Abstract. Increasing aridity attributed to climate change is the main threat to the diversity and survival of Mediterranean forests including Tunisian pine species. The impact of this climatic condition in three pine species was examined in order to detect their responses to drought and guide their selection. Three Tunisian pine species: *Pinus halepensis*, *Pinus brutia* and *Pinus canariensis* growing in different climatic zones: humid, sub-humid, and semi-arid were studied in two months March and July 2016. Measurements carried out within this study are leaf gas exchange, twig water potential, and soil water content. The results showed a decrease in stomatal conductance and twig water potential in July in all pine species with increase in vapor pressure deficit and low soil water content. *Pinus halepensis*, *P. canariensis* and *P. brutia* had stronger stomatal control in semi-arid, sub-humid and humid climate, respectively (62, 95 and 63 mmol m^{-2} s^{-1}) and had higher stem water potential; for *P. halepensis* (-2.04 MPa) in semi-arid climate; for *P. canariensis* and *P. brutia* (-2.21, -2.39 MPa) in sub-humid and humid climate, respectively. *Pinus halepensis*, *P. canariensis* and *P. brutia* are better adapted to semi-arid, sub-humid and humid climates, respectively. Nevertheless, *P. halepensis* is considered the most resistant species as that could maintain higher photosynthesis, stomatal control and water use efficiency particularly in semi-arid climate. These findings help to assess the interaction between species and climate on the physiological response of pine species in mid-summer water deficit, and to select among these species the most resistant for future reforestation programs.
Keywords: *drought, leaf gas exchange, water potential, Mediterranean forest, genetic variability*

Introduction

Mediterranean forest tree species are exposed to a range of pressures (Ramirez-Valiente et al., 2010) and are mainly vulnerable to drought (Allen et al., 2010; Choat et al., 2012). An increase in aridity is particularly expected in the Mediterranean regions and, is the main threat to the diversity and the survival of forest trees (Peñuelas et al., 2017). Pine forests are one of Mediterranean forest species that may be threatened by rising temperatures and reduced precipitations (Manzanera et al., 2016).

To resist to these hydric stress conditions (Rubio-Casal et al., 2010; Letts et al., 2011), Pinus species may develop mechanisms of tolerance or avoidance (David et al., 2007; Mittler, 2002). Resistance to high temperature and drought strongly differs among

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_001013

plant species (Matías et al., 2012) being correlated to transpiration, hydraulic adaptations (Martínez-Vilalta et al., 2009) and water use efficiency (Warren et al., 2001). Plants protect themselves from excessive water losses (diffusion out of the leaf) under water-limited environments through a reduction of stomatal conductance (gs), which in turn leads to less carbon uptake (diffusion of CO_2 into the leaf) and possibly subsequent physiological stress (McDowell et al., 2008; Will et al., 2013), reduction of transpiration (Bréda et al., 1993; Granier et al., 2008), that has been recognized as the main environmental factor limiting plant photosynthesis on the global scale (Nemani et al., 2003).

This situation underlines the need to study leaf gas exchange as indicators of the ecophysiological tolerance of pine forests (Manzanera and Martinez-Chacon, 2007). Thus, pines species maintain rather constant leaf water potential in soils with low water status and/or under high evaporative demand (Martinez-Vilalta et al., 2004). Water use efficiency (WUE) is a critical metric parameter that quantifies the trade-off between photosynthetic carbon assimilation and transpiration at the leaf level (Farquhar et al., 1982). Leaf gas exchange and water potential variables were studied on three Mediterranean pine tree species located in three bioclimatic zones in Tunisia.

Aleppo pine (*Pinus halepensis* Mill.) is an important forest tree in the Mediterranean region (Klein et al., 2011). Its continental range extends from northern Africa and Middle East, up to southern Mediterranean Europe. It is native and the most abundant pine species in Tunisia (You et al., 2016). The majority of Aleppo pine forests are located in central and northwestern Tunisia, mainly in Kasserine, Kairouan, Kef, Seliana and Zaghouan (Ayari et al., 2012).

Calabrian pine (*Pinus brutia* Ten.), native to the eastern Mediterranean, can be found in many southern Mediterranean countries. It is the most pine specie that widely distributed in Turkey (Kucuk et al., 2012). Because of their drought tolerance, they are well adapted to dry summer conditions (Lopéz et al., 2016). In Tunisia, this species was introduced in 1960 in Souiniet, Tebaba, et Jebel Abderrahmane (Khouja et al., 2002).

Canary pine (*Pinus canariensis*) is an endemic species of the Canary Islands (de Nascimento et al., 2009). Despite its small distribution area (western islands, occupying much of La Palma, Tenerife, El Hierro and Gran Canaria, the species grows across a wide climate (from xeric conditions to mixed forest). In Tunisia, this species was introduced since 1965 in Souiniet, Henchir Naam, Jebel Abderrahmane (Khouja, 2001).

The purpose of this study was: (i) to assess drought tolerance of three pine species from the gas exchange data and water potential, (ii) to detect if climate has an effect on the degree of tolerance of species to drought, and (iii) to select the most droughts tolerant pine species. Therefore, our objective was to compare the physiological responses to drought in three pine species, Calabrian pine (*Pinus brutia*), Canary pine (*Pinus canariensis*) and Aleppo pine (*Pinus halepensis*), in different bioclimatic zones of Tunisia.

Materials and methods

Study sites

The study was carried out in three different arboretums (*Fig. 1*) on three pine species (*Pinus halepensis*, *P. brutia* and *P. canariensis*). The first, Souiniet "SNT", is located in northwest Tunisia (*Table 1*). The shrub layer is composed of trees of *Arbutus unedo*,

DOI: http://dx.doi.org/10.15666/aeer/1801_001013

Erica scoparia, *Erica arborea*, *Myrtus communis*, *Phillyrea media*, *Halimium halimofolium*, *Cistus salvifolius* and trees of *Quercus suber*

The second, Jebel Abderrahmane "JAB", is located in northeast Tunisia. Vegetation consists of Mediterranean maquis with *Quercus coccifera*, *Erica arborea*, *Calycotome intermedia*, *Halimium halimofolium*, *Pistacia lentiscus*, and *Phillyrea media*.

The third arboretum, Henchir Naam "HNM", is located in northwest Tunisia and is characterized by a semi-arid climate with moderate winters and hot dry summers. Pine trees: *P. halepensis*, *P. brutia* and *P. canariensis* are found in forest mosaics along with other tree species, including *Picris echioides*, *Phalaris truncata*, *Brassica amplexicaulis*, *Euscari comosum* and *Centaurea nicaensis*.

Sampling

Three experiments were carried out in this study: leaf gas exchange, twig water potential, and soil water content on 11th in the month of March and July 2016 in SNT, JAB, and HNM.

Three different trees of each pine species were considered of a high of 13.5 ± 2.5 m and mean diameter at breast height (DBH) of 16 ± 0.3 cm. From each tree, three branches were collected. Thus, a total nine branches of each pine species were taken for leaf gas exchange (Santiago and Mulkey, 2003). The measurements of leaf gas exchange and twig water potential were taken immediately after the collection of branches.

Leaf gas exchange measurements

Leaf gas exchange were measured using a Licor 6400® (Li-Cor, Lincoln, NE, USA) on two-year old needles leaves. At the top of each tree, three lateral branches 90 cm in length were cut with pruning shears from three different trees of each pine species (n = 27) in the morning between 06:00 and 08:00 a.m, and immediately measured in the field. Branches placed in a bucket containing cold water during the measurements to maintain leaf gas exchange at a constant level. Photosynthetic rate of the leaves was measured at the ambient CO_2 concentration (400 ppm) with an open infrared gas analysis system (Li-Cor 6400-40 equipped with a red-blue LED source; Li-Cor Inc., Lincoln, NE, USA). Measurements for attached leaves were operated at 25 °C leaf

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_001013

temperature and at an airflow rate of 300 cm3 min^{-1}. The vapor pressure deficit was kept at 1.2 ± 0.2 kPa. During the experiment, leaf temperature was maintained at 25 °C, photon flux density at 1500 µmol m^{-2} s^{-1}, ambient CO_2 molar ratio (Ca) at 400 ppm and humidity of the incoming air were kept at 60%. The variables measured were: leaf stomatal conductance (gs, in mmol H_2O m^{-2} s^{-1}), net carbon assimilation (An, in µmol CO_2 m^{-2} s^{-1}), and transpiration (Tr, in mmol H_2O m^{-2} s^{-1}). The instantaneous water use efficiency (WUE, in µmol CO_2 mol^{-1} H_2O) was determined according to *Equation 1:*

$$WUE = \frac{An}{Tr} \quad \text{(Eq.1)}$$

Twig water potential (TWP)

Water potential was measured at mid-day between 12:00 and 14:00 on three small twigs (5-7 cm long) from the considered trees using a Scholander pressure chamber (SKPM 1400®, Skye Instruments Ltd., Powys, UK) (Scholander et al., 1965).

Soil water content

Soil water content (SWC) was monitored using a time domain refractometry (TDR, Trase system I, Soil Moisture Equipment Corp., and USA) for the three sites.

Statistical analysis

Data analysis were done using Analysis of Variance ANOVA (SAS version 9.0) by GLM procedure and the mean values of species were compared using SNK test (Student-Newman-Keuls) tests at 95% confidence interval ($P < 0.05$). Pearson correlation coefficient was used to evaluate the correlations between physiological parameters studied.

Results

Gas exchange measurements at the leaf level

Drier conditions during the summer had a strong effect on gas exchange activity. Leaf gas exchange revealed significant differences in all variables (carbon net assimilation, transpiration and water use efficiency) between species ($p < 0.001$) and sites ($p < 0.001$), except for stomatal conductance where there was a significant difference between species ($p < 0.05$) but no difference between sites ($p = 0.145$). For any given species, there were differences among sites ($p < 0.001$) except for stomatal conductance in *Pinus canariensis* ($p = 0.812$). For any given site, there were differences among species ($p < 0.001$). The interaction between species x sites was significantly ($p < 0.001$) (*Table 2*).

At the leaf level, An was lower for all pine species in July compared to March, except for *P. halepensis*, which registered the highest values. Moreover, *P. halepensis* showed a sharp decrease (52%) in An from March to July in semi-arid climate ($p < 0.001$) than the other two species. For *P. canariensis*, there was a slight difference in reduction of An between humid, sub-humid and semi arid climates (44.07%, 41.77%

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_001013

and 48.7%). While for *P. brutia*, the reduction of An was (51%, 47.56% and 46.23%) in humid, sub-humid and semi arid climates (*Table 2*).

Transpiration rate, (Tr) was significantly lower in July than in March ($p < 0.001$) and between sites ($p = 0.006$). *Pinus canariensis*, *P. halepensis* and *P. brutia* showed a sharp decrease from March to July ($p < 0.001$) in sub- humid, humid and in semi-arid climates. It was (77.72%, 77.5% and 82.30%, respectively) (*Table 2*).

Water use efficiency rate, (WUE) was significantly different between months and species ($p < 0.001$). Higher WUE values were measured in July in semi-arid climate. The overall means were (17.44 and 15.52 µmol CO_2 mol^{-1} H_2O), in *P. halepensis*, and *P. brutia*, respectively except for *P. canariensis* the highest value was measured in sub-humid climate (15.03 µmol CO_2 mol^{-1} H_2O).

There was also a difference in water use efficiency between climates for the same species however, in *P. canariensis* the difference was more pronounced between humid and semi-arid (7.71 µmol CO_2 mol^{-1} H_2O, 8.5 µmol CO_2 mol^{-1} H_2O) and JAB (15.03 µmol CO_2 mol^{-1} H_2O).

Table 2. *Net assimilation rate (µmol CO_2 m^{-2} s^{-1}), transpiration rate (mmol H_2O m^{-2} s^{-1}), stomatal conductance (mmol m^{-2} s^{-1}), and water use efficiency (µmol CO_2 mol^{-1} H_2O) in March and July of Pinus canariensis, Pinus halepensis, P. brutia in Souiniet, Jebel Abderrahmane and Henchir Naam. Mean ± SE with distinct letters are significantly different at 5% (SNK test)*

An: Net assimilation rate Tr: transpiration rate gs: stomatal conductance WUE: water use efficiency, Sp: species, PC: *Pinus canariensis*, PH: *P. halepensis* and PB: *P. brutia*

In July, there was a high positive correlation between An and gs: r^2 coefficient. The correlation was more important in *P. halepensis*, *P. brutia*, and *P. canariensis* in semi-arid climate than others climates. The coefficients were ($r^2 = 0.623$, $r^2 = 0.58$, $r^2 = 0.95$), respectively (*Table 3*).

Stomatal control and twig water potentials

Stomatal conductance was significantly lower in July than in March ($p < 0.001$) for all pine species. The highest rate of decline of stomatal conductance between the two months was recorded for *P. halepensis*, *P. canariensis* and *P. brutia* in semi-arid, sub-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_001013

humid and humid climates, respectively. The rate of loss was (84.87, 78.41 and 88.54%), respectively (*Table 2*).

Twig water potentials revealed a significant difference between species ($p < 0.001$), sites ($p < 0.001$) and months ($p < 0.001$). For any given species, there were differences among sites ($p < 0.001$) and for any given site; there were differences among species ($p < 0.001$). The interaction between species and sites was significantly ($p < 0.001$).

Table 3. *Correlation coefficient r^2 of An and gs in July of P. halepensis, P. brutia and P. canariensis in Souiniet, Jebel Abderrahmane and Henchir Naam*

Sites	*P. halepensis*	*P. brutia*	*P. canariensis*

Henchir Naam	0.62	0.58	0.95

An: Net assimilation rate, gs: stomatal conductance

The water potential decreases significantly from March to July in all pine species in different climates (sites). The lowest rates of decline of water potential between the two months were 17.91%, 31.40% for *P. halepensis* and *P. canariensis* in semi-arid climate. For *P. brutia* the lowest rate was 47.53% detected in humid climate (*Table 4*).

Table 4. *Water potential (Ψ: MPa) of P. canariensis, P. halepensis, and P. brutia in two months March and July in Souiniet, Jebel Abderrahmane, and Henchir Naam. Mean ± SE with distinct letters are significantly different at 5% (SNK test)*

PC: Pinus canariensis, PH: P. halepensis and PB: P. brutia

Stomatal conductance (gs) decreased significantly as VPD increased in July in three sites (*Fig. 3*). In July and under semi-arid climate with (VPD = 2.4 kPa), the lowest minimum rate in gs was recorded in *Pinus halepensis* (62 mmol m^{-2} s^{-1}). While in a sub-humid climate and with (VPD = 1.68 kPa), stomatal conductance was lower in *P. canariensis* (95 mmol m^{-2} s^{-1}). In a humid climate and with (VPD = 1.9 kPa), *P. brutia* species recorded the lowest stomatal conductance value (63 mmol m^{-2} s^{-1}).

Soil water content

Soil water content (SWC) showed significant differences between months ($p < 0.001$) and sites ($p = 0.017$). The interaction term was also significant ($p = 0.02$), being higher in March than in July (*Table 5*). In July, the correlation between soil water content and gs was high and positive for *P. brutia*, *P. canariensis*, and *P. halepensis* $r^2 = 0.916$, $r^2 = 0.798$ and $r^2 = 0.931$, respectively in all sites.

Discussion

Ecophysiological measurements and stomatal control

Drought may reduce leaf net carbon assimilation by both stomatal and metabolic limitations (Farquhar and Sharkey, 1982). In addition, the decrease in stomatal conductance is the main factor of photosynthesis inhibition during dehydration as previously reported (Cornic and Fresneau, 2002; Flexas and Medrano, 2002).

In this study, a significant decrease in "gs" and "An" was found in July in *P. halepensis*, *P. canariensis* and *P. brutia* under different climates compared to results of March. Both parameters (gs and An) plummeted concomitantly as aridity increased. In Spain, Manzanera et al. (2016) found the same results on *Pinus sylvestris*, *Pinus pinea* and *Pinus halepensis*.

In our study, *P. halepensis, P. canariensis* and *P. brutia* suggest a higher stomatal control and decreased their water potential in semi-arid, sub-humid and humid climate, respectively to a lesser in the other climates. Also a strong reduction of stomatal conductance under drought conditions slows transpiration allowing plants to keep high water potentials (*Table 2*).

In France, Lebourgeois et al. (1998) found that pine species were tolerant to drought and a significant decrease of stomatal conductance of *Pinus nigra* was not correlated

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_001013

with obvious variation in water potential. They usually exhibit drought avoidance strategy with efficient stomatal control of transpiration loss, a decrease of stomatal conductance (up to 30%) and no change in water potential.

In July, our results (*Table 2*) revealed that the net carbon assimilation of *Pinus halepensis* was lower in humid climate (3.43 μmol m^{-2} s^{-1}) than sub-humid climate (4.12 μmol m^{-2} s^{-1}). However, Aleppo pine showed a higher assimilation rate than the other pine species in semi-arid climate (4.36 μmol m^{-2} s^{-1}). Similarly, in Spain, Salazar-Tortosa et al. (2018) found that net carbon assimilation in *P. halepensis* was (3.4 μmol m^{-2} s^{-1}) in the same season July 2014. It can maintain CO_2 uptake and photosynthesis by mean lower stomatal control.

The net carbon assimilation of *P. canariensis* was lower in July in semi-arid than humid climate but it maintain the high value in sub-humid climate. While, for *P. brutia* the net carbon assimilation was lower in semi arid climate but it can keep a high net assimilation in humid and sub-humid climates (*Table 2*).

Ecophysiological mechanisms driving WUE enhancement

In March and July, physiological activity and phenological development of the three pines species were critical. In March water availability in the soil was important and the radiation was not excessive, which leads to having a maximum value of photosynthesis, and the development of shoots and needles began. Whereas, in July water availability in the soil was limited; the radiation was excessive and lead to having minimal photosynthesis. The development of the shoots was complete and that of the needles was in progress.

For all studied pine species, the large fluctuations in WUE between March and July appear to be mainly related to changes in environmental conditions (soil water content, precipitation and temperature). Thus, soil water content was negatively correlated with WUE for all pine species under semi-arid, humid and sub-humid climate. These results revealed the degree of adaptation and resistance of three pine species particularly in these climates under drought conditions. The significant interaction observed between site (climate) and species clarify the behaviour of each pine species: *Pinus canariensis* have better water use efficiency in sub-humid than in humid and semi-arid. *Pinus brutia* have a high water use efficiency in the three sites with pronounced value in semi-arid. However, Aleppo pine showed higher water-use efficiency in different climates, supporting the notion that assimilation was less limited by climatic conditions (*Table 1*). As far as Klein et al. (2012) found that Aleppo pine has the ability to survive and grow in various environments indicates thus is a highly tolerant species**.** In contrary to previous study realized by Sardans and Peñuelas (2007) and Vila et al. (2008) confirmed that Aleppo pine is expected to suffer from changes in timing and duration of drought, particularly in spring and summer.

The effect of VPD and soil water content on stomatal response of pine species

Oren et al. (1999) emphasized that high VPD may be one of the signals that lead to stomatal closure. In our study, stomatal conductance decreased in July for all pine species in different climates with the increase of the VPD. Both high VPD and low SWC explained the reductions in stomatal conductance, transpiration and photosynthesis in all pine species under different climates (*Table 2*). The results were also in agreement with those reported in USA by Sulman et al. (2016) that worked on

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_001013

Acer saccharum, *Liriodendron tulipifera*, *Sassafras albidum*, *Quercus alba*, *Quercus velutina*, and *Quercus rubra*. Under drought conditions and with low SWC or high VPD, these 5 plant species close stomata reduce transpiration and photosynthesis.

P. brutia was more resistant to drought in two climates humid and semi arid. Awada et al. (2003) showed that *P. brutia* was a drought-resistant species occupying the driest sites around the Mediterranean Basin. Furthermore, *P. canariensis* was resistant to drought in the three climates in Tunisia with less tolerance to humid climate. Jiménez et al. (2005) showed that *P. canariensis* was able to modulate its physiology (with a good stomatal control), depending of the site where it grows with. However, the performance of *P. halepensis* was much higher as much as this species exhibited higher stomatal control, higher photosynthesis and water use efficiency in a dry month (July) and under semi-arid climates. Salazar-Tortosa et al. (2018) showed that Aleppo pine would require less water in the carbon capture process when it is planted with limited water availability. This strategy allowed *P. halepensis* to be one of the more conservative species.

Conclusion

The findings showed significant differences in leaf water potential and gas exchange measurements among pine species. The responses are depending not only on species but also on the climate in which they grow.

Under dry conditions, *P. halepensis*, *P. canariensis* and *P. brutia* are better adapted to a semi-arid, sub-humid and humid climate, respectively. All pine species avoid drought by reducing stomatal conductance to water through conservation of soil water content at high VPD and thus avoiding future drought. While this strategy would result in a net increase in WUE, it would be at the expense of photosynthesis during periods of high VPD. The findings of these experiments may help to quantify the impact of mid-summer water deficit on Mediterranean pines and evaluate their potential responses to future climate regimes. Monitoring of these three species is required to reveal how ecological restoration is progressing and where management interventions are required.

Therefore, in Tunisia, it is highly recommended to plant *P. halepensis* in semi-arid climate, *P. brutia* was recommended to be planted in humid and semi-arid climates. While, it is recommended to plant *P. canariensis* in sub-humid and semi-arid climates.

Abstract. The yield of rubber tree is influenced by environmental factors and its own variety characteristics. In this study, a simulation model for the stem volume of standing rubber trees was developed. Compared to the general model, the RMSE and R^2 values between the simulated and measured data were increased by 28.0% and 4.5%, respectively. Through analysis, the regression model Y_{dr1} (take the relative stem volume increment and climatic variables as independent variables), Y_{dr2} (take the climatic variables and disaster index as independent variables), and Y_{dr3} (take the relative stem volume increment, climatic variables and disaster index as independent variables) were established for the dry rubber yield prediction of a single plant. The result showed that, the RMSE and R^2 values of the yield prediction model Y_{dr3} were 0.0354 kg and 0.9862, they increased by 76.8% and 32.6% with respect to the model Y_{dr2} and rose 66.8% and 17.4% compared to the yield prediction model Y_{dr1}, respectively. In applying the prediction model Y_{dr3} to the yield prediction in different sub-compartments of a rubber plantations, the mean absolute error was 35.7 kg/ha. This study's newly established model could provide decision support for dry rubber yield prediction of rubber plantation over large areas.
Keywords: *climatic element, meteorological disaster, rubber tree, stem volume, yield prediction*

Introduction

The rubber tree (*Hevea brasiliensis*) is currently the main source of natural rubber. This species is native to the Amazon River Basin in South America, and is commonly found in a climatic environments with high temperature, high humidity, and abundant and evenly distributed rainfall, where it can avoid meteorological disasters hazards, such as typhoon, too-low temperature, and drought (Roberts, 1988; Yu et al., 2014).

China is now an important producer of natural rubber, with a yield is the fourth highest globally. In Hainan Province, the cultivated area is about 5.3×10^5 hm^2, and the rubber yield accounts for 53% of the national production, making it the largest production base of rubber in China (Xu et al., 2017). Rubber production is highly sensitive to various climatic factors. The locality in Hainan is prone to typhoons and chilling damage, which are mostly absent from rubber's native range (Chen et al., 2012; Liu et al., 2015; Roy et al., 2017). Against the background of global climate change, extreme weather events are more likely to occur than ever before. This raises a pressing question: How to quantitatively evaluate the effects of climatic element and disasters hazards on the rubber production. Predicting rubber yield is vital for promoting regional rubber production, so new models are presumably needed.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_015032

The theoretical yield of rubber tree is mainly determined by the species variety used (Lacote et al., 1998), while in its non-native range, annual fluctuations in yield are jointly affected by the market (Xu etal., 2017) and climate factors (Devakumar et al., 1998; Rao et al., 1998; Zomer et al., 2014; Golbon et al., 2015; Nguyen and Dang, 2016), in addition to meteorological disasters (Chen et al., 2012; Liu et al., 2015). The regular growth of rubber tree requires more than 2000 h of annual sunshine duration, over 1500 mm of annual precipitation, over 150 d of rainy days in a year, with an average relative humidity of more than 80% in the planting region. Additionally, the minimum limit temperature for its growth is 18 °C, while higher temperatures and stronger solar radiation are beneficial to this tree's photosynthesis. But if the temperature is < 10 °C and > 40 °C, then photosynthesis will cease. The range of 18–28 °C is the most suitable for rubber production, while that of 18–24 °C is the most suitable for rubber discharging temperatures (Yu et al., 2014; Yang, 1989; Priyadarshan et al., 2005; Kokmila et al., 2010; Carr, 2012).

In evaluating the relationships between climatic factors and rubber yield, much prior research has looked into various climatic factors to establish the yield prediction equation (Yu et al., 2014; Golbon et al., 2015; Nguyen and Dang, 2016; Zhang et al., 2014, 2017; Kim et al., 2017). For example, Yu et al. (2014) analyzed the relationship between the 5-d average yield of a single rubber tapping tree and the following: average temperature 1 day and 1 month before rubber tapping, day-night temperature difference, and sunshine duration 1 day and 1 month before the rubber tapping. They found that the day-night temperature difference was an important factor influencing the rubber yield, and established their yield prediction equation by using partial least squares regression and classification in a regression tree model. Golbon et al. (2015) considered the average value of rainfall, lowest temperature, highest temperature, and maximum relative humidity 30 days before the rubber tapping as the optimum yield predictors; using them, they established a prediction model of rubber yield by using a linear mixed model. Feng et al. (2016) reported that nine climatic factors influencing the rubber yield were ranked as follows: sunshine > highest temperature > average humidity > average temperature > lowest humidity > evaporation > wind speed > lowest temperature > precipitation; based on this they established a monthly rubber yield prediction model for Xishuangbanna, China. In other work, Nguyen and Dang (2016) analyzed the relationship between the yield and the average temperature, average highest temperature, and average lowest temperature, in the rubber tree varieties GT1 and PB235 in Vietnam for three consecutive years (during 2007~2009). Those rubber yields showed significant negative correlation with all three climatic factors. Earlier Liu et al. (2002) reported that a significant correlation between the diameter at breast height and dry rubber yield of two strains, RRIM600 and PR107. Some have researched the correlations among the laticifer differentiation capability of the rubber tree, the combined efficiency of rubber, and the rubber yield; this was then applied to early rubber yield predictions (Chen, 2014; Yu, 2007).

Until now, research on rubber yield prediction has mainly taken a single climatic factor or a physic-ecological index as the main predictor variable, thereby overlooking the effect of meteorological disasters and varietal characteristics on the predicted yield. In this study, the relative stem volume of rubber tree and a disaster index were introduced as the key predictors, and a new forecasting model for the dry rubber yield of rubber tree was developed, tested, and established. This work thus provides a theoretical basis for the accurate yield estimation in the rubber production over large areas of its cultivation in China.

Materials and methods

Study site

Hainan has a tropical oceanic monsoon climate. In this jurisdiction, the annual average temperature of various regions is 23.1~27.0 °C, with annual precipitation that is 940.8~2388.2 mm. The annual average sunshine duration is 1827.6~2810.6 h. During years of 2014–2017, rubber plantations differing in their stand ages were selected, as *Figure 1* shows, in Dongchang Farm of Dapo Town, Haikou City (Location: N19°36', E110°37'; Rubber cultivation: 1333.3 ha), Xinzhong Farm of Wanning City (Location: N18°51', E110°11'; Rubber cultivation: 5593.3 ha) and Xiqing Farm of Danzhou City (Location: N19°32', E109°28'; Rubber cultivation: 4573.3 ha). The sampling of the forest stand is the pure rubber plantation that has been tapped manually and the cultivated soil is red soil. The variety studied is RRIM600. The spatial position of the plantation sub-compartments is shown in *Figure 1*.

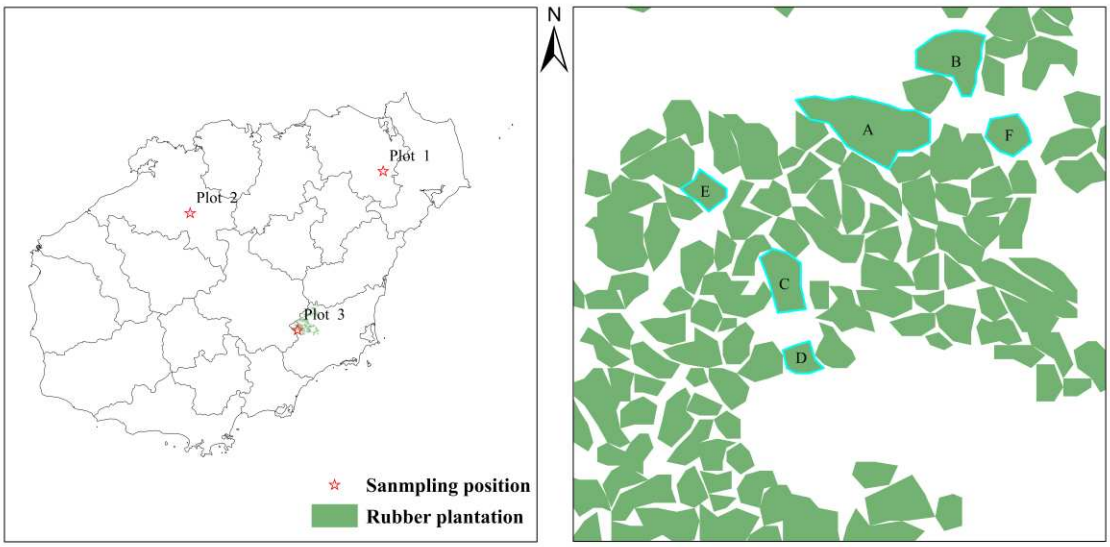

Figure 1. *Distribution of sampling points in the study area. (Plot 1 is Dongchang Farm in Haikou City, Plot 2 is Xiqing Farm in Danzhou City, and Plot 3 is Xinzhong Farm in Wanning City. A, B, C, D, E, and F are the sub-compartments of a rubber plantation with different stand ages at the Xinzhong Farm)*

Data sources

Forest characteristics collection

During 2014-2015, on December 20-31 every year, the sampling was carried out in differently aged stands in plot1 and 2. In the sampling rubber plantation of the farm, the tree height, diameter at breast height (at 1.3 m above the ground) and the thickness of the bark were measured, the crown area was calculated using elliptic area formula (the vertical projection width of the canopy from east to west and north to south was used as diameter). 100 trees were measured at each sampling point every year, a total of 400 samples were obtained until the end of 2015. The data sets applied for training.

During 2016-2017, on December 20-31 every year, the same sampling was carried out in differently aged stands in plot3. 100 trees were measured at this sampling point every year,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_015032

a total of 200 samples were obtained until the end of 2017. The data sets applied for validation.

Data for tree volume calculation

Differential planimetry is often used to calculate timber volume. In this method, the trunk is divided into several segments, and the volume of each segment is calculated respectively, and finally calculate the volume of the trunk. The precision of this method mainly depends on the number of segments. In this study, the trunk characteristics of rubber trees were comprehensively analyzed, and the number of trunk segments is determined to be 10. The trunk height of the sampled rubber tree was measured, and then the trunk was divided into 10 segments on average according to the height, and the diameter of each segment was measured.

The historical sequence data of tree diameter

In each plot, 20 rubber trees aged > 40 years with undamaged tree form were selected for destructive sampling (point 1:45 years old, point 2: 47 years old, point 3: 46 years old). After being felled, a disk of the tree trunk at 1.3 m was removed and marked in the cardinal directions. The disk was polished until the annual ring boundary was clearly visible. Along the north-south direction of the disk, a section of 1 cm × 30 μm was cut by a slicer, and then made into a microsection of annual rings. Under a microscopic projector (XTL-2400), each annual ring width of the section from the pith to the bark was measured to the nearest 0.01 mm. The magnification used was 40x (Rahman et al., 2017). The annual tree wheel width of 20 rubber trees measured at each sampling point was averaged as the annual tree diameter (without bark). The annual tree diameter was multiplied by bark coefficient (bark coefficient = skin diameter/skin diameter) as the historical sequence of tree diameter (with bark).

Meteorological data

From the Hainan Meteorology Administration, the data of daily mean temperature, precipitation, wind speed and sunshine hours was obtained for the years 1960–2017. From the "tropical cyclone yearbook", the data of maximum wind speed (m/s) and maximum instantaneous wind speed (m/s) in each process was obtained for the years 1960–2017.

Rubber production data

The data on rubber yields came from production records of farms (Dongchang, Xiqing, Xinzhong) during the same period (1960-2017), including the total production of dry rubber and plant cutting, and further calculate the dry rubber yield of single plant (total production of dry rubber/plant cutting).

Meteorological index

K_I is the heat-index, P_I is the precipitation-index, R_I is the sunshine-index, and D_I is the disaster-index, with their calculations made as follows (*Eqs. 1-6*):

$$K_I = 0.724 \sum_{i=1}^{n} (T_1 - 18) + 0.276 \sum_{j=1}^{n} (T_2 - 10) \quad \text{(Eq.1)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_015032

T_1 is the daily average temperature during April-November, T_2 is the daily average temperature from December in the last year to March in the next year (°C), and n is the number of days of regular rubber tree growth. The critical temperature for this regular growth is 18 °C and 10 °C.

$$P_I = (P - 1500)/n \quad \text{(Eq.2)}$$

P is the annual precipitation (mm), with 1500 mm being the minimum annual precipitation required by the rubber tree; n is the number of rainy days.

$$R_I = (R_i - 2000)/2000 \quad \text{(Eq.3)}$$

The term R_i is the annual sunshine duration (h), with the rubber tree requiring 2000 h of annual sunshine duration for regular growth.

$$D_I = 0.724I_{tc} + 0.276I_c \quad \text{(Eq.4)}$$

Itc is the typhoon disaster index. V_{m1}, V_{m2}, R_t, and R_m are the standardized values of maximum wind speed (m/s), maximum instantaneous wind speed (m/s), total precipitation (mm), and daily maximum precipitation (mm), respectively; I_c is the chilling damage index, and X_1-X_6 are the standardized values of yearly lowest extreme temperature (°C), maximum temperature drop in degrees (°C), sustained days of chilling damage, radiant accumulated coldness, advective accumulated coldness, and the sustained days of cold weather process with the longest advection. The coefficients in the formula are calculated by the analytic hierarchy process.

$$I_{tc} = 0.340 * \sum_{i=1}^{n} V_{ml}^2 + 0.280 * \sum_{i=1}^{n} V_{m2}^2 + 0.136 * \sum_{i=1}^{n} R_t + 0.244 * \sum_{i=1}^{n} R_m \quad \text{(Eq.5)}$$

$$I_c = 0.064X_1 + 0.143X_2 + 0.282X_3 + 0.100X_4 + 0.207X_5 + 0.204X_6 \quad \text{(Eq.6)}$$

Calculation of stem volume of felled rubber trees

The stem volume (V) of a sampled rubber tree was calculated using the average basal area quadrature method (*Eq. 7*; Zeng, 2011).

$$\mathrm{V} = \frac{\pi}{4}\left(\frac{D_0^2 + D_{10}^2}{2} + \sum_{i=1}^{9} D_i^2\right)\theta \quad \text{(Eq.7)}$$

In this formula, V is the stem volume of fallen tree (m^3); D_0, D_n, and D_i are the cross-sectional diameters of the segment at the bottom, top and in the middle of the trunk (m), respectively; θ is the segment length; and the number of segments is 10.

Model construction

Model construction for the crown area and the height of tree

Referring to previous studies, it can be seen that the relation between tree height and the diameter at breast conforms to Richard equation, and the crown area and the diameter at breast conform to Weibull equation (Zeng et al., 1999; Bi et al., 2012). The

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_015032

tree height model *RH* (*Eq. 8*) and crown area model *RA* (*Eq. 9*) was established respectively.

$$H_r = \lambda_1 * (1 + (\lambda_2 - 1) * \exp(-\lambda_3 * (D - \lambda_4)))^{(1/(1-\lambda_5))} \quad \text{(Eq.8)}$$

$$A_r = \gamma_1 * (1 - \exp(-(\gamma_2 * (D - \gamma_3))^{\gamma_4} \quad \text{(Eq.9)}$$

where λ_1, λ_2, λ_3, λ_4, λ_5, γ_1, γ_2, γ_3, γ_4 are the model parameter, *Hr* is tree height (m), *Ar* is crown area (m^2), and D is diameter at breast height (cm), respectively.

Stem volume of a single standing tree

A general model(V1) based on tree height and DBH is used to calculate the stem volume of standing tree (*Eq. 10*) (Gonzalez-Benecke et al., 2012, 2013, 2014; Zhou et al., 1995):

$$\mathrm{LnV1} = \alpha_1 + \alpha_2 Ln(D^2 H) \quad \text{(Eq.10)}$$

where *V* is the living wood growing stock (m^3), *D* is DBH (the diameter at breast height) (cm), *H* is the tree height (m), and α_1 and α_2 are the model parameters for estimation.

Since the crown area is an important factor influencing the stem volume of standing tree, by incorporating it into model V1, the stem volume model of a standing tree could potentially be improved. Thus, a prediction model V2 that includes three tree characteristics-namely diameter at breast height, tree height, and crown area—was established, which had the following form (*Eq. 11*):

$$\mathrm{Ln(V2)} = \alpha_1 + \alpha_2 \cdot Ln(D^2 H) + \alpha_3 \cdot Ln(CA) \quad \text{(Eq.11)}$$

where α_1, α_2, and α_3 are the model parameters, respectively, for the characteristics: *D*, diameter at breast height (cm); *H*, tree height (m); and *CA*, crown area (m^2).

Model construction for dry rubber yield prediction

Under a scenario of reasonable growth management, the theoretical rubber yield is mainly affected by its own strain, while the actual yield is also jointly influenced by environmental factors including the climatic variables and disasters hazards (Zhang et al., 2017; Gouvea et al., 2013; Slipi et al., 2006). During the plantation of rubber trees in Hainan, the first 10 years are usually the non-economic production period, whereas the update and elimination are carried out when the stand age is over 35 years. Therefore, a subsection regression prediction equation was established to forecast the rubber yield of single plant in the economic production period. In this research, the yield model Y_{dr1} including the relative stem volume increment and climatic variables, Y_{dr2} including the climatic variables and disasters hazards, and Y_{dr3} including the relative stem volume increment, and both climatic and disaster factors, were established and compared and analyzed (*Eqs. 12-14*):

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_015032

$$Y_{dr1} = \begin{cases} 0 & n \leq 10 \\ \beta_1 + \beta_2\left(\frac{V_n - V_{n-1}}{V_{n-1}}\right) + \beta_3 T + \beta_4 K_I + \beta_5 P + \beta_6 R_I & 10 < n \leq 35 \\ 0 & 35 < n \end{cases} \quad \text{(Eq.12)}$$

$$Y_{dr2} = \begin{cases} 0 & n \leq 10 \\ \beta_1 + \beta_2 T + \beta_3 K_I + \beta_4 P + \beta_6 R_I + \beta_6 D_I & 10 < n \leq 35 \\ 0 & 35 < n \end{cases} \quad \text{(Eq.13)}$$

$$Y_{dr3} = \begin{cases} 0 & n \leq 10 \\ \beta_1 + \beta_2\left(\frac{V_n - V_{n-1}}{V_{n-1}}\right) + \beta_3 T + \beta_4 K_I + \beta_5 P + \beta_6 R_I + \beta_7 D_I & 10 < n \leq 35 \\ 0 & 35 < n \end{cases} \quad \text{(Eq.14)}$$

where β_1, β_2, β_3, β_4, β_5, β_6, and β_7 are the model parameters, respectively. n is tree age.

Model testing

Using a separate validation dataset, the prediction precision ability of tree height, crown area, stem volume, and yield model were tested. Differences among the simulations in their precision were compared and analyzed by comparing precision differences of the yield models differing in their predictors between the conventional stem volume model and our newly proposed model. The simulation precision of all model variants was assessed by calculating the mean absolute error (MAE), the root-mean-square error (RMSE), and the determination coefficient (R^2) between the observed and simulated (predicted) values (Yu et al., 2014; Zhang et al., 2014).

$$\text{RMSE} = \sqrt{\frac{1}{N}\sum_{t=1}^{N}(d_{observe} - d_{predict})^2} \quad \text{(Eq.15)}$$

$$\text{MAE} = \frac{1}{N}\sum_{t=1}^{N}\left|d_{observe} - d_{predict}\right| \quad \text{(Eq.16)}$$

In *Equations 15-16:* $d_{observe}$ and $d_{predict}$ represent the empirically measured value and predicted value from the model simulations, respectively.

In this study, the statistical analysis of the data was done by programming in MATLAB2016, and the model fitting was done via equation parameter fitting in the software Origin v9.0.

Results

Model fitting

Model fitting for tree height and crown area

Using the sampled data of rubber tree from 2014–2015 (*Table 1*), the relationship of diameter at breast height (D) against tree height and crown was analyzed. Fitted curves were drawn as shown in *Figure 2*. Evidently these were non-linear correlations. There is an exponential relationship between the tree height as a function of diameter at breast height, as well as the crown and tree height (Bi et al., 2012; Zeng et al., 1999).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_015032

By the model fitting the data in *Table 1,* the fitting equations of tree height and crown with the diameter at breast height and tree height as variables were established, respectively, with the fitting results of the equation parameters given in *Table 2*. All parameters in the equations passed the significance threshold of $p < 0.001$. Based on the fitting results of the tree height and crown area models, we obtained corresponding R^2, RMSE values that were 0.99, 0.84 m and 0.98, 0.77 m^2, respectively (as shown in *Fig. 3*).

Model fitting for stem volume of single standing tree

The correlations between the stem volume of single standing tree and its diameter at breast height, tree height, and crown area, were all clearly positive. A general model(V1) based on tree height and DBH is used to calculate the stem volume of standing tree (*Eq. 10*) (Gonzalez-Benecke et al., 2012, 2013, 2014; Zhou et al., 1995). In this research, the existing model has been improved, in that another remarkable factor in the stem volume response was added: crown area. According to *Table 1,* the binary stem volume model (*Eq. 10*) and the improved model equation of stem volume (*Eq. 11*) were established, and the fitting results of their equation parameters are shown in *Table 2*. These all passed the significance threshold of $p < 0.001$. By comparing the

DOI: http://dx.doi.org/10.15666/aeer/1801_015032

binary fitting equation of stem volume (V1) to the improved fitting equation (V2), it can be seen that the fitting precision of two equations to the stem volume were both high: When compared with the binary volume model V1, for the improved model V2 added the crown area, RMSE decreases 0.0045, and reaches 0.0116 m^3. Meanwhile, R^2 increases 0.0434, and is 0.9975. Hence, the model precision has been improved significantly (as shown in *Fig. 3*). Therefore, V2 was selected as the volume calculation model.

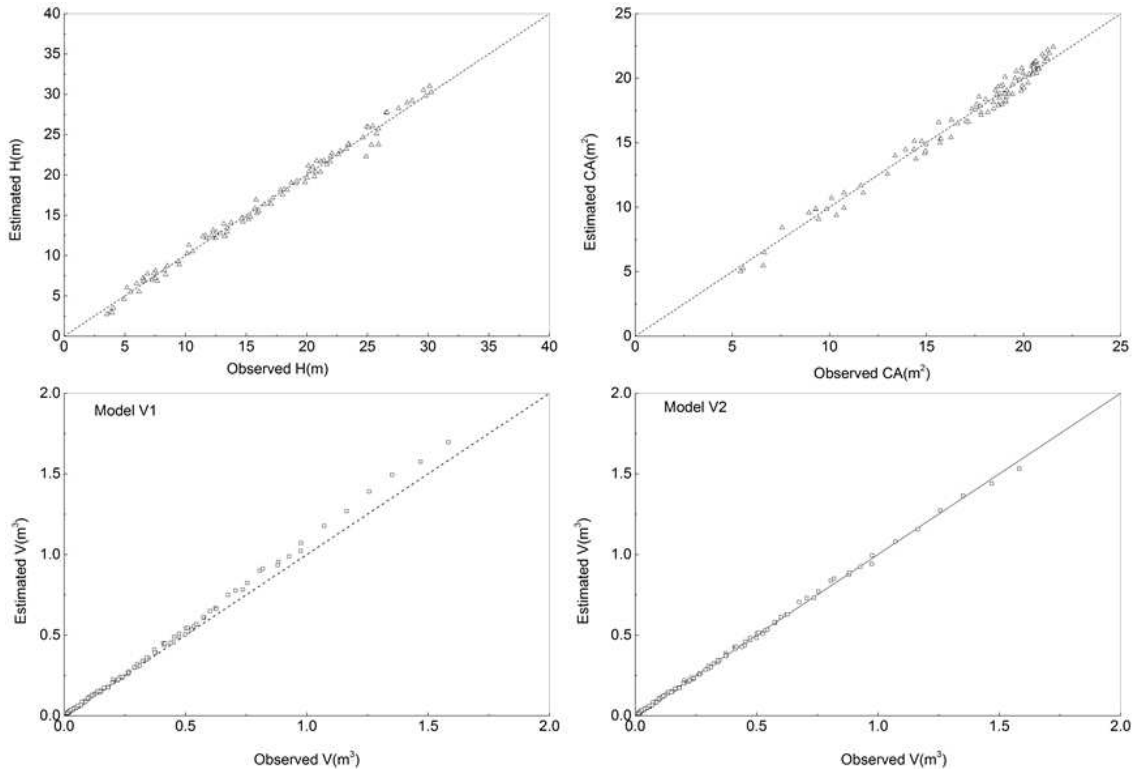

Figure 3. *Comparison analysis of the estimated and observed values of tree height (H), crown area (CA), and stem volume (V)*

Model fitting for yield of a single plant

By parsing the data of annual ring widths and using the stem volume equation (from the sampling farms of Dongchang and Xiqing), the annual stem volume produced is obtained, and the relative stem volume increment may be calculated. Based on the historical meteorological data of the sampling sites, we calculated the heat, precipitation, sunshine, and disaster indexes. Moreover, the annual average temperature was summarized. From the correlation analysis using the yield of a single plant in the sampling section, it can be seen that the precipitation index ($p < 0.05$) and disaster index ($p < 0.01$) are negatively correlated with the yield, while the sunshine index ($p < 0.05$) and other factors ($p < 0.01$) are all positively correlated with the yield.

Using the data from Dongchang Farm of Haikou City and Xiqing Farm in Danzhou City, fitting of the models of rubber tree yield Y_{dr1}, Y_{dr2}, and Y_{dr3} with the relative stem volume increment, annual average temperature, precipitation index, sunshine index and disaster index as the variables were performed, respectively. Through the follow-up comparison and analysis, the mode Y_{dr1} with relative stem volume increment, annual average temperature, heat index, precipitation index, and sunshine index as the predictor variables showed the lowest precision, having an RMSE and R^2 of 0.1525 and 0.7439, respectively. However, the rubber tree yield models Y_{dr2} and Y_{dr1} with annual average temperature, heat index, precipitation index, sunshine index, and disaster index as predictors showed increased RMSE and R^2 values, reaching 0.1065 and 0.8397, respectively. Nevertheless, it was the fitting of the model of rubber tree yield Y_{dr3} with the relative stem volume increment, annual average temperature, heat index, precipitation index, sunshine index, and disaster index as the predictors, which gave the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_015032

highest precision. Compared with Y_{dr1}, Y_{dr2}, the corresponding RMSE and R^2 values of Y_{dr3} were 76.8%, 32.6% and 0.9862, 0.0354, respectively (as shown in *Fig. 4*). Therefore, when trying to forecast the rubber plantation yield, the stem volume increasing as determined by the varietal characteristics is not the only condition affecting the yield. As demonstrated in these results, the climatic variables and disasters hazards are also significant factors that play a role in this prediction of rubber yield. Ydr3 was selected as the yield prediction model in this study.

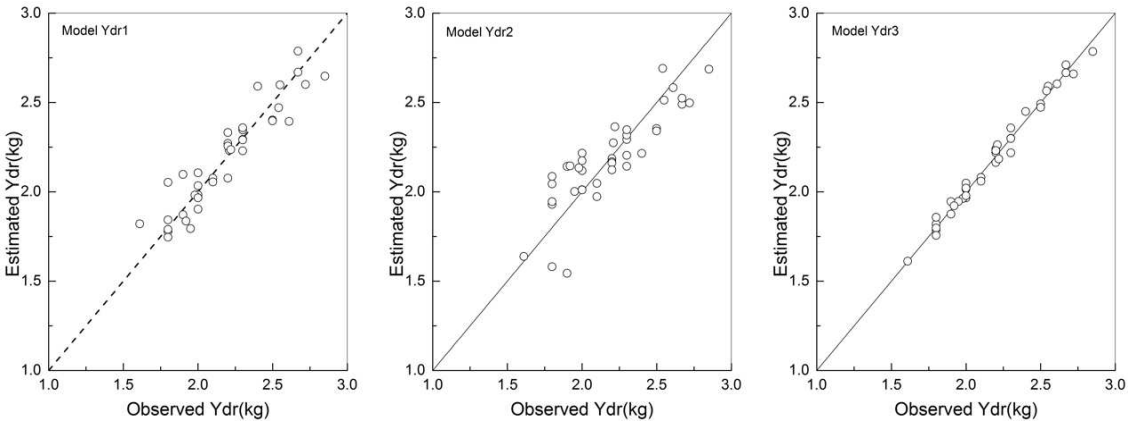

Figure 4. *Comparison analysis of the estimated and observed values of dry rubber yield of a single rubber tree*

Model validation

Validation of tree height and crown area

Based on model *RA* and *RH*, the sampled data from 2016–2017 (*Table 1*) in plot3 were used to calculate the tree height and crown area. The model settlement results were compared with the measured data of tree height and crown area for model verification. The results are shown in *Table 3* and *Figure 5*. According to the error analysis of the observed and predicted values, these two models can be used to simulate tree height and canopy area.

	H (m)	**CA (m^2)**	**V (m^3)**	**Ydr (kg/plant)**
MAE	0.5045	0.4750	0.0150	0.0279
RMSE	0.5680	0.5464	0.0157	0.0528

Validation of stem volume

Based on model *V2*, the sampled data from 2016–2017 (*Table 1*) in plot3 were used to calculate the stem volume. The model settlement results were compared with the measured data of stem volume for model verification. The results are shown in *Table 3* and *Figure 5*. According to the error analysis of the observed and predicted values, this model can be used to simulate stem volume.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_015032

Validation of dry rubber yield of a single tree

Based on model *Ydr3,* the sampled data and meteorological statistical data from 2016–2017 (*Table 1*) in plot3 were used to calculate the dry rubber yield of a single tree. The model settlement results were compared with the measured data of dry rubber yield. The results are shown in *Table 3* and *Figure 5*. According to the error analysis of the observed and predicted values, this model can be used to simulate dry rubber yield of a single tree.

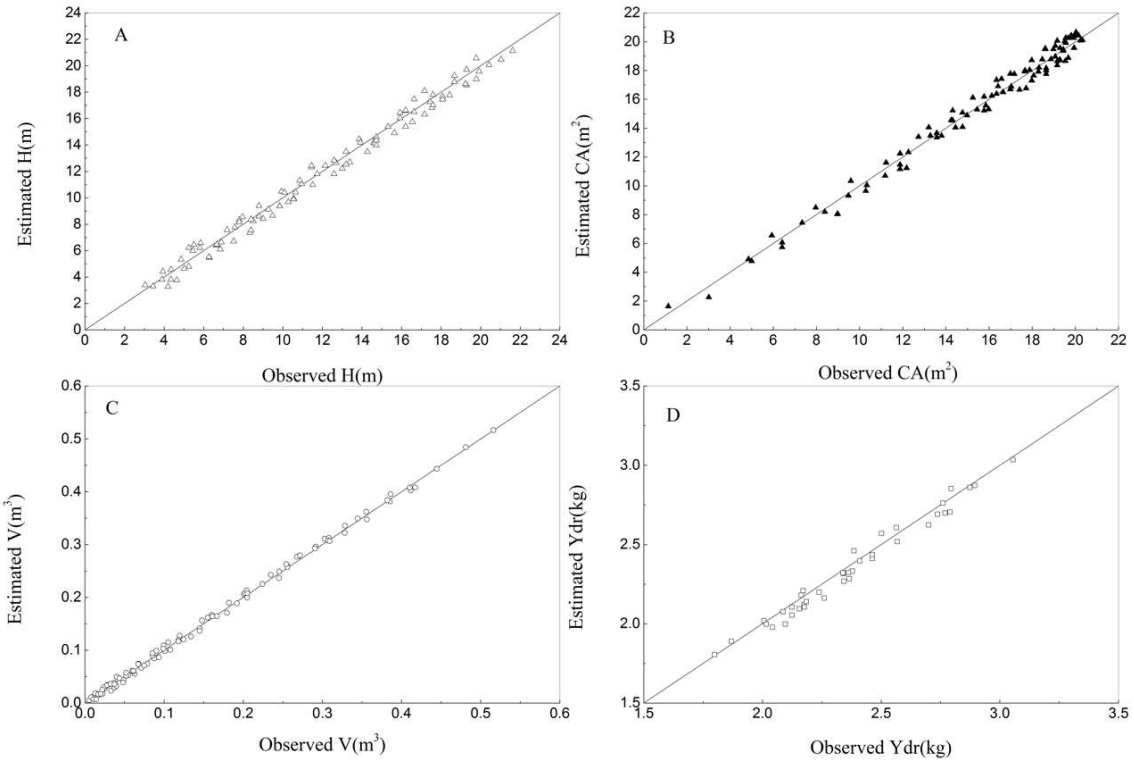

Figure 5. *Comparison analysis of the estimated vs. observed values of the rubber tree height (A), crown area (B), stem volume (C), and yield (D)*

Validation of sub-compartmental dry rubber yield

The stand-level plantation data (i.e., average diameter, density, and area of woodland) sampled randomly in six different stand sub-compartments (the variety is RRIM600) of Xinzhong Farm (refer to *Fig. 1*), and the rubber yield data in the sub-compartment during 2016-2017 (as shown in *Table 4*) were used to verify the application of model *Ydr3* in actual production. Based on the meteorological observation data, we calculated the heat, precipitation, sunshine, and disaster indexes. Using the established stem volume model V2 and yield model *Ydr3*, the yield of rubber plantation in 2017 is estimated, and the results are shown in *Table 4*. This yield simulation shows that the average absolute error of the model in different sub-compartments is 35.7 kg/ha. When the accurate yield estimation is done on a large-scale the precision is high; hence, it can be applied to rubber production on an industrial scale.

F	15.6	16.7	436	1.9	2144.9	2169.5	34.0

The average diameter is the mean value of 30 randomly trees in each sub-compartment, and the yield is the actual yield in the sub-compartment; the simulated yield is the product of the yield of singe plant and the total number of rubber trees which can be tapped

Discussion

The general stem volume model of rubber trees is mainly based on DBH and tree height (Gonzalez-Benecke et al., 2012, 2013, 2014; Zhou et al., 1995). Previous studies have shown that the crown growth of trees is closely related to stem volume, which generally increases with the decrease of crown length (Liu et al., 2002). Therefore, this study improved the existing model by adding another important response factor of stem volume, canopy area, and significantly improved the model accuracy (see *Fig. 3*).

In this study, when establishing the prediction model of rubber yield per plant, we consider the actual growth of rubber trees and combine it with the actual production, and finally established the prediction model of yield at different stages. Although the volume of rubber tree will increase in seedling stage, it is not cut during production, so the yield is not considered. From the beginning to the flourishing stage is the main economic production period of rubber trees, and the yield fluctuates under the influence of volume increase, climatic factors and disasters. The economic value of the rubber tree in the aging period, will be greatly reduced, so the yield is not taken into account. Therefore, the establishment of a piecewise prediction model for the yield of rubber trees in the main economic production period is more practical than a single prediction model for the whole growth period, which can improve the prediction accuracy of the model.

Previous studies have found that the diameter of rubber trees, the laticifer differentiation capability and the yield of rubber trees are significantly correlated (Chen, 2014; Liu et al., 2002). In our study, the variation and trends analysis in the cumulative growth and annual growth in the stem volume of rubber tree show that (*Fig. 6*): the volume of rubber trees increased rapidly from seedling stage to sapling stage (1-10 years), and from primary stage to flourishing stage (11-35 years), and decreased significantly from aging stage (35 years), which was consistent with previous studies (Gonzalez-Benecke et al., 2012, 2013; Gouvea et al., 2013; Ohashi et al., 2001; Xu et al., 2002; Luo et al., 2015). The main explanation for this result is that stem volume increment reflects the increase of nutrients and resource capture by the tree's canopy area and the enhancement of the laticifer differentiation capability in the bark, which thus promotes the synthesis of photosynthate and the generation of latex. In the senescence stage, when the stem volume increment is reduced significantly, the diameter at breast height only increases slowly. This is mainly due to the gradual aging

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_015032

of secondary phloem system and a gradual decrease in the laticifer differentiation capability, thus resulting in a yield reduction. Therefore, the yield prediction model with the annual volume increment of rubber tree as a variable has higher precision than the prediction equation with only meteorological elements as a variable.

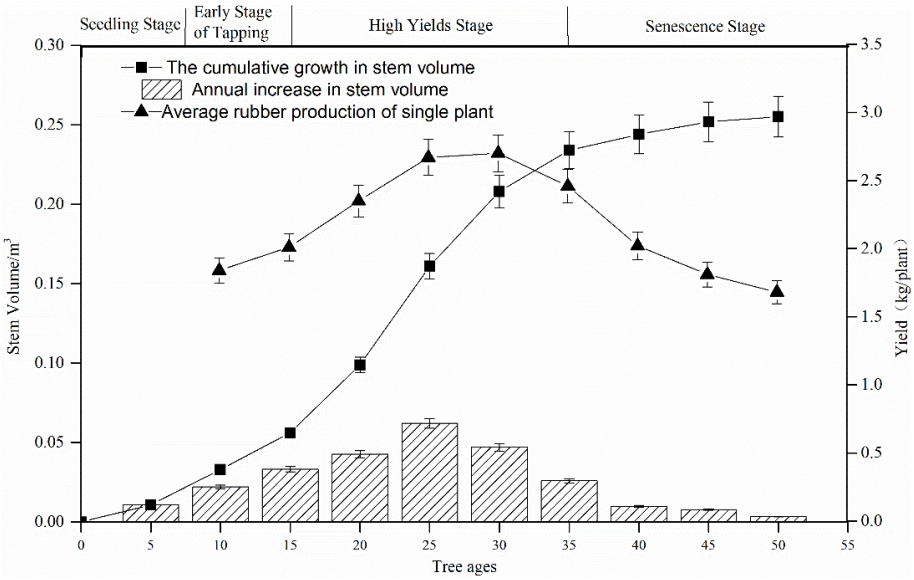

Figure 6. *Cumulative growth and annual growth means for the stem volume of rubber tree*

Under the condition of standardized and consistent management mode, the annual variation in the trends of the stem volume and yield of rubber tree are mainly determined by tree age and variety, while the differences in the interannual fluctuations is affected by the environmental factors among others, with the climatic variables and meteorological disaster hazard being the main factors influencing the yield of rubber trees. Published research has shown that climate variables, such as the temperature, precipitation, and sunshine, are all closely related to the photosynthesis rate in rubber trees (Roberts, 1988; Devakumar et al., 1998; Satheesan et al., 1984; Rao et al., 1990; Carr, 2012; Zhao et al., 2014), their respiration and transpiration (Zhao et al., 2014), and their synthesis of latex (Lacote et al., 1998; Zomer et al., 2014; Golbon et al., 2015). Therefore, in previous studies, meteorological factors such as temperature, precipitation, humidity and sunshine were often used as variables to establish yield prediction models（Yu et al., 2014; Zhang et al., 2014, 2017; Golbon, 2015; Nguyen and Dang, 2016; Kim et al., 2017). In our study, the heat indexes of effective accumulative temperature over 10 °C (after the tapping from December to March in the next year) and 18 °C (from April to November) had significant correlations with the dry rubber yield. The heat index can better reflect the demand for heat in the actual growth of rubber trees than the heat factor that only considers the daily average temperature, average maximum temperature and average minimum temperature (Yu et al., 2014; Nguyen and Dang, 2016). The precipitation index, which included not only the rainy days but also the minimum annual precipitation suitable for the growth of rubber, had a significant negative correlation with the yield. Compared with the previous prediction model of rubber tree yield only considering precipitation, the precipitation index eliminated the effect of cumulative precipitation caused by the increase in rainy days. In a region with

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_015032

enough precipitation to meet the regular growth requirement, clearly moisture was not the limiting factor to a change in yield. The rainy days had more obvious effects on the yield (Rao, et al., 1990; Carr, et al., 2012; Zhao, et al., 2014). The disaster index reflected the combined effects of typhoon and chilling damage on the rubber yield. It was significantly positively correlated with the yield, thus suggesting it was also an important factor for the yield prediction. Until now, this important factor was always ignored in prior research publications. In our study, based on the previous prediction model simulating the rubber yield but only considering the climatic variables (average temperature, average maximum temperature, average relative humidity, sunshine duration, and precipitation) (Yu et al., 2014; Zhang et al., 2014, 2017; Golbon, 2015; Nguyen and Dang, 2016; Kim et al., 2017), the collective climate impact was corrected via inclusion of a heat index, precipitation index, and sunshine index. Meanwhile, the relative stem volume increment and disaster index were introduced as predictors to establish a novel model for rubber yield prediction. Compared to the prediction model that uses just a single influencing factor, the precision of our new model was elevated significantly. By applying this yield prediction in the sub-compartment of a rubber plantation, the results revealed that the newly established model was suitable for accurate yield estimation in the study region. As such, it could also provide technical support for the yield forecast or yield loss estimation of different forest sections in the production of rubber over time.

In rubber tree plantations, the stem volume and yield are often impacted by geographical conditions, such as altitude, slope aspect, and slope gradient, albeit to varying extent among sites (Liu et al., 2015; Nguyen, 2013). In our prediction model, these considerations were not further studied, since we sampled a single source. Nonetheless, the stand density did show a certain correlation with the rubber yield: as the stand density increased, the yield of single plant decreased. In our study, the effect of stand density on stand-levels yields was not considered (Naji et al., 2014; Rodrigo and Stirling, 1997). Additionally, the forecasting model for dry rubber in this paper was based on the species variety RRIM600 that was planted in Hainan Province. Hence, the applicability and adaptability of our forecasting to other Chinese regions and cultivated rubber tree varieties requires testing and verification.

Conclusion

In this study, a simulation model for the stem volume of standing rubber trees on the basis of tree diameter at breast height, tree height and, tree crown area was developed. Based on this result, the relative stem volume increment, annual average temperature, heat index, precipitation index, sunshine index, and disaster index were the main factors considered in a forecasting model for the dry rubber yield of single plant. In applying the prediction model to the yield prediction in the different sub-compartments of a rubber plantation, the mean absolute error was 35.7 kg/ha. This study's the newly established model could thus provide management with decision support for the dry rubber yield prediction of rubber plantation over large areas.

In the future, the morphological, yield, and meteorological features of rubber tree plantations could be sampled in the main rubber growing regions of China, which would enable a more suitable prediction model to be established. We plan to couple the model with satellite remote sensing technology for rubber plantations of different ages, so that research on the large-scale rubber yield prediction will be advanced.

(Received 27th Mar 2019; accepted 19th Jun 2019)

Abstract. Agro-industrial sectors in Ethiopia are highly expanding sector and offers substantial challenges for the environment and public health. The brewery industries use large quantities of water for their production processes and at the end, they discharged large amount of effluents that contains a high strength organic waste. The main objective of this review paper is to discuss and summarize the characteristics, treatment techniques, fertilizer potential and other available management options of breweries sludge generated from wastewater treatment plants. Recent (2015) research finding indicated that the brewery sludge contains a very high nitrogen and potassium content, i.e., 420.25 kg ha^{-1} and 840 kg ha^{-1} respectively compared to the control. Scientific evidences indicated that brewery sludge amended soil they have the tendency to produce more yields (4081.6 kg ha^{-1}). Brewery sludge has also other beneficial advantages in production of biogas and building materials with co-digestion with other organic solid residues. The probable drawbacks of the use of sludge on agricultural land application is its pollutant loads including heavy metals, organic compounds and pathogens. Therefore, more research investigation has to be done on the possible sludge treatment mechanisms and the feasibility of sludge generated from brewery industries for agricultural recycling.
Keywords: *brewery sludge, nutrient, treatment plant, fertilizer and yield*

Introduction

Background information and justification

Rapid industrialization and urbanization in Ethiopia demanded huge increase in the extraction of resources and release of huge volume of wastes. Agro-industrial sectors in Ethiopia are a highly expanding sector and offers substantial challenges for the environment and public health (Tadese and Seyoum, 2015). Even if, the brewing sectors hold a planned economic position by increasing their production capacity (Fillaudeau et al., 2006). But, they also become one of the known industry by producing by-products such as effluent, spent grain, excess yeast and sludge from the wastewater treatment plant (Alemu et al., 2017). The brewery industry uses large quantities of water and lastly discharged large amount of effluents that contains a high strength organic wastes (Kanagachandran and Jayaratne, 2006).

DOI: http://dx.doi.org/10.15666/aeer/1801_033057

Besides its advantage, at moderate and low temperatures, removal of Chemical oxygen demand (COD) by Up-flow Anaerobic Sludge Blanket (UASB) reactor is limited and long hydraulic retention time is needed to provide efficient hydrolysis. Therefore, anaerobic effluent requires post- treatment to remove the remaining Chemical oxygen demand (COD), nutrients and pathogens. Post- treatment of Up-flow Anaerobic Sludge Blanket (UASB) reactor effluent by aeration systems is one among the different techniques (Bodík, 2005). An aerobic treatment process oxidized organic substances to carbon dioxide, water, sulfate, phosphate and nitrate by different microbial communities dominated by heterotrophic bacteria and fungi. This aerobic process produces large volumes of sludge requiring further treatment and disposal (Stocks et al., 2002). According to Stocks et al. (2002) report, the UK breweries generates around 40-50 m^3 of brewery sludge has been removed by tanker each weekday for application to local agricultural land. The 1991 reports also indicate that the beer Thai generates 100-120 m^3/day of sludge as a waste (Babel et al., 2009).

There are different disposal methods of sludge such as landfilling, solidification, incineration, deep well injection and land application (Dolgen et al., 2004). Landfill is the common disposal method of brewery wastewater treatment plant sludge. Whereas, land application is an alternative option to avoid these high cost techniques, landfill cost and available of land space as well as public opposition on the offensive odor problems. Most research investigation shows that land application of agro-industrial wastewater treatment plant sludge for agricultural purposes can be recommended as an ultimate disposal alternative without any hazardous effect, since the presence of low heavy metal concentration and high organic carbon content are typical features of agro-industry sludge for soil conditioner. However, if it is not properly managed, potential risks to both environment and public health may occur from the accumulation of heavy metals (lead, cadmium, zinc and mercury), organic compounds, salts and pathogen contamination in soil and crops resulting such components entering in to the food chain (Dolgen et al., 2004; Babel et al., 2009; Olowu et al., 2012).

The application of sludge generated by industrial plants is limited due to fears of the accumulation of toxic matters in soils and plants. There are little scientific evidences in Ethiopia on the application of brewery wastewater sludge for increment of productivity of different crops through supplying nutrients and organic matter. Alemu et al. (2017) conducted a field trial in Daker, Harari regional state of eastern Ethiopia using different ratios of brewery sludge and commercial fertilizer to grow sorghum. Results demonstrated that 15 t ha^{-1} of brewery wastewater sludge amended sorghum plots produce crop yields higher than that of commercial fertilizer. In line to this, Wendimagegn (2016) has also investigated similar results, i.e., addition of 2.5% BWS produced more number of tomato fruits (16.33) compared with addition of 200 mg of urea/kg of soil and control yields 13.0 and 7.67 tomato fruits respectively. However, these studies are not adequate enough to conclude on the feasibility of sludges generated from brewery industries for agricultural recycling. Brewery sludge is the easiest byproduct to handle but the most difficult due to its diverse in characteristics and variable composition that vary with the raw materials and product manufacturing process systems followed. Due to the increasing environmental issues and strict regulations, there should be further investigation on the feasibility, levels of application, economic benefits and assessing the environmental safety of brewery industrial wastewater treatment plant sludges to utilize it in an environmentally friendly approach (Erdem and Ok, 2002; Thomas and Rahman, 2006; Abushammala et al., 2009).

Review of literature

By amount, beer is the fifth highest consumed beverage in the world next to tea, carbonated drinks, milk, and coffee (Fillaudeau et al., 2006). The brewing steps for beer produce large volume of wastewater effluent and solid wastes that must be discarded of without affecting in negative way the quality of water and soil. According to dos Santos Mathias et al. (2014), some of the solid waste that can come from the breweries are waste yeast, hot rub as well as the spent diatomite. This kind of wastes creates a residual sediment layer at the fermenter bottom. Every year in Ethiopia about 4 million hL of beer is usually produced. Since all Ethiopian breweries used diat-omite forclarification used in the total amount of BWS produced each year is estimated to be about 69,000 metric tons (dos Santos Mathias et al., 2014).

Beverage and its wastewater treatment systems

Beer production process

Beer is a fermented beverage which has low alcohol content and made from barley, wheat, maize and other grains. The beer production steps include grinding of the malt to grist, mixing of grist with water to produce mash in the mash tun, wort production, separation of grist residues from liquid wort, boiling of wort with hops, separation of the wort from the trub/hot break, addition of yeast to cooled wort, fermentation, separation of spent yeast by filtration, centrifugation or settling and bottling or kegging (Ramya et al., 2015). In line to this production, wastewater management and waste disposal becomes a major cost factor and an important factor in the running of a brewery operation. Every brewery tries to keep waste disposal costs low whereas the legislation imposed for waste disposal by authorities becomes more stringent. Water consumption in a brewery is an economic parameter and a tool to determine its process performance in comparison with other breweries. Furthermore, the position of beer as a natural product leads the brewers to pay attention to their marketing image and to make waste treatment (wastewater, spent grain, Kieslguhr sludge, yeast surplus) into account as shown in *Figure 1* (Fillaudeau et al., 2006)

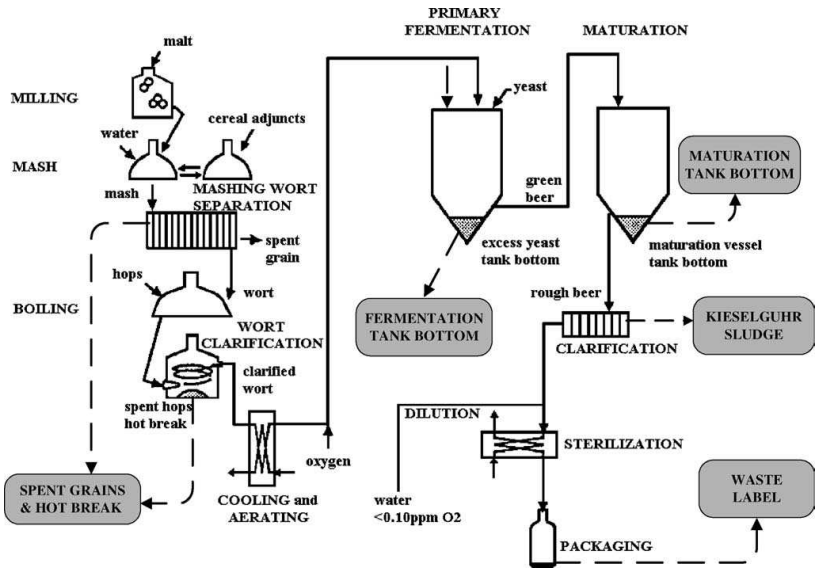

Figure 1. *Brewing process and main wastes*

Brewery wastewater treatment processes

Biological wastewater treatment works on the principle of activity of bacteria and microorganisms living in their own organic matter can occur in the presence of oxygen, called aerobic process and in the absence of oxygen called anaerobic process. Most commonly used treatment system of agro-industrial wastewater is summarized in *Figure 2* (Berni et al., 2014). Whatever the process or process combination is suitable for wastewater treatment methods are generally the following: Mechanical pre–treatment with removal of large particles using rakes, sieves, grit chambers and preliminary sedimentation; Chemical-physical pre-treatment using neutralization and metering of chemicals; and Biological wastewater treatment such as Anaerobic pre-treatment, Anaerobic-aerobic treatment and Aerobic treatment (Bodík, 2005; Asia et al., 2008). Anaerobic and aerobic biological treatment are widely applied. Previously, aerobic treatment has been applied for the treatment of brewery wastewater. However, recently anaerobic systems have become more attractive option. Because, the aerobic treatment of brewery effluent requires a comparatively large energy input compared to anaerobic treatment. During aerobic process, complex organic substances are completely oxidized to carbon dioxide, water, sulfate, phosphate and nitrate by a community of microorganisms dominated by heterotrophic bacteria and fungi. This produces large amounts of biomass (Kanagachandran and Jayaratne, 2006).

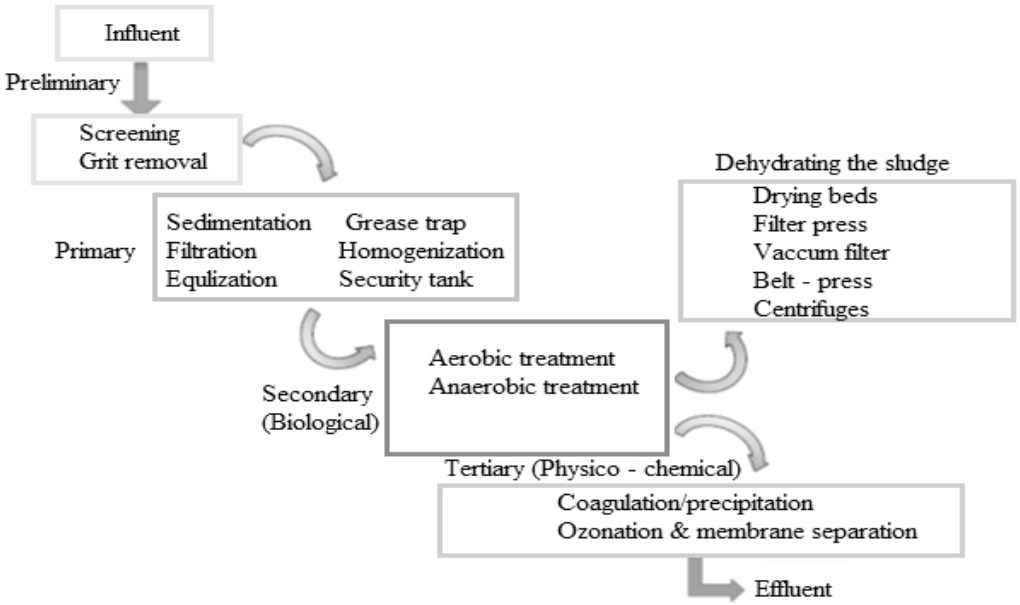

Figure 2. *Scheme of agro-industrial wastewater treatment process*

Brewery biomass (sludge) produced by aerobic, anaerobic, physicochemical, combined aerobic/physicochemical and combined anaerobic/physicochemical methods. Physicochemical method increases the quantity of sludge solids, thus making the sludge suitable for land reclamation. Whereas biological treatment methods (aerobic and anaerobic) can reduce the quantity of sludge before disposal. Processing and disposal of sludge is economic and environmentally friendly manner is currently of great importance to local authorities and industry. The disposal or reuse of sludge is a significant part of wastewater treatment program (Asia et al., 2008).

