate until reaching the equilibrium.

Based on the above assumptions, the income matrix of the ecological compensation can be obtained, as is shown in *Table 1*.

Table 1. *Income matrix of the evolutionary game model of ecological compensation*

Social capital side	**Government departments**	
	Ecological compensation	**Non-ecological compensation**
Ecological protection	$(b_sIR+L_1-C_1+K,$ $(1-b_s)IR+L_1-C_2-K)$	$(b_sIR+P_2L_1-C_1+P_2K,$ $(1-b_s)IR+P_2L_1-P_2C_2-P_2K)$
Non-ecological protection	$b_sIRP_1+P_1L_1+e(1-P_1)-$ $P_1C_1+K-(1-P_1)S,$ $(1-b_s)IRP_1+P_1L_1-$ $C_2-K+(1-P_1)S$	$b_sIRP_1+P_1P_2L_1+e(1-P_1)-$ $P_1C_1+P_2K-(1-P_1)S,$ $(1-b_s)IRP_1+P_1P_2L_1-$ $P_2C_2-P_2K+(1-P_1)S$

Assuming that ratio of adopting "ecological protection" by the social capital side is x and the ratio of adopting "non- ecological protection" is $1-x$ ($0 \le x \le 1$); the ratio of adopting "ecological compensation" by government departments is y and the ratio of adopting "non-ecological compensation" is $1-y$ ($0 \le y \le 1$). In this way, the benefits θ_{11} and θ_{12} when adopting "ecological protection" and "non-ecological protection" and the group average benefit $\bar{\theta}_1$ are showed in *Equations 1–3:*

$$\theta_{11}=y(b_sIR-C_1+K)+(1-y)(b_sIR-C_1+P_2K) \quad \text{(Eq.1)}$$

$$\theta_{12}=y(b_sIRP_1+e(1-P_1)-P_1C_1+K-(1-P_1)S)+(1-y)(b_sIRP_1+e(1-P_1)-P_1C_1+P_2K-(1-P_1)S) \quad \text{(Eq.2)}$$

$$\bar{\theta}_1=x\theta_{11}+(1-x)\theta_{12} \quad \text{(Eq.3)}$$

The replicated dynamic equation of the social capital side is showed in *Equations 4* and *5:*

$$G(x)=\frac{dx}{dt}=x(\theta_{11}-\bar{\theta}_1)=x(1-x)\begin{pmatrix}(b_sIR-e-C_1+S+L_1P_2)(1-P_1)\\+L_1y(1-P_1)(1-P_2)\end{pmatrix} \quad \text{(Eq.4)}$$

$$G'(x)=(1-2x)\begin{pmatrix}(b_sIR-e-C_1+S+L_1P_2)(1-P_1)\\+L_1y(1-P_1)(1-P_2)\end{pmatrix} \quad \text{(Eq.5)}$$

In the same way, the replicated dynamic equation of local government department is showed in *Equations 6* and *7:*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1442514434

$$G(y)=\frac{dy}{dt}=y(\theta_{21}-\bar{\theta}_2)=y(1-y)\begin{pmatrix}(-C_2-K+L_1P_1)(1-P_2)\\+L_1x(1-P_2)(1-P_1)\end{pmatrix} \quad \text{(Eq.6)}$$

$$G'(y)=(1-2y)\begin{pmatrix}(-C_2-K+L_1P_1)(1-P_2)\\+L_1x(1-P_2)(1-P_1)\end{pmatrix} \quad \text{(Eq.7)}$$

Make $G(x)=0$, $G(y)=0$, and obtain the five local equilibrium points in this evolutionary game system is $A(0,0)$, $B(1,0)$, $C(0,1)$, $D(1,1)$. When $0\le x^*\le 1$ and $0\le y^*\le 1$, the $E(x^*,y^*)$ is also the local equilibrium point in this evolutionary game system. In *Equations 8* and *9:*

$$x^*=\frac{C_2+K-L_1P_1}{L_1(1-P_1)} \quad \text{(Eq.8)}$$

$$y^*=-\frac{b_sIR-e-C_1+S+L_1P_2}{L_1(1-P_2)} \quad \text{(Eq.9)}$$

The Jacobian matrix corresponded to *Equations 4* and *6* is shown in *Equation 10:*

$$J=\begin{bmatrix}\frac{\partial G(x)}{\partial x} & \frac{\partial G(x)}{\partial y}\\ \frac{\partial G(y)}{\partial x} & \frac{\partial G(y)}{\partial y}\end{bmatrix}=\begin{bmatrix}(1-2x)\begin{pmatrix}(b_sIR-e-C_1+S+L_1P_2)(1-P_1)\\+L_1y(1-P_1)(1-P_2)\end{pmatrix} & x(1-x)L_1(1-P_1)\\ y(1-y)L_1(1-P_2) & (1-2y)\begin{pmatrix}(-C_2-K+L_1P_1)(1-P_2)\\+L_1x(1-P_2)(1-P_1)\end{pmatrix}\end{bmatrix} \quad \text{(Eq.10)}$$

The determinant and trace of this Jacobian matrix can be obtained from *Equation 10,* see *Equations 11* and *12:*

$$\det.J\left(\det e\min ant.Jacobian,\det.J\right)=\frac{\partial F(x)}{\partial x}\square\frac{\partial F(y)}{\partial y}-\frac{\partial F(y)}{\partial x}\square\frac{\partial F(x)}{\partial y} \quad \text{(Eq.11)}$$

$$trJ\left(trace\,Jacobian,trJ\right)=\frac{\partial F(x)}{\partial x}+\frac{\partial F(y)}{\partial y} \quad \text{(Eq.12)}$$

If $\det.J>0$ and $trJ<0$ are satisfied, then the equilibrium point of the replicated dynamic equation is evolutionary stable strategy.

Results

Make $\pi_1=(b_sIR-e-c_1+S+L_1)(1-P_1)$ as the net income of social capital side who implement the ecological protection measures under the ecological compensation of government departments, $\pi_2=(b_sIR-e-c_1+S+L_1P_2)(1-P_1)$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1442514434

as net income of social capital side who implement the ecological protection measures under the non- ecological compensation of government departments, $\pi_3 = (-c_2 - K + L_1)(1 - P_2)$ as the net income of government departments who perform ecological compensation when social capital side implement the ecological protection measures, and $\pi_4 = (-c_2 - K + L_1 P_1)(1 - P_2)$ as the net income of government departments who perform ecological compensation when social capital side fails to implement the ecological protection measures. From the formulas, $\pi_1 > \pi_2$ and $\pi_3 > \pi_4$.

The local equilibrium point stability of the Jacobian matrix of the system in Case (1) ($\pi_1 < 0$, $\pi_3 < 0$) were analyzed as shown in *Table 2*. Similarly, the evolutionary stable strategy of the system with different parameter value ranges, as shown in *Table 3*.

Table 2. *Analysis of equilibrium point stability in case (1)*

Equilibrium point	det. J	trJ	$\pi_1 < 0, \pi_4 < 0$		
			det. J	trJ	**Stability**
$A(0,0)$	$\pi_2 \cdot \pi_4$	$\pi_2 + \pi_4$	+	-	ESS (evolutionary stable strategy, ESS)
$B(1,0)$	$-\pi_2 \cdot \pi_3$	$-\pi_2 + \pi_3$	-	±	Saddle point
$C(0,1)$	$-\pi_1 \cdot \pi_4$	$\pi_1 - \pi_4$	-	±	Saddle point
$D(1,1)$	$\pi_1 \cdot \pi_3$	$-\pi_1 - \pi_3$	+	+	Instability

Table 3. *Analysis of equilibrium point stability with different parameter values*

	Parameter value range		**Evolutionary stability strategy**
(1)	$\pi_1 < 0, \pi_3 < 0$	$A(0,0)$	{no protection, no compensation}
(2)	$\pi_1 < 0, \pi_3 > 0, \pi_4 < 0$	$A(0,0)$	{no protection, no compensation}
(3)	$\pi_1 < 0, \pi_3 > 0, \pi_4 > 0$	$C(0,1)$	{no protection, compensation }

(9)	$\pi_1 > 0, \pi_2 < 0, \pi_3 > 0, \pi_4 < 0$	$D(1,1)$	{protection, compensation}

Discussion

Analysis of the system stability strategy

In line with comparison and analysis of the data in *Table 3:*

(1) It can be concluded from Cases (1), (2) and (4) that only when $\pi_2 < 0$ and $\pi_4 < 0$, namely $b_s IR - c_1 + L_1 P_2 < e - S$ and $c_2 > L_1 P_1 - K$, the point $A(0,0)$ refers to the evolution stable strategy of the system, namely non- ecological protection by social capital side and non-ecological compensation by government departments. And the rest of the points are in a temporarily stable state, which means that once affected by factors, they will deviate from this state.

(2) It can be concluded from Cases (3) that only when $\pi_1 < 0$ and $\pi_4 > 0$, namely $b_s IR - c_1 + L_1 < e - S$ and $c_2 < L_1 P_1 - K$, ESS is $C(0,1)$, referring to non-ecological

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1442514434

protection by social capital side and ecological compensation by government departments.

(3) From Cases (5), it can be concluded that only when $\pi_2 > 0$ and $\pi_3 < 0$, namely $b_s IR - c_1 + L_1 P_2 > e - S$ and $c_2 > L_1 - K$, ESS is $B(1,0)$, indicating ecological protection by social capital side and non-ecological compensation by government departments.

(4) From Cases (6), (7), (8) and (9), it can be told that only when $\pi_1 > 0$ and $\pi_3 > 0$, namely $b_s IR - c_1 + L_1 > e - S$ and $c_2 < L_1 - K$, ESS is $D(1,1)$, referring to ecological protection by social capital side and ecological compensation by government departments.

Analysis of the system evolutionary trend

In line with the stability theorem of the differential equation and the nature of the evolutionary stable strategy, the value of y under $G'(x) < 0$ and the value of x under $G'(y) < 0$ can constitute the evolutionary stable strategy. Therefore, if $G(x) = 0$, $x_1 = 0$ and $x_2 = 1$ are the two stable state points of the dynamic equation of the social capital side. When $y = y^*$, $G(x) \equiv 0$, indicating all x refer to the stable state of the social capital side. When $y > y^*$, $G'(x) < 0$ shall be met. As $G'(1) < 0$, $x_2 = 1$ is the evolution stable strategy, when government departments choose "ecological compensation" strategy with the $y > y^*$ level, the social capital side tends to choose the strategy of ecological protection. When $y < y^*$, $G'(x) < 0$ shall be met. As $G'(0) < 0$, $x_1 = 0$ is the evolution stable strategy, when government departments choose "ecological compensation" strategy with the $y < y^*$ level, the social capital side tends to not choose the strategy of ecological protection.

If $G(y) = 0$, $y_1 = 0$ and $y_2 = 1$ are the two stable state points of the dynamic equation of government departments. When $x = x^*$, $G(y) \equiv 0$, indicating all y are in the stable state. When $x > x^*$, $G'(y) < 0$ shall be met. As $G'(1) < 0$, $y_2 = 1$ is the evolution stable strategy, when the social capital side choose "ecological protection" strategy at the $x > x^*$ level, the government departments tends to choose the strategy of ecological compensation. When $x < x^*$, $G'(x) < 0$ shall be met. As $G'(0) < 0$,$y_1 = 0$ is the evolution stable strategy, when the social capital side choose "ecological protection" strategy with the $x < x^*$ level, the government departments tends not to choose the strategy of ecological compensation.

Based on the above analysis, the evolution trends of the system under different parameter values are as shown in *Figure 1* (value ranges).

The strategic choice of the social capital side

Define $b_s IR - c_1 + L_1$ and $b_s IR - c_1 + L_1 P_2$ as the project investment profits of the social capital side under the ecological compensation and non- ecological compensation strategy of government departments, with $b_s IR - c_1 + L_1 > b_s IR - c_1 + L_1 P_2$. $e - S$ are defined as the speculative profits of the social capital side. For the social capital side, when $y^* > 1$ (the value range in cases (1) (2) (3)), $b_s IR - c_1 + L_1 < e - S$. The trend of evolution is that as long as the project investment profit is less than the speculative profit under the ecological compensation by the government, no matter what kind of strategy the government department adopts, the social capital side will tend to adopt the non- ecological protection strategy. When $y^* < 0$ (the value range in cases (5) (6) (7)), $b_s IR - c_1 + L_1 P_2 > e - S$. And the evolution trend is that as long as the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1442514434

investment profit of the project is greater than the speculative profit under the non-ecological compensation of the government, the social capital side will tend to adopt the strategy of ecological protection regardless of the strategy adopted by the government. When $0 < y^* < 1$ (the value range in cases (4) (8) (9)), $b_s IR - c_1 + L_1 P_2 < e - S < b_s IR - c_1 + L_1$, and the strategy choice of the social capital side is related to the selection of government departments. When the proportion of government departments adopting the strategy of " ecological compensation" is large enough ($y > y^*$), the social capital side will eventually choose to implement the ecological protection strategy after evolution. However, if the government at this time fails to strengthen compensation ($y < y^*$), then the social capital side will be more likely to choose not to implement the ecological protection strategy.

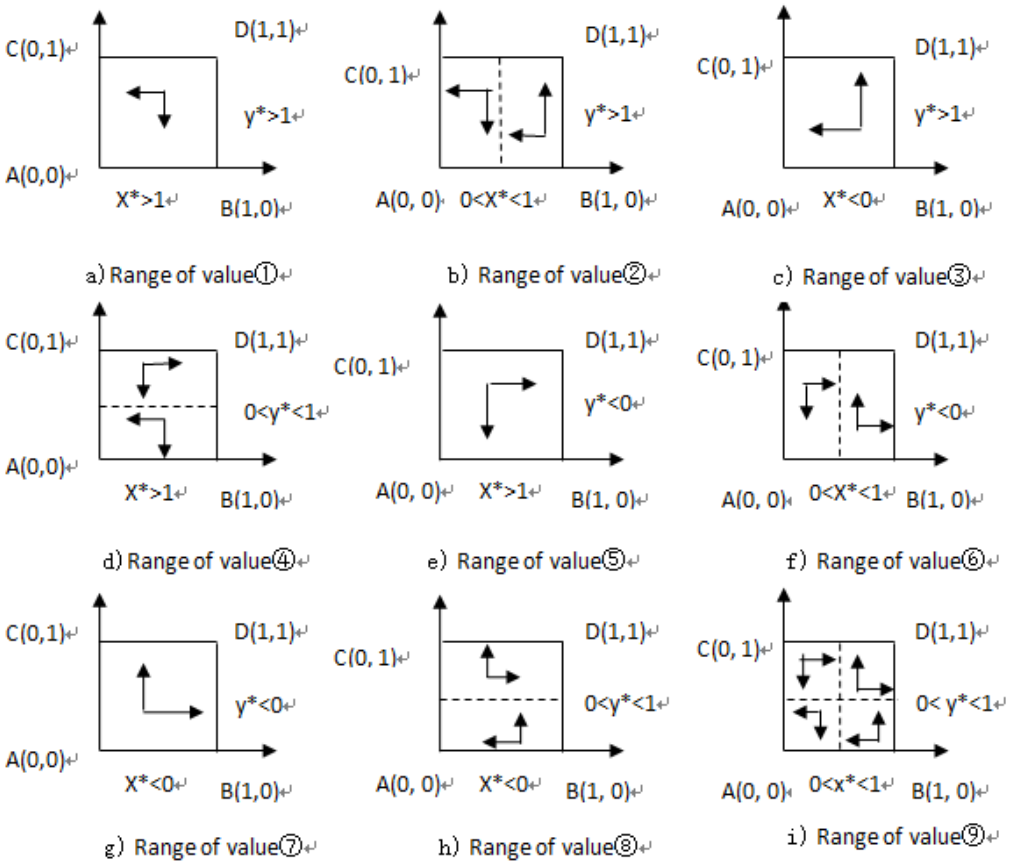

Figure 1. *Game evolution phase diagram of ecological compensation*

The strategic choice of government departments

Define $L_1 - K$ and $L_1 P_1 - K$ as the ecological benefits of government departments under the ecological protection and non-ecological protection strategy of the social capital side. For the government, when $x^* > 1$ (the value range in cases (1) (4) (5)), $c_2 > L_1 - K$. In this case, the evolution trend is that as long as the supervision cost is greater than the ecological benefits, the government department will tend to adopt the non-ecological compensation strategy regardless of the strategy adopted by the social capital side. When $x^* < 0$ (the value range in cases (3) (7) (8)), $c_2 < L_1 P_1 - K$, and the evolution trend is that as long as the supervision cost is less than the ecological benefits,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1442514434

the government departments will tend to adopt the ecological compensation strategy regardless of the strategy adopted by the social capital side. When $0 < x^* < 1$ (the value range in cases (2) (6) (9), $L_1P_1 - K < c_2 < L_1 - K$, and the government departments' strategy choice is related to the selection of the social capital side. As long as the social capital party increases the proportion of the strategy of "ecological protection"($x > x^*$), the government department will eventually choose ecological compensation strategy after evolution. However, if the ratio is lowered in this case ($x < x^*$), government departments are more likely to choose non-ecological compensation strategy.

The evolutionary game characteristics of ecological compensation in state-owned forest areas

The evolutionary game analysis of ecological compensation in state-owned forest areas is different from that in other fields. This paper is based on the Public-Private Partnership model. The role of the government is no longer a supervisor, but a cooperator. In the process of setting model parameters, three characteristics of Public-Private Partnership model should be embodied: partnership, benefit sharing and risk sharing. Therefore, in the process of the economic transformation of state-owned forest areas, the government departments and the social capital side can actively use the results of this study to achieve the consistency of project objectives. At the same time, the model construction in this paper is a theoretical analysis under a series of basic assumptions, but the reality is more complex. For example, the dishonest behavior of the government, the high financing cost of the social capital, and the complexity of the transaction structure, and so on. All of these have a certain impact on the strategic choice of the government departments and the social capital side on ecological protection.

Conclusions

(1) In this paper, evolutionary game tools were used to study the decision-making of ecological compensation strategies by government departments and the social capital side in the process of economic transformation of Lutou forest farm. The motivation and interaction between the two sides are emphasized. The government's guidance and support and the leading and coordinating role of the social capital side are used to protect the ecological environment, improve economic, social and ecological benefits, and realize the sustainable development of forestry.

(2) The income matrix of different selection of ecological compensation strategies by government departments and the social capital side was established through introducing social capital's ecological protection strength and cost, government's ecological compensation strength and supervision cost, opportunity benefit, penalty quota, ecological subsidy and profit distribution ratio.

(3) In order to achieve the coordinated development of ecological construction and economic transformation, the ecological protection by social capital and the ecological compensation by government departments were the best strategies. Only when the investment profit of the project was greater than the speculative profit under the non-ecological compensation of the government departments and the supervision cost of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1442514434

government departments is less its ecological profit, the optimal strategy could be achieved in the game evolution.

(4) Through the analysis of the evolvement trend of government departments and social capital side, we could draw that: reducing the ratio threshold y^* of ecological compensation by government departments, it is conducive for the social capital side to select the ecological protection strategy; reducing the ratio threshold x^* of ecological protection strategy by the social capital side, it is conducive for government departments to select the ecological compensation strategy.

(5) In order to make the ecological compensation strategies of government departments and the social capital side evolve smoothly to a satisfactory state, we should clarify the dominant position of the government, actively promote the ecological compensation systems and reward and punishment restraint mechanisms, Give full play to the key role of the social capital side, coordinate their interests distribution and conflict, build the reasonable mechanism of cost sharing and benefit sharing, improve their initiative to protect the ecological environment, and reduce the risk of participating in the economic transformation of the state-owned forest areas.

Abstract. In this paper, *Xylaria venosula* strains were inoculated separately into wood blocks of *Alnus nepalensis*, *Betula alnoides*, *Aquilaria sinensis* and *Pinus kesiya*, and induced artificially to create spalted woods with zone lines. The results showed that: (1) *Aquilaria sinensis* could easily form black zone lines, where the mycelia were denser than elsewhere. (2) The zone lines on and within *Aquilaria sinensis* were the most obvious when the wood blocks contained 50% water. In this case, zone lines were rich and beautiful and the wood was not severely rotten. (3) The largest spalt was observed on *Aquilaria sinensis* blocks. This type of wood underwent the most serious spalting, with 6.64% of its surface and 1.84% of its interior covered by spalts. As the wood blocks rotted over time, the weight loss rates of spalted woods were on the rise, while the compressive strengths parallel to grain were gradually falling. The unitary linear regression shows significant correlation between the mass loss ratio and the compressive strength parallel to grain. It can be concluded that *Xylaria venosula* did not destroy the cell walls within the woods, and had little effect on the strength of the woods.
Keywords: *Xylaria venosula strains, water content, weight loss rate, compressive strength, regression analysis*

Introduction

Spalting is a manifestation of fungi causing discoloration of wood. The wood after discoloration is called Spalted wood. The spalting generally manifests in four types: white rot, stains, zone lines, and brown rots, and actually the first three have practical values. It mainly occurs on the felled wood, and also on the standing timbers under harsh environmental conditions. Generally, one or more of the above three types can be formed on the same piece of wood. Currently, spalted wood with rich zone lines are the most valuable in the foreign market. *Xylaria venosula*, making the wood coloring to form the mottling pattern, is onekindoffungususedtoformthe line-patterned varietal wood, which can form a unique decorative effect and a certain medicinal value.

The fungi that can form spalted pattern are mainly basidiomycetes and a few ascomycetes, and the polymorpha charcoal which can form the striatum line alone is often used in the laboratory to study the planting of *Aquilaria sinensis*. According to previous studies and speculations, Robinson et al. of the College of Forestry, University of Toronto, Canada, believe that the zone lines are the spalts formed as a defensive mechanism against the obstacle between the strains (Robinson et al., 2009); in their experiment, 25 species of fungi were isolated from the wood, and then incubated on an agar medium in pairs; where they produced a distinct pigment on the agar medium

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1443514454

between the two fungi and the line of resistance between the two strains, the two fungi that formed zone lines on the medium were inoculated separately at both ends of the sugar maple block, for a total of 21 pairs of fungi combinations, two of which produced stable zone lines and white rot, that is, *Bjerkandera adusta/Trametes versicolor* and *Polyporusbrumalis/Trametes Versicolor*, while the fungi of the remaining 22 woody plants did not form stable spalts. In addition, Robinson et al. believe that the zone lines can be formed on any wood species. The broadleaf woods are whiter in colour, and the trees with low content of extracts are more likely to form spalting, such as *Acer* spp., *Betula* spp. and *Fagus* spp. (Xu et al., 2013). Robinson and Turnquist studied the *Xylari polymorpha*, which can form zone lines independently by inoculating it on *Populus tremuloides*, *Acer saccharum*, *Betulaalleghaniensis* and *Tilia Americana*; with the time extension on the medium, it is observed through the amount of spalts that *Populus tremuloide*s and *Acer saccharum* produced more zone lines than the other two (Robinson et al., 2009).

Based on the concept of the spalted wood, this paper probes into the artificial preparation of spalted wood using the *Xylaria venosula* strain to infect the wood block, and then studies the related ways and characteristics of the strain infection. By inoculating *Xylaria venosula* strain on different kinds of woods, it focuses on comparing the similarities and differences of the formed zone lines, the influence of water content, wood property, weight loss, and spalting formation etc. Besides, it studies the formation and mechanism of the zone lines in spalted woods. Thus, the random variation of the surface lines on the spalted wood can help to produce the green, low-carbon, environmentally-friendly and beautifully crafted products and attaching veneers, and improve the comprehensive utilization and added value of the wood. This is of high economic value and social significance, and also lays a theoretical foundation for the stably and continuously acquiring the spalted wood.

Materials and methods

Experimental materials

Main material:

(1) The *Xylaria venosula* strain: purchased from the China Forestry Culture Collection Centre, and prepared by the screening test of fungal strains in the same genus or the same species, as shown in *Figure 1*.

(2) Wood specimens: they were collected from variety of trees such as *Alnus nepalensis*, *Betula alnoides*, *Aquilaria sinensis*, and *Pinus kesiya* on April 9 and 29, 2017 in Jindian Park, Kunming City, Yunnan Province, China, and nearby forests.

(3) Filtered water: It is filtered by YJD laboratory water purifier (Yongjieda Purification Technology Co., Ltd., Hangzhou, China) filter.

Cultivating the fungus of spalted wood

First, the liquid potato-Dextrose-agar (PDA) culture medium was placed into a 250 ml triangle flask or culture bottle, for about 100 ml per bottle, then autoclaved and sterilized for 30 min under high pressure. Afterwards, the *Xylaria venosula* was inoculated into the bottle, and cultured for 7-12 days using the thermostat oscillator SHA-B (A) (Chengdu Yike Instrument Equipment Co., Ltd., Sichuan, China), to obtain

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1443514454

the bacterial suspension with a large number of agglomerated mycelia inside (Fournier et al., 2011; Osono et al., 2011; Zink and Fengel, 1988).

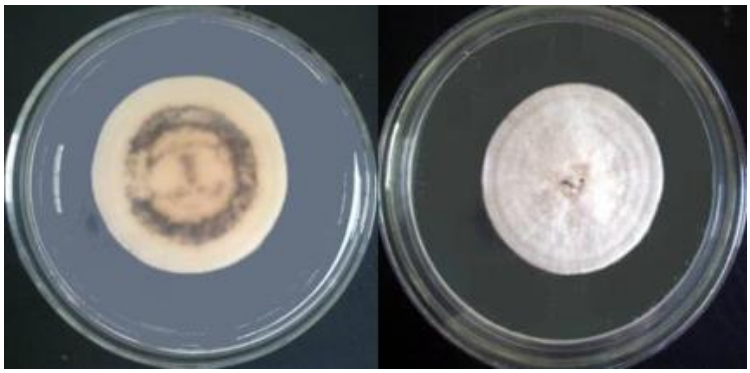

Figure 1. *Morphological characteristics of the Xylaria venosula strain*

Pre-treating the inoculated wood block

From the four easily spalted tree species of *Alnus nepalensis*, *Betula alnoides, Aquilaria sinensis*, and *Pinus kesiya*, 60 pieces of 30 mm × 20 mm × 20 mm wood blocks were taken respectively, for a total of 240, and placed into the bottle (Robinson and Laks, 2010), which was filled with appropriate amount of filtered water and then sterilized for 45 min in the YM30Z vertical autoclave (Sanshen Medical Instrument Factory, Shanghai, China), together with the cultural medium and the medium vermiculite.

Inoculation of wood blocks

First, cut the plate PDA strain into 10 mm × 20 mm pieces, clip it with the tweezers and stick it on the wooden block, put it into the culture bottle and cover it with vermiculite, and add 10-25 ml of filtered water to wet the vermiculite and the wood block before fastening the cap. Then, for liquid inoculation, use the tweezers to clamp the wood block and cover the bacteria solution, cover it with vermiculite, add 10-25 ml of water to wet the vermiculite and wood block. Next, the inoculated wood blocks were placed in a constant temperature and humidity chamber (produced by Blue Sky Laboratory Instrument Factory, Hangzhou, China) at 27 °C under dark conditions (Robinson and Laks, 2010), cultivating for about 80 days. Finally, take out the wooden block, scrape off its surface mycelium, wash and dry it, and observe whether there has formed a clear zone line inside and outside the block.

Observing the characteristics of the spalted wood with zone lines

The 10 mm × 10 mm × 10 mm blocks with rotten zones were taken from the four wood species of *Alnus nepalensis*, *Betula alnoides*, *Aquilaria sinensis*, and Pinus kesiya. They were sliced with German Leica 2000R slicer (Leica Microsystems Nussloch GmbH, NuBloch, Germany), and stained by double staining to better observe mycelia (Pearce, 1984), then observed and recorded using an Eclipse 80i microscope. Besides, electron microscopy (HC300X type Shengtian Instrument Co., Ltd., Shenzhen, China) was used to observe the morphology and distribution of mycelia inside and outside the rotten area.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1443514454

Analysis of wood microstructure

From the four kinds of woods, namely, *Alnus nepalensis, Betula alnoides, Aquilaria sinensis, and Pinus kesiya*, 5 mm × 5 mm × 5 mm cubes were made, ensuring that the transverse section, radial section, and tangential section can be found on each wood block as much as possible. In our experiment, the wood block was softened first at a certain extent with hot water, then cut evenly at each face with a sharp blade without leaving any scratches, and finally undergo air drying at room temperature. Since the dried wood is basically non-conductive, in order to clearly observe the ultrastructure of the wood cell wall and the rotting degree of the strain *Xylaria venosula* in the wood tissue, it is necessary to metallize the surface of the wood block (Passarini et al., 2013). For the gold-coated wood blocks, the SEM-EDXA scanning electron microscopy (FEI Company, Eindhoven, the Netherlands) was adopted to observe the extent of damage to the wood cell wall by the activity of mycelium in the rotten area (Læssøe et al., 2013; Robinson et al., 2011).

Experimental steps of wood water content

The four types of wood blocks mentioned above were made into 2 cm × 2 cm × 2 cm squares with CS70EB precision woodworking table saw (FESTOOL, Germany). They were dried in a blast drying oven at 60 °C ± 5 °C, and then weighed. The vermiculite was dried to absolute dryness at 60 °C ± 5 °C. Through preliminary experiments, the relationship between the amount of water added and the water content of the wood block was obtained. Then, one specimen from each tree species, 10 g vermiculite, and unequal amount of filtered water were added to each culture bottle respectively. 5 pieces of blocks were prepared repeatedly for each gradient, sterilized in autoclave, and cooled for 6-8 h and weighed again. Then, the blocks containing the 10%, 30%, 50%, 70%, 90% of water were prepared. The water content calculation formula is shown as (Tian et al., 2013):

$$M_c = [(m_1 - m_2)/m_2]\ 100\% \quad \text{(Eq.1)}$$

M_c-water content; m_1-mass at the end of the test (g); m_2-mass (g) at the start of the test.

Determining the average mass loss percentage

Before inoculation, all the blocks were placed in a blast drying oven at 60 °C for 48-60 h until reaching constant weight, and the mass m_2 was weighed; after they're autoclaved at high temperature, inoculated and placed in a constant temperature and humidity chamber, infected by fungi for 4, 6, 8, 10, and 12 weeks, the blocks were taken out and the surface mycelium were scraped off, and then dried in a blast drying oven at 60 °C to a constant weight (Passarini et al., 2013; Læssøe et al., 2013), thus the mass m_3 was weighed. Then, the average mass loss rate of the rotted wood block was calculated as (Robinson et al., 2007):

$$L = [(m_3 - m_2)/m_3]\ 100\% \quad \text{(Eq.2)}$$

L-mass loss rate; m_2-mass at the start of the test (g); m_3-mass (g) at the end of the test.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1443514454

Determining compressive strength

The blocks with the mass loss rate measured and the untreated healthy wood were dried in a blast drying oven at a temperature of 103 °C for more than 48 h until constant weight in an absolute dry state. The RGT-20A versatile experimental machine (REGER Instrument Co., Ltd., Shenzhen, China) was used to determine the compressive strength of the blocks. The experimental results are the average of 5 specimens according to the experimental standard ISO 3787-1976 *Wood-Test Method-Determination of Ultimate Stress in Compression Parallel to Grain* (Liers et al., 2006).

Unitary linear recursive analysis

Unitary linear recursive analysis was conducted about the weight loss rate and compressive strength of the four tree species using SPSS18.0 software. The Pearson correlation coefficient between the two variables is less than 1, indicating a highly linear correlation between the two.

Results and discussion

Morphology and distribution of mycelium in wood

From the successfully cultivated spalted woods with black zone lines in the four species of trees, four samples were selected, as shown in *Figure 2.*

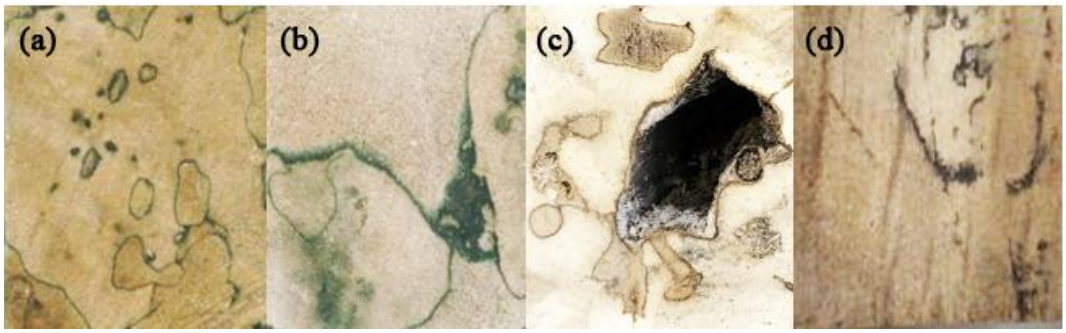

Figure 2. *Visual characteristics of the artificially formed spalted woods' macrostructure. (a) Alnus nepalensis, (b) Betula alnoides, (c) Aquilaria sinensis, (d) Pinus kesiya*

Figure 2 shows the micrograms of the spalted woods artificially cultivated from the four species of trees. The linear parts in dark colour were spalts. When the *Xylaria venosula* strain infected the woods, a large amount of melanin was excreted in their respective areas of the woods for mutual defences, producing black short lines, small spots, and irregular strips and forming bands, thereby forming the zone lines. Due to the extremely fineness of mycelium, it is easily damaged during slicing and cleaning, but the zone lines formed are still obvious. Therefore, if properly controlled, the sap stain fungi could be used to secrete the pigment, and colour the surrounding wood tissue. Thus, a beautiful natural pattern can be formed.

The micro-structure of artificially cultivated spalted wood was observed by light microscopy. 6 pictures in transverse section, radial section and tangential section were selected for research analysis, as shown in *Figure 3.*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1443514454

Figure 3 shows the morphology and distribution of mycelium in wood block under light microscope: a represents an area of distinct black zone lines in the radial section of *Alnus nepalensis* under 10-fold light microscope, and the area around the line was shallow in wood colour, significantly different from the area outside; one obvious feature was that the black zone lines extends outward at the wood ray. b represents the black zone lines in the radial section of *Alnus nepalensis* under the 40-fold light microscope, which was formed by the melanin secreted by the fungus in each wood tissue; the arrow refers to the mycelium filled in the duct within the zone line area, and the area outside the zone lines on the right has no difference from the normal wood, only with a small amount of mycelium distributed near the black zone line area. c indicates the V-shaped black zone lines in the tangential section of *Alnus nepalensis* under the 4-fold light microscope, and the V-shaped inner area was light yellow, and the wood colour outside the V-shaped area was normal. d represents the mycelial distribution at the black zone lines in the tangential section of *Alnus nepalensis* under the 40-fold light microscope, which clearly indicates that the mycelia were mainly distributed in ray parenchyma cells, axial parenchyma, and wood fibre connected with parenchyma cells, and the black zone lines were the macroscopic performance of the mycelia that are entangled into a group. However, in the wood fibre cells closely spaced from the mycelium (the area between the two arrows in the figure), there was very little mycelium distribution, which is more common in white rot fungi (Robinson et al., 2011; Tudor et al., 2012, 2013). This may be because there are fewer nutrients in the fibre cells, and the parenchyma cells are the tissues that transport nutrients in the wood, containing more starch, polysaccharides and oils; the fungus will not decompose the cell walls to absorb nutrients until these substances are completely decomposed. e represents the distribution of the black zone line in the transverse section of the *Betula alnoides* under the 4-fold light microscope. f represents the mycelial distribution of the black zone lines in the transverse section of the *Betula alnoides* under the 40-fold light microscope; it can be observed that there were many mycelia distributed in the fibre cells and wood ray cells, and a large amount of melanin was accumulated in the wood ray cells and cell walls.

Microstructure analysis of spalted wood

In the experiment, the black zone lines were successfully cultivated from the four species of trees. For each species, several sections were scanned and analysed.

Figure 4 shows the growth of *Xylaria venosula* in the *Alnus nepalensis*, where a represents the mycelial distribution in the duct lumen and wood fibre lumen, and b is the mycelial distribution on the pits inside the vessel element, c and d are the mycelial distribution of the vessel element and the wood ray in the tangential section of *Alnus nepalensis.*

Figure 5 shows the growth of Xylaria venosula in the wood of *Betula alnoides*, where a and b represent the mycelial distribution in the lumen of the duct and wood fibre, and c represents the mycelial distribution on the pit in the radial section, d represents the mycelial distribution of vessel element and wood ray on the tangential section of *Betula alnoides*.

Figure 6 shows the growth of *Xylaria venosula* in the wood block of *Aquilaria sinensis*, where a and b represent the mycelial distribution in the lumen of the duct and wood fibre, and c represents the mycelial distribution on the pit inside the radial section, d represents the mycelial distribution of vessel element and wood ray.

DOI: http://dx.doi.org/10.15666/aeer/1706_1443514454

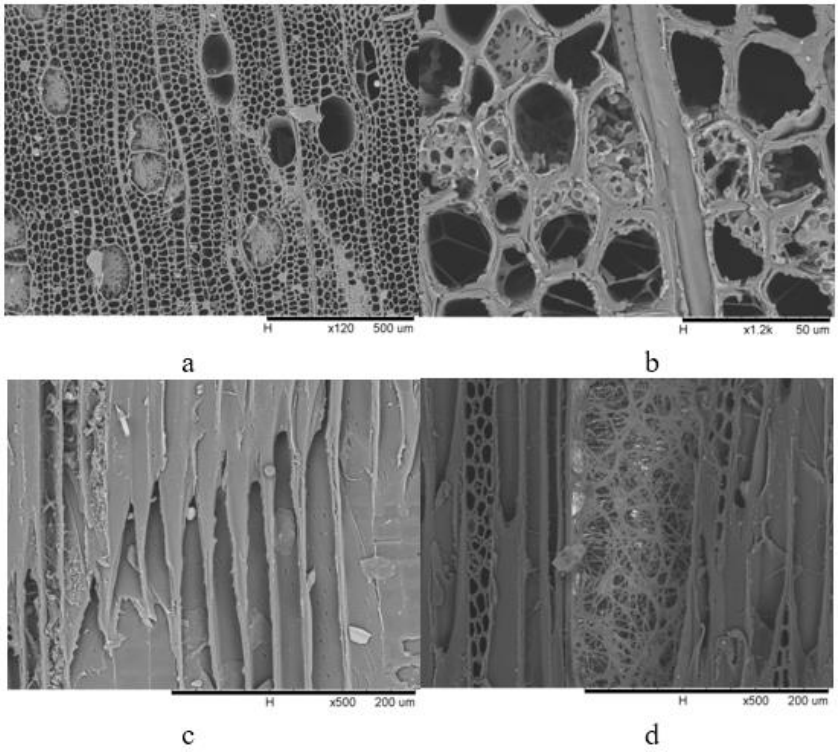

Figure 5. *Influence of Xylaria venosula on wood structure of Betula alnoides*

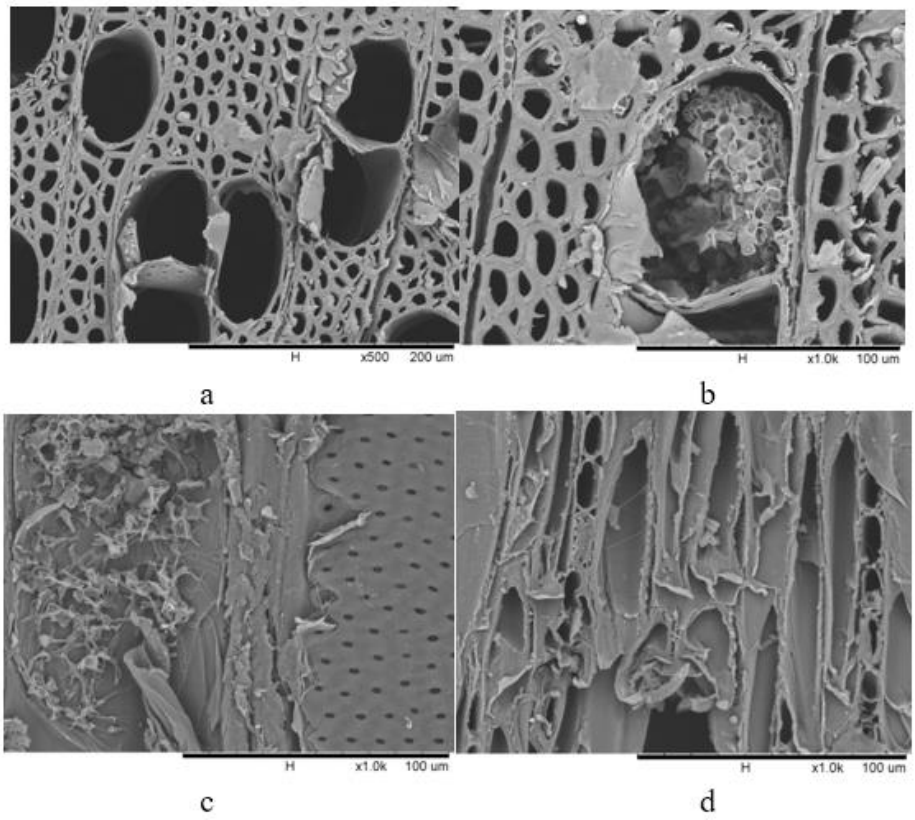

Figure 6. *Influence of Xylaria venosula on wood structure of Aquilaria sinensis*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1443514454

Figure 7 shows the growth of Xylaria venosula in the wood of *Pinus kesiya*, where a and b represent the mycelial distribution in the lumen of the duct and wood fibre, and c represents the mycelial distribution on the pit in the radial section, d represents the mycelial distribution of the vessel element and wood ray on the tangential section of *Pinus kesiya*.

Based on the results in *Figures 3–7,* no obvious rot was found in the samples, and the strain *Xylaria venosula* was grown along natural cavities such as wood ducts, wood fibres, and parenchyma cells, even crossing between adjacent cells with the pits as the passages. A large amount of mycelial distribution was seen in the lumen of the duct, but no signs of disrupting the cell wall. Xylaria venosula is a white rot fungus. It is an initial rot from the mycelial distribution and morphology, and has little effect on the strength of wood.

The mycelia were mainly concentrated in the duct, parenchyma cells and the fibre cells connected to the parenchyma cells. Some of the fibre cells were close to the mycelia but have few mycelia, mainly due to a small number of nutrients inside. These characteristics indicate that these fungal infestations on specimens are performed by means of minimal resistance and the fastest access to nutrients anatomically (Dai, 2012).

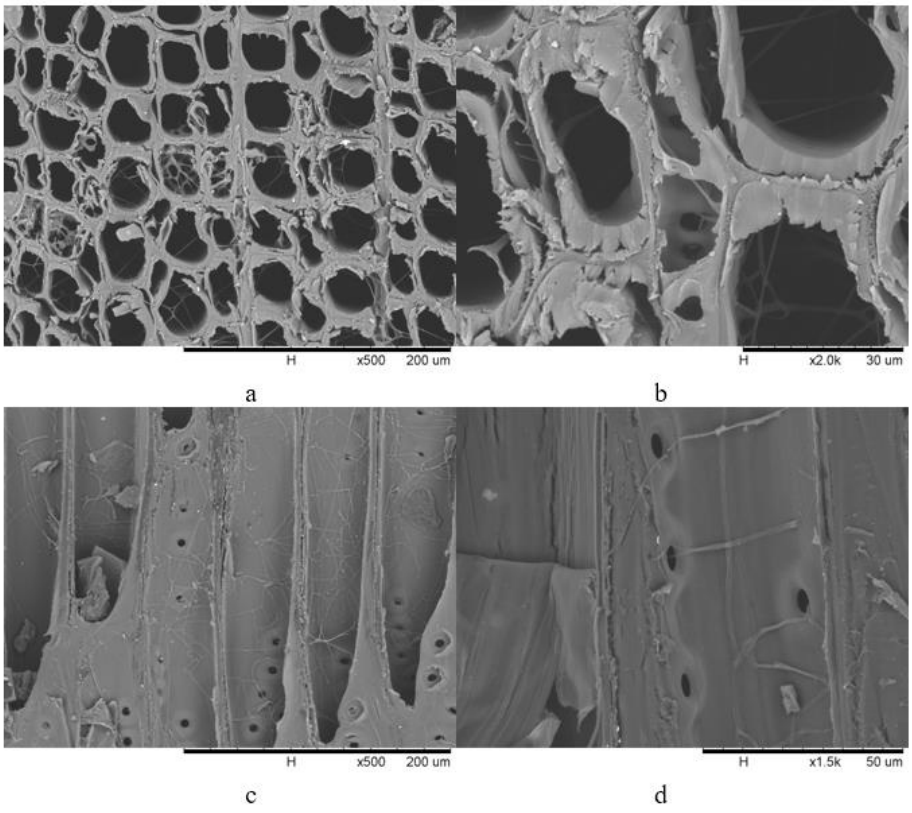

Figure 7. *Influence of Xylaria venosula on the wood structure of Pinus kesiya*

There is a certain amount of mycelium inside the zone lines, but significantly less than the centre of the zone lines; outside the zone lines the mycelium may exist or not. The zone lines appear in the same colour as the mycelium itself entangled in a group and they're formed by the secreted pigment layer in the cell cavity and cell wall. One

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1443514454

common feature is the mycelia in the rotten area were denser than outside, and the peak density appeared at the centre of decayed area. This just proves that the formation of the zone lines is closely related to the water content of wood rot fungi, especially white rot fungus. There were some closed areas at the zone lines, which could provide the most suitable humidity for the fungi in the wood incubated area, because pseudo-bacterial nucleus produced by the fungus restricts the evaporation of water on the surface of the closed region, or maybe the boundary formed by the contact of two different mycelium also plays the same role (Nagy et al., 2012; Dai et al., 2012). The melanin secreted by the fungus has certain toxicity and is resistant to attack of other microorganisms. Thus, the rotten area in the wood is a barrier that the fungus uses to resist the invasion of other microorganisms so that it can keep utilizing the resources in the enclosed area. Almost all mycelia enter the adjacent cells through the pits of the wood's natural channel, which does not cause a significant decrease in the strength of the wood so that the 8-month-old spalted wood can fully meet the requirements for the production of handicrafts.

Effect of wood water content on the formation of spalts

Statistical analysis of the percentage of the spalts in the area of wood block

Figure 8 shows the percentage of external spalts on the four types of wood blocks infected by the strain *Xylaria venosula* under different water contents. Wood water content was evaluated using *Equation 1*. The SPSS one-way analysis of variance (ANOVA) ($\alpha = 0.05$, $n = 30$) showed that their external spalts were significantly different; when the water content reached 10%, the area of spalts on the *Aquilaria sinensis* block by the strain *Xylaria venosula* was 3.72%, which was the most serious spalting; when the water content reached 50%, the spalt on the four wood blocks reached the largest, and that of *Alnus nepalensis, Betula alnoides, Aquilaria sinensis* and *Pinus kesiya* reached 6.35%, 5.81%, 6.64%, and 6.23% respectively; but with the increase in water content, the external spalt on the blocks decreased, which is consistent with Yan Huang's research results (Huang et al., 2017); when the water content reached 90%, the spalt area of *Alnus nepalensis, Betula alnoides, Aquilaria sinensis* and *Pinus kesiya* was reduced to 5.03%, 4.42%, 5.18% and 4.57%. Studies have shown that when the water content of the wood block reaches 50%, the living environment is most suitable for the growth of the strain *Xylaria venosula*, and the surface spalting is the most serious. Through comparing the four types of wood blocks, it is found that the external spalt on the *Aquilaria sinensis* wood block was the largest, and its spalting was the most serious, followed bythe *Alnus nepalensis* wood block, only 0.29% lower than that of *Aquilaria sinensis*.

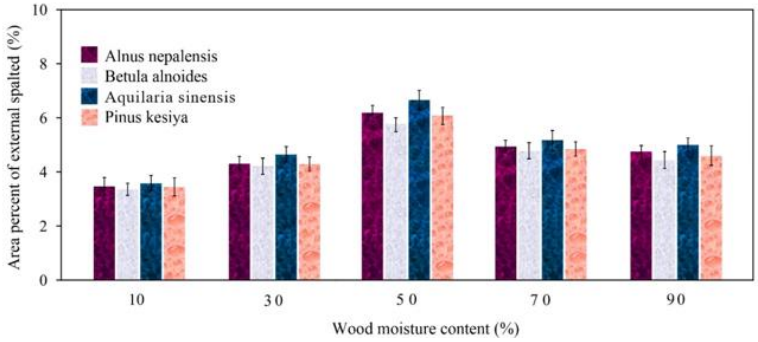

Figure 8. *Percentage of surface spalts area formed by strains under different water contents*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1443514454

Figure 9 shows the area percentage of the internal spalts in the four wood blocks formed by the strain *Xylaria venosula* under different water contents. The SPSS ANOVA ($\alpha = 0.05$, $n = 30$) indicates that the area percentage of the internal zone lines was significantly different; when the water content reached 10%, the percentage of the internal zone lines formed by the strain *Xylaria venosula* in the *Aquilaria sinensis* block was 0.4%; when the water content reached 50%, the area percentage of the internal spalts of the four blocks was the largest, the spalts percentage of *Alnus nepalensis, Betula alnoides, Aquilaria sinensis* and *Pinus kesiya* was 1.75%, 1.61%, 1.84%, and 1.67%, respectively; as the water content increases, the internal spalt area of blocks was reduced; when the water content reached 90%, the spalt area of *Alnus nepalensis, Betula alnoides, Aquilaria sinensis* and *Pinus kesiya* decreased to 1.23%, 1.09%, 1.28% and 1.17%. Studies have shown that when the water content of the wood block is 50%, this living environment is most suitable for the growth of the strain *Xylaria venosula*, and the internal zone line is the largest; among the four types of blocks, the internal spalts of *Aquilaria sinensis* are most obvious; that of the *Alnus nepalensis* block was second, 0.19 lower than *Aquilaria sinensis*.

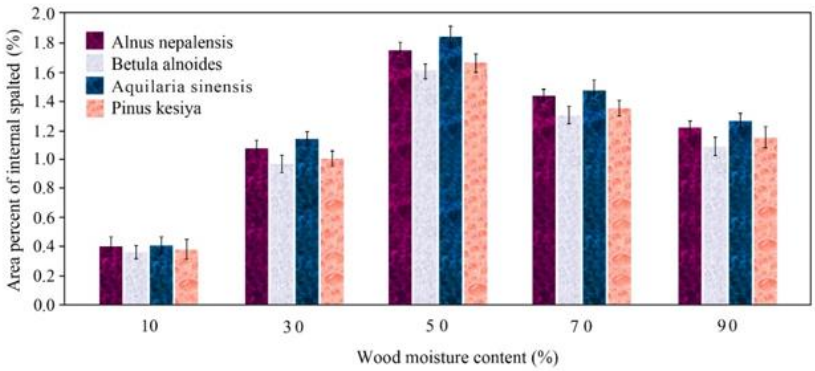

Figure 9. *Percentage of internal spalts formed by strains at different water contents*

The average mass loss percentage was evaluated using *Equation 1*. The fibre saturation point of the wood block is generally 30%. When the water content of the wood block exceeded 30%, free water molecules were present in the cell cavity for fungal growth and utilization; when it was below 30%, there were very few free water molecules in the cell cavity, which is not conducive to fungal growth; when it was too high, the free water of the cell cavity occupied the lumen of the wood cell, with an extremely low air content, which is also unfavourable for the growth of the fungus.

When the water content of the wood block was 30-50%, there was certain free water in the cell cavity, but still more air inside. The cell cavity was like a capillary tube, in which the free water keeps moving. In order to maintain the moisture required for its own growth, the fungus forms zone lines or stains to prevent the moisture movement, which is the main reason for the formation of large spalts.

Mass loss rate of wood block

Figure 10 shows the mass loss rates of the spalted woods obtained by the strain *Xylaria venosula* under different water contents of four wood specimens. It is found that the maximum value was 6.39%, the minimum value was 4.36%, and the average mass

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1443514454

loss was 5.15%, with little mass loss. The following results were obtained using the SPSS one-way analysis of variance ($\alpha = 0.05$, $n = 5$).

The strain *Xylaria venosula* has the highest mass loss rate under the water content 50% of wood blocks, and the lowest mass loss rate under the water content of 10%. The strain *Xylaria venosula* had certain differences in mass loss rate under the different water contents of the four wood specimens. The mass loss rate of the *Betula alnoides* block was the highest, reaching 6.69%, which exceeded that of *Aquilaria sinensis* block by 0.62%, while the mass loss rate of *Aquilaria sinensis* was second to it.

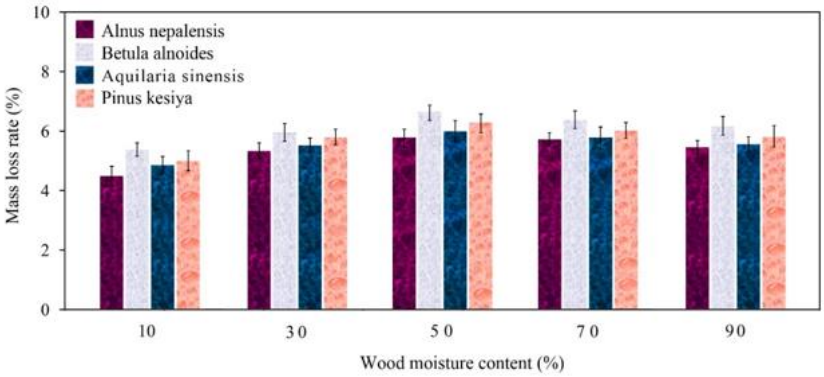

Figure 10. *Average mass loss rate of spalted wood under the condition of different water contents*

Effect of strain Xylaria venosula on the mass loss rate and the parallel-to-grain compressive strength

Result of the experimental was evaluated using *Equation 3*. *Table 1* shows the results of weight loss rate and compressive strength parallel to grain of the spalted woods varying with the rotted time through the experiment, in which these four types of wood blocks were infested with *Xylaria venosula* strain for 4, 6, 8, 10, and 12 weeks at a water content of 50%, and 12 pieces were weighed every 2 weeks, for a total of 240 pieces. It can be seen that with the increase of rotten time, the weight loss rate of the spalted wood was on the rise, and its compressive strength parallel to grain was correspondingly reduced, which is consistent with the research results of Daniela Tudor (Hladki and Romero, 2010).

Unitary linear recursive analysis was conducted about the weight loss rate and compressive strength of the four tree species using SPSS18.0 software. *Table 2* lists the correlation coefficients of *Alnus nepalensis*, in which the Pearson correlation coefficient between the two variables was -0.986, indicating a highly linear correlation between the two. *Table 3* lists the linear equation coefficients. It can be seen that the regression coefficients in the regression model are: the constant of 67.739, and the independent variable mass loss rate of -3.613. Then, the regression equation is given as:

$$y = -3.613x + 67.73 \quad \text{(Eq.3)}$$

Table 1 also indicates that the weight loss rate of the four tree species has a linear relationship with the compressive strength. Their regression equation is shown in *Figure 11*.

Dependent variable: compressive strength of *Pinus kesiya*

In summary, the unitary linear regression analysis shows that the correlation between the weight loss rate and the compressive strength parallel to grain is very significant, and both are highly negatively correlated. The weight loss rate of the specimens did not change much; with the increase of rotten time, the weight loss rate of the specimens was on the rise; while the compressive strength parallel to grain of the spalted woods was gradually reduced. The strain *Xylaria venosula* does not destroy the internal cell wall of the spalted wood, and has little effect on the strength of the wood, since it is an initial decay in terms of the mycelial distribution and morphology.

Conclusions

Spalting is the coloration of wood caused by fungal colonization with beautiful patterns, it can be made into green, low-carbon, environmentally friendly and nice decorative crafts and wood veneer products, so as to enhance the rate of multipurpose utilization and additional value, it is provided with a very high economic value.

This paper aims to carry out a preliminary study and discussion on the spalted woods with zone lines induced artificially by fungi and the related mechanism. For this purpose, the strain *Xylaria venosula* was selected and inoculated into the wood blocks for preparing the spalted wood. Then, using the light and electron microscopy, it analyses the microfeatures of the spalted wood, and conducts experiments on the measurement of compressive strength and the influence of wood water content on the spalt formation. Finally, the following conclusions were drawn:

(1) The microfeatures of the spalted woods were analysed by light and electron microscopy, revealing that *Aquilaria sinensis* could easily form black zone lines, which are mainly distributed in ducts, parenchyma cells and fibroblasts connected with

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1443514454

parenchyma cells, indicating that these fungal infestations on specimens are performed by means of minimal resistance and the fastest access to nutrients anatomically; the mycelia inside the zone lines were denser than outside, and the peak density appeared at the centre of each zone line; the black zone lines in the wood is a barrier that the fungus uses to resist the invasion of other microorganisms, so that the resources in the enclosed area can be utilized continuously.

(2) Analysis for the effect of wood water content on the spalts formed by *Xylaria venosula* showed that when the water content of the wood was 50%, the amount of external and internal spalts formed was the most and the most obvious, and the surface spalts formed on the four wooden blocks reached the maximum; The largest spalt was observed on *Aquilaria sinensis* blocks; this type of wood underwent the most serious spalting, with 6.64% of its surface and 1.84% of its interior covered by spalts. In this case, zone lines were rich and beautiful and the wood was not severely rotten. Thus, this wood and the water content offer the most suitable conditions for the growth of *Xylaria venosula* strains.

(3) The measured results of mean mass loss percentage and compressive strength show that as the wood blocks rotted over time, the weight loss rates of spalted woods were on the rise, while the compressive strengths parallel to grain were gradually falling. When the water content was 10%, the mass loss rate of the specimen was the smallest; when it was 50%, the mass loss rate of *Aquilaria sinen*sis was large, reaching 6.07%, but lower than Alnus nepalensis.

(4) The compressive strength measurement showed that the weight loss rate of *Alnus nepalensis* was increased with rotten time, and the compressive strength of the spalted wood was correspondingly reduced. A linear regression analysis was conducted about the weight loss rate and the compressive strength parallel to grain of the artificially prepared spalted wood, to find that the correlation between the two was very significant and also highly negatively correlated. Also, there was no sign of destroying the cell wall inside the spalted wood formed by the strain *Xylaria venosula*. In terms of distribution and morphology, the mycelium was an initial decay and had little effect on the strength of the wood.

To sum up, the spalted wood cultivated by artificially inoculated *Xylaria venosula* has good stability, natural and beautiful pattern, and low corrosiveness. It has no big effect on mass loss rate and the compressive strength of wood blocks. Therefore, it has a good prospect for the use of the strain *Xylaria venosula* to prepare the spalted wood has a good prospect which is suitable for application and promotion.

These contents will become the next study. First, directional generation of zone lines. Then, the generation time of zone lines will shorted.

Abstract. Considering the irreversible impacts of urban master plan on the eco-environment, the specific impacts must be evaluated in a comprehensive manner before preparing the plan. As a result, this paper studies the impacts of urban planning on eco-environment, sets up an assessment system for it based on the pressure-state-response (PSR) model, and applies the system to assess the eco-environment before and after the implementation of an urban master plan. The evaluation results show that the medium to long-term urban master plan promoted the eco-environment of the city. The research results shed new light on the eco-environmental impact assessment of urban master plans.
Keywords: *urban planning, eco-environmental impact assessment, pressure-state-response (PSR) model, analytic hierarchy process (AHP), eco-environmental pressure*

Introduction

In recent years, following the rapid development of China's urban economic level, the urbanization process has continued to advance (Wang et al., 2008). The extensive economic development model with high resource consumption brings not only the rapid urban development, but also "urban diseases" such as resource wasting, population expansion, and environmental damage (Crainic et al., 2009). All these affect the city's sustainable development, which will inevitably lead to irreversible problems for the city if not valued (Mancini et al., 2010; Liu et al., 2011). Therefore, it is necessary to design a master plan of urban land use and resource allocation for the healthy, orderly and harmonious development of the city.

Eco-environmental impact assessment was first proposed by American scholars in 1969, accompanied by an increasing environmental problem (Elena et al., 2008). After 40 years of development, it has been further verified that an urban master plan must consider its impact on the eco-environment under the condition of not destroying and improving the eco-environment (Pang et al., 2015). Only the environmentally friendly urban planning can ensure the sustainable development of the city, provide long-term benefits for environmental protection and the city, and further promote the decision-making system for environmental protection (Seenivasaperumal et al., 2010). For this, a study on comprehensive impact assessment of urban planning on eco-environment should be conducted, which not only helps the public to obtain effective information about the environmental impact of urban planning, but also enables government departments to realize the top-priority environmental indicators needed in plan implementation (Fitzpatrick et al., 2008).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1445514463

Over the years, China has attached more importance to environmental protection, and its research results on environmental impact assessment have become increasingly abundant (Shiojiri et al., 2010; Muthu et al., 2010). However, environmental impact assessment is mostly limited to engineering construction, and the research on eco-environmental impact assessment of urban master plan is still at the exploratory stage (Maj, 2015; Boulay et al., 2015). Thus, in order to ensure the coordinated and sustainable development of the overall city, the eco-environment should be improved in a scientific, orderly, efficient and reasonable manner, which can truly alleviate the pressure of eco-environment in urban planning (Zhou et al., 2013).

Therefore, this paper firstly introduces the connotation of PSR model. Based on this, an eco-environment evaluation system under the impact of urban planning was constructed. Then, the author proposed eco-environment improvement measures through comprehensive evaluation of the eco-environment of one city. The research results demonstrate feasibility of the comprehensive eco-environment impact assessment in urban master plan for the sustainable and harmonious development of cities, and also the objectivity and feasibility of the PSR model.

Materials and methods

The eco-environmental impact assessment of urban planning means to analyse and evaluate the impacts of the eco-environment and its ecosystems after urban planning of the structure, layout and land use, and then propose measures to mitigate the adverse effects (Wolfslehner and Vacik et al., 2008). The impact assessment system of urban planning on eco-environment is shown in *Figure 1*.

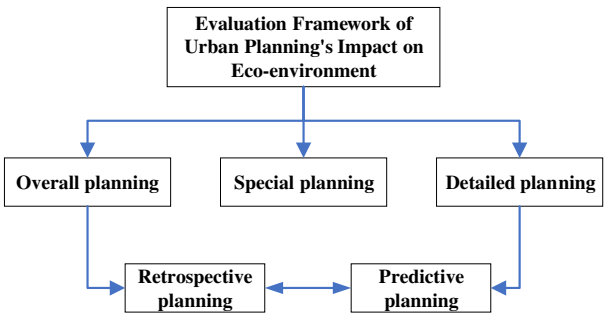

Figure 1. *Urban planning impact assessment system on eco-environment*

It should be noted that due to the different eco-environment conditions in different cities, the water environment, soil, plant diversity, natural disasters, etc. must be selected according to the environmental characteristics.

Pressure-state-response model

The PSR model is used for comprehensive assessment of eco-environmental impacts (Korol et al., 2016). It aims to construct one assessment system in three aspects: what the problems are, why the problems happen, and how to deal with these problems. *Figure 2* shows the framework of the PSR model.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1445514463

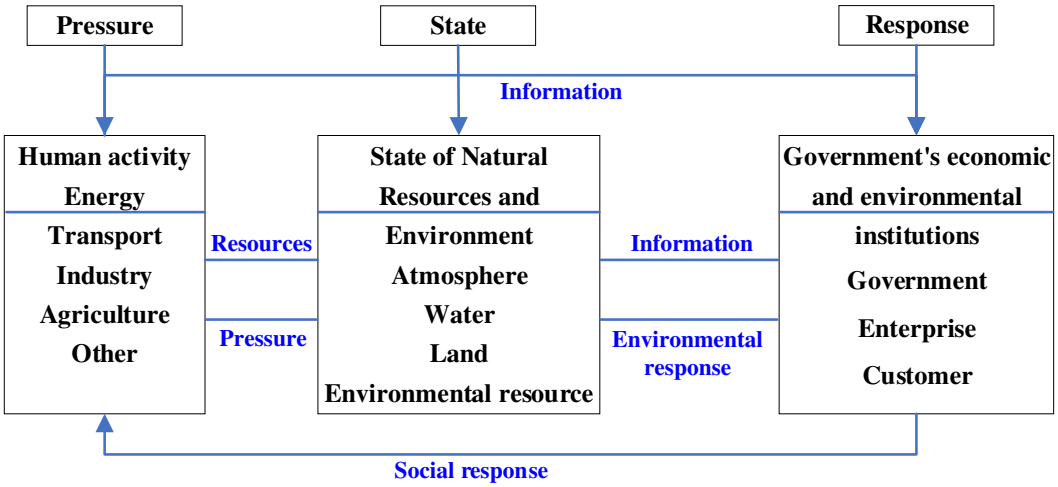

Figure 2. *PSR framework*

It can be further seen from *Figure 2* that the PSR model contains a strong logical causality. First, it shows the degree of improvement or even deterioration for the eco-environment by describing the "state" of the eco-environment. Secondly, it discusses the impact degree of the eco-environment on social and economic development under the economic and social "pressure". Finally, through the "response" at the institutional and policy levels, the measures are taken for the "state" of the eco-environment.

Eco-environmental impact assessment system based on PSR model

With reference to the relevant research literature (Jr et al., 2013; Prestrelo and Monteiro-Neto, 2016), the eco-environmental impact assessment indicators based on the PSR model were established, as shown in *Table 1*.

Table 1. *Eco-environmental impact assessment indicators based on PSR model*

Target layer	Criterion layer	Indicator layer
Eco-environmental status index	Socio-economic pressure (P)	Per capita GDP
		Urbanization level
		Traffic network density
	Ecological environment state (S)	Vegetation coverage
		Plant and biodiversity
		Water resources abundance and deficiency index
	Policy response (R)	Protection index of ecologically sensitive areas
		Indicators of land reclamation
		Intensive utilization of rural residential areas

Different indicators vary in their dimensions, making it impossible to compare the indicators and to truly reflect the current relationship between the indicators. So, it is necessary to standardize the assessment indicators. When these indicators and the eco-environment shows a positive and negative relationship, the standardized values of indicators are expressed in *Equations 1* and *2* below, respectively. The research data on

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1445514463

urban planning were collected through statistical survey and published on the *China Statistical Yearbook* released by National Bureau of Statistics, China.

$$PI_i = \frac{X_i - X_{\min}}{X_{\max} - X_{\min}} * 100\% \quad \text{(Eq.1)}$$

$$PI_i = \left(1 - \frac{X_i - X_{\min}}{X_{\max} - X_{\min}}\right) * 100\% \quad \text{(Eq.2)}$$

where PI_i is the normalized value of the i th indicator, X_{min} is its minimum value, X_i is its actual value, and X_{max} is its maximum value.

Among them, with PI_i being closer to 100%, it indicates a better eco-environment reflected by this indicator.

Furthermore, it is necessary to analyse the correlation of the indicators and screen out the highly correlated indicators, as shown in *Equation 3*.

$$r = \frac{\sum(X - \bar{X}) \cdot (Y - \bar{Y})}{\sqrt{\sum(X - \bar{X})^2 \cdot \sum(Y - \bar{Y})^2}} = \frac{\sum XY - \frac{\sum X \sum Y}{n}}{\sqrt{\left[\sum X^2 - \frac{(\sum X)^2}{n}\right]\left[\sum Y^2 - \frac{(\sum Y)^2}{n}\right]}} \quad \text{(Eq.3)}$$

where r is the correlation coefficient between the indicators; X and Y are the normalized value of the different indicators.

r is usually between -1 and + 1; the degree of correlation between indicators is positively correlated with the absolute value of r.

Determination of indicator weights

Analytic Hierarchy Process (AHP) can decompose the relevant factors of the problem into three layers: goals, criteria and alternatives. As shown in *Figure 3,* the goal layer A lists the goal of problem solving, i.e. the overall objective of the AHP; the criterion layer B gives the criteria that affect the realization of the goal; the alternative layer C provides the various indicators that promote the achievement of the goal.

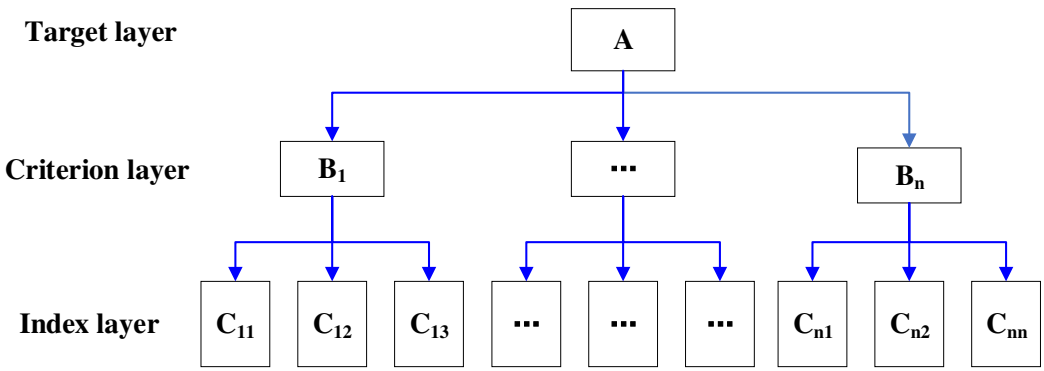

Figure 3. *AHP structural model*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1445514463

The AHP was used to construct a judgment matrix (*Eq. 4*) by pairwise comparison between indicators, perform a consistency test (*Eq. 5*), and then determine the weight of each indicator.

$$\begin{pmatrix} A & B_1 & B_2 & \cdots & B_n \\ B_1 & c_{11} & c_{12} & \cdots & c_{1n} \\ B_2 & c_{21} & c_{22} & \cdots & c_{2n} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ B_n & c_{n1} & c_{n2} & \cdots & c_{nn} \end{pmatrix} \quad \text{(Eq.4)}$$

$$CR = \frac{\sum_{j=1}^{m} CI(j)c_j}{\sum_{j=1}^{m} RI(j)c_j} \quad \text{(Eq.5)}$$

In *Equation 5,* CI is the consistency indicator, and CR is the consistency ratio.

Classification of eco-environment indicators

The eco-environment evaluation is shown in *Equation 6*.

$$EI = \sum_{i=1}^{n} w_i \cdot c_i \quad \text{(Eq.6)}$$

where w_i is the indicator weight; c_i is the normalized value of the indicator.

Generally, the eco-environment indicators can be classified into four grades, namely excellent, good, fair, and poor, as shown in *Table 2*.

Table 2. *Classification of eco-environment indicators*

Level	Excellent	Good	Commonly	Bad
Index	$EI \geq 80$	$60 \leq EI < 80$	$40 \leq EI \leq 60$	$EI < 40$

The extent of the eco-environment changes before and after urban planning can be divided into: significant change, obvious change, slight change, and almost no change. The specific changes and the corresponding values of each level are shown in *Table 3*.

Table 3. *Different impact degrees of urban planning on the eco-environment*

Level	Significant change	Obvious change	Slight change	Almost invariable
Index	$\|\Delta EI\| \geq 10$	$5 \leq \|\Delta EI\| < 10$	$2 \leq \|\Delta EI\| < 5$	$\|\Delta EI\| < 2$
Description	The ecological environment has changed significantly. If ΔEI is positive, it shows a significant improvement, and vice versa, a significant deterioration	The ecological environment has been greatly changed. If ΔEI is positive, it shows a marked improvement, and vice versa, a marked deterioration	The ecological environment has changed slightly. If ΔEI is positive, it means slightly better, and vice versa, slightly worse	The state of ecological environment has hardly changed

Results

One certain city was selected to plot the urban master plan for its three districts and six counties during the period of 2020-2040. The base data were collected from 2009 to 2018, with 2018 being the base year. The actual values of various eco-environment indicators are shown in *Table 4,* where B1~B6 are productivity, stability, protection, economic vitality, social acceptance, and policy response, respectively; C1~C20 are land utilization rate, area ratio of basic farmland, ratio of non-agricultural construction land, per unit area yield of grain, diversity of land use, land development rate, land consolidation rate, land reclamation rate, farmland conversion rate, area ratio of ecological land, forest coverage, water surface index, per capita public green area in urban areas, output index of construction land, output index of agricultural land, per capita GDP, economic density, expert satisfaction, protection index of ecologically sensitive area, intensive utilization of rural residential areas.

Based on the PSR model, the evaluation value of the urban planning impact on the eco-environment was obtained (*Fig. 4*).

Figure 4 indicates the overall upward trend of the eco-environment under the influence of the urban master plan for this City from 2018 to 2040, of which 2018-2025 is a slowly rising process, which is consistent with the development trend of this city, and also the city's environmental protection facilities and economic base are in a slow development stage; from the mid-term planning of 2025 to the long-term 2035, the city's ecological situation has made a qualitative leap and reached a new level in 2040.

Discussion

Figure 5 shows the variation trend of all indicators at the criterion layer from 2018-2040. *Table 5* lists the grading levels of different indicators.

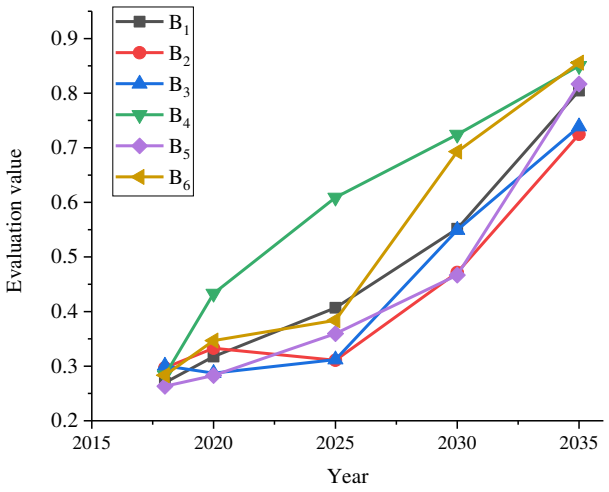

Figure 5. *Variation trends of the primary indicators during the period 2018-2035*

Table 5. *Classification of eco-environment levels of primary indicators during the period 2018-2040*

Index/Year	2018	2020	2025	2030	2035	2040
B1	Relatively low	Relatively low	Secondary	Secondary	Relatively high	High
B2	Relatively low	Secondary	Secondary	Relatively low	Relatively high	High
B3	Relatively low	Relatively low	Relatively low	Secondary	Relatively high	Relatively high
B4	Relatively low	Secondary	Secondary	Secondary	Relatively high	High
B5	Relatively low	Relatively low	Secondary	Relatively high	Relatively high	High
B6	Relatively low	Relatively low	Secondary	Secondary	Secondary	Relatively high

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1445514463

From the 6 primary indicators in *Figure 5* and *Table 5,* it can be seen that all these indicators in 2018 were at a relatively low development level, but after several years of construction until 2025, most of the indicators have reached a medium level, and by 2035 it reaches a high level.

In order to accelerate the improvement of the eco-environment, it is recommended to continuously improve the internal driving force for urban development by appropriately increasing the related planned value of the indicators to economic development; to relieve the impact of urban planning on the environment, such as reducing the emissions of carbon dioxide and sulphur dioxide, control the discharge of water pollution etc.

Conclusions

This paper studies the urban planning impact assessment on the eco-environment. The main conclusions are as follows:

(1) With the purpose of realizing the urban planning impact assessment on eco-environment, a comprehensive analysis of the urban master planning process was conducted, and then a system diagram for this impact assessment was established.

(2) Based on the PSR model, an indicator system for impact assessment of urban planning on the eco-environment was constructed, including the goal layer, the criterion layer l and the alternative layer.

(3) AHP was used to determine the weight of each indicator, and evaluate the eco-environment of one certain city. The evaluation results show that under the current urban planning, the variation trend of eco-environment is consistent with the sustainable development of this city.

The complete eco-environmental impact assessment of urban planning should cover the predictive assessment in the preparation phase of the urban master plan, the inspective assessment in the implementation phase, and the retrospective assessment after the implementation. This paper only deals with the predictive assessment of the eco-environmental impacts of urban planning. The future research will tackle the inspective and retrospective assessments of the eco-environmental impacts of urban planning during and after the implementation of the urban master plan.

Abstract. The life of urban residents demands sufficient material supply and a good eco-environment. The rapid expansion of cities has stimulated the urban population and economy, exerting irreversible changes on the eco-system. During the urban evolution, it is of great importance to evaluate the overall impacts of urban development on biodiversity. The evaluation aims to integrate biodiversity protection into urban development and maintain it in a harmonious and stable state. Focusing on ecosystem sustainability, this paper designs the architecture to evaluate the impacts of urban evolution on plant diversity, and creates an integrated evaluation system for biodiversity from five perspectives, namely, species richness, species diversity, species evenness, species importance and population diversity. On this basis, the proposed system was applied to assess the biodiversity in a city. The assessment results show that continuous biodiversity evaluations can ensure the sustainable development of species during urban evolution. The research findings provide new insights into the diversity and sustainability of urban species.
Keywords: *urban evolution, ecosystem, biodiversity, sustainable development, structure of plant community*

Introduction

In recent years, following the rapid advancement of urbanization, human society has been facing unprecedented problems such as environmental damage, increased pollution, over-exploitation of resources, reduction of green spaces, and shortage of water resources, which urgently require the protection of the diversity of the city and improvement of the city's ecological environment while promoting the living standards of human beings (Olofson et al., 2009). Also, with the current urban development, the biodiversity and ecological stability are seriously threatened. Therefore, the issues of protecting the environment, rationally utilizing biological resources, and ensuring the biodiversity for sustainable development have gradually attracted people's attention (Hunter and Philip, 2007; Karmaker et al., 2018).

Multi-level, sustainable and stable use of ecological resources is an important part of biodiversity protection (Kaushal et al., 2014). With the acceleration of urban evolution, the natural appearance has also undergone great changes. In particular, the destruction of ecosystems has greatly affected the living space of biological species, seriously threatening the biodiversity closely related to urban ecological environment and human settlements (Crawford and Goldstein, 2010). Therefore, it's of great significance to protect the biodiversity for ecological cities in development, continuously improving

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1446514474

ecosystems, and the overall level of urban construction, and achieving sustainable urban development.

Over the years, during the process of urban development, the rural population has gradually moved into the city, increasing the urban population rapidly (Loreau, 2001), which resulted in the excessive exploitation and utilization of various biological resources, and the continuous destruction of the soil and microbial environment, and even pushed some species to the verge of extinction. All these have further challenged the diversity of protected organisms (Lavorel, 2002; Reiss et al., 2009). Therefore, it is necessary to carry out a comprehensive evaluation study on the impact of urban development on biodiversity in the process of urban evolution, which not only enables the public to obtain effective information on the impact of urban development on biodiversity, but also makes the government departments to well realize the top-priority biodiversity indicators in the decision-making process of urban development (Miki, 2009).

As more emphasis is gradually put on ecological environment and biodiversity conservation in China, research results on biodiversity conservation have been also becoming more abundant (Tscharntke et al., 2005). But the research on the impact of urban evolution on biodiversity is still in the exploratory stage (Weiland et al., 2008; Lubbe et al., 2012). In order to develop the city and urban ecosystems sustainably together, it is necessary to ensure the biodiversity and the harmony of the ecological environment (Anstead et al., 2003; Burd et al., 2006).

As above, this paper constructs a comprehensive evaluation system of biodiversity based on urban evolution in order to understand the relationship between biodiversity and urban development. Then, taking the evaluation of a city as an example, it proposes relevant measures to further improve biodiversity. The research results indicate that during the urban evolution, a comprehensive evaluation considering the impacts of biodiversity is feasible for the conservation and sustainable development of biodiversity.

Materials and methods

The green space types of urban vegetation include residential green space, ecological landscape green space and public green space (Symstad et al., 2003). In order to study the impact of urban evolution on plant diversity, an evaluation system considering the impact of urban evolution on plant diversity was established (*Fig. 1*).

Evaluation index of species diversity

The index of species diversity mainly includes species richness, diversity, evenness, importance and population diversity (Gamfeldt et al., 2006), as shown below.

(1) Richness index

$$R = \frac{S-1}{\ln N} \qquad \text{(Eq.1)}$$

where S and N respectively, indicate the number of species and the number of individuals.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1446514474

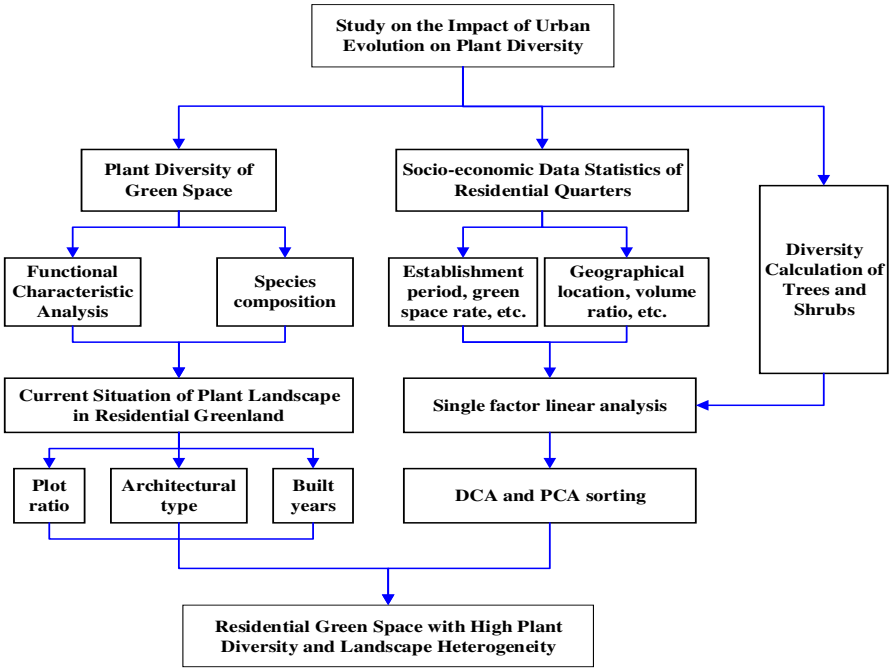

Figure 1. *Evaluation system considering the impact of urban evolution on plant diversity*

(2) Diversity index

$$H = -\sum_{i=1}^{S} P_i \ln P_i \quad \text{(Eq.2)}$$

$$D = 1 - \sum_{i=1}^{S} P_i^2 \quad \text{(Eq.3)}$$

where H, D respectively, refers to the *Shannon-Wiener* index and *Simpson* index; N_i is the number of individuals for the i-th species, and P_i is the proportion of the species.

(3) Evenness index

$$J = \frac{H}{\ln S} \quad \text{(Eq.4)}$$

J is *Pielou* index.

(4) Importance index

$$I_i = \frac{(DR_i + FR_i + CR_i)}{3} \quad \text{(Eq.5)}$$

where DR_i, FR_i, and CR_i are the relative density, relative frequency, and relative coverage of the i-th plant respectively.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1446514474

(5) Population diversity index

It is divided into arbors, shrubs, and herbs. The population diversity refers to the average diversity of the three plants.

$$D = \frac{W_1 D_1 + W_2 D_2 + W_3 D_3}{3} \quad \text{(Eq.6)}$$

In *Equation 6,* D_1, D_2, and D_3 respectively refer to the diversity index of the arbor, shrub, and herb; W_1, W_2, W_3 are the weight coefficient corresponding to the three plants.

An integrated evaluation system of plant diversity

In order to objectively and comprehensively evaluate the impact of plant diversity in urban evolution, it is necessary to build the evaluation index from the three aspects of species such as the biological characteristics (ornamental value, anti-pollution, pest-resistance, etc.), ecological properties (light tolerance, drought tolerance, cold endurance etc.), combined greening effects (humidification, bactericidal, cooling, air purification, etc.) (Breton et al., 2007; Sun and Xu, 2010), as shown in *Figure 2*.

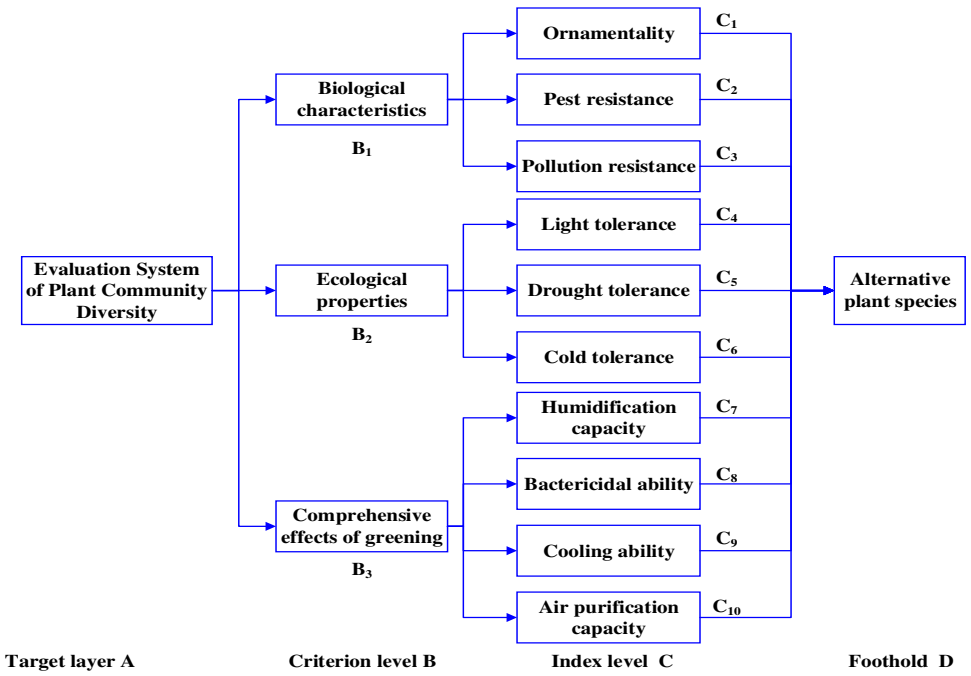

Figure 2. *Evaluation system of plant diversity*

Determination of index weights

Analytic hierarchy process (AHP) was adopted to construct the judgment matrix. Let

$$a_{ji} = 1/a_{ij} \, (a_{ij} > 0) \quad \text{(Eq.7)}$$

Use 1-9 and its reciprocal as the scale to determine the value of a_{ij}. The composition of the Judgement Matrix *(JM)* is shown in the *Equation 8* below.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1446514474

$$JM = \begin{pmatrix} A & B_1 & B_2 & \cdots & B_n \\ B_1 & c_{11} & c_{12} & \cdots & c_{1n} \\ B_2 & c_{21} & c_{22} & \cdots & c_{2n} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ B_n & c_{n1} & c_{n2} & \cdots & c_{nn} \end{pmatrix} \quad \text{(Eq.8)}$$

Further, the square root method was used to solve the weights of each index, and the consistency test was performed. The single-layer consistency test is shown in *Equations 9* and *10,* and the comprehensive consistency test is shown in *Equation 11*.

$$CI = \frac{(\lambda_{\max} - N)}{N - 1} \quad \text{(Eq.9)}$$

$$CR = CI / RI \quad \text{(Eq.10)}$$

$$CR = \frac{\sum_{j=1}^{m} CI_j c_j}{\sum_{j=1}^{m} CR_j c_j} \quad \text{(Eq.11)}$$

where λ_{max} is the largest eigenvalue of *JM*, *CI* is the consistency indicator, and *CR* is the consistency test indicator.

Results

Taking the centre of Nanning as the sampling origin, a grid with a spacing of 1 km was adopted, and the intersection point was the sampling point for analysis of urban green space and plant diversity. Nanning City is located in the southwest of Guangxi Zhuang Autonomous Region, about 50 km south of the Tropic of Cancer, and in the transitional zone from south subtropics to northern tropics. It belongs to the south subtropical monsoon climate. Its geographical coordinates are at 22°40'-23°06' north latitude, and 107°45'-108°27' east longitude. Facing Southeast Asia, it is backed by the southwest, bordering Hong Kong, Macao, and Hainan in the east, and Indian Peninsula in the west. It is the junction of the two major economic zones of the South China coastal region and the southwestern coastal region, and the connecting point of the Southeast Asian economic circle.

Through the comprehensive survey of selected survey sites, the representative plant communities in the survey sites were selected, and the 10 m × 10 m samples were prepared respectively using typical sampling methods. The survey was conducted on January 1st to December 31st, 2018 in six types of green spaces such as the comprehensive park, theme park, roadside green space, residential green space, public facilities green space, and road green space: the survey sites of the comprehensive parks include People's Park, Binjiang Leisure Park and Nanhu Park, with 14 sampling points; those of theme parks include Nanning Zoo and Guangxi Medicinal Botanical Garden, with 19 sampling points; those of roadside green space include Nanhu Square and Chaoyang Square, with 17 sampling points; those for residential green space include

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1446514474

Beihu Anju Community, Cuihu New City, Hengda New City, Mingxiu Community, and Zhenning Cuifeng community, with 18 sampling points; those of public facilities green space include Guangxi University, Guangxi Sports General Administration, Nanning Theater, tand he First Affiliated Hospital of Guangxi Medical University, with 13 sampling points; those of road green space include Minzu Avenue, Zhonghua Road, Chaoyang Road, and University Road, with 9 sampling points. According to statistics, there were 90 effective sampling points and 476 plant species, including 127 genera and 349 species. *Table 1* lists the specific composition. *Table 2* shows the ratios of population to vegetation land in the urban, suburban, and remote suburbs.

Table 1. *Composition of plant species at sampling points*

Classification		Section		Genus		Species	
		Quantity	Proportion	Quantity	Proportion	Quantity	Proportion
Fern		10	7.9%	9	2.6%	19	4.0%
Gymnosperm		10	7.9%	10	2.9%	20	4.2%
Plant	Monocotyledons	85	66.9%	233	318	66.8%	65.6%
	Dicotyledons	22	17.3%	97	119	25.0%	28.1%
	Subtotal	107	84.3%	330	437	91.8%	93.7%
Total		127	100%	349	100%	476	100%

Table 2. *Proportion of population and vegetation land in urban, suburban and remote suburbs*

Region	Area	Population density	Population growth rate (%, 2000~2018)	Proportion of vegetation land
Urban	1405	5321	76	63
Suburban	3581	764	65	27
Outer suburbs	9860	213	38	11

Through the judgment matrix, the weights of biological characteristics, ecological performance and greening effects were derived as W = (0.32, 0.22, 0.46). 5 experts with a certain reputation in the industry were selected to score the above 10 indicators using 10-points system, and obtain the weights of each indicator (*Table 3*). The consistency test results are shown in *Table 4*.

Table 3. *Index weights*

Index	C_1	C_2	C_3	C_4	C_5	C_6	C_7	C_8	C_9	C_{10}
Weight	0.127	0.112	0.081	0.037	0.117	0.066	0.113	0.145	0.076	0.126

Table 4. *Consistency test of indicators*

Consistency test	A-B	B_1-C	B_2-C
λ_{max}	3.0195	4.0445	3.0105
CI	0.0107	0.0157	0.0067
RI	0.5815	0.9015	0.5815
CR	0.0177	0.0177	0.0097

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1446514474

At these sampling points, the top 10 vegetations in terms of importance degree were selected respectively from the three plants of arbor, shrub and herb for evaluation. According to the weights shown in *Table 3,* the comprehensive scores were finally obtained (*Table 5*).

Table 5. *Rankings of three plants (arbors, shrubs and herbs)*

Arbor name	Score	Shrub name	Score	Herbs	Score
Grid wood	4.392	Chinese wolfberry	4.885	Cricket grass	4.772
Rag leaf	4.251	Bush clovers	4.764	Field spinning	4.544
White cicada	4.107	Wild jujube	4.652	Dandelion	4.346
Juglans mandshurica	4.029	Patrinia	4.498	Duchesnea indica	4.207
Pu Shu	4.004	Lygodium microphyllum	4.442	Black jujube	4.156
Acer mon	3.989	Three white grass	4.299	Bletilla striata	4.056
Seven leaf lotuses	3.974	Centella asiatica	4.094	White Ginger Lily	4.036
Tilia amurense	3.981	Vitex negundo	4.091	Madder	4.028
Wood butterfly	3.910	Leptopus chinensis	3.905	Kerosene	3.905
Pistacia chinensis Bunge	3.917	Crabgrass	3.513	Light bamboo leaves	3.759

It can be seen from *Table 5* that the top 3 plants in the arbors are: Grid wood, Rag leaf, White cicada; the top 3 in the shrub plants are: Chinese wolfberry, Bush clovers, Wild jujube; the top 3 of herbs are: Cricket grass, Field spinning, and dandelion.

Based on the principle of "sustainable development" and "ecological priority", it is necessary to first select plants that are easy to cultivate, adaptable, and easy to promote, and give priority to the five plants with higher scores in *Table 5* as garden species and green resources, in order to continuously enrich the diversity of plants.

Discussion

The relationship between plant species distribution and population density is shown in *Figure 3,* and the relationship between plant species distribution and cultivated land area is shown in *Figure 4*. The 10 regions in the figure represent People's Park, Binjiang Leisure Park, Nanhu Park, Chaoyang Square, Cuihu New City, Mingxiu Community, Zhenning Cuifeng Community, Minzu Avenue, Chaoyang Road and University Road.