Sources of sludge

Bio-solids/sludge's are nutrient rich organic matter solid residues generated from wastewater treatment plant (Sampson, 2016). Sludge is most commonly produced from secondary wastewater treatment plants. However, half of the solids suspended in wastewater are removed through primary treatment. The residual material from this process is a concentrated suspension called primary sludge, which will undergo further treatment to become bio-solids. Preliminary wastewater treatment (extracts of coarse solids by screening and other filtering devices) and tertiary (mainly chemical addition to clean the final effluent are called chemical sludge) wastewater treatment processes are also produce solid byproducts which are not incorporated in sludge or bio-solids (Şengün, 2007).

Characteristics of sludge

Environmental concerns regarding to land disposal of sludge causes surface-water and ground water pollution, contamination of soil and crops with toxic substances and transmission of human and animal diseases. Chemical analysis of a sludge shows that sludge consists of nitrates, ammonium and organic nitrogen, soluble and organic phosphate, potassium, heavy metals of cadmium, copper, nickel, lead and zinc, and selected organic compounds such as polychlorinated biphenyls (PCB) (Wendimagegn, 2016). Other chemical analysis on brewery sludge also revealed that it has high nitrogen, phosphorus, potassium, volatile fatty acids and nutrients which are important requirements for plant growth. Brewery sludge is also consisting of various important organisms like heterotrophic fungi and actinomycetes (Ramya et al., 2015).

In the present scenario, there is an increasing interest of recycling sludge's for agricultural application due to their valuable components such organic matter, nitrogen, phosphorus and other plant nutrients. However, the chemical properties of the sludge may be affected by the treatment process applied to wastewater and sludge (i.e., extent of industrial pretreatment, primary, secondary or tertiary wastewater treatment and chemicals used in the treatment, and method of sludge stabilization) and the original pollution load of the wastewater (Şengün, 2007).

Characterization of sludge is extremely important prior to sludge disposal or application to farm land because of associated risks of toxic elements accumulation in soil and potential health hazard of pathogens. The sludge physicochemical and biological content depend on the original pollution load of the treated water, treatment process applied to wastewater and sludge (Usman et al., 2012). The physicochemical and biological composition of brewery wastewater sludge is presented in *Table 1*.

In sludge content of heavy metals

The results of the BWS selected heavy metals indicates that the sludge can be used in farming since they are well below the EU standards as shown in *Table 2*. Trace elements of heavy metals are toxic in the living organisms even if they are not in large amounts under the natural systems. With the existence of the soil-plant system that helps in the reducing of the toxicity of the trace elements, there is negligible issues of health in humans as well as animals. Nonetheless, if the amounts are high and the concentrations of these heavy metals are high, there could be some problems such as toxicity of the soil and harmful effects to humans and animals. Cadmium, selenium, mercury, nickel, zinc and copper are come the metals that gives a huge anxiety when it

DOI: http://dx.doi.org/10.15666/aeer/1801_033057

comes to bio-solids. These trace elements are indispensable nutrients in the health of animals and plants and have less risks in small amounts due to their low solubility a sound aerated soil at 6.0 to 7.5 PH (Şengün, 2007).

Brewery sludge nutrient content

In *Table 3*, the sludge of the brewery was seen to be virtually neutral. The normal range of the brewery sludge PH is between 6.5 and 11.5 (Luque et al., 1990). Various disparities in the treatment of the wastewater in the plants and the raw water attributes to the differences in the PH observed. The Organic carbon of the control soil was 1.5% while that of the sludge was 31.12% showing a great improvement. The BWS Soil parameters on the other hand attributes to the high-water holding capacity. Greater potential of cation exchange capacity, more organic matter, and other nutrients. has investigated that BWS amendments enhanced pH of acidic soils and improved the organic carbon, exchangeable cations, soluble cations and anions (Luque et al., 1990)

Sludge treatment methods

Sludge treatment techniques: Sludge must be processed for economic and hygienic reasons. Sludge processing reduces the volume, stabilize the sludge, remove water and kill pathogenic organisms. There are different sludge treatment techniques, such as thickening, conditioning, dewatering and stabilization. *Figure 3* shows that the possible sludge treatment processes, each treatment effect on the sludge and how that treatment techniques may affect the sludge application to land. Reducing sludge volume is an important thing which helps to limit its handling and transporting costs. There are series of constructive sludge treatment technologies possible to reduce sludge volume up to 2% of the initial volume. Mechanical and thermal dewatering increases the concentration of dry solids from 2% up to 90%, making the dried and stabilized sludge ready for easy storage and reuse as soil conditioner or fertilizer, depending on its composition. When sludge physicochemical composition does not allow for agricultural reuse, the best alternative option is sludge destruction by incineration. Since sludge contains energy which can be recovered either by digestion in anaerobic reactors to produce biogas or by incineration which generates heat and can be used as thermal energy for sludge drying process and transformed into steam for electricity production. Sludge treatment has generally the following advantages: Reduction of pathogens: Reduce the excess sludge mass and handling cost, improve rheological, mechanical and biological properties of the waste sludge, prevent fermentation and odor problems and Improve soil physical properties such as porosity, water retention and stability. (www.waterleav.com)

Thickening

Sludge generated from wastewater treatment plant contains lots of water and it has to be thickened to reduce the volume and make some of its water free. Thickening is the process of increasing solids content of sludge by the removal of a proportion of its liquid content. Gravity thickening is the simplest and least expensive process for thickening sludge (Garg and Tanyimboh, 2009). Sludge treatment systems are usually physical in nature. They include gravity settling, floatation, centrifugation, and gravity belts (Hänel, 1988).

Conditioning

This method involves modification of the sludge structure by removing more water from it. This method can improve thickening, and dewatering. Chemical method is one of the conditioning system which uses mineral agents like lime or salts or an organic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_033057

compound to remove the water content. Thermal method is another method in which sludge is heated to 150-200 °C for 30-60 min. It involves the chemical or physical treatment of sludge to enhance its dewatering characteristics. The most applied conditioning systems are the addition of chemicals and heat treatment. Other conditioning processes include freezing, irradiation and elutriation (Garg and Tanyimboh, 2009).

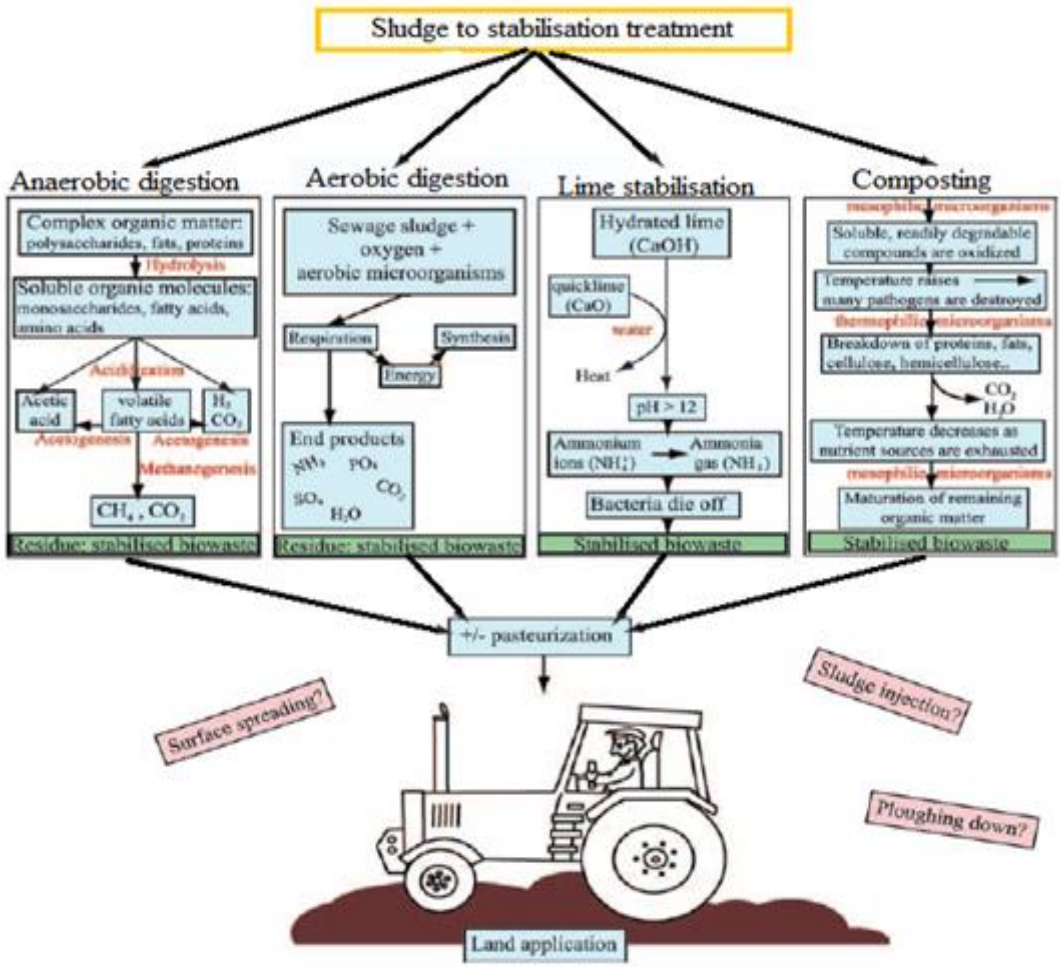

Figure 3. *Flow chart of sludge treatment steps with the view to yield an end by product with high microbial quality for subsequent use as a crop fertilizer. (Source: Arthurson, 2008)*

Stabilizing

Sludge stabilization is necessary to reduce pathogen content, eliminate offensive odors and reduce or eliminate the potential for putrefaction. Technologies that used for stabilization of sludge are liming, heat treatment aerobic digestion, anaerobic digestion and composting (*Fig. 3*) (Garg and Tanyimboh, 2009). Because, these treatment systems reduce the organic matter content, water content, emission of unpleasant odors and concentration of pathogenic micro-organisms. Anaerobic digestion of sludge at mesophilic (30-38 °C) and thermophilic (50-60 °C) is used to inactivate pathogens.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_033057

Thermophilic treatment is more efficient in minimizing the content of pathogenic bacteria and parasites than mesophilic. Thermophilic treatment sludge fulfils class A bio-solids results from sludge digestion at 60-75 °C which has low pathogen content compared to class B bio-solids, hence class A bio-solids can be used for unrestricted public contact. Whereas, class B results from mesophilic sludge digestion at 28-38 °C, contains fecal coliform density as an indication of pathogenic level. The major advantage of anaerobic digestion is to generate biogas as an end product that used for the treatment facility. Aerobic digestion process is performed by aerobic microorganisms and generates heat. However, this stabilization does not reduce the pathogen content to the acceptable standards for unrestricted use of sludge in agriculture. This indicates that sludge should be under go additional stabilization step to achieve a product with sufficiently high microbial quality to enable recycling of residues. Some of sludge stabilizing methods are pasteurization (heated at temperature 70-80 °C) (Arthurson, 2008).

Dewatering

This is mainly useful to reduce the volume of the sludge via water separation. In this process, it is possible to remove a certain proportion of free, adhered and capillary water with the technology available technology. Among these processes; drying beds, centrifuging, filter belt and filter press. All process except drying beds, other process requires addition of a chemical conditioning agent (Sullivan, 2015). Dewatering is a vital step in sludge treatment processes. In this process, belt filter press and/or a centrifuge are mostly applied (Evans, 2008). Dewatering process is a physical unit operation used in reducing the moisture content of sludge. This process is not incinerated, but achieved by applying sand beds or by mechanical dewatering equipment. Selection of appropriate sludge dewatering technique depends upon the nature/characteristics of the sludge to be dewatered, available space, and moisture content requirements of the sludge cake for ultimate disposal. Sludge dewatering may also be improved by chemical conditioning such as addition of polymer. However, if land is available and sludge quantity is small, natural dewatering techniques such as drying beds and drying lagoons are most attractive (Garg and Tanyimboh, 2009).

Sludge disposal methods

Sludge disposal without treatment changes public perceptions and legislation of worldwide to make disposal to landfill less popular. Due to this issue, in many countries agricultural use of sludge is becoming more attractive for sustainability. There are different sludge disposal methods such as landfill, incineration, and land application. Among these, incineration end product is not sustainable for beneficial use (Şengün, 2007).

Landfill

Landfill system is the simplest solution to handle sludge by concentrating the material in a single location. This disposal system causes bio-sludge borne pollutants and pathogens to ecosystems and humans if landfill is not properly constructed and maintained. Landfill is economically feasible disposal options, but it is risky. Buried organic matters undergo anaerobic decomposition which produces methane gas. This gas is a greenhouse gas and causes global warming. Therefore, there is a need to collect at some landfills and utilize the energy content. On the other hand, the chemicals and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_033057

nutrients can pose risk to local groundwater from older landfills if it does not have synthetic liners that protects seepage. Pathogen content in sludge has also a risk and additionally, the potential content of organic matter and plant nutrients in the sludge will be lost with landfilling (Şengün, 2007).

Incineration

This process is one of most expensive method and working by burning of sludge at high temperatures in a closed device in order to reduce the sludge volume, kills pathogens and destroys most organic chemicals, but this disposal method requires extra energy for safe disposal of the resulting ash. The end product of incineration, i.e., ash is a stable inorganic material containing 10-20% of the original solids. The associated problem with this method is that it does not destroy trace elements rather than concentrating them in the ash. Beside this, it also produces carbon dioxide which also a greenhouse gas causes global warming and lose of beneficial plant nutrients and organic matter for plant. The aim of integrated sludge treatment is to maximize the intrinsic value of sludge in its volume reduction processes. Depending on the type of sludge characteristics, one or more sludge treatment steps are used to optimize the sludge volume.

Land application

Land application of sludge is an alternative to landfilling or incineration because of the negative environmental impacts and high costs of sludge management practices. The high organic and nutrient content of the sludge makes it a valuable resource for farmers as it increases soil quality and crop yields and decreasing the need for expensive chemical fertilizer costs (Stout, 2002). Land application of sludge is less expensive and can improve the structure of the soil as fertilizer by supplying nutrients to crops and other vegetation's grown in the soil. Application of sludge that contains organic matter can improve the physical, chemical and biological properties of the soil. Because presence of organic matter can increase water infiltration, reduce soil erosion, increase water holding capacity, reduce soil compaction and increase soil granulation, increase the ability of soil to retain nutrients and provide nutrients for plant growth and food and energy for beneficial microorganisms. All of these beneficial properties make sludge considered a good choice for homeowners, landscapes, farmers and foresters. One type of sludge application as organic fertilizer is more commonly in the form of dried and/or pelletized. Producing sludge in this form is complex and expensive, however, dried sludge are often blended with other materials and marketed as an organic fertilizer with balanced nutrient levels. However, agricultural use of these sludge showed a great variability over time depending on weather conditions and crop type. Therefore, scheduling sludge transport and application are compatible with agricultural planting, harvesting and possible adverse climatic conditions requires careful management (www.waterleav.com, 2017).

Factors affecting land application of sludge

Bio-solids

Contain significant amounts of macro- and micronutrients which are economically attractive for land application. Bio-solids are rich in organic matter and essential plant nutrients which can be utilized as soil conditioner and fertilizer through the contribution of organic matter and as a fertilizer by supplying essential micro- (zinc, copper and iron)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_033057

and macronutrients (nitrogen, phosphorus and potassium) that increase the plant growth and productivity, improve soil quality, water holding capacity, air and water transport. The slow release of nutrients prevents leaching of excess plant available nutrients and possible contamination of ground and surface water (Wendimagegn, 2016). The only drawbacks of the use of sludge on agricultural land application is its pollutant load including heavy metals, organic compounds, and pathogens. The potential toxic elements such as cadmium, copper, nickel, lead, zinc, mercury and chromium concentrated in the sludge as a result of their association with settable solids during primary and secondary treatment processes (Usman et al., 2012).

Heavy metals

Trace elements are elements that exists in natural systems in small amounts and when they present in excessive concentrations they become toxic to living organisms. The plant-soil system has its own protective mechanisms that limits the potential toxicity of trace elements in their areal portions and these minimizes health problems of animals and humans. However, excessive accumulation of these trace elements in plants can cause either reduced yields or health problems to animals or humans that ingest the plants. Toxicity of heavy metals to plant species depends on their concentration in the soil. Some potentially toxic heavy metals may occur at increased levels in the food chain. There are two concerns regarding to trace element additions to agricultural soil amendment might become toxic to crops and sufficiently concentrated in an edible crop to have harmful effects on an animal or human that consumes it. Cadmium, copper, mercury, molybdenum, nickel, selenium and zinc are the greatest concern in bio-solids. In fact, many of these trace elements are essential nutrients for plant and animal health. These metals cause little hazard to crop production or plant accumulation because of their low solubility at pH 6.0 to 7.5 in a well aerated soil where field crops are typically grown or are present in bio-solids in small quantities (Şengün, 2007).

Organic contaminants

In line with presence of beneficial organic matter, bio-sludge also may contain toxic organic contaminants. Particularly, those organic substances that do not decompose will likely be strongly adsorbed onto the organic matter particles present in bio-solids. Sludge does not only contain urine or faces from human but also contain hormones and pharmaceutical substances that could possibly constitute a risk of influencing the microflora of the land. Sludges may contain synthetic organic chemicals from industrial wastes, household products and pesticides. These chemicals may be volatilized, degraded, sorbed to sludge or discharged in the aqueous effluent. Degradation results in the formation of other products that can be toxic or less toxic than the original compounds (Şengün, 2007).

Salts

Different kinds of salts can be present in bio-solids which can cause an effect to seed germination or growth of young plants through accumulation in the root zone of the soils. Soluble salts are not expected to be a problem with agronomic rates of bio-solids that used for soil amendment of disturbed land, because leaching by rainfall will remove excess amount of salt from the root zones. However, large rate application of bio-solids is contributing high salt discharges to the sewer system (Şengün, 2007).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_033057

Pathogens

As sludge vary in quality and quantity of its organic and inorganic content, it also varies in the type and number of pathogens it contains. In sewage sludge and similar wastes, most of the pathogens will be hazard, but a few salmonella typhi, E. coli and some mycobacteria have a higher rating of hazard. Bacteria, viruses, protozoa and parasitic worms are disease causing pathogens. These pathogens can present a public health hazard if they are transferred to food crops grown on land to which bio-sludge are supplied and contained in runoff to surface waters from land supplied sites. Advanced and conventional sludge treatment systems produce a stabilized final product where such organisms are unlikely to multiply to large numbers and problems arising from bacterial toxins during sludge storage or application (Şengün, 2007).

Objective

The objective of this review paper is to discuss and summarize the characteristics, treatment techniques, fertilizer potential and other available management options of breweries sludge generated from wastewater treatment plants.

Materials and methods

This review paper was written using searching key phrases "Brewery sludge generation", "Sludge chemical composition", "Brewery sludge disposal", "Brewery sludge treatment" and "Brewery sludge management" in Springer link, science direct, library genesis, jester, and www.nap.org searching web pages. From these searching, peer reviewed journals, review papers and MSc. Thesis were used. The interpretation of the result of each document was done using bar graphs, lines and scatter plot in a Microsoft excel. Result measurement units of sludge physicochemical parameters investigated by different scholars were reorganized and expressed in similar units for comparison.

Results and discussion

Characteristics of BWWS

BWWS amended with clay loamy soil

According Remya et al. (2015), the brewery wastewater sludge (BWWS) were characterized and tested for chilly seed germination. Plant growth trials were conducted to evaluate the application of BWWS as organic fertilizer. This brewery wastewater sludge was amended with clay loamy soil in different proportion of soil to BWWS with controls. The physicochemical characterization result showed that the pH of the sludge alone and its composite ranges almost neutral (i.e., 6.08-7.62).

The brewery sludge is also shows a rich source of nitrogen, and potassium were very high, i.e., 420.25 kg/ha and 840.0 kg/ha respectively as compared to the clay loamy soil. On the contrary to nitrogen and potassium increased application of sludge decreased the availability of phosphorus. *Figure 4a, b, c* and *d* indicates that the levels of nitrogen, phosphorus, potassium, organic carbon, electrical conductivity, and pH in clay loamy soil amended with brewery sludge (Ramya et al., 2015).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_033057

Figure 4. *a, b, c and d: Levels of N, P, K, OC, EC and pH in clay loamy soil amended with BWWS*

From *Figure 4* the percentage of organic carbon of the sludge was 2.90, which is greater than all composite and control values (clay loamy soil). This may be due to addition of brewery sludge that improve the organic carbon content of the clay loamy soil significantly and the higher water retention capacity is linked to the high organic matter, high cation exchange capacity and other nutrients.

Analysis of heavy some selected heavy metals (Pb = 0.004%, Ni = 0.0024%, Hg = below detection limit, and Cd = traces) in BWWS were present below the standard levels and the sludge can be safely used for agricultural application (Ramya et al., 2015).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_033057

Similar research investigation by Erdem and Ok (2002) also proves that brewery sludge amendments improved the carbon and nitrogen content of the soil. Organic carbon content of the amended soil was increased as the BWWS loading rates were increased. The total nitrogen has also indicated the increasing trend with the addition of BWWS for all incubation periods. Whereas, the pH and salinity of soil shows fluctuations. The pH of amended and un-amended soil samples decreased with the incubation time. The decreased pH values could be explained by organic acids produced during nitrogen mineralization and release of soluble electrolytes such as nitrates and sulfates in the soil solution. While salinity increment arises from addition of BWWS, which does not at a level to affect the yield of sensitive crops. The increment of organic carbon and nitrogen content of the amended soil as brewery sludge loading rates increased was indicated in *Figure 5* (Erdem and Ok, 2002).

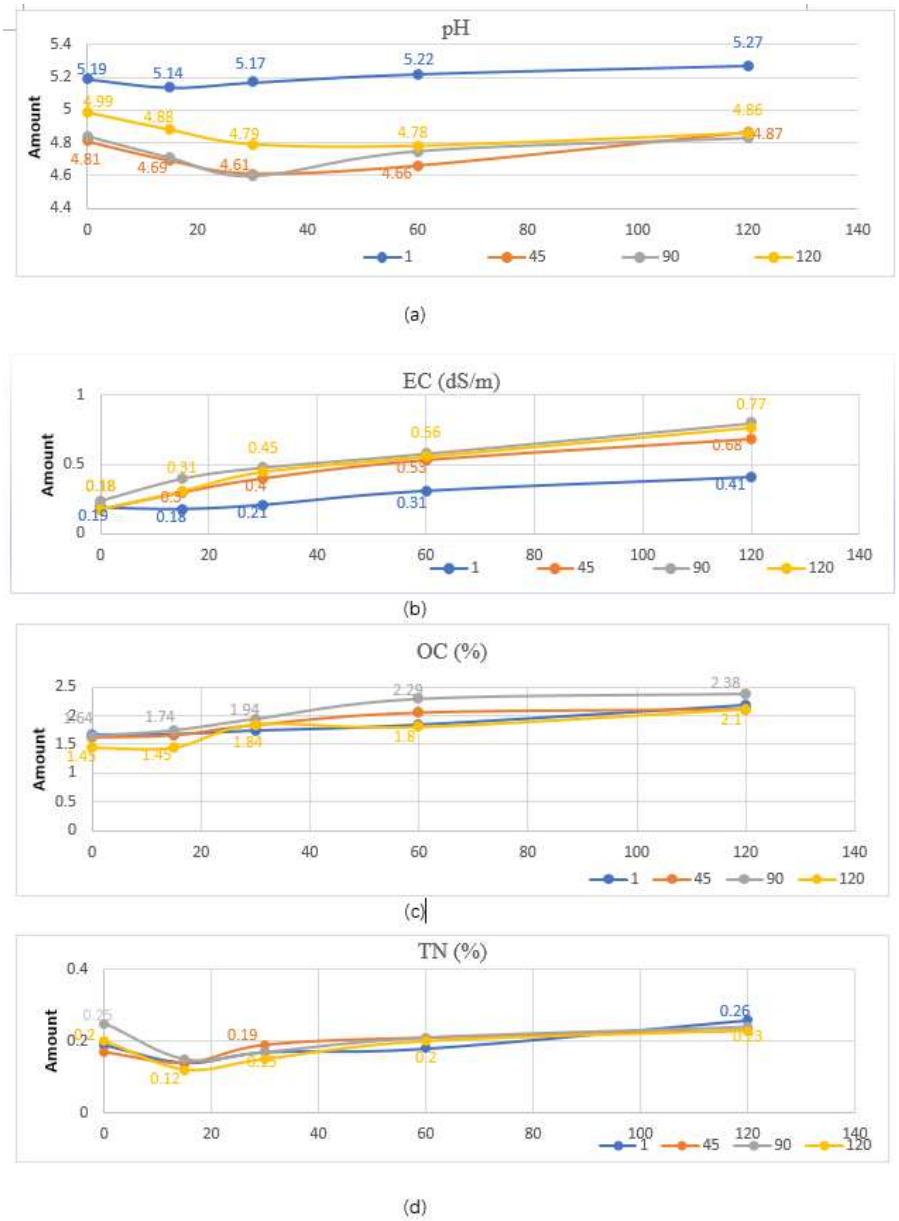

Figure 5. *a, b, c and d: Changes in some chemical characteristics of BWWS addition on soil sample*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_033057

Physicochemical properties of dried (brewery waste sludge) BWWS

Kanagachandran and Jayaratne (2006) investigates the brewery wastewater sludge potential application as an organic fertilizer alone and with combination of municipal solids and farm solids for germination of pumpkin seeds. Before the pilot scale trial was conducted, sun dried brewery wastewater sludge (denoted as BWS), mixtures of BWS with municipal solids (denoted as compost A) and farm solids (denoted as compost B) were analyzed for both chemical and physical parameters. The results of physicochemical characteristics of BWS, Compost A and Compost B are explained in graph (*Fig. 6*).

	moisture	pH	volatile matter	organic carbon	TN	available nitrogen	TP	K
BWWS	10.7	6.97	9	27.1	4.5	0.4	3.3	0.2
Compost A (BWWS+MS)	13.2	8.64	12.5	9.8	1.1	0.4	0.6	0.7
Compost B (BWWS+FYW)	15.83	8.4	9	18.3	1.6	0.2	3.2	2.7

Figure 6. *Physicochemical properties of dried BWWS, Compost A and Compost B*

The pH of (Brewery waste sludge) BWWS investigated by Kanagachandran and Jayaratne (2006) was approaches to neutral whereas compost A and compost B appeared under alkaline conditions. This may be due to the differences in the presence of mixtures of other substrates in BWWS. The total nitrogen and organic content of BWWS was higher than compost A and compost B which are derived from municipal wastes and farm yard wastes. This has a vital role in plant nutrition and ecosystem functioning. The total phosphorus content of BWWS was equivalent to farm yard compost. While, potassium, and the micronutrients manganese, copper and zinc contents were lower in BWWS compared to both composts. Water holding capacity is one of the valuable property and important in soil for releasing humidity to the plants when they require. The water holding capacity of BWWS was the highest compared to compost A and compost B. This property may be linked to the high content of organic matter and nutrients. Presence of heavy metals is one of the main hurdle in the agricultural application of wastewater sludge because of their toxic effects on crops and soil and the leaching of heavy metals into the nearby water sources.

The concentration of metals in (Brewery waste sludge) BWWS, compost A and compost B are explained in *Figure 7*. The analysis of heavy metals in BWWS revealed that the level of lead and nickel were lower than the expected Sri Lankan standards for organic fertilizer which are 250 mg/kg and 100 mg/kg, respectively.

Figure 7. *Content of minerals in BWWS, Compost A and Compost B*

The effects and potential of brewery sludge (BWWS) as application of organic fertilizer

Effects on treatment of acidic soils and heavy metals

Dessalew et al. (2017) also tried to analyze the effect of BWSS on the treatment of acidic soils and there result showed that the PH of BS samples presented alkalinity that ranged from 8.79 in fresh BS to 8.37 in a two-year old sample as shown in *Table 4*. According to Luque et al. (1990), alterations in the source of water and processing method can create a difference in PH as shown from the South American breweries which gave their PH oscillating from 6.5 to 11.5. Using BS as a method of modifying the soil can alter the micronutrients and macronutrients availability. Therefore, combination of BS with some other compounds can help in lowering the PH values. Conversely plants that can endure alkalinity can be used in such cases.

Since about 40% of the cultivated land in Ethiopia have soils that are acidic (Mesfin, 2007), then BSDS can be utilized so as to make the fertility of the soil to be better. Additionally, since there is decline of PH of BS with age, then the aged BSDS can be useful in impartial or alkaline soils (Dessalew et al., 2017).

Khan et al. (2014), found that the soil (control) and brewery sludge are slightly acidic in nature. Nitrogen, phosphorus, potassium and heavy metals (Zn, Cu, Cd, Pb, and Cr) content in brewery sludge were higher than the soil. The characteristics of soil and brewery sludge are presented in *Table 5*. Importantly, the content of heavy metals in both brewery sludge and soil are below the permissible limits of the United States Environmental Protection Agency (USEPA, 1997).

Table 5. *Effect of brewery sludge on curd yields of cauliflower*

Parameters	Brewery sludge	USEPA (1997) limit	Soil	USEPA (1997) limit
pH	6.2	-	6.01	-
OM (g/kg)	265.3	-	14.1	-

Cd (µg/kg)	2.25	20	0.73	0.6

Effect of brewery sludge on curd yields of cauliflower

The presence of heavy metals in BWWS affect the soil physicochemical characteristics. For example, soil zinc from 20 Mg ha^{-1} BWWS application was significantly increased compared to 5 and 10 Mg ha^{-1} sludge addition. Higher rate application of BWWS was also increased the accumulation of copper and lead in soil significantly as compared to the other treatments The lowest copper and lead concentration was found in the control. This indicates that high loading rate of BWWS increases the accumulation of heavy metals in soil (see *Fig. 8*) (Khanal et al., 2014).

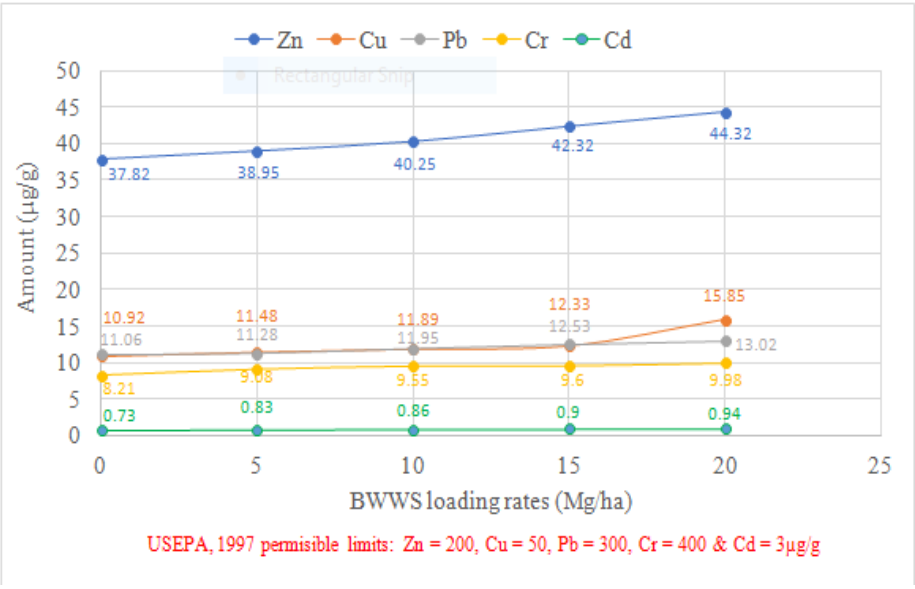

Figure 8. *Effect of BWWS on heavy metals content of soil (control)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_033057

A good percentage of nitrogen, phosphorus and potassium in sludge also make them a valuable resource for agricultural production. Such sludge is spread on land surface and when they decompose can serve as a source of those minerals to plant growth.

The potential of BWSS as application of organic fertilizer

Grain protein content

BWSS role on grain protein content was investigated in Ethiopia and the research result can be seen in *Table 6*. From this table, the wheat and teff protein contents were also differing among the various treatments. RIF treated crops gave the highest grain protein of 12.53% teff and 12.09% wheat owing to better grain nitrogen acceptance by wheat and teff. Control treated crops gave the lowest grain protein of 10.25% teff and 9.98% wheat (Dessalew et al., 2017).

These results were in line with other researches by Lemon (2007), Blumenthal (2008) and also Mariani (1995). From all these researches, it can be seen that in addition to better performance in the biomass yields and grain of teff and wheat, BSDS also improves the grain protein content. In this regard, with BSDS as s substitute to RIF, it can greatly improve nutritional recompenses of low-contribution agroecosystems.

Table 6. *Comparison of protein content of wheat and teff treated with BWSS (brewery spent sludge), FYM (farmyard manure) and RIF (recommended inorganic fertilizer) (Dessalew et al., 2017)*

Treatment	Cereals									
	Teff					Wheat				
	Control	FYM	BSD	RIF		Control	FYM	BSD	RIF

A good percentage of nitrogen, phosphorus and potassium in sludge also make them a valuable resource for agricultural production. Such sludge is spread on land surface and when they decompose can serve as a source of those minerals to plant growth. The fertilizer value of sludge is evaluated by the percentage concentrations of nitrogen, phosphorus and potassium (NPK) present in it. A typical NPK value of recommended fertilizer has NPK composition of 8% N, 8% P and 8% K. It may become difficult to achieve these compositions of NPK value in sludge. From the results of NPK concentrations definitely do have fertilizer values. The aerobically digested brewery and textile sludge's indicates that a nutrient composition of 4.1% N, 2.0% P, 0.6% K and 2.6% N, 0.5% P and 0.6% K. Whereas the results of anaerobically digested sludge indicate brewery sludge had 9.7% N, 0.9% P and 1.4% K. While textile processing sludge had a N, P, and K concentration of 9, 0.2 and 0.5% respectively. If these nutrients concentration are improved upon by a suitable complementary method such as composting, they can be used to fertilizer soil (Asia et al., 2008). The results of the fertilizer values (NPK) of the sludge are presented in *Figure 9*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_033057

	Recommended NPK	Brewery sludge (aerobic)	Brewery sludge (anaerobic)	Textile sludge (aerobic)	Textile sludge (aanerobic)
N	8	4.1	9.7	2.6	9
P	8	2	0.9	0.5	0.2
K	8	0.6	1.4	0.6	0.5

Figure 9. *NPK value of anaerobically and aerobically processed brewery and textile sludge's*

Brewery waste sludge (BWWS) for vegetable and crop cultivation

The pot experiment (500-g container germination study of chilly plant indicated that increased growth of the plants when compared to that controls (*Fig. 10*). However enhanced plant growth was observed with increasing proportions of brewery sludge in clay loamy soil. For example, plant height in 9:1, 8:2, and 7:3 amended with BWWS illustrates an increment in plant height (Ramya et al., 2015).

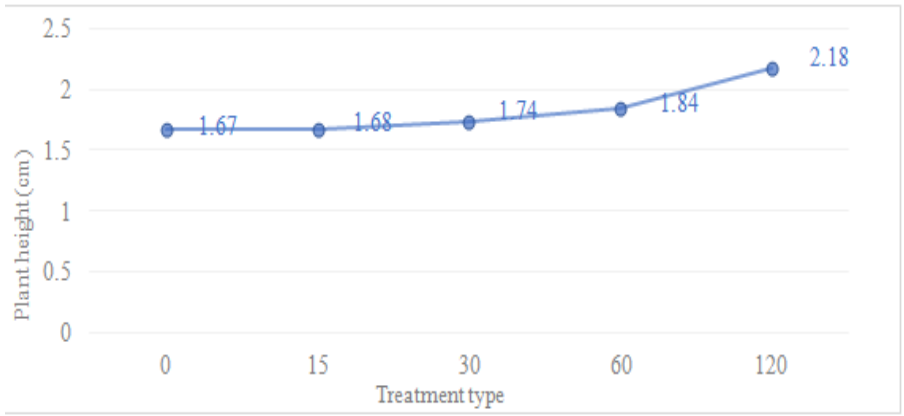

Figure 10. *Comparison of plant height planted in clay loamy soil amended with brewery sludge*

Beside this plant height increment, application of BWWS in river sand soil media has also shown a significant increase in yields. This confirms that brewery sludge would have a positive input for yield increase in relation to poor and semi-arid soils (*Fig. 11*).

Improvement on grain yield

Ramya et al. (2015) also agreed with Khan et al. (2014), in which the effect of brewery sludge (*Fig. 12*) on the yield of curd were shows an increasing trend with an increasing application of brewery sludge. The highest curd yield (i.e., 12.43 Mg ha^{-1})

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_033057

was obtained from 20 Mg ha^{-1} brewery sludge application rate whereas the lowest curd yield (i.e., 7.0 Mg ha^{-1}) was obtained from the soil (control). This highest yield was also significantly higher compared to the control and 5 Mg ha^{-1} brewery sludge application.

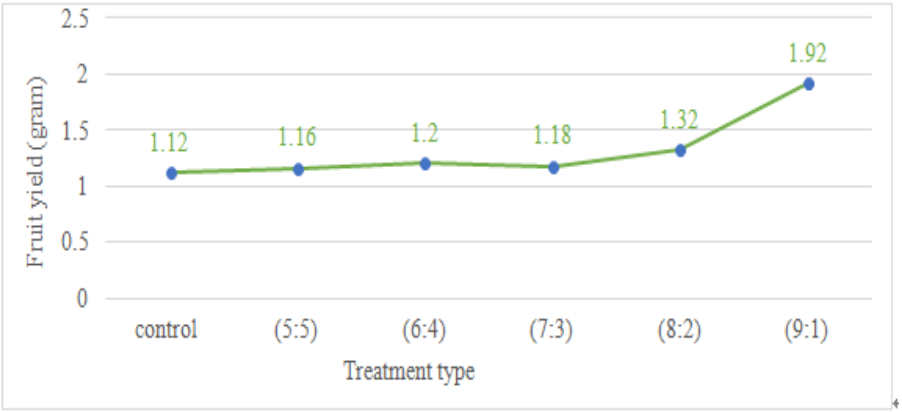

Figure 11. *Comparison of fruit height cultivated in river sand amended with BWWS*

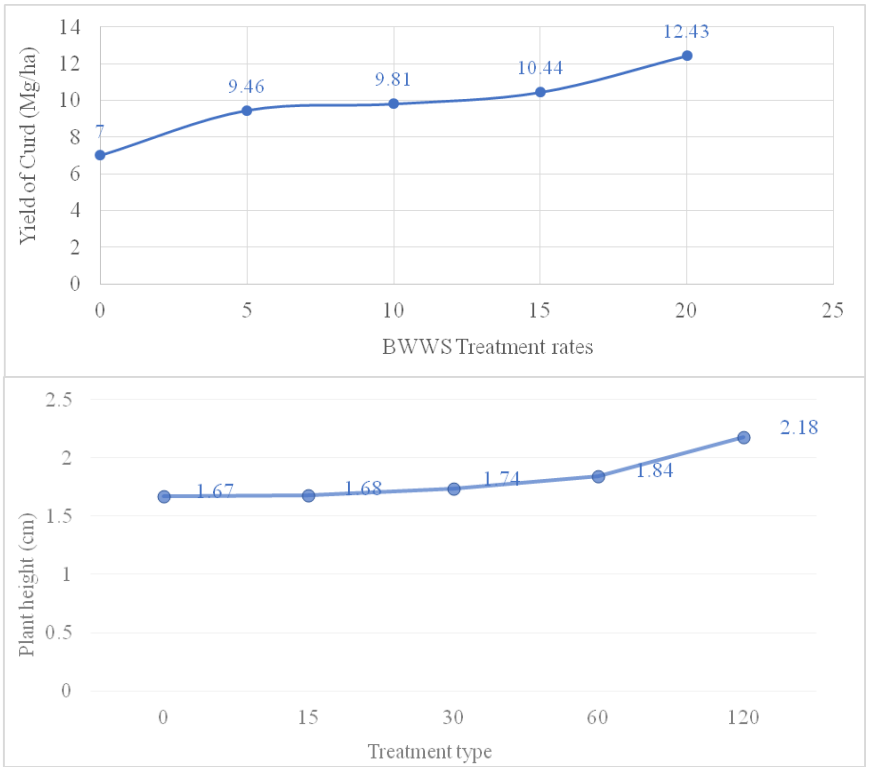

Figure 12. *Role of BWWS on curd yields of cauliflower*

However, Wendimagegn's (2016) research finding indicated that there was a negative effect on the yields of tomato fruit when brewery sludge loading rates was increased. According to Alemu et al.'s (2017) investigation, increased application from 0 to 15 t ha^{-1} to 2.5 t ha^{-1} increased plant height consistently. However, further increasing of sludge application from 2.5 t ha^{-1} to 15 t ha^{-1} not increased plant height

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_033057

significantly indicating the application of brewery sludge beyond 2.5 t ha^{-1} did not significantly increase plant height.

However, as compared to the control and NP fertilized plots, brewery sludge application at all levels showed significance difference and the increment ranged from 23 to 27% and 8 to 11% respectively. This increment in plant height is due to the increase in crop cell elongation and cell division improved as a result of application of brewery sludge that might enhanced availability of essential nutrients for the growth of plants. Similarly, total grain yield of sorghum crop was affected significantly by application of brewery sludge, where sludge at 15 t ha^{-1} treated plot gave the highest (4081.6 kg/ha) mean grain yield. When averaged across the application levels, sorghum grain yield showed a significant variation due to the brewery sludge application. The sludge treated plots produced 261.7 and 75.6% more grain yield than that of control and NP applied plots, respectively. The low response to NP might have been due to the fact that part of the applied NP would not be available to plants, rather it tends to fixed by the soil and existing available nutrients reserve of the soil might be very low (*Fig. 13*).

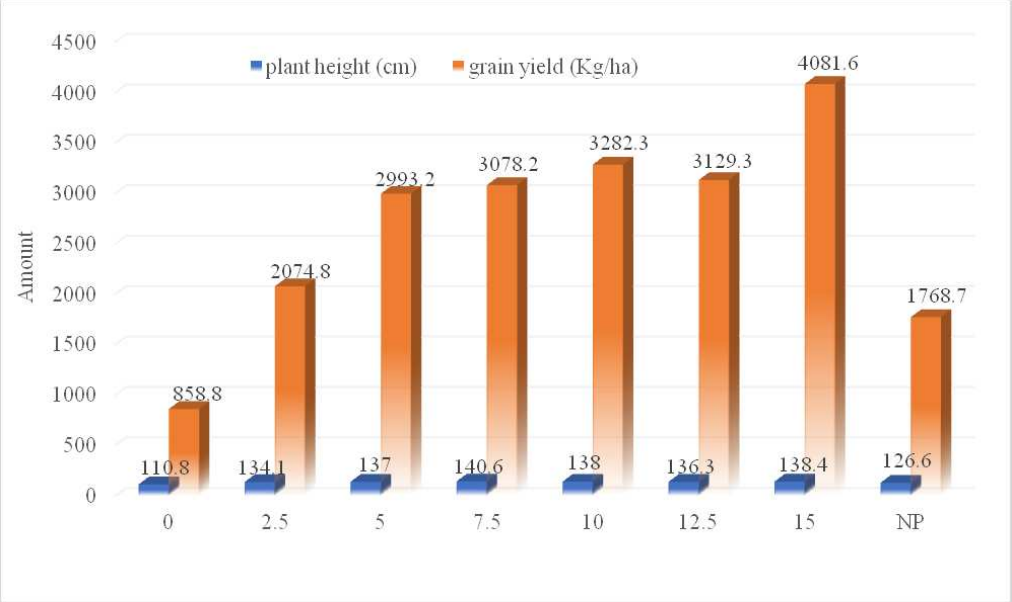

Figure 13. *Plant height and grain yield of sorghum cultivated under different levels of BWWS and NP*

In addition to this, the results of a research conducted in one of the city found in Ethiopia on Teff and wheat grain yield can be seen in *Figure 14* and *Table 7*. From these results, RIF gave the highest yields followed by soils that were added BWSS and lastly the soils where no was fertilizer added (control) and those for FYM. From the addition of BWSS for both teff and wheat, the yields were doubled in comparison with the yields from control; 1.5 times for teff and 1.3 for wheat in comparison with the yields from FYM. This gave a yield of 2.45 t/ha for teff and 2.65 t/ha for wheat in Ethiopia (Dessalew et al., 2017). This increase in yields goes hand in hand with other research works such as Luque et al. (1990) and Iliescu (2009). Therefore, BWSS can serve as a good organic fertilizer that can be applied in the farming areas which is cost effective and with lesser enduring undesirable significances for the quality of water and soil, along with the general public health.

(Source; G. Dessalew et al. 2017)

Biomass yield

As the result showed in *Table 7*, the treatments between biomass harvest showed substantial variances ($p < 0.05$) during the analysis of variance. BWSS usage gave far much better results than FYM (farmyard manure) but lower than RIF (recommended inorganic fertilizer). Like in the case of the grains, the addition of (Brewery waste

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_033057

sludge) BWSS for biomass yields, were doubled in comparison with the yields from control; 1.5 times for teff and 1.3 for wheat in comparison with the yields from FYM; but lesser yields when compared to RIF due to the fast release of if RIF than BWSS (Dessalew et al., 2017).

Conclusions and recommendations

Conclusions

Brewery wastewater sludge is generated as the result of biological wastewater treatment process. Previously, this sludge is considered as a waste product, but now it can be substituted for fertilizers and avoid the need of costly inputs of chemical fertilizers because of its valuable nutrients for plant growth and high water retention capacity. To do this, cost effective and environmentally friendly treatment technique should be developed to convert brewery sludge into bio-fertilizer. Composting with other organic wastes like straw and paper generally offers a relatively cheap and environmentally sound method of recycling organic brewery by-products.

Currently, in Ethiopia there is an increased expansion of agro-industrial sectors mainly beverage industries. This expansion may increase sludge production along with increase in their beer productions. Therefore, it is inevitable to focus on the development of appropriate agro-industrial sludge waste management strategy enabling to reutilize the sludge in an environmentally friendly manner.

Recommendations

Most of the Ethiopian breweries have wastewater treatment plant and generates large amount of sludge which is disposed anywhere. Limited research evidences are available (i.e., only restricted to Harare sofi and Heineken breweries) on the possibility of recycling brewery wastewater sludge for land application at pilot scale levels. Therefore, more research has to be investigated on potential fertilizer values of Ethiopian breweries wastewater sludge's.

(Received 6th May 2019; accepted 15th Nov 2019)

Abstract. This paper takes 4,225 articles on the relationship between haze and economic growth in the Web of Science database from 1992 to 2017 as the research object, and uses CiteSpace to explore the spatial and temporal distribution, research topics and hot trends of the literature. The results show that: (1) The relevant literature volume keeps growing at a high speed. (2) The cooperative group of high-yield authors represented by Huang GH and Streets DG is basically formed. (3) The research institutions are divided into the top international colleges and universities represented by Tsinghua University and the University of California, Berkeley, as well as the two major groups of international well-known scientific research institutes represented by the Chinese Academy of Sciences and the American Environmental Protection Agency. (4) The cited high literature is concentrated in the six international high level journals such as "Science". (5) The two major cooperation bodies of "the United States–China" and "Holland–France–Italy–Spain" have been formed. (6) The research topics are mainly about the economic mechanism of haze formation, its relationship with economic growth, spatial spillover effects and countermeasures. (7) The research hotspots show trends from "air pollution" and "health" to "$PM_{2.5}$" and "CO_2 emission".
Keywords: *$PM_{2.5}$, EKC, spatial spillover, knowledge map, CiteSpace, hot trend*

Introduction

In recent years, with the continuous expansion of China's population and rapid economic development, energy consumption has been increasing, and air pollution problems such as smog and haze have become increasingly serious. Haze will not only seriously affect people's physical and mental health, but also cause a certain degree of impact on traffic safety, agricultural production, ecological environment and economic development. According to the calculation results of official agencies such as the World Bank and the environmental protection administration, the annual loss due to environmental pollution in China is about 10% of GDP (Zhou, 2011). The high frequency of haze and the great influence have attracted the attention of people from all walks of life. In 2017, Premier Li Keqiang wrote the "resolutely fighting the blue sky defence war" into the government work report.

In addition to natural factors, serious haze pollution is largely attributed to extensive economic development mode and unbalanced industrial structure. Studying and exploring the internal relationship between haze and economic growth will help in finding out the root causes of frequent haze, and put forward the regulation mechanism of coordinating air pollution and economic development represented by haze, so as to provide scientific basis and policy suggestions for regional economic development and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_059075

ecological environmental protection, so as to achieve the goal of green development and ecological civilization construction.

The relevant research work in the world has been carried out relatively early. Many scholars have studied the relationship between haze pollution and economic growth from different perspectives, such as the formation mechanism of haze and the analysis of influencing factors, the health economic loss caused by regional particles ($PM_{2.5}$, PM_{10}, etc.), and environmental Kuznets curve test, etc. These documents reflect the research results of this field only in one way, but it is difficult to grasp the dynamic development and hot trend of the international research field in a comprehensive way. Through the method of knowledge map, the research dynamic and development trend of professional field can be presented in the form of visual atlas (Hou et al., 2009). At present, the map of science knowledge has made great achievements in many fields, such as management, pedagogy and so on (Feng et al., 2017). However, the academic circles still lack the bibliometric analysis of the relationship between haze and economic growth. Based on this, this paper selects the bibliography of haze and economic growth in the core collection database of Web of Science (hereinafter referred to as WoS) during 1992-2017 years as the analysis data. Through CiteSpace visualization software, using knowledge mapping method and related tools, this paper makes a holistic and multi-dimensional visualization analysis of the international research on the correlation effect of haze and economic growth. The aim is to sort out the research hot spots and trends of international literature, which not only helps domestic scholars to understand the research status of the correlation between haze and economic growth in the world, track its frontier hot spots, explore and grasp the development trend and potential of this field, but also provide some reference for the haze control and ecological environmental protection in China, whether for academic research or practical.

Materials and methods

Research methods

The development of information technology and bibliometrics provides a basis for the generation of visual software. The visualization software provides a new way for document processing and analysis (Shi and Li, 2016). Based on this, this paper chooses CiteSpace as the main measurement and visualization software, and Excel as an auxiliary measurement tool. Firstly, CiteSpace is used to describe the current research status and hot trend in the field of international haze and economic growth, and then the literature is read critically according to the analysis results provided by the software, so as to summarize the research topics in this field.

Data sources

In order to explore the status of international research in the area of haze and economic growth and ensure the integrity of the literature search, this paper searches relevant literature in the WoS database by means of TS = ((Economic OR Economy) AND ($PM_{2.5}$ OR PM_{10} OR haze OR smog OR air quality OR air pollution). The time span is 1992-2017 , and the literature types are pure scientific documents (ARTICLE), PROCEEDINGS PAPER and EDITORIAL MATERIAL, and a total of 4730 literature data are obtained. Later, using the Remove duplicates function in CiteSpace, the duplicate documents were filtered, and finally 4,225 effective records were obtained.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

Results

Time distribution

The amount of document information can reflect the heat level and research process of a certain area to some extent, which is an important part of scientific bibliometrics. According to the statistical results in WoS, the time distribution map of the literature (*Fig. 1)* is drawn by Excel mapping in order to understand the time distribution and growth of the literature on the related effects of haze and economic growth in the world.

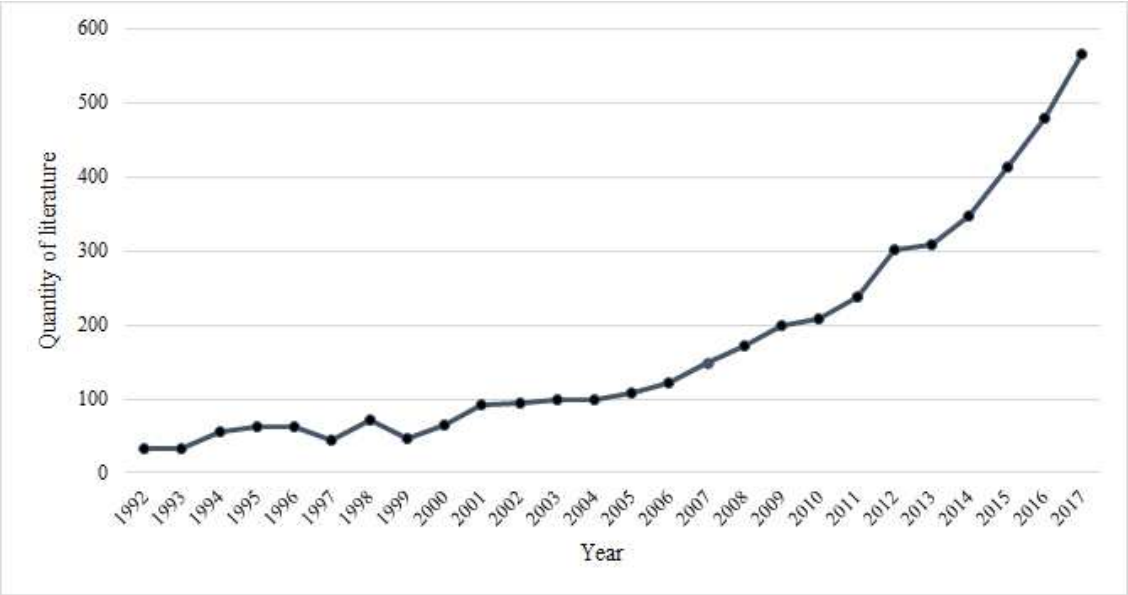

Figure 1. *Time distribution of literature on correlation between haze and economic growth*

As can be seen from *Figure 1*, the international literature on the correlation between haze and economic growth shows a relatively rapid growth trend. One of the reasons is that the number of journals on ecological environment and environmental economy is increasing, but the more important reason is that the problem of haze has become more and more serious in recent years, which has attracted extensive attention and research from scholars all over the world. According to *Figure 1*, the time distribution of relevant literature can be roughly divided into three stages: (1) Stage 1 (1992-2000 year): the number of literature is small, and the fluctuation range is not large, indicating that the international research in this field started very early, but the research progress is relatively slow. (2) Stage 2 (2001-2010 year): In the first half of this phase (2001-2005), the amount of literature fluctuated around 100, and it did not increase until 2006. (3) Stage 3 (2011-2017 year): the stage of rapid literature growth. Since 2011, the continuous broadcasting of $PM_{2.5}$ by the US Embassy has aroused widespread social concern. Academic circles have also paid great attention to the correlation effect between haze and economic growth, and have done a lot of research on it, and achieved a lot of research results. It can be seen that the literature in this stage is gradually increasing, and the growth rate is gradually accelerating.

According to the law of the logical growth curve of literature, the growth of literature can be divided into four stages (Qiu JP, 2007). The first stage is the embryonic stage, the growth of literature is relatively slow; the second stage is the rapid growth stage, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_059075

literature grows sharply; the third stage is the mature stage, the growth rate is slow; the fourth stage is the saturation stage, and the literature growth rate approaches zero. From the above theory, it can be inferred that the literature on the correlation between haze and economic growth is in a state of rapid growth, so it accords with the second stage of literature development, and it is predicted that the volume of literature will remain high growth in the next few years (Sun and Wang, 2016).

Spatial distribution

In this paper, we use the co-occurrence network of the provided by CiteSpace, the co-occurrence network of research institutions, the co-citation network of the periodicals, the shared network function of the country and the region, to analyze the scientific research cooperation network in the field of haze and economic growth in the world from the micro, meso and macro levels, thus showing the spatial distribution characteristics of the field (Liu et al., 2017).

Micro layer – author analysis

1) Author's analysis: initially formed a batch of high-yielding authors

Through the analysis of the amount of the author's publications, we can understand the author's scientific research ability and level, and make a quantitative analysis of the author's publications in the field of the correlation effect haze and economic growth, and can get the international high-yielding author group in this field (Liu et al., 2011).

According to *Table 1*, the most frequently published research topic in the field of haze and economic growth is the Huang GH of North China Electric Power University, who has published 32 articles. According to Price formula (*Eq. 1*):

$$M = 0.749 * (N_{max})^{1/2} \quad \text{(Eq.1)}$$

M is the number of papers, N_{max} refers to the number of the highest producers, the authors who have published more than M are called high-yielding authors (Sun and Wang, 2016). This paper calculates the threshold of high-yielding authors in the field of correlation between haze and economic growth, which is 4.24. Therefore, this paper takes the author whose articles are more than or equal to 5 to be a high-yielding author. There are 46 high-yielding authors (*Table 1*). These high-yielding authors are relatively active in the research field, and have strong scientific research ability. Altogether 397 papers are published, accounting for 9.40% of the total. This indicates that a certain number of high-yielding authors have been formed to some extent in the field of international academia.

2) Author cooperation analysis: high-yielding authors gathered and the rest of the authors dispersed and coexist

In order to identify the core scholars in the research field and their mutual cooperation strength, the author analyzes the literature from the perspective of author's co-occurrence.

In CiteSpace, the time zone is selected from 1992-2017, the time slice is 2, the threshold is "Top N = 30", the other parameters use the default value, Node Types selects the Author, and generates *Figure 2*. *Figure 2* shows that there are 296 nodes and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_059075

303 connections in the map, and the density is 0.0069. The node in the map represents the author, the size of the node indicates the author's volume of publications, and the thickness and color of the connection indicate the strength of the cooperation relationship and the year in which the co-occurrence relationship first occurred (Chen et al., 2014).

Table 1. *High-yielding author statistics (Number of documents ≥ 5)*

Number of documents	Name	The year of the first paper	Number of documents	Name	The year of the first paper
32	Huang GH	2008	6	Carmichael GR	1999
25	Zhang Q	2010	6	Chen L	2006

7	He KB	2014	5	Scasny M	2010
6	Paltsev S	2008	5	List JA	2003

As shown in *Figure 2*, a number of nodes are concentrated in the center of the map, and there are many connections between these nodes; at the same time, many isolated nodes are dispersed around it. It shows that there are different degrees of cooperation between the authors of the central region, and the flow of knowledge between each other is better, but the authors in the scattered parts around them lack communication and cooperation and are in a state of isolation. At the same time, most of the node connections in the center of the original map are orange red (corresponding to 2012-2017 year). It shows that the cooperative group has been formed in the last five years. It is now in the stage of strengthening communication and deepening the cooperation. It is expected that the future part of the author will create more research results through cooperation.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_059075

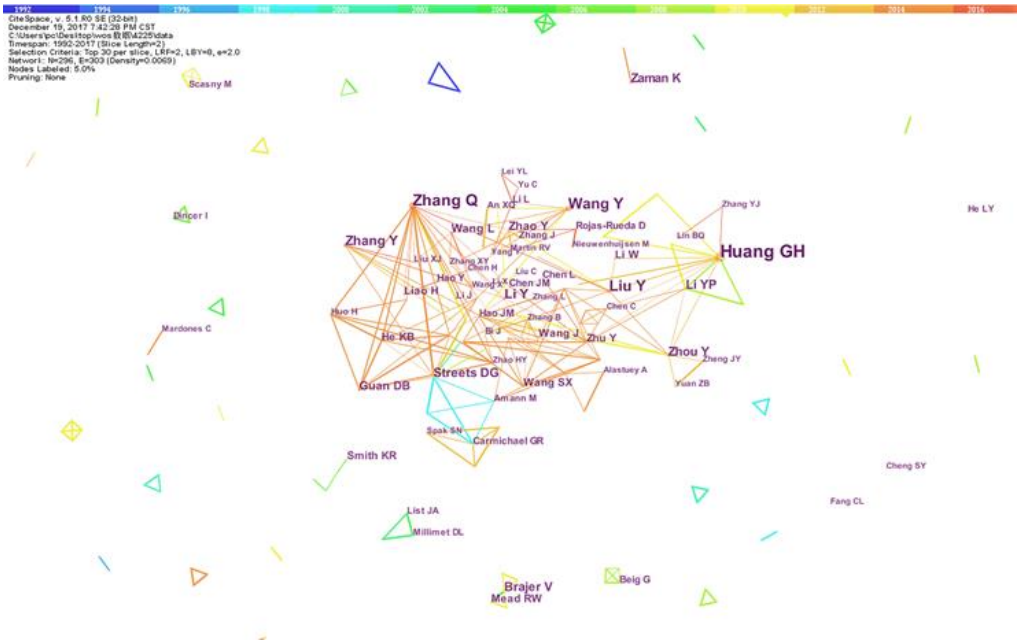

Figure 2. *Co-occurrence map of scholars*

Meso level – research institutions and periodicals analysis

1) Cooperation analysis of research institutions: focusing on top international universities and research institutes

Research institutes can identify the status and importance of each research institution in the field, and the degree of cooperation between them (Liu et al., 2017). In order to make the map display more concise and clear, the time slice is 4, the threshold "Top 5% per slice" is selected, and the image is "pruned" using the minimum spanning tree algorithm (MST), and *Figure 3* is obtained. As shown in the following figure, there are 165 nodes and 194 connections. The overall density of the network is 0.0143. *Table 2* lists the detailed information of the top 20 institutions.

Figure 3. *Co-occurrence map of institutions*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_059075

Combined with the analysis of *Figure 3* and *Table 2,* we can see: (a) the research power of the correlation between haze and economic growth is concentrated in universities and research institutes. Tsinghua University, Univ Calif Berkeley, Peking University and Harvard University are among the top international universities with environmental and economic advantages. The largest node is the Chinese Acad Sci. Its scientific research level is highly recognized both in China and internationally. (b) There are many connections in the central area of *Figure 3,* and there are scattered nodes in the non-central area. It shows that most of the research institutions in this field work closely, but there are still some institutions that lack cooperation, which should continue to strengthen exchanges and cooperation between institutions.

Table 2. *Top 20 institutional information*

2) Co-cited analysis of journals: research results concentrate on six high level journals

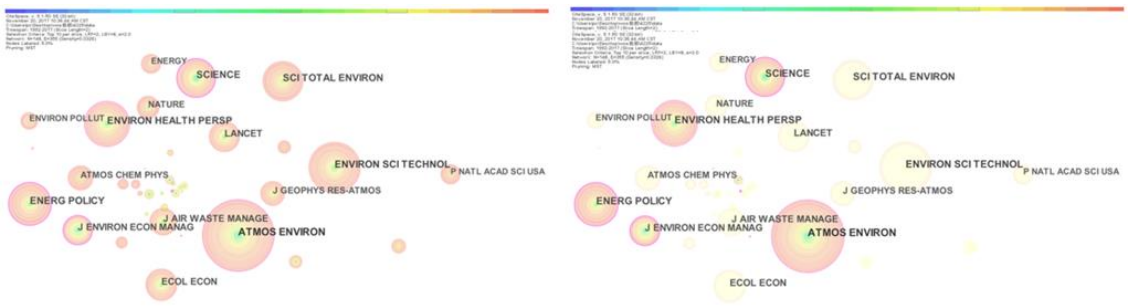
The “Cited Journal” function is selected to reflect the relevance between the various journals and disciplines by the phenomenon that the two journals are cited by the same document, so as to further analyze the knowledge base distribution in the area of haze and economic growth (Chen et al., 2014). The parameter is set to Top N = 10, and MST is selected for pruning to highlight its main components.

As shown in *Figure 4A,* the journal co citation map has 148 nodes and 355 connections. The density is 0.0326, and there are many nodes in the annual ring. Combined with the analysis of background data, the six journals of “Atmospheric Environment”, “Environmental Science & Technology”, “Environmental Health Perspectives”, “Energy Policy”, and “Science of the Total Environment” and “Science” have concentrated most of the research literature on the association effects of haze and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_059075

economic growth. The related papers are of academic value, data value and applied value, representing the research hotspots and frontiers in this field. Among the representative journals, the impact factors of "Science", "Environmental Health Perspectives" and "Environmental Science & Technology" from 2016 to 2017 are larger, and the impact factor of Science is even as high as 37.205, which is one of the most authoritative academic journals in the world. All of these show that the correlation between haze and economic growth has received international attention.

Then, through the Spotlight function in CiteSpace, the nodes with high centrality (purple circle nodes) are highlighted (*Fig. 4B*). It can be found that the number of nodes with purple circles in the journal's co-citation map is relatively large. Among them, the intermediary centrality of "Science" and "Energy Policy" is more than 0.2, indicating that these journals are in the key position in the network, which is the object that scholars in this field should focus on (Liu et al., 2017).



(A) (B)

Figure 4. *Co-citation map of journals*

The macro level – national co-occurrence analysis: "USA–China", "Holland–France–Italy–Spain" are two largest emerging cooperatives

At the macro level, through the analysis of the national cooperation network, we can understand whether there is a cooperation relationship and the intensity of cooperation among the countries in the field of the correlation effect between haze and economic growth. Therefore, the node selects "Country", the parameter is set to Top N = 10, and the time slice is 2, the result is shown in *Figure 5*.

From the background data analysis of *Figure 5,* 28 countries have published more than 3 papers in the field of the correlation between haze and economic growth, but a large number of documents are obviously concentrated in a few countries. The data show that there are five countries with more than 200 papers, but the total number of papers in these five countries is up to 2941, that is, nearly 70% papers in this field are produced from these countries. Among them, the United States has a very obvious advantage, with a total of 1382 (32.71% of the total), and the centrality is as high as 0.55, indicating that the United States is in a key dominant position in the field of haze and economic growth, with a high achievement and outstanding contribution. China's paper output ranks second, with a total of 770, followed by the UK (a total of 334 articles), Canada (a total of 247 articles) and Germany (a total of 208 articles). In *Figure 5*, the thickness of the connection indicates the strength of the cooperation. The color of the line in the original figure indicates the time of cooperation between

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_059075

countries. Based on this, it can be concluded that "the United States-Canada" and "Canada-Germany" had close cooperation in the early period (1992-2000). "The United Kingdom-Canada-China" had strong cooperation in the medium term (2001-2008), while the two cooperation bodies of "the USA–China" and "Holland–France–Italy–Spain" were formed in recent years (2009-2017).

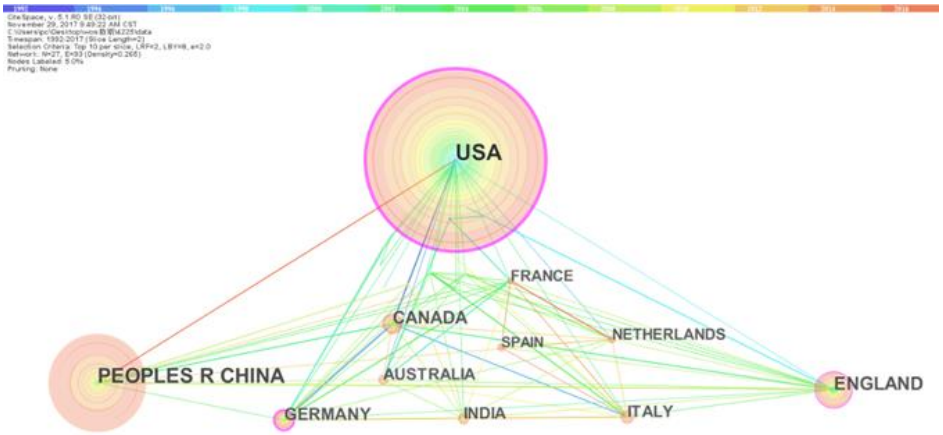


Figure 5. *National cooperation network map*

From the analysis of *Figure 5*, we can see that the research power in the field of the correlation effect between haze and economic growth in the world is mainly concentrated in the developed countries such as the USA and the UK, as well as the rapidly developing countries such as China, indicating that these countries are more concerned with the field relative to other countries and have corresponding researchers. At the same time, *Figure 5* shows that there are many links between countries, indicating that their cooperation and exchange are relatively close, which is conducive to the in-depth research in this field and the output of more scientific research results. However, the original map shows that the connection between some countries is a tone, indicating that the cooperation between these countries only existed for a period of time, and has not always maintained cooperation. In the future, countries should strengthen continuous contacts and exchanges, maintain long-term cooperation so as to further promote sustainable development in this field.

Discussion

Research topics

From the previous analysis, we can see that the research literature on the correlation between haze and economic growth is very rich, but the research topic is more scattered. Combined with the high-frequency keyword clustering processed by CiteSpace (*Table 3*), and reading and sorting out the existing literature, the author divides the research topics into four aspects: (1) the economic mechanism of haze formation; (2) the relationship between haze and economic growth; (3) the spatial spillover effect of haze; (4) the countermeasures of haze control.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_059075

The economic mechanism of haze formation

Some scholars believe that energy and industrial structure and other factors have led to the emergence of haze weather. Jessie (2006) found that when entering the heavy industry stage, the consumption of coal increased continuously, the $PM_{2.5}$ concentration also increased, and the air pollution problem became more and more serious. Wang et al. (2015) found that the aggravation of haze pollution is mainly caused by the rising consumption of coal energy in industrial production. Improving industrial structure is an important way to control haze. Antonakakis (2017) analyzed the relationship between carbon emissions and economic growth, and found that the increase of global carbon emissions is accompanied by rapid economic growth.

However, some scholars have raised questions and conducted research: Antweiler (2001) established a theoretical model and used the data of SO_2 concentration to test the theory, and finally came to the conclusion that more free trade seems to be favorable to the environment. He (2012) analysed the impact of the three heavy transformation processes on the environment, such as marketization, globalization and decentralization, and concluded that the marketization and decentralization are harmful to the urban environment, while the economic globalization is beneficial to the urban air quality.

The relationship between haze and economic growth

1) Empirical research based on EKC

Panayotou (1993) applied the Kuznets curve to the analysis of the relationship between environmental quality and economic growth, and proposed the EKC hypothesis (an inverted U-shaped relationship between environmental pollution and economic growth) for the first time. Selden and Song (1994) analyzed and found that the per capita emissions of suspended particulate matter, SO_2, NOx and CO had a reverse relationship with GDP per capita. They believed that although emissions would be reduced in the long run, it was expected that global emissions would continue to grow rapidly in the next few decades. Grossman and Krueger (1994) found that economic growth brought about environmental deterioration in the early stages of economic growth and improvement in the later stages; and the turning points of different pollutants were different.

With the deepening of research, different voices have emerged in academia: Ansuategi (2003), by analyzing the panel data of SO_2 emissions in Europe, proposed that EKC would be established only when the pollutants are semi-local and have medium-term effects. Stern (2004) pointed out that there are some problems in EKC hypothesis, such as omission of variable bias, heteroscedasticity and endogeneity. Dinda (2004) combed the related literature, background history and conceptual insights, and summarized two general explanations for the formation of EKC. At the same time, there were some doubts about EKC from the perspective of concept and method. However, Tamazian and Rao (2010) considered the questions raised by the predecessors and examined them again. The results still showed the environmental Kuznets hypothesis was valid.

Hao and Liu (2016) used spatial error model and spatial lag model to analyze the direct relationship between $PM_{2.5}$ and economic development. The results show that the relationship between $PM_{2.5}$ and per capita GDP is inverted U-shaped. Secondary industry has a significant positive impact on urban $PM_{2.5}$ concentrations. Sarkodie et al. (2019) concluded that the per capita $PM_{2.5}$ emissions and income levels showed an

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_059075

inverted U-shaped curve, which confirmed the validity of the Kuznets curve hypothesis between air pollution and urbanization.

2) Theoretical research

Compared with empirical analysis, the theoretical research in this field is relatively weak: Bovenberg and Smulders (1993) explored the relationship between environmental quality and economic growth in the endogenous economic growth model under the technological change driven by pollution. Chichilnisky (1994) put the environment and pollution into the neoclassical production function and utility function to analyze, and believed that the different property rights created different regional trade motives.

The spatial spillover effect of haze

Many scholars in the world believe that the haze pollution in a certain region will affect the environmental quality of the surrounding areas, and its governance will also affect the surrounding areas. That is, there is a spatial spillover effect of haze. Therefore, it is necessary to explore the relationship between the environment and the economy in the space framework, although it will make the relationship more complex.

In the early twenty-first Century, Anselin (2001), a famous international econometric economist, applied the spatial econometric modeling method to the perspective of environment and resource economy, and studied the importance of spatial factor analysis. Maddison (2007) selected SO_2, NO_2 and other pollutants as the typical measure of air quality, and used the spatial econometric method to establish a model. It was found that there was a spillover effect on the pollution and governance of haze between countries under this model. Poon et al. took Chinese provinces as the research object. By simulating the impact of energy, transportation and trade on local air pollution emissions, it was confirmed that spillover effect did exist in Chinese provinces Poon et al. (2006). Hosseini and Kaneko (2013) used six kinds of weight matrices to create six spatial models, demonstrating that air pollution does have spillover effects between countries. Dimitriou and Kassomenos (2014) studied the origin of $PM_{2.5}$ in Rome and its impact on air quality, indicating that pollutants have potential external spillover effects.

The countermeasures of haze control

According to the policy connotation reflected by EKC, economic growth will ultimately help improve environmental quality, and pollution is only a “by-product” on the growth path (Lu and Sun, 2015). However, accelerating economic growth is not a panacea for improving environmental quality (Arrow et al., 1995). Grossman and Krueger (1995) believed that the effective way to solve the environmental problems is to improve the technology and optimize the industrial structure. Based on the theory of sustainable development, Karki (2005), taking the ASEAN region as an example, believed that in order to maintain sustainable development under the condition of growing economy, comprehensive management of resources and energy was needed. Ma et al. (2019) analyzed haze in eastern and northern China, and believed that emission reduction and regional joint prevention and control would help improve air quality.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_059075

Some scholars use the Computable General Equilibrium (CGE) model to study the methods and countermeasures of haze control. Jie (2005) established a static CGE model, and found that under the policy of flue gas desulfurization, the economic growth rate will decrease, and clean energy will be used instead of polluting energy to achieve the purpose of reducing pollution. Based on the CGE model, scholars such as Xu (2009) and Allan (2014) have proposed the idea of using tax tools, including sulfur taxes and carbon taxes, to control haze. Chander (2018) proposed to strengthen the current policy system to solve the haze problem in Indonesia, including the implementation of various tax laws.

Research hotspots and trend analysis

Research hotspots

Keyword co-occurrence network can reflect the current research hotspots in a certain field. Based on this, the network node of CiteSpace is selected as "Keywords", the time slice is 3, the threshold is set to "Top 10% per slice, up to 30", and the Pathfinder algorithm is selected to be simplified. After that, the clustering analysis is carried out, and key words are extracted with LLR (logarithmic likelihood algorithm) as the clustering identifiers. The results are shown in *Figure 6* and *Table 3*.

The upper left corner of *Figure 6* shows that the Q value of the co-occurrence network of haze and economic growth is $0.5682 \geq 0.3$, and the S value is close to 0.5, which indicates that the network structure is significant and the result is basically reasonable. The graph has 221 nodes and 424 connections, with a density of 0.0174. The greater the node is, the higher the number of occurrences is. The nodes with purple outer ring will play an important role in the network. In this paper, the keywords with intermediary centrality (≥0.1) are selected to explore the research hotspots in various fields in the different periods, as shown in *Table 4*.