Figure 3 shows that the population density is negatively correlated with the distribution of plant species, and the region with smaller population density is richer in plant diversity, indicating that human activities directly affect the distribution of plant species, such as logging directly destroying plant species, land clearing, etc.

Figure 4 shows that the area of cultivated land is negatively correlated with the distribution of plant species, and the area with larger cultivated land area is richer in plant diversity, indicating that the area with high forest coverage has a certain protective effect on the diversity of plant species due to the small artificial disturbance.

Therefore, in order to ensure the sustainable development of plant diversity, the following countermeasures were proposed:

(1) In the planting area, the plant species needs should be selected according to local conditions such as local soil, climate, and water quality etc.;

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1446514474

(2) When introducing new varieties, more emphasis needs to be put on species adaptability and pest control, so as to ensure that new species can adapt well to local natural ecosystems;

(3) It is necessary to achieve the proper management and maintenance of plants, and establish a scientific management system. In particular, the education and guidance should be strengthened to protect plant diversity.

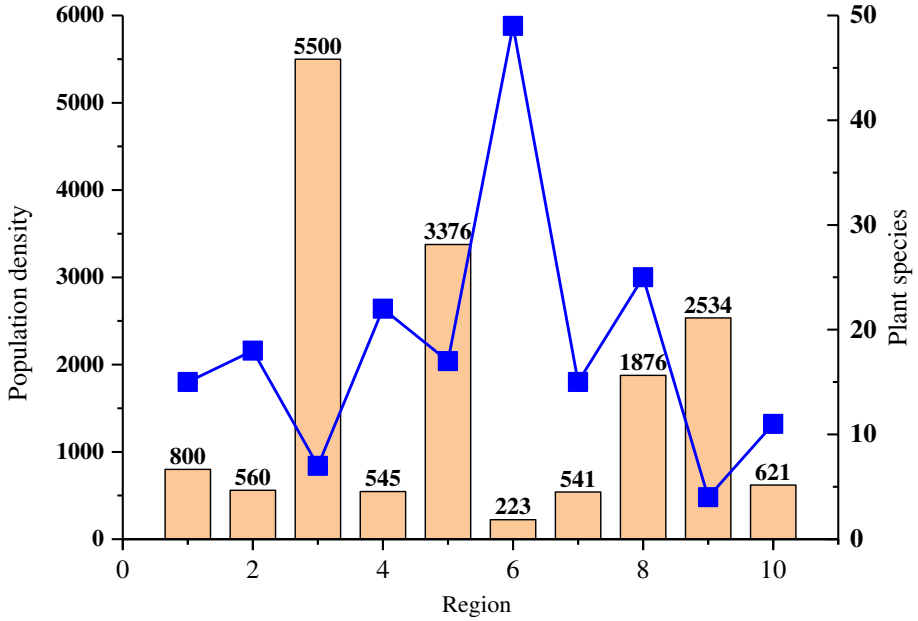

Figure 3. *The relationship between plant species distribution and population density in each region*

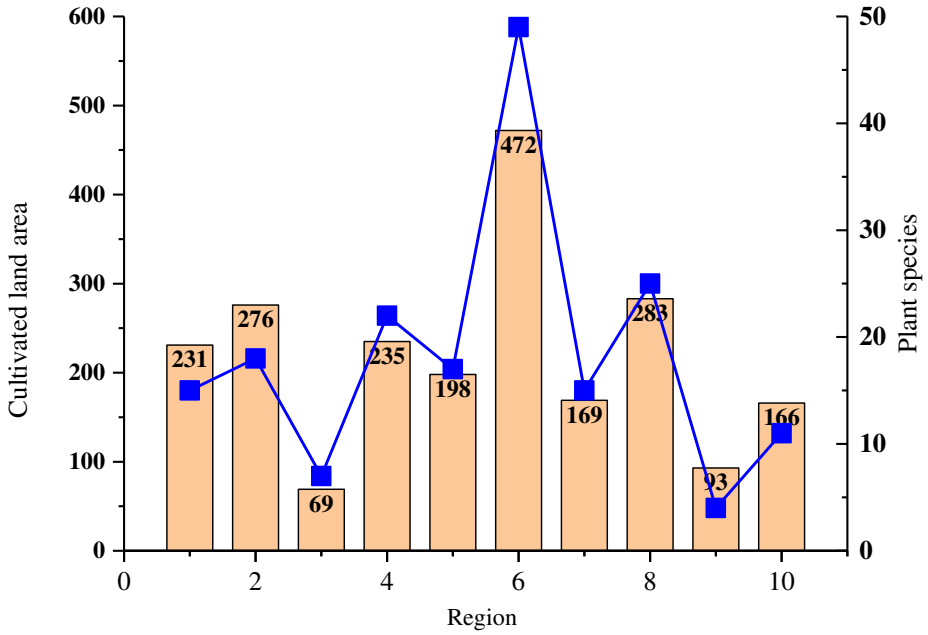

Figure 4. *The relationship between plant species distribution and cultivated land area in each region*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1446514474

The result analyses of this study were based on data from the one-year Nanning plant diversity survey. These data are currently the most comprehensive, widely, and convincing among the plant diversity surveys in Nanning. Through related analysis, the overall situation of different species of plants in Nanning was obtained, and the key distribution areas of alien invasive plants in Nanning were proposed, which provide the main scientific basis for the plant protection in Nanning and invasive plants prevention (Huangfu et al., 2019).

Conclusion

This paper studies the impact pf urban development on plant diversity. The main conclusions are as follows:

(1) An evaluation system on the impact of urban evolution on plant diversity was established, to solve the related impact evaluation problem of plant diversity;

(2) An integrated evaluation system consisting of five evaluation indicators of plant diversity from the perspectives, namely, species richness, species diversity, species evenness, species importance and population diversity, and three layers: target layer, criteria layer and alternative layer (biological characteristics, ecological performance and greening combined effect) were established; AHP method was used determine the weight of each index;

(3) Taking a city as an example, the plant diversity in the urban evolution process was assessed. The assessment results can provide an important scientific basis for the protection of urban biodiversity and the sustainable development of ecosystems.

In the comparative analysis of the diversity for plants, only the data in each unit sample of the same type of green space was used for comprehensive analysis, rather than the overall information of the same type of green land such as its number of species. In the subsequent study, it is a problem worthy of further discussion on how to use this information for comprehensive evaluation.

Abstract. This paper monitors and analyzes the surface water and sediments in the Dongxinkai (DXK) River basin. The analysis shows that the water bodies mainly suffer from aerobic pollution, with chemical oxygen demand (COD) and ammonia nitrogen (NH_3-N) being the primary causes of pollution. Considering the main causes of the pollution, the author put forward an integrated pollution control plan for the basin focusing on pollutant interception, source control, and ecological construction. After the treatment, the dissolved oxygen (DO) values at all sampling points were greater than 2 mg/L, the NH_3-N values were all smaller than 8 mg/L and the water transparency values were all above 25 cm, indicating that the river is no longer black or odorous. The implementation of the entire plan costs RMB 26.2×10^8 yuan. The research findings shed important new lights on pollution control in other rivers across China.
Keywords: *black and odorous waterbody, chemical oxygen demand (COD), ammonia nitrogen (NH_3-N), wetland, sponge city*

Introduction

As urbanization has been picking up speed in China, a lot of sewage have been discharged into rivers without any treatment. As a result, water quality indices like chemical oxygen demand (COD), ammonia nitrogen (NH_3-N) and total phosphorus (TP) have greatly surpassed limits in many rivers, making the water bodies black and odorous (Wang et al., 2014, 2016a; Corsino et al., 2016). In 2015, the State Council, China's cabinet, unveiled its *Action Plan for Water Pollution Prevention and Control*, setting out the goal to control the proportion of black and odorous water bodies in urban built-up regions at prefecture-level and push it below 10% by 2020 (Chi et al., 2019; Li et al., 2018).

In light of the above, this paper attempts to prepare an integrated plan to solve the water pollution in the basin of Dongxinkai (DXK) River, northeastern China's Jilin Province, aiming to control the water quality indices within the limits. The prepared plan would promote the construction of sponge cities and provide reference to river pollution control across China.

With a basin of 98.12 km^2, the DXK River is a 16.5-km-long primary tributary of Yitong River, which crisscrosses Jilin Province. The mean slope of the river is about 1.5‰. The main tributaries include Xibaizi (XBZ) Ditch, Dabaizi (DBZ) Ditch, Baizi (BZ) Ditch, Weizi (WZ) Ditch, Jinqian (JQ) Ditch, etc. Currently, the water bodies are of poor quality in the river basin. The COD and nutrient salts (nitrogen and phosphorus)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1447514486

far exceed their respective limits. As a typical black and odorous water bodies, the river and its tributaries cannot even reach Class V specified in China's environmental quality standard for surface water, which seriously affects the life quality of nearby residents. This calls for immediate pollution control and regulation.

Materials and methods

Sampling and analysis method

During 11:00-15:00 on March 22- 25, 2016, the project team collected water samples from 50 cm of obvious flow on both Banks and river center in each monitoring section at the same time. After fully mixing, 500 ml of mixed water samples were taken, sealed with polyethylene bottles, and brought back to the laboratory for physical and chemical determination within 24 h. Each indicator of each water sample was measured three times and averaged. The surface water and sediment samples were collected from 29 points (*Fig. 1*) in the DXK River and its main tributaries. During the collection, a YSI (Yellow Springs Instrument Co) water quality meter and other portable water quality analyzers were adopted to measure the following indices of the surface water samples: temperature, pH, oxidation reduction potential (ORP), conductivity and dissolved oxygen (DO) (Moungar et al., 2018; Uddin et al., 2017; Zhao et al., 2016, 2019). Meanwhile, the surface sediments were collected with a gravity column sampler (Behaddya and Hadjel, 2014; Bhuiyan et al., 2010; Wang et al., 2016).

The sediments were analyzed to determine their water content, organic content, particle size and heavy metal content. Specifically, the distribution of particle size was determined by a laser particle size analyzer, while the heavy metal content was measured by inductively coupled plasma optical emission spectrometry (ICP-OES). Before the ICP-OES, the sediment samples were freeze-dried by a freeze dryer, and then digested by microwave (Zhou et al., 2011).

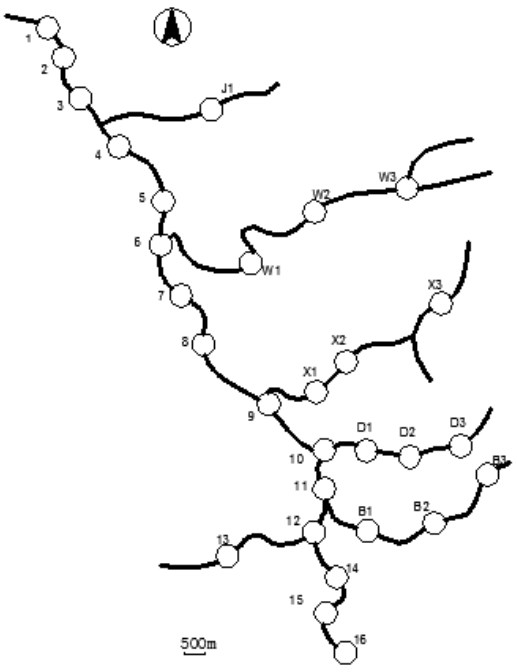

Figure 1. *Distribution of sampling points*

DOI: http://dx.doi.org/10.15666/aeer/1706_1447514486

Water quality analysis

The results of water quality and sediment analysis are listed in *Table 1*. In general, the surface water COD in the river basin fell in 13~222 mg/L, averaging at 106.9 mg/L. The WZ Ditch and DBZ Ditch had relatively high mean CODs, respectively, 166 mg/L and 148 mg/L. The values were 4 and 5 times that for Class V in China's environmental quality standard for surface water. In the main stream, the COD at about 82% of sampling points was greater than the Class V level.

*NO_3-N: nitrate nitrogen. TC: total carbon. SRP: soluble reactive phosphorus. TS: total sulfur. LOI: loss on ignition. COD: chemical oxygen demand. TN: total nitrogen. TP: total phosphorus. NH_3-N: ammonia nitrogen

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1447514486

The NH_3-N in the water bodies ranged between 0.04 mg/L and 5.83 mg/L. In the main stream and each tributary, the NH_3-N gradually decreased streamwise. The mean NH_3-N was the highest in the BZ Ditch, while that of the WZ Ditch and the DBZ Ditch were 36 mg/L and 13.1 mg/L respectively. In the main stream, the NH_3-N exhibited an obvious spatial difference. In the downstream, the NH_3-N obeyed a relatively uniform distribution and all exceeded the Class V level. This is attributable to the industrial wastewater and domestic sewage discharged from cities, towns and villages.

The total nitrogen (TN) fluctuated between 4.61 mg/L and 107.7 mg/L across the river basin, and always stayed above the Class V level. The peak TN was observed at the sampling point W1, about 54 times the Class V level. This means all water bodies in the basin have been seriously polluted by nitrogen.

The mean TP in the basin stood at 2.4 mg/L, more than 7 times the Class V level (0.4 mg/L).

The soluble reactive phosphorus (SRP) of the basin averaged at 2.26 mg/L, indicating that an average of 84% phosphorus in the water bodies mainly exist in the dissolved state. The SRP proportion of the main stream even surpassed 90%.

Sediment analysis

The analysis results in *Table 1* show that the TP of surface sediments in the basin averaged at 613.03 mg/kg, far above the internationally accepted TP threshold (500 mg/kg) for sediments. The TN of surface sediments in the basin averaged at 1,951.3 mg/kg. This level greatly surpassed the internationally accepted TN threshold (1,000 mg/kg) for sediments, posing the risk of pollutant release.

The sediment samples differed greatly in total carbon (TC), which ranged between 0.27% and 6.6%. The peak TC belonged to the sampling point W3. The distribution of TC changed significantly from place to place in the tributaries.

The total sulfur (TS) of sediment samples, an indicator of pollutant content, averaged at 0.113%, and peaked at sampling points 8 and B1. The spatial distribution of TS was relatively stable.

The loss on ignition (LOI) characterizes how much organic matter exists in the sediments, and how much gaseous products come from the thermal decomposition of sediments. The analysis results demonstrate an obvious difference in organic content between sediment samples. The highest organic content was discovered at sampling points 6 and B2. Therefore, TC and LOI must have similar pollution sources.

The author monitored 29 sampling points with 4 indicators including TN, TP, COD and NH_3-N for a total of 4 times in March 2016, and extracted 3 samples from each sampling point for a total of 1392 ($29 \times 4 \times 12$) monitoring samples for laboratory analysis. The specific statistical description of the results is shown in *Table 2*. According to the statistical data, the flowing water of this river is seriously polluted. TN, NH_3-N and TP all seriously exceed the category V of surface water environmental quality standards. Normal test was carried out on the average data set of sampling points, and the results showed that all monitoring indexes except TN followed normal distribution with 95% or higher reliability.

Diagnosis of water environment problems

The water bodies in the river basin mainly suffers from aerobic pollution, with COD and NH_3-N being the primary pollutants. According to the analysis on surface water

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1447514486

quality indices, the surface water is severely polluted by nutrient salts. On average, the surface water samples exceeded the standard level by 7.3 times, 13.6 times, 5.8 times and 2.6 times in terms of NH_3-N, TN, TP and COD. Considering the current states of pollution and sewage pipe network, the blackness and odor of the water bodies can be attributed to the following reasons:

(1) Our survey shows that agricultural land (63.02 km^2) takes up 64.2% of the river basin (98.12 km^2); For the pollution load of the basin, 70% comes from agricultural non-point source pollution and 5% from scattered discharge of rural sewage. Thus, the rural area is the main contributor to non-point source pollution of the basin. The non-point source pollution load in the river basin is specified in *Table 3*.

(2) There is no sewage treatment plant in the river basin. Neither has any sewage treatment plant been planned for this region. The sewage is mainly collected by the pipe network, and transported to the Beijiao Sewage Treatment Plant in the downstream. As a result, the water flow in the middle and lower reaches of the DXK River is not stable. The river often dries up in the dry season.

(3) The runoff is seriously polluted in rainy days. In the basin, the rainwater and sewage are still discharged in the same pipe network. During rainstorms, the sewage often flows over and carry garbage into the river.

(4) The rivers have weak self-purification ability due to ecological degradation. The river basin does not have enough ecological space (Podani, 1994; Xu, 2005). Many river channels are illegally occupied by buildings and lots of beaches are turned into farmland, leaving a narrow watercourse for flood discharge (Lazaro, 1979). These behaviors severely undermine the regional flood control and discharge, water regulation and storage, river self-purification and river landscape. This is the main threat to the ecological space of the river basin.

Results

The cause analysis of the black and odorous river bodies indicates that the river basin is mainly affected by agricultural non-point source pollution. Considering the segmented features of the pollution status, the author put forward a pollution control

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1447514486

plan focusing on pollutant interception, source control, and ecological construction. The plan mainly covers five areas, namely, sewage treatment plant, sponge city, garbage treatment and sediment cleaning, rural water pollution control and wetland construction.

Table 3. *Non-point pollution load in the river basin*

Land use	Area km^2	Percentage %	TSS*	COD	TN t/a	TP	NH_3-N

(1) The sediment and garbage were removed from 46.4-km-long river channels. In total, 8.4×10^4 m^3 of sludge was cleaned away, which effectively reduces the sediment release and boosts the flood discharge ability. The sediments being removed were separated from water through a five-stage coagulative precipitation tank, dried in open air, and finally backfilled (Bohn, 2002). After dredging, COD and NH_3 - N index of the river cut nearly 50%, after dredging, adding the volcanic debris (size 6 ~ 10 mm) and pebbles on the bottom of the riverbed sediment improvement, on the microorganism immobilized bacterium agent, the bacteria agent by photosynthetic bacteria, spores, bacteria, to produce alkali bacteria, yeast and other 10 genera and more than 120 kinds of microorganism distribution and slow release cycle for 3 ~ 6 months.

(2) The sponge city project was implemented in view of the following facts: the surface runoff coefficient (0.7) and surface runoff is obviously higher in the built-up area than other areas in the basin, the water quality is greatly affected by surface runoff, and the ecosystem is serious undermined. Specifically, a 0.8 km^2 wetland park was built in the upstream of the DXK River and another 5.4 km^2 one was constructed in the downstream of the JQ Ditch. The two parks were constructed to restore the natural water system and wetlands, which can retain, regulate and purify the surface runoff pollution, reduce the load of non-point pollution from the upstream, and ensure the ecological flow in the river basin. In addition, a pilot program of sponge city was implemented in the middle reaches of the WZ Ditch. The 4.7 km^2 sponge city could cut down the surface runoff load by 50~75%.

(3) The 82 ponds in the basin were expanded into a pond-wetland system. To maintain the water volume and purify the water in the basin, the following key wetlands were constructed: two reservoir wetlands, three pond wetlands, one estuary wetland and one artificially enhanced wetland (using the tail water from sewage treatment plant) (Ascelin et al., 2002; Zhu et al., 2019; Barinova, 2017). The area, pondage, and pollution reduction amount of each wetland are listed in *Table 4*. The locations of the wetlands are shown in *Figure 2*.

(4) The urban sewage was carried by lift pump stations to the sewage treatment plant for centralized treatment. The plant was newly constructed, with a capacity of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1447514486

1×10^4 t·d^{-1}. Using the Anaerobic/Anoxic/Oxic (A/A/O) process, the sewage treated by the plant can reach the IA level in the *Discharge Standard of Pollutants for Municipal Wastewater Treatment Plant* (GB18918-2002). The pollutant interception pipe network was constructed as an auxiliary project of the plant. The quality of the treated sewage is illustrated in *Figure 3*.

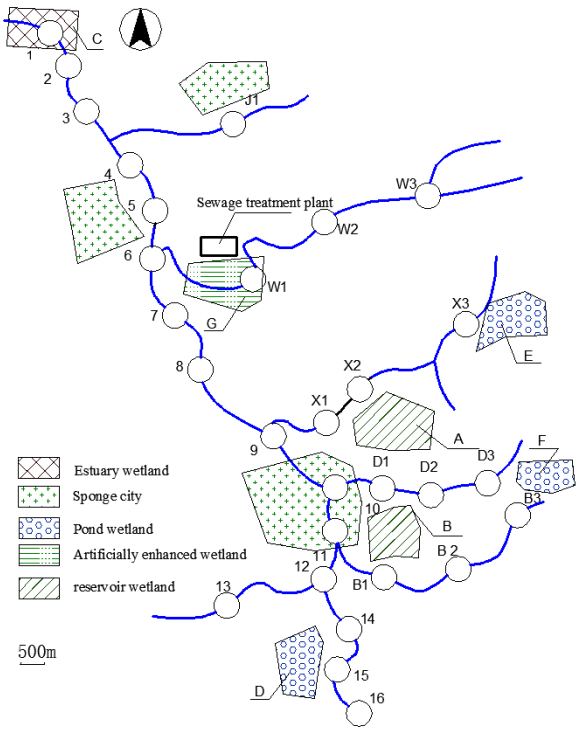

Figure 2. *Distribution of different types of wetlands and sponge cities. (J: JQ Ditch, W: WZ Ditch, X: XBZ Ditch, D: DBZ Ditch, B: BZ Ditch)*

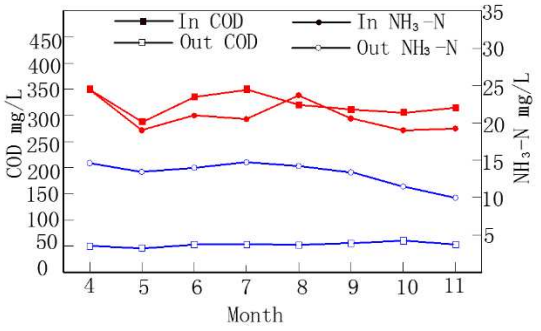

Figure 3. *Comparison between inlet and outlet water of the A/A/O sewage treatment plant*

(5) In light of the scattered discharge of rural sewage in the basin, the author developed a system to utilize and purify domestic sewage and rainwater. The system, encompassing rainwater and sewage collectors, sewage purifier, and ecological pools, can collect and purify domestic sewage and rainwater separately, and discharge them after they reached the relevant standard. In this way, the proposed system makes full use

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1447514486

of water resources, and opens up a new way to replenish the groundwater. As shown in *Figure 4,* the sewage purifier consists of such four parts as sewage collector, primary purification tank, secondary purification tank and tertiary purification tank. The primary purification tank has three layers, which respectively filters coal cinder, medium-coarse sand and fine sand. The secondary purification tank mainly relies on a fiber filter layer consists of bio-fiber straws extracted from corn and wheat. This layer provides the function of biological purification. The tertiary purification tank works with an activated carbon filter layer. After entering the sewage purifier, the sewage passes through the three purification tanks in turn, and undergoes thorough purification.

Discussion

The treatment of black and odorous waterbody should be adapted to local conditions and different treatment schemes should be adopted in different areas. The lower reaches of Fuchuangxi River in HaiNan province of China are tidal river sections with high salinity. Therefore, sewage interception, wastewater treatment, aeration and mangroves ecosystem were used to remediate the black and odorous waterbody of Fuchuangxi River (Chi et al., 2019). Yitng river of JiLin province, black and odorous waterbody is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1447514486

caused by farming and agriculture, so the construction of biogas greenhouse ecological system, heat storage and utilization of the manure, straw compost renewal, on the one hand, can make use of biogas technology in biochemical treatment, on the other hand can purify livestock farming aquaculture wastewater, reduce its pollution material such as COD, nitrogen, phosphorus content, reach discharge standards to reduce the surface water pollution (Zhao et al., 2019). Considering the segmented features of the pollution status, the author put forward a pollution control plan focusing on pollutant interception, source control, and ecological construction. The pollution control plan mainly covers five areas, namely, sewage treatment plant, sponge city, garbage treatment and sediment cleaning, rural water pollution control and wetland construction.

The pollution control plan was fully implemented by October 2017. From May to November, 2018, the author collected water samples from the DXK River at sampling points 5, 11 and 14, and analyzed the DO, ORP, NH_3-N and transparency of the samples. The results in *Figure 5* show that, through the seven months, the DO values at all three points were greater than 2 mg/L, the NH_3-N values were all smaller than 8 mg/L and the water transparencies were all above 25 cm, indicating that the river is no longer black or odorous. The implementation of the entire plan costs USD 3.47×10^8. The investment is break down in *Table 5*.

Table 5. *Main workloads and investment breakdown of the pollution control plan*

No.	Name of project	Project contents	Workload	Investment (USD thousand)
1	Drainage system and sewage treatment plant	Main sewage pipes ng the rivers	Pollutant interception pipes (49 km)	45714
		Rainwater and sewage interception wells	Interception wells (39)	55714
		Sewage treatment plant	10^4 m^3/d	29997

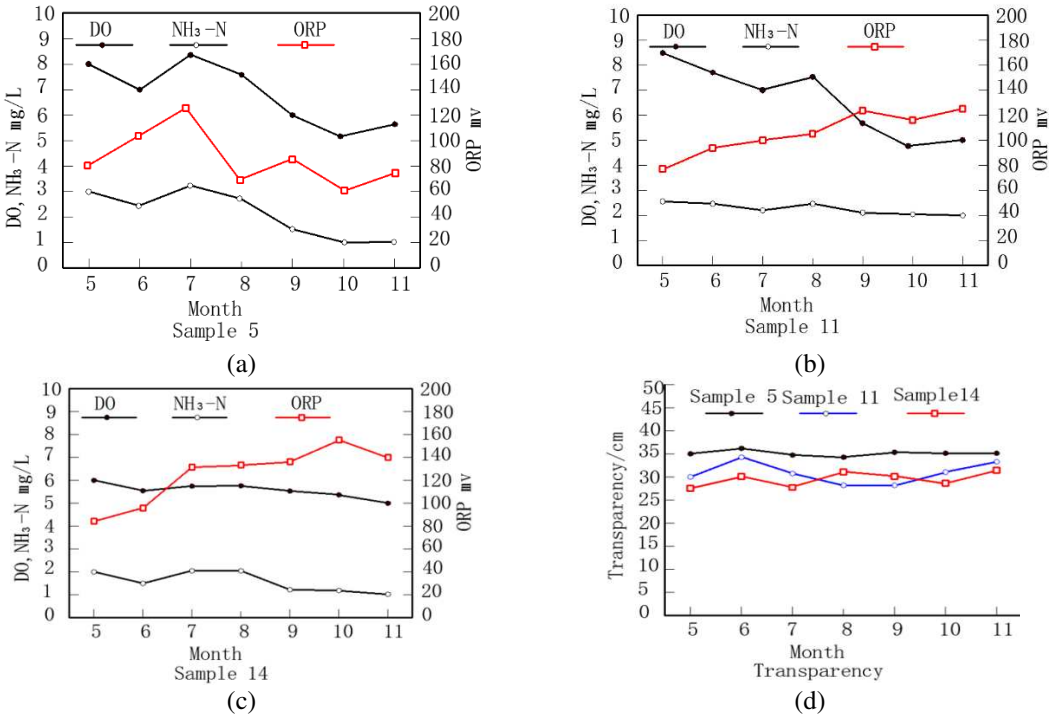

Figure 5. *Analysis results on water sample quality*

Conclusions

This paper monitors and analyzes the surface water and sediments in the DXK River basin, and discovers that the water bodies mainly suffer from aerobic pollution, with COD and NH3-N being the primary pollutants. Agricultural non-point source pollution accounts for 70% of the pollution load, and scattered discharge of rural sewage accounts for 5% of the pollution load, which is the main source of water pollution.

Considering the main causes of the pollution, the author put forward an integrated pollution control plan for the basin focusing on pollutant interception, source control, and ecological construction.

Removing the sediment and garbage from the river can reduce COD, NH3-N and other indicators in the river by nearly 50%. The immobilized microbial agent was used to remove NH_3-N and COD in black and odorous waterbody. The construction of wetland park, the ponds in the basin were expanded into a pond-wetland system, can significantly reduce NH_3-N and COD.

After the treatment, the DO values at all sampling points were greater than 2 mg/L, the NH_3-N values were all smaller than 8 mg/L and the water transparencies were all above 25 cm, indicating that the river is no longer black or odorous. The implementation of the entire plan costs USD 3.47×10^8. The research findings shed important new lights on pollution control in other rivers across China.

Also suggested that the basin water pollution comprehensive treatment to pollution load distribution in the process, on the one hand, it can realize basin within the scope of reasonable layout and the load sharing ratio of the control area, on the other hand, within the scope of the basin can be unequal distribution of technical and economic investment, implement the specific implementation of total amount control load index, the governance effect is better.

(Received 7th Jun 2019; accepted 10th Oct 2019)

Abstract. Increasing concern about carbon emission reduction demands knowledge on the industrial structure of carbon linkages in an economy. Based on sectorial input-output analysis and network analysis, this paper develops a combined method to construct the industrial network of carbon correlation (INCC) serving as an essential tool to provide insight about carbon emission transfer and emission responsibility. Using China's 2005, 2010 and 2015 Input-Output Tables and China Energy Statistical Yearbook, China's INCCs under the transition period were constructed and the relationship structures were analyzed. Research shows that carbon emission has a decreasing trend as a whole in the transition period in China. The main consumer responsibility sectors and the critical emission transfer paths were identified to provide the analysis basis for decision makers and planners in industrial carbon management. In addition, the industry group analysis provided useful analytical techniques for carbon emission reduction policies.

Keywords: *Weaver-Thomas index, carbon correlation coefficient, CO_2 emission reduction, carbon transfer path, carbon cycle correlation*

Introduction

Concerns over climate and environment makes the public more and more aware of the problem of greenhouse gas emissions most of which is in the form of carbon dioxide. China is currently the world's largest emitter of carbon dioxide (Lin and Sun, 2010). So the production sectors in China (including electric power production and metal smelting) became the first the focus of emission reduction. The fact that the production sectors received more attention was warranted due to the fact that these sectors account for more than half of the total carbon emissions. (Sonis et al., 1995). However, further analysis shows that carbon emissions from an industrial sector include not only direct emissions, but also indirect emissions (Chang, 2015). Some consumption sectors which have less direct emissions have a higher carbon responsibility because of their intermediate inputs, including various equipment and services. However, people pay less attention to them just because the direct emission is small (Zhang et al., 2017).

Production cannot be separated from consumption. Consumption sectors cannot be excluded to committing carbon emissions responsibilities because of their required massive intermediate inputs. As we know, industrial linkages among varied sectors can be explored by the Input-Output Table. So, Input-Output analysis is a good perspective to describe industrial linkages. Scholars (Chang and Lin, 1998; Machado et al., 2001; Labandeira and Labeaga, 2002; Jain and Gupta, 2019; Xu et al., 2019; Kaivo-oja and Luukkanen, 2004; Tahara et al., 2005; Mongelli et al., 2006; Lixon et al., 2008; Lin and Sun, 2010; Seppälä et al., 2011; Brown et al., 2012; Cadarso et al., 2012) have taken

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1448714503

advantage of Input-Output of various countries or cities to track Carbon footprint. Most of their works in early discussions have found that the production sectors (such as electric power production and metal smelting) were the focus of emission reduction. Their works also established some important linkages between vary sectors, making understructure for emission responsibility and assessment in economic structures. Later, scholars gradually realized that industrial linkages would shift the responsibility of carbon emissions among the industrial sectors (Egilmez et al., 2013; Mózner, 2013; Arto et al., 2014). So we cannot explore low-carbon development in the isolated production sectors. Carbon metabolic (Baccini, 1996; Chen and Chen, 2012; Zhang et al., 2014; Wu et al., 2016; Zhang Du and Wang, 2018; Zhang et al., 2018) is then raised to investigate carbon flow and carbon transfer in social economic system. Most of these works were based on international trades and the primary target was to find the discharging countries and districts. However, carbon flows within different sub-systems or sectors were scare (Zhao et al., 2014; Zhang et al., 2018).

Carbon related responsibility can be divided into two parties, emission responsibility and requirement responsibility. In most of the study of CO_2 emission problems, the direct emission factors are targeted and some main factors can be found by the Factor Decomposition Method. In view of indirect factors of carbon emissions, Structural Decomposition Method is used to study the issue of carbon emission reduction. Most of the researchers pay close attention to emission responsibility and the potential methods of reduction of high carbon emission sectors. These studies enrich the carbon emission theory and provide a reference for carbon emission reduction from the view of emission responsibility. However, existing literatures have not analyzed the main requirement responsibility of carbon emissions, this is to say, which sectors' requirement lead to the increase of emission responsibilities, and in which path industrial sectors are transmitting these responsibilities.

Network is often used to express the nodes and the relationships in group study. Analyzing network structure can excavate the deep inner structure relationships among individuals. Defining the industrial network of carbon correlation (INCC) needs to clarify all kinds of sector structures and their effects. The INCC consists of the high carbon emission sectors and some closely related consumption sectors. According to the comprehensive analysis of the INCC, we can determine which sectors are the high carbon emission sectors and which sectors are committed directly or indirectly requirement responsibilities. We can also determine which linkages are the primary transmission paths and which industrial sectors have grouped together in carbon emissions. The clarity of these problems provides the basis for adjusting policy for better developing industrial correlation structure and constructing low carbon industrial system.

This paper firstly analyzes the carbon relationships among industrial sectors, defining the concept and calculation method of industrial carbon correlation coefficient. Secondly, regarding industrial sector as node and carbon relationship as edge, this paper designs the method of constructing INCC. Thirdly, based on the Input-Output Table and the Energy Statistic Yearbook of China in 2005, 2010 and 2015, this paper constructs and analyzes the INCCs of China. Finally, through the paths and sub-graphs analysis, the main carbon emission responsibility sectors and consumption responsibility sectors are identified for industrial reduction management.

Materials and methods

Analysis of the carbon correlation between industrial sectors

As we all know, production process often release CO_2 directly by burning fossil fuels. An industrial sector requires a variety of intermediate inputs which probably emit a lot of CO_2 in their production processes. Therefore, the production activities of an industrial sector often lead to other sectors emitting CO_2 by intermediate demand. When sector *i* supplies intermediate products to sector *j*, sector *i* transfers CO_2 emissions responsibility to sector *j*, and these two sectors form a carbon linkage due to industrial linkage. Similarly, sector *j* may establish a carbon linkage with sector *k*. In this way, the industrial sectors in a region have formed carbon correlations due to industrial linkages, which lead to a network of industrial sectors, i.e., the industrial network of carbon correlation (INCC). According to INCC, the main responsible sectors for CO_2 emission and the path of responsibility transmission can be identified, which provide the basis for CO_2 emission reduction.

From the view of investment, the production of an industrial sector *i* requires various intermediate inputs from multiple sectors, which emit CO_2 directly in producing these inputs. All of the CO_2 emitted directly by those inputs is caused by the sector *i*, so the requirement responsibility should be attributed to sector *i*. From the view of distribution, the products of sector *i* can be divided into two parts, one part as intermediate inputs for other sectors, and the other as final product. The emission responsibility of sector *i* should also transfer to demand sectors or final consumers with product distribution. When sector *j* demands the product of sector *i* which discharges CO_2, it is considered that sector *i* transfer emission responsibility to sector *j*, so there is a carbon correlation between sector *i* and sector *j*.

In order to express the carbon correlation between industrial sectors, we define the industrial carbon correlation coefficient as: To manufacture one unit product of sector *j* need to be directly invested in a certain number products of sector *i*, the direct CO_2 emission quantity of sector *i* in producing such products is called the carbon correlation coefficient of sector *i* to sector *j*. The greater the coefficient, the higher is the carbon correlation strength between these two sectors. Obviously, when the amount of utilization from sector *i* to sector *j* increases, the industrial carbon correlation coefficient c_{ij} increases. Also, when the amount of CO_2 produced in one unit by sector *i* increases, c_{ij} increases, so

$$c_{ij} = d_i \times a_{ij} \quad \text{(Eq.1)}$$

In *Equation 1,* a_{ij} is the direct consumption coefficient of sector *j* from sector *i*; d_i is the CO_2 amount directly discharged from sector *i* for one unit.

We assume that *C* is the carbon correlation coefficient matrix, *A* represents the direct consumption coefficient matrix, and *D* is generated by the diagonal matrix d_i. So,

$$C = DA \quad \text{(Eq.2)}$$

In *Equation 1,* the direct consumption coefficient a_{ij} can be calculated from the Input-Output table. The emission amount per unit in production of sector *i*, i.e., d_i can be calculated by combining the Energy Statistical Yearbook with the Input-Output Table according to the following method.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1448714503

In order to calculate d_i, it is necessary to calculate the total amount of CO_2 emitting directly from this sector. Direct emission CO_2 from an industrial sector occurs at the stage of burning fossil fuels, in which fossil fuels contain three primary energy sources (coal, crude oil and natural gas) and five secondary energy sources (coke, gasoline, kerosene, diesel, fuel oil). So the direct emissions of each industrial sector can be calculated according to the consumption of fossil fuels. For the non-secondary petrochemical energy conversion sector i, the total direct emissions CO_2 from the production process are the total emissions CO_2 from the consumption of various fossil fuels. Let it be D_i, then

$$D_i = \sum_{s=1}^{8} u_s(i) \times e_s \quad \text{(Eq.3)}$$

In the *Equation 3,* $u_s(i)$ is the total amount of energy s consumed by sector i, and e_s is the CO_2 emission coefficient of energy s.

Unlike the general sector, petroleum processing, coking and nuclear fuel processing consume primary energy for obtaining secondary energy. In those productive process most of the primary energy has not changed to CO_2, but has been transformed into secondary energy. However, the CO_2 emissions from the secondary energy burning have already been taken into respective user sector. Therefore, in calculating the direct CO_2 emission of petroleum processing, coking and nuclear fuel processing sectors, it is necessary to use *Equation 1* to subtract the secondary fuels CO_2 produced by them.

From the total output of each industrial sector and the total amount of CO_2 emissions, we can calculate the amount d_i of CO_2 emissions per unit in sector i. Let the total output of sector i be X_i and the total direct CO_2 emission be D_i, the unit output of sector i is calculated by *Equation 4:*

$$d_i = D_i / X_i \quad \text{(Eq.4)}$$

Construction of industrial network of carbon correlation

The industrial network is a directed graph constructed by the industrial sectors and the relationships between these sectors. This graph can describe the structure of industrial sectors, revealing characteristics and laws of industrial correlation. Similarly, the INCC takes the industrial sector as the vertex and the inter-departmental carbon correlation as the edge to construct a directed graph to reveal characteristics of a given industrial carbon correlation. There are many ways to build industrial networks (Wang and Yang, 2015; Yan et al., 2017; Zhao and Yang, 2016). Here we use Weaver-Thomas index to calculate the threshold and build INCCs.

The production of an industrial sector requires different inputs from multiple sectors which vary greatly in CO_2 emitting in manufacturing process. In order to find the main carbon linkages among industrial sectors, it is necessary to find the inflection point as the critical value from many carbon correlation coefficients. When the carbon correlation coefficient between the two sectors is greater than the critical value, it is considered that there exists a carbon linkage between them; otherwise there is no carbon linkage. By this way, The Weaver-Thomas index can find the key connections. So, we calculate the Weaver-Thomas index for building INCCs.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1448714503

By comparing the observed distribution with the hypothetical distribution, the best fitting approximate distribution is established to identify the key elements in the numerical sequence. For the industry including n sectors, c_{ij} is the carbon correlation coefficient of sector j to sector i. If we arrange the carbon correlation coefficients c_{1j}, c_{2j}, ..., c_{nj} from the large to the small for sector j, the Weaver-Thomas index of sector i is:

$$w(i,j)=\sum_{i=1}^{n}\left[s(k,i)-100\times\frac{c_{kj}}{\sum_{l=1}^{n}c_{lj}}\right]^2 \quad \text{(Eq.5)}$$

Here, $s(k,i)=\begin{cases}100/i,(k\le i)\\ 0,(k>i)\end{cases}$.

Now we set, $k=\min\{w(1,j),w(2,j),\cdots,w(n,j)\}$.

So, the corresponding coefficient c_{kj} of sector j is the critical value of sector k.

By calculating the Weaver-Thomas index of each sector, we can obtain n independent critical values. If the carbon correlation coefficient between two sectors is greater than the critical value, it means that here exists a carbon correlation edge, and the corresponding element in the adjacency matrix is 1. Otherwise, it means that there is no correlation edge, and the corresponding element in the adjacency matrix is 0. Similar to the industrial network, the INCC focuses on the correlation among various sectors and not the ring in the network, so the diagonal element of the adjacency matrix is set to 0.

Analysis and expansion of INCC

The INCC describes the carbon linkages between various industrial sectors. When there is a directed edge from sector i to sector j in an INCC, sector i emits CO_2 by providing input for sector j. It also can be considered that sector i transfers CO_2 emission responsibility to sector j at the same time. This transmission make sector j taking on more carbon emission requirement responsibility, as shown in *Figure 1a.* When there is no directed edge from sector i to sector j, sector i does not have CO_2 emission responsibility transmitted directly to sector j. However, it is possible there existing a directed path in the INCC, such as, sector i passes to other sectors (e.g., sector l, k, *etc.*), which in turn passes to sector j. Like this, there is an indirect carbon correlation between sector i and sector j, as shown in *Figure 1b.*

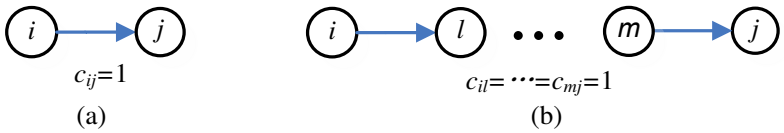

Figure 1. *A directed edge and a directed path in an INCC*

If all the directed edges and paths in an INCC are connected along the directed road, the extended INCC can be obtained. The degree of vertices in the extended INCC reflects the number of all other sectors linked with a sector, including direct and indirect linages. The in-degree of a sector reflects its degree of accepted requirement responsibility. When an in-degree of a sector is large, it means many sectors

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1448714503

transmitting CO_2 emission responsibility to this sector. It is a recipient and a major consumer responsibility sector. Out-degree reflects the degree of a sector transmitting emission responsibility. When an out-degree of a sector is large, it means that it is a main sector of emission responsibility source.

China's industrial network of carbon correlations (INCCs)

According to the Input-Output Table and the Statistical Yearbook of China in 2005, 2010 and 2015, we construct China INCCs for these three years. For facilitating comparison, the Input-Output Tables of each year and the division of sectors in the Energy Statistics Yearbook are unified, in which some industrial sectors are merged. In the Input-Output Table of 2015, "general equipment" and "professional equipment" are divided into two, while in the other two years they are unified, so we merged them. In the Input-Output Tables in 2005 and 2015, "other manufacturing" and "waste scrap" are two sectors, while in the Table of 2010 these two sectors are one, so they are merged. In the Statistical Yearbook, "transportation, warehousing and postal", "wholesale, retail and accommodation, catering" and "other industries" are combined to one into correspondence with the Input-Output Table. The correspondence between the specific industrial sector and the code is shown in *Table 1*.

Table 1. *Industry sectors and codes after merger*

Code	Industrial sector	Code	Industrial sector
1	Agriculture, forestry, animal husbandry and fishery	15	Metal products sector
2	Coal mining and washing sector	16	General purpose and special equipment manufacturing sector
3	Petroleum and natural gas extraction sector	17	Transportation equipment manufacturing sector
4	Metal mining sector	18	Electrical machinery and equipment manufacturing sector
5	Nonmetallic ores and other mining and mineral processing sectors	19	Communications equipment, computers and other electronic equipment manufacturing sector
6	Food manufacturing and tobacco processing sector	20	Instrumentation and cultural office machinery manufacturing sector
7	Textile sector	21	Crafts and other manufacturing sectors (including waste products)
8	Textile, clothing, shoes, hats, leather, feather and its products sector	22	Production and supply of electricity and heat
9	Wood processing and furniture manufacturing	23	Gas production and supply sector
10	Paper making, printing, cultural, educational, sporting goods manufacturing	24	Water production and supply
11	Petroleum processing, coking and nuclear fuel processing sector	25	Construction business
12	Chemical sector	26	Transportation, storage and post
13	Nonmetallic mineral products industry	27	Wholesale, retail, accommodation and catering sectors
14	Metal smelting and calendering processing sector	28	Other sectors

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1448714503

According to the second part of the analysis and *Equations 1-4,* the correlation coefficient of INCCs is calculated. According to the third part of the modeling method, we build China's INCCs and the extended INCCs.

Results

Correlation coefficient analysis of INCCs

According to *Equations 1-4,* the industrial carbon correlation coefficients among different sectors in China' INCCs in 2005, 2010 and 2015 are calculated. The number of correlation edges in these three years 85, 76 and 83 were found significant respectively of all the 784 linkages, which means about 10% (10.8%, 9.7% and 10.6%) of the linkages pass the critical values. The top 30 in each year are listed in *Table 2*.

Table 2. *China's top 30 INCC coefficients in 2005, 2010 and 2015*

DOI: http://dx.doi.org/10.15666/aeer/1706_1448714503

We can see from *Table 2,* in these three years of China's transition period the correlation coefficients rise in the first and then decline. The means of carbon correlation coefficients of the top 5, 12, and 30 in also show this trend. In 2010 the coefficient is the highest, indicating that carbon emissions may reach a high peak during this period (*Fig. 2*). This is in line with the accelerated investment of Chinese traditional industries in this period. In 2005 the coefficient is in the second place, maybe because the quantities of various industrial outputs were not so vast. After 2010, the carbon correlation coefficients show a decreasing trend from 2010 to 2015, indicating dynamic energy conversion of economic development may be acting up. To further and more comprehensive observe this trend, the first 50 carbon correlation coefficients are represented in *Figure 3*.

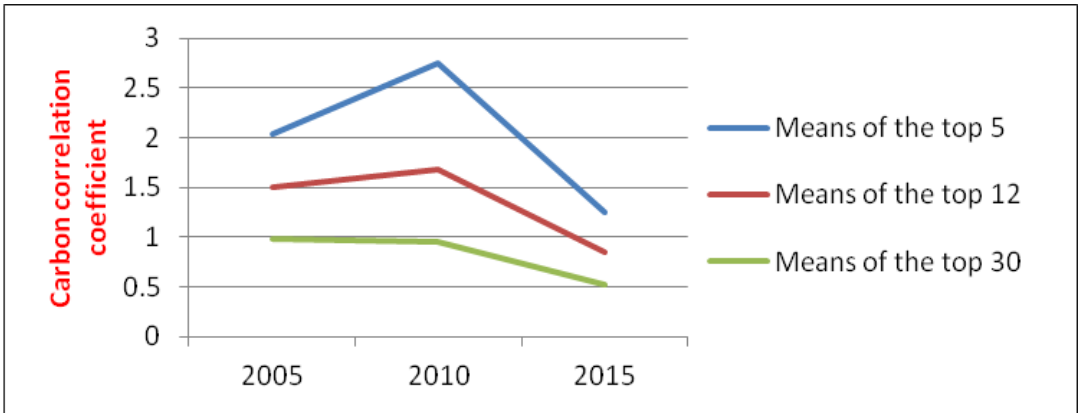

Figure 2. *The means of INCC coefficients in China in 2005, 2010 and 2015*

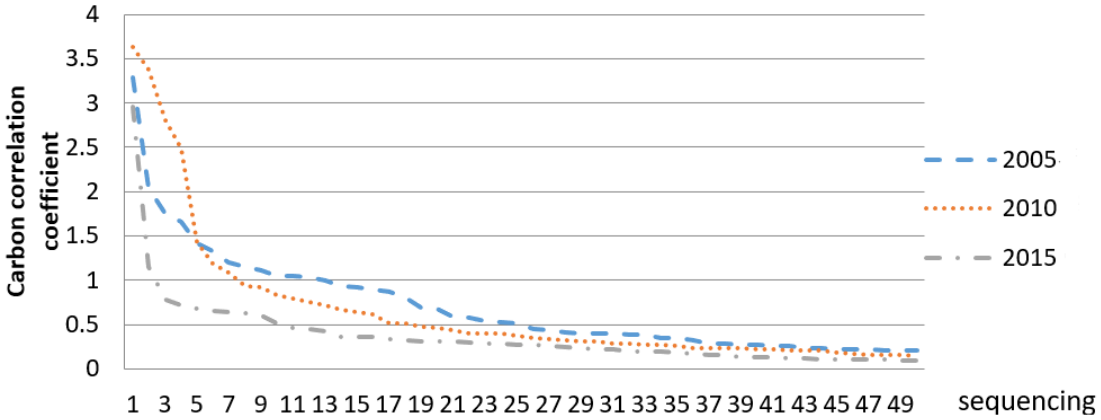

Figure 3. *The top 50 INCC coefficients in China in 2005, 2010 and 2015*

In each year of these transition periods, these carbon correlation coefficients show the same unbalanced state, which is the power law distribution. Among the significant coefficients which were though tested, only a few coefficients were higher, and most of them were lower. Further analysis of *Table 2* and *Figure 3* shows that in the first 50 carbon correlation coefficients, the main direct emission sector possessing the highest coefficients is the production and supply of electricity and heat (22), possessing 13, 11 and 13 edges in each year, nearly half of the highest carbon emission coefficients

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1448714503

coming from this sector. The main indirect discharging sectors possessing the highest coefficients are water production and supply (24), metal mining and dressing, and electricity (4) and thermal production and supply (22), which emit a lot of carbon by using products from other sectors.

Analysis of China's INCCs

Analyzing the structural characteristics can excavate the intrinsic characteristics of carbon linkages among China's various industrial sectors. The basic statistical characteristics of China's INCCs in 2005, 2010 and 2015 are shown in *Table 3*. It is particularly interesting that, contrary to correlation coefficients trend, significant edge numbers decline in the first and then rise. In 2010, there were 76 linkages, less than 85 linages in 2005 and 83 linages in 2015. Why the carbon correlation coefficients becoming greater and the significant numbers becoming less happened at the same time in 2010? Further analysis shows that this was probably related to China's large-scale investment into some special industries in 2008.

Table 3. *Basic characteristics of China' INCCs in 2005, 2010 and 2015*

	Significant numbers	**Self-circulation sectors numbers**	**Sector numbers with more than 5 in-degrees**	**Sector numbers with 0 out-degree**	**Sectors of the top five out-degree**
2005	85	9	3	16	22, 11, 12, 14, 13
2010	76	8	3	16	22, 11, 12, 14, 26
2015	83	10	1	14	22, 11, 12, 14, 26

We can see there were existing 9, 8 and 10 sectors with self-recycling in these three years, that is, nearly one-third of the industrial sectors possess self-recycling carbon emissions. So, self-circulation problem in INCCs were prominent. We have also noticed that there were 7 sectors (6, 7, 10, 12, 13, 14, 22) always possessing self-recycling in these three years and there were 2 sectors (2, 11) possessing self-recycling in these two years. So most self-recycling sectors have always kept stable. About half of the sectors (16, 16 and 14 in these three years) having zero out-degree show that these sectors do not transmit emission responsibility to other sectors. They just accept carbon transmission to them and become carbon consumption sectors. These sectors are not "innocent". It is just because of their requirements that the carbon emission sector excludes a large amount of carbon, so they should bear the responsibility of carbon transfer. We have listed the sector numbers with more than 5 in-degrees for a special purpose. They were sector 8, 9 and 21 in 2005, sector 6, 8 and 20 in 2010, and sector 20 in 2015. High in-degree means these sectors bear more responsibility of carbon transfer. And the sectors with more than 5 in-degrees changed from sector 8, 9 and 21 in 2005 to sector 6, 8 and 20 in 2010 and to sector 20 in 2015. The sectors had changed considerably during this transition period. Contrary to the sectors with more in-degrees, the sectors of the top five out-degrees had remained broadly consistent over the past ten years. Sector 22, 11, 12 and 14 maintained the top four in these three interval years, and the order remained unchanged. Only the fifth changed from sector 13 in 2005 to sector 26 in 2010 and 2015. From the perceptive of in-degree and out-degree, there were typical star nodes and strong sub-graphs in China's INCC graphs of these three years. The INCC graphs of these three years are shown in *Figure 4*.

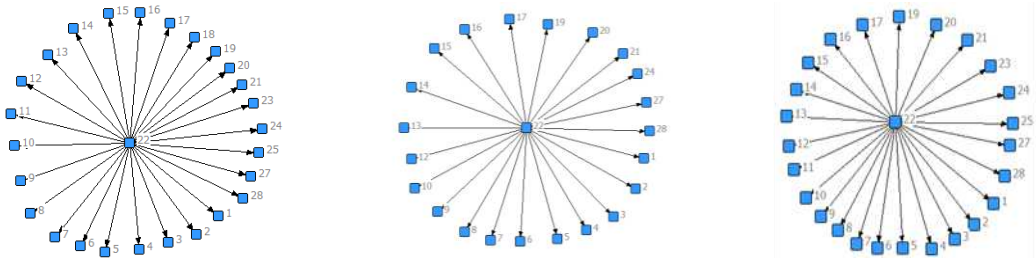
Star node sector in INCC

Out-degree star topology

As shown in *Figure 4,* there is a common prominent feature in these three network diagrams. Each network diagram has showed 4 or 5 star topologies, in which node sectors transmit emission responsibility to other sectors, as presented in *Figure 4.* According to the number of out-degree, the same top four sectors, namely, power, thermal production and supply (22), petroleum processing, coking and nuclear fuel processing (11), chemical sector (12) and metallurgical smelting and calendaring (14), have constructed a sub-network with maximum out-degree of 27 and minimum out-degree of 10 in these three years. The non-metallic mineral products sector (13) ranked fifth in 2005, with an out-degree of 9, falling to 4 in 2010 and 2015. At the same time, transportation, storage and postal service (26) increased from 3 in 2005 to 5 in 2010 and 2015. It can be seen that these sectors were the main emission sectors and that they pass the emission responsibility to other sectors through industrial linkages. *Figure 5* showed the carbon emission sub-graphs of electricity and thermal production and supply (22) in these three years. Almost all connections to 22 passed the significant test.

It is of great significance to study the sub-network which constructed by the emission sectors and their consumption sectors. As the cores of these sub-networks, these sectors act as responsibility transfer source and have immediately responsibility for carbon emission. For these sub-networks, the most important thing is controlling key nodes. Although the utilization efficiency of fossil fuels, such as in electricity and thermal production and supply, is an old problem, it is also a common problem. Research and development of common technologies for carbon emission reduction is the management emphasis of out-degree star topology.



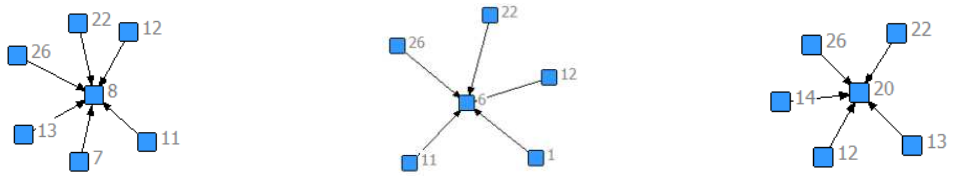
(a) 2005 (b) 2010 (c) 2015

Figure 5. *Carbon emission sub-graphs of electricity and thermal production and supply (22). (Please refer to Table 1 for the meanings of the sector numbers in the figure)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1448714503

In-degree star topology

Different from the out-degree star topology, the in-degree star topology have smaller degrees, the maximum in-degree being 6, and a few sectors being 4, 5 or 6. Since the beginning of the 21st century, China's economic growth mode has changed from extensive to intensive, and the focus of economic development has gradually shifted from textile manufacturing, food manufacturing to machinery manufacturing. The development of key industries requires many other sectors' products, resulting in Changes in the in-degree star node sector. The largest in-degree sectors in 2005, 2010 and 2015 were respectively Textile, clothing, shoes, hats, leather, feather and its products industry (8), Food manufacturing and tobacco processing industry (6) and Instrumentation and cultural office machinery manufacturing industry (20), as shown in *Figure 6*. These sectors do not necessarily emit a lot of carbon in the process of producing their own products. However, these sectors have to bear indirect carbon responsibility because they receive products from other sectors that emit a lot of carbon in manufacturing process. Careful analysis of these three sectors in *Figure 6* shows that these three highest in-degree sectors all receive carbon emissions from electricity, thermal production and supply sectors (22), chemical sector (12) and transportation, warehousing and postal services (26).



(a) sector 8 in 2005 (b) sector 6 in 2010 (c) sector 20 in 2015

Figure 6. *Carbon emissions graphs of the in-degree star node sector. (Please refer to Table 1 for the meanings of the sector numbers in the figure)*

The research about in-degree star topology is a meaningful job that few scholars have done before. First of all, we can identify the main demand responsibility sectors, which define the transfer destination of carbon emissions from the demand side. From the perspective of the social responsibility system, the complete responsibility system of carbon emissions needs perfecting analysis from both demand side and supply side. Secondly, study about in-degree star topology lays the foundation for the construction of carbon supply chain network. Carbon emissions from the demand side and the supply side can constitute a complete chain network. Thirdly, from the perspective of management regulation, In the formulation of industrial policies on carbon emissions, besides strengthening the supervision of direct carbon emission sectors, we also need to strengthen the management and control of more carbon receiving sectors.

Carbon cycle correlation in INCC

Further analysis of China's INCCs of each year reveals that there is a cyclic structure among industrial sectors. Among this cycle, the first sector provides significant carbon emissions for the second sector, while the second sector provides significant carbon emissions for the first sector directly or by other(s). Those sectors and these significant linkages form a cycle which expands the role of individual sector in carbon emissions.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1448714503

We can see from these three years, the cycles always embraced petroleum and natural gas extraction sector (3) and petroleum processing, coking and nuclear fuel processing sector (11). The difference was, these two sectors interflowed through production and supply of electricity and heat (22) in 2005, while in 2010 and 2015 these two sectors directly formed the main body of mutual carbon consumption. However, due to the sparse linkages in China's INCCs and the existence of typical star node sectors, there are not many sectors entering the circular structure, as shown in *Figure 7*.

(a) In 2005 (b) In 2010 and 2015

Figure 7. *Industry carbon cycle structure. (Please refer to Table 1 for the meanings of the sector numbers in the figure)*

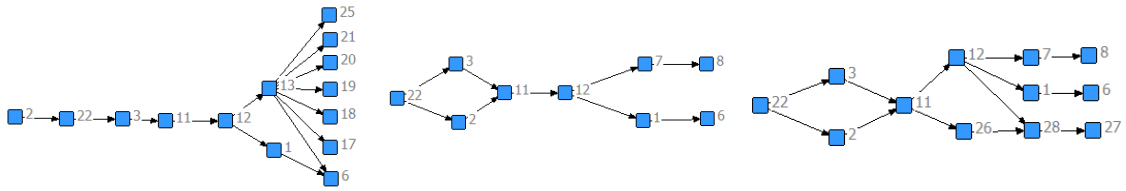
Although the structure of carbon correlation cycle among industrial sectors is rare, self-cycling exists in many sectors. There were respectively nine, eight and ten sectors with self-cycling correlations of carbon emissions in 2005, 2010 and 2015. There are seven common industrial sectors in these three years, namely, food manufacturing and tobacco processing (6), textile (7), paper making, printing, cultural, educational, sporting goods manufacturing (10), chemical (12), nonmetallic mineral products (13), metal smelting and calendering processing (14), production and supply of electricity and heat (22). It can be seen that these sectors bear significant carbon emission responsibility because of the use of products in their own sectors.

Both the circular structures and self-cycling sectors in INCC deserve great attention. Because these sectors related these bidirectional overflow structures are always establishing high carbon driving force in INCCs, including propulsive force and pulling force. Finding these micro-structures and self-circulation within and outside the sectors can help us to explore the carbon trajectory in a more subtle way. These studies also contribute to the construction of industrial balance and carbon ecosystem.

Carbon emission transmission path

The directed path in the INCCs shows the transmission path of carbon emission responsibility. In one path, the starting sector transfers the carbon emission responsibility to the intermediate sectors, while the intermediate acts as a transmitter and the terminal sector receives the responsibility from multiple sectors through multi-step transmission. As shown in *Figure 8,* in 2005 the longest carbon transmission path consists of six steps: 2→22→3→11→12→1(13)→6(17\18\19\20\21\25). In 2010, the longest carbon transport path is five steps: 22→3(2)→11→12→1(7)→6(8). In 2015, the longest carbon transmission path is also five steps, but there are two main paths: 22→3(2)→11→12(26)→17(28)→6(8\27). In 2005 the carbon emission transmission paths were longer and wider than in 2010 and 2015. Sector 13 (nonmetallic mineral products) has greatly broadened the width of the path. The transmission paths in 2010 and 2015 are similar, but the transmission paths in 2015 are more complex, adding some new branches and connections.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1448714503



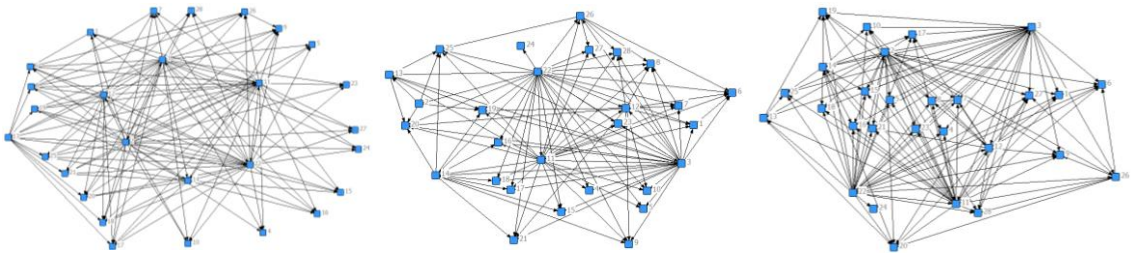
(a) In 2005 (b) In 2010 (c) In 2015

Figure 8. *Carbon emission transmission path. (Please refer to Table 1 for the meanings of the sector numbers in the figure)*

Path study not only emphasizes the source and destination of carbon emissions, but also emphasizes the role of "bridge" and "intermediary". Some sectors, such as sector 3 (Petroleum and natural gas extraction sector), sector 11(petroleum processing, coking and nuclear fuel processing sector) and sector 12(chemical), undertakes a strong channel role. They digest and absorb products that contain large amounts of carbon emissions, and transfer products that emit large amounts of carbon to other sectors.

Analysis of extended INCC

According to previous defining, we can also build three extended INCCs diagrams for these three years, as shown in *Figure 9*. As we know, in these extended INCCs, all the directed edges and paths are connected along the directed road. Directed edges are connected between two nodes with paths in the extended INCC graph. That is to say, if only there is a carbon transmission responsibility between two sectors, there is a linkage. Therefore, the significance of node degree in the extended INCC graph is more obvious. The degree of a vertice in the extended INCC reflects the number of all other sectors linked with the sector, including direct and indirect linages. So the degree of a sector in the extended INCC can be more comprehensively demonstrated the carbon linkages.



2005 2010 2015

Figure 9. *China's extended INCC in 2005\2010\2015 (Please refer to Table 1 for the meanings of the sector numbers in the figure)*

Out-degree in the extended INCCs reflects the overall emission responsibility of a sector transmitting to others. When an out-degree of a sector is large, it means that it is a main sector of emission responsibility source. As shown in *Figure 9* in the extended INCC in 2005, there were four sectors (2, 3, 11 and 22) which possess 28 out-degrees, which can transmit carbon emission responsibilities to all other sectors. In the extended INCCs in 2010 and 2015, there were four sectors possessing more than 25-outdegree

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1448714503

(sector 2, 3, 11 having 25, sector 22 having 27), which can transmit carbon emission responsibility to almost all other sectors. We contrast the extended INCCs and the customary INCCs, discovering sector 2 and 3 is the hidden emission source.

The in-degree in the extended INCCs reflects its overall accepted requirement responsibility of a sector. When an in-degree of a sector is large, it means many sectors transmitting CO_2 emission responsibility by varied paths to this sector. It is a recipient and a major consumer responsibility sector. In all industrial sectors of three years, the largest in-degree was 7. these sectors are food manufacturing and tobacco processing (6), textile, clothing, shoes, hats, leather, feather and its products (8), wood processing and furniture manufacturing (9), communications equipment, computers and other electronic equipment manufacturing (19) and instrumentation and cultural office machinery manufacturing industry (20). It can be seen that these sectors accept carbon emission responsibilities directly or indirectly from 7 sectors. We contrast the large in-degree sectors in the extended INCCs and the customary INCCs, finding that little change is found and the carbon consumption sectors sustain stable.

Discussion

Based on Weaver-Thomas index, we combine sectorial input-output analysis and network analysis to construct the industrial network of carbon correlation (INCC) for carbon emission management. We also use the data of China's 2005, 2010 and 2015 to analysis the developmental trajectories of transition period. The contribution of this paper lies in the following.

On the theoretical side, we apply network analysis to the carbon correlation study, and the carbon flow laws among industrial sectors are sorted out as a whole. Carbon correlations have formed transmission responsibilities of carbon emission between industrial sectors. We use Industrial Carbon Correlation Coefficient to describe the amount of carbon directly emitted by an industry sector in producing a unit product for another sector. The greater the coefficient, the stronger is the carbon correlation between these two sectors. Base on Industrial Carbon Correlation Coefficient, we construct INCC which is a directed graph among various industrial sectors, to describe the transmission structure of carbon emission responsibilities among industrial sectors. Constructing a national or regional INCC and analyzing the structural characteristics of the network can excavate the characteristics of carbon emissions among these national or regional industrial sectors, thus providing an analytical basis for emission reduction and other decisions.

On the practical side, we use the INCCs to find that there are typical significantly characteristics in China's INCC graphs of this transition period. First, in recent years, the carbon correlation coefficient of the same ranking has become smaller, in which 2015 is almost half of 2005. It can be seen that with the development of societies, emission reduction has been gained more effective. Secondly, these three years' INCCs indicate that there are relatively sparse significant carbon correlations between sectors and there are obvious star nodes in the INCC graphs. Star nodes are divided into out-degree type and in-degree type. As for the out-degree node, we can see that these sectors are relatively unified, and that the most prominent is the power and thermal production and supply sectors which transmit emission responsibility to almost all other sectors. Most of transmissions are direct, while some are indirect. The following sectors are petroleum processing, coking and nuclear fuel processing (11), chemical (12) and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1448714503

metal smelting and calendering (14). As for in-degree node type, more than half of all industrial sectors are in-degree nodes which only accept emissions responsibility from other sectors. The maximum in-degree sectors are food manufacturing and tobacco processing (6), textile, clothing, shoes, hats, leather, feather and its products (8), and instrumentation and cultural office machinery manufacturing sector (20). Third, there are only a few correlation cycles among transmission responsibility which involve fewer sectors in INCCs. We can see that there is only but always a cycle in the three INCCs between petroleum and natural gas extraction sector (3) and petroleum processing, coking and nuclear fuel processing sector (11). Fourth, the path in these INCCs are not very long, only 5-6 steps. There is a stable carbon emission path in the three INCCs. That is, the production and supply of electricity and heat (22) → oil and natural gas extraction (3) → oil processing, coking and nuclear fuel processing (11) → chemical (12) → agriculture, forestry, animal husbandry and fishery (1) → food manufacturing and tobacco processing (6).

The EU's carbon trading system is a leader in the global carbon trading market, and in January 2005, the EU officially launched the Greenhouse Gas Emissions Trading System (EUETS), it is the world's first greenhouse gas emissions quota trading market, using the "total limit and trading" rule. New Zealand and Australia are actively promoting the carbon trading market, New Zealand introduced mandatory carbon trading in 2008 in a step-by-step approach, Australia is one of the first countries in the world to implement mandatory greenhouse gas reduction programmes, and on July 1, 2012, Australia began implementing carbon trading nationwide.

Conclusions

In order to reduce greenhouse gas emissions such as CO_2, different measures should be taken for different sectors. As the research reveals, the industrial carbon correlation coefficient between sectors is not only related to the direct input between sectors, but also related to the carbon emissions per unit. For the main out-degree sectors, such as power, thermal production and supply industries, relevant measures should be taken to reduce their direct CO_2 emissions, such as reducing thermal power and increasing other forms of electricity, promoting the use of geothermal, improving energy conversion rate and so on. For the main in-degree sectors, the important ways to reduce CO_2 emissions are taking measures to change the proportion of their inputs, reducing the demand of high carbon emission sectors, and trying to reduce the final demand for these products. As circle can enlarge carbon emissions, changing one or two linkages in this circle can greatly reduce carbon emissions. For long transmission paths, reducing their length can cut down carbon emissions for the whole system. In overall, Discussions about correlations, key sectors and paths allow us to look deeply into the internal productive linkages within an economy with implications for CO_2 emission. They provide valuable information for planners and decision makers in formulating feasible and practical industrial polices with implications for CO_2 emissions.

In the future research, we should focus on how to reduce the direct carbon emission and interrupt the correlation of carbon emission between sectors, so as to achieve the goal of energy conservation and emission reduction. How to reduce carbon dioxide emissions from industrial sector units into products; How to accurately position the responsibility of carbon emission, and can give relevant solutions.

ANALYSIS TECHNOLOGY OF ENVIRONMENTAL MONITORING DATA BASED ON INTERNET OF THINGS ENVIRONMENT AND IMPROVED NEURAL NETWORK ALGORITHM

ZHAI, W.

Xi'an Aeronautical University, Xi'an 710077, China
(e-mail: 2587842805@qq.com)

(Received 7th Jun 2019; accepted 10th Oct 2019)

Abstract. With the development of industrialization, the problem of environmental pollution has become increasingly serious. Environmental monitoring data, as a measurement index of environmental quality, is increasingly valued by governments and citizens. However, the environmental data accumulated through real-time monitoring at the current stage is mostly used to write basic reports, while the hidden laws or values still need to be further explored. This paper proposes two original environmental prediction models and improves upon these two methods separately to predict the quality of the atmospheric environment. The following research results are obtained: the multivariate linear equation is optimized through stepwise linear regression, which can accurately predict the short-term atmospheric environmental quality; the improved BP neural network can predict the mid-term and long-term atmospheric environmental quality through short-term training.
Keywords: *environmental monitoring, neural network, environmental quality, data analysis, prediction*

Introduction

With the rapid advancement of industrialization and the rapid increase of urban population, the environmental pollution problem is becoming more and more serious (Beck et al., 1961; Jeffrey et al., 2000), including atmospheric pollution, such as acid rain and fog; water environment pollution, such as black odorous water, water bloom and red tide; solid waste pollution, such as construction waste and tailings pond pollution. In recent years, the atmospheric pollution has been particularly prominent. It directly leads to a decline in the quality of people's living environment, affecting human health and causing huge economic losses (Lauth et al., 2010; Abramovitch et al., 2015). In order to avoid the occurrence of air pollution, large funds have been invested in the prevention of air pollution at various levels in our country (Bey et al., 2017) and an atmospheric environment monitoring Internet of Things has been established. Through the monitoring of the quality of the atmospheric environment, it can be controlled in real time, which guides the industrial production and the construction of related pollution prevention facilities (Rodgers et al., 2015; Lochner et al., 2011; Zhang et al., 2018a). At present, almost all atmospheric environmental monitoring data is used to prepare environmental reports such as daily newspapers and annual reports (Arsie et al., 2010; Marino et al., 2017) while the value of data needs to be further explored (Li et al., 2014). For example, through historical monitoring data, the future trend of atmospheric environmental quality can be predicted so as to better guide people's production activities (Chien et al., 2005, 2010). Meanwhile, it provides relevant scientific evidence for government decision-making and management departments in the formulation of systems concerning this area (Chien et al., 2003).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1450514516

At present, the methods for predicting the quality of atmospheric environment mainly include numerical prediction and statistical prediction. However, the model precision of numerical prediction is lower than that of statistical prediction and the scope of application is limited (Chien et al., 2007; Song, 2018; Cooper and Ekström, 2005; Reifman et al., 2000; Zhang et al., 2018b; Zhao et al., 2018). Therefore, this paper adopts the statistical prediction with easy data acquisition and high prediction precision, including the back propagation (BP) neural network and multiple linear regression equation for the analysis of atmospheric environment prediction.

Materials and methods

Multiple regression model

When there is a linear relationship between two or more independent variables and dependent variables, it is a multiple linear regression. Its mathematical model is shown in *Equation 1:*

$$y = a_1 + a_2 x_1 + a_3 x_2 + \cdots\cdots + a_{m+1} x_m + \varepsilon \quad \text{(Eq.1)}$$

In this formula, $a_1, a_2, a_3, \ldots a_{m+1}$, are regression coefficients; ε is a random error.

The estimated value of regression coefficient is shown in *Equation 2:*

$$Q = \sum_{t=1}^{n} [y_1 - (a_1 + a_2 x_{1t} + a_3 x_{2t} + \cdots\cdots a_{m+1} x_{mt})]^2 \quad \text{(Eq.2)}$$

After obtaining the multiple linear regression equation, it needs to be tested to determine its precision. The commonly used test methods include correlation coefficient test, F test and t test.

(1) Correlation coefficient test

The correlation coefficient is an index used to measure the fitting degree of the linear models. The mathematical expression is the ratio of the regression sum of squares to the total sum of squares, as is shown in *Equation 3:*

$$R^2 = \frac{SSR / p}{SST / n - p - 1} \quad \text{(Eq.3)}$$

(2) F test

The F test is used to test whether the relationship between the independent variable and the dependent variable is significant in the linear model and it is expressed by *Equation 4:*

$$F = \frac{\sum_{i=1}^{n} (\hat{y}_1 - \bar{y})^2 / p}{\sum_{i=1}^{n} (y_i - \hat{y}_1)^2 / (n - p - 1)} = \frac{SSR}{SSE / (n-2)} = \frac{R^2}{1 - R^2} (N-2) \sim F(1, n-2) \quad \text{(Eq.4)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1450514516

(3) T test

The t test can be used to determine whether a variable is retained as an independent variable in the model and it is expressed by *Equation 5:*

$$t = \frac{\frac{\hat{\beta}_1}{\sigma} \sim t(n-p-1)}{\sqrt{\sum_{j=1}^{n}(x_{ij} - \overline{x_{11}})^2}} \quad \text{(Eq.5)}$$

In this equation:

$$\hat{\beta} \sim N\left[\frac{\sigma^2}{\sum_{j=1}^{n}(x_{ji} - \bar{x})}\right], \quad \hat{\sigma}^2 = \frac{SSE}{(n-p-1)}.$$

In *Equations 3–5,* SST represents the deviation sum of squares of the difference between the observed value and the mean value of the dependent variable. SSR is the deviation caused by the independent variable, which is the regression sum of squares. SSE is the residual sum of squares caused by the experimental error. The relationship is shown in *Equation* 6*:*

$$SST = \sum_{i=1}^{n}(y_i - \bar{y})^2 = \sum_{i=1}^{n}(\hat{y}_1 - \bar{y})^2 + \sum_{i=1}^{n}(y_i - \hat{y}_i)^2 = SSR + SSE \quad \text{(Eq.6)}$$

BP neural network

BP neural network is a neural network of error inverse propagation, as is shown in *Figure 1:* after the data is input, it is forwardly propagated from the input layer to the output layer via the hidden layer. According to the set error, the output layer corrects the weight through the hidden layer, which is the error inverse propagation, thereby achieving a stepwise improvement of the precision of the output value of the neural network.

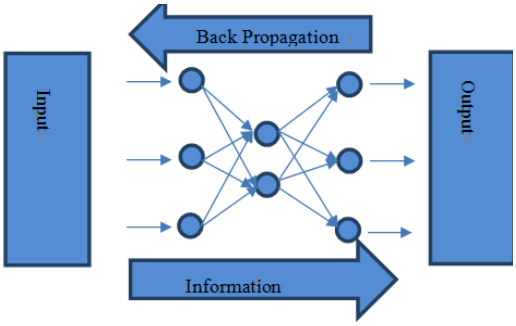

Figure 1. *BP neural network topology*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1450514516

Genetic algorithm

The genetic algorithm is developed from the Darwin's theory of evolution and Mendel's genetics. It uses the imitation of biological gene coding to encode individuals, serving as the initial population. The selection, crossover and mutation are completed according to the principle of survival of the fittest. The new population is formed and the above operation is repeated, thereby realizing the retention of excellent genes and inheriting these genes to the offspring. Therefore, the population can better adapt to the environment and continue to breed and evolve.

Data collection and processing

We adopt the GB3095-2012 standard to evaluate the atmospheric environmental quality in the suburbs of Shijiazhuang. The air quality automatic monitor was used to measure the PM2.5, PM10, CO, SO2, O3 and NO2 in the air; temperature-humidity sensor, anemometer and barometer were used to measure meteorological conditions such as temperature, humidity, wind speed, wind direction and air pressure, etc. For example, when the humidity is high, the degree of air pollution will increase. Therefore, this paper will collect 6 indexes of atmospheric pollutants and corresponding 5 meteorological indexes.

Data collection

This paper downloads the monitoring data of atmospheric environment of the environmental protection bureau in the Shi Jiazhuang by writing the crawler software. The data collection process is shown in *Figure 2*.

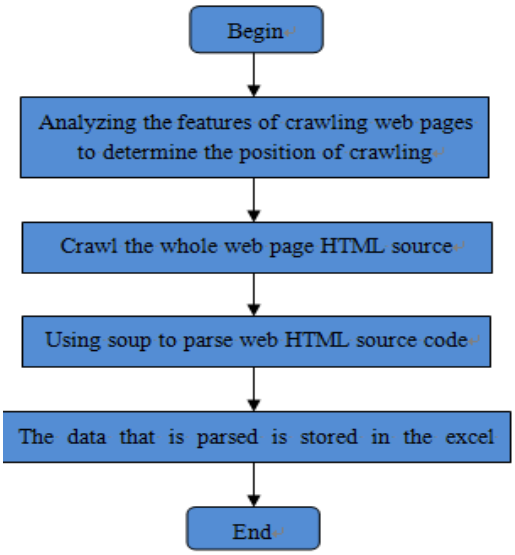

Figure 2. *Flow chart of web crawler*

Data processing

Data preprocessing plays an important role in the in-depth, accurate mining and analysis of data. In this paper, the collected data is preprocessed in the following two ways.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1450514516

(1) Eliminating abnormal data

According to the reasonable distribution range and mutual relationship of each atmospheric data, it is checked whether there is abnormal or contradictory value in the data and the abnormal data is eliminated. In addition, the collected data may be invalid or missing and the mean value of variables is used for the estimation and supplement.

(2) Data normalization

In order to reduce the deduction in the precision of the prediction model caused by the difference in magnitude and dimension between the atmospheric monitoring data, the normalization is conducted on the data. The following two normalization methods are adopted for the multiple linear regression model and the neural network model respectively:

1) Normalized to the interval of [0, 1]

Set x_{max} and x_{min} represent the maximum and minimum value of the original data respectively; x_i is the actual data; and $\hat{x}_i$ represents the normalized value. The normalization equation is:

$$\hat{x}_t = \frac{x_i - x_{\max}}{x_{\max} - x_{\min}} \quad \text{(Eq.7)}$$

The output value is then converted using the formula $x_i = (x_{max} - x_{min})\hat{x}_t + x_{min}$.

2) Normalized to zero mean and unit variance

After all the raw data is calculated as the mean value of each dimension, the mean is subtracted from each dimension and finally each dimension of the data is divided by the standard deviation of the dimension. The equation is:

$$\hat{x}_i = \frac{x_i - \mu}{\sigma^2} \quad \text{(Eq.8)}$$

Then, the output value is then converted using the formula $x_i = \hat{x}_t\sigma^2 + \mu$.

Results and discussion

The crawler software is used to obtain atmospheric pollutants such as PM2.5, PM10, CO, SO_2, O_3, NO_2, as well as the meteorological data such as temperature, humidity, wind speed, wind direction and pressure. There are 22,000 pieces of PM10 concentration data, of which 20,000 pieces of data are used as training data and the rest 2,000 pieces of data are used as test data at the monitoring point.

Traditional multivariate model

The preprocessed data is constructed into a multiple linear regression model, and correlation coefficient test, F test and t test are performed. The predicted result is then compared to the test data.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1450514516

Traditional multiple linear regression prediction model

The dependent variable is PM10 and the independent variable is five types of meteorological data such as temperature and pressure. The modeling method is all input.

1) The correlation coefficient test results are shown in *Table 1* and R2 represents the fitting effect. The larger the value, the better the fitting effect.

Table 1. *Test of correlation coefficient*

Model	R	R2	R2 adjusted	Standard deviation rate error
1	0.438	0.509	0.507	26.73%

2) The result of the F test is shown in *Table 2*. As it can be seen from the table, the result of F test is < 0.01. Therefore, five meteorological indexes have a significant impact on the concentration of PM10.

Table 2. *Test of significance*

Model	Square	Df	Mean square	F	Significance
Regression	237971.932	5	475897.746	80.792	0.00
Residual	3424801.21	579	5883.049		
Statistics	5804671.02	596			

3) The result of the t test is shown in *Table 3*. The non-normalized coefficient is used to list the regression equation. The normalization coefficient is used to reflect the degree of influence of the independent variable on the dependent variable; the partial regression coefficient is used to determine whether the influence of an independent variable on the dependent variable is statistically significant. When it is < 0.05, it indicates significant statistical significance; when it is < 0.01, the statistical significance is extremely significant.

Table 3. *T-test*

Model	Unstandardized coefficients	Standardized coefficient	T	Significance
constant	398.212		5.461	0.00
Pressure/Pa	-3.796	-0.248	-5.377	0.00
Temperature/°C	-1.296	-0.0497	-0.981	0.032
Moisture/%	2.223	0.379	9.201	0.00
Wind speed/m/s	-55.059	-0.228	-7.068	0.00
Wind direction	-0.207	-0.179	-5.425	0.00

4) The linear regression equation of the prediction model is:

$$y = -3.796 \times 1 - 1.296 \times 2 + 2.223 \times 3 - 55.059 \times 4 - 0.207 \times 5 + 398.212.$$

The comparison between the true value and the predicted data is shown in *Figure 3*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1450514516

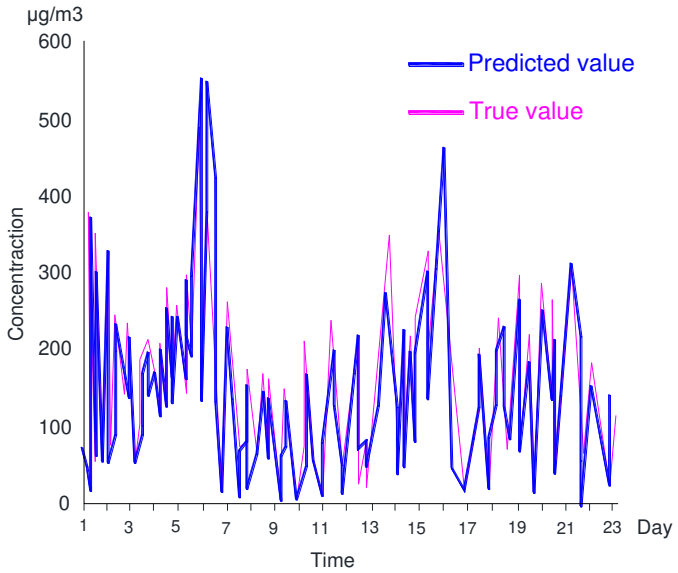

Figure 3. *Comparison of predicted value by traditional multiple linear regression model and true value*

Improved multiple linear regression prediction model

Considering the physical and chemical reactions between pollutants and the significant impact of seasonal factors on pollutants, other pollutants and seasonal factors are included in the multivariate equation for the optimization. The seasonal variables are: spring 108.1 μg/m^3, weight 0.25; summer 97.8 μg/m^3, weight 0.2; autumn 112.3 μg/m^3, weight 0.25; winter 121.9 μg/m^3, weight 0.3.

The significance test is performed by introducing independent variables one by one into the regression model until all significant independent variables are introduced into the regression model. The result of the stepwise regression model is shown in *Table 4*.

Table 4. *Model abstract*

Model	R	R2	R2 adjusted	Standard deviation rate error	Introduce variable
1	0.781	0.739	0.821	20.89%	Constant, PM2.5, season
2	0.813	0.769	0.825	20.75%	Constant, PM2.5, season, temperature, O_3
3	0.836	0.808	0.825	20.17%	Constant, PM2.5, season, wind speed, temperature, O_3
4	0.852	0.817	0.827	19.964%	Constant, PM2.5, season, wind speed, temperature, O_3, pressure
5	0.863	0.842	0.829	19.697%	Constant, PM2.5, season, wind speed, temperature, O_3, pressure, moisture
6	0.881	0.842	0.828	19.603%	

It can be seen from *Table 4* that PM2.5 has the most significant impact on PM10, while the impact of atmospheric pollutants SO_2, NO_2, CO and the meteorological factor, wind direction on PM10 can be negligible. Therefore, after eliminating these indexes, *Table 5* can be obtained.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1450514516

Table 5. *Test of correlation coefficient*

Model	Unstandardized coefficients	Standardized coefficient	T	Significance
Constant	-90.087		-4.875	0.00
PM2.5/ppm	30.304	0.937	89.851	0.00
Temperature/°C	19.729	0.113	8.	0.032
O_3/ppm	-0.359	-0.10	-7.61	0.00
Wind speed/m/s	8.541	0.038	4.31	0.00
Pressure/Pa	0.897	0.059	5.081	0.00
Moisture	5.184	0.029	2.857	0.003
Season	10.280	0.269	20.351	0.005

The regression equation can be obtained:

$$y = 30.304 \times 1 + 19.729 \times 2 - 0.359 \times 3 + 8.541 \times 4 + 0.897 \times 5 + 5.184 \times 6 + 10.28 \times 7 - 90.087.$$

Using this model, the true value and the predicted value are shown in *Figure 4.*

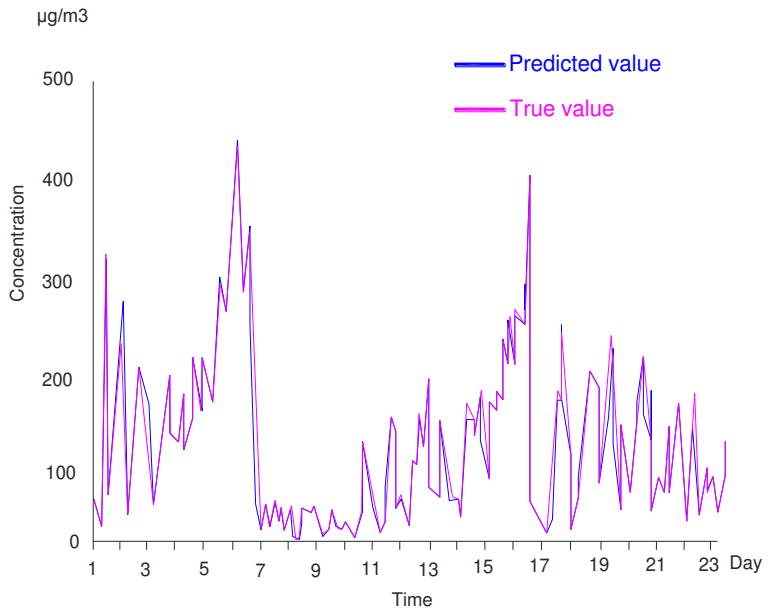

Figure 4. *Comparison of predicted value by optimal multiple linear regression model and true value*

It can be seen from *Figure 4* that the fitting degree of the optimized model reaches 0.828, which is significantly higher than that of the original model, indicating that the prediction for PM10 by the stepwise linear regression method is more precious after considering meteorological factors and other pollutants.

In addition, it can also be seen from *Figure 4* that the prediction error in the short term (4 days) is the smallest. At the same time, PM2.5, wind speed, air pressure, humidity and season have an enhancing effect on PM10 concentration. The impact of PM2.5 on PM10 is the greatest; while O_3 and temperature has a weakening effect on PM10.

Traditional BP neural network model

The neural network structure needs to be determined by the number of hidden layers, the number of nodes in the input layer, the number of nodes in the hidden layer, the number of nodes in the output layer, the activation function, training method and training parameters. In this paper, a three-layer neural network with a layer of hidden layer is used and it is set to be 11 and 1 according to the principle that the number of input and output nodes is as small as possible. The number of neurons in the hidden layer is determined by formula $M = \sqrt{n+m} + a$. In the formula, a is a constant between 0 and 10, and m and n are the number of neurons in the input layer and the output layer respectively. The number of hidden layers in this paper is 6. The input function in the hidden layer is $f(x) = \frac{1}{1+e^{-x}}$ and the linear activation function is used on the output layer. The learning rate is 0.01.

The fitting relationship between the predicted value and the true value of the BP neural network is shown in *Figure 5*.

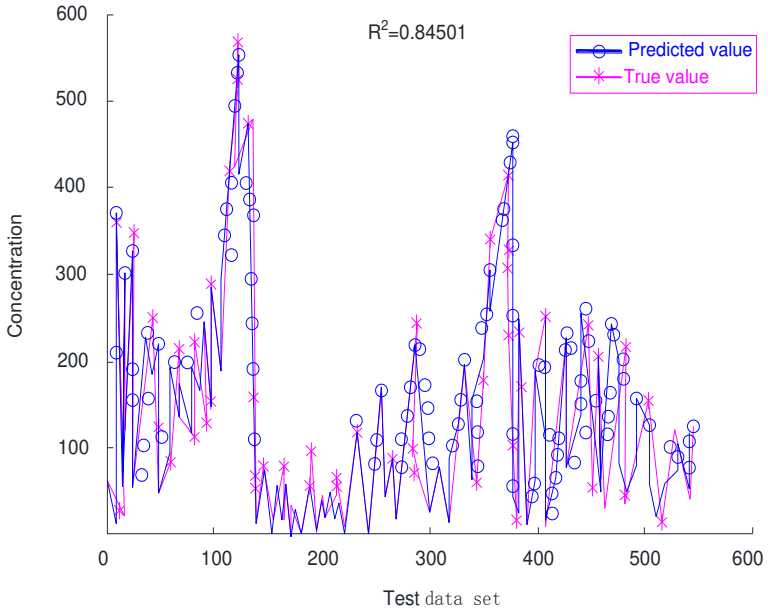

Figure 5. *Comparison of predicted value of BP neural network and true value μg/m³*

It can be seen from the *Figure 5* that the traditional BP neural network can better reflect the variation trend of atmospheric pollution in the future and can relatively accurately predict the concentration of atmospheric pollutants. Its goodness of fit is 0.84501.

Improved BP neural network prediction model

The traditional BP neural network uses the gradient descent method to train the neural network, which may lead to problems such as insufficient neural network search ability and slow training speed. This problem can be solved by genetic algorithm. By calculating the fitness value of each individual, it can conduct three genetic operations of selection, crossing and mutation to improve its global search ability and find the individual with the best fitness.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1450514516

The number of input and output layers in the neural network are 11 and 1, respectively. It is found through the experiment that when the number of nodes in the hidden layer is 11, the prediction effect is the best. There are a total of 120 weights and 11 thresholds in the optimized neural network. The individual coding length is 131; the population size is 22; the evolution number is 57; the crossover probability is 0.22; and mutation probability is 0.1, as is shown in *Table 6*.

Table 6. *Learning and training of GA-BP*

Network structure	Population size	Evolution times	Initial crossover probability	Initial mutation probability
11-11-1	22	57	0.22	0.1

The fitting of the predicted value in the optimized BP neural network is shown in *Figure 6*. The goodness of fitness in the optimized BP neural network is 0.87925.

The comparison of the effect of these four types of neutral network prediction model is shown in *Table 7*.

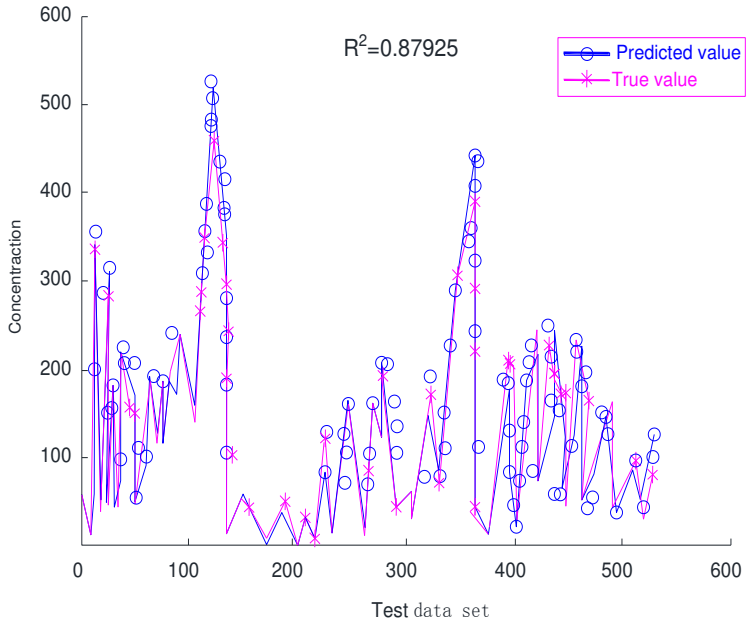

Figure 6. *Comparison of predicted value of optimized BP neural network model and true value* $\mu g/m^3$

Table 7. *Comparison of prediction results of four models*

	Traditional multiple regression model	Multiple regression model after optimization	Traditional BP neural network model	Optimized BP neural network model
Goodness of fit	0.509	0.819	0.862	0.882
PM10 mean square error	30.27	12.31	8.81	5.38
PM10 mean absolute error	0.163	0.085	0.069	0.047

Conclusions

With the increase of people's requirement for environmental quality, the prediction for the variation trend of environmental quality using the monitoring data becomes increasingly important. In this paper, the original multiple linear regression model, the original BP neural network and the optimized model are used to predict the atmospheric environmental quality. The following research conclusions are drawn:

(1) The traditional multiple linear regression model can only predict the variation trend of atmospheric environmental quality coarsely; while the other three models can predict the concentration of future atmospheric pollutants accurately.

(2) The stepwise linear regression can be used to predict PM_{10} more accurately after considering meteorological factors and other pollutants. The prediction error for the short term (4 days) is the smallest.

(3) The prediction for the mid-term and long-term atmospheric environmental quality is the best using the optimized BP neural network model.

(4) This paper applied the IoT environment and the improved neural network algorithm to the analysis of environmental monitoring data, which had improved the analysis accuracy and provided a theoretical basis for subsequent data management, atmospheric environment prediction and map management.

INVERSION OF TOTAL SUSPENDED SEDIMENT IN TAIHU LAKE BASED ON MEASURED SPECTRAL DATA

XU, J. J.

Taizhou College, Nanjing Normal University, Taizhou 225300, China
(e-mail: x_j_j1981@126.com; phone: +86-181-3665-8696)

(Received 7th Jun 2019; accepted 10th Oct 2019)

Abstract. The concentration of suspended sediments is an important indicator of the water quality of inland water bodies. Several single sensitive bands were employed to locate the bands in the mixed spectrum on water surface (WS-MS) that are sensitive to the TSS. However, this approach was proved wrong, for a high concentration of suspended sediment was derived from the WS-MS measured in the same water area under strong sunlight (i.e. high surface reflectivity). As a result, the single sensitive bands were replaced with the reflectivity ratio between the two bands most correlated with the TSS (the reflectivity ratio), such as to eliminate the impact of sunlight intensity. Correlation analysis shows that (R639 + R544)/(R639/R544) had closer correlation with the TSS than any other band combination. Based on the measured reflectivity ratio and concentration of suspended sediments, the TSS in the target water body was inverted separately by the least squares method and fuzzy regression. The results show that the inversion by fuzzy regression was not affected by measurement uncertainties or error, indicating that the fuzzy regression inverse model is more applicable than the least squares inverse model.
Keywords: *sediment remobilization, reflectivity ratio, mixed spectrum on water surface (WS-MS), least squares method, fuzzy regression*

Introduction

Background and significance

The SS concentration is a critical indicator for water environment evaluation. The SS (Suspended Sediment) refers to all particulate matters suspended in water, including organic detritus resulting from dead phytoplankton and inorganic suspension particles produced by resuspending terrestrial or lake sediments (Cai, 1998). In inland water, it is a more common phenomenon that there are the SSs, mainly seen in estuaries, coastal waters and shallow lakes with a high or low concentration affecting the sunlight transmission, the growth of underwater crops and the use of light by phytoplankton, and worse, the SSs may also change the aquatic ecological environment and restrict the primary productivity of the whole waters (Yang et al., 2002).

Foreign scholars have studied this area long ago. Traditional water quality monitoring in Lake Erie has been conducted using in situ and laboratory observations. The USEPA Great Lakes National Program Office (GLNPO) has conducted spring and July water quality sampling on Lake Erie since the early 1980s (Barbiero et al., 2018) and the NOAA Great Lakes Environmental Research Laboratory (GLERL) has been conducting weekly monitoring for over five years. Liu et al. (2019) also found in the study of hyperspectral remote sensing inversion that spectral reflectance ratio is more suitable for hyperspectral remote sensing inversion than single-band spectrum. The study of Binding et al. (2003) has shown that the optical parameters (backscatter coefficient and absorbance) in the water body are the most principal factors affecting the water reflectivity, affording a theory reference for quantitatively exploring suspended sediments. Suspended particles play an important role in coastal waters by controlling to a large extent the variability of the water inherent optical properties

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1451714528

(IOPs). In this study, focused on the complex waters of the Southern North Sea, the relationships between the concentration, composition and size of suspended particles and their optical properties (light absorption, and attenuation in the visible and near-infrared spectral regions) are investigated.

Some scholars in China have also attempted to explore the remote sensing inversion on suspended sediments since the 1980s. Shi et al. (2015) found that the spectral reflectance and total suspended solids had a strong correlation at 645 nm wavelength from the measured data of water body. Based on this, an empirical inversion model of total suspended solids with strong adaptability was developed and good results were achieved. Zhang et al. (2016) developed an analytical method to retrieve the total suspended solids by remote sensing in view of the complex situation of the turbidity and optical factors of Xinanjiang Reservoir, and achieved good results. Li et al. (2002) created the suspended sediment inversion model for the Yangtze River estuary at band ratio (R555 + R670)/(R555/R670). These studies have shown that the inversion of suspended sediment concentration using the remote sensing method is feasible. Cao et al. (2016) studied Nansi Lake and found that there was a relationship between the measured spectra and suspended matter concentration.

Owing to uneven distribution of TSSs in vertical space, it is difficult to measure TSS concentration with conventional water sample unable to timely reflect current water quality due to a manually realtime field inspection at a long cycle. In this study, given spectrum data as measured and the concentration at local sampling point, a TSS concentration inversion model can be built to monitor how the TSS changes in time and space in a timely manner.

Materials and methods

Survey of study area

Situated in the southern margin of the Yangtze River Delta, 30°55’40”~31°32’58” latitude North and 19°52’32”~120°36’10” East longitude, Taihu Lake is one of the five largest freshwater lakes in China. With the lakeshore line of 393.2 km in total length, the average water depth of 1.9 m and the maximum water depth of 2.6 m, Taihu Lake has an average annual runoff of 7.5 billion m^3, water storage capacity of 4.4 billion m^3, and annual average water temperature of 17.1 °C, that is, 4 °C in January, 25 °C in July. The Taihu Lake covers a lake area of 2427.8 km^2, the water area of 2338.1 km^2. There are hilly mountains in the west and southwest sides, and plains and water net in the east.

As a shallow-water inland lake, Taihu Lake has suspended sediments mostly dominated by inorganic sediments and organic carbonized particles. Inorganic sediments derive from branch river system, and organic carbonized particles mainly come from some eutrophic remains of dead algae. Analyzing the curves of surface sediment fining and volume concentration as a function of time, we find that the suspended sediment particles are dominated by silt and clay.

Taihu Lake is open with strong wind, but moderate in the average depth. Therefore, the lakebed sediments are easily agitated, resulting in a higher concentration of suspended sediments in the water body. Over many years’ water sample monitoring at the hydrological station, the concentration of suspended sediments in Taihu Lake varies in different times and spaces. In horizontal space, it is higher in the estuary area and the wind-agitating lake center, and low in the closed arm of lake (such as Meiliang Bay),

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1451714528

but the minimum is in Dongtai Lake, mainly because there are lush hydrophytes, and less agitated suspended sediments.

Data sample

Data

The measured concentration used hereof is available from the lab, where the water sample is filtered and weighed after collecting at a sampling point preset (as shown in the figure), see *Table 1* for specific data.

Here, water sample is available by the hierarchical collection method, namely, water is divided into three layers in depth: 0.2D, 0.5D, D (D is the water depth at the time of measurement), each takes 1/3 of the water yield. Water samples collected from three layers are mixed.

In the lab, water sample is filtered and weighed by the following way: put 0.45 μm filter membrane into an oven at 40 °C, let it dry for 24 h at a constant temperature, and then remove the dried filter membrane from the oven and place it in a drying bottle to be stable, weigh it with a one ten-thousandth balance, then, number the filter membrane, and filter the water sample. The sediment available by filtration is placed in an oven at 40 °C and weighed with the above balance.

Sample SS concentration analyzed in the lab

The concentrations measured for SS samples available on November 13, 2017 (*Fig. 1*) and July 27, 2018 (*Fig. 2*) are shown in *Tables 1* and *2*.

Table 1. *Concentration of SS samples (13/11/2017)*

Sample number	SS (mg/L)	Sample number	SS (mg/L)	Sample number	SS (mg/L)
1	31.40	9	23.35	17	30.56
2	49.90	10	10.32	18	24.55
3	39.33	11	54.08	19	36.72
4	29.19	12	63.26	20	35.76
5	28.34	13	33.61	21	29.43
6	53.71	14	30.59	22	76.17
7	69.21	15	48.74		
8	60.92	16	39.94		

Table 2. *Concentration of SS samples (27/07/2018)*

Sample number	SS (mg/L)	Sample number	SS (mg/L)

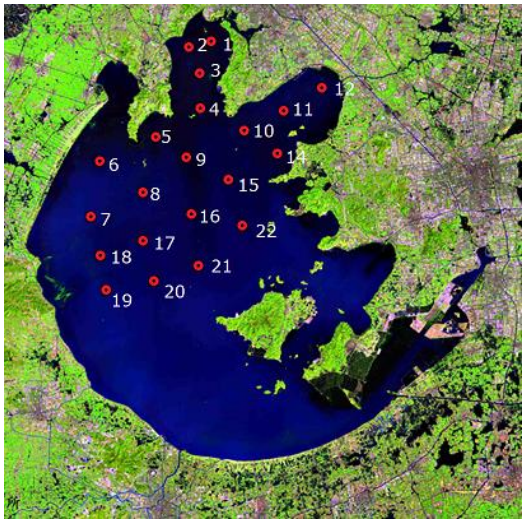

Figure 1. *Distribution of samples (23/11/2017)*

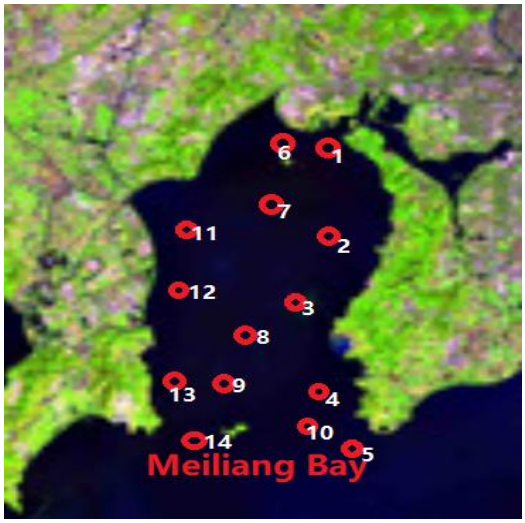

Figure 2. *Distribution of samples (27/07/2018)*

As seen from data measured in the lab, the concentration of suspended sediments in autumn is low, for example, the maximum in *Table 1* is 76.17 mg/L, the minimum is 9.44 mg/L; the concentration of suspended sediments in July is high, for example, the maximum in *Table 2* is 94.1 mg/L, and the minimum is 66.05 mg/L. However, due to the concentrated sampling points, there is a small gap between the maximum and the minimum.

Hybrid spectrum signature measured on water surface

On November 13, 2017, the hybrid spectrum on water surface was measured by a handheld ASD spectrometer of the United States at 22 points of the Meiliang Bay in North Taihu Lake (after removing the anomaly points, 16 points can be available), and treated by the ASD ViewSpec. During hyperspectral measurement, impacted by other external factors, the available SS spectrum has many tiny peaks, which makes it

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1451714528

difficult to extract and analyze the spectral signature of suspended sediment. For this purpose, the characteristic wavelength corresponding to each reflection peak is analyzed. It is preferred to smooth spectral data (moving average, namely, five bands are chosen every time, and averaged as the center band value). Smoothing not only effectively eliminates the noise, but also retains useful information. The resulting spectrum curve is shown below.

In this area, 22 samples (14 out of them are available) are measured for remote sensing reflectance spectra using the same device on July 27, 2018, and the curve are shown in *Figure 4.*

As shown in *Figures 3* and *4,* two spectral curves available in November and in July differ a lot since chlorophyll spectrum features the reflectance peaks at around 550 nm, around 620 nm, around 700, and 820 nm. Most strikingly, there is a reflectance peak appeared at around 700 nm. Whether it appears or not is generally considered as the basis for determining whether there are lots of algae chlorophylls. These spectral signatures get blur when the algae concentration is low. Otherwise, water surface reflectivity sharply increases due to the strong reflectance of algae cells in the near-infrared band if the algae bloom, as shown in *Figure 4.* In *Figure 3,* there is no similar signature (8# sample is removed as anomaly point because there is phytoplankton on the lake). The too high concentration of chlorophyll has a effect on the overall spectral reflectance, so that the monodrome inversion will have a error.

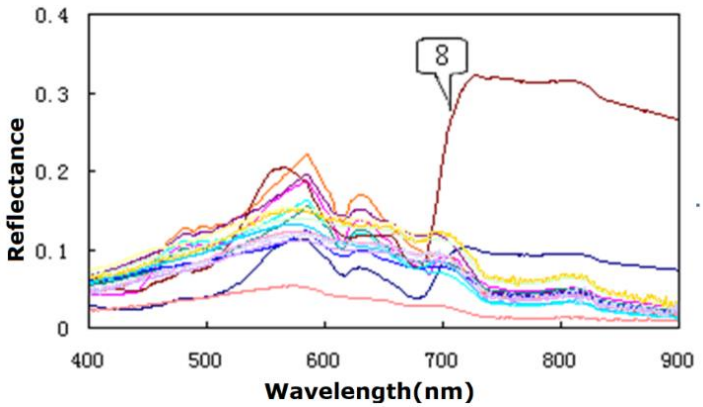

Figure 3. *Curve of sample water surface reflectance spectrum in North Taihu lake (13-11-2017)*

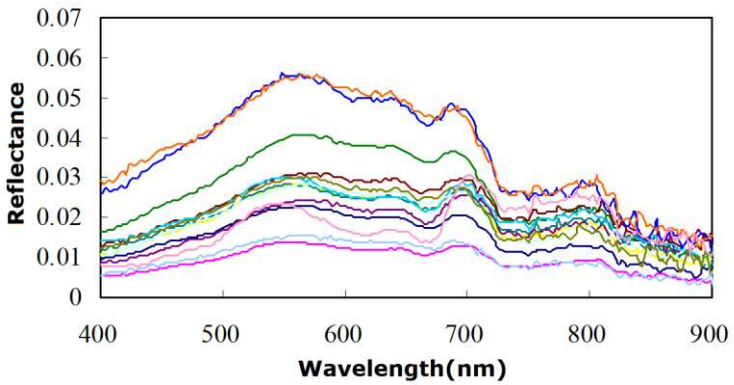

Figure 4. *Curve of sample water surface reflectance spectrum in Meiliang Bay (29-07-2018)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1451714528

SS-sensitive band analysis and inversion model construction

Establishment of linear regression model

To extract the characteristic wavelength of the suspended sediment, the spectral curve, if used directly, will make it impossible to identify it. Introductory spectrum theory is used here. Based on the derivative spectrum theory, the second derivative of suspended sediment spectrum is preferentially obtained. Here, the wavelength in the visible light range is chosen for the following reasons: the "red shift phenomenon" will occur in the infrared band when the suspended sediment concentration is higher. As shown in *Figure 5,* the reflection peaks appear at 447 nm, 500 nm, 544 nm, 585 nm, 593 nm, 623 nm, 639 nm, and 695 nm. The existing theory holds that the characteristic spectrum of suspended sediment is at 510-600 nm, 630-700 nm, and derivative analysis concludes the characteristic wavelength that roughly coincides with the existing conclusion (Doxaran et al., 2002; Xue et al., 2012).

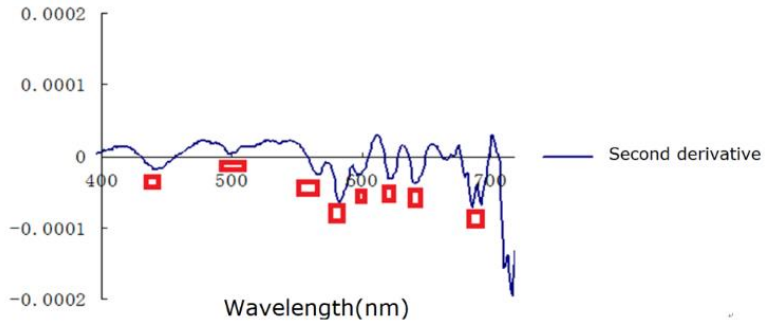

Figure 5. *Second derivative and characteristic peak of suspended sediment spectrum*

Since the second derivative of suspended sediment spectrum is very sensitive, some fine impure peaks are also erroneously assumed as characteristic peaks of the suspended sediment concentration. As a result, the correlation between the flux concentration and the measured spectral reflectivity is analyzed to further determine the characteristic peaks of suspended sediment spectrum. As shown in *Figures 6* and *7,* the characteristic peaks at 447 nm, 544 nm, 593 nm, 623 nm, 639 nm and 695 nm still exist, but are not highly correlated with the concentration of suspended sediments. In particular, it is almost irrelevant in the curve of the spectrum as a function of the concentration of sample (27-07-2017), mainly because the solar rays are too strong.

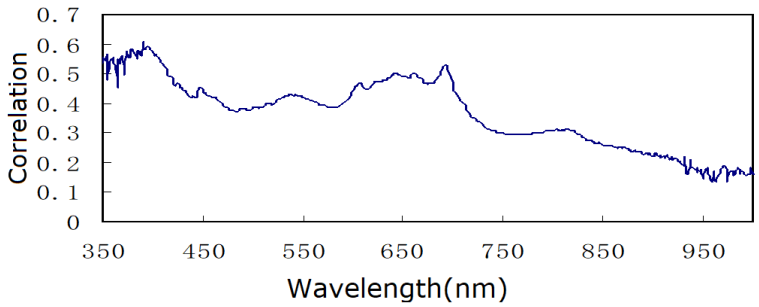

Figure 6. *Correlation between spectrum reflectivity and suspended sediment concentration of sample (13-11-2017)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1451714528

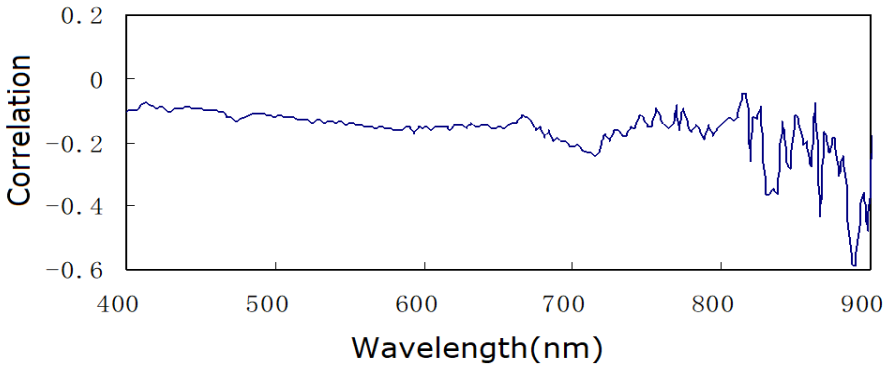

Figure 7. *Correlation between remote sensing reflectivity and suspended sediment concentration of sample (13-11-2017)*

To eliminate the interferences of solar ray intensity, ambient environment, water surface smoothness and other background factors, the characteristic spectrum ratio can be used (Pulliainen, 2011). The Chen et al. (1991) found that the natural logarithm of suspended sediment concentration is well correlated with water surface spectrum reflectivity, as shown in *Figures 8* and *9*.

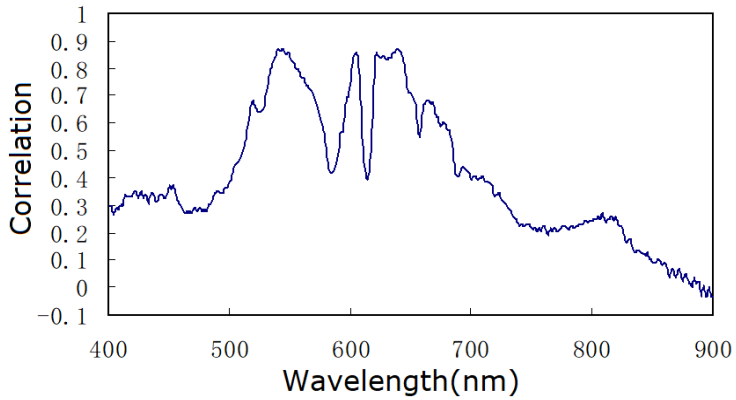

Figure 8. *Correlation of the concentration (13-11-2017) logarithm with reflectivity ratio*

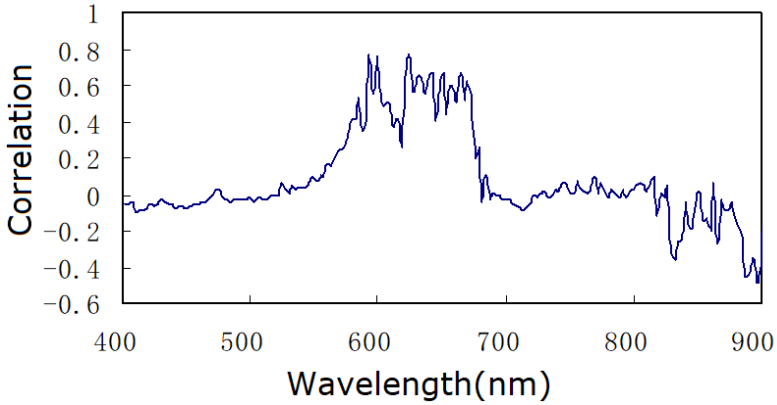

Figure 9. *Correlation of the concentration (27-07-2018) logarithm with reflectivity ratio*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1451714528

As shown in *Figure 8,* there is a high correlation between 530 nm and 680 nm, and the first two values at which the correlation is higher are chosen to obtain the ratio. It is found that the maximum value in *Figure 8* appears at R639 and R544 (consistent with the previous single-band characteristic peaks), i.e. R639/R544; in *Figures 2–9,* there is a high correlation between 580 nm and 680 nm, and the first two values at which the correlation is higher are chosen to obtain the ratio. The maximum values appear at R623 and R593 nm (consistent with the previous single-band characteristic peaks), i.e. R623/R593; the hybrid spectra measured on the surface of water bodies on 13-11-2017 and 27-07-2018 are respectively correspond to the lnSS (natural logarithm of the SS) to plot a scatter diagram and find the appropriate linear regression equation, as shown in *Figure 10.*

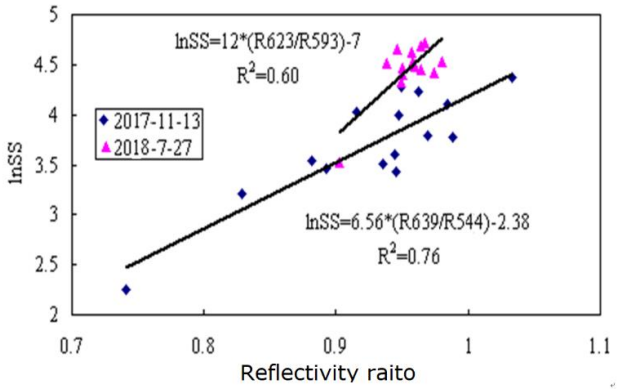

Figure 10. *Relationship between reflectivity ratio and InSS*

With the regression equation (see *Fig. 1*) fitted by the reflectivity ratio and lnSS, the RMSEs (Root Mean Square Error) between the inverted SS concentration and the concentration of the sample in the lab are 10.79 mg/L (13-11-2017) and 14.99 mg/L (27-07-2018).

As seen from the RMSEs, the sample in November is significantly better than that in July. The main reason is that the solar intensity in July has an effect on the overall reflectance of the measured spectrum on the water surface. Next, in July, the phytoplanktons bloom in Taihu Lake due to the eutrophication of water bodies, blocking the projection of the SS spectrum onto the spectrometer. Therefore, the significance of the model in November ($R^2 = 0.76$) is better than that in July ($R^2 = 0.60$).

Although the regression model in *Figure 10* can be applied, there are still some errors due to the uncertainty of spectrometer and the laboratory SS quality error measured by Hu et al. (2004) and so on. However, this kind of error always changes around the model, so that the fuzzy regression method is used to establish the model hereof since it can eliminate the error caused by measurement and weighing. In fuzzy regression, spectral measurement and SS weighing errors are the inherent ambiguity of the system. The SS concentration inverted by the ratio of the measured spectra is not a value, but an interval (with the upper and lower bounds), i.e. it can take any value in this interval. Therefore, the fuzzy regression model focuses on the possibility rather than a specific value.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1451714528

Establishment of fuzzy regression model

The fuzzy regression model was first proposed by Tanaka and Watada (1998) in 1982, and the specific model is as follows:

$$\tilde{Y}_i = \tilde{A}_0 x_{i0} + \tilde{A}_1 x_{i1}, (i = 1, 2, 3, \ldots n) \quad \text{(Eq.1)}$$

Let $x_i = (x_{i0}, x_{i1}) = (1, x_{i1})$, the fuzzy coefficients $\tilde{A}_0$, $\tilde{A}_1$ are usually the symmetric triangular fuzzy numbers, i.e. $\tilde{A}_j = (m_j, w_j), j = 0,1$.

Its membership function is:

$$\mu_{\tilde{A}_j}(n_j) = \begin{cases} 1 - \frac{|m_j - n_j|}{w_j} & , m_j - w_j \leq n_j \leq m_j + w_j \\ 0 & , other \end{cases} \quad \text{(Eq.2)}$$

where m_j is the center value $\tilde{A}_j$; w_j is the span value. Then the membership function of $\tilde{Y}_i$ can be obtained using the extension principle, expressed as:

$$\mu_{\tilde{Y}_i}(y_i) = \begin{cases} 1 - \frac{|y_i - x_i m|}{w^T |x_i|}, x_i \neq 0 \\ 1 \quad x_i \neq 0, y_i \neq 0, \forall i = 1, 2, \ldots . M \\ 0 \quad , x_i = 0, y_i = 0 \end{cases} \quad \text{(Eq.3)}$$

The last is to convert the fuzzy regression model into the following optimal model.

$$\begin{cases} \min \sum_{j=0}^{1} \left[w_j \sum_{i=1}^{M} |x_{ij}| \right] \\ 1 - \frac{|y_i - x_i m|}{w^T |x_i|} \geq h, \end{cases} \quad \text{(Eq.4)}$$

where $0 \leq \square \leq 1, w \geq 0, w^T = (w_0, w_1), m^T = (m_0, m_1)$.

Results

The fuzzy level *h* is arbitrarily set based on the number of samples, and the size of preset *h* determines the model fitting degree. In general, when there are sufficient samples, *h* should be set to as small as possible; the lower the fuzzy level, the smaller the span; when the number of samples is not enough, *h* should be set to be as large as possible. In this case, the fitting degree builds up regardless of the rising fuzzy level. There are lesser samples collected in this project, so that the fuzzy level *h* is set to 0.1. With the natural logarithm of the SS concentration of laboratory measurement sample as the dependent variable, and R639 and R544 spectrum values as the independent variables, the fuzzy regression equation of the suspended sediment is available as below:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1451714528

$$\ln \tilde{S} = (1.1678, 0.9269) + (18.587, 0) * (R639 + R544) / （R639 / R544） \quad \text{(Eq.5)}$$

Discussion

The built model should be tested for its fitness. In this study, the least square method is compared with the established fuzzy regression model. For the least square method as the statistical regression model, it is required to try to minimize the sum of the squares of the error between the inversion concentration and the observation value. A good fuzzy regression model should try to minimize the sum of absolute value of difference between the inversion concentration fuzz scope (the upper and lower bounds of the interval) and the observation value. The inversion results between the two are shown in *Table 3*.

Table 3. *Least squares and fuzzy regression inversion of SS concentration*

Sample number	Measurement of suspended solids concentration (mg/L)	Prediction results of least squares method (mg/L)	Prediction results of fuzzy regression (lower bounds) (mg/L)	Prediction results of fuzzy regression (central value) (mg/L)	Prediction results of fuzzy regression (upper bounds) (mg/L)	Absolute error of least square prediction (mg/L)	Absolute error of forecasting lower boundary value of fuzzy regression (mg/L)	Absolute error of fuzzy regression center value prediction (mg/L)
1	28	44	26	50	108	-16	2	-34
2	29	47	27	54	117	-18	2	-38
3	169	84	54	114	256	85	115	82
4	169	128	90	198	447	41	79	-43
5	98	86	55	118	264	12	43	-31
6	169	212	168	381	869	-43	1	-318
7	218	146	106	234	532	72	112	-25
8	104	142	102	227	515	-38	2	-185
9	22	24	14	24	46	-2	8	-2
10	18	33	18	34	70	-15	0	-23
12	134	129	91	201	455	5	43	-100
13	106	128	89	198	446	-22	17	-137
14	113	124	86	191	431	-11	27	-117
15	25	24	14	23	44	1	11	3
16	18	20	12	18	34	-2	6	0
17	78	36	20	38	78	42	58	61
18	24	17	10	15	27	7	14	13

As shown in *Table 3:* (1) Intuitively, it seems that the inversion of the least square regression model is better. In fact, that is not the case. The fuzzy regression reflects a concentration range, such as 1# sample, absolute error predicted by the least squares is -16. Although the absolute error of center value in the fuzzy regression model is high, the absolute error between the measured value and the lower bound is only 2; for 6# sample, for example, the absolute error of the center value in the fuzzy regression model reaches -318, but the deviation from lower bound error is only 1. (2) Overall, the inversion effects of the least squares and the fuzzy regression are better. Fuzzy regression reflects a range of an interval, so is more flexible and greater in the information content. (3) There is a bit error in the high SS concentration area since original data for the model is mainly concentrated in the low concentration area, so that the high concentration has a poor fitness to the model that needs to be optimized later.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1451714528

Conclusion

Based on the measured spectra measured on the water surface and the SS concentration of the sample at different times, here draw the following conclusions:

(1) The model is built with spectrum data measured on the water surface and the SS concentration, the inversion effect is poor since single reflectivity value is greatly affected by the background factors. This paper uses the reflectivity ratio and the optimal bands R639/R544, R623/R593 and the SS concentration to build the inversion model for samples, for example, in July and November, respectively.

(2) Due to the uncertainty of spectrameter and the error of laboratory weighing on suspended sediment, the linear regression inversion model established has a poor significance. As a result, this paper attempts the fuzzy regression inversion model for suspended sediment concentration and compares it with the least squares method. It is found that the fuzzy regression model established herein gives not only the inversion concentration but also the interval in which the inverted concentration changes. The model features strong significance and fitness.

Outlook

The measured spectrum has great application potential in the monitoring of water quality in inland lakes. Because some theories and methods are still immature, its application is limited in water quality monitoring. In the study of the inversion model of total suspended solids in Taihu Lake, there are still some problems that need to be further solved.

(1) The particle size, mineral composition, surface roughness and color of the suspended solids cause significant differences in the spectral characteristics of the suspended solids. Therefore, in the estimation of suspended solids, the influence of different types of suspended solids should also be considered. Secondly, although the spectral characteristics of individual water quality parameters such as chlorophyll, suspended matter, and yellow matter are currently well understood by experimental means, the interaction between them is not well understood, so it is necessary to strengthen the analysis of the effects of chlorophyll and yellow matter on the concentration estimation of suspended solids in the future. It is only possible to establish a more accurate and effective model after separating the water quality parameters and clarifying the interaction between them.

(2) Since the sample data is still relatively small, the stability and representativeness of the model need further verification. In future works, the number of samples can be increased and the representativeness of the samples improved.

Abstract. Uranium is of great importance to China's nuclear energy and national defense. As a clean energy, the nuclear energy helps to adjust and optimize the energy structure, improve the eco-environment, and reduce the CO_2 and S emissions, paving the way to sustainable development and ecological civilization. The sandstone-type uranium deposit, one of the four types of uranium deposits for industrial use, is an important supplier in China. This type of uranium deposit mainly exists in sandstone basins. And the basin is a complex space of different sedimentary strata and facies. Hence, basin analysis is an essential approach to determine the distribution and variation law of uranium resources. This paper mainly studies the sandstone-type uranium deposits on the northern margin of the Ordos Basin, China. Firstly, the author collected typical data of the geological features on the basin, and sorted data gathered from typical boreholes. Next, the Markov process model was adopted to analyze the sedimentary sequence and evolution in the basin. Finally, the relationship was clarified between the spatial distribution of uranium resources and the stratum evolution of the sedimentary basin.
Keywords: *uranium, spatial distribution, sandstone-type, deposit, strata*

Introduction

Uranium resources is a very important strategic material in China's nuclear energy strategic objectives and national defense construction. It is also an important guarantee for China's nuclear energy development. The national medium and long-term development plan for nuclear power (2011-2020) states that carbon dioxide emissions per unit of GDP will drop by 40% to 45% by 2020 compared with 2005, and the proportion of non-fossil energy in primary energy consumption will reach around 15%. The proportion of nuclear energy in most developed countries in the world has exceeded 20%, while that in China is less than 2%. In order to ensure the long-term stable supply and strategic reserve of uranium resources in China, it is necessary to have enough natural uranium supply and reserve resources as guarantee (Jin et al., 2015). Therefore, it is of great significance to adjust and optimize China's energy structure, improve the ecological environment, and reduce CO_2 and S emissions.

There are two giant uranium metallogenic belts in the world, one is the giant uranium metallogenic belt running through north and South America, the other is the giant uranium metallogenic belt in Europe and Asia. The sandstone uranium metallogenic belt in northern China is located in the eastern section of the Eurasian uranium metallogenic belt. It indicates that China has superior geological conditions and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1452914541

resource potential for uranium mineralization. Sandstone-type uranium deposit has many advantages such as large scale, low cost of in-situ leaching and environmental protection, at present, it has become the main type of ore deposit in the world and the main type of uranium resources in China. Sandstone-type uranium deposit is one of the four major industrial uranium mine types in China. As we know the majority of uranium mine in China is sandstone type deposits, and it plays a very important role in the supply of uranium resources in China. The formation conditions of such a deposit are relatively stable, so it is easy to form large and ultra-large deposits (Liu et al., 1997). Sandstone uranium deposit is a major uranium resource type around the world, it mainly exists in sandstone basins (Adler, 1974), and the basin which are complex formation spaces for different sedimentary strata and facies. As studies indicated sandstone uranium deposits in the north of China is very huge (Wang et al., 2019). Therefore, sedimentary basin analysis has become an important area of the study of the distribution and variation law of uranium resources, and the analysis of ore-bearing space involves the analysis of these dimentary sequence of strata (Zhang and Han, 2008), the sedimentary phase change law, and the localization of redox environment. And now, quantitative analysis and digital simulation of basins have become an important direction and trend for the researches in this field at home and abroad (Brookins, 1976; Cohenour, 1960; Elmasour and Elseed, 2018; Fu et al., 2018; Liu et al., 2006; Liu and Jiao, 2013; Miao and Jiao, 2010; Wyborn et al., 1995).

Materials and methods

Basic geological conditions of the Ordos Basin

The Ordos Basin is located in the western part of the North China Plate and is one of the large inland depression sedimentary basins in China (Zhang and Chen, 2010). The basin is rectangular-shaped and spreads from north to south direction, covering an area of about 250,000 km^2. It is an important basin containing coal, oil, natural gas, uranium and other resources, as shown in *Figure 1*.

The Ordos Basin has a two-layer structure. The basement layer consists mainly of metamorphic rocks of the Archaean Eonothem and the Paleoproterozoic Erathem, together with marine facies limestone and clastic sedimentary rocks of the Mesoproterozoic Erathem (Chen and Li, 2003; Chen and Xiang, 2010), the Neoproterozoic Erathem, and the Paleozoic Erathem. The caprock layer is continental facies clastic sedimentary rocks of the Mesozoic Erathem and the Cenozoic Erathem. The Dongsheng sandstone-type uranium deposit is located in the eastern part of the Ordos Basin. The ore-bearing stratum is the gray medium sandstone and medium-coarse sandstone in the lower section of the Middle Jurassic Series Zhiluo Formation, and these sandstones are composite watercourse sands of multi-stage braided river in deeply incised valley under humid climate conditions (Adler et al., 1974). The erosion surface of the sandstone was developed, where in the Middle Jurassic Series Zhiluo Formation in the ore-bearing stratum conformably or disconformably capped on the coal-bearing stratum of the Middle Jurassic Series Yan'an Formation (Miao and Jiao, 2010; Lin et al., 2007). In terms of geotectonic structure, it belongs to the Ikh Juu League uplift zone. In the Early Paleozoic Era, the basin accepted the shallow marine clastic rocks and carbonate sedimentary rocks, and in the Late Paleozoic Era, the marine facies and continental facies deposited stably and alternately. In the Late Triassic Epoch, the inland depression formed, and very thick Mesozoic Erathem fluviatile-lacustrine facies

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1452914541

clastic rocks deposited, then the later Yanshan movement caused the Upper Jurassic Series and the Upper Cretaceous Series missing from the Mesozoic Erathem. During the development of the basin, paleogeographic conditions such as the climate changed from wet to dry and several regional sediments had been interrupted, had laid a basis for the formation of sandstone-type uranium deposits.

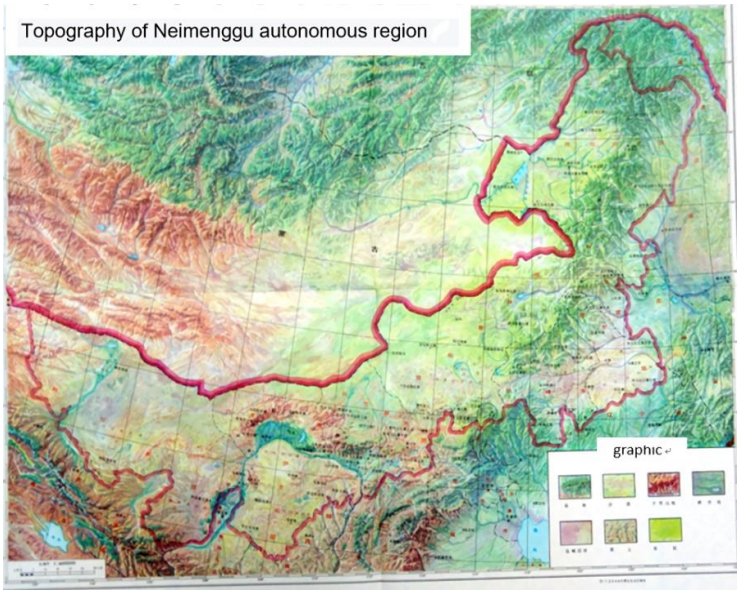

Figure 1. *Terrain of the Ordos Basin*

Borehole data of the Ordos Basin

This study collected several dozens of the sandstone uranium samples from the Dongsheng sandstone uranium mine area in the Ordos Basin and from several wells in the Huanglong area. The rock type of the uranium-bearing minerals is mainly variegated grayish-green sandstones of the Middle Jurassic Series Zhiluo Formation, with medium-grained sand-like structures. Thin section identification results indicate that the sandstones are mainly composed of plagioclase, quartz, muscovite, chlorite and epidote (Chen and Li, 2003), and the cement consists of clay minerals, carbonates and a small part of limonite.

The sampling of sandstone uranium was completed in the 28th Brigade of the Ministry of Nuclear Industry, which is a subordinate unit of the geology and minerals department of the CNNC (China National Nuclear Corporation), it is a deputy-department level national secondary public institution with 1,500 employees and 6 Grade-A qualification certificates such as the regional geological survey certificate. Since 2000, it has made major breakthroughs in uranium mines and made important contributions to rapidly improving the uranium resources capacity of China.

To ensure the uranium content of the samples, detailed geological and geophysical exploration and cataloging of the newly constructed boreholes was carried out to deepen our macroscopic understanding of the ore-bearing sandstones. The boreholes of the uranium industry were selected as research objects. The surrounding rocks (including gray sandstones and grayish-green sandstones) at different positions around the ore-bearing stratum, mineralized sandstones and uranium ore samples were collected, and every sample was subject to the radioactivity measurement on the site. The well logging

DOI: http://dx.doi.org/10.15666/aeer/1706_1452914541

borehole samples are shown in *Figure 2,* and the well logging data are shown in *Table 1* and *Figure 3*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1452914541

According to the identified sandstone-type uranium mines and the collected coalfield radioactive well logging data we can know that, the uranium-bearing strata in the northeastern Ordos Basin are mainly the Zhiluo Formation, followed by the Yan'an Formation.

The Yan'an Formation is a set of sedimentary stratum dominated by fluviatile-lacustrine delta facies, which are mainly dark-colored sandstones, mudstone and shale interbeds, and stably developed coal seams, containing rich animal and plant fossils and organic matters. Generally (Zhang and Li, 2010), it is composed of two lithologic sections that are tapered upwards; the lower section consists of gray medium-grained and fine-grained mingled sandstones and mudstones. The sand body is rich in reducing media such as charcoal and pyrite; nonuniform thickness, the sandstones' cementation matter is mainly the mud, and the consolidation degree is relatively loose; the upper section is dominated by grayish-white medium- or fine-grained sandstones, followed by gray or black mudstones, quartz sandstones are seen locally, and grayish-white kaolinized sandstones are seen at the top, with mud as cementation matter and high degree of consolidation, local sections were altered and became kaolin, which is a unique weathering product when the Yan'an Formation is exposed on the surface. The currently found mineralized uranium is mainly concentrated in this section, as shown in *Figure 4.*

Figure 4. *Rock core of the Yan'an Formation*

According to the characteristics of well logging curve, lithology, cycle and color, the Zhiluo Formation can be divided into the lower section and the upper section. The lower section of the Zhiluo Formation is stable throughout the whole area, and it is mainly composed of primary gray clastic rocks, and the sand body of fluviatile facies had developed. *Figure 5* shows the stratigraphic division and logging response of the Zhiluo Formation.

Markov probability

If a process is given a "present", then its "future" is independent of its "past", and such a random process is called a Markov process. The Markov chain is a time-discrete, state-discrete Markov process. In a Markov chain, the transfer of system states can be represented by a transition probability matrix, namely $P = [P_{ij}]$. The elements in the transition matrix are called transition probabilities. The transition matrix has two important properties, that is, all elements are non-negative and the sum of the elements is equal to 1, namely $P_{ij} \geq 0$, $\sum P_i = 1, 2, 3, \ldots, n$. Therefore, the formula is as follows:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1452914541

$$(P_{ij})_{n\times n} = \begin{bmatrix} P_{11} & P_{12} & \cdots & P_{1n} \\ P_{21} & P_{22} & \cdots & P_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ P_{n1} & P_{n2} & \cdots & P_{nn} \end{bmatrix} \underline{\Delta} P, \sum_{j=1}^{n} P_{ij} = 1 \qquad \text{(Eq.1)}$$

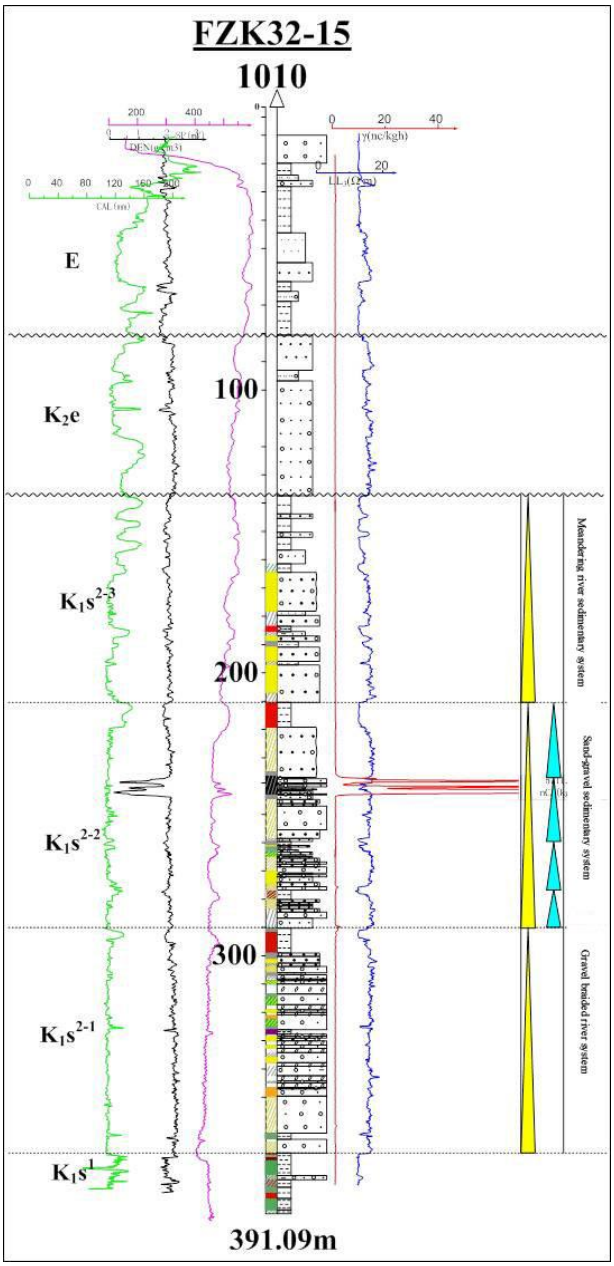

Figure 5. *Stratigraphic division and logging response of the Zhiluo Formation*

When the system state starts from any fixed state i, goes through a transition and reaches the state j, then it will generates states $E_1, E_2, E_3, \cdots, E$, so P_{ij} would constitute a probability matrix, which is a first-order transition probability matrix. Therefore, accordingly, there are also second-order, third-order, and n-order (high-order) transition probability matrices. And high order transition probability matrix can be obtained by matrix multiplication: $P^{(n)} = P^{(1)} \cdot P^{(n-1)}$, and the formula is as follows:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1452914541

$$(P_{ij}(k))_{n\times n} = \begin{bmatrix} P_{11}(k) & P_{12}(k) & \cdots & P_{1n}(k) \\ P_{21}(k) & P_{22}(k) & \cdots & P_{2n}(k) \\ \vdots & & & \\ P_{n1}(k) & P_{n2}(k) & \cdots & P_{nn}(k) \end{bmatrix} \triangleq P(k) \quad \text{(Eq.2)}$$

Therefore, the k-th transition probability matrix is equal to the k-th power of one-time transition, namely:

$$P(k) = (P_{ij}(k))_{n\times n} = P(1)^k = \begin{bmatrix} P_{11} & P_{12} & \cdots & P_{1n} \\ P_{21} & P_{22} & \cdots & P_{2n} \\ \vdots & & & \\ P_{n1} & P_{n2} & \cdots & P_{nn} \end{bmatrix}^k \quad \text{(Eq.3)}$$

Markov prediction model

Assume the system has n mutually incompatible states, and the initial state vector of the system is:

$$S(0) = [S_1(0), S_2(0), \cdots, S_j(0), \cdots, S_n(0)] \quad \text{(Eq.4)}$$

where, $S_j(0)$ is the initial probability that the system is in the state j.

Since after *k*-steps transition the probability that the system is in state *j* is S_j(k), then after *k*-steps transition, the state vector is:

$$S(k) = [S_1(k), S_2(k), \cdots, S_j(k), \cdots, S_n(k)] \quad \text{(Eq.5)}$$

where, $S_j(k)$ is the probability that the system is *j* in a state at the moment k.

Therefore, the Markov prediction model is:

$$\begin{aligned} S(k) &= S(k-1)\cdot P = S(k-1)\begin{bmatrix} P_{11} & P_{12} & \cdots & P_{1n} \\ P_{21} & P_{21} & \cdots & P_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ P_{n1} & P_{n2} & \cdots & P_{nn} \end{bmatrix} \\ &= S(0)\cdot P^k = S(0)\cdot \begin{bmatrix} P_{11} & P_{12} & \cdots & P_{1n} \\ P_{21} & P_{21} & \cdots & P_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ P_{n1} & P_{n2} & \cdots & P_{nn} \end{bmatrix} \end{aligned} \quad \text{(Eq.6)}$$

The spatial distribution of the basin sediment formation is multicomponent, heterogeneous, periodic and extensive, and the distribution in each stratum layer is regular. The research results show that the distribution of the sedimentary strata in the basin has Markov characteristics. The sedimentary strata have the characteristics of complexity and cyclicity. In the structure of the basin, the uranium-bearing stratum is only one of the sections. If each stratum is regarded as a state, then the probability of the stratum can be represented by the number of times the stratum appears in the entire sedimentary strata, and a Markov probability matrix can be constructed with the probabilities of all strata. Therefore, the Markov process can be used to clarify the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1452914541

sequence of the sedimentary process of the strata and even the cyclic or the phase change law, thus establishing a Markov process model for stratum sediment.

According to the collected logging data, part of the borehole data is shown in *Figure 6*. The basin stratum sequence can be sorted from bottom to top. According to the borehole data, there were a total of 55 stratum samples, which can be divided into 36 lithologic states after repeated screening, and some lithology states after screening are shown in *Table 2*.

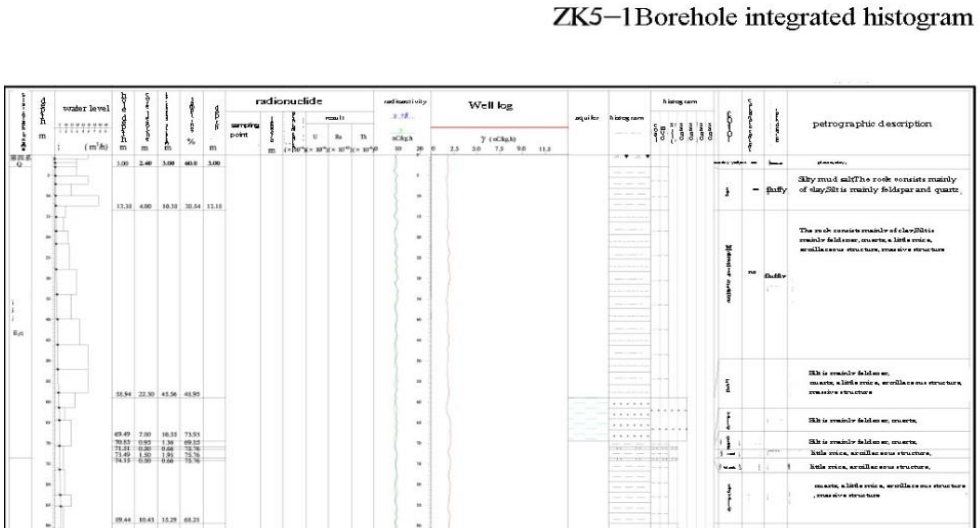

Figure 6. *Partial comprehensive histogram of the Ordos Basin*

Table 2. *Partial lithology states after screening*

Layer	Petrographic description	Type	Layer	Petrographic description	Type
1	Coarse gravel sandstone (light grayish green)	1	15	Coarse gravel sandstone (light brown yellow)	10
2	Carbonaceous mudstone (grayish black)	2	16	Silty mudstone (blue gray)	3
3	Silty mudstone (blue gray)	3	17	Coarse gravel sandstone (gray, off-white)	12
4	Coarse gravel sandstone (off-white)	4	18	Oil sand salt (gray, off-white)	12
5	Fine gravel salt (off-white)	5	19	Coarse gravel sandstone (off-white)	4
6	Coarse gravel sandstone (off-white)	6	20	Medium pebbled sandstone (off-white)	13
7	Silty mud salt (blue grey)	3	21	Fine sand salt (off-white)	5
8	Carbonaceous mud salt (gray black)	2	22	Oil sand salt (light brown yellow)	14

Therefore, the one-step probability matrix of the mutual transition of 36 lithology is calculated by MATLAB:

$$P_{36}=\begin{bmatrix}0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & \cdots & 0\\ 0 & 0 & 0.33 & 0 & 0 & 0 & 0.33 & 0.33 & \cdots & 0\\ 0 & 0.33 & 0 & 0.33 & 0 & 0 & 0 & 0 & \cdots & 0\\ 0 & 0 & 0 & 0 & 0.25 & 0 & 0 & 0 & \cdots & 0\\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots\\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \cdots & 1\\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \cdots & 0\end{bmatrix} \quad \text{(Eq.7)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1452914541

The probability of two-time transitions is:

$$P_{36}{}^{2} = \begin{bmatrix} 0 & 0 & 0.33 & 0 & 0 & 0 & 0.33 & 0.33 & \cdots & 0 \\ 0 & 0.43 & 0 & 0.27 & 0 & 0 & 0 & 0 & \cdots & 0 \\ 0 & 0 & 0.1 & 0 & 0.08 & 0 & 0.1 & 0.1 & \cdots & 0 \\ 0 & 0 & 0.25 & 0.25 & 0.12 & 0 & 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \cdots & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \cdots & 0 \end{bmatrix} \quad \text{(Eq.8)}$$

According to the modeling process, if the initial state of an event at moment (or period) K is known, then by using *Equation 2* we can obtain its possible variation trend at the first moment (or period) after one-time state transition, as shown in *Figure 7.* Therefore, through calculation, we can get the probabilities of various possible states after one-time transition, as shown in *Figure 8.* And so on, we can also obtain the variation trend of the event's two-time state transition at the second moment (or period), as shown in *Figure 9*. And the prediction of the probability of two-time transition is shown as *Figure 10.*

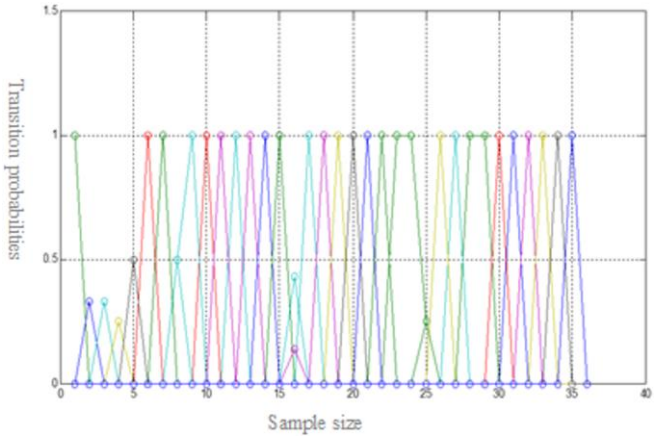

Figure 7. *Variation trend of one-time state transition*

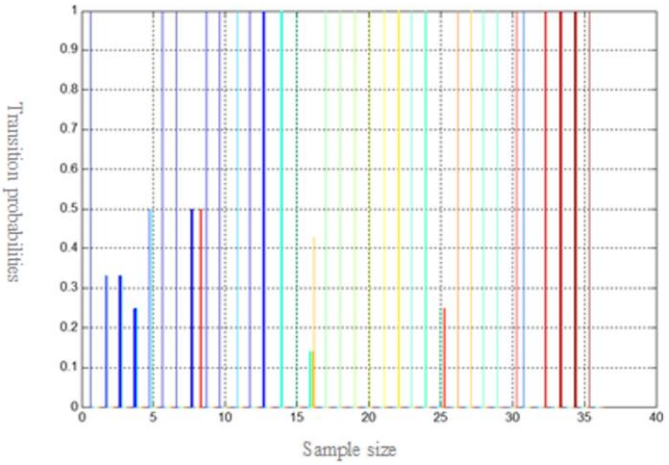

Figure 8. *Probability of one-time state transition*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1452914541

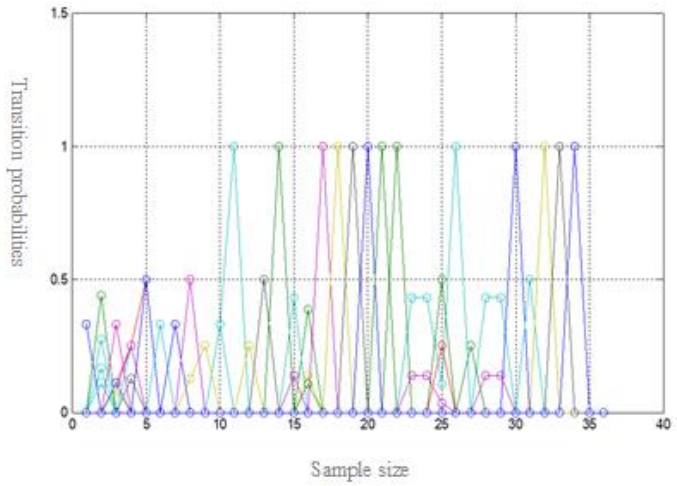

Figure 9. *Variation trend of two-time state transition*

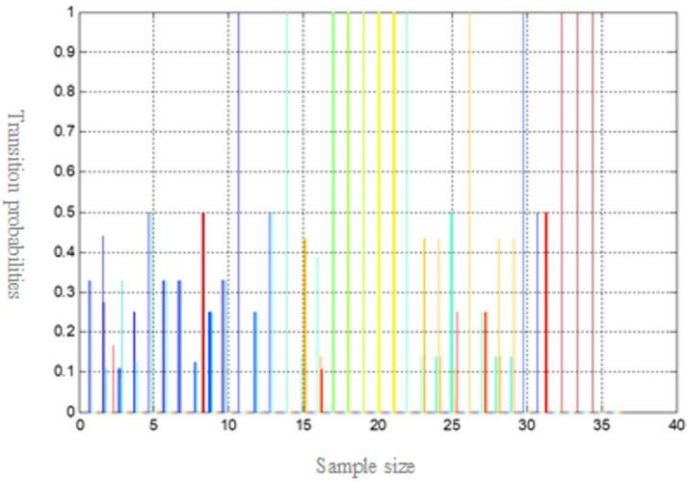

Figure 10. *Probability of two-time state transition*

Results

Therefore, through the Markov probability modeling process we can know that, regardless of the one-time transition probability or the two-time transition probability, the transition probability of all lithology does not exceed 1. Color is a simple and direct feature mark of rocks. Color is usually used to describe rocks and distinguish mineral components, and the color change of rock surface is an important basis for obtaining and identifying rock and mineral information. By looking up the lithology transition states we can see that, in the one-time transition probabilities, the probability of transferring from carbonaceous mudstone (grayish black) to silty mudstone (blue-gray) is 33%, the probability of transferring from carbonaceous mudstone (grayish black) to coal (black) is 33%, the probability of transferring from carbonaceous mudstone (grayish black) to mudstone (dark grayish green) is 33%. The probability of transferring from silty mudstone (blue-gray) to carbonaceous mudstone (grayish black) is 33%, the probability of transferring from silty mudstone (blue-gray) to coarse-grained sandstone (gray-white) is 33%, the probability of transferring from silty mudstone (blue-gray) to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1452914541

coarse-grained sandstone (gray, grayish white) is 33%. They have the same transition probability. Therefore, it can be seen that the organic matter is not oxidized and the uranium signal reaches the normal background value.

Discussion

In the two-time transition probabilities, the probability of transferring from carbonaceous mudstone (grayish black) to carbonaceous mudstone (grayish black) is 43.9%. There are usually accompanying elements such as molybdenum, selenium, vanadium, plumbum in the sandstone-type uranium deposits. For the radioactive elements such as uranium and thorium contained in the grayish green and grayish-black lithic feldspar sandstone, there is data show that the content of uranium in the grayish-green sandstones is significantly lower than that in the grayish-black sandstones. The average uranium content in the former is 3.38×10^{-6}, while in the latter this number is 14.33×10^{-6}. In the two kinds of sandstones, the content of thorium varies little, therefore, for the thorium/uranium ratio, the former is larger, with an average ratio of 1.78, and the latter is smaller, with an average ratio of 0.31. The uranium content, thorium content and strontium/uranium ratio in the grayish-green sandstone indicate that uranium has obvious outward migration, which also indicates that the grayish-green sandstones were subject to strong oxidation. Molybdenum and vanadium often co-migrate with uranium during oxidation and precipitate and enrich in a reducing environment. It can be seen from the transition probability and the variation trend that the probability of transferring from carbonaceous mudstone (grayish black) to silty mudstone (blue-grey) is 33%, and grayish-black carbonaceous mudstones have higher yttrium, zirconium and niobium contents than blue-grey silty mudstones, and the enrichment of these alkaline elements is due to the introduction of alkaline fluids. The geochemical characteristics of trace elements in grayish-black sandstones also indicate that they experienced a slightly acidic oxidation at an earlier time, and then were subject to the alkaline chloritization alteration. In view of the two giant uranium mineralization belts in the world, Russia attaches great importance to and pays close attention to the search of uranium mineralization resources, and applies the most commonly used geological distribution rules to search. In this paper, Markov process model is applied to analyze the sedimentary sequence and evolution relationship of the basin by means of transfer probability, which is of great importance to the distribution law of sand-salt uranium ore.

Conclusion

The study area of this paper is the northern margin of the Ordos Basin. Through the derivation of the Markov one-time transition and two-time transition probabilities, it can be seen that the black organic veins in the target sandstone layer of the study area have the mixed sources of coal-generated gas and oil gas, which also indicates that a strong oil-gas effect occurred after the formation of the sandstones. Studies have shown that there are also good conditions for oil and gas traps in the northern part of the Ordos Basin. The oil and gas fluids are generally alkaline and have a strong reduction effect; high-valent iron is reduced to low-valent iron, under such reductive and alkaline fluid conditions, the indication significance of the grayish-green sandstone for the uranium mineralization are well known, and the grayish-green sandstone indicates the reductive

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1452914541

geochemical environment. After recognizing that it is a product of ancient oxidation and re-reduction, we can realize the essence through the appearance. In the northern part of the Ordos Basin, the grayish-green sandstones indicate a strong ancient oxidation effect, that is, a strong inter-layer oxidized uranium mineralization effect had occurred. The contact position between the grayish-black sandstones and the grayish-green sandstones, namely the pinch-out of the front of the ancient inter-layer oxidation zone, is the most favorable position for uranium mineralization. The obvious changes of sedimentary rhythm or sedimentary microfacies of river sand bodies, the transition zone of grayish-black sandstones and grayish-green sandstones, and the abnormal diffusion halo of uranium are caused by the different formation causes of the upper and lower sub-sections of the Zhiluo Formation, which resulted in significant differences in the sand body, structure and scale. The lower sub-section sand body has a larger scale and better connectivity, while the upper sub-section sand body has a smaller scale and a stronger heterogeneity. This law has an important guiding effect in understanding the expansion of sandstone uranium mineralization in the northern Ordos Basin, and it has important practical guiding significance for the exploration of similar deposits, especially sandstone uranium deposits in basins with rich oil, gas or coal resources. With the continuous development and progress of prospecting and exploration technology in the future, a variety of high-tech analytical and testing technologies can be applied to predict and evaluate the rules of uranium diagenesis and mineralization.

Abstract. By monitoring the change of dust fall concentration at the same height and different distances near the boundary of a building demolition site, this paper tries to study the law of dust formation and diffusion in the area site. In order to conduct quantitative analysis on the raise dust distribution in the construction site at the demolition stage, the amount of fine particulate matter $PM_{2.5}$ and inhalable particle PM_{10} in such a site where an experimental demolition is performed measured. The data measurement is carried out with the help of logarithm conversion, so as to reduce the data variability and enable it to approach normal distribution, and the data with the confidence coefficient of 95% is selected. The main components of $PM_{2.5}$ and PM_{10} emissions are extracted to indicate the emission intensity. According to the emission intensity, a construction site can be divided into three categories for analysis by hierarchical clustering, so as to obtain the desired results. Through the comparison and analysis of the monitoring quantitative and discrete phase model, the motion, diffusion and settlement equations of the dust of the demolition site are verified, indicating that the simulation results using the discrete phase model are credible.

Keywords: *raise dust in construction, formation mechanism, discrete phase model, diffusion mechanism, monitoring quantification*

Introduction

In recent years, the value orientation of the public policy making in China has gradually transformed from emphasizing the pursuit of economic efficiency to focusing more on social equity, with an expectation of balancing the, dual goals of economic development and social welfare. With the acceleration of the urbanization process, the demolition of old buildings is increasing day by day. As a way to the old buildings in an unprecedented manner, the building demolition project is also included in one of the important tasks of the construction project. The demolition of old buildings has produced a lot of construction waste. "The amount of construction waste in China already accounts for 30 to 40% of the total amount of urban waste," said Qiu Baoxing, a former vice-minister of housing and urban-rural development. According to the rough statistics of the loss of construction materials of brick and concrete structure, whole cast-in-situ structure and frame structure, in the construction process of every 10,000 m^2 of buildings, only the construction waste will produce 500 to 600 tons; Every 10,000 m^2 of old buildings demolished will generate 7,000 to 12,000 tons of construction waste, and 40% of the old buildings demolished in China each year. Wang Guangtao, former minister of construction, said that by 2020, China will add 30 billion m^2 of construction area, and the total amount of construction waste will be 1.8 billion tons. This poses a huge environmental threat to China. These construction units or individuals usually do not carry out any treatment on the muck, spoil, waste, mud and other waste generated in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1454314559

the demolition of various buildings, structures and pipe networks. Moreover, the raise dust, sand dust and other problems generated in waste transportation and stacking have caused serious environmental pollution. Raise dust can be hazardous human health and it is likely to cause dust pollution, which in turn leads to deterioration of the surrounding environment. Studies have shown that air pollution can be divided into two types: gaseous pollution and particulate pollution. Particles with a diameter of less than 10 μm are called inhalable particles (PM_{10}), which are rather harmful to human health. Inhalable particles can be divided into fine particles ($PM_{2.5}$) and coarse particles according to the particle size. In recent years, the $PM_{2.5}$ index has attracted a lot of people's attention. The main reason is that fine particles (also known as microparticles) can directly enter and precipitate in human lungs. Its impact on human health is permanent. If a large amount of building raise dust enters the lung, it will cause obstructive damage to the respiratory system, reduce the ventilatory function of the bronchus, and lose the air exchange function the alveoli. In the meanwhile, fine particles adsorbed in the lungs stimulate the cell wall, causing bronchitis, asthma and other diseases. In addition, the increased concentration of PM_{10} and $PM_{2.5}$ in the atmosphere will lead to cardiovascular disease, resulting in an increase in the incidence rate of cancer. The increase of particles in the air easily leads to the appearance of haze weather condition and affects people's normal travel. Acidic substances in the air have a certain corrosive effect on buildings. If the amount of acidic substances increases, the corrosion degree is improved, and the hazard is rather serious especially after rainfall. Therefore, the research on the generation, movement law and concentration of raise dust in the demolition construction site of existing buildings is the basis for the construction site employees to make preparations and control in advance, an important means to protect the health and life of employees, and an important prerequisite for ecological environmental protection.

For many years, various researches have been carried out on raise dust pollution in building construction at home and abroad, including the exploration of raise dust emission factors for building construction (Muleski et al., 2005; Toropov et al., 2018). Raise dust is an open pollution source entering the atmosphere and it is an important component of total suspended particulates in the ambient air. According to the dust research, the causes of dust mainly come down to the following two aspects: The powder is separated from the powder flow because of the influence of the surrounding air during the falling process, and it suspends in the transition layer of the powder flow (Ansart et al., 2009), thus generating the dust cloud. The falling powder particles collide with particles and walls in the bag to produce impact dust and suspend in the air (Wang et al., 2014). The essence of the phenomenon that powders take up air and the air affects particles is gas-solid collaboration effect (Alekhfne, 2012; Cerecedo et al., 2009). Fan et al. (2019) conducted accumulated dust load sampling and laboratory screening analysis on typical roads, measured the road dust particle size distribution and particle size multiplier by resuspension system and particle size spectrometer, investigated the road vehicle composition and calculated the vehicle weight, and applied the model method to establish a localized road raise dust $PM_{2.5}$ emission factor. Based on the survey data of architecture and municipal construction projects in Xi'an, Xiao et al. (2019) combined with two sets of emission factors of typical cities in northern China measured by different institutions to estimate the emission amount and emission strength of the architecture construction raise dust PM_{10} and $PM_{2.5}$ in Xi'an in 2017, so as to construct a list of particulate matter emissions from county-level buildings in Xi'an, and analyze

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1454314559

the spatial distribution characteristics. All local governments have attached great importance to this and have issued a series of guidelines and policies to monitor the raise dust pollution. However, the current construction raise dust pollution monitoring still relies on manual patrol and fixed-point monitoring, which is inefficient and ineffective, and there is no more effective monitoring techniques. The construction environment monitoring mainly focuses on the raise dust and material waste and so on at the construction site (Kohlman et al., 2014), in which, the construction raise dust control is a research hotspot. In terms of monitoring methods, instrument sampling is the main method and video monitoring is feasible as well (Wu et al., 2015). However, although the above methods have high precision, they are not efficient because of being easily interfered. In recent years, UAV (Unmanned Aerial Vehicle) images have been used for water pollution monitoring, chemical gas pollution monitoring, vehicle identification, building deformation monitoring and so on (Chen et al., 2016). Construction dust is the main source of atmospheric pollutants and the key object of construction environment monitoring, but the traditional monitoring methods have limited efficiency and effectiveness. For this purpose, Ma et al. (2018) integrated the use of UAV and image recognition technology, designed the structure, function and operation process of the construction dust pollution source automatic monitoring system with HSV (Hue, Saturation, Value) feature extraction, histogram comparison, nonzero pixel calculation as the core, and tested the operation test. It is found that the pollution source characteristic comparison effect is relatively stable, basically meeting the construction dust pollution source monitoring demand Wu et al. (2017) designed a construction site environmental monitoring system to achieve real-time monitoring of the construction site environment. In order to propose a targeted construction dust prevention and control measure, ensure the occupational health and safety of construction workers, Li et al. (2014) selected two main residential projects in Beijing and arranged the raise dust concentration monitoring sites in the main construction activity areas at the second structure and indoor rough decoration stages to analyze the emission characteristics and main distribution laws of raise dust. Huang et al. (2013) considered that the screening of dust source samples is an elementary test for studying the dust pollution characteristics. It has a wide application. The screen test is required whether it is to determine the critical friction wind speed of wind erosion dust, road dust load and other parameters, or to prepare a dust source resuspension test sample for studying the particle size distribution and source composition spectrum of total suspended particulate matter. Shi et al. (2013) applied laser demand technology to find that the non-structured particles in the near-surface atmosphere have important theoretical and practical values. The laser demand technology is used to detect the raise dust of urban construction sites, and the outer wall of the building is utilized to conduct relatively calibration of the laser demand signal. Afterwards, according to the laser demand equation, the extinction coefficient of the raise dust particles along the optical path is solved, and the extinction coefficient distributions of multiple paths are obtained through the process control scanning station. In the end, the two-dimensional mass concentration distribution condition is achieved by combining with the mass extinction efficiency factor.

Dong et al. (2019) such as using the positive definite matrix factorization model (PMF) - the health risk assessment model (HMHR) explores the Yangzhou fine particulate matter (PM2.5) in heavy metal pollution sources and little pollution, and combine the health risk assessment model (heavy metal health risk, HMHR) to calculate

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1454314559

the influence of different pollution on human health, to reveal the different sources of pollution potential harm to human body health to provide scientific information. Atmospheric fine particulate matter (PM2.5) (aerodynamic equivalent diameter < 2.5 micron) has an impact on human health and environmental air quality. Among them, heavy metals have a particularly significant impact on human health, which can enter the human body through hand ingestion, breathing and skin contact, and further lead to functional dysfunction and irreversible injury. Elements Cr and Pb are elements with the highest potential health risks in cities, which can cause diseases of the nervous system and blood system, especially for infants and young children (Thomas et al., 2009). PM2.5 receptor samples were collected, positive matrix factorization (PMF) was used to analyze the contribution of different pollution sources to PM2.5 and different heavy metals, and the heavy metal health risk HMHR was combined to calculate the impact of different pollution sources on human health (Peng et al., 2016). Li et al. (2015) evaluated the pollution of construction workers by dust at different construction stages by establishing a model of health damage caused by construction dust. Chou et al. (2015) calculated the economic loss caused by CO2 emission to construction workers in the construction process by establishing Monte Carlo simulation model. However, most of these studies only focus on the occupational health damage to construction workers, which to some extent cannot accurately reflect the impact scope and degree of construction dust.

Sung et al. (2006) observed that building demolition was one of the most common activities in the construction industry. The commonly used demolition techniques are mechanical demolition, demolition and mixed demolition. Although deconstruction is advocated in an environmentally friendly way, the cost comparison of demolition projects with different technologies is rarely studied. Mohamed et al. (2008) proposed a new framework for building pollution control based on multi-objective optimization. The method used in the proposed framework is based on the calculation of pollution from dust, hazardous gases and noise to each activity involved in the project. Madelyn et al. (2010) proposed a new method based on the building cost system (BCS) to deal with the costs associated with construction and demolition waste management, which improves accuracy and produces estimates independent of the general budget. Water suppression to mitigate the spread of dust is the most popular and a universal method to deal with construction dust (Zuo et al., 2017). However, countries or regions which experience water shortage find this technique to be expensive and morally incorrect. Maintaining standard heights for stockpiling, wetting objects before cutting or grinding, wetting while sweeping are very easy methods to control some of the dust generated at sites. Use of chemical agents, electrical sweepers, dust screens, local exhaust ventilation, *etc*., are some technologies that are available for the construction companies to manage dust pollution (Wu et al., 2016).

At present, China has carried out rather sufficient research on the raise dust pollution in construction projects and storage yards, but there is indeed insufficient research on raise dust in demolition projects. The raise dust emission law of the demolition project is rather complicated. Up to now, China has not published any feasible management method with the emission limit as the basis, which can be used to quantitatively evaluate the raise dust emission strength of the demolition projects. Although some provinces and municipalities have published a series of prescribed measures for the raise dust of demolition projects and put forward corresponding controls to the generated raise dust in heavy demolition area, most of these regulations are behavioral

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1454314559

regulations, which are lack of quantitative understanding and control, and researches on the emission characteristics of demolition raise dust pollution, so it is difficult to accurately grasp the emission intensity of dust emission in demolition projects. This study takes the formation and diffusion of raise dust in the demolition process of existing buildings as the research object, explores the relevant laws of dust formation and diffusion, regards green construction environmental protection as the objective, provides theoretical and practical basis for the raise dust monitoring quantification of the construction site. Based on the gas-solid two-phase flow theory, the method of simulation, monitoring and quantification of the movement, diffusion and settlement equation of demolition construction dust is used to study the formation and diffusion of dust in the demolition construction.

Methods

Variable selection and model establishment

Confirmation of raise dust formation and diffusion impact factor

This research selects the falling dust as the inspection index of analyzing the laws of raise dust formation and diffusion. Falling dust refers to particulates that naturally settle to the surface by gravity under airborne conditions. The amount of dust generated in the demolition construction is not only related to the construction stage and construction strength factors, but also has a certain correlation with the climatic conditions in demolishing the building. Through literature research and consultation with experts, it has been determined that the raise dust formation and diffusion impact factors include: dust particle diameter, gas density, dust particle density, dust moisture content, construction strength, wind speed, temperature, humidity, height and other factors.

Equation of motion of the dust in the air

The dust unmooring load refers to the force overcoming the gravity of the dust particles, the gravitation and adhesion force among particles to fly the dust. The critical load that causes the dust to rise is called the ultimate unmooring force. However, according to Zhi et al. (2018), the VWD (Visual Web Developer) force is used to calculate the gravitational attraction between dust particles, which is negligible under normal conditions. In studying the dust in this paper, it is assumed to be a spherical particle. The stress of the dust is very complicated at the construction site. The force of the dust particles in demolishing the existing buildings is analyzed, and the dust is found to be affected by gravity, buoyancy force, air resistance and other external forces. The resultant force $F_{\alpha 0}$ of the dust is determined by the following equation:

$$F_{\alpha 0} = F_g + F_f + F_d + F_{un} \quad \text{(Eq.1)}$$

In the equation, $F_{\alpha 0}$ is the resultant force of the dust, with the unit of N. F_g is the weight of the powder particle, with the unit of N. F_f is the adhesion force among powder particles, with the unit of N. F_d is the air resistance of the dust particles, with the unit of N. F_{un} is other forces of the dust particles, with the unit of N.

The movement law of dust in the air essentially belongs to the research area of gas-solid two-phase flow (Zhu et al., 2017). The volume of dust particles is much smaller than the volume of air. In order to simplify the equation of motion of dust at the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1454314559

construction site, the volume occupied by dust particles can be neglected. In gas-solid two-phase flow, solid particles are exerted with more and complex forces. For the convenience of calculation, it is assumed that the dust is not affected by other forces, but only the force caused by the relative motion of the gas-solid two phases, the equation of motion of the dust is established in Cartesian coordinates according to Newton's second law (Sun et al., 2016):

$$m_p \frac{dv_p}{dt} = \frac{\pi}{6} d_p^3 \rho_p g + \frac{\pi}{6} d_p^3 \rho_g g + \frac{\pi C_d d_p^2 v_p^2 \rho_p}{8} \quad \text{(Eq.2)}$$

After simplification, it can be expressed as:

$$\frac{dv_p}{dt} = \frac{3C_d \rho_g \left(v_g - v_p\right)^2}{4 d_p \rho_p} \quad \text{(Eq.3)}$$

In the equation: m_p is the dust mass, with the unit of mg; v_p is the dust movement speed, with the unit of m/s; t is the movement time, with the unit of s; d_p is the dust particle diameter, with the unit of m; ρ_P is the dust particle density, with the unit of $kg \cdot m^{-3}$; g is the gravitational acceleration, with the unit of m/s^2; ρ_g is the gas density, with the unit of $kg \cdot m^{-3}$; C_d is the air resistance coefficient; v_p is the moving speed of the dust particles, with the unit of $m \cdot s^{-1}$; v_g is the gas movement speed, with the unit of $m \cdot s^{-1}$; π is valued as 3.14.

Diffusion equation of dust in air

The dust particles with smaller particle diameter generated in the demolition process of the existing building have small gravity and low sedimentation speed. Due to the impact of the Brownian motion of the air molecules, irregular movements are generated accordingly. The research shows that the smaller the particle size of the dust particles, the more intense the dust particles move. This movement is named as the dust diffusion movement.

Any particle fluid unit in the space (as shown in *Fig. 1*) is used to analyze the dust diffusion motion (Li et al., 2006), assuming that the volume of the particle unit is $\Delta V = \Delta x \cdot \Delta y \cdot \Delta z$. The mass flux of a substance (called as flux for short) refers to the mass of a substance that flows through.

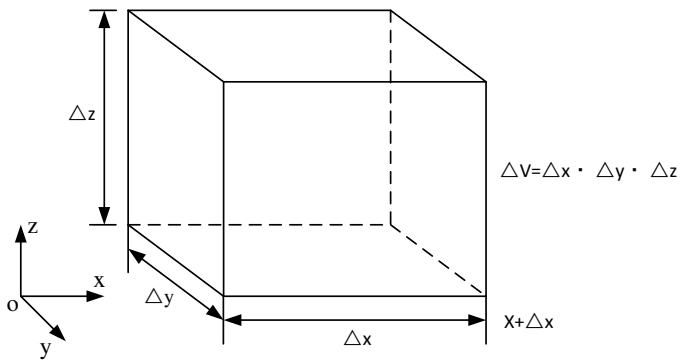

Figure 1. *Diagram of dust diffusion model*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1454314559

According to the gradient conveying theory, the amount of dust passing through a unit area along the x direction for the dust unit time suspended in the air is proportional to the dust mass concentration gradient in the x direction. The flux of dust in the x direction is:

$$Q_x = -K_x \frac{\partial c}{\partial x} \quad \text{(Eq.4)}$$

In the equation: Q_x is the flux of dust in the x direction, with the unit of $mg \cdot m^{-3} \cdot s^{-1}$; K_x is the diffusion coefficient of dust in the x direction; c is the mass concentration of dust, with the unit of $mg \cdot m^{-3}$; $\frac{\partial c}{\partial x}$ is the dust mass concentration gradient along the x direction.

Under the action of the wind flow at the construction site, the dust particles will move along the wind flow direction under the action of the wind flow. Combined with the diffusion action of the dust, the dust concentration in the wind flow movement direction will keep on changing. The wind speeds in the x, y, and z directions are set as v_x, v_y, and v_z, respectively. According to the mass conservation equation, the net inflow in three directions is equal to the cumulative rate, then:

$$\frac{\partial c}{\partial t} = -v_x \frac{\partial c}{\partial x} - v_y \frac{\partial c}{\partial y} - v_z \frac{\partial c}{\partial z} + K_x \frac{\partial^2 c}{\partial x^2} + K_y \frac{\partial^2 c}{\partial y^2} + K_z \frac{\partial^2 c}{\partial z^2} \quad \text{(Eq.5)}$$

In practical applications, in order to simplify the calculation, a one-dimensional stationary diffusion equation can be selected for the research in the three-dimensional coordinate system. When the x-axis direction in the three-dimensional coordinate system is selected for the calculation, $v_y = v_z = 0$. The above equation (*Eq. 5*) can be simplified as:

$$\frac{\partial c}{\partial t} + v_x \frac{\partial c}{\partial x} = K_x \frac{\partial^2 c}{\partial x^2} + K_y \frac{\partial^2 c}{\partial y^2} + K_z \frac{\partial^2 c}{\partial z^2} \quad \text{(Eq.6)}$$

When the wind speed and turbulence intensity are in a steady state, $\frac{\partial c}{\partial t} = 0$. When the ambient wind speed is high, the diffusing capacity of the dust in the x direction $K_x \frac{\partial^2 c}{\partial x^2}$ can be negligible. In such condition, the above equation (*Eq. 6*) can be further simplified as:

$$v_x \frac{\partial c}{\partial x} = K_y \frac{\partial^2 c}{\partial y^2} + K_z \frac{\partial^2 c}{\partial z^2} \quad \text{(Eq.7)}$$

The diffusion coefficients of the dust particles with the same property in the x, y, and z directions are equal, which are uniformly expressed by K_p (Chen et al., 2015). The

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1454314559

differential equation (*Eq. 7*) is solved by Gauss formula, so as to obtain the diffusion equation of dust in air as follows:

$$c = kx^{-1} \exp\left[-\frac{v_x}{4K_p x}\left(y^2 + z^2 \right) \right] \quad \text{(Eq.8)}$$

In the equation, k is the Boltzmann constant, which is valued as 1.38×10^{-23} J·K^{-1}.

Sedimentation equation of the dust in the air

Dust particles settle under gravity during the process of demolishing existing buildings. During the sedimentation process, the particle velocity changes continuously, and the resistance transforms accordingly. When the gravity, buoyancy and air resistance reach a balance, the dust particles settle at a constant speed, and the sedimentation velocity also reaches a maximum value at this moment. Such a speed is called Stokes velocity.

When the dust settles gradually, it is in the stress equilibrium status, and it is $F = F_g - F_f = F_d$ at this moment. Hence, the following equation is obtained:

$$\frac{\pi}{6} d_p^3 \left(\rho_p - \rho_g \right) g = \frac{\pi C_d d_p^2 v^2 \rho_p}{8} \quad \text{(Eq.9)}$$

When the dust begins to settle evenly, the sedimentation velocity also reaches a maximum value, that is, $v = v_t$. The dust sedimentation speed is as follows:

$$v_t = \sqrt{\frac{4(\rho_p - \rho_g) g d_p}{3 \rho_g C_d}} \quad \text{(Eq.10)}$$

(a) When $Re_p \leq 1$, the movement of the dust particles is in a laminar flow state, $C_d = \frac{24}{\mathrm{Re}_p}$. (b) When $1 < Re_p < 500$, the movement of the dust particles belongs to the turbulent transition state. (c) When $500 < Re_p < 2 \times 10^5$, the movement of dust particles belongs to the turbulent state, and C_d hardly changes with Re_p, which is approximately $C_d \approx 0.44$. The Reynolds number of the dust particles Re_p is a dimensionless number reflecting the relationship between the inertial force and the viscous force in fluid flowing process. Its value is related to the flow velocity, feature size and fluid viscosity. Reynolds number $Re_p = \frac{d_p \rho_g v}{\mu_g}$. In the formula, μ_g is the dynamic viscosity of air, with the unit of *Pa·s*.

Empirical analysis

Profile of demolition project

The demolished buildings in the demolition project include 107, 107A, 107C, 107D buildings and some demolition projects above the ground surface, with a total floor area of about 5000 m^2 and a total construction area of about 13798.95 m^2. Among them, 107

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1454314559

is a teaching building with five-story frame structure, 107A is a hospital with two-story brick-and-mortar structure, 107C is a dormitory building with four-story frame structure, and 107D is an auditorium with two-story brick-concrete. The demolition of the building is required to be completed in September 11, 2018~October 5, 2018. The construction site is completely enclosed by iron sheets, with a height of no less than 1.8 m. The safe distance of the building enclosing structure away from the building is 1.5 times of the building height, with its east side connected with the wall (refer to *Figure 2:* construction site planar graph for the building enclosing structure).

Monitoring quantification method

The research results show that particles with a particle size of less than 50 μm will float in the atmosphere for a long time because of the buoyancy and eddy functions, and will be transported to a distant place. Particles with a particle size of 50-100 μm can be kept in suspension, but settle down soon. Particles with a particle size larger than 100 μm can only roll on the ground under the action of wind.

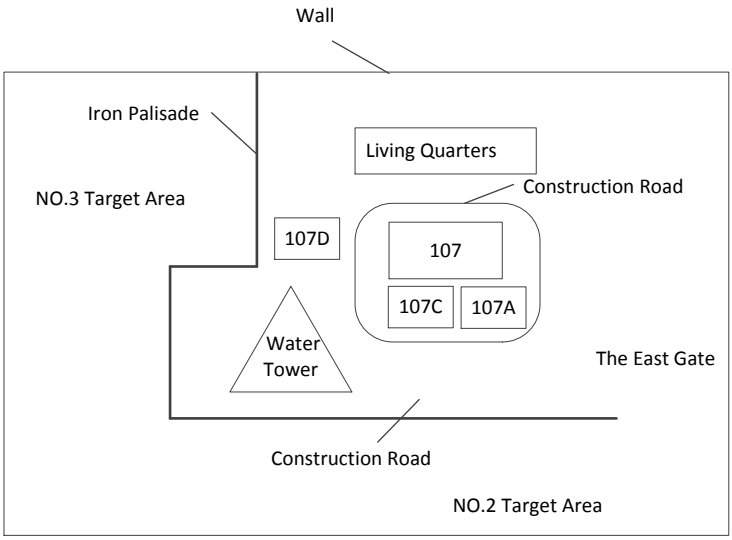

Figure 2. *Construction site planar graph*

In this research, monitoring is carried out by combining dust removal cylinder collection and weighing and $PM_{2.5}$ automatic detector. The dust removal cylinder is mainly located at the boundary of the construction site, and the height is no less than 3 m. The particles collected in the dust removal cylinder have a diameter of below 100 μm, mainly 50-100 μm particles. The instrument for measuring the concentration of particles adopts Xinsite handheld $PM_{2.5}$ laser dust concentration detector, with the model of HT-9600. The instrument employs the $PM_{2.5}$ photoelectric sensor principle, and the pumping sampling method is more accurate. The measuring height is about 1.5 m and the measuring time of each measuring point is 50 s. At the demolition stage, each measurement point shall be recorded of the reading for every 1 h. The monitored data includes: temperature, relative humidity, $PM_{2.5}$ concentration, PM_{10} concentration, dust particle size (0.3 μm, 2.5 μm, 10 μm) and time record. The hourly mean value of $PM_{2.5}$ and PM_{10} measured by the air quality real-time monitoring station at the location

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1454314559

of building demolition was selected as the background value. This study only conducted raise dust monitoring to the demolition project of 107 teaching building. 16 measuring points were selected around the 107 teaching building, and 16 dust removal cylinders were placed in the measuring points to collect dust. The position of the measuring point is shown in *Figure 3*. According to the measuring point arrangement method in the similar literature, the wind speed measuring points and the dust mass concentration measuring points were respectively arranged at the demolition site, which were arranged with a certain interval along the wind flow direction. The wind speed measuring points were arranged to have a space of 20 m, and a total of 7 measuring points were arranged. Each measurement point was conducted with the data measurement of no less than 3 times, and then an average value was calculated.

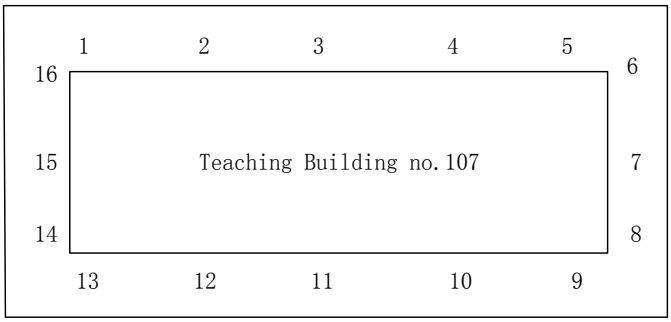

Figure 3. *Measuring point position diagram*

Data preprocessing

SPSS22.0 and Excel are used to process the data, logarithmically transform the obtained $PM_{2.5}$ and PM_{10} data, so as to reduce the data variability of the original data, and enable the data distribution to approach the normal distribution. Cases with a confidence coefficient of 95% were selected for the analysis, namely, cases with the data exceeding ($\mu - 1.96\sigma$, $\mu + 1.96\sigma$) were eliminated (μ and σ are the mean and standard values of the normal distribution, respectively). Afterwards, the original data and the logarithmic data are analyzed, and the inspection level a is valued as 0.05. Through conducting correlation analysis to the two groups of data after logarithmic transformation, it shows that the Pearson correlation coefficients of the data after the logarithmic transformation and the original data are 0.898 and 0.941, respectively, presenting an extremely strong correlation. In other words, the logarithmic transformation process is reasonable. 325 measured data is obtained during the demolition phase, and 296 is selected, showing a data efficiency of 91.08%. After the completion of the demolition phase, there is a total of 120 measured data, in which, 112 is selected, showing a data efficiency of 93%. The statistical description of the cases after screening is shown in *Table 1*.

Quantitative data analysis

Emission intensity index

Correlation analysis is conducted to $PM_{2.5}$ and PM_{10} emissions. The Pearson correlation coefficient of the two variables is obtained through analysis: 0.950, showing that the two variables have an extremely strong correlation. The principal component

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1454314559

analysis can be used to extract a principal component to achieve variable dimension reduction. Refer to *Table 2* for the index characteristic values and contribution rates of the component extraction process obtained by principal component analysis. The factor load matrix is shown in *Table 3*.

Table 1. *Case selection and statistical description*

Category	Demolition stage		After completing the staged work of demolition	
	$PM_{2.5}/(\mu g \cdot m^{-3})$	$PM_{10}/(\mu g \cdot m^{-3})$	$PM_{2.5}/(\mu g \cdot m^{-3})$	$PM_{10}/(\mu g \cdot m^{-3})$
Minimum	10.18	49.36	10.01	28.91
Maximum	432.30	495.40	189.24	202.20
Mean	94.409	156.521	59.511	92.881
Standard deviation	60.573	81.404	33.220	35.444

Table 2. *Index characteristic values and contribution rates*

Times	Initial characteristic value	Variance percentage /%	Accumulated variance percentage
1	1.904	95.189	95.189
2	0.096	4.811	100

Table 3. *Factor load matrix*

Project	Principal component 1 load
$PM_{2.5}$ emission	0.955
PM_{10} emission	0.955

It can be seen from *Table 2* that the contribution rate of the first principal component extracted is 95.189%. This principal component is selected to reflect the emission intensity of $PM_{2.5}$ and PM_{10} on the site. If it is recorded as *Z*, the emission intensity *Z* can be prepared combined with the component matrix:

$$Z = 0.512 \times \Delta PM_{2.5} + 0.512 \times \Delta PM_{10} \quad \text{(Eq.11)}$$

The principal component values of each measured case can be calculated according to the principal component equation. Refer to *Table 4* for the average principal component value of each measured position.

Table 4. *The average principal component value of each measured position*

Location	Average principal component value	Location	Average principal component value
Road side	69.854	Living quarter of the workers	59.003
Waste recycling area	77.315	Gunnery area	145.951
Working passage	227.444	Out of the construction wall	48.080
Excavator	159.201	Loading vehicle	109.694
Plane transport corridor	91.343	Construction waste dump	133.256

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1454314559

In order to identify the location of raise dust emissions to be concentrated during the construction process, and understand the sources and influencing factors of dust at different locations, the locations are classified according to emission intensity. The SPSS self-contained system clustering method is used to classify the locations. After standardizing the emission intensity, the square Euclidean distance is used for classification, so as to draw the system clustering spectrum shown in *Figure 4*.

According to the diagram, the sixteen positions are divided into three categories: the first category is the outer wall of the construction site, and the average value of the main component *Z* is 10.416, indicating that the dust amount at this position is only slightly higher than the background value. It shows that the construction wall has a good restraining effect on dust diffusion. The second category includes the plane transport corridors, the living quarter of the workers, road side, waste recycling area, and around the load vehicle. The third category includes the construction waste dump, gunnery area, excavator area, and working passage. These positions have the highest raise dust emissions and the strongest construction intensity on the construction site. An independent sample T test is performed on the classification results, obtaining a T-test P-value matrix among the three categories as shown in *Table 5*.