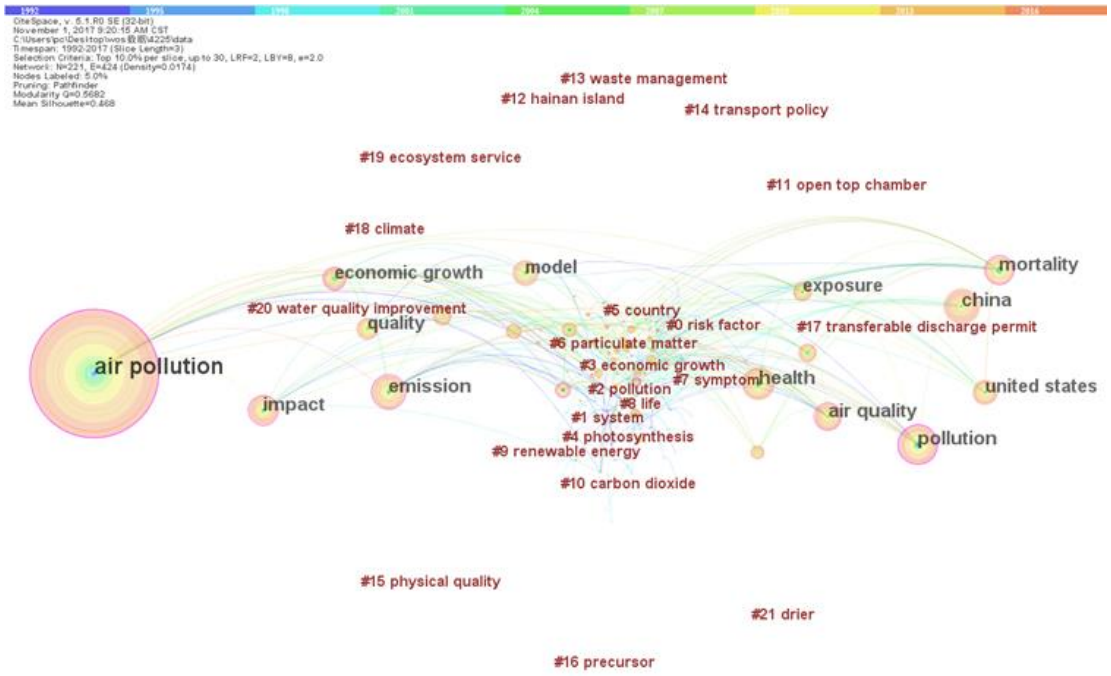

Figure 6. *Keywords co-occurrence map*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_059075

Table 3. *Keywords clustering*

Serial number	Cluster size	The tightness of clustering	Label	High frequency keywords
0	39	0.617	Risk factor	Health(313); mortality(275); exposure(203)
1	27	0.7	System	Climate change(179); energy(153) performance(112)
2	26	0.549	Pollution	China(330); impact(277); air quality(272)
3	24	0.723	Economy growth	Emission(328); policy(165) environmental Kuznets curve(113)
4	19	0.808	Photosynthesis	Acidification(14); deposition(8); critical load(7)
5	17	0.76	Country	CO_2 emission(103); consumption(46); lead(15)
6	14	0.757	Particulate matter	Aerosol(94); pm_{10}(81); $pm_{2.5}$(65)
7	14	0.771	Symptom	Particle(40); water(15); respiratory health(14)
8	12	0.771	Life	Benefit(63); cost(50); industry(27)
9	11	0.865	Renewable energy	Plant(12); environmental impact(8); greenhouse effect(7)
10	5	0.976	Carbon dioxide	Abscisic acid(6); SO_2(5); transport policy(3)

Table 4. *Keywords with intermediary centrality ≥ 0.1*

Serial number	Frequency	Centrality	Key word	Serial number	Frequency	Centrality	Keywords
1	1076	0.45	Air pollution	8	228	0.14	Quality
2	365	0.23	Pollution	9	203	0.14	Exposure
3	328	0.22	Emission	10	313	0.13	Health
4	330	0.19	China	11	270	0.12	Air quality
5	275	0.18	Mortality	12	108	0.11	System
6	52	0.18	Children	13	175	0.1	Particulate matter
7	153	0.15	Energy	14	5	0.1	Acid rain

According to the map analysis, the keywords “air pollution”, “pollution”, “emission”, “mortality” and “China” are ranked in the top five, and their co-occurrence frequency is more than 200 times. These keywords with high frequency and centrality represent the issues that researchers have paid close attention to and conducted a lot of research during this period, and play a key pivotal role in the study of the correlation effect between haze and economic growth.

Trend analysis

Timezone view focuses on the evolution trend of research topics over time and their impact on each other. Therefore, the timezone view of keyword co-occurrence network can show the hot trends in the field of the correlation between haze and economic growth in the world. The network node is selected as “Keywords”, the time slice is 3, the threshold is set to “Top N = 20”, and the MST algorithm is selected for pruning to get the main hot trends in this field. Finally, the time map of the keyword evolution since 1992 is obtained (*Fig. 7*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_059075

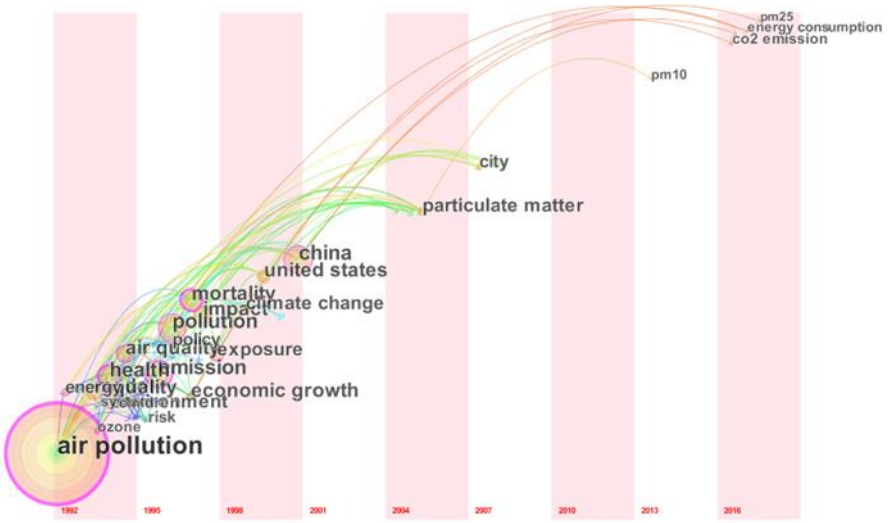

Figure 7. *Keywords time zone map*

Through the analysis of *Figure 7* and its background data, there are many key words in the early stage of the evolution of the correlation between haze and economic growth, such as "air pollution", "health", "economic growth" and "energy". These keywords are the most important focus of the academic community on the correlation between smog and economic growth in the 1990s. Since the 21st century, keywords such as "China", "particulate matter", "city" and "$PM_{2.5}$" "CO_2 emission" have attracted wide attention and become the current research hotspot in this field, which may continue to be hot in the future. On the whole, *Figure 7* shows the trend of international research on haze and economic growth.

Conclusion

In view of the fact that the current research has not yet fully demonstrated the development of international research on the correlation between haze and economic growth, and the lack of scientific visual quantitative analysis, this paper systematically analyzed the research on the correlation effect between haze and economic growth by using knowledge map method and CiteSpace tool. The time distribution of the literature in this field is distributed. The author's publications and cooperation in this field is analyzed by using the co-occurrence map of the author. Through the analysis of the research institutions, national co-occurrence and co-cited of journals, the main research forces in the field and the high level journals are found. The research hotspots and trends in this field are explored by using the keyword co-occurrence map and time zone map.

The main conclusions are as follows: (1) In the past sixteen years, the international academia has paid more and more attention to the correlation effect between haze and economic growth, and the literature in this field is increasing. According to the four stages of the logical growth curve of the literature, we can see that it is now in the T_1-T_2 period (rapid development stage), which has abundant research results, and the growth rate of the literature volume remains relatively high. (2) At the international level, a group of high-yielding authors headed by Huang Guohe of North China Electric Power

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_059075

University, has been formed in this field, and the cooperation between these high-yielding authors is closer in the last five years and is in the stage of deepening cooperation. But the other authors lack communication and are in a state of isolation. (3) The main research forces in the field are concentrated in the international top universities and scientific research institutes. "The USA-China" and "Holland-France-Italy-Spain" are the main cooperation bodies in recent years. (4) Literature with great value in this field in the world is mainly concentrated on "Science", "Environmental Health Perspectives" and "Environmental Science & Technology". The related papers in these journals represent the hot and frontier research in this field, and have high academic value. (5) The research topics in this field mainly include the economic mechanism of haze formation, the relationship between haze and economic growth, the spatial spillover effect of haze and the countermeasures for haze control. (6) Keywords such as "air pollution", "health", "economic growth" and "energy" have been released in the early stage of the field. Since the 21st century, "China", "particulate matter", "city", "$PM_{2.5}$" and "CO_2 emission" have become the research hotspots.

In short, from the perspective of economic growth, the phenomenon of haze can be studied in many aspects. However, from the perspective of system theory and scientific development concept, the existing research still has the following shortcomings: (1) In terms of research content, there are many studies on the causes and countermeasures of haze, but little attention has been paid to the transmission mechanism of haze and its relationship with economic growth, especially the lack of theoretical research on this issue; (2) In terms of research methods, the normative analysis of haze and economic activities is more, but the empirical analysis of spatial statistics and econometrics is relatively lacking. Therefore, as a hot research topic in the interdisciplinary field of environment and economy, the use of spatial statistics and econometric methods to study whether haze and economic growth are related, and what kind of correlation exists is a further research direction in the future.

Abstract. Arsenic (As), Cadmium (Cd), Chromium (Cr), Copper (Cu), Lead (Pb), and Zinc (Zn) concentrations in Manila clam from Liaodong Bay (China) were determined by inductively coupled plasma mass spectrometry. Tissue-specific bioaccumulation, geographical variability (using metal pollution indices) and health risks (using target hazard quotients and maximum daily consumption values) were assessed. Cd concentrations were high at all sampling sites, particularly S6 and S7, where it reached Category III. Other metal concentrations were high at S7 (As), S1 (Cr), S5 (Pb), and S5 and S7 (Zn). As, Cr and Cu accumulated to a higher degree in the viscera than muscles, but Cd accumulated more in muscles than viscera. Heavy metal (HM) contamination was worse in the west than that in the east. The Cd target hazard quotients were greater than 1, but the other HM target hazard quotients were less than 1 at all sites, indicating Cd posed the greatest health risks to humans. The maximum daily consumption values also indicated Cd poses health risks.
Keywords: *heavy metals, clam, bioaccumulation, geographical variability, health risk estimate, Liaodong Bay*

Introduction

Liaodong Bay is one of the three main bays in the Bohai Sea. Water exchange between Liaodong Bay and the open sea is slow, so pollutants are not readily transported out of Liaodong Bay. Many rivers (e.g., the Dalinghe River, Liaohe River, and Xiaolinghe River) flow into the bay area. There are cities of different sizes around Liaodong Bay, and large parts of the coast are occupied by harbors, industrial areas and aquaculture facilities. Large amounts of domestic sewage and industrial effluent containing various pollutants are discharged into Liaodong Bay (Zhang et al., 2016; Naser, 2013; Gargouri et al., 2011; Wan et al., 2008a). These wastewaters also contain large amount of heavy metals (HMs). HM contamination is a serious issue around the world (Zhang et al., 2016; Gao and Chen, 2012; Hu et al., 2013).

HMs are persistent, stable, toxic, non-biodegradable, and bioaccumulative. HMs can accumulate in organisms and can cause many diseases (Li et al., 2015). HMs in the marine environment therefore pose health risks to aquatic organisms and humans consuming aquatic organisms. It is necessary to determine HM concentrations in aquatic media and organisms to gain an understanding of the health risks posed by contaminated seafood to humans consuming (Wei et al., 2014; Li et al., 2015).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_077088

Bivalves as benthic species can accumulate many pollutants, including HMs, to which they are very tolerant. Bivalves are therefore used as bioindicators of HM contamination in aquatic systems (Li and Gao, 2014; Won et al., 2016; Shoults-Wlison et al., 2015). The bivalve Manila clam (*Ruditapes philippinarum*, *Rud*) is generally found in sediment and tends to accumulate HMs present in the sediment (Zhao et al., 2012). *Rud* is easily collected in Liaodong Bay. *Rud* is considered to be delicious, and is consumed in large quantities. Determining the concentrations of HMs in *Rud* in Liaodong Bay will allow HM pollution of the aquatic environment and health risks posed to humans consuming contaminated seafood to be assessed (Liang et al., 2004).

In previous studies of HM in the Bohai Sea, most sampling sites were located along the Bohai Bay coast (Li et al., 2015; Zhang et al., 2016; Wang et al., 2005) and in Laizhou Bay (Liu et al., 2017). Few sampling sites in Liaodong Bay were used. In this study, we determined the concentrations of Arsenic (As), Cadmium (Cd), Chromium (Cr), Copper (Cu), Lead (Pb), and Zinc (Zn) in muscles and viscera from *Rud* collected from seven sites along the Liaodong Bay coast. The main objectives were 1) to determine HM concentrations in *Rud* from the different sampling sites, 2) to assess tissue-specific HM bioaccumulation by *Rud* 3) to assess geographical variability in HM concentrations in *Rud* using metal pollution indices (MPIs), and 4) to assess the risks posed by HMs in *Rud* to human health using national and international guidelines, target hazard quotients (THQs), and maximum daily consumption rates (CR_{max}s).

Materials and methods

Samples were collected from seven sites along the coastal area of Liaodong Bay (China) in July and August 2017, which is the main fishing season (*Fig. 1*). Attached mud and debris was removed from the surface of each shell. The *Rud* weights and shell lengths were measured. Muscle and viscera tissue samples were collected. Muscle tissue from three individuals were combined and homogenized to form a single sample. Viscera from 15 individuals were combined and homogenized to form a single sample to provide sufficient analytes for analysis (Liu et al., 2017). Six mixed muscle samples and six viscera samples from each sampling site were analyzed. The samples were lyophilized and ground into powder. The samples were analyzed using a previously described method (Li et al., 2015). Briefly, 0.2 g of a dry sample was placed in a polytetrafluoroethylene tube containing 3 mL HNO_3 (65%) (Suprapur; Merck, Damstadt, Germany) and 1 mL H_2O_2 (35%) (Suprapur; Merck). The tube was then placed in a Mars-5 microwave digestion instrument (CEM, Buckingham, UK) to digest the mixture. The digest was then diluted to 50 mL with ultrapure water and passed through a 0.45 μm membrane filter. The HM concentrations in the digest were determined using an Agilent 7500i inductively coupled plasma mass spectrometer (Agilent Technologies, Santa Clara, CA, USA). A standard reference material (GBW08571, mussel tissue) was analyzed to ensure the HM analysis method gave acceptable results. The mean recovery rates of the metals that were analyzed in the reference material samples were 82–112%.

The MPI was calculated for each sampling site to allow geographical variability in the HM concentrations in the Rud tissues to be assessed (Liu et al., 2017). The MPI was calculated using *Equation 1:*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_077088

$$MPI = \left(Cf_1 \times Cf_2 \times \cdots \times Cf_n\right)^{\frac{1}{n}} \quad \text{(Eq.1)}$$

where Cf1 is the concentration of the first HM in muscle tissue (in this study) from the sampling site of interest, Cf2 is the concentration of the second HM, Cfn is the concentration of the nth HM, and n is the total number of HMs analyzed.

The risks posed by HMs in *Rud* to human health were assessed using THQs and CR_{max}s (US EPA, 2000; Li et al., 2015). The THQs and CR_{max}s were calculated from the HM concentrations in the muscle samples using *Equations 2* and *3:*

$$THQ = \frac{C \times W_{clam} \times ED \times EF}{BW \times RfD \times Atn} \times 10^{-3} \quad \text{(Eq.2)}$$

and

$$CR_{max} = \frac{RfD \times BW}{C} \quad \text{(Eq.3)}$$

where C is the mean concentration of a HM in *Rud* muscle (in mg/kg wet weight (ww)), W_{clam} is the daily *Rud* ingestion rate for an adult (38.9 g/d) (National Bureau of Statistics of China, 2009), ED is the exposure duration (74.8 y, the expected average lifetime) (MEP, 2013), EF is the exposure frequency (365 d/y), BW is the average body weight (63 kg for an adult) (National Physique Monitoring Center of China, 2012), RfD is the average oral reference dose for the HM of interest (US EPA, 2014), Atn is the average exposure time for a non-carcinogen (ED × 365 d/y), and 10^{-3} is the unit conversion factor.

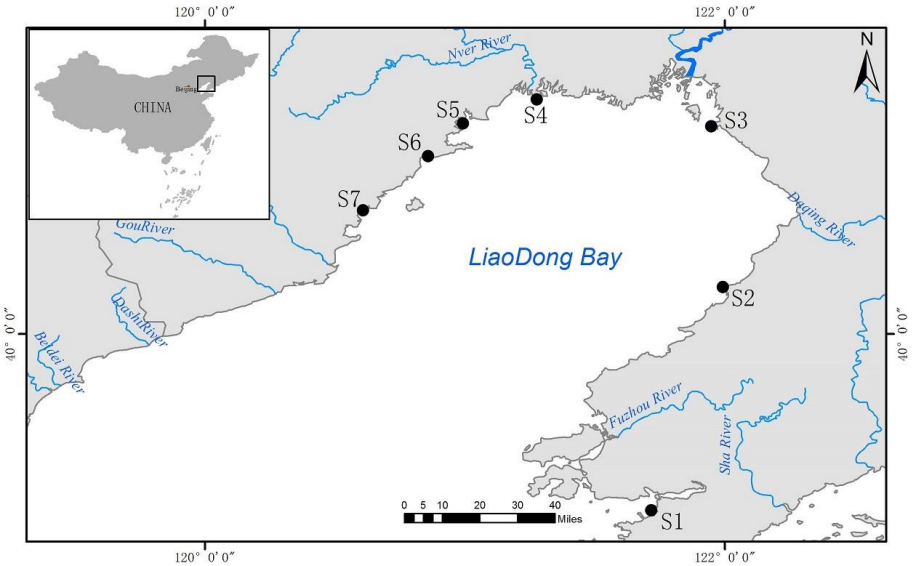

Figure 1. *Map of sampling sites at the Liaodong Bay, China. Data analyses were performed using SPSS 18.0 software (IBM, Armonk, NY, USA). Each result is expressed as the mean ± standard deviation. ANOVA, SNK, and post hoc multiple comparisons, etc. were used to detect differences between groups. Differences between results for groups of samples were considered to be statistically significant at $P < 0.05$.

Results

Heavy metal concentrations in Rud

The HM concentrations found in the *Rud* muscle and viscera samples from each sampling site are shown in *Figure 2*. The Cd concentrations were quite high in the samples from all of the sites, particularly S6 and S7, the samples from which had Cd concentrations much higher than the Category III standard for Cd. The Cd concentrations in the samples from sites S1, S3, and S4 exceeded the Category II standard. The maximum permissible level for Cd, set by the World Health Organization in 1982, is 2 mg/kg ww, which is equivalent to the Category II standard. This indicated that attention needs to be paid to Cd pollution in Liaodong Bay. The As concentrations were higher in the samples from site S7 than in the samples from the other sites. The As concentration in the viscera samples from site S7 exceeded the Category II standard for As. The Cr concentrations were higher in the samples from site S1 than in the samples from the other sites but lower than the Category II standard for Cr. The Cu concentrations in all of the samples were low and were lower than the Category I standard for Cu. The Pb concentrations were higher in the samples from site S5 than in the samples from the other sites but were lower than the Category II standard for Pb. The Pb concentrations in the samples from the other sites were lower. The Zn concentrations in the samples from sites S5 and S7 exceeded the Category II standard.

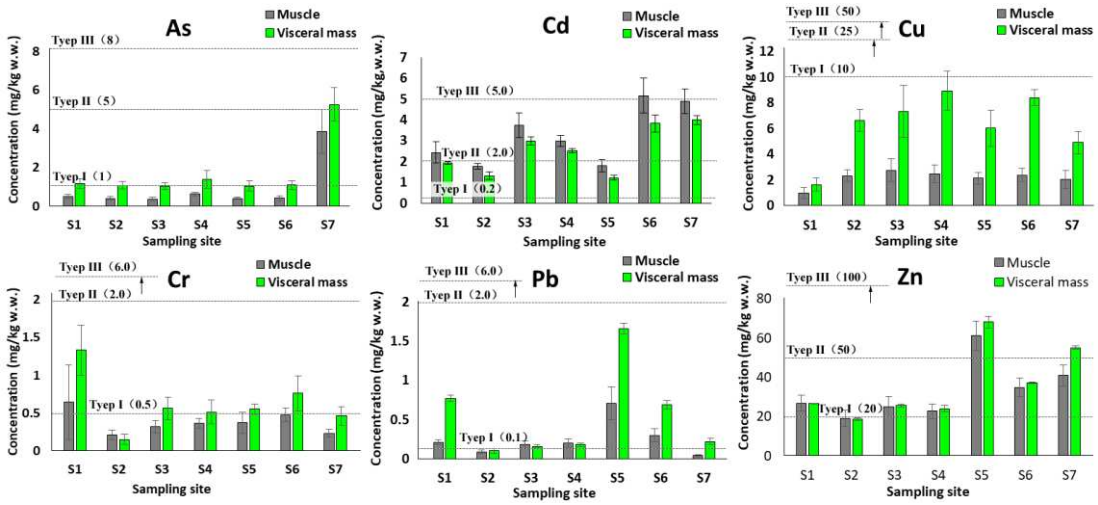

Figure 2. *Concentration ranges of heavy metals in different tissues at different sampling sites*

According to the standard (*Table 1*; *Fig. 2*), the concentrations of Cd, Pb and Zn in *Rud* have exceeded the allowable limits. Moreover, compared with previous studies (*Table 1*), the concentration of Cd was the highest and the others were present at a moderate level in the Liaodong Bay.

Tissue-specific bioaccumulation of HMs in Rud

The results of one-way analyses of variance in the HM concentrations in the muscle and viscera samples are summarized in *Table 2*. The concentrations in the muscle and viscera samples were significantly different for As, Cd, Cr, and Cu ($p < 0.05$) but not for Zn and Pb ($p > 0.05$). Different tissue-specific bioaccumulation patterns were found for different metals (*Fig. 3*). The Cd concentrations were significantly higher in the muscle samples than the viscera samples ($p < 0.05$). The As, Cr, and Cu concentrations were significantly higher in the viscera samples than the muscle samples ($p < 0.05$).

Table 2. *One-way ANOVA results running on the heavy metal concentrations (mg/kg wet wt) in the muscles and visceral masses of Rud from Liaodong Bay*

HM	Cd	Cr	As	Cu	Zn	Pb
F	4.29	10.93	4.59	65.76	0.73	9.40

n.s.: no statistical difference

Geographical variability in the HM concentrations in Rud

HM concentrations in samples from different areas

Comparison of the HM concentrations (mg/kg dry wt) in the muscles of *Rud* in different sampling regions of Liaodong Bay are summarized in *Figure 4*. The west coast is S4–S7, and the east coast is S1-S3. The As, Cd, and Pb concentrations were significantly higher along the west coast than along the east coast ($p < 0.05$). The Cr, Cu, and Zn concentrations along the east and west coasts were not significantly different ($p > 0.05$).

DOI: http://dx.doi.org/10.15666/aeer/1801_077088

Rud MPIs in different areas

MIPs were calculated according to *Equation 1*. The MPIs for the different sampling sites are summarized in *Table 3*. The MPIs for the sampling sites decreased in the order S4 > S5 > S6 > S7 > S3 > S1 > S2. The MPIs were higher for the west coast (sites S4–S7) than the east coast (sites S1–S3). These results indicated that HM contamination is more serious along the west coast than the east coast.

Health risks posed to humans by HMs in Rud

The HM concentrations in the muscle tissues and national and international guidelines for the HMs are summarized in *Table 4*. The Cd concentrations in the muscle tissue samples from sites S1, S3, S4, S6, and S7 (2.45–5.18 mg/kg ww) exceeded the relevant limits for Cd (1–2 mg/kg ww). The As concentrations in the samples from sites S4 and S7 (0.6 and 3.84 mg/kg ww, respectively) exceeded the Chinese national guideline of 0.5 mg/kg ww. The Cr, Cu, Pb, and Zn concentrations (0.21–0.64, 0.98–2.76, 0.04–0.71, and 18.94–60.97 mg/kg ww, respectively) were within the relevant limits (2, 50, 1.0–1.5, and 100 mg/kg ww, respectively).

The potential health risks posed by HMs in *Rud* to humans were estimated by calculating THQs and CR_{max}s according to *Equations 2* and *3*. The results are summarized in *Tables 5* and *6*. Inorganic As is more toxic than organic As, and the calculations were performed assuming that inorganic As contributed 3% of the total As concentrations (Li et al., 2015).

Table 6. *Estimated maximum consumption rates (CR_{max}) for Rud*

HMs	CR_{max} (g w.w.)						
	S1	S2	S3	S4	S5	S6	S7
Cd	12.86	17.70	8.42	10.50	17.31	6.08	6.42
Cr	295.31	900.00	590.63	525.00	510.81	402.13	821.74
As	1285.71	1615.38	1800.00	1032.79	1657.89	1575.00	164.06
Cu	2571.43	1081.55	913.04	1028.57	1183.10	1058.82	1235.29
Zn	706.54	997.89	759.95	834.07	309.99	543.26	463.35
Pb	3000.00	7000.00	3500.00	3150.00	887.32	2100.00	15750.00

A THQ ≤ 1 was taken to indicate no risks were posed to humans, and a THQ > 1 was taken to mean risks were posed to humans (Li et al., 2015). The Cd THQs (2.189–6.397) were higher than the other metal THQs for all the sampling sites. The concentrations of the HMs other than Cd in *Rud* from all of the sampling sites were found not to pose significant risks to humans (THQ < 1).

HMs can accumulate in *Rud*. Consuming certain amounts of contaminated *Rud* could therefore cause adverse health effects. CR_{max}s for theHMs in *Rud* were therefore calculated. The Pb CR_{max}s were relatively high, at 887.32–15750.00 g ww). The Cd CR_{max}s (6.08–17.70 g ww) were lower than the CR_{max}s for the other HMs, meaning the probability of health risks being posed to humans consuming *Rud* from Liaodong Bay was higher for Cd than the other HMs.

Discussion

HMs in Rud

Liaodong Bay is the largest bay in the Bohai Sea. A complete water exchange cycle in Liaodong Bay takes 15 y (Wan et al., 2008a). Many rivers (including the Cishanhe River, Dalinghe River, Liaohe River, Shuangtaizihe River, Xiaolinghe River, and Wulihe River) discharge into Liaodong Bay. These rivers are thought to be important sources of HMs to Liaodong Bay (Wan et al., 2008b). The Cd concentrations in the samples from all of the sampling sites were quite high, and the concentration in the muscle samples from site S6 exceeded the Category III standard for Cd. This indicated that attention needs to be paid to Cd pollution in Liaodong Bay. The Cr and Pb concentrations were higher in the samples from sites S1 and S5, respectively, than in the samples from the other sites but lower than the Category II standards. The As concentrations in the viscera samples from site S7 exceeded the Category II standard for As, and the Zn concentrations in the viscera samples from sites S5 and S7 exceeded the Category II standards. These results indicated that the sites mentioned may be contaminated with these HMs. The Pb concentrations were not high. Pb and its salts can cause kidney damage and negatively affect the nervous system. Even low Pb concentrations in food cannot be ignored (Gao et al., 2014).

Compared with other domestic and international bays, Liaodong Bay has higher Cd concentration in shellfish (Lei et al., 2013; Li et al., 2015; Liu et al., 2017; Gu et al., 2016; Copat et al., 2013; Jovic and Stankovic, 2014; Alfonso et al., 2013). Cd pollution is worthy of attention.

Tissue-specific differences in HM concentrations

In clams, HMs tend to accumulate more efficiently in viscera than muscles (Husmann et al., 2012; Sarkar et al., 2008; Liu et al., 2017). Viscera play important roles in metabolic processes related to HMs. The hepatopancreas and kidney play important roles in HM absorption, transport, storage, and excretion. HMs in muscle tissue can be removed relatively quickly. In this study, As, Cr, and Cu had similar tissue-specific accumulation characteristics. The concentrations of these HMs were higher in the viscera than the muscles. In contrast, the Cd concentrations were higher in the muscles than the viscera. Similar results have been found in previous studies (Liu et al., 2017; Tarque et al., 2012). Insufficient data were available to explain this. In aquatic environments, Cd is mainly in the dissolved phase. Cd may easily be absorbed by tissues it comes into contact with (e.g., the mantle) in *Rud*. Large amounts of Cd may therefore accumulate in the mantle (Liu et al., 2017). This could explain the Cd concentrations being higher in the muscle samples than the viscera samples. Zn is an essential element that is absorbed and eliminated through various physiological processes in different tissues. Excess Zn may accumulate in the mantle of a clam. These factors may affect Zn accumulation in the muscles and viscera and explain the Zn concentrations in the muscle and viscera samples not being different.

Geographical differences in HM concentrations

HM contamination of *Rud* was more severe in the west of Liaodong Bay (at sites S4–S7) than in the east (sites S1–S3). Geographical variations in HM concentrations in clams are generally considered to be related to the distributions and characteristics of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_077088

local sources of pollutants. The sampling sites along the west coast of Liaodong Bay were in Jinzhou Bay, a small cove in the northwestern part of Liaodong Bay. Jinzhou Bay has been contaminated by industrial effluent from chlor-alkali plants, petrochemical plants, the Huludao zinc plant, and the Bohai shipyard (Gao et al., 2014). Water in Liaodong Bay and the open sea is exchanged quite weakly, so HMs are not quickly transported from Liaodong Bay into the open sea. HMs released into Liaodong Bay can therefore accumulate in aquatic environmental media (e.g., sediment and clams).

Assessment of the risks posed by HMs in Rud to humans

The Cd concentrations in the muscle samples from sites S1, S3, S4, S6, and S7 exceeded the relevant limit. In particular, the Cd concentrations in the samples from site S6 exceeded the limit by a factor of ~2.5. The Cd THQs for all of the sampling sites were > 1 and were higher than the THQs for the other metals. The Cd CR_{max}s (6.08–17.70 g ww) were lower than the CR_{max}s for the other HMs that were analyzed. These results indicated that Cd would pose health risks to humans consuming *Rud* from the study area.

Industrial and other human activities are the main causes of Cd entering the environment. Cd can effectively accumulate in clams. Cd is very toxic to humans and can seriously affect the structures and functions of the bones, central nervous system (including the brain), kidneys, lungs, liver, and placenta. The *Rud* in the study area were heavily contaminated with Cd. Humans living around Liaodong Bay and consuming local *Rud* for a long period may be exposed to risks posed by Cd.

Rud was the only source of HMs to humans considered in the risk assessments performed in this study. Other sources include other types of seafood, rice, vegetables, and water, but these were not included in the risk assessments. The health risks found to be posed by HMs to humans in the risk assessments would have been stronger if all possible sources of HMs were considered.

Conclusions

The Cd concentrations were quite high in the samples from Liaodong Bay. The Cd concentrations in the samples from sites S6 and S7 were in the Category III standard for Cd. The concentrations of Cr in the samples from site S1, As in the samples from site S7, Pb in the samples from site S5, and Zn in the samples from sites S5 and S7 were also quite high. The *Rud* samples had typical tissue-specific heavy metal bioaccumulation patterns. Cd tended to accumulate more efficiently in muscle than viscera, whereas As, Cr and Cu tended to accumulate more efficiently in viscera than muscles. Pb and Zn were not significantly different in the muscle and viscera samples. Heavy metal contamination of *Rud* tended to be worse in the west than the east of Liaodong Bay. The heavy metal THQs and CR_{max}s for the muscle samples and national and international guidelines indicated that Cd was the main source of health risks to humans through consuming *Rud* from Liaodong Bay.

In summary, Cd was found to have an impact on the local environment and human health. Effective measures should be taken to control Cd pollution. Distribution characteristics and the bioaccumulation of HMs in seawater, surface sediments and other marine organisms will be studied in the future in order to take effective measures to control the pollution of HMs.

Abstract. Cotton seed germination and seedling development is severely restricted, when the seed is exposed to low temperature stress. It is urgently needed to explore cotton seed germination characteristics and the mechanism involved in low temperature stress tolerance. Different cotton genotypes (Upland cotton Xinluzao65 and Island cotton Xinhai35), and three temperatures levels i.e. 12-15 °C, 18-21 °C and 25-28 °C (CK) were studied to explore germination characteristics, antioxidant enzymes activities and osmotic adjustment substances responses. The results show that with the decline of temperature, germination characteristics, cold resistance index and that water absorption of cotton seeds significantly decreased at ($P < 0.05$), and XH35 shows stronger resistance to cold. The activities of antioxidant enzymes and osmotic adjustment substances of cotton seeds were substantially increased under low temperature. Superoxide dismutase (SOD), peroxidase (POD), catalase (CAT) activities, soluble protein (SP), soluble sugar (SS) and free proline (FP) contents of XH35 were increased by 31.06%, 17.03%, 12.33%, 23.80%, 9.63%, and 5.36%, respectively than those of XLZ65. The principal component analysis revealed that SS and FP are the main drivers, hindering cotton seeds germination. Therefore, Island cotton shows a higher cold resistance by increasing water absorption rate, antioxidant enzyme activities and osmotic adjustment.
Keywords: *seed germination characteristics, water absorption rate, correlation analysis, principle component analysis*

Introduction

Cotton (*Gossypium hirsutum* L.) is the world's leading crop as it provides fiber and oil. Even though it has been introduced to temperate zones at high latitudes, it still shows sensitivity to low temperature stress (Barrero-Gil and Salinas, 2013). Xinjiang is rich in light and heat and is one of the major cotton planting areas in China, accounting for 19.77% of global cotton production (Chen et al., 2017). According to the meteorological data in the past years, damages caused by low temperature (7.72~10.52 °C) in the cotton seeding time (April-May) in Xinjiang occur frequently, and the area reseeded, destroyed and replanted each year accounts for 5 to12% of the total cotton planting area (Wu et al., 2012). The low temperature has become one of the main factors affecting the efficient production of cotton (Khan et al., 2017; Wang et al., 2016a). Therefore, it has become one of the most important problems for sustainable

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_089105

cotton production and cotton breeding program. It is essential to identify physiological responses of cotton seeds and the mechanism involved in low temperature tolerance.

The optimal growth temperature for cotton is 20~30 °C, however, when the daily temperature average is lower than 15 °C, the growth of cotton will be inhibited (Barrero-Gil and Salinas, 2013b; Ashraf, 2002), especially during the germination and seedling phases (Chen, 2003). Lauterbach (1999) concludes that the minimum temperature for germination of cotton seeds is 10.5~12 °C. Wang et al. (2016b) can effectively identify cotton cold resistance in its cotyledon stage according to the fact that the cotton can grow as normal when it undergoes low temperature treatment of 4 °C in its cotyledon stage. The response of cotton of different genotypes also differs largely in the seedling phases. Seedlings of high-cold-resistant cotton have more sensitive and efficient active oxygen scavenging capacity and osmotic adjustment response mechanism in low temperature. At the same time, the resistance to low temperature of cotton seedlings is enhanced by maintaining a high photosynthetic rate (Wu et al., 2014). Yan et al. (2016) used 17 cotton varieties in three major (Yangtze River, Yellow River and Northwest Inland) cotton growing areas as experimental materials, and it was found that low temperature stress could significantly weaken the correlation between seed vigor and physical characteristics. Therefore, it is important to know the physiological mechanism for responding to low temperature of cotton seeds of different cold-tolerant genotypes in terms of germination, which plays a pivotal role in working out cold-resistant cultivation measures and breeding cold-tolerant varieties.

Island cotton (*Gossypium barbadense*) has better comprehensive tolerance and excellent fiber properties, and is an important raw material for top-grade and special cotton textiles (Liu et al., 2015). Xinjiang is the only growing area for Island cotton in China due to its suitable light and heat conditions. The perennial planting area is 100,000 hm^2, and its total output accounts for about a quarter of the world's ELS (including Egyptian long-staple cotton with its velvet length $\leq$ 35mm) (Tian et al., 2014). At present, the research on cold tolerance of Island cotton in low temperature mainly focuses on seedling stage, flowering and boll stage (Sawan et al., 2011; Yan et al., 2019), and fiber quality (Mei et al., 2012; Avci et al., 2013). However, it has not been systematically studied to transform ingredients and physiological regulation mechanism in the germination of cotton seeds, especially the physiological mechanism for responding to low temperature of cotton seeds of different cold-tolerant genotypes (Island cotton and Upland cotton) in terms of germination.

Therefore, the objectives of this experiment are (i) to study the germination index of different genotypes (Island cotton and Upland cotton) under low temperature stress, (ii) to analyze the antioxidant enzyme activity, osmotic adjustment substance content and membrane lipid peroxidation products dynamic changes and intrinsic relationship under low temperature stress, and (iii) to clarify the intrinsic relationship between the germination characteristics, physiological indexes of cotton seeds and the cold tolerance of cotton varieties; it is expected to provide a theoretical basis for studying the cold resistance mechanism of cotton and the breeding of low temperature resistant cotton varieties.

Materials and methods

Plant materials

Cotton varieties of different genotypes: Xinluzao65 (Upland Cotton) and Xinhai35 (Island Cotton) were used. These materials were obtained from Cotton Institute of

Xinjiang (45°22′43.4″N, 84°50′32.5″E) Academy of Agricultural Sciences. The experiment was carried out in the artificial climate chamber (GXZ-208B, Ningbo Jiangnan Instrument Factory, China) of Shihezi University. The biological characteristics of cotton seeds of different genotypes are shown in *Table 1*. The content of protein, adipose, and starch in Xinhai35 (XH35, *Table 2*) is respectively 19.02%, 50.85% and 4.83% higher than those of Xinluzao65 (XLZ65), grain weight and seed vigor of XH35 are 20.02%, 6% higher than those of XLZ65, respectively, but water content of XH35 is 56.2% lower than that of XLZ65. Preliminary experiments showed that different genotypes of cotton had different germination effects under low temperature stress (*Fig. 1*).

Experimental design

Three temperature levels i.e. 12-15 °C, 18-21 °C and 25-28 °C (*Table 2*) were targeted. During the test, the environment of cotton seed germination under field conditions was simulated in the artificial climate chamber (GXZ-208B, Ningbo Manufacturing Factory, Zhejiang, China), where the relative humidity was 50%, the light/dark ratio was 14 h/10 h and the light intensity was 283 μmol m^{-2} s^{-1}. Cotton seeds with full grain, intact embryo, no mildew and of same size were selected for the experiment. Seeds were sterilized in 200 ml of 1% potassium permanganate for 3 to 5 min, and then rinsed with deionized water for 3 to 4 times. After that, seeds were placed neatly in Petri dishes (φ = 15 cm) with 2 layers of filter paper (GB/T1914-93, Hangzhou Xinhua Paper Ltd., China), 50 seeds in each dish. The sterile distilled water was added until saturation. The dishes were placed in climatic chambers at 15/12 °C, 21/18 °C and 28/25 °C, respectively, to test germination. Each treatment was repeated 5 times, and every 24 h 5~10 ml distilled water was added.

Test items and methods

Determination of germination index

It is taken as germination when germ is longer than 1/2 of the cotton seed. The number of germinated seeds was counted daily from the first day. The following parameters were determined: Germination rate (%) = (number of all germinated seeds during the germination test / number of cotton seeds tested) ×100%; Germination potential (%) = (number of normally germinated seeds within 96 h / number of cotton seeds tested)×100%; Germination index (GI) = ∑Gt/Dt, Mean time of germination (MTG) = ∑(GtDt)/∑Gt, while Gt refers to the germination rate at t and Dt refers to germination days; Water absorption rate (%) = (wet weight-dry weight)/dry weight×100%; Germination index = 1.00×n3 + 0.75×n5 + 0.5×n7 + 0.25×n9 (n3, n5, n7, n9 represent the seed germination rate on the 3rd, 5th, 7th and 9th day respectively); Seed germination cold resistance index = germination index in low temperature/control germination index.

Measurement of physiological index of germination

The sampling time was determined according to the water uptake rate of cotton seeds. At the temperature of 25~28 °C, seeds were sampled at: 2 h, 4 h, 6 h, 12 h (0.5 d), 24 h (1 d), 48 h (2 d); at the temperature of 18~21 °C, seeds were sampled at: 2 h, 4 h, 6 h, 12 h (0.5 d), 24 h (1 d), 48 h (2 d), 72 h (3 d), 96 h (4 d); at the temperature of 12~15 °C, seeds were sampled at: 2 h, 4 h, 6 h, 12 h (0.5 d), 24 h (1 d), 48 h (2 d), 72 h (3 d), 96 h (4 d), 120 h (5 d). About 50 cotton seeds weighing 4~6 g were taken and frozen with liquid nitrogen directly at -80 °C. With the seed coats removed, enzymes were extracted to test activity; the samples were put in 10 ml container and then ground using a freezing grinder for 45 s, and they were used to measure the content of soluble sugar (SS), soluble protein (SP), free proline (FP), malondialdehyde (MDA) and hydrogen peroxide (H_2O_2), as well as the activities of superoxide dismutase (SOD), peroxidase (POD) and catalase (CAT).

Antioxidant enzymes (SOD, POD, and CAT) activities in seed

The activities of enzymatic antioxidants viz., SOD, POD, and CAT in seed were assessed according to the standard procedure (Kochba et al., 1977; Kraus and Fletcher, 1994). The SOD activity was the amount of extract that gave 50% inhibition in nitrotetrazolium blue chloride (NBT) photoreduction detected at 560 nm (Q/YXLZ82, Shanghai Precision Science Instrument Co., Ltd. China). The POD activity was based on the determination of guaiacol oxidation at 470 nm by H_2O_2 and was presented as μmol H_2O_2 g^{-1} (FW). The change in absorbance at 470 nm was recorded every min by a spectrophotometer. One unit of POD activity is the amount of enzyme that causes the decomposition of 1 μg substrate at 470 nm for 1 min in 1 g fresh sample at 37 °C. The

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_089105

CAT activity was measured using the 0.5 g fresh seed sample. The CAT activity was defined as the amount of enzyme that causes the decomposition of 1 μmol H_2O_2 at 405 nm per min in 1 g fresh sample at 37 °C.

Osmotic adjustment substance (SS, SP, and FP) contents in seed

0.5 g seed germ powder was put in a 10 ml centrifuge tube, 5 ml 80% ethanol solution was added to it, and then it was kept in a water bath at 80 °C for 30 min, then cooled to room temperature and centrifuged at 4000 rpm for 10 min, and then 2 ml of supernatant was taken and mixed well with anthrone-sulfuric reagent. The mixture was heated in a boiling water bath at 100 °C for 10 min, and the absorbance was measured at 620 nm after cooling it to room temperature. SP was extracted by adding homogenized 0.5 g of seed germ powder in a 10 ml centrifuge tube. The homogenate was centrifuged at 5000 rpm for 10 min, and then 0.1 ml of the supernatant was thoroughly mixed with 0.9 ml of distilled water and 5 ml of Coomassie brilliant blue G-250 reagent; after 2 min, the absorbance was measured at 595 nm. Free proline content of cotton seed was assayed by the method (Bates et al., 1973). The samples were homogenized in 5 mL of 3% sulfosalicylic acid and centrifuged at 6000 rpm for 10 min. Supernatant was heated with 2 mL of ninhydrin and glacial acetic acid at 100 °C for 1 h. The reaction was further extracted with 4 ml of toluene by vigorous vortexing for 30 s. The absorption of the chromophore was determined at 520 nm (Tecan-infinite M200, Switzerland).

Lipid peroxidation (MDA and H_2O_2)

Lipid peroxidation in cotton seed was determined as MDA content using the thiobarbituric acid method (Bailly et al., 1996). A 1.0 ml aliquot of supernatant of tissue extract (seed) was mixed with 4 ml of 20% (v/v) trichloroacetic acid containing 0.5% (v/v) thiobarbituric acid. The mixture was heated at 100 °C for 30 min, and was cooled down and centrifuged at 10,000 rpm for 10 min. The absorbance of the supernatant was assayed at 532 and 600 nm. H_2O_2 content was determined according to Nakano and Asada (1987). H_2O_2 was extracted by homogenizing 0.5 g seed embryo powder in 3 ml cold acetone. The homogenate was centrifuged at 3000 rpm for 10 min, with the supernatant mixed with 0.1 mL 5% (w/v) $TiSO_4$ and 0.2 mL ammonia water. After centrifuging the solution at 10,000 rpm for 5 min, the precipitate was washed with acetone till the supernatant was colorless. The precipitate was solubilized in 3 ml 1 M H_2SO_4, with the absorbance measured at 415 nm. H_2O_2 content was expressed as mmol g^{-1} FW.

Data analysis

Data were processed and mapped by Microsoft Excel 2010, R Studio, Origin and SigmaPlot 12.5. Single factor analysis of variance and correlation analysis were performed by SPSS 18.0. Significant difference examination was carried out using Duncan test at ($\alpha = 0.05$).

Results

Effect of low temperature on germination index of cotton seeds

The relative germination rate, relative germination potential, relative sprouting index, germination index and water absorption rate of the two cotton varieties decreased with

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_089105

the decline of temperature (*Table 3* and *4*). The average germination time shows an increasing trend under low temperature treatment, with obvious differences exiting in all control groups ($P < 0.05$). The germination rate, germination potential and germination index of XH35 are respectively 30.70%, 12.22% and 16.22% higher than those of XLZ65, and the water absorption rate of XH35 was significantly higher than that of XLZ65 ($P < 0.05$), which indicates that the water absorption rate is closely related to the germination of cotton seeds.

According to the results of variance analysis, cotton seed germination indices at different temperatures show great variations. The germination rate, germination index, cold resistance index and water absorption rate of different varieties show significant differences. Germination index, the interactions between temperatures and variations are significantly different ($P < 0.05$), but there is no significant difference between the varieties. With the decrease of temperature, the germination cold resistance indices of the two cotton varieties significantly decreased, and show significant differences in temperatures and variations and their interactions. This indicates that cotton seeds of different genotypes show different cold resistance abilities.

Effect of low temperature on protective enzyme activities in cotton seeds in process of imbibition

The activity of SOD in the cotton seed embryos of XH35 is 10.00% higher than those of XLZ65. With the decrease of temperature, the activities of SOD enzyme under low temperature are higher than those of control groups at normal temperature (*Fig. 2*). The activity of SOD in XLZ65 embryos decreased with the time of low temperature and stress intensity. However, after 4 h of stress treatment, the activity of SOD of L12 and L18 are respectively 22.83% and 10.92% higher than that of L25 (*Fig. 2A*). The SOD activity of XH35 reaches a peak after 4 h of stress treatment (rapid water absorption phase), and increases respectively by 13.00%, 9.44% and 3.10% at different temperatures, especially after 24 h of imbibition, the enzyme activities of H25, H18, H12 increase respectively by 18.66%, 27.19% and 29.10%, compared with those after 12 h of imbibitions (*Fig. 2B*).

Before imbibition, POD activity of XH35 (dry seeds) was 35.16% lower than that of XLZ65 (*Fig. 2*). Over imbibition time, the POD enzyme activity of XLZ65 treated by low temperature treatment was higher than that of control groups. After 12 h of imbibition, POD activity of L12 and L18 was 39.23% and 9.11% higher, respectively, than of L25 (*Fig. 2C*). The POD enzyme activity of XH35 increases starting from the initial imbibition phase. After 4 h of imbibition, the increase of POD enzyme activities of H12 and H18 are significantly different from that of H25, and 20.28% and 20.27% higher, respectively, than that of control groups. After 12 h of imbibition, no significant differences were observed among variations (*Fig. 2D*).

CAT activity was increased under low temperature during germination of cotton seeds, and the CAT activities between varieties showed significant differences (*Fig. 2*). After 2 h of stress treatment, the CAT activity of L12 increased, while that of L18 and L25 first decreased and then decreased. After 24 h of stress treatment (slow water absorption phase), the CAT activity of L12 and L18 was 26.83% and 33.98% higher than that of L25, which shows a significant difference (*Fig. 2E*). The CAT activity of XH35 greatly decreased at the initial stage of imbibition, and the decrease of that of H25, H18 and H12 were 47.23%, 46.59% and 37.64%, respectively. After 24 h of imbibition, the CAT activity of H12 and H18 peaked 34.84% and 22.80% higher respectively than H25 (*Fig. 2F*).

Effect of low temperature on osmotic adjustment substances in cotton imbibition process

The content of soluble sugar (SS) decreased with imbibition, but the differences between the varieties were obvious at 4 h (*Fig. 3*). The content of SS increased in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_089105

XLZ65 at 4 h under low temperature (*Fig. 3A*). The SS content of the XH35 decreased with the decline of temperature, that of H12, H18 and H25 increased at 6 h, 24 h and 4 h, respectively. Whilst a rapid reduction was observed in H25 after 12 h of imbibition (*Fig. 3B*).

Under low temperature treatment, soluble protein (SP) content in XH35 seed embryos was 19.04% higher than that in XLZ65's (*Fig. 3*). After imbibition for 2 to 4 h, the content of SP decreases rapidly, and L12 was 22.68% higher than that of L25. However, no significant differences were noted after 4 h of imbibition (*Fig. 3C*). H35 had similar trend in SPA content with no obvious differences (*Fig. 3D*).

The content of free proline (FP) shows significant differences between varieties; under low temperature FP content increased (*Fig. 3*). After 6 h of imbibition, the content of FP in H12 and H18 increased respectively by 40.31% and 31.97%, compared with that of H25 (*Fig. 3F*). The FP content of XLZ65 was significant, and after 6 h of imbibition, L12 and L18 resulted in the highest FP content (*Fig. 3E*).

Effect of low temperature on the contents of hazardous substances (mda, h_2o_2) in cotton imbibition

With the decrease of temperature, the MDA content increased significantly compared with control (*Fig. 4*). After 2 h of imbibition, the MDA content of L12 and L18 increased by 64.83% and 62.15% respectively, while L25 increased by 15.09% (*Fig. 4A*). With the decrease of temperature, there is no significant increase in MDA content of XH35, and after 2 h of imbibition, the MDA content in its cotton seeds decreased significantly (*Fig. 4B*). Since the beginning of imbibition, the H_2O_2 content shows a significant decrease, and with the decrease of temperature, the H_2O_2 content was higher than that of control groups at normal temperature. At the initial stage of imbibition, the H_2O_2 content of XH35 was 28.55% higher than that of XLZ65 (*Fig. 4*).

Correlation analysis on cotton seeds germination and their physiological and biochemical indices at low temperature

Correlation analysis of physiological parameters of cotton seeds germination are shown in *Fig. 5*. The activity of POD shows extremely significant and positive correlation to SOD, CAT, MDA, SP, H_2O_2, SS ($P < 0.001$), and significant and positive correlation to FP ($P < 0.05$). A significant and positive correlation between SOD and CAT, SP, H_2O_2 and SS ($P < 0.001$) was observed. CAT activity was highly positively with SP, H_2O_2 and SS ($P < 0.001$), and significantly correlated with MDA ($P < 0.05$). There is an extremely significant and positive correlation between MDA and SS ($P < 0.001$); SP extremely significantly and positively correlated with H_2O_2 and SS ($P < 0.001$); H_2O_2 had extremely significant and positive correlation with SS ($P < 0.001$).

Dry seed stage had a significant and positive correlation with SP, H_2O_2, SOD and CAT (*Table 5*), SS ($P < 0.05$), extremely and negatively correlated with POD ($P < 0.01$), and with FP ($P < 0.05$). The rapid water absorption stage was significantly positively correlated with SP ($P < 0.05$), but significantly negatively correlated with MDA and CAT ($P < 0.01$). The slow water absorption stage had a significantly positive correlation with SP and SOD ($P < 0.01$), but highly negatively correlated with CAT ($P < 0.05$) and MDA ($P < 0.01$). Germination stage was strongly positively correlated with SP, SOD, POD and CAT ($P < 0.01$), but is extremely negatively correlated with FP ($P < 0.01$).

Effect of low temperature on the variation of physiological parameters of cotton seeds germination

The principle component analysis of eight physiological parameters, i.e. SOD, POD and CAT in cotton seeds of different genotypes was conducted; the cumulative contribution rates of the first two principal components extracted are 81.49% and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_089105

80.46%, which are important in interpreting the total variation of the data set (*Fig. 6*). Principle component 1(PC1) explains the variations of 64.73% (XLZ65) and 65.59% (XH35), and can clearly distinguish different imbibition time. Principal component 2 (PC2) shows the variations of 16.76% and 14.87%, and can distinguish different low temperature treatments. In principle component 1, the weight coefficients of SP, SS and PSD of Xinluzao65 were higher than 0.400 (*Table 6*), indicating that the imbibition time has a significant effect on SOD, POD and SS of upland cotton and SP and SS of XH35. In principal component 2, the load values of MDA and FP of L65 and FP of XH35 are greater. This indicates that FP is obviously affected by temperature.

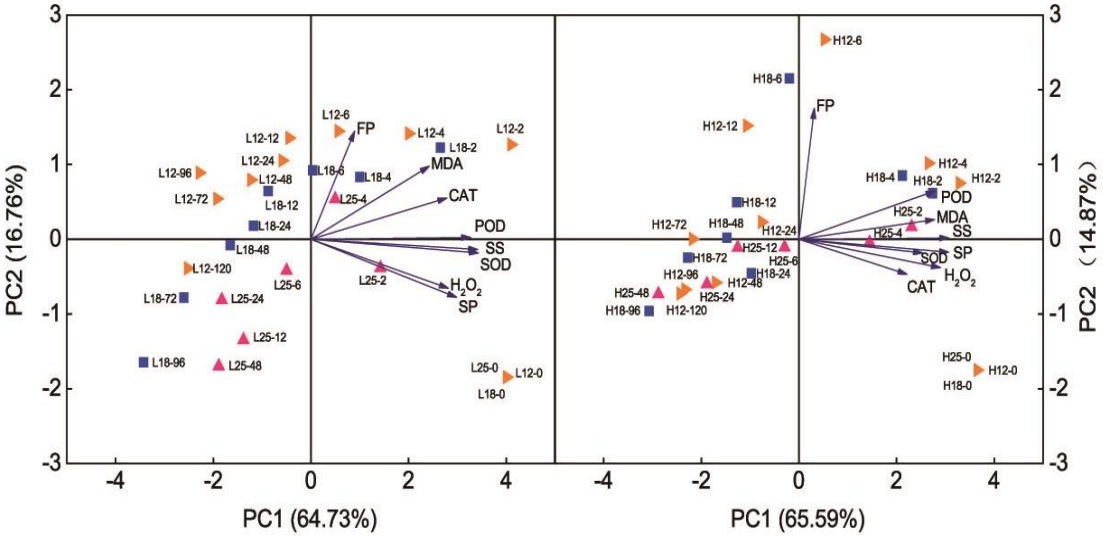

Figure 6. *Principal component analysis showing the relationship of the couple of low temperature stress and genotypic differences on cotton germination parameters. The couple of seed imbibition time and physiological and biochemical indices. L showed XLZ65, H showed XH35, 12 showed temperature 12~15 °C; 18 showed temperature 18~21 °C; 25 showed temperature 25~28 °C (CK), 0, 2, 4, 6, 12, 24, 48, 72, 96, 120 showed the cotton seed imbibition time. Soluble Sugar (SS), Soluble Protein (SP), Free Proline (FP), Malondialdehyde (MDA) and Hydrogen Peroxide (H_2O_2), superoxide dismutase (SOD), peroxidase (POD) and catalase (CAT)*

Discussion

Cotton seeds are susceptible to temperature in the early stages of germination. When the temperature is below 10 °C, cotton seeds fail to germinate (Kargiotidou et al., 2008). Yang (2015) shows that low temperature reduces the water absorption rate of wheat (*Triticum aestivum L.*) seeds, resulting in a decrease in their respiratory rate and delayed germination. This study shows that with the decrease of temperature, the water absorption rate, sprouting rate and germination index of cotton seeds of different genotypes shows a downward tendency. This indicates that low temperature influences the water absorption rate of seeds leading to reduced water intake and interferes with metabolic activities in seed embryos. As a result, germination ability of cotton seeds is decreased. Cutting watermelon (*Citrullus lanatus*) seed coat at low temperature can improve water absorption capacity, making it able to maintain high cold resistance and increase germination rate (Nerson et al., 1985). This study shows that with the decrease of temperature, water absorption, germination index and germination cold resistance index of XH35 were higher than those of XLZ65. Consequently, a high water absorption rate and capacity was the main reason for the strong cold resistance of Island cotton.

Active oxygen accumulation can cause chilling injuries in plants (Baek and Skinner, 2003; Xu et al., 2006). The antioxidant enzyme system plays an important role in the active oxygen injury caused by low temperature (Imahori et al., 2008; Ashraf, 2009). Zhang and Xie (2013) find that at low temperature, the activities of SOD, POD and CAT in cotton seedlings were significantly reduced, which inhibit the growth of cotton seedlings. In the current study, the activities of cotton seed enzymes under low temperatures were higher than those of control groups in normal temperature. It may be that low temperature inhibits the expression of enzyme activities in cotton seeds, delays the metabolism of storage materials and hinders the germination of cotton seeds. Ren et al. (2017) find that low temperature inhibits the enzymes involved in metabolism in peony (*Paeonia suffruticosa Andr.*) seeds, leading to delayed degradation of starch and other metabolites which affects glycolysis resulting in inhibition of seed germination. However, the contents of SOD and CAT in XH35 seed embryos were higher than those in XLZ65's, and after 4 h of low temperature treatment, the POD content of XH35 was higher than that in XLZ65, the water absorption capacity and rate of XH35 are higher than those of XLZ65, which accelerate the metabolism and transformation of substances at low temperature, increasing the germination rate of Island cotton.

Under stress conditions, soluble sugar, soluble protein and proline in plants can alleviate cell damage caused by low temperature and improve low temperature resistance of plants (Duncan and Widholm, 1987; Solomon et al., 1994). Chang et al. (2018) found that the contents of soluble sugar and soluble protein increased at low temperature, and the increase of proline in low temperature resistant varieties was large. This study shows that after low temperature treatment, the contents of soluble protein and soluble sugar were higher than those of control groups, which may delay the physiological metabolic reaction due to low temperature, causing the content to change more slowly than in normal temperature. This is consistent with previous studies (Liu et al., 2012). Soluble sugar, soluble protein and free proline contents of XH35 were higher than that of XLZ65, which is consistent with the results of the study by Mambetale et al. (2017). This is probably because of the adjustment capacity produced by the protection system of Upland cotton under stress conditions is lower than that of Island cotton. Therefore, the contents of soluble protein, soluble sugar and free proline in the embryo

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_089105

after low temperature treatment can be used as physiological indices of cold resistance of cotton seed germination.

Malondialdehyde (MDA) reflects to some extent the degree of damage to the cell membrane (Velikova et al., 2000). Gao et al. (2018) found that at low temperature, the MDA content of low temperature resistant varieties remained almost unchanged, and low temperature resistant varieties were increased. The data from this study shows that higher MDA content of XH35 after low temperature treatment was lower than XLZ65, indicating that Island cotton was less damaged by low temperature compared with Upland cotton due to its poor membrane stability. Ou-yang et al. (2007) reported that increase of H_2O_2 content in tomato (*Solanum lycopersicum*) peel can induce the enhancement of cold resistance of tomato. This study shows that due to the high content of H_2O_2 in XH35, the activities of antioxidant enzymes were enhanced, and the damage caused by low temperature stress were alleviated, thereby improving cotton seeds germination ability under low temperature.

Correlation analysis of physiological indicators of cotton seedlings that the improvement of antioxidant enzyme activity provides a favorable metabolic environment for maintaining the normal physiological balance of cells and the accumulation of soluble substances (Wu et al., 2013). This experiment shows that there is an extreme significant or significant relationship between osmotic adjustment substances content and antioxidant enzyme activities exist under high stress conditions. This indicates that by adjusting SS, SP contents and POD, SOD and CAT activities to reduce oxidative damage and osmotic balance is maintained and cold resistance of cotton seeds is improved. Numerous researchers use principal component analysis to determine the strength of resistance of test varieties in stress resistance studies (Dai et al., 2014; Gulhane and Kolekar, 2014; Farshadfar et al., 2013). Wu et al. (2012) convert 12 individual items of cotton seedling leaves at low temperature into 7 independent comprehensive indicators by principal component analysis, and use cluster analysis to objectively obtain the cold resistance of the tested varieties. In this study, the principal component analysis of eight individual indicators in cotton embryos at low temperature shows that the imbibition time has a great influence on the physiological indices of cotton seed germination, i.e. the main component 1 in *Figure 5* explains variations of 64.73% (XLZ65) and 65.59% (XH35). With the increase of imbibition time, low temperature decreased SOD, POD activities and FP content. This might be of the low temperature that inhibits water absorption rate and capacity of cotton seeds, slows the transformation of metabolites, and increases content of harmful substances which depress cotton germination. However, the physiological traits of cotton seeds of different genotypes were significantly different. SOD and POD activities of Island cotton increased in the first 4 h of inhibition, which reduces MDA content, thus improving the cold tolerance of Island cotton.

Conclusions

Water absorption is critical in seeds germination and the absorbing speed and volume decide the speed of germination. With the decrease of temperature, a significant decrease in water absorption rate of cotton seeds of both genotypes was observed. However, water absorption rate of Xinhai35 was 14.29% higher than that of Xinluzao65. Germination rate, germination index and cold resistance index of Island Cotton rate are respectively 30.70%, 34.63% and 32.10% higher than those of Upland

DOI: http://dx.doi.org/10.15666/aeer/1801_089105

Cotton. As a result, Island cotton shows low temperature tolerance. As the imbibition lasts, the activity of antioxidant enzymes and contents of osmotic adjustment substances were declined. Correlation analysis that there exists significant relation between the contents of osmotic adjustment substances and the activity of antioxidant enzymes. By coordinating the 8 indices in principle component analysis, it is found that SS and FP were the main factors affecting cotton seeds germination.

Therefore, under low temperature stress, it is required for seed to increase the water absorption and water absorption rate, and to quickly reach saturation state, thereby regulating metabolic pathways such as osmotic adjustment substances and antioxidant enzymes, and starting a corresponding anti-reverse response mechanism to maintain the metabolic balance and further enhance the low temperature resistance of cotton seedlings and avoid damage during germination.

Abstract. High-throughput sequencing and traditional microbial culturing were used to analyze the effects of the addition of free or immobilized degrading bacteria on the soil physicochemical properties and microbial community structure by simulating the pollution of 2, 2', 4, 4'-tetrabromo diphenyl ether (BDE-47), and to measure the degradation rates. The results showed that (1) The soil physicochemical properties including pH, organic matter, total nitrogen, total phosphorus and total potassium were not significantly affected by the addition of BDE-47, free or immobilized bacteria; (2) *Proteobacteria*, *Acidobacteria*, and *Actinobacteria* were the dominant phyla in the simulation systems, of which the relative abundance of *Proteobacteria* and *Acidobacteria* decreased whereas that of *Actinobacteria* increased through the simulation. *Firmicutes* was dominant in the simulation system B. Seven phyla, including *Bacteroidetes*, *Gemmatimonadetes*, and *Nitrospirae*, were shared by all simulation systems. The free degrading strain adapted well to the simulation system, and the cell count increased from $(5.0 \pm 0.1) \times 10^4$ Colony-forming unit (CFU) /g to $(1.0 \pm 0.2) \times 10^5$ CFU/g at the end of the simulation; (3) The degradation of BDE-47 occurred in the original soil used for the simulation, while the addition of the free degrading strain promoted the degradation of BDE-47 at a rate of 39.77%. The addition of the immobilized strain also promoted the degradation of BDE-47, but only at a rate of 36.94%, slightly lower than that of the free strain.
Keywords: *BDE-47, microbial degradation, immobilization, high-throughput sequencing*

Introduction

As persistent organic pollutants, polybrominated diphenyl ethers (PBDEs) are a class of brominated flame retardants (BFRs) widely used in the electronics industry, electrical appliances, household appliances, textile, oil and construction materials (Dewit, 2002). The general chemical formula of PBDEs is $C_{12}H_{(0-9)}Br_{(1-10)}O$, and there are 209 homologs with different numbers of bromine atoms (Costa et al., 2008). As of 2001, the market demand for the flame retardants PBDEs has exceeded 67,440 metric tons and keeps rising (Arias, 1992; Dewit, 2002). Due to a lack of chemical bonds, PBDEs added to products can easily enter their environment through volatilization and leaching, and with the migration to the atmosphere and water bodies, they may extensively pollute the atmosphere, water, sediments, soil, and biosphere. PBDEs are highly lipophilic,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10011011

chemically stable, and resistant to degradation. Numerous studies have found that PBDEs have endocrine disrupting toxicity (Walter et al., 2017), developmental neurotoxicity (Chen et al., 2014), and immunotoxicity (Talsness, 2008), all of which can be enriched, amplified along food chains (Zhou et al., 2016) and transferred to the next generation through breast milk, placenta, and cord blood (Chen et al., 2014; Xu et al., 2017), posing a potential threat to human and environmental health. Therefore, at the 4th Meeting of the Conference of the Parties (COP-4) of the Stockholm Convention on Persistent Organic Pollutants (POPs) in May 2009, tetrabromo and pentabromo diphenyl ethers in commercial pentabromide products, and the hexabromo and heptabromo diphenyl ethers in commercial octabromide products were added to the Annex A of the Convention as new POPs.

As the primary commercial, pentabromo diphenyl ether (Penta-BDE) monomer 2, 2', 4, 4'-tetrabromo diphenyl ether (BDE-47) is very toxic and can cause harm even at very low doses. Soil is one of the final destinations of BDE-47 and plays a very important role in the spatiotemporal distribution and geochemical cycling of BDE-47. The micro-ecological environment of the polluted soil is complex, where microbes play the central part and the abiotic and biotic factors interact with each other. As an essential biological component of the soil environment, microbes play a pivotal role in the migration and transformation of BDE-47. At present, physical, chemical and biological methods are mainly used for remediation of contaminated soil. Microbial remediation, as the main means of bioremediation, is widely used because of its economic and non-secondary pollution characteristics. One of the widely applied bioremediation techniques is microbial enhancement technology. It improves the pollutant degradation ability of soil or a system by adding bacterial strains screened from a natural source to the soil or biological treatment system for quickly removing the pollutants. As a microbial enhancement technology, microbial immobilization basically confines or localizes free cells or microorganisms to a defined spatial region by using chemical or physical methods to keep them active and reusable. The advantages of this technique include high microbial density, fast reaction rate, strong resistance to toxicity, and low microbial loss.

In the present study, the trends of the dominant bacteria in the simulation systems were dynamically tracked using high-throughput sequencing technology. Chen et al. (2006) reviewed the methods for determining the structural and functional diversities of microbial communities in polluted soils at China and abroad in recent years, and observed that the analysis and research on the microbial diversity of polluted soils were still not robust and conclusive. One of the reasons for this was the fact that the methods and techniques for determining microbial species had not yet considerably developed for comprehensive and accurate analysis of the soil microbial diversity, while the other was the high heterogeneity of the environment. The local spatial-temporal environment kept changing all the time (Vanelsas et al., 1997). In recent years, with the development of high-throughput sequencing technologies, more studies on the microbial structure changes in polluted soils are being conducted. Wang (2016) used high-throughput sequencing to analyze the response of various farmland soil microbial communities to oil spill pollution and planted black locusts. Likewise, the characteristics of the microbial

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10011011

community structure and distribution in petroleum-contaminated soil were analyzed by Liang using high-throughput sequencing (Yang et al., 2013).

In this study, indoor simulation of BDE-47 contaminated soil environment was carried out; an immobilized degrading strain was used to simulate soil remediation, and the changes in microbial community structural during the restoration was analyzed. Our study provides a theoretical basis and technical support for the microbial remediation of BDE-47 polluted soil.

Materials and Methods

Immobilization of the degrading strain

A strain with a good aerobic degradation ability for BDE-47 was isolated and purified from the soil of an electronic waste dismantling site in Taizhou City, Zhejiang Province, China. The strain was identified as *Bacillus laterospora* of the genus *Bacillus* and is deposited in the China General Microbiological Culture Collection Center (deposition number CGMCC No. 8616). The optimum growth temperature for the strain is 30-37°C, with reddish brown colonies on the bacterial solid medium, having moist surface and uneven edges.

In this study, sodium alginate was used as the immobilization carrier for the bacteria, and the cells were embedded inside according to the embedding method discussed. In brief, before simulation, the degrading strain was acclimated in an inorganic liquid culture medium containing 500 μg/L BDE-47, for 10 d acclimation period and a total of four periods. The acclimated strain was enriched in liquid culture and the cells were collected by centrifugation and washed three times with sterilized water to prepare the bacterial suspension (OD_{600} = 2.5) for immobilization. The bacterial suspension was added to the sodium alginate sol, thoroughly stirred and mixed. The mixed solution was dropped into a calcium chloride solution using a syringe, to form beads which were fixed at 4°C. Then the beads were washed with 0.85% sterilized physiological saline and filtered. After drying on a sterilized filter paper, they were stored at 4°C. According to the comprehensive properties of the immobilized beads, the final immobilization conditions were set as bacteria (2 g/L), sodium alginate (4% w/v), calcium chloride (3% w/v), and fixation for 4 h.

Construction of the simulation systems

Taizhou, Zhejiang is a typical e-waste dismantling site in China. To explore the effect of the preliminary screened free strain and its immobilized form on the polluted soil, the soil sample for simulation in this study was collected from the surface (0-20 cm) at the Taizhou Park with no BDE-47 pollution. During the collection, the debris such as plant residues were removed. The soil sample was sealed in a sampling bag and transported to the laboratory in a sampling box with an ice pack. One part (about 15 kg) of the soil sample was directly filtered through a 10 mm sieve for indoor simulation experiments, the other part (about 2 kg) was ground and air-dried, filtered through a 60 mm sieve for

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10011011

preparing the polluted mother soil, and the remaining part was stored at respective 4°C (about 1 kg) and -20°C (about 200 g) for further soil physicochemical analyses and high-throughput sequencing, respectively.

Construction of microbial remediation simulation system for BDE-47 contaminated soil: The vases of height 18 cm and an opening diameter of 21 cm were selected as the simulation containers. In system A the simulated soil and pollutant BDE-47 were added. In system B the simulated soil, pollutant BDE-47, and the free degrading bacteria were added, while the degrading bacteria were in the form of a bacterial suspension. In system C, the simulated soil, pollutant BDE-47 and the immobilized degrading bacteria, in the form of 100 g/kg immobilized beads were added. The soils were turned once every 30 days. The concentration of BDE-47 in the simulation systems were approximately 1,500 ng/g. A certain amount of sterilized water was added to the simulation systems regularly to maintain the water content of the tested soil. Each simulation system had two replicates and the simulation remediation time was 90 days.

Preparation of bacterial suspension: Before the simulation, the degrading strain was acclimated in the inorganic liquid culture medium containing 500 μg/L BDE-47, for 10 d as an acclimation period and four periods totally. The acclimated strain was enriched in the Luria-Bertani (LB) liquid medium, collected by centrifugation and washed three times with sterilized water to avoid the interference of nutrients in the bacterial liquid medium. Then the bacterial suspension was prepared for further simulation experiment with free degrading bacteria.

LB liquid medium: peptone, 10 g; yeast extract, 5 g; and NaCl, 10 g were added to 1 L water. The pH was adjusted to 7 and the medium was sterilized at 121°C for 20 min.

Determination of physicochemical properties of the soil sample

The soil pH, organic matter (OM), total nitrogen (TN), total phosphorus (TP) and total potassium (TK) were determined by the potentiometric method (NY/T1377-2007), potassium dichromate was determined by external heating method (NY/T1121.6-2006) and semi-micro Kjeldahl method (NY/T1121.24-2012), sulfuric acid was determined by perchloric acid digestion (NY/T88-1988) and flame photometric method (NY/T87-1988) (Bao et al., 2008).

Determination of microbial count and community structure

Determination of microbial count: Soil sample (10 g) was aseptically transferred to an Erlenmeyer flask containing 90 mL of sterilized water with an appropriate amount of glass beads in the flask, shaken for 2 h at 37°C and 120 rpm. Then, 1:10 dilution was prepared, which was further diluted 1:10 and a ten-fold serial dilution was made as described above. For each dilution, 1 mL of each dilution was plated on a sterilized LB plate, with three replicates for each dilution. The plates were cultured at 37°C for 36 h, and those with 30-300 total colonies were considered for determining the microbial count.

Determination of microbial community structure: Microbial community structure test analysis process as shown in the literature (Edgar et al., 2011; Knight et al., 2018).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10011011

Determination of BDE-47 content in the soil

The soil of each simulation system was collected, dried, ground, and filtered through a 100-mesh sieve. The soil sample (10 g) was added with an appropriate amount of diatomaceous earth, mixed, and extracted with an accelerated solvent extractor. The extraction tank was 34 mL, the solvent used was hexane/dichloromethane (1:1), and the static extraction was performed at 100°C and 1.03 kpa for five minutes and two cycles. The extract was transferred to a 100 mL rotary evaporator flask for rotary evaporation at 30°C to 1-2 mL, then 10 mL hexane was added to it and rotary evaporated to 1-2 mL again. The prepared sample was loaded on a silica gel alumina column and eluted with 75 mL hexane/dichloromethane (1:1) for purification. The eluent was collected and again rotary evaporated at 30°C to 1-2 mL, then 5 mL acetonitrile was added and concentrated again to approximately 1 mL. Next, it was transferred to a 2 mL sample vial, concentrated under nitrogen, fixed with 1 mL with acetonitrile, and filtered through a 0.22 μm membrane. Finally, it was loaded onto the Waters ACQUITY UPLC C18 column, sized 2.1 mm × 50 mm × 1.7 μm, with 100% acetonitrile as the mobile phase. The flow rate was set to 0.2 mL/min, the column temperature was 30°C, and the absorbance was measured at 226 nm.

Results and discussion

Changes in soil physicochemical properties

Compared with the original, natural soil, there was no significant change in the soil pH, OM, TN, TP or TK in the simulation systems, indicating that in the simulation processes, the addition of BDE-47, free or immobilized bacteria, had no significant effect on the soil physicochemical properties (*Table 1*). Liu et al. (2011) showed that the OM in soil could maintain soil water content and water availability, and thus, can be used as a routine indicator to measure soil water retention and availability. The increase of soil OM content may cause changes in soil aggregate structure to loosen the texture and increase the water permeability and water holding capacity (Guo, 2007). The nitrogen in the soil exists primarily in the surface soil and is closely related to the organic matter content. Nearly 80~97% of the total nitrogen in the surface soil comes from the decomposition of organic matter (Ros et al., 2004). Therefore, the changes in OM content change the soil nitrogen content (Huangshan, 1998). Total phosphorus is an index measuring the sum of various forms of phosphorus in soil. Its value is greatly impacted by the soil parent material and soil formation, and it is also related to soil texture and organic matter (Ding et al., 2010). While the changes in soil physicochemical properties directly affect the microbial community structure, various physicochemical properties synergistically affect the microbial community. As a result, none of the tested simulation systems demonstrated significant changes in physicochemical properties, thus, indicating that the simulation process does not significantly impact the microbial community structure.

A, B, and C represent the three simulation systems, and E represents the end of the simulation

Analysis of microbial structure changes

Changes in microbial community structure

As mentioned in *Fig. 1*, *Proteobacteria*, *Acidobacteria*, and *Actinobacteria* were the dominant phyla in the simulation systems. During the initial stage of the simulation, *Proteobacteria* accounted for 41.58%, 34.47% and 40.97% in systems A, B, and C, respectively. Along the simulation process, its percentages depleted, and accounted for 31.53%, 27.33%, and 29.35%, respectively, at the end of the simulation. The changes in *Acidobacteria* population was similar to that of *Proteobacteria*. The percentage of *Actinobacteria* went up along the simulation, changing from initial 18.62%, 12.27%, and 19.81% to the final 42.02%, 37.66%, and 43.34%, respectively, for the systems A, B, and C. *Firmicutes* were the dominant phylum in system B, and its percentages before and after simulation were 18.80% and 13.89%, respectively. The phyla *Bacteroidetes*, *Chloroflexi*, *Gemmatimonadetes*, *Verrucomicrobia*, *Nitrospirae*, *Planctomycetes*, and *Candidate_division_WS3* were common in all simulation systems, while the other bacteria were rarely found.