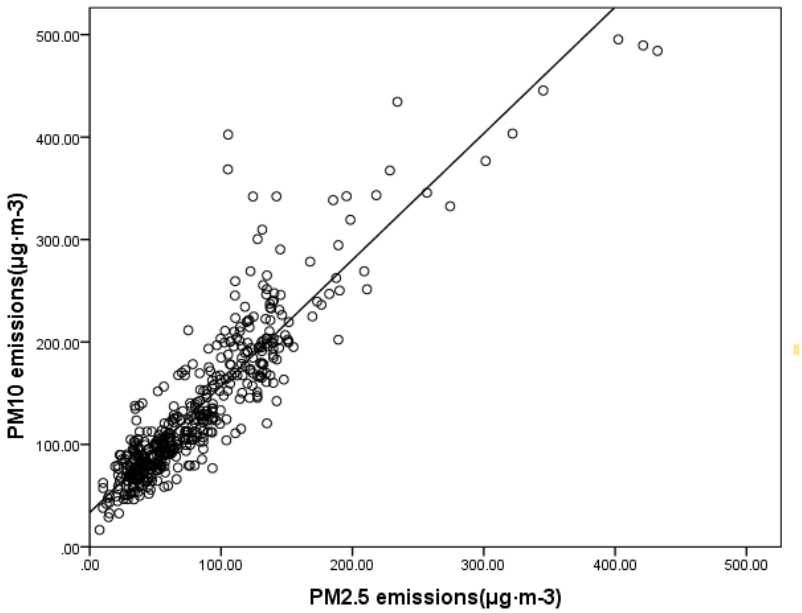

Figure 4. *Linear fitting of PM_{10} and $PM_{2.5}$ emission*

Table 5. *Independent sample T test on the classified result*

T test	The first category	The second category	The third category
The first category	1	0.019	9.5×10^{-5}
The second category	0.019	1	2.4×10^{-5}
The third category	9.5×10^{-5}	2.4×10^{-5}	1

According to the test standard $P < 0.05$, it can be seen that the classification of the measuring points into three categories has a good effect.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1454314559

$PM_{2.5}$ and PM_{10} emission correlation

A linear fitting is conducted to PM_{10} and $PM_{2.5}$ emissions of each region. The R^2 fitting between two types of particle emissions in the region of the first category is 0.806, while the R^2 of linear fitting in the region of the second category is 0.481. The two has a good linear relationship in the third region with the highest emission intensity.

The linear fitting of PM_{10} and $PM_{2.5}$ emissions is shown in *Figure 5,* with a confidence coefficient of $R^2 = 0.817$. The following equation can be obtained for linear fitting:

$$\Delta PM_{10} = 1.234 \times \Delta PM_{2.5} + 33.496 \quad \text{(Eq.12)}$$

It can be seen from the fitting equation R^2 that the linear relationship between the two variables is good, indicating that the $PM_{2.5}$ and PM_{10} emissions have the same emission source in the region of the third category. The paired sample T test is used to test the two emissions, thus obtaining the significance coefficient $4.1^{-12} < 0.05$, that is, the PM_{10} emission is significantly larger than that of $PM_{2.5}$ in the demolition stage, and the particles discharged are mainly larger than 10 μm. When the demolition machinery in the region of the third category is working, the construction dust will be generated in the construction area, and the measured dust produces a large amount of $PM_{2.5}$ and PM_{10}. An independent sample T test is performed on the emission intensity in doing the demolition work and completing the demolition staged work, obtaining the double-tailed significance coefficient between the two categories is $0.025 < 0.05$. In other words, the dust emission in the demolition process is significantly higher the dust emission after completing the demolition staged work.

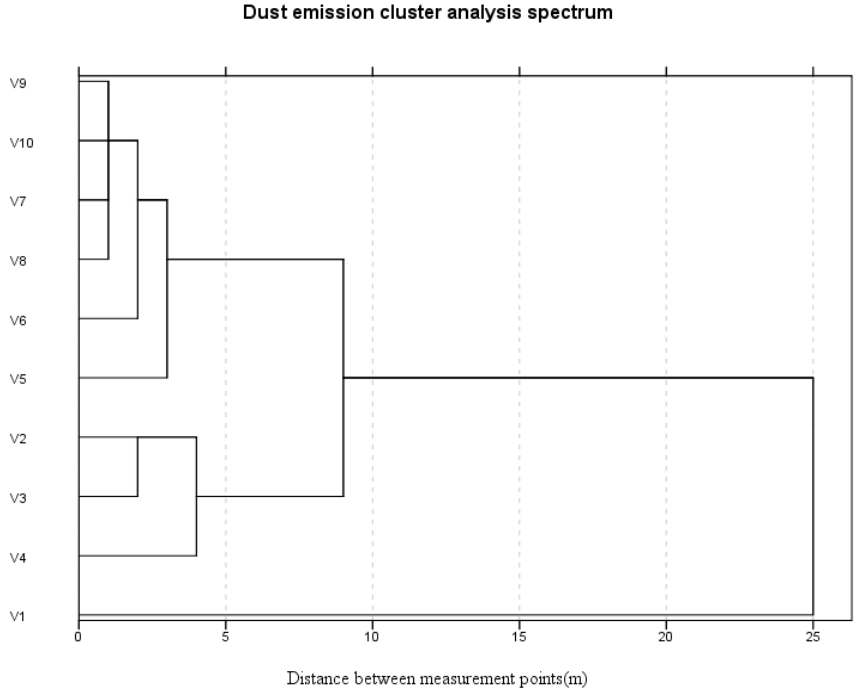

Figure 5. *Clustering analysis spectrum. V1: the working channel passage; V2: excavator working area; V3: the hydraulic crushing hammer working area; V4: the construction waste dump; V5: loading vehicle; V6: the plane transport corridor; V7: the waste recycling area; V8: the road side; V9: living quarter of the workers; V10: out of the construction wall*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1454314559

Correlation between emission intensity and temperature and humidity

Based on the classification result of system clustering, the correlation analysis of emission intensity, temperature and humidity for the location of each category is conducted. The analysis result is shown in *Table 6*.

Table 6. *Correlation between emission strength and climate factor*

Factor	The first category	The second category	The third category
Temperature	0.296	0348**	0.091
Humidity	-0.353	-0.352**	-0.15

** indicates the significant correction in 0.01

According to the results of the correlation analysis, it can be seen that only the emission intensity in the region of the first category is significantly correlated with temperature and humidity. The region of the second category has the largest area in the construction site, and the dust emission intensity is negatively correlated with humidity and positively correlated with temperature. A higher relative humidity in the air enables the particles in the construction site to combine into the larger particles with waters and gases, and promotes PM_{10} to be converted into larger particles, reducing the content of inhalable particles in the air, and decreasing the dust diffusion capacity, so as to decline the emission intensity index in the region of the second category. The emissions of the planar transport corridor, living quarter of the workers, roadside, waste collection area and loading vehicle in the region of the second category is mainly caused by the diffusion of particles.

As the area with the largest amount of dust emission on the construction site, the emission intensity in the region of the third category is mainly affected by the construction intensity, and the particles mainly come from themselves. It has a greater impact on the surrounding area and is less affected by temperature and humidity, so the correlation between emission intensity and these two factors is not significant. The emission intensity outside the wall is low, which is greatly affected by other factors such as the dust of the vehicle, thus reducing the correlation.

Results

It can be seen from *Figure 6* that during the demolition process, the simulation result of the dust mass concentration is basically consistent with the measured data, and the distribution and variation laws are basically the same. The slight deviation between the two values is due to some errors in the field measurement, geometric model establishment and parameter setting process. Through comparative analysis, the movement, diffusion and settlement equations of demolition dust are verified, proving that it is feasible to use the discrete phase model to monitor and quantify the demolition construction dust distribution, and the simulation result is credible.

The region with the highest emission strength in the construction site is the operation channel, excavator working area, gunnery working area and construction dump. An independent sample T test is used to inspect the classification effect, a sound classification result has been obtained.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1454314559

In the region with the highest emission intensity, PM_{10} emission has a strong positive correlation with $PM_{2.5}$ emission ($R^2 = 0.817$), namely, both pollutants have the same source of pollution.

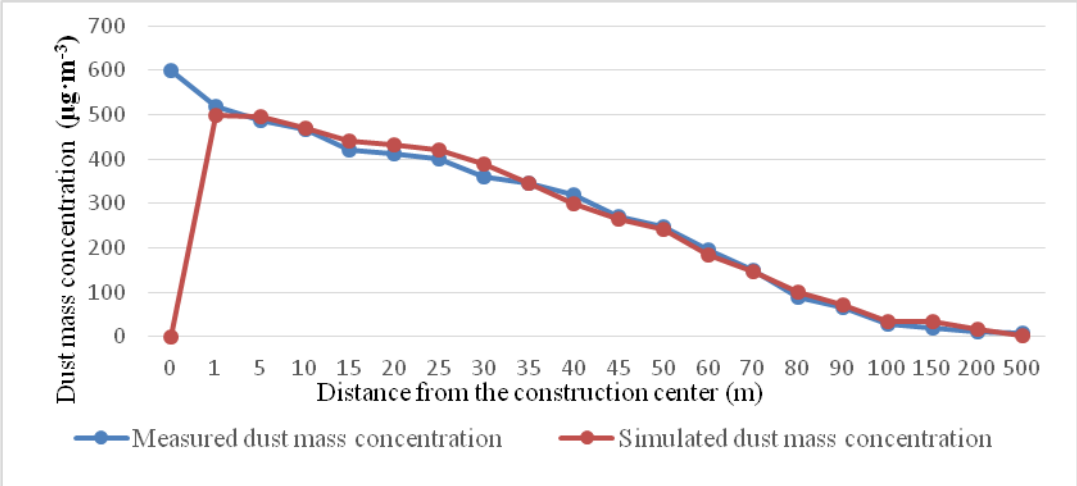

Figure 6. *Comparative analysis of dust mass concentration simulation and actual measurement*

Discussion

After analyzing the correlation between emission intensity and meteorological factors, it is concluded that the emission intensity of the plane transport corridor, living quarter of the workers, roadside, waste collection area and loading vehicle has a significant positive relationship with the temperature and a significant negative relationship with the humidity.

Moisture content of the dust: The higher the moisture content of the dust, the less likely the dust is to be raised.

Air temperature: When the temperature is low, the phenomenon of temperature inversion will probably occur, which hinders the convective movement of the air, so that the dust particles near the ground layer are not easily diffused, causing dust pollution. In the same condition, a lower temperature will lead to the probability of a higher dust concentration.

Air humidity: When the humidity of the air is high, the dust particles suspended in the air collide with the water molecules in the air, increasing the volume and mass of the dust particles, and enhancing the probability that the fine particles are mutually combined into large particles, thereby facilitating the sedimentation of dust particles.

Conclusion

Dust pollution during demolition operations creates a huge challenge for companies involved in such operations with regards to health and safety of workers and the neighboring community. By monitoring the change of dust concentration at the same height and at different distances near the boundary of the blasting site, this paper studied the dust diffusion law and formation law of the case study site in detail.

The main factors affecting the generation of construction dust include: (1) Moisture content of the dust. The higher the moisture content of the dust, the less likely the dust

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1454314559

is to be raised. (2) Air temperature. When the temperature is low, the phenomenon of temperature inversion will probably occur, which hinders the convective movement of the air, so that the dust particles near the ground layer are not easily diffused, causing dust pollution. In the same condition, a lower temperature will lead to the probability of a higher dust concentration. (3) Air humidity. When the humidity of the air is high, the dust particles suspended in the air collide with the water molecules in the air, increasing the volume and mass of the dust particles, and enhancing the probability that the fine particles are mutually combined into large particles, thereby facilitating the sedimentation of dust particles.

Due to the limitations in the theory, there is no unified method or quantitative analysis possible to derive demolition intensity. Therefore, the influence of demolition intensity on dust emission intensity was not considered in this study. It could be a very useful further research as demolition intensity was found to be a deciding factor on dust generation. As a further research area, developing a quantitative tool to represent demolition intensity would facilitate an in-depth study of the relationship between the demolition method, its intensity and dust generation and diffusion.

Abstract. As one of the most concerned topics in environmental and ecological research, the environmental performance of firms is extensively studied while little notices the relationship between firms' geo-location and major cities. Focusing on the spatial agglomerations of corporate environmental performance (CEP) surrounding major cities in China, we examine the research question of "How could major cities affect firms' environmental performances". We propose that major cities affect CEP through knowledge spillover, while the strength of influences depends on firms' spatial proximity to the central area of major cities. Besides, we argue that CEP knowledge spillover principally consists of knowledge transfer and knowledge conversion, the two modes via which CEP knowledge spills over. Based on a sample of 193 Chinese firms, we find that Firms in spatial proximity to major cities centers could obtain more knowledge transfer and conversion on CEP, and thereby improving their environmental performance. Finally, we discuss the research findings, limitations, and future research directions.
Keywords: *spatial proximity, major cities, corporate environmental performance, knowledge spillover, knowledge transfer, knowledge conversion*

Introduction

With the rapid development of China's economy, environmental and ecological issues constantly snowball and draw attention. As one of the most influential economic entities, firms significantly affect the environment and ecology while their environmental performance gradually turns into a crucial concern in theory and practice. In recent years, while overall corporate environmental performance (CEP) has improved in many countries, the distributions show obvious spatial imbalances, such as the prominent CEP agglomeration around major cities. For example, in the United States, firms closer to New York and Chicago are significantly more active in environmental performance, while those in other locations are relatively mediocre (Husted et al., 2016). Extant wisdom shows that major cities could significantly impact corporate environmental performance in both form and content while the impact is tightly related to firms' spatial closeness to major cities (Marquis and Tilcsik, 2016). However, how do firms' spatial proximities to major cities affect their environmental performances? Extant literature lacks a unified and detailed explanation (Marquis and Battilana, 2009; Husted et al., 2012). Thus, correctly clarifying the influence of major cities on CEP and identifying the potential factors that explains the effect of geo-location on firms' environmental performance have become the primary concern.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1456114576

In extant literature, most scholars have studied the mechanisms between firms' spatial proximity to major cities and CEP from the institutional perspective. Based on the neo-institutional theory, researchers suggest that institution is the key reason that a firm's geo-location affects its environmental performance (DeBoer et al., 2017). Similar to industry-related organizational fields (DiMaggio and Powell, 1983), space-related stakeholders could form geographic fields. To obtain legitimization positions in local fields, companies conduct and adjust environmental strategies to meet the legitimacy demands of local stakeholders (Marquis et al., 2007; Hoi et al., 2018). Since the legitimacy requirements in geographic fields are often different, firms' environmental performance vary by locations (Attig and Brockman, 2017; Marquis et al., 2013). In the meantime, related literature suggests that geo-location could influence a firm's organizational practices through efficiency mechanisms, not only in innovation but also in many other organizational practices, including internationalization (Lejpras, 2015), competitive strategy choice (Liarte and Forgues, 2008), legislation resistance behaviors (Simons et al., 2016), stock backdating (Audia and Yao, 2017), and so forth. In such cases, some scholars focus on the efficiency perspective and seek for other theoretical explanations that could bridge proximity to major cities and CEP.

Despite the prevalence of institutional perspective, a few scholars argue that local resources also matter in the influence of geo-location on firms' environmental performances. They propose that firms' geo-locations determine the local resources that are necessary for organizational practices, such as local labor, news media, and information (Sorenson and Baum, 2003). Among those local resources, knowledge resource is of particular importance to corporate environmental performance. Through knowledge spillover, CEP knowledge could significantly promote firms' environment-friendly actions. For instance, Nyuur argues that knowledge spillover from FDI could increase domestic firms' uptake of environment-protection activities (Nyuur et al., 2016). Ning and Wang propose that environmental knowledge spillover could improve local firms' environmental performances (Ning and Wang, 2018). Although a few scholars have noticed the influence of knowledge spillover on CEP, the corresponding research is quite limited, leaving critical issues unanswered. Specifically, how proximity to major cities influence corporate environmental performance through knowledge spillover.

To address the gap mentioned, this study integrates stakeholder theory and knowledge spillover theory to study the mediating role of knowledge spillover between firms' spatial proximity to major cities and environmental performance. We initially analyze the dimension of CEP knowledge spillovers and identify two modes - knowledge transfer and knowledge conversion- via which CEP knowledge spills over. Then we construct the theoretical model that consists of the "spatial proximity-knowledge transfer-CEP" path and the "spatial proximity-knowledge conversion-CEP" path. We hypothesize that knowledge transfer and knowledge conversion are the two potential mediating roles between proximity to major cities and CEP. Furthermore, we empirically test the research hypotheses. Finally, we discuss research findings, limitations, and future research directions.

Materials and methods

Study area

The study area includes multiple major cities from different regions in China mainland, including eastern coastal regions and western inland regions. *Figure 1* shows the location

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1456114576

of the study area, the gray area represents the administrative boundary of China mainland, the blue labeled area represents the cities that our sample firms located in.

Those cities typically inhabit more population and other stakeholders, which derives the influence in social, economic, cultural, and political aspects, on the national or regional scale. For instance, Beijing (21.54 million), Shanghai (24.24 million), Guangzhou (14.9 million), and Shenzhen (13.03 million) are the top four cities in China, while Nanjing (8.44 million), Hangzhou (9.81 million), Xining (2.37 million), Hefei (8.09 million), and Zhengzhou (10.13 million) are provincial capital (population in the brackets).

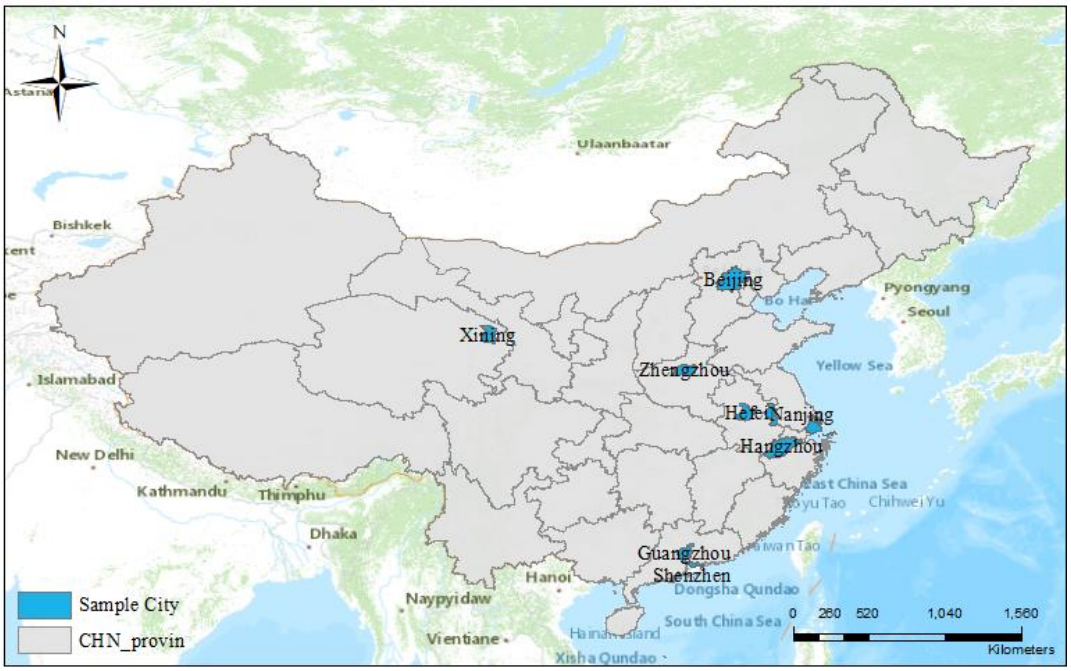

Figure 1. *Location of study area*

Theories and hypotheses

CEP knowledge spillover: knowledge transfer and conversion

As an essential concept in economic geography, knowledge spillover is controversial in its definition (Stanko and Olleros, 2013; Yang and Steensma, 2014; Qiu et al., 2017). Relevant literature extensively diverges on various facets in the process that knowledge spills over. For instance, the intentionality of knowledge providers (Fallah and Ibrahim, 2004), the content of knowledge (Lejpras, 2015; Simons et al., 2016; Wang and Wu, 2016), and whether receivers adjust the knowledge they gained (Eapen, 2012; Battke et al., 2016). Despite the above disputes, we follow Ko and Liu that define knowledge spillover as 'the process that firms receive information, technique, and experience from knowledge providers, and improve the action efficiencies' (Ko and Liu, 2015).

In early research, knowledge spillover mostly is correlated to the efficiencies of production or innovation (Krugman, 1991; Glaeser et al., 1992; Fukugawa, 2017). However, with the extension of application extent, this concept has been gradually employed in other fields. Knowledge attribute embeds not only in innovation which is knowledge-intensive but also in many other organizational practices, such as

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1456114576

international expansion (Lejpras, 2015), entrepreneurship (Dahl and Sorenson, 2012), and stock backdating (Audia and Yao, 2017), etc. Similarly, CEP practices also require different types and extent of knowledge, which could make CEP practices more cost-efficient, encouraging firms to further engage in CEP (Mcwilliams and Siegel, 2001). For instance, managers who received ethic knowledge training are more likely to integrate ethics codes into corporate's strategic decisions, because they know how to fulfill environmental performance efficiently and thus be encouraged to do more (Stevens et al., 2005). Similarly, FDI could promote the environmental performance of local firms, since foreign companies could provide local firms CEP knowledge (Nyuur et al., 2016).

How can firms obtain CEP knowledge? Besides the endogenous growth from learning by doing (Arrow, 1962), firms could acquire CEP knowledge from the external as well. While CEP knowledge spillover differs from other knowledge spillovers in terms of knowledge content, they are fundamentally similar in other aspects. Therefore, based on the two modes of knowledge spillover and context-specific trait of CEP (Williams, 2007; Aguinis and Glavas, 2012), we define CEP knowledge spillover as 'the process that firms receive information, technique, and experience that are related to CEP, and thereby improve CEP efficiencies.' Furthermore, we propose that CEP knowledge spillover happens via two modes: knowledge transfer and knowledge conversion.

In CEP knowledge spillover, knowledge receivers acquire knowledge from different providers, such as local or industrial peers, NGOs, academic institutes and even governments (Miles, 2015). In some cases, receivers would find the acquired knowledge fits the CEP practices and can be applied without modification. Based on Fallah's definition of knowledge transfer (Fallah and Ibrahim, 2004), we define this dimension as CEP knowledge transfer. Meanwhile, not all the CEP knowledge spills over via this mode because the external CEP knowledge is often not completely applicable. Since firms' environmental performance is context-specific organizational actions and policies, successful applications of CEP knowledge are often bounded within specific contexts, such as national context (Matten and Moon, 2008; Kim et al., 2013), industrial context (Wanderley et al., 2008; Cordeiro and Tewari, 2015), and organizational context (Aguinis and Glavas, 2012). In this case, the external CEP knowledge should be conversed according to receivers' external environment and internal conditions, which is termed as knowledge conversion.

Spatial proximity, major cities and corporate environmental performance

Recent studies have discovered the influence of major cities on CEP. Drawing on the neo-institutional theory, scholars argue that major cities could form geo-institutional communities, which exert institutional pressures on firms and drive them to engage in CEP (Ning and Wang, 2018). The primary logic is, the three pillars of institutional pressures-regulatory pressure, normative pressure, and cognitive pressure originates from the different type of stakeholders, which intensively resident in major cities. In the meantime, compared with the peripheral areas, the central areas of major cities inhabit much more stakeholders, including residents, universities, local communities, and NGOs, and so forth.

Besides residents, the other stakeholders also tend to locate concentrated in the central areas of major cities (Taylor, 2005). While the major cities' influence on CEP majorly results from those stakeholders, the influence would be stronger in those areas

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1456114576

populated with more stakeholders. Therefore, compared with the peripheral areas, the central areas of major cities are more likely to function as the influences sources and affect firms' environmental performances. Meanwhile, the influences from stakeholders in major cities centers could transmit across geographic distance via face-to-face interactions (Sorper and Venables, 2004), which means the remote firms could also be affected by major cities centers and engage in CEP. However, the influence would decade with distance due to the economic and time cost of interactions, which means firms close to the major cities centers would be influenced more and thereby engage in CEP more. The following hypotheses are therefore proposed:

Hypothesis 1: Firms in spatial proximity to major cities centers engage in CEP more than their more remote counterparts.

Proximity to major cities centers and knowledge spillover

According to Boschma (2005), geographic proximity is "the spatial or physical distance between economic actors". In this study, spatial proximity to major cities centers refers to "the spatial distance between the focal firm and the central area of the nearest major city". Urban economists argue that knowledge spillover happens more intensively in major cities, no matter inter- or intra- industries (Jacobs, 1969; Carlino et al., 2007). In the meantime, we argue that knowledge spillover happens more intensively in the central areas of major cities than the peripheral areas, which would be further explained in the following.

In economic geography, knowledge is an important resource that could boost firms' efficiencies, which is arduous to transport (Krugman, 1991). Stakeholders in the major cities centers could be viewed as CEP knowledge reserve, from which firms could acquire CEP knowledge by interacting (Porter and Kramer, 2011). Through direct or indirect, pro-active or passive interactions, companies can obtain CEP knowledge from nearby non-peer stakeholders (Miles et al., 2006). *Figure 2* is created by utilizing diagramming software Visio 2016, as the figure shows, local peers are also an important source to obtain CEP knowledge via inter-firm knowledge spillover (Appleyard, 1996). Comparing to those remote peers, nearby firms are more convenient to contact, while the CEP knowledge from them is regarded as more legitimate and proper (Haveman, 1993). For those knowledge receivers, CEP knowledge would be beneficial to the CEP practices by bettering the cost-efficiencies. Therefore, because of knowledge spillovers from local stakeholders, a firms' geo-location could influence its accessible CEP knowledge and thereby the cost-efficiency of CEP practices.

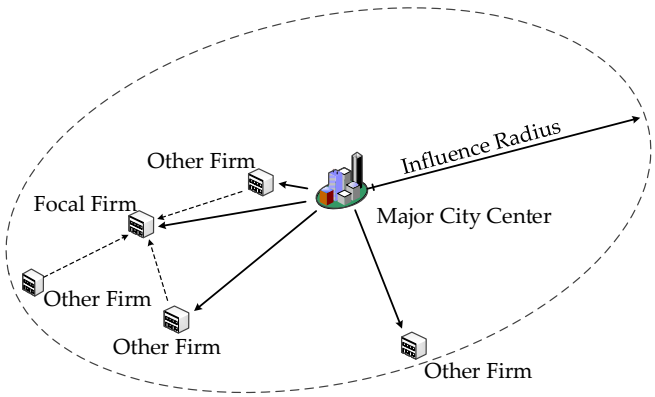

Figure 2. *The model of major cities centers' influence on knowledge spillover*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1456114576

Although CEP knowledge flows from major cities centers toward nearby firms, its spatial-bounded trait limits the long-distance transmission (Boschma, 2005), which means effective knowledge spillover only happen within a limited geographic extent. Although IT technologies could help explicit knowledge flows beyond geographic limits, face-to-face interaction is still an important channel for knowledge spillovers, especially tacit knowledge (Storper, 2004). Besides, the interpretation and absorption of explicit knowledge might still need implicit knowledge (Howells, 2002). Hence, the spillover of codified CEP knowledge could also be spatial-bounded. In this case, the spatial closeness between knowledge receiver and provider would be a must for effective CEP knowledge spillover, no matter knowledge transfer or knowledge conversion. The following hypotheses are therefore proposed:

Hypothesis 2a: Firms in spatial proximity to major cities centers obtain more knowledge transfer on CEP than their more remote counterparts.

Hypothesis 2b: Firms in spatial proximity to major cities centers obtain more knowledge conversion on CEP than their more remote counterparts.

Knowledge spillover and corporate environmental performance

Despite the disputes of available conceptualizations, we avoid confusion by following Aguinis and Trumpp (Aguinis and Glavas, 2012; Trumpp et al., 2015), and define CEP as "context-specific organizational actions and policies that take into account stakeholders' expectations in environmental performance". In the past decades, due to the limited role of knowledge in CEP practices, studies about knowledge spillovers and CEP were carried out independently, and few scholars noticed the connections. With the evolution of CEP in theory and practice, the importance of knowledge on firms' environmental performance gradually draws attention.

As a significant channel that knowledge spills over, training programs can deepen the financial supervisors' understanding of ethical regulations, who thereafter consider more environment-friendly action in decision-making. Stevens finds that financial executives who received relevant training are more inclined to integrate ethic codes into strategic activities because they know how to do so effectively (Stevens et al., 2005). The dialogue between firms and stakeholders contribute to the flow of tacit knowledge and help firms make better decisions about CEP (Miles et al., 2006). When other conditions remain unchanged, obtaining knowledge makes CEP practices more cost-efficient, and firms that receive CEP knowledge will be more environment-friendly (Stevens et al., 2005). For instance, FDI could promote local firms in host countries to engage in CEP more. In most developing countries, because of more knowledge and experience in CEP foreign companies function as important CEP knowledge sources for domestic companies (Nyuur et al., 2016). During communication with foreign peers, local domestic firms could acquire CEP knowledge as well as technological knowledge.

Knowledge spillover enables firms to acquire knowledge, increasing cost-efficiency in the same practice. Similarly, CEP knowledge can guide firms to know how to effectively perform CEP, encouraging firms to further engage in CEP activities (McWilliams and Siegel, 2001). Driven by different motives such as organizational interest, institutional pressure or managerial preference, firms would increase the CEP engagements to a certain extent. However, the influences of these drivers are usually limited. Similar to the other organizational practice such as internationalization, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1456114576

decreasing marginal profits restrict firms to participate in CEP unconditionally but stay at a certain cost-benefit equilibrium point (Kim et al., 2015). For firms that gain operational efficiency from CEP knowledge spillover, the CEP capabilities are further enhanced, enabling those firms to reduce the cost or improve the revenue when performing environment-friendly actions. Those firms could break the initial equilibrium point and further participate in CEP until reaching the new equilibrium point. In this process, no matter knowledge transfer or knowledge conversion, CEP knowledge spillover always follow the "knowledge-efficiency-action" path, providing firms with CEP knowledge to enhance the CEP efficiencies, and further promotes firms to engage in CEP activities. The following hypotheses are therefore proposed:

Hypothesis 3a: Obtaining knowledge transfer on CEP promotes firms' CEP engagements.

Hypothesis 3b: Obtaining knowledge conversion on CEP promotes firms' CEP engagements.

The mediating role of knowledge spillover

The recent study shows that proximity to major cities should promote firms to engage in CEP more (Husted et al., 2012, 2016). The arguments overwhelmingly derive from the belief that various stakeholders in major cities centers could exert institutional pressures on nearby firms, driving them to improve environmental performance and obtain legitimacy in local communities (Marquis and Tilcsik, 2016; Marquis et al., 2007; Attig and Brockman, 2017). Meanwhile, some scholars argue that the influence of major cities centers on firms' practices is usually comprehensive, including not only legitimacy mechanism of institutional pressures but also efficiency mechanism of knowledge spillover (Jacobs, 1969; Carlino, 2001). On this basis, we argue that legitimacy mechanism maybe not the unique channel that links major cities to CEP. One alternative is that proximity to major cities may influence CEP through the efficiency mechanism that typically derives from knowledge spillover.

Based on knowledge spillover theory, we argue that firms close to major cities could benefit from local knowledge reserve via knowledge spillover, which enhances the efficiency of environmental actions and encourages firms to engage in CEP more (Lejpras, 2015; Audia and Yao, 2017). During the process of CEP knowledge spillover, firms could obtain CEP knowledge through knowledge transfer or knowledge conversion from the local knowledge reserve embedded in major cities. Knowledge transfer offers firms proper CEP knowledge that could be applied directly, and knowledge conversion offers firms partially proper CEP knowledge that is applicable after adaptation. Because of knowledge transfer and knowledge conversion, firms close to major cities could access CEP knowledge spillover more, and thus more actively engage in CEP. Furthermore, whether knowledge transfer and knowledge conversion mediate the relationship between proximity to major cities and CEP warrants an empirical test. The following hypotheses are therefore proposed:

Hypothesis 4a: Firms in spatial proximity to major cities centers obtain more knowledge transfer on CEP than their more remote counterparts, and thereby engage in CEP more.

Hypothesis 4b: Firms in spatial proximity to major cities centers obtain more knowledge conversion on CEP than their more remote counterparts, and thereby engage in CEP more.

Research design

Sample and procedures

In this research, we collect data primarily through a questionnaire survey. A total of 474 questionnaires are distributed with 278 returned, which means a 58.65% response rate. After discarding questionnaires that contain missing information, 193 questionnaires are usable. To ensure the diversity and reliability of our sample, in our survey three principles are followed.

First, we manage to ensure the diversity of firms' regions and industries. This study examines the connection between major cities and corporate environmental performance from a spatial proximity perspective, hence the dispersion of geography and industry is particularly important. Considering the actual influence radius of major cities centers, in this study we only distribute questionnaires to those firms located in the administrative areas of major cities. The research samples include major cities in the eastern coastal areas such as Beijing, Shanghai, Nanjing, Hangzhou, Guangzhou, Shenzhen, and those in the inland provinces such as Xining, Hefei, and Zhengzhou. In terms of industry distribution, the research samples' industry includes manufacturing (51.30%), financial (8.80%), real estate (12.95%) and others (26.94%).

Second, we manage to ensure the diversity of firms' age and size. Extant literature suggests that a firm's age, size, and ownership could significantly affect its environmental performance [238, 261]. Therefore, we pay particular attention to those corporate characteristics in sample selection. Based on the survey results, the research sample of this study has good representativeness in terms of age, scale, and ownership, including 22.80% for less than eight years, 45.60% for 8 to 15 years, and 31.6% for 15 years or more. In terms of firm size, 100 or less accounted for 31.61%, 101 to 500 people accounted for 26.94%, 501 to 1000 people accounted for 10.88%, and more than 1,000 people accounted for 30.57%.

Third, to ensure the reliability of data acquired, we invite senior executives and key management personnel to fill out the questionnaire to obtain comprehensive and accurate survey results. We distribute questionnaires through channels including social networks, economic development zone management committees, and college MBA centers to ensure the participation of senior managers or CEP-related managers.

Measures

Except for the "proximity to major cities" variable, all other variables were measured by multi-item scales with a five-point Likert scale (1 = strongly disagree, 5 = strongly agree).

Spatial proximity to major cities. We utilize the instrumental variable "driving distance" to measure "spatial proximity to major cities". The calculation involves two coordinate points, including the coordinates of the target enterprise and the coordinates of the center point of the nearest major city. Following DeBoer, this study utilizes Google Map software to calculate the driving distance between target firm and the central point of the major city, the driving distance could reflect the accessibility and convenience of communication between socio-economic entities (Husted et al., 2016; DeBoer et al., 2017). Based on the operational definition from Mahafzaa (Mahafza et al., 2017), we adopt the logarithm of the driving distance between the firm's location and the city center point as the measurement of proximity to major cities. Also, in case

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1456114576

that the target firm's distance to the central point is less than 1 km, we increase all the measured distance by 1 km before taking the logarithm (Broekel and Boschma, 2011).

Knowledge transfer. Knowledge transfer is measured by adopting a four-item scale developed by modifying the relevant scale and theoretical arguments (Ko and Liu, 2015; Tho and Trang, 2015). Sample items include: "Our company obtains entirely suitable CEP knowledge from local peers, governments, NGOs or academic institutions", and "Our company improves the efficiency of CEP practices by directly applying acquired CEP knowledge". The Cronbach's α is 0.899.

Knowledge conversion. Knowledge conversion is measured by adopting a four-item scale developed by modifying the relevant scale and theoretical arguments (Williams, 2007; Islam et al., 2017). Sample items include: "Our company obtains entirely suitable CEP knowledge from local peers, governments, NGOs or academic institutions", and "Our company improves the efficiency of CEP practices by adjusting or improving acquired CEP knowledge". The Cronbach's α is 0.926.

Corporate environmental performance. Corporate environmental performance is measured by a 4-item scale developed by modifying extant scales to fit our research context and purpose (Turker, 2009; Moneva and Ortas, 2010). Sample items include: "Our company participates in activities which aim to protect and improve the quality of the natural environment", "Our company implements special programs to minimize its negative impact on the natural environment", "Our company conducts environmental training of employees", and "Our company supports environmental NGOs working in problematic areas". The Cronbach's α is 0.876.

Control variables. Due to the potential effects of firm demographics (e.g., firm size, age, region, and industry) on corporate environmental performance (Brik et al., 2011; Wu et al., 2015), we control for firm size, firm age, firm industrial type, and firm region type. We collect the data of control variables through a questionnaire survey, firm size (employee number, 1 = less than 100, 2 = 101 – 500, 3 = 501 – 1000, 4 = more than 1000), firm age (establishment years, 1 = 1 – 7, 2 = 8 – 15, 3 = more than 15), and firm industry (1 = manufacture, 2 = finance, 3 = real estate, 0 = others) are represented by category variables, while a dummy variable represents firm region (1 = coastal cities, 0 = non-coastal cities).

Methods and models

To examine hypothesis 1 and 2, this study utilizes the following regression model 1 (*Eq. 1*), model 2 (*Eq. 2*), and model 3 (*Eq. 3*). Symbol *i* represents each firm, *CEP* represents the dependent variable corporate environmental performance, *Distance* represents the independent variable spatial proximity to major cities centers, *Transfer* represents the mediator knowledge transfer, and *Conversion* represents the mediator knowledge conversion. *Controls* represents the control variables, including firm size, firm age, firm region, and firm industry. ε represents random error terms. β represents parameters to be estimated.

$$CEP_i = \beta_0 + \beta_1\, Distance_i + \beta_2\, Controls_i + \varepsilon_i, \quad \text{(Eq.1)}$$

$$Transfer_i = \beta_0^{'} + \beta_1^{'} Distance_i + \beta_2^{'} Controls_i + \varepsilon_i, \quad \text{(Eq.2)}$$

$$Conversion_i = \beta_0^{''} + \beta_1^{''} Distance_i + \beta_2^{''} Controls_i + \varepsilon_i, \quad \text{(Eq.3)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1456114576

To examine hypothesis 3 about the relationship between knowledge spillover (knowledge transfer and conversion) and CEP, we construct model 4 (*Eq. 4*) and model 5 (*Eq. 5*), meanwhile, we integrate the above models and construct the regressions model 6 (*Eq. 6*) and model 7 (*Eq. 7*) to further examine the mediating effects of knowledge transfer and knowledge conversion.

$$CEP_i = \beta_0''' + \beta_1''' Transfer_i + \beta_2''' Controls_i + \varepsilon_i, \quad \text{(Eq.4)}$$

$$CEP_i = \beta_0'''' + \beta_1'''' Conversion_i + \beta_2'''' Controls_i + \varepsilon_i, \quad \text{(Eq.5)}$$

$$CEP_i = \beta_0''''' + \beta_1''''' Transfer_i + \beta_2''''' Distance_i + \beta_3''''' Controls_i + \varepsilon_i, \quad \text{(Eq.6)}$$

$$CEP_i = \beta_0'''''' + \beta_1'''''' Conversion_i + \beta_2'''''' Distance_i + \beta_3'''''' Controls_i + \varepsilon_i, \quad \text{(Eq.7)}$$

Results

Descriptive statistics

Table 1 presents the means, standard deviations, and correlations of all critical variables. As shown in the table, proximity to the major city significantly correlates with knowledge transfer (r = -.469, p < .01), knowledge conversion (r = -.606, p < .01) and CEP (r = -.700, p < .01). Besides, both knowledge transfer (r = .428, p < .01) and knowledge conversion (r = .544, p < .01) are positively associated with CEP. The above results provide primary support to our hypotheses.

Table 1. *Means, standard deviations, and correlations*

Confirmatory factor analyses

We first examined a four-factor model, in which distance, knowledge transfer, knowledge conversion, and corporate environmental performance are included. Following suggestions by Hair (Wu et al., 2015; Hair et al., 2006), we utilize the overall model's Chi-square, the comparative fit index (CFI), the Tucker-Lewis Index (TLI), and the root mean square error of approximation (RMSEA) to assess the model fit. A cutoff value closes to or above .90 for CFI and TLI, and a cutoff value below .08 for RMSEA

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1456114576

indicate a relatively acceptable fit between the proposed model and the observed data. Our theoretical model consists of two mediating structures, including SP→KT→CEP path and SP→KC→CEP path, and the results suggest that our model fits the data well (χ^2 / df = 1.468 < 3; RMSEA = 0.049 < 0.08; CFI = 0.978 > 0.9; TLI = 0.983 > 0.9). Besides, all the factor loadings were significant, providing evidence for convergent validity.

Hypotheses testing

In the above, we raise hypotheses to predict that knowledge transfer mediates the relationship between spatial proximity to major cities centers (measured by instrumental variable distance) and corporate environmental performance. We conduct hierarchical multiple regression analysis to test those hypotheses by entering the control variables, the independent variable (distance), and mediator variable (knowledge transfer) on separate steps.

The results in *Table 2* show that (1) distance is negatively related to knowledge transfer (β = -0.409, p < 0.01, model 2), which supports H2a; (2) distance is negatively related to corporate environmental performance (β = -0.632, p < 0.01, model 4), which supports H1; (3) knowledge transfer is positively related to CEP (β = 0.281, p < 0.01, model 5), which supports H3a; and (4) the relationship between distance and corporate environmental performance remains significant (β = -0.584, p < 0.01, model 6) when knowledge transfer presents (β = 0.119, p < 0.05, model 6), which indicates the partial mediation of knowledge transfer and supports H4a.

Discussion

As interest in the topic of geo-location and CEP steadily grows (Marquis and Tilcsik, 2016; Attig and Brockman, 2017), the lack of understanding of the influence mechanism of major cities on CEP emerges. Drawn on knowledge spillover theory and stakeholder theory, we seek to unravel the hidden path that links major cities and CEP. Based on empirical tests, the evidence from China supports our proposals, which we would further discuss in the following.

First, we find a strong correlation between proximity to major cities and CEP practices in China ($\beta = -0.743$, $p < .01$), which is consistent with extant research findings that based on U.S. samples (Husted et al., 2016). As a significant geographical element that could shape firms' environmental performances, major cities inhabitant varieties of stakeholders, including firms, residents, NGO, and governments (Marquis et al., 2007). In the meantime, this influence decays with distance, which means nearer firms are affected more. Answering Husted's call (Husted et al., 2016), our study finds that this particular relationship holds across different national contexts, not only in developed economies like the U.S. but also in emerging economies like China.

Second, in the relationship of proximity to major cities and CEP in China, knowledge transfer and knowledge conversion function as essential mediators. As independent channels via which firms acquire CEP knowledge, both of them are negatively correlated with proximity to major cities ($\beta = -0.396$, $p < 0.01$; $\beta = -0.576$, $p < 0.01$), which means firms that are more proximal could acquire more CEP knowledge. Despite the different ways of obtaining knowledge, both knowledge transfer and conversion significantly affect corporate environmental performance ($\beta = 0.303$, $p < 0.01$;

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1456114576

$\beta = 0.360$, $p < 0.01$). Besides, both knowledge transfer ($\beta = -0.107$, $p < 0.01$) and conversion ($\beta = -0.077$, $p < 0.1$) remain significant when present simultaneously with independent variable in affecting CEP, indicating their mediating effects.

Third, based on the mediating role of knowledge transfer and knowledge conversion, via which CEP knowledge spills over, we also argue that knowledge spillover mediates the relationship between proximity to major cities and CEP. Besides the prevalent legitimacy mechanism based on institutional pressure (Marquis and Tilcsik, 2016; Marquis et al., 2013), major cities also promote firms to engage in CEP by offering relevant knowledge and efficiency mechanism. For nearby firms, major cities play as the sources of both institutional pressures and knowledge spillovers, and firms could absorb CEP knowledge while bearing pressures. It is noticeable that CEP knowledge providers include local peers and non-peer stakeholders, such as local governments, NGOs or academic institutions.

Conclusion

As the forms that firms participate in environmental actions being more diversified, the related capability gradually plays more significant roles when firms perform environment-friendly actions. Despite its importance in boosting firms' ability, the influence of knowledge on CEP is still not adequately recognized. Therefore, in the research about the impact of major cities on CEP, few scholars examine the connections from the knowledge perspective, leaving this critical path undiscovered. Based on stakeholder theory and knowledge spillover theory, this study conducts a theoretical and empirical analysis of the mediating role of knowledge spillovers between firms' proximity to major cities and CEP engagements. The research not only enriches the front-end research of corporate environmental performance, but also further expands the application scope of knowledge spillover theory.

As with any study, our study is not without limitations. There are boundaries to our theorizing and limitations to our approach, which future research could address. In this study, we introduce and build connections between knowledge spillover and CEP; meanwhile, we notice that there are some puzzles left unsolved. For example, the impact of FDI knowledge spillovers on CEP, the effect of implicit and explicit knowledge spillovers on CEP, and whether absorptive capacity moderates the relationships. Those questions worth further studies to fully discover the links between knowledge spillover and CEP.

Besides, future research could extend the logic chain and test the influence of knowledge-driven CEP engagements on financial performance. So far, our findings support that knowledge spillover could facilitate firms' CEP engagements, but we still know little about the financial outcomes of those CEP engagements. Will the knowledge-driven CEP practices benefit corporates' financial performance? Future research may incorporate financial performance into the analytical framework, follow the "S-C-P" paradigm and construct "space-behavior-performance" framework, and thereby strengthen its instructive value on CEP practices.

(Received 7th Jun 2019; accepted 10th Oct 2019)

Abstract. As urbanization picks up speed, great changes have taken place in the Urban Landscape Pattern (ULP), which in turn causes variation in urban climate. The Heat Island Effect (HIE), a prominent feature of the changing urban climate, poses a huge threat to our life and health. Starting with HIE and with the aid of geographic information system (GIS) and remote sensing (RS), this paper studies the remote sensing images of Beijing from 1995 to 2015, which were captured by Landsat Thematic Mapper (TM) and infrared technology. Specifically, the author analyzed the evolution laws of the ULP and the HIE in Beijing, discussed the relationship between the two factors, and disclosed the controlling effect of the ULP on the HIE. The results show that: the accelerated urbanization has fragmented the landscapes in Beijing dramatically; the HIE can be alleviated by increasing the greenery coverage, reducing the spacing between green lands, and enhancing their density. Finally, several suggestions were put forward to construct a secure and ecological ULP in Beijing from the angle of adjusting the green land landscape pattern. This research sheds new light on the relationship between the ULP and the HIE and lays a basis for the planning and construction of eco-cities.
Keywords: *heat island effect (HIE), urban landscape pattern (ULP), eco-environment benefit (EEB), Beijing, secure and ecological ULP*

Introduction

With the rapid growth of population and economy, the urbanization process is accelerating, and the cities are gradually expanding over surrounding areas. As a result, the changes in landscape pattern and land use, and the environmental pollution have caused ecological problems such as the soil property variation (e.g. unbalanced soil acid-base property and poor adsorption), urban heat island effect, etc. (Connors et al., 2013), which pose threats to people's health, and even influence the sustainable development of the cities. Therefore, analyzing the ULP and the evolution of the ecological environment is of great significance for constructing a secure and ecological ULP (Goward, 1981).

The city is a human-centered landscape ecosystem (Estoque et al., 2017). Urban ecosystems are composed of two ecosystems, or more precisely, it is dominated by the artificial ecosystem and supplemented by the natural ecosystem (Li et al., 2014). Land use is a main factor affecting the artificial ecosystem, so the research on the changes in land use is the focus of urban ecological security research (Yang et al., 2017). In the landscapes, the evolution of ecological processes such as biological migration, surface temperature, and local air flow, as well as the spatial distribution will all be influenced by the changes in landscape patterns. HIE is a phenomenon in which the urban temperature is significantly higher than the surrounding areas, it occurs as a result of the the process of urbanization and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1457714586

is caused by the destruction of vegetation and water bodies, the increment of residential land construction, and the aggregation of population (Bao et al., 2016). HIE is one of the main consequences of the changes in ULP, it changes the urban climate and produces adverse effects on the health of residents and the ecological environment of the city (Chen et al., 2016). Xiao Rongbo adopted correlation analysis to study the actual surface temperature and related influencing factors of urban land in Beijing, and the results showed that ULP and land use situation are closely related to HIE (Chen et al., 2014). Cao Liping proposed through research that the human impact on the climate shows a trend from weak to strong with the progress of urbanization (Mohajerani et al., 2017). However, currently there are few researches on the correlation between ULP and HIE, and no unified conclusion has been formed yet.

Based on the above analysis, this paper carries out research on the HIE-based ULP and the EEB, and selects the data of Beijing city from 1995 to 2015 to analyze and study the evolution of ULP, the heat island spatial distribution and the causes of formation, as well as the heat island areas and green land patterns in Beijing. From the perspective of adjusting the green land landscape pattern, this paper proposes suggestions for constructing a secure and ecological ULP in Beijing, in the hopes of providing a reference for the planning and building of eco-cities.

Materials and methods

Data source of the evolution of ULP in Beijing and the research methods

This paper selected the GIS and RS data of Beijing from 1995 to 2015, and divided the landscapes within the Sixth Ring Road of Beijing into five categories: urban land, agricultural land, green land, water-area land and unused land (Xie et al., 2016). The study used the landscape index method and the gradient analysis to conduct quantitative analysis on the evolution of ULP in Beijing, and adopted the Fragstats landscape index calculation software to calculate the selected indices such as the SHDI (diversity index), the Contagion index, the MN-SHAPE (mean shape of the plaque) index, and the PD (Plaque Density) index, etc.

Shannon's diversity index (SHDI):

$$SHDI = \sum_{i=1}^{m} (P_i \times \ln P_i) \quad \text{(Eq.1)}$$

Contagion index (Contagion):

$$Contagion = \left[1 + \sum_{i=1}^{m} \sum_{j=1}^{n} \frac{P_{ij} \ln(P_{ij})}{2 \ln(m)} \right] (100) \quad \text{(Eq.2)}$$

Mean shape of the plaque (MN-SHAPE):

$$MN - SHAPE = \frac{\sum_{i=1}^{m} \sum_{j=1}^{n} \left(\frac{0.25 P_{ij}}{\sqrt{a_{ij}}} \right)}{N} \quad \text{(Eq.3)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1457714586

Plaque density (PD):

$$PD = \frac{n_i}{A} \quad \text{(Eq.4)}$$

where: P_i is the occurrence probability of the i-type plaque, m is the total number of plaque types, P_{ij} is the probability that two adjacent grid cells belong to types i and j, A is the total area of all landscapes, n_i is the total area of the i-type landscape elements.

Data source of HIE in Beijing and research methods

Although the data of surface temperature obtained by the field measurement method is accurate, it requires to set up a large number of meteorological stations in reasonable layout, which would consume huge financial resources and time (Chang et al., 2011), the development and application of thermal infrared remote sensing technology enable us to obtain the surface temperature of large areas, which has overcome the shortcomings of the traditional field measurement method. Therefore, this paper selected the Landsat TM/ETM + images from 2000, 2005, 2010 and May 2015 to study the relationship between the built areas of Beijing and the heat island spatial distribution changes.

Generally, the temperature of the black body that radiates radiation energy equal to the observed object is called the brightness temperature, which is slightly less than the real temperature, and its relationship with the real temperature is $T = \varepsilon^{\frac{1}{4}} t$ (Huang et al., 2013). Using *Equation 1,* we can unify the range of surface brightness temperature to 0-1, meanwhile, the density segmentation method was applied to eliminate the time-phase differences in the images of the four seasons as much as possible (Zhang et al., 2013). *Figure 3* shows the distribution of brightness temperature in Beijing in 2000, 2005, 2010 and 2015. According to historical statistics, the meteorological conditions of the dates selected in this paper are basically the same and comparable. According to the temperature, the brightness temperatures are divided into seven levels: very-high temperature (44-47 °C), high temperature (40-44 °C), sub-high temperature (36-40 °C), medium temperature (32-36 °C), sub-medium temperature (28-32 °C), low temperature (24-28 °C) and very-low temperature (20-24 °C). The seven levels are indicated by brown, red, orange, yellow, light green, green and blue.

$$N_i = \frac{T_i - T_{\min}}{T_{\max} - T_{\min}} \quad \text{(Eq.5)}$$

Data source of urban heat island and urban green land pattern and research methods

Urban green land can increase the value of real estate, provide people with leisure and entertainment places, moreover, they have multiple important ecological functions such as reducing surface runoff, alleviating urban heat islands, cooling and humidifying (Cannistraro et al., 2017; Gehrt and Chelsvig, 2003; Jiao and Fang, 2018), as well as reducing ecological and environmental damages caused by urbanization. However, if we want to achieve the goal of improving the urban ecological environment through the urban green land system, we must not only ensure large areas of green land, but also scientifically plan the shape and spatial distribution of urban green land (Dai et al.,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1457714586

2010; Dong et al., 2018). Therefore, this paper selected the urban images of Beijing taken by SPOT5 satellite in 2015, and adopted the gradient analysis and landscape index method (main landscape indices are calculated according to *Eqs. 1-4*) to analyze heat island areas in Beijing and the green land pattern on the main extension axes.

Table 1 shows the green landscape pattern of districts with different interference intensities.

Table 1. *Greenland landscape pattern in districts with different interference intensities*

Landscape index	Urban heat island area	Urban cold island area
Greenery coverage %	30.2	13.6
Average nearest neighbor distance (m)	41.62	56.45
Aggregation index	93.27	89.88
Average plaque area (h m^2)	0.86	0.53
Plaque density (/k m^2)	195	108

Results

Evolution of ULP in Beijing

Figure 1 shows the overall landscape dynamic changes of urban districts in Beijing from 1995 to 2015.

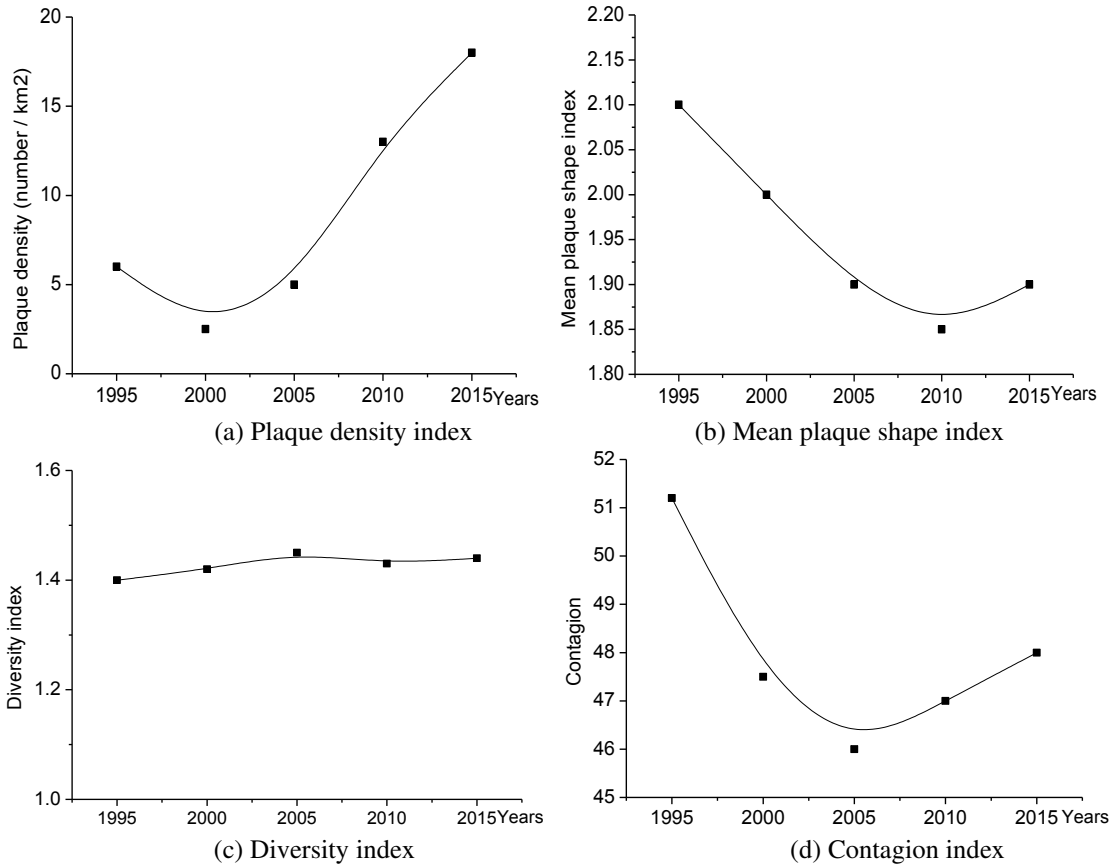

Figure 1. *Dynamic changes of overall landscape in urban districts of Beijing*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1457714586

Figure 1 shows the dynamic changes of the overall landscape of urban districts in Beijing from 1995 to 2015, it can be seen from the figure that the density of plaques has shown a downward trend from 1995 to 2000, and a rapid upward trend after 2000. The landscape diversity index has shown a linear increase with the year, and for the MN-shape index and the Contagion index, both have presented a large downward trend at first, then hit the bottom in 2010 and 2005, respectively, after that, both rebounded, indicating that as the urbanization in Beijing has sped up, the degree of landscape fragmentation has intensified.

Figure 2 shows the proportion of urban land in Beijing in the four directions from 1995 to 2015. In terms of the distance from the city center, the south and west directions are negative, and the north and east directions are positive.

It can be seen from *Figure 2* that in the past 20 years, Beijing has shown a comprehensive and large-scale expansion of urban land from the city center to the surroundings in different directions, with a largest increase of about 50%, the expansion mainly concentrated in the plain area in the southeast, it is because the mountains in the west and north of Beijing have played a certain role in hindering the development of the city, so the development is relatively slow.

The rapid growth of Beijing's economy and population has led to an increase in urban residential construction land and related infrastructures such as the roads, and the conversion of suburban land into urban land has destroyed the original landscape pattern, which is the main reason for the evolution of ULP in Beijing.

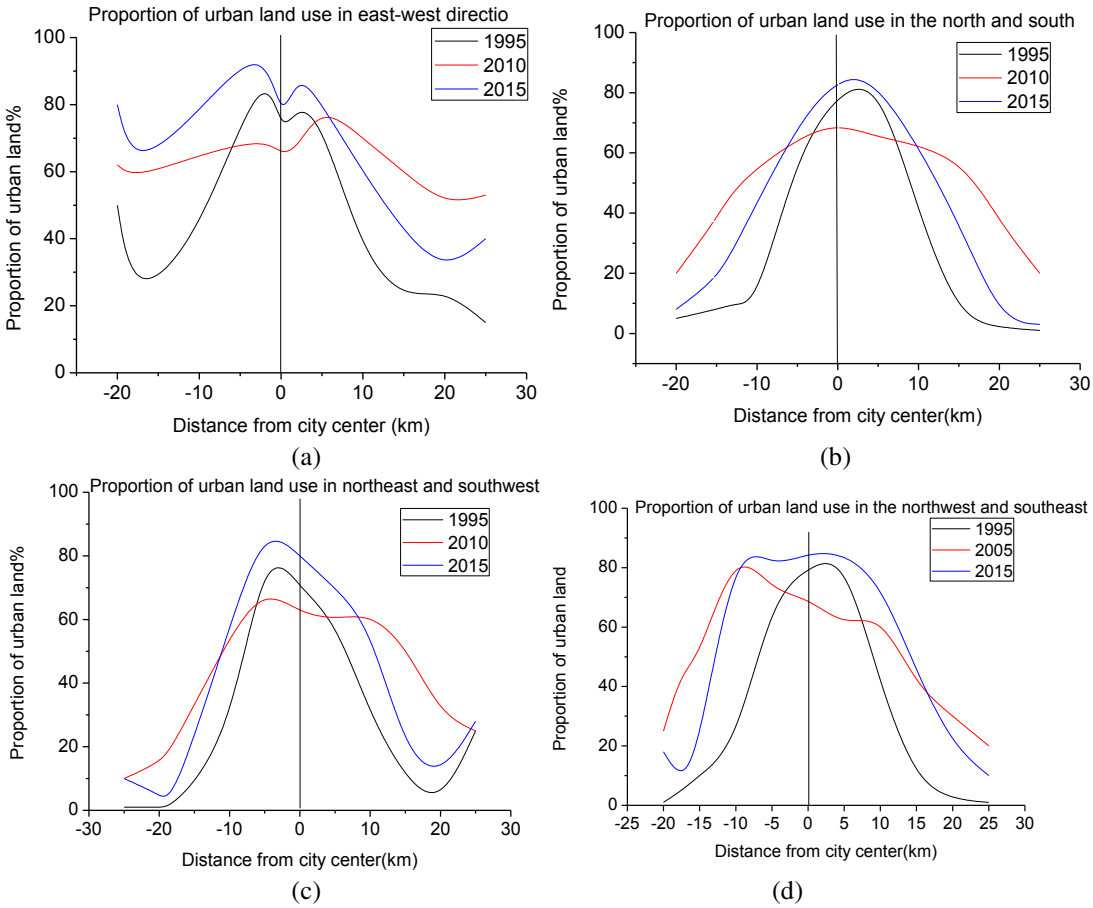

Figure 2. *Proportion of urban land in Beijing from 1995 to 2015*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1457714586

Spatial distribution and formation causes of urban heat islands in Beijing

Figure 3 shows the heat island brightness temperature distribution in Beijing, it can be seen from the figure that, the very-high temperature area (brown), the high temperature area (red) and the sub-high temperature area (orange) in Beijing have spread to the surroundings and increased year by year from 2000 to 2015. Wherein, the Shougang Plant Area, the Dashilan and the Yongdinghe River have been in high temperature areas for many years, while Yuyuantan Lake, Kunminghu Lake, Beihai, Shichahai and other water areas have been in the low temperature areas for many years. In the city center areas, there are vegetation and water body areas, as well as scattered low temperature areas, and the brightness temperature areas present a tendency to gradually increase from the center to the periphery. In addition, by 2015, the HIE in the downtown area within the Third Ring Road had been alleviated significantly, while the intensity of HIE around the Fourth Ring and the Fifth Ring roads had increased, this is because the newly-developed residence and technology parks are concentrated near the Fourth Ring and the Fifth Ring roads, while the green land construction had been strengthened within the Third Ring Road, so the isolation belt had separated the Third Ring Road from other high temperature areas.

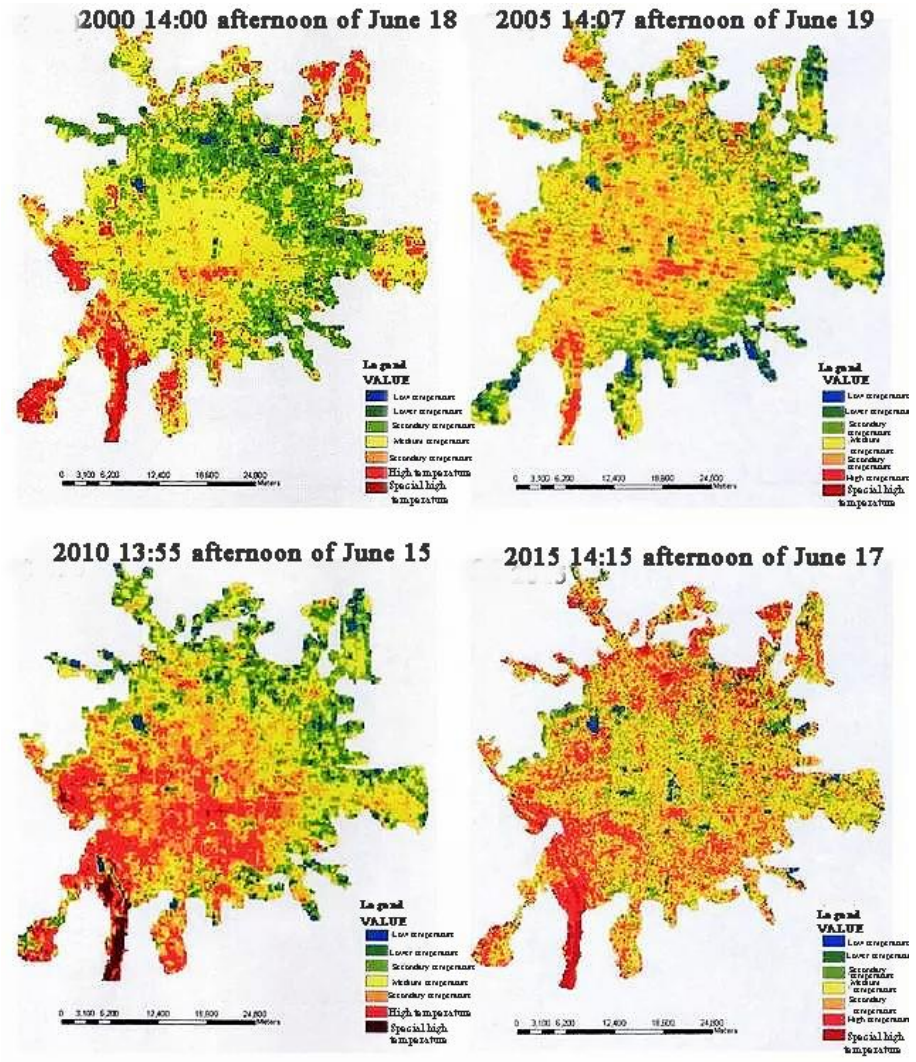

Figure 3. *Bright temperature distribution map of Beijing in 2000, 2005, 2010 and 2015*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1457714586

Figure 4 shows the comparison of the areas of urban districts in Beijing. It can be seen from the figure that since 2000, the area occupied by the urban heat island had decreased slightly, and the proportion of the low temperature area had gradually increased, indicating that the HIE had been alleviated.

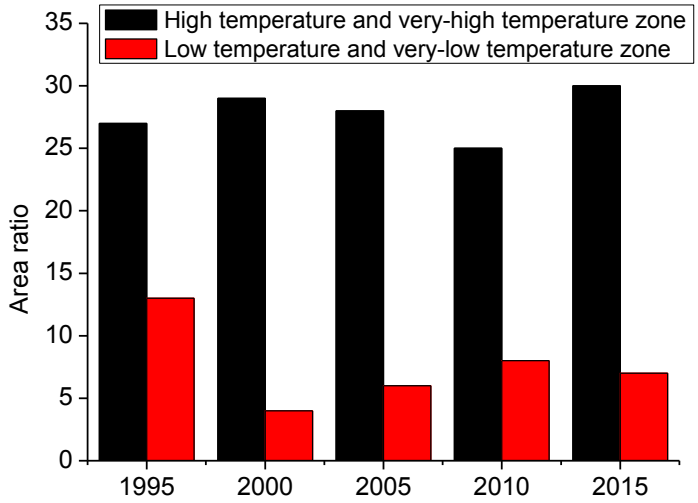

Figure 4. *Comparison of the areas of urban districts in Beijing*

Analysis of the heat island area and green land pattern in Beijing

Figure 5 shows the area ratio of green land plaques of different area levels and in different directions.

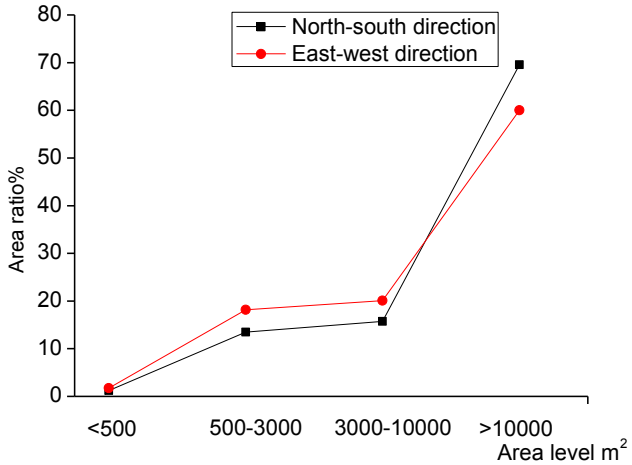

Figure 5. *Area ratio of green land plaques of different area levels and in different directions*

Figure 6 shows the changes of greenery coverage in the east-west and north-south directions.

It can be seen from *Figures 5* and *6* that the greenery coverage in all directions of the urban extension axes has no obvious correlation with the distance, and fluctuates between 10 and 30%. Overall, the north-south direction is slightly higher than the east-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1457714586

west direction. In the east, west, south-north directions, peaks appeared at the positions of 4 km, 6 km, and 12 km, respectively, by analysis it is found that it is mainly due to the existence of park green land such as Yuyuantan Park, and the Olympic Park near these spots. In areas that have no park, the greenery coverage is below 15%, and the number of large plaque areas with a plaque area of more than 60% is less than 10%. These plaques are mainly concentrated in government units and urban parks, indicating that the distribution of large park green land determines the size of greenery coverage. It can be found from the data in *Table 1* that the anti-interference intensity of the landscape pattern increases with the increase of greenery coverage, plaque spacing and density, therefore, the artificial interferences can be eliminated by increasing the greenery coverage, reducing the spacing, and increasing the density.

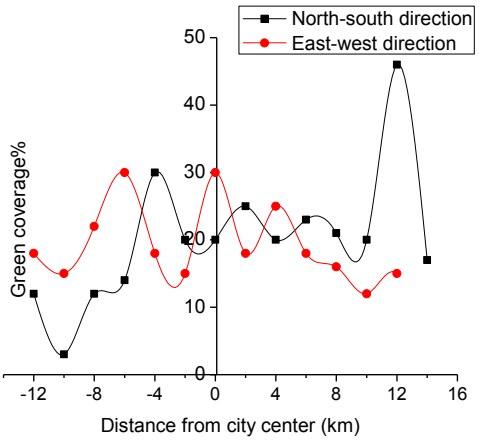

Figure 6. *Greenery coverage changes in two directions*

Discussion

In order to alleviate the HIE in Beijing and construct a secure and ecological ULP in Beijing, this paper combines with the evolution of ULP, the HIE, and the green land pattern in Beijing to analyze the results, and proposes countermeasures and suggestions from the following three aspects:

Plan the development pattern scientifically

Change Beijing's current development pattern which is circle-shaped and single-centered; use evacuation and integration methods to alleviate the problem that the human activities often gather in the center of the city. To achieve the goal of multi-center development, relevant policies should be adopted to encourage and guide the migration of economy, population and industrial belt. In addition, the density of buildings is also one of the main factors of HIE. Therefore, in order to avoid the distribution of urban buildings from distributing in clusters and blocks, the spacing between buildings should be properly arranged and the density of the buildings should be strictly controlled.

Save energy, reduce emission, and develop ecological buildings

Previous research results (Oberndorfer et al., 2007) have confirmed that greenhouse gases from vehicle exhaust and industrial production, and heat emission caused by

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1457714586

human activities are important factors for the formation of HIE, therefore, we should make full use of renewable green resources such as wind energy and solar energy to reduce the use of gasoline and diesel, and meanwhile adopt new thermal insulation equipment, heating and ventilation equipment, and other energy-saving technologies to develop green buildings and reduce heat emissions caused by human activities.

Increase water body, greenery coverage, and improve the natural ecosystem

According to the research results of this paper, the green land and water body inside the city can effectively alleviate and reduce the HIE. Therefore, we can build heat island green belt inside the city, adjust the current green land pattern, and construct corridors between the central green land and other middle and small green land, so as to achieve the ideal status in which there are both scattered and concentrated green land, and at the same time, protect the suburb farmland and river surface from pollution and damage.

Conclusion

- The evolution of ULP in Beijing showed that the urbanization level of Beijing increased significantly between 1995 and 2015, mainly concentrated in the plain area in the southeast direction, due to the acceleration of urbanization and the changes in urban land use structure, the landscape pattern of Beijing had been fragmented more dramatically.
- The research results of Beijing's heat island spatial distribution and the cause of formation showed that, the very-high temperature area (brown), the high temperature area (red) and the sub-high temperature area (orange) in Beijing had spread to the surroundings and increased year by year from 2000 to 2015. Since 2015, the HIE within the Third Ring Road had alleviated significantly. In term of spatial distribution, we can see that in spots where the industry and population are gathered and the greenery coverage is low, the HIE is stronger.
- The analysis results of the heat island area and green land pattern in Beijing showed that the distribution of large park green land determines the size of greenery coverage, and the anti-interference intensity of landscape pattern increases with the increase of greenery coverage, plaque spacing and density.
- This paper proposed countermeasures and suggestions for constructing a secure and ecological ULP from three aspects: plan the development pattern scientifically; save energy, reduce emission, and develop ecological buildings; and increase water body, greenery coverage, and improve the natural ecosystem.
- The study of ULP and HIE requires to combine factors of various aspects to conduct case study and evaluation. This paper only discussed from the two aspects of urban land use and landscape pattern change, so it is not comprehensive enough, in future researches, we should also analyze other ecological process types and scales as well.

(Received 7th Jun 2019; accepted 10th Oct 2019)

Abstract. The high energy consumption and the large amount of pollutants discharged by high-energy-consuming industries in the production process have posed a great threat to the ecological environment. This paper takes the theory of circular economy and the basic concept of sustainable development as the research foundation to study energy conservation, emission reduction and eco-economic construction of high-energy-consuming industries; and then it proposes countermeasures and suggestions for the ecological construction and development of such industries. The research shows that the reduction of energy consumption has contributed a lot to the reduction in the total energy consumption and the comparable energy consumption; In recent years, the energy consumption per one ton of steel has been decreasing year by year, and the energy conservation and emission reduction measures such as technological reform, policy regulation and economic coordination have played a major role in it; the energy-conservation and emission-reduction eco-economic system based on circular economy can mitigate improve the high energy consumption of the industries, which has laid a foundation for their ecological development. This paper has provided theoretical support and guidance for the energy conservation, emission reduction and the eco-economic construction of high-energy-consuming industries.
Keywords: *circular economy, high energy-consuming industry, ecological economy, energy conservation and emission reduction, analytic hierarchy process*

Introduction

Protection of the global environment, energy conservation and emission reduction, and the concept of sustainable development have become development strategies for industries around the globe (Price et al., 2011; Tu and Ma, 2018; Krishna, 2018; Liao, 2011). In recent years, the rapid development of the world economy, resources and industries has damaged to the environment. In order to build an environment-friendly and resource-saving society, countries have implemented energy conservation, emission reduction and the development of circular economy into the economic construction, in the hopes of maintaining the balance of environment and ecology, and controlling the severe pollution and high energy consumption in industrial development, thus improving the utilization of resources around the globe and building an ecological society (Lei et al., 2009; Tao et al., 2014; Cheng et al., 2012). In recent years, the demand for oil and coal resources has increased year by year, and the domestic resource supply cannot meet the demand in actual economic development (Algaba et al., 2012; Habib et al., 2016). In addition, at present, China's energy utilization rate is not high, and our mining and utilizing technology is not mature enough, which has caused

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1458714598

adverse effects on the environment to a certain extent in the process of resource exploitation. Therefore, the research and practice of energy conservation, emission reduction and ecological development of high-energy-consuming industries is one of the main issues to be solved urgently.

Among various industries, the metallurgical industry is one of the industrial types that have high energy consumption and high pollutant emissions (Danza et al., 2018; Mostafaei et al., 2019; Trica et al., 2019; Jonas et al., 2018; Hobson and Lynch, 2016; Rudra and Chakraborty, 2017). The energy consumption in steelmaking and other metal smelting processes accounts for nearly a quarter of the total industrial energy consumption (Murray et al., 2017; Cordova-Pizarro et al., 2019; Rigueiro-Rodríguez et al., 2018). Although the country's energy consumption control policies and administrative measures have improved the problem of energy consumption and pollution emission to some extent, the efforts on energy conservation and emission reduction still unable to catch up with the control level in the developed countries. And the main reasons for the unsatisfactory control effects include: low energy utilization rate, inadequate control of pollutant emissions, low level of waste recycling technology, and lacking of effective control measures (Tiening and Jimei, 2018; Gallagher et al., 2017; Peters et al., 2007; Tomi and Schneider, 2017).

Based on the above-mentioned issues, the theory of circular economy and the basic concept of sustainable development, this paper starts from the perspective of energy conservation and emission reduction of metallurgical industry, and combines the development characteristics and overall trend of today's high energy-consuming industries to study the energy conservation, emission reduction and the ecological and economic construction of high-energy-consuming industries, and proposes countermeasures and suggestions for the ecological construction and development of high-energy-consuming industries, in the hopes of providing theoretical support for the energy conservation, emission reduction and the ecological and economic construction and development of high-energy-consuming industries.

Materials and methods (related theories of circular economy)

Circular economy theories

In the development of traditional economic, production activities such as ecological resource development, energy utilization, agricultural and industrial production, and waste generation have produced serious damages and environmental pollutions to our ecological environment. In today's society, environmental problems are becoming increasingly prominent, and countries around the world are gradually realizing that only by optimizing the economic development mode can we achieve coordinated construction and sustainable development of environment and social economy. In such social context, circular economy emerges as a new type of economic development mode.

The emergence of circular economy has alleviated or eliminated the conflicts and contradictions between environment and economic and social development to a certain extent, and realized the harmonious coexistence of the natural environment and human beings. The concept of circular economy refers to transform the traditional economic mode into an economic mode with resource recycling and energy conservation as the development goals within a complex system of nature, human, and technological development. The circular economy mode is a process of value re-creating, economy

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1458714598

developing and environment coordinating with minimizing input costs and achieving maximal economic and environmental benefits through high resource utilization rate and low emission of exhaust pollutants as the goals.

In order to realize the ecological construction and development of the economy, the economic mode follows three principles: resource reduction, that is, reduce resource consumption, waste generation and reducing environmental damages during the production process; product recycling, that is, re-cycle and re-use the products, renovate or remould the old products and re-use them, so as to prolong the life cycle of the products; waste recycling, that is, convert the wastes generated during production into resources as much as possible with the highest conversion rate, thereby reducing consumption of natural resources and energy.

Basic concepts of energy conservation and emission reduction

Speaking from a micro level, the concept of energy conservation and emission reduction is to save energy and reduce pollutant emissions; while speaking from a macro level, this concept refers to save natural resources and energy sources, and reduce harmful substances and pollutant emissions. Studies have shown that the economic development process needs to be able to meet the requirements of humans and kept within a bearable range of the environment. If the regeneration ability of the nature and the self-coordination ability of the environment are destroyed during the development process, it will cause extremely serious ecological problems, and the social economy could not develop effectively and sustainably

The proposal of energy conservation and emission reduction stems from the problems of environmental degradation and resource crisis emerged from the traditional economic development mode, so countries around the globe have begun to adopt energy conservation and emission reduction measures. The above problems and the motivations for energy conservation and emission reduction can be attributed to the following reasons: the needs of human survival and social development, the decrease of non-renewable resources, the deterioration of ecological environment and the requirements of sustainable social development. Therefore, environmental and energy issues are not only problems for the development of human beings, but also the premise for human to live in harmony with the nature.

Development of high energy-consuming industries

In recent years, high-energy-consuming industries such as the metallurgical industry are developing gradually, and the entire production processes (mining, smelting, processing, molding, etc.) consume a large amount of energy and discharge a large amount of wastes. The manufacturing procedures of steelmaking and the generated wastes are shown in *Figure 1*.

Due to the nature of the data in this paper, the complexity and cumbersomeness of the data such as the steel industry's energy consumption and types, this paper obtained some data from the public agency management department and the China Iron and Steel Association (CISA). Then, based on the statistical data of the CISA, further analysis was performed to achieve the development trends and internal laws. In addition, a combination of literature survey and data report analysis was applied in this study to summarize the data analyzed below for enhancing the use value and statistical significance of the data.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1458714598

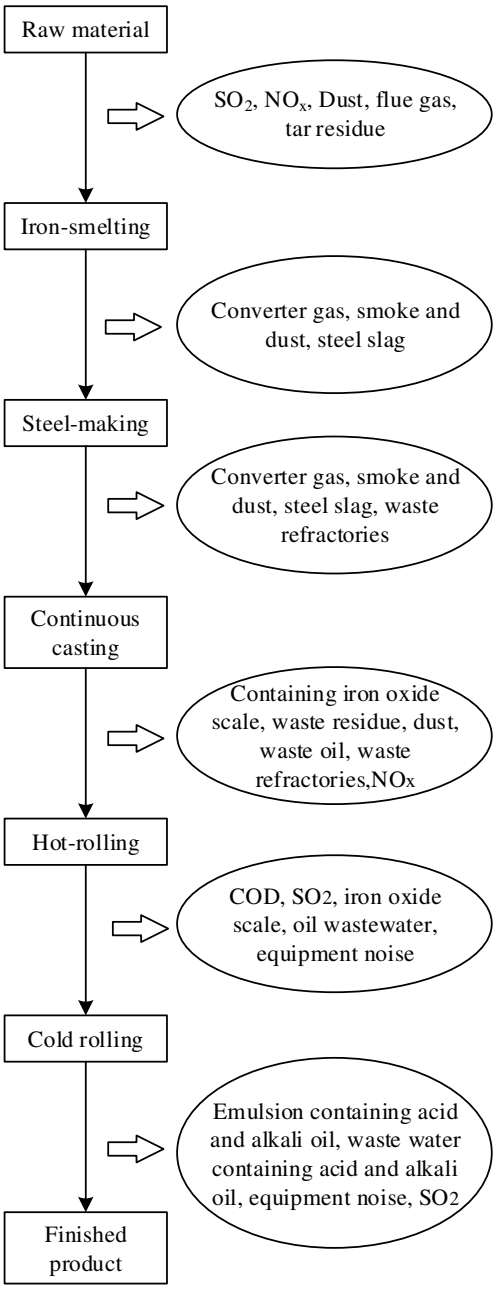

Figure 1. *Manufacturing procedures of steelmaking and the generated wastes*

According to the survey results obtained from public agency management and CISA, the energy consumption of major steelmaking companies in 2016 and 2017 is counted and shown in *Table 1,* and the statistical results are shown in *Figure 2*. Compared with the energy consumption in 2016, the energy consumption of the steelmaking industry decreased by about 3%, and the electricity and water consumption of per ton steel production had been significantly reduced, which had brought great benefits to the economic development and energy-saving of the companies. In addition, the reduction in energy consumption of the manufacturing procedures has made great contributions to the reduction of total energy consumption and comparable energy consumption in steelmaking.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1458714598

Table 1. *Energy consumption in steelmaking industry (kgce/t)*

	Energy consumption	Sinter	Pelletizing	Coking	Furnace	Steel rolling	Power consumption (kWh/t)	Water consumption (m^3/t)
2016	668.7	48.6	27.1	98.5	434.7	59.8	451.4	3.12
2017	648.4	46.8	25.4	94.8	425.1	56.3	438.9	3.09
Reduction	20.3	1.8	1.7	3.7	9.6	3.5	12.5	0.03

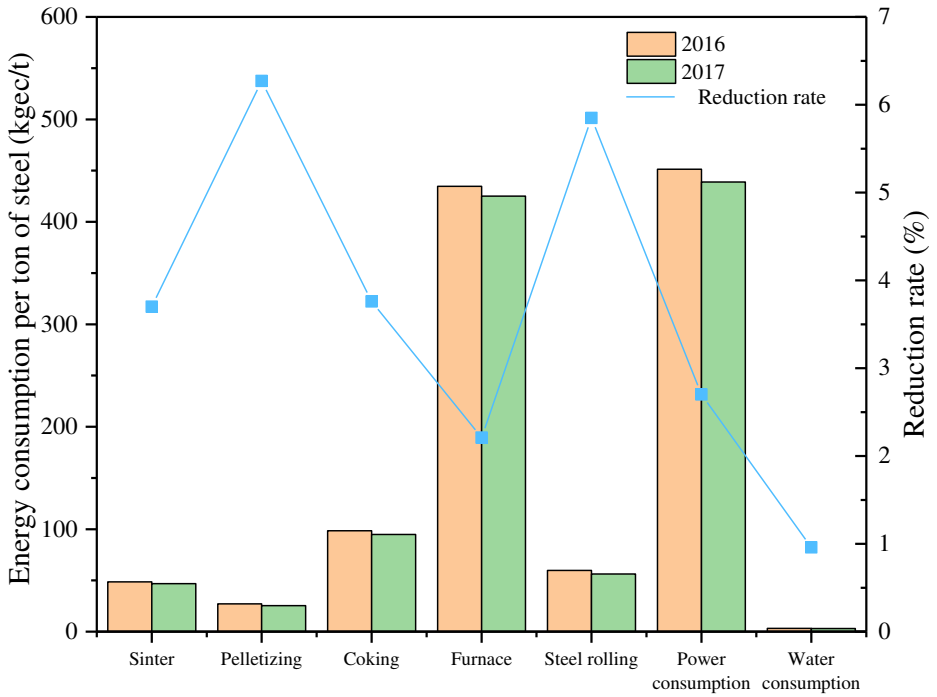

Figure 2. *Energy consumption of per ton steel in each process (kgce/t)*

In the past 7 years, the change trend of energy consumption of per ton steel production of major steelmaking companies is shown as *Figure 3*. It can be seen that the energy consumption of per ton steel production is decreasing year by year, indicating that the processing technologies of the metallurgic industry has made new progress, which is closely related to the policy control of energy conservation and emission reduction of high-energy-consuming industries and the develop of technology. However, from the perspective of circular economy, steel production still consumes a lot of energy, so the strategy of energy conservation and emission reduction still needs to be further implemented.

The CISA provides the data about the energy consumption per ton of steel in key steel industries in the past seven years. It can be seen from *Figure 3* that the comprehensive energy consumption and comparable energy consumption of the per ton steel produced by the metallurgical industry are decreasing year by year, indicating that the technology of the steel enterprises is improving continuously, and the energy consumption of each process is also reduced to varying degrees, which has provided support for the reduction of comprehensive energy consumption and the emission of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1458714598

waste. However, the energy consumption of these enterprises is still at a high level worldwide, and there is still room for improvement. If such enterprises can combine multiple aspects such as economy, government policy and technology to carry out the improvement, they will be able to realize further-level energy conservation and emission reduction, and build an ecological economy.

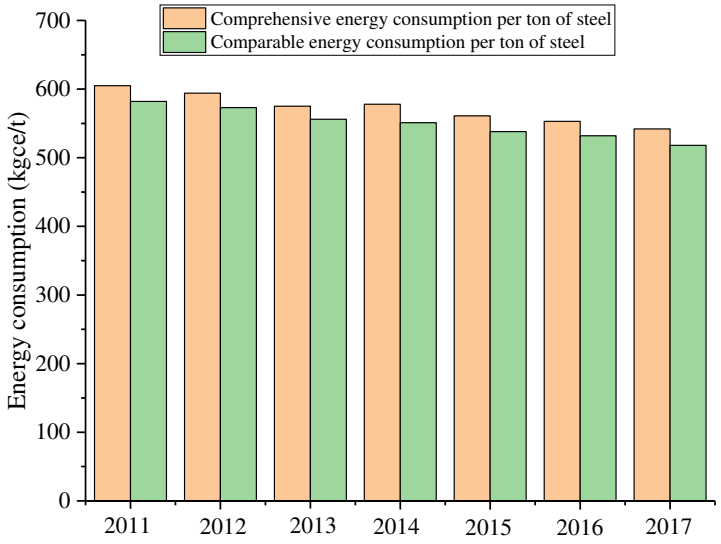

Figure 3. *Changes in energy consumption of per ton steel in steelmaking companies*

At present, in order to further implement energy conservation, emission reduction and develop ecological economy, the high-energy-consuming industries represented by the metallurgical industry have gradually transformed from economic benefit-oriented companies to harmonious enterprises, constantly rethinking the relationship between economic development, ecological environment and resources; in addition, these high-energy-consuming enterprises have also changed the traditional extensive management, and gradually improved to intensive management, thereby improving their unit output, and increasing social and economic benefits by optimizing resource allocation and elements of various links.

Results (eco-economics of high energy-consuming industries)

Construction of energy conservation and emission reduction system

The development of high-energy-consuming industries such as the metallurgical industry consumes a large amount of energy and resources. Therefore, based on the basic theory and principle of circular economy, we should adopt a comprehensive approach combining economy, policy and laws to implement energy conservation and emission reduction, and systematically build a comprehensive energy-saving and emission-reducing system. Therefore, based on the basic mechanism of energy conservation and emission reduction, combining with relevant theories of circular economy, this paper proposes the Best management Practices (BMP) comprehensive system for the energy conservation and emission reduction of high-energy-consuming industries, the basic processes are shown in *Figure 4*. Based on information platform,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1458714598

human resources and management, it adopts policy incentives, index constraints, target assessment and other approaches to guarantee the implementation, thereby achieving the goal of energy conservation and emission reduction of high-energy-consuming enterprises.

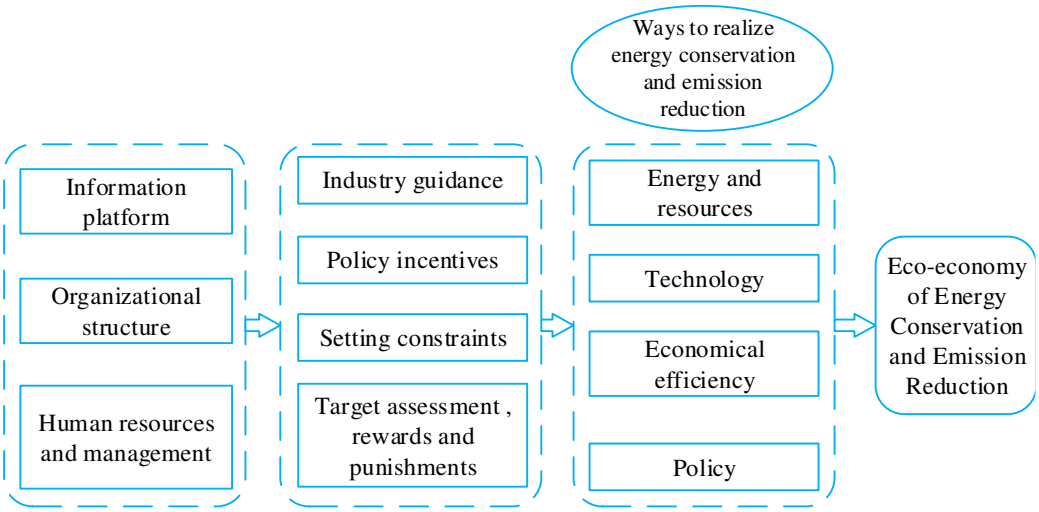

Figure 4. *Energy conservation and emission reduction system*

Structure of energy conservation and emission reduction system

When building the energy-conservation emission-reduction system, the construction of the system is guaranteed from three aspects: information platform, organizational structure and human resources. The information platform for energy conservation and emission reduction can integrate informationization and industrialization in depth, through information collection, processing, analysis and sharing of the energy conservation and emission reduction and the whole production process of the high-energy-consuming enterprises, it conducts dynamic monitoring and optimization processing on the whole production process, resource utilization, allocation of equipment and materials, and the condition of energy consumption, balances the economic benefits and energy, and finally achieves industrialized energy conservation and emission reduction. The management of the organizational structure is a comprehensive management system with government policies and regulations as guidance, production enterprises as subjects, and public and third parties as supervisors. The first is the government's guidance and control of the companies' production, energy conservation and emission reduction according to laws, regulations, and relevant economic policies, while within the companies, through hierarchical management and internal strategies, assessment system and reward and punishment policies for energy conservation and emission reduction are set up, and relevant liability system are established, so as to ensure the realization of the goal of energy conservation and emission reduction. And the human resources are to enable enterprises to cultivate professional and compound talents for energy conservation and emission reduction, learn the related theoretical knowledge of energy conservation and emission reduction and apply it to the actual production. The operation mechanism of the energy-conservation emission-reduction system is shown in *Figure 5,* mainly including fiscal policies, rewards and punishments, and taxation policies.