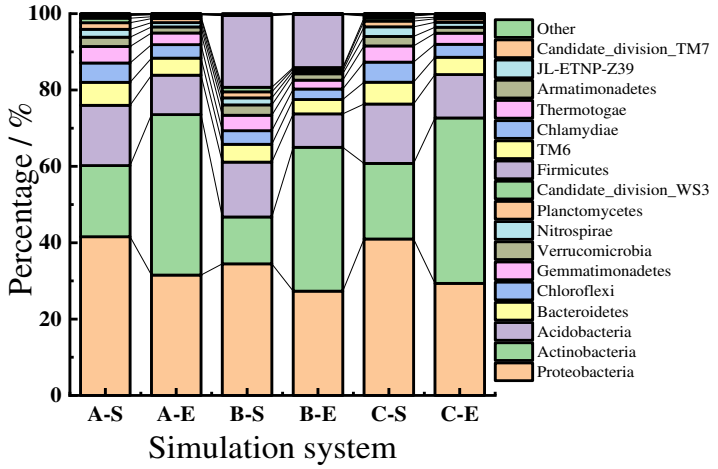

Figure 1. *Analysis of microbial community structure at Phylum level start and end each simulation system. A: Soil + BDE-47; B: Soil + BDE-47 + free degradation bacteria; C: Soil + BDE-47 + immobilized strains; S: Simulation start; E: Simulation end*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10011011

In system A and C, as the simulation progressed, the proportions and trends of the bacterial phyla were consistent, indicating that the addition of the immobilized degrading strain did not affect the microbial community structure in the soil significantly. Although, the addition of the free degrading strain actually impacted the original microbial community structure to some extent. For system B, the dominant role of *Firmicutes* was observed because the added free degrading bacteria belonged to this phylum. In summary, for the simulation systems, the change of the microbial community structure in the soil was related more closely to the addition of the degrading bacteria in the simulation process. The degrading strain was screened and isolated from the contaminated soil in Zhejiang and was more adaptable to the soil ecological environment in that province. Hence, when it was applied to remediate the soil polluted by BDE-47 in Zhejiang, it had less impact on the soil microbial community structure.

Analysis of the trend of the degrading strain

As per the high-throughput sequencing results (*Figure 2*), the dynamic tracking of the degrading strain which belonged to *Bacillus* showed that the relative abundance of *Bacillus* in system A dropped from 0.0062 at the initial stage to 0.0041 at the later stage. Whereas in system B, the addition of the degrading *Bacillus* strain directly caused its relative abundance to increase to 0.1857 at the initial stage, and decrease later to 0.13813, although it was still the dominant species. In the system C, the relative abundance of *Bacillus* at the initial stage was 0.00553, and with the simulated remediation, its relative abundance increased by 0.16% to the final 0.00714. The analysis of the free degrading strain count by the traditional microbial culturing technique in system B showed an initial count of $(5.0 \pm 0.1) \times 10^4$ CFU/g, which increased along the simulation to a final count of $(1.0 \pm 0.2) \times 10^5$ CFU/g (*Fig. 3*).

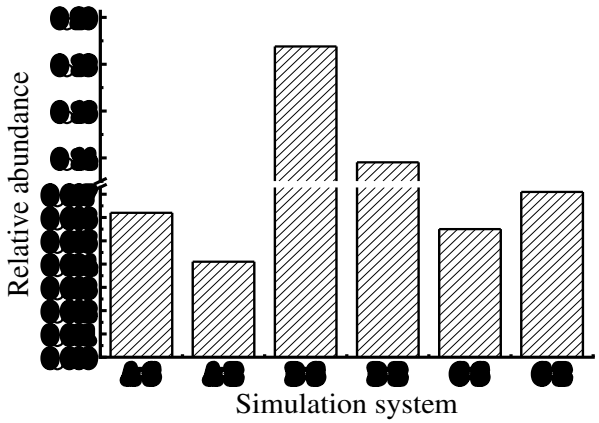

Figure 2. *Analysis of relative abundance variation of Bacillus sp in each simulation system*

The two approaches revealed that the free degrading strain adapted well to the simulated soil environment and that the decrease in *Bacillus* may be due to cell death and DNA degradation during the simulation process, resulting in a decline in final relative

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10011011

abundance. At present, only about a dozen strains have been found capable of aerobic degradation of PBDEs, and the reported ones include *Sphingomonas* sp. (Schmidt et al., 1992, 1993; Hundt et al., 1999), *Rhodococcus* sp. RR1, *Seudonocardia dioxanivorans* CB1190 (Robrock et al., 2009), *Lysinibacillus fusiformis* strain DB-1 (Deng et al., 2011), *Bacillus cereus* JP12, *Acinetobacter*, *Pseudomonas*, and *Staphylococcus* (Wang et al., 2016). Currently, there are very limited reports on the application of free strains for environmental remediation.

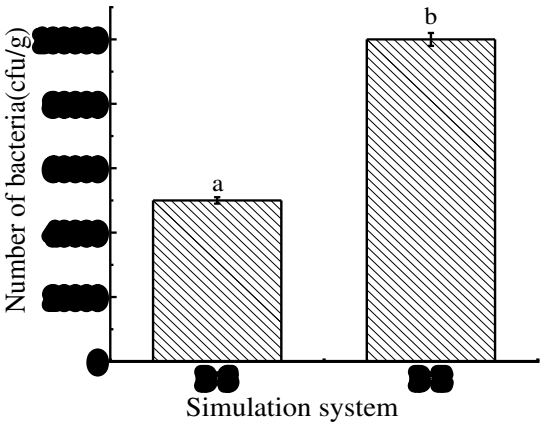

Figure 3. *Change in the number of free bacteria in B simulation system*

BDE-47 degradation analysis

As shown in *Table 2*, at the start of simulation, the BDE-47 concentrations were 1,504 ng/g in system A, 1,775 ng/g in system B, and 1,654 ng/g in system C. After 90 days of simulation remediation, the remaining BDE-47 concentrations were 1,135 ng/g in system A, 1,069 ng/g in system B, and 1,043 ng/g in system C. The degradation rate of BDE-47 in system A was 24.53%, demonstrating existence of BDE-47 degrading strain in the simulated original soil. The degradation rate in system B was 39.77%, indicating that the added free degrading strain potentially promoted the degradation of BDE-47. The degradation rate in system C was 36.94%, indicating that while the added immobilized strain could promote the degradation of BDE-47 as well, but it was inferior to the free strain. The micro-ecological environment of the polluted soil consists mostly of microorganisms, which are important biotic components of the soil environment. The soil used for simulations was collected from Taizhou, Zhejiang and the added degrading strain was also screened from a contaminated site in Taizhou, Zhejiang. Therefore, the free strain could adapt well to this soil environment, promoting the degradation of the pollutant BDE-47. Although studies show that the immobilization of degrading bacteria can increase the concentration of microorganisms, keep the strains highly active and repeatedly usable, and greatly enhance the environmental adaptability of the immobilized microbes and their ability to degrade organic matter (Karamanev et al., 1998; Su et al., 2006, 2008; Lu et al., 2015). In this present study, although the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10011011

immobilization increased the concentration of bacteria inside the immobilized beads, the bacteria could not diffuse. Therefore, it was not conducive to the degradation of pollutant in the soil.

Table 2. *BDE-47 concentration chromatographic results*

System	Simulation time (day)	Peak time (min)	Peak area (μA/s)	Peak height (μA)	BDE-47 concentration (ng/g)
A	0	1.106	264969	135094	1504
	90	1.104	204801	106061	1135
B	0	1.106	308973	154296	1775
	90	1.105	194046	100537	1069
C	0	1.104	289360	147979	1654
	90	1.104	189882	94948	1043

Conclusions

a) In all simulation systems, the addition of pollutant BDE-47, and the free or immobilized strain had little effect on the soil physicochemical properties such as pH, OM, TN, TP, and TK.

b) The dominant phyla in the simulation systems were *Proteobacteria*, *Acidobacteria*, and *Actinobacteria*. A total of seven phyla including *Bacteroidetes*, *Gemmatimonadetes*, and *Nitrospirae* were common bacteria shared by all three simulation systems. The *Firmicutes* became the dominant bacterial phylum because the added strain of free bacteria belonged to this phylum. The free degrading strain adapted well to the simulation system, and its count was increased in the later stages.

c) The original soil used for the simulation contained the BDE-47 degrading strain, and the addition of the free degrading strain could promote the degradation of BDE-47 at a rate of 39.77%. The addition of the immobilized strain also promoted the degradation of BDE-47, although the degradation rate was 36.94%, slightly below that of the free strain. The next research plan focuses on the degradation pathway of BDE-47, which lays the foundation for regulating the degradation process of BDE-47.

(Received 13th Jul 2019; accepted 25th Nov 2019)

Abstract. Replacement feasibility of inorganic fertilizer using biogas slurry was investigated via two-season pot culture experiments in greenhouse. Three biogas slurry treatments (treatment 1, T1; treatment 2, T2; treatment 3, T3) and a inorganic fertilizer treatment (CK) were set to explore the effects on tomato growth, yield, quality and root-zone soil environment. The volume concentrations of biogas slurry in T1, T2 and T3 treatments were 20, 15 and 10%, respectively. Results showed that T1 and CK treatments maintained a high leaf area index (LAI), photosynthetic rate and chlorophyll (a+b) contents during the whole growing period. T1 treatment can obtain an equivalent yield to CK, however, the yield of T2 and T3 treatments were inferior to that of CK. For the quality of tomato, T1 treatment can improve the soluble sugar and titratable acid contents for about 19.07 and 4.17% when compared to CK, and T2 treatment can improved about 7.55 and 4.17%. Furthermore, T1 and T2 treatment can get a better sugar-acid ratio and tastes. In comparison with inorganic fertilizer treatment, all biogas treatments could increase soil porosity and soil aggregate, decrease soil debris, in which the superior treatment is T1 and can be considered as a good organic fertilizer.
Keywords: *leaf area index, photosynthetic rate, chlorophyll, comprehensive benefit evaluation, soil saturated hydraulic conductivity, soil organic matter, soil total nitrogen, soil microstructures*

Introduction

Application of inorganic fertilizers has played a significant role in the development of food and other agricultural crop productions (Smith et al., 2015). However, recent researches showed that the production benefit did not increase proportionately with the quantity of fertilizer input (Liu et al., 2017). Application of fertilizer in excess, not only increased the cost of agricultural products, but also result environmental problems such as soil hardness and soil acidification of the cultivated lands. A reduction in the amount of applied fertilizer could bring the cost of agricultural production down, enhance efficiency, save energy and reduce emissions. As a result the national food security, agricultural product quality and agricultural ecological condition all become saved (Li et al., 2016). It has been verified that organic fertilizers could promote the healthy growth

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10131029

of crops and enhance yield and quality of crops through improving soil structure of fungal community (Ding et al., 2017; Rong et al., 2018). Thus, the replacement of inorganic fertilizer with the organic ones could bring a safer food production system with adequate achievements of ecological and environmental safety of the cultivated lands.

Biogas slurry is the post-product of biogas production technology via anaerobic fermentation process. It is an effective organic fertilizer, which contains the most basic water soluble nutrients necessary for crop growth, such as N, P and K. Besides, it also contains microelements like Ca and Mg and some essential amino acids as well as growth stimulating and regulating materials including vitamins and growth hormones. Application of biogas slurry irrigation could enhance crop yield, optimize fruit quality, promote crop seed germination, prevent diseases and pests, and improve soil quality (Tambone et al., 2010; Ledda et al., 2013; Oh et al., 2014). Duan et al. (2011) applied biogas slurry as liquid fertilizer on greenhouse cucumber production. They obtained high yield and good quality of cucumber compared with inorganic fertilizer treatment. Their experiment had also achieved a reduction of greenhouse gas emission. Alburquerque et al. (2012) showed that the application of biogas slurry could effectively improve soil environment and obtain yield which was comparable with that obtained by traditional fertilizer application. Using biogas slurry in the field increased the population of microorganisms which contributed to the formation of soil organics (Coban et al., 2015). Nabel et al. (2017) carried out a comparative experiment of three years duration and showed that the application of biogas slurry as fertilizer could enhance carbon content, water holding capacity and fertility of soils. Lu et al. (2012) showed that irrigation by appropriate biogas slurry could enhance rice yield compared with traditional fertilizer use. Besides, the heavy metal concentration of underground water, soil and rice, determined after one week of biogas slurry irrigation were seen unaffected. Actually biogas slurry contains high water content and low fertilizer properties. However, in current researches, biogas slurry was treated simply as fertilizer and applied each time according to the calculated equivalent fertilizer application amounts. This had resulted in the loss of nutrient and a decrease of nutrient utilization efficiency. In addition, current researches did not consider comprehensively the effect of biogas slurry on crop growth elements, yield and quality, soil nutrient and micro-aggregation structure of roots over the whole growth period. Besides, there was a lack of study on the effect of application of biogas slurry as replacement of inorganic fertilizer. Considering the above mentioned knowledge gaps, it has been aimed in the present research to study the effect of application of biogas slurry in different concentrations on tomato cultivation. In the present research, physiological and ecological indexes, yield and quality, as well as the soil environment of root of tomato plant were considered to study over the entire growth period. Another objective of this research was to evaluate the tomato comprehensive benefit using the 'Technique for order preference by similarity to ideal solution' (TOPSIS). This would enable to obtain appropriate biogas slurry irrigation mode during the whole tomato growth period in realization of providing theoretical support for further field application as total replacement of inorganic fertilizer.

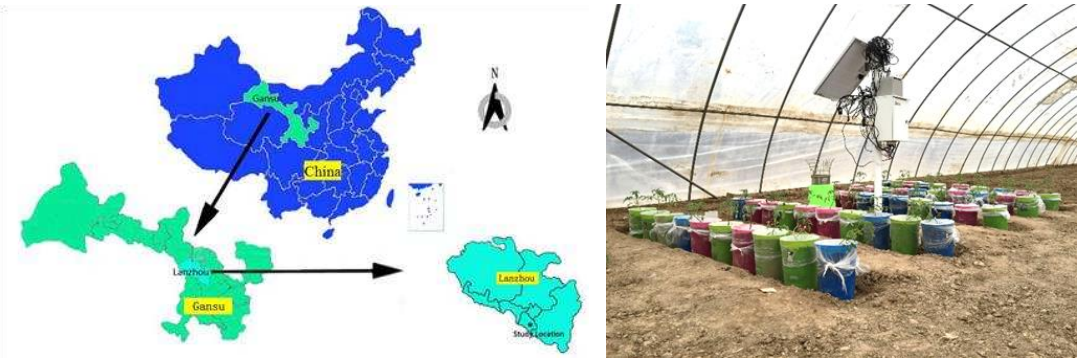
Materials and Methods

Experimental materials

In the present research, pot culture experiments were performed in the spring and autumn seasons of 2017. The experimental site was the greenhouse of the demonstration

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10131029

site of integration of facilities, vegetables, water and fertilizer at Weiling Country, Qilihe District, Lanzhou City, Gansu Province of the People's Republic of China. The experimental criteria were: Daylight greenhouse with the type of ridge 50.0 × 10.5 ×4.0 m (L×W×H) at 36º03' N and 103º40' E and with an average altitude of 1872 m (*Figure 1*). The study area is subjected to a temperate continental dry climate with sufficient sunlight and little rain. Average annual temperature was 8.9ºC with a no-frost period of about 150 d. Average annual precipitation and evaporation were 310.5 and 1158.0 mm, respectively. There was a minimized automatic weather site in greenhouse to constantly monitor conventional meteorological data.



(a) (b)

Figure 1. *Research site location and pot culture experiment equipment in greenhouse. (a) The research site location; (b) the pot culture experiment equipment*

Tomato (*Solanum lycopersicum* L.) cultivar "No.3 of Hongbao" was tested in pot culture experiments. The soil used in this experiment was collected from the indoor surface layer of 0-40 cm within the greenhouse complex. Soil particle size distribution was determined by laser particle size analyzer (MS2000). The calculated ratios of sand, silt and clay to total weight were 25.3, 64.6 and 10.1%, respectively. According to International soil texture classification standard, the tested soil was silt. Soil nutrient condition was determined before potting. Contents of total N, organic matter, and total P were 1.022, 9.08 and 1.616 g/kg, respectively. The bottom and top diameter of the cultivation container, the height of soil and the unit weight of soil were 16, 22 and 22 cm and 1.35 g/cm^3, respectively. Field water holding content, namely, weight water fraction θ_f was 23.5%. A hole at the bottom of pot was drilled for ventilation. Gauze and filter paper were put at the bottom to prevent the leakage of soil. To monitor soil water fraction a hole was drilled at the wall of the pot. Tomato was permanently planted with a seedling of four big leaves and one heart. The growth period of tomato in the experiments was shown in *Table 1*. In the experiment 1500 ml slow seedling water in permanent planting was unifiedly irrigated. The plastic film was covered 5 d after permanent planting. Soil evaporation could be neglected. Other cropping management practices, such as pesticide and herbicide application, were consistent with those used by local farmers.

The tested biogas slurry was collected from the biogas tank with normal fermentation and normal gas production in Gansu Hesitan cows breeding center in Huazhuang Country, Lanzhou City. After two months of aeration and standing, the clear liquid was extracted for further use until the physicochemical properties stabilized. The biogas engineering perennially used cow dung as fermentation material. Nutritional status of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10131029

biogas slurry were 10.75, 1.036, 0.533 and 1.186 g/L for organic matter, total N, P and K contents, respectively.

Table 1. *The growth period of tomato in the experiments*

Planting time	Growth period	Date	Days	Planting time	Growth period	Date	Days
Plant in spring	Seedling stage	12-28th May	16	Plant in autumn	Seedling stage	14-29th September	16
	Flowering stage	May 29th to June 9th	12		Flowering stage	September 30th to October 9th	10
	Fruit swelling stage	June 10th to July 3rd	24		Fruit swelling stage	October 10th to November 10th	31
	Fruit maturity stage	4-21st July	18		Fruit maturity stage	11-29th November	19

Experimental design

In the experimental trials, hole irrigation water-biogas slurry integration method was applied (Tan et al., 2015). Four treatments were set, wherein CK was the routine fertilizer treatment and T1, T2 and T3 were the biogas slurry treatments with volume concentrations of 20, 15 and 10%, respectively. Inorganic fertilizer application of CK treatment in tomato growth period was as follows: once in each of the seedling and flowering stage and twice in each of the fruit swelling stage and fruit maturity stage with urea, P and K fertilizer. The application amounts for NPK were 78, 94.5 and 97.5 kg/ha, respectively.

During the entire growth period, the biogas slurry treatment adopted integration irrigation of water and biogas slurry. Namely, irrigation was conducted with biogas slurry of different concentrations. The irrigation amount was calculated by the evaporation amount of the standard evaporating dish of Φ20 cm which was put at the height with a distance of 20 cm to tomato canopy. The evaporation amount of cumulative 2 d was set as the irrigation standard. The irrigation frequency was 1 time/2 d.

The calculation method was according to (*Eq.1*) (Azizi-Zohan et al., 2008)

$$M = K_p \times S \times E_p \quad \text{(Eq.1)}$$

where, M was the irrigation water amount in mL; Kp was the crop-pan coefficient; S was the irrigation water amount control area with the unit of cm^2; Ep was the evaporation amount of the evaporating dish in the gap between two irrigation with the unit of mm.

To illustrate the difference between the integration irrigation of water and biogas slurry and traditional fertilizer treatment in tomato whole growth period as well as to obtain appropriate biogas slurry concentration, none of water deficit treatment was set in different growth periods of crop in experiment.

Thus, Kp value was set as 1.0 in the experiment. In addition, three replicates were set for each treatment.

The determination of indexes and methods

The determination of physiological and ecological indexes

Leaf area index (LAI) was determined by the image method using Photoshop software. Three plants in each treatment were chosen to measure and the final LAI are the average

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10131029

value. In the seedling and flowering stages, the LAI for each treatment was measured once. However, in the fruit swelling and maturity stages this parameter was measured twice for the longer period of these two growth stages. The measurement of LAI followed the scanning of the leaf first with the help of a scanner and then the leaf area was calculated with the software of Photoshop. Finally, the value of LAI was obtained according to the equation (Eq.2):

$$\mathrm{LAI} = A_l / A_s \quad \text{(Eq.2)}$$

where, A_l is the total leaf area of a single plant, A_s is the irrigation water amount control area of a plant.

Soil water fraction was determined by WET three parameter calibrated tester. The determination was done at 2 days during the growth period. Chlorophyll was determined by the mixed solution method of acetate and ethanol (Liu et al., 2018) before and the third day after the first fertilizer application as well as before the second fertilizer application in the fruit swelling stage. The photosynthetic rate was determined by CIRAS-I portable photosynthesizer (made in UK) during 9:30 to 10:30 AM of sunny day in different tomato growth periods. The photosynthetic rate was determined on May 22 and September 21 in seedling stage, and measured on June 2 and October 6 in flowering stage, on June 24 and October 19 in the fruit swelling stage and on July 15 and November 20, 2017 for tomato planted in spring and autumn. Weights of dry materials were determined by the drying method. Samples were collected at the end of different tomato growth periods. For each treatment, three crops were determined separately, whose average value was reported as experimental final result.

Quality index determination

Soluble solids of tomato fruit contents were determined by WAY-2S Abbe refractometer. Vitamin C, soluble protein, total soluble sugar and the titrate acidity were determined by Molybdenum blue colorimetry, Coomassie brilliant blue G-250 staining method, Anthrone colorimetry method and the titration method (Liu et al., 2018), respectively.

Soil environment index determination

Soil saturated hydraulic conductivities were determined by the variable water level method with soil sampling by cutting ring after experiment. Total N content in soil was determined by Kjeldahl method. Soil microstructure was determined by imaging via scanning electron microscope (SEM), whose figure was treated by Photoshop CS6 software.

Data processing and analysis

Each data was the average of three replicate determinations. Turkey HSD of the variance analysis and the significance of difference were conducted by SPSS 19.0 statistical analysis software. Figures were drawn by Excel 2010 and Origin 8.0. Tomato comprehensive benefit was evaluated by TOPSIS analysis method.

Results and analysis

The response pattern of tomato physiological and ecological indexes on different treatments

LAI

Figure 2 showed the changing pattern of LAI of different treatments over the whole growth period. It showed that LAI of tomato which was planted in spring was significantly larger than that of autumn treatment. LAIs of different biogas slurry treatments in two growth periods were in a descending order of T1>T2>T3, whereas LAI of CK treatments in stages of seedling, blossoming and fruiting, and pre fruit swelling stage of tomato was the maximum among all, namely CK>T1>T2>T3, respectively. However, LAI of CK treatment in the late fruit swelling stage gradually decreased to be lower than that of T1 treatment. The pattern followed T1>CK>T2>T3. Besides, LAI in the late fruit maturity stage decreased dramatically. The changing trend of LAI illustrated that the fertilizer application in tomato nutritional growth period could provide optimum nutrient supply for tomato, whereas during the gradual transition of tomato from nutritional growth to reproductive growth, CK treatment on the aspect of sustainable support of crop growth was insufficient. In addition, LAI of T1 treatment demonstrated a much higher level in the entire tomato growth period, especially in the fruit swelling stage. During which period the value was far higher than those of other treatments. Thus, it demonstrated better growth persistence and illustrated that the water and fertilizer supply of T1 treatment could obtain better LAIs with the corresponding biogas slurry concentration and irrigation frequency.

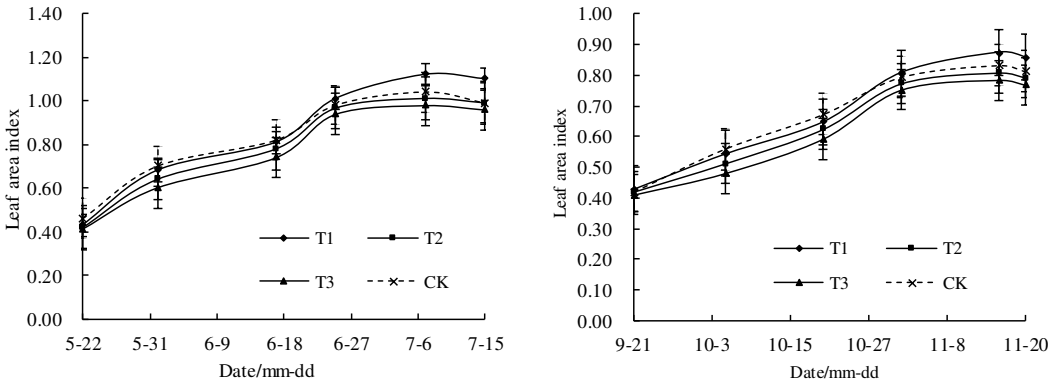

Figure 2. *Growth stage variations of tomato leaf area index under different treatments. The error bars mean a 5% range of error. CK is the control treatment applied with inorganic fertilizer, T1, T2 and T3 are treatments applied with biogas slurry of 20, 15 and 10% in volume concentrations, respectively*

The photosynthetic rate

From *Table 2*, leaf photosynthetic rates of CK treatment in tomato seedling as well as flowering stages in both spring and fall experiments were significantly higher than those of biogas slurry treatments (T1, T2 and T3) and with apparent advantages. Leaf photosynthetic rates of T1 treatment in fruit swelling and maturity stages were apparently higher than those of other treatments. It followed a descending order of T1>CK>T2>T3.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10131029

The leaf photosynthetic rates of T1 treatment were 0.06 and 0.07 μmol/m^2/s as well as 0.10 and 0.09 μmol/m^2/s higher than those of CK treatment in spring and fall cultivation, respectively.

Table 2. *Leaf photosynthetic rate of tomato in different growth stages*

Treatments	Planted in spring				Planted in autumn			
	Seeding stage (μmol $m^{-2}s^{-1}$)	Flowering stage (μmol $m^{-2}s^{-1}$)	Fruit swelling stage (μmol $m^{-2}s^{-1}$)	Fruit maturity stage (μmol $m^{-2}s^{-1}$)	Seeding stage (μmol $m^{-2}s^{-1}$)	Flowering stage (μmol $m^{-2}s^{-1}$)	Fruit swelling stage (μmol $m^{-2}s^{-1}$)	Fruit maturity stage (μmol $m^{-2}s^{-1}$)
CK	7.96aA	8.26aA	8.06abAB	8.12bA	8.16aA	7.86aA	7.46bB	6.76bB
T1	7.84bB	8.16bB	8.12aA	8.19aA	8.10bA	7.82aAB	7.56aA	6.85aA
T2	7.82bB	8.06cC	8.00bB	7.98cB	8.08bA	7.76bBC	7.42cC	6.66cC
T3	7.80bB	8.00cC	7.86cC	7.82dC	8.06bA	7.72bC	7.34dD	6.46dD

Lowercase a, b, c, d indicate significantly differences among treatments at the level of $P<0.05$; Capital letters A, B, C, D indicate significantly differences among treatments at the level of $P<0.01$. CK is the control treatment applied with inorganic fertilizer, T1, T2 and T3 are treatments applied with biogas slurry of 20, 15 and 10% in volume concentrations, respectively

In the two seasonal experiments namely, spring and autumn, leaf photosynthetic rates of T1, T2 and T3 treatments were 0.8 and 1.3%, 2.1 and 2.4%, as well as 4 and 4.5% higher than those of CK treatment, respectively. In tomato seedling stage, there was no significant variation among different biogas slurry treatments (T1, T2 and T3), e.g. the largest variance was only 0.5%. In the flowering stage of spring cultivation, there was significant difference between tomato leaf photosynthetic rate of T1 treatment and those of T2 and T3 treatments. But there were no significant difference between T2 and T3 treatment In addition, rate of T1 treatment was 1.2 and 2.0% higher than those of T2 and T3 treatments, respectively. However, in the flowering stage of fall cultivation, rate of T1 treatment was 0.8 and 1.3% higher than those of T2 and T3 treatments, respectively. This means that there started a certain degree of differentiation between the nutrient supply of biogas slurry and the tomato growth demand at the time of gradual transition from tomato nutritional growth to reproductive growth. This also affected the leaf photosynthesis to some extent. In the stages of fruit swelling and fruit maturity, the photosynthetic rate of T1 treatment was significantly higher than those of T2 and T3 treatments. This indicates that T1 treatment could better promote leaf photosynthetic rate of tomato during tomato reproductive growth stages which promotes further the synthesis of photosynthetic products.

Chlorophyll

Chlorophyll in leaves could demonstrate the photosynthetic ability of leaf to some extent. *Figure 3* showed the variation of chlorophyll (a+b) content with different treatments. Chlorophyll (a+b) content of CK treatment before the first fertilizer application in the fruit swelling stage was 0.055 and 0.025 mg g/FW which was lower than that of T1 treatment in two seasonal experiments, respectively (*Figure 2*).

Leaf chlorophyll (a+b) contents at the 3rd-5th day after the fertilizer application which were 0.067 and 0.048 mg g/FW higher compared to the values before fertilzer application, respectively. The values were the highest among those of different treatments, namely, 0.045 and 0.028 mg g/FW higher than those of T1 treatment.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10131029

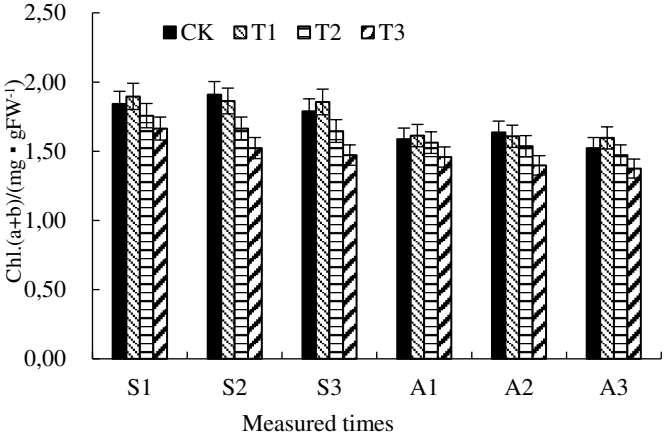

Figure 3. *Chlorophyll (a+b) content in tomato leaves under different treatments. S1, S2 and S3 were the chlorophyll (a+b) in spring experiment, and A1, A2 and A3 were that in autumn experiment of 2017. CK is the control treatment applied with inorganic fertilizer, T1, T2 and T3 are treatments applied with biogas slurry of 20, 15 and 10% in volume concentrations, respectively. The error bars mean a 5% range of error. Chl., chlorophyll; FW, fresh weight*

Leaf chlorophyll (a+b) content of CK treatment before the second fertilizer application in the fruit swelling stage decreased 0.119 and 0.113 mg g/FW compared with those of T1 treatment, respectively. Leaf chlorophyll (a+b) content of T2 and T3 treatments were lower than those of CK and T1 treatments and demonstrated a decreasing trend. The overall change of leaf chlorophyll (a+b) content of T1 treatment was the most stable among those of different treatments with respective changing amplitudes of only 0.04 and 0.017 mg g/FW of two seasonal experiments.

Besides, the changing amplitude of T3 treatment in two seasonal experiments was the largest i.e., 0.119 and 0.113 mg g/FW, respectively. The next largest changing amplitude was 0.111 and 0.09 mg g/FW of CK treatment. Thus, it showed that T1 treatment could maintain leaf chlorophyll (a+b) content at a stable level.

The response trend of tomato yield and quality

From *Table 3*, in 2017 spring experiment, the yield of T1 treatment was highest. The next was that of CK treatment. The yield of T1 treatment was 11.8 and 31.7% higher than those of T2 and T3 treatments, respectively. There was a significant difference between CK and T1 treatment at the level of p=0.05.

However, in 2017 autumn experiment, the yield of CK treatment was the highest. The next was that of T1 treatment. The yield of CK treatment was 15.5 and 18.2% higher than those of T2 and T3 treatments, respectively. However, there was no significant difference between the yield of CK treatment and that of T1 treatment at levels of p=0.05 and p=0.01.It illustrated that T1 treatment could not only replace fertilizer but also obtain the yield which was comparable with that of traditional fertilizer treatment. Different nutritional qualities of T1 and T2 treatments in two season experiments were higher than those of CK treatment, wherein total soluble sugar and titrate acid contents of T1 treatment were 19.07 and 16.30% as well as 4.17 and 10.32% higher than those of CK treatment, respectively.

Besides, total soluble sugar and titrate acid contents of T2 treatment were 75.5 and 7.70% as well as 2.24 and 7.54% higher than those of CK treatment, respectively.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10131029

Table 3. *Effects of different treatments on tomato yield and nutritional quality*

Planting time	Treatments	Yield/(g)	Nutritional quality				
			Titration acid/(%)	Total sugar/(%)	Sugar/Acid	Vitamin C /(mg•100g^{-1})	Soluble protein/(mg•g^{-1})
Planted in spring	CK	321bA	0.312abA	3.178cC	10.186cC	20.834cC	1.078cC
	T1	332aA	0.325aA	3.784aA	11.643aA	23.465aA	1.132aA
	T2	287cB	0.319abA	3.418bB	10.715bB	22.722bB	1.105bB
	T3	252dC	0.286bB	2.859dD	9.997dD	20.011dD	0.986dD
Planted in autumn	CK	268aA	0.252cB	2.626cC	10.421bB	18.847cC	0.912bB
	T1	259aA	0.278aA	3.054aA	10.986aA	19.973aA	0.967aA
	T2	232bB	0.271bA	2.828bB	10.435bB	19.077bB	0.923bB
	T3	219cB	0.244dB	2.311dD	9.471cC	18.376dD	0.881cC

Lowercase a, b, c, d indicate significantly differences among treatments at the level of $P<0.05$; Capital letters A, B, C, D indicate significantly differences among treatments at the level of $P<0.01$. CK is the control treatment applied with inorganic fertilizer, T1, T2 and T3 are treatments applied with biogas slurry of 20, 15 and 10% in volume concentrations, respectively

In addition, the sugar acid ratio of T1 treatment was 14.3, 8.6 and 16.5% higher than those of CK, T2 and T3 treatments, respectively in spring cultivation as well as 5.4, 5.2 and 16.0% higher in autumn cultivation, respectively. Besides, the sugar acid ratio of T2 treatment was 5.19 and 0.13% higher than those of CK treatment in spring and fall, respectively.

Vc contents of T1 and T2 treatment were 12.58 and 5.97% higher than those of CK treatment in spring cultivation as well as 9.02 and 1.02% higher in fall cultivation, respectively. Different nutritional quality indexes of T3 treatment was the lowest among those of different treatments.

Results showed that T1 and T2 treatments not only obtained a higher soluble sugar content and the titrate acidity but also increased the sugar acid ratio, Vc, and soluble protein contents. All these factors contributed to increase the nutritional value as well as the taste and flavor of tomato. However, T3 treatment was unfavourable to the formation of tomato nutritional quality, illustrating the effect of biogas slurry irrigation frequency and concentration on tomato yield and quality to some extent. Thus, the appropriate biogas slurry irrigation mode could effectively improve the nutritional quality of tomato.

Tomato comprehensive benefit evaluation by the TOPSIS method

To obtain the optimum biogas slurry irrigation mode over the whole growth period of tomato, seven indexes such as yield, soluble solids, the soluble sugar, the titrate acid, the sugar acid ratio, the soluble protein and vitamin C were chosen. Besides, as shown in *Table 4*, tomato comprehensive benefit was evaluated by the TOPSIS method. Thus, in 2017 spring and fall experiments, comprehensive benefit indexes (CIs) of different treatments as well as comprehensive sorting were in a descending order of T1>T2>CK>T3. In addition, CI value of T1 treatment was 31.21 and 40.86% higher than those of CK treatment, respectively. This illustrated that T1 treatment was better than traditional fertilizer treatment. So, on the comprehensive benefit aspects of tomato yield and nutritional quality, T1 could be recommended as reference mode for the replacement of fertilizer with biogas slurry.

D^+ and D^- mean the weighted distances between each alternative and the optimal or inferior ideal solutions, respectively; A^+ and A^- are the optimal and inferior ideal solutions, respectively. CK is the control treatment applied with inorganic fertilizer, T1, T2 and T3 are treatments applied with biogas slurry of 20, 15 and 10% in volume concentrations, respectively

The effect of different treatments on soil environment

Soil saturated hydraulic conductivity and soil organic matter

By studying the trend of soil saturated hydraulic conductivities of different treatments, it has been seen that T1 was apparently higher than other treatments (*Figure 4*). Soil saturated hydraulic conductivities (Ks) of different treatments was in a descending order of T1>T2>CK>T3. In the two experiments carried out in both the seasons, the values of T2 treatment were 0.002 and 0.005 cm/min higher than those of CK treatment, respectively. Besides, values of T3 treatment were the lowest, illustrating that T1 and T2 treatment could provide higher soil saturated hydraulic conductivities than CK treatment.

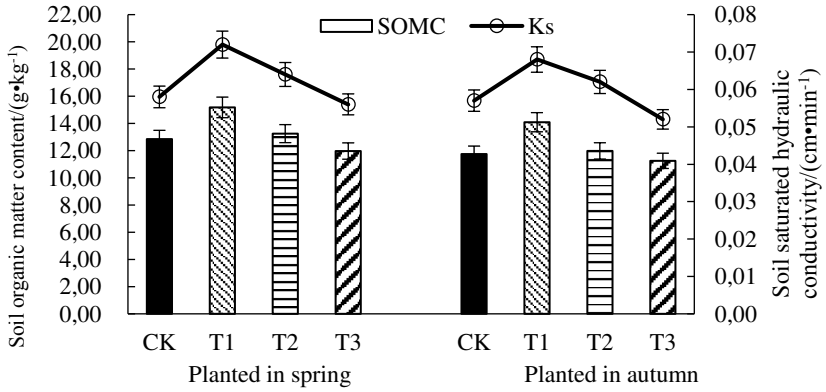

Figure 4. *Soil organic matter and saturation conductivity under different treatments. CK is the control treatment applied with inorganic fertilizer, T1, T2 and T3 are treatments applied with biogas slurry of 20, 15 and 10% in volume concentrations, respectively. The error bars mean a 5% range of error*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10131029

In 2017 spring and autumn experiments, soil organic matter content (SOMC) of all treatments increased compared with the original soil as shown in dashed line of *Figure 4*. Besides, values of CK treatment which were 22.80 and 18.39% higher than those of original soil, respectively, were lower than those of T1 and T2 biogas slurry treatments.

SOMC of different treatments related in a descending order T1>T2>CK>T3. Its content in T1 and T2 treatments were 18.13 and 19.91%, respectively which were 10.34 and 8.77% higher than CK treatment. However, the contents were 3.57 and 3.63% higher than those of T3 treatment, respectively, in spring and fall experiments. All these illustrated that T1 and T2 treatment were better than CK treatment on the aspect of increasing SOMC. Therefore, the finding supports that appropriate biogas slurry irrigation could increase SOMC.

Change of soil total N content

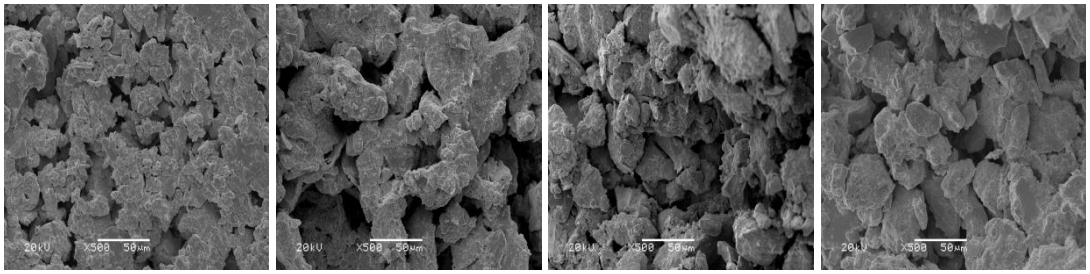
From *Table 4*, soil total N content of CK treatment was the highest in tomato different growth stages in spring and fall and the next was T1 treatment. On the other hand, the soil total N content was the lowest in T3 treatment. The soil total N contents of different treatments from the seedling to the flowering stages, increased to some extent. The increasing amplitudes of soil total N of T3 treatment were the smallest i.e., 0.007 and 0.002 g/kg, in spring and fall, respectively. This illustrates that N supply of different treatments from the seedling stage to the flowering stage was surplus. Thus, N fertilizer application amount or biogas slurry concentration could be proportionately decreased in the application process. T3 treatment could be used as reference for the application during the corresponding growth period. Considering soil N contents in stages of blossoming and fruiting, fruit swelling stage and fruit maturity stage, the change of T1 treatment was stable with the smallest changing amplitudes or increasing amounts of only 0.007 and 0.004 g/kg. On the other hand, the increased amounts of CK treatment were 0.117 and 0.216 g/kg, illustrating that N element provided by traditional fertilizer treatment has been accumulated to some extent in soil. However both the T2 and T3 treatments demonstrated the decreasing trend, especially T3 whose soil N content was already lower than that of original soil (1.022 g/kg) in stages of fruit swelling stage and fruit maturity stage. This clarifies that T3 treatment could not satisfy the N element demand of tomato growth. Values of T1 treatment were stable.

The influence of different treatments on soil microstructures

Soil microstructure reflects the original soil characteristics which is directly related to soil fertility and happens to be an important compositional part of soil quality (Kapur et al., 2007; Price et al., 2007). From *Figure 5*, soil of CK treatment was in debris aggregation state with the close contact between soil bone particles and soil matrix. Soil of T1 treatment was in the status of cementitious compactness with a microstructure distribution of flocculated mass as well as the loose contact of bone particles and soil matrix. Soil debris of T2 treatment was fewer than that of CK treatment with apparent better soil pore development than that of CK treatment.

There was a compacting contact between soil bone particles and soil matrix in T3 treatment as well as an apparent higher amount of soil debris than those of T1 and T2 treatments but lower amount than that of CK treatment. The pore area, average pore area and average pore size of T1 treatment, which were the highest among different treatments were 31.62, 55.39 and 14.51% higher than those of CK treatment, respectively (*Table 5*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10131029



CK T1 T2 T3

Figure 5. *Comparison of soil microstructure under different treatments (500 times). CK is the control treatment applied with inorganic fertilizer, T1, T2 and T3 are treatments applied with biogas slurry of 20, 15 and 10% in volume concentrations, respectively*

Table 5. *Pore parameters of different treatments after image treatment*

Treatments	The pore area (μm^2)	Average pore area (μm^2)	Average pore size (μm)	Area ratio
CK	4824.00c	19.93d	3.79b	0.071
T1	6349.21a	30.97a	4.34a	0.081
T2	5118.24b	21.24c	3.83b	0.073
T3	2859.68d	24.87b	3.70c	0.051

CK is the control treatment applied with inorganic fertilizer, T1, T2 and T3 are treatments applied with biogas slurry of 20, 15 and 10% in volume concentrations, respectively

It illustrated that the intensity of soil aggregation could be increased by biogas slurry application, leading the loose contact between bone particles and soil matrix which promoted the formation of different loose pores as well as the improvement of soil quality.

Discussions

LAI, photosynthetic rate as well as chlorophyll (a+b) were important indexes which demonstrated plant growth status and related to the sufficiency of N element supply to some extent (Inoue, 2003; Roca et al., 2018; Feng et al., 2018). In this work, LAIs of CK treatment in stages of seedling, blossoming and fruiting, and pre-fruit swelling stage were the highest. However, the value decreased gradually until a lower value than T1 treatment in the late fruit swelling stage is reached. The photosynthetic rate of CK treatment was the highest in stages of seedling as well as blossoming and fruiting.

T1 treatment was the best at key stages of the crop yield like fruit swelling stage and fruit maturity stage over the tomato reproductive periods. It also maintained stable chlorophyll (a+b) content of the crop. However, there was an apparent phase effect for current fertilizer application modes and methods. The promotion effect of which existed only for a short time period and after application decreased gradually with the increase of time. Thus it demonstrates a poor sustainability.

In the present experiment, biogas slurry concentration and irrigation frequency of T1 treatment could make tomato different physiological indexes over the growth period more stable compared with CK treatment. This indicates that a lot of inorganic N as well as many active materials which stimulated the growth of plants could be more easily absorbed by plants compared with inorganic fertilizer applications. Thus, it enhanced the nutrient absorption and utilization efficiency of crop plants (Wu et al., 2013; Rive et al.,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10131029

2016). In all the treatments of the present experiment same irrigation methods were adopted. This verified that the integration technology and fertilizer application were appropriate. Water availability and nutrient absorption by crops with the same irrigation methods were optimum, wherein the reasonable nutrient concentration in the integration of water and fertilizer (Liang et al., 2013; Abalos et al., 2014; Al-Qurashi et al., 2015) could better promote the growth of crops.

The reasonable utilization of water and fertilizer was the key factor to enhance crop yield, quality and utilization efficiency of water and fertilizer (Hebbar et al., 2004). Al-Qurashi et al. (2015) showed that nutrient concentration was the key factor which influenced the crop yield. In this study, yield of T1 treatment was higher in spring and lower in fall than that of CK treatment. On the other hand, there was no significant difference between those two, illustrating that T1 treatment could satisfy the water and nutritional condition of tomato yield. Thus, T1 treatment could be an alternative for the replacement of traditional fertilizer use. However, crop quality determined market competitiveness. With the improvement of people's living standard, crop fruit quality has been paid more and more attention (Luo and Li, 2018). Nutritional quality of vegetables usually depends upon their genetic characteristics and environmental factors such as irrigation, soil and fertility. Yue et al. (2003) proposed that whether or not, tomato was delicious and tasty, that depends on the soluble sugar content as well as absolute content of the titrate acid. In this study, soluble sugar content and absolute content of the titrate acid of T1 and T2 treatment were higher than those of CK. Whereas, those of T3 treatment were the lowest, illustrating that appropriate biogas slurry concentration could effectively improve nutritional quality of tomato. After analysis, various organic and inorganic salts, microelements and soluble materials of many amino acids, hydrolase, etc. were found to be present in biogas slurry (Wu et al., 2013). These were generated via fermentation process, wherein the microelements not only involved directly in many physiological metabolic processes of plant but also were the basis of dry material accumulation (Xing et al., 2014). Besides, those active materials of amino acids and hydrolase had important regulatory functions of crop growth and development. Thus, application of reasonable concentration of biogas slurry as well as the utilization water-biogas slurry integration provided better conditions for the formation of crop yield as well as the quality enhancement.

Soil saturated hydraulic conductivity was not only an important factor for the calculation of soil water movement but also a comprehensive ratio coefficient which described the permeability of porous media (Liang et al., 2009). In addition, organic matter was the main driving factor of increasing soil saturated hydraulic conductivity (Peng et al., 2010).

Results from the present study showed that every treatment could increase not only soil saturated hydraulic conductivity but also soil organic matter content. Current research showed that organic matter could absorb more cations and make soil nutrient preserving capability and the buffering capacity high. Parallel to this it could also loosen the soil, contributing to the formation of soil structure (Nabel et al., 2017). From the soil microstructure image obtained in this study, it was seen that there were more soil debris, less soil pores and more compact contact between soil bone particles and soil matrix in CK treatment.

However, there was a microstructure distribution of flocculated mass in soil of T1 treatment. Besides, soil of T1 treatment possessed a loose contact between bone particles and soil matrix, more pores with larger pore size. In addition, soil debris with T2 and T3

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10131029

treatment were apparently lower than that of CK treatment. From initial analysis, there were a certain number of organic suspended particles in biogas slurry which entered into the soil with water during the irrigation process. Later on those were absorbed at the surface of soil particles and could be considered as input of exogenous organic matter. In the meantime, appropriate biogas slurry irrigation made microbial activities of crop root and enzyme catalyzed reactions active. This had contributed to the formation of soil aggregation and further enhanced water saturated water conductivity.

Application of fertilizer or CK treatment didn't possess the input of exogenous organic matters. In those, the enhancement of soil organic matter occurred due to rapid increase of soil effective nutrient content which quickly satisfied the nutritional demand of crop growth and development. Thus, a higher crop biomass as well as the resultant input of soil organic matter were obtained (Lee et al., 2009), which did not have a promotion effect for the formation of soil aggregation and pore.

Conclusions

(1) Compared with CK (the inorganic fertilizer) treatment, T1 (biogas slurry volume concentrations of 20%) treatment could provide more stable nutrient supply to tomato crop over the growth period, keeping LAI, photosynthetic rate, and leaf chlorophyll (a+b) content at a relatively stable level in tomato growth stage.

(2) T1 treatment could obtain yield which was comparable with that of CK treatment. T1 and T2 (biogas slurry volume concentrations of 15%) treatments could not only obtain higher absolute contents of soluble sugar and the titrate acid but also better coordinated the sugar acid ratio, whereas T3 treatment was adverse to the formation of tomato nutritional quality.

(3) In tomato seedling stage, N fertilizer application amount or biogas slurry concentration could be decreased appropriately. From the stage of blossoming and fruiting to fruit maturity stage, T1 and CK treatment could both increase N content in soil. The increase amplitude of T1 treatment was a little smaller (0.007 and 0.004 g/kg in spring and fall cultivation, respectively) than that of CK treatment (0.117 and 0.216 g/kg of CK treatment). This illustrates the much more stable trend which was appropriate for a long term application. N content in soil of T2 and T3 treatments decreased dramatically from the stage of blossoming and fruiting to fruit maturity stage.

(4) Each treatment could increase soil organic matter content, whereas the increase amplitudes of soil organic matter as well as soil saturated water hydraulic conductivities of T1 and T2 treatments were all higher than those of CK treatment. This illustrates that T1 and T2 treatment could be more effective to increase soil organic matter content and thus improve soil water holding capacity. Compared with CK treatment, different treatments with biogas slurry could increase the number of soil aggregates, decrease soil debris and increase the number of soil pores, wherein T1 treatment had the most apparent effect.

In all, T1 (biogas slurry volume concentrations of 20%) treatment could provide more stable nutrient supply for the growth and development of tomato. While not only obtaining the yield comparable with that of traditional fertilizer treatment but also improving tomato nutritional quality. T1 treatment improved soil environmental conditions, which could be used as reference for the replacement of fertilizer with biogas slurry.

The effects of different biogas slurry irrigation amounts on crop growth, fruit quality and soil environment, also the effects on other crops should be explored in future studies.

Abstract. In Turkey, in order to protect nature, there are strategies and categories depending on differences between local environmental conditions as in many countries in the world. The term of "protected environments", is also supported by laws as in other countries around the world. Natural protected environments are divided into the following three categories "Critical Environments under the Protection of Law" (SAPUL), "Natural Protected Environments with Qualifications" and "Sustainable Protection and Controlled Usage Environments", according to the resolution Conditions of Protection and Use of Natural Protected Environments, dated 2017, of Turkish Republic Ministry of Environment and Urban Planning. A map of Natural Protected Environments has been generated as a result of evaluation of 81 polygons which have been specified as natural protected environment borders by the Protection Commission of the Turkish Republic Ministry of Environment and Urban Planning, the strategy for determining (SAPUL) is approached as this article's subject. According to this strategy, in Çeşme (Izmir/Turkey) district, 20 polygons were specified to belong to the categories (SAPUL) among 81 polygons based on the terms and definition of the resolution of Izmir City and Çeşme district. Borders of natural protected environments, which were specified by the protection commission of the Turkish Republic Ministry of Environment and Urban Planning, each polygon is generated based on up-to-date land use information, have been formed based on the visuals taken from İKONOS satellite in 2017. The natural areas that carry the status of SAPUL were specified based on the specifications of the landscape and criteria of landscape assessment as the "use of the land", "live natural landscape", "historical landscape", Hereat, each polygon has been evaluated and mapped according to their specifications of landscape. Primarily, sample map has been created by using quantitative evaluation, which is supported by geographical information system (GIS). It is thought that this strategy will be useful for the resolutions that will be taken by the Committee on Conservation of Cultural Assets in Turkey in the Ministry of Environment and Urban Planning.
Keywords: *natural protected areas, Çeşme Peninsula, İzmir City, Çeşme District, environments under the protection of the law, GIS*

Introduction

In general, when the topic is about the protection of nature the following factors are considered: plants, animals, their environment where they grow and live and some pieces of nature which are thought to be valuable according to some criteria for the guarantee of human life (Caner, 2007; Yücel, 1995). Protection of nature covers protection of wild animals, varieties of plants, their natural living environments, securing landscapes with natural conditions, pieces of landscape and protective

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10311050

measurements (Çolak, 2001). The term of protection is shorty and newly defined as; the usage of the Earth's sources in a rationalist way (Mac Kinnon et all., 1986). The term "natural protected area", which is the main topic of this research, is known under different names in different countries. According to Gülez (1984) natural protected areas are defined as the environments that have topographical, hydrologic, biological, aesthetics- perceptive, cultural-historical values. In general, the environments that have historical and natural beauty, are considered as natural protected areas (Mumcu, 2009; Yenilmez Arpa, 2016). Nowadays, in so many countries, the necessity of protection of the inherited natural protected areas is accepted at national level. Thus, every nation participates in protecting biological diversity and resources with their own affords (Türkyılmaz, 1991).

Çesme District which is the research zone, is located in west of Anatolia and was a port town known as Ildiri. This port town was a part of Erythrai which was one of 12 Ion cities B.C. 1000. Erythrai was a very important city in 6th century B. C. Erythrai had good relations with Cyprus, Egypt and some western countries and developed its trade routes. Çeşme was under the rule of Persians, Romans and Byzantium.

It is important to determine the characteristics of the area before taking it under protection because the land should have some required characteristics to be under the protection (Özer, 2004; Buchwald, 1980; Heydemann, 1981; Mac Kinon, 1986; Green, 1985; Yücel, 1995; Yazıcı et al., 2017). The strategies of evaluation and classification of the lands must suit to three conditions;1) The strategy must be understandable for the planners, 2) Local people must take advise from naturalists, 3) Rational goals should be set to overcome the legal barriers (Frederic et al., 1988). Different kinds of grades are given to the areas according to the different criteria in the system of identifying priority of natural protection (Mackinnon et al., 1986). There are some measurements to specify and categorize the natural protected areas. Those measurements should be set with bio-ecologic (flora, fauna, habitat), geological, hydrogeological, geomorphologic characteristics of the landscape. In the evaluation made by the Ministry of Environment and Urban Planning in terms of specifications of landscape, it is considered if the field has the natural characteristics, manmade or not and it was supported by *GIS*. *GIS* is a database where bulky geographical data is collected, stored and processed. The data in *GIS* helps users during the period of decision for areas/locations to prevent planing problems of complex social, economic, enrivonmental problems (Yazıcı et al., 2017; Yazıcı and Gülgün, 2018a). Geographical Information System is an important support base for the protection of natural protected areas (Yazıcı et al., 2018b).

Materials and methods

Çesme District, which has cultural values, is one of the tourist centers of our country as well as of the world. Therefore, it is needed to be managed effectively in order to keep the sustainability of natural and cultural values. The main material of the research is the research field. Research field Izmir city (Turkey) Cesme district (*Fig. 1*).

Cesme, is one of the districts of Izmir, it is located in the west of the country, in the Aegean Region, in the southwest of the Karaburun Peninsula. Cesme district is 94 km away from Izmir city at 38.32 North latitude and 26.30 East longitudes. The district is surrounded by Urla district in the east Karaburun district in the north, and the Aegean Sea in west and south. Square measure of Cesme district is 260 km². Cesme has one town (Alaçatı) and four villages. According to the census in 2017, the district has a

DOI: http://dx.doi.org/10.15666/aeer/1801_10311050

population of 41.278 (Anonymous, 2019b) However during the summer/tourism period it increases more than 20 times. Tourism designate the economic structure. Cesme is one of the few places in Turkey that are domestic and international tourism centers.

Figure 1. *Cesme district general layout (Anonymous, 2019a)*

Material

Main materials of the research are research field (Cesme District) images taken from Ikonos satellite in 2017, image analyst (Intergraph) program, 1/25000 scale map of current natural protected area, 1/25000 scale map of Cesme District's topographic map and Microstation (Bentley) program that provides the geometrical corrections, Geomedia 6.0 program, Ipad Air tablet. *Table 1* shows the distinguishing specifications of "SAPUL" based on the conditions of Natural protected areas resolution dated 2017 by the Ministry of Environment and Urban Planning. In this chart, the explanations of "yes", "no", "partly" are quantitatively interpreted according to the specialists' opinions and evaluations. Specifications such as being *organic, inorganic, historical, renewable and sensitive*, specified 20 polygons out of 81 in the category of "SAPUL" (*Fig. 2*) based on the terms and definition of resolution of Izmir City, which was considered while scoring as seen in *Tables 3–7.* The methods in research studies of Green (1985), Mackinnon et al. (1986), Gülez (1990), Türkyılmaz (1991, 2005) and Uzun and Müderrisoğlu (2010) have been used while evaluating the specifications of the landscape.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10311050

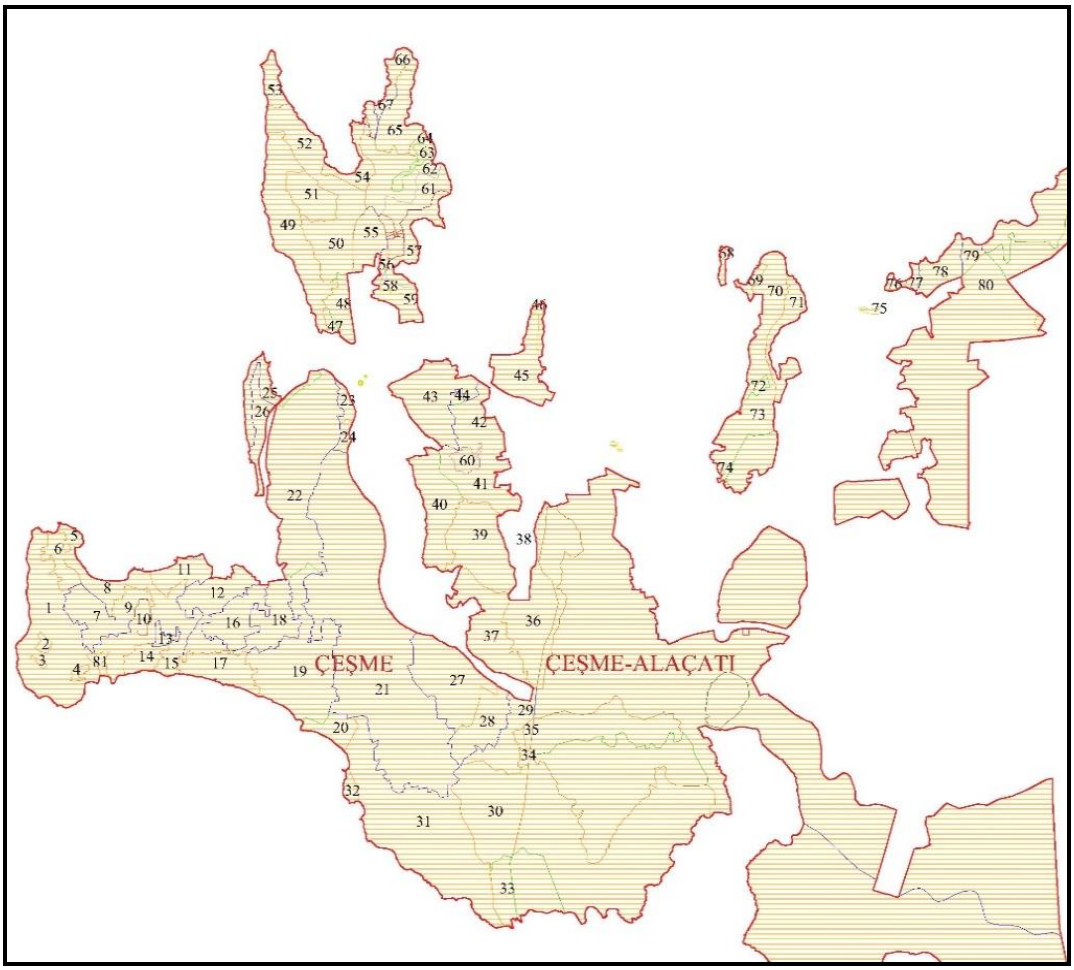

Figure 2. *Borders of natural protected area polygons determined by Protection Commission of Cesme District. (The numbers seen in the figure, were given by the researchers so the polygons in Figure 2. shown in the map could be evaluated. Those numbers are used in Table 15 to create the result map)*

Method

The research method was designed with the stages shown below.

First Stage: 6 tables, which show specifications of evaluation the research field, have been created in consideration of *Table 1* and each chart has been graded based on the matrix method in itself.

In the second stage, the materials, which show the distinguishing specifications, are questioned in consideration of *Table 2.* Border of cultural natural protected area polygons and status of each polygon given by protection commission was adapted with the grading method in the first stage. Qualitative evaluation such as "yes", "no", "partly" was quantified with GIS in order to create natural protected area map in terms of specifications of landscape.

The evaluating method has been approached based on the explanations given in *Table 2.*

Each polygon, which generates the map shown in *Figure 2,* was digitalized by using Ikonos satellite images with GIS program so the specifications of land use plan have been stated.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10311050

The land use map has been classified in four fields. These are:

1. Residential area
2. Agricultural areas
3. Tarsius spectrum + Garrigue + Forest areas
4. Litosolig + Garrigue areas

Table 1. *Distinguishing specifications of "environments under the protection of the law*

Distinguishing specifications of "environments under the protection of the law"		Yes	No	Partly	Opinions and evaluations of specialists
a	They have regional, national and global extraordinary ecosystems and species	12-13-14	7-8	9-10-11	Evaluated based on the specifications of organic natural landscape (*Table 3*)
b	Specifications of geologic, geomorphologic	7-8-9	2-3	4-5-6	Evaluated based on the specifications of Inorganic natural landscape (geologic-*Table 4*)
c	In general, came to existence without human effect	2-3-4	-2-(-3)	-1-0-1	Evaluated based on the specifications of cultural landscape
d	Because of human effect, it is under the risk of perishment	6-7-8	1-2	3-4-5	Evaluated based on the specifications of organic natural landscape (sensitivity *Table 7*)
e	The area does not contain human effect which is against its protection targets	18-19-20-21-22 (historical landscape)	9-10-11	12-13-14-15-16-17 (historical landscape)	Evaluated based on the specifications of (organic + inorganic) + historical landscape If there is touristic area, it is mentioned (*Tables 3–5)*
f	It contains large percentage of the local species that is expected to exist. It has the ability to transform itself to the intensity with natural process or limited interferences	19-20-21-22-23-24	10-11-12	13-14-15-16-17-18	Evaluated based on the specifications of (Natural organic landscape + renewable ability) (*Tables 3* and *6*)
g	In order to reach the aim of protection it has very vital and continuous interference	25-26-27-28-29-30-31-32	12-13-14-15	16-17-18-19-20-21-22-23-24	Evaluated based on the specifications of (Natural organic landscape + ability to renew itself + Natural inorganic landscape (*Tables 3, 4* and *6*)
h	It is surrounded by the use of areas that will help the area to reach the aims of protection when it is possible and necessary				It has been evaluated based on the natural zone around the polygon
ı	It could be managed by application of simple interference	8-10	3-4	5-6-7	It has been interpreted based on the ability to renew itself (*Table 6*)
i	It contains the reproduction area for the species that are aimed to be protected				It has been evaluated based on the floristic evaluation report of the area

Table 2. *Evaluation of acreage of the specifications of land use in polygons, which belong to "the natural areas protected under law" (SAPUL)*

Polygon No	Status of natural protected areas	Land use	Area (m^2)	Area (%)
	(SAPUL)	1		
	(SAPUL)	2		
	(SAPUL)	3		
	(SAPUL)	4		
		Total		**100.00**

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10311050

Cultural Landscape values of suitability, levels of suitability and abbreviations:

Suitability value	Suitability level	Abbreviation
4	Most suitable	M.S.
3	Suitable	S.
2	Partial suitable	P.S
1	Less suitable	L.S.
0	Least suitable	Lea. S.
-1	Not suitable	N.S
-2	Partially not suitable	P.N.S
-3	Not suitable at all	N.S.

Cultural landscape values of suitability in *Tables 3–7* have been set after considering the percentage of the 1 (residential) and 2 (agricultural) areas specifications. According to the given information in *Table 2,* if there is no residential area in the polygon the following calculations have been used; [(<1%) the least suitable] was given "0" point, if percentage of area (%) reached [(%1-33); not suitable] it was given "-1" point, if percentage of the area (%) reached [(%34-66); Partially not suitable] it was given "-2" points, if percentage of area (%) reached [(67-100%); Not suitable at all.] it was given "-3"points. According to the given information in *Table 2,* if there is no agricultural area in the polygon the following calculations have been used; [(<%1) The most suitable] "4" points were given, if the percentage of the area (%) reached [(1-33%); Suitable] "3"points were given, if percentage of the area (%) reached [(34-66%)]; Partial suitable] "2" points were given, if the percentage of the area (%) reached [(67-100%); Less suitable] "1"point was given. Thus, cultural landscape values of suitability have been set. 81 polygons have been evaluated separately by using GIS and 20 polygons have been determined as the areas will be under protection. Thus, the map of suggested natural protected areas has been created in *Table 15* and *Figure 10.*

Below it has been defined how the index values has been created in *Tables 3–7.*

According to the organic natural landscape index values (*Table 3*), each polygon is determined after considering the research studies on the field (each polygon has been checked and compared based on the 2017 satellite images and the actual area) and map of land use and listed according to their importance. According to this information; evaluation has been done as the followings. If the area is stony and rocky 1 point is given, if there is a Frigana-Maquis 2 points are given, if there is a forest 3 points are given, if there is an endemic and sensitive area 4 points are given.

Table 3. *Combining of qualifications of organic natural landscape index values and cultural landscape of suitability*

Organic natural landscape		Suitability value								Cult. lands.
		Residential areas				Agricultural areas				
		N.S. at all 67-100%	P.N.S 34-66%	N.S 1-33%	Lea.S <1%	L.S 67-100%	P.S 34-66%	S 1-33%	M.S <1%	
Index value		**-3**	**-2**	**-1**	**0**	**1**	**2**	**3**	**4**

		"no" scale score *(Table 1)*		*"partly"* scale score *(Table 1)*		*"yes"* scale score *(Table 1)*				

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10311050

In *Table 3* cultural landscape values of suitability points and organic natural landscape index points have been combined and total evaluation points have been created and organic natural landscape points have been created for each polygon.

In *Table 4* each polygon has been determined according to the map of land use and has been pointed based on their importance. Thus; Inorganic natural landscape specifications have been set based on the criteria given below.

Elevation from sea level: Accruement of the polygon positively according to sea level "0". It has been evaluated as +1.

Ascending slope: The map with scale 1/25000 of Cesme district was evaluated and if the landscape has 12% and above slope, it is accepted that the landscape has an ascending slope and it is estimated as caterpillars cannot be operated on the landscape. (If the slope is 12% > on the area the caterpillars will not be able to work in the area.

Shore-Edge: The polygons which has edges to shore next to the sea, has been evaluated +1 points.

Dune: The polygons which has edges to shore and has dune areas, has been evaluated +1 points.

Geologic- geomorphologic: If the cultural landscape point is 3 or above, it has been evaluated +1 points.

In *Table 4,* cultural landscape values of suitability and inorganic natural landscape index points have been combined and evaluation points have been created. Considering this table for each polygon, inorganic natural landscape points have been created (those points can be seen in *Table 15*).

Table 4. *Combining of inorganic natural landscape index values specifications and cultural landscape values of suitability*

Inorganic natural landscape		**Suitability value**								**Cult. lands.**
		Residential areas				**Agricultural areas**				
		N.S. at all 67-100%	**P.N.S 34-66%**	**N.S 1-33%**	**Lea.S <1%**	**L.S 67-100%**	**P.S 34-66%**	**S 1-33%**	**M.S <1%**	
Index value		**-3**	**-2**	**-1**	**0**	**1**	**2**	**3**	**4**	
Height	**1**	1	1	1	1	1	1	1	1	
Slope	**1**	1	1	1	1	1	1	1	1	
Shore-edge	**1**	1	1	1	1	1	1	1	1	
Dune	**1**	1	1	1	1	1	1	1	1	
Geologic-geomorphologic	**1**	1	1	1	1	1	1	1	1	
		2	**3**	**4**	**5**	**6**	**7**	**8**	**9**	
		"no" scale score *(Table 1)*		*"partly"* scale score *(Table 1)*			*"yes"* scale score *(Table 1)*			

In *Table 5,* each polygon has been determined according to the observations on the field and considering map of land use. Thus, in addition to the cultural landscape score if there is an urban protected area, it has been evaluated + 1, if there is an archeological protected area it has been evaluated +2. In *Table 5* each polygon has been evaluated separately and historical landscape score has been set up based on combining each index value with the values of suitability that creates cultural landscape by using matrix method.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10311050

In the *Table 5,* each polygon has been evaluated separately and natural landscape score has been set up based on combining each values of suitability with qualification of use of terrain that creates cultural landscape.

Table 5. *Combining of historical landscape specifications index values and cultural landscape values of suitability*

Historical landscape		**Suitability value**								**Cult. lands.**
		Residential areas				**Agricultural areas**				
		N.S. at all 67-100%	**P.N.S 34-66%**	**N.S 1-33%**	**Lea.S <1%**	**L.S 67-100%**	**P.S 34-66%**	**S 1-33%**	**M.S <1%**	
Index value		**-3**	**-2**	**-1**	**0**	**1**	**2**	**3**	**4**	
Urban protected area	**1**	1	1	1	1	1	1	1	1

Main findings and argument

The reason for evaluation each Polygon separately on each table (*Tables 9–14*) that is determined as "Environments under the protection of the law" (SAPUL) is because each polygon is evaluated based on the scoring of different systems as a result of GIS examination which was explained in the above table.

- Turkish Republic Ministry of Environment and Urban Planning protection commission has specified and mapped 81 polygons as a result of a study. In this study they wanted to specify what kind of status the polygons would have. In order to do so, the polygons, which create sensitive areas that will be protected under GIS environment polling, have been set up based on the point scoring system in the *Table* 7 and the areas that polygon cover their percentages has been given in *Table 8* and mapped in *Figure 3*.
- The map and the areas that polygons cover, which was specified as sensitive areas that will be protected by the law (SAPUL), are given in *Table 9* and *Figure 4* based on the point scoring system that belongs to forest areas that has qualifications of usage of landscape.
- The total scoring is given in *Table 15,* according to qualifications of the forest's ability to renew itself. The index value of the areas, which has the qualifications of forest zone, is given as "3" in *Table 9.*

Table 8. *The total areas and the areas the polygons with the status of sensitive areas that will be definitely protected cover based on specifications of usage of landscape and their percentages*

Usage of landscape	**Area (m^2)**	**Area (%)**
1	152 817.90	0.55%
2	3 609 881.10	12.9%
3	22 044 944.00	78.9%
4	2 133 453.70	7.6%
Total	**27 941 096.70**	**100.0%**

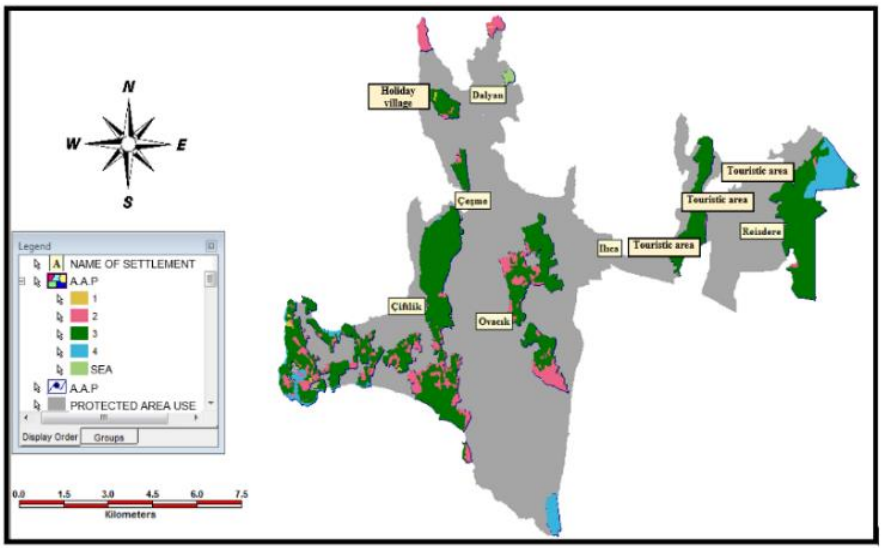

Figure 4. *Map belonging to Table 9*

- The map of the areas that polygons cover is shown in *Table 10* and *Figure 5.* Those polygons are known as sensitive areas that will be protected by the law according to rare species point scoring system. The total point scoring based on "sensitiveness" characteristic could be seen in *Table 15*. In *Table 10,* the index value has been taken as "4" for the polygons with "forest zone" qualification.
- The criterion score has been examined based on models that have been developed on CBS according to these sensitive areas that will be protected by the law. In *Table 15:*
  - Cultural landscape score is evaluated as ≥ 2. (Considering *Table 2:* It was considered to make a decision for the index value if the residential areas are less than agricultural areas in polygons).
  - Organic landscape score is evaluated as ≥ 7. (Considering *Table 3:* Forest formation and endemic-rare species were considered to make a decision for the index value).
  - Inorganic landscape score is evaluated as ≥ 3. (Considering *Table 4:* At least 3 qualifications that set the criteria of inorganic landscape, were considered to make decision for index value).
  - Sensitiveness score is evaluated as ≥ 0 (Considering *Table 7:* because the Sensitiveness is evaluated separately, it is not necessary to look for rare endemic species in polygon).
  - Renewing itself score is evaluated as ≥ 3 (Considering *Table 6:* Forest formation is considered to make decision for the index value in polygons).
- The Map and the area coverage of polygons are shown in *Table 11* and *Figure 6.* Those areas are known as sensitive that will be protected by the law (SAPUL) based on the points of cultural landscape, organic landscape, inorganic landscape and ability of renewing itself on the GIS platform. According to the qualifications given above, the total scoring could be seen in *Table 15*. Polygons in *Table 11*, the scores given above are evaluated as index values.

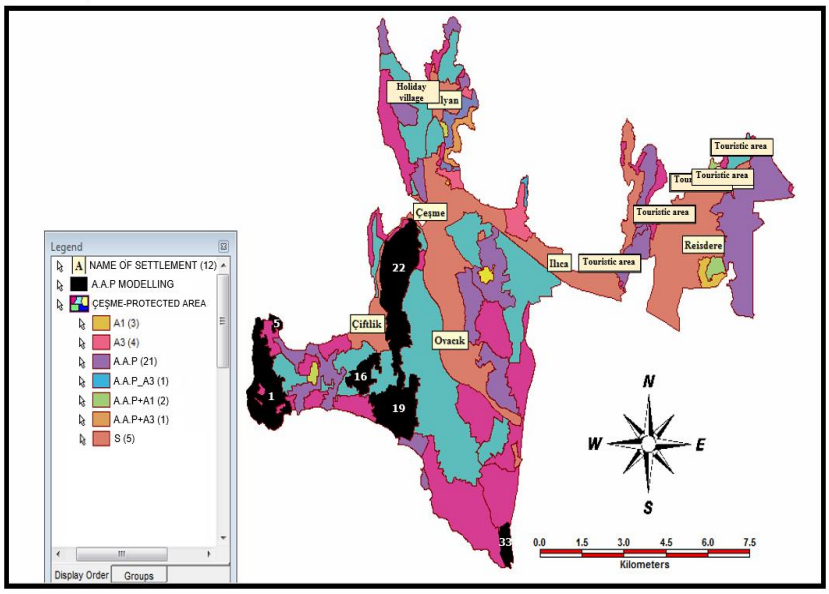

Figure 6. *Map belongs to Table 11*

- The criterion score has been examined based on models that have been developed on GIS according to these sensitive areas that will be protected by the law. In *Table 15*
  - Cultural landscape score is evaluated as ≥ 3 (Considering *Table 2:* residential areas' being so less and absence of agricultural areas are considered to make decision for the index value in polygons).
  - Organic landscape score is evaluated as ≥ 3 (Considering *Table 3:* forest formation existence is considered to make the decision for index value in polygons).
  - Inorganic landscape score is evaluated as ≥ 3 (Considering *Table 4:* at least 3 qualifications in inorganic landscape qualification table (*Table 4*) that set the criteria of inorganic landscape, were considered to make decision for index value).
  - Sensitiveness score is evaluated as ≥ 0 (Considering *Table 7:* it is not necessary to look for rare endemic species in polygon).
  - Historical landscape score is evaluated as ≥ 1 (Considering *Table 5:* at least 3 qualifications in historical landscape qualification table (*Table 5*) that set the criteria of historical landscape, were considered to make decision for index value).
  - Renewing itself score is evaluated as ≥ 3 (Considering *Table 6:* forest formation is considered to make decision for the index value in polygons).

The Map and the area coverage of polygons are shown in *Table 12* and *Figure 7.* Those areas are known as sensitive areas that will be protected by the law (SAPUL) based on the scores of cultural landscape, organic landscape, inorganic landscape, historical landscape and ability of renewing itself which has specifications of archeological protected areas on the GIS platform. According to the qualifications given above, the total scoring could be seen in *Table 15*. Polygons in *Table 12,* the scores given above are evaluated as index values.

Table 15 has been generated by obtaining usage of areas according to satellite visuals and based on the tables above scoring qualifications of "cultural, organic, inorganic, historical landscape and ability of renewing itself. Landscape criteria values have been evaluated based on the database of GIS (Geomedia). As a result of modeling done above, polygons mentioned in *Tables 9–14* have come forth and *Table 15* has been created. *Table 15,* landscape criteria score mirrors landscape criteria scores of 20 polygons among 81 polygons that has been specified as sensitive areas and will be protected by the law (SAPUL) by Protection Commission of the Ministry of Environment and Urban Planning. As a result, the "suggested map of natural protected areas" has been created *Figure 10.*

Results and suggestions

The scores of cultural, organic, inorganic, historical landscape and ability of renewing itself and sensitivity of the areas that will be protected by the law has been presented based on the area usage status which has been evaluated on GIS platform by the Protection Commission of the Ministry of Environment and Urban Planning in order to finalize the legal decisions about natural protection fast and accurate. As a result of the examinations that have been made above (modellings), 20 polygons, which will be evaluated as sensitive areas that will be protected by the law in 5 different maps have been appeared. Those maps have been appeared based on the charts. The polygons known as sensitive areas that will be protected by the law (SAPUL) is classified based on their types of the area usage. According to this:

- Areas of Cesme district is covered by residential areas 0.54%, agricultural areas 12.82%, scrub + garrigue + forest 78.27%, lithosolic + garrigue 7.58%. Scrub + garrigue + forest areas are 22.044.944.00 m² which is 11.79% of Cesme district's square measure.
- According to the result map of ability to renew itself only in 73rd polygon there is no forest area. But this 73rd polygon establishes a buffer zone between other polygons that has the protection status.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10311050

- According to the sensitiveness map; in the forest areas in 1st, 5th, 15th, 16th, 19th, 20th, 22nd, 23rd polygons, there are *"Juniperus oxycedrus* subs. *Macrocarpa"* (large size fruited bushy juniper) and *Pistacia lentiscus.* Also there are *Chia* (gumwood) in enough quantity. According to this map the areas with sensitive qualifications covers 54.84% in the polygons that have been determined as scrub + garrigue + forest sensitive areas that will be protected by the law (SAPUL).
- In the given maps in *Figures 4–8* and examined models, according to the evaluation which has been done based on the landscape criteria scores, 20 polygons have been determined as sensitive areas that will be protected by the law (SAPUL) (*Fig. 10; Table 15*).

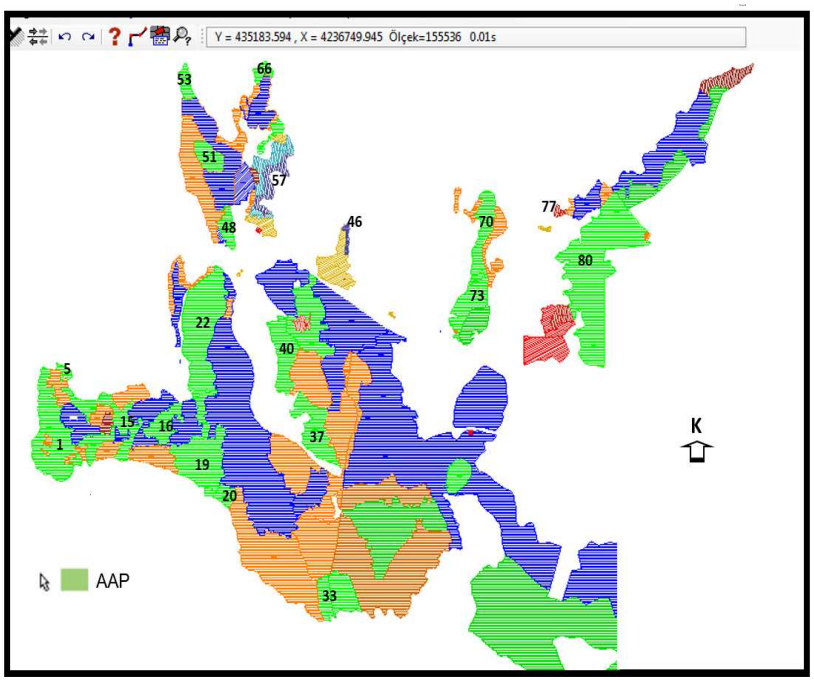

Figure 10. *The map that shows the sensitive areas that will be protected by the law*

It is aimed to suggest natural protected area mapping method supported by geographical information system which is based on true and scientific information in order to generate the maps of natural protected areas that are supposed to be prepared by the Cultural and Natural Heritage Preservation Board affiliated with the Ministry of Environment and Urban Planning. The results of the applications that will be obtained after the research studies are completed in Cesme district, will allow building a source and data to prevent disoperation which are still being applied. It is hoped that it will be an accurate and objective guiding method for the maps of natural protected areas that are supposed to be prepared by the Cultural and Natural Heritage Preservation Board affiliated with the Ministry of Environment and Urban Planning in Turkey as well as the other related institutions and organizations around the world.

(Received 25th Jul 2019; accepted 4th Dec 2019)

Abstract. The combination of rapid urbanization and industrialization expansion increased waste volumes. Most of the wastewaters generated from either domestic or industrial sources are still discharged without adequate treatment processes, and impact on the environment and public health. The objective of this paper was to provide a comprehensive literature review on the application of horizontal subsurface flow constructed wetlands in treating a variety of wastewaters, discussing its feasibility in pollutant removal efficiency and additional benefit in climate change mitigation through carbon sequestration. The following results were obtained: 98%, 96%, 85%, 90%, 92%, 88% for BOD5, COD, TSS, TN, NH_4 –N, PO_43- respectively in Kenya; 98.46% and 98.55% for COD and BOD5 in Indonesia; and ranges from 94-99.9%, 91.7-97.9% and 99.99% for BOD5, COD and TFC respectively in Costa Rica. Whereas in Ethiopia, the HSSFCW achieved the following abatement efficiencies: COD ranges from 58 to 80%, BOD ranges from 66 to 77%, TKN ranges from 46-61%, sulfates ranges from 53 to 82%, and NH_4 – N range from 64 to 82.5% for tannery wastewater treatment. For domestic wastewater treatment; 99.3%, 89%, 855, 84.05%, 77.3%, 99% and 94.5% were achieved for BOD5, COD, TSS, TN, PO_4^3-, TP, Sulfate, and TFC, respectively. In addition to improving water quality, CWs have a CSP. For example, CWs showed CO_2 equivalent of 4119.54 g C/m^2/yr CSP (carbon sequestration potential) which is 15118.7118 g CO_2. The methane equivalent to this amount of carbon sequestration is 604.748472 g/m^2/yr. Generally, research results indicated that constructed wetlands are efficient wastewater treatment techniques and should be encouraged for wastewater management as a strategy to reduce wastewater pollution. However, constructed wetland performance efficiency sustainability is affected by the operational conditions of HSSFCW including plant species, media/substrate types, water depth, hydraulic loading, and hydraulic retention time and feeding mode.
Key words: *carbon sequestration potential, horizontal subsurface flow, climate mitigation, wastewater, constructed wetland, performance evaluation, and greenhouse gases, carbon cycle*

Introduction

Globally, wetland ecosystems are more and more being used for the treatment and disposal of wastewater because they have been known as low-cost and operative treatment schemes (Brix et al., 2001). Their potential to advance the quality of water from inflow to outflow has been recognized (Donald, 1989) Constructed wetland schemes use a conglomerate of biological physical, and chemical parameters. The combination of rapid urbanization and industrialization expansion increased waste

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10511089

volumes. Most of the wastewater generated from either domestic or industrial sources are discharged still without adequate treatment processes. The discharging of untreated or partially treated wastewater by cities and industries causes an impact on the environment and public health resulting in the contaminated downstream water supplies becoming unfit for drinking, irrigation and recreational activities (Birhanu and Seyoum, 2007), due to the presence of nutrients, heavy metals, toxic organic pollutants and pathogens. Research reported by Bahri et al. (2008) also agreed that untreated wastewaters discharged into the freshwater bodies change the quality of freshwater. Besides deteriorating the freshwater bodies, the farmland soil characteristics are also changed due to using contaminated river waters or direct use of wastewater for irrigation. According to Bayrau et al. (2008) surveyed results in the case of Ethiopia outbreaks of waterborne diseases in addition to eutrophication of surface water and farmland resources are common.

The use of constructed wetlands for wastewater management is becoming more and more popular all over the world. This is due to its efficient wastewater management ability with cost-effective option in both developed and developing countries. Most of these systems are easy to operate, require low maintenance, and have low investment cost (Ballesteros et al., 2016; Langergraber, 2013). Today horizontal subsurface flow CWs (Constructed wetlands) are quite commonly used in many developed countries such as Germany, UK, France, Denmark, Australia, Poland and Italy. Constructed wetlands are also appropriate for developing countries but they are rarely investigated and implemented (Prasad et al., 2016). Water body deterioration is becoming a serious issue in developing countries due to indiscriminate discharge of wastewaters and lack of comprehensive management techniques. In developing countries constructed wetlands (CWs) are used to treat a wide variety of wastewaters such as domestic, municipal, industrial, landfill leachate as well as agricultural and highway runoff (Tilak et al., 2016). Wetland technologies are a reliable onsite wastewater treatment technology and work with a higher rate of biological activity which enables conversion of many of the pollutants that are contained in the wastewater into non-toxic byproducts and serve as secondary or tertiary treatment level that meets the regulatory standards. CWs have shown to successfully control macro (organic material, nutrients and pathogens) pollutants and provide high quality water used for irrigation, recreational and other reuse purposes. Generally, this technology serves as an active and low-cost alternative technology for the treatment of wastewater all over the world (Mustafa, 2013).

Treatment wetlands are technologies that are able to remove nutrients, toxic metals, organic pollutants, emerging contaminants and pathogenic organisms effectively (Belmont et al., 2009; Chen et al., 2012). Their effective pollutant removal is associated with several mechanisms involved in the constructed wetland systems. These are sedimentation, filtration, volatilization, adsorption, plant uptake and bacterial activity (Chazarenc et al., 2009; Ballesteros et al., 2016; Langergraber, 2013). The mechanisms of treatment in constructed wetland are complex processes which can happen simultaneously or sequentially involving microbial degradation, plant uptake, sorption, sedimentation, filtration and precipitation. In designing the good wetland, the main biological component in the CW is aquatic plants (macrophytes). However, it is important in determining the appropriate plant species that can survive in the wastewater environment, because only suitable plant species can treat a high concentration of pollutant in the waste water (Prasad et al., 2016). The selection of media type is also very important, because clogging problems are observed in subsurface flow constructed wetlands and linked hydraulic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10511089

retention time and hydraulic conductivity. Therefore, adequate selection of granular media could decrease the estimated wetland area and improve the removal efficiencies (Lopez-Lopez et al., 2015). The vegetation biomass from the constructed wetlands can provide economic importance to communities by harvesting it for biogas production, animal feed, fiber for paper making and compost (Lakshman, 1987).

They also have an important role in carbon sequestration (CS) and reports indicated that the highest CSP (carbon sequestration potential) was recorded for Typha latifolia (741.02 g m^{-2}/yr) followed by Phragmites australis (740.5 g m^{-2}/yr) and the lowest for Carexsp (137.37 g m^{-2}/yr) from wetlands (Maqubool et al., 2013). Generally, CW can provide economical on-site wastewater treatment that is both effective and aesthetically pleasing (El-Gohary, 2008), and become a popular subject among many community leaders, health officials, and home owners. However, in developing countries the use of CWs is certainly lower in comparison to their use in Europe or the United States, despite the enormous potential and the great necessity of these countries to implement low-cost treatment for better wastewater management strategy to achieve the required standards (Belmont et al., 2004; Zurita et al., 2006, 2008). In order to establish the performance of constructed wetland systems under different conditions various research studies have been carried out to investigate constructed wetland systems in the removal of pathogens, organic matter and nutrients. To date however, very limited research works on the performance of CW, especially under tropical conditions have been reported. Therefore, the purpose of this review paper was to provide a comprehensive literature review on the application of horizontal subsurface flow constructed wetlands in treating a variety of wastewaters, and to discuss its feasibility in pollutant removal efficiency and additional benefit in climate change mitigation through carbon sequestration.

Objective

This systematic review was aimed to assess and to provide a comprehensive literature review on the application of horizontal subsurface flow constructed wetlands in treating a variety of wastewaters, and to discuss its feasibility in pollutant removal efficiency and additional benefit in climate change mitigation through carbon sequestration.

Method

This review paper was written using searching key phrases “HSSF (Horizontal Sub Surface Flow) practice in the world”, “Factors affecting treatment efficiency and “benefits and limitation of Constructed wetland” in springer link, science direct, library genesis, jester, and www.nap.org searching web pages. From these search results, peer reviewed journals and review papers were used. The interpretation of the result of each document was done using bar graphs, lines and scatter plot in a Microsoft Excel. In view of the current demand of this review, the performance assessment assignment employed a range of tools to gather and analyze data from secondary sources. The review approach considered and used specific indicator parameters that are important for the environment. The parameters used include: Total suspended solids (TSS), Total phosphors (TP), Total Kjeldahl nitrogen (TKN), Biological oxygen demand (BOD), Chemical oxygen demand (COD) and NH_4-N (ammonia nitrogen).

Constructed wetland historical background

Natural wetlands are usually found between water bodies and terrestrial areas. These systems naturally screen and collect pollutants such as silt and nutrients as they migrate towards water bodies. Natural wetlands were historically used as wastewater discharge sites (Kadlec, 2003). This system is still used for wastewater treatment under controlled conditions and the use of constructed wetlands has increased significantly. The purposeful construction and study of wetlands to treat wastewater was started at the Max Plank Institute in 1952 by Seidel (Vymazal, 2011).

Research in this area has accelerated since 1985 because of the simplicity of the systems regarding mechanical operation, biological complexity and high level of treatment. The other attractive advantage for developing countries is that construction may be completed using local materials and labor. The first full scale horizontal flow constructed wetland was constructed and used in the Netherlands in the 1975 but vertical flow wetlands dated back to the time of Seidel (Kadlec, 2008). Horizontal subsurface flow constructed wetland is the most widely used technology in Europe. This technology is designed typically in a rectangular bed form, and contains planted macrophytes and lined with an impermeable membrane or made from concrete. Mechanically raw or pretreated wastewater is fed in at the inlet and passes slowly through the filtration medium under the subsurface of the bed in a horizontal path until it reaches the outlet zone before discharging via level control arrangement at the outlet (Vymazal, 2005).

Constructed wetland classification

General classifications

Constructed wetlands for wastewater treatment are typically classified into two types according to the wetland hydrology, i.e. free water surface (FWS) constructed wetland and subsurface flow (SSF) constructed wetlands (Saeed and Sun, 2012).

In the FWS system, the water flowing through the system is exposed to the atmosphere, while in the SSF system, water is designed to flow through a granular media, without coming into contact with the atmosphere. FWS wetlands can be subdivided into four categories based on their dominant type of vegetation: emergent macrophyte, free floating macrophyte, free floating leaved macrophyte and submerged macrophyte. However, the subsurface flow wetlands (which by definition must be planted with emergent macrophytes) can be sub-classified according to their flow patterns: horizontal or vertical (Vymazal and Kröpfelová, 2008).

Surface flow systems are further subdivided based on the type of macrophytes that grow on them as free floating macrophytes (e.g. duck weed and water hyacinth), submerged macrophytes, free floating leaved macrophytes and floating mat macrophytes. FWS systems are similar to natural wetlands, with shallow flow of wastewater over saturated substrate. Whereas, in SSF systems, wastewater flows horizontally or vertically through the substrate which supports the growth of plants, and based on the flow direction, SSF constructed wetland is divided further into horizontal flow (HF) and vertical flow (VF) systems. A combination of various wetland systems was also introduced for the treatment of wastewater, and this design generally consisted of two stages of several parallel constructed wetlands in series, such as VF-HF CWs, HF-VF CWs, HF-FWS, CWs, and FWS-HF, CWs (Vymazal, 2013). In addition, the multiple-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10511089

stage constructed wetlands that were comprised of more than three stages were used (Kadlec, 2008). In the recent years, enhanced artificial constructed wetlands such as artificial aerated CWs, baffled flow CWs, Hybrid towers CWs, step feeding CWs and circular flow corridor CWs have been proposed to enhance the performance of the system for wastewater treatment (Wu et al., 2014). According to Haberl (1999) design configurations of constructed wetlands are classified on the basis of the following parameters, as illustrated in *Figure 1*.

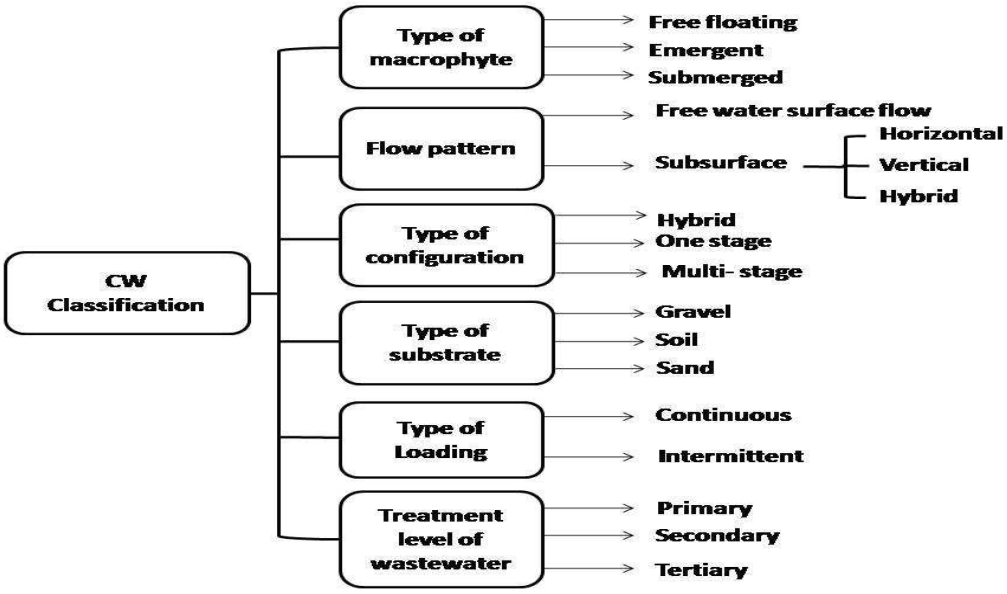

Figure 1. *Classification and types of constructed wetland systems. Performance evaluation of constructed wetlands (Haberl, 1999)*

Performance evaluation of constructed wetlands

Constructed wetlands are considered as natural treatment processes to stabilize, sequester, accumulate, degrade, metabolize and mineralize pollutants. They are used for a wide range of wastewater treatment such as municipal, domestic, agricultural, industrial, acid mine drainage, petroleum refinery wastes, compost and landfill leachates, and storm wastewaters (Vymazal, 2005). The treatment system involves macrophytes, substrates and microorganisms able to improve the water quality for reuse purposes. Macrophytes and Medias are an active component of horizontal subsurface flow constructed wetland (Vymazal, 2011). The selection of media type is also very important, because clogging problems are observed in subsurface flow constructed wetlands and linked hydraulic retention time and hydraulic conductivity (Lopez-Lopez et al., 2015).

Wastewater treatment is accomplished through the integrated combination of physical, biological and chemical interactions among biotic and abiotic components of the ecosystem and macrophytes cultivated in constructed wetlands make one of the basic components in the treatment process.

They influence plant microorganism's wastewater interactions by providing microbial attachment sites, sufficient wastewater residence time, trapping and settlement of suspended wastewater components as a result of resistance to hydraulic flow, surface area for pollutant adsorption, uptake and storage in plant tissue and diffusion of oxygen from aerial parts to the rhizosphere (Kyambadde et al., 2005). Wetlands remove metals using a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10511089

variety of processes such as filtration of solids, sorption onto organic matter, oxidation and hydrolysis, formation of carbonates, formation of insoluble sulfides, binding to iron and manganese oxides, reduction to immobile forms by bacterial activity, and uptake by plants and bacteria. Metal removal rates in both surface flow and subsurface flow wetlands can be high, but can vary greatly depending upon the influent concentrations and the mass-loading rate (Vymazal, 2005).

A study conducted in Kenya to assess the effectiveness of CW in treating domestic wastewater showed that the removal of BOD5, TSS, COD, TN, NH4-N and Orthophosphate were highly effective with a removal value of 98%, 85%, 96%, 90%, 92%, and 88%, respectively (Nyakango, 1999). This was mainly because this wetland consists of a combination of an SF system followed by three SSF wetland cells in a series adjacent to it. A case study conducted in Italy, to assess the treatment performance of an SSF CW by Pucci et al. (2000) showed high removal efficiencies for COD (93%), TSS (81%), hygienic parameters (TC 99%, FC 99.7%), but relatively low for nitrate (55%), total nitrogen (50%) and ammonium (30%), and very low for total phosphorus (20%). This is mainly due to poor nitrification and denitrification in the system. There is substantial evidence in the design of CW that a number of cells in series can consistently produce a higher quality effluent. Because this process minimizes the short-circuiting effects of any one unit and maximizes the contact area in the subsequent cell (Gearheart, 2004).

Constructed wetland contaminant removal mechanisms

Nitrogen removal mechanisms in wetland are nitrification in aerobic zone, de-nitrification in anaerobic zones which release N_2 and N_2O gases, plant uptake, sedimentation, decomposition, ammonia volatilization, and accumulation of organic nitrogen in gravels because of redox potential of hydric sediment conditions (*Fig. 2*).

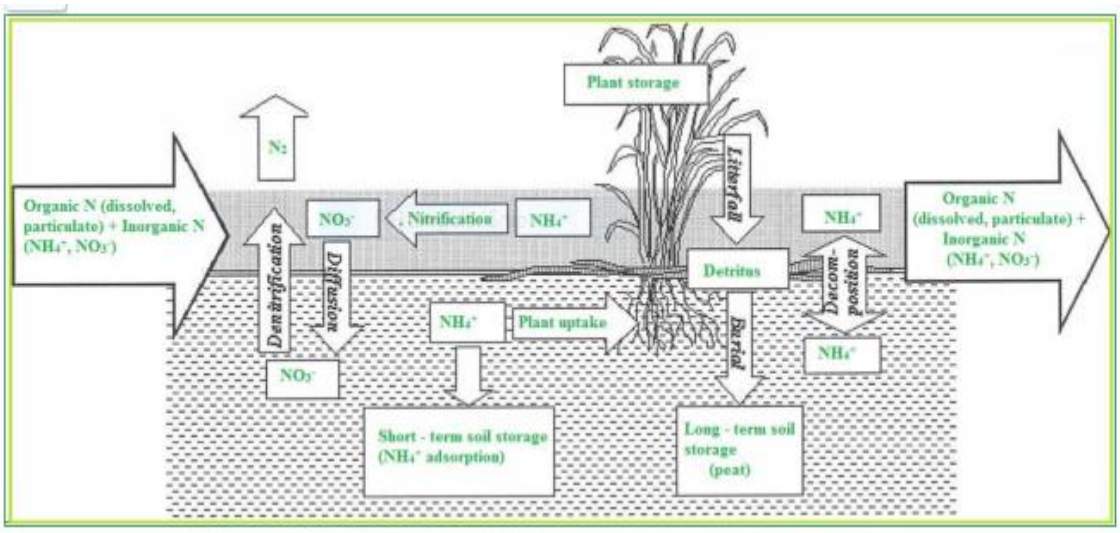

Figure 2. *Nitrogen removal processes in wetland (Vymazal and Kröpfelová, 2008)*

The fate of phosphorus is quite different in wetland soils, since there are no mechanisms comparable to de-nitrification as phosphorus has no gaseous phase.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10511089

Consequently, plant uptake, sorption, decomposition and long-term storage occur, and then phosphorus tends to accumulate in wetlands. Precipitation of phosphate minerals can provide a significant sink for phosphorus in wetlands with large stores or inputs of iron and aluminum or calcium (*Fig. 3*) (Vymazal and Kröpfelová, 2008).

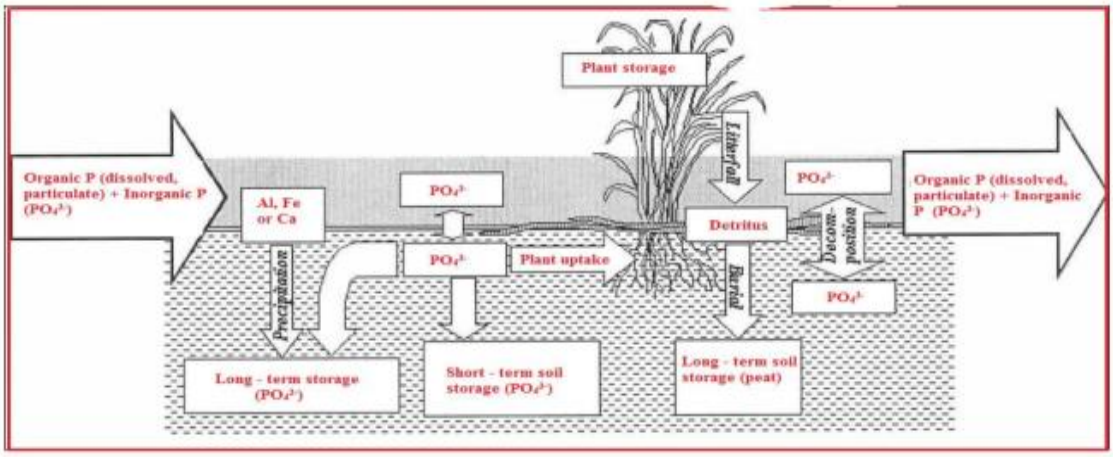

Figure 3. *Phosphorus removal mechanisms (Vymazal and Kröpfelová, 2008)*

The wetland treatment mechanism is a dynamic process acting wastewater purification under the cooperation of emergent macrophytes, substrates and attached microorganisms. In general, in constructed wetlands it is important to study biomass accumulation and nutrient flux in order to understand the dynamics of nutrients.The carbon cycle in wetlands has been investigated to understand the linkage between biomass generation and carbon sequestration (Kayranli et al., 2010). Wastewater treatment may also serve as a carbon sequestration offset (Rosso and Stenstrom, 2008). Wetland ecosystems are acting as a net carbon emission and sequestration systems depending on the time scale and hydrology operational strategies (Whiting et al., 2001), and as a component of a larger system treating wastewater (Rosso and Stenstrom, 2008). Constructed wetlands are passive natural processes and avoid carbon emission equivalent of 1.3 Mt C/yr for every 1.0 MGD as compared to conventional high rate treatment facilities such as activated sludge. There are many mechanisms for the capture and release of carbon in a wetland (*Fig. 4*). Pathways for the release of carbon in the constructed wetland system are slow decomposition, respiration, and physical removal. Photosynthesis is the process whereby a plant transforms atmospheric carbon in the form of CO_2 into the carbon of the plant tissue or biomass. The process of plant respiration releases some CO_2 to the atmosphere as a byproduct of cellular growth. In addition to respiration, plants release carbon as a byproduct of decomposition in the form of CO_2 and CH_4 (Burke, 2011).

Factors affecting the performance of constructed wetlands

Temperature

This is a key environmental factor that determines the activity of nitrifying bacteria and the de-nitrification potential in treatment wetlands (Langergraber, 2013). Nitrogen removal by biological means is most efficient at 20-25 °C and temperatures above this

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10511089

affect both microbial activity and oxygen diffusion rates in the constructed wetlands. The microbial nitrification and de-nitrification activities can decrease considerably at water temperatures below 15 °C or above 30 °C, and most microbial communities for nitrogen removal function at temperatures greater than 15 °C (Kuschk et al., 2003). Literature revealed that the activity of de- nitrifying bacteria in constructed wetland sediments is generally more robust in spring and summer than in autumn and winter and the overall removal rate of nitrate is higher in the summer than in winter (Oostrom, 1994). De-nitrification is commonly believed to cease at temperatures below 15 °C, but some studies have demonstrated de-nitrification activity at 14 °C or lower temperatures. Richardson et al. (2004) reported that the optimum temperature range for nitrification is 30-40 °C in soils and the optimal ammonification is carried out at 40-60 °C at the optimal pH between 6.5 and 8.5. At low temperature, nitrification is insufficient to prevent a net increase in ammonia concentration due to ammonification (Akratos and Tsihrintzis, 2007).

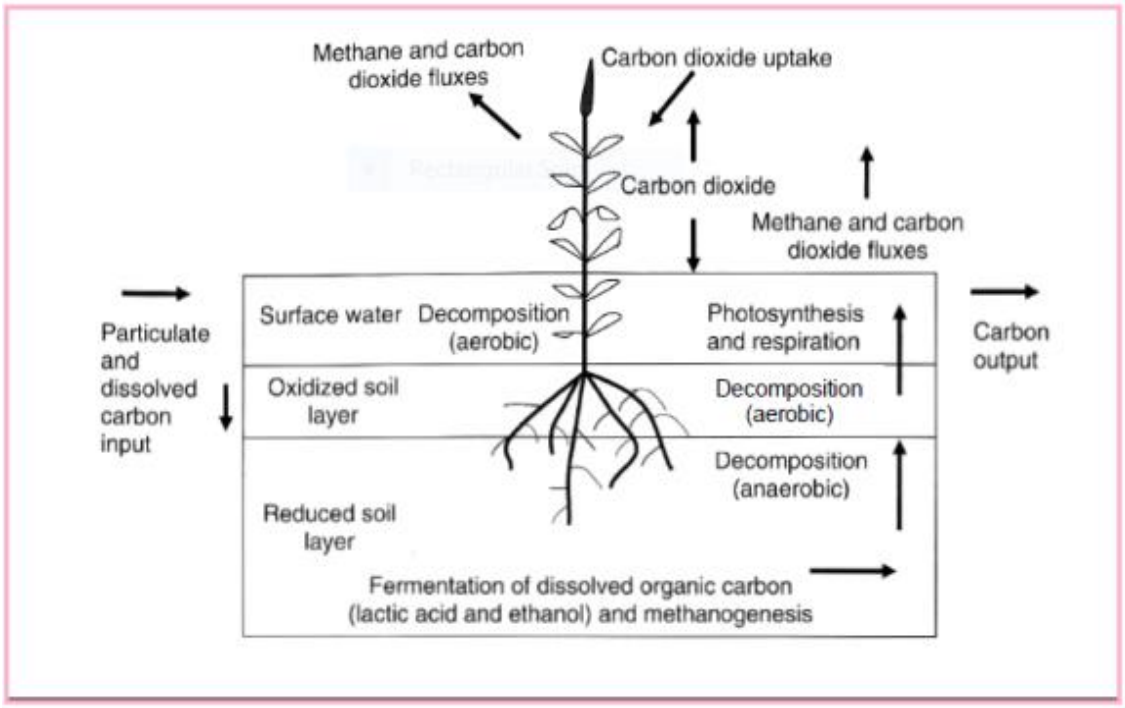

Figure 4. *The carbon cycle (Kayranli, 2010)*

HRT

The high purification efficiency of constructed wetlands can be achieved by choosing suitable growth media. Particle size, surface nature, bulk porosity and pore spaces of the growth media are important factors in selection of media type for wastewater treatment. Growth media provide not only physical support for plant growth but also additional sites for biofilm growth and the adsorption of nutrients, heavy metals and promote the sedimentation and filtration of pollutants. In general, the inconsistent treatment efficiency of constructed wetlands depends on the type of feeding mode, the plant types and type of media used (Abdelhakeem et al., 2016). According to Huang et al. (2000) explanation, ammonium and total Kjeldhal Nitrogen (TKN) concentrations in treated effluent decreased diagrammatically with increased wastewater retention time. In most

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10511089

wetland systems, efficient nitrogen removal requires longer retention time compared with organic matter (COD and BOD) removal efficiency. Accordingly, nitrogen removal efficiency varies greatly with flow conditions and HRT (Taylor et al., 2006).

In subsurface constructed wetlands, media perform the function of rooting material for macrophytes surface for microbial biofilm growth, screen organic and inorganic suspended matter, and distribute inflow and collect outflow water (U.S. EPA, 1993). Keeping the water level below the surface of the bed, this reduces the risk of human contact with pathogens, and reduces the opportunities for breeding vector organisms such as mosquitoes. Media can also provide adsorption sites for phosphorus (Kadlec, 2003). According to this researcher, potentially active industrial byproduct substrates include blast furnace slag, crushed rock, fly ash, and crushed concrete, burnt oil shale, iron ochre and wood chips. The microorganisms responsible for the degradation of pollutants are located at the surface of the media and the smaller sized media has a larger surface area than the coarser media (Vymazal and Kröpfelová, 2008).

Well graded media (containing all gravel sizes in the selected range) is better than poorly graded media as it offers greater pore space and provides good removal of particulate matter. In general, the substrate alone also provides significant wastewater treatment, but vegetation further improves treatment efficiency (Abdelhakeem et al., 2016). Therefore, the high purification efficiency of constructed wetlands can be achieved by choosing suitable growth media.

Types of plant species

Plants are often grown in gravel beds to stimulate uptake and create suitable conditions for the oxidation of the substrate, thereby improving the ability of the system to treat the wastewater and create aesthetic value, exhibit several properties which enhance wastewater treatment processes and thus, make them an essential component of the treatment wetland. These properties influence wastewater treatment through physical effects such as filtration, provision of surface area for the growth and attachment of microorganisms and regulation of undesirable water temperature as well as surplus algal growth. Macrophytes are the main biological component of wetlands and their presence has been hypothesized to play a key role in wastewater remediation (Luckeydoo et al., 2002). Macrophytes are also play an important role in wastewater treatment through uptake of nutrients, surface bed stabilization and other mechanisms (Kadlec, 2008). Wetland plants must survive the potentially toxic effects of the effluent and enhance the treatment process of wetlands in several ways such as filtering wastes, regulating flow, providing surface area for microbiological treatment, providing shed and controlling algae growth, contributing oxygen to the cells, taking up and storing some metals and nutrients from the wastewater (Kyambadde et al., 2005).

Metabolically, plants take up pollutants; produce organic carbon and oxygen, thereby improve the water to varying extents. They are not only assimilating pollutants directly into their tissues, but also act as catalysts for purification reactions by increasing the environmental diversity in the rhizosphere, promoting a variety of chemical and biological reactions that enhance purification. Several studies have shown that plants enhance treatment efficiency by providing a favorable environment for the development of microbial populations and by oxygenating the system. The roots of macrophytes provide surface areas for microbial growth and aerobic zones in constructed wetlands. The root facilitates various physical and biochemical processes caused by the relationship of plants, microbial communities, soil and contaminants. Wetland systems with

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10511089

vegetation typically remove greater amounts of total nitrogen than non-vegetated systems (Taylor et al., 2006). Nutrient removal by the emergent plants is achieved by two processes: absorption of the plant itself and microorganism activity around the rhizome (Cooper and Boon, 1987). In general, the main role of macrophytes in constructed wetlands is to promote microbial growth with the media surfaces, and to assist the permeation velocity of the wastewater for pollutant treatment efficiency (*Table 1*).

Table 1. *Pollutant removal processes in surface flow constructed wetland (Tousignant and Fankhauser, 1999)*

Pollutant type	Removal process
Organic material (COD and BOD)	Particular organic matter is removed by settling and filtration then converted to soluble BOD Soluble organic matter is fixed by biofilms and degraded by attached bacteria in the biofilm on stems, roots sand particles etc.
Suspended solids (TSS)	Filtration Decomposition by bacteria during long retention time
Nitrogen	Nitrification and de-nitrification in biofilm Plant and microbial uptake
Phosphorus	Adsorption (retention in the media) Precipitation with Ca, AL or Fe
Pathogens	Filtration, adsorption, predation (feeding) by protozoa Die-off due to long retention times
Heavy metals	Precipitation and adsorption Plant uptake
Organic contaminates	Adsorption by biofilm and clay particles Decomposition due to long retention time and by bacteria

Other factors

Other important factors are wetland depth, pH, and DO. The nitrification and denitrification process depend upon water pH, the presence or depletion of dissolved oxygen, hydraulic loading rate, and the hydrological period of the wetland. At low DO concentration, nitrification occurs in the aerobic zone but denitrification occurs in the anoxic zone (Kadlec, 2008). The biofilm may improve the denitrification; because of algae provide a desirable carbon source for denitrifies (Mariñelarena and Di Giorgi, 2001). In general, in order to maintain and improve nitrogen removal and water quality in constructed wetlands, attention should be given to factors that promote the growth rate of macrophytes and bacteria, such as planting depth, harvesting time, optimization of temperature, pH, DO and HRT.

Performance efficiency of horizontal sub surface flow constructed wetland (HSSFCW): a case in other countries

This section presents different macrophytes used for treatment of wastewater in constructed wetland and their effectiveness in treating wastewater pollutants. The focus of each case study is according to parameters related to the overall constructed wetland design, macrophyte species, hydraulic loading rates and the efficiency of pollutant removal. In order to evaluate the performance efficiency of a CW unit, the percentage of concentration reduction and mass removal is reported. The wetland effluent is being

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10511089

irrigated on vegetation, nutrient levels in the effluent do not need to be as strict as for direct discharge into a water course (Tousignant and Fankhauser, 1999). These systems are highly effective at improving water quality have many benefits such as habitat creation and low-cost operations (Kadlec, 2008). According to Mustafa (2013), the monitoring of horizontal flow constructed wetland indicates that the general performance of the system was good and it successfully reduced pollutants even under fluctuating pollutant loading resulting from power breakdown. The average reduction of BOD concentration over the treatment periods was 50% with mean effluent concentration of 34 mg/L. Whereas, the average removal efficiency of the treatment system for COD, TSS, ammonia–nitrogen, orthophosphate and fecal coliform were 44%, 78%, 49%, 52% and 98% with mean effluent concentrations of 68.3 mg/L, 45 mg/L, 9.7 mg/L, 3.7 mg/L and 3.0 x 10^3 CFU (Colony-forming units)/100 ml respectively.

In general, the monitoring of horizontal flow constructed wetland indicates that it was good and successful in reducing pollutants from wastewater up to the required standards even under fluctuating pollutant loading. The outcomes revealed that if constructed wetlands are properly planned and operated, they can be used as secondary or tertiary treatment level under local conditions and finally delivers high value water that can be used for landscape irrigation and also for other helpful uses. The COD removal efficiency of HSSFCW even at low concentration which might be due to high degradation rate in the wastewater collection systems and in settling tank before entering the CWs. In overall, the results obtained in Indonesia, Thailand, and Costa Rica revealed that, the local macrophytes and local natural substrates can perform successfully in the treatment of domestic wastewater (*Table 2*). The organic contaminants and pathogens can be removed successfully, therefore, the treated water can be used safely for irrigation, fishery or out-door uses. In addition, the treated water can replace a part of the fresh water need supplied from the pipe distribution systems and be potential to protect surface and ground water reduces from the pollutants. Moreover, the use of macrophyte creates a green space in a single house yard or green public views for neighborhood (Qomariyah et al., 2017).

Table 2. *The effective removal of pollutants in CWs with local macrophytes and natural substrates (Qomariyah et al., 2017)*

Type and size of CW	Type plant	Type of substrate	Country	Removal efficiency (%)
HSSFCW (1.7 x 0.7 x 0.7 m)	C. papyrus	Sand & gravel	Indonesia	BOD=98.55% COD=98.46% TSS=88 – 96% Detergent=99.86%
HSSFCW (2 x 1 x 1 m)	Canna & Helicona	Gravel	Thailand	BOD=94-99.9% COD=42-83% TSS=88%-96% TN=4 – 37% TP=6 – 35%
HSSFCW (14 x 1.2 x 0.6 m)	Coix lacrymajodi	Crushed rock	Costa Rica	BOD=94-99.9% COD=91.7-97.9% FC=99.99%

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10511089

The performance efficiency of subsurface flow constructed wetland in Italy done by Pucci et al. (2000) indicates that it has high removal efficiency for COD (93%), TSS (81%) and total coliform (99%), but relatively less removal for nitrates (55%), total nitrogen (50%), ammonium (30%) and total phosphorus (20%). This is mainly due to poor nitrification and denitrification in the treatment system. A study done in Kenya also revealed that the effectiveness of the constructed wetland in treating domestic wastewater and indicated a removal efficiency of 98%, 85%, 96%, 90%, 92% and 88% for BOD5, TSS, COD, TN, NH_4–N and PO_4 respectively (Nyakango, 1999). This achievement was due to the wetland design which consists of a combination of a surface flow system followed by three subsurface flow wetlands in a series adjacent to it.

The removal efficiency of constructed wetlands varies with hydraulic retention time, hydraulic loading, wetland design, temperature, substrate and vegetation. Although considerable number of reports has contributed to our understanding of the physical, chemical and biological processes that facilitate the removal process, inconsistence results suggest that further studies are required to optimize the system functioning. For example, many scholars show that, a wetland scheme with vegetation has advanced efficiency of removal than that without plants (Bwire et al., 2011) although others did not notice any significant change between planted and unplanted systems (Baldizon et al., 2002). Similarly, the percentages of nutrient (nitrates/nitrites and phosphates) removal obtained in the planted constructed wetland cell were higher than the averaged percentages of nutrient removal rates in the unplanted cell.

Thus, the average nitrate/nitrite percentage removal was 58.1% for planted cells and 21.6% for unplanted cell while the phosphate percentage removal averaged 40.1% for planted cells and 5.2% for unplanted cell (Mairi et al., 2012). Bacteria may be reduced by sedimentation, chemical reactions, natural die-off and predation by zooplankton, nematodes, lytic bacteria and attacks by bacteriophages (Denny, 1997). The role of plants related to the treatment of wastewater is the physical effects brought about by the presence of the plants. The macrophytes alleviate the surface of the beds, offer good condition for physical filtration and deliver enormous surface area for attached microbial growth (Brix and Schierup, 1989). Furthermore, macrophytes reduce the velocity of wastewater into the wetland system and also supply oxygen at the root zone which is used by aerobic microbes, thereby enhancing purification process of wastewater in addition to purification done by anaerobic microbes (Watson et al., 1989).

The performance efficiency of different constructed wetland systems that contain different HRT, substrate, plant species and wastewater type were reviewed in order to regulate the performance of constructed wetland parts in elimination of contaminants. The influent and effluent concentrations including percentage removal were summarized in *Table 3*.

Table 3. *HSSFCW percentage abatement in different locations planted with Phragmites australis*

DOI: http://dx.doi.org/10.15666/aeer/1801_10511089

As indicated in *Table 4,* the nitrogen removal in constructed wetlands depends upon system design, environmental chemistry (roots, plants, water and sediments), plant uptake, available carbon and material type. The mean removal efficiency of the planted (reeds) and unplanted constructed wetlands during the three months of warm and cold study periods are indicated in *Figure 5*. In general, proper performance and high removal at the first treatment unit (septic tank) increases the efficiency of the treatment plant (Farzadkia et al., 2015).

Table 4. *Treatment efficiency of HSSFCW in different countries*

Type of waste water	Type of media	Plant type	HLRL/D	HRT/D	Removal efficiency	Country	Reference

HLR = hydraulic loading rate, HRT = hydraulic retention time

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10511089

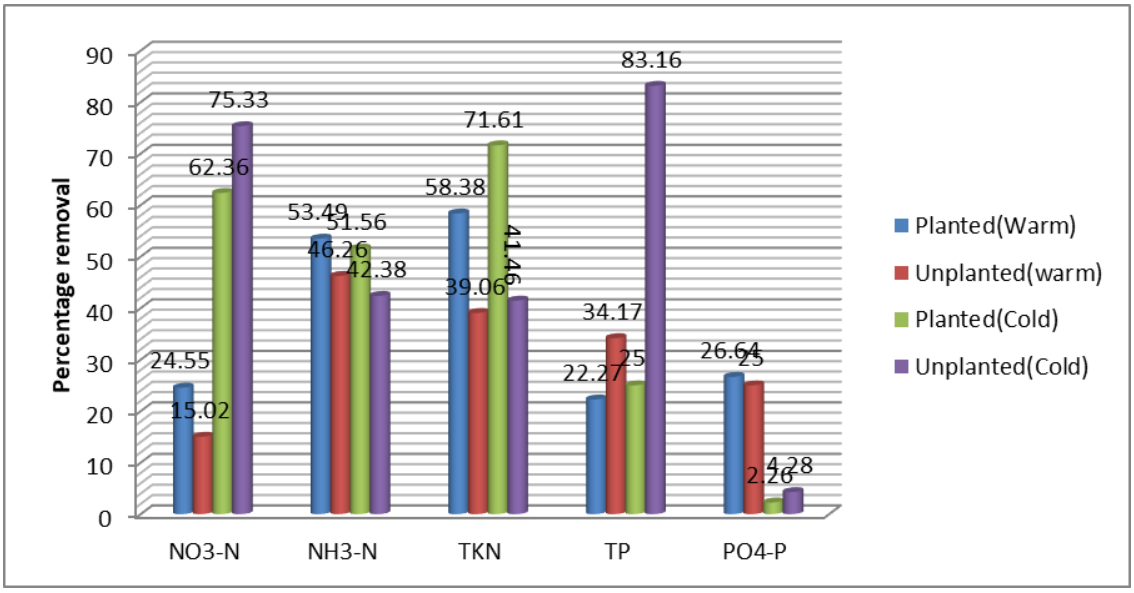

Figure 5. *Effect of vegetation, climate and media on nutrient removal (Farzadkia et al., 2015)*

The mean influent concentration of COD, TSS, NH4–N, NO3–N and PO4–P in January were 144, 54, 96, 2.76 and 3.62 mg/L, respectively. The effluent concentrations after treating with constructed wetland were 64, 8, 62, 1.69 and 3.55 mg/L, respectively. The mean percentage removal reductions for COD, TSS, NH4–N, NO3–N and PO4–P in this month were 55%, 85%, 35%, 39% and 2%, respectively. The mean influent concentrations of these pollutants in February were 192, 38, 63, 2.91 and 4.12 mg/L, respectively. The mean effluent concentrations were 64, 4, 28, 2.33 and 1.05 mg/L, respectively. The mean percentage removal efficiency of the wetland was reached 66%, 89%, 55%, 20%, and 75% for COD, TSS, NH4–N, NO3–N and PO4–P, respectively. In hydrologic comparison in the constructed wetland indicated that the COD, TSS, NH4–N, NO3–N and PO4-P reductions were considerably greater in February compared to January. This was due to the lower HLR and greater HRT in February compared to January. The major mechanisms of TSS and COD removals in constructed wetlands are sedimentation, filtration and physical entrapment in the void pores of the sand and gravel medias. The higher HRT also allows for greater physical settling of suspended particles, which reduces the TSS and the higher residence time allows wetland plants to uptake nutrients effectively thereby decreasing the effluent concentrations (Tilak et al., 2016). The nitrogen content of Pistia stratiotes, Typha latifolia and Lemon grass in the subsurface flow constructed wetland were 37.4 g/kg, 27.1 g/kg and 15.8 g/kg, respectively.

The phosphorus accumulation capacity of these plant species were also 8.4 g/kg, 2.96 g/kg and 2.29 g/kg, respectively for Pistia stratiotes, Typha latifolia and Lemon grass in the constructed wetland (*Fig. 6*) (Tilak et al., 2016). Subsurface flow constructed wetlands are good in utilizing pollutants in a symbiotic relation between aquatic plants and microorganisms in the media and the plant root system. Composite organic compounds confined in wastewater will be used up by plants as a nutrient, while the root structure of the aquatic plants will yield oxygen that can be used as energy or catalyst for a sequence of metabolic courses for heterotrophic aerobic microorganisms. Plants that are usually used include Cyperus alternifolus, Canna indica,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10511089

Phragmites australis, Typha spp., Scirpus spp., etc. these plants reduce the concentration of BOD, COD, ammonia, nitrites, phosphorus and bacterial contaminants (Wijaya et al., 2016).

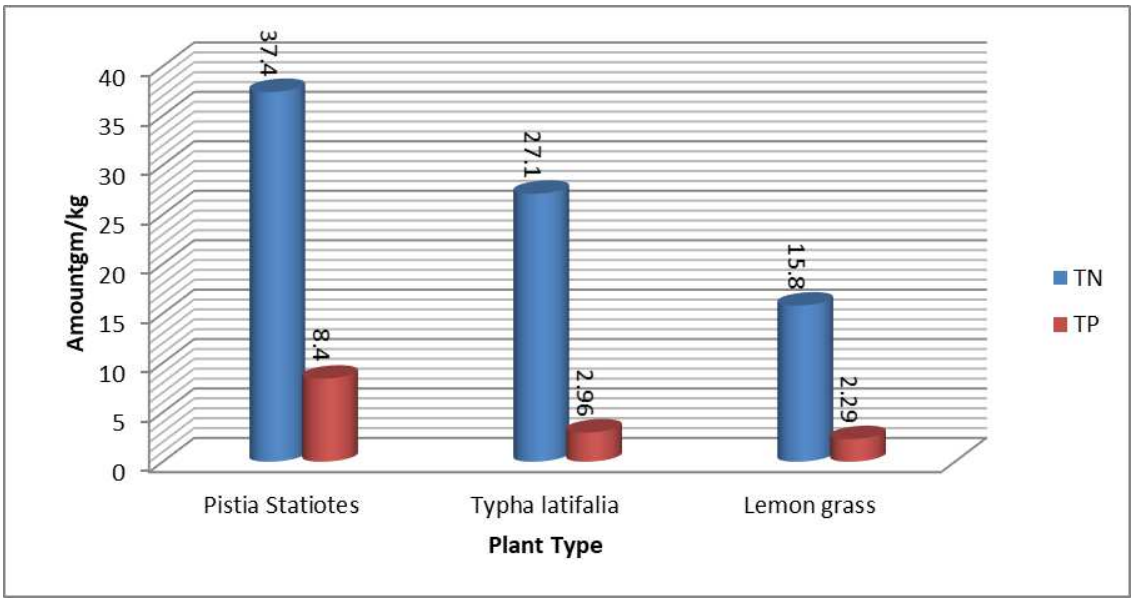

Figure 6. *Nutrient accumulation in the wetland plants (Tilak et al., 2016)*

The removal of nutrients from constructed wetlands are also dependent on the media types. The accumulation of total nitrogen and phosphorus in the constructed wetland media was also investigated by Tilak et al. (2016) as indicated in *Figure 7*.

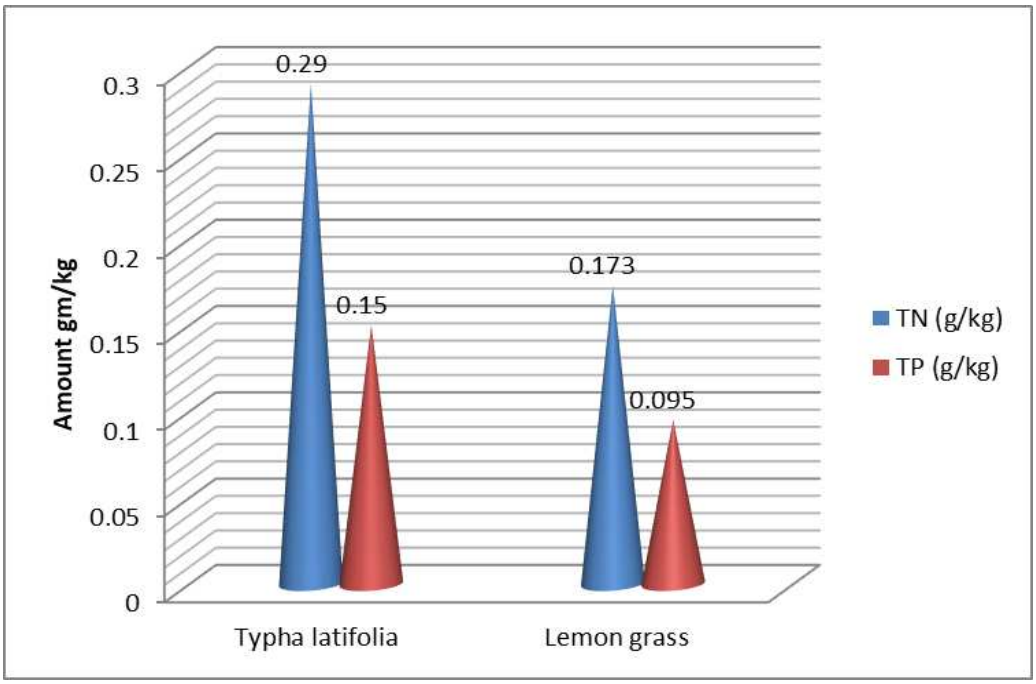

Figure 7. *Nutrient accumulation in sand media (Tilak et al., 2016)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10511089

The effect of vegetation on the organic matter removal was better than (i.e., 5 to 15%) those of the unplanted. In general, the organic removal results suggest that control treatment influences wetland performance more than the type of macrophytes. The TSS removal efficiencies varied from 35 to 76% in both dry and nortes season. The organic matter (COD and BOD) removal showed similar pattern to that of TSS, which was varied from 36 to 68% and 28 to 69% for COD and BOD, respectively in the dry season, and whereas for the nortes season, they varied from 40 to 78% for COD and 49 to 74% for BOD. The nutrient removal efficiencies ranged from 47 to 66% and 59 to 79% for TN, 53 to 67% and 50 to 75% for NH_4 + and 69 to 84% and 60 to 75% for NO_3- respectively for dry and nortes seasons. In general, the performance efficiency of the horizontal subsurface flow constructed wetland in organic matter, nutrient and pathogens were shown in *Figures 8* and *9*. The overall result clearly indicates that HRT is a key factor in the removal of a wide variety of contaminants (COD, BOD, TSS, TN, NH_4 + NO_3 - and TP) in horizontal subsurface flow constructed wetland treating swine wastewater. According to the findings, the Typha latifolia and Eleocharis interstincta are the most suitable macrophyte species to be used for the treatment of piggery wastewater. In spite of the fact that high contaminant concentrations in wastewater may have masked the macrophytes; contributing to the overall treatment efficiency of HSSFCW, vegetated beds usually provide better effluent quality than unplanted beds (Puigagut et al., 2007).

The above graph indicates that the local macrophytes and natural substrate can perform successfully in the treatment of domestic wastewater. The results demonstrated that removals of organics (COD and BOD) are high in the horizontal subsurface flow constructed wetlands. The treatment efficiency of BOD nan COD ranged between 76 and 99.4% and 76 and 8.46%, respectively except COD removal studied results in Thailand which varied between 42 and 83%.

Performance efficiency of HSSFCW: a case in Ethiopia

In Ethiopia, environmental degradation within and downstream of cities has multiple consequences for public health, in particular through the use of untreated wastewater in irrigated agriculture. Significant wastewater treatment efforts are done by Addis Ababa Water Supply and Sewerage Authority (AAWSSA), but it remained limited. Due to the combination of poor sanitation and undulating topography, almost all wastewaters generated in the city finds its way through a dense network of streams into Akaki Rivers (Little and Great Akaki rivers). Several factories also discharge their untreated effluents into the rivers. Wastewater collection and treatment are limited and treated wastewater is also discharged into the same river. Discharges from industry, domestic, and agricultures can cause an impact on environmental condition in river and coastal waters. Eutrophication is an accelerated growth of algae on higher forms of plant life caused by the enrichment of water by nutrients, especially compounds of nitrogen and/or phosphorus and inducing an undesirable disturbance to the balance of organisms present in the water and to the quality of the water concerned. Eutrophication of fresh water ecosystem is one of the most prevalent environmental problems responsible for water quality degradation on a world-wide scale. At present hardly any infrastructure is available for the effective treatment of sewage in developing countries.

Municipal sewerage and the extent of domestic and industrial wastewater treatment are inadequate in most urban situations. When there is a municipal sewerage network in place, the coverage is usually incomplete and the treatment level is insufficient. Even when treatment facilities exist, poor maintenance and operation often results in failing treatment processes, causing pollution of the effluent receiving surface waters. The risk of water borne diseases may actually increase in developing countries as a result of the introduction of a conventional sewerage scheme, since it is usually not accompanied by effective end-of-pipe treatment (UNEP/GPA, 2004). Untreated effluent contains high concentrations of salts, total suspended solids, chemical oxygen

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10511089

demand, nitrogen and phosphorous and toxic compounds, such as heavy metals and chlorinated organic compounds. Industrial effluents can seep into the aquifer and pollute groundwater or where it is discharged without proper treatment can affect the physico-chemical properties of the receiving water and consequently its biota (Kambole, 2003).

All this unregulated discharge of wastewater undermines biological diversity, natural resilience and has a significant impact on macro-invertebrates composition due to the water quality deterioration (Beyene et al., 2009). Addis Ababa City Rivers are highly affected by pollution of heavy metals, pathogens, organic compounds, synthetic chemicals, micro-plastics and nutrients (Aregawi, 2014). Study reports indicated that the city water bodies and surrounding agricultural soils are contaminated with heavy metals such as Hg, As, Pb, Sb, Ni, Sr, and Cd (Elias and Yohannes, 2017), which are extremely toxic even at low concentrations and cause gastrointestinal, skin, nerve damage, lung damage, cancer, nervous, immune system, and kidney damage, brain damage, liver damage, and etc. (Kassa, 2012). Beside these, water, soil and air pollution due to industrial and domestic waste discharges cause peculiar diseases. Study and literature report showed that most people found in Akaki Kality industrial zone are affected by peculiar diseases such as cough (76.5%), diarrhea (58.8%), typhoid (51%), typhus (45.1%), gastrointestinal (39.2%), skin problem (29.4%), asthma (33.3%), and bronchitis (3.9%) (Aregawi, 2014; Elias and Yohannes, 2017). This may be due to long term intake of food that contains high levels of heavy metals and pathogens, and contact with sediments containing heavy metals and pathogens, posing risks to human health (Itanna, 2002; Bekele, 2008) To protect water bodies from pollution, serious waste management implementation should be conducted. The main challenge mentioned by researchers is selecting the appropriate wastewater treatment techniques. Therefore, locally available effective pollution control systems are very important based on the country's economy. For this problem, constructed wetlands can be a good alternative options.

In Ethiopia, Terfie and Asfaw (2004) conducted a research on five pilot scale subsurface flows constructed wetlands; four units vegetated with Cyprus altenifolius, Typha domingensis, Phragmites karka and Borassus aethiopum and the fifth left as unvegetated (control). The performance efficiency of each cells in removing organic matter (COD & BOD5), ammonium and total nitrogen including total chromium under the 5-day hydraulic retention time and hydraulic loading of 120 L/day showed promising results. The wastewater analysis indicated that COD reduction by 58-80% for an inlet organic loading rate (OLR) ranged from 2202-8100 mg/L and BOD5 reduction by 66-77% for an inlet OLR ranged from 650-1950 mg/L. The removal of inorganic substances such as nitrates, sulfates, sulfides, total nitrogen and ammonia-nitrogen ranged from 30-57%, 82-92.4%, 53-82%, 46-61% and 64-82.5%, respectively (*Table 5*). Similarly, Kassa and Mengistou (2014) tested pilot scale HSSFCWs efficiency in treating domestic wastewater in vegetated and unvegetated conditions at HLR and HRT of 7 day and 26 L/day HLR. The results showed that the nutrient removal efficiency of HSSFCW was significantly higher in the planted species than in the unplanted treatment system. The average removal efficiency of orthophosphate in the treatment beds was 84.05% for C. papyrus, 65.29% for P. Karaka and 50.20% for the unplanted. She proved that the average removal efficiency of planted cells was higher than unplanted due to the macrophytes role to accumulate high biomass and remove nutrients.

		Unplanted			NO_3-N = 36.1%. PO_4-P = 50.2%		
Domestic	Gravel (8-16 mm)	P. australis	18	6	BOD_5 = 82. TSS = 78.3. TN = 27		Ayano, 2013
		Unplanted	18	6	BOD_5 = 82. TSS = 78.3. TN = 27		

Jehovah Witnesses Branch Office (JWBO) full scale HSSFCW performance was evaluated by Birhanu (2007) and the result showed average removal efficiency of the constructed wetland system for BOD5, COD, TSS, ammonium, nitrate, total nitrogen, orthophosphate, total phosphorus, sulfate, sulfide and total coliform was 99.3%, 89%, 85%, 28.1%, 64%, 61.5%, 28%, 22.7%, 77.3%, 99% and 94.5%, respectively. The individual cells removal efficiency indicated that the wetland planted with Cyprus papyrus showed higher removal efficiency for nitrate (82.4%), ammonium (24.8%), total nitrogen (54.8%), orthophosphate (23.5%), and total suspended solids (83.9%) as compared to the other wetland systems. In the same regard, wetland cells planted with Phoenix canariensis showed higher removal efficiency for total phosphorus (17%), sulfide (99%), BOD5 (98%), COD (90%) and total coliform (94%). Whereas, the other wetland cells planted with Cyprus alternifolia showed higher removal efficiency only for sulfate ion (82.2%). The performance efficiency results indicated that, this wetland system has excellent removal capability for BOD5, COD, TSS, sulfate, sulfide and total coliform bacteria. However, since the HRT of the constructed wetland system (2.16

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10511089

days), the nutrient (nitrogen and phosphorus) removal efficiency was low. The organic matter removal efficiency of JWBO CW investigated by Brhanu (2007) was similar to that of the study done in the USA: i.e., BOD5 (93%) (USEPA, 1993); in Kenya: BOD5 (98%), COD (96%) and TSS (85%) (Nyakango, 1999); in Northern Alabama: BOD5 (85%) (Kathleen, 2000); and in Italy: COD (93%) and TSS (81%) (Pucci, 2000). The higher removal of the planted treatment beds may be due to a combined biochemical reaction mechanism favored by plants, substrates and microorganisms. The most important effects of the macrophytes in relation to the wastewater treatment processes are the physical effects of the plant tissues that give rise to filtration effect and provide surface area for attached microorganisms. In addition to this, the media and macrophytes roots in SSF may provide a greater number of small surfaces, pores, and crevices which create the opportunity for the availability of a vast number of organic matter utilizing microorganisms adapted to the aerobic and anaerobic environment of wetland ecosystems which facilitate the organic matter removal process of CW more effectively (USEPA, 1993; Michael, 2006). On the other hand, the effectiveness may be associated with the presence of easily biodegradable organic matters in domestic wastewater by biological decomposition process within a short HRT (Reddy, 1991). According to Ayano' (2013) demonstration on the performance efficiency of horizontal subsurface flow constructed wetland at deferent depth with the same media type (gravel, 8-16 mm), wetland area and different hydraulic loading rate of 18 L/m^2/day and 36 L/m^2/day for depths 25 cm and 50 cm in planted and unplanted conditions, showed no significant difference in removal of pollutants at the same HLR. The removal of BOD5 and TSS were not different between planted and unplanted beds. However, areal and volumetric rates for planted beds were significantly greater than the unplanted beds for TKN. Unplanted beds may be more anaerobic than planted beds to favor reducing bacteria. Garcia et al. (2004) reported that the removal of HSSFCW increased with decreasing depth and attributed high oxidation reduction potential which is responsible for increasing nitrification. The result showed that constructed wetlands are successful in removal of nutrients from domestic wastewater.

Heavy metal removal efficiency of HSSFCW

The toxicity nature of most heavy metals

Recently there has been an increase in the river pollution trend in Addis Ababa and other cities, due to the discharge of untreated wastewater from the industries and municipal wastes. Constructed wetlands have a good potential for the removal of heavy metals from wastewater (Sahu, 2014). According to Sahu report, the horizontal subsurface flow constructed wetland reduced the concentration of Hg, Cr, Fe and Ni from the initial concentrations by 43%, 54%, 46% and 49%, respectively. The potential heavy metal remediation of HSSFCW planted with Phragmites australis was investigated by Bahre (2013) and achieved high removal efficiency of 99.33%, 93.67%, 89.24%, 96.14% and 98.33%, respectively for Fe, Mn, Pb, Cu and Zn at hydraulic loading rate of 22 L d^{-1} and hydraulic retention time of 28th days. In the same regard, the unplanted unit showed removal efficiency of 98.43%, 91.66%, 85.01%, 90.70% and 85.19% for Fe, Mn, Pb, Cu and Zn, respectively at the same conditions. The result indicates that uptake on roots for Pb and Cu was higher than the uptakes by plant leaves and stems. The soil media heavy metals accumulation also showed the highest adsorption capacity for the analyzed heavy metals from the planted and control systems.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10511089

This demonstrates that horizontal subsurface flow constructed wetland planted with Phragmites australis and red ash gravel can remove heavy metals from leachate.

This result is similar to the reported metal removal efficiency of subsurface flow constructed planted with S globulosus and E. sexangulare in treating leachates, which were 81.33% and 94.19%, respectively for Cu and Pb; while 86.91% and 95.88% removal in E. sexangular, respectively for Cu and Pb (Mohamed and Baskar, 2018). This finding also agrees with the result of Refidah (2002) who reported the removal efficiency of surface flow constructed planted with S. sumantresisana in treating leachate; which was 89%, 90% and 89%, respectively for Fe, Zn and Mn. The analysis of results showed that up to 99.3% of chromium was reduced from tannery wastewater for an inlet average Cr loading rate of 40 mg/L (Amenu, 2015). Similar values were reported by Terfie and Assfaw (2014) of total chromium in HSSFCW beds. The plant parts analysis on the accumulation of chromium showed similar results, more Cr was accumulated in root parts of the plants than in the shoot. This indicates that constructed wetland is a cost effective and environmentally friendly treatment method in removal of not only organic maters, nutrients and pathogens, but also heavy metals, and hence it can be used as an alternative treatment method for developing countries (*Table 6*).

Table 6. *Heavy metal removal efficiency of HSSFCW in Ethiopia*

Types of waste water	Media type	Plant type	HLR (L/d)	HRT (day)	Removal efficiency (%)	Standards (EEPA, 2000)	Reference
Leachates	Redish gravel (40-80 mm) (15-25 mm)	P. australis	22	28	Fe = 99.33. Mn = 93.6. Pb = 89.24. Cu = 96.14. Zn = 98.33		Bahre, 2008

		T. domingensis			Cr = 48.68		
		B. aerthiopium			Cr = 26.96		
		P. karka			Cr = 30.26		
		Unplanted			Cr = 59.6 for clay, 38.15 for Gravel		
Syntatic	-	-	48.6	9	Cr = 51. Ni = 47 Fe = 45. Hg = 43		Sahu, 2014

Heavy metals in plant tissues and substrate media

The probable recognized biological processes for metal removal in wetlands are plant uptake and adsorption on the substrate media. The Pb and Cu uptake ability of P. australis by its roots may be due to the localized properties of the root, mainly predominated rhizofiltration mechanisms to accumulate heavy metals (Zhu et al., 1999). Similarly, Kadlec and Wallace (2009) reported that plants can accumulate higher concentrations of metals in their roots. This may be due to the slow mobility of metal transport from the root to shoot. In the same case, substrate media is also one of the important factors for the removal of heavy metals. *Figures 10* and *11* indicate the role of substrate media for Pb and Cu removal from leachate. However, the retention time and the type of media have an effect on the treatment of wetland (Knox et al., 2004). Since media provides a viable

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10511089

condition for maximum removal of pollutants, due to its diverse treatment mechanisms including sedimentation, adsorption, precipitation and microbial interaction (USEPA, 1993). In general, the control HSSFCW showed the higher removal efficiency of Pb and Cu than the planted wetland. Similar finding was observed in the removal of chromium from tannery wastewater (Terfie and Assfaw, 2014). This may be due to chemical precipitation and sorption of metals on substrate media.

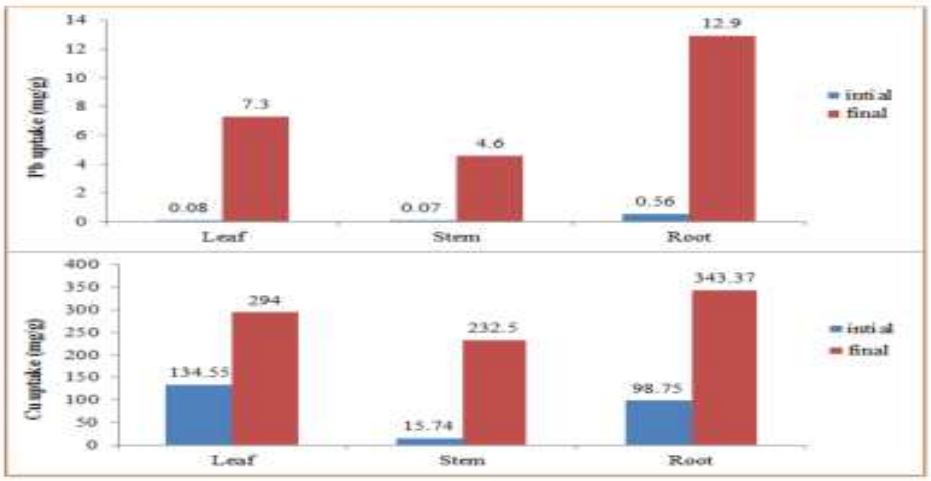

Figure 10. *Pb and Cu uptake of different parts of P. australis in CW (Knox et al., 2004)*

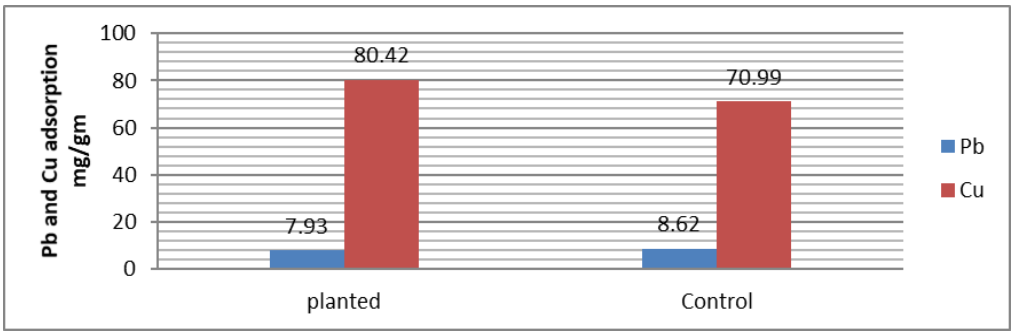

Figure 11. *Pb and Cu adsorption in planted and control CW beds (substrate media, red ash gravel) (Knox et al., 2004)*

Terfie and Assfaw (2014) investigation data indicates clearly the fate of total chromium in the horizontal subsurface flow constructed wetland (*Fig. 12a*). Whereas Kassa and Mengistou (2014) investigated data on the fate of total phosphorus is under question mark, where the fate of TP is in a constructed wetland (*Fig. 12b*).

However, the removal efficiency of heavy metals is dependent on the HRT, flow rate (Q) and pH. Sahu (2014) determined the effect of HRT on the reduction of different heavy metals. The treatment efficiency was observed increased as HRT increases from 1 to 7 days at a flow rate of 8 cm^3/min (*Fig. 13*). As *Fig. 13* showed the maximum removal of 54%, 49%, 46% and 43% were obtained respectively for Cr, Ni, Fe and Hg at 7 days HRT. The effect of HRT on the removal of heavy metals was also determined by Bahre (2013) and presented in *Figure 14*.

Figure 14. *Effect of vegetation and HRT on the removal efficiency of heavy metals (Bahre, 2013)*

Factors affecting the performance efficiency of constructed wetlands

Vegetation and HRT

The TSS removal efficiency of planted and unplanted constructed wetland at different HRT was significantly different. The initial TSS concentration was 106 mg/L. Some while after treatment under CW were reduced to 35.4 and 19.7 mg/L at 2 and 4 days HRT with a removal efficiency of 66.7% and 81.5%, respectively in the vegetated one. Whereas, for the unplanted CW, TSS were reduced to 62.3 and 49.8 mg/L for 2 and 4 days HRT with total removal efficiency of 41.5% and 53.2%, respectively. The planted CW had higher results in TSS removal than the unplanted one (*Fig. 15*). Increase of HRT resulted in better TSS removal efficiency even for the non-vegetated CW. The efficiency of BOD5 removal was 52% and 73.4% at HRT of 2 and 4 days in the planted beds. Constructed wetland without plantation removed only 20-35% BOD5 from the influent.

Constructed wetland planted with Canna indica L. gave higher BOD_5 removal efficiency than non-vegetated CW. The BOD5 removal also increased at higher HRT (i.e., almost half BOD5 removed at 4 days HRT) than shorter HRT (i.e. 2 days HRT). TKN removal in the vegetated CW also gave the maximum removal efficiency compared to the non-vegetated CW. This removal efficiency of TKN may be associated with addition of plant activity. CW planted with Canna indica L. removed TKN for 45.3% for 2 days HRT and 69.6% for 4 days HRT. TKN removal efficiency had increased at increasing HRT (Panrare et al., 2015). This TKN removal of the CW technique may be due to volatilization, plant uptake and bacterial assimilation (Vymazal, 2007). The vegetated CW at 4HRT also gave the highest phosphate removal efficiency (77.7%). This phosphate removal in CW could be normally by plant and bacterial uptake, adsorption at the media and sedimentation. The effect of vegetation and HRT on the performance efficiency of constructed wetland is indicated in *Figure 15*.

DOI: http://dx.doi.org/10.15666/aeer/1801_10511089

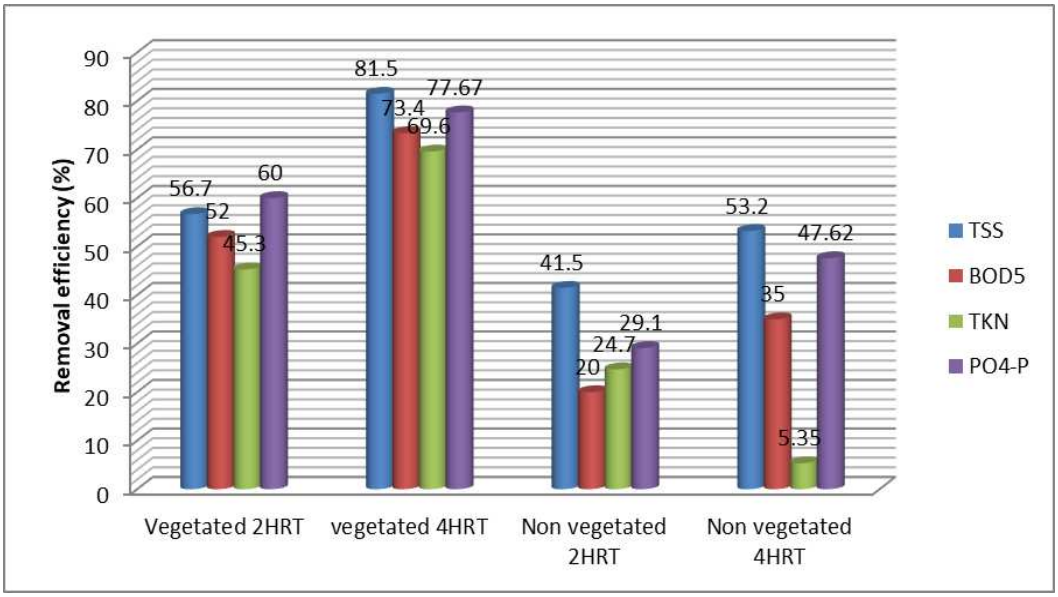

Figure 15. *Effect of vegetation and HRT on pollutant removal efficiency of CW*

Plant species

Plants used in constructed wetlands play a major role in absorbing nutrients from wastewater. Some of the most important plant species with nutrient absorbing ability is summarized in *Table 7*.