DOI: http://dx.doi.org/10.15666/aeer/1706_1458714598

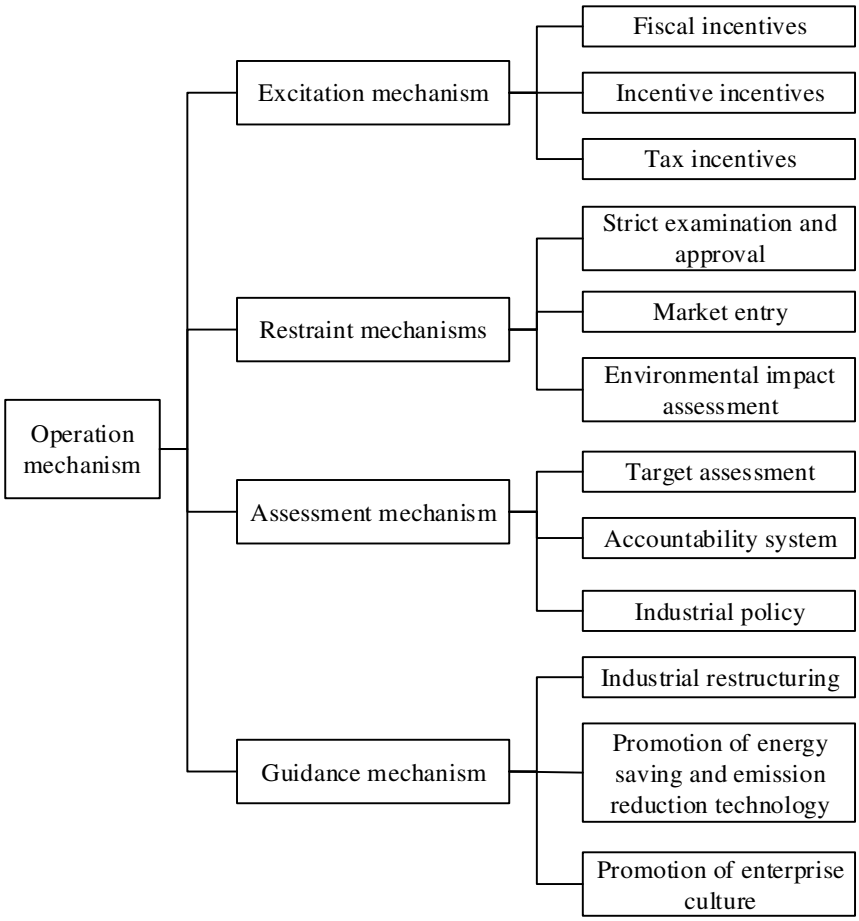

Figure 5. *Operation mechanism of energy conservation and emission reduction system*

Discussion (analytic hierarchy process (AHP) of energy conservation and emission reduction)

This paper first adopted the AHP to decompose the problem, as shown in *Figure 6,* the problem of circular economy development and energy conservation and emission reduction of high energy-consuming industries was divided into four layers (target layer, standard layer, index layer and scheme layer). The corresponding judgment matrix established is shown in *Table 2*. For the judgment matrix results, the value assignment was made according to the importance of factors, as shown in *Table 3*.

Based on the above judgment matrix, the relative weights of the elements were calculated using the sum method. For the inconsistent judgment matrix, the weights of the vectors in each column were calculated according to *Equation 1,* as for the consistent judgment matrix, after normalizing the vectors in each column, the corresponding weights could be obtained.

$$W_i = \frac{1}{n}\sum_{j=1}^{n}\frac{a_{ij}}{\sum_{k=1}^{n} a_{ki}} \quad \text{(Eq.1)}$$

After the relative weights of the elements were calculated, the consistency of the judgment matrix was tested, and the specific steps are as follows: calculate the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1458714598

consistency indicator *C.I.* according to *Equation 2,* and determine the average random consistency indicator *R.I.* according to *Table 4;* then according to *Equation 3,* use the consistency indicator and the average random consistency indicator to calculate the consistency ratio *C.R.*, thereby determining the consistency of the judgment matrix. When the value of *C.R.* is less than 0.1, the judgment matrix is considered to be consistent; otherwise, it is inconsistent and needs to be modified.

$$C.I. = \frac{\lambda_{\max} - n}{n - \mathbf{1}} \quad \text{(Eq.2)}$$

$$C.R. = \frac{C.I.}{R.I.} \quad \text{(Eq.3)}$$

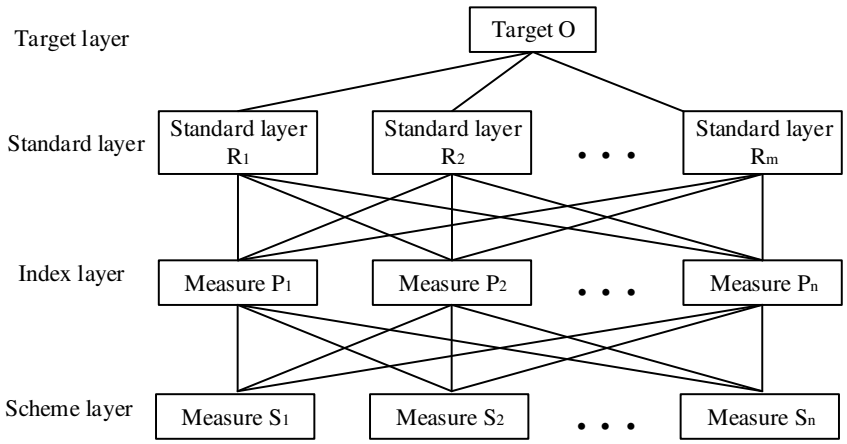

Figure 6. *Model structure of analytic hierarchy process for green economy development*

R.I.	1.46	1.49	1.52	1.54	1.56	1.58	1.59	-

Finally, the weights of factors in each layer relative to the upper layer factors were calculated top-down layer by layer, and sorted according to the weight, and then subject to the consistency check according to *Equation 4*. If the value of $C.R.^{(m+1)}$ of the total elements in (m + 1) layer is less than 0.1, then the total sorting is considered to be consistent, otherwise, it is not consistent.

$$C.R.^{(m+1)} = \frac{C.I.^{(m+1)}}{R.I.^{(m+1)}} \quad \text{(Eq.4)}$$

where:

$$C.R._j^{(m+1)} = \left(C.R._1^{(m+1)}, C.R._2^{(m+1)}, ..., C.R._n^{(m+1)}\right) W^m \quad \text{(Eq.5)}$$

$$R.I._j^{(m+1)} = \left(R.I._1^{(m+1)}, R.I._2^{(m+1)}, ..., R.I._n^{(m+1)}\right) W^m \quad \text{(Eq.6)}$$

Based on the AHP and above steps, the weights of the high-energy-consuming enterprises' energy conservation, emission reduction, and circular economy development level can be calculated, analyzed and evaluated comprehensively. According to the above-mentioned energy-conservation emission-reduction economic comprehensive system and the AHP, the eco-economic development of energy-conservation and emission-reduction of several high-energy-consuming industries had been evaluated, and it is found that the effects of energy-conservation and emission-reduction of such enterprises are obvious, which is conducive to the development of eco-economy.

Conclusion

Based on the theory of circular economy and the basic concept of sustainable development, combining with data research and analysis, this paper carried out researches on the energy conservation and emission reduction and eco-economic construction of high-energy-consuming industries. The main conclusions are as follows:

- The energy consumption data of the metallurgical industry in the past 7 years shows that the energy consumption and comparable energy consumption of per ton steel are decreasing year by year, indicating that technological reform, policy regulation, economic coordination and other countermeasures have exerted positive effects on reducing energy consumption and pollutant emission and improving economic benefits of the industries during the production process.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1458714598

- For the energy conservation and emission reduction of high-energy-consuming industries, this paper constructed an energy conservation and emission reduction eco-economic system based on circular economy, which gradually achieved energy conservation and emission reduction through policy, technology, organizational structures, resources, and other approaches, it promoted the upgrade of the industries, and combined with the policies and economic countermeasures, and implemented the energy conservation and emission reduction of the industries from two aspects of inside and outside.
- The energy conservation and emission reduction eco-economic system of high-energy-consuming industries based on circular economy is conductive to the improvement of the high energy consumption of the industries, and it laid a foundation for the eco-economic development of high-energy-consuming industries and the sustainable development of the society.
- This paper conducts a preliminary study on the energy reduction of high-energy-consuming industries from a macro perspective. However, at the micro level, it still requires more in-depth and systematic research on how the high-energy-consuming industries coordinate economic interests and social interests by organically combining them to effectively improve the level of ecological economic construction in energy conservation and emission reduction.

(Received 7th Jun 2019; accepted 10th Oct 2019)

Abstract. Green parks are indispensable to urban ecosystem, and critical to living environments, urban greening and city development. Based on the theory of landscape ecology, this paper explores how environmental landscape structure (ELS) affects the distribution features of plant communities in several green parks in Jiangmen, southern China's Guangdong Province. The study was carried out with analytical hierarchy process (AHP), geographic information system (GIS) and remote sensing (RS). The research results show that: Compared to the other two parks, Penglai Park, a downtown park surrounded by residential buildings and highways, boasts a high overall temperature, and witnesses limited variations in temperature and PM10. In addition, this park outperforms the other two parks in plant height, the density/overall height/mean coverage of shrub and herb layers, as well as the ecological benefit. In contrast, Jiangbin Park, which is greatly affected by wind from the nearby river, saw great variations in the temperatures inside and outside plant communities and the PM10. As a result, this park lags behind the other two parks in the following aspects: the average height/average coverage of shrub and herb layers, and the mean diameter at breast height (DBH) of arbor layer. The research findings provide a good reference to optimizing the plant communities in green parks and promoting urban ecology.
Keywords: *environmental landscape structure (ELS), urban park, plant community, distribution features, temperature changes, PM10, urban green park protection*

Introduction

Green parks are an important part of urban ecosystems and the most concentrated areas of urban biodiversity and green spaces (Kruess, 2003). They provide citizens with recreation and fitness places, and have the ecological functions of conserving water, purifying air, reducing noise, and regulating the local climate of the city (Schmucki et al., 2012). The collection of all plants living in a certain area is called a plant community (Svenning et al., 2004). Plant communities are basic components of green parks, and a reasonable plant community layout is the basis for maintaining a green park and exerting its ecological role (Wallgren et al., 2009). In the plant communities, there are certain correlations between the plants and the environment, and between the plants; the surrounding environment has a strong influence on the growth of plants. Therefore, studying the influence of ELS on the distribution features of park plant communities is of great significance.

At the end of the 18th century, in order to solve the problem of urban development and the quality of urban living environment, foreign countries began to study the construction of urban green parks, and the Regent's Park and the Birkenhead Park in England were built in this context (Miller et al., 2016). Subsequently, ecological design has become a main trend for green parks in western countries. In the 19th century, designers chose different tree species and designed a number of green parks according to the structure of the natural communities (José et al., 2016). In the 1920s, designers and ecologists such as Broerse and Springer imitated the natural plant communities and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1459914609

their habitats to create urban ecological gardens (Chiron et al., 2014). China's research on landscape ecology and urban green parks started relatively late, but in recent years, as people are paying more attention to the urban ecological environment, Chinese landscape architects have also applied the ecological concept to the design of urban green parks (Davidson et al., 2011). In 1998, in order to effectively transform an urban garbage dump, designers used native plants to build artificial plant communities and construct the Shimen Park in Dashiba, Chongqing city (Amici et al., 2015). Ding Fenghua et al. took the Changsha Martyrs Park as an example and analyzed its current plant landscaping situations (Wrbka et al., 2008). Liu Yanhong et al. investigated the biodiversity characteristics and plant species of urban green parks in Beijing (Goodwin and Fahrig, 2002). Zhang Jing et al. classified the typical plant communities of green parks in Shanghai (Moebiusclune et al., 2013). Concerning the researches on plant communities and environmental factors, current domestic and foreign studies focus mostly on the landscape functions, maintaining biodiversity, cooling and humidifying, and other aspects (Rodrigo León Cordero et al., 2016). The comprehensive effect of plant community structure, the structure model of plant communities and environmental factors based on 3S technology, the dynamic monitoring of plant community structure, and the quantitative analysis of their correlations, will be the main trends and focuses of researches in the future (Bouasria et al., 2012).

Based on the above analysis, this paper aims to study the influence of environmental landscape structure on the distribution features of plant community in green parks by selecting Jiangbin Park, Penglai Park and Donghu Park in Jiangmen city as the research area, and analyzes the plant community structure features of these parks according to the three layers: arbor layer, shrub layer and herb layer; three indices of diversity index, ecological advantage index and richness index have been selected to analyze the structure features of the plant communities in the three parks; meanwhile two ecological factors of temperature and PM10 which are largely affected by the environmental landscape structure have also been selected to analyze the influence of ELS on the ecological factor features of plant communities in the park; then this paper comprehensively compares the plant community distribution features of each park under different ELS conditions and proposes related suggestions for the optimization of plant communities in the parks, in the hopes of providing relevant references for the construction of eco-cities.

Materials and methods

Research objects and methods of plant community structure in major regions

Research object

The distribution of plant communities is largely interfered by the surrounding landscape pattern and human factors, which leads to large differences between plant communities in parks and in natural state. This study used GIS and RS technology to obtain the overall plan of Jiangmen City, Guangdong Province, China. After systematic investigation of the vegetation in the parks of Jiangmen City, this paper selects Jiangbin Park (sample area 135,772 m^2), Penglai Park (sample area 68,732 m^2) and Donghu Park (sample area 87,521 m^2) in Jiangmen city as the research areas. *Figure 1* shows the specific location of these three parks in Pengjiang District: 1 for Penglai Park, 2 for Jiangbin Park, 3 for Donghu Park. In addition, it uses AHP to conduct sampling and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1459914609

survey on the target areas. The sampling area of Jiangbin Park was 1,800 m^2 (east longitude 113.118431, north latitude 22.602591), Penglai Park sampling area was 1,800 m^2 (east longitude 113.08728, north latitude 22.581711), and Donghu Park sampling area was 2,100 m^2 (east longitude 113.087898, north latitude 22.591829). Excel software and landscape pattern analysis software were used for calculation.

Founded in 1958 and opened to the public in July 2014, Donghu Park is located in the center of Jiangmen with the green ecology as the theme. It covers an area of 53 ha, including 17 ha of lake area. It has the elegant restaurant and tea house, as well as the specialties of the hometown. Jiangbin Park is located on the Xijiang River in the North Street of Jiangmen City, covering an area of 3.8 ha. It was built in 1984 as the only park in the city for barbecue. It also has an open-air lounge. Penglai Park was built in 1983 and covers an area of 0.95 ha. It is located at the intersection of Penglai Road and Jianshe Road in Jiangmen City. It was first built with plant landscaping and was renamed as Children's Park in 1990.

Calculation methods

(1) Diversity index (D_1)

$$D_1 = 1 - \sum_{i=1}^{s} \frac{N_i(N_i - 1)}{N(N-1)} \quad \text{(Eq.1)}$$

The larger the D_1 value, the higher the diversity (Ames et al., 2016).

(2) Ecological advantage index (D_2)

$$D_2 = \sum_{i=1}^{s} \frac{N_i(N_i - 1)}{N(N-1)} \quad \text{(Eq.2)}$$

The smaller the D_2 value, the higher the diversity and the smaller the ecological advantage (Brunzel et al., 2004).

(3) Richness index (R)

$$R = \frac{S-1}{\ln N} \quad \text{(Eq.3)}$$

where: N is the number of individuals of all species, N_i is the number of individuals of species i, and S is the number of plant species within the sampling area.

Selection of ecological factors

The various environmental factors that affect biological organisms are called ecological factors, and there are many types of ecological factors. No matter which type, all ecological factors would influence the survival, reproduction and various functions of plant individuals and the whole plant community, moreover, there are interactions among the ecological factors, which would also have an impact on the plant

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1459914609

community; on the one hand, ecological factors are related to season, climate and other factors in the nature, on the other hand, they are also affected by the landscape of surrounding environment. In order to study the influence of ELS on the distribution features of plant communities in green parks, this paper selects two ecological factors, temperature and PM10 (Herrera et al., 2016), which are strongly influenced by environmental landscape, as the objects of measurement to measure the ecological factors of plant communities inside and outside the parks.

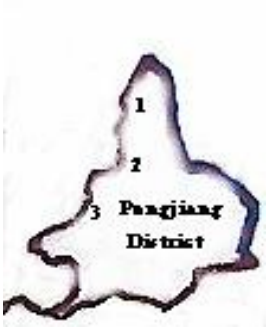

Figure 1. *The specific location of the three parks in the Pengjiang District*

The temperature and PM10 were measured using the Testto608-H2 dual-purpose thermometer and the hand-held PM10 hand-held dust meter respectively. The measuring instruments were placed at a height of 1.5 m from the ground. For the external ecological factors of plant community the measuring instruments were mainly placed in the park square and lawn, while for the internal ecological factors of the plant community, the instruments were placed in a sample plot with rich community, with the central position of the shade as the main measurement point. *Figure 2* shows the pictures of the measured temperature and PM10 at the experimental site of Donghu Park.

Figure 2. *Temperature and PM10 picture of the experimental site of Donghu Park*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

Results

Analysis of plant community structure features

Through investigation, the plant communities in green parks in Jiangmen city were divided into three community layers: the arbor layer, the shrub layer and the herb layer. *Figures 3–5* show the statistical results of the structure features of plant communities in the three parks (number of plants, average height, average coverage). *Figure 6* shows the average DBH of the arbor layer.

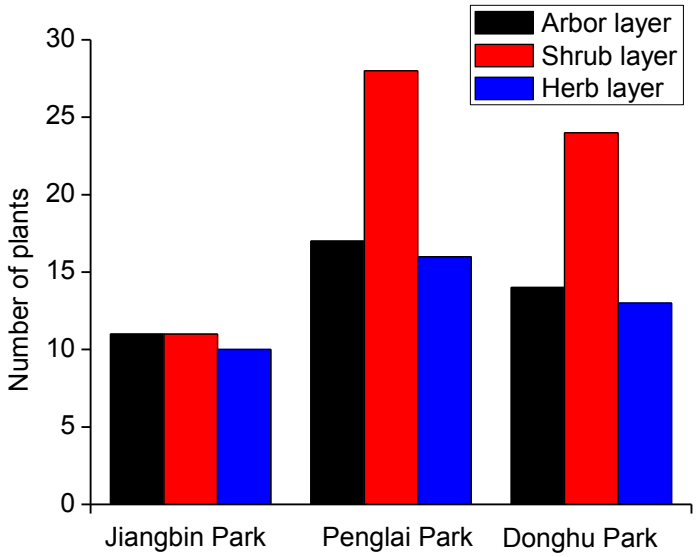

Figure 3. *Number of plants of each community layer in the three parks*

It can be seen from *Figure 3* that the number of shrub layer plants in the three parks is the largest, and the number of herb layer plants is the smallest; in the Jiangbin Park, the number of arbor layer plants, shrub layer plants, and herb layer plants are basically the same, and are much less than those of the Penglai Park and the Donghu Park.

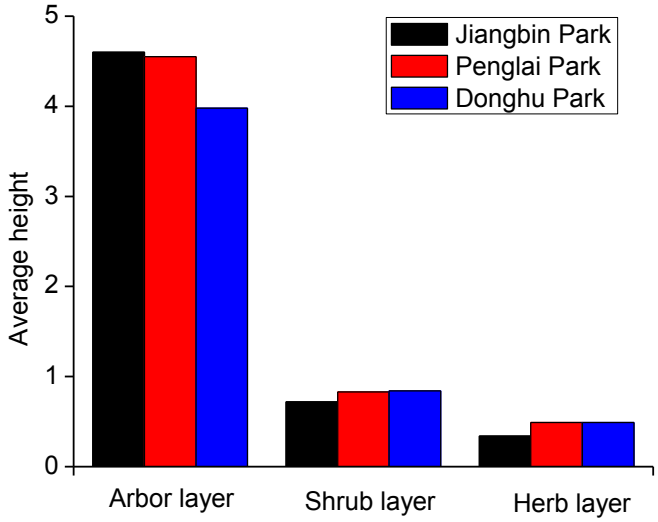

Figure 4. *Average height of plant communities in the three parks*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1459914609

As can be seen from *Figure 4,* for the Jiangbin Park, the average height of the arbor layer is the highest, and the average heights of shrub layer and the herb layer are the lowest; for the Donghu Park, the average height of the arbor layer is the lowest; There is a small difference in the average height of shrub layer and herb layer between the Penglai Park and Donghu Park, which can be considered to be basically the same.

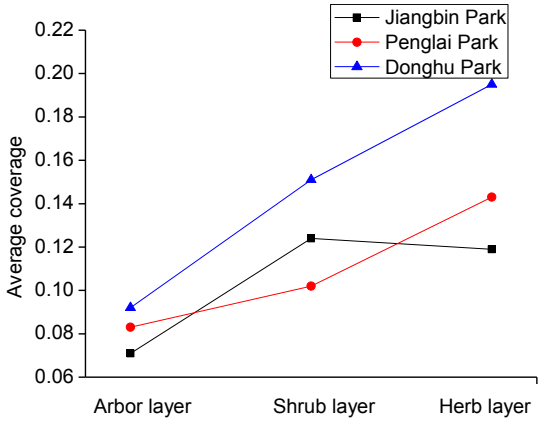

Figure 5. *Average coverage of each plant community layer in the three parks*

It can be seen from *Figure 5* that the average coverages (Average coverage = the sum of the vertical projection areas of all plants of a tree species/the total area of the sample) of the arbor, shrub and herb layers of Donghu Park are much higher than the other two parks. The average coverage of the shrub layer in Jiangbin Park is higher than that of the Penglai Park, while the average coverages of arbor and herb layers of Jiangbin Park are lower than those of the Penglai Park.

Calculate the average DBH of the arbor layer according to *Equation 4:*

$$DBH = \frac{D_1 \times K_1 + D_2 \times K_2 + D_3 \times K_3 + \cdots D_n \times K_n}{K_1 + K_2 + K_3 + \cdots K_n} \quad \text{(Eq.4)}$$

where: DBH is the average DBH, D_1 is the first diameter grade value, and K_1 is number of trees in the first diameter grade.

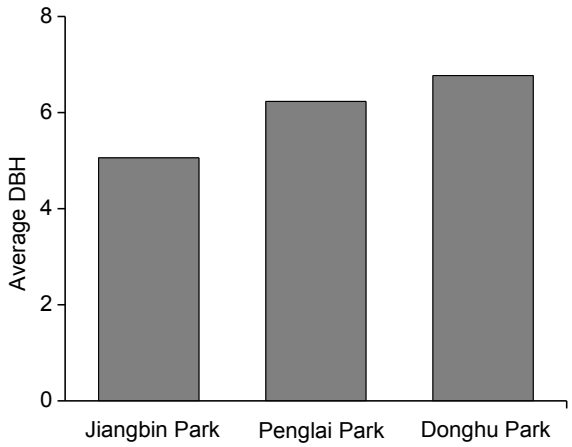

Figure 6. *Average DBH of the arbor layer in the three parks*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1459914609

It can be seen from *Figure 6* that the order of the average DBH of arbor layer is: Donghu Park > Penglai Park > Jiangbin Park.

Based on the above analysis, it can be seen that the density and overall height of the shrub layer and the herb layer in Penglai Park are higher and its ecological benefit is better.

Analysis of structure feature indices of plant communities in the parks

According to *Equations 1, 2* and *3,* the diversity index (D_1), ecological dominance index (D_2) and richness index (R) of park plant community structure were calculated. *Figure 7* shows structure features of plant communities in the three parks, it can be seen from the figure that in the three parks, the diversity index (D_1) and richness index (R) of the arbor layer, shrub layer and herb layer of the Penglai Park are the highest, while its ecological advantage index (D_2) is the lowest; the ecological advantage index (D_2) of the arbor layer, shrub layer and herb layer of the Jiangbin Park is the highest.

Influence of ecological factors of plant communities in parks

Temperature changes inside and outside the plant communities in parks

Table 1 shows the statistics of temperature changes inside and outside the plant communities of each park. It can be seen from the table that the highest temperature of each park appeared in the three months of July, August and September, and the lowest temperature appeared in March and December. Wherein the internal and external temperatures of Jiangbin Park fluctuated greatly, the highest internal and external temperatures were 34 °C and 35 °C, and the lowest internal and external temperatures were 8 °C and 6 °C. This is mainly because the Jiangbin Park is located by the riverside near the Jiangbei Bridge, so the temperature is greatly affected by the wind from the river. In the summer, the inside of the plant community is influenced by the evaporation of the river water, so the temperature rises, while in the winter, the influence is smaller, and there are fewer plant types in the plant community, so the warming effect of the plant community is not obvious, plus the influence of the wind from the river, so the temperature is very low in winter. As for the Penglai Park, the internal and external temperature fluctuations were relatively small, its highest temperature and lowest temperatures were 1 °C lower than that of the Jiangbin Park, respectively, and its external temperature was about 1–2 °C higher than the internal temperature, this is mainly because the Penglai Park is located in the center of the Jiangmen city, and surrounded by roads and buildings, therefore, its external temperature is higher; inside the park, due to the rich structure of the plant community, and the distribution is reasonable, so the cooling function in the summer and the warming function in the winter are significant.

PM10 inside and outside the plant communities in the parks

Figure 8 shows the changes of PM10 inside the plant communities of each park, and *Figure 9* shows the changes of PM10 outside the plant communities of each park. It can be seen from the figures that the PM10 inside the plant communities of each park was about 10-15 $\mu g/m^3$ lower than the external PM10 level, wherein, the PM10 in the Penglai Park in autumn was as low as 80 $\mu g/m^3$. As for the Jiangbin Park, since it is near the river and the wind is strong in winter, so the PM10 values in summer and winter are much higher than that in the autumn; for the Donghu Park, it is in the leeward

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1459914609

of production forest farms, so the PM in autumn is higher than that in summer and winter; and for the Penglai Park, its surroundings are mostly residence, plus the distribution of plant community inside the park is reasonable, so the PM10 varies little in summer, autumn and winter.

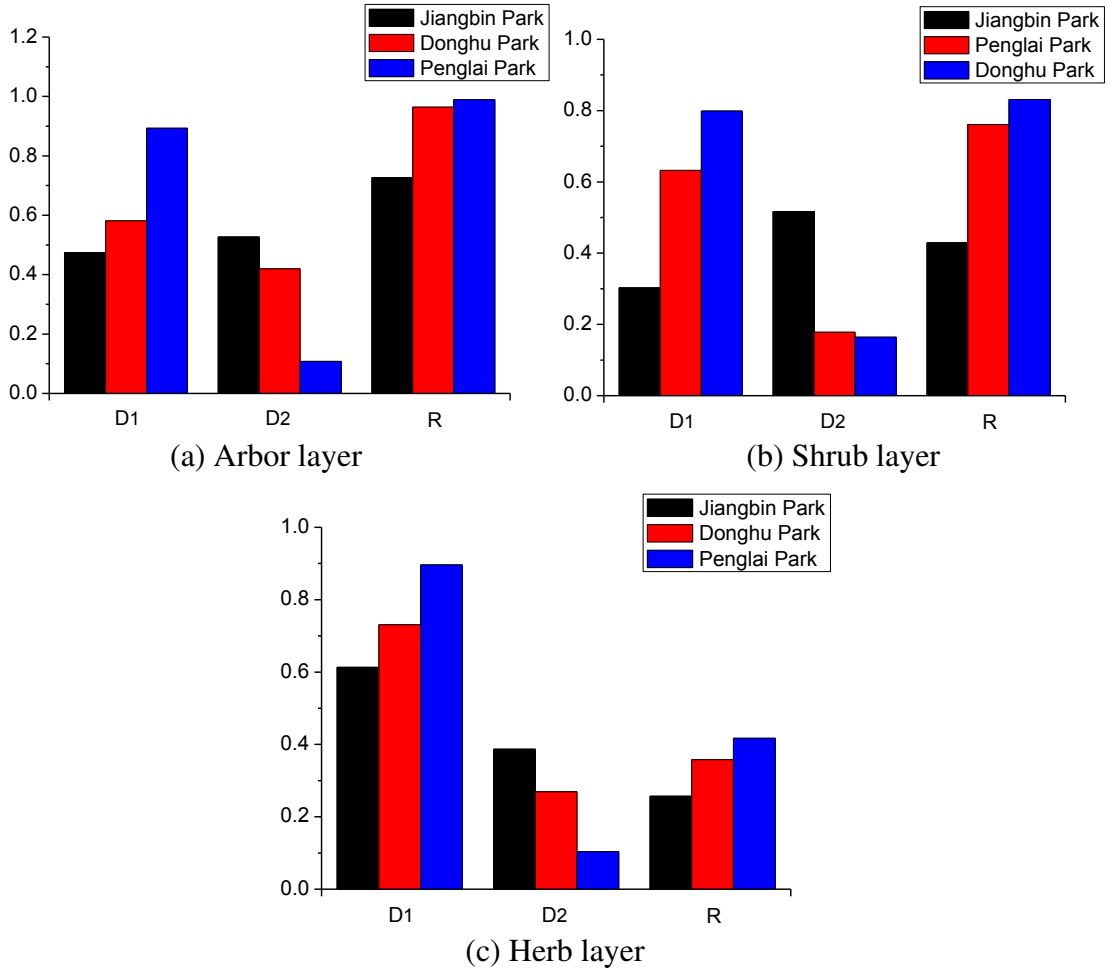

Figure 7. *Structure features of plant communities in the three parks*

Discussion

Influence of ELS on the distribution features of plant communities in green parks

According to above analysis results we can see that, the Penglai Park is located in the center of the city, and surrounded by residential buildings and highways, the temperature changes little, and the overall temperature is higher than the other two parks; its fluctuation of PM10 is small, the density, overall height and average coverage of the shrub layer and herb layer, and the ecological benefit of the Penglai Park are all higher than the other two parks, which is basically in line with the previous research results. As for the Jiangbin Park, since it is near the river and greatly affected by the wind from the river, the temperature inside and outside the plant community and the PM10 vary greatly, therefore, its average height and average coverage of the shrub layer and the herb layer, and the average DBH of the arbor layer are all lower than the other two parks. In the past, there have been few studies on the distribution features of plant communities by ecological factors. This study is expected to provide reference for future research in this regard.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

Countermeasures and suggestions for green park protection in Jiangmen City

Improve urban green space system planning

Green parks are only a part of the urban green space system, to make the distribution of park plant communities more reasonable, we should reduce damages and development of urban green space and enhance green land construction along highway, in squares and tourist attractions, make use of every single space, form a complete urban green space system, and provide a good ELS for green parks.

Strengthen the design of plant communities in green parks and enrich the diversity of plant communities

When designing the green parks, we should introduce more native tree species and landscapes, enrich the diversity of plant community by planting plants of different heights, and afforest reasonably outside the plant communities, so as to conserve water, lower the temperature and increase relative humidity, thereby improving and exerting the overall ecological benefits of the plant community.

Conclusion

- The analysis of plant community structure features showed that the order of the average DBH of the arbor layer in the three parks is: Donghu Park > Penglai Park > Jiangbin Park. The density and overall height of the shrub layer and the herb layer in Penglai Park are higher, indicating that the overall ecological benefit of the Penglai Park is better.
- The analysis results of the indices of the plant community structure features showed that, the diversity index (D_1) and richness index (R) of the arbor layer, shrub layer and herb layer in the Penglai Park are the highest, and its ecological advantage index (D_2) is the lowest.
- The analysis results of the influence of ELS on the distribution features of plant communities in green parks showed that, the Penglai Park is located in the center of the city, and surrounded by residential buildings and highways, both the temperature and the PM10 change little, and its overall temperature is higher than the other two parks; the density, overall height and average coverage of the shrub layer and herb layer, and the ecological benefit of the Penglai Park are all higher than the other two parks. As for the Jiangbin Park, since it is near the river and greatly affected by the wind from the river, the temperature inside and outside the plant community and the PM10 vary greatly, therefore, its average height and average coverage of the shrub layer and the herb layer, and the average DBH of the arbor layer are all lower than the other two parks.
- Taking the urban green parks of Jiangmen City as examples, this paper studies the influence of environmental landscape structure on the distribution features of plant communities in green parks. It comprehensively compares the distribution features of plant communities in different parks under different environmental landscape structures, and proposes relevant suggestions for the optimization of park plant communities. This shall provide a theoretical reference for urban ecological construction.

(Received 7th Jun 2019; accepted 10th Oct 2019)

Abstract. The current scale of space division cannot effectively protect and manage the biodiversity in different natural geographic regions across China. To solve the problem, this paper optimizes natural geographic regions on a small scale based on the eco-sustainability and biodiversity in China, and prepares an optimized layout plan for China's ecological nature reserve system. The research results show that different natural geographic regions require different division scales, e.g. small-scale spatial layout is suitable for forest ecology and wild plants; the reduction in spatial scale has varied impacts on the protection of the different; the optimization of spatial scale is affected by vertical and horizontal gradients, e.g. the vegetation system is better protected in a region with small spatial scale; the small-scale spatial optimization of natural geographic regions makes the division of eco-environmental protection grids more effective; the regions with high biodiversity should be divided into denser grids to promote eco-sustainability. The research findings lay the theoretical basis for the planning of natural geographic regions and the maintenance of eco-diversity.
Keywords: *eco-environment, biodiversity, sustainability, spatial layout, spatial optimization*

Introduction

Today, the man-nature relationship gets increasingly strained, and the huge inputs in biodiversity protection have created an enormous social and economic burden on China. Protection for natural geographical areas has yielded an indistinctive result, especially for small and medium-sized ecological environments (Cochrane and Perrella, 2012). To study the best way to scientifically optimize the geographical regionalization grid, it is significant to effectively protect natural ecosystems and their biodiversity, and also improve it (Senator, 2017). The spatial optimization layout of China's natural geographical areas focuses primarily on the lists of protected species and important ecosystems, but lacks the integrated geographical regionalization on natural reserves, and never includes comprehensive and systematic protection of biodiversity (Maiano et al., 2006; Matchanov et al., 2016). Spatial optimization of natural geographic areas renders important basic data for regional biodiversity and eco-environmental protection and system construction of nature reserves. This lays a broad scientific foundation for developing regional biodiversity policies (Liu et al., 2014).

In recent years, scholars at home and abroad have made extensive studies on the spatial optimization of geographical areas, but the optimization methods vary according to different backgrounds, regionalization, bio-communities and other reference indicators. In response to the local geomorphological pattern, a small-scale spatial layout suitable for reserves has not yet been proposed (Sperry et al., 2016; Hübner and Schaal, 2017a). The principles of spatial optimization for natural geographic areas include relative consistency, the integration and the integrity. According to the regional

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1461114619

geomorphology, the natural geographic areas can be divided into tier-1, 2, 3 and 4 spaces (Dyck and Willems, 2013). The regional spaces should be divided and optimized aiming at the construction of nature reserve systems with definite purposes, and the hierarchical regionalization system should overall be improved and more scientific (Hübner and Schaal, 2017b). Based on the sustainability of the ecological environment, this paper makes a spatial optimization for the natural geographical areas on a small-scale according to the biodiversity in China, and gives the optimal layout program for the ecological nature reserve system in China.

Materials and methods

Through the course of eco-environment protection, there are still many common problems. To reasonably protect the eco-environment, the best practice is to correctly evaluate current situation of the reserves and identify the existing key issues (Kaufmann and Banerjee, 2014). There are many types of small spaces included in natural geographic areas, including the natural reserves, wilderness reserves, the national parks, the natural monument museums, the habitat and species management reserves, the terrestrial and marine landscapes, etc. (Jiang and Liu, 2012). The spatial scale of natural geographical areas can be determined according to spatial acreage of the nature reserves. In general, the area greater than 10,000 km^2 is called a large-scale space, and the area less than 100 km^2 is called a small-scale space (Krasnov et al., 2015). According to the incomplete statistics, China's nature reserves cover an area of more than 106 km^2, and the layout of most spaces are statistically designed as required by the provinces as the large scales, thus leading the statistical species to averaging (Jiang et al., 2013).

Using statistical survey method, according to data from the Bureau of Land and Resources, currently, there are 2392 nature reserves having been divided in China, among which, there are more than 400 small-scale ones. As shown in *Figure 1,* different types of national nature reserves as percentage of the total areas are figured out, where the desert ecology ranks the first, followed by the wild animals and inland wetlands. The desert ecology is suitable for large-scale spatial layout in natural geographical areas, and for the forest ecology and wild plants, they are suitable for small-scale spatial layout. *Figure 2* illustrates the number of different types of the national nature reserves. It is obvious that there is a great difference in the construction layout in different times between various nature reserves. There are even more layouts for the forest ecology due to the fact that forest ecology is mostly divided on a small scale.

Results

Small-scale spatial division for regional system

To divide the small-scale spaces in natural geographical areas, it is conducive to safeguard the ecosystems, rare and endangered animals and plants, as well as the sites and relics. According to the existing areas as divided, the number of national nature reserves in different natural geographical areas and the corresponding upland areas are not directly proportional to each other, and there are disparities in the scale division between the natural geographical areas. For the number and the area of small-scale spaces in the nature reserves, see *Figure 3*. It is obvious that the number of small-scale spaces in China increases year by year, but their mean area calculated by the ratio of the area to the number gradually decreases.

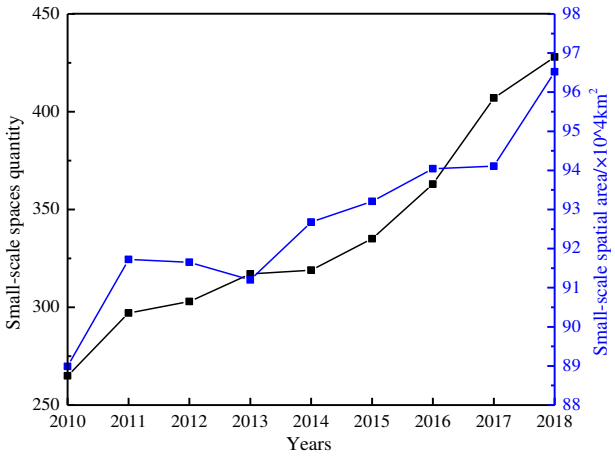

Figure 3. *Quantity and area of small-scale space in nature reserves*

The small-scale spaces as percentage of the natural geographical areas at different protection ratios are shown in *Figure 4,* more than 30% of them are protected at less than 5%. Among them, there are the maximum small-scale spaces in the unprotected natural geographic areas in the northwest warm temperate zone, exceeding 70% of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1461114619

total. Further, except for the Qinghai-Tibet Plateau, a natural geographical area, the protective area of small-scale spaces in other geographical areas is generally 3% lower than that of other land areas. The total small-scale spaces as percentage of the natural geographical areas at different protection ratios are shown in *Figure 5*. In the east and south China, the small-scale spaces as percentage of the natural geographical areas at the protection ratio below 5% is the maximum, followed by those in the north China and in the northwest China. As the scale spaces diminish, the effective protection in different natural geographic areas varies from unit to unit.

Analysis of vegetation ecosystem protection potency

Investigation research shows that the vegetation system is suitable for dividing small-scale spaces in the natural geographical areas. The regional biodiversity may be subject

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1461114619

to the spatial layout of vegetation. It is impossible to make up for the gap in the conservation of existing reserves by evaluating biodiversity distribution data with divided scale spaces. The vegetation ecosystem may be subjected to the topography, altitude and climatic environment. Vegetation distribution pattern and its conservation have a significant impact on global biodiversity and the protection of natural ecosystems. Vegetation systems in small-scale spatial areas will be protected at a higher rate. In different natural geographical areas, some reserves have a concentrated layout, and the coverage of upland areas as they did in different areas varies greatly. The current situation of small-scale spaces as percentage of the total conserved vegetation systems is illustrated in *Figure 6*. As we can see, more than 60% of the vegetation systems are conserved at a rate of less than 5%.

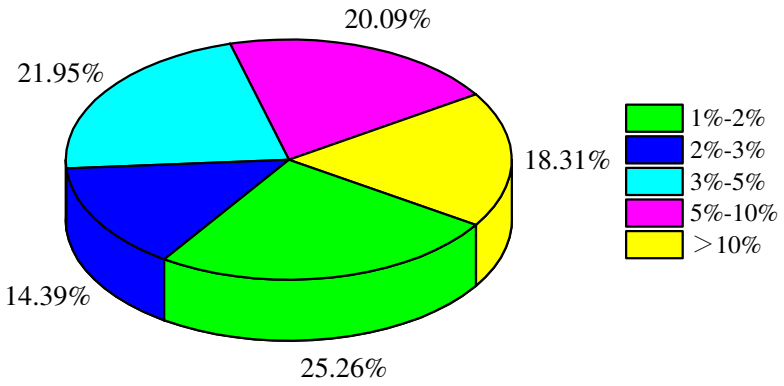

Figure 6. *Current status of small-scale spatial conservation proportion of vegetation system*

Figure 7 illustrates the small-scale spaces as percentage of natural geographical areas at different altitudes. As can be seen, the small-scale spaces are mainly distributed at low altitude (<200 m) and 1000-3000 m altitude in North China (*Fig. 7a*); at 1000-3000 m altitude in the southwest of central China (*Fig. 7b*); and relatively uniform in the northeast areas (*Fig. 7c*), presenting the tendency to decrease with the increase of altitude height. The small-scale spaces of the natural geographical area in the Qinghai-Tibet Plateau (*Fig. 7d*) are all centralized in the high altitude areas (>3000 m).

Discussion

Evaluation on biodiversity conservation value by small-scale spatial optimization

The small-scale space divided in the natural geographical areas is an important form for biodiversity conservation. The priority and biodiversity of small-scale spaces particularly value the typicality and non-substitutability of species and their habitats. There are some main evaluation indicators for biodiversity conservation value, including diversity, representative, scarcity, natural type, area suitability and vulnerability, etc. Great attention should be paid to the diversity of habitat types, while in different scale spaces, the evaluation indicators for biodiversity conservation values vary, but they all focus on the rare and endangered features, protection classes and geographical distribution tendencies of the species. For example, in Jilin Changbai Mountain, there are large chunks of rare animals and plants in the natural geographical areas, so that its diversity protection value is high.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1461114619

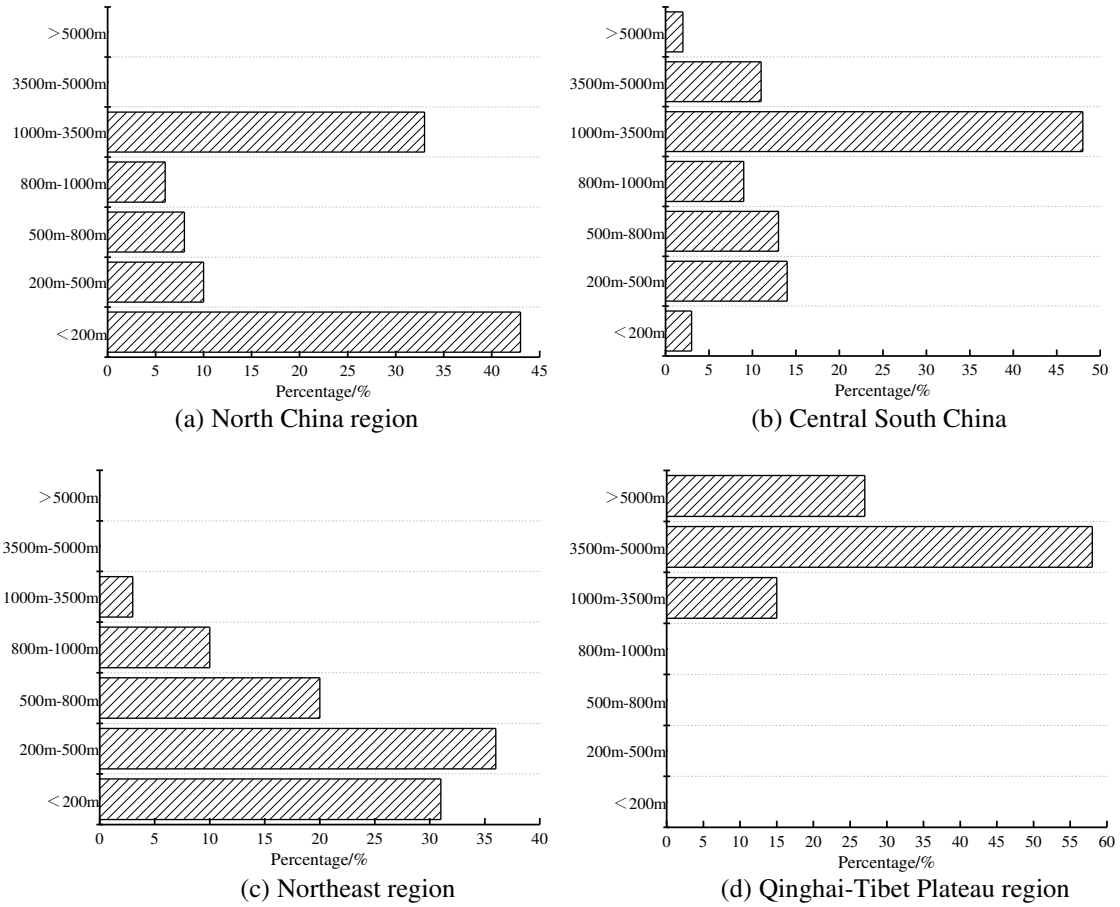

Figure 7. *Proportion of small-scale space in natural geographical regions at different altitudes*

To evaluate how the biodiversity conservation values are susceptible to small-scale spatial optimization, 39 small-scale spaces in the northeastern areas are chosen for study, and different attributes of individual species in the scale space grid are assigned the values at different levels. Those scale spaces with the highest protection value index mainly concentrate in the deciduous broad-leaved forest area of the Taihang Mountain, while those with the maximum protection value index of wild plant diversity fall in the cultivated vegetation and wetland area of Haihe Plain.

Optimized layout plan for China's ecological nature reserve system

On the whole, China has divided the natural geographical areas, but the optimization for small-scale spaces is a complex process involving multiple protection targets and strategies, habitat quality. The existing large-scale space is divided into several small-scale spaces to establish a more effective eco-environmental protection network. It is preferable to divide the area with high biodiversity conservation value into a spatial grid for small-scales, or connect several reserves near each other into a reserve network, this is an important strategy for realizing the natural conservation. Specifically speaking, it is to set up eco-environmental lag zones, and divide them into two categories according to the optimization difficulty: the barely-coordinated ecological optimization zone and the nearly-uncoordinated ecological optimization zone. The land types that need to be renovated are adjusted to forest land, garden land, wetland and other ecological

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1461114619

environments so as to improve the land types that can produce positive effects. According to the existing natural geographical division grid and the preferred biodiversity reserves, the scale space optimization program is designed based on the layout principle of building the areas with low diversity conservation value into the large-scale spaces, and preferentially optimizing the national or international important nature geographical areas into small-scale spaces. In the key natural areas, the species should be highly protected. Those mall-scale spaces with higher conservation values can be preferentially promoted to the national nature reserves.

Figure 8 shows the comparison of the national nature reserves at the protection ratios after small-scale spaces are optimized. As we can see, the bio-conservation coverage in natural geographical areas increases after the spatial optimization layout for small-scale spaces. *Figure 9* shows the optimal composition of small-scale spaces in natural geographic areas. The small-scale spaces in the natural geographical areas are mainly composed of forest ecology, inland wetlands and wild animals. Small-scale spatial layout can effectively fulfill the protection and management targets to more quickly make management measures and tools.

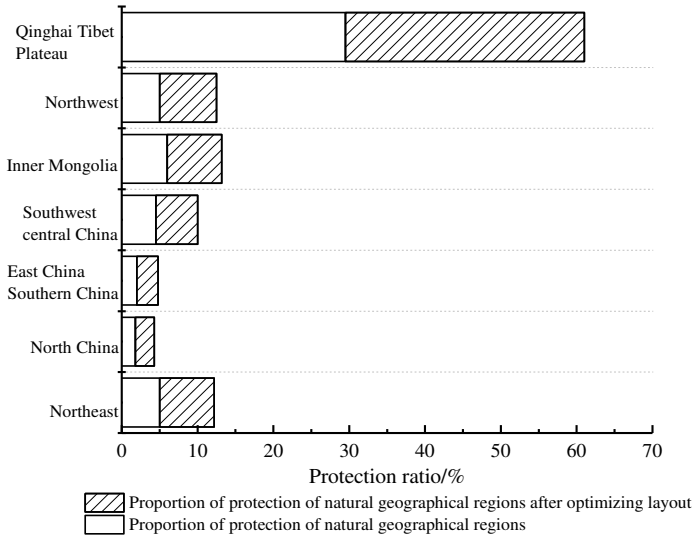

Figure 8. *Proportion of national nature reserves after small-scale space optimization*

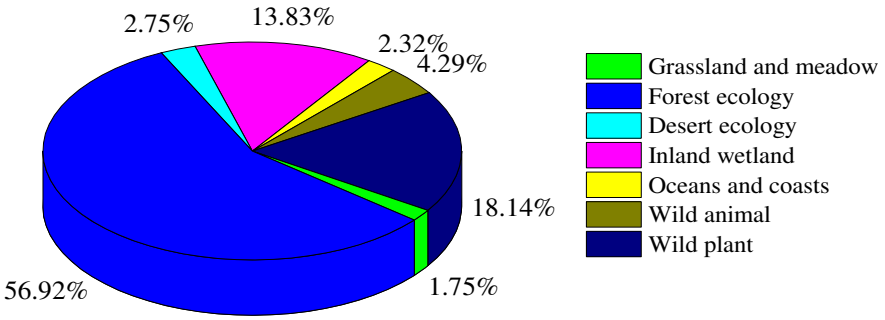

Figure 9. *Small-scale spatial optimization composition of natural geographical regions*

DOI: http://dx.doi.org/10.15666/aeer/1706_1461114619

Conclusion

Based on the sustainability of the ecological environment, this paper optimizes the small-scale spaces in the natural geographical areas in line with the biodiversity of China. In doing so, the optimal layout program is given for the ecological nature reserve system in China. Here come specific conclusions:

- The number of small-scale spaces in China increases year by year, but the mean area of small-scale spaces gradually decreases. In the east and south China, the small-scale spaces as percentage of the total at a protection ratio of less than 5% in the natural geographical area 5% is the highest, followed by those in north China and in north-west region.
- The vegetation system in the small-scale spaces will be protected at a higher ratio. In different natural geographical areas, some protected areas have a concentrated spatial layout, quite different from coverage ratio of the land area in different zones.
- The existing large-scale space is divided into several small-scale ones to establish a more effective eco-environmental protection network. It is preferable to divide the area with high biodiversity conservation value into a small-scale spatial grid, or connect the reserves near each other into a reserve network. This is an important strategy for realizing ecological environmental protection and species diversity.
- This paper analyzed the advantages of spatial optimization for ecosystem development based on actual data. With the sustainable and coordinated development of ecological environment reserves as the principle, it optimized the allocation of ecological spaces and provided a reference for natural geography and land use.

(Received 7th Jun 2019; accepted 16th Oct 2019)

Abstract. This paper analyzes the community structure of edaphic oribatid mites from the tropical forest at Los Tuxtlas, Veracruz, showing its monthly variation during only one year, considering two contrasting tree species and their relation with abiotic edaphic parameters. Randomly, five *Astrocaryum mexicanum* and *Guarea glabra* plants were chosen and near the stem of each one, a sample of soil was taken and processed in the same biological station with Berlese-Tullgren funnels. The most abundant families were Scheloribatidae, Oppiidae, Xylobatidae, Arceremaeidae, and Galumnidae. The Kruskall-Wallis test showed that structure of oribatid mite community is not significative related to tree identity, which they are associated. Pearson's multiple correlation showed that the edaphic temperature is one of the most important abiotic factors in the structuring of oribatid mites communities. The abiotic variables explained 58% of oribatid community variance in its first two axes, with temporality and CO_2 being the factors with most influence over the community. It is concluded that tree identity is not a factor that affects the structuring of oribatid mite communities in this tropical forest, while temporality, soil temperature and CO_2 are the factors that most influence its establishment, this last factor as an indirect indicator of system productivity.
Keywords: *arboreal identity, community diversity, temporality, Astrocaryum mexicanum, Guarea glabra*

Introduction

From several decades edaphic communities have been observed to have a high value of biotic diversity, it is even estimated that our current knowledge covers less than 10% of the total number of species worldwide, due in part to the lack of studies, low efficiency in extraction methods and methodological issues (André et al., 2002). Together with the canopy, the need to study edaphic communities to understand the functioning of ecosystems has been evidenced, considering the soil as one of the last biotic frontiers (André et al., 1994). Anderson (1975) mentions that the mechanisms by which such diverse communities exist are poorly understood, and he named it as the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1462114639

"enigma of animal diversity in the soil". Since then, multiple factors associated with this phenomenon have been proposed, although most of them are focused on the litter diversity, reporting the environmental heterogeneity, content of organic matter, temperature, soil pH, humidity and altitude as some of the determining factors of the communities (Perdue and Crossley, 1989; Urhan et al., 2006; Mumladze et al., 2015). Nielsen et al. (2010) hypothesized that small-scale environmental heterogeneity in respect to organic and mineral soil can be responsible of this high species richness, and recently Bernier (2018) emphasizes the importance of the type of humus for the establishment of the edaphic fauna, not only as a transition point between the soil and litter, but also as a kind of habitat with particular characteristics.

Forest soils are ecosystems characterized by being extremely fertile, in addition to having a great biodiversity in their first 20 cm, which contributes in the cycle of nutrients and decompositions of organic matter (Gessner et al., 2010). In the edaphic communities of tropical forests, oribatid mites are numerically dominant organisms, and species richness of their biotic community is generally around 70 species (Kaneko et al., 2005; Mumladze et al., 2015). Wunderle (1992) reports 82 species of oribatids with an average density of 61,500 individuals per m^2 for a low rain forest in Peru, while Ferreira et al. (2012) recorded 143 species of oribatids and up to 460 morphospecies for the Brazilian Amazon. In Mexico, there have been communities in tropical forests up to 120 species for the state of Quintana Roo (Vázquez, 2006).

It has been reported that abundance of oribatid mites show spatial and temporal (seasonal) variations, which reflects different dynamics of the microhabitat, although the taxonomic composition often does not reflect this pattern (Irmler, 2006; Wehner et al., 2018). Temporal variations in abundance are usually related to parameters such as temperature, humidity and even the availability of food, although sometimes these effects tend to influence particular species but frequently not all the community in general (Gergócs et al., 2011). Despite registering patterns of seasonal variation in his abundances, little is known about the role of the leaf litter and identity of the plants in relation to the stability of the community of mites that inhabit the soil near them.

Although the incorporation of leaf litter into the soil of ecosystems contribute with elements such as nitrogen, phosphorous and carbon differentially in relation to the plant species and senescent phase (Fonte and Schowalter, 2004), the diversity of oribatids on the litter is not much influenced by plant richness, nor by the accumulation of organic matter from different species (Kaneko et al., 2005), even with plants with allelochemical attributes that directly influence the chemical composition of the soil by the production of metabolites and other substances, are not capable of altering the structure of his communities (Osler and Beattie, 2001). However, in other papers this group has responded positively in relation to the increase in plant richness and diversity of litter (Kaneko and Salamanca, 1999; Hansen, 2000). Because most of the investigations are focused on analyzing the structure of the community in upper litter of the forest soils, it is not known if the community has this same behaviour belowground.

The tropical rain forest of Los Tuxtlas in the state of Veracruz is one of the last relicts of high tropical evergreen forest in Mexico. The Sierra of Los Tuxtlas is a mountain formation of volcanic origin, located in the coastal plain of the Gulf of Mexico, within this region is the Los Tuxtlas Tropical Field Station (hereafter referred to as LTS), this station was founded in 1968 and is operated by the Universidad Nacional Autonóma de México, actually has an area of 640 ha and its elevation range goes from 150 to 720 m asl (Dirzo et al., 1997).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1462114639

The palm *Astrocaryum mexicanum* Leibm. is the most abundant plant species of LTS, can register from 300 to 1,230 individuals per hectare and constitutes 20 to 61% of the total density of plants (Piñero et al., 1977), it has a longevity of 140 years and have heights of 1.5 to 6 meters (Piñero et al., 1984). This plant is favoured by disturbance, since its population grew from 1975 to 2013 with an average of 2.9% per year due to habitat alteration, edge effect and anthropogenic impact (Martínez-Ramos et al., 2016).

This palm is characterized by a monocaule stem of 10 cm thick and spiny leaves up to one and a half meters that have a development of 1.6 to 5 leaves per year in relation to the degree of light which they are exposed (Núñez-Castillo and Álvarez-Sánchez, 2003). Due to architecture, form of growth and the large number of thorns up to 6 cm that present in the stem, fruit and leaves, this plant has the ability to store a large amount of organic matter in its petioles, mainly of leaf litter from other trees, which gives an extra contribution of nitrogen and phosphorous by means of the decomposition on the plant that later reaches the soil by cauline flow (Raich, 1983; Álvarez-Sánchez et al., 2016).

Guarea glabra Vahl., also abounds in LTS (Álvarez-Sánchez and Guevara, 1999). It reaches heights of 25 m and has up to 30 cm in diameter (Coronado, 2006). It can persist for periods close to 100 years (Ibarra-Manríquez et al., 1997), has a strong trunk that begins to branch from near three meters and all the year constantly generates leaves, the fruits typically occur from May to July (Wenny, 1999) in reproductive season, its fruits cover small regions of soil, being a strong contribution of nutrients and organic matter to it.

Both plant species are part of different functional groups: *A. mexicanum* has a lower contribution of organic matter to the litter and soil and presents a slow decomposition rate (León, 2003) compared to *G. glabra* which is constantly generating and releasing leaves to the soil, also the genus *Guarea* present a quick green-leaf decomposition rate (Fonte and Schowalter, 2004). They have a different architecture and the first one enriches the soil by means of the continuous decomposition of organic matter that it captures in its leaves and petioles, incorporating nutrients into the soil by caulinar flow (Álvarez-Sánchez et al., 2016), while the contribution of nutrients and organic matter by *G. glabra* comes from the decomposition of leaves and temporarily from its fruits, incorporating magnesium, sodium and potassium mainly in the superior edaphic profiles (Barrantes and Ortiz, 2011).

The objective of this work is to analyze the effect of tree identity of two species of taxonomic and morphologically contrasting plants, monthly variation and soil abiotic parameters (pH, organic matter, organic carbon, CO_2, porosity and soil moisture) on the diversity and structure of the belowground oribatid mite community in this Mexican tropical forest.

Our first hypothesis is that tree species will have a significant effect on the structure of the belowground oribatid community, we infer that in the soil associated with *G. glabra* the diversity, richness and abundance of oribatids will be greater due to the abundant and constant contribution of organic matter by this plant to the soil. *A. mexicanum* releases few leaves and most of the nutrients it contributes to the soil come from captured organic matter that decomposes on it, so that the amount of plant material and decomposition rate is lower, also we assume a different species composition in oribatid communities of both plants soils, with more species inhabiting soil related with *G. glabra* due to a bigger thickness of soil organic horizon in comparison of *A. mexicanum*. Our second hypothesis is that the community will show a significant variation in its richness, abundance, diversity and composition in relation to temporality

(months), and soil abiotic parameters, being the families Galumnidae, Scheloribatidae, Haplozetidae, Oppidae, Phthiracaridae and Carabodidae more abundant as reported in literature for others tropical rainforest (Franklin et al., 2006; Caruso et al., 2019).

Materials and methods

Study area and description

LTS geographically is located in state of Veracruz, Mexico, between 18°34' to 18°36'N and 95°04' to 95°09'W (see *Fig. 1*). This station is mostly covered by evergreen tropical rain forest favoured by a warm climate with rainfall throughout the year, rainfall in the driest month is above 60 mm and are accentuated in the months of June to February marking a season of "rains" and one of "dry" in March to May, being September the month with greater precipitation. In addition, presents a scarce thermal variation, keeping mostly between 24 and 26 °C (Soto and Gama, 1997).

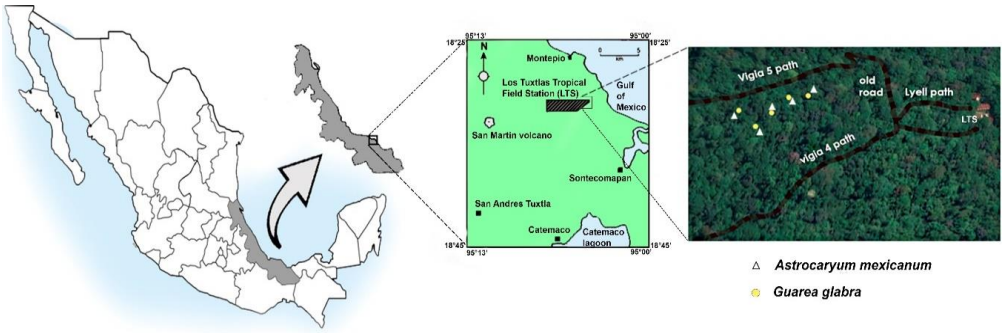

Figure 1. *Location of Los Tuxtlas Tropical Field Station (LTS) in Veracruz, Mexico, and position of sampling sites within LTS (modified from Flores et al., 2014)*

Sampling method

To analyze the effect of the leaf litter on the structure of belowground oribatid mite community, at random in a non-traveled area outside the walking paths Vigia 4 and 5 within the LTS (*Fig. 1*) five plants of *G. glabra* and another five of *A. mexicanum* were chosen in a paired design, the litter near the trunk was removed manually and immediately five samples of soil were taken associated with different arboreal individuals of *A. mexicanum* and five more with *G. glabra* with soil nucleators (11 cm wide and 5 cm deep) (see *Fig. 2*). The material was collected monthly from March 2016 to February 2017 and processed *in situ* the same day of collection in Berlese-Tullgren funnels during six days (three days without light and three days with 25-watt bulbs).

The record of environmental parameters of temperature, relative humidity and CO_2 was made by using a thermo-hygrometer IAQ-Calc^{TM}, model 8760 at ground level. Additionally, 100 g of soil were taken to determine the gravimetric humidity of the soil, porosity, pH, percentage of carbon (%C) and organic matter (%O.M.).

Laboratory techniques

The soil pH was measured with 10 g of sifted soil diluted in distillate H_2O with a pH meter. %O.M. was obtained by Walkey-Black method (Walkey, 1947) with 0.2 g of sifted soil, percentage of carbon (%C) was calculated as in *Equation 1:*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1462114639

$$\%C = (\%O.M.)(0.58) \quad \text{(Eq.1)}$$

For obtaining soil porosity (Jackson, 1976; Van Reeuwijk, 2002) we first measured apparent density (*Ad*) of soil by weighting a test tube of 10 ml, then added soil until 10 ml, using a funnel and hit above-down from 20 cm ten times softly, posteriorly added again soil to refill 10 ml and weight again the test tube, by resting the test tube weight and dividing it in test tube volume we obtain de apparent density (g/cm^3), the density of solid particles of soil was obtained by pycnometer method (Blake and Hartge, 1986). First the dry pycnometer was weighted (*S*), then 5 g of soil was added and the pycnometer is filled with water (*s* + *a*), finally the soil is removed and the pycnometer is filled with water and weighted (*S* + *A*). We calculate the of soil particles density (*Sd*) with *Equation 2*.

$$Sd = \frac{S}{S+A} - s + a \quad \text{(Eq.2)}$$

The total porosity (*Ptotal*) was obtained using the apparent density and density of soil particles with *Equation 3*.

$$Ptotal = \frac{(1-Ad)(100)}{Sd} \quad \text{(Eq.3)}$$

The mites were separated and quantified manually under the stereoscopic microscope (Zeiss^{TM}, Stemi 2000), later they were mounted in semi-permanent preparations in Hoyer´s solution. Identifications were made at the finest taxonomic level possible by dichotomous keys (Balogh and Balogh, 1992) and specialized literature for each family, those with identification problems were assigned to morphospecies, the specimens are deposited in the collection of Collembola and edaphic mites of the Laboratory of Ecology and Systematics of Microarthropods (LESM), Faculty of Sciences, UNAM, Mexico.

Numerical and statistical analysis of the community

To observe the fit of data and type of analysis to be performed, its normality was tested with Kolmogorov-Smirnov test in software R (R Core Team, 2016), and homoscedasticity with Statistica v.8.0. (Statsoft Inc, 2007). For each sample of tree species was obtained the abundance and oribatid species richness (S) by direct count, also, Pielou´s equitativity (*J´*), Simpson´s dominance (*D*) and Shannon diversity index (*H´*) were calculated in PAST 3.22 software (Hammer et al., 2001) with *Equations 4*, *5* and *6,* respectively.

$$J' = \frac{H}{\ln(S)} \quad \text{(Eq.4)}$$

$$D = \left(\frac{n_i}{n}\right)^2 \quad \text{(Eq.5)}$$

$$H' = -\sum \frac{n_i}{n} \ln \frac{n_i}{n} \quad \text{(Eq.6)}$$

The effective species number (^1D) was obtained through Shannon exponential with *Equation 7* (e^H; Jost, 2006).

$$^1D = \exp(H') \quad \text{(Eq.7)}$$

To determine the effect of the identity of the plant species on the abundance, density, species richness, dominance and equity of the community of oribatid mites a nonparametric Kruskall-Wallis test was carried out between each plant community data in R software. Also, a t test with Shannon diversity index (*H´*) were performed in PAST 3.22 software for analyze possible variations in this community attribute between plants.

The relationship and significance between the community structure and soil abiotic factors was tested by a multiple correlation analysis of Pearson in software R with $\alpha = 0.05$, including factors as abundance, density of individuals, richness (*S*), diversity (*H'*), effective species number (^1D), equity (*J´*), dominance (*D*) and soil parameters like CO_2, pH, temperature, moisture, %O.M., %C and porosity. We performed a Canonical correspondence Analysis (CCA) using the CCorA function in vegan package (Oksanen et al., 2016) with Software R (R Core Team, 2016) to detect interactions between the community of oribatid mites and abiotic parameters, the envfit function ("Fits an Environmental Vector or Factor Onto An Ordination) was used with 999 permutations, to get the p-value or correlation of each variable with overall oribatid community, samples with total absence of specimens was removed from the analysis.

Results

A total of 2577 Oribatid mites with a mean monthly density of 289.49 ind/m^2, belonging to 41 families and 72 species (see *Table 1* and *Appendix 1*). Most abundant families were Scheloribatidae (320 specimens), Oppiidae (288), Oripodidae (285), Protoribatidae (266), Arceremaeidae (222), Galumnidae (186) and Haplozetidae (148). Total abundance of oribatid present in soil of *G. glabra* (1,321) was slightly higher than that recorded in *A. mexicanum* (1,256). Most abundant species throughout the study

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1462114639

were *Scheloribates ca. grandiporosus*, *Tecteremaeus cornutus*, *Brasilobates* sp. nov. and *Benoibates* sp. nov. with 9.5%, 8.6%, 8.4% and 8% respectively from the total of individuals.

Specific composition of oribatids between soils from trees was shared in 78%, with 56 species in common between both communities, while seven were exclusively in *G. glabra* soils and nine in soils of *A. mexicanum*, although most of these records were made through the presence of a single specimen. *Acrotritia ardua* (March, April, May and August) and *Rostrozetes cubanus* (October, November and December) were the only species that present records in at least three months in soil of *G. glabra* and *A. mexicanum* respectively. Most abundant species related to *G. glabra* were *Benoibates* sp. nov. and *Scheloribates* ca. *grandiporosus*, while in *A. mexicanum* they were *Tecteremaeus cornutus* and *Brasilobates* sp. nov.

No homoscedasticity was found in the samples corresponding to both plant species, the Kolmogorov-Smirnof test showed that oribatids abundance was not a normal distribution ($D = 0.166$, $p = 0.0026$), making it necessary to use nonparametric methods for its analysis.

No significant differences were found between the community of oribatids associated to *G. glabra* and *A. mexicanum* through the analysis of Kruskall-Wallis in relation to abundance ($X^2 = 0.203$; $p = 0.651$), density ($X^2 = 0.204$; $p = 0.651$), richness (S) ($X^2 = 0.117$; $p = 0.733$), dominance (D') ($X^2 = 0.008$; $p = 0.927$) and equity (J') ($X^2 = 1.8162$; $p = 0.178$). The t-test for diversity between the community associated with these two plants using the Shannon entropy index (H') showed no significant differences ($t_{22} = 1.7691$, $p = 0.077$). Due to the lack of significant effects of tree species to the edaphic community of oribatids, their abundance from both plants was grouped for the analysis of temporal variation and its relationship with abiotic soil factors.

The highest abundance was recorded in March 2016 (*Table 1*), while the lowest was presented in February 2017; there is a second period of population increase in July and August 2016 with 372 and 305 specimens respectively. In March 2016, there were four species with the greatest abundance: *Brasilobates* sp. nov., *Scheloribates* ca. *grandiporosus*, *Rostrozetes foveolatus* and Galumnidae gen. nov. In July 2016 three species that showed high abundance in March again increase their population numbers; however, five different species increased their abundance in this season (*Tecteremaeus cornutus*, *Benoibates* sp. nov., Multio*ppia* sp., *Mesoplophora longisetosa*, and *Scheloribates praeincisus*), which shows a temporal differentiation in relation to the specific composition of the oribatid community. The variation of the abundance of the oribatid species was very evident in some months (see *Appendix 1*), with families which live throughout the year (Arceremaeidae, Protoribatidae, Galumnidae, Epactozetidae, Neoliodidae, Oppiidae), others that are only temporary (Epilohmannidae, Mesoplophoridae, Malaconothridae) and some circumstantial like Cymbaeremaeidae, which normally can be found inhabiting in the trunk or canopy of trees.

The highest richness (S) was presented in August (*Table 1*), followed by July and June, the lowest richness was recorded in February. The average diversity of all months according to the Shannon index was high ($H' = 2.96$), the greatest true diversity (^1D) was reported in November and July, while the lowest was in February and May, with an average of 20.24 effective species number per month. The highest dominance (D) was registered in February due to the low number of specimens and the big abundance of a member of *Truncozetes sturmi* (Epactozetidae), and in May mainly due to the high abundance of three species of families Oppiidae (*Multioppia* sp.), Scheloribatidae (*Scheloribates praeincisus*) and Protoribatidae (*Brasilobates* sp. nov.). The values of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1462114639

equity index (*J′*) showed quite homogeneous communities, because they were always above $J' = 0.75$, the month with the greatest equity were January and November, while the least equitable was May. Statistically significant differences between each collecting month and numerical attributes of oribatid mites community can be found in *Appendix 2*.

J′	0.86	0.79	**0.78**	0.85	0.85	0.81	**0.78**	0.89	0.90	0.85	**0.92**	0.86

Maximum and minimum values of each parameter in bold
Abundance (N) = total number of individuals; density (Ind/m^2) = monthly mean of individuals/m^2; Species richness (S) = Number of species; Shannon diversity index (H′) = Shannon entropy index using ln; true diversity (^{1}D) = Effective number of species with rank 1 ($^q = 1$); D′ = Dominance index; J′ = Pielou′s equity (evenness)

Kruskall-Wallis analysis showed a significant relation between collecting month with abundance and density ($X^2 = 56.53$; $p < 0.001$), Richness (*S*) ($X^2 = 51.99$; $p < 0.001$), diversity (*H′*) and effective species number (^1D) ($X^2 = 48$; $p < 0.001$) and marginally significative with Dominance (*D′*) ($X^2 = 19.52$; $p = 0.052$), only the relation with equity (*J′*) was not significative ($X^2 = 14.653$; $p = 0.199$). With which the monthly seasonality showed to be a key factor in the structuring of the community of oribatids in this jungle (*Appendix 2*).

For the Pearson′s correlations between the edaphic parameters and the structural attributes of the community, only the relation between soil temperature with the density ($r = 0.641$, $p = 0.0009$), richness ($r = 0.621$, $p = 0.0022$), dominance ($r = 0.524$; $p = 0.0420$) and true diversity ($r = 0.604$, $p = 0.004$) were significative and positive, so the soil temperature is one of the factors that most influence the communities structure of these mites in the jungle; while porosity, percentage of organic matter, pH, humidity and organic carbon did not have a significant interaction with the community of oribatids (*Table 2*).

The canonical correspondence analysis for the soil abiotic variables (*Fig. 3*) explains in its first two axes 58% of the variance in the community of oribatids (axis 1, 36%, axis 2, 22%). The monthly temporality shows a high negative correlation with axis 1 ($r = -0.9222$); similarly, the percentage of soil CO_2 shows a high negative correlation with axis 2 ($r = -0.7211$); CO_2 is indicative of the high primary productivity of the system and therefore of the high amount of food available for the oribatids (Herrera et al., 2001). The variables that correlate significantly with the ordination were temporality, soil temperature, CO_2, soil relative humidity, percentage of organic matter and organic carbon (*Table 3*). The species most related to axis 1 are *Licneremaeus discoidalis* (Ld),

DOI: http://dx.doi.org/10.15666/aeer/1706_1462114639

Kaliptrazetes desaussurei (Kd) and *Berlesezetes peruensis* (Bp), these last two species are also related positively to axis 2, *Klappericheș* sp. nov., *Protoribates capucinus* and *Epilohmannia pallida* are the species more related negatively to this axis (*Table 4*).

Species abbreviations: L.d. = Licneremaeus discoidalis; K.nov. = Klappericheś* sp. nov.*; K.d. = Kalyptrazetes desaussurei; B.p. = Berlesezetes peruensis; P.c. = Protoribates capucinus; E.p. = Epilohmannia pallida*

Table 4*. CCA species scores of the species more related with Axis 1 and 2*

Family	Genus and species	CCA axis 1	CCA axis 2
Licneremaeidae	*Licneremaeus discoidalis*	**1.640062**	-0.420947
Microzetidae	*Kalyptrazetes desaussurei*	**1.474698**	1.849525
Microzetidae	*Berlezesetes peruensis*	**1.468658**	1.846099
Carabodidae	*Klapericches* sp. nov.	0.639038	**-1.902672**
Protoribatidae	*Protoribates capucinus*	0.684869	**-1.551144**
Epilohmannidae	*Epilohmannia pallida*	0.9484	**-1.513977**

Bold number denotes to which axis are more related

Discussion

There is a large amount of information about the close interaction between the community of edaphic fauna and plant species, especially because they provide a large amount of organic matter and their roots exudates to the soil, which are captured by litter and reintegrated into the soil with the help of degrading organisms (Bardgett and Wardle, 2010). This litter has mainly a structural function for oribatids, maintaining habitat heterogeneity necessary to sustain their complex communities, without significant influence

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1462114639

of the identity of the litter (even with more than 25 species of leaves) on the community of these mites (Kaneko et al., 2005), this is due to the decrease of leaf litter quality as the decomposition process progresses, and also to the high range of food resources that can be consumed by the oribatids (Scheu, 2005; Kaneko et al., 2005).

Contrary to our first hypothesis, specific identity of the trees studied (*A. mexicanum* and *G. glabra*) is not a determinant factor on the communities structure of soil oribatids in this tropical forest, so there are no significant differences in abundance, richness, dominance, equity and diversity; also, a similarity of 72% was observed among their species, and many of them were represented by a single specimen (*Appendix 1*). This can be because the litter under these plants in natural conditions is still heterogeneous and the decomposition process and abundant rains unmasks the possible differences between types of litter and generates a redistribution of organic matter and nutrients (Donoso et al., 2013). Finally, because the low evolutionary relationship between these mites and the plant resources they ingest, is common to find oribatids with general food habits (Wardle, 2006; Donoso et al., 2010, 2013) feeding indistinctly of any type of organic matter.

It is known that the abundance of mites depends on the seasonality of the ecosystems, since the quantity and quality of the organic matter in litter varies with the season and climate. In a tropical forest in Panama, a decrease in the abundance and richness of oribatids was observed in the last months of the year (November) since litter tended to be shallower (Donoso et al., 2013).

In this study, the total abundance (2,577 specimens) and richness (72 spp.) was lower than that reported by Minor et al. (2017a), who registered 10,585 specimens and 139 spp. in a tropical forest of Vietnam. Also the density of oribatids per sample in this forest goes from 12 to 984 ind/m^2, with a monthly mean of 289.5 ind/m^2 (see *Table 1*) which was low compared to the records (between 4,000 and 40,000 ind/m^2) for other tropical forests (Bluhm et al., 2016; Minor et al., 2017a); although there are records at the soil of rainforest Vietnam, with densities lower than 180 ind/m^2 (Minor et al., 2017b). The densities found in LTS are still below even compared with a dry forest in western Mexico, where densities greater than 8,000 ind/m^2 have been recorded (Palacios-Vargas et al., 2007).

In respect to our second hypothesis, our results show a similar tendency in the decrease of oribatids abundance at winter season, which is generally related to a reduction in the specific richness and diversity in the community, registering the three lowest abundances in December, January and February, and the highest in March, which is explained by the presence of a large number of tropical and northern cyclones that naturally occur in the region in the winter season from November to January (Soto and Gama, 1997), and that during our sampling, they were present very intensively from October to February, flooding large areas of the jungle and part of our collection points (University Network of Atmospheric Observatories, RUOA, http://www.ruoa.unam.mx), which generates a large number of soils oribatids perish, migrate vertically, or they resort to some morphophysiological strategy to survive, however the success and survival time to the floods is dependent on each species (Bardel and Pfingstl, 2018; Smrž, 1996; Pequeno et al., 2017), also only the families Scheloribatidae, Oppidae, Oripodidae, Protoribatidae and Arceremaeidae were abundant in this forest which possess generalist feeding habits, contrary to our expectations Phthiracaridae and Carabodidae was low abundant families.

The edaphic temperature result one of the main determinants of community structure of oribatids, since there is a great dependence of poikilothermic animals with this

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1462114639

parameter for physiology (mainly metabolic and respiratory) throughout their life cycle (Stamou et al., 1995); this relationship is generally reported as negative, so that as the temperature increases, the abundance of many groups of the mesofauna decreases, among them the oribatid mites. Maximum lethal temperatures for them are close to 40 °C (Wehner et al., 2018; Ermilov and Lochynska, 2008; Bezci et al., 2017), other factors that significantly influence these communities are content of organic matter, soil pH, porosity and humidity (Urhan et al., 2006; Wissuwa et al., 2013); however, in our study none of these parameters were significant, suggesting that among the factors analyzed, only the soil temperature plays a key role in structuring oribatids in this rainforest.

The analysis of canonical correspondence explains about 60% of the variance of the community of oribatids in relation to temporality and the percentage of CO_2, the temporality has been previously addressed as a structuring character of the communities of these mites; however the CO_2 has been used as a measure of the productivity of the system, observing that the greater amount of this compound, tropical plant species increase their photosynthetic rate, increasing their productivity and possibly their hydric status (Herrera et al., 2001). However, high levels of CO_2 generate changes in the edaphic flora and microbiota, which in short-term studies do not show enough interaction to modify the structure of the oribatid mites (Haimi et al., 2005), although in studies of modification of the amount of CO_2 in soil in the long term, after 18 months in plots with increase of this compound with 200 ppm above the environmental values, there are significant differences in the decrease of the populations of these mites in up to 61%, due to the variation in the microbiota and litter quality (Hansen et al., 2001).

Conclusions

No significant effect of tree identity was found on the structure of the oribatid mite community in Los Tuxtlas rainforest. Soil constitutes a continuum in conditions and resources as proposed by Wehner et al. (2016) in its hypothesis about litter, being considered as a connecting bridge between the organisms; besides that litter quality decreases as the decomposition process advances and therefore they end up masking the differential properties of leaves (Scheu, 2005; Kaneko et al., 2005); however, it is relevant to mention that contrary cases have been reported for temperate forests (Eissfeller et al., 2013).

The community structure of oribatids mites showed significant differences in relation to collecting months, finding in general terms two large demographic increases in March 2016 and July 2016, which show a differentiation in the specific composition and allow a greater richness in the community.

Within the soil abiotic factors only soil temperature had a significant relationship with soil community according to Pearson correlation analysis; however, in the CCA ordination with envfit, additionally to temporality and edaphic temperature, the % of CO_2, the edaphic relative humidity, percentage of O.M. and O.C. was also significant and have an effect on the structuration. Even so, analyzed factors are insufficient to explain the whole variation in the community structure of the Oribatid mites.

Subsequent analyzes are necessary to know if the plant identity does not affect the communities of oribatid mites inhabiting the litter or even the trunks or canopy of morphological and functionally contrasting trees in this tropical ever-green forest, and also compare these results with others tropical forest for the world.

Acknowledgments. We thank to the Postgraduate doctoral program in Biological Sciences of the UNAM for all the support given during the realization of this work. CONACyT gave a scholarship to the senior author for this doctoral study. This project was supported by the project PAPIIT (DGAPA, UNAM) IN214816: "Microarthropod ecology of Los Tuxtlas forest, Veracruz" in charge of José G. Palacios Vargas. We had logistic help from the personal of Tropical Biology Station of Los Tuxtlas, Veracruz, mainly from Rosamond Coates and Martha Madora, Maira Montejo gave assistance in the ecological analyzes, Ricardo Iglesias supported the taxonomic determination of oribatid mites, Tila Pérez support with valuable suggestion for the improvement of this paper.

DISTRIBUTION AND GENETIC DIVERSITY OF TOBACCO ETCH VIRUS IN TURKEY AND RESISTANCE OF IMPROVED CAPSICUM LINES

ARPACI, B. B.

Department of Horticulture, Faculty of Agriculture, University of Kilis 7 Aralik, 79100 Kilis, Turkey
(e-mail: bbarpaci@kilis.edu.tr; phone: +90-348-814-2666; fax: +90-348-814-2667)

(Received 9th Jun 2019; accepted 10th Sep 2019)

Abstract. Tobacco etch virus (TEV) belonging to *Potyviridae* is among the most destructive viruses and widespread Worldwide but it has been found only Turkey in Mediterranean Basin. Both dominant and recessive pvr alleles contribute resistance against potyviruses. Prevalence of TEV in main pepper cultivation areas in Turkey and phylogenetic diversity of the isolates based on their coat protein region were determined in this study. Transferring resistance genes both recessive and dominant to susceptible chilli pepper lines was aimed with a breeding program including CM334 and Perennial known as resistance sources against several potyviruses. Two geographically and genetically distinct TEV isolates 1002 and 774 were inoculated to pepper genotypes carrying *Pvr4*, *pvr2*$^{+}$, *pvr2*^{1}, *pvr2*^{2}, *pvr2*^{3} alleles and 15 lines improved from CM334 carrying *Pvr4*, *pvr2*^{3} and Perennial carrying *pvr6* allele and QTLs. None of the pvr alleles contribute to resistance to isolate 774 while *pvr2*^{2} provides resistance to isolate 1002. All the pepper cultivation areas are infected by TEV in Turkey mainly Aegean Region and the isolates found in Turkey are close to those from Chinese isolate. Polygenic resistance was transferred by breeding program to line 4 could resist to both Turkish isolates.
Keywords: *polygenic resistance, pvr2 alleles, coat protein, pepper, phylogenetic analysis*

Introduction

Due to widespread cultivation of pepper in the World, harmful pests and diseases caused by fungi, viruses and bacteria of this plant have become prevalent. Capsicum spp. widely grown in the world is exposed to 70 viruses and more than 20 important viruses limit its production (Moury and Verdin, 2012; Green and Kim, 1991; Florini and Zitter, 1986). Among these viruses, the most prevalent ones are Tobamoviruses; Potyviruses, Cucumoviruses; and thrips-transmitted tospoviruses and Potyviruses (Moury and Verdin, 2012). Tobacco etch virus (TEV; genus *Potyvirus*; family *Potyviridae*) is an important pathogen in solanaceous crops with 10 described species that are very destructive and distributed with regard to continental pattern (Moury et al., 2005; Janzac et al., 2008). Potyviruses is characterized by flexuous, rod-shaped particles with approximately 10 kb in length single-stranded, positive sense RNA encapsidated coat protein (CP). Tobacco etch virus (TEV) causes up to 70% yield loss in pepper and spread mainly in North and Central America and the Caribbean (Nutter et al., 1989; Ariyaratne et al., 1996; Green and Kim, 1991). The use of resistant genotypes is one of the most efficient methods to protect crops from the yield losses caused by viruses. Using resistant varieties reduce incidence of TEV in pepper cultivated fields and increase fruit yield (Padgett et al., 1990).

Pepper resistance genes and alleles whether dominant or recessive are efficient against several potyviruses. The dominant gene *Pvr4* which originates from *Capsicum annuum* Criollo de Morelos 334 (CM334) confers to a broad range resistance of potyviruses (Kim et al., 2017). *Pvr4* gene provides resistance to PepSMV (Pepper severe mosaic virus) and PTV (Peru tomato mosaic virus), but carrying genotypes this gene are susceptible to ChiVMV (Chilli veinal mottle virus), PVMV (Pepper veinal mottle virus) and TEV

DOI: http://dx.doi.org/10.15666/aeer/1706_1464114651

(Janzac et al., 2009). Recessive genes *pvr1* and *pvr2* in pepper have been observed for resistance to potyviruses including tobacco etch virus but many virulent strains of TEV overcome most of these recessive genes (Parrella et al., 2002). Two main alleles from *Capsicum annuum* at the *pvr2* locus have been transferred to modern pepper cultivars (Kyle and Palloix, 1997) and *pvr1* from *C. chinense* (PI 152225) (Venkatesh et al., 2017) so that to provide resistance against potyviruses. Digenic recessive resistance to another potyvirus PVMV has successed by combination of recessive allelic series *pvr2* and *pvr6* allele corresponding to the eIF4E and eIF(iso)4E, respectively (Moury et al., 2005; Rubio et al., 2009).

In this study, spreading of TEV in the main open-field and protected pepper cultivation areas in Turkey has been determined and genetic diversity of CP region of some isolates compared with World isolates. Improved pepper lines from Perennialand CM334 resistance sources carrying pvr alleles were selected as resistant to two isolates determined distinct both genetically and geographically in this study. The genetic diversity of TEV infecting pepper was analysed in Turkey, to understand the diversity of TEV populations and to estimate the response of improved pepper genotype transferred both recessive resistance allele *pvr2*^{3}, *pvr6* and dominant gene *Pvr4* from resistant donors and the impact of geographic location on that structure. Transferring resistance genes against potyviruses both recessive and dominant to susceptible chili pepper lines was aimed with a breeding program including CM334 and Perennial as resources of resistance and Sena chili pepper variety which were commercial and susceptible to pathogen.

Materials and methods

Breeding population

First four years of breeding program resistant sub-populations were improved so that collecting resistance alleles. These populations were derived from crosses between the resistant donor Criollo de Morelos 334 (CM334) and Perennial inbred lines resistant to several potyviruses. CM334 (male) carrying *Pvr4* and *pvr2*^{3} genes and Perennial (female) carrying *pvr2*^{3} and *pvr6 genes* were crossed and 106 F_2 individuals were self-pollinated for three years. Selected as new resistant sources were crossed by Sena which was suitable for paprika production but susceptible variety against infections of TEV. F_1 progeny were not backcrossed to susceptible recipient (Sena) but self-pollinated and resistant individuals backcrossed to susceptible recipient and self-pollinated again. After two backcrossing and self-pollination alternately, selected 15 lines were mechanically inoculated by two TEV isolates 1002 and 774.

Field surveys and collecting of TEV isolates

TEV isolates were collected from June to August in 2013 and 2014 (open field) and March to May 2013 and 2014 (protected cultivation) with hierarchical (nested) sampling method (Ben Khalifa et al., 2009; d'Urso et al., 2003) from important pepper growing areas in Turkey. The factors was assessed by hierarchically partitioning the sample population among region, (West, South and East), cultivation system (open and protected) and sites (11 provinces) and samples were collected from 51 fields and 39 greenhouses. The pepper production values and sampling number of provinces were given in *Table 1*. Totally 1525 leaf samples and/or small pepper fruits were randomly collected from plants having symptoms related with viral infection.

Serological analysis and molecular characterization of TEV pathotypes

Samples were analyzed by DAS-ELISA (double antibody sandwich enzyme-linked immunosorbent assay) with antibodies against TEV (Agdia, France) and sequenced CP cistrons. Total RNAs were extracted with the Tri-Reagent kit (Molecular Research Centre Inc.) from fruit flesh or leaf (0.5 g) of collected pepper plants. Viral populations were characterized by two steps reverse transcription-polymerase chain reaction (RT-PCR) amplified with Avian myeloblastosis virus reverse transcriptase (Promega Corp., Madison, WI, USA) and Taq DNA polymerase (Promega Corp.) and primers reported by Buzkan et al. (2015). Degenerated primers were designed as reverse primer positions from 9273 to 9297 (CCCTAATAGTGTGTGCATGTTACGG) and the forward primer positions from 8538 to 8560 (TGCTGAYGCYGGYAAGAAGAAAG) produced a 760 nucleotide amplicon for TEV CP cistron. RT-PCR products were sequenced with primers corresponding to viral polarity by Medsantek (İstanbul, Turkey). CLUSTAL W program (Thompson et al., 1994) were used to align nucleotide sequences of CP coding regions of TEV and sequences retrieved from databanks were compared with Turkish isolates. MEGA version 6.06 software (Tamura et al., 2013) was used to select appropriate nucleotide substitution model with MODELTEST (Posada and Crandall, 1998). Neighbor joining, maximum likelihood and maximum parsimony methods were used to estimate nucleotide diversity and phylogenetic construction and evaluation with 1000 bootstrap resampling.

Biological characterization of TEV pathotypes, inoculation and screening improved pepper lines

Selected two different TEV isolates in relation to their geographical origin (774 from Hatay and 1002 from Gaziantep) and corresponding to phylogenetic tree (*Fig. 2*) were mechanically inoculated on the pepper genotypes possessing *pvr2* alleles Yolo Wonder (YW), Yolo Y (YY), Florida VR2 (VR2) and W4. YW genotypes. YY, VR2 and W4

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1464114651

are homozygous for the *pvr2*$^{+}$, *pvr2*^{1}, *pvr2*^{2} and *Pvr4* resistance genes, respectively. Isolate 774 was selected as viral material because of its resistance breaking ability over *pvr2*^{2} allele from Florida VR2 confers resistance to TEV isolates (Caranta et al., 1997). Isolate 1002 is not be able to overcome *pvr2*^{2} allele. Two TEV isolates were multiplied on Nicotiana to obtain high titer inoculum for tests on *C. annuum*. Nicotiana leaves showing severe symptoms of the TEV were weighed as 1 g and homogenized in 4 ml of 0.03 M phosphate buffer (pH 7.0) supplemented with 2% (wt/vol) diethyldithiocarbamate, active charcoal at 20 mg/ml, and Carborundum at 20 mg/ml. Inoculum multiplied on tobacco plants were inoculated on the two cotyledons of 15 seedlings from each pepper genotype. *C. annuum* test plants were inoculated manually at cotyledon leaf stage with same as well as in tobacco plants. Symptoms were recorded between 14 and 30 days postinoculation (dpi) and genotypes without symptoms were re-inoculated by two isolates 1002 and 774. Virus multiplication in the pepper genotypes were assessed by DAS-ELISA after one month post-inoculation (Moury et al., 2004). Genotypes were considered as positive and susceptible when their absorbance values at 405 nm was higher than three times that of negative control (Murphy et al., 1998).

Results and discussion

Distribution of tobacco etch virus in main pepper cultivation areas in Turkey

DAS-ELISA and two-steps reverse transcription polymerase chain reactions (RT-PCRs) were used to assess Tobacco etch virus both open field and protected pepper cultivation areas in Turkey (*Fig. 1*). Total 1525 fruit and/or leaf samples from different provinces of Turkey were tested. Tobacco etch virus was most prevalent in Bursa and Çanakkale provinces in open field pepper cultivation areas. According to ELISA signals TEV did not spread through Balıkesir, İzmir and Şanlıurfa provinces. But RT-PCR results indicated that TEV was also prevalent in these provinces. Assessing both ELISA and RT-PCR results TEV was widespread all the pepper cultivation areas both open field and protected (*Table 1*). In Mediterranean Basin TEV was only presence in Turkey (Moury and Verdin, 2012). Americas, Africa and Asia especially China also were infected with TEV (Green and Kim, 1991). Some of the pepper cultivation areas with local varieties nearly whole of the field infected with TEV in Çanakkale province located western side of the Turkey. Benner et al. (1985) and Abdalla et al. (1991) indicated that the incidence of the TEV can be reach nearing %100.

Genetic diversity of tobacco etch virus

The phylogenetic tree of the CP coding region displayed that the Turkey was clustered three subgroups. Isolate 1002 from Gaziantep province and 774 from Hatay were distinct (0.025 p distance) from each other based on their CP (coat protein) sequences (*Fig. 2*). This distinction was sourced from threonine to alanine substitutions on 57th position on CP region (T57A). Two haplotypes were defined according to the amino acid sequence of the CP corresponding to isolate 1002 (KR024266.1) and 774. Other distinction based on amino acid substitutions were originated by A49S (isolate 1496), N6S (isolate 851), and S1T (isolate 861) among the Turkish isolates. Clustering of other Turkish isolates was based on synonymous substitutions of nucleotides. All of the survey area only isolates of Hatay (774 to 1506) could be sequenced. Single amino

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1464114651

acid substitution of CMV-CP (Cucumber mosaic virus-Coat Protein) induced chlorosis on tobacco (Shintaku, 1991; Shintaku et al., 1992). Mochizuki et al. (2008) reported that substitution of the amino acid in the coat protein of Melon necrotic spot virus preventing from transmitting by *Olpidium bornovanus* zoospores. Dolja et al. (1994) indicated that mutation of CP of TEV affects movement of the virus in the plant.