Table 7. *Nutrient absorption capacity of macrophytes (Brix, 1994)*

Media type		***Cyperus alternifolus***	***Typha latifolia***	***Eichornia crassipes***	***Pistia stratoites***	***Potamogeton pectinatus***	***Certophylum demersum***
Absorption capacity kg/ha/h	N	1100	1000	2400	900	500	100
	P	50	180	350	40	40	10

Media type

The level of permeability and hydraulic conductivity of the media is very influential on the retention time of wastewater, in which the retention time is enough to give a chance to contact between microorganisms in wastewater and oxygen released by plant roots. The main function of the media in the constructed wetland is to provide places for plants to grow, microbial attachment for pollutant transformation process, and nutrient absorption (Dadan, 2016). The performance of subsurface flow constructed wetland based treatment can be shown in *Table 8.*

Microorganisms

Preferably heterotrophic aerobic microorganisms are present due to faster processing ability than anaerobic types. The oxygen content in the media will be supplied by plant roots, which is a byproduct of the process of photosynthesis of plants with the help of sunlight (Dadan et al., 2016).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10511089

Temperature

The temperature of wastewater affects the activity of microorganisms and plants, furthermore it will affect the performance of processing (Dadan et al., 2016).

Table 8. *Performance of SSFCW media (Khiatuddin, 2003)*

Media type		Gravel	Soil	Sand	Clay

Constructed wetland as climate change mitigation

Constructed wetlands are increasingly widespread for wastewater treatment in small communities and households where in addition to the fundamental purifying function, they also have decorative function that imposes the choice of plants characterized by high functional, amenity, and aesthetic values (Ghermandi et al., 2010). Constructed wetlands carbon cycles contribute to the global greenhouse gases (GHGs) balance through their CO_2 and CH_4 emissions. In particular, they can act as CO_2 sinks by photosynthetic CO_2 assimilation from the atmosphere or as a source of CO_2 through bed respiration (Barbera et al., 2009) and organic matter decomposition (Brix et al., 2001). The rate of carbon decomposition in constructed wetlands depends on the redox chemistry of the soil, the bioavailability of organic carbon and temperature. For example, in summer season, oxygen diffusion to the topsoil can reduce methanogenesis and stimulate methane oxidation (Grünfeld and Brix, 1999). However, an increase in temperature can decrease dissolved oxygen in deeper subsoil and enhance methane production. All biochemical reactions increase as temperature increases C and N turnover in constructed wetlands causing high variations in GHG emissions in different regions. Due to this more data and investigation are needed on constructed wetland types for better extrapolation of GHG emissions. Hence, organizing more information on nutrient removal efficiency and GHG emissions across CW in different CW types is necessary for better management. Emissions of GHG in CWs can vary across CW types, e.g., surface flow or subsurface flow (*Tables 9* and *10*).

Generally, methane emissions are higher in surface flow CWs (SFCWs) than subsurface flow constructed wetlands (*Table 9*), but may vary with season. Nitrous oxide and carbon dioxide emissions are higher in VSSFCWs than in HSSFCWs and SFCWs. Aquatic plants play an important role in GHG production and transport to the atmosphere by releasing GHG through their interconnected internal gas lacunas. Emergent plants can transport atmospheric oxygen to the rooting zone and contribute to increase the N_2O and CO_2 production and methane consumption (Brix, 1989). Release of low molecular weight organic matter that is labile in nature is more likely to produce GHGs than stable forms. A fluctuating water table in CWs has significant impacts on GHG dynamics (Mander, 2011). In aerobic and anaerobic conditions, incomplete nitrification and denitrification increase N_2O emissions (Healy et al., 2007). In general, assessment of GHG emissions in various types of CWs which are vegetated or unvegetated *is necessary in the light of the national and global GHG budgets.*

Even if constructed wetlands are contributors of GHG, on the other hand, constructed wetlands present an important opportunity for carbon sequestration and greenhouse gas offsets by virtue of their potential for restoration using known and innovative land management methods. Because constructed wetlands are inherently highly productive and accumulate large below-ground stocks of organic carbon. Wetlands are major carbon sinks. While vegetation traps atmospheric carbon dioxide in wetlands and other ecosystems alike, the net-sink of wetlands is attributed to low decomposition rates in anaerobic zones. Recently, constructed wetlands used for wastewater treatment and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10511089

protecting wetland bodies clearly represent an immediate and large opportunity for enhancing carbon sequestration (Kanungo et al., 2017). The percentage of organic carbon (OC%) content of the 15 emergent macrophytes varied between 34.97 to 50.92, 34.98 to 52.04, 34.96 to 52.01 and 34.91 to 50.94. similarly, biomass (g/m ^{2}) ranged from 104 to 687, 16 to 1382, 141 to 1493 and 122 to 635. The carbon sequestration potential (CSP) was determined by multiplying the OC in per gram of dry weight to the biomass of that species (Wang et al., 2011) and the total CSP of all the emergent macrophytes was obtained by the summation of individual CSP of all species. Based on this calculation, the highest CSP was recorded for Typha latifolia followed by Phragmites australis and the lowest for Carexsp. (*Fig. 16*) which exhibited from the highest carbon content of 53.62% which was greater than the 44% value reported by Wang et al. (2011) for Typha orientalis.

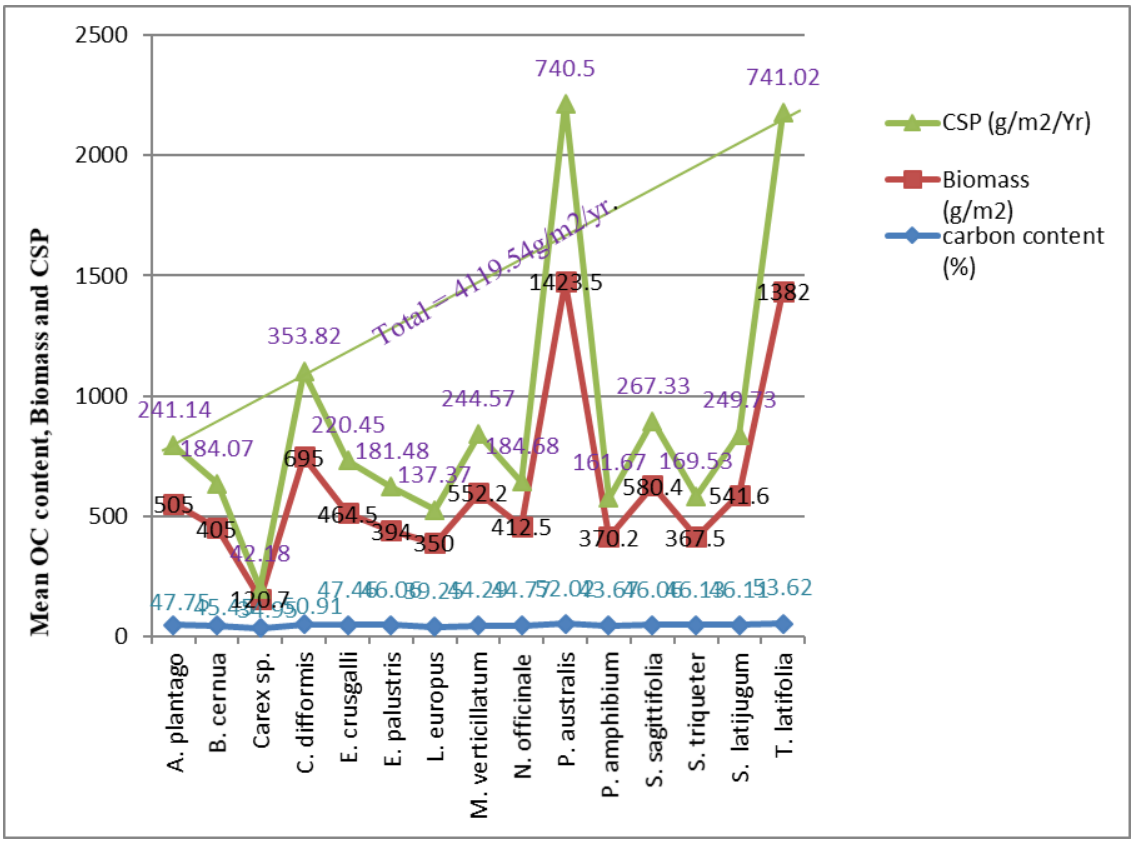

Figure 16. *Mean carbon content, biomass and carbon sequestration of macrophytes (Mitsch et al., 2015)*

Wang also reported 44.7%, 44.1% and 41.8% of carbon for Phragmites communis, Cyprus malaccensis, and Eleocharis dulcis, respectively which is lower than the values of Phragmites australis, Cyperus difformis, and Eleocharis palustris, respectively obtained by Khan and Maqubool (2014). These macrophytes species carbon content and hence their CSP was higher when compared with other reported results for Scirpus lacustris (44.12%), Eleocharis palustris (43%) (Fernández-Aláez et al., 1999); Phragmites australis (29.2%) and Myriophyllum salsugineum (15.8%) (Piola et al., 2008). Furthermore, Costa and Henry (2010) observed the highest carbon content for E.

DOI: http://dx.doi.org/10.15666/aeer/1801_10511089

azurea (43.7%), Myriophyllum aquaticum (43%), Cyperus esculentus (41.6%) and Polygonumspectable (38%). Assuming 4119.54 $gC/m^2/yr$ as the rate of carbon sequestered in each year in this system, the limit for carbon emissions can be calculated to determine the point at which the system offsets carbon emission. To compare the physical sequestration and the gaseous emissions both are converted to carbon dioxide equivalents (CO_2e) (Forster et al., 2007). The CO_2e allows the comparison of different masses and gases as they relate to their greenhouse warming potential. Methane has 25 times the potential as CO_2. Each gram of carbon is equivalent to 3.67 g of CO_2. The CO_2 equivalent of 4119.54 $gC/m^2/yr$. is 15118.7118 g CO_2. The methane equivalent to this amount of carbon sequestration is 604.748472 $g/m^2/yr$. Constructed wetlands showing methane emission values less than 1,600 kg/ha/yr are considered as potential for carbon sequestration (Kayranli et al., 2010). Based on this argue, the above treatment plant has a carbon sequestration potential.

Constructed wetlands are purposely constructed in order to reduce input of nutrients and organic pollutants to water bodies. When these systems are used for wastewater treatment, microbial processes and gas dynamics are likely to be altered. With increased inputs of nutrients and organic pollutants, there is an increase in greenhouse gases production due to decomposition processes. Constructed wetlands therefore, can be sources of important greenhouse gases. The average CH_4, N_2O and CO_2 fluxes for surface flow constructed wetland were 2.9, 1.05, and 15.2 $mg/m^2/h$, respectively. Whereas the average higher fluxes were found from free water surface constructed wetland with average CH_4, N_2O and CO_2 fluxes at 5.9, 1.8, and 29.6 $mg/m^2/h$, respectively, corresponding to the average global warming potential (GWP) of 392 mg CO_2 equivalents/m^2/h and 698 mg CO_2 equivalents/m^2/h, respectively for SSFCW and FWSCW (*Fig. 17*) (Chuersuwan et al., 2014).

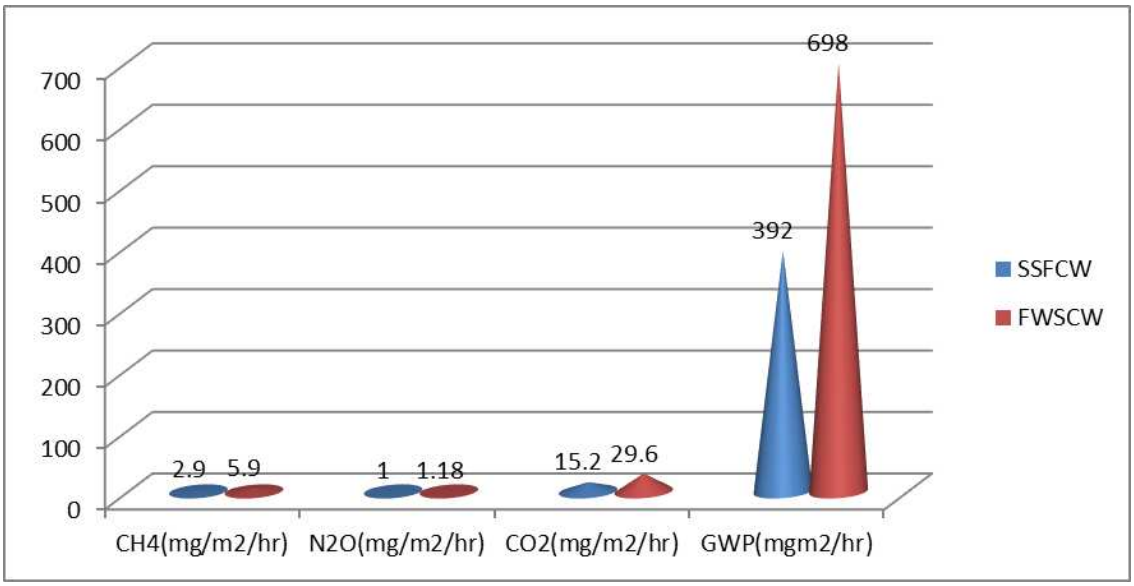

Figure 17. *Comparison of greenhouse gas emissions and GWP of free water and subsurface flow CWs (Chuersuwan et al., 2014)*

In another study by Maucieri et al. (2014), the comparison of vegetated and unvegetated horizontal subsurface flow constructed wetland effect on the CO_2 (eq)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10511089

balance showed a significant difference. The average CO_2 emission of the whole monitored period were 15.5, 15.1, and 3.6 g m^{-2} d^{-1} for Arundox donax L. Phragmites australis and unvegetated beds, respectively. Whereas, cumulative estimated CH_4 emissions during the study period were 159.5, 134.1 and 114.5 g m^{-2} d^{-1} for A. donax, P. australis and unvegetated beds, respectively. CO_2 (eq) balance showed that the two vegetated beds act as CO_2 (eq) sinks, while the unvegetated bed act as CO_2 (eq) source. Considering only the above-ground plant biomass in the CO_2 (eq) budgets, P. australis and A. donax determined uptakes of 1.3 and 8.35 kg CO_2 m^{-2} d^{-1}, respectively, and generally the plant biomass carbon content and the bed biomass yield in the vegetated cell fixed 11.61 and 27.03 kgCO_2 (eq) m^{-2} d^{-1}, respectively for P. australis and A. donax, showing a positive balance, while the unvegetated bed had a negative balance (*Fig. 18*). Carbon dioxide and methane emissions and carbon budgets in a horizontal subsurface flow pilot constructed wetland with vegetated with C. papyrus and Chrysopogon zizanoids Roberty and Mischantus giagnteus, showed higher biomass accumulation in M. giganteus (7.4 kg m^{-2}) followed by C. zizanoids (5.3 kg m^{-2}) and C. papyrus (1.8 kg m^{-2}).

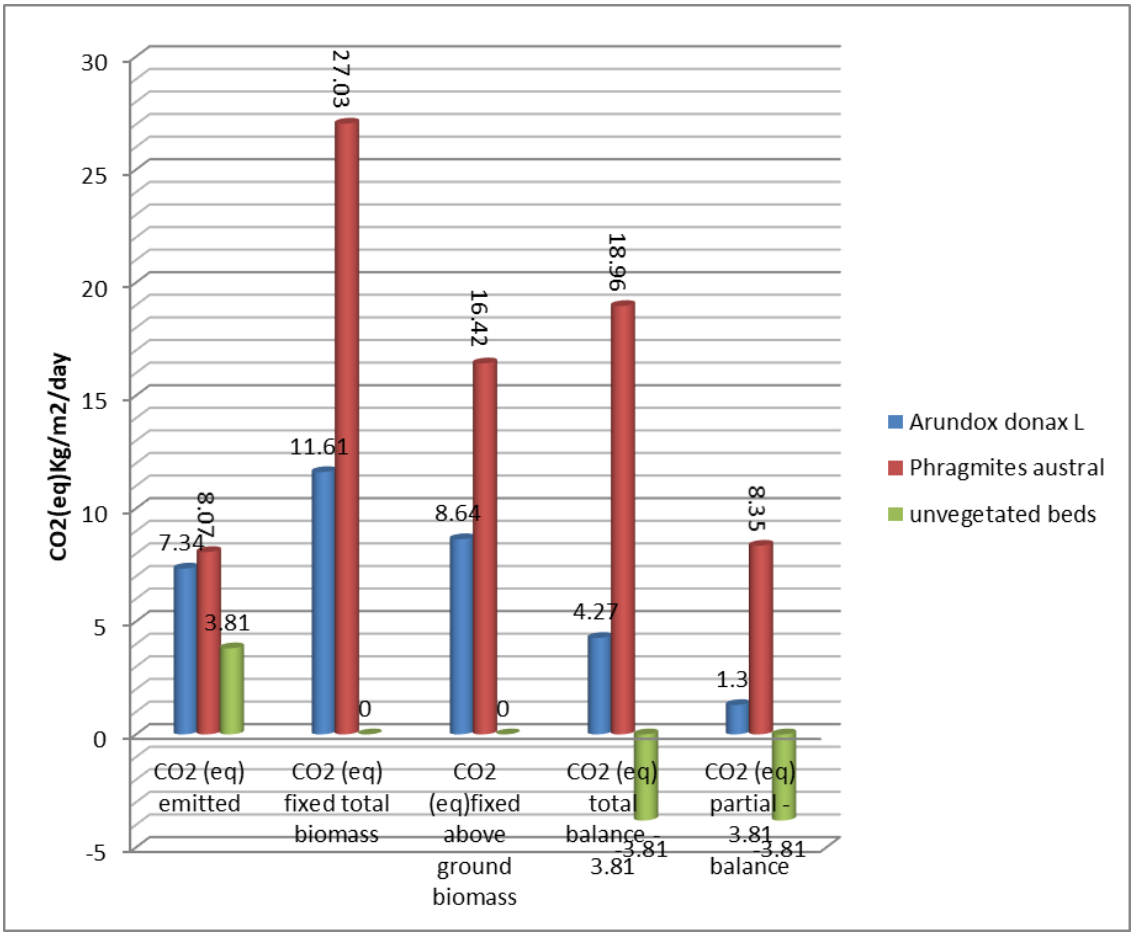

Figure 18. *HSSFCW beds carbon dioxide equivalent balance (Maucieri et al., 2014)*

The cumulative CO_2 emissions by C. papyrus and C. zizanoids during the 1-year monitoring period showed similar trends with final volumes of about 775 and 1074 g m^{-2}, respectively, whereas M. giganteus emitted 3,395 g m^{-2}. Cumulative methane emission

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10511089

showed the greatest methane emission for C. zizanoids bed with 240.3 g m^{-2} followed by C. papyrus (12 g m^{-2}) and M. giganteus. The organic carbon abatment determined the carbon flux in the atmosphere. Gas fluxes were influenced both by plant species and monitored months with average carbon emitted to carbon removed ratio for C. zizanoids, C. papyrus and M. giganteus of 0.3, 0.5 and 0.9, respectively. The growing season carbon balances were positive for all vegetated beds with the highest carbon sequestered in the bed with M. giganteus (4.26 kg m^{-2}) followed by C. zizanoids (3.78 kg m^{-2}) and C. papyrus (1.89 kg m^{-2}) in *Figure 19*.

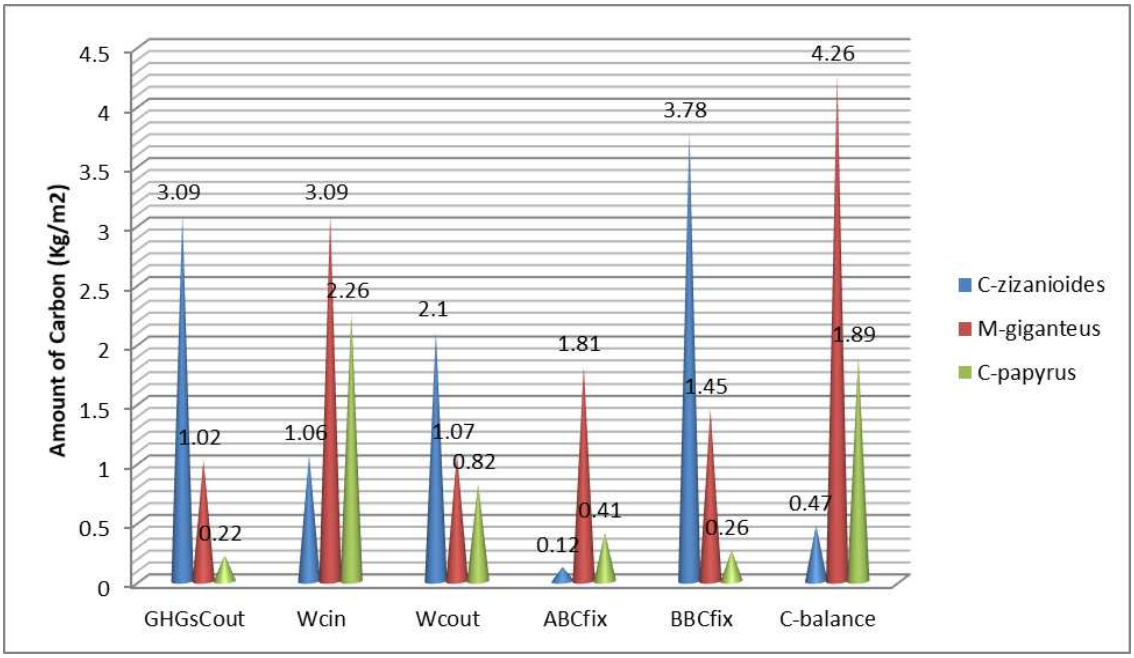

Figure 19. *Carbon balance in HSSFCW*

Conclusion

The reviewed results showed that the HSSFCWs perform good removal efficiencies for organic matter and SS under low C:N:P loading conditions. Nowadays, the strategies of treating domestic and municipal wastewaters by decentralized way become common in rural and urban areas using constructed wetland technologies. Besides this, constructed wetlands are accepted as a reliable wastewater technology as post treatment of effluents. Because they are low cost, easily operated and maintained and have a strong prospective for application in developing countries.

Most research investigation results revealed that use of a subsurface horizontal flow phytoremediation treatment system is a promising natural technology in the treatment of municipal or industrial wastewater. Because, CW treatment system was found to comply with WHO (1989) standards for treated effluent reuse. Globally, the following abatement efficiencies were achieved by HSSFCW treatment system: 98%, 96%, 85%, 90%, 92%, 88% for BOD5, COD, TSS, TN, NH_4–N, PO_4^3-, respectively in Kenya; 98.46% and 98.55% for COD and BOD5 in Indonesia; and ranges from 94-99.9%, 91.7-97.9% and 99.99% for BOD_5, COD and TFC, respectively in Costa Rica. Whereas in Ethiopia, the HSSFCW achieved the following abatement efficiencies: COD ranges from 58 to 80%, BOD ranges from 66 to 77%, TKN ranges from 46 to 61%, sulfates ranges from 53 to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10511089

82%, and NH_4–N ranges from 64 to 82.5% for tannery wastewater treatment. For domestic wastewater treatment; 99.3%, 89%, 855, 84.05%, 77.3%, 99% and 94.5% were determined for BOD5, COD, TSS, TN, PO_4^3-TP, Sulfate, and TFC, respectively.

The pollutant removal efficiencies and greenhouse gas emissions from the CWs increased with the rise in temperature. The HSSF CWs had the highest tendency to emit CH_4 and thus global warming potential of CWs, and the combined CWs by way of contrast showed low global warming potential. Due to the climate demonstrative of CW and periodic changes, further study to observe the seasonal fluctuations of CH_4 and N_2O emission is necessary. CWs have been found to be potential sinks of Carbon in terms of organic carbon. We face several significant questions regarding the potential for carbon sequestration in wetlands. Constructed wetlands can be managed as net carbon sinks over time. From the Reviewed results point of view, the net carbon gain and the biomass was comparatively higher, carbon storage in biomass and reduced CO_2 emissions. For example, the City of Arcata sequesters carbon in all three treatment units at a rate equivalent of 80,000 kg CO_2/yr. Most research investigation results revealed that horizontal subsurface flow constructed wetlands have been successfully employed to abate key contaminants from wastewater and able to meet the required standard discharge limits.

However, constructed wetland performance efficiency sustainability is affected by the operational conditions of HSSFCW including plant species, media/substrate types, water depth, hydraulic loading, and hydraulic retention time and feeding mode. Though the Total Carbon value at the CW is particularly beneficial for the growth of emergent macrophyte. CWs can be used to treat the wastewater from an industry or community development and also provide an additional benefit as green belts around the industries or the community development. By adopting these Biological CW treatment systems, we can not only achieve our plan of carbon emission reduction but also generate huge amount of savings and earn carbon credits too to ensure a Clean Development Mechanism.

Recommendations

In this paper, encouraging reviewed results were obtained on the role of HSSF CWs on the performance of climate mitigation and wastewater treatment. Based on this review, recommendations for the educational community and user of the technology are suggested. In order to obtain refined results for further long-term research on the performance of the wetlands with respect to all parameters using advanced sized wetland is essential. Besides, further analysis of carbon sequestration potential for climate mitigation and nitrification potential using the HSSF constructed wetlands is recommended for better results. For the user of the technology it can be chosen for application and their construction cost is evidently cheaper. However, evapotranspiration was peak and overstated during dry seasons in planted beds. Furthermore; it is worthwhile to use HSSFCW as one part of the treatment system to reduce GHG emission effect and infection before applying wastewater to recycle in irrigation.

(Received 24th Jun 2019; accepted 25th Oct 2019)

Abstract. Water issues are still here, urbanization and industries generate different types of wastes which then affect water. Many technologies have been introduced for water treatment and efforts are being made to improve and maintain water quality, while also providing easily available and low-cost technologies. Several methods which are easily available but due to high cost, they cannot be introduced everywhere, especially rural areas. Recently, constructed wetlands have been proven to be an efficient technology to treat water. With its biological, physical and chemical treatment, constructed wetland technology becomes the best choice by many countries around the world. Existing research shows that COD (Chemical Oxygen Demand), BOD5 (Biological Oxygen Demand), TKN (Total Kjeldahl Nitrogen), TSS (Total suspended solids) etc. have been removed to a significant degree by using constructed wetlands. This technology is a system of different materials, such as gravel, vegetation and recently introduced tool knows as biochar. The combination of these makes the system efficient for water treatment but some factors such as area, weather conditions, type of wastes do matter. Selection of constructed wetland type and suitable plants is very important. In this paper, efficiency of constructed wetland system, its mechanism, the types of plants used in the system and role of plants to enhance the efficiency of the wetland system from all over the world are widely reviewed and discussed.
Keywords: *constructed wetlands, water treatment, removal mechanisms, removal of pollutants, plants in wetlands*

Introduction

Recent environmental issues and the discovery of their solutions have been increasing rapidly throughout the world. The discharge of wastewater from industries is a threat to nature creating water borne diseases. Recently, the lack of proper wastewater treatment, rapid urbanization is making the situation worse (Varga et al., 2017; Sanjrani et al., 2017; Brix et al., 2013). There are many options available for water treatment, but wetland technology is more efficient and less-cost. One of the valuable services given by natural, restored, or constructed wetlands is that they generally protect downstream waterways from the impact of nutrient pollution. This happens naturally because constructed wetlands are complex systems with a large number of active physical, chemical, and biological processes that mutually influence each other. Nutrient removal use some of the main physical processes such as particle settling known as sedimentation or volatilization, it releases as a gas into the atmosphere, and sorption which includes a nutrient adhering to a solid or diffusing into another liquid or solid. The chemical processes are involved with transformations and precipitation. The biological processes by plants, algae, and bacteria and further process of transformation are conducted by microbes. Wetland compartments have all of these processes with water; biota i.e. plants, algae, and bacteria; litter; and soil.

DOI: http://dx.doi.org/10.15666/aeer/1801_107127

Around the world, wastewater treatment by constructed wetlands has become one of the efficient solutions (Varga et al., 2017; Sanjrani et al., 2019; Jácome, 2016).

CWs are applied to the treatment of varieties of wastewaters created either from industries or human settlements. Some of them are: food industry effluents (including dairy, abattoir, fruit, vegetables and meat industries), effluents of petrochemical and refinery industry, distillery and winery effluents, textile, aquaculture, tannery, steel and mixed industrial effluents, pulp and paper industry etc (Varga et al., 2017). CWs are planned engineered systems that are generally constructed and designed by natural processes such as wetland vegetation, soils, and their associated microbial assemblages (Vymazal, 2014). In this process, it also needs to create a specific environment for the growth of microorganisms and hydrophytes (aquatic and semi aquatic plants) which can live in aerobic, anaerobic and facultative anaerobic environmental systems. Their interactions bring many changes, such as the intensification of oxidation and reduction responsible for the removal and retention of pollutants. These processes are generally supported by sorption, sedimentation and assimilation (Skrzypiec and Gajewska, 2017).

Wastewater is being treated by different types of wetland, i.e. H.F and V.F and a combination of VF and HF systems, known as hybrid wetlands. They are also known as: horizontal subsurface flow constructed wetlands (HSSFCWs), vertical subsurface flow constructed wetlands (VSSFCWs) and free water surface constructed wetlands (FWSCW). Wetlands for the treatment of wastewater, sludge, storm-water, and leachate have been evaluated in laboratory, pilot, and full-scale studies. Due to the benefits acquired from wetlands, wetlands are now at the centres of human evolution and the development of this planet's diverse cultures. Without water we would not exist. In Europe countries, these constructed wetlands are treating water at several places, i.e. tourist resorts, farms and landfills. Various CWs systems show different results in treatment efficiency (Mander et al., 2000). Moreover, recent studies have shown that every country relies on some type of wetlands (Jiang et al., 2016; RAMSAR, 2016; Sirianuntapiboon and Jitvimolnimit, 2007).

Recently, the use of biochar to enhance constructed wetland performance in wastewater has highly appreciated. Different types of biochar have been used to promote wetlands activities. Combining both of these technologies can greatly augment the efficiency of the system. Pollutant removal performance was compared between the controlled and experimental wetland beds. Study reveals that the wetlands with biochar are more efficient as compared to the wetland with gravels alone, which had the average removal rate (Prabuddha et al., 2015). The present paper documents an overall review on the efficiency of wetland systems and common pollutant removal around the world. It also attempts about overall review on the role of the wetland plants in constructed wetlands, efficiency of constructed wetland system, its mechanism, and the types of plants used in the system. Recommendations for future studies have been recommended to improve the efficiency for better treatment.

The efficiency of wetland systems for wastewater treatment

The efficiency of wetland systems for Wastewater Treatment has been proved that it is the best technology around the world. The first experiment on the use of wetland plants for treatment of wastewater was carried in the early 1950s by Dr. Kathe Seidel in Germany. The first full scale systems were put in operation during the late 1960s and since then constructed wetland systems have been speeding throughout the world (Vymazal and Kröpfelová, 2009). Different types of wastes are being treated by wetland technology and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_107127

have shown promising results for the removal of pollutants (Newman et al., 2015). This is the reason; this technology is developing everywhere around the world. There are now more than 1,000 constructed wetland systems (CWs) in the UK (WRC UK, 2012). In Northeastern USA and Eastern Canada, 25 full-scale CWs treated agricultural wastewater and showed an average of good removal efficiencies: BOD5, TKN, TSS, NH4+-N, NO3−-N and TP (Rozema and Andrew, 2016a; Rozema and Zheng, 2016b). In Russia, geographical conditions and the weather, depending on the possibilities for accommodation of certain types of CWs really need careful consideration. Recently, the use of constructed wetlands for xenobiotics removal in climatic conditions in Russia has been conducted. This project was both efficient and low-cost (Schegolkova et al., 2015).

In Korea, because of its lower construction cost and simplicity in operation and maintenance, many different types of wetland treatment systems have been built during the last 10 years, the efficiency of removal of pollutants is great. However, Kim et al. (2006) identified some issues; systems suffer from the reduced effectiveness in performance during the winter. And need to evaluate the partial treatment accomplished during six to seven months per year (Kim et al., 2006). In Pakistan, this technology was introduced relatively late, between 2009 and 2010, a small NGO Sindhica Reforms Society (Sindhica) initiated "Pakistan's first community managed Constructed Wetland" with the support of Indus for All Programme-WWF Pakistan and the technical support of UN HABITAT water for Asian cities Programme, South Asia region. Constructed wetland Majeed Keerio was designed, with the realization that substrate of the wetland can rapidly fill up with debris, grit, and solids from raw waste water if these materials are not removed prior to the wetland. Therefore, Majeed Keerio was designed as: (1) Preliminary treatment: Removal of large contaminants, such as solid waste and grit to avoid operation and maintenance problems; (2) Primary treatment: Removal of suspended solids and organic matter; (3) Secondary treatment: Removal of biodegradable organic matter; (4) Tertiary treatment: Removal of specific pollutants such as nutrients. This wetland has brought good results in removing pollutants from water (Keryo, 2012).

In Egypt, there are two major challenges that affect the ecosystem and the urban environment: the first being water scarcity and the second being wastewater management. Egypt is an arid country; it is important that reusing wastewater be encouraged as it is documented that reused wastewater is safe and economically feasible. There are several available methods for wastewater treatment; however treatment by wetlands is the most effective method (ElZein et al., 2016). In Malaysia, Faculty of Engineering, Universiti Putra Malaysia has been trying to resolve water treatment issues in Malaysia. In their study (Katayon et al., 2008), results showed that the constructed wetlands have removed 27-96% of NH4+, 50-88% of TSS, 56-77% of COD, 20-88% of TP, and 99% of total coliform numbers. In Kerala, India, a CW system made using a laboratory scale model; including plant 'Reed' has given good results for removal efficiencies for domestic wastewater treatment at a considerable level (Midhun et al., 2016).

In Ireland, 52 constructed wetland sites from 17 local authorities were aimed to identify the best performing types of constructed wetlands; some constructed wetland sites achieved long or frequent periods of zero effluent discharge and thus did not transfer any waterborne pollution to their receptors during these periods (Hickey et al., 2017).

Besides, there are very few disadvantages of this technology. Depending on design, constructed wetlands may possess a larger land-area than other technology. Mosquito populations increased because of wetlands and can be the reason for the diseases like malaria or other diseases caused by mosquitoes. Wetlands produce about one quarter of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_107127

Earth's atmospheric methane through the anaerobic decomposition of organic matter. Sometimes nutrients are changed to harmless forms year-round by wetland bacteria. Constructed wetlands may not to treat highly toxic modern wastewater till it is pre-treated in special installations. In climates with cold winters, bacteria and plants living in the constructed wetland's soil die back and release their own nutrients back into the system. A constructed wetland's biological processes are not well understood. Residual pollutants may have a negative effect on the reserve's wildlife (Gutiérrez, 2011; Kielmas, 2018; Permaculture, 2015; Akers, 2012; Patil, 2016).

Removal of pollutants by wetlands

Various studies have documented that wetlands are the best and low-cost available option for removing several pollutants from water. It can be concluded that the use of constructed wetland is very effective in removing major nutrients and pollutants. Some recent studies from all over the world have been mentioned in *Table 1,* which prove that this technology is best option for pollutants removal up to 99%.

Table 1. *Removal percentage of pollutants by wetlands*

The data shows that high levels of removal were detected for Total Phosphorus (TP) and Soluble Reactive Phosphorus (SRP), Total Nitrogen, ammonium/ammonia, nitrate and nitrite, Biological Oxygen Demand (BOD), Chemical Oxygen Demand

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_107127

(COD), and Suspended Sediments (SS). Large amounts were reduced for all these parameters. It can be concluded that constructed wetland systems are effective for the reduction of several pollutants

Removal mechanisms and wastewater constituents

There are many mechanisms involved in the wetlands system which can remove BOD, COD, and Nitrogen, as shown in *Table 2*.

Table 2. *Removal mechanisms and wastewater constituents. (Source: modified from: Newman et al., 2015; Keryo, 2012; FCN, 2014)*

Removal mechanisms and wastewater constituents	
Wastewater constituents	**Removal mechanisms**
Heavy metals	Sedimentation, adsorption, plant uptake, chemical precipitation, infiltration
Bacteria/pathogens	Sedimentation, natural die off
Synthetic organics	Sedimentation, adsorption, oxidation, volatilization, infiltration
Hydrocarbons	Bio-filtration, microbial decomposition, oxidation, plant uptake metabolism
Total phosphorus	Matrix sorption, plant uptake, sedimentation bio-filtration
Nitrate	Denitrification
Nitrite	Denitrification
Ammonia	Nitrification
Biological oxygen demand	Sedimentation, bio-filtration,
Chemical oxygen demand	Sedimentation, bio-filtration, oxidation
Suspended solids	Sedimentation, filtration
Soluble organics	Aerobic microbial degradation, anaerobic microbial degradation
Total nitrogen	Ammonification followed by microbial nitrification, denitrification, plant uptake, matrix adsorption, ammonia volatilization

Efficiency of vegetation in wetlands for water treatment

Efficiency of wetland systems increases with different vegetation for common pollutant removal; it has been demonstrated in several studies around the world. Roy et al. (2016) described that the basin morphometry of constructed wetlands is not same as natural wetlands, which explains the difference in vegetation composition. Plants provide a substrate for microorganisms, and microorganisms, with a source of carbon, are the most important processors of wastewater contaminants. There are various processes through with plants can incorporate pollutants are: (i) Phyto-extraction: the process in which a plant's leaves and roots play a role in concentrating heavy metals. (ii) Rhizo-filtration: the process in which plants roots play role in absorption and precipitations of metals from contaminated liquid. They are also used to degrade organic compounds. (iii) Phyto-stabililzation: the process in which metal-tolerant plants reduce the power of mobility of metals -- especially chlorinated compounds -- to air or groundwater. (iv) Phyto-stimulation: the process in which roots help bacterial and fungal development for biodegrading the compounds, i.e. petrochemical hydrocarbons, benzene, polyaromatic etc. (v) Phytovolatilization: the process in which plants take up heavy metals and some organic compounds via transpiration and place them into the atmosphere. (vi) Phyto-decomposition: the process in which both terrestrial and aquatic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_107127

plants get organic compounds to decompose and decrease toxicity at a considerable level (FCN, 2014; Leiva, 2018).

Sieben et al., (2016a) studied about the classification of the vegetation in specific type of wetland habitats in semi-arid regions of South Africa and presented the overview. There are two types of resilience (physical human disturbance and altered hydrology). From this, conclusion has been drawn that hydric species are not resilient to hydrological impacts than terrestrial species. Pretorius and Brown (2016) studied different types of wetlands while planting the main drivers of vegetation species in South Africa. This study suggested that vegetation composition vary with the wetland type so they should be evaluated individually for better results. In addition, the immoderate use of these wetlands may accelerate their deterioration because tall indigenous vegetation in wetlands can be used as fibers for traditional crafts and construction (Sieben et al., 2016b; Sieben and Nyambeni, 2016c). Vegetation in CWs also plays a vital role in the removal of nutrients from wastewater because the removal efficiency depends on the type of plants. As Leung et al. (2016) studied about efficiency of CWs on treating mangrove plants (*Bruguiera gymnorrhiza and Aegiceras corniculatum*) and non-mangrove plants (*Canna indica, Phragmites australis, and Acorus calamus*). Comparisons results showed that Mangrove CWs planted with A. corniculatum gave higher application values than the non-mangrove CWs to treat toxic wastewater. Additionally, water hyacinth plant has also efficiency to remove nutrients from wastewater (Patil and Munavalli, 2016). In Eastern Africa, Moges et al. (2016) developed a plant-based index of biological integrity with 122 plant species belonging to 37 families, aiming to evaluate the long term natural wetland conditions, also provide an effective tool, and therefore, facilitate the management of wetlands. In the United States, CWs got big problem due to erosion, which is degrading playa-wetlands in this semi-arid country, so Haukos et al. (2016) evaluated the role of vegetation surrounding playa-wetlands for removal of nutrients, metal, and dissolved/suspended solids from runoff. According to the results, vegetative Buffers removed about 78% of N, 70% P, 58% TDS and 83% TSS. It was suggested that vegetation buffers could be an economical conservation tool for playa-wetlands (Haukos et al., 2016). Ge et al., (2016) highlighted the influence on contaminants removal in the sense of seasonal change. In the study, efficiency of three plants was recorded. *Thalia dealbata outperformed C. indica and Lythrum salicaria* in the removal of total nitrogen (69.96%) and total phosphorus (82.4%) from urban storm-water runoff sewage. It is concluded that it is important to select most suitable plant communities for CWs. Wetland vegetations are important components of wetlands which play several roles in relation to the wastewater treatment processes.

Plants used in constructed wetlands around the world:

There are many plants planted in constructed wetlands (Wu, 2010; Polomski, 2007; Vymazal, 2007). Study (Oluseyi et al., 2011; Wang et al., 2016c) shows the result that three aquatic tropical plants (*Canna indica, Phragmites australis and Sacciolepis africana*) can be planted effectively. Some aquatic plants used in constructed wetlands are: *Lemna valdiviana, Spirodela sp., Typha angustifolia, Typha domingensis, Typha latifolia, Cyperus involucratus, Cyperus giganteus, Thalia dealbata, Cyperus giganteus, Juncus effuses, Phragmites communis, Sagitaria lancifolia* (Appenroth et al., 2010; Sohsalam and Sirianuntapiboon, 2008; Vymazal, 2011).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_107127

Many studies have concluded that most commonly used species, which are given in *Table 3,* are robust species of emergent plants, such as the cattail (*Typha latifolia*), common reed (*Phragmites australis*), and bulrush (Appenroth et al., 2010; Sohsalam et al., 2008; Vymazal and Kröpfelová, 2011).

Most commonly plants used in CW

Around the world, four most commonly genera plants used in CW are: *Canna, Iris, Heliconia, Zantedeschia, Phragmites and Typhas* have been recommended as the main species planted in constructed wetland due to their effectiveness, even though they are considered invasive and outside their native range. Common plants planted in constructed wetlands in North America are *cattails* (*Typha latifolia*). *Cattails (Typha latifolia)* have the ability to grow at different water depths, are easy to transport and transplant, and they have broad tolerance of water composition (including pH, dissolved oxygen, salinity, and contaminant concentrations), making them ideal plants for constructed wetlands. Another species known as Common Reed (*Phragmites australis*) is also commonly found in both black-water treatment and in grey-water treatment systems to clean wastewater. *Bulrush* is also known as effective species (Appenroth et al., 2010; Sohsalam and Sirianuntapiboon, 2008; Vymazal, 2011).

Conclusion

The overall finding of this review is that all wetland types are very effective at reducing major nutrients and suspended sediments. Constructed wetland is recommended for wastewater treatment because it treats water biologically, physically and chemically, making it the best option. It is no surprise that many countries around the world opt to use constructed wetlands. The data previously published have concluded that consistently high levels of removal were found for Total Nitrogen, nitrate and nitrite, ammonium/ammonia, Total Phosphorus (TP), Biological Oxygen Demand (BOD), Chemical Oxygen Demand (COD) and Suspended Sediments (SS). Therefore, it can be concluded that wetland systems are effective for the reduction of all of these parameters as they were reduced by large amounts. While reviewing, it was found that “Biochar” is being used in wetlands. The use of biochar to enhance

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_107127

constructed wetland performance in wastewater has highly appreciated. Different types of biochar have been used to promote wetlands activities. Combining both of these technologies can greatly augment the efficiency of the system, so it is recommended that Biochar from different materials be considered for further improvement. With this change, societies around the world may get easy and sustainable way of water treatment, especially in the affected areas, while also keeping in mind of the social, cultural and economic status of the population. It is concluded that most of plants play a vital role to enhance the efficiency of wetlands to treat all the types of wastewater, either it is natural wetlands or constructed wetlands. Several studies around the world have proved that plants have ability to remove the contaminant at considerable level.

It is recommended that before selection of plants for wetlands; consider the condition such as weather of the area, type of wetlands, and type of water need to be treated so that removal percentage should be higher. Addition of biochar/ACF boosts efficiency of the system. It is recommended that select an efficient material for media. Wood biochar is less expensive than other synthetic materials like granular activated carbon. Therefore, use of wood biochar for removal efficiency is recommended as a simple, cost effective, and environmentally friendly solution for constructed wetland system especially in developing countries. Furthermore, future research is needed on combination of different advanced techniques to undertake stability and mechanism of things which are involved in the constructed wetland system for better solution during water treatment. Additionally, it is important to elucidate the possibility and efficiency of suitable approaches to treat and safely dispose of the resultant material after the treatment process. There is still gap and need to investigate as industrialization and urbanization is changing the world every day and creating different water issues.

Abstract. The anthropogenic activities change hydrological pattern of mangrove ecosystems affecting their carbon accumulation and methane emissions. For this reason, the aim for this study was to estimate carbon and nitrogen quantity, in addition to methane emission associated with physicochemical parameters from sediment into three mangrove ecosystems (*Los petenes* Biosphere Reserve (BR), *Laguna de Términos* and *Champotón*) with different anthropic pressure and hydrological characteristics along the Campeche coast. Sampling was realized in rainy season and pH, Redox from interstitial water were measured, soil parameters, salinity, methane emissions and carbon concentration were determined simultaneously. Carbon sequestered average in the three study areas was 170 Mg ha^{-1}, significant differences were not observed ($F_{2,29}$=0.02, p=0.97). The highest methane emissions were found in *Laguna de Términos* (673.24±922 mg $m^{-2}h^{-1}$), with significant differences ($F_{2,29}$=3.55, p=0.042) among the three ecosystems. Carbon sequestration in *Los Petenes* BR established an inverse relationship with methane emissions (Y=482.4–2.245x, R^2=0.67, p<0.025). In *Champotón* ecosystem, carbon sequestration presented a direct correlation with salinity (Y=-116.3+11.53x, R^2=0.70, p<0.008). Methane emissions in *Laguna de Términos* established an inverse relationship with soil pH (Y=12027–2190x, R^2=0.77, p<0.0001), attributed to different environmental conditions and different prevailing anthropic pressures in each ecosystem.
Keywords: *redox potential, soil, greenhouse gases, interstitial water, elemental analyzer, environment*

Introduction

Globally, mangroves cover approximately 13,776,000 ha (Giri et al., 2011), with Mexico being one of the four countries with the largest mangroves of the 125 countries and territories in which this ecosystem is found, comprising an estimated cover of 770,057 ha (Rodríguez-Zúñiga et al., 2013). Mexico's mangrove forests are found in the watersheds of the Pacific, the Gulf of Mexico and the Gulf of California (Sandoval-Castro et al., 2014). The state of Campeche contains the largest area of mangroves in the country (25.2%) (CONABIO, 2009). The mangroves on this coast are mainly located in the

DOI: http://dx.doi.org/10.15666/aeer/1801_10911106

Laguna de Términos Flora and Fauna Protection Area, the *Los Petenes* Biosphere Reserve and on the Champotón river (Agraz-Hernández et al., 2015).

With the mangroves contributing a great variety of goods and services, they are considered one of the most productive ecosystems of the biosphere (Mazda et al., 1997; Barbier, 2008). They are characterized by functions of great ecological, economic and social value, providing diverse ecosystem services, such as protection against hurricanes and the mitigation of the erosion caused by winds and tides, while also functioning as natural barriers against marine currents and flooding (Alongi et al., 2004). In turn, the mangroves contribute to the retention of sediments and act as a deposit, as well as processing, recycling and exporting organic material and nutrients, and producing oxygen (Vázquez-Lule et al., 2019). Over the last 50 years, approximately a third of the world's mangrove forests has been lost due to anthropogenic activities, such as tourism, badly developed or unsustainable aquaculture, unmoderated industrial and urban development, highway construction, and unsustainable livestock and agricultural practices (Alongi, 2014).

The carbon stock is one of the most important ecosystem services provided by the mangroves, given that it contributes to minimizing the effects of climate change (Kauffman et al., 2013). The efficiency of a mangrove forest in capturing atmospheric CO_2 mainly depends on its density and productivity, the basal area, height and age of the trees, and the photosynthetic efficiency of each species (Sitoe et al., 2014), which are, in turn, influenced by the physicochemical characteristics of the water and soil, the topography, the hydroperiod, the sediment dynamics and the climate. The carbon capture capacity of mangroves varies greatly on a global, regional and local level (Mitsch and Gosselink, 2000; De la Peña et al., 2010; Adame et al., 2013).

Alongi (2014) describes how the soil plays an important role in the carbon cycle, also mentioning that carbon sequestration in the mangrove forests occurs due to their low pH values, salinity concentration and hypoxic conditions, which contribute to the accumulation of carbon. However, soil use change caused by anthropogenic activities has negative effects on the carbon cycle, due to the modification of the decomposition rate of litterfall, sedimentation, the loss of plant biomass, and increased methane emission, causing more reduced conditions due to the decreased redox potential. This thus indicates the depletion of oxygen in the soil, an effect which occurs with greater intensity in the presence of the discharge of urban, agricultural, livestock and industrial waste water into the wetlands (Zinn et al., 2005; Lal, 2005). The mangrove wetlands do not efficiently accumulate carbon via photosynthesis, requiring a large amount of nitrogen-based nutrients, such as the nitrites and nitrates produced by the biogeochemical cycle. In this regard, Alongi et al. (2004) mention that the recycling of nutrients, such as nitrogen (N) and carbon (C), in mangrove forests occurs via the decomposition of organic material through the production and defoliation of litterfall, for which reason, the concentration of nitrogen in the soil increases in line with carbon sequestration (Rivera-Monroy et al., 1995; Yimer et al., 2006).

The accumulation of nitrogen in the soil is also associated with the cover and the aerial plant biomass (Hooker and Compton, 2003; Liao, 2007).

The wetlands store carbon with a minimal release of greenhouse gases, due to the inhibition of methanogenesis by sulfates and salinity (Graham et al., 2005). However, various authors have demonstrated that the higher levels of nutrients of anthropic origin (eutrophication) found in mangrove forests generate higher methane emissions into the atmosphere by means of increased microbial activity (Kreuzwieser et al., 2003; Chen et

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10911106

al., 2010). Abril and Iversen (2002) report that, within marine systems, estuaries are an important source of methane emitted into the atmosphere as a consequence of the constant supply of nutrients of anthropogenic origin. Given the foregoing, the measurement of greenhouse gases (GG), such as methane (CH_4) and nitrous oxide (N_2O), in mangrove ecosystems has generated great interest, at both a global and national level (IPCC, 2001). For years, global estimates of wetland GG levels have been inaccurate, due to the lack of either flow measurements or an understanding of the environmental factors that control them (Lu et al., 1999). The objective of the present study was to estimate the amount of carbon, nitrogen and methane emissions in the soils of four mangrove forests along the length of the Campeche coast and presenting differences in environmental conditions and anthropic activity. It also seeks to relate the capture of carbon and nitrogen and methane emissions to the physicochemical variables of the soil during the rainy season.

Material and methods

Study area and sample collection

The geographical area studied here comprises the southeastern and northeastern parts of the state of Campeche and is divided into three zones: the *Laguna de Términos* (LT) Protected Natural Area, with two sampling sites (Xibujá and Atasta); *Río Champotón* (RC), with one site; and, *Los Petenes* Biosphere Reserve (RBP), with one site (*Río Verde*) (*Figures 1 and 2*).

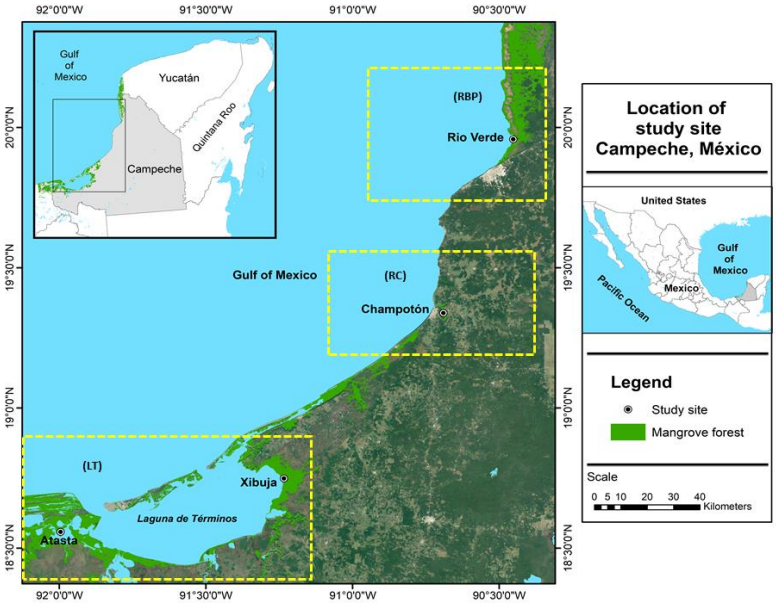

Figure 1. *Geographical location established for three mangrove study areas in the southeast of Campeche: The Protected Natural Area Laguna de Términos (LT), Río Champotón (RC) and the Los Petenes Biosphere Reserve (RBP), Campeche*

A sampling site was established within two plot of 0.01 hectares for each of three mangrove areas (RBP, RC and LT). Duplicate Samples of interstitial water and soil were obtained in each month of the rainy season (September and October, 2017) for every sampling site.

Figure 2. *Measurement of the physicochemical parameters of the soil, interstitial water and sampling sites location*

Located in the northern region of the state of Campeche, the *Los Petenes* Biosphere Reserve (*Reserva de la Biósfera Los Petenes*, or RBP) forms part of an ecoregion that includes the *Ría Celestún* Biosphere Reserve and the *El Palmar* Protected Natural Area in the state of Yucatán. These areas contain a high diversity of flora and fauna and unique ecosystems, particularly those found in *Los Petenes* and the seagrass beds, with the latter considered to be the largest in the country and in the best state of conservation. In 2004, the *Los Petenes* Biosphere Reserve was declared a RAMSAR site (named after the 1971 Ramsar Convention on Wetlands of International Importance especially as Waterfowl Habitat) in recognition of the peten (or hammock) ecosystems (complex habitats that develop as islands of varied vegetation). These ecosystems are found in only three parts of the world, the Yucatán Peninsula, Cuba and the Florida Peninsula, and are recognized as a wetland of international importance. The *Los Petenes* Biosphere Reserve is found within one of the regions of Mexico considered a priority under all existing categories: *Regiones Prioritarias Terrestres* (RPTs or Priority Terrestrial Regions) (*Petenes-Ría Celestún*, RPT No. 145); *Regiones Marinas Prioritarias* (RMPs or Priority Marine Regions) (*Anillo de Cenotes*, RMP No. 102.); and, *Áreas de Importancia para la Conservación de las Aves* (AICASs or Important Bird Conservation Areas) (Petenes, Clave SE-28). Considered the dominant vegetation, mangroves occupy approximately 50% of the terrestrial surface area of the *Los Petenes* Biosphere Reserve. Their principal components are the red mangrove (*Rhizophora mangle*), black mangrove (*Avicennia germinans*), white mangrove (*Laguncularia racemosa*) and the button mangrove (*Conocarpus erectus*). The mangroves of the *Río Verde* study area (located at coordinates Latitude North: 20.756793 and Longitude East: 90.551896) are characterized as fringe-type with riverine, fringe and scrub tendencies.

The municipality of Champotón is located in the central region of the state of Campeche.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10911106

The Champotón river, located in *Región Hidrológica Prioritaria* (RHP or Priority Hydrological Region) No. 31 (19°22'LN and 90°43'LN), is approximately 48 kilometers in length from its source close to the community of San Juan Carpizo to where it discharges into the Gulf of Mexico (*Figure 1*). The Champotón river basin is close to 650 km^2 in area, while the river's volume reaches an annual average of approximately 483.93 million m^3. Its median discharge has been estimated at 0.2 x 10^9 m^3 $year^{-1}$, while its mouth is approximately 85 m wide with an median depth that varies from 2.5 to 4.5 m depending on the tides. The predominant climate is warm subtropical with rains in the summer, with a total annual precipitation of 1100-1500 mm, while the average annual temperature is between 26 and 28ºC. The predominant soil types are mainly vertisol, gleysol and lithosol. The *Comisión Nacional para el Conocimiento y Uso de la Biodiversidad* (CONABIO or the Mexican National Commission for the Knowledge and Use of Biodiversity) identifies various types of vegetation in the Champotón river basin, such as tall semideciduous forests, medium subdeciduous forests, low floodable forests, low flood forest, mangroves, flood-prone palm groves, thorn scrub, savannah and cultivated grassland. Among the main anthropogenic activities undertaken in the Champotón river basin are agricultural practices and, to a lesser extent, livestock farming and tilapia aquaculture. Wastewater discharge from the *La Joya S.A de C.V.* sugar mill, based in the former ranch at Haltunchen, is carried by run-off into the river during the rainy season (Dzul-Caamal et al., 2016). The area of mangrove studied in the present research is found on the margin of the Champotón river, at the coordinates 19.35 Latitude and -90.7167 Longitude (*Figure 1*).

The *Laguna de Términos* Flora and Fauna Protection Area (*Área de Protección de Flora y Fauna de Laguna de Términos* or APFFLT) is located between 18°01'54" and 19°13'30" Latitude North and 92°32'33" and 90°59'15" Longitude West. Aquatic and terrestrial plant associations are found in the APFFLT, with high biodiversity, wherein 374 plant species and 1,468 fauna species are identified, the majority of which have been traditionally exploited since pre-hispanic times by the local communities. The surrounding vegetation mainly comprises four mangrove species: *R. mangle*; *A. germinans*; *L. racemose*; and *C. erectus*.

The trees of the *R. mangle* forests in the Atasta, Río San Pedro, and Sontecomapan areas and the mouth of the Grijalva river reach a height of 30 m. and above. In the northern part of the laguna, the *A. germinans* trees reach a height of up to 15 m., while, in the internal areas of the Sabancuy estuary that border the edge of the laguna, scrub-type mangroves, dominated by *R. mangle* and with a height of no higher than 1.5 m., can be found on an exposed soil on a karst topography (Agraz-Hernández et al., 2011 – *Figure 1*).

Chemistry of interstitial water

Two PVC tubes, with a diameter of 10 cm and a length of 1.5 m, were installed at each study site. Orifices, 1 cm in diameter, were made in the lower part of each tube up to the 30 cm mark (the depth at which the maximum root biomass is found). Each tube was installed at a depth of 50 cm from the surface of the soil. The sample was collected once the tube had been drained and the filtration of water into the interior of the tube had been stabilized. In order to determine the availability of the dissolved oxygen in the interstitial water (Chan-Keb et al., 2018), the redox potential was measured by means of the chemical activity of the electrons using a multi-parametric probe (HACH, model HQ40d) and an ORP (Oxidation Redox Potential) electrode. The salinity was determined with an A&O

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10911106

refractometer, with a 0 to 100 PSU (Practical Salinity Units) measurement interval (Agraz-Hernández et al., 2011). The interstitial water collected during the rainy season in each piezometer was then transferred, via a vacuum pump, to 50 ml flasks, to enable sulfate concentration measurement, which was carried out based on the criteria proposed by Agraz-Hernández et al. (2018) using ion chromatography (IC advanced 861).

Determination of the physicochemical parameters of the mangrove sediments

The soil samples were extracted using corers constructed with PVC tubes 15.24 cm in diameter and 10 cm deep, following the criteria proposed by Satheeshkumar and Khan (2009). Two samples were taken from the first strip of mangrove forest. The pH and redox potential of the soil were taken *in situ* using a multiparametric IQ150. The samples were transported to the coastal wetlands laboratory for physicochemical analysis.

Determination of carbon and nitrogen

The organic carbon and total nitrogen (TN) analysis was conducted via the dry combustion method based on the Dumas principal described by Ruiz-Fernandez et al. (2018), using a FLASH 2000 elemental analyzer.

Between 5 and 10 mg of soil was weighed in silver capsules using a METLER TOLEDO XP6 micro balance with a 0.001 mg precision. The soil was then digested with HCl 1:1 until the inorganic carbon was eliminated, as indicated when the sample ceased bubbling, and then placed in the elemental analyzer. The samples were dried on a heating plate at 50°C and then sealed. In order to obtain precise results, the elemental analyzer was calibrated using both the known standard (sulfanilamide and methionine) and a target.

Soil bulk density

The Soil bulk density was determined via the known volume cylinder method (gcm^{-3}) (Rodríguez-Fuentes and Rodríguez-Absi, 2002). This method consists in introducing the cylinder (sampler) to a depth of 10 cm and a diameter of 15.2 cm, with the cylinder, now saturated with soil, then extracted and transferred to a receptacle and placed in an oven at 105ºC until the constant dry weight is obtained. The Soil bulk density was then measured by dividing the dry soil weight by the volume of the cylinder.

Quantification of organic carbon sequestered in the soil

The carbon content in each 10 cm soil core was obtained by multiplying the carbon concentration per depth interval by its apparent density, the corresponding length, and the average amount of organic carbon in the cores extracted per parcel, giving, as a result, the subterranean carbon for each physiognomic type of mangrove identified (Mg C ha^{-1}).

Methane Emission

Methane emissions were determined using static cylindrical chambers manufactured from polyvinyl chloride (PVC) tubes, caps and couplings, which were closed prior to high tide, allowing the accumulation of gases in a minimum time period of three hours, with another sample extracted during low tide. The extraction of gas was undertaken, using a vacuum pump, via brass connectors with ½" hoses and a 1-liter Tedlar Bag manufactured with classic duPont ® film (SNC, cat No. 232 - 01). The bags were transported to the coastal wetland laboratory, to determine the methane (CH_4) level via a Trace 1310 gas

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10911106

chromatograph fitted with a flame ionization detector (FID) and a Q 15 m x 0.32 x 10.0 µm TG-Bond column. The working temperatures were 225°C (FID), 230°C (SSL injector) and 60°C. Nitrogen (N_2) at 40 mL/min was used as a carrier gas, while the compressed air flow was 350 mL/min and H_2 was used as a catalyzer gas for the FID at 35 mL/min. The methane concentrations were calculated based on the criteria proposed by Mendoza-Mojica et al. (2013).

$$Flow = \frac{(Cf - Ci)\ x\ Volume}{Time\ x\ Area} \quad \text{(Eq.1)}$$

where Ci is the initial concentration and Cf the final concentration of CH_4 gas in mg L^{-1},
Volume = Volume of the static chamber in liters,
Time = Time in the emission of methane gas in hours,
Area = Area of the static camera in m^2,
Flow = Flow of the emission of methane gas in CH_4 m^{-2} h^{-1}.

Statistical analysis

A database was generated with the physicochemical parameters of the sediment (NT, Soil bulk density, pH, carbon sequestration and methane emission), as well as the chemical parameters of the interstitial water (salinity, redox potential and sulfates), in the mangrove forests of the coast of the state of Campeche.

A one-way analysis of variance was applied in order to determine the variation among the sites (mangrove areas). Subsequent post hoc analysis Fisher's Least Significant Difference test (LSD) was applied to determine significant differences among means at $p \leq 0.05$ level of significance. For this analysis, the normality of the physicochemical variables was validated by means with a significance level of $\alpha = 0.05$ on non-compliance with the supposed normal distribution. The data were transformed using the Box-Cox method as recommended in Zar (2010), while, principal component analysis (PCA) was applied in order to determine the environmental variables of greatest importance to the soil and interstitial water of the mangrove forests. A simple linear regression analysis was then performed in order establish the relationship among the physicochemical parameters of the interstitial water and sediment in terms of carbon sequestration, methane emission and total nitrogen concentration. The statistical analysis was undertaken with a significance level of $\alpha = 0.05$, using the Statgraphics Centurion XVII software (Statpoint, 2014).

Results

Physicochemical parameters of the interstitial water

In the rainy season, mesohaline conditions presented in the three mangrove areas under study (RBP, RC and LT), which comprise the large part of the cover found in the state of Campeche. The highest salinity levels were registered in RBP and LT (36.0 ± 8.7 and 33.5 ±8.3 UPS), while the lowest levels were observed in RC (26.3 ± 8.3 UPS). On applying a one-way ANOVA, significant differences were established in the salinity levels measured in three study areas ($F_{2,29} = 3.8$, $p = 0.033$) (*Figure 3a*). Similar behavior was registered for sulfate concentration, with maximum levels found in RBP and LT (2976.2 ± 1255.2 mg L^{-1} and 3,180 ± 1580 mg L^{-1}) and minimum levels in RC

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10911106

(2,333 ± 1,074 mg L^{-1}); however, significant differences were not found ($F_{2,29}$ = 0.99, p = 0.38) (*Figure 3b*).

The oxido-reduction conditions established in the interstitial water in RBP were an oxic-hypoxic type of -290 ± 23 mV, while RC and LT presented hypoxic-type conditions, with values of -321 ± 27 and -301 ± 47 mV, respectively. Significant differences were not established during the rainy reason along the length of the Campeche coast ($F_{2,29}$ = 1.28, p = 0.29) (*Figure 3c*).

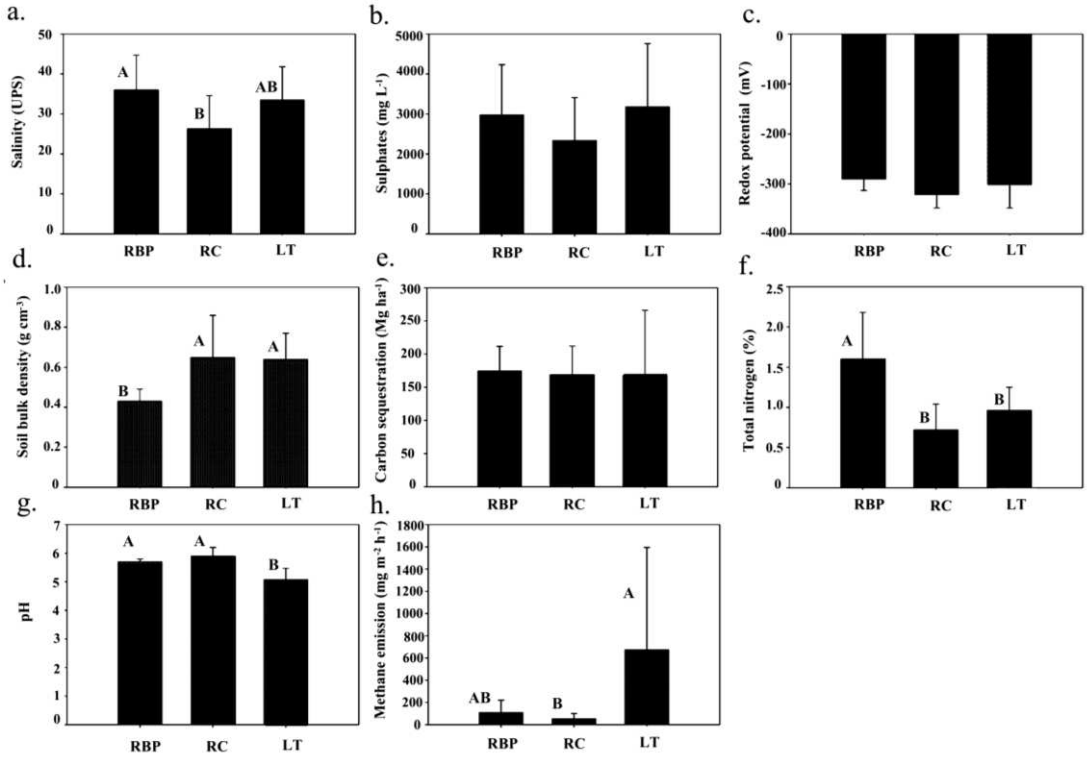

Figure 3. *Physicochemical parameters of the interstitial water and soil in three mangrove ecosystems on the coast of the Campeche state. RBP: Reserva de la Biosfera de los Petenes (Los Petenes Biosphere Reserve); RC: Río Champotón (Champotón river); and, LT: Laguna de Términos. the site that do not share a letter are significantly different (p≤0.05). Error bars represent standard deviation*

Physicochemical parameters of the soil

The highest Soil bulk density values were registered in RC and LT (0.65 ± 0.21 gcm^{-3} and 0.64 ± 0.13 g cm^{-3}), while they were lower in RBP (0.43 ± 0.06 g cm^{-3}), presenting significant differences ($F_{2,29}$ = 6.4, p = 0.005) (*Figure 3d*).

The highest concentration of total nitrogen (NT) in the soil was 1.6 ± 0.58% in RBP, followed by 0.96 ± 0.29% for LT and, finally, 0.72 ± 0.32% in RC, with significant differences found among them ($F_{2,29}$ = 12.83, p = 0.0001) (*Figure 3f*).

The pH conditions of the soil were acidic in the three mangrove areas studied: RC (5.9 ± 0.3); RBP (5.7 ± 0.1); and, LT (5.07 ± 0.40). The one-way ANOVA test revealed significant differences among these ecosystems, despite the minimal differences ($F_{2,29}$ = 20.29, p = 0.0001) (*Figure 3g*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10911106

Carbon sequestration

The highest carbon sequestration levels were observed in RBP (174.6 ± 37 Mg ha^{-1}), followed by RC and LT (169 ± 43 Mg ha^{-1} and 168 ± 98 Mg ha^{-1}, respectively), despite which, significant differences were not observed among the mangrove ecosystems in RBP, RC and LT ($F_{2,29}$ = 0.02, p = 0.97) (*Figure 3e*).

Behavior of methane emissions

Average methane emissions were higher in LT, with a flow of 673.24 ± 922 mg m^2h^{-1}, and lower in RBP and RC, with values of 109.80 ± 111 mg m^2 h^{-1} and 51.73 ± 48 mg m^2 h^{-1}, respectively. These flows presented significant differences between the study areas ($F_{2,29}$ = 3.55, p = 0.042) (*Figure 3h*).

Behavior of methane emissions, in terms of interstitial water conditions and the soil

The results of the PCA, considering the variables of methane emissions and the physicochemistry of the interstitial water and soil, presented three components that explain 71.01% of the total variance in the mangrove forests that border the coast of the state of Campeche. Thus, the first component (28.72%) describes the most important sulfates with a direct relationship with both the salinity and the redox potential of the interstitial water. The second component (22.02%) defines the pH of the soil as the most important factor, presenting an inverse correlation with the methane emissions, while the third component (20.27%) shows that carbon sequestration is the most important parameter, establishing a direct relationship with the TN (*Table 1*).

Table 1. *PCA applied to chemical parameters in the soils of the mangrove forests, with an accumulated 71.01% of the total variance in the first three factors of the mangrove forests on the coast of the state of Campeche*

Modeling of carbon sequestration and methane emissions, in relation to the chemical conditions of the interstitial water and soil

In general, the mangrove forests that border the northern (RBP), central (RC) and southern (LT) regions of the state of Campeche have established a direct relationship between carbon sequestration and the TN concentration in the soil (*Table 2*). The TN presented a direct relationship with carbon sequestration, while methane emissions registered an inverse relationship with the pH of the soil (*Table 2*).

CS: Carbon Sequestration; TN: Total nitrogen; ECH_4: Methane emissions; SO_4^{-2}: sulfates.
Where: X_1 (Salinity in UPS); X_2 (IW redox potential in mV); X_3 (Sulfates in mg L^{-1}); X_4 (Soil bulk density in g cm^{-3}); X_5 (pH); X_6 (CS in Mg ha^{-1}); and, X_7 (TN in %). Level of significance: $\alpha = 0.05$

Specifically, methane emissions in RBP presented an inverse relationship in terms of the redox potential of the interstitial water and carbon sequestration, while the contrary was found for the RC wetlands, in which carbon sequestration presented a direct relationship with the salinity of the interstitial water and the concentration of TN in the soil. For LT, a direct correlation was found with the sulfate concentration, salinity and redox potential of the interstitial water. Similarly, the relationships were significant ($p<0.05$) (*Table 2*).

Discussion

Behavior of the physicochemical parameters of the interstitial water

The salinity and sulfate concentration varied among sites, increasing from south (LT) to north (RBP). This may be related to the level of ingress of seawater and the ingress from superficial and subterranean rivers, causing a dilution effect in the interstitial water (Chan-Keb et al., 2018) in each of the areas. The ingress of freshwater into the mangroves in this lagoon system is drawn from the Champotón river to the center, with a higher flow in the south (LT), from such sources as the San Pedro, San Pablo, Grijalva and Palizada rivers (Chan-Keb et al., 2018), and descreasing towards the north. The results of this study are similar to that reported by Barreto et al. (2016), who describe how sulfates originate in the seawater and are directly related to the salinity of the interstitial water. Moreover, in Zanzíbar, Africa (Sitoe et al., 2014), and in Florida, USA (Rivera-Monroy et al., 2007), the low salinity levels found in the mangroves are reported to indicate a higher level of freshwater ingress. Flores-Verdugo et al. (2007) establish that, in the mangrove forests, the interstitial salinity levels are caused by the hydrological pattern, variation in the level of the soil, the evaporation rate and, moreover, the ingress of salts of anthropic origin. The general tendency of the oxido-reduction conditions of the interstitial water in the mangrove areas (RBP, RC and LT) results from the different levels of ingress of freshwater (rivers) and seawater (tides). It is also a consequence of the intensity and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10911106

direction of the winds by season of the year ('northerlies' and 'southerlies') and, therefore, the circulation of the lagoon system and/or the marine front.

In turn, this tendency is defined by annual hydrometeorological cycles (precipitation) and the type of anthropic pressure exerted on each ecosystem. Gleason et al. (2003) state that the oxido-reduction conditions are related to hydrology (the residence time of the water, the frequency of flooding due to the effect of the tides, and the ingress of urban and/or industrial wastewater). The highest redox potential values were registered in RBP due to the lower water residence time caused by the continual ebb and flow of the tide, as well as the higher level of freshwater ingress (interstitial and subterranean) during the rainy season. In this regard, Chen et al. (2010) indicate that, during the rainy season, the redox potential increases, as a result of the runoff caused by the rain, the increased river flow and the effect of the tide.

The RC and LT study areas, despite receiving a higher level of freshwater ingress from the rivers than that received by the wetlands of RBP, receive large amounts of organic material resulting from anthropogenic activities, thus causing a greater demand for dissolved oxygen, due to the oxidation of organic material, and, thus, a decrease in redox potential. Mitsch and Gosselink (2000) describe how the hydrological pattern (hydroperiod) and the ingress of organic material are determinants of the oxido-reduction conditions in the mangrove forests, establishing changes in the redox potential. Similar redox potential values have been reported in both Campeche (Chan-Keb et al., 2018) and the Laguna de Términos Flora and Fauna Protection Area (Agraz-Hernandez et al., 2012).