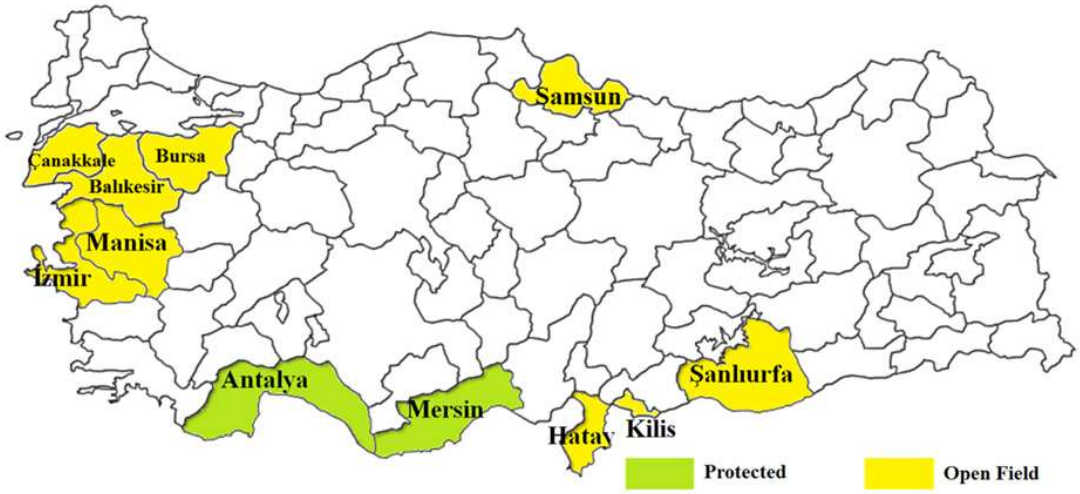

Figure 1. *Survey area of tobacco etch virus isolates on open and protected cultivation field in Turkey*

The TEV virus infections in surveyed regions are widespread through Turkey in main pepper grown fields. They are built a distinct phyletic group from the other isolates in the World related with CP regions. This group is clustered to three subgroups because of amino acid substitution. TEV was presence in only Turkey among the Mediterranean countries (Moury and Verdin, 2012). Americas (USA, Canada, El Salvador, Puerto Rico, Jamaica, Mexico) Africa (Nigeria) and Asia especially China also were infected with TEV (Olawale et al., 2015; Ariyaratne et al., 1996; Green and Kim, 1991). The nucletide sequences of isolates from these countries except Nigeria have been registered in GenBank. Potato virus Y (PVY) is widespread in the World, while TEV isolates occur mainly in North and Central America and in the Caribbean (Caranta and Palloix, 1996). Bootstrap values associated to the branches of the tree supported the existence of three major clades (*Fig. 1*). The first clade includes TEV isolates from Turkey and SD1 isolate AY787757 from China. The second one includes Chinese, Jamaican and Mexian TEV isolates. Several Chinese and Jamaican isolates grouped in same cluster but also they built distant clades. Complete sequences of the TEV isolates (MK688996, MK688997 and MK680813) from Trinidad and Tobago have been recorded recently. These isolates clustered more distantly from Turkish isolates in the third clade. However the closest isolate to Turkish ones from the world was SD1 registered as AY787757 from China (*Fig. 2*).

Virulence properties TEV isolates against resistance sources and improved pepper lines

Two isolates (774 and 1002) clustered different group both molecular related their CP region and geographic origin were evaluated against improved pepper lines and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1464114651

homozygous reference pepper genotypes for the *Pvr4*, *pvr2*^{1}, *pvr2*^{2} and *pvr2*$^{+}$ genes (or alleles) (*Fig. 3*). On the basis of ELISA results assessed one month post-inoculation on apical leaves, both TEV isolates multiplied in and infected to susceptible Yolo Wonder carrying *pvr2*$^{+}$ Yolo Y; *pvr2*^{1} and W4; *Pvr4* and many of the improved lines selected as resistant. Florida VR2 carrying *pvr2*^{2} alleles resisted to isolate 1002 but infected by isolate 774. Improved lines 62 and 63 also resisted to isolate 1002 but resistance failed by inoculation of isolate 774 except two plants of line 63 (*Table 2*). Only one improved line 4, showed resistance to both isolates. *pvr2*^{2} contributes resistance to TEV but virulent strains are overcome resistance *pvr2* alleles providing restriction of cell-to-cell movement or inhibition of viral coat protein accumulation (Pallard et al., 2002). *Pvr4* did not provide any resistance against TEV (Janzac et al., 2009).

Table 2. *Numbers of resistant and susceptible individuals of improved lines and genotypes carrying pvr alleles to tobacco etch virus infections determined by DAS-ELISA*

Related with resistance provided by the *Pvr4* dominant gene to potyviruses is not effective to prevent TEV (Janzac et al., 2009; Moury and Verdin, 2012). CM334 originated *Pvr4* and *pvr2*^{3} resistance also is not effective for TEV (Janzac et al., 2009). Line 4 was improved from CM334 and Perennial which was carrying recessive alleles *pvr2*^{3} and *pvr6* (Caranta et al., 1997) expressing resistance to TEV. Caranta and Palloix (1996) reported that resistance to several potyviruses can be controlled by recessive alleles and/or by a dominant allele from Criollo de Morelos 334 and by polygenic resistance in Perennial. In this study Line 4 which has been improved as resistant to both 1002 and 774 TEV isolates probably has *pvr2*^{3} alleles from CM334 and *pvr6* Perennial along with some QTL (Quantitative trait loci).

pvr2^2 and *pvr6* allele combinations were identified as providing resistance source to another potyvirus PVMV (Rubio et al., 2009). Systemic infection of TEV isolate 774 breaking down *pvr2*^{2}-mediated resistance could be prevented by the combination between *pvr2*^{3} and *pvr6* alleles. Lines possessing the *pvr2*^{2} and *pvr6* genes resist to systemic infection by PVMV or ChiVMV potyviruses (Moury et al., 2005). Because of the lack of resistance ability of the *pvr2*^{2} allele against isolate 774 it is suggested that TEV resistance resulted from complementary effects between recessive alleles transferred both resistant and susceptible parents. With respect to the pepper-TEV interaction, not much more alleles were characterized that confer complete resistance to TEV while eleven chromosomal regions were found to be associated with quantitative resistance to PVY (Caranta et al., 1997). Also heterozygoty of *pvr2* alleles has been found to increase resistance efficiency against potyviruses (Moury et al., 2005; Rubio et al., 2009). Kang et al. (2005) demonstrated that TEV (both highly transmitted by aphids and non wilting isolates) infectivity could be blocked by wild-type eIF4E in *pvr1* (234) and *pvr1*^{2}. Murphy et al. (1998) indicated that *pvr1* does not confer resistance to Mex21 TEV isolate. Finally, pathogenic processes of TEV and potyviral resistance interactions determine resistance of improved lines.

Conclusion

Viral pathogens threaten to crop production world wide as a consequence of the evolution of viral genomes to overcome resistance genes in plants and to adapt vector organisms causing epidemics. In the last decade resistance breaking Tomato spotted wilt virus isolates have overcome *Tsw* (Tentchev et al., 2011), a local strain of Paprika mild mottle virus have broken *L3* mediated resistance (Luria et al., 2018) and poleroviruses exclusively transmitted by aphid have adapt to whiteflies (*Bemisia tabaci*)

as a vector (Ghosh et al., 2019) and Zucchini yellow mosaic virus has appeared in peppers (Verma et al., 2019).

Potyviruses is in the top ten list of plant viruses (Rybicki, 2015) and pepper (*Capsicum annuum* L.) affected by five major potyviruses including tobacco etch virus which has resistant breaking abilities on both many recessive *pvr* alleles and dominant *Pvr* genes. Conclusively, our results further emphasize the threat to pepper breeders and growers around the world especially in Turkey that evolvement of virulent TEV isolates and the possibility of combining recessive alleles will be able to provide resistance to infection of tobacco etch virus. The mechanisms of multigenic resistance can be explored further and combination of resistance alleles against TEV need to be searched by associating host pathogen interactions.

(Received 9th Jun 2019; accepted 10th Sep 2019)

Abstract. Since their first observing in Japan, poleroviruses have threatened pepper cultivation all around the World. Symptoms of vein yellowing originating from poleroviruses have become widespread in both open field and protected pepper cultivation areas recently. In this work samples collected from highly infected pepper fields in South East Turkey have been determined as Pepper Vein Yellows Virus (PVYV) and Beet Western Yellows Virus (BWYV) (genus *Polerovirus*, family *Luteoviridae*). Recombinant PVYV isolates have been observed from intra and interspecific combination in relation to part of the RNA-dependent RNA polymerase coding region subjected to recombination detection methods. One of the PVYV isolates has induced recombination between BWYV and PVYV and located middle of the PVYV and BWYV isolates. Another isolate recombined from intraspecific combination has been transferred onto pepper genotypes carrying pvr alleles and landraces under both artificial and natural conditions to determine their response. None of the pvr alleles in pepper genotypes used in this study could contribute to resistance to PVYV isolates.
Keywords: *poleroviruses, capsicum, resistance, Luteoviridae, genetic diversity*

Introduction

Pepper crops are exposed to many pests and diseases because of their wide geographical distribution and cultivation areas. Mono-cultivation of pepper intensively along with climate changes increase the vector and virus infection in Mediterranean Basin. Capsicum spp. is exposed to over 70 viruses and pepper production is limited by more than 20 important plant viruses (Florini and Zitter, 1986; Green and Kim, 1991; Moury and Verdin, 2012). The new viruse causing interveinal yellowing symptoms was recently sequenced and identified by Murakami et al. (2011) as Pepper vein yellowing virus (PeVYV). Denomination and identification starts in Japan with Pepper vein yellows virus (PeVYV) (Yonaha et al., 1995) and continue Pepper yellow leaf curl virus (PYLCV) in Israel (Dombrovsky et al., 2010), Pepper vein yellowing virus (PeVYV) in Japan (Murakami et al., 2011), Pepper vein yellows virus (PVYV) in Turkey and Tunisia (Buzkan et al., 2013) and Pepper Yellows Disease (PYD) in Greece (Lotos et al., 2017). Regardless of nomenclature many researcher reported causing yellowing symptoms in pepper having similar genome organization in Spain (Villanueva et al., 2013), India, Indonesia, Mali, Philippines, Thailand and Taiwan (Knierim et al., 2013), Sudan (Alfaro-Fernández et al., 2014), China (Tan et al., 2015), Australia (Maina et al., 2016) and Saudi Arabia (Kamran et al., 2017).

Poleroviruses belonging *Luteoviridae* have icosahedral virions in 26–30 nm diameter including about 6.2 kb positive-sense single-stranded RNA without envelope (Kenyon et al., 2014). *Luteoviridae* family tends to recombination related their nucleotide substitution of coat protein region (Pagán and Holmes, 2010). Recombination and mutation are main factor to generate genetic variability for the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1465314664

viruses (Desbiez et al., 2011). Buzkan et al. (2013) emphasized the recombinant nature of PVYV compared different countries related their RNA-dependent RNA polymerase region. Fiallo-Olivé et al. (2018) confirmed recombinant structure of PVYV by phylogenetic analysis of full length genome and classified the virus from PeVYV-1 to PeVYV-5 related their genome organization.

Breeding sweet and large-fruited blocky-type peppers has been limited because of undesirable traits exist among wild accessions. Wild accessions of *Capsicum annuum* species differ in many yield and quality characters comprising cultivated varieties (Ben-Chaim and Paran, 2000). Disease resistance genes from wild accessions have been transferred by many researchers into sweet blocky types (Lefebvre et al., 1995; Daubeze et al., 1995; Caranta et al., 1997; Lapidot et al., 1997; Paran et al., 1998).

In this study the recombination events of PVYV isolates were determined from one location highly infected by poleroviruses. Both PVYV and BWYV (Beet western yellows virus) were determined in the same location and recombination evidence was calculated intra- and interspecific combination. Response of local pepper landraces, varieties and genotypes possessing *pvr* alleles to PVYV were also determined.

Materials and methods

Plant material

Pepper genotypes including different genotypes and varieties were used to test resistance against PVYV in natural and artificial aphid transmission conditions. PVYV isolate 24 were inoculated by aphid (*Myzus persicae*) transmission on the pepper plants carrying *pvr2* alleles in Yolo Wonder (YW), Yolo Y (YY), Florida VR2 (VR2) and W4. YY, VR2 and W4 are homozygous for the $pvr2^{+}$, $pvr2^{1}$, $pvr2^{2}$, and *Pvr4* resistance genes, respectively. Criollo de Morelos 334 was also used as control plants in the experiment. Şahinbey variety and eleven inbred line having blocky pod type were used for resistance experiment.

Virus detection

The presence of PVYV in leaf samples was determined both reverse transcription polymerase chain reaction (RT-PCR) and Double antibody sandwich enzyme-linked immunosorbent assay (DAS-ELISA) with cucurbit aphid-borne yellows virus (CABYV) antibodies which are strongly cross reacted poleroviruses (Buzkan et al., 2013). Total RNAs were extracted from symptomatic pepper leaf samples and aphids fed on leaves using TRI Reagent (Sigma) according to the instructions. RT-PCR method was carried out with Moloney murine leukemia virus (M-MuLV) reverse transcriptase and Taq DNA polymerase (Invitrogen).

Two-step reverse transcription polymerase chain reactions (RT-PCRs) were performed by using primers Pol-G-F (5′-GAYTGCTCYGGYTTYGACTGGAG-3′) and Pol-G-R (5′-GATYTTATAYTCATGGTAGGCCTTGAG-3′) designed by Knierim et al. (2010) from conserved regions from all poleroviruses. PCR conditions were at 60 °C for annealing temperature and 90 min for extension time. RT-PCR amplification products at 1.1-kb (RNA-dependent RNA polymerase coding region, the intergenic noncoding region and part of the coat protein coding region) were directly sequenced with primer Pol-G-F by MEDSANTEK (Istanbul, Turkey).

DOI: http://dx.doi.org/10.15666/aeer/1706_1465314664

Recombination analysis

Aligned sequences by ClustalW program were implemented in the software MEGA 7 (Kumar et al., 2016) and confirmed Blastn program. Neighbor-joining, Tamura-Nei model was implemented with 500 bootstrap resampling to assess the robustness of branches (Saitou and Nei, 1987). Recombination events between sequences were predicted using RDP4 software and confirmed by boot scan analysis using SimPlot software (http://sray.med.som.jhmi.edu/SCRoftware) with the Kimura 2-parameter distance model (Lole et al., 1999).

PVYV isolates and inoculation

Thirty pepper plants showing inter-veinal yellowing and curling symptoms on leaves were collected diagonally in one highly infected field with poleroviruses (Bogazkirim, Dorucak/Musabeyli/Kilis/Turkey 36° 49' 49.9" N and 36° 51' 47.2" E) in Kilis province (southeastern Turkey) in August 2015 (*Fig. 1a, b* and *c*). The plants were numbered, potted and transferred from field to insect proof greenhouse. The PVYV isolates were detected as described at virus detection section by reverse transcription polymerase chain reaction (RT-PCR) and Double antibody sandwich enzyme-linked immunosorbent assay (DAS-ELISA) and isolate 24 determined as recombinant isolate was used as viral material.

Artificial inoculation

Aphids (*Myzus persicae*) collected from upper leaves of peach trees were propagated on sweet pepper (cv. Yolo Wonder) plants at the true leaf stage to use aphid transmission. Isolate 24 was used to determine response of pepper genotypes to PVYV. Aphids propagated on Yolo Wonder leaves were allowed a 48-h acquisition access feeding period on plant infected by isolate 24. Two aphids were transferred from infected plants to lower leaf surface of healthy ten pepper plants of each genotype at four-leaf stage for artificial inoculation. Plants were treated with the insecticide after inoculation access feeding of 48 h. PVYV could be transmitted efficiently by at least two aphid vectors *M. persicae* (Dombrovsky et al., 2010).

Transmission on greenhouse conditions

Artificially infected ten Yolo Wonder plants by isolate 24 were transplanted in greenhouse along with the genotypes which will have been tested. Fifteen plants of each genotype were transplanted at four true leaves stage between 70 and 50 cm spaces in rows. Twenty aphids were placed on each infected Yolo Wonder plants. Three months after planting PVYV were detected on genotypes both DAS-ELISA and RT-PCR. Isolate 24 was re-isolated from plants (*Fig. 1e*) and confirmed by sequencing (*Fig. 2a*).

Results and discussion

Because of the lack of specific antibodies to PVYV and presence of serological cross-reactions between these viruses, CABYV antibodies were used in DAS-ELISA (Buzkan et al., 2013). Twenty-nine of the collected plants strongly reacted to CABYV antibodies. Pol-G-F and Pol-G-R primers designed by Knierim et al. (2010) from conserved regions in the polerovirus genome were used and 1.1-kbp amplicons were

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1465314664

produced after two-step reverse transcription polymerase chain reactions. Fifteen of the twenty-nine samples reacted CABYV antibodies were shown similarity with PVYV and seven of the samples were identified as BWYV after using the Blastn program after aligned using the ClustalW software. Six of the RT-PCR products directly sequenced by Pol-G-F primer could not been identified because of low sequencing quality (*Table 1*). Aphids fed on pepper plants infected isolate 24 was also confirmed by RT-PCR and sequence analysis.

Intergenic noncoding region and part of ORF3 (open read frame 3: the coat protein coding region) of sequences were trimmed and aligned by ClustalW (Thompson et al., 2003) and converted the file format to detect recombination events. Part of the RNA-dependent RNA polymerase coding region subjected to recombination detection methods by RDP4 software (Martin et al., 2015). Two of seven different methods implemented in the software RDP4 showed small recombination evidence ($P = 10^{-2}$ to 10^{-5}) in isolate 24 (*Fig. 2*). This recombination event would involve isolate 15 as a major parent while isolate 21 used to infer unknown parents (*Fig. 3*). Recombination event confirmed by SimPlot software (Lole et al., 1999) with the Kimura 2-parameter with 100 replicates (*Fig. 4*).

DOI: http://dx.doi.org/10.15666/aeer/1706_1465314664

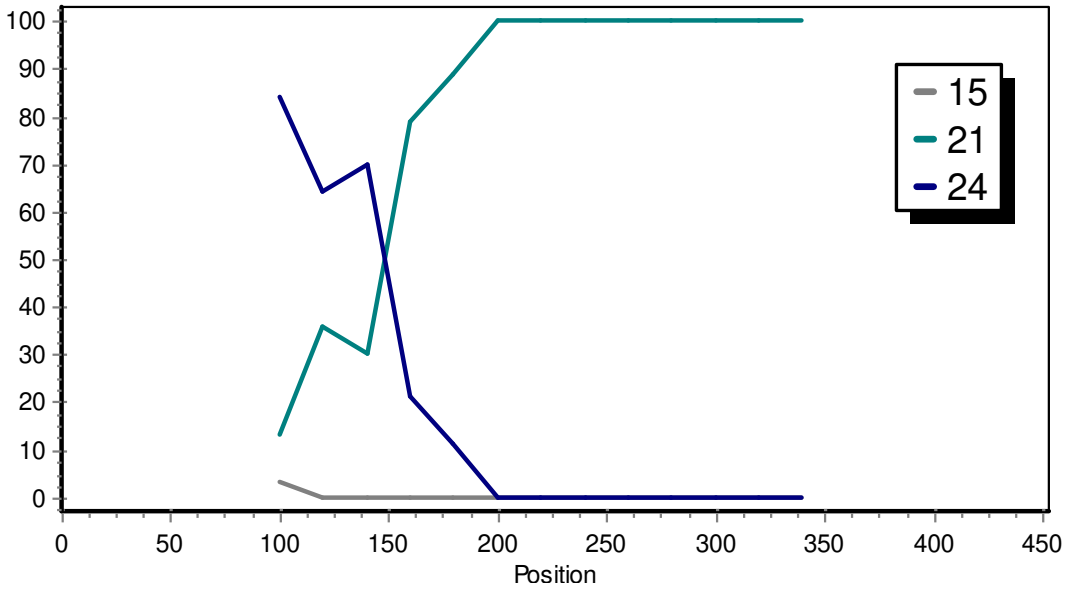

Figure 4. *Recombination position of the nucleotide sequence of parental isolates*

Recombination event was also detected between BWYV and PVYV. Recombination evidence was confirmed by GENECONV (1.292×10^{-2}) using RDP4 software (*Fig. 5*).

Isolate R22 was recombined by PVYV isolate 4 and BWYV isolate 38. Putative recombinant isolate 24 rooted different groups from their estimated parents isolate 15 and 21. PVYV isolates have shown between 79 and 98% similarity (*Figs. 2* and *3*) Neighbor-Joining phylogeny implemented in MEGA 7 using Tamura–Nei distance with 500 bootstrap re-samplings grouped BWYV and PVYV in different clades. Recombinant PVYV isolate R22 was placed between BWYV and PVYV in relation to part of the RNA-dependent RNA polymerase coding region (*Fig. 6*). Fiallo-Olivé et al. (2018) declared that PeVYV was a recombinant of CABYV and TVDV concerning with whole genome sequencing.

Buzkan et al. (2013) found a high prevalence of poleroviruses in open field pepper cultivation areas both Turkey and Tunisia. They showed an evidence PVYV-like isolate recombined from another region of Tunisia. Dombrovsky et al. (2010) hypothesized that PeVYV was a recombinant of Tobacco vein distorting virus (TVDV) while Fiallo-Olivé et al. (2018) were declared it as distinct from other poleroviruses. They proposed the name of the virus as Pepper vein yellows virus and classified from 1 to 5 corresponding to their complex genome organization due to recombination events. In this study, recombinant isolates corresponding C-terminal part of the RNA-dependent RNA polymerase were determined only one location pepper cultivation area widespread infected by poleroviruses (*Fig. 1*). Pagán and Holmes (2010) determined the occurrence of recombination within and between the RdRp and CP genes for each of the *Luteoviridae* species.

Pleiotropic effects of both viral and coat protein genome mutations have been observed on Capsicum. Pepper resistance genes and alleles whether dominant or recessive are efficient against several potyviruses. Sacchi et al. (2003) identified potyviruses in Brazil and improved resistant progenies to Potato Virus Y. Dominant *Pvr4* gene provides resistance to PepSMV (Pepper severe mosaic virus) and PTV (Peru tomato mosaic virus), but carrying genotypes this gene are susceptible to ChiVMV

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1465314664

(Chilli veinal mottle virus), PVMV (Pepper veinal mottle virus) and TEV (Tobacco etch virus) (Janzac et al., 2009). Recessive genes *pvr1* and *pvr2* in pepper have been observed for resistance to potyviruses including TEV but many virulent strains overcome most of these recessive genes (Parrella et al., 2002). Yolo Wonder ($pvr2^{+}$), Yolo Y ($pvr2^{1}$), Florida VR2 ($pvr2^{2}$) and W4 (*Pvr4*) did not resist to PVYV isolate 24 at greenhouse condition. CM334 originated *Pvr4* and $pvr2^{3}$ resistance also was not effective for PVYV both aphid transmission and under protected cultivation experiments. Şahinbey variety selected from blocky type pepper population in Gaziantep and other blocky type lines also did not resist to PVYV under both inoculation methods (*Table 2*).

PVYV transmitted by grafting and aphids persistent circulative manner not through seed or by mechanical inoculation (Yonaha et al., 1995) except mix infection with umbraviruses like as Potato leaf roll virus (Ryabov et al., 2001). Restriction of mechanical inoculation and absence of infectious clone of PVYV obstructs to determine response of pepper genotypes to the agent wide spreading Worldwide. The evolutionary period of the poleroviruses has been estimated as with in the last 4000 years. This evolutionary change is shorter than that proposed for the Potyviridae which is including species causing the most destructive diseases on plants (Pagán and Holmes, 2010).

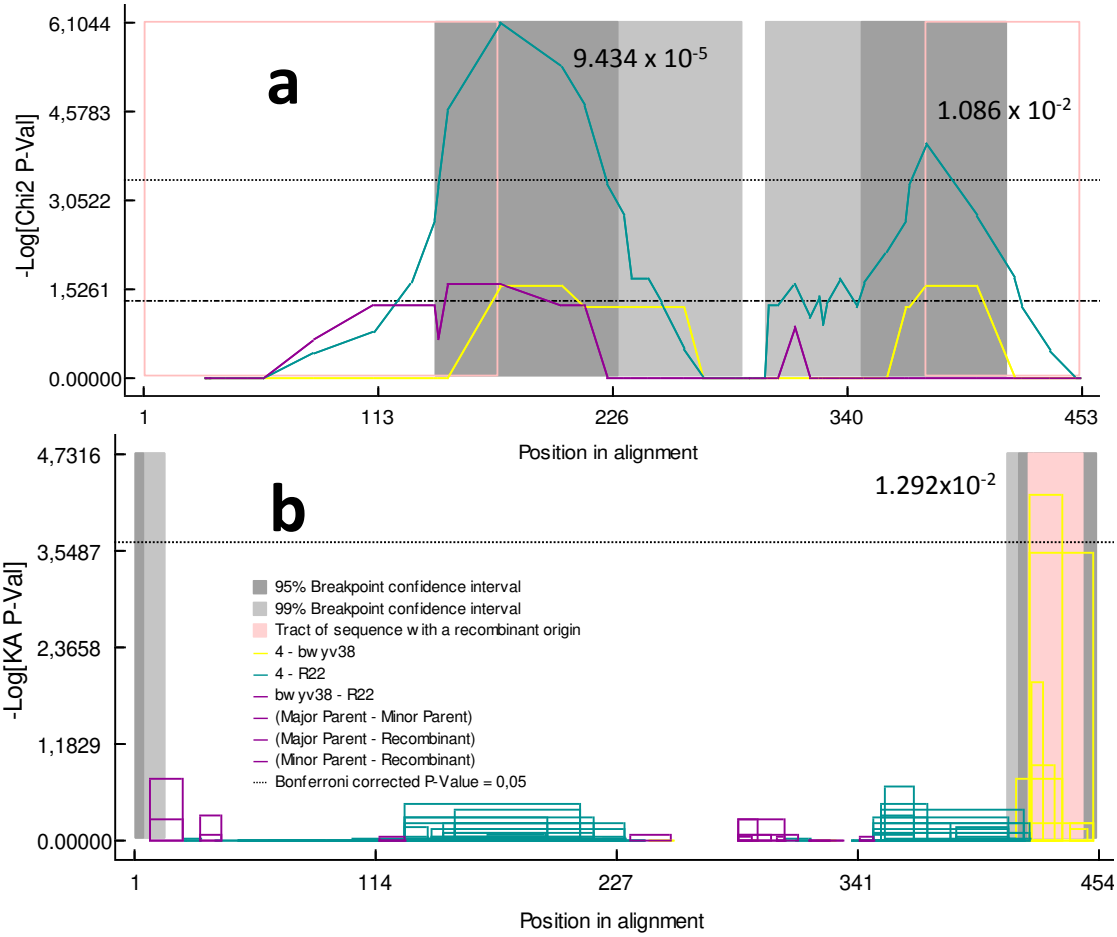

Figure 5. *The main putative recombination event of major parent: PVYV isolate 15 and minor parent: PVYV isolate 21 by MaxChi (9.434 x 10-5) for PVYV isolate 24 and 3Seq (1.086 x 10-2) (a) and PVYV isolate 4 and BWYV isolate 38 by GENECONV (1.292 x 10-2) for PVYV isolate R22*

Gibbs et al. (2008) indicated that the evolution of potyvirus CP region has been occurred in the last 6,560 years. The high evolution rate of the Luteoviruses and Poleroviruses can be change their host selectiveness. As a matter of fact that Pepper vein yellows virus has been detected on *Physalis spp.* (*Fig. 1d*) a weed host in this study. Adnyani (2018) detected the PVYV on cucurbit plants in Bali. Ghosh et al. (2019) reported whitefly (Bemisia tabaci)-transmitted polerovirus known as exclusively transmitted by aphids, and named the new virus as Pepper whitefly-borne vein yellows virus (PeWBVYV) highly homologous to Pepper vein yellows virus.

Conclusion

Recently described poleroviruses Pepper vein yellows virus and Beet western yellows virus has been spreading on pepper cultivation areas in Turkey and other countries in the World. The isolates of the PVYV can be easily changing their genetic structure even restricted geographical region because of its high recombination ability. PVYV can be evolved both intra and interspecific recombination. Pvr alleles are not contributing any resistance to PVYV.

Because of appearance new vectors such as insect resistance whitefly for their transmission and reported new host range of PVYV along with their relative viruses will threaten both pepper and other crops cultivated in the world in the future. The epidemiology of PVYV and biological, serological and pathological properties of isolates should be investigated in next studies. The improvement of infectious clone can be enabled to determine response of pepper genotype to PVYV. The availability of infectious clones will facilitate investigation of resistance genes whether dominant or recessive in pepper and other crops.

Abstract. Quantifying the biomass–density (M–N) exponent and size inequality in plant communities has become a long-standing issue in both theoretical and empirical studies. The biomass–density (M–N) exponent and size inequality of the tree populations have not been studied so widely as that of herbaceous plants. we studied the variation of biomass–density (M–N) exponent and size inequality at different stages of development clusters along erosion gradient in *Haloxylon ammodendron* populations. The results showed that the value of the M-N exponent ranged from 1.21 to 1.73 in sapling stages, -0.691 to -0.437 in Adult stages and -0.934 to -0.812 in senescence phase along a erosion gradient, the M-N exponents at different stages of development showed an downward trend, and indicated that when the density of the cluster increases, which is a process of self-thinning. Moreover, the populations size inequality in different locations decreased with the increase of wind erosion intensity. The size inequality also showed a downward trend in various stages of development, that of the first two stages of development were significantly greater than the later development stages. Our study showed that interactions among individuals at different stages of development have an important impact on the population structure.
Keywords: *density, interaction, Haloxylon ammodendron, Severe environment, cluster*

Introduction

Mass–density (M–N) scaling relationship describes variation in population density with body size in the plant community and can be described as $M = K \times N^{\gamma}$. In past 40 years, many ecological scientists have devoted themselves to research M–N scaling relationship, and most of these researches proved the -3/2 (Yoda et al., 1963) or -4/3 M–N scaling relationship (Equist et al., 1998; Brian et al., 2003). However, -3/2 and -4/3 exponents of M–N scaling relationship were also criticized on theoretical and empirical grounds (Kozlowski and Konarzewski, 2004; Deng et al., 2006), controversy continues over the underlying value and variability of the M–N scaling exponent. Many literatures indicate that γ varies with soil fertility (Morris, 2003), water availability (Deng et al., 2006), aridity gradient (Bai et al., 2010), hormone response (Zhang et al., 2006, 2016) and salinity gradient (Zhang et al., 2010), all of the above experiments showed γ is an exponent that increases as the pressure gradient increases or vary with different forest types (Zhang et al., 2011). Chu found that the density regulation of plant populations is actually affected by the positive and negative effects among individuals (Chu et al., 2008), which think that environmental factors can affect the law of density regulation by affecting the interaction between plants. The law of density regulation is the external performance of interaction between plants and plants, between plants and the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1466514677

environment. The result of plant competition leads to a decrease in the growth rate of the individual, which in turn affects biomass accumulation and ultimately affects the biomass-density relationship. If the interaction between individuals is not competition, but reciprocity, it is inevitable that the average individual biomass will increase with the increase of density (Chu et al., 2008; Lin et al., 2012). Therefore, it can be assumed that the interaction among individual plants and density regulation exponent is closely related.

A lot of studies have shown that the balance of competition and facilitation shifts among the various life stages of two interacting species (Chapin et al., 1994; Long et al., 2014; Zhang et al., 2012; Lin et al., 2012). However, facilitative and competitive mechanisms do not act in isolation from each other in nature, and by co-occurring within the same community, and even between the same individuals, they may produce complex and variable effects. Some studies have shown that life stages (e.g. seed, seedling, juvenile, pre-reproductive adult, reproductive adult, senescent adult) may affect the outcome of interactions between plant species (Rousset et al., 2000). Since the positive and negative interactions are different at different stages of development, is the M–N scaling exponent different? Or how does it change in different stages of development? It seems to attract little attention.

Large variation in individual size is a ubiquitous feature of natural plant populations and this variation has major implications for plant ecology and evolution. There have been a few studies on size inequality among individuals (Weiner et al., 2001; Chu et al., 2009). They found that the different spatial patterns, different density gradients of plant populations (Weiner et al., 2001) and different pressure gradients (Zhang et al., 2012) have a significant impact on population size inequality, Weiner (Weiner et al., 2001) showed that at low densities and early in growth, spatial pattern played a more important role than size asymmetry of competition in generating size inequality, but at high densities or after longer periods of growth, the size asymmetry of competition was more important than spatial pattern. Zhang et al.'s (2012) experiments on the growth of mung bean with different intensity of ultraviolet radiation found that the balance among positive interactions, stress, and mortality driven by competition determined the size inequality of the populations (Zhang et al., 2012). However, studies on the variation of size inequality in developmental stages of tree populations are rare.

Haloxylon ammodendron, which belongs to genus *Haloxylon*, is a typical desert plant, primarily found on shifting or semi-shifting sand dunes of the narrow sub-desert areas in middle and western Asia (Zou et al., 2010). The species is also termed a super xerophyte due to its particular drought tolerance that enables it to survive in prohibitive environments (Gao et al., 2010). This species had been selected as a pioneer plant for sand dune stabilization, and it is an excellent plant for evaluating disturbance and vegetation restoration in Gurbantunggut Desert (Bedunah and Schmidt, 2000). However, the area of natural *Haloxylon ammodendron* forest is decreasing because of land development, groundwater mining, excessive deforestation, and overgrazing. Hence, *Haloxylon ammodendron* has been listed as a national grade 3 endangered plant in China (Guo et al., 2005). A 35-yr-old replacement series of *Haloxylon ammodendron* clusters in the Gurbantunggut Desert has provided a condition to study the density change of cluster under severe stress environments. The *Haloxylon ammodendron* is distributed in the form of cluster on top of sand dunes in the desert, which suffer from strong wind erosion and they grows in aggregate pattern. There is no more aggregation pattern to be found except at the top of the hill. Interestingly, there is a significant phase

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1466514677

difference in the density change process of *Haloxylon ammodendron* clusters, therefore, it provides us with a convenient way to study the variation of the M–N scaling exponent and changes in size inequality in different developmental stages. Thus we will ask the following three questions: (1) How does the M–N exponent change in different developmental stages of *Haloxylon ammodendron*? (2) How does the size inequality of *Haloxylon ammodendron* change during different developmental stages? (3) Is there a positive self-thinning exponent and how much is its size?

Materials and methods

Description of the study site

This study has been conducted along a natural wind speed gradient at five sites (Xinhu, Shihezi, Kuitun, Guertu and Jinghe) in the Gurbantunggut Desert, Xinjiang, which is located in the hinterland of the Junggar Basin in northwest China (44°11′ to 46°20′N, 84°31′ to 90°00′E), with an area of up to 48,800 km^2. The Gurbantunggut Desert is the second largest desert in China. Due to its long distance from any ocean, it has a temperate arid desert climate. The annual precipitation is 80 mm to 190 mm. The annual average temperature is 5.0 to 5.7 °C. *Haloxylon ammodendron* is the dominant species in this desert, and the ephemeral plant layer is well-developed (*Figs. 1* and *2*).

Field surveying

At the beginning of 2016, we chose five sites at the study area, and all the sites were located in different spot from low wind speed to high wind speed (*Table 1*), since the difference in height and shape of sand dunes at each location is not large, the influence of different shapes on wind speed can be ignored, in addition, the rainfall in the entire Gurbantunggut desert is almost the same. Data were collected from local weather stations respectively. A 40 × 40 m plot was selected at different research sites and the clusters of five development stages were selected for each plot, to avoid sample size inhomogeneity, we initially selected 10-15 clusters for each stage of development, then selected three representative clusters from among them. According to the distribution situations of the age of *Haloxylon ammodendron* clusters, we only need to find the maximum age for each cluster because each *Haloxylon ammodendum* cluster is composed of uneven-aged individuals. *Haloxylon ammodendron* is divided into five developmental stages, which can be expressed as follows, sapling: 1-6 yr; Adult phase I: 7-13 yr; Adult phase II: 14-20 yr; senescence phase: 21-27 yr; death phase: 28-34 yr; Age formula comes from previous research results (Song et al., 2011), and they are used to determine the age of the cluster. In addition, we selected 1 × 1 m quadrat in each cluster to collect the basal diameter, crown width and tree height data of each *Haloxylon ammodendum*. Moreover, in order to reduce difference of sample scale and avoid edge effects, each plot is close to the middle of the clusters and each quadrat was replicated three times, meanwhile, the number of *Haloxylon ammodendron* per square meter was measured to calculate the density.

Table 1. *Descriptions of the five experimental sites*

Parameters	Site

The above data are from the local monitoring result from 1975 to 2015

Biomass estimation

To picks representative *Haloxylon ammodendron* individuals of each age to measure his above-ground biomass, height, basal diameter for deriving the biomass calculation formula, three representative *Haloxylon ammodendron* plants were selected for each age, the whole tree (above the ground) was excavated and weighed, and adopt the age separation excavation method, a total of 45 *Haloxylon ammodendron* plants were dug at each site. Parts of the samples were brought back to the laboratory to be dried and weighed, and then above ground biomass (ATB) was calculated accordingly. The biomass calculation formulas of Xinhu, Shihezi, Kuitun, Guertu and Jinghe are respectively:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1466514677

$$B_{Xin} = 0.2012(d^2h)^{0.8231} \quad \text{(Eq.1)}$$

$$B_{Shi} = 0.1965(d^2h)^{0.7953} \quad \text{(Eq.2)}$$

$$B_{Kui} = 0.1834(d^2h)^{0.7826} \quad \text{(Eq.3)}$$

$$B_{Gu} = 0.1238(d^2h)^{0.7492} \quad \text{(Eq.4)}$$

$$B_{Jing} = 0.1107(d^2h)^{0.7223} \quad \text{(Eq.5)}$$

where B were the individual biomass weight, d were basal diameter, h were tree height.

Calculation of the size inequality of individual Haloxylon ammodendron

We analysed the size inequality of different parameters which can be expressed by the coefficient of variation (CV) of basal diameter, height, individual mass of *Haloxylon ammodendron*. To quantify size inequality in *Haloxylon ammodendron* clusters, the CV used is $CV = SD/X_{mean}$ (Weiner et al., 2001; Chu et al., 2009), SD is the standard deviation, X_{mean} is the sample mean.

Collection of stress factors

The collected field data are supposed to contain the five different wind erosion intensity which are to be used as abiotic stress factors, usually from March to May, the average wind speeds of Xinhu, Shihezi, Kuitun, Guertu and Jinghe are 4 m/s, 5.4 m/s, 6.5 m/s, 7 m/s, 9.5 m/s respectively, which show a trend of decreasing from west to east. Wind speed at the top of the dune is greater than that of the sand-driving wind velocity (6 m/s) and the top of the sand hill is exposed to the process of wind erosion, the above data are from the local monitoring result from 1975 to 2015.

Data analysis

All data were analyzed by spss 22 and Excel 2016, the plotted results was conducted via Origin 8.0 software, the scaling exponents and intercepts of M–N relationships were estimated by the standard major axis (SMA) regression of log-transformed data. Significance between the CV value (coefficient of variation) of different stages of development are expressed by the means of the Duncan's test, $p > 0.05$.

Results

Density changes

For the trend of the density changes of *Haloxylon ammodendron* clusters in five sites with wind erosion, a rapidly increased is found firstly in Sapling phase while a rapid decrease is found in Adult phase I, after that, a slow decline trend appears (*Fig. 3*). In Xinhu, *Haloxylon ammodendron* reaches its maximum density (30 trees/m^2) at the ninth age, subsequently, the density is in rapid decline from age 9 to age 13, after that the decline in density enters a relatively slow process. The Kuitun site reached its maximum density (41 trees/m^2) in the seventh year. Seven to eleventh years is regarded as a rapid decline period, which is slightly steeper than that Shihezi and Xinhu (*Fig. 3*). In Jinghe,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1466514677

the density reach its maximum (60 trees/m^2) in the fourth year. Similarly, in the period from fourth to eighth year, a rapid decline period can be seen, this stage in Jinghe has the steepest change compared with the change other four location. After that the downward trend began to be slower (*Fig. 3*). Compared to the other four locations at the same time, obviously, the density of *Haloxylon ammodendron* increased with the increase of wind erosion and showed a more intense pattern of aggregation. Another fact is that wind erosion significantly accelerated the onset of *Haloxylon ammodendron* density-dependent mortality, especially at the Jinghe site, the density-dependent mortality occurred earlier than that in other four locations. However, the density of the five sites during the death phase is similar (*Fig. 3*).

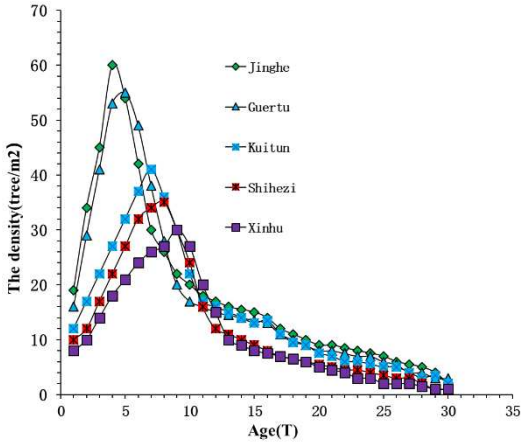

Figure 3. *The trend of the density change of Haloxylon ammodendron at five different locations, respectively*

The M-N exponents

There are three parts of density changes concerning rise and rapid fall, slow decline during self-thinning period (*Fig. 4*), so we calculate the M-N exponents in three sections respectively. The value of the M-N exponent ranged from 1.73 to 1.21 for phase along a erosion gradient (*Table 2*), the density exponent of the sapling phase were significantly larger than the traditional -3/2 and -4/3 ($p > 0.05$) based on the 95% CI; the density exponent of the adult phase were also significantly different from -3/2 and -4/3. In the senescence phase, the density exponent of Xinhu, Kuitun and Jinghe had no significant difference with -4/3, which indicates that the relationship between the average individual biomass and density on the ground during the senescence phase follows the -4/3 M-N exponent rule, meanwhile, in the same sites, with the increase of *Haloxylon ammodendron* age, the M-N exponents at different stages of development showed a downward trend.

Size inequality

At the top of the dune, different wind speed significantly influenced the size inequality of the *Haloxylon ammodendron* different parameters. For the basal diameter, High, Crown width and biomass, the CV value (coefficient of variation) of size inequality at Jinghe (strong wind) was lower than those in other four places, the highest CV value (coefficient of variation) is found at Xinhu site (*Fig. 5*). The CV Values

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1466514677

(coefficient of variation) of various parts under different wind erosion conditions in the same developmental stage are also significantly different (*Fig. 5*), The CV values (coefficient of variation) of size inequality of the sapling stage and Adult phase I was significantly higher than those in other stages of development.

M is aboveground average individual biomass, N is density. M:N is log M : log N. 95% CIs are confidence intervals for λ and K, n is the number of samples

Discussion

The density changes with developmental stages

Our natural *Haloxylon ammodendron* clusters show there is a pattern of hump-shaped density change, apparently, *Haloxylon ammodendron* cluster density in the Sapling phase showed a rapid growth trend. The survival rate of clusters was significantly higher than the mortality rate when the maximum density is reached, but due to the fact that individual clusters are too dense, some smaller individuals do not receive sufficient light and other nutrition so that the mortality rate has increased dramatically, resulting in a large number of individual deaths during the adult I period. Experience observation suggests that light is an important factor in the growth of *Haloxylon ammodendron*, subsequently, the trend of decreasing density has gradually become more moderate. Moreover, the worse the environmental gradient is, the sooner the *Haloxylon ammodendron* cluster enters self-thinning period (*Fig. 3*). This phenomenon was inconsistent with the previous model study in which the asymmetric facilitation delays the onset of density-dependent mortality (Lin et al., 2015), this situation may be caused by the fact that the cluster is trying to resist wind erosion, a large number of individuals colonize the top of the dune in high density, resulting in density-dependent deaths. The initial density is proportionally related to the environmental stress gradient (*Fig. 3*), in order to compete limited resources, the higher the initial density is, the more fierce the density-dependent death among individual will be. Moreover, the density decreasing degree in Adult phase I is significantly different from that of subsequent periods. So we speculate that the essential cause of phase

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1466514677

change of the density of cluster during different development period is the result of the transformation of the interactions between individuals (Chu et al., 2008). Therefore, it is very meaningful to study the characteristics of density variation between different developmental stages of tree populations under extreme conditions. How to changes the interaction among *Haloxylon ammodendron* individuals with the density and development stage will be an important direction for future study.

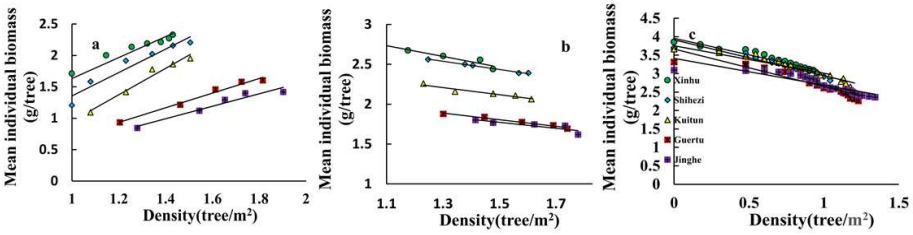

Figure 4. *Density-biomass exponents along wind erosion gradient at different development stages. The self-thinning line of sapling phase (a), the self-thinning line of adult phase I (b), the self-thinning line of adult (c)*

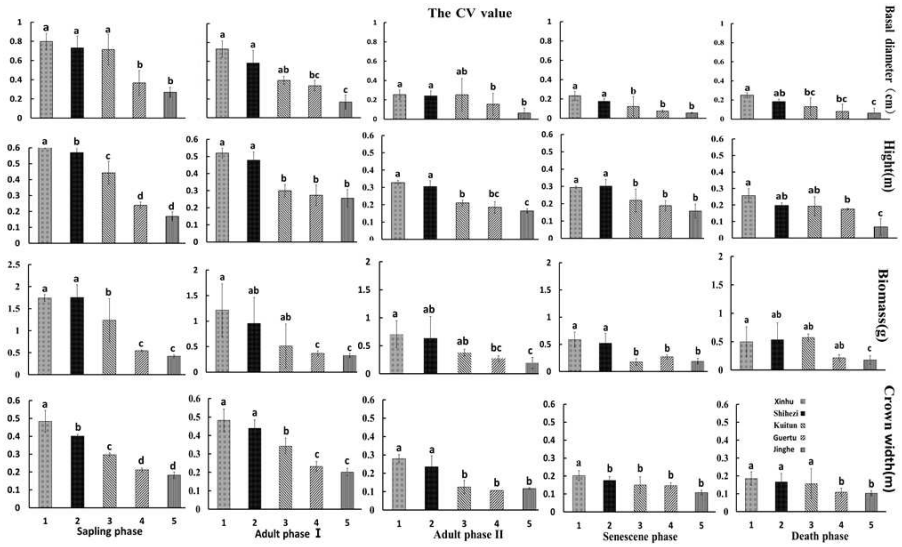

Figure 5. *The CV value of the stem, High, Crown width and the whole Haloxylon ammodendron biomass were calculated under different wind erosion stress gradient in the different stages of growth. Different places represent different wind erosion. 95% confidence intervals for unbiased values were determined by using the Duncan's test*

The M-N (self-thinning) exponents and size inequality

In our study, there was no general predicted value that can describe all the M–N relationships exponents for different stages development across different wind erosion gradient, also different from the -3/2 and -4/3 "law" (Deng et al., 2006; Zhang et al., 2011, 2017). According to the definition of population self-thinning, when the mortality rate within the population reaches 20%, it indicates that density dependent death has occurred (Maina et al., 2015). The *Haloxylon ammodendron* cluster we studied was originally planted on top of a dune in the form of a small area, in order to resist the

erosion of wind, the density of *Haloxylon ammodendron* seedlings reaches dozens, so that the intertwined roots fix the sand in a higher density, as the *Haloxylon ammodendron* cluster grows, the clusters expand radially around the center of the initial colonization site and grow usually in high density and seeds added in subsequent years, except for falling inside the clusters, must fall near the initial settlement, and if they are far away, they will not survive. So when the clusters grow to 2 to 3 years, the competition among individuals is more intense, a lot of individuals begin to die and can beyond 25% mortality rate (*Table 3*), at the same time, the occurrence of this process is accompanied by a higher survival rate and the survival rate is much greater than the mortality rate, therefore, the essential reason for the increase in density is that the new planting individual counteracts the death individual, resulting in a "trend of increasing density". This phenomenon is different from the tree population self-thinning in the traditional sense that is generally colonized in a certain area in a random distribution, the occurrence of self-thinning is often accompanied by a decrease in population density (Xu et al., 2018; Zhang et al., 2011; Deng et al., 2006; Chu et al., 2010). Moreover, although a small number of individuals die in the early stages of population development, but the death is not density-dependent death, but is caused by other external causes, such as disease, weakness or harsh environmental conditions, so self-thinning can be a process of increasing density, which proves that there is a positive self-thinning exponents in nature. The self-thinning exponent of three-phase decreases monotonously as the different developmental stages increases (*Fig. 4*). Self-thinning exponent was positive in the previous one to five years, after the cluster reaches the highest density, self-thinning has become very fierce, especially in Adult phase I. Later it shows a negative Self-thinning exponent, which may be caused by the fact that there is strong wind erosion stress at the top of dune, thus there may be a strongly facilitation effects among *Haloxylon ammodendron* individuals (Bertness et al., 1994; Callaway and Walker et al., 1997; Callaway et al., 2002, 2007). The strong positive effect promotes the individual average biomass of cluster to increase with the density in Sapling phase. In fact, this situation has been predicted by previous research, which suggested that the allometric exponents (or regression slopes) might even become positive under the most extreme conditions where facilitation is commonly observed, the above study predicted this result, but it was not confirmed in reality yet (Deng et al., 2006). The results of this paper has just verified the existence of positive M-N exponents and proved the complexity of the self-thinning patterns of different species. It can be seen herbs have a shorter developmental history, but not long enough for us to observe its phase effects. As for arbor plants with long developmental history, it is more convenient to observe a series of change characteristics during the developmental stage. Therefore, it is very meaningful to discover the characteristics of different interacting species and natural stress factors (Maestre et al., 2009).

In addition, the coefficient of variation of different parameters of *Haloxylon ammodendron* at different developmental stages also decreases with increasing wind erosion in this same location, however, previous study (Zhang et al., 2012) showed that size inequality (coefficient of variation) was simply monotonic decreases in Mung beans growing phase 1 with the increase of UV-B stress strength, but non-monotonic decreases is with UV-B radiation increased in phase 2 and 3. They attribute the result to the spatial pattern of plant growth and the symmetry of competition (Chu et al., 2009; Weiner et al., 2001). Our study does not need to consider these factors, because the entire process of cluster development is in a state of self-thinning, so there is no effect

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1466514677

of spatial patterns. It can more accurately reflect with environmental pressure gradient how the size inequality (coefficient of variation) changes for each developmental stage. For each parameter, sapling, We speculate, this may be related to the predominance of facilitation in the previous period, in the same facilitation patterns sapling stage and adult phase I, the clusters are constantly recruit new individuals and accompanied by the death of some individuals. *Haloxylon ammodendron* individuals that are constantly settled and death exacerbate the size inequality of clusters, lead to a relatively high size variation, in the adult phase II, senescene phase, death phase the changes in density have slowed and subsequent supplements can only survive for 1-3 years. The difference in the age of surviving individuals at this stage is much smaller than that in the previous period, thus clusters show a more neat trend.

Table 3. *Changes of Haloxylon ammodendron clusters plants number during sapling phase*

Age		Jinghe	Guertu	Kuitun	Shihezi	Xinhu
One year	Survival	19	16	12	10	8
	Deaths/current year	0	0	0	0	0
	Mortality rate	0	0	0	0	0
Two year	Survival	34	29	17	12	10
	Deaths/current year	12 (9)	10 (8)	8 (5)	6 (4)	4 (3)
	Mortality rate	26%	25%	32%	33%	28%
Three year	Survival	45	41	22	17	14
	Deaths/current year	34 (15)	26 (11)	16 (6)	14 (5)	12 (5)
	Mortality rate	33%	28%	26%	32%	36%
Four year	Survival	60	53	27	22	18
	Deaths/current year	60 (18)	56 (13)	31 (10)	23 (8)	18 (6)
	Mortality rate	30%	25%	37%	35%	33%
Five year	Survival	54	55	32	27	21
	Deaths/current year	98 (22)	83 (18)	35 (19)	43 (8)	29 (7)
	Mortality rate	41%	33%	60%	29%	34%
Six year	Survival	42	49	37	32	24
	Deaths/current year	107 (14)	100 (14)	77 (14)	67 (14)	40 (7)
	Mortality rate	35%	29%	37%	43%	31%

The survival number and death number in the table are cumulative values, and all death individuals will disappear due to wind erosion two to three years after death. Current Year is the number of deaths is the number of individuals who died in the current year. When calculating the mortality rate, the number of deaths is the number of individuals who died in the current year

Conclusion

(1) The density of clusters increased rapidly at the sapling stage, decreased rapidly at the adult stage, and then decreased slowly at the later stage. By comparing five different wind erosion sites, we can clearly find that the density of *Haloxylon ammodendron* increases with the increase of wind erosion intensity, showing a denser growth pattern. Wind erosion significantly accelerated density-dependent death of *Haloxylon ammodendron*.

(2) the self-thinning indexes of *Haloxylon ammodendron* clusters along different wind erosion gradients were all positive at the rapid rising stage, it is significantly

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1466514677

different from the traditional -3/2 and -4/3 self-thinning indices; in the stage of rapid density decline, the negative value presents an upward trend along the wind erosion gradient, which is significantly different from the traditional -3/2 and -4/3 self-thinning indexes; the difference between the -4/3 self-thinning index and self-thinning index of Xinhu, Kuitun and Jinghe in the stages of aging and death is not obvious, indicating that the self-thinning stage conforms to the -4/3 self-thinning rule. With the growth and development of cluster, the self-thinning index of the same location showed a decreasing trend.

(3) The CV values of the cluster size inequality of the sapling stage and adult phase I was significantly higher than those in other stages of development.

Future research should explicitly evaluate how to incorporate different developmental stages of arbor species into current conceptual and mathematical models, which can be used to improve the SGH (stress-gradient hypothesis) framework. The computer models of tree species need to be made to explore the changing patterns of positive and negative interactions among individuals, the facilitative effect from key species is essential for ecological system diversity and stability (Brooker et al., 2008; Vellend, 2008), which help us extend the SGH (stress-gradient hypothesis) framework and foster research on facilitation in ecology (Brooker et al., 2005, 2008; Maestre et al., 2009).

Abstract. This study was aimed at isolating indigenous soil bacteria exhibiting cadmium (Cd)-resistance, and characterizing their ability to improve growth and reduce Cd bioaccumulation of Thai rice (*Oryza sativa* L.) PSL2 seedlings. Repeated enrichment, microorganisms were selectively propagated from agricultural soils receiving dredged sediments that contained Cd at 30-50 mg kg^{-1}, in Western Thailand. Over a range of 0-1,000 ppm, the enriched bacterial consortia had a maximum tolerance to Cd at 800 ppm. In batch cultures containing 50 or 100 ppm Cd, they exhibited 53-56 and 69-78% Cd removal, respectively. The inoculation of enriched consortia ameliorated Cd phytotoxicity by promoting rice biomass and growth, and lowering tissue Cd content upon high Cd exposure (50-100 ppm). 16S metagenomic analysis showed that at least the top bacterial phyla of *Proteobacteria, Firmicutes,* and *Bacteroidetes* were enriched in the naturally polluted topsoil microorganisms with dominant bacterial phyla including *Planctomycetes, Proteobacteria, Acidobacteria, Verrucomicrobia, Bacteroidetes, Chloroflexi, Actinobacteria, Firmicutes,* and *Gemmatimonadetes*. In the enriched consortia, certain predominant detoxifiers (e.g., *Acinetobacter* sp.*, Comamonas* sp.*, Enterococcus* sp., and *Pseudomonas* sp.) were explored at a finer taxonomic level among other detected genera. These results emphasized that indigenous soil Cd-resistant microorganisms have potential to cope with metal stress and improve crop plant growth and yield for agricultural benefits.
Keywords: *bioremediation, Cd-resistant bacteria, food safety, microbial community, rice seedling*

Introduction

Biosphere pollution by heavy metals has risen due to industrial activities and extensive use of agrochemicals. Particularly in developing countries, unorganized industrialization and waste management significantly accelerate the release of heavy metals into the soil and water bodies (Sharma et al., 2008). Toxic metals such as cadmium (Cd) have been deposited on the surface soil via industrial operations such as mining and alkaline battery manufacturing.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1467914697

Cadmium confers carcinogenicity and mutagenicity, even at low concentrations. In addition, Cd can interfere with renal function by its accumulation in the proximal tubular cells and also cause bone demineralization (Bernard, 2008). In addition to its adverse health effects, excessive Cd levels in the soil cause plant growth retardation, symbiosis interference, and crop yield reduction (Wani et al., 2007).

Soil pollution is one of the main factors causing Cd contamination in rice grains and human exposure via the food chain, indicating that a key point is to remedy Cd pollution from the paddy area, in order to minimize plant Cd uptake from soil and reduce its bioaccumulation in rice grains (Deng et al., 2014). Remarkably high levels of Cd in agricultural soils have been detected in the Padaeng zinc mining area of the southeast region of Mae Sot District, Tak Province, Thailand (Simmons et al., 2003, 2005). This has become a major concern since the International Water Management Institute demonstrated significant Cd contamination in rice grains and paddy soils in this province (Simmons et al., 2003). These Cd levels (ranging from 3.4-284.0 mg kg^{-1} in the agricultural areas) are much higher than the European Community limit of 3 mg kg^{-1}, posing high risk to the environment and human health (Swaddiwudhipong et al., 2012). Therefore, it is essential to remediate Cd-polluted soil in order to alleviate phytotoxicity, improve crop yield, and ultimately prevent direct human exposure.

A number of physicochemical approaches have been utilized for the reduction of toxicity and recovery of polluted agricultural sites. Nevertheless, bioremediation with use of indigenous heavy metal-resistant microorganisms conferring heavy metal removal and plant growth promoting potential would be a cost-effective choice for sustainable agricultural benefits (Govindasamy et al., 2011). The main issue is selection of indigenous heavy metal resistant microorganisms and their implementation in the contaminated area in a sustainable, ecologically friendly manner. Some soil microorganisms playing a dual role in both Cd resistance and plant growth promotion would be greatly in demand when applied in agricultural areas contaminated with heavy metal, as has been described for example, *Variovorax, Rhodococcus, Flavobacterium, Pseudomonas, Klebsiella, Bacillus, Stenotrophomonas, Serratia, Leifsonia* and *Enterobacter* (Ahmad et al., 2014, 2015; Belimov et al., 2005; Etesami, 2018; Mitra et al., 2018; Sharma and Archana, 2016). Metal tolerance of plants can be improved by selection of the crop species; however, microorganisms conferring metal immobilizing abilities would be potentially applied to minimize pollutant uptake (Kuffner et al., 2010).

Rather than a single microbial isolate, biofilm-like indigenous soil microorganisms having relatively high Cd tolerance and rice growth promotion would be useful for long-term management and recovery of the metal-polluted rice paddy. The objective of the present study was to isolate indigenous Cd-resistant microbial consortia from the contaminated agricultural soils by repeated enrichment culture, characterizing their Cd-tolerance and -removal capacities, and assessing their effects on the seed germination and seedling growth of Thai rice cultivar (*Oryza sativa* L.) PSL2, as well as tissue Cd content upon high Cd stress.

Materials and methods

Study site

Soil samples were collected from a Cd and zinc (Zn)-contaminated agricultural area in Pha Dei Village, Mae Sot District, Tak Province, Thailand (N 16° 40′ 35.9″ E 98° 37′ 37.4″) at an altitude of 197 m. The study site is controlled by the subtropical monsoon

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1467914697

climate with average annual temperature of 26 °C and average annual precipitation of 1,448 mm. This rice paddy is usually cultivated either with rice-corn or rice-bean crops in a cropping year. For enrichment and isolation of indigenous Cd resistant microorganisms, soil samples were collected from the agricultural area and alongside an irrigation streamline adjacent to the rice paddy in a single site (the sampling site is shown in *Fig. A1* in the *Appendix*). Thirty-six samples of topsoil (<20 cm in depth, ca. 1 kg in weight each) were collected from May to July 2016 (rainy season) and January to March 2017 (dry season).

Physicochemical studies of Cd-contaminated soil

The topsoil samples were collected as described above. Soil samples were divided into 2 main portions: one for physicochemical analyses and another one for the culture enrichment. The following soil properties were determined: pH (1:5 soil/water suspensions) using field-moist samples and a pH meter; electrical conductivity (EC) using an EC meter; organic matter (OM) content by wet oxidization and titration according to the modified Walkley-Black procedure (Nelson and Sommers, 1996); and oxidation-reduction potential (ORP) using field-moist samples and an ORP meter; and cation exchange capacity (CEC) was tested after leaching with 1N ammonium acetate (NH_4OAc) buffer.

The collected soil samples were oven-dried and crushed using an agate mortar before being passed through a 200-mesh sieve. The samples then were analyzed for total Cd concentration in a flame atomic absorption spectrophotometer (FAAS, AAnalyst 200, PerkinElmer®) after HNO_3 digestion (APHA, AWWA, and WEF, 2005). Bioavailable soil Cd was determined by FAAS after extraction with 0.05 M diethylene triamine pentaacetic acid (DTPA) (APHA, AWWA, and WEF, 2005). Total nitrogen (N) was measured by the Kjeldahl method (Blake, 1965). Extractable phosphorus (P) and potassium (K) were determined by the Bray II method and extraction with neutral NH_4OAc buffered to pH 7.0, respectively (Bray and Kurtz, 1945). Soil texture was examined with the hydrometer (Allen et al., 1974). Physicochemical characteristics of soil samples are listed in *Table 1*.

Table 1. *Selected physicochemical properties of the contaminated agricultural soil*

Parameter	Rainy season		Dry season	
	#1	#2	#3	#4
Temperature (°C)	24	25	26	27

Enumeration of total cells and of cultivable microorganisms in the polluted soils

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1467914697

The total microbial cells isolated from the original soil samples were enumerated by fluorescent blue dye Hoechst® 33342 staining method, as previously described by Brunk et al. (1979) with some modifications. Ten grams of each soil sample was resuspended with 90 ml PBS buffer. The suspension was stirred for 30 min at 200 rpm, sonicated in a sonication bath for 5 min, and then centrifuged at 3,000 rpm for 5 min. The supernatant was subjected for enumeration of total cells.

To determine the cell concentration of cultivable bacteria by the viable plate count technique, they were first inoculated in nutrient broth and incubated at 30 °C, 100 rpm for 18 h. Each serially diluted cell suspension was subsequently spread on nutrient agar plates without and with $CdCl_2$ at 50 and 100 ppm. After 24 h incubation at 30 °C, colonies of Cd-resistant bacteria were counted and referred to as colony forming units per ml (CFU ml^{-1}).

Enrichment and isolation of Cd-resistant bacteria

For enriching the Cd-resistant bacteria, the first 5 g of each sample was added to 95 ml of nutrient broth (NB, 0.5% peptone, 0.3% meat extract, pH7.0) containing 50 or 100 ppm cadmium chloride ($CdCl_2$). After 2 weeks of incubation at 30 °C, the bacteria were cultured on nutrient agar plates (NA, nutrient broth and 1.5% agar) supplemented with $CdCl_2$ for 72 h at 30 °C. The colonies of Cd-resistant bacteria were quantified as colony forming units per ml (CFU ml^{-1}). Each single bacterial colony with different morphology was then streaked onto agar medium for 24 h at 30 °C.

16S-Metagenomic analysis of the Cd-resistant consortia

Bacterial diversity and composition of the enriched consortia in comparison to the originally polluted soil consortia were analyzed using 16S rRNA gene Illumina MiSeq sequencing. Total genomic DNA was extracted from 0.5 g of frozen soils and 10 ml of the enriched culture (three replicates per treatment) using QIAamp® DNA Stool Mini Kit (Qiagen, Germany) according to the manufacturer's instructions with some modifications. The 16S rDNA (V3-V4) universal bacterial primers containing the Illumina overhang adapter sequences (as underlined) 341F (5' - TCGTCGGCAGCGTCAGATGTGTATAAGAGACAGCCTACGGGNGGCWGCAG) and 805R (5'- GTCTCGTGGGCTCGGAGATGTGTATAAGAGACAGGACTACHVGGGTATCTAATCC) were utilized for PCR amplification (Herlemann et al., 2011). The PCR mixtures (25 µl) contained 12.5 µl of 2x KAPA HiFi Hot Start Readymix (KAPA Biosystems, USA), 5 µl of each primer (1 µmol l^{-1}) and 2.5 µl of target DNA (5 ng μl^{-1}). The PCR cycling conditions consisted of an initial denaturation step at 94 °C (3 min), followed by 25 cycles of 98 °C (20 s), 55 °C (30 s) and 72 °C (30 s) and a final elongation at 72 °C (5 min). The PCR products were cleaned-up on AMPure XP beads (Agencourt Bioscience, USA). The purified amplicons (550-bp fragments) were submitted to the Omics Sciences and Bioinformatics Center (Chulalongkorn University, Bangkok, Thailand) for paired-end sequencing on the Illumina MiSeq platform.

Subsequently, the purified 16S amplicons were then indexed using 2X KAPA hot-start ready mix and 5 µl of each Nextera XT index primer in a 50 µl PCR reaction, followed by 8-10 cycles of PCR amplification. The PCR cycling was set as aforementioned. Next, the indexed 16S amplicons were purified on AMPure XP beads (Agencourt Bioscience, USA), pooled and diluted to a final loading concentration of 4 pM. Cluster generation and 250-bp paired-end read sequencing were done on an Illumina MiSeq using the MiSeq Reagent Kit at the Omics Sciences and Bioinformatics Center (Chulalongkorn University, Bangkok,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1467914697

Thailand). Amplicon sequence analysis was performed with QIIME version 1.9.0. (Caporaso et al., 2010). All sequence reads were sorted based on their unique barcodes, trimmed for sequence quality, and clustered at 97% identity for operational taxonomic units (OTUs). The UCHIME algorithm was used to discard chimera sequences (Edgar et al., 2011). The microbial diversity index in terms of diversity (Shannon index) and richness (Chao1 index) were then computed using the MOTHUR (Schloss et al., 2009). To study the microbial composition and diversity, the Shannon diversity index, an estimator of species richness and diversity using a natural logarithm, accounts for both abundance and evenness of the taxa present, while Chao1 richness estimator is used to estimate diversity from abundance data and number of rare taxa missed from under-sampling.

Determination of maximum tolerance concentration (MTC) of Cd

In brief, the enriched consortia and isolated strains were inoculated in nutrient broth supplemented with $CdCl_2$ (50 to 1,000 ppm). After 18 h incubation at 30 °C, each culture was then spread on nutrient agar plates with $CdCl_2$ at the same concentrations. The highest concentration of metal ions at which growing colonies of bacteria were observed was defined as the maximum tolerance concentration (MTC) of Cd for the tested bacteria. Media without $CdCl_2$ serves as controls. All experiments were performed in triplicate.

Determination of Cd removal capacity of the enriched consortia in batch culture

Effect of the enriched Cd-resistant microbial consortia on reduction of water-soluble Cd concentration in culture medium was examined according to the method of Chen et al. (2008) with some modifications. In brief, the enriched consortia were initially cultivated in nutrient broth, harvested by centrifugation, and washed twice with sterile deionized water. Cell pellets were then resuspended in the sterile water. Triplicate flasks of nutrient broth supplemented with 50 or 100 ppm $CdCl_2$ were inoculated with microbial suspension of either the enriched consortium or the selected single strain, compared to microbial-inoculated culture without Cd and the control (uninoculated culture with Cd addition). After 24 h incubation at 30 °C, the microbial growth in the cultures was measured at the optical density (OD_{600}) for quality control (data not shown). The cell pellets were harvested by centrifugation and their dry cell weight were measured while the water-soluble Cd concentration in the supernatant was then determined with an AAnalyst 200 Perkin-Elmer® FAAS. The percentage of Cd removal of each culture was calculated using *Equation 1:*

$$\%\ Cd\ removal = \frac{CI-CF}{CI} x\ 100 \qquad \text{(Eq.1)}$$

where CI is the initial Cd concentration in the medium; CF is the Cd concentration that remains in the supernatant.

Effect of Cd-resistant bacteria on rice seedlings using the filter paper system

The plant root/shoot elongation promoting ability of the enriched consortia was assessed using the modified root elongation assay of Belimov et al. (2001). Bacteria were grown on nutrient broth containing Cd for 48 h at 30 °C and resuspended to 5×10^7 cells ml^{-1} in sterile deionized water. Six milliliters of the bacterial suspensions at final concentration 1×10^6 cells ml^{-1} or sterile water (uninoculated control) were added to glass Petri dishes containing filter paper that was soaked with 50 or 100 ppm $CdCl_2$ (final concentration) in comparison to bacterial inoculation without $CdCl_2$ as control. The seeds of rice cultivar (*Oryza sativa*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1467914697

L.) PSL2 were surface-sterilized with a mixture of ethanol and 30% H_2O_2 (1:1) for 20 min, washed twice with sterile water and placed on the wetted filter paper. Root/shoot length and number of fibrous roots of seedlings were measured after incubation at 28 °C for 7 and 14 days in the dark. Dry biomass was determined after plant materials were oven-dried at 80 °C for 4 days prior to weight determination. The assay was repeated two times with six dishes (20 seeds $dish^{-1}$) for each treatment.

Effect of Cd-resistant bacteria on Cd accumulation of rice tissues

The plant root/shoot Cd content was measured according to the method of Ihnat (2000). After 14 days of incubation at 28 °C in the dark, rice seedlings grown in Cd with or without bacteria inoculation were washed twice with sterile water, oven-dried at 80 °C for 2 h, and weighed prior to Cd quantification. The Cd concentration of 30 rice seedlings per treatment was measured using an AAnalyst 200 Perkin-Elmer® FAAS after HNO_3 digestion (APHA, AWWA, and WEF, 2005). The assay was performed in triplicate.

Statistical analysis

Data were subjected to the statistical analysis using the student's t-test. The treatment means were compared by setting the significant difference at the 5% probability level (*P*-value ≤ 0.05).

Results

Enrichment and isolation of Cd-resistant soil microorganisms

During the selection of Cd-resistant microorganisms, thousands of growing colonies were observed on nutrient agar plates containing 50-100 ppm $CdCl_2$. Fluorescent nuclear staining revealed that total microbial abundance in the naturally polluted soils ranged from 1.8×10^8-8.9×10^9 cells ml^{-1} after Hoechst® 33342 dye blue staining (*Fig. 1*). The direct cultivable microbial abundance in the polluted soils ranged from 1-5 $\times 10^7$ CFU ml^{-1} after cultivation on nutrient agar plates without $CdCl_2$. After 2 weeks of repeated enrichment culture, the average number of enriched microorganisms was found to be 1.5-7.5 $\times 10^8$ CFU ml^{-1} on nutrient agar plates with 50 ppm $CdCl_2$. Thereby, indigenous Cd-resistant microbial consortia were successfully isolated by the repeated enrichment method and sequential dilution technique.

Relative abundance and composition structure of the enriched consortia

The relative abundance and composition of the enriched consortia were assessed and compared to the originally polluted topsoil consortia by a 16S metagenomic sequencing approach. *Table 2* shows the alteration in the functional diversity indices of the enriched consortia, in comparison to the polluted topsoil consortia. Diversity indices of the enriched consortia were altered when compared to the naturally polluted topsoil samples, as shown by the decrease in the Shannon diversity index and the Chao1 richness estimator.

**Indicates respective significant difference at P-value ≤ 0.05, by comparing the selected parameters (Chao1 richness or Shannon diversity estimator) of the bacterial enriched consortia (BC) to that of the original polluted topsoil (TS) samples. OTUs represent operational taxonomic units. BC indicates Cd-resistant bacterial consortia after Cd-added culture enrichment, and TS indicates topsoil samples originally contaminated with Cd

Figure 2a presents the relative abundances of the bacterial phyla in the polluted topsoil and the enriched consortia. *Planctomycetes, Proteobacteria, Acidobacteria, Verrucomicrobia, Bacteroidetes, Chloroflexi, Actinobacteria, Firmicutes* and *Gemmatimonadetes* were the most dominant phyla, accounting for 90% of the total bacterial 16S rRNA gene sequences in the polluted topsoil. *Planctomycetes* occupied the highest proportions (47.5%) of the bacterial sequences. *Proteobacteria, Acidobacteria, Verrucomicrobia, Bacteroidetes, Chloroflexi, Actinobacteria, Firmicutes* and *Gemmatimonadetes* were identified in all topsoil samples at cumulative relative abundance (ca.42.5%). Approximately 2% of bacterial phyla were unassigned.

The consecutive addition of Cd at increasing concentrations (20-100 ppm) could select population of Cd-resistant bacterial phyla among other Cd-sensitive phyla. The 16S metagenomic result showed that the 3 top phyla including *Proteobacteria* (47.7%) *Firmicutes* (36.5%) and *Bacteroidetes* (15.5%) were markedly enriched relative to the original topsoil (P-value ≤ 0.05) (*Fig. 2a*). The relative abundances of *Proteobacteria, Firmicutes*, and *Bacteroidetes* increased across the culture enrichment period, while those

DOI: http://dx.doi.org/10.15666/aeer/1706_1467914697

of *Acidobacteria, Actinobacteria, Chloroflexi, Gemmatimonadetes, Planctomycetes,* and *Verrucomicrobia* decreased. In the enriched consortia, predominant detoxifiers at finer taxonomic level of *Proteobacteria* (including *Arcobacter* sp., *Comamonas* sp., *Pseudomonas* sp., *Acinetobacter* sp., *Stenotrophomonas* sp., and *Delftia* sp.), *Firmicutes* (including *Leuconostoc* sp., *Enterococcus* sp., *Lactobacillus* sp., and *Lactococcus* sp.), and *Bacteroidetes* (including *Wautersiella* sp., *Myroides* sp., *Cloacibacterium* sp., *Paludibacter* sp.) were uncovered among other genera (*Fig. 2b*). The enriched microbial consortia were successfully established and subjected to subsequent characterization.

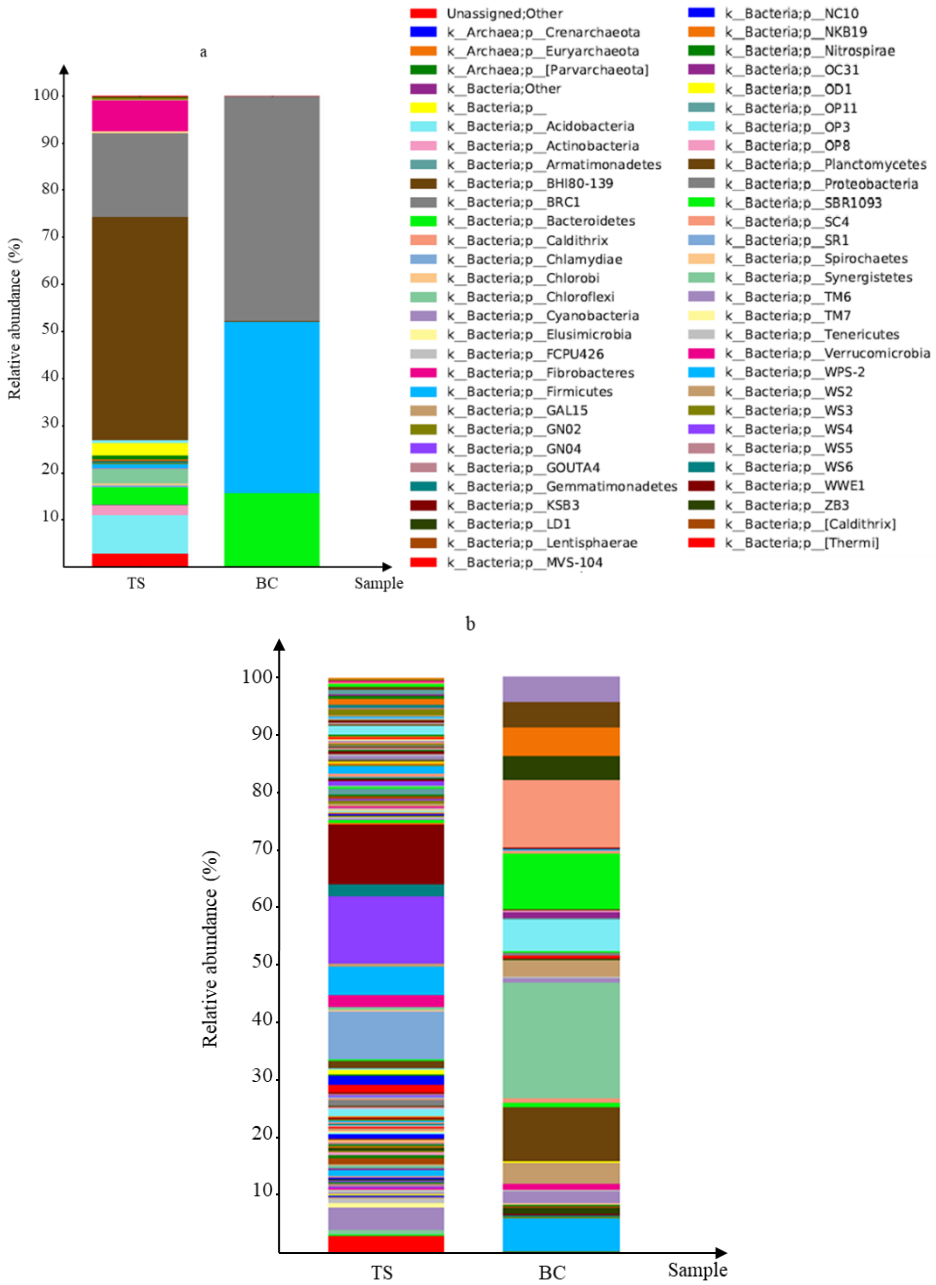

Figure 2. *Representative images showing relative abundance levels of dominant bacterial phyla (a) and genera (b) in the contaminated topsoil (TS) and the enriched cadmium-resistant bacterial consortia (BC) (cultivable Cd) based on 16S metagenomic sequencing*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

Determination of maximum Cd tolerance and Cd removal capacity of the enriched consortia

The maximum tolerance of the enriched microbial consortia toward $CdCl_2$ (0-1,000 ppm) were determined in comparison to that of selected single strains. Viable plate counts showed that the enriched consortia grew well and survived on nutrient agar containing $CdCl_2$ up to 800 ppm (*Fig. A2* in the *Appendix*), while most of the isolated single strains could only grow on the media with much lower $CdCl_2$ up to 200 ppm (*Fig. A3* in the *Appendix*).

Furthermore, the effect of enriched consortia on immobilization of toxic Cd in the batch culture was investigated. After 24 h incubation, the water-soluble Cd concentration in each supernatant was remarkably decreased upon inoculation of either enriched consortia or single isolates. In presence of 50 ppm Cd, the enriched consortia had Cd removal capacities ranging from 19.3 ± 0.9 to 25.5 ± 0.8 mg g^{-1} cell dry weight, equivalent to 52.8-56.3% Cd removal (*Table 3*). At a higher Cd concentration of 100 ppm, the Cd removal capacities ranged from 37.4 ± 1.2 to 48.6 ± 0.6 mg g^{-1} cell dry weight, equivalent to 68.7-77.5% Cd removal (*Table 3*). This indicated that the inoculation of Cd-resistant microorganisms could reduce water-soluble level of toxic Cd in order to possibly overcome Cd toxicity in the culture, and that the exogenous addition of Cd affected Cd removal capacities of the enriched consortia.

Table 3. *Cadmium removal capacity of indigenous Cd-resistant bacterial consortia (BC) after batch culture in nutrient broth containing $CdCl_2$ at 50-100 ppm*

germination and growth studies at seedling stage of the Thai rice cultivar PSL2 in the presence or absence of Cd. After 7 days of incubation, the length of roots and shoots and number of fibrous roots were measured in rice seedlings treated with or without the enriched consortia inoculant, in comparison to a soil bacterium *Bacillus*-inoculated group and non-metal treated group (control) upon Cd exposure (either 50 or 100 ppm). The control rice exhibited normal growth (*Fig. 3a; Table 4*), while the Cd-treated groups exhibited symptoms of toxicity; showing inhibited primary root growth and reduced shoot length (*Fig. 3a; Table 4*). Indeed, the obvious effect of Cd toxicity on rice roots rather than shoots was observed. Seedlings treated with the bacterial inoculant at 1×10^6 CFU ml^{-1}, in the absence of $CdCl_2$, exhibited normal root elongation and somewhat enhanced fibrous root number. Upon Cd exposure, the enriched consortia-inoculated seedlings markedly enhanced root length and fibrous root number, and moderately increased shoot length, compared with uninoculated seedlings (*Fig. 3a, b*). Particularly, the addition of enriched consortia inoculant obviously enhanced the length of roots and number of fibrous roots by 2.1- and 12-times, and by 1.9- and 18-times, respectively, in rice seedlings exposed to 50 ppm and 100 ppm Cd when compared to the uninoculated group, but the addition of *Bacillus cereus* did not (*Table 4*). A bacterial inoculant at 1×10^6 CFU ml^{-1} could alleviate phytotoxicity, as evidenced by promoted rice germination and seedling growth even under Cd stress.

Table 4. *Effect of indigenous Cd-resistant bacterial consortia (BC) on 7-day rice germination of the Thai rice PSL2 on filter paper system containing $CdCl_2$ at 50 or 100 ppm, with Bacillus cereus as control*

Treatment	Root length (cm in average)	Shoot length (cm in average)	No. of fibrous root (in average)

BC indicates Cd-resistant bacterial consortia after Cd-added culture enrichment

Effect of Cd-resistant consortia on biomass and Cd accumulation of rice tissues toward high-concentration Cd in vitro

In absence of Cd, the enriched consortia enhanced biomass production of shoot and particularly root of Thai rice PSL2 seedlings. The exogenous addition of Cd at 100 ppm decreased root and shoot dry biomass of rice by 16.1 and 44.5%, respectively, compared to control (*Table 5*). However, within 14 days of exposure the microbial consortia-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1467914697

inoculated seedlings significantly ($p > 0.05$) increased both root and shoot dry biomass at least at one concentration of $CdCl_2$ (50 or 100 ppm) as compared to the Cd-treated group alone (*Table 5*). Our result indicated that the inoculation with enriched consortia at 1×10^6 CFU ml^{-1} positively affected root biomass production and moderately influenced the shoot length upon high Cd exposure level.

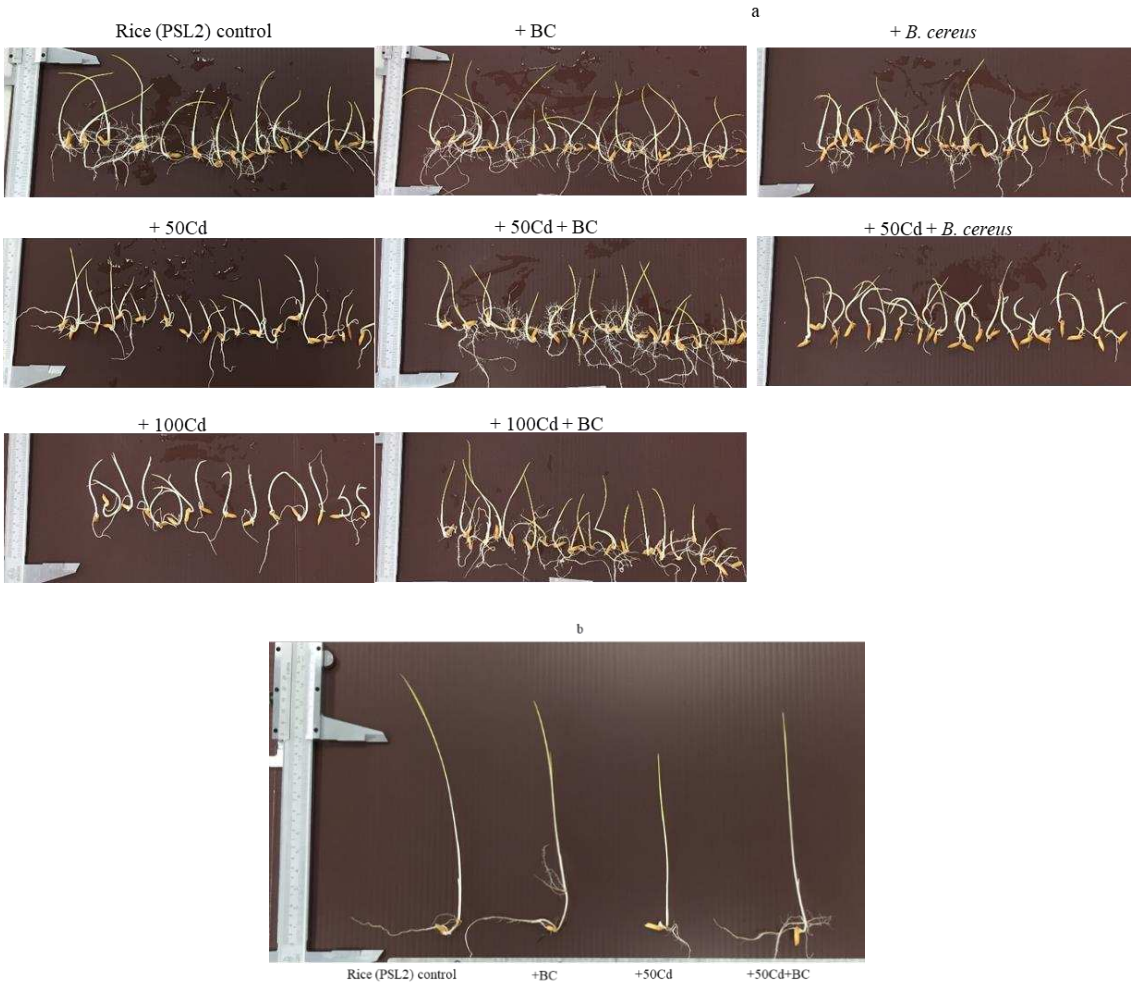

Figure 3. *Effect of indigenous Cd-resistant bacterial consortia (BC) on (a) 7-day rice germination in filter paper cultures containing $CdCl_2$ at 50 or 100 ppm, with use of Bacillus cereus as control bacteria, and on (b) 14-day representative growth of rice seedling inoculated with the bacterial consortia in absence or presence of Cd at 50 ppm, as compared to the uninoculated bacterial consortia*

Cadmium content in rice root and shoot was influenced by exogenous addition of Cd; however, the inoculation of enriched consortia remarkably ameliorated Cd accumulation in rice tissues even at the initial seedling stage (*Table 5*). Cadmium accumulation in rice root and shoot significantly ($p > 0.05$) decreased when the treatment with enriched consortia at both levels of Cd exposure (50 and 100 ppm). Notably, the inoculation with enriched consortia at 1×10^6 CFU ml^{-1} led to mitigated metal phytotoxicity due to reduced Cd bioconcentration and promoted biomass production in rice seedlings toward high Cd exposure level, as summarized in *Figure 4*.

Discussion

Inoculation of plant inhabiting extreme environments (such as Cd-polluted soils) with specific metal resistant microorganisms could allow them to be more tolerant to high metal stress (Sharma and Archana, 2016). Selection of these metal resistant microorganisms which are capable of promoting plant growth in contaminated environments and minimizing accumulation of metal in edible parts is our intention. Out of concern for the Cd contamination in agricultural areas of Western Thailand and its effects on human health, indigenous soil microbial consortia with high Cd tolerance were herein screened for potential application to reduce Cd accumulation in rice tissues. This experiment was designed with the idea that these indigenous Cd-resistant microorganisms have high intrinsic fitness to the local area, and cause minimum disturbance to the local micro-ecological niche.

In this study, indigenous Cd-resistant soil microbial consortia that were successfully enriched on media successively supplemented with Cd had a maximum tolerance to Cd of 800 ppm while the selected single strains mostly exhibited much lower tolerance to Cd. Microbial growth was primarily inhibited upon Cd exposure, but the consecutive addition of Cd could induce microbial tolerance to this metallic element. The tolerance to higher Cd levels might be attributed to several tolerance mechanisms, including biosorption, intracellular/extracellular sequestration, complexation, and active efflux (Gadd, 2004; Sharma and Archana, 2016). Indeed, microbial consortia in microenvironments are mostly present as biofilms, which promotes resistance of microbial cells by forming a protective sheath, as well as transforming toxic metal ions into non-toxic forms after biosorption (Hall-Stoodley et al., 2004). Certain metal resistant plant-growth promoting microorganisms can excrete extracellular polymeric substances (e.g., polysaccharides, glycoproteins and lipopolysaccharide) and consequently stimulate biofilm formation in response to toxic metal, as well as facilitating the plant to obtain more water and nutrients. In addition to biosorption, bioaccumulation has a major role in heavy metal uptake and further detoxification by metal-resistant plant-growth promoting microorganisms. Moreover, the enriched consortia had much higher Cd removal capacities. They also showed *in vitro* ability to promote rice germination, growth, and biomass production at the seedling stage; however, whether these traits would be active in the paddy field depends on their survival in the natural conditions and capability to colonize rice roots.

Upon high Cd exposure (50 or 100 ppm), the inoculation with enriched Cd-resistant microbial consortia to PSL2 rice (*Oryza sativa* L.) enhanced root length and biomass and fibrous root number particularly, and moderately increased shoot length and biomass, compared with the uninoculated seedlings. The increase in root biomass and development of numerous fibrous roots might improve plant performance by extracting more water and nutrients, and consequently promote plant growth under Cd stress (Ahmad et al., 2014). As previously evidenced by the root and shoot biomass data, the inoculation of a metal-resistant *Pseudomonas* sp. bacterium was regarded as an effective approach for protecting plants against toxic metals (Rajkumar and Freitas, 2008). *Pseudomonas* spp. belonging to the plant growth-promoting bacterial group is capable of heavy metal biosorption and bioaccumulation, consequently reducing the metal phytotoxicity to the plant (Zaidi and Musarrat, 2004). Similar to our study, the inoculation by enriched Cd-resistant microbes ameliorated Cd toxicity and promoted germination of rice seedlings. The microbial load at 1×10^6 CFU ml^{-1} could enhance rice germination and seedling growth even at high Cd exposure level.

DOI: http://dx.doi.org/10.15666/aeer/1706_1467914697

Our finding was consistent with a previous study that reported that monocotyledonous plants under stressful conditions generally develop a shallow and fibrous root network, enabling them to anchor and efficiently collect surface water (Uraguchi and Fujiwara, 2012). Siripornadulsil and Siripornadulsil (2013) demonstrated that *Cupriavidus taiwanensis* isolates enhanced fibrous root growth and shoot length in rice seedlings, as well as enhancing germination under Cd exposure. Notably, the enriched consortia had significant ($p > 0.05$) ability to reduce metal phytotoxicity in terms of root and shoot elongation, even at high Cd level (50 ppm). Lee et al. (2010) have revealed increased levels of Glutathione (GSH) and oxidative stress-responsive proteins in the rice root in response to Cd stress. Furthermore, the enriched consortia increased metal tolerance in rice seedlings, as shown by the increase in root and shoot biomass production. Our study demonstrated that the indigenous Cd-resistant microbial consortia isolated from long term Cd-contaminated agricultural area of Western Thailand performed well with the Thai rice PSL2 cultivar widely-cultivated in this area. The inoculation of high metal-resistant and bioaccumulating microorganisms might hold promise to improve plant tolerance to metal stress.

Using 16S next generation sequencing, 3 top phyla including Proteobacteria (47.7%) Firmicutes (36.5%) and Bacteroidetes (15.5%) were detected across the culture enrichment period and accounted for 99.7% of total bacterial sequences. In the enriched consortia, predominant genera of detoxifiers of Proteobacteria (including *Arcobacter* sp., *Comamonas* sp., *Pseudomonas* sp., *Acinetobacter* sp., *Stenotrophomonas* sp., and *Delftia* sp.), Firmicutes (including *Leuconostoc* sp., *Enterococcus* sp., *Lactobacillus* sp., and *Lactococcus* sp.), and Bacteroidetes (including *Wautersiella* sp., *Myroides* sp., *Cloacibacterium* sp., *Paludibacter* sp.) were identified, among other genera. Bacteroidetes is regarded as a soil health indicator, and the prevalence of certain Proteobacteria and Firmicutes is positively associated with soil-borne disease suppressiveness (Sanguin et al., 2009). Previous reports have documented Cd resistance, bioaccumulation and biotransformation in microorganisms belonging to the *Acinetobacter, Agrobacterium, Arthrobacter, Bacillus, Cupriavidus, Flavobacterium, Mycobacterium, Pseudomonas, Rhotococcus, Aspergillus,* and *Trichoderma* genera (Belimov and Dietz, 2000; Belimov et al., 2005; Roane and Pepper, 2000; Siripornadulsil and Siripornadulsil, 2013). Certain metal-resistant microorganisms, such as *Pseudomonas, Cupriavidus, Bacillus* and *Acinetobacter*, confer beneficial properties for plant growth and development (e.g., nitrogen fixation, phosphate solubilization, and phytohormones production). Recently, an isolated strain of *Delftia* sp. could stabilize Cd by intracellular bioaccumulation, and thereby decrease Cd accumulation in rice grains (Liu et al., 2018). Above mentioned microbial strains would be potentially appropriate for Cd detoxification and bioremediation of Cd-contaminated soils, as well as sustainable plant growth.