Behavior of the physicochemical parameters of the soil

The variations found in Soil bulk density in the study areas are attributed to the variations in the organic and inorganic composition of the soil among these ecosystems (Agraz-Hernández et al., 2011). Specifically, RBP presents a lower apparent density, due to the high organic material content, the opposite of which was found in RC and LT. Similar behavior is described by Chen and Twilley (2005) in the soils of the mangroves of the state of Florida, USA, and by Moreno et al. (2002) in soils of the mangroves of the state of Tabasco, Mexico.

The general behavior of the pH registered in the three study areas (RBP, RC and LT) presented acidic conditions due to the production of hydrogen sulphide and the formation of humic and fulvic acids during the decomposition of the organic material caused by the ingress of sulfates originating in seawater. Moreover, this was also due to the discharge of wastewater from agricultural and livestock activities. This behavior is similar to that reported by Marchand et al. (2004) and Moreno et al. (2002).

Carbon sequestration

In general, similar carbon sequestration was found among the RBP, RC and LT study areas ($p>0.05$), despite presenting differences in the physicochemical parameters of the interstitial water and the soil. The foregoing is attributed to the interaction among the hydroperiod, topography and ingress of organic material (Kristensen et al., 2008; Schmidt et al., 2011; Alongi, 2014; Lehmann and Kleber, 2015). The higher levels of carbon sequestration registered in the RBP and RC study areas may be attributed to the ingress of organic material resulting from the generation of *R. mangl*e litterfall. *R. mangl*e leaves contain a high concentration of lignin, cellulose and lipids, which are complex in structure, thus causing a slow decomposition speed and favoring carbon sequestration (Hogarth, 1999). Other influential factors are the mineralization of organic material and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10911106

the decrease in microbial activity in response to the high salinity concentrations (Kreuzwieser et al., 2003; Chen et al., 2010). The opposite was found in LT, where carbon sequestration was lower due to the greater dominance of *A. germinans* (Chan-Keb et al., 2018).

The lower water residence time in RC and LT has established hypoxic conditions in the interstitial water, thus limiting the degradation of organic material and generating carbon sequestration. However, the carbon sequestration results identified by this research are lower than those reported by Kauffman et al. (2011, 2013) in the mangroves of Micronesia (53.4 Mg ha^{-1}), Bangladesh (16.9 Mg ha^{-1}) and Indonesia (28 Mg ha^{-1}), at a depth of 10 cm.

Concentration of total nitrogen

The NT concentration in the three study areas (RBP, RC and LT) presented significant differences ($p<0.05$), due to the ingress of organic material originating in both litterfall and anthropogenic activity (Rivera-Monroy et al., 1995, 2007). Similarly, the TN concentration in RC and LT may be attributed to the discharge of urban, agricultural and livestock wastewater. Adame et al. (2015) and Alongi et al. (2004) describe how the levels of carbon and nitrogen in the mangroves also originate in allochtonous sources, such as the discharge of urban, agricultural and livestock wastewater, as observed in this study.

Carbon sequestration presented a direct and significant relationship ($p<0.05$) with the concentration of total nitrogen in the three study areas (RBP, RC and LT) (*Tables 1 and 2*).

In this regard, authors such as Yimer et al. (2006) and Xue and Shaoshan (2019) mention that mangrove forests are efficient in the accumulation of not only carbon, but also nitrogen (Vázquez-Lule et al., 2019).

This is due to the interaction that occurs during the biogeochemical cycle, with these authors emphasizing that nitrogen concentration increases along with increases in carbon sequestration.

Behavior of methane emissions

The variation in methane emissions ($p<0.05$) in the three mangrove ecosystems on the coast of the state of Campeche results from the differences in the dynamics of the carbon present in first 10 cm of soil, influenced by the prevailing environmental conditions in each study area (Agraz-Hernández et al., 2015). According to the results obtained by the present study, the highest methane emissions are released in the mangrove forest of the LT study area.

The foregoing is a consequence of the constant ingress of terrigenous nutrients (from the Atasta and Palizada rivers), anthropogenic activity, topographic gradient, and, thus, the water residence time and the extent of the flooding, reducing oxido-reduction conditions, pH levels, and salinity, in contrast with the forests of RC and RBP.

Studies by various authors show that increased organic discharge into coastal ecosystems result in significant increases in methane gas emissions (Heyer and Berger, 2000; Purvaja and Ramesh, 2001; Muñoz-Hincapie et al., 2002; Chiu et al., 2004; Punshon and Moore, 2004), caused by the bacterial degradation of this organic material during the processes of methanogenesis. Authors such as Purvaja and Ramesh (2001) consider that mangrove soils are sources of the emission of CH_4, given that they are especially sensitive to methanogenesis and other biogeochemical processes. This increases considerably due to other factors, such as changes to the hydrological pattern,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_10911106

the ingress of wastewater, or deforestation. However, the results of the present research indicate lower levels than those reported by Alongi et al. (2005), who report an emission level of 0.088 mg $m^{-2}h^{-1}$ in the Changning Estuary in China. Moreover, the results obtained by the present study are similar to that reported by Purvaja and Ramesh (2001), who reported emission levels of 15.41 mg $m^{-2}h^{-1}$ for the Adyar Estuary in India, while May-Herrera (2017) report methane emissions ranging from 45 to 948 mg $m^{-2}h^{-1}$ in the San Pedro river, in the state of Nayarit, Mexico.

Mukhopadhyay et al. (2002) report emissions of 15.4 to 32 mg $m^{-2}h^{-1}$ in mangrove forests recieving runoff from the Sundarban river in India.

Conclusions

The highest amount of sequestered carbon was registered in the *Los Petenes* Biosphere Reserve, while, in comparison, significant differences were not observed for the Champotón river and *Laguna de Términos*. In turn, the carbon sequestration presented a direct relationship with the concentration of total nitrogen in the three study areas. This may be due to the production of litterfall by the dominant species, with *R. mangle* dominating the northern and central areas of the Campeche coast, as well as the ingress of organic material and nitrogen of anthropogenic origin.

The highest methane emissions were registered in *Laguna de Términos* (673.24 ± 922 mg m^{-2} h^{-1}), while the lowest were found in Champotón (51.73 ± 48 mg m^{-2} h^{-1}), with significant differences found between the study areas ($p<0.05$). The highest level of methane released in the mangrove forest in LT presented an inverse relationship with the pH of the soil.

This is a consequence of the constant ingress of terrigenous nutrients (from the Atasta and Palizada rivers), anthropogenic activity, topographic gradient, and, thus, the water residence time and the extent of the flooding, reducing oxido-reduction conditions, pH levels, and salinity, in contrast with the forests of RC and RBP.

The results of the present study demonstrate that the quantity of carbon and methane emitted on the coast of the state of Campeche depended on the hydrochemical variables of both the soil and the interstitial water, as well as the different prevailing anthropic pressures in each ecosystem.

The results in this study were obtained only in the rainy season, so carbon sequestration and methane emission could be different throughout year and to be influenced by other physicochemical parameters of interstitial water and soil. For further research on this topic it is necessary to include physicochemical parameters of interstitial water such as micronutrients and monitor the profiles (quantities) of sequestration and emission of methane at three different times of the year.

Abstract. The arid and semi-arid regions of Loess Plateau in China are major winter wheat producing areas where water shortage is limiting wheat production. Present study was designed to analyzed the water consumption characteristics of plastic film-mulched wheat under different seeding rates in order to attain a high yield of dryland wheat. Wheat was sown in dryland areas of Shanxi province, China during the 2014-2016 growing seasons at different seeding rates (60, 75, 90, 105 and 120 kg h^{-1}) under ridged plastic film mulching and flat sowing without mulching. The results showed that the plastic film mulching had increased the total water consumption (7.8-11%), water use efficiency (7.6%-11.3%), number of tillers (8-16%), and grain yield (15.9-23.6%). Water use efficiency, water consumption, and yield were highest at 90 kg h^{-1} under film mulching and 105 kg h^{-1} under no mulching. Increasing seeding rate had increased the number of tillers per unit area and leaf area index, while reduced the number of grains per panicle and 1000 grains weight whereas, yield was increased first and then decreased. Therefore, film-mulching with appropriate seeding rate is an effective approach to enhance yield and water use efficiency of dryland wheat.
Keywords: *dryland wheat, biomass, grain to leaf ratio, planting density, water consumption*

Introduction

Insufficient precipitation during the growth stages of wheat and shortages of irrigation water in dryland wheat (*Triticum aestivum* L.) producing areas are major constraints to high yield (Li et al., 2017). The arid and semi-arid area of the Loess Plateau is typical rainfed and 60% of the dryland area is under wheat cultivation (Jin et al., 2007). Previous reports indicated that there is a potential to increase wheat yield in this region by sufficient irrigation (Mo et al., 2005; Liu et al., 2007). However, due to the distribution of the area and limited surface and ground water, an increase in irrigation is not possible, therefore, increasing water use efficiency is of great importance (Huang et al., 2003; Mo et al., 2005). The cropping system of the Loess Plateau is mainly a monocropping of winter wheat with a 3-month fallow during the rainy summer season (Deng et al., 2006). Even though the precipitation in this region is enough for the wheat requirement but most of rainfall (60-70%) falls during summer season which does not coincide with the growing season of winter wheat (Liu et al., 2007). Therefore, less soil water content severely limits the wheat yield (Sun et al., 2016). Conserving soil moisture at the summer fallow period and adjusting water consumption rate according to the growth stages of plant are the main objectives for sustainable wheat production in Loess Plateau (Zhang et al., 2013; Liang et al., 2019; Xue et al., 2019). Management practices which modulate the plant population density and conserve soil moisture can regulate the seasonal partitioning of water use (Zhang et al., 2013).

DOI: http://dx.doi.org/10.15666/aeer/1801_11071127

Reduction in grain yield also depends on the physiological stage of the plants under water stress (Destro et al., 2001). Grain yield could be expressed as the product of yield components such as grain weight, number of grains per spike and number of effective tillers. Tillering is important trait which effect yield as less tillers reduce yield by producing less spikes while too high tillering affect yield by reducing water use efficiency, competition for resource utilization and inducing lodging (Hou and Huang, 2009; Wang et al., 2009; Yang et al., 2019). Number of seeds planted and effective number of tillers significantly effect yield. Number of tillers survived until reproductive stage to contribute to yield (Yang et al., 2019). Water stress at the booting and stem elongation stage resulted in tillers mortality by restricting water and nutrient availability. Seeding rate also affect the yield by tillering and water consumption (Ren et al., 2019; Yang et al., 2019). Previous studies indicated that increasing seeding rate to a certain amount could increase the number of spikes and yield of dryland wheat (Ma et al., 2018; Yang et al., 2019). However, higher seeding rate could also increase the water consumption which could induce water shortage at later growth stages (Ren et al., 2019).

Using reasonable cultivation measures to maintain soil moisture and increase yield have always been the main objectives of research in dryland area (Yang and Chai, 2019). Film mulching is one of the effective measures to improving soil water storage and agronomic traits (Wang et al., 2009; Ren et al., 2017). Mulching can effectively conserve the rainwater by reducing evaporation and increase soil water content, promote the transfer of soil moisture from deep to the surface layer by vapor transfer, which can increase efficiency of water utilization during critical growth stage (Hou et al., 2014; Ma et al., 2018). Wang and Shagguan (2015) reported that ridge furrow mulching is the best practice for conserving soil moisture at planting and increasing yield of dryland wheat. It has been studied that the increase in yield by film mulching is based on the higher water consumption of crops, and the water consumption during the whole growth period of crops after mulching is significantly higher than that of open field (Gan et al., 2013; Hou et al., 2013). However, some studies have shown that the film mulching increased water consumption by higher vegetative growth which resulted in less soil moisture at the later stages of growth, leading to reduced yield (Li et al., 2000; Zhang et al., 2013). Du et al. (2005) reported that plastic film-mulching increased grain yield but reduced the reproductive allocation and increased the number of sterile tillers due to increased competition between the survived plants.

The water consumption process of crops is affected by many factors and change of soil hydrothermal conditions after film mulching will inevitably affect the growth and development process of crops, which in turn will affect the water consumption characteristics of crops, leading to changes in crop yield and water use efficiency (Huang et al., 2005). In order to reduce the problems caused by water shortage, balancing water consumption by adopting plastic film-mulching and adjusting plating density is one of the important cultivation measures to achieve high yield.

Although plastic film-mulching is being extensively applied in semi-arid and arid regions of North and Northwest China to increase yield, however the underlying mechanisms and impact of plastic film-mulching on crop yields is still under debate. At present only a few researches had focused the water consumption characteristics under plastic film-mulching. Therefore, we designed a two-year study with objectives (i) to analyze the difference in water utilization efficiency and biomass allocation of wheat between ridge-furrow plastic film-mulching and flat planting with no mulching condition, (ii) to optimize the effect of different sowing rates on the water consumption

DOI: http://dx.doi.org/10.15666/aeer/1801_11071127

and tiller formation, and (iii) to access the contribution of mulching and seeding rate to enhancing yield traits of dryland wheat.

Materials and methods

Site description

Subheading

The field experiment was performed in wheat growing season from 2014-2016 at the Agriculture Station of Shanxi Agricultural University, China. Experimental site is alongside a hill at the dryland area of Loess Plateau, located to the north of Yuncheng Basin, Shanxi province. This winter wheat planting area has semi-arid, monsoon climate with cold and dry winters and warm summers with the typical characteristics of the Loess Plateau. The average annual rainfall is 450-630 mm, average annual temperature is 11-13 °C, annual sunshine is 2,200-2,500 h, and 190-230 frost-free days. Experimental field has a flat terrain, and soil is clay loam with good permeability and pH of 20 cm soil was 7.5-8.0. Nutrient contents of soil are presented in *Table 1*.

Table 1. *Soil properties in experimental location*

Year	Organic matter (g kg^{-1})	Total nitrogen (g kg^{-1})	Alkaline hydrolysis nitrogen (mg kg^{-1})	Available phosphorus (mg kg^{-1})
2014-2015	10.55	0.68	37.65	17.64
2015-2016	9.27	0.86	41.31	10.25

In this experimental area, wheat is planted once a year without irrigation. Natural precipitation is the main source of water for crop cultivation in this area, and precipitation mainly concentrating in July-September, which is the fallow period of wheat. Precipitation during experimental years and long-term average of 10 years are given in *Table 2*. Total precipitation in 2014-2015 was 516.7 mm, from which 151.1 mm was during winter wheat growth period and 365.6 mm was in the fellow periods. In 2015, precipitation before flowering was more than average in 2015, but flowering to maturity was 73% less than the long-term average, and drought was during the grain filling period. In 2015-2016, total precipitation was 386.8 mm, and precipitation during growth and fallow period was 292.1 mm and 94.7 mm, respectively. Precipitation from sowing to wintering and jointing to maturity was abundant, but the fallow period and wintering to jointing precipitation was about 64% less than the average precipitation with severe drought during the early growth period.

Table 2. *Precipitation at the experimental site in Wenxi (mm)*

Year	Fallow period	S-W	W-J	J-A	A-M	Total
2005-2016 mean	265.0 ± 107.5	53.2 ± 35.9	30.2 ± 13.6	37.8 ± 15.8	64.4 ± 29.7	450.5 ± 96.7
2014-2015	365.6	21.5	50.8	61.2	17.6	516.7
2015-2016	94.7	101.2	11.0	57.1	122.8	386.8

Experimental design and treatments

The wheat cultivar 'Jinmai92' used in this experiment was obtained from Wenxi Agriculture Bureau. The two factors split-plot design was adopted, the seeding method as the main factor and sowing density as sub-plot factor. The sowing methods were film mulching with ridges and no mulching without ridges. The seeding rates were 60, 75, 90, 105, and 120 kg h^{-1} (D_{60}, D_{75}, D_{90}, D_{105}, D_{120}). All treatments were replicated 3 times. The area of each plot was 135 m^2 (9 m × 15 m).

Winter wheat was sown in October in 2014 and 2015 and harvested in June of the following year. Stubble (about 25 cm high) was left in field after harvesting wheat. In mid-July, deep ploughing was conducted at the depth of 25-30 cm and 1500 kg h^{-1} of commercial organic fertilizer (containing 45% organic matter, 1.2% available N, 1% available P, 0.3% available K) was applied to the soil. In August, rotary tillage was used to crumble large lump and level the fields. Before sowing, 150 kg h^{-1} of nitrogen (46% urea), phosphorous (16% P_2O_5) and potassium (52% K_2O) were applied to soil and no fertilizer was applied during growth seasons. Ridging, mulching and sowing are completed at one time. The width and height of ridge was 30 cm and 15 cm respectively and ridges were covered from top with plastic film (*Fig. 1*).

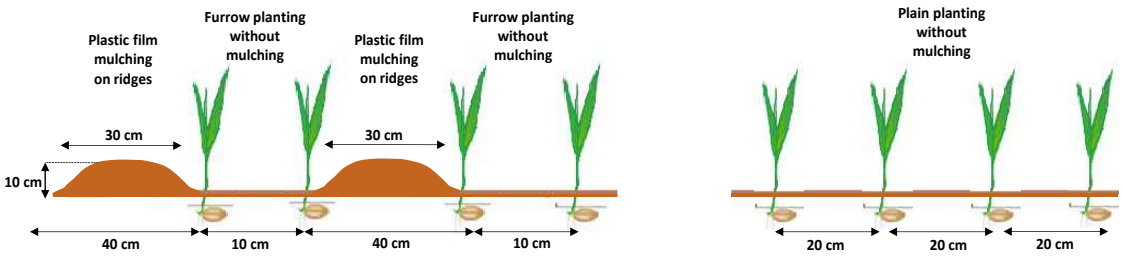

Figure 1. *Schematic representation of ridged film-mulching and without mulching*

The transparent plastic film with 0.008 mm thickness and 1.2 m width was used for mulching. Two rows of wheat were planted on the sides of the ridges at narrow row spacing of 20 cm and wide row spacing of 40 cm (*Fig. 2*). At three-leaf stage, planting density of 150 × 10^4, 187.5 × 10^4, 225 × 10^4, 262.5 × 10^4, 300 × 10^4 plants h^{-1} was attained by thinning. Plastic film was removed 10-15 days after anthesis (mid-May of the next year). In no mulching plots, seeds were sown at 3-5 cm soil depth at a row spacing of 20 cm. Crop phenology was recorded when half of the plants reached the wintering (GS23), jointing (GS31), anthesis (GS61), and maturity stage (GS92), using the Zadoks scale (Zadoks, 1974). Weeds were controlled by hand.

Plant sampling and analysis

The plants and soil samples were collected for analysis, according to the phenology of wheat crop (Zadoks, 1974) when 50% of the wheat plants reached at the corresponding jointing (GS30), anthesis (GS60), and maturity (GS100) stage.

Determination of total stem and tiller and effective tillers rate

The total number of stems or tillers was investigated at the jointing stage and the number of fertile tillers were counted at late grain filling stage. The number of tillers was calculated from the area of 1 m^2 at 3 random points from each plot and average at

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11071127

each plot was the number of stem and tillers. The effective tiller rate was calculated as the proportion of main stem and tiller at jointing stage to the number of effective panicles at maturity.

Figure 2. *Field preparation at experimental site of Shanxi Agricultural University*

Biomass and yield

At maturity, the number of panicles per unit area, the average number of grains per panicle and weight of 1000 grains were investigated from 50 plants per plot, and plants from 20 m^2 area were harvested to calculate economic yield. For determining the aboveground dry biomass, plants samples were kept at 105 °C for 30 min, and then oven dried at 75 °C for 12 h until constant weight.

Leaf area index

For the determination of leaf area, the length and width of the second leaf and total number of leaves were calculated. Leaf area was measured using the following formula:

$$\text{Leaf area} = \text{length} \times \text{width} \times \text{number of green leaves} \times 0.85 \quad \text{(Eq.1)}$$

where 0.85 was the adjustment factor. Then leaf area index (LAI) was calculated by dividing the leaf area (cm^2) by the ground surface area.

Grain to leaf area ratio

Grain to leaf ratio was calculated according to Feng et al. (1999), using *Equations 2* and *3*:

$$\text{Grain number to leaf area ratio} = \frac{\text{total number of grain per unit area}}{\text{total leaf area on the same plot at booting stage}} \quad \text{(Eq.2)}$$

$$\text{Grain weight to leaf ratio} = \frac{\text{grain weight (mg) per unit area}}{\text{total leaf area on the same plot at booting stage}} \quad \text{(Eq.3)}$$

Total leaf area was taken from the same plot at booting stage (cm^2).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11071127

Soil sampling and analysis

Determination of soil moisture

Soil was drilled from 0-300 cm depth were with soil drill at sowing, wintering, jointing, flowering and maturity stages. The soil was divided into 20 cm layers and soil water content and soil water storage were determined.

The soil water storage was calculated by methods as described by He et al. (2009):

$$SWSi = Wi \times Di \times Hi \times \frac{10}{100} \quad \text{(Eq.4)}$$

where SWS_i is the soil water storage capacity (mm) of the i-th soil layer; W_i is the soil water content (%) of the i-th soil layer; D_i is the soil bulk density (g cm^{-3}) of the i-th soil layer; H_i is the thickness of soil layer (cm). The soil water content and soil bulk density were both measured using the oven-drying method (Gardner et al., 1986).

Water consumption

Water consumption in wheat fields was measured using simplified formula as described by Xue et al. (2019):

$$ET = P - \Delta S \quad \text{(Eq.5)}$$

where P is the effective precipitation (mm) during that stage and ΔS is reduction of soil water storage at each stage and was measured as $\Delta S = S_1 - S_2$, where S_1 and S_2 were the soil water content at the beginning and end of the stage, respectively. Whereas, runoff and drainage were considered negligible.

The water consumption intensity (CWR, mm d^{-1}) was calculated as:

$$CwR = \frac{ET_i}{d} \quad \text{(Eq.6)}$$

where ETi is the water consumption (mm) of wheat in each growth stage and d is the number of days in the growth stage.

Water use efficiency (WUE)

The yield water use efficiency (WUEy) was calculated as:

$$WUEy \frac{Y}{ET} \quad \text{(Eq.7)}$$

where: Y is the output, and ET is the total water consumption calculated from *Equation 5*.

Data processing

Two-way analysis of variance (ANOVA) was performed to determine the significance of sowing rate and mulching and statistical analysis was carried out using DPS7.05 software and the significant difference among treatments were calculated by least significant difference test (LSD) at the significance level of $p \leq 0.05$. Graphs were

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11071127

constructed using Microsoft Excel 2010. Pearson correlation coefficients between water consumption and yield related components were assessed at $p \leq 0.05$.

Results

Soil water content

Soil water content of 0-300 cm soil layer was recorded at the wintering, jointing, anthesis and maturity stages under film-mulching and no-mulching (*Fig. 3*).

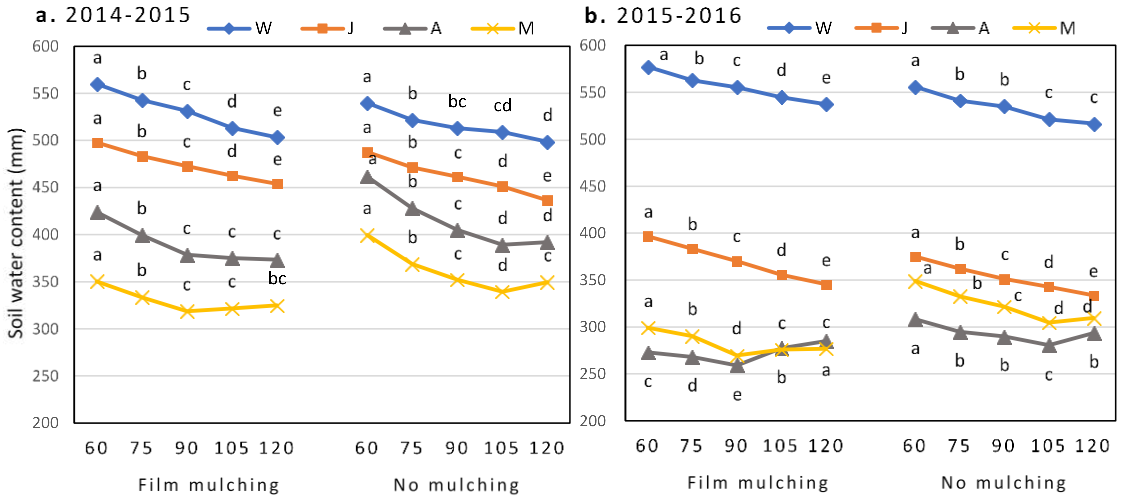

Figure 3. *Effects of sowing methods and sowing rates on water content in 0-300 cm soil layer at different growth stages of dryland wheat. W, J, A and M indicate wintering, jointing, anthesis and maturity stages of winter wheat represented by GS23, GS31, GS61 and GS92 respectively, according to Zadoks system. Different letters indicate significant difference among treatments at the significance level of $p \leq 0.05$*

At wintering and jointing stages, soil water content of film-mulching treatment was higher than no mulching whereas at the anthesis and maturity stages, water content of no-mulching was higher than the film-mulching. Soil water content was significantly decreased with increasing the seeding rate at wintering and jointing stage. At anthesis and maturity stage, the soil water content was first decreased by increasing the seeding rate and then did not further decreased. Soil water content was also affected by the stages with maximum at wintering, whereas minimum soil water content in 2014-2015 was at maturity and in 2015-2016 was at anthesis stage.

Water consumption at different stages of plastic film mulched wheat

The total water consumption of plastic film mulched dryland wheat was significantly increased as compared to no mulched during all the growth stages (*Fig. 4*). By increasing the seeding rate, water consumption was increased first and then decreased, and the highest water consumption was observed at 90 kg h^{-1} under the conditions of film mulching, and at 105 kg h^{-1} under conventional sowing without mulching.

The water consumption of sowing-jointing stage was increased with the increase of sowing quantity (*Fig. 4*). By increasing the sowing amount, the water consumption at

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11071127

jointing-flowering was increased first and then decreased in 2014-2015 with highest at 90 kg h^{-1} under film-mulching and 105 kg h^{-1} under conventional sowing. Whereas in 2015-2016 water consumption at jointing-flowering was reduced with increasing the seeding rate. At flowering to maturity stage, water consumption was decreased in 2014-2015 whereas increased in 2015-2016 with increasing the seeding rate. It can be seen that the total water consumption of dryland wheat was increased by film mulching, but the difference of precipitation during the growth stages also have a great influence on the water consumption of each stage.

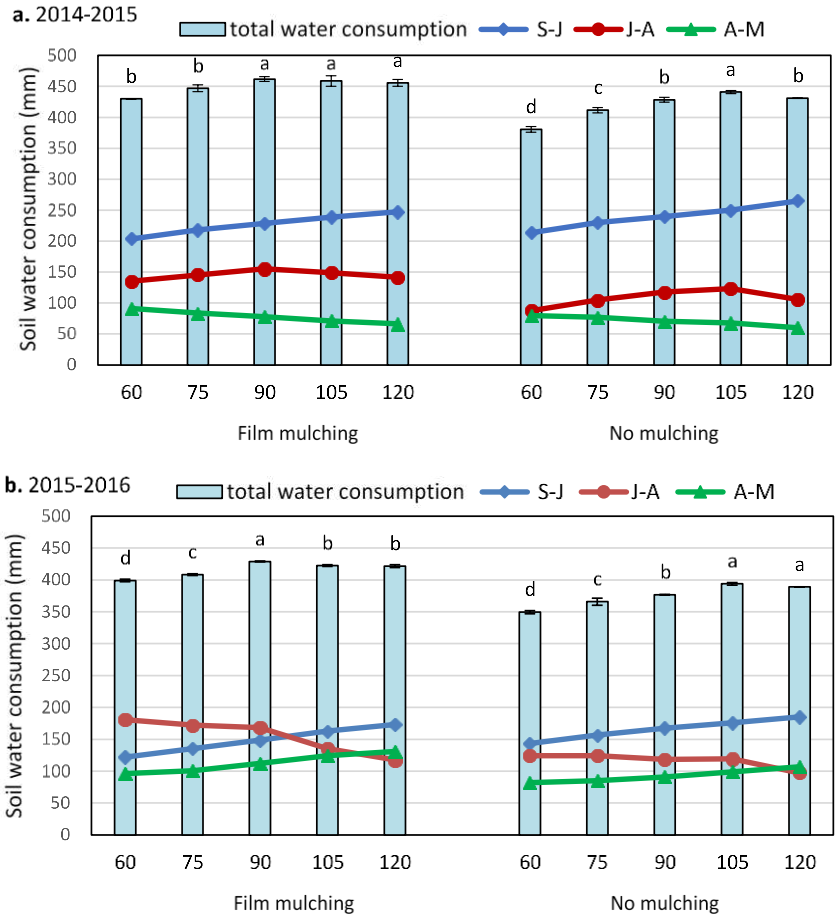

Figure 4. *Effects of sowing methods and sowing rates on water consumption of 0-300 cm soil layer at different growth stages of dryland wheat. S-J: Sowing stage to jointing stage, Oct 1 to Apr 10 in the following year; J-A: Jointing stage to anthesis, Apr 11 to May 10; A-M: Anthesis to maturity, May 11 to Jun 10. Different letters indicate significant difference among treatments at the significance level of* $p \leq 0.05$

Water consumption rate

Film mulching reduced the water consumption rate from the sowing-jointing stage compared with no mulching, whereas water consumption rate from jointing to anthesis and anthesis to maturity stage was increased by film mulching (*Fig. 5*). The water consumption rate of the jointing to anthesis stage was increased first and then decreased with the increasing seeding rate in 2014-2015 and lowest water consumption rate was observed at 90 kg h^{-1} under no-mulching and at 105 kg h^{-1} under film-mulching,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11071127

whereas, in 2015-2016, water consumption rate from jointing to anthesis was decreased with increasing seeding rate. The water consumption rate during the flowering to maturity stage was decreased by increasing the seeding rate in 2014-2015 while in 2015-2016 the water consumption was increased with increasing seeding rate.

Effect of sowing rate and mulching on leaf area and dry biomass

Film mulching had significantly increased the leaf area index and dry biomass in both years (*Table 3*).

Table 3. *Effect of sowing rate on dry matter formation of wheat covered with plastic film*

Means followed by different small letters indicate significant difference among treatments within seeding method, and capital letters indicate difference among seeding method at 0.05 level. D_{60}, D_{75}, D_{90}, D_{105}, and D_{120} are 60, 75, 90, 105 and 120 kg seeds h^{-1}; GW: grain weight; GN: grain numbers per spike

In film mulched plants, the leaf area index was increased by 13-16%, the grain weight to leaf area ratio was increased by 2.7-3.8%, the grain number to leaf area ratio was increased by 0.6-3%, and grain yield was increased by 4.9-7.5% as compared to no mulching. It can be seen that the film mulching treatment has improved the balance of source reservoir relationship and increased grain yield of wheat during the growth and development of wheat as compared to no mulching.

The leaf area index was gradually increased with the increase in seeding rate and leaf area index at 120 kg h^{-1} was significantly higher than the lower rates. Grain to leaf ratio was first increased and then decreased under film-mulching with maximum grain to leaf area observed at 90 kg h^{-1}. The dry biomass was minimum at the lowest seeding rate and was increased by increasing seeding rate reaching maximum at 120 kg h^{-1}. Without

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11071127

mulching, increasing seeding rate did not significantly enhanced the grain to leaf area ratio. Therefore, the yield could be effectively increased by improving the grain to leaf ratio in the suitable range of leaf area index.

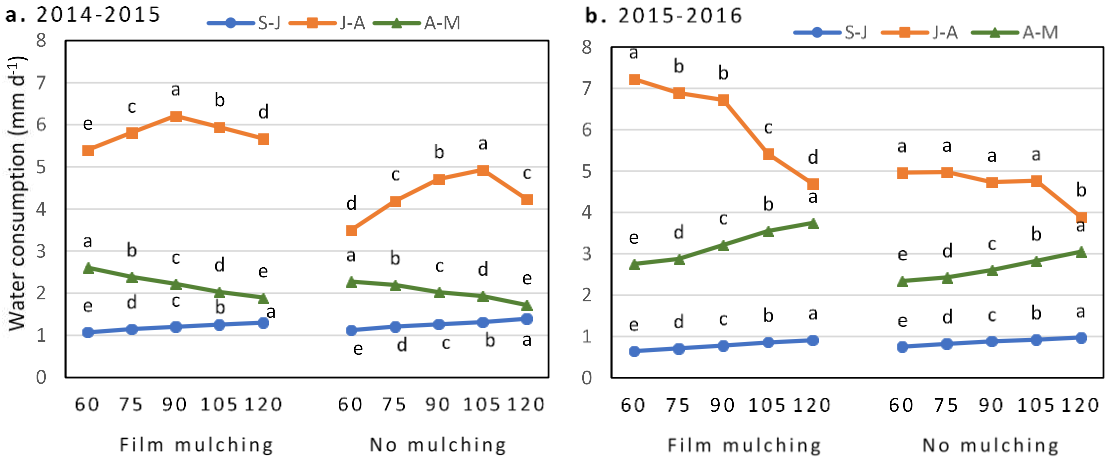

Figure 5. *Effects of sowing rate on daily water consumption amount of dryland wheat at different growth stages under different sowing patterns. S-J: Sowing stage to jointing stage, Oct 1 to Apr 10 in the following year; J-A: Jointing stage to anthesis, Apr 11 to May 10; A-M: Anthesis to maturity, May 11 to Jun 10. Different letters indicate significant difference among treatments at the significance level of* $p \leq 0.05$

Effect of sowing rate and mulching on tillers formation of wheat

The mulching has effectively increased the number of tillers at jointing by 3-4% and the effective number of panicles by 8-16% as compared to the conventional sowing (*Fig. 6*).

The number of tillers at the jointing stage was increased by increasing the amount of sowing rate, whereas, the effective number of tillers at maturity was first increased and then decreased at higher sowing rates. The highest number of effective tillers were recorded at seeding rate of 105 kg h^{-1}. Under the same sowing rate, the number of effective tillers were increased by 0.83-7.02% in film mulched as compared with no mulching.

Effect of sowing rate and mulching on yield

The grain yield and yield related traits were significantly increased by film mulching as compared to no-mulching (*Table 4*). The number of grains per pod were increased by 4.25-7.04%, the 1000-grains weight were increased by 1.2-2.0%, the grain yield was increased by 16-24%, and water use efficiency was improved by 8-11% as compared to no mulching. With the increase of sowing rate, the 1000-grain weight was decreased gradually and lowest grain weight was observed at the highest density (120 kg h^{-1}). In film-mulched plants, the number of grains were not increased by increasing the seeding rate whereas in no-mulching treatment, number of grains were firstly increased by increasing seeding rate reaching maximum at 105 kg h^{-1} and then decreased by further increasing seeding rate to 120 kg h^{-1}.

The yield and water use efficiency were increased by increasing seed rate with maximum at 90 kg h^{-1} under film mulching and 105 kg h^{-1} without mulching (*Table 4*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11071127

However further increasing seeding rate had significantly decreased the yield and water use efficiency. The conventional treatment with 105 kg h^{-1} was the highest, and the yield increased by 5.4-30.4% compared with other treatments. Mulching has increased yield by 5.4-30.4%, 5.8-29.5% in 2014-2015 and 2015-2016 respectively as compared to without mulching. The water use efficiency was improved by 4.7-21.4% and 3.4-11.8% by plastic film mulching in 2014-2015 and 2015-2016 respectively as compared to without mulching.

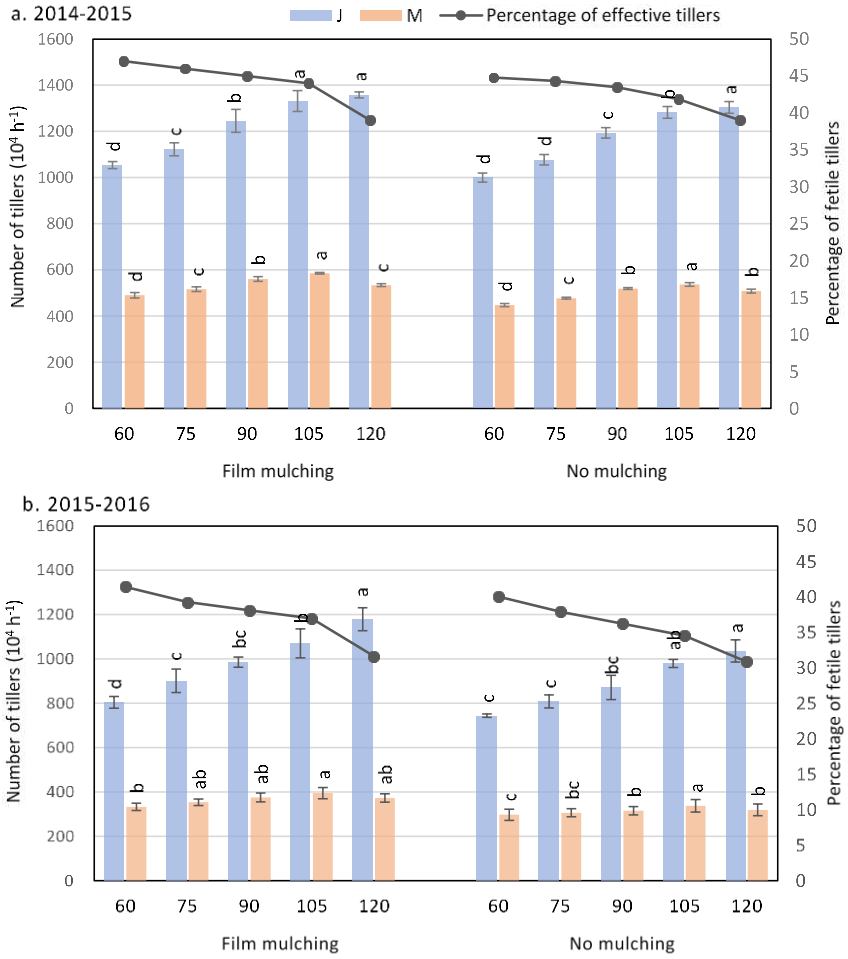

Figure 6. *Effects of different sowing rates and mulching on number of tillers at jointing and maturity stage and percentage of effective tillers. Different letters indicate significant difference among treatments at the significance level of $p \leq 0.05$*

Correlation analysis of water consumption from soil at different growth stages and yield and yield related components of wheat

The correlation between water consumption from soil at sowing to jointing, jointing to anthesis and anthesis to maturity stage and yield components were determined (*Table 5*). It can be seen that the water consumption during different stages have different impact on biomass and yield traits. There was a significant and positive correlation between the leaf area index, grain yield and number of grain and spikes and the amount of water consumed in sowing-jointing and jointing-anthesis stage, and the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11071127

influence of water consumption in the stage of sowing to jointing was higher than that in jointing to anthesis. Water consumption in the anthesis-maturity stage was positively correlated with 1000-grain weight, whereas, negatively related with aboveground biomass, LAI, number of spikes, number of grains and grain yield.

Table 4. *Effects of different sowing rates on yield formation of wheat covered with plastic film*

Discussion

Water stress is the main limiting factor for wheat production in Loess Plateau and other arid and semiarid regions (Liu et al., 2007). The growth of winter wheat plants

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11071127

depends on the soil water stored by rainfall during summer fallow season (60-70%) and growing season (30-40%). The roots of rainfed winter wheat are not able to utilize water from deeper soil layers and ground water in Loess Plateau is below 5 m (Li et al., 2017). Hence, the limiting precipitation during growth season means that winter wheat must utilize soil water stored from precipitation during fallow season (Xue et al., 2019).

Soil water availability and water use efficiency by ridge plastic mulching

Mulching is an effective measure to increase soil moisture in arid and semiarid areas. Film mulching can reduce soil surface evaporation and thus improve soil moisture content and promote crop growth and yield (Li et al., 2013). Ridge mulching is one of the main measures to increase agricultural production in arid regions (Zhang et al., 2013). In the present study soil water content of 0-300 cm depth was higher by plastic film mulching at the wintering and jointing stages. Thus, our study indicated that plastic film mulching effectively relieved the drought stress at early stages of winter wheat growth as similar with Zhao et al. (2016) and Yang et al. (2018). Zhang et al. (2013) reported that ridges mulched with plastic film was better than the straw mulching and other conservation practices in conserving rainfall of summer fallow periods by reducing soil water evaporation.

However, soil water content at anthesis and maturity was higher under no-mulching than the film mulching. This might be because plastic mulching reduces soil surface evaporation at early stages and promote the accumulation of biomass at the vegetative growth with more leaf area which increase transpiration rate (Li et al., 2001). The results of present study also indicated that the biomass and leaf area index of mulched wheat was higher than in no mulching (*Table 3*). Positive effect of plastic film mulching on leaf area index and biomass of wheat was also previously reported (Li et al., 2013; Xie et al., 2005).

Therefore, more vegetative growth and high transpiration rate increases utilization of soil water content and manifested by less soil water at late growth stages. Yang et al. (2018) also reported that plastic film mulching conserve soil water in top layers at the early growth stages of spring wheat by decreasing evaporation rate while plants consumed more water from the soil at the middle growth stage under film mulching.

The present study showed that the plastic film-mulching had increased water consumption by 8.4-11%. The plastic film mulch also increased the development and production of biomass by improving the water consumption, similar as previously reported by Niu et al. (2004). Furthermore, increasing water absorption and water consumption by plant also lessen water loss by evaporation (Li et al., 2013).

The water use efficiency of plastic film mulched plants was increased by 7.6-11.3%, which was consistent to Hou et al. (2013). Water use efficiency was 10.9 kg ha^{-1} mm^{-1} and 7.6 kg ha^{-1} mm^{-1} under film mulching and 10 kg ha^{-1} mm^{-1} and 6.8 kg ha^{-1} mm^{-1} under no mulching in 2014-2015 and 2015-2016 respectively, as compared with the globally measured average water use efficiency of 6-17 kg ha^{-1} mm^{-1} for wheat (Zwart and Bastiaanssen, 2004) and 7-10 kg ha^{-1} mm^{-1} for rainfed wheat in Loess Plateau (Huang et al., 2003; Deng et al., 2006). WUE indicates the relationship of production of grain yield and water consumption of the crop (Mo et al., 2005; Jin et al., 2018).

The water for evapotranspiration during the early growth stage comes from stored soil water before sowing and rest from precipitation during growth season (Huang et al., 2003). Soil water conserved at early growth stages is utilized to accumulate biomass and yield formation at the later growth stages and thus improve water use efficiency of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11071127

the crop by changing the pattern of water consumption. Huang et al. (2003) reported that almost 68% of total water consumed was derived from seasonal precipitation and 32% derived from the soil water stored from rainfall before planting. The variation in water use efficiency is also attributable to yearly variation in rainfall.

The daily water consumption varied with the growth period of winter wheat and was minimum at sowing to jointing stage and then increased to maximum at jointing to anthesis stage and then decreased at anthesis to maturity. The higher water consumption is at the active growth stage of wheat (Hou et al., 2016). It can be seen that the film mulching reduced the water consumption rate of the initial growth stage (sowing to jointing) and increase the water consumption rate at the late growth stage (jointing to anthesis and anthesis to maturity).

Effect of mulching on yield and relationship between water consumption and yield

This study showed that both seeding rate and film mulching had significant effects on wheat yield and its components. The number of panicles per unit area was increased by 8-16%, the number of grains per spike were increased by 4.25-7.04%, and the 1000-grain weight were increased by 1.2-2.0%, and the yield was increased by 16-24% in film mulched plants as compared to no mulching and this increase in yield was more prominent in the dry years. Increase in yield of wheat covered by plastic film is mainly to increase the number of spikes per unit area and number of grains per plant. This is because the film mulching can effectively reduce the evaporation of soil moisture, enhance the soil moisture in deep soil layer and improve the growth and development and water use efficiency (Li et al., 2013; Zhang et al., 2013, 2018b).

Zhang et al. (2019) reported a 31% reduction in soil evaporation and 28% increase in transpiration rate by plastic film mulching, improving water use efficiency. Similarly, Zhang et al. (2018b) reported 16.1% increased of grain yield by plastic film mulching and attributed this increase of yield to increase in number of spikes per area and number of grains per spike. However, some contrary studies have shown that mulching resulted in reduced grain yield due to vigorous growth at early stages and lack of soil moisture at the later stages (Li et al., 2001). Zhang et al. (2013) reported that ridge plastic mulching caused increased yield in 20% cases under different tillage treatments, while 8% reduction in yield is due to fast depletion of soil water at the early growth stage of wheat due to favorable water conditions under plastic film mulching, which caused water stress at the grain filling stages. Li et al. (2017) reported that grain yield of dryland wheat is mainly limited by soil water content at sowing and increasing soil water at sowing could improve yield.

Previous research indicated that the high yield of the film mulched wheat is based on high water consumption and water utilization efficiency (Hou et al., 2014, 2016; Yang et al., 2015). Plastic film mulching increased the available water content and water consumption during the whole growth period of wheat. This study showed that the number of spikes, grain number and grain yield were significantly positively correlated with water consumption from sowing to jointing and jointing to flowering stage, while negatively correlated with water consumption from flowering to maturity stage (*Table 5*). The effect on the number of effective panicles was higher than that in jointing-flowering stage. This might be because the number of spikes and grain numbers were determined at early reproductive stage and higher water consumption at jointing to flowering stage resulted in more spikes and grain numbers but with less water content at grain filling stage. In contrast to other yield traits, 1000 grain weight was positively

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11071127

related to water consumption from flowering to maturity, showing the importance of available soil water after anthesis on grain filling. Yang et al. (2018) showed that there was a significant positive correlation between yield and water consumption.

Higher soil moisture contents under film mulching also improved the absorption of N and other nutrients and thus improve the nutrient use efficiency. Studies have shown that the mulching had improved the N translocation rate before anthesis, N accumulation to grains after anthesis and nitrogen use efficiency of dryland wheat (Zhang et al., 2016).

The grain yield in 2014-2015 season was higher than in 2015-2016 under both plastic film mulching and no mulching condition. The fluctuation of rainfall in Loess Plateau in different years causes variation in grain yield of dryland wheat (Ren et al., 2019). The total precipitation in 2014-2015 was higher, while in 2015-2016 was less than the long-term average precipitation of the site. Grain yield of wheat is not only influenced by variation in total water content available from seasonal rainfall but also by the pattern of water consumption with growth stages of wheat (O'Leary and Connor, 1997; Ren et al., 2019). Huang et al. (2003) reported a significant relationship between yield of wheat and water consumption during fallow or precipitation during growing season precipitation.

Modulating water consumption and water use efficiency with seeding rate

Establishing a population structure with high light use efficiency and low water consumption is the fundamental content of high water-saving cultivation of wheat. The water consumption of wheat in dryland is closely related to planting methods and seeding rate. A large number of studies have shown that the amount of seeding rate had a significant impact on wheat growth and water use efficiency (Wang et al., 2017; Ren et al., 2019); therefore, appropriate seeding rate is conducive to increasing soil water storage capacity and water use efficiency in dryland wheat planting areas where soil moisture is the most limiting factor at various growth stages (Ren et al., 2019). Therefore, in the present study wheat was sown at different seeding rates in a ridge and furrow planting method using plastic film mulching whereas, no mulching and plain field was used as a control.

The experimental study showed that the total water consumption during the whole growth period of wheat increased first and then decreased with the increase of the seeding rate and total water consumption was highest at 90 kg h^{-1} under film mulching and 105 kg h^{-1} under no mulching. This indicated that too high or small seeding rate could reduce the water consumption of winter wheat, which is consistent with the results of Wang et al. (2017). However, some studies have shown that water consumption during the whole growth period increases with the increasing seeding rate (Zhang et al., 2018a; Ren et al., 2019). This may be because the water consumption gradually increases from vegetative to reproductive stage. Water consumption at the early stage of wheat from sowing to jointing was increased with increasing the seeding rate due to increase in the amount of evaporation in the wheat field by increasing plant population. Whereas, reduction in field water consumption at jointing to anthesis and anthesis to maturity by increasing seeding rate up to a certain limit might be due to the inhibited growth and premature senescence of high seeded population due to the lack of soil moisture. Therefore, it is necessary to regulate the amount of seeding rate to improve the utilization of water resources and effectively increase crop yield.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11071127

Soil water content was decreased with increasing the seeding rate at wintering, jointing and anthesis stages whereas at maturity stage, soil water content was lowest at 90 kg h^{-1} and 105 kg h^{-1} under film mulching and no mulching respectively. In present study, the pre-anthesis water consumption ratio is higher than the post-anthesis. Ratio of pre-anthesis to post anthesis water consumption varies with the pattern of rainfall, from 3:1, when post-anthesis precipitation was less, to 6:1 with high post-anthesis rainfall. It has been reported that water used by wheat in a ratio of 2:1 before and after anthesis favors yield (Passioura, 1983; Zhang et al., 2013).

Effect of sowing rate on tillering and yield formation

Population density could influence the ratio of water used and thus yield (Wang, 2010; Zhang et al., 2013). Increasing the amount of seeding rate improves the efficiency of radiation utilization efficiency, and ultimately have a positive effect on formation of grain yield. However, increasing the amount of seeding rate will increase the competition of wheat for resources such as water and nutrients, which will further reduce the grain yield of wheat, accelerate leaf senescence and even reduce the final yield of wheat (Liu et al., 2016). This study showed that the seeding rate had significant effects on wheat yield and its components. Grain yield was first increased with increasing seed rate and reached maximum at 90 kg h^{-1} under mulching and 105 kg h^{-1} under no mulching and then decreased by further increasing seeding rate. Grain yield was maximum at seeding rates where maximum water consumption was observed. Similarly, Ren et al. (2019) also reported that the highest water consumption during the growth stage of winter wheat resulted in highest grain yield in Loess Plateau both in years with low and high rainfall.

Tillering is a key component in determining wheat yield by influencing the photosynthesis rate, plant canopy size and fertile tillers bearing grains. Results from present study indicated that the number of tillers were increased by increasing the seeding rate from 60 to 120 kg h^{-1} at jointing stage whereas at maturity was increased first and then decreased. However, the percentage of fertile tillers were decreased gradually by increasing seeding rate indicating that the number of unproductive tillers were increased at high seeding rate. Generally, from the total tiller initiated, only a proportion of tillers survive to become fertile and others are destined to abort (Xie et al., 2016). The number of aborted tillers varies with the seeding rate and most of previous studies indicated that the effective number of tillers were decreased with increasing the seeding rate (Evers et al., 2006; Kondić et al., 2017). Increasing numbers of unproductive tillers also resulted in high water consumption (Wang et al., 2017). Therefore, seeding rate should be properly optimized because higher number of non-surviving tiller are detrimental for yield due to the loss of dry matter especially in a condition where increase in water use efficiency and yield is most important (Berry et al., 2003).

Number of tillers are determined by the tillers produced and tillers survived. Percentage of effective tillers was highest at the lowest seeding rate but the grain yield was minimum. Because if the seeding rate is too low, the number of tillers per area will be also low due to smaller population resulting in less grain yield per area. This is also indicated by our results as the minimum number of tillers at the jointing and maturity stages were produced at the lowest seeding rate. Increasing seeding rate up to optimum rate at which increasing the number of tillers balance the competition among plants and transfer of photosynthetic products to the grain, and harvest index and the yield per plant are highest. However, if the seeding rate is too high, the grain weight, tillering and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11071127

number of effective tillers are reduced due to the competition for nutrient and light resulting in low yield per plant (Ren et al., 2019). It was obvious from the present results that under film mulching, the maximum yield was attained at relatively low seeding rate (90 kg h^{-1}) as compared to without mulching at which the highest yield was attained at 105 kg h^{-1}. The high yield at relatively less seeding rate might be related to higher number of effective and survived tillers and increased competition between tillers for resource allocation.

The grain-to-leaf ratio is an effective indicator reflecting the coordination of source and sink relationship and related to density (Serrago et al., 2013). The grain number to leaf area ratio reflects the storage capacity per unit leaf area, while the grain weight to leaf area ratio shows the contribution of unit leaf area to yield, which is used to explain the source quality level and transfer capacity of the source (Wang et al., 2016). Studies have shown that within the range of suitable leaf area index, expanding the total storage capacity and increasing the ratio of grain to leaf is conducive for high yield (Bijanzadeh and Emam, 2010).

This study showed that by increasing the sowing amount, the grain weight-to-leaf ratio and the grain number-to-leaf ratio were increased first and then decreased. The ratio of leaf area to grain weight and number was positively correlated with grain number per spike and 1000 grain weight. Therefore, increasing the ratio of grain to leaf can effectively increase the yield, which is consistent with the results of Yu et al. (2005). Maximum grain weight to leaf area ratio and grain number to leaf area ratio was attained at 90 kg h^{-1} under film mulching and at 105 kg h^{-1} for plants without mulching.

Conclusion

The water consumption at different growth stages of dryland wheat field is closely related to wheat yield. The water consumption from sowing to jointing and jointing to anthesis stage was positively related with the spike number, grain number, and grain yield whereas higher water consumption from anthesis to maturity stage was positively related with 1000 grain weight. Plastic film mulching with ridge and furrow planting significantly increased water use efficiency and wheat yield by improving the effective tillers per unit area and number of spikes. Under film mulching, maximum yield was attained at relatively lower seeding rate (90 kg h^{-1}) as compared to no mulching at which maximum yield was attained at 105 kg h^{-1}. Thus, for the dryland wheat production in Shanxi, seeding rate of 90 kg h^{-1} under film mulching improved the grain to leaf area ratio and relationship between source and sink, increase the number of grains per panicle and 1000-grain weight, increase yield and moisture under the premise of ensuring water use efficiency. Furthermore, in future the effect of different mulching methods on water consumption could be compared.

Abstract. *Rhizobium* species and the soybean cyst nematode (SCN, *Heterodera glycines*) are attracted by the root exudates of soybean and colonize its roots. There is complicated relationship between the soybean, Rhizobium species, and SCN. This study intended to discover the effect of *Sinorhizobium fredii* Sneb183 culture filtrate on SCN second-stage larvae (J2), egg hatching and J2 chemotaxis. The mortality of J2 treated with *S. fredii* Sneb183 culture filtrate increased with the exposure duration. Additionally, *S. fredii* Sneb183 culture filtrate reduced egg hatching within cysts, neutralized the positive effect of a susceptible soybean cultivar root exudate on hatching, and postponed the peak of hatching, thereby revealing other mechanisms for reducing nematode infection and J2 numbers. *Heterodera glycines* J2 were repelled by the culture supernatant of *S. fredii* Sneb183, the movement of J2 towards the susceptible cultivar root exudate and soybean roots was disrupted by a mixture of susceptible cultivar root exudate with *S. fredii* Sneb183 culture filtrate or by dipping the root into culture filtrate. These results indicate that *S. fredii* Sneb183 may be a potential economic, eco-friendly and effective biocontrol microorganism against SCN.
Keywords: *root exudate, biocontrol, chemotaxis, mortality, susceptible*

Introduction

Plant-parasitic nematodes pose a serious threat the food production of many economically important crops. Soybean cyst nematode (SCN) (*Heterodera glycines* Ichinohe) was first reported as a pest of soybean in 1899. Currently it is one of the most damaging pathogen for soybean, causing more than 30% yield losses annually in the United States (Allen et al., 2017). The combination of the use of SCN-resistant cultivars and non-host crop rotation are important means of managing the pest population levels in the field. Nevertheless, an overdependence on resistant cultivars coupled with genetic variation in SCN field populations has led to population shifts (Mitchum et al., 2007; Niblack et al., 2008). Meanwhile, public concern over environmental hazards evoked by chemical pesticides has steadily increased (Pimentel and Burgess, 2014). Therefore, alternative control strategies are highly desirable for the control of SCN. Biological control of plant diseases is usually an eco-friendly and potential component of integrated disease management; biological control of SCN has been studied for more than 40 years (Davies and Spiegel, 2011). Zhou et al. (2017) Demonstrated that combination of multiple rhizobacterial strains applied through seed coating may be a better management method for SCN.

DOI: http://dx.doi.org/10.15666/aeer/1801_11291140

Rhizobia are the best known beneficial plant-associated bacteria because they can fix nitrogen, which occurs during the *Rhizobium*-legume symbiosis (Zahran, 1999; Long, 2001). Several strains of *Rhizobium* spp. inhibit the growth of several root-infecting fungi to various degreed. For example, reports determined that *Rhizobium* could inhibit spores germination, and hyphae growth of some plant pathogens, including *Phoma medicaginis*, *Macrophomina phaseolina* and *Rhizoctonia solani* (Omar and Abd-Alla, 1998; Dileep Kumar et al., 2001). Drapeau et al. (1973) isolated *Rhizobium* strain TL-3 with obviously suppressive effects on *Pyrenochaeta terrestris*, *Colletotrichum destructivum* and *Coniothyrium* sp. Antagonism toward the potato cyst nematode *Globodera pallida* and the root-knot nematode *Meloidogyne incognita* by *Rhizobium etli* G12 is associated with its ability to induce systemic resistance (Hallmann et al., 2001; Martinuz et al., 2013). Numerous observations confirm that rhizobia may function as potential induces of plant disease resistance.

Sinorhizobium fredii Sneb183, isolated from soybean nodules, could induce systemic resistance in soybean against SCN; the number of juveniles and cysts significantly decreased as a result of Sneb183 inoculation (Tian et al., 2014). The oxygen consumption rate of J2 was decreased by 93.1% after 24 h treated with Sneb183 culture filtrate, while after 48 h treatment, J2 body fluids exuded and the conductivity was increased by 62.4% (Tian et al., 2014). The present study is conducted to evaluate the effect of *S. fredii* Sneb183 fermentation filtrate on the activity of J2, the hatching rate of eggs within cysts, and J2 chemotaxis, with the goal being to expand the potential of this strain as a new agent for biological control of soybean cyst nematode.

Materials and methods

Experimental Design

Current study has been conducted to evualte efficacy of *S. fredii* Sneb183 against *H. glycine* at Nematology Institute of Northern China, Shenyang Agricultural Univerity, Liaoning, China during 2018.

Isolation of cysts and J2 of SCN

H. glycine was first reported as pest of soybean in 1899. Surface soil samples (2 cm depth) were removed from the rhizosphere of soybean (*Glycine max* cv Liaodou 15, a SCN-susceptible cultivar *H. glycine* was first reported as pest of soybean in 1899. Cysts were obtained from experimental field of Nematology Institute of Northern China, and collected by following elutriation and hand-picking under a stereomicroscope. Cysts were surface-sterilized by immersion in 0.1% $HgCl_2$ solution for 1 minute followed by rinsing three times with sterile distilled water. The cysts were then placed in Baermann funnel at 25℃. J2 were collected from the bottom of the Baermann funnel every two or three days (Liu, 1995).

Preparation of soybean roots and root exudates

Soybean seeds (‘Liaodou 15’) were rinsed with distilled water, sterilized in 75% ethanol for 1 min, and rinsed several times with sterilized water. After the seeds were swollen for 4 h in Petri dish covered with sterile moist filter paper, then they were placed in sterile petri dishes filled with sand sterilized (160℃ for 1 h). After one week, apical

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11291140

1 cm segments of roots were rinsed with sterilized water and stored in 4℃ for subsequent use.

The sterilized sand and soil (V:V=2:1) in pots 25 cm in diameter was seeded with one of the surface-sterilized soybean seeds, and plants were watered with N-free Hoagland's solution on alternate days, in which $Ca(NO_3)_2$ and KNO_3 were replaced with $CaCl_2$, K_2HPO_4 and KH_2PO_4, as recommended (Hoagland and Arnon, 1950). The soybeans were grown in a greenhouse at 28 ± 2°C with a 16/8 h light/dark photoperiod. Soybean root exudates were obtained via a slightly modified procedure of Tefft and Bone (1985) and Levene et al. (1998) such as five soybean seedlings were used for root exudate. The soybean seedling roots after grown 20 d were rinsed with tap water and distilled water, placed in sterile 50 mL centrifuge tubes containing sterile water of volume sufficient to submerge the roots, incubated in a dark room at room temperature for 24 h, one soybean seedling in each centrifuge tube. Some root exudates was stored at 4℃ for subsequent egg hatch bioassays and 50 mL exudate was placed in a rotary evaporator, concentrated to 5 mL under reduced pressure at 50℃, and stored at 4℃ for chemo-attraction experiments.

Preparation of Rhizobium Sneb183 fermentation filtrate

Sinorhizobium fredii Sneb183 was originally isolated from pine rhizosphere and identified by Zhao et al. (2009). Strain was stored at -80℃ at Nematology Institute of Northern China, Shenyang Agricultural University, Liaoning, China. *S. fredii* Sneb183 was suspended in sterilized water and adjusted to 1.0×10^8 cfu/ml with a hemocytometer under a microscope, then 1.0 mL of this suspension was added to 50 mL sterilized TY liquid medium (Duelli and Noel, 1997). Cultures were maintained at 28℃ and 150 rpm for 168 h, and were then centrifuged at 5590 g for 20 min. The fermentation filtrated through 0.22 um filter was used for the impact of J2 lethality and chemotaxis assays and egg hatching bioassays (Hasky-Guenther et al., 1998; Reitz et al., 2000).

J2 lethality assay

100 J2 was transferred into a 5 ml glass petri dishes containing 2.0 ml Sneb183 fermentation filtrate (Sneb183F) and sterilized TY liquid medium (TY), respectively. After that dishes were incubated at 25℃ and covered by coverslip. The number of dead nematodes was determined at 12 h, 24 h, 48 h, and 72 h. Three independent experiments were done and each experiment has three replicates. J2 treated with sterilized water was used in the control treatment. The J2 were regarded dead when they were remained static once touched with hair-needle (Cayrol et al., 1989). The lethality (L) of J2 was calculated by *Eq.1*.

$$L=\frac{Lt}{100}\times100 \qquad \text{(Eq.1)}$$

where, L_t stands for the number of dead J2 in assay.

Cyst hatching inhibition assay

Plump and brown cysts were crushed and 1000 eggs were picked into glass petri dish under room temperature to test the hatching rate. The experiment included four treatments with nine replicates per treatment: 10 ml soybean root exudate (SRE),10 ml Sneb183

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11291140

fermentation filtrate (Sneb183F), a mixture of 5.0 mL soybean root exudate and 5.0 mL Sneb183 fermentation filtrate (SRE+Sneb183F), 10 mL Sterile water (Control). The treatment solution was replaced and numbers of hatched J2 were determined every three days until no additional J2s were observed in the control treatment. The hatching rate (HR) was calculated by (Eq.2).

$$HR = \frac{T.N.H.J2}{1000} \times 100 \quad \text{(Eq.2)}$$

where, *T.N.H.J2* stands for the total number of hatched J2.

Chemotaxis assays

Indirect method with filter paper

The effect of *S. fredii* Sneb183 fermentation filtrate on nematode movement and chemotaxis was studied on Pluronic F-127 gel in 60 mm diameter petri dishes (Wang et al., 2009), with the bottom engraved with concentric circles of radii 1.0 and 2.0 cm (Hewlett et al., 1997; Schroeder and MacGuidwin, 2010). Filter paper (r = 0.5 cm) was soaked with soybean root exudate (SRE), Sneb183 fermentation filtrate (Sneb183F), an equal proportional mixture of soybean root exudate and Sneb183 fermentation filtrate (SRE+Sneb183F) was placed in the center of the dish. 50 freshly hatched J2 in 1 ml sterile water were uniformly distributed in the radius of 1-2 cm along the circumference of dish. After 24 h at 25℃, the number of J2 distributed in the different sections was counted. Sterile water was used as a control. Three independent experiments were done and each experiment has three replicates. The distribution rate, regarded as an index of chemotaxis, was calculated as follows: $DR_s=DN_s/50$. DR_s represents the distribution rate in each section and DN_s represents the distribution number in each section.

Direct method with in vitro root

A direct method for observing chemotaxis utilized 5 cm young soybean roots at the growing point instead of filter paper. Roots were soaked in Sneb183 fermentation filtrate and sterile water, respectively. The remaining operations are the same as indirect method with filter paper. After 24 h at 25℃, counted the number of J2 distribute in different sections of Petri dish and their distribution rate.

Statistical analysis

Data were analyzed using one-way analysis of variance (ANOVA). Means for each trial in each assay were separated by the Duncan multiple range test.

Results

J2 activity assay

This result strongly indicates that Sneb183 has biocontrol potential against SCN. The fermentation filtrate of *S. fredii* Sneb183 showed high nematicidal activity (*Fig. 1* and *Table 1*). When exposed to Sneb183 fermentation filtrate, J2s of *H. glycines* displayed significant time-dependent mortality. Treatment with Sneb183 fermentation filtrate for 24 h and 72 h, the lethality (L) of J2 reached to 46.66% and 86.66%, respectively. These

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11291140

results indicated that *S. fredii* Sneb183 can produce some extracellular substances to kill nematodes.

Data repesent the Mean±Standard deviation of lethality of J2 of *H. glycines*. Whereas; SS (Sum of square); Df (Degree of freedom); MS (Mean square); *F* (F-value); *P* (Significant value). The different letter within columns are significantly different according to Duncan's multiple range test (P>0.05). Whereas; Control (Sterile water), TY (Fermenation liquid without bacteria), Sneb183F (Sneb183 Fermentation filtrate)

Egg hatching assay

The effects of the four treatments on the hatching of soybean cyst nematode eggs were determined. The results showed that SRE significantly promoted the hatching of soybean cyst nematode eggs compared with the control, the hatching rate reached to 56%. Treatment Sneb183F significantly inhibited the hatching of soybean cyst nematode eggs, the hatching rate was only 0.63%, and the inhibition rate was 98.75%. SRE+Sneb183F also showed inhibition of egg hatching, with an inhibition rate of 39.04% (*Fig. 2* and *Table 2*), the inhibition effect is lower than that of Sneb183F. According to *Fig. 3*, treated with Sneb183F, J2 were not hatched out until 18d, it was almost the deadline of other treatments. It could be seen that all the treatments containing Sneb183F can significantly reduce the hatching rate of soybean cyst nematode eggs as well as delay the peak period of egg hatching (*Fig. 3*).

Data repesent the Mean±Standard deviation egg hatching of H. glycines. Whereas; SS (Sum of square); MS (Mean square); Df (Degree of freedom); F (F-value); P (Significant value). The different letter within columns are significantly different according to Duncan's multiple range test (P>0.05). Whereas; Control (Sterile water), SRE (Soybean root exudate), Sneb183F (Sneb183 Fermentation filtrate), SRE+Sneb183F (Soybean root exudate + Sneb183 fermentation filtrate)

Chemotaxis assays

The influence of fermentation filtrate of *S. fredii* Sneb183 on the chemotaxis of J2 was determined by an indirect method utilizing filter paper. The distribution rate of J2 in different region of dish varied in different treatment (*Fig. 4* and *Table 3*). In the control treatment, the nematodes placed within 1-2 cm area originally were evenly distributed in three sections after 24 h. At 0-1 cm, the distribution rates of J2 in the root exudate and in the *S. fredii* fermentation filtrate treatments were the highest and the lowest, respectively. The majority of J2 were attracted to the central area where soybean root exudate-impregnated filter paper was placed. The opposite happened at 2-3 cm, treatment with fermentation filtrate of *S. fredii* Sneb183 or in the equal mixture of fermentation filtrate and root exudate, most J2 were repelled to the region of 2-3 cm. Overall, the effect of J2

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11291140

attracted by root exudate was remarkably reduced with the addition of fermentation filtrate. Therefore, *S. fredii* Sneb183 fermentation filtrate is repellent to *H. glycines* J2.

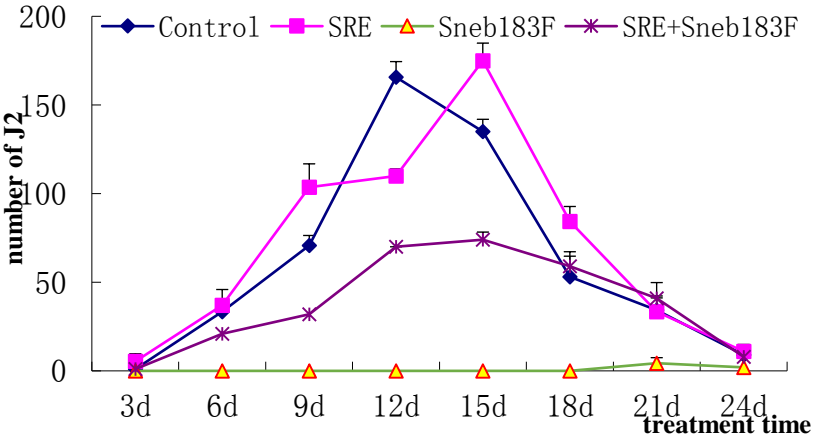

Figure 3. *Effects of 4 treatments on the number of Heterodera glycines eggs hatching at different treatment times. Whereas; Control (Sterile water), SRE (Soybean root exudate), Sneb183F (Sneb183 Fermentation filtrate), SRE+Sneb183F (Soybean root exudate + Sneb183 fermentation filtrate)*

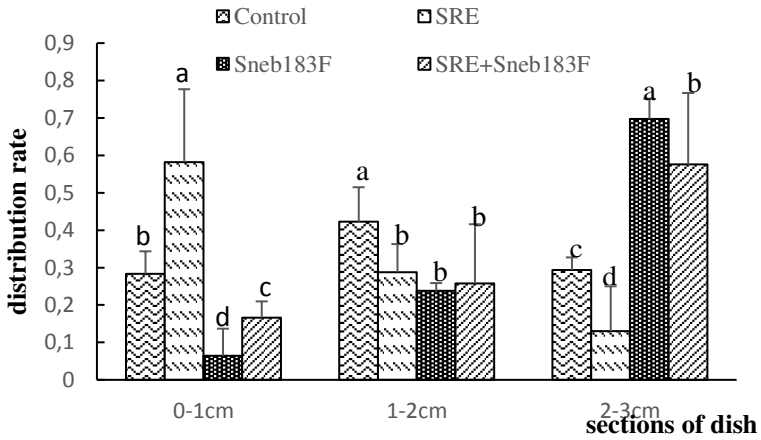

Figure 4. *Effect on chemotaxis of Heterodera glycines J2 to filter paper treated with four treatments. Different letters on bar indicates that values are significantly different according to Duncan multiple test at P>0.05. Whereas; Control (Sterile water), SRE (Soybean root exudate), Sneb183F (Sneb183 Fermentation filtrate), SRE+Sneb183F (Soybean root exudate + Sneb183 fermentation filtrate)*

In the direct method of chemotaxis with roots in vivo, the distribution rates of J2 significantly differed among treatments with Sneb183F and sterile water. At original region (1-2 cm), the distribution rate of J2 in the two treatments is not much different. The young root treated with sterile water strongly attracted J2, the distribution rate of J2 in the sterile water reached 0.6 in the region of 0-1 cm, whereas the treatments with fermentation filtrate was only 0.15, which was significantly different from that in the control treatments (*Fig. 5* and *Table 4*).

Discussion

The *Rhizobium*-legume symbiosis is a special mutualistic relationship (Hirsch et al., 2001). In which beneficial bacterial symbionts provide the nitrogen source for soybean as a result of rhizobia-soybean coevolution (Coba de la Peña et al., 2018). Using *Rhizobium* as a biocontrol agent against *H. glycines* should not only provide nitrogen for soybean plants but also ease to colonize the rhizosphere of soybean. Some studies on the use of *Rhizobium* strains to control nematodes and other pathogens indicate that rhizobia may become excellent biological control agents for disease control. We obtained *Sinorhizobium fredii* Sneb183 out of more than 300 rhizobial strains isolated from the roots of different plants and rhizosphere soils to study their potential against *H. glycines*. A mixture of *Sinorhizobium fredii* Sneb183 and other strains greatly reduced SCN reproduction and significantly promoted plant growth (Zhou et al., 2017).

In this study, we evaluated *S. fredii* Sneb183 action against *H. glycines* by investigating its suppression of juvenile survival and egg hatching and its disruption of host-finding behavior. The fermentation filtrate from *S. fredii* Sneb183 had obvious nematicidal activity against J2, with lethality directly correlated with the duration of exposure, reaching a maximum of 84% at 72 h. Although numerous in vitro studies have discovered the antibiotic or nematicidal activity of bacterial culture filtrates (Sikora, 1992; Li et al., 2005), reported the production of rhizobial compounds that inhibit the growth of other organisms are few. Chakraborty and Purkayastha (1984) discovered toxic substances in the fermentation liquid of *R. japonicum,* and identified one as rhizobitoxine; fermentation liquid of *R. japonicum* inhibited *Macrophomina phaseolina* at 48 h.

Nematode egg hatching in soil is known to be affected by host root exudate, as well as by some chemicals, enzymes, toxins and metabolic by-products of microorganisms (Schmitt and Riggs, 1991; Hu et al., 2017). Previous studies have shown that egg hatching may be stimulated by exudates from roots of susceptible cultivars (Yang et al., 2016). In our current study, the root exudate of soybean 'Liaodou 15' stimulated egg hatching, but the supernatant from *S. fredii* Sneb183 culture inhibited egg hatching strongly and reduced the stimulatory effect of Liaodou 15 root exudate on egg hatchability, thereby possibly reducing the speed at which nematode populations can establish within a root. Using microorganisms to inhibit egg hatching may be an effective strategy resulting in reduced nematode populations in soils and lowered disease severity in infected plants.

Plant-parasitic nematodes were attracted by root exudates to search, locate, penetrate and establish a feeding site in host roots (Yang et al., 2016). Their movement toward host roots may be disturbed by regulating their behaviour. We found that the attraction of J2 to host roots significantly declined during treatment with supernatant from *S. fredii* Sneb183 culture. Whether an indirect or direct assay was employed, the fermentation filtrate not only strongly repelled J2 but also effectively weakened J2 chemotaxis to root exudate and soybean roots.

Nematodes dwelled in soils containing millions of soil microbes. Inevitably, nematodes exposed to fungi and bacteria interacted with them (Tian et al., 2007), including rhizobia. In general, plant-parasitic nematodes inhibit nodulation and nitrogen fixation of roots of leguminous plants (Hussey and Barker, 1976). Horiuchi et al. (2005) reported that the microbivorous nematode *Caenorhabditis elegans* mediates the interaction between roots and rhizobia positively, leading to nodulation through transfer of the rhizobial species *Sinorhizobium meliloti* to the roots of the legume *Medicago truncatula*. Some plant-pathogenic nematodes like *Meloidogyne* spp. have positive

DOI: http://dx.doi.org/10.15666/aeer/1801_11291140

effects on the symbiosis between rhizobia-legume interactions by enhancing the number of nodules and the amount of nitrogen fixed (Baldwin et al., 1979).

Conclusion

It is concluded that *Sinorhizobium fredii* Sneb183 culture filtrate showed nematicidal potential toward soybean cyst nematode (*Heterodera glycines*). The results of current research reveal a unique interaction between *S. fredii* Sneb183 and *H. glycines*, possibly providing a foundation as a biocontrol agent for new prospects of future utilization of rhizobia. However, further study is needed to determinants of *S. fredii* Sneb183 responsible for the activity of nematicide, mechanism of action and screening of active components.