Bacteria habituating in different microenvironments have varying adaptabilities to heavy metals. The currently recognized fundamental mechanisms of heavy metal resistance are: 1) metal biosorption on the bacterial cell wall; 2) intracellular sequestration of metal by thiol-rich proteins; 3) extracellular sequestration on biosurfactants; 4) metal complexation by sulfur and phosphate; and 5) metal efflux (Sharma and Archana, 2016). Cadmium resistance of soil bacteria primarily relies on active efflux of metal ions by P-type ATPases, cation diffusion facilitator (CDF) transporters, (cobalt/zinc/cadmium) CzcCBA transporters belonging to the resistance, nodulation, cell division (RND) type efflux pump, and chemiosmotic transporters. P-type ATPases and CDF transporters are

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1467914697

widely present in various bacterial species, while CBA transporter likely acts as determinant for a high-degree of heavy metal tolerance (Nies, 2003). In Gram-negative bacteria, such as *Pseudomonas aeroginosa*, Cd efflux is mediated by Czc-based zinc efflux and (nickel/cobalt/cadmium) Ncc-based nickel efflux systems in combination with the proton pump ATPase (Das et al., 2016; Hrynkiewicz et al., 2015). In Gram-positive bacteria, Cd efflux occurs by Cd-exporting P-type ATPase, so called CadA pump, first identified in *Staphylococcus aureus* (Silver et al., 1989). In addition, CadA-like proteins exist in other Gram-positive bacteria, such as *Bacillus* sp. and *Listeria* sp (Bruins et al., 2000). In this respect, detailed mechanistic studies underlying metal-immobilizing and plant growth-promoting capabilities of the target enriched microorganisms under various rice stages would be meaningful for optimization and further achievement of their efficient field performance.

The beneficial effect of these Cd-resistant microbial consortia was obvious, even at the high concentration Cd, as they could remove a certain amount of Cd (ca. 50% and higher) and had tolerance to Cd (up to 800 ppm). Thus, the utilization of these consortia will be a practical, cost-effective, biotechnological approach, which is an alternative to the hugely difficult or expensive and laborious physicochemical treatment of Cd-polluted paddy soil at a large scale. Regarding our findings, the indigenous Cd-resistant microbial consortia with bioremediating and plant-growth promoting potential would be useful to improve rice crop yield and quality in a sustainable, ecologically friendly manner.

Conclusions

Taken together, our findings demonstrated that the indigenous Cd-resistant microbial consortia were successfully propagated by repeated enrichment culture. They exhibited good performance on alleviating Cd phytotoxicity and lowering Cd bioaccumulation in the Thai rice cultivar (*Oryza sativa* L.) PSL2, resulting in better plant growth upon high Cd exposure level. The 3 top phyla represented in the detoxifying consortia included *Proteobacteria, Firmicutes,* and *Bacteroidetes* (e.g., *Acinetobacter* sp., *Comamonas* sp., *Enterococcus* sp., and *Pseudomonas* sp.) but other genera were also present. The enriched consortia showed Cd-removal capacities upon high Cd exposure level. These results highlight the great promise that such Cd-resistant microbial consortia hold for bioremediation of soils for producing low Cd-accumulating rice; however, further studies of the mechanisms underlying their metal-stabilizing effects resulting in healthy plants and field performance studies should be further undertaken for better understanding and appropriate implementation.

Abstract. Carbonic anhydrases (CAs, E.C.4.2.1.1) are an important metalloenzyme family that catalyzes reversible CO_2 hydration and HCO_3^- dehydration in organisms. CA inhibitors can be used in the treatment of many diseases such as glaucoma, epilepsy, obesity, and cancer. This study aimed to determine the effects of oil and methanol extracts of Cefan melon (*Cucumis melo* L.) seed (CMS) on CA enzyme activity. While both extracts activated hCA-I isoenzyme, they inhibited hCA-II. In order to determine the active substance causing inhibition or activation in CMS, essential oil content, phenolic substance profile and macro-micronutrient elements were investigated. Dominant fatty acids were identified as linoleic and oleic acid, while the dominant phenolic compound was gallic acid. Besides, it was found that CMS contained high concentrations of Ca, K and Na, and was rich in Se. Results demonstrated that essential oil and phenolic compounds in Cefan melon have potential applications as alternative natural products for pharmaceutical industries. In addition, Cefan melon seed has a wide range of applications for food and cosmetic industries based on the research into the fatty acid, phenolic content, and nutrient elements.
Keywords: *inhibition, activation, fatty acid, phenolic compound, ICP MS*

Introduction

Carbonic anhydrase enzymes (CAs, E.C.4.2.1.1), containing Zn^{2+} ion as a cofactor in their structure, belonging to the metalloenzyme class, alternately catalyze the hydration of CO_2 and dehydration of HCO_3^- (Supuran, 2008). CAs are encoded by different genes in many families. The class of α CAs which includes high vertebrate organisms contains 16 different isoenzymes. These isoenzymes are tissue-specific and could be seen in different compartments of cells, and they could be used as disease markers (Lehtonen et al., 2004; Cankaya et al., 2007; Uymaz, 2017; Akkemik et al., 2018). CAs are very important in terms of their physiological roles, and besides their role as being pH regulator enzyme, they are involved in many physiological and pathological events such as calcification, tumor growth and biosynthetic reactions such as urea synthesis, lipogenesis and gluconeogenesis (Scozzafava et al., 2006; Supuran, 2008). Inhibition or activation of these isoenzymes is of paramount importance in many diseases such as glaucoma, epilepsy, gastric, neurological disorders, obesity and cancer (Scozzafava et al., 2006; Supuran, 2008; Aggarwal et al., 2013; Uymaz, 2017). Also, it has been stated that CA activators could be used in the treatment of Alzheimer's disease (AD) (Dilek, 2017; Akkemik et al., 2018).

hCA-I in cell cytosol is involved in the process of pH homeostasis, respiration and erythroid differentiation (Chegwidden et al., 2000; Picaud et al., 2009; Hassan et al.,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1469914713

2013). What makes this isoenzyme important is its relationship with some pathological processes such as chronic acidosis, diabetic macular edema, proliferative diabetic retinopathy and vasogenic edema (Chegwidden et al., 2000; Picaud et al., 2009; Hassan et al., 2013). Furthermore, it has been stated that it is a biomarker for many cancer types such as colorectal cancer (Woolley, 1975), non-small cell lung cancer (Dodgson and Forster, 1985) and prostate cancer (Gay et al., 1984). The function of CA II is necessary for bone resorption, osteoclast differentiation and liquid secretion regulation to the ophthalmic anterior chamber. Recent findings suggest that CA II activity functions in connection with several ion carriers, and CA II act as mediators of certain metabolic pathways through providing additional substrates to balance cytosolic pH of carriers. As a result of these interactions, CA II is involved in the pathogenesis of various diseases such as glaucoma, renal tubular acidosis, cerebral calcification, hypertrophy of cardiomyocytes, growth retardation and osteoporosis (Coleman, 1975; Nishimori et al., 2007; Casey et al., 2009; Torring et al., 2009). Lack of expression and reduced or abnormal expression of these isoenzymes disrupt the balance of the system, which could lead to various diseases. Many synthetic drugs are used to reestablish and sustain this balance. However, synthetic drugs involve expensive synthesis and characterization procedures, and have many side effects. Phytotherapy using natural products has gained importance recently. However, a study examining the effects of melon on CA enzyme activity is not available in the literature.

Melon (*Cucumis melo*) belongs to the Cucurbitaceae family and is consumed commonly because of its pleasant aroma and flavor. Not only melon fruit but also its peel and seed are consumption material. Moreover, sufficient consumption of melon is beneficial for health. Given the 2017 data of FAO, 75% of melon production is realized in the Asia continent (FAOSTAT, 2018). While China ranks in the first place in world melon production with 17,082,608 tons, Turkey ranks second with 1,813,422 tons (FAOSTAT, 2018). There are many melon varieties grown in Turkey. Among the known medical uses of melon are the elimination of kidney stones, treatment of alcohol intoxication and even prevention of heart attacks (Van Wyk and Gericke, 2000; Nyam et al., 2009).

Therefore, In the present study, the effects of the oil and methanol extracts of Cefan melon on the activity of hCA-I and hCA-II isoenzymes were investigated the first time. We hypothesized that oil and methanolic extracts of Cefan melon seeds could exhibit different effects on two isoenzymes in a manner that will keep the system in balance to prevent the onset of diseases. Moreover, in order to determine the active substance causing inhibition or activation in Cefan melon seed, essential oil content, phenolic substance profile, and macro-micronutrient elements were investigated using GC-MS, HPLC, and ICP-MS.

Materials and methods

Melon seed material

Cefan melon (CM) is a melon variety growing in TRC3 region covering Siirt, Mardin, Batman and Şırnak in Turkey. Cefan melon was commercially purchased from markets, and maintained in Siirt University, Science and Technology Application and Research Center throughout the study. Dried seeds constituted approximately 6.6% of Cefan melon.

Extraction of phenolic compounds and oil

Extraction of oil was performed based on Malićanin method (Malićanin et al., 2014). This method was modified according to our laboratory conditions. For oil extraction, approximately 30 g of dried and the ground sample was wrapped in a filter paper and placed in Soxhlet extractor. 400 ml of petroleum ether was added in volumetric flasks which were placed on a hot plate. The condenser was adjusted, and the process was started. The extraction continued for 60 min at 23°C. Oil was purified by evaporating petroleum ether of oil mixture obtained at the end of the process in an evaporator (Hei Polphl/Heilbad-hei-vap evaporator). **The** extraction of phenolic compounds was performed according to method described by Xu et al. (2010). For the preparation of methanol extract, 5 g granulated melon seed was taken into a volumetric flask. 20 mL 1:1 distilled water: methanol mixture was added, and the flask was taken to a shaking water bath (Julabo/SW22) with 200 rpm at 50 °C for 2 h. After the incubation, centrifugation was performed at 5,000 rpm for 5 min (Thermo Scientific/Megafuge 16R). The supernatant was taken and used in furthers analyses. All analyses were replicated three times.

In vitro effects of phenolic compounds and oil extracts on human erythrocyte carbonic anhydrase I-II isoenzymes

Purification of CA I and II isozymes from human erythrocyte was performed in a single step by sepharose-4B-L tyrosine-sulfonamide affinity column. Erythrocyte was hemolyzed with iced pure water at 1:5 (v:v) ratio. The hemolysis solution was centrifuged at 10.000×g for 30 min and the upper layer of hemolysate was collected. The pH of the hemolysate was adjusted to 8.7 with solid Tris. Then, the hemolysate was applied to the affinity column pre-equilibrated with 25 mM Tris-HCl/0,1 M Na_2SO_4 (pH 8.7) and the column was washed with 25 mM Tris-HCl/22 mM Na_2SO_4 buffer (pH 8.7). The washing process was continued until the absorbance difference of eluate and equilibration buffer reached to 0.05 at 280 nm. Then 1 M NaCl/25 mM Na_2HPO_4 (pH 6.3) and 0.1 M $NaCH_3COO$/0.5 M $NaClO_4$ (pH: 5.6) buffers were used to elute the hCA-I and hCA-II isoenzymes, respectively. All experiments were carried out at +4 °C (Akkemik et al., 2018). The presence of the enzymes in tubes was determined by measuring the absorbance at 280 nm using elution buffers as blind samples. Then, the enzyme solution was dialyzed against 0.05 M Tris-SO_4 (pH 7.4). The enzyme purity was checked with 3-10% SDS-PAGE in accordance with Laemmli procedure (Protein Standard; Abcam Inc USA, ab48854) (Laemmli, 1970). Protein determination was performed using the Bradford assay (Bradford, 1976). The esterase activity assay of the hCA isozymes was conducted spectrophotometrically by following the change in absorbance at 348 nm of 4-nitrophenol produced from 4-nitrophenylacetate by CA catalyzed reaction. The reaction mixture contained 0.05 M Tris-SO_4 (pH 7.4), 3 mM p-nitrophenol acetate, distilled water and enzyme solution (Verporte et al., 1967; Akkemik, et al., 2018). To determine the inhibitory effect of samples on hCA isoenzymes I and II, esterase activity was measured on samples at five different concentrations. Control cuvette activity was accepted as 100% in the absence of inhibitor. An Activity % − [Extract] graph was drawn for each extract. Calculation of K_i constants was performed using the Cheng–Prusoff equation (Cheng and Prusoff, 1973). VWR UV-6300PC double beam spectrophotometer was used in all spectrophotometric analyses. All analyses were replicated three times.

Essential oil, phenolic acid and nutrient element composition analyses of Cefan melon

All content analyses in this study were performed in Siirt University, Science and Technology Application and Research Center.

Analysis of essential oil content by GC-MS

The fatty acid analysis was performed using a GC-MS Thermo/ISQLT series Gas chromatograph-mass spectroscopy (GC-MS, Thermo Fisher Scientific, the US) based on the method described by Kılıçoğlu (2018) with a slight modification. **The** GC-MS analysis was conducted with helium gas (1.2 mL/min) in the Thermo Scientific TG-WAXMS column (60 m-0.25 mm, 0.25 µm film thickness). GC furnace temperature was kept at 70 °C for 6 min, then increased to 230 °C at a rate of 4 °C/min and was finally kept stable for 15 min at this temperature. Purge flow was adjusted to 5.0 mL/min. The split flow was adjusted to 6.0 mL/min and injection volume was 1 µL. Mass spectrometer scan range was adjusted to m/z 50-550 atomic mass unit (amu) and screening time was adjusted to 0.2 s. NIST and Wiley GC-MS libraries were used in the determination of the components. The relative percentages of the separated components were calculated from the total ion chromatography through the digital integrator. These analyses were replicated twice.

Analysis of phenolic acid composition by HPLC

The methanol extract was added to vials using 0.22 µm filters. The phenolic composition analysis was performed by a Thermo/DIONEX Ultimate 3000 series high-performance liquid chromatography (HPLC-DAD, Thermo Fisher Scientific, the US) based on the method described by Duran (2014) with a slight modification (Montealegre et al., 2006; Duran, 2014). HPLC was performed with a C-18 Inertsil ODS-3 column (5 µm particle, 4.6 × 250 mm ID) which was equipped with a UV detector. The UV detector absorbance was monitored at 280 nm. The mobile phases consisted of solvent A (98: 2 (Water: Formic Acid)) and solvent B (78: 20: 2 (water: Acetonitrile: Formic Acid)). The flow rate was set at 0.75 ml/min, and the column temperature was maintained at 28 °C throughout the test. Gallic acid (60 ppm), chlorogenic acid (40 ppm), caffeic acid (38 ppm), 4-hydroxybenzoic acid (50 ppm) and vanillic acid (56 ppm) were used as standards (*Table 1*). The sample injection volume was 20 µL. The concentrations of phenolic acids in the sample were calculated using standard curves from a plot of peak areas versus levels for a series of standard solutions. The results were multiplied by the dilution factor. These analyses were replicated three times.

Table 1. *Analytical parameters for HPLC-DAD analysis*

No	Compounds	UV	Coeff. det %	Linearity range (ppm)	Slope
1	Gallic acid	280	99.9039	60-6.0	0.8979
2	Chlorogenic acid	280	99.7478	40-4.0	0.6237
3	Caffeic acid	280	99.9179	38-3.8	0.5663
4	4-Hydroxy benzoic acid	280	99.9734	50-5.0	1.3758
5	Vanillic acid	280	99.9868	56-5.6	0.6652

Determination of nutrient elements by ICP-MS

For the inductively coupled plasma-mass spectrometry (ICP-MS) technique, 0.2-0.4 g of Cefan melon seeds were dissolved in 6 mL of concentrated nitric acid (65%) and 2 mL hydrogen peroxide (30%), digested in a microwave system (Berghof Microwave Digestion Speedwave MWS-2), and then decomposed 15 min at 180 °C. After cooling, the preparation was filtered. One milliliter of each filtrate was pipetted into a falcon tube and diluted to 25 mL with ultrapure water. All samples were then placed in the ICP-MS autosampler unit (Thermo Scientific iCAP Q, 02878R ICP-MS; Plasma power, 1550 W; nebulizer flow, 1.17/min; cooling flow, 14/min; auxiliary flow, 0.8/min). These analyses were replicated at least three times (Kuru et al., 2019). The mean values of three measurements were calculated. Calibration solutions were prepared at six different concentrations ranging from 25.00 to 1000.00 ppb using standard solution (ICP Multielement Standard; Sigma Aldrich-1.11355) (*Table 2*).

Results and discussion

CAs that are the subject of the present study have roles in pH regulation in living organisms, and they serve as one of the major buffering systems. Further, they take part in biosynthetic reactions such as urea synthesis, lipogenesis and gluconeogenesis (Scozzafava et al., 2006; Supuran, 2008). However, enzymes of this family are disease markers or disease factors in many physiological and pathological processes such as calcification, tumor formation and Alzheimer's (Scozzafava et al., 2006; Supuran, 2008; Aggarwal, 2013; Akkemik et al., 2018). For this reason, inhibition or activation of these isoenzymes is of high importance in many diseases. For example, currently, CA inhibitors are used in the treatment of various diseases such as glaucoma, epilepsy, gastric and neurological disorders, obesity and cancer (Scozzafava et al., 2006; Supuran, 2008; Aggarwal et al., 2013). There are many studies reporting that activators can be used in AD treatment (Dilek, 2017; Uymaz, 2017; Akkemik et al., 2018). Considering the side effects and high costs of synthetic drugs, demand for natural products has been increasing. Therefore, effects of Cefan melon seed extracts on hCA-I and hCA-II isoenzymes have been investigated in the present study.

The undesirable side effects of synthetic drugs have started to direct many people to natural products. Therefore, research on treatment with natural products has begun to gain popularity. Furthermore, inhibition or activation effects of many plant extracts on carbonic anhydrase enzyme activity have been investigated. In a study the effects of black, green and white, and herbal teas on bovine and human erythrocyte carbonic anhydrase were investigated (Karaçelik, 2018). In a different study, inhibition effects of *Artemisia dracunculus* L. extracts were investigated against hCA I-II (Yurtvermez, 2016). In another study effects on hCA I-II enzymes activities of *Ferula rigidula*, *Eremurus spectabilis*, *Rheum ribes* and *Prangos ferulacea* taxa were determined (Sevim, 2018). There are many studies wherein the effects of plant extracts on different enzymes or properties are investigated (Oluba et al., 2007; Bangou, 2011; Sacan, and Yildiz, 2014; El-Hadary and Ramadan, 2019).

Cefan melon was chosen as the subject of the present study because it is a lesser known type of melon, although it is common in a small geographic region. Moreover, it has a sour taste in contrast to other melon species. To our best knowledge, inhibition or activation effects of Cefan melon seed on hCA I-II were determined first time. Two isoenzymes of carbonic anhydrase enzyme were initially purified. For this purpose, sepharose 4B-L-tyrosine-sulfonamide activated with cyanogen bromide affinity column was used. Enzyme purity was checked with SDS-PAGE (*Fig. 1*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1469914713

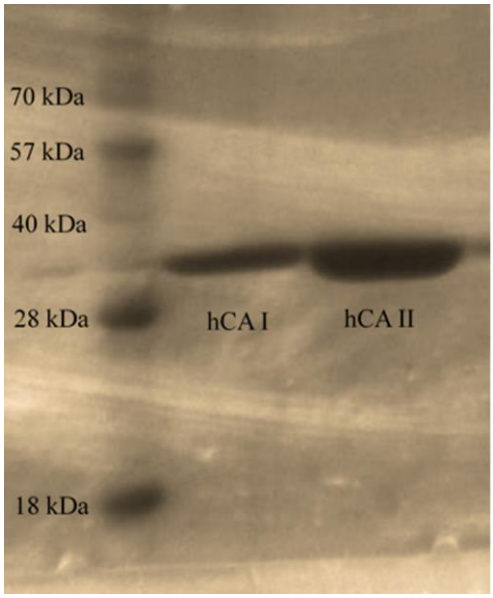

Figure 1. *SDS-PAGE bands of hCA I and hCA II*

The effects of oil and methanol extracts of melon seed on hCA-I and hCA-II were investigated *in vitro* conditions (*Fig. 2*). While both extracts activated hCA-I isoenzyme (AC_{50} 0.333 ng/mL and 80.369 µg/mL, respectively), they inhibited hCA-II isoenzyme (IC_{50} 0.497 ng/mL and 10.98 µg/mL, respectively) (*Table 3*).

Furthermore, the active substance causing inhibition and activation effect in the Cefan melon seeds was also investigated in the present study. Therefore, the oil content was determined by GC-MS, while phenolic substance content was analyzed using HPLC and nutrient content using ICP-MS.

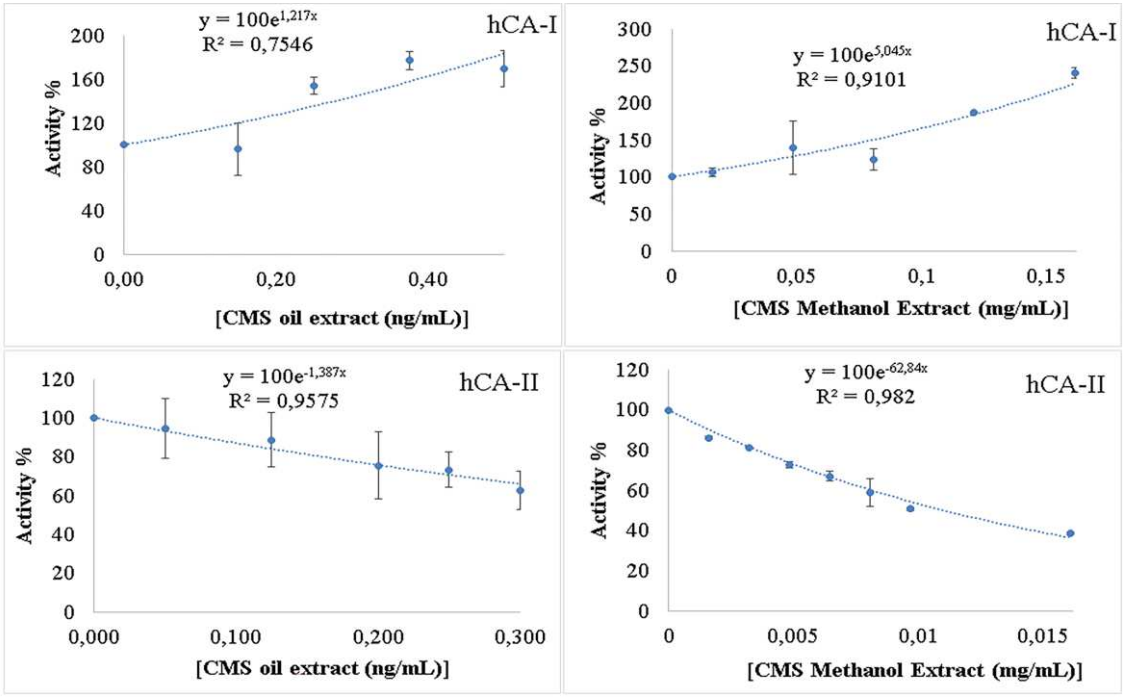

Figure 2. *Effects on hCA I and hCA II of melon seed oil and methanol extracts*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

Table 3. *Effect of extracts on isoenzymes of human carbonic anhydrides I and II*

Sample	Melon seed oil extract		Methanol extract	
Enzyme	**hCA-I**	**hCA-II**	**hCA-I**	**hCA-II**
AC_{50}	0.333 (ng/mL)	-	80.369 µg/mL	-
IC_{50}	-	0.497 ng/mL	-	10.98 µg/mL
R^2	0.7546	0.9575	0.9101	0.9820
K_i	-	0.369±0.166 ng/mL	-	7.25±0.400 µg/mL

In the present study, Cefan melon seed was found to contain approximately 25.00 ± 0.01% crude oil. Seeds of different melon cultivars contain about 33.0% crude oil (Ramakrishna et al., 1970; Teotia and Ramakrishna, 1984; Mello et al., 2001; Kale, 2017). Crude oil extracts obtained were analyzed for fatty acid contents in the GC-MS device. It was found out that the dominant fatty acids in melon seed oil were linoleic and oleic acids (*Table 4*). Unsaturated fatty acids constituted 67.09% of total fatty acids in melon seed oil extract.

Table 4. *GC-MS data of melon seed oil extract*

Seed oil acids	Retention time (min)	%
Linoleic acid (18:2)	48.33	33.13
Oleic acid (18:1)	47.13	26.24
Palmitic acid (16:0)	42.03	12.24
Stearic acid (18:0)	46.59	7.96
N-decylbenzene ($C_{16}H_{26}$)	35.69	7.76
γ-Linolenic acid (18:3)	50.84	4.48
Dimethylamine, N(Neopentyloxy)	44.31	3.29
α-Linolenic acid (18:3)	58.02	3.24
Octadecanoic-D4 acid	48.91	33.13

Inhibitors of hCA-II are used in the treatment of diseases such as glaucoma and epilepsy. Inhibition of hCA-II by very low concentration of both extracts in the present study indicates that both extracts could be efficiently used in the treatments of these diseases. However, an evaluation of IC_{50} value revealed that oil extract was more effective compared to methanolic extract, possibly because Cefan melon seeds contain a considerable amount of unsaturated fatty acids. Most of these unsaturated fatty acids were essential fatty acids. They are the fatty acids that must be taken through food. Inadequate unsaturated fatty acid intake through food may lead to many diseases such as cardiovascular disease, AD, depression, osteoporosis, and prostate, breast, intestinal and lung cancers (Liperoti et al., 2009; Lee and Park, 2014; Bentsen, 2017). Therefore, Cefan melon seed oil extract may provide a cure for diseases like glaucoma, epilepsy, etc.

The predominant fatty acids in the extracted Kalahari melon seed oil were linoleic (62.2–63.1%), oleic (16.8–17.1%), palmitic (11.4–12.4%), stearic (7.5–8.1%), linolenic (0.7–1.2%), and eicosenoic acids (0.3%) (Nyam et al., 2009). Another study mentioned that although the seeds of a different melon variety contained unsaturated fatty acids such as palmitic and stearic acids, the dominant fatty acid was unsaturated ones,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1469914713

especially linoleic and oleic acids (Mehra et al., 2015). Similarly, as a result of the analysis conducted in the seed oil of 10 different kinds of melon, it was stated that they contained 57.14-74.66% linoleic acid, 12.95-28.37% oleic acid, and 6.98-10.07% palmitic acid (Kale, 2017). Comparing the data from the present study and results in the literature, we could say that the fatty acids are similar. However, they vary in terms of amount. For example, Cefan melon seed contained relatively less linoleic acid.

An *in vitro* study was performed to investigate the effect of oil extract of melon seeds on serum lactate dehydrogenase, alanine transaminase, aspartate transaminase and γ-glutamyl transpeptidase levels in rats. It was reported that activities of the specified enzymes were lower in rats fed with melon seed oil extract (Oluba et al., 2007). Their results demonstrated that melon seed oil extract has a regulatory role in metabolism and this finding supports our results.

The methanolic extract showed an activation effect on hCA-I activity, whereas its effect on hCA-II activity was inhibitory. There was an 8-fold difference in the concentration range at which methanolic extract was effective on hCA-I and hCA-II. Different effects in different doses of both isoenzymes lead to selective inhibition. This finding showed that the inhibition effect was more pronounced.

In our study, the main phenolic compound in Cefan melon seed was found to be gallic acid. According to the HPLC results, Cefan melon seed contained 247.401 ± 5.9816 ppm gallic acid, 50.1811 ± 8.8379 ppm chlorogenic acid, 3.6850 ± 1.5866 ppm 4-hydroxybenzoic acid and 2.7173 ± 1.8528 ppm vanillic acid while caffeic acid was not detected (*Fig. 3*). In a study where a phenolic analysis was conducted both in peel and seeds of a kind of melon grown in Brazil, it was stated that gallic acid was the dominant phenolic compound in both samples, which also contained catechins, salicylic acid, and eugenol (Rolim, et al., 2018). Furthermore, they also found that the peel extract contained more phenolic acid compared to seeds (Rolim et al., 2018). In a different study, it was stated that gallic acid, caffeic acid, and catechins were dominant phenolic compounds in melon seed extract (Zeb, 2016). In a study where a phenolic analysis was conducted in peel, fruit, and seeds of Cefan melon, it was stated that gallic acid was the dominant phenolic compound in all samples (Özbek, 2019). A comparison of the results from the present study with the data in the literature showed that the content and concentration of the phenolic compounds vary in different varieties grown in different areas of the world, which could be due to climatic conditions (Zeb, 2016; Rolim et al., 2018).

While phenolic compounds were suggested to cause inhibition by interacting (through hydrogen bonding) with water molecules around Zn^{2+} in the active region of the carbonic anhydrase enzyme (Durdagi et al., 2011), no clear mechanism for the activation was proposed. In our study, the gallic acid was dominant compared to other phenolic compounds in methanol extract. Therefore, although oil and methanol extracts were expected to inhibit both isoenzymes, they activated hCA-I isoenzyme. These results were somewhat surprising. Gallic acid was dominant in the methanol extract in CMS, but the activation or inhibition effect was not necessarily related to that compound since no purified gallic acid was used in the experiments. This effect could be due to the mixing of phenolic compounds. However, given the selective inhibition or activation effect, these findings are very important.

In a study where mineral content was conducted in peel, fruit, and seeds of Cefan melon, it was seen that different the results were obtained from our study. There were some deficiencies in Özbey's (2019) study. For example, the method was not explicitly

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1469914713

stated in the relevant study. And also results of Özbey (2019) were not explained in detail.

In our study, oil and methanol extracts had different effects on the activities of the two isoenzymes. We believe that this could be caused by the mineral content of the Cefan melon seed extract. For this purpose, elemental content was analyzed by ICP-MS in melon seed extract.

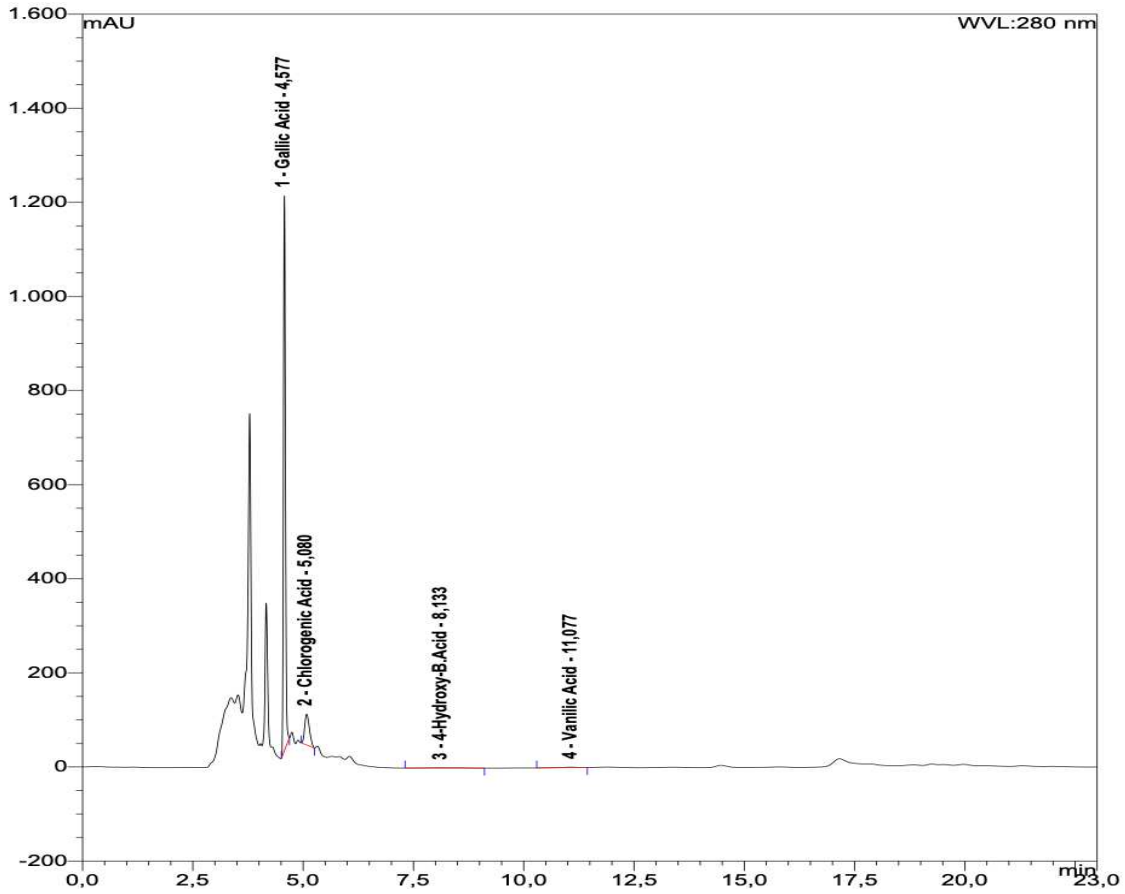

Figure 3. *HPLC chromatogram of Cefan melon seed*

Mineral content was also analyzed using ICP-MS. The mineral analysis of Cefan melon seeds showed that they were rich in calcium (6960.59 ± 220.66 ppm), sodium (4059.93 ± 80.199 ppm), potassium (1291.18 ± 44.49 ppm) and magnesium (858.534 ± 20.173 ppm). Moreover, Cefan melon seeds contained low levels of aluminum (361.247 ± 10.852 ppm), iron (326.523 ± 13.409 ppm), molybdenum (278.718 ± 7.1555 ppm), chrome (143.515 ± 4.3967 ppm) and selenium (141.241 ± 14.824 ppm) (*Table 5*). Data obtained in the present study indicated that 48% of inorganic matter in Cefan melon seed was Ca.

Analysis of Cefan melon seed showed that it contained metals of the 1A and 2A group as well as the transition metals. It was reported that groups containing free OH interact with heavy metals and transition metals, whereas those containing benzene ring interact with alkaline and alkaline earth metals (Çalışır, 2014). hCA-I and hCA-II contain about 260 amino acids, but amino acid sequences show only 60% similarity. (Hassan et al., 2013). In other words, their amino acid sequences are quite different.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1469914713

While CA isoenzyme, which has a high number of aromatic amino acids, interacts with alkaline and alkaline earth metals, the isoenzyme which contains a higher amount of amino acids such as serine and threonine interacts with heavy metals and transition metals. Therefore, they may not give the same response to inhibitors and activators.

Conclusion

Cefan melon seed is rich in phenolic compounds, unsaturated fatty acids, calcium, sodium, potassium, and magnesium. Thus, Cefan melon seed, which was found to have beneficial *in vitro* effects, could be useful in different food or cosmetic products because of active substances in it. In addition, extracts can also be used as alternative natural sources for the treatment of different diseases. Our study could be evaluated as a preclinical study. Preclinical studies are needed for clinical studies. Therefore, the present study provides the information needed by many researchers conducting *in vivo* studies. In the present study, oil and methanol extracts of Cefan melon seed showed different effects on hCA I-II activity. Synthetic drugs involve expensive synthesis and characterization procedures and have many side effects. Therefore, Cefan melon seed may be preferred instead of synthetic drugs in the treatment of diseases such as glaucoma, epilepsy, gastric, neurological disorders, obesity, cancer, and AD. Clinical trials are needed to indicate the potency of a chemical as a drug. Therefore, it would be useful to conduct clinical studies with melon seed extracts for the treatment of the above-mentioned diseases.

CURING THE DRUG RESISTANCE PLASMID IN *E. COLI* O157:H7

OZDEMIR, K.

Department of Basic Science, Faculty of Engineering and Natural Science, Bandırma Onyedi Eylül University, Balikesir, Turkey
(e-mail: keremozdemir@bandirma.edu.tr; phone: +90-532-609-0335)

(Received 12th Jun 2019; accepted 25th Oct 2019)

Abstract. In this study, twenty five isolates of *E. coli* O157:H7 were identified among 200 samples taken from children under ten years old suffer from diarrhea. Isolates were identified from stool sample by using cultural, morphological, biochemical characteristics and serological test. The plasmid profile has been conducted by using gel electrophoresis. To control the antibiotic resistance of the tested *E. coli* O157:H7 isolates, curing of plasmid DNA was conducted using Ethidium bromide (EB) and elevated temperature (ET) at 46 °C. One of the most resistance isolate was chosen for this purpose E15 then treated with Ethidium bromide at 125 μg/ml. The results revealed that the genes encoded resistance to AK (Amikacin), CIP (Ciprofloxacin), CN (Gentamicin) and TMP + SXT (Trimethoprim + Sulphamethoxazole) (were cured from E15 and the percentage of curing was 28.57%. The results confirmed by conducting gel electrophoresis and showed that EB removed three plasmid of E15, while two plasmids remained. On the other hand, elevated temperature used also as curing agent for the same isolate and the results revealed that resistance to AK, CIP, CN and TMP + SXT genes were cured from E15 and the curing percent was 35.71% after incubating the isolate at 46 °C. The results confirmed by conducting gel electrophoresis and showed that tested isolate lost three plasmids after incubation at 46 °C.
Keywords: *E. coli O157:H7, antibiotic resistance, plasmid profile, plasmid curing*

Introduction

The human large intestine ordinarily harbors a huge microbial population, most bacterial, protozoan, and viral agent of diarrhea are not members of this normal gut flora but are acquired through contaminated food or water (Talaro and Talaro, 2002). *Escherichia coli* O157:H7 is an emerging public health concern in most countries of the world (Schlundt, 2001). It is an important cause of foodborne human disease. Complications related to infection include diarrhea, hemorrhagic colitis, and hemolytic uremic syndrome (Nataro and Kaper, 1998). The constant increase in the antibiotic resistance of clinical bacterial strains has become an important clinical problem (Adamus-Bialek et al., 2013). This is a major problem in the world now "antibiotics resistance", so the medicine manufactures which yearly produced new generations of antibiotic to solute this problem, specially there are some bacteria considered a multiple antibiotic resistance as *Escherichia coli*, *Klebsiella* and others (Al-Faisal, 1999). Plasmids allow the movement of genetic material, including antimicrobial resistance genes between bacterial species and genera (Hamad, 2009). Antimicrobial resistance (AMR) is a global problem hindering treatment of bacterial infections, rendering many aspects of modern medicine less effective. AMR genes (ARGs) are frequently located on plasmids, which are self-replicating elements of DNA. They are often transmissible between bacteria, and some have spread globally. Novel strategies to combat AMR are needed, and plasmid curing and anti-plasmid approaches could reduce ARG prevalence, and sensitise bacteria to antibiotics (Michelle et al., 2018).

Antibiotic resistance increases the likelihood of death from infection by common pathogens such as Escherichia coli and Klebsiella pneumoniae in developed and developing countries alike. Most important modern antibiotic resistance genes spread

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1471514727

between such species on self-transmissible (conjugative) plasmids. These plasmids are traditionally grouped on the basis of replicon incompatibility (Inc), which prevents coexistence of related plasmids in the same cell. These plasmids also use post-segregational killing ('addiction') systems, which poison any bacterial cells that lose the addictive plasmid, to guarantee their own survival (Kamruzzaman et al., 2017).

Between 2000 and 2010, global human use of antibiotics increased by 36%, and the use of two last-resort antibiotics, carbapenems and polymyxins, increased by 45% and 13%, respectively (Van Boeckel et al., 2014). Antimicrobials have many non-human uses including in animals for growth promotion, veterinary treatment and aquaculture (Vyas and Piddock, 2015; Van Boeckel et al., 2015). In 2013, an estimated 131 109 tons of antimicrobials were used globally in food animals; by 2030 this is expected to increase to 200 235 tons (Van Boeckel et al., 2017). However, there is a growing trend to improve antimicrobial stewardship in many countries. For example, in Switzerland veterinary antimicrobial sales increased between 2006 and 2008, but then steadily decreased, reaching a 26.2% reduction in 2013 (Carmo et al.2017). In addition to human and animal use, many cleaning and personal hygiene products contain biocides, such as triclosan, which can select for mutants resistant to biocides, and in some cases to antibiotics used in medicine (Vyas and Piddock, 2015; Webber et al., 2015, 2017).

Plasmid curing is the process by which plasmids are removed from bacterial populations. This is an attractive strategy to combat AMR (antimicrobial-resistant) as it has the potential to remove ARGs (AMR genes) from a population while leaving the bacterial community intact. This means, for example, that the structure of the gastrointestinal microbiome of a chicken treated with a plasmid curing agent might remain largely unchanged, but potentially pathogenic bacteria which may unfortunately be transmitted into the food chain would be susceptible to antibiotics. Alternatively, a plasmid curing agent could be given to a patient prior to surgery, to reduce the likelihood of a resistant hospital acquired infection. Plasmid curing agents could also be taken by international travellers to reduce the global spread of AMR. Unfortunately, at the moment no such treatment options are in use. In fact, there are very few curing mechanisms that have been tested in vivo, even in experimental models. Therefore, research in this area is urgently needed. Recently, it was shown that 24% of non-antibacterial drugs impact growth of members of the human microbiome (Maier et al., 2018). Studies such as this would be important for determining any impact of anti-plasmid compounds on the microbiome.

The risk of *E. coli* O157:H7 occurs in its plasmid, because of its ability to transfer plasmids to other bacteria or other strains of *E. coli* by transformation, conjugation and transduction processes (Jawetz et al., 2004). Therefore, controlling and elimination of the resistance that conferred by R -plasmid by using biological mutagen, physical and chemical or other curing agents will be quite useful to eliminate such resistance (Jawetz et al., 2007). For this reasons this study concerned with the isolation and identification of *E. coli* O157:H7 from children suffering from diarrhea, study the antimicrobial resistance patterns of the isolated *E. coli* O157:H7 to different antibiotics, characterization of the plasmid DNA profile pattern of the isolates using gel electrophoresis technique, and elimination of the bacterial resistance to antibiotic for some isolates by curing using ethidium bromide and elevated temperature.

Materials and methods

Specimen collection

The samples were collected during the period 20st May 2013 to 1th November 2013. A total of two hundred (200) stool specimens were collected from infants and children (68 males and 132 females), aged one day- 10 years attending Rapareen Teaching Hospital for Children in Erbil City (Iraq) and the relevant information were recorded from each patient including age and sex. All stool samples were collected in clean disposable plastic containers from diarrheal patient**.** The specimens were transferred to the laboratory and processed within half an hour of collection.

Bacterial identification

Bacterial isolates were identified by performing morphological, cultural, biochemical, and serological test.

Antibiotic susceptibility test

To study the effect of different antibiotics on the isolates of *E. coli* 0157:H7, Mueller-Hinton agar was used as growth media (Wayne, 2005). Antibiotic resistance patterns of the isolates were determined using the Disc diffusion (Kirby Bauer) method; bacterium inoculate was adjusted to 0.5 McFarland standard of Clinical and Laboratory standards institute (Clinical and Laboratory Standard Institute, 2007). The test inoculums were spread onto Muller-Hinton agar using a sterile cotton swab. The tested antimicrobial agents were aseptically placed on the inoculated Muller Hinton agar and incubated overnight. The zones of inhibition were measured and interpreted according to (Clinical and Laboratory Standard Institute, 2007).

Plasmid DNA extraction (Gene Aid Company) laboratory protocol

Plasmid DNA was extracted and purified from 5 ml overnight culture of the selected isolates of the *P. mirabilis* grown in LB broth medium containing 100 µg/ml Ampicillin using a plasmid DNA purification kit, according to the manufacturer's instructions. A single bacterial colony was used to inoculate 5 ml LB, which was incubated overnight in a shaker incubator at 37 °C. A volume of 3 or 5 ml of each isolate in an eppendorf tube was centrifuged for 30 s at 13,000 rpm and the supernatant discarded. The bacterial pellet resuspended by vortexing in 250 µl of resuspension buffer (RNase A solution was added), until no clumps of the cell pellet remain. Two-hundred and fifty µl of lysis buffer added to resuspended cells and the tube closed and gently mixed by inverting the tube several times without vortexing. Three-hundred fifty µl of neutralization buffer was added and gently mixed by inverting the tube several times. Resuspended cells centrifuged at 13,000 rpm for 10 min at 4 °C, then a column inserted into collection tube. After centrifugation, supernatant transferred promptly into the column, and centrifuged at 13,000 rpm for 60 s. The column removed from the collection tube, the filtrate in collection tube discarded. The spin column placed back in the same collection tube. Five hundred µl of washing buffer A added and centrifuged at 13,000 rpm for 60 s. The column removed from collection tube, the filtrate discarded in collection tube, and then placed the spin column back in the same collection tube. Seven-hundred µl of washing buffer B was added, centrifuged at 13,000 rpm for 60 s. The filtrate discarded in collection tube and column placed back in the same collection tube, Centrifuged at

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1471514727

13,000 rpm for 60 s to dry the filter membrane. The column put in a clean and sterile eppendorf. Fifty µl of elution buffer added to the upper reservoir of the column, and let stand for 1 min. Then, the tube centrifuged at 13,000 rpm for 60 s. The purified DNA plasmid used immediately in downstream applications or store at -20 °C (Manufacturer protocol).

Plasmid profile

The extracted plasmids were electrophoresed in 0.7% agarose gel with Tris-borate ethylene diamine tetra-acetic acid (TBE), Agarose gel electrophoresis was used to separate DNA fragments according to size, 0.7% (w/v) agarose gel was made by adding 0.7 gm of agarose to 100 ml of 1X TBE buffer solubilized by heating at boiling temperature in microwave oven for 2 min, then the agarose was left to cool down at 55 °C before pouring in a tray to solidify. A comb was placed near one edge of gel, and gel was left to harden. After gel solidification, the comb was removed gently and the gel was soaked in a gel tank contain 1X TBE buffer and the placement of the gel in the tank should be in a way that the wells located on the negative (cathode) pole. The amount of TBE buffer had to be sufficient to cover about 2-3 mm of the gel, 1 kb DNA ladder (Fermentas) was used as molecular size marker of DNA fragment, 3µl of loading buffer was mixed with 10 µl plasmid DNA extract, and then samples were added carefully to individual wells. After loading the samples into wells, the power supply was set on 45 V for 15 min. Then the voltage changed to 75 V and the gel was run for 90 min. until the bromophenol blue dye migrated to the other end of the gel. The gel was immersed in ethidium bromide (0.5 µg/ml of D.W.) for 30-45 min. The gel was visualized by UV-trans illuminator and then photographed (Sambrook and Russella, 2001).

Ethidium bromide as a curing agent

Curing by ethidium bromide was done by the procedure mentioned by (Tomoeda et al., 1974). Five ml of LB broth containing appropriate antibiotic at final concentration inoculated with single colony of *E. coli* O157:H7 isolate, incubated at 37 °C for 24 h, after overnight 0.1 ml of the broth bacterial culture were inoculated into 5 ml LB broth containing 125 µg/ml of ethidium bromide agents and incubated with shaking at 37 °C for 48 h. Serial dilutions were prepared up to 10^{-6}, 0.1 ml from the last three dilutions were spread onto nutrient agar plates and incubated at 37 °C for 24 h. After incubation time, fifty colonies were transferred to nutrient agar plate and incubated over night at 37 °C representing the master plate. Five colonies were randomly chosen, picked up and transferred to Muller Hinton agar plates and tested for antibiotic sensitivity pattern, incubated at 37 °C for 24 h. After overnight incubation the percentages of curing colonies for antibiotic sensitivity pattern were calculated.

Curing of plasmid DNA by elevated temperature

This curing was carried out according to (Baldwin and Strickland, 1969). Ten ml of LB broth inoculated with single colony of *E. coli* isolate, after inoculation for 24 h at 37 °C, 10 ml LB broth culture inoculated with 0.2 ml of bacterial culture, incubated with shaking (100 rpm at 46 °C for 24 h), serial dilutions were prepared up to 10^{-7}, then 0.1 ml from last three dilutions spread on nutrient agar plates and incubated at 37 °C for 24 h. After incubation time, fifty colonies were transferred to nutrient agar plate and incubated over night at 37 °C representing the master plate. Five colonies were

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1471514727

randomly chosen, picked up and transferred to Muller Hinton agar plates and tested for antibiotic sensitivity pattern incubated at 37 °C for 24 h. After overnight incubation the percentages of curing colonies for antibiotic sensitivity pattern were calculated.

Antibiotic resistance pattern after plasmid curing

The colonies were screened for antibiotic resistance by the disk diffusion method after curing. Cured markers were determined by comparison between the pre- and post-curing resistance pattern of isolates. Loss of resistance markers gave an indication that those markers were probably located on plasmid and not on the chromosome.

Results and discussion

Identification of E. coli O157 isolates

They produce bright metallic green sheen colonies on Eosin Methylene Blue (EMB) agar and on Sorbitol MacConkey agar colonies of *E. coli* O157:H7 appear as colorless colony due to non sorbitol fermenting which consider as a selective media (Wistreich and Lechtman, 1980). Bacterial cells from smear preparation are gram negative short rods, motile, non-spore forming and presumptively are *E. coli* O157:H7 which in accordance with previous observations (Sharma et al., 2007). The biochemical tests for all bacterial isolates were negative for citrate, oxidase and urease production test, but they were positive for catalase and indole test. On Kligler Iron Agar (KIA) medium, all isolates of *E. coli* understudy produce a yellow slant and a yellow butt A/A reaction due to the fermentation of lactose and glucose and negative for H_2S production (Wistreich and Lechtman, 1980).

Serological test

Samples serotyped by application of solid agglutination test, using anti *Escherichia coli* O157:H7. Once the agglutination was detected, the reaction was considered positive according to the materials used. Three drops of physiological normal saline were added on a clean slide, and then with the aid of the loop, a small piece of fresh bacterial growth was mixed with the 3 drops in order to obtain a homogenous mixture. After that a drop of polyvalent antisera was added to the two drops (mixture) while the third drop was considered as control test. The appearance of clear agglutination within 1 min indicates a positive result.

Antibiotic sensitivity test

Antibiotic sensitivity testing was done for all isolates by using fourteen antibiotic types which include amikacin (AK), ampicillin (AMP), chloramphenicol (C), cephalothin (KF), ciprofloxacin (CIP), cefepime (FEP), ceftriaxone (CRO), cefotaxime (CTX), gentamicin (CN), imipenem (IPM), metronidazole (MET), tetracycline (TE), trimethoprim (TMP) and trimethoprim + sulphamethoxazole (SXT). Antibiotic discs of Amikacin (30 μg), Imipenem (10 μg), Ampicilin (25 μg), Gentamicin (30 μg), Chloramphenicol (30 μg), Cephalothin (30 μg), Ciprofloxacin (10 μg), Cefepime (30 μg), Cefotaxime (30 μg), Ceftriaxone (30 μg), Metronidazole (5 μg), Tetracycline (30 μg), Trimethoprim (5 μg) and Sulphamethoxazole (25 μg) were applied on the plates. The resistance rate of the isolates toward these antibiotics were 100% for AMP,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1471514727

96% for MET, 76% for CTX, 72% for TE and KF, 68% for TMP, 56% for FEP, 52% for C and SXT, 48% for CRO, 28% for AK, 20% for CIP, while the lowest percent 16% was for CN, and all isolates were sensitive for IPM (*Table 1*).

Table 1. *Percentages of resistance of bacterial isolates to different antibiotics*

Antibiotics	Abbreviation	No. of Isolates	Resistant percentage of resistance %
Amikacin	AK	7	28
Ampicillin	AMP	25	100
Chloramphenicol	C	13	52
Cephalothin	KF	18	72
Ciprofloxacin	CIP	5	20
Cefepime	FEP	14	56
Cefotaxime	CTX	19	76
Ceftriaxone	CRO	12	48
Gentamicin	CN	4	16
Imipenem	**IMP**	**0**	**0**
Metronidazole	MET	24	96
Tetracycline	TE	18	72
Trimethoprim	TMP	17	68
Sulphamethoxazole	SXT	13	52

IPM was the most effective antibiotic against isolates of *E. coli O157* and 100% of these isolates were susceptible to IPM, this result was agree with Hadi (2008), Al-Hilali (2010), and Shamki et al. (2012). They reported that all *E. coli* isolated from different clinical source were sensitive for IPM. The high efficiency of these antibiotics may be the usage rarely in studied area and it is expensive drug. In the present work, 68% of the isolates were resistant to TMP, this result was in agreement with Nanakaly (2013) who stated that 52% of *E. coli* isolates were resistant for TMP, also Salah (2007) and Al-Hilali (2010) found that 59.03% and 72.2% of *E. coli* isolates were resistant to TMP. This may be result from mutational changes that lead to over production of the bacterial dihydrofolatereductase (Salah, 2007). Regarding to C resistance, 52% of isolates was resistant to it. Taye et al. (2013) mentioned that 100% of the *E. coli* O157:H7 isolates were resistant to C and Salah (2007) who found that 97.59% of isolates were resistant to C, while in a study conducted by Shamki et al. (2012) and Momtaz et al. (2012), it was found that 32.14% and 29.8% *E. coli* isolates were resistant to C. In the current study, it has been shown that the resistance raised to the third generation of cephalosporin 3GC such as CTX, and the results were 76% for CTX. These results were agreed with Al-Hilali (2010). Shamki et al. (2012) and Nanakaly (2013) they mentioned that (68.2, 96.4% and 87%) respectively of the isolates resistant for the CTX. High resistance pattern for AMP reported with a percentage of 100%, similar result obtained by Zinnah et al. (2008), Shamki et al. (2012) and Taye et al. (2013) whom found the resistance to AMP as 90%-100%, and 100% while Albert et al. (2009) reported 45.9%. This was explained by the overuse of antibiotics especially AMP in Erbil Hospitals, and also to the misuses of these antibiotic as they are prescribed without sensitivity test (Decre et al., 2002). On detecting the resistance of *E. coli* O157:H7 for KF, it was found that 72%

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1471514727

of the isolates was resistant to it, Shamki et al. (2012) and Dehkordi et al. (2014) reported that 100% and 48% respectively, of *E. coli* isolates showed resistance for KF, while Bekele et al. (2014) showed that the resistance of the isolates for KF was 12.8%. In our work, 56% of the isolates were resistant to FEP, this result agree with Kalantar et al. (2010) who found that 40.5% of the isolates resistance for FEP while Al-Hilali et al. (2010) and Shamki et al. (2012) mentioned that 77.3%, 92.85%of the isolates resistance for FEP. The resistance to CIP was 20%, this result in agreement with (Shamki et al., 2012; Bekele et al., 2014) recorded 25% and 17.9% respectively but the result that mentioned by Zinnah (2008) and Al-Hilali (2010) disagree who reported that all isolates were sensitive to CIP. This is due to that the ciprofloxacin is newly used in treatment in comparison with other antibiotics. Moreorever, Rice et al. (1992) showed that increasing uses of antibiotics was associated with development of resistance against them. The clinical use of fluoroquinolone in children should be restricted because of potential cartilage damage that occurred in research with immature animals, the safety and efficacy of oral ciprofloxacin in children is understudy (Elder, 2004). Jalal et al. (2010) showed that the resistance in bacterial population can be spread either by transfer of bacteria between people or transfer of resistance genes between bacteria (usually on plasmids) and by transfer of resistance genes between genetic elements within bacteria, on transposons or may chromosomally located. Susceptibility to antibiotics is changing in general and increase in antibiotic resistance has been shown worldwide. The main reason for this trend is the increase in antibiotic consumption, the abuse of board spectrum antibiotics or self medication (Younis et al., 2009).

Plasmid profile of E. coli O157:H7

Extracted plasmids analyzed by gel electrophoresis on 0.7% agarose gel as shown in *Figure 1*. The results revealed that most isolates have one band with molecular weight more than 10 kb while (E11, E13 and E21) have two bands with molecular weight more than 10 kbp, E16, E20 and E24 have three bands but E15 which is resistant for 13 antibiotics have 5 bands with molecular weight ranging between (2 kbp- more than 10 kbp) bp in size.

Analysis of plasmid DNA content by agarose gel electrophoresis showed variation in their size and more than one DNA bands appeared in many isolates. These results revealed that among 25 *E. coli* O157:H7 isolates, the size of the bands ranged from 2 Kbp to more than 10 Kbp. The presence of more than one DNA band in the agarose gel is a good indication for existence of more than one plasmid DNA species. The variation in the molecular weights of plasmids might be a result of these plasmids carrying different gene cassettes for resistance against different classes of antibiotics (Khan et al., 2007). The reported results indicate the dissemination of plasmids among *E. coli* O157:H7 isolates which may be carrying resistant genes against wide spectrum of clinically used antibiotics, which may explain the reason of evolution antibiotic resistant patterns in studied bacterial cultures. The study of Ehywarieme (2011) showed that some *E. coli* O157:H7 isolates had plasmid bands with sizes > 1.5 kbp. Aibinu et al. (2007) mentioned that all isolates of *E. coli* O157:H7 had harbored plasmids ranging in size between 21,563 and 27,444 kb. In a research conducted by Malkawi (1998) on *E. coli,* he demonstrated that the plasmid sizes were from (1.5–54) kbp. Tsen (1996) reported that a range of (2 – 22) kbp for plasmid sizes among *E. coli* isolates. Danbara et al. (1987) have also reported plasmid size variations between 3.9 kbp and 50 kbp in *E. coli* strains. As ampicillin showed the most resistance, therefore we have suggested

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1471514727

that the gene coding for ampicillin resistance could be located on the plasmid. Possibly, some antibiotic resistance genes may not be located on the plasmid but may be on the bacterial chromosome or on transposable elements (Transposon) (Farshad et al., 2012). This indicates that plasmids allow the movement of genetic materials, including antimicrobial resistance genes between bacterial species and strains.

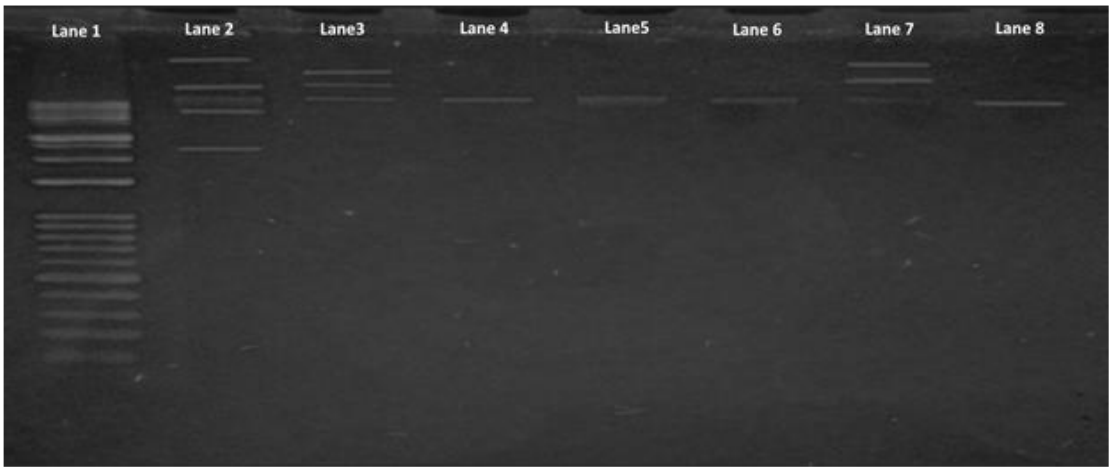

Figure 1. *Plasmid profile of E. coli O157:H7 isolates. (Lane 1: 10 000 bp DNA ladder, Lane 2: Plasmid content of E15, Lane 3: Plasmid content of E16, Lane 4: Plasmid content of E17, Lane 5: Plasmid content of E18, Lane 6: Plasmid content of E19, Lane 7: Plasmid content of E20, Lane 8: Plasmid content of E21)*

Curing of plasmid in E. coli O157:H7 isolate E15 by ethidium bromide

Table 2 demonstrates the curing percent of plasmid DNA from *E. coli* O157:H7 isolates by ethidium bromide. For E15 isolate, ethidium bromide affect AK, CIP, CN and SXT genes with (28.57%). *Figure 2* shows the plasmid DNA profile for *E. coli* O157:H7 isolate (E15) and it is clear that two plasmid DNA were remain in the E15 isolate after treating with ethidium bromide.

Table 2. *Curing of plasmid DNA from E. coli O157:H7 (E15) isolate by using ethidium bromide (EtBr)*

Treatment	Antibiotic resistance pattern														
	AK*	AMP	C	KF	CIP	FEP	CTX	CRO	CN	IPM	MET	TE	TMP	SXT	
E15	R	R	R	R	R	R	R	R	R	S	R	R	R	R	28.57%
EtBr + E15	S	R	R	R	S	R	R	R	S	S	R	R	R	S	

Among various plasmids present in bacterial strains, R plasmids are very significant as they confer resistance to one or more antibiotics, thus possess a threat to chemotherapy. Treatment of cells with certain chemical and physical agents enhances the elimination of plasmids from host cells. This phenomenon is referred to as curing and has been used to ascertain the plasmid associated nature of genes. Susceptibility to curing agent also varies among plasmids (Madigan et al., 2000). Hamad (2009) study the effect of plasmid curing on the drug resistance determinants of MDR *E. coli*, the results revealed that some of the resistance markers (chloramphenicol and nalidixic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1471514727

acid) were stably lost in all isolates, thereby confirming their location on plasmid that showed missing of 15 Kbp plasmid band after treating MDR *E. coli* with ethidium bromide, the results also showed losing of all resistant markers for (ampicillin, ceftazidime, cefotaxime, chloramphenicol, nalidixic acid and tetracycline) in some strains of MDR *E. coli,* no plasmid band obtained when these strain subjected to electrophoresis**.**

Ehywarieme (2011) study the impact of plasmid curing on the drug resistance determinant of *E. coli* O157:H7 by using acridine orange*,* the results showed that some of antibiotic resistance marker (Ciprofloxacin and Nalidix acid) were equally observed to be lost in all isolates except E4. The effect of ethidium bromide as curing agent might be due to their action as intercalating agent. This mutagen became inserted between two abnormal conformation can lead to insertion or deletion, thus can induce frameshift mutation (Nariman et al., 1998). On the other hand, the unsuccess of ethidium bromide in curing process for certain antibiotic genes may be attributed to their failure in inhibition of plasmid replication that carry resistance to these antibiotics due to incapability to create mutation in the original replication that specific for this plasmid, or because of their disability to prevent plasmid distribution mechanism on daughter cell as a result remaining of these plasmids in these isolates.

Curing of plasmid DNA by elevated temperature

Elevated temperature at 46 °C was used to cure the plasmid DNA that confers resistance to antibiotics in *E. coli* O157:H7 (E15) isolate and the main results are represented in *Table 3*. *Table 3* indicates that the E15 when treated with elevated temperature at 46 °C AK, CN, CIP, CRO and SXT genes were affected and the curing percent was (35.71%). *Figure 2* shows that E15 tested isolate missing three bands of plasmid DNA after incubation at 46 °C.

Table 3. *Curing of plasmid DNA from E. coli O157:H7 (E15) isolates by using elevated temperature*

Treatment	Antibiotic resistance pattern														
	AK*	AMP	C	KF	CIP	FEP	CTX	CRO	CN	IPM	MET	TE	TMP	SXT	
E15	R	R	R	R	R	R	R	R	R	S	R	R	R	R	35.71 %
Elevated temperature 46 °C + E15	S	R	R	R	S	R	R	S	S	S	R	R	R	S	

Nariman et al. (1998) studied the effect of elevated temperature on eliminating plasmid from *E. coli* isolates and the results indicated that CEP, CTX and CRO determinant were plasmid encoding and they concluded that this may due to the existence of two separate R-plasmids or one plasmid is carrying these antibiotic resistance genes. Nanakaly (2013) performed curing of plasmid DNA by elevated temperature (46 °C) for uropathogenic *E. coli*, she mentioned that E3 when treated with elevated temperature at 46 °C, the ciprofloxacin, ceftriaxone, nitrofurantoin, chloramphenicol, Cefotaxime sodium, gentamycin, sulfamethoxazole/trimethoprim and amikacin genes were affected and the curing percent was (66.6%), while when E25 isolate treated with elevated temperature at 46 °C, genes which responsible for ciprofloxacin, ceftriaxone, nitrofurantoin, cefotaxime, gentamycin,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1471514727

sulfamethoxazole/trimethoprim and amikacin resistance were affected with the percentages of (58.3%). From the obtained results, a conclusion can be made that curing by elevated temperature is efficient method for plasmid curing, and this may be due to the fact that the enzymes which contribute to the DNA replication processes are more affected by this high temperature. The inactivation of these enzymes may be due to the change in the folding of polypeptide at this temperature, i.e. the enzymes are sensitive to elevated temperature (Khder, 2002). These results also agree with Radi and Rahman (2010) they concluded that curing by elevated temperature is the most efficient method among others. Furthermore, enzymatic activity declines above the optimum temperature that is characteristic of the heat stability of the particular enzyme (Hardy, 1986). However, plasmids appear to be dependent on host enzymes for their replication, therefore, most of the proteins synthesized during changing of temperature might be utilized for cell division, by that, chance of plasmid replication decreases then curing occurred (Radi and Rahman, 2010). Many researchers demonstrated the mechanism by which the elevated temperature create curing of plasmid DNA, of these, the effect of elevated temperature on plasmid curing may be due to decreasing the amount of synthesized DNA.

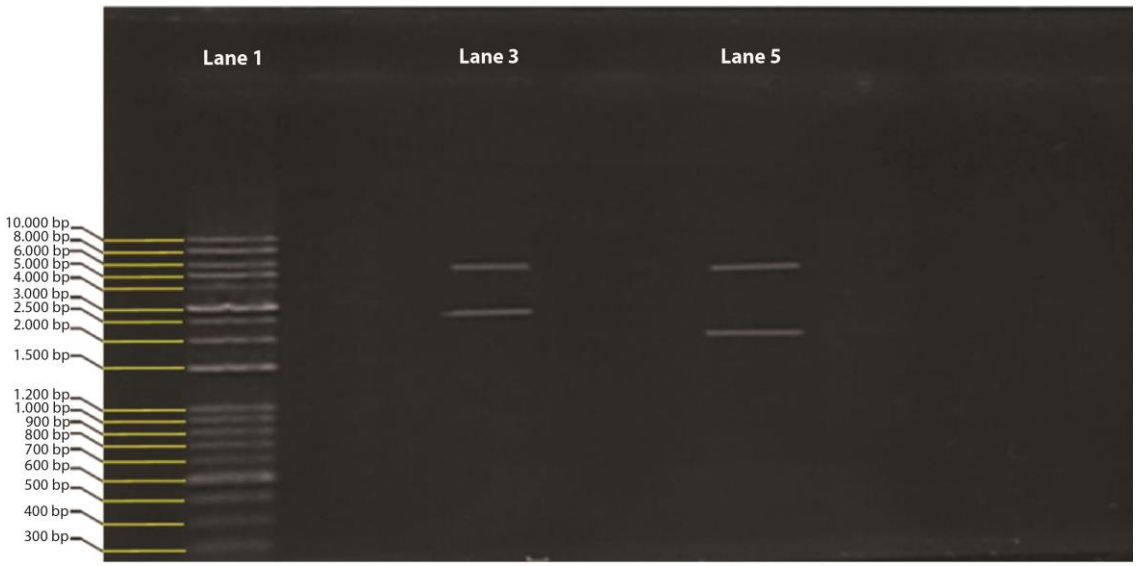

Figure 2. *Plasmid profile of cured E15 by ethidium bromide and elevated temperature. (Lane 1: 10 000 bp DNA ladder, Lane 3: E15 after curing with ethidium bromide, Lane 5: E15 after curing with elevated temperature)*

Conclusion

The article aimed to cure the drug resistance genes twenty-five isolates of E. coli O157:H7 obtained from 200 child stool samples, using using cultural, morphological, biochemical characteristics and serological test to identify the bacteria, and gel electrophoresis to register the plasmid profile, and utilizing Ethidium bromide and elevated temperature to cure the plasmid DNA.

For this purpose, two different types of curing methods were used and the results obtained was a preliminary indication of association of drug resistance of the clinical isolate of *E. coli* O157:H7 (E15*)* with plasmids. Among the two curing method used, elevated temperature displayed greater success rate than the ethidium bromide.

Abstract. Blood is the main carrier of nutrients and the first indicator of changes occurring in an organism. Hence, the aim of the study was to demonstrate the effect of the day length and the total protein content in the diet for farmed fallow deer (*Dama dama*) on the selected mineral contents of the plasma and blood haematology. The investigation of farmed fallow deer revealed an increase in the level of red blood cells (RBC) and haemoglobin (HGB) induced by altered light conditions, which may the evidence stimulation of erythropoiesis by an increased concentration of androgens. The level of white blood cells (WBC) changed significantly in the control group, which was kept in the least favourable conditions, as indicated by leukocytosis. In the present study, animals exposed to a changed day length exhibited a significant increase in the plasma concentrations of most minerals (phosphorus - P, magnesium - Mg, copper - Cu, calcium - Ca, iron - Fe) after the winter period in the first year of studies, which indicates accelerated development of antlers in farmed fallow deer. However, there was no equally intensive increase in the plasma mineral content (except for Ca) in the same group of animals in the second year of the study. This probably resulted from the administration of adequate nutrition, which prevented changes in the blood mineral concentration despite the antler growth.
Keywords: *Dama dama, wintering conditions, photoperiodism, nutrition, haematology, minerals*

Introduction

Blood is a living tissue composed of different cells which are suspended in the liquid part of the blood called plasma. Its components form a highly developed defense and transport system on which animal body health highly depend. It is, among others, a transporter of various compounds that provides cells with oxygen, nutrients, removes carbon dioxide and other unnecessary or harmful by-products of metabolism, but is also a carrier of hormones, chemical messenger substances, and thus participates in the transmission of information throughout the body. In addition, blood is involved in the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1472914750

regulation of body temperature, performs defense functions, protects against pathogens, cures the body - thanks to its coagulation properties (Weiss and Wardrop, 2010).

All this makes so blood is the main and the first indicator of changes occurring in the organism (Weiss and Wardrop, 2010). All factors that can affect an animal are reflected by basic blood tests. Adequate nutrition and enhanced light conditions are often used in farm breeding. The impact of the photoperiod and an appropriate composition of the feed ration have been extensively investigated in cervids, but insufficient attention has been devoted to the closely related fallow deer (*Dama dama*). It is difficult to find literature with data on the influence of an altered day length on the basic haematological parameters in European fallow deer. The day length is extremely important in the life of cervids (Jaczewski, 1954; Pollock, 1975) especially in their hormonal economy (Asher et al., 1989; Suttie et al., 1984; Sempere et al., 1992; Elliott et al., 1996), which may affect the basic haematological parameters.

One of the most important stages in the life of deer is the growth of the antlers regulated by among other things, the hormonal economy which is affected by the daily photoperiod as demonstrated by Jaczewski (1954). Goss (1969) subsequently demonstrated that acceleration of antler cycles can be induced by increasing the frequency of annual daylight cycles with up to four complete antler growth cycles being achieved in 12 months. Changes in food intake, behaviour and plasma hormone concentrations of red deer stags were also fully entrained to a 6-monthly photoperiod cycle (Goss, 1969).

Growing Cervids require an additional 14–20% protein (Ullrey et al., 1967) especially during the growth of antlers. However, Dryden (2016) showed antler growth in adult stags is little affected by diet protein concentrations over 7%, but supplements of protected protein or methionine may improve antler growth. Richardson et al. (2008) research has shown growing antlers consist almost entirely of protein (collagen) and typically consist of 35–45% protein once they harden or "mineralize." While antlers are growing, bucks require a diet of 13–16% protein for optimum development, along with other required nutrients. Only 6–10% protein is required for maintenance of adult deer (Richardson et al., 2008). Antler development in deer results from the collective contribution of nutrition, genetics and age (Ullrey, 1982). It was shown that, white-tailed deer require a diet containing 13 to 16% crude protein (including adequate levels of carbohydrates, fats, minerals and vitamins) in order to express their genetic potential for antler development. In the other studies showed wild cervids require roughly 5% crude protein of dry matter intake for maintenance, but up to 25% for reproduction (Dryden, 2011; Felton et al., 2018). Natural forage for northern cervids typically contains 5–15% crude protein, with rare extremes of 25–30% (Marell et al., 2006; Wam et al., 2016). The objective of protein diet and supplementation is therefore to provide additional nutrients to the deer's natural diet during times when native forage is thought to be inadequate in quantity or quality (especially winter months in the temperate climate zone). Moreover Felton et al. (2018) revealed a lack of evidence that cervids more strongly select for protein in summer than they do in winter. In addition, under farm conditions, the amount of feed consumed by cervids can be controlled only in winter (outside the pasture period).

It has been proven that changes in animal nutrition affect the basic haematological parameters and the concentration of minerals in the blood (Kováč et al., 1997). Also blood is a very sensitive indicator of metabolic changes in both the physiological and pathological status of animals (Weiss and Wardrop, 2010). Thus, the aim of the study

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1472914750

was to demonstrate the effect of the day length and total protein content in the diet for farmed fallow deer on the plasma level of selected minerals and haematological blood indices.

Materials and methods

Experimental design

The research was carried out at the Research Station of the Institute of Parasitology, Polish Academy of Sciences, Kosewo Górne (Region of Warmia and Mazury; Poland; N: 53°48'; E: 21°23'). All analyses were performed with the consent of the Local Ethics Committee 0069, Resolution No. 42/2016. The study involved 36 male stags in the 3rd-6th year of life divided on an analogous basis into three equal groups (n = 12) receiving different nutrition and provided with different daily photoperiods in winter months (from January to the end of March 2016 and from December 2016 to the end of March 2017):

Experimental group I: Standard farm nutrition with a total protein level of 16% (each animal ingested on average 600 g of the mixture per day with the following composition: 70% of crushed oats in 15% of universal rapeseed concentrate (producer: Eko-pasz, Mońki, Poland) containing 33% of crude protein and in 15% of universal soybean concentrate (producer: Eko-pasz, Mońki, Poland) with 45% crude protein content). The diet included hay and grass silage provided *ad libitum* and a mineral feed mixture Opas Ekstra 7669 from LNB (producer: Cargill, Polska) (*Table 1*). The supplement constituted 2.5% of the standard farm nutrition - 15 g. The experimental group I animals were kept on a run between 7:00 and 15:00 and spent the rest of the day inside the shelter; they were exposed to the natural length of the daylight.

Table 1. *Composition of the diet supplement provided to all groups farmed fallow deer*

Premix composition	Components	Content (in 1 kg)
Macronutrients (%)	Calcium (Ca)	21
	Phosphorus (P)	3
	Sodium (Na)	10
	Magnesium (Mg)	4
Micronutrients (mg)	Manganese (Mn)	3 000
	Zinc (Zn)	6 000
	Iron (Fe)	4 000
	Copper (Cu)	1 000
	Cobalt (Co)	25
	Iodine (I)	100
	Selenium (Se)	25
Vitamins	A (j.m.)	500 000
	D3 (j.m.)	100 000
	E (mg)	1 000
	B1 (mg)	4 000

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1472914750

Experimental group II: Nutrition was identical as in the experimental group I. Group II was subjected to changed photoperiod conditions, i.e. the day length was artificially prolonged in relation to natural conditions. The experimental group II animals were kept on a run adjacent to the shelter between 7:00 and 15:00 and spent the rest of the day inside. The shelter was equipped with electric LED lamps with a nominal power of 18 W and a declared light stream of 1850 lumens. The emitted light was cold white (colour temperature 6000 K). Light intensity in the shelter and outside was measured using an AB-8809A luxometer (producer: Abatronic, Radom, Poland).

In accordance with the adopted assumptions, the day length was extended by illumination of the shelter from January to the end of March 2016 and from December to the end of March 2017. Unfortunately, the same length of the artificial illumination plan was not used in both years, because in the first one the work associated with the breeding treatment performed annually was delayed by a month. The light in the shelter was turned on and off automatically. The comparison of the length of the natural daylight and the applied photoperiod regime are presented in *Figure 1*.

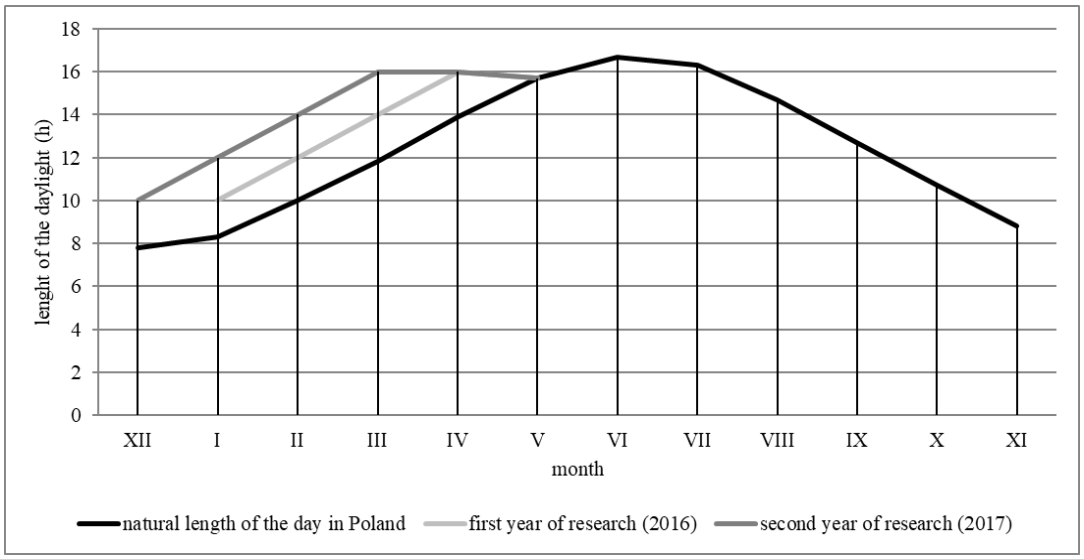

Figure 1. *Comparison of the natural day length in Poland and the photoperiod regime in 2016 and 2017*

Control group III: Standard farm nutrition with a total protein content of 10%. The diet included hay and grass silage provided *ad libitum* and a mineral feed mixture Opas Ekstra 7669 from LNB (producer: Cargill, Poland) (*Table 1*). The supplement constituted 2.5% of the standard farm nutrition - 15 g. The group was kept on a run throughout the day and exposed to the natural length of the daylight.

Observations and measurements

The animals from groups I and II spent the winter (December - March) under a shelter situated in the wintering ground divided into two identical rooms so that it was possible to control the amount of consumed feed. The walls of the shelter were constructed of horizontal wooden boards and provided protection against the adverse impact of weather conditions. Under the shelter, there was a feeding rack for haylage, water containers, and feeding troughs for concentrated feed. The concentrate was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1472914750

provided once daily. The animals had free access to water over the entire winter period. After the winter period, the animals stayed on the available pasture without supplementation (April - October) (*Fig. 2*). Body weight was measured with the use of a set of MP 800 sensors coupled with a Tru-Test DR 3000 weight reader LNB (producer: Tru-Test Group, Auckland, New Zealand). As declared by the manufacturer, the accuracy of this set is +/- 1% and the minimum resolution is 100 g.

Figure 2. *Farm fallow deer during the pasture period*

In accordance with the routine zootechnical practice adopted on the farm, antlers were cut at a height of 1 cm above the rose, which is the minimum height in technical terms. This treatment not only does not affect the welfare of experimental animals but also enhances their safety during the mating season, as a high density of relatively large groups of males on farms with limited space increases the risk of serious injuries and even deaths. After removal of dried velvet and mineral impurities and after final drying (in natural conditions) for 30 days, the antlers were weighed (each beam separately) on an electronic balance WLC F1/K with an accuracy of +/- 0.5 g (producer: Radwag, Poland).

Sampling

Samples were collected while the fallow deer were standing inside a small handling box (2 m × 2 m × 0.6 m) (*Fig. 3*) with no need of sedation. Blood samples were collected from *vena jugularis externa* always at the same time (from 1 to 3 h after dawn) to avoid variations associated with circadian rhythms as in research of Gáspar-López et al. (2011). For haematological analyses, 5-ml blood samples were collected into vacuum tubes containing an anticoagulant agent (EDTA) and into tubes with heparin as an anticoagulant. The samples were chilled (4-8 °C) within 15 min after collection. Haematological analysis was carried out within 2 or 3 h after extraction with the use of an automated haematological analyzer Mythic 18 (producer: Orphee S.A.,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1472914750

Switzerlan). The device was calibrated each time before the analysis of the samples. The blood was analysed for the content of white blood cells (WBC), red blood cells (RBC), haemoglobin (HGB), and haematocrit (HCT).

Figure 3. *Farm fallow deer in the handling box*

Concurrently, plasma for analysis of the biochemical parameters was obtained by centrifugation of whole blood at 3000 rpm for 10 min in a laboratory centrifuge MPW-350R (producer: MPW Medical Instruments, Warsaw, Poland) at a temperature of 4 °C. After centrifugation, plasma zinc (Zn), phosphor (P), magnesium (Mg), copper (Cu), calcium (Ca), iron (Fe) levels were determined using reagent kits (BioMaxima, Lublin, Poland) according to the manufacturer's protocols and a random access biochemical analyser Metrolab 2300 GL (producer: Metrolab SA, Buenos Aires, Argentina).

The haematological parameters and the plasma content of selected minerals were determined in two terms: before and after the winter in 2016 and 2017, because in these times all animals were kept in the handling box and where weighed. After the procedure, they are moved to a suitable room (before winter) depending on the group to which they belong or to the pasture (after winter). The article is part of a cycle of research of farmed fallow deer. These animals have participated too in study in which we examined some hematological parameters (Tajchman, 2019).

Statistical analysis

The results were analysed statistically. The values were presented as a mean value and standard deviation in the case of measurable parameters and as cardinality and percentage in the case of non-measurable variables.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1472914750

The normality of the distribution of variables in the analysed groups was verified with the Shapiro-Wilk test. The differences between the two measurement terms were assessed with the Student's t-test or with the Mann-Whitney test for dependent samples and with the paired-samples Wilcoxon test when the conditions for application of the former test were not met. The differences between the three experimental groups were evaluated with the ANOVA analysis of variance and the post-hoc RIR Tukey test. When the conditions for application of the former analysis were not fulfilled, the Kruskal-Wallis test was used. In order to analyze the interaction of the effect of various factors (diet, lighting, time/year), a mixed multivariate ANOVA analysis of variance was performed. In the case of sphericity disorders (tested by the Meuchly test), the Greenhouse-Geisser correction was applied to the *F* statistics. A significance level of $P < 0.05$ was assumed, which indicated the presence of statistically significant differences or correlations. The database was compiled and statistical analyses were carried out in the Statistica 9.1 software (StatSoft, Polska).

Results

The investigations consisted in comparison of the haematological parameters and mineral concentration in the blood plasma of the farmed fallow deer assessed before the winter period in the first year (2016) of the study and before the winter period in the second year (2017). There was a significant decline from 5.288 to 3.638 $\times 10^9$ L^{-1} ($P = 0.041$) in WBC in group I and on average from 14.397 to 11.564 $\times 10^{12}$ L^{-1} ($P < 0.05$) in RCB in all experimental groups (*Table 2*). In turn, the Zn content increased significantly, on average by 19.11 μmol L^{-1} ($P < 0.05$), in all groups. The highest increase, i.e. by 30.559 umol L^{-1} was noted in group I. A significant increase by 0.267 ($P = 0.034$) in the plasma P content was noted in group I, while the level of Mg increased by 0.174 mmol L^{-1} ($P = 0.0015$) in group II. The plasma Ca content increased significantly in all study groups assessed in the pre-wintering period in 2016 and 2107, with the highest increase by 0.685 ($P < 0.05$) observed in the control group. The Fe concentration also increased significantly in all groups, and the highest increase was noted in group II, i.e. by 13.046 ($P = 0.004$) (*Table 2*).

A statistical analysis of differences between the haematological parameters and the plasma mineral content recorded after the winter period in the first (2016) and second (2017) years of the study was carried out. The data showed a significant increase by 0.657 $\times 10^9$ L^{-1} ($P = 0.049$) in WBC only in the control group and a significant reduction of RBC, on average by 2.404 $\times 10^{12}$ L^{-1} ($P < 0.05$), in all groups (*Table 3*). The plasma Zn concentration increased in group I and in the control, with a higher value in the control group (III), i.e. by 16.970 umol L^{-1} ($P < 0.05$). The plasma P concentration declined on average by 0.875 mmol L^{-1} ($P < 0.05$) after the winter period. There was a significant reduction on the Mg level (by 0.145 mmol L^{-1}) in group II. The levels of Ca and Fe in group I significantly increased by 0.381 mmol L^{-1} and 16.024 umol L^{-1}, respectively (*Table 3*).

We also compared the haematological parameters and plasma mineral content recorded before and after the wintering periods in 2016 and 2017. In the first year of the research, RBC and HCT significantly decreased by 1.031 $\times 10^{12}$ L^{-1} and 2.239% ($P < 0.05$), respectively, after the winter period. In group I, a higher level of only Cu (by 5.168 umol L^{-1}) was observed. With the exception of Zn, the plasma concentrations of all minerals increased significantly in group II. There was an increase in the level of P from 2.448 to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1472914750

2.812 mmol L^{-1}, Mg from 0.682 to 0.880 mmol L^{-1}, Cu from 12.438 to 16.437 umol L^{-1}, Ca from 2.301 to 2.596 mmol L^{-1}, and Fe from 32.386 to 36.106 umol L^{-1} ($P < 0.05$). A significant increase in the control group was only noted in the case of P, Mg, and Cu. The content of P increased from 1.988 to 2.442 mmol L^{-1}, Mg from 0.641 to 0.747 mmol L^{-1}, and Cu from 12.277 to 15.754 μmol L^{-1} ($P < 0.05$) (*Table 4*).

In the second year of the investigations, there was a significant decrease (by 0.61 × 10^9 L^{-1}) in WBC in the control group (III) after the winter period, whereas RBC and HGB significantly increased by 0.896 × 10^{12} L^{-1} and 1.200 g L^{-1}, respectively, ($P < 0.05$). The plasma Zn and P concentration in group I decreased after the winter period from 49.979 to 29.697 umol L^{-1} and from 2.802 to 1.629 mmol L^{-1}, respectively ($P < 0.05$). In turn, the Mg and Cu content increased from 0.675 to 0.766 mmol L^{-1} and from 11.867 to 15.063 umol L^{-1}, respectively ($P < 0.05$). In the other groups (II and III), the content of Ca declined statistically significantly after the winter period, i.e. by 0.349 mmol L^{-1} (*Table 5*).

Additionally, the antler and body weight was compared in the study groups. In all groups, the weight of the animals' antlers increased significantly between 2016 and 2107. The increase was substantially higher in group I (from 941.176 to 1558.235 g) and III (from 1064.706 to 1450.588 g) than in group II (from 1062.437 to 1185.000 g) ($P < 0.05$). The body weight of the fallow deer before and after the winter period significantly increased in all groups as well (*Table 6*). Furthermore, the cycle of antler growth, velvet loss, and antler shedding was accelerated by on average 3 weeks in group II.

The changes in the haematological parameters and plasma mineral content in the farmed fallow deer were analysed statistically. A statistically significant difference was found in the magnitude of the change in the Zn level between the groups analysed in the pre-wintering period in the first and second year of the study ($F = 11.653$, $P = 0.003$). Statistically significant differences were found between groups I and II (a mean increase by 30.559 umol L^{-1} in group I and by 12.609 umol L^{-1} in group II) and between groups I and III (a mean increase by 12.609 umol L^{-1} in group I and by 14.185 umol L^{-1} in group III) (*Table 7*).

There was a statistically significant difference in the magnitude of the change in the Ca content between the analysed groups ($H = 8.343$, $P = 0.015$) before the wintering period in 2016 and 2017. Statistically significant differences were found for groups I and II (a mean increase by 0.260 mmol L^{-1} in group I and by 0.661 mmol L^{-1} in group II) and between groups I and III (a mean increase by 0.260 mmol L^{-1} in group I and by 0.684 mmol L^{-1} in group III) (*Table 7*).

After the wintering period in the first and second year of the study, there was a statistically significant difference in the magnitude of the change in the levels of Mg ($F = 5.001$, $P = 0.013$) and Ca ($F = 4.041$, $P = 0.027$) between the analysed groups. Statistically significant differences were found between groups I and II. On average, the Mg content increased by 0.114 mmol L^{-1} in group I and declined by 0.144 mmol L^{-1} in group II. Similarly, the content of Ca increased on average by 0.382 mmol L^{-1} in group I and decreased by 0.143 mmol L^{-1} in group II (*Table 7*). There was a statistically significant difference in the magnitude of the changes in the antler weight between the analysed groups ($H = 18.544$, $P = 0.0001$). Statistically significant differences were found between groups I and II (a mean increase in the weight by 617.059 g in group I and by 122.563 g in group II) (*Table 7*).

Statistically significant differences were also found between the measurement terms in the study years. Before and after the wintering periods in 2016, there were

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1472914750

differences in the magnitude of changes in the levels of Ca ($F = 4.464$, $P = 0.017$) and Fe ($F = 3.727$, $P = 0.032$). Statistically significant differences were noted between groups I and II. On average, the Ca content decreased by Ca o 0.144 mmol L^{-1} in group I and increased by 0.296 mmol L^{-1} in group II. Similarly, the Fa content increased on average by 2.989 umol L^{-1} in group I and increased by 3.720 umol L^{-1} in group II (*Table 8*). Before and after the wintering period in 2017, there were significant differences in the magnitude of the changes in the Zn content only ($F = 4.199$, $P = 0.024$). Statistically significant differences were found between groups I and III. On average, the Zn content decreased by 20.283 umol L^{-1} in group I and decrease by 0.998 umol L^{-1} in group III (*Table 8*).

The research also analyzed the effect of out-object (natural and artificial light length and 10% and 16% protein in the diet) and intra-object (change of results over time). No statistically significant effect of time as well as the effect of protein alone and light on WBC was observed. However, a significant effect of time and protein interaction was noted (F (3, 60) = 3.864, $P = 0.038$, $eta^2 = 0.162$) and the effect of time and light interaction (F (3, 60) = 4.089, $P = 0.032$, $eta^2 = 0.170$) (*Table 9*).

In the case of RBC, only the effect of time (F (3, 60) = 26.913, $P < 0.001$, $eta^2 = 0.574$) was significant, the difference was between the measurements from 2016 and 2017: 1 - 3, 1 - 4, 2 - 3, 2 - 4 (*Table 9*).

No significant effect of time, protein and light, and interaction between them on HGB and HCT was observed (*Table 9*).

In the case of Zn, a significant effect of time alone was demonstrated (F (3, 60) = 32.972, $P < 0.001$, $eta^2 = 0.507$), the significant difference was met between the measurements from 2016 and 2017: 1 - 3, 1 - 4, 2 - 3, 2 - 4. A significant effect of time and protein interaction (F (3, 60) = 5.374, $P = 0.008$, $eta^2 = 0.144$) and time and light interaction (F (3, 60) = 4.793, $P = 0.013$, $eta^2 = 0.013$) were also met for Zn concentration in fallow deer plasma. However, the time effect itself was the strongest ($eta^2 = 0.507$) (*Table 9*).

No significant effect of time, protein and light as well as the relationship between them on the P plasma concentration of animals was observed (*Table 9*).

The plasma Mg content was influenced by the time effect (F (3, 60) = 5.625, $P = 0.001$, $eta^2 = 0.149$), a difference was dependent between measurements from 2016 and 2016 and 2017: 1 - 2, 1 - 3, 1 - 4. A significant effect of time and light was also shown (F (3, 60) = 2.816, $P = 0.043$, $eta^2 = 0.081$). The time effect was stronger ($eta^2 = 0.149$) (*Table 9*).

The plasma Cu content was affected only by the time effect (F (3, 60) = 5.551, $P = 0.005$, $eta^2 = 0.148$), a statistically significant difference was between measurements 1 - 2, 1 - 4 (*Table 9*).

In the case of Ca, a significant effect of time alone was demonstrated (F (3, 60) = 20.736, $P < 0.001$, $eta^2 = 0.393$), the significant difference was between the measurements from 2016 and 2017 and from 2017 alone: 1 - 3, 1 - 4, 2 - 3, 3 - 4. In addition, a significant effect of time and light interaction (F (3, 60) = 4.923, $P = 0.003$, $eta^2 = 0.133$) on the fallow deer plasma Ca content was also demonstrated. The time effect itself was again stronger in this case (*Table 9*).

Demonstrated a significant effect of time alone on plasma Fe concentration (F (3, 60) = 12.506, $P < 0.001$, $eta^2 = 0.281$), a significant difference was between the measurements: 1 - 3, 1 - 4, 2 - 3, 2 - 4 (*Table 9*).

Discussion

There are only few studies on the effect of nutrition and altered day length on haematological parameters and plasma mineral concentrations in farmed fallow deer. Studies on various temperate cervid species conducted with the use of artificial manipulations of the daily photoperiod have shown that light has a significant impact on cervids (Jaczewski, 1954; French et al., 1960; Goss, 1969; Pollock, 1975; Simpson et al., 1983/84; Snyder et al., 1983).

Changing breeding conditions exert an effect on animal physiology, as evidenced by the results of the present study. The level of WBC in the farmed fallow deer usually had lower values in all groups (except for group I before the winter period in 2016 when the values were similar) than values reported in investigations of farmed deer (Gaspar-López et al., 2011) in the respective months. It was shown in the fallow deer that the WBC count changed significantly in the control group, especially in 2017. This group was provided with the least favourable conditions, as reflected in the elevated plasma WBC levels. In the other research groups, the WBC count did not change significantly after the wintering period, as shown by Landete-Castillejos et al. (2002) or Landete-Castillejos et al. (2007), although that was the beginning of the antler development period. Another factor contributing to the slight reduction of WBC and the increase in RBC can be ascribed to the diet, as shown in the present study and investigations reported by Tomkins et al. (1991). The level of leukocytes varies seasonally and may constitute an adaptation to anticipated immune challenges by variation of the use of day length by animals (Nelson, 2004). Unfortunately, the present investigations do not confirm this finding. The RBC level in the farmed fallow deer was usually higher (especially in 2016); it was similar to the values noted in April by Gaspar-López et al. (2011) only after the winter period in 2017. Similarly, the HGB level was higher in the farmed fallow deer than those reported in investigations of farmed deer (Gaspar-López et al., 2011). HCT was higher in the farmed fallow deer, with the exception of group I, in which the value was similar to that reported by Gaspar-López et al. (2011) only after the winter period. The investigations conducted by Gaspar-López et al. (2011) demonstrated characteristic fluctuations in the RCB, HGB and HCT levels, which were substantially lower in November-December than in March-April. As suggested by DelGiudice et al. (1992), changes in nutrition may be a cause of seasonal fluctuations, which could explain the differences related to the altered light conditions in the present study. However, Gaspar-López et al. (2011) suggested another cause of these changes. The high testosterone level during the mating period (Gaspar-López et al., 2010) may be associated with high levels of the haematological parameters described in this study. Available literature provides evidence for stimulation of erythropoiesis by androgens (Gordon et al., 1970). Contrasting data were presented by Bubenik (2006), who suggested that antlers grow during a period of low concentrations of reproductive hormones. Interestingly, the RCB and HGB levels in the present study increased under the impact of the altered light conditions in the second year of the study, which may confirm stimulation of the erythropoiesis process probably by the increased estradiol content during this time. The investigations conducted by Bubenik et al. (1979) demonstrate an increase in the concentration of this hormone in spring and autumn in male white-tailed deer (*Odocoileus virginianus*). Estradiol blocks of the activity of testes and its high levels in spring prevent premature stimulation of spermatogenesis in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1472914750

a period that is unsuitable for deer reproduction. This was confirmed by Bubenik et al. (2005) by analysis of blood collected from growing antlers and velvet, where this hormone was present in high concentrations.

The plasma concentration of Ca, P, and Mg in the farmed fallow deer in the analysed months was higher than or similar to the values reported by Kuba (2014). In the present study, the animal group exposed to the altered day length regime exhibited a significant increase in the plasma concentration of most minerals (P, Mg, Cu, Ca, Fe) after the winter period in 2016, which indicates accelerated development of antlers in the farmed fallow deer. Only the Cu content increased in group I and higher Mg and Cu levels were observed in group III. However, as early as in 2017, such an intensive increase in the mineral content (except for Ca) was not noted in the plasma of the group exposed to the greater day length. This was probably associated with the proper and constant level of nutrition, which prevented changes in the blood mineral concentration despite the period of antler growth (Gaspar-López et al., 2011). Interestingly, group I only, which was supplemented with a higher amount of protein in the diet, exhibited lower Zn and P content and a higher Mg and Cu level in the plasma after the winter period in 2017.

Additionally, high Zn concentrations in the plasma of the farmed fallow deer were observed before the winter period in all groups in 2017. This was probably related to the fact that the animals were subjected to the experimental conditions a month earlier than in 2016. Zn is responsible for the normal testosterone concentration and proper function of the immune system (Bartoskewitz et al., 2007). After antler growth and mating periods, the immune system of cervids can return to homeostasis, hence the increased uptake of this mineral in the blood (Kun et al., 2015). This may also be a result of supplementation, as shown by Suresh et al. (2013).

The concentration of P and Mg in the plasma of the farmed fallow deer was in the range reported by Kučer et al. (2013). The Cu content in the fallow deer plasma significantly increased after the winter period in all groups in 2016 and only in group I in 2017. This indicates a high demand for Cu after the pasture period as well as a need for adequate supplementation and the necessity to provide the animals with appropriate conditions in winter to compensate for nutritional deficiencies caused by the decline in the nutritional value of pastures in late autumn (Padilla et al., 2000; Bao et al., 2010).

The fallow deer body weight in the pre-wintering period was evidently higher than after the winter, which was reported in investigations of other cervid species as well. Increased liveweight gain during summer in comparison to winter has been recorded in all arctic, boreal and temperate deer so far studied (McEwan, 1968; Bandy et al., 1970; Pollock, 1975; Asher, 1993). The deer voluntarily reduce their appetite during winter (McEwan, 1968). The cycle of voluntary food intake and growth are known to be under photoperiodic control (Suttie and Simpson, 1985). Whereas for reproductive seasonality the short days of autumn are thought to provide a stimulatory cue for reproduction in temperate deer.

The body weight increased on average by 9.6 kg in the groups with higher protein content in the diet and with the modified day length and by only 6.7 kg in the control group (III). Appropriate conditions provided to animals during winter are essential, as confirmed by experiments conducted by Olguin et al. (2013), Gaspar-López et al. (2011), Janiszewski et al. (2008) and in the present study.

Similarly, the antler weight depended on the conditions provided to the animals during the winter period. However, the greatest effect was exerted by the protein content in the diet, adequate supplementation, and milder wintering conditions. In turn,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1472914750

the extended day length accelerated development of antlers and velvet loss; hence, the antlers in this group exhibited the lowest weight. This phenomenon was confirmed by Suttie et al. (1991) as well as Suttie and Webster (1995).

Conclusion

In conclusion, an appropriate level of total protein and supplementation of the stag nutrition had a positive effect on animal fitness and antler growth. Time had the greatest effect on selected haematological parameters and mineral content in farm fallow deer plasma. The differences were mainly observed between the 2016 and 2017 measurements for RBC, Zn, Mg, Cu, Ca and Fe. In contrast, the equations between the measurements were in the first year of testing only in the case of Mg concentration, while in the second year in the case of Ca. Generally, prolonged repeated of breeding treatments give a greater effect. The effect of time and protein interaction had on WBC and Zn, while the effect of time and light interaction on WBC, Zn, Mg, Ca. Increased protein supply, separately, in the fallow deer diet causes an increase in the concentration of P, Mg, Cu and Ca in their plasma, while the extension of the light day has a positive effect on the content of RCB, HGB, P, Mg, Cu and Ca. On the other hand, the reduction in the quality of wintering conditions for animals was marked by an increase in WBC (*Table 10*). Therefore it can be assumed that the results of the present study have not only a theoretical but also application value.

In future research, it is planned to take blood from deer more often and determine hematology and mineral levels to capture more accurate changes over time. In addition, an identical artificial lighting plan should be used. In addition, as recommended by other researchers (Felton et al., 2018) to assess digestibility protein and energy both in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1472914750

vivo and in vitro. Estimations of protein- and energy-digestibility are problematic to extrapolate to the population level, because of complex interactions between diet and individual, and many of the studies were compiled at the population level. Furthermore, in the case of research into small ruminants, a constant supply of drinking water should be ensured in pasture management (Fischer et al., 2017), which would also be worth to check in moderate climate conditions.

Abstract. In this study, sediment samples were taken at three different points in Edremit Bay at different depths from the sea floor. In Edremit Bay, it was investigated whether the pollution was marine or terrestrial. According the results of measurement of TOC (Total Organic Carbon) values have been yielded results between 10.35-20.36 (Küçükkuyu), 8.14-16.40 (Güre), and 2.71-12.60 g/kg (Dikili) in the marine sediments. The fact that first and second regions are susceptible to mountainous and intra-continental erosion (sedimentation 5.743 and 7.509 mm/year) increased the TOC value. The highest TOC/TN ratio (12.33-46.89) was found in the second region. No linear change in TOC and TOC/TN (Total Nitrogen) ratios was observed at all three points depending on the depth. At results of compared all carotes, the low TOC/TN (2.82-14.48) ratio have been observed in the BH1 carotes, probably the result of small stream beds and low intra-continental erosion. This study shows that TOC and TOC/TN ratios in different parts of Edremit Gulf show inconsistency and this inconsistency arises not only from the marine contribution their natural organic matter, but also from the continent.
Keywords: *inland pollution, marine pollution, TOC, TN, TOC/TN*

Introduction

In this study, total organic carbon (TOC), inorganic carbon (IC), total carbon (TC) and total nitrogen (TN) concentrations in the sea sediments of Edremit Bay (Balıkesit/Turkey) were investigated. Stable isotopes, such as carbon (C) and nitrogen (N), are the tools used to assess the geochemical processes in the environment and to determine the anthropogenic effect. C and N, the major constituents their organic matter, can bear the footprints of their hydrological flows and sediment processes, including anthropogenic modifications in the natural system (Zetsche et al., 2011; De Souza et al., 2017). Elemental composition and C/N ratios are frequently used as markers for organic carbon sources in sediments (Jacob et al., 2009). Soil, sediments, organic carbon, and nitrogen are mainly the result of the decomposition of plants and animals or plankton or anthropogenic sources such as chemical contaminants, fertilizers, or organic-rich wastes (Avramidis et al., 2015). Hydrocarbons in sediments are considered effective tracers because they correlate well with the sources of their formation (Meyers et al.,1984). The atomic TOC/N ratio separates the organic matter from marine or terrestrial. The terrestrial organic matter is enriched in carbon relative to nitrogen and shows a high TOC/N ratio

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1475114765

(Hecky et al., 1993). Terrestrial plants are rich in cellulose, and algae contain nitrogen-rich compounds. The TOC/N ratio of terrestrial organics ranges from 12 to 14 (Meyers et al., 1984). TOC/N ratios in vascular land plants and mangrove leaves were higher than 20 (Lallier-Verges et al., 1998; Azevedo, 2003). If the TOC/N ratio is between 6 and 8, it reflects the nature of planktonic marine origin organic matter (Venkatesan et al., 1987). An intermediate value of TOC/N = 10 reflects the characteristic of the mixing zones between marine and terrestrial sources (Stein, 1991). Allochthonous (ice-fed) and autochthonous (in-situ) carbonates can be distinguished by assuming that carbonates are glacial or biogenic in their origin and that the organic matter is biologically derived (organic carbon is negligible in glacial source material) (Koziorowska et al., 2016). TOC value varies between 1 mg/L in sea waters, 2-10 mg/L in lake or river waters, and up to 10 g/L in swamps (Bayram et al., 2011). Accumulation of OC in marine sediments as a result of biological degradation is known to contribute significantly to the reduction of atmospheric CO_2. Changes in total alkalinity increase or decrease CO_2 emissions from the atmosphere. In contrast, the formation of biogenic carbonates reduces alkalinity and leads to the opposite effects (Koziorowska et al., 2016). Most of the metals in the aquatic systems are associated with the particle phase, and more than 99% of the pollutants are present in fine-grained precipitates in complex with organic matter and oxides (Bartoli et al., 2012; Martínez-Santos et al., 2015).

In the marine environment, organic matter (OM) is composed of compounds that are resistant to biochemical oxidation. In non-contaminated natural waters, TOC results from humic substances and partially degraded plants or animal substances (Visco et al., 2005; Bayram et al., 2011). In a study conducted by Yümün and Önce (2017), heavy metal pollution and foraminiferal populations were determined in the samples obtained from the sea floor soundings in Küçükkuyu (Çanakkale) region. Refractory compounds (humic and fulvic acids), structural carbohydrates, and black carbon usually form the majority of sedimentary organic matter and are often brought to sea from land (Winogradow et al., 2018). C_{org}/TN ratios indicate the greater availability of paleolakes-combined nitrogen and possibly loading of algae-derived organic matter. In order to understand biogeochemical cycles, the formation of organic matter and accumulation in sediments are very important (Waterson et al., 2008; Sampaio et al., 2010). The results of studies to date show that 60-80% of C_{org} originates from land (allochthonous), but other studies show that marine organisms play an important role in OM in sediments (Koziorowska et al., 2016).

In this study, analyses of the total carbon (TC), the total inorganic carbon (IC), the total nitrogen (TN), and C/N were performed in the sludge samples taken from the seabed. It was concluded that the inland pollution dominated in the sediment samples taken from the sea floor in the Küçükkuyu, Güre, and Dikili regions.

Material and Methods

In the Bay of Edremit (Güre, Küçükkuyu, and Dikili), three drillings with an average depth of 20 m were made using a pontoon drilling machine that was modularly constructed on the sea. The sediment cores obtained from the drillings were preserved in special core boxes and analyzed in this study. The depth of the samples was calculated from the top of the sediments.

The Dikili district is located on the northern coast of the Aegean Region in the west of the Aegean Sea, northeast of the Madra Mountains, and south of Çandarlı Bay. Güre is a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1475114765

town on the Edremit Bay in the Edremit district, Balıkesir. The town of Edremit is 12 km away. The district is located in the Aegean region between Edremit Bay and Kazdağı. Küçükkuyu is a tourist town in Ayvacık, Çanakkale. Güre is located in the west of Altınoluk with Behramkale in the east and Ayvacık in the northeast. There is no river in the Güre-Küçükkuyu region, but there are the Edremit-Zeytinli, Kızılkeçili, Güre, and Altınoluk streams with a length of 6-10 km in this area. From these streams to the coastal section, mostly domestic wastewaters are present (Önce, 2014).

The location and location map of the study area are given in *Figure 1*. Three sea drilling samples were taken from the Güre (13.20 m - 16.00 m), Küçükkuyu (13.00 m - 28.00 m), and Dikili (10.00 m - 19.00 m) area with a modular sea bottom and semi-hydraulic drilling machine (*Figure 2*). The samples were brought to the laboratory in corrugated boxes which were not exposed to sunlight. A total of three samples were taken from the top, bottom and center sections of each drilling core. Total of 15 samples were examined from three drillings. The samples were analyzed in duplicate. The precision for TOC, TN, IC and TC was ± 0.02 wt%, ± 0.01 wt%, ± 0.01 wt% and ± 0.01 wt%, respectively (n=5). The range of TOC-LCSH/CPH is 4 µg/L (ppb) - 30,000 mg/L (ppm).

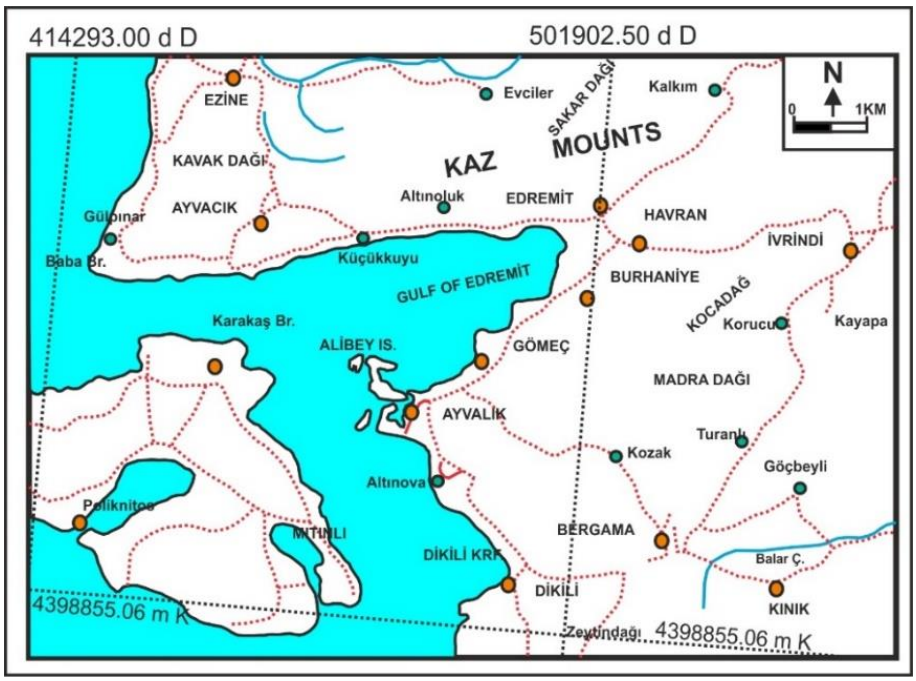

Figure 1. *Map of study area and sampling points (Dikili BH-1, Güre BH-3, and Küçükkuyu BH-3)*

The coordinates of the sample points were shown in *Table 1*. For the analysis of organic matter, 200 grams of sediment samples were taken from the cores with an average of 50 cm spacing (a long depth) and sent to Namık Kemal University Central Research Laboratory (NABİLTEM). A TOC-L series analyzer (Model SSM 5000 A) was used for the analysis of the total organic carbon in 15 samples collected along the drilling depth. TC, TOC, and IC measurements were made with this device. The concentrations of the samples collected at each 50 cm depth were divided by the number of samples collected along the selected depth to find the mean concentrations in each depth range. Total nitrogen (TN) measurements were performed to determine the C/N ratio in the samples.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1475114765

Nitrogen measurement was performed with a Vapodest VAP 20s model device. In the measurement of TOC, both total carbon (TC) and inorganic carbon (IC) were measured. The total amount of organic carbon can be obtained by subtracting the amount of inorganic carbon from the total carbon content.

Figure 2. *A view of Küçükkuyu BH3 and drilling machine*

Sample No	Coordinates (WGS-84, 6 Deegre), 2016		Driling depth (m)	Length Of sample (m)
	East (Y)	North (X)		
Dikili (BH-1)	490060.55	4324738.74	10.00 - 19.00	9.00
Güre (BH-3)	489776.20	4381514.27	13.20 - 16.00	2.80
Küçükkuyu (BH-3)	466009.22	4377155.44	13.00 - 28.00	15.00

Results and Discussion

Three soundings were made in the Aegean Sea by Yümün Mühendislik in Dikili (İzmir), Güre (Balıkesir), and Küçükkuyu (Çanakkale) regions, and cores obtained from drilling were used in this study. Five samples of sediment were collected from each core samples at the base, middle, and upper levels, and TOC, OC, IC, and TN concentrations were measured in the laboratory. Inland and marine pollutions were determined by taking into consideration the formation time of the precipitate.

Based on these analyzes, the TOC values were found to be high in Küçükkuyu and Güre. In Dikili, the TOC values obtained at the highest level of drilling were higher than at the lower part. Nitrogen values were generally high at the intermediate levels of the drillings. Previous studies have used the C/N ratios used to monitor dominant carbon resources accumulated in coastal deposits (Zhang et al., 2007; Pan et al., 2019). Hence,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1475114765

we used C/N ratios to characterize organic matter sources. In the samples taken from Edremit Bay, the TOC/N ratio was variable throughout the depth (increase/decrease), indicating that there was no pollution the result of the population concentration. The organic matter in the sediments is a mixture of materials. It is derived from particles caused by intra-continental erosion, and organic matter is produced from biological activity in the aquatic environment (Chen et al., 2008).

As can be seen in *Figure 3*, the samples taken from the sea bottom near Güre show the TC, IC, TOC, and TN analysis results. There was no linear relation between the TC, TOC, and IC parameters and depth. The TOC concentration varied between 8.14-16.40 g/kg (0.814-1.64%). Walinsky et al. (2009) found that the TOC content of sediments on the coast of Southeast Alaska ranged from 0.3-8% by weight.

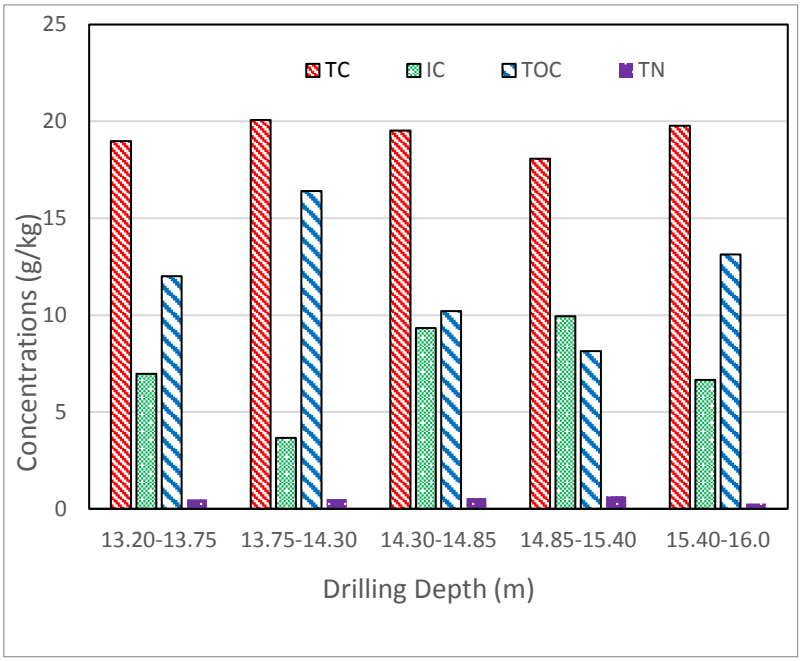

Figure 3. *Total Carbon, Inorganic Carbon, Total Organic Carbon and Total Nitrogen concentration change depending on depth in Güre seabed drilling*

When the surface and deeper samples were compared, no standard increase or decrease was found. Many researchers have reported that fine and coarse-grained clay and sand deposits were effective in changing TOC and TN concentrations (Keil et al.,1994; Ogrinc et al., 2005). The TOC concentration in the sample from the top layer was found to be 12.01 g/kg. The sediment deposition rate was 7.509 mm/year. As a result of the analysis of core samples taken from 13.75-14.30 m depth, the TOC concentration was found to be 16.40 g/kg. Considering the annual amount of sedimentation (Vs=7.509 mm/year) and the population and agricultural structure of the region, this region was not contaminated by humans approximately 100 years ago. In this case, it was concluded that there is natural intra-continental pollution the result of total precipitation intensity. The lowest TOC concentration was measured in the sediment sample taken in the range of 14.85-15.40 m. The TOC concentration increased to 13.13 g/kg in the sample taken at a depth of 15.40-16 m. High TOC showed that pollution was of inland origin (plant origin). Irizuki et al. (2015) conducted a study in Kasado Bay, all samples were below 20 mg/g TOC

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1475114765

content and stated that eutrophication was not severe. At the same point, a very low total nitrogen concentration (0.28) showed that pollution was not from organic matter of algae and marine plants. Algae contain high levels of nitrogen. At this sample point, the concentration of inorganic carbon in the samples taken at the depth was between 3.67-9.94 g/kg. IC concentrations did not show a linear increase or decrease over depth. The low total nitrogen (0.28-0.49 g/kg) (0.028-0.049%) and TOC values compared to the other regions indicate that this area has greater biological activity in the seabed. The concentration of TC in the samples taken from the Güre BH-3 point varied between 18.08-20.07 g/kg. The total carbon values throughout the depth were 18.98 g/kg (13.20-13.75 m), 20.07 g/kg (13.75-14.30), 19.53 g/kg (14.30-14.85 m), 18.08 g/kg (14.85-15.40 m) and 19.78 g/kg (15.40-16 m). The region was stable in terms of TC ratio (mean 19.288 g/kg). In the study conducted by Xu et al. (2017), TOC and TN values were found to be between 0.19-0.67 and 0.03-0.09. In another study conducted by Gao et al. (2008), the TOC content ranged from 0.86 to 1.60% of dry sediment weight and ranged from 1.25% on average. In a different study by Gao et al. (2008), total nitrogen content averaged 0.146% in the range 0.096-0.206% by weight of dry sediment.

At the Küçükkuyu BH-3 point, carrot samples were taken from the seabed at a depth of 13-28 m (*Figure 4*). Total nitrogen concentrations in this point were measured as 1.09, 1.34, 1.12, 1.57 and 1.2 g/kg at 13-16, 16-19-22, 22-25 and 25-28 m depths, respectively. The total nitrogen concentrations (1.09-1.57 g/kg) were found to be highest in this region.

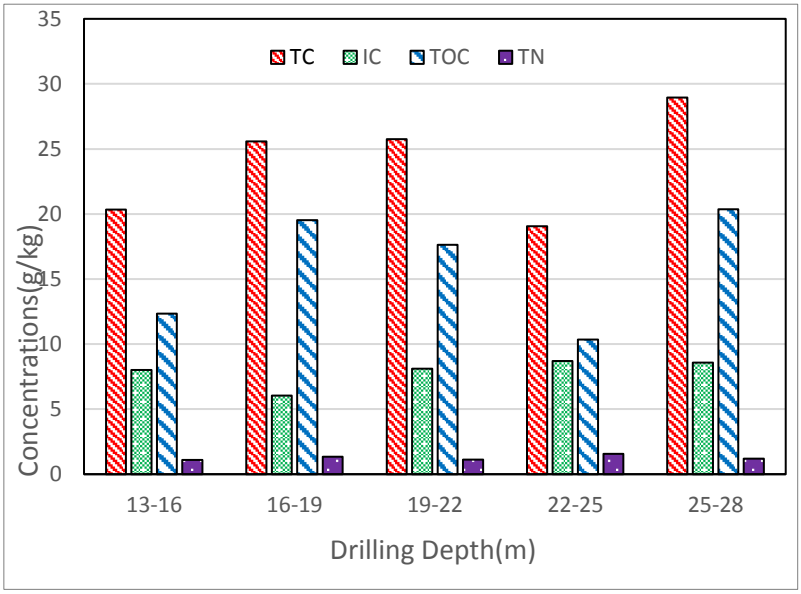

Figure 4. *Total Carbon, Inorganic Carbon, Total Organic Carbon and Total Nitrogen concentration change depending on the depth of Küçükkuyu seabed drilling*

The sedimentation rate at the Küçükkuyu BH-3 point was 5.743 mm/year. The TOC concentration ranged from 10.35 to 20.36 g/kg. The lowest and highest TOC values were in the last two layers. The high total nitrogen and TOC in this region indicated that both marine and continental pollution were present. Higher C/N values may represent a greater portion of terrestrial organic matter (Chen et al., 2008). The inorganic carbon concentration varied between 6.05-8.71 g/kg. Güre and Küçükkuyu regions were similar in terms of IC concentrations. The TOC/TN ratio was greater than 10, except for one

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1475114765

point. The high nitrogen and carbon concentrations in the sediment indicated that the biodegradation of carbonaceous and nitrogenous substances is slow, and, in this area, the nitrification and denitrification rate in the seabed is low. Otherwise, the nitrogen concentration should be lower. The TOC concentration in the sample taken from 13-16 m (top layer) was 12.34 g/kg. In the samples taken between 16-19 m and 19-22 m, the TOC value was measured as 19.54 and 17.64 g/kg, respectively. The lowest TOC value (10.35 g/kg) was found in the sample taken between 22-25 m. In parallel with the current studies (Irizuki et al., 2015), it has been found that eutrophication has not occurred in this field. The TOC/TN ratio was found to be 6.53 at this point. In this period, it was concluded that there was no intra-continental pollution and limited biological activity at the sea bottom (high concentration of total nitrogen). The limited number of agricultural areas in the Küçükkuyu region indicated that high nitrogen concentrations measured in the sediments were the result of algae. Total carbon concentrations along the depth in the Küçükkuyu region were 20.35 g/kg (13-16 m), 25.59 g/kg (16-19 m), 25.76 g/kg (19-22 m), 19.06 g/kg (22-25m) and 28.95 g/kg (25-28 m). The highest total carbon concentration was found in this region (mean 23.94 mg/kg). Küçükkuyu region contains higher concentrations of TOC than Güre region. Küçükkuyu sediments contain less stabilized sludge than Güre region. The TOC and TN values measured in Küçükkuyu region were higher than those of Xia et al. (2019).

Figure 5 shows the variation of the TC, IC, TOC, and TN values in the samples taken from the BH3 point. Sediment samples were taken from the sea floor at depths of 10 to 19.0 m.

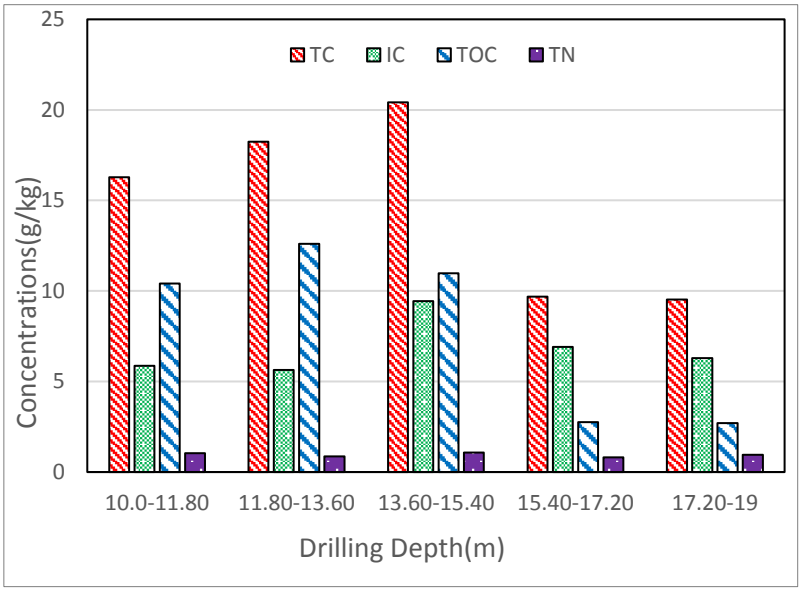

Figure 5. *Total Carbon, Inorganic Carbon, Total Organic Carbon and Total Nitrogen concentration change depending on the depth of Dikili seabed drilling*

The TOC value ranged between 2.71-12.60 g/l. The value here is in good agreement with the findings of Gao et al. (2008) and Xu et al. (2017). The TOC concentration was found to be 2.71 and 2.76 for 15.40-19 meters. Normally, a value of 6-8 represents a root of predominantly marine origin for the organic matter (Aitkenhead et al., 2000). It was very low compared to the upper sediment layers, showing that terrestrial and marine

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1475114765

pollution was minimum. The lowest IC concentration (5.64-9.43 g/kg) was found at this point. Sedimentation rate in this area was 1.217 mm/year. The high levels of TOC in the upper layers indicated that intra-continental (carbon from high plants) and marine pollution (marine plants) is high. Low TOC concentration (<20 mg/g) indicated that there was no eutrophication in this area (Irizuki et al., 2015). The main mechanism for algae growth was the nutrient increase caused by river currents and floods. As a result of nutrient growth, excessive algae growth occurs. Algae growth results in an increase in organic carbon in sediments (Yamamuro et al., 2005; Zhang et al., 2009). The time of formation of the top two layers corresponded to 2958 years. TC concentration increases as the depth increases and decreases again after a certain point. Total carbon concentrations along the depth were 16.28 g/kg (10-11.80 m), 18.24 g/kg (11.80-13.60 m), 20.41 g/kg (13.60-15.40 m), 9.678 g/kg (15.40-17.20 m), and 9.52 g/kg (17.20-19.0 m), respectively. This is the result of the high IC concentration at this point. The total nitrogen concentration has different values throughout the depths. A specific increase or decrease in these sample points was not noted. The TN concentration ranged from 0.81 to 1.89 g/kg. Inland pollution originating from the continent (high plant carbon) was dominant at the depth of 11.80-13.60 (1479 years). High nitrogen concentrations at the sample points indicated that biological degradation (nitrification and denitrification) was poor. Previous studies have shown that degradation of organic matter is most active near the water sludge interface (Middelburg et al., 1993; Niggemann et al., 2006). In region Dikili, higher TOC values were found in the upper layers and decreased towards the lower layers.

In order to make a regional comparison, the correlation graphs of the percentages of TN, TC, IC, and TOC values of the drilling samples taken in Dikili, Güre, and Küçükkuyu were given along with their depths in *Figure 6*.

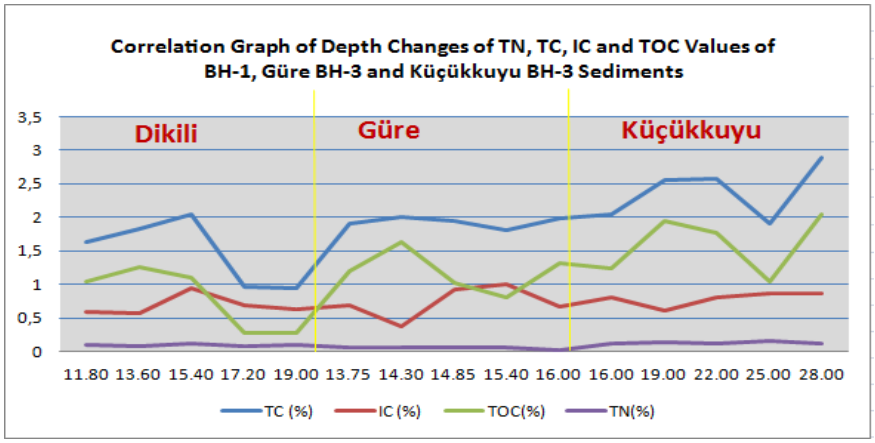

Figure 6. *Correlation Graph of Depth Variations of TN, TC, IC and TOC Values of Dikili BH-1, Gure BH-3 and Küçükkuyu BH-3 Sediments*

As can be seen in *Figure 6*, TOC values were higher in the Küçükkuyu region (10.35-20.36 g/kg) than Dikili (2.71-12.6 g/kg) and Güre (8.14-16.4 g/kg). In terms of heavy metal concentrations, these sample points represent a clean environment when compared to the Pollution Index (PI) map made by Yümün and Önce (2017). In the Küçükkuyu, Dikili, and Güre regions, it was observed that the terrestrial and marine nitrogen sources were similar over a long period of time. When the BH1 (Dikili) (0.81-1.08 g/kg), BH3

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1475114765

(Küçükkuyu) (1.09-1.57 g/kg) and BH3 (Güre) (0.28-0.66 g/kg) regions were compared, the lowest nitrogen concentrations were found in the BH3 (Güre) region. Unlike Chen et al. (2008), there was no linear relationship between TOC and nitrogen exchange in this study. Total nitrogen, total organic carbon and inorganic carbon concentrations increased in Küçükkuyu region and therefore the increase in total carbon concentration was highest in this area (*Figure 6*). As seen from the curve, the total carbon concentration increased gradually from Dikili to Güre and Küçükuyu. Küçükkuyu region has steep mountainous and rich vegetation. TOC and total nitrogen concentrations were considered to be high due to the high intra-continental transport.

Unlike organic carbon, inorganic carbon (IC) values were seen equally in all three regions. The similarity of these values shows that the sources of inorganic carbon from the terrestrial area are similar. Considering that the seabed sediments were formed over more than 2000 years, it was determined that organic pollution was not related to the existing industry and population.

As a result of drilling on the sea floor in the Güre region, the TOC/TN ratios were found to be 24.61 at a drilling depth of 13.20-13.75 meters (*Figure 7*).

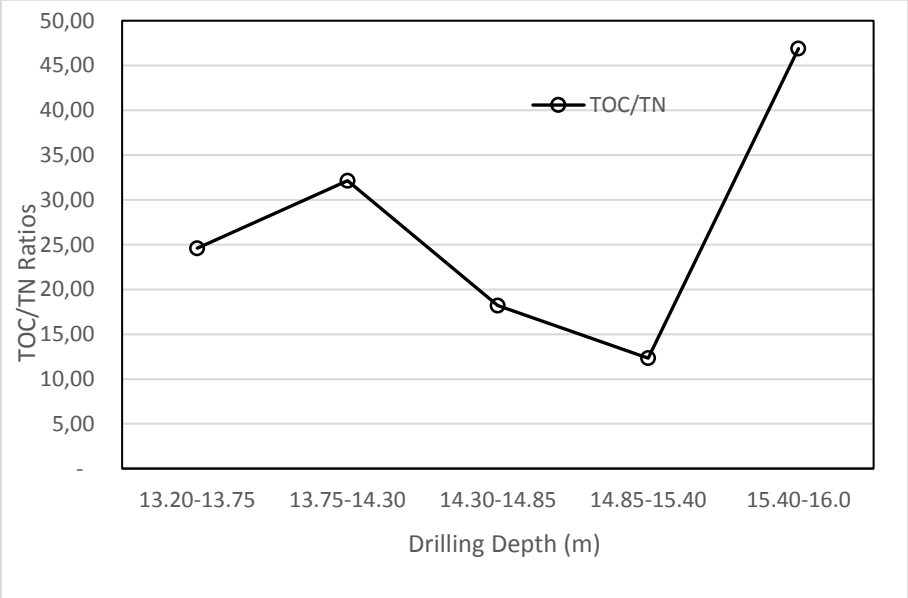

Figure 7. *Change of TOC/TN ratios depending on the depth of drilling in the deep sea bottom(Güre)*

It was found that intra-continental pulural (plant origin) was intense in this area. The intra-continental organic pollution (TOC/TN = 32.16) in the sediment layer of 13.75-14.30 meters increased. At 14.85-15.40 meters sediment thickness, the TOC/TN ratio decreased to 12.33. In the 220-year period required for precipitation formation in this thickness, the transport of intra-continental organic matter (plant origin) decreased considerably. In the 15.40 - 16.0 meter sediment range (80 years), the increase in intra-continental organic matter was found to be very high (TOC/TN = 46.89). Intracurrent contamination increased towards the upper layers of the sediment. Higher C/N values may represent the proportion of organic matter originating mainly from terrestrial areas (Chen et al., 2008). As a result, it was thought that transport of organic matter was carried out in certain periods of time although there were no rainfall records for that period. The

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1475114765

TOC/TN (12.33-46.89) ratios measured in this area (Güre) were much higher than similar studies (Xu et al., 2017; Xia et al., 2019). In the Güre region, the TOC/TN ratios were measured 24.61 (13.20-13.75 m), 32.16 (13.75-14.30 m), 18.21 (14.30-14.85 m), 12.33 (14.85-15.40 m) and 46.89 (15.40-16.0 m) along the depth, respectively. In this area (Güre), the TOC/TN ratio varied between 12.33-46.89. On the coast of Southeast Alaska, these values (C/N) ranged from 7.7 to 12.7 (Walinsky et al., 2009). The average TOC/TN ratio in the Güre region (26.84) was much higher than in the seas such as Jiaozhou Bay (11.48) (Kang et al., 2017), Yellow Sea (7.99) (Limin et al., 2013), East China Sea (7.14) (Limin et al., 2012; Dong et al., 2015). The TOC/TN ratio of the samples taken at 13-16 meters depth in Küçükkuyu region was approximately the same as the samples taken at depths of 14.85-15.40 m in Güre region.

TOC/TN values in the Küçükkuyu region were measured as 11.32 (13-16 m), 14.58 (16-19 m), 14.46 (19-22 m), 6.52 (22-25 m), 16.97 (25-28 m). The TOC/TN ratio was found to be 11.32 at the 13-16 meter sediment depth in Küçükkuyu Bay (*Figure 8*).

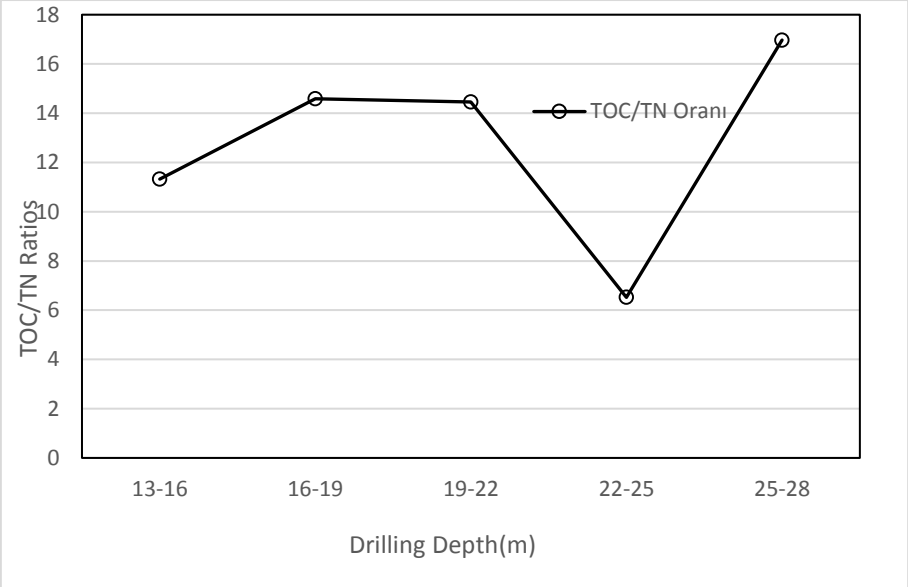

Figure 8. *Change of TOC/TN ratios depending on drilling depth in Küçükkuyu seabed*

The TOC/TN ratio in the sediment range of 16-22 meters remained constant at 14. The C/N ratio in sediments was used to investigate the sources and cycles of organic materials (Azevedo, 2003; Chen et al., 2008). A TOC/TN ratio of 14 indicates continental pollution (Meyers et al., 1984). In accordance with the current literature, this period of precipitation was dominated by inland organic matter (plant origin). The TOC/TN ratio decreased rapidly in the time of 22-25 m precipitate formation. The TOC/TN ratio was 6.52. Since the sedimentation rate was 5.743 mm/year in this region, the organic matter transport remained constant over a period of 500 years. Bacteria play a critical role in the transformation and mineralization of organic carbon and nitrogen in marine sediments (Kawasaki et al., 2006). For the drilling depth of 25-28 m, the TOC/TN ratio was measured as 16.97. In this time period, it was concluded that intra-continental organic matter transport (from high plants) was more dominant than the marine environment. The average TOC/TN ratio in the Küçükkuyui region (12.77) was similar to the Jiaozhou Bay (11.48) (Kang et al., 2017). The TOC/TN ratio in this region was higher than in the seas

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1475114765

such as Yellow Sea (7.99) (Limin et al., 2013) and East China Sea (7.14) (Limin et al., 2012; Dong et al., 2015). At this point, intra-continental pollution increased towards the upper layers of the sediment. The TOC/TN ratio of the samples taken at 13-22 meters depth in Küçükkuyu region was approximately the same as the samples taken at depths of 11.80-13.60 m in Dikili region.

The TOC/TN change in the Dikili area depending on the drill depth was shown in *Figure 9*. The TOC/TN ratio was found to be high in the precipitated upper layers. The TOC/TN ratio decreased as the sample depth increased.

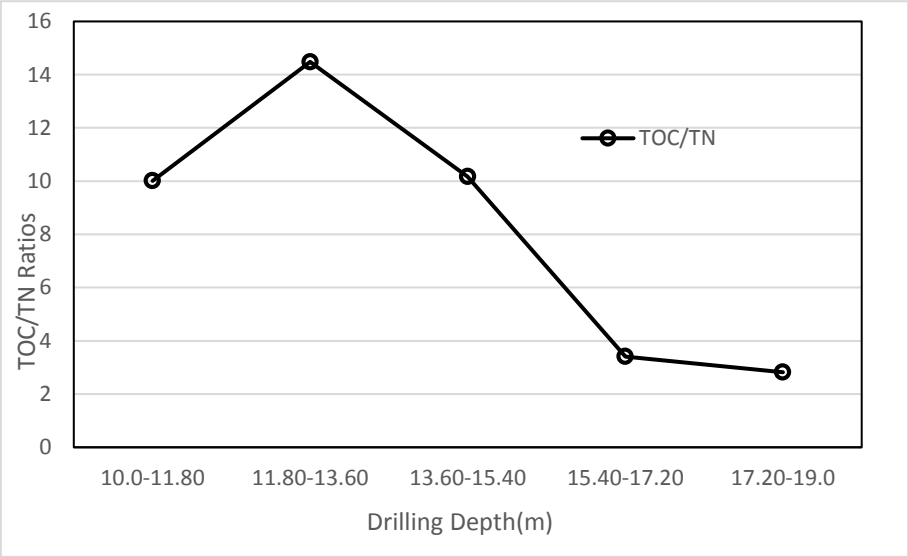

Figure 9. *Change of TOC/TN ratios depending on drilling depth in Dikili seabed*

The TOC/TN ratio was found to be 10.01 at the drilling depth of 10-11.80 meters. In the upper section, it was determined that the source of organic matter originated from the sea's own structure (biological activity). The TOC/TN ratio was measured as 14.48 at the drilling depth of 11.80-13.60 m. C/N ratios showed different distribution ratios depending on depth. The source of organic matter was found to be marine and terrestrial (Venkatesan et al., 1987). Since the sediment deposition rate in this area was 1.217 mm/year, 1479 years was required for 1.8 meters of sediment formation. In this period, intra-continental pollution caused by terrestrial plants increased. The TOC/TN ratio was found to be 2.82 at a drilling depth of 17.20-19.0 meters. It has been found that the transport of intra-continental organic matter in this period of precipitation was very low. The decrease in TOC/TN ratios was the result of the contribution of marine algae (Liu et al., 2012). In this area, the TOC/TN ratios measured in deeper layers were found to be lower than other researchers (Walinsky et al., 2009; Xia et al., 2019). The average TOC/TN ratio in the Dikili region (8.178) was similar to that in the seas such as Jiaozhou Bay (11.48) (Kang et al., 2017), Yellow Sea (7.99) (Limin et al., 2013), East China Sea (7.14) (Limin et al., 2012; Dong et al., 2015). At this point, although the TOC/TN ratio increases towards the upper layers, the TOC/TN ratio does not show intra-continental pollution. Dikili district has less rugged terrain compared to the other two sample areas. Therefore, the sediment formation rate was quite small compared to other regions due to the low intra-continental transport.

Conclusion

TC, TOC, IC and total nitrogen measurements were carried out in Edremit Bay (Küçükkuyu, Güre, and Dikili). As a result of these measurements, TOC/TN ratios were found depending on the depth of the drilling. The total nitrogen concentrations in the Küçükkuyu region ranged from 1.09 to 2.1 g/kg. The total nitrogen concentration increased throughout the drilling depth. It was concluded that this was the result of nitrogen-rich algae activity in the marine environment. TOC concentrations were 12.34-20.36, 12.01-13.13, and 2.71-10.41 gr/kg in Küçükkuyu, Güre, and Dikili marine sediments, respectively. The biodegradation of organic matter and the nitrogen accumulated in the sea floor in Kucukkuyu Bay was low. It was thought that nitrogen-containing organic substances could not be converted to nitrate the result of the oxygen limitation in Küçükkuyu sediments, and, thus, denitrification did not take place.

The decrease in total nitrogen concentration along the depth of the seabed in the Güre region indicated that nitrification and denitrification reactions occur. The decrease of TOC and TN in the depth in the Dikili region indicated that denitrification is performed in the base sediments. The highest TOC/TN ratio was measured at 46.89 at a 15.40-16.0 m depth at the Güre DS3 point. The lowest TOC/TN ratio was found to be 2.82 in Dikili BH1. At the BH3 point in Güre, the TOC/TN increased throughout the depth indicating organic pollution from terrestrial high plants. According to Meyers et al. (1984), if the TOC/TN ratio is between 12-14, it is a terrestrial source of organic matter. It can be concluded that terrestrial pollution prevails in the Güre region. Venkatesan et al. (1987) indicated that organic matter had a planktonic origin if the ratio of TOC/TN was between 6 and 8. At the depth of 15-19 m at the Dikili BH1 point, the organic matter was found to be of marine origin. At other points, terrestrial and marine organic matter formation was observed.

The TC concentration is equal to the sum of IC and TOC. The highest total carbon content was observed in Küçükkuyuda and the lowest in the Dikili region. TC content was found between 19.06-28.95 in the Küçükkuyu region, between 18.08-20.07 in the Güre region, and between 9.52-20.41 in the Dikili region. In the future study, δ13C, and δ15N isotopic parameters should be measured in this area. In addition, in-continental soil samples should also be examined. The research area should be carried out in a wider area and at more sample points.

(Received 13th Jun 2019; accepted 2nd Sep 2019)

Abstract. Effects of environmental stress (e.g. salt stress) on the plant invasions are still relatively unknown. Therefore, we analyzed the physiological characteristics of *Alternanthera philoxeroides* (Mart.) Griseb. as an invasive plant and *Alternanthera sessilis* (L.) R.Br. ex DC. as a native plant under single and mixed planting, in green house, Jiangsu University, China. Plants were subjected to four different levels of salt stress treatments "i.e.", control, low (0.8%), medium (1.6%) and high (2.4%) that were made with equal proportion of NaCl and $CaCl_2$ followed by rewatering. The results showed, that different levels of salt stress affect the plant growth of both species differently. The net photosynthetic rate (Pn) for *A. philoxeroides* was higher from low to high stress of both single and mixed planting that of *A. sessilis*. Afterwards, during rewatering, the increments in Pn from low to high salt stress were also found higher in *A. philoxeroides*. In addition, the reduction in photosynthetic activity in *A. sessilis* under mixed planting during salt stress markedly affected the plant growth. After rewatering the comparative increments in plant growth parameter were also noted higher in *A. philoxeroides* than *A. sessilis*. Our results thus suggest that *A. philoxeroides* may possess a better adaptability to salt stress, which results in a successful competitive dominance.
Keywords: *invasiveness, growth, mixed planting, physiological responses, salt tolerance*

Introduction

Biological invasions are among the major global environmental challenges that can cause disturbing effects on the ecosystems (Quinet et al., 2015; Ricciardi et al., 2017; Zenni et al., 2017; Vitousek et al., 1997). Invasive plants may change the ecosystems by threatening the native biodiversity (Schweiger et al., 2010; Vilà et al., 2011). Certain non-native plant species possess some opportunistic characteristics that increase their probability to become invasive. It is related to their ability to proliferate, grow rapidly from germination to reproductive stage, and particularly, their tolerance to the environmental stresses (Van Kleunen et al., 2010). Invasive species compete with natives through a strategy known as jack-of-all-trades, which states that, the invasive species has an ability to maintain their fitness in unfavorable and stressful conditions (Richards et al., 2006), and under favorable conditions they maximize their fitness (Gioria and Osborne, 2014). It has also been well known that invasive plants have a stronger ability for adaptation than native species to heterogeneous environments (Keser

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1476714785

et al., 2015; Drenovsky et al., 2012). Nonetheless, our knowledge is still limited about the survival, tolerance and competitive dominance of invasive plants over native plants regarding why and how they adapt to heterogeneous abiotic factors.

Among heterogeneous abiotic factors, salt stress is one of the major abiotic concerns, threatening crop productivity (Asrar et al., 2017). Salinity may play an imperative part in the plant invasiveness. Up to now, limited research work has been conducted in the area of the impact of salt stress on plant invasion, and some contradictory results were revealed by a few researchers. As Kolb and Alpert (2003) exhibited high salt stress significantly decreased the relative-competitive-ability of the native species. Whereas, Noe and Zedler (2001) pointed out that salt stress was affecting the invasion by invasive species. The two key principals through which high-salt-levels stressed the plants are: (i) increase in osmotic potential imposed water-stress on plants by the result of high solute concentrations in the soil, and (ii) oxidative stress caused by high-concentration of nonessential-ions is poisonous to plants (Flexas et al., 2012).

Stress causes the changes in cell-water relationships and the ability of the plant to absorb water from the root zone decreases gradually (Ashraf and Foolad, 2007). The decrease in the amount of available water affects the plant growth development (Memon et al., 2010; Habib et al., 2012). In saline-conditions, salinity disturbed the plants' morphological, physiological and biochemical processes. Particularly, its limiting the plant growth (Meloni et al., 2004; Sekmen et al., 2007; Amirjani, 2010) by damaging the net photosynthetic rate (Pn), stomatal conductance (gs), transpiration (E) and leaf water potential (Ψ^{LW}) (Van Kleunen et al., 2010; Azeem et al., 2017b; Zheng et al., 2009). Each parameter which is affected, influenced by many factors up to some extent, including the stress severity and the total duration (Nawaz et al., 2010), the plants species and genotypes (Croser et al., 2001; Morais et al., 2012), the concentration of saline solution (Kosma and Jenks, 2007).

The effects of salt stress on physiological features can be alleviated and recovered through rewatering. Rewatering of saline water is a good approach for a plant to recover and sustain its growth and improve plant survival under salinity stressed environment (Javed et al., 2018). Invasive plants may become more competitive than their co-occurring native plants due to their better adaptation under increasing salt stress (Ozaslan et al., 2016) following rewatering. Therefore, we selected invasive and native species for this research to find out the physiological responses under salt stresses which are rarely tested before. *Alternanthera philoxeroides* (Mart.) Griseb. was taken as invasive species for this research. It mainly spreads by stem and root sprouts and causes serious environmental problems globally. *A. philoxeroides* is a clonal invasive weed, native to South America but growing in both riparian strip and terrestrial zones (You et al., 2018; Schooler, 2012). While, *Alternanthera sessilis* (L.) known as sessile joyweed, was considered as native species. It is a very common plant found in Brazil and in many tropical and subtropical areas of Africa, South Asia, Japan, New Zealand, Pacific Islands, Central America and South America. *A. sessilis* prefers wet surroundings but can grow under a variety of soil conditions (Gunasekera, 2008). Consequently, this study could be a little contribution to our knowledge about the invasiveness of *A. philoxeroides* in saline conditions. To justify this statement, the purpose of this research was to examine how *A. philoxeroides* and *A. sessilis* respond to salt stress followed by rewatering based on physiological properties. Meanwhile, the study also focused on the competitive growth among *A. philoxeroides* and *A. sessilis* under stress and rewatering during mixed planting.

Materials and methods

Species

Alternanthera philoxeroides (Mart.) Griseb is native to the high temperate region of South America . Except from the temperature zones, it has been also found in both aquatic and as well as in dry terrestrial habitats, and it continues to expand its range around the world. *A. philoxeroides* is considered as an invasive species in China, has phenotypic plasticity, high growth rate and more vegetative propagation (Chen et al., 2008, 2010; Yang et al., 2019). It mainly reproduces through stem and root splitting (Dong et al., 2010).

Alternanthera sessilis (L.) is native to Brazil, broadly distributed all over the tropic and sub-tropic regions of the word. *A. sessilis* prefers wetland areas and grows up to 1 m tall with white flowers. *A. sessilis* is a common leafy-vegetable, and is used as a medicinal plant in South-East- Asia. While, in many places of the world like Sri Lanka, the stems and leaves of *A. sessilis* are cooked and eaten as a vegetable (Hemakanthi de Alwis et al., 2006). In Tropical-Africa, *A. sessilis* is used in different ways, such as sauces and soup in Benin, as soup in Nigeria, as herb in Madagascar and as vegetable in Guinea. *A. sessilis* is also used for simple stomach problem, diarrhea, and as a plaster for diseased or wounded skin (Gunasekera, 2008; Niraimathi et al., 2013; Sun et al., 2010).

Site, culture condition and plant material

The experiment was carried out at Jiangsu University, China (32.20°N, 119.45°E) (*Fig. 1*) under greenhouse conditions in early September 2018. The greenhouse had natural lighting with (25/18) ± 2 °C (day/night) temperature and 70% relative humidity. *A. philoxeroides* and *A. sessilis* were chosen for this experiment, and about 360 ramets per species were collected from the same habitat at the main campus of Jiangsu University. Afterwards, the ramets of both species were grown in nutrient soil filled plastic pots. The chemical and physical characteristics of the nutrient soil were: pH 7.0, organic matter 38%, total nutrients 3.8%, water content 20% and electrical conductivity of 2 ds/m. while, the size of experimental pots were: outer diameter 21 cm, inner diameter 17.7 cm, bottom diameter 11.4 cm and height 12 cm. All pots were randomly arranged and the plant of both species were planted with different densities in mono (2: 0, 0: 2) and mixed planting (2: 2). Each group was irrigated with strengthen Hoagland solution as compound fertilizer to meet the basic requirements and healthy growth of seedlings for a week to keep the plants at full water level without shortage level to a total of seven weeks. After one-week plants were irrigated with fresh water every two days up to saturation levels. In the 2nd week of September, 2019, homogenous seedlings showing a healthy growth about 240 ramets per species were selected for treatments' implementation.

Treatments

Plants were treated with different concentrations of salted water for two weeks, which were prepared by mixing equal quantities (1:1) of NaCl and $CaCl_2$ in fresh water. Salt concentrations were i) control (0%), ii) 0.8%, iii) 1.6%, and vi) 2.4% per liter of fresh water. The division of the treatments for *A. philoxeroides* and *A. sessilis* under single and mixed planting were; AP0: Control received 0% of NaCl and $CaCl_2$;

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1476714785

AP1 received 0.8% of NaCl and $CaCl_2$; AP2 received 1.6% of NaCl and $CaCl_2$; AP3 received 2.4% of NaCl and $CaCl_2$; AS0: control received 0% of NaCl and $CaCl_2$; AS1 received 0.8% of NaCl and $CaCl_2$; AS2 received 1.6% of NaCl and $CaCl_2$; AS3 received 2.4% of NaCl and $CaCl_2$; MAP0: control received 0% of NaCl and $CaCl_2$; MAP1 received 0.8% of NaCl and $CaCl_2$; MAP2 received 1.6% of NaCl and $CaCl_2$; MAP3 received 2.4% of NaCl and $CaCl_2$; MAS0: received 0% of NaCl and $CaCl_2$; MAS1 received 0.8% of NaCl and $CaCl_2$; MAS2 received 1.6% of NaCl and $CaCl_2$; MAS3 received 2.4% of NaCl and $CaCl_2$, respectively following rewatering. Control treatment received only the fresh water (*Table 1*).

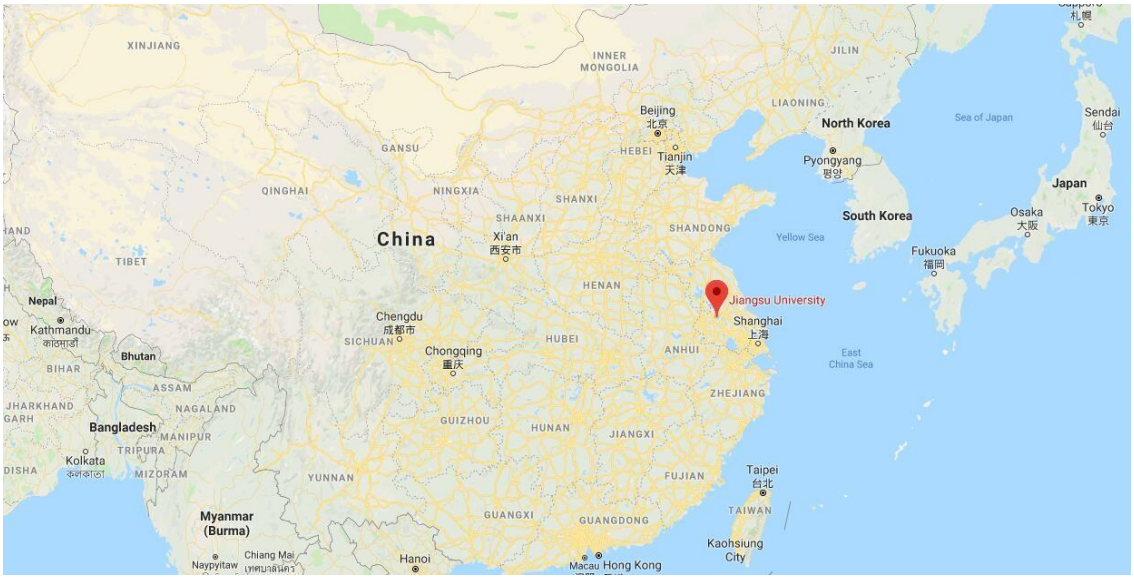

Figure 1. *A map indicating the location of the sampling site*

Rewatering was done on the 5th week from the onset of salt-stress treatments. The order of rewatering is shown in *Figure 2*. The experiment was conducted in randomized-block-design and a total of five replicates were chosen for each physiological measurement.

Photosynthetic traits and growth parameter measurements

Net photosynthetic rate (Pn), stomata conductance (gs), and transpiration rate (E) were measured by using a portable LI-6400XT photosynthesis measurement system (*LI-COR, Lincoln*, NE, USA. We prefer the growing young leaves from the top rather than mature old leaves to check photosynthesis response and growth traits of *A. philoxeroides* and *A. sessilis* in salt-stress phase following rewatering. All these data were recorded during full-sunshine at 9:30–11:30 a.m. after every four days in both salt stress and rewatering phase, respectively. Five plants from each treatment group were selected for the measurement. The following settings were noted during data collection: photosynthetic active radiation (PAR) was 800 µmol m^{-2} s^{-1}, temperature 28 °C and CO_2 concentration was 500 µmol mol^{-1}.

Growth measurements were considered after salt stress and after rewatering in both cases. The measurements chosen for growth traits analysis were: plant's height (PH); stem-diameter (SD), root-length (RL), fresh-weight of shoot (FW^S), dry-weight of shoot

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1476714785

(DW^S), fresh-weight of root (FW^R) and dry-weight of root (DW^R). The PH was measured with a tape and SD was measured with the help of digital Vernier caliper. Afterwards, FW^S, DW^S, FW^R and DW^R were measured by using weighing scale.

Leaf water potential and water use efficiency

Leaf water potential (Ψ^{LW}) of *A. philoxeroides* and *A. sessilis* were measured by using dew point microvolt meter in a C-52-SF universal sample room (Psypro, *Wescor*, USA). The Ψ^{LW} were recorded at 9:30–11:30 a.m. in salt stress subsequently in re-watering phase, respectively. While, water use efficiency (WUE) was calculated according to Javed et al. (2018):

$$WUE = Pn / R_T \quad \text{(Eq.1)}$$

where Pn is the net photosynthetic rate and R_T is the transpiration rate.

Statistical analysis

All measurements were examined statistically through SPSS 22 software (SPSS Inc., Chicago, IL, USA) and Origin Pro 9.0. Variance analysis with two crossed fixed factors was applied to discriminate the effects of species, salt stresses, rewatering and their interaction on physiological characteristics and plant growth properties under mono and mixed planting. The Tukey test was applied to determine the differences at 5% significance level ($P \leq 0.05$) between means (n = 5).

Results

Physiological responses

Net photosynthetic rate, stomatal conductance and transpiration

Net photosynthetic rate and stomatal conductance decreased significantly with increasing salt stress in comparison with the control. The response of the species to salt stress levels are given in *Table 2*. *A. philoxeroides* showed more tolerance from low to high concentration of salts. The values of Pn *for A. philoxeroides* at low concentration levels for single and mixed planting at AP1, MAP1 were 7.63 and 6.64 μmol (CO_2) m^{-2} s^{-1}, higher than the values of Pn for *A. sessilis*, which were 6.68 and 4.90 μmol (CO_2) m^{-2} s^{-1} at AS1 and MS1, respectively. It was found that, Pn was affected more under high stress at AS3, AP3, MAS3 and MAP3 in *A. sessilis* compared to *A. philoxeroides* (*Fig. 3a*). Upon comparing, the average Pn values of *A. sessilis* and *A. philoxeroides*, mixed planting decreased the Pn values more in *A. sessilis* respectively. Similarly, the response of the gs to salt stress levels are given in *Table 2*. The reduction in gs was found higher at high concentration for both *A. philoxeroides* and *A. sessilis* but comparatively less in *A. philoxeroides*. The gs values in mol (H_2O) m^{-2} s^{-1} for both *A. philoxeroides* and *A. sessilis* at high concentration under single and mixed planting were AS3: 0.066 AP3: 0.094 and MAS3: 0.044, MAP3: 0.086, respectively. It was showed that, during competition under mixed planting, *A. sessilis* exhibited maximum reduction in *Np* and afterwards in Cs as compared to single planting (*Fig. 3b*).

The response of Pn and gs during salt stress following rewatering are also shown in (*Table 2; Fig. 3a, b*). It was observed that *A. philoxeroides* exhibited significantly better recovery from stress phase to re-watering phase. During rewatering, by comparing the means under salt stress and rewatering, the increments in Pn from low to high salt concentration (AP1 (1→0), AP2 (2→1), AP3 (3→2)) for single-*A.*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1476714785

philoxeroides were 21.50%, 19.95% and 13.70% but for single-*A. sessilis*, increments in Pn at AS1(1→0), AS2(2→1), AS3(3→2) were noted as 16.04%, 10.23% and 5.34%, respectively. The Pn was not recovered well even after rewatering in case of mix-*A. sessilis* and showed less recovery comparatively to mix-*A. philoxeroides* (*Fig. 3a*). In rewatering phase, the increments in gs under low to high salt stress were found lower in *A. sessilis* plants (*Fig. 3b*). Consequently, high salt stresses affected gs and left adverse effect under mixed planting (*Table 2; Fig. 3b*).

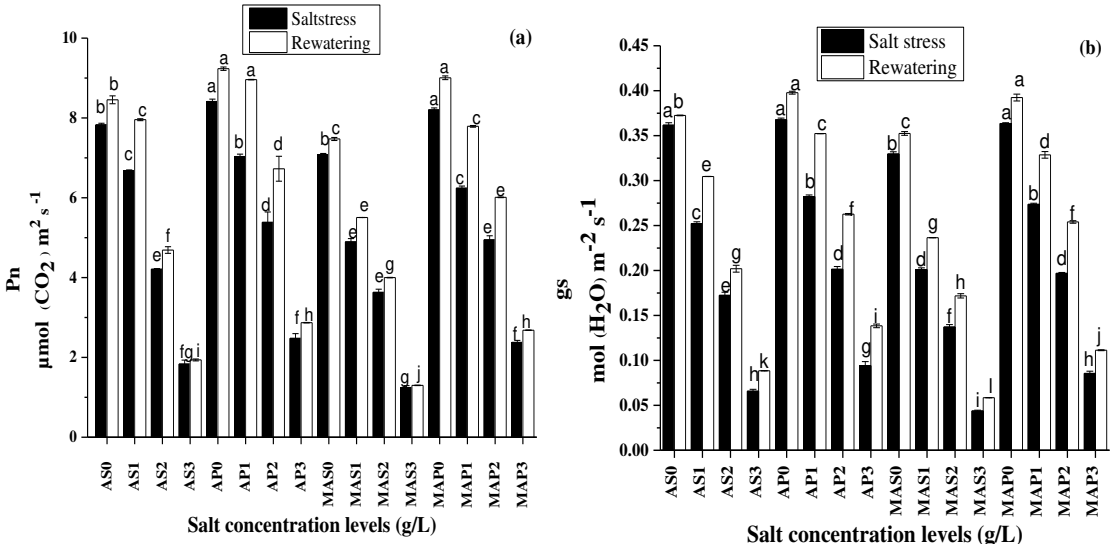

Figure 3. *Subsequent impact of salt stress under rewatering on (a) net photosynthetic rate and (b) stomatal conductance of A. philoxeroides and A. sessilis under single and mixed planting. Mean values sharing different letters are significantly different at $p \leq 0.05$ under different salt treatment levels*

Transpiration, water use efficiency and leaf water potential

Table 2 represented the results of E, WUE and Ψ^{LW}. The results exhibited the significant differences among treatment species and their interactions. The values of E decreased during salt treatments at low to high concentration levels, as compared to control (*Table 2*). Transpiration of *A. sessilis* decreased significantly in the stress and recovered up to moderate level AS2 for single planting during re-watering phase as shown in *Figure 4a*. But the salt stress severely affected *A. sessilis* E at AS3 and it did not recover. The E declined in *A. philoxeroides* throughout salt treatments at low to high concentration levels, as compared to control and recovered well from low to high stress. Therefore, in the rewatering phase, *A. philoxeroides* is also showed better E under mixed planting and was found to be recovering well from low MAP1 (1→0) to moderate level MAP2 (2→1) and less recovered at high level AP3 (3→2) and MAP3 (3→2) (*Fig. 4a*). Recovery of E confirms that *A. philoxeroides* can use more water to decrease the E and can improve plant development after rewatering. On the other hand, rewatering did not leave the positive effect on E recovery of the plant during competition with *A. philoxeroides* under mixed planting. Water potential (Ψ^{LW}) tends to decline as the relative water content of plant leaves decreases under stress condition. According to our results, Ψ^{LW} was affected with increasing salt stress compared with control (*Table 2*).

$T_{=}$ treatments, $S_{=}$ species, $T \times S_{=}$ interaction among the treatments and species, significant at $P \leq 0.001$ and $P \leq 0.005$ according to two-way ANOVA

The WUE showed the significant increase for *A. sessilis* from control to low stress, and the increment after rewatering was found as 31.65% and 23.55% at AS1 and MAS1 followed by medium stress (27.55%, 22.03%) at AS2 and MAS2, respectively. The maximum increments in WUE were recorded under low and medium stress for *A. philoxeroides* (36.16%, 32.13%, 33.53% and 31.90) under AP1, AP2, MAP1 and MAP2, respectively (*Fig. 4b*). However, the stress-persuaded maximum reduction was noted for *A. sessilis* under high stress at AS3 and MAS3. While comparatively, rewatering was reducing the effect of salt stresses significantly, and exposed the significant rise in WUE for *A. philoxeroides* (*Fig. 4b*).

In case of single planting of *A. philoxeroides* and *A. sessilis*, the minimum decrease in Ψ^{LW} was noted as -1.18 MPa and -2.00 MPa under low concentration levels at AP1 and AS1, respectively for both species as compared to moderate and high stress levels. But, the maximum decrease in Ψ^{LW} was noted as -2.82 MPa and -3.10 MPa at AP3 and AS3, respectively. While under mixed planting, *A. sessilis* is becoming more sensitive to salt stress and Ψ^{LW} was affected seriously from moderate to high concentrations (*Fig. 5*). However, in the competition, Ψ^{LW} was severely decreased in *A. sessilis* as compared to *A. philoxeroides*, respectively. As a comparison between single and mixed plantation, salts badly affected the Ψ^{LW} in *A. sessilis* than *A. philoxeroides* (*Fig. 5*).

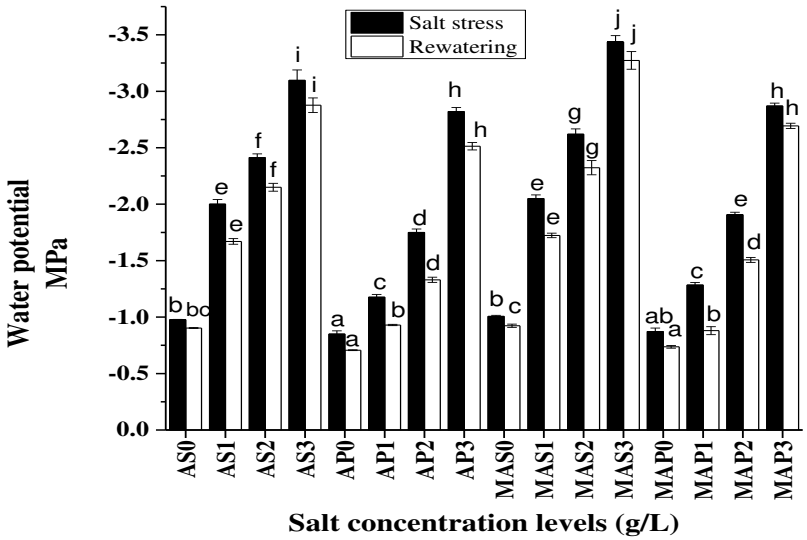

Figure 5. *Subsequent impact of salt stress under rewatering in leaf water potential of A. philoxeroides and A. sessilis under single and mixed planting. Mean values sharing different letters are significantly different at $p \leq 0.05$ under different salts treatment levels*

Table 2 also presents the values of Ψ^{LW} in salt stress following rewatering. The recovery in Ψ^{LW} was found less in single-*A. sessilis* from low to high stress (*Fig. 5*). Water potential was not recovered at high concentration levels for single-*A. sessilis* plants. However, the degree of salts was still showed its adverse effect on *A. sessilis* in the increment of Ψ^{LW} from moderate to high stress even during re-watering under mixed planting (*Fig. 5*).

Plant growth responses

Plant height and stem diameter

Stresses significantly affected the growth of *A. sessilis* and *A. philoxeroides* through reduction in plant height and stem diameter. The results showed significant differences among treatments, species and their interactions of growth parameters (*Table 3*). Plants growth of *A. sessilis* is more affected in competition under mixed planting as compared to *A. philoxeroides* (*Fig. 6a, b*). *A. philoxeroides* showed more tolerance from low to high stress in single as well as in mixed planting. Plant height and stem diameter were significant as compared to control. Upon comparing *A. philoxeroides* with *A. sessilis* under single and mixed planting, the PH (cm) are AP1: 42.30, AS1: 36.80, AP2: 37.30, AS2: 31.80, AP3: 32.40, AS3: 28, MAP1:40.30, MAS1: 33.80, MAP2: 35.30, MAS2: 28.80, MAP3: 30.60, MAS3: 25.50 (*Fig. 6a*); following SD (mm) which are AP1: 3.71, AS1: 2.98, AP2: 3.42, AS2: 2.39, AP3: 2.97, AS3: 2.23, MAP1: 3.34, MAS1: 2.49, MAP2: 3.16, MAS2: 2.28, MAP3: 2.77, MAS3: 2.00 (*Fig. 6b*). So, the *A. sessilis* exposed its sensitivity during competition under mixed planting, more reduction was found in plant height and stem diameter (*Fig. 6a, b*).

The subsequent PH and SD under salt stress under rewatering are also explained in *Table 3*. It was observed that *A. philoxeroides* exhibited significantly better recovery from stress phase to re-watering phase. While in re-watering phase, by comparing the means, the increments in PH and SD under moderate to high salt stress was found to lower in *A. sessilis*. By comparing, relatively, more increments in PH and SD were found in *A. philoxeroides* (*Fig. 6a, b*). The increments in PH after rewatering are AP1: 24.60%, AS1: 13.62%, AP2: 17.29%, AS2: 12.15%, AP3: 7.95%, AS3: 5.72%, MAP1: 21.44%, MAS1: 12.89%, MAP2: 22.08%, MAS2: 7.99%, MAP3: 6.13%, MAS3: 1.16% (*Fig. 6a*); following by SD as AP1: 19.00%, AS1: 18.36%, AP2: 16.79%, AS2: 13.41%, AP3: 5.41%, AS3: 2.62%, MAP1: 21.60%, MAS1: 17.00%, MAP2: 15.28%, MAS2: 9.52%, MAP3: 4.48%, MAS3: 1.48%, respectively. Rewatering alleviate the effect of salt stress more effectively in *A. philoxeroides* and left positive impact on plant growth.

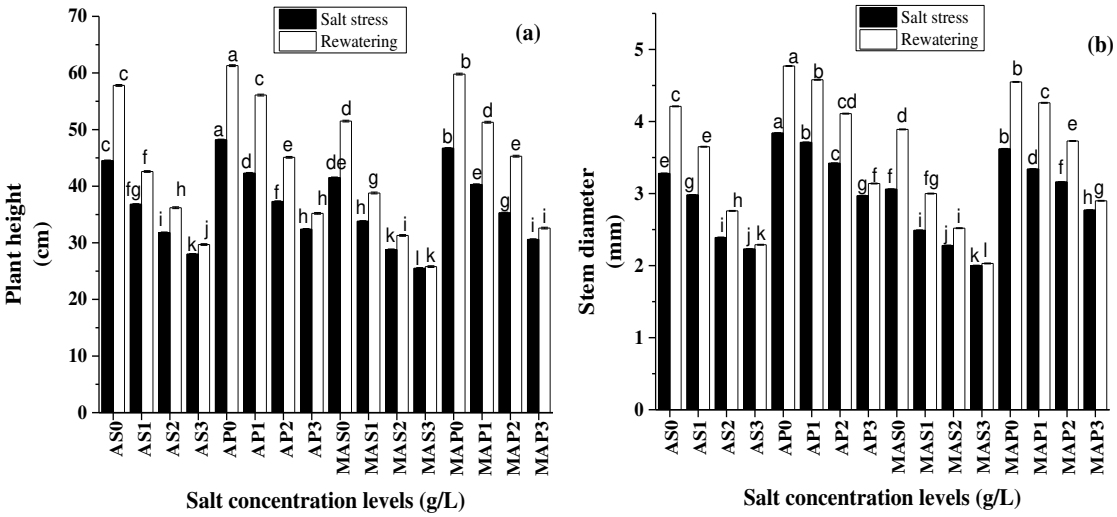

Figure 6. *Subsequent impact of salt stress under rewatering on (a) plant height and (b) stem diameter of A. philoxeroides and A. sessilis under single and mixed planting. Mean values sharing different letters are significantly different at $p \leq 0.05$ under different salts treatment levels*

Fresh and dry weight of shoot

Fresh and dry weight of shoot of both species for each treatment was presented in *Table 3*. As expected, mean of Fresh and dry weight decreased depending on salt concentration (*Table 3; Fig. 7a, b*). The variations in the results of shoot fresh and dry weight are different in both species. FW^S in single-*A. sessilis* is relatively more affected than mono-*A. philoxeroides* under high salt stress as AS3: 5.60 g, and AP3: 8.93 g following DW^S as AS3: 0.20 g, and AP3: 0.28 g, respectively. While, in competition under mixed planting FW^S and DW^S of *A. sessilis* declined more comparatively with mixed-*A. philoxeroides* (*Table 3; Fig. 7a*). The FW^S under mixed planting are MAS1: 10.30 g, MAP1: 21.27 g, MAS2: 5.20 g, MAP2: 12.43 g, MAS3: 2.57 g, MAP3: 7.97 g (*Fig. 3c*), following DW^S as MAS1: 0.37 g, MAP1: 3.03 g, MAS2: 0.18 g, MAP2: 0.60 g, MAS3: 0.11 g, MAP3: 0.24 g, respectively (*Fig. 7b*). Though, *A. philoxeroides* showed more tolerance from low to high stress in both single and mixed planting.

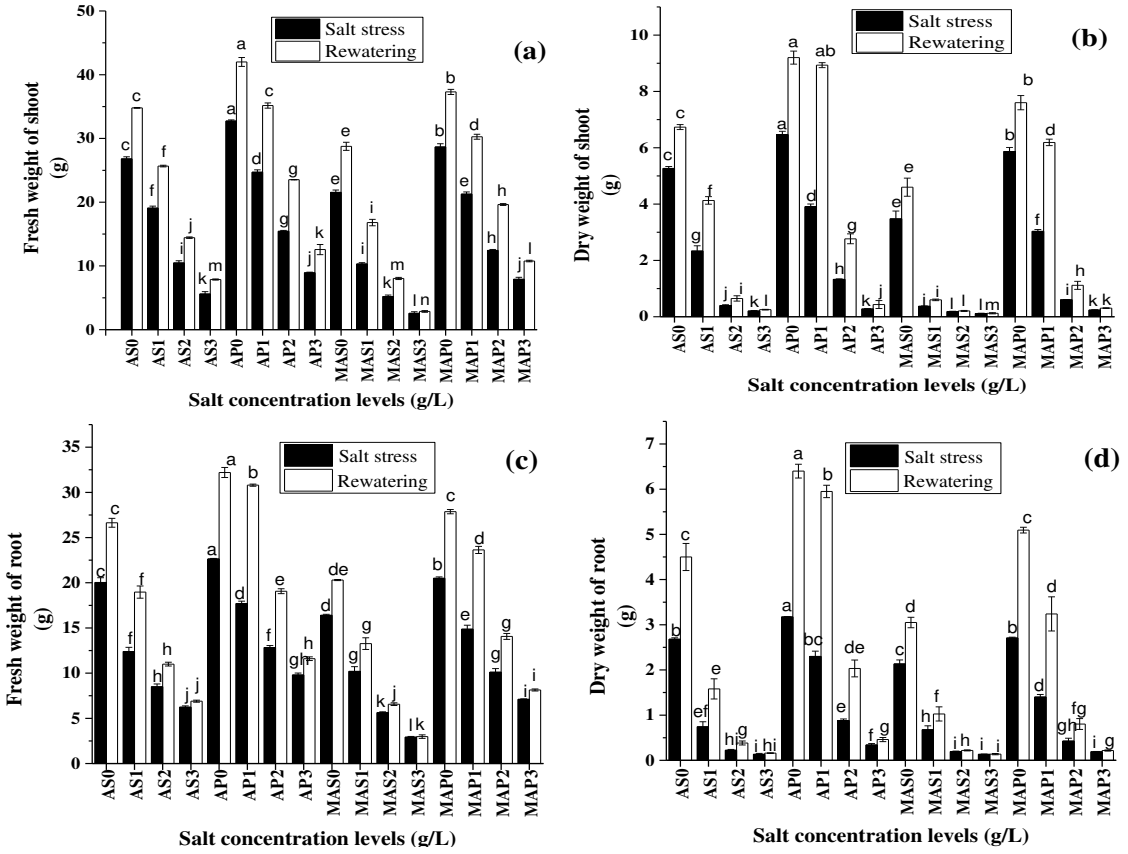

Figure 7. *Subsequent impact of salt stress under rewatering on (a) fresh weight of shoot, (b) dry weight of shoot, (c) fresh weight of root, and (d) dry weight of root of A. philoxeroides and A. sessilis under single and mixed planting. Mean values sharing different letters are significantly different at $p \leq 0.05$ under different salts treatment levels*

Subsequent salt stress under re-watering, is shown in *Table 3* for FW^S and DW^S. The plants showed recovery significantly from stress phase to re-watering phase (*Fig. 7a, b*). During re-watering phase, the increments in FW^S followed by DW^S under moderate to high salt stress were found to lower in *A. sessilis* that are AS2: 33.06%, AP2: 67.47% and AS3: 18.89, < AP3: 30.28%; AS2:38.97%, AP2: 56.27% and AS3:19.74%, AP3: 36.14%, respectively (*Fig. 7a, b*). Relatively, the maximum increment in FW^S and DW^S was observed for single and mixed-*A. philoxeroides* as 87.22%, 71.94%, 56.27%, 51.00% while for mono and mixed *A. sessilis*, it was calculated as 66.67%, 60.28%, 43.52%, 24.42% at AP1, MAP1, AS1, and MAS1, respectively (*Fig. 7a, b*). Comparing with other stress levels after re-watering, relatively, more decrements in FW^S and DW^S were found in *A. sessilis* under mixed planting and minimum recovery found after rewatering.

Fresh and dry weight of root

Fresh and dry weight of root of both species for each treatment was presented in *Table 3*. FW^R and DW^R decrease by increasing salt concentration relatively affected more in *A. sessilis* than *A. philoxeroides* under high salt stress (*Table 3; Fig. 7c, d*). The FW^R under single planting of *A. sessilis* at high concentration was observed as AS3: 6.23 g, and as AP3: 9.80 g (*Fig. 7c*) following DW^R as AS3: 0.13 g, and as AP3: 0.34 g,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1476714785

respectively (*Fig. 7d*). Comparatively, the FW^R of *A. sessilis* under mixed planting was affected more following the same trend by DW^R, respectively. Though, *A. philoxeroides* showed more tolerance from low to high stress in both single and mixed planting.

The FW^R and DW^R under salt stress following rewatering for both *A. philoxeroides* and *A. sessilis* is shown in *Table 3*. Recovery in FW^R and DW^R is initiated during re-watering phase (*Fig. 7c, d*). The minimum increments were noted in FW^R under moderate to high salt stress for *A. sessilis* which were AS2: 22.73%, AP2: 32.69% and AS3: 9.66%, AP3: 15.66% (*Fig 7c*), followed by DW^R as AS2: 41.74%, AP2: 56.72% and AS3: 16.69%, AP3: 26.09%, respectively. The maximum increment in FW^R and DW^R were recorded for single and mixed-*A. philoxeroides* as 42.53%, 37.09%, 61.34%, 56.79% and 34.62%, 23.12%, 52.96%, 34.09% were found for single and mixed-*A. sessilis* at AP1, MAP1, AS1, and MAS1, respectively. By comparing with other stress levels after re-watering, relatively, more decrements in FW^R and DW^R were found in *A. sessilis* under mixed planting even after rewatering (*Fig. 7c, d*).

Combined effect of salt stress and invasive plant on native plant

Using the linear regression equation to develop relationship between *A. philoxeroides* and *A. sessilis* under salt stress levels is shown in *Equation 2,* as given below:

$$MAS(FWS) = 0.149Lss + 1.040MAP(FWS) \quad \text{(Eq.2)}$$

where *MAS (FWS)* is shoot fresh weight of *A. sessilis* under mixed planting; $MAP(FWS)$ is shoot fresh weight of *A. philoxeroides* under mixed planting; *Lss* is salt stress levels.

It is well noted that the relationship between fresh weight of *A. philoxeroides* (MAP) under mixed planting, salt stress levels (Lss) and fresh weight of *A. sessilis* (MAS) under mixed planting can well characterize the combined effect of an invasive plant as *A. philoxeroides* and salt stress on its competitor native plant *A. sessilis*. The determination coefficient (R^2 = 0.9310), showed the best relationship between shoot fresh weight, salt stress and species and it is fitted better with the linear regression equation as compared with the other growth parameters.

Discussion

Salinity is a toxic environmental stress and severely influences several growth traits (Ashraf et al., 2012), particularly the photosynthetic rate. Salt stress initially damages the plant roots, disturbs the soil water potential and slows the growth rate of plants (Abbas et al., 2014). In our studies, the interaction between the species and salt stress has shown the significant differences (*Tables 2* and *3*). The salt stress limited the Pn as a result of stomata closure in both *A. sessilis* and *A. philoxeroides*. The Pn *of A. philoxeroides* and *A. sessilis* responded in a different way to different salt stresses (*Fig. 3a*). During the whole period of salt stresses, comparatively, plants kept a lower gs in single and mixed-*A. sessilis* at high salt concentrations (AS3 and MAS3) (*Fig. 3b*) and directly influenced the Pn. Low Pn had an adverse effect on PH and SD in *A. sessilis* (*Fig. 6a, b*), that was the cause of reduction in FW^S, DW^S, FW^R, and DW^R (*Fig. 7a, b, c, d*). It may be because of the disturbed leaf-water-status caused by distribution and accumulation of salts within the plant body that in turn has a marked impact on the plant water and nutrients uptake, resulting in toxicity and low Ψ^{LW} (Ashraf and Foolad, 2007; Zaki, 2016). The variations

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1476714785

in Ψ^{LW} within tissues (*Fig. 4*) from low (AS1, AP1, MAS1, MAP1), medium (AS2, AP2, MAS2, MAP2) and high stress (AS3, AP3, MAS3, MAP3) in both species under single and mixed planting affected the opening and closing of stomata in *A. sessilis* under mixed planting (*Fig. 3b*). It caused an imbalance in gaseous exchange, and decreased the E (*Fig. 4a*). Under these circumstances, plants have to utilize extra energy to make biochemical adjustments through osmolytes' accumulation for extracting water from the soil. This additional energy is diverted from the processes involved in plant growth, and results in marked reduction in yield and plant growth development (Munns and Tester, 2008; Ashraf et al., 2018), as noted in *A. sessilis* under single and mixed planting at AS3 and MAS3, respectively to *A. philoxeroides* (*Figs. 6* and *7*).

During competition under mixed planting, *A. sessilis* might be suppressed by two factors; one is competition with *A. philoxeroides* and other is its sensitivity to high salt stress. The combined effect of *A. philoxeroides* and salt stress on growth of *A. sessilis* is explained through linear regression (*Eq. 2*). In their meta-analysis, Van Kleunen et al. (2010), demonstrated that invasive species had higher values for numerous beneficial parameters of plant physiology, such as Pn and WUE than native species. Accordingly, *A. philoxeroides* showed photosynthetic tolerance from low stress levels (AP1 and MAP1) to high stress levels (AP3 and MAP3) under both single and mixed planting. Thus, this condition confirmed the best-threshold adaptability of photosynthetic traits and tolerance of *A. philoxeroides* under saline environment. Quinet et al. (2015) have also reported that *Impatiens parviflora* DC. is a better competitor in stress environments characterized by low water availability and shade. *Impatiens parviflora* copes well with shady conditions, it is tolerant to water-stress and maintains the photosynthetic activity under water-stress conditions. Ozaslan et al. (2016) did experiment on two invasive *Physalis species* and found that both species have a potential to withstand against water limited supply and high salinity environment. Although, WUE increased strongly in response to water stress (*Fig. 4b*), and plants adjusted their water potential (*Fig. 4a*) to maintain their water regulation for the fitness and continuation of growth. *A. philoxeroides* also grew well with high FW^S, DW^S, FW^R and DW^R and tolerate salt stresses from low to high concentration of salts at AP1, AP2, AP3 and more effectively and strongly under mixed planting at MAP1, MAP2, and MAP3 relative to its competitor *A. sessilis* (*Fig. 7a, b, c, d*). Liu et al., 2018 examined the response of three invasive and one native species under low, moderate and high water with low or high nitrogen availability. The growth, biomass and development of invasive species were higher relative to the native plant. Besides, higher salt accumulation in leaves of *A. sessilis* lowered the soil-water potential and in high stress at MAS3 prevented water uptake from soil to plant, causing dehydration of plants, with high reduction in PH, SD, (*Fig. 6a, b*). According to Qian and Ricklefs (2006) and Weed and Schwarzländer (2014), invasive plants have competitive advantages over neighboring native species. But these characteristics are varying from species to species and according to the kind of environmental stress (Lorenzo et al., 2010).

Rewatering relieved the stress and left better result on plant growth and development (Javed et al., 2018). But under stress, the variation in plant growth (*Figs. 6a, b, 7a, b, c, d*) did not associate with Pn recovery (*Fig. 3a*) when plant suffered under high stress conditions in *A. sessilis*. The production part of photosynthesis might have been used for the regeneration of ribulose-1,5-disphosphate. Therefore, at that point, an increment in Pn values for *A. sessilis*' plants under mixed planting noted as MAS1: 11.08%, MAS2: 9.25%, MAS3: 4.10%, which was not helpful in recovery of *A. sessilis*' plants (*Fig. 3a*). However, *A. philoxeroides* recovered and maintained its growth and photosynthetic traits

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1706_1476714785

effectively under single planting (at AP1, AP2, and AP3) subsequent under mixed planting (at MAP1, MAP2, and MAP3) as compared to control levels. Our results supported by findings of Yousfi et al. (2016) for all species of *Medicago laciniata* (L.) and Xing et al. (2018) for *Orychophragmus violaceus*, are proposed that reduction in gs after severe drought-stress, resulted in declined Pn with slow plant growth, as found in *A. sessilis*. Thus, unhealthy growth of *A. sessilis* was observed due to inadequate water-uptake that abruptly decreased the E (*Fig. 4a*). Water regulation through stomata under high stress could not maintain to stable water content and is becoming the reason of reduction in leaf-water-potential. Accordingly, it was hard for *A. sessilis* to improve its growth after rewatering due to the excessive salts-stresses under AS3, MAS2 and MAS3, respectively.

Salt stress following rewatering is found as an important index which specifies the better growth of plant after re-watering and a good method to utilize saline water after dilution in order to safe fresh water resources (Javed et al., 2017a, b; Xing et al., 2018). Because addition in water content after re-watering was directed to the Pn increment comparatively in leaves of *A. philoxeroides* with high growth rate and biomass as PH, SD, FW^S, DW^S, FW^R and DW^R under both single and mixed planting conditions. The massive reduction of water potential by decreasing E under high stress exposed the wilting point, and high demand of water for plants (Azeem et al., 2017a). For that reason, it is also needed for plants to be rewatered before wilting-stage. The relative effect of salts after rewatering, under mono planting of *A. philoxeroides* at AP1 (1→0), AP2 (2→1), AP3 (3→2) was almost the same with mixed planting under MAP1 (1→0), MAP (2→1) and MAP (3→2), respectively. It is concluded that salts were more toxic to plant growth of *A. sessilis* under single-AP3 and all levels of mixed planting, because of its sensitive nature suppressed through competition with *A. philoxeroides* as an invasive plant. It is also demonstrated that *A. philoxeroides* has a good competition ability with its competitive native plant *A. sessilis* and has a stress bearing adaptability to stressful environmental conditions.

Conclusions

In this article, we identified physiological and growth traits linked to salts-stresses tolerance in *A. philoxeroides* and *A. sessilis*. The physiological and growth response confer the competitive capability to both species under stressful environment. Under salt stress followed by rewatering, *A. philoxeroides* had higher values of Pn, gs, Ψ^{LW}, PH and SD with high biomass (FW^S, DW^S, FW^R, and DW^R) than *A. sessilis* in both single and mixed planting. Nevertheless, the competitive ability of the invasive plant *A. philoxeroides* was higher than that of the native species *A. sessilis* under mixed planting. Comparatively, *A. philoxeroides* showed better effect of rewatering with good improvement in plant growth. It can be concluded that, under single and mixed planting, tolerance of *A. philoxeroides* to salt stresses and its restoration after rewatering may aid its invasion success over *A. sessilis* species. Thus this study will be an initial prediction about future distribution of *A. philoxeroides* in the saline environment. In addition for future perspective, the further study could be done by considering different environmental factors based on their biological characteristics. Therefore, investigating the relationship between plant growth and environmental factors is helpful for predicting the invasive potential of non-native plant species.