Abstract. Myrtle is known native to Southern Europe and North Africa and was naturally grown in tropical and subtropical regions. Myrtle could be grown successfully in soils under hot, arid environments. Myrtle has several genotypes with yellowish-white or bluish-black colored fruits. The present study aimed to investigate genetic diversity among myrtle genotypes with different fruit colors from different parts of Turkey. A total of 28 myrtle genotypes were collected from Adana, Mersin, Hatay provinces of Turkey. 19 ISSR primers were used for the characterization of the 28 myrtle genotypes. In total, 19 ISSR primers produced 99 clear and reproducible DNA band profiles, 89 of which were polymorphic. Therefore, the average polymorphic was 89.90%. In conclusion, we determined that the ISSR molecular markers could differentiate the white and dark-fruited myrtle genotypes. Myrtle genotypes were also separated according to their geographical origin.
Keywords: *molecular marker, PCR, genetic diversity, plant genetic resources, different fruit-colored*

Introduction

Myrtus communis L., commonly called Myrtle, is one of the significant medicinal and aromatic species (Wannes et al., 2010; Dahmoune et al., 2015). Myrtle is a diploid (2n = 2x = 22) plant known to be native to Southern Europe and North Africa (Serce et al., 2008). Myrtle is known to be a member under the Myrtaceae family, which contains 3,000 species were naturally grown in tropical and subtropical regions. Myrtle is largely consumed as spice having several practices in the food, pharmaceutical, and industries (Sumbul et al., 2011; Casaburi et al., 2015). Myrtle plant could also be used as ornamental purposes such as fencing, roadsides, and green cutting (Skekafandeh, 2007; Danial, 2009). Myrtle grows roughly at an altitude of 500–600 m, most particularly in pine forests and riversides in the Taurus Mountains of Turkey (Aydin and Ozcan, 2007). Myrtle is also called as "hambeles," "mersin," or "murt" in Turkish. It can be grown successfully in soils under hot, arid environments. Myrtle has several genotypes with yellowish-white or bluish-black colored fruits (San et al., 2015; Simsek et al., 2017a).

Many different biotechnological methods could be performed to fruit crops to get better ones during plant breeding strategies. One of significant application of biotechnology is known to be molecular markers in fruit science (Donmez et al., 2016). In recent years, it has been observed that biotechnology studies have been adapted to the breeding activities carried out in many plant species together with classical breeding. Especially, it is possible to shorten the breeding process by adapting the molecular

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11411149

techniques to the breeding processes and make a selection in terms of some features in the early period by using molecular markers (Simsek et al., 2017b). In recent years, molecular techniques in plant breeding can be beneficial in many ways. Among these molecular techniques, ISSR markers having high usage rates have an important place. Molecular markers overcoming the limitations of morphological and biochemical markers avoid the influence of the environment on the performance of genotypes (Madadi et al., 2017). There are several studies on molecular characterization of myrtle genotypes having different origins in literature by various molecular markers (Bruna et al., 2004, 2007; Messaoud et al., 2007, 2011; Serce et al., 2008; Albaladejo et al., 2009; Melito et al., 2013, 2016, 2017; Nora et al., 2015; Ghafouri et al., 2018; Mele et al., 2019). The present study aimed to investigate genetic diversity among different fruit-colored myrtle genotypes from different parts of Turkey. Especially fruit color was chosen as phenotypic trait besides plant materials were collected from different locations of Turkey to ensure that ISSR markers could discriminate myrtle genotypes.

Materials and methods

Plant material

A total of 28 myrtle genotypes were collected from Adana, Mersin, Hatay provinces of Turkey (*Table 1*). A map with the sampling sites is presented in *Figure 1*.

DNA extraction

Total genomic DNA was extracted from leaves tissues by CTAB method (Simsek et al., 2008). The quality and quantity of DNA were detected by NanoDrop (ND 100) spectrophotometer (NanoDrop Technologies, Inc., Wilmington, DE, USA) and agarose gel electrophoresis. DNA samples were subsequently diluted to 10 ng/µl for ISSR-PCR reactions and stored at -20 °C.

ISSR-PCR analysis

19 ISSR primers were used for characterization of the 28 myrtle genotypes (*Table 2*). All ISSR-PCR reactions were carried in a reaction containing 2X PCR Mastermix (Fermentas K0171, Waltham, MA, USA), 1 U Taq DNA polymerase (Fermentas EP0402), 25 mM $MgCl_2$, 10 μM primer, and 10 ng of myrtle DNA. Mixtures were assembled at 0 °C, transferred to a thermal cycler, and then precooled to 4 °C. The amplification was carried out in a model Master Gradient thermal cycler (Eppendorf, Hauppauge, NY, USA) using an optimized in-house program consisting of an initial denaturation step of 3 min at 95 °C, and then 35 cycles of 45 s at 94 °C, 1 min at 55 °C, 45 s at 72 °C, followed by a 7-min elongation step at 72 °C. ISSR-PCR amplification products were separated by agarose gel electrophoresis on 1.5% agarose gels and 0.5 g/mL ethidium bromide in 1X TAE buffer (40 mM Tris-acetate, 1 mM EDTA, pH 8.0) for 3.5 h at 80 V. The fragment patterns were photographed under UV light for further analysis. A 1-kb DNA ladder (Fermentas) was used to determine the fragment size.

Data analysis

ISSR data were recorded as 1 for the presence of a band and 0 for its absence to generate a binary matrix. Only reproducible bands were scored for all the accessions tested. All data were analyzed by Principle Coordinate (PCoA) and Cluster analyses using PAST program (Hammer et al., 2001). First, a similarity matrix was generated using Jaccard coefficients. This matrix was then used for PCO. For cluster analyses, the UPGMA (Unweighted Pair Group Method using Arithmetic Average) method was used to construct dendrogram. The bootstrap values for the clusters were calculated by 1000 replicates using PAST program. The representativeness of dendrogram was evaluated by estimating cophenetic correlation for the dendrogram and comparing it with the similarity matrix, using Mantel's matrix correspondence test (Mantel, 1967). The result of this test is a cophenetic correlation coefficient, r, indicating how well dendrogram represents similarity data.

Results

In total, 19 ISSR primers produced 99 clear and reproducible DNA band profiles, 89 of which were polymorphic. Therefore, the average polymorphic was 89.90%. The results of the ISSR analyses for myrtle genotypes are presented in *Table 3*. The number of alleles determined by each primer ranged from 4 to 7, with an average of 5.2. In terms of the total number of alleles, UBC811, and UBC824 loci produced the highest number of alleles (7), PIC values ranged between 0.41 (UBC835) and 0.90 (UBC824).

Total		250-2500	99	10	89	33.33-100.00	

The dendrogram generated from the UPGMA algorithm based on ISSR data is presented in *Figure 2.* The validity of the dendrogram in reflecting the genetic relationships among the myrtle genotypes was indicated by a high cophenetic correlation coefficient (r) of 0.88. Genetic similarity coefficients ranged from 0.37 to 0.97. The UPGMA clustering pattern grouped all the genotypes into two major clusters (*Fig. 1*). Principle coordinate analysis (PCoA) was also performed using the similarity matrix, and the two-dimensional dendrogram corroborated UPGMA analyses (*Fig. 3*). While the first axis (Coordinate 1) explained 55.95% of the total molecular variance, the second axis (Coordinate 2) explained 13.56%.

Genetic similarities among all myrtle genotypes ranged from 0.37 to 0.97. The highest similarity rate (1.00) was among Antakya, Samandağ, Baltacık, Harbiye1 genotypes collected from the city of Hatay in southern Turkey, on the eastern Mediterranean coast and they all are white-fruited. The lowest similarity rate was 0.27, and it was obtained between dark-fruited Akpınar1 collected from Adana and white-fruited Antakya, Samandağ, Baltacık, Harbiye1 collected from Adana.

Based on the similarity index, a clustering dendrogram was constructed using UPGMA. The dendrogram separated all genotypes except Antakya, Samandağ, Baltacık, Harbiye1. The dendrogram grouped all genotypes into two main clusters. The first main cluster included all dark-fruited genotypes except Harbiye2. The second main cluster included all white-fruited genotypes and dark-fruited genotypes (Harbiye2).

Discussion

Plant genetic resources are significant plant materials for breeders. The collection and identification of these plants is the first and important step of plant breeding. The assessment of genetic diversity is a necessary step to protect natural myrtle populations. We examined the genetic diversity among Turkish myrtle genotypes in comparison with fruit color and geography origin. 19 ISSRs produced 89.90% polymorphism; this result was higher than the results of previous genetic diversity studies (AFLP 56%: Bruna et al., 2007; RAPD 51.9%; Messaoud et al., 2007; RAPD 72.9%: Serce et al., 2008) conducted by different molecular markers.

The evolutionary relationships between the wild and cultivated myrtle types are not well-known. The large-fruited, cultivated type was likely domesticated from the white-colored, wild types. The fact that all the cultivated myrtle accessions are white-fruited, and the dark-fruited from is prevalent in nature indicates that the white color was preferred during the domestication process (Serce et al., 2008). In our study, we used white and dark-fruited genotypes to estimate evolutionary relationships between white and dark-fruited genotypes. Based on the results, all dark-fruited myrtle genotypes were clustered together except Harbiye2. Harbiye2 is also dark-fruited genotype; however, it is collected different provinces of Turkey. Totally five different genotypes (one of them is dark-fruited) were collected from the city of Hatay. They were clustered together, but the only one dark-fruited genotype Harbiye2 from Hatay was different from the other white-fruited genotypes from Hatay. This result showed that dark-fruited genotypes are certainly different from white-fruited genotypes; however, the differences were also related to geographical origin. Serce et al. (2008) used two sets of myrtle accessions from Hatay, Turkey. Set 1 consisted of two wild accessions, dark- and white-colored forms, and six cultivated selections, while Set 2 contained three open-pollinated individuals from each accession of Set 1. The researcher examined genotypic variation of Sets 1 and 2 using RAPD markers. According to results, the molecular analysis clearly separated the cultivated types from the wild accessions. In the present study, we used different white and dark-fruited myrtle genotypes from Hatay, Adana and Mersin provinces of Turkey. We confirmed that ISSR analysis separated the cultivated white-fruited types from the wild dark-fruited genotypes. Melito et al. (2013) investigated genetic diversity of 80 wild accessions of Sardinian myrtle collected four different localities (Corsica, Asinara, Surigheddu and Oristano) via ISSR markers. The researchers used totally 17 ISSR primers and among them 12 ISSR primers were informative. Based on the results, there was no convincing evidence of a correlation between genotype and geographical origin. In another study Melito et al. (2016) explored the morphological, chemical, and genetic diversity of wild myrtle populations in Sicily, with the aim to provide a first characterization of a core collection of 36 accessions from 7 localities (Ispica, M. Pellegrino, Misilmeri, R. Zingaro, Scopello, Ribera, Sciacca) for future domestication programs. AFLP fingerprinting generated 152 polymorphic fragments. Structure analysis identified three genetic clusters (cluster A: most of the Misilmeri samples, cluster B: Scopello, Ribera, Sciacca, and M. Pellegrino, cluster C: Ispica and Ribera) corresponding to specific geographical origin. In our study; we used 19 ISSR primers and all ISSR primers proved to be informative. PIC values obtained from ISSR primers were ranged from 0.41-0.90. In the present study, myrtle genotypes collected from different parts of Turkey were used and genotypes were clustered by geographic origin.

Conclusions

In conclusion, we determined that the white and dark-fruited myrtle genotypes could be differentiated by the ISSR molecular markers. Myrtle genotypes were separated according to their geographical origin. It is shown that there are significant myrtle genetic resources that are genetically and morphologically different from each other in Turkey.

(Received 1st Aug 2019; accepted 28th Nov 2019)

Abstract. The first hybrid generation (F1) individuals of grass carp (*Ctenopharyngodon idellus*, ♀) × barbel chub (*Squaliobarbus cunrriculus*, ♂) commonly show obvious growth diversity, even though they are from the same parents and cultured in the same environment. To characterize the molecular mechanism of the growth diversity, the present study compared the expressions of growth-related genes of the fast-growth population (FGP) and slow-growth population (SGP). The expression of growth-inhibiting *SRIF* gene was significantly higher in the SGP hypophysis than in the FGP. The expressions of growth-promoting *GHR* and *IGF-I* genes in blood, *GHR*, *IGF-I* and *IGF-II* genes in liver, and *IGF-I* and *IGF-II* genes in muscle of the FGP were significantly higher than those of the SGP in liver. The results implied that hypernomic-expression of *SRIF* gene in hypophysis caused the expressions of *GHR* and *IGF-I* genes in blood, *GHR*, *IGF-I* and *IGF-II* genes in liver, and *IGF-I* and *IGF-II* genes in muscle of the SGP to be significantly lower than those in the FGP, which caused the lower growth of the SGP. These results provided valuable reference for studying the relationship between growth-related genes and fish growth, and the molecular mechanism of fish growth.
Keywords: *fish, growth axis, quantitative reverse transcriptional PCR, growth-inhibiting gene, GHR gene, expression analysis*

Introduction

Grass carp (*Ctenopharyngodon idellus*) is already the largest freshwater aquaculture product worldwide (Ni and Yu, 2013; Ni et al., 2014) and it is an important aquaculture species in Asia. Approximately 5.90 million tons of grass carp was produced ever year only in China (Department of Fisheries of Ministry of Agriculture of China, 2017). However, frequent occurrence of diseases in grass carp culture has caused serious loss and severely restricts sustained development of grass carp culture (Nie and Pan, 1985; Chen et al., 2012). Hybridization between different fish species is extensively used as their offspring exhibit growth and disease-resistant superiority compared to their parents. For instance, the first hybrid generation (F1) of Kaluga sturgeon (*Huso dauricus*, ♀) × sterlet (*Acipenser ruthenus*, ♂) exhibits fast-growth and disease-resistant superiority (Yin

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11511159

et al., 2004). The hybrid offspring of rainbow trout (*Oncorhynchus mykiss*, ♀) × speckled trout (*Salvelinus fontinalis*, ♂) exhibit disease-resistant superiority (Wu et al., 2014). The F1 of grass carp (♀) × topmouth culter (*Erythroculter ilishaeFormis*, ♂) also exhibits disease-resistant superiority (Aquaculture Research Group of Jianhu County of Jiangsu Province, 1974).

Barbel chub (*Squaliobarbus curriculus*) as well as grass carp belongs to the Leuciscinae subfamily of fish. The shape of barbel chub is similar to grass carp, and barbel chub exhibits strong adaptability and disease-resistant superiority (Liu et al., 2012). In addition, a previous study has showed that disease resistance of the F1 of grass carp (♀) × barbel chub (♂) was significantly higher than that of grass carp (He et al., 2015). However, the F1 individuals of grass carp (♀) × barbel chub (♂) commonly emerge obvious individual difference in size during culture process, even though they are from the same parents and cultured in the same environment (Zhou et al., 2017).

Fish growth is influenced by various internal (such as incretion) and external factors (such as environment and nutrition) (Su et al., 2012; Valente et al., 2013). The incretion factors regulate fish growth through *GH/IGF-I* axis, which involves the hypothalamus, the hypophysis, and the liver (Lin, 1996; Peng and Peter, 1997). Hypothalamus secretes stimulators and inhibitors. The stimulators, such as growth hormone releasing factor (*GRF*), gonadotropin-releasing hormone (*GnRH*), pituitary adenylate cyclase activating polypeptide (*PACAP*), dopamine (*DA*) and neuropeptide Y (*NPY*), stimulate the release of growth hormone (*GH*) in the hypophysis (Parker et al., 1997; Montero et al., 1998), while the inhibitors, such as somatostatin (*SRIF* or *SS*), 5-serotonin (*5-HT*), norepinephrine (*NE*) and glutamate (*Glu*), inhibit the release of *GH* that induces the secretion of *GRF*, *GnRH*, *PACAP*, and *NPY* (Peter and Marchant, 1995; Peng and Peter, 1997). Secretion of stimulators and inhibitors regulates the secretion of *GH,* and *GH* is transmitted to the surface of liver cell membrane through the circulation system and then it binds to growth hormone receptor (*GHR*) to trigger the transduction of insulin-like growth factors (*IGFs*). Then *IGFs* are transmitted to each tissue through the circulation system to promote fish growth.

Considering the F1 individuals of grass carp (♀) × barbel chub (♂) commonly emerge obvious individual difference in size during culture process, to characterize the molecular mechanism of the growth diversity of the F1 populations, the present study compared the expressions of growth-related genes of the fast-growth population (FGP) and slow-growth population (SGP) using fluorescence quantitative reverse transcriptional PCR (qRT-PCR). The results provided valuable reference for studying the relationship between growth-related genes and fish growth, and the molecular mechanism of fish growth.

Materials and Methods

Sample collection

The F1 samples were collected from Wulong Fishing Ground located at Beisheng Town, Liuyang City of China (28.295 N, 113.436 E). The F1 fish were cultured 150 days from 1^+ years of F1 offspring with the same parents. They were fed with commercial puffed compound feed-8110 (Dabeinong, China), which contains equal more than 36.0% of crude protein, equal more than 4.0% of crude fat, and equal more than 15.0% of crude ash. The F1 samples were distinguished to two populations, i.e. the FGP (their body weights were more than 500 g) and the SGP (their body weights were equal or less than

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11511159

500 g), according to their body weight. Each population was collected 7 healthy samples, and the samples were anaesthetized using an overdose of neutralized MS222 (ethyl 3-aminobenzoate methane-sulfonic acid). Then the samples were dissected as approximately 80 mg of their hypothalamus, hypophysis, liver and muscle, and 2 ml of blood was collected and stored in liquid nitrogen.

RNA extraction and synthesis of cDNA

The tissues stored in liquid nitrogen were put in homogenizing pipe with 1 ml TRK lysis buffer and homogenized three times (15 s per time with 6000 rpm/min, 5 s of interval between homogenizing). Subsequently, RNAs were extracted from the homogenates using an E.Z.N.A. total RNA kit I (OMEGA, USA) according to the manufacturer instructions. The RNAs were used to synthesize the first strand of cDNA by a RevertAid first strand cDNA synthesis kit (Thermo, USA), with Oligo$(dT)_{18}$ and random primers.

qRT-PCR

To design the primers for qRT-PCR, fragments of *GH*, *GHR*, *IGF-I*, *IGF-II*, *PACAP*, *SRIF*, *MSTN-1* and *MYOG* genes of the F1 were cloned and sequenced. To clone these gene fragments, the primers (*Appendix 1*) were designed using primer 6.0 referenced cDNA sequences of these genes from Cyprinidae in GenBank. The fragments were amplified using the first strand of cDNA of the F1 as templet. Each 50 μl of the PCR reaction mixture contained 1×Ex Taq Buffer (TaKaRa, China), 1.25 U of Ex Taq polymerase (TaKaRa, China), 10 nmol of each primer, 40 nmol of each NTP, and 2 μl of cDNA. The PCR amplified procedure was carried out at 94°C for 5 min; at 94°C for 30 s, at 52~56°C (β-actin: 54°C; EF-1α: 54°C; GH: 56°C; GHR: 54°C; *IGF-I*: 55°C; *IGF-II*: 55°C; *PACAP*: 52°C; *SRIF*: 52°C) for 30 s, at 72°C for 90 s, in 30 cycles; and finalized at 72°C for 5 min. Then the fragments were sequenced using AB3730 sequencer at Beijing Aokedingsheng Bio-Science Ltd., China (*Appendix 2*). Finally, the primers that used to qRT-PCR were designed based on these fragments using primer 6.0 (*Table 1*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11511159

The expressions of *PACAP* and *SRIF* genes in the hypothalamus, *PACAP*, *SRIF* and *GH* genes in the hypophysis, *GH*, *GHR*, *IGF-I* and *IGF-II* genes in the blood, *GHR*, *IGF-I* and *IGF-II* in the liver, and *IGF-I*, *IGF-II*, *MYOG* and *MSTN-1* genes in the muscle were tested through qRT-PCR using a SYBR Premix Ex Taq™ II kit (TaKaRa, China). The first strand cDNA from the tissues was used as templet. The β-actin and EF-1α genes were used as internal controls. The qRT-PCR was conducted using a CFX96Touch TM real-time PCR detection system (Bio-Red, USA). Each 10 μl of the qRT-PCR reaction mixture contained 5 μl of SYBR Green PCR master mix (CWBIO, China), 0.4 μl of each primer (10 μM), 1 μl of cDNA, and 3.2 μl of ddH_2O. The PCR amplified procedure was carried out at 94°C for 10 min, followed by 35 cycles of 95°C for 10 s, 60°C for 10 s, and 72°C for 15 s. The solubility curve was obtained by raising 0.5°C per 5 s from 65°C to 95°C. Seven samples in each group and triplicate of each sample were analyzed. Data were collected and analyzed using CFX manager software 3.1 (Bio-Rad, USA).

Data analysis

The results are presented as the mean ± standard error (S.E.) for each group. One-way ANOVA and t-test was conducted using R 3.5.1 (R Core Term, 2014). Differences for which *P* values were < 0.05 were considered statistically significant.

Results and Discussion

The body lengths of the FGP and the SGP were 38.043 ± 0.44 and 26.243 ± 0.48 cm, respectively (*Fig. 1A*). The body weights of the FGP and the SGP were 932.86 ± 50.41 and 312.43 ± 22.70 g, respectively (*Fig. 1B*). The average body length and body weight of the FGP were significantly higher than those of the SGP, respectively (independent t-test, $p < 0.001$).

Expressions of *PACAP* (Welch two sample t-test, $t = 1.393$, $P = 0.230$) and *SRIF* (Welch two sample t-test, $t = 0.448$, $P = 0.670$) genes in the hypothalamus of the FGP were not detected significantly different to the SGP (*Fig. 2A*). However, the relative expression of the *SRIF* gene in the hypophysis was significantly increased in the SGP than those in the FGP (Welch two sample t-test, $t = -13.818$, $P < 0.001$; *Fig. 2B*). The results implied that the high expression of *SRIF* gene in the SGP hypophysis was probably the major reason that caused the slow growth of the SGP, as *SRIF* is considered as an inhibitor that inhibits secretion of *GH* in the hypophysis (Peter and Marchant, 1995; Peng and Peter, 1997; Lin and Peter, 2001). Meanwhile, *SRIF* also reduces the combination of *GHR* to *GH* and transcriptional level of *IGF-I* gene in the liver (Tanaka et al., 1995; Masini et al., 1999). The *GH* gene was rarely expressed in the hypophysis and in the blood, and its expressions were not detected significantly different between the hypophysis of FGP and SGP (Welch two sample t-test, $t = 1.266$, $P = 0.250$; *Fig. 2B*) and in the blood (Welch two sample t-test, $t = -0.576$, $P = 0.605$; *Fig. 2C*). However, the expressions of *GHR* (Welch two sample t-test, $t = 3.162$, $P = 0.014$) and *IFG-I* genes (Welch two sample t-test, $t = 5.663$, $P = 0.002$) in the FGP blood were significantly higher than those in the SGP (*Fig. 2C*).

The expressions of *GHR* (Welch two sample t-test, $t = 3.334$, $P = 0.039$), *IGF-I* (Welch two sample t-test, $t = 5.157$, $P < 0.001$) and *IGF-II* (Welch two sample t-test, $t = 5.995$, $P = 0.004$) genes in the FGP liver were significantly higher than those in the SGP liver (*Fig. 2D*). In addition, the expressions of *IGF-I* (Welch two sample t-test,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11511159

$t = 7.744$, $P < 0.001$) and *IGF-II* (Welch two sample t-test, $t = 3.594$, $P = 0.012$) genes in the FGP muscle were significantly higher than those in the SGP muscle. *IGF-I* and *IGF-II* genes are mainly expressed in the liver. Therefore, these genes were higher expressed in the liver than in the muscle (*Fig. 2E*). Fish growth mainly shows as fast growth of muscle. The growth of muscle was regulated by *GH-IGF* axis. *GH* regulates expression of genes that promote muscle growth, such as myostatin and muscular atrophy genes. *IGFs* mainly regulate expression of genes that regulate muscle form (Fuentes et al., 2013). In addition, the external factors, such as environment and nutrition, also influence fish growth through the *GH/IGF-I* axis (Reinecke, 2010; Su et al., 2012). However, the expressions of *MYOG* and *MSTN-1* genes in the muscle were not significantly different between the FGP and the SGP (Welch two sample t-test, $t = 0.569$, $P = 0.589$ for *MYOG* gene, and $t = -2.006$, $P = 0.090$ for MSTN-1 gene).

DOI: http://dx.doi.org/10.15666/aeer/1801_11511159

GH is synthetized in the hypophysis and transported to target tissues through the circulatory system. The growth-promoting performance of *GH* is vitally needed to mediate *GHR* and *IGFs*. Therefore, fish growth could not be expressed only by the expression of *GH* gene, but the expressions of *GHR* and *IGF* genes are also vital. In the present study, the expressions of *GHR*, *IGF-I* and *IGF-II* genes in the FGP liver were significantly higher than those in the SGP, consistent with previous studies in goldfish (*Carassius auratus*) (Zhong et al., 2012), Japanese pufferfish (*Takifugu rubripes*) (Kaneko et al., 2011), mud carp (*Cirrhinus molitorella*) (Zhang et al., 2006), Nile tilapia (*Oreochromis niloticus*) (Cruz et al., 2006), European eel (*Anguilla anguilla*) and half-smooth tongue sole (*Cynoglossus semilaevis*) (Degani et al., 2003; Ma et al., 2012). In addition, *GH* also regulates muscle growth through regulating the expressions of myogenic factors. For instance, expressions of *MYOG, MYOD2, MYF5V* and *MEF2A* genes in the muscle of the fast-growth transgenic fish were significantly higher than those of wildtype fish (Devlin et al., 2013). However, we did not detect significant difference between the expression of *MYOG* and MSTN-1 genes in the muscle of the FGP and the SGP.

Conclusion

The significantly higher expression of *SRIF* gene in the SGP hypophysis than in the FGP hypophysis caused the expressions of *GHR* and *IGF-I* genes in the blood, *GHR*, *IGF-I* and *IGF-II* genes in the liver, and *IGF-I* and *IGF-II* genes in the muscle of the SGP to be significantly lower than those in the FGP, which caused the lower growth of the SGP than the FGP. However, whether increasing the expression of *SRIF* gene in the hypophysis could increase growth in other fishes still needs further study.

Abstract. The *Taxodium 'zhongshanshan'* is one of the main wetland plants of lakeside of a plateau Dianchi Lake, in Southwest of China. The sediments and overlying water samples of the *T. 'zhongshanshan'* wetland were collected. The temporal and spatial distributions of the total nitrogen (TN), total phosphorus (TP) and total organic matter (OM) were analyzed by principal component analysis (PCA) and correlation coefficient method. The pollution risk assessment of *T. 'zhongshanshan'* in Wetland. The results showed that: (1) There were differences in the temporal and spatial distributions of nutrients in the dynamic groundwater of *T. 'zhongshanshan'* wetland. In overlying water, the TP, TN and SS were higher in rainy season than in dry season. The removal rates of TN and TP were higher in dry season than in rainy season. The pollutant in the upstream were higher than the downstream. (2) The sediment pollution sources of nitrogen and phosphorus in wetland were also different in the rainy and dry seasons. The TP in sediment were higher in rainy season than in dry season. (3) The comprehensive pollution index was combined with the organic index to provide an evaluation method. The TN and TP content reached a heavy pollution level and the organic contaminants were at a medium level.
Keywords: *Taxodium 'zhongshanshan' wetland, nutrients distribution characteristics, pollution index, organic matter index, organic nitrogen index*

Introduction

Dianchi Lake Basin is a region with the highest level of urbanization in Yunnan Province, Southwest of China. The deterioration of the water environment and eutrophication in Dianchi Lake seriously restrict the sustainable development of the region (Xue and Lu, 2015; Li et al., 2015). It is the key watershed of "Three rivers and three lakes" management project in China. People have paid close attention to the temporal and spatial distribution characteristics and environmental significance of nutrient elements, assessment pollution risk of nutrients in lakeside wetlands of Dianchi.

The Lakeside wetlands could intercept pollution into lakes, restore the function of terrestrial and aquatic ecosystems and maintain water quality of lakes and improve the ecological landscape of lakes, which play an important role as barrier for eutrophic lakes (Wondie, 2018; Reeves et al., 2018). Also the lakeside wetlands control the lake eutrophication. To restore the ecosystem of eutrophic lakes, a 54,000 ha of lakeside ecological rehabilitation zone and 800,000 plants of *T. 'zhongshanshan'* ecoregion have

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11611174

been constructed in the lakeside wetland of Dianchi Lake. There are many studies have shown that the *T. 'zhongshanshan'* have a good capacity to purify different concentration of eutrophic water (Hua et al., 2013; Han et al., 2015) and reduce the concentration of nitrogen and phosphorus in the ecological rehabilitation zone of wetland (Mayo et al., 2018; Oldenborg and Steinman, 2018).

Although, there are many related research reports in the Take Griffin Lake Wetland, Louisiana Rainy Land, Caohai Typical Plateau Wetland and Typical Lakes of Qinghai-Tibet Plateau (Zhang et al., 2013; Marton et al., 2014; Fulton et al., 2015). These results indicated that the spatial distribution and release potential of pollutant indicator have the obvious differences in lakeside wetlands. Temporal and spatial of nutrients has important impact on wetland ecosystem restoration and further affected the restoration of eutrophic lakes. However, combined nutrient distribution and assessment risk of pollutant has rarely been reported, especially in the lakeside wetland of plateau eutrophic lake.

The Laoyuhe River is one of the 35 main rivers input Dianchi Lake, which is typical contaminated non-point source pollution. During 2002 and 2004, the water quality of the Laoyuhe River was worse than Grade V due to lack of protection and management, and the main pollution index were the TN and TP. According to Laoyuhe River pollutants characteristics, a 20 hm^2 of the *T. 'zhongshanshan'* ecological restoration area was constructed near the estuary of Laoyuhe River. The removal rate of TP and TN respectively reached 37.1% and 67.5% in ecological restoration wetland of the Laoyuhe River. The annual COD reduction of the pollution load was 473.2 t, TP 1.703 t, TN 79.1 t and SS 483.7 t by the ecological restoration wetland of the Laoyuhe River (Ma et al., 2007). Laoyuhe River wetland is the largest, last biological barrier in the lakeside of Dianchi Lake where *T. 'zhongshanshan'* is the typical and main trees. It plays an important roles in reduce pollution from the agricultural non-point source.

This research is aim to systematically analyze the temporal and spatial distributions characteristics and ecological effects of sediments in the ecological restoration area of the *T. 'zhongshanshan'* in the lakeside wetland. It is contained the temporal and spatial distribution characteristics of TP, TN and OM in sedimentsand the interaction between sediment-overlying water and the evaluation of pollution level in *T. 'zhongshanshan'* wetland.

Materials and methods

Study area and Sampling sites as shown in *Figure 1*. The Laoyuhe River wetlands about 53.34 hm^2(108°48'46"-108°52'09"E,22°56'28"-23°0'49"N) has formed a wetland ecosystem in the River-Lake interaction area. In addition, plenty of *T. 'zhongshanshan'* has been planted in that wetland area which plays an important role in purifying water quality, intercepting pollutants, controlling soil loss and improving lakeside landscape.

Moreover, the study area forms the unique regional precipitation unit in the dry season during October to April and rainy seasons during May to September in the Yunnan-Guizhou Plateau. So that the hydrological processes (Weyer et al., 2018), wetland vegetation suitability (Pan et al., 2012), nutrient transport and transformation in sediments (Naranjo et al., 2019) of the Laoyuhe River are mainly affected by dry and rainy seasons.

Sediment and water sample treatment and statistical analysis

In this study, 27 sample sites (A1-A9, B1-B9, C1-C9) as marked in *Figure 1* were located in the central of *T. 'zhongshanshan'* ecological restoration area in Laoyuhe River wetland near Dianchi Lake. A1-A9 were located at downstream, B1-B9 were

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11611174

located at midstream, C1-C9 were located at upstream. Surface sediment (0-10 cm) and overlying water are collected by using a home-made core Plexiglas sampler (Zhang, 2014) in May 27, 2018 (rainy season) and November 27, 2018 (dry season). The samples collected from each site consisted of three parallel samples. Following collection, the sediment and overlying samples were sealed in plastic bags and bottles were transported to the laboratory in cooled boxes at 4 °C. Each sediment sample was freeze-dried, ground, and passed through a 0.15-mm sieve.

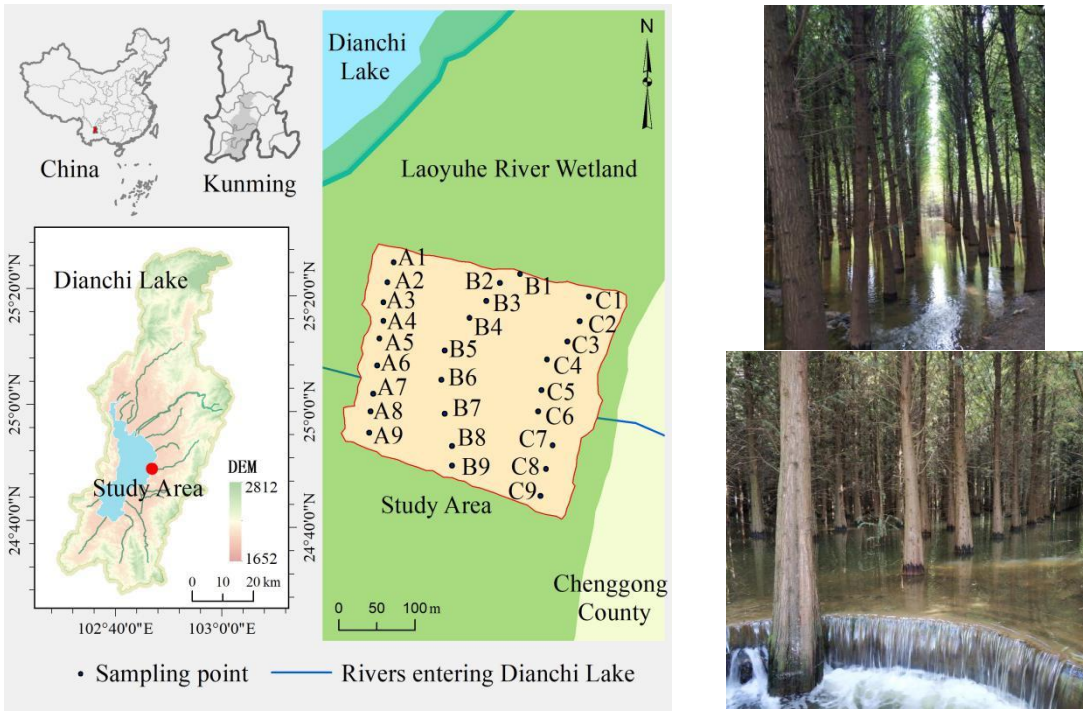

Figure 1. *Locations of sampling sites and pictures of Laoyuhe River wetlands around Dianchi*

To measure TP in the sediment samples, TP in acid-digested extract was determined by the ascorbic acid method using a Shimadzu UV-3600 spectrophotometer. TN was determined using an elemental analyzer (CE-440, Exeter Analytical, Inc., North Chelmsford, MA, USA). To measure OM which were analyzed by potassium dichromate oxidation-external heating (Zhang et al., 2014).

Suspended Solids (SS), Total nitrogen (TN) and Total phosphorus (TP) were tested and analyzed in overlying water. The parameters of water samples were determined according to the *Monitoring Method for Water and Wastewater* (4th Edition). SS was filtered by centrifuge and filter paper. National Standards HJ 636- 2012 and GB 11893-89 illustrated that TN was determined by alkaline potassium persulfate oxidation-ultraviolet spectrophotometry and that TP was determined by ammonium molybdate spectrophotometry. The average of three parallel samples for each index is tested for reduce error, and the laboratory error is controlled within 5%. The data were analyzed by SPSS20.0 and Excel 2013 software for the principal components of TN, TP, OM in sediments and SS, TN and TP in the overlying water of each sampling point in the research area. Then the correlation between different index also be studied.

DOI: http://dx.doi.org/10.15666/aeer/1801_11611174

The nutrient element distribution diagram of the study area was drawn by GraphPad.Prism5 software in order to compare and analyze the distribution characteristics of different nutrient elements in the sediment-overlying water in the dry and rainy season.

Pollution assessment method of T. 'zhongshanshan' ecoregion

Comprehensive pollution index evaluation

The assessment criteria of TN and TP (0.55 and 0.60 g/kg) used in this paper. They are consistent with the contents of TN and TP in sediments that can cause the lowest level of ecological risk effects issued by the Department of Environment and Energy, Ontario, Canada (1992) (Li et al., 2016). The formula for calculating single pollution index is (Kapelewska et al., 2018):

$$S_i = \frac{C_i}{C_s} \quad \text{(Eq.1)}$$

$$FF = \frac{\sqrt{F^2 + F_{max}^2}}{\sqrt{2}} \quad \text{(Eq.2)}$$

where S_i is a single evaluation index or standard index, $S_i > 1$ indicates that the content exceeds the evaluation standard value; C_i is the measured value of evaluation factor i (g/kg); C_s is the evaluation standard value of evaluation factor i (g/kg). The C_s of TN is 0.55 g/kg, the C_s of TP is 0.60 g/kg; FF is the comprehensive pollution index; F is the average value of n pollutant pollution indices (average of *STN* and *STP*); F_{max} is the maximum single pollution index (maximum of *STN* and *STP*). The comprehensive pollution for the surface sediments of Laoyuhe wetland shown in *Table 1*.

Table 1. *Classification of comprehensive pollution degree of surface sediments in Laoyuhe River wetland*

Grade	STN	STP	FF	Pollution Level
1	STN < 1.0	STP < 0.5	FF < 1.0	Non-pollution
2	1.0≦STN < 1.5	0.5≦STP < 1.0	1.0≦FF < 1.5	Mild pollution
3	1.5≦STN < 2.0	1.0≦STP < 1.5	1.5≦FF < 2.0	Moderate pollution
4	STN > 2.0	STP > 1.5	FF > 2.0	Heavy pollution

Organic pollution index evaluation

The sediment pollution in *T. 'zhongshanshan'* wetland of Dianchi Lakeside was further evaluated by organic pollution index method for improve the evaluation results (Zhang et al., 2015; Yang et al., 2017). It is output of comprehensive information (Zhu et al., 2019) then it has advantages over the comprehensive pollution index evaluation.

According to *Equations 3–5* and *Table 2*, the evaluation results of organic pollution of surface sediments in *T. 'zhongshanshan' ecoregion* around Dianchi Lake are shown in *Table 4*.

$$IO = OC(\%) \times ON(\%) \quad \text{(Eq.3)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11611174

$$ON = TN(\%) \times 0.95 \quad \text{(Eq.4)}$$

$$OC = {}^{OM(\%)}/_{1.724} \quad \text{(Eq.5)}$$

where *OC* is organic carbon.

Table2. *Evaluation criteria of organic index of surface sediments in Laoyuhe wetland*

Project	**OI < 0.05**	**0.05≦OI < 0.20**	**0.20≦OI < 0.5**	**OI≧0.5**
Level	Non-pollution	Mild pollution	Moderate pollution	Heavy pollution

Results and analysis

Spatial distribution characteristics of nutrients in the ecological restoration area of the T. 'zhongshanshan'

The Distribution characteristics of TN, TP and SS of the overlying water is shown in *Figure 2* and TN, TP and OM contents in surface sediments of Laoyuhe River wetland during dry and rainy seasons is shown in *Figure 3*.

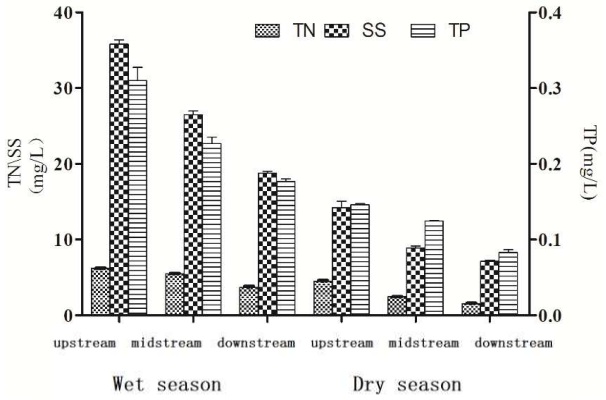

Figure 2. *Distribution characteristics of TN, TP and SS of the overlying water in the ecological restoration area*

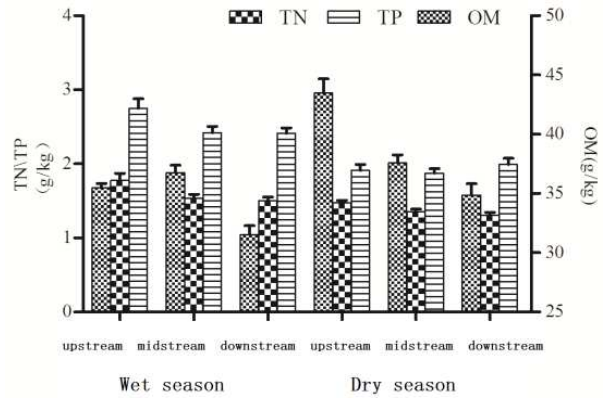

Figure 3. *Distribution characteristics of TN, TP and OM contents in surface sediments of Laoyuhe river wetland during dry and rainy seasons*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11611174

In the research area overlying water, the average values of TN was 5.13 mg/L and TP was 0.24 mg/L in rainy season, while TN is 2.83 mg/L and TP is 0.12 mg/L in dry season. The TN and TP in rainy season were nearly twice higher than in dry season.

All of TN, TP and SS decreases when the water flow through the ecological restoration area. The TN removal rate was 40.3% in rainy season and 65.9% in dry season. The TP removal rate was 43.0% in rainy season and 43.2% in dry season. The removal rates of TP and TN in dry season are higher than in rainy season. The removal efficiency of TN is higher than TP. The removal rates of SS in the overlying water 47.58% in rainy season and 49.88% in dry season.

Distribution of nutrients in sediments of ecological restoration area was obviously different. The OM was 38.64 g/kg in dry season and 34.58 g/kg in rainy season. Moreover, it was 33.19 g/kg in downstream and 39.48 g/kg in upstream. But the TN in sediment was 2.53 g/kg in rainy season and 1.92 g/kg in dry season. It was 0.21 g/kg higher in upstream than that in downstream. The TP was 1.61 g/kg in rainy season and 1.38 g/kg in dry season. It was 0.22 g/kg higher in upstream than that in downstream.

Correlation analysis of nitrogen, phosphorus and organic matter in sediment and overlying water

The correlation coefficient matrix of TN and TP in sediment-overlying water of *T. 'zhongshanshan' ecoregion* in rainy and dry season in Laoyuhe River was shown in *Table 3*. The correlation coefficient between TP and TN in sediment was 0.943 in rainy season and 0.757 in dry season ($P < 0.01$). There was a significant positive correlation between TN and OM in overlying water in rainy season ($P < 0.05$) with a correlation coefficient of 0.808. There was a significant positive correlation between TN and TP in water and TP in sediment in dry season ($P < 0.05$) with a correlation coefficient of 0.540 and 0.662. In dry season, TP and OM in sediments were positively correlated with TN and TP in overlying water ($P < 0.05$).

Table 3. *Correlation analysis of surface sediment-water nitrogen, phosphorus and organic matter in dry and rainy seasons of Laoyuhe river wetland*

Rainy season	**Sediment TN**	**Sediment TP**	**Sediment OM**	**Overlying water TN**	**Overlying water TP**
Sediment TN	1	0.943**	0.360	0.465	0.594*

Assessment pollution risk of the ecological restoration area of the T. 'zhongshanshan'

This paper used the comprehensive pollution index evaluation method and organic index evaluation method to evaluate the pollution status of surface sediments in the T. 'zhongshanshan' wetland of Dianchi Lake. It based on the distribution characteristics of TN, TP and OM in the surface sediments. The results were shown in the *Table 4*. The results showed that the comprehensive pollution index which all of them belong to severe pollution is as follows: upstream > midstream > downstream (rainy season); downstream > upstream > midstream (dry season).

Table 4. *Comprehensive assessment pollution risk of surface sediments in dry and rainy seasons of assessment pollution risk*

	Area	STP	Grade	STN	Grade	FF	Level
Rainy season	Upstream	2.96	4	5.00	4	4.52	Heavy
	Midstream	2.56	4	4.40	4	3.97	Heavy
	Downstream	2.51	4	4.38	4	3.94	Heavy
	Area	**STP**	**Grade**	**STN**	**Grade**	**FF**	**Level**
Dry season	Upstream	2.45	4	3.47	4	3.23	Heavy
	Midstream	2.26	4	3.40	4	3.13	Heavy
	Downstream	2.18	4	3.62	4	3.28	Heavy

Applying the organic pollution index to evaluate the organic pollution of surface sediments of *T. 'zhongshanshan' ecoregion* is shown in *Table 5*. The distribution of organic pollution in the rainy or dry seasons of *T. 'zhongshanshan' ecoregion* along the lakeside is as follows: upstream > midstream > downstream. The organic pollution was moderate except water inlet in rainy season that was level III (heavily polluted).

Table 5. *Assessment of organic pollution in surface sediments of Laoyuhe river wetland in dry and rainy seasons*

	Area	OC/%	ON/%	OI/%	Level
Rainy season	Upstream	2.06	0.26	0.54	IV
	Midstream	2.13	0.23	0.49	III
	Downstream	1.83	0.23	0.42	III
	Area	**OC/%**	**ON/%**	**OI/%**	**Level**
Dry season	Upstream	2.52	0.18	0.46	III
	Midstream	2.18	0.18	0.39	III
	Downstream	2.02	0.19	0.38	III

Discussion

Spatial distribution characteristics of nutrients elements in the ecological restoration area of the T. 'zhongshanshan' in Dianchi Lakeside wetland

(1) There are differences in nutrient elements in overlying water between rainy season and dry season. Compare with dry season, the average content of TN in rainy season was 2.3 mg/L higher than in dry season, while TP in rainy season was 0.12 mg/L

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11611174

also higher than in dry season. Dianchi Lake Basin is a phosphorus-rich area, the lakeside wetland of the Laoyuhe River is located in the East Bank of the Dianchi Lake (Zeng et al., 2017) where agricultural non-point sources have become the main pollution sources.

According to research, crops such as flowers and vegetables in dry season are widely planted which were the main causes of agricultural non-point source pollution in the basin. These crops require large amounts of fertilizer and have high nutrient surpluses (Zeng et al., 2017). Therefore, the loss and migration of phosphorus have become an important source of water pollution in the phosphorus-rich area, Dianchi Lake, with the increase of precipitation in rainy season. The nitrogenous and phosphorus fertilizer in the soil with the heavy rain washed into the river channel and finally entered the *T. 'zhongshanshan'* wetland. Then, it makes the content of nutrients in the overlying water in rainy season are much higher than those in dry season.

(2) In *T. 'zhongshanshan'* wetland, the removal rate of TN and TP in overlying water in dry season is higher than that in rainy season. The removal rate of TN was 25.6% higher in dry season than in rainy season. The removal rate of TP in dry season was 0.2% higher than in rainy season. The first reason is that the content of TN, TP and other nutrients in the overlying water is higher in rainy season than those in dry season. Secondly, the higher hydraulic load and longer hydraulic residence time can makes higher removal efficiency. There are an amount of water, fast flow rate and short hydraulic retention time in *T. 'zhongshanshan' ecoregion* in rainy season. That is consistent with that the purification effect of *T. 'zhongshanshan'* on mild and moderate eutrophic wastewater was better than heavy (Hua et al., 2013; Han et al., 2015). Meanwhile, that the growth of *T. 'zhongshanshan'* is stable in the dry season causes the unique climatic conditions of Kunming (Ma et al., 2011). So the nutrient elements removal rate such as TN and TP are kept at a certain rate to promote TN and TP reduction in dry season.

(3) The content of TP in sediment is higher in rainy season than in dry season. Also it is higher in upstream than downstream in research area. The spatial and temporal distribution of nutrient elements such as TN, TP and OM in sediments are mainly affected by many reasons such as exogenous inputs, sedimentary environment, human factors, hydrodynamic conditions and pollution conditions (Marton et al., 2014). The content of TP in the sediment in rainy season is higher than that in dry season because of a large amount of phosphorus entered the *T. 'zhongshanshan'* wetland with soil erosion in rainy season especially Dianchi Lake which is located a phosphorus-rich area (Ma et al., 2015). The particulate phosphorus in the soil is intercepted and settled into the sediment by the roots of *T. 'zhongshanshan'* and other plants. The absorption of phosphorus nutrients in the roots of plants plays a certain role in reducing the pollution of total phosphorus in sediments. Therefore, the content of TP in the sediment in upstream of *T. 'zhongshanshan'* ecological restoration area was higher than that in the downstream which is consistent with Varol's (2013) and Dzakpasu et al.'s (2015) studies.

(4) The effect of *T. 'zhongshanshan'* on the TN removal efficiency in overlying water and sediment are not consistent which mainly due to the different morphology of N in water-sediment system (Hossain et al., 2016). The TN in overlying water was 3.98 mg/L with the removal efficiency of 41.65%, while the TN in sediment was 1.99 g/kg with the removal efficiency of 27.29%. The average content of TN in surface sediment of *T. 'zhongshanshan'* wetland was higher than many other lakeside wetlands.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11611174

such as Taihu Lake, Chaohu Lake, Hongze Lake, the nitrogen substances also was mainly absorbed from the overlying water in the growth process of *T. 'zhongshanshan'* which played indispensable role (Stottmeister et al., 2003). Furthermore, nitrogen is released and returned to the sediment because the dense *T. 'zhongshanshan'* restoration area produced a large amount of litters which degrade. It increased the content of TN in the sediment (Jacobson et al., 2014).

Based on the monitoring results of TP, TN, OM at the 27 sampling sites, the spatial distribution of average TP, TN, OM in the surface sediment of *T. 'zhongshanshan'* wetland is shown in *Figure 4a, b*.

Correlation of nutrient elements in Sediment- Overlying water

According to correlation analysis, the TP in sediments was a significant positive correlation with TN in sediments ($P < 0.01$), but no correlation with OM in rainy season. The TP in sediments was positively correlated with OM ($P < 0.01$) but not with the TN in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11611174

sediments in dry season. It indicated that there are differences in the sources of nitrogen and phosphorus pollution in the sediments of the Laoyuhe River wetland in the different seasons. Compared with the research of Sediments in Tigris river basin, lake mouth wetland of Erhai Lake and Taihu Lake basin (Yang et al., 2014; Wang et al., 2016; Ouyang et al., 2018) the reduction of N and P in the rainy season is significantly correlated, while the OM in the dry season was a significant source of TP in sediments. The TN and TP mainly affect by exogenous factors while OM affect by endogenous factors. Also, the source of pollution is mainly exogenous in rainy season and endogenous in dry season.

In addition, the OM play an important role on the release of nitrogen and phosphorus. For example, Wang et al. (2011) and Di Luca et al. (2017) found that the larger variation range of nitrogen and phosphorus release in sediments when it under heavy organic pollution. So it can be inferred that the potential release risk of nitrogen and phosphorus from surface sediments of *T. 'zhongshanshan'* wetland around Dianchi Lake during rainy season is higher. It was more likely to cause secondary pollution to overlying water.

Pollution assessment of T. 'zhongshanshan' ecoregion on the lakeside of Dianchi Lake

Currently, there is no report on the methods and standards for evaluated the pollution status in shallow lake sediments. The research is mainly focused on the Organic Index (OI) and Organic Nitrogen (ON) evaluation methods which that only considered the OM and ON, but ignored the presence of phosphorus (Qiu et al., 2016). Some researchers adopted the method developed by Ontario Department of Environment and Energy in Canada since 1992, for the environmental quality assessment standard (Li et al., 2016). Although the method has derived from the ecological toxicity analysis of marine sediments, it takes the phosphorus into account.

The comprehensive and organic pollution levels were between moderate and severe levels in the sediments of *T. 'zhongshanshan'* wetland which has consistent results on the FF and OI. The pollution level of surface sediment of *T. 'zhongshanshan'* wetland around Dianchi Lake is at a high level which showed a difference with the plain wetland such as Sundarbans mangrove forest wetlands, Hongkong coastal wetland and Min River Estuary Wetland's evaluation results of sediment pollution (Mustafa et al., 2011; Hossain et al., 2016; Hu et al., 2014).

Sediment is a reservoir of nitrogen and phosphorus nutrients in wetlands (Zhang et al., 2013). The release of nitrogen and phosphorus from sediments will gradually become the focus of eutrophication control of water after the control of exogenous sources. Although not all forms of nitrogen and phosphorus can be released into water, the TN and TP forms of sediments represent the pollution degree and potential release risk of nitrogen and phosphorus in sediments (Wang et al., 2012).

The FF and OI indices of sediments from *T. 'zhongshanshan'* wetland in the lakeside of Dianchi were higher in rainy season than in dry season.

It is easy to cause sediment of *T. 'zhongshanshan'* wetland disturbance and resuspension under the action of hydraulic force when an amount of increased water enter in rainy season. It is helpful for the release or regeneration of nutrients.

Conclusion

This study quantitatively assessed the spatial distribution of nutrient levels as indicated by TP, OM, TN and SS in sediment and overlying water of *T. 'zhongshanshan' wetland of Dianchi* Lakeside to lay the groundwork for further

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11611174

sedimentary remediation and pollution prevention. The contents of nutrients were higher in water inlet than in water outlet. The removal rates of TN and TP in water are higher in upstream than in downstream. Meanwhile, the reduction of TN was significantly different in water and sediments. TP and TN in the rainy season were significantly higher than in the dry season. TN were mainly from agricultural non-point source pollution. TP were mainly from rich phosphorus around Dianchi ((Zeng et al., 2017); Ma et al., 2015). They washed into wetlands as exogenous pollutes in rainy season, then they settled and released into wetlands as endogenous pollutes in the dry season. The nitrogen and phosphorus pollution of sediments were all severe pollution both in dry and rainy season of *T. 'zhongshanshan'* ecoregion, but the organic pollution was basically moderate.

The *T. 'zhongshanshan'* lakeside wetland is the first ecological restoration area around Dianchi. Non-point resource pollutants are rapidly and efficiently absorbed, degraded and converted. Although the reduction effect of this single plant is efficient, there is still a part of the pollutants flowing into the next ecological restoration area along with surface runoff. Therefore, other wetland plants such as *Typha orientalis presl* and *Phragmites communis* in the downstream restoration areas should be mainly constructed. These repair strategies should form a complementary function and strengthen the interception of pollutants in the lakeside wetland of Dianchi Lake.

Acknowledgments. We thank reviewers from Kunming Dianchi Lake Pollution Prevention and Control Cooperative Research Center, China. This study was financial supported by Yunnan Provincial Fund project (2019J0573).

Abstract. Heavy metals were emitted from motor vehicles and industries as part of the effects of rapid urbanization. This study aims to measure the heavy metal concentrations (Cu, Fe, Zn, Pb, Mn, Cr) at Kota Kinabalu, Sabah using transplanted lichen. Samples of *Usnea misaminensis* were transplanted to the environment of the urban area. The lichen was collected from Mt. Kinabalu Park which is a remote area. Fifteen sampling stations were selected and transplanted lichens were exposed to heavy metals in those stations for about 4-6 weeks. Exposed lichens were analyzed using the inductively coupled plasma mass spectrometry (ICP-MS) to determine the concentration of heavy metals in each sample. One-way ANOVA also has been used to test whether there is significant variation between heavy metals concentration at Kota Kinabalu, Sabah. The result showed that iron (Fe) has the highest concentration with 84.43 μg/g and chromium (Cr) has the lowest concentration with 0.66 μg/g. A statistical One-way ANOVA test showed that there is a significant variation between heavy metal frequency with P-value is $0.0000 < 0.05$. A Tukey test also revealed that Fe has significantly higher concentration compare to the others. These findings prove that the increasing number of motor vehicles will also elevate the concentration of heavy metals in the atmosphere. Transplanted lichen can be the alternative approach in assessing air pollution in Malaysia's urban area.
Keywords: *lichen, air pollution, urban ecosystem, applied ecology, environmental management, Malaysia*

Introduction

Human well-being has been degrading tremendously due to the air pollution that caused by industrialization and urbanization in the city. In Malaysia, strategies to tackle environmental issues have been enacted by enforcing several policies such as National Policy on Environment (DASN) and the ratification of multi-lateral environmental agreement for example Paris Agreement 2015 (Sulaiman et al., 2018). These strategies were designed in order to sustain the human well-being in the city and also actions have been taken to create a liveable vicinity. One of the most common causes of the degradation of human well-being in Malaysia is air pollution according to statistics 54% of Malaysia's happiness disturbance was from air pollution. The Department of Environment has outlined a few protocols to be followed. But, in terms of the measurement it still not sufficient. The three major causes of air pollution are transportation, stationary sources and open burning. The problem they face now is that the quality of air in areas far away from their air monitoring stations is difficult to determine, hence lichen has been selected as a potential bio-indicator for this purpose.

Heavy metals can be measured and analyzed using two approaches which are sampling directly from the atmosphere and sampling using biological indicator. According to Carreras and Pignata (2002), High volume air samplers and glass fiber

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11751182

filters were used to collect the samples containing heavy metals. Collected samples were digested using a mixture of analytical grade nitric acid and analytical grade hydrochloric acid, and analyzed to evaluate the levels of heavy metals by atomic absorption spectrophotometry. Heavy metals also can be sampled from lichen where selected lichen from specific sampling location brought to the lab and analyzed using atomic absorption spectrophotometry (Samsudin et al., 2013a). Heavy metals also can be found from the dust inside a building as studied by Abas et al. (2017) where they stated heavy metals such as Fe, Pb, Zn, Cu and as are existed inside the university building which can bring harm to the occupant health.

Lichen has been used as bio-indicator for air pollution for decades ago. In Italy, a standard called Lichen Biodiversity Index been developed and used to monitor air pollution in the district of Faenza, Italy (Cioffi, 2009). Also, Loppi and Frati (2006) conducted research in Central Italy measuring the nitrogen compounds in foliose lichen. Foliose-type lichen *Hypogymnia physodes* also been used and collected to analyse the heavy metals contents due to traffic pollutants (Blicharska et al., 2016; Koroleva and Revunkov, 2017). Transplanting foliose type lichen from remote and clean air area to much more polluted area is widely used to monitor the air pollution in certain vicinity. As examples, in Thailand they used *Parmotrema tinctorum* to monitor airborne trace elements near a petrochemical industry complex (Boonpeng et al., 2017). Apart of assessing outdoor pollution, transplanted lichen also used to indicate the level of indoor air quality where heavy metals such as As, Cd, Cr, Cu, Hg, Ni, and Pb also 12 Polycyclic Aromatic Hydrocarbon (PAH) been recorded (Abas, 2015; Protano et al., 2017). In Malaysia, research on lichens more focused on lichens dwelling in the highland such as Gunung Machincang, Cameron Highland, Genting Highland, Fraser Hills, Pulau Pangkor and Bukit Larut (Sulaiman et al., 2018; Abas et al., 2019). In addition, these researches only touched about the ecological and chemical part of the lichen (Din et al., 2010; Zulkifly et al., 2011). None of them studied the relationship between lichen and its vicinity, not until 2015 where a study on lichen diversity distribution in Kuala Lumpur (Abas and Awang, 2017). The research found that lichen diversity distributions are much related to the population density in Kuala Lumpur.

The study of monitoring air pollution using lichen in Malaysia is still based on lichen diversity and frequency. There is still lacking in using transplanting method to monitor air pollution in Malaysia especially in an urban area. Therefore, the aims of this study are; to analyze the heavy metals contents using transplanted lichen *(Usnea minaminensis)* as the alternative approach in air quality measurement and to determine the relationship between motor vehicles frequency and heavy metals concentration.

Methodology

Area of study

The City of Kota Kinabalu, Sabah (5.9804° N 116.0735° E) is situated at the west coast of Sabah, part of Borneo Island. As one of the largest city in Malaysia, Kota Kinabalu has a total population of 457,326 people with density of 1,463/km² according to census in 2018. Kota Kinabalu has developed into an over-concentrated urban area where recent studies showed the air quality in Kota Kinabalu has depleted.

Sampling procedures

Lichen *Usnea minaminensis* samples were collected from remote area (unexposed from excessive air pollution) of Mt. Kinabalu Park, Sabah, Malaysia (6.0192 N 116.5369 E). All samples were segregated into 45 samples for 15 sampling locations and only one sample was excluded from the segregation to be the control sample. *Table 1* and *Figure 1* show the location of 15 sampling stations that have been selected randomly around the City Centre of Kota Kinabalu, Sabah. This research was conducted using lichen transplanting method where lichen *Usnea minaminensis* was taken from remote area then placed on selected stations for approximately 1 month (from 20th Aug 2018 to 20th Sept 2018). About 50g of lichen samples were put in a punctured paper bags and placed on trees 1.5 m above ground facing the source of air pollution. After that, all samples were collected and brought to the lab for heavy metals concentration analysis (Nimis et al., 2002; Abas et al., 2016).

Laboratory analysis

After about 2-4 weeks, those samples were collected and placed in sealed containers and were taken to the laboratory to be analysed. In the lab, the samples were air dried for about two days in the open air. Then, those samples were heated in the oven for another two days at about 50 °C in in order to remove any excessive moisture. Any debris or dust on the samples was then picked out using clean tweezers before it then has been crushed into powder form. 1.0 g of each samples from the control area and all sampling stations later were weighed for the digestion process. After that, the digestion process was carried out by mixing 5 mL concentrated nitric acid and 15 mL perchloric acid into one conical flask. The samples were then heated on a hot plate until the initial volume was reduced into half. Then, the samples were then cooled off and later rinsed using 5 mL concentrated nitric acid before filtered into the 150 mL conical flask using Whatman No. 42 filter papers. During the filtration process, the samples were rinsed with 5% nitric acid and the filtrates were diluted to 50 mL using 5% nitric acid. The dilution later placed in Inductively Coupled Plasma Mass Spectrometry (ICP-MS) to detect heavy metals such as copper (Cu), manganese (Mn), lead (Pb), zinc (Zn), iron (Fe) and chromium (Cr).

Statistical analysis

One-way ANOVA been used in this research to determine whether there are any statistically significant differences between heavy metals concentration among all sampling stations. Tukey Test was also performed to check significant comparisons between each of the heavy metals.

Results and discussion

Table 2 shows the concentration of heavy metals determined in the lichen samples transplanted and collected from all 15 sampling stations including a control sample.

15	63.73 ± 0.26	15.72 ± 0.12	15.79 ± 0.07	1.39 ± 0.03	1.84 ± 0.09	1.55 ± 0.06

The table shows that the heavy metals' concentration in all of the lichen samples from sampling stations are higher compared to the control sample. Iron (Fe) has the highest concentration in all lichen samples with sampling station number 9 has the highest concentration and number 11 has the lowest concentration, followed by manganese (Mn) (highest is number 7 and the lowest is number 10), zinc (Zn) (the highest is number 7 and the lowest is number 10), lead (Pb) (the highest is number 7 and the lowest is number 10), copper (Cu) (the highest is number 8 and the lowest is number 10) and the lowest is chromium (Cr) (the highest is number 9 and the lowest is number 10). Among all sampling stations, sampling station number 7 have the highest accumulation of heavy metals in the lichen samples, followed by number 8, number 9, number 6, number 13, number 14, number 1, number 2, number 15, number 3, number 4, number 5, number 11 and the lowest is sampling station number 10.

Table 3 shows the one-way ANOVA analysis result. Based on the table, it has been shown that p-value is < 0.05 meaning that there is significant variation between heavy metal groups. A Tukey post hoc test has revealed that the concentration of Fe in the transplanted lichen is significantly higher compare to the other heavy metals, while Zn and Mn has lower significant differences in concentration but higher compare to the other 4 and Cu, Pb and Cr also has lower significant difference in concentration but higher towards the other heavy metals as shown in *Table 4*.

Our results demonstrate that heavy metals concentration in lichen *Usnea minaminensis* closely reflected the heavy metals deposition in the City Centre of Kota Kinabalu, Sabah. We presumed that heavy metals accumulation in lichen samples were due to automobile traffic pollution. Based on previous studies in the urban area of Malaysia, there was a high correlation between heavy metals accumulation in lichen and automobile traffic (Abas and Awang, 2015; Abas and Awang, 2017; Abas et al., 2018). A similar pattern has been found in many other areas of the world, that is, that air pollution caused by heavy metal deposition generally tends to be higher in urban zones with more traffic, than in rural areas with less traffic (Benitez et al., 2019). All those heavy metals usually come from anthropogenic activities such as industrial activity and motor vehicles emission. In addition, in densely populated urban area heavy metals are

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11751182

trapped by buildings and prevent it from flew away from the urban vicinity (Samsudin et al., 2013b; Amil et al., 2016).

Iron (Fe), zinc (Zn), manganese (Mn) and copper (Cu) are categorized as an essential nutrient for organism as those metals are needed for growth and body development. Whereas, lead (Pb) and chromium (Cr) are known as non-essential heavy metal to living things and only exist in the surroundings due to industrial activity and automobile traffic emission. All of the heavy metals showed a similar pattern, with higher concentration was found in lichen samples of highly dense urban area than in nearby forest or highland. We also found that the heavy metals concentration varied depending on the location of the sampling station. Sampling stations that nearby the city centre such as Anjung Senja, Sinsuran and Gaya Street showed higher heavy metals concentration than sampling stations that located in rural areas such as Signal Hill and KK Sky City.

All the heavy metals are so much related to the density of automobile traffic where Zn deposition in lichens typically related to increases of traffic along traffic routes serving inner city urban areas. Air pollution from Zn can typically be ascribed to tyre wear, and this metal is also a common component of antioxidants used as dispersants to improve lubricating oils. Lead was originated from the fuel combustion of automobile traffic and its concentration is much higher in diesel oil.

Conclusion

This research shows that lichen *Usnea minaminensis* can be used to determine the heavy metal deposition in urban area. Besides that, there is significant variation between heavy metals in Kota Kinabalu. The concentration of heavy metals in Kota Kinabalu is varied, where location nearby to the city centre has higher concentration than nearby the rural or forest area.

(Received 8th Aug 2019; accepted 25th Nov 2019)

Abstract. Applicability of ammonia bioremediation by efficient bacterial isolates was investigated under static batch culture conditions. *Bacillus aerius* (M.1), *Bacillus bingmayongensis* (M.2) and *Bacillus toyonensis* (M.3) were isolated from the Inlet of El-Bahr El-Saedy drinking water treatment plant, Rosetta Branch, Egypt and identified based on their morphological, cultural and biochemical characteristics. Identification of these isolates via genomic 16S rRNA sequencing technique was also performed. To optimize ammonia removing process, effect of some environmental conditions (pH, temperature and ammonia concentrations) were tested. Results indicated that a pH of 6.5 and 7.0, and the temperature between 30 and 35ºC were the most optimal values for removing ammonia by the three tested isolates. Ammonia was consumed effectively during the first five incubation days, indicating maximum consumption rate, but it was reduced to its lowest level 25 days after incubation. Ammonia consumption rates were increased by increasing its concentration for all tested isolates, indicating growth activation and no substrate inhibition. Ammonia consumption rate by the ternary mixture reached its maximum of 1.60 mg $L^{-1}day^{-1}$ five days after incubation, and then reduced slowly to 0.38 mg $L^{-1}day^{-1}$ 25 days after incubation. It indicated sequential and synergistic effects between the isolates in their ternary mixture during the removal of ammonia.
Keywords: *aquatic system, bacillus isolates, consumption rate, genomic sequences, pollution*

Introduction

Nile River is the main source of fresh water used for drinking, agricultural activities, industry, navigation, recreation and fish production in Egypt. So, it is of dominating influence on the economic, cultural, public health, social and political aspects of the country (Ibrahim et al., 2018). Nile receives enormous amounts of environmental pollutants including fertilizers, fishing activities, pesticides and great amounts of industrial wastes, municipal and domestic materials which drained directly or indirectly into it. Due to their limitation, fresh water resources worldwide required more attention, especially in Egypt, to overcome the harmful effects of such pollutions against all vital activities. Nile pollutants are derived from sources such as industrial wastewater, oil pollution, municipal wastewater and agricultural drainage (Abou-Elela et al., 2017). The pollution status of the water of Nile River is an important indicator of water quality (Ibrahim et al., 2018). In this aspect Abdel-Satar et al. (2017) reported that the problem of Nile pollution will increase in Egypt, if Nile's low water level was done; especially after completing the Ethiopia Dam building.

The cost needed for environmental degradation due to water pollution is relatively high with serious health and quality of life consequences; as well as increasing the severity of water scarcity problems (Zenhom et al., 2017). Hence, increasing water pollution causes not only the deterioration of water quality, but also threatens human health and the balance of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11831196

aquatic ecosystems, economic development and social prosperity (Fawzy et al., 2012). Nitrogen is one of the most common element appearing in wastewater as ammonia, nitrite, nitrate and organic nitrogen. Organic nitrogen is decomposed to ammonia which has effects on human health (Nieder et al., 2018). Ammonia is a common pollutant in Nile River where it increases in winter because of the winter block which causes low water levels and the leaching of fertilizer residues used on the agriculture into the aquatic environment (Al-Rashedy et al., 2018). The maximum acceptable concentration of ammonia in the drinking water is equal to 0.5 mg/dm^3 according to WHO Guidelines for drinking water and Egyptian standards (WHO, 2006). Bioremediation of ammonia using microorganisms shows great potential for future development due to its environmental compatibility and possible cost-effectiveness (Belal et al., 2017). Microorganisms, such as *Burkhulderia cepacia* G4, are effectively used in bioremediation processes due to their natural capacity to oxidize toxic hazardous substances such as phenol and benzoate as a sole source of carbon (Shalaby, 2007). Chemosynthetic autotrophic bacteria, Ammonia Oxidizing Bacteria (AOB) and Nitrite Oxidizing Bacteria (NOB) can convert ammonia to nitrate, and heterotrophic bacteria converts ammonia directly to microbial biomass. Microbes like chemolitho-autotrophic bacteria converts ammonia into nitrite and nitrates. These nitrates are again converted to nitrogen gas by denitrification process (Holmes et al., 2019).

Therefore, this study was carried out to isolate and identify some ammonia-degrading bacterial isolates from the Nile River and to evaluate their substrate consumption rates at different ammonia concentrations from the aquatic samples. As well as, ability of the tested bacterial isolates to remove ammonia at different levels of pH, temperature and ammonia concentrations was also aimed to be described. As well as, removing of ammonia by a ternary mixture of isolates was also evaluated under static batch culture conditions.

Materials and methods

Sampling

Thirty samples were collected in bottles reached their total volume 1000 ml according to APHA (2005) at the end of December 2017 from Inlet of El-Bahr El-Saedy drinking water treatment plant, Rosetta Branch River Nile, Sidi-Salem, Kafr El-Sheikh Governorate, Egypt. Location of the studied area based on GPS information was done (*Table 1*). As well as, overview of the sampling site by GPS was recorded and a photo was taken as shown in *Figure 1*.

Media

For screening, isolation and enrichment of the microbial population, plate count agar media containing 5.0 g tryptone, 2.5 g yeast extracts, 1.0 g glucose, 9.0 g agar and 1.0 L reagent-grade water was used (APHA, 2005). Nutrient agar (NA) media (1 L; pH 6.3-6.8) contained 5.0 g peptone, 3.0 g beef extract and 15.0 g agar was also used for bacterial cultivation and purification after Vincent (1970). The shaking flask culture media namely Minimal Salt Broth (MSB) media containing different ammonia (NH_3) concentrations as a sole source of Nitrogen were used instead of $(NH_4)_2SO_4$ to determine efficiency of the tested three selected bacterial isolates in removing ammonia. MSB media containing 3.5 g $Na_2HPO_4.2H_2O$, 1.0 g KH2PO$_4$, 0.1 g $MgCl_2.6H_2O$, 0.05 g Ca $(NO_3)_2.4H_2O$ was added to the tested NH_3 doses (Belal et al., 2017). For biochemical tests, different media were also used. To determine catalase activity, Mannitol Salt Agar media (MSA) containing 75.0 g

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11831196

NaCl, 10.0 g D-Mannitol, 0.025 g Phenol Red, 15.0 g agar as described by Gerhardt et al. (1981) were used. All media were autoclaved at 121°C for 30 min before use.

Isolation of ammonia-degrading bacteria

Screening of the microbial population and isolation of ammonia-degrading bacteria from site El-Bahr El-Saedy drinking water treatment plant by cultivation on plate count agar media at 35±0.5°C for 48 h was done by enrichment technique. Bacterial isolates were purified on nutrient agar media using the standard spatial streaking method. Based on their morphological characteristics, ten isolates were transferred into Minimal salt broth (MSB) media containing 5 mg L^{-1} ammonia (NH_3) as a sole source of Nitrogen, instead of $(NH_4)_2SO_4$ as in the preliminary test. Cultures were incubated at 35±0.5°C for 25 days. To detect their performance in degradation of ammonia, absorbance degree of the cultures was assayed by using spectrophotometer (CECIL of CECIL INSTRUMENTS, CAMBRIDGE, ENGLAND) at 420 nm as described by APHA (2005) and consumption rates were considered. Based on their preliminary test, three bacterial isolates (M.1, M.2 and M.3) were selected to evaluate their efficiency in removing ammonia in MSB media.

Identification

The efficient isolates were identified on the basis of morphological, cultural and biochemical characteristics. Data were optimized with those described based on Bergey's Manual of Systematic Bacteriology (1984) and then confirmed genetically using 16S rRNA by Boye et al. (1999). The molecular techniques were performed by sigma, Cairo, Egypt.

Morphological, cultural and biochemical tests

Samples were examined microscopically to investigate shape of cells, formation of endospores, gram staining reaction and motility. Starch hydrolysis, growth on 5% NaCl and at 40°C were tested as recommended. Catalase activity was determined using a 3%

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11831196

H_2O_2 solution on MSA slant media as described by Gerhardt et al. (1981). Oxidase test was carried out by observing color change of trypticase soy agar (TSA) medium (containing 15.0 g Pancreatic Digest of Casein, 5.0 g Peptic Digest of Soybean Meal, 5.0 g Sodium Chloride, 15.0 g Agar) from pink to maroon and finally to purple within 30 sec after adding 2-3 drops of 1% of P-aminodimethyl aniline oxalate solution on the cultures (Cappuccino and Sherman, 1996). Urease test was performed on 5 ml of urea broth (20 g L^{-1}) (containing 20 g of urea, 9.5 g of Na_2HPO_4, 9.1 g of KH_2PO_4, 0.1 g of yeast extract) at pH 6.8 in test tubes containing phenol red (0.012 g L^{-1}) as the pH indicator. The cultures were transferred into the sterilized urea broth and incubated for 24 h. The development of red color indicates a positive reaction for the test (Cappuccino and Sherman, 1996). Citrate utilization test was carried out by changing coloration of Simmons citrate agar medium (containing 5.0 NaCl, 2.0 g Sodium Citrate dehydrate, 1.0 g Ammonium Dihydrogen Phosphate) from green to blue due to pH change, which indicated positive reaction, according to Seeley and Vandemark (1981). To test indole production, isolates were inoculated into sterilized glucose tryptone broth (containing 2% (w/v) tryptone, 0.5% (w/v) yeast extract, 10 mM NaCl, 2.5 mM KCl, 10 mM $MgCl_2$, 10 mM $MgSO_4$, and 20 mM glucose, pH 7.0.) in test tubes. After 48 h of incubation, 0.3 ml of Kovac's reagent was added (10 gm of p-dimethyl aminobenzaldehyde were dissolved in 150 ml of isoamylalcohol and then slowly 50 ml of concentrated HCL were added) and mixed well. The reddening of the alcohol layer within few minutes indicated indole production (Seeley and Vandemark, 1981).

16S rRNA sequencing tests

To confirm their identification, genomic 16S rRNA sequencing technique was carried out for the selected bacterial isolates. This technique was performed by Sigma, Cairo, Egypt and GATC Company, Germany. Genomic DNA of the tested bacterial antagonists was extracted according to use protocol of GeneJET™ genomic DNA purification Kit (Thermo K0721). The 16S rRNA gene was amplified through the recommended 37 thermal cycling conditions using Maxima Hot Start PCR (Polymerase Chain Reaction) Master Mix (Thermo K1051) according to Eden et al. (1991) were used. PCR reaction set-up (5 µL DNA Template + 1 µl (20 µM) Forward Primer + 1 µl (20 µM) Reverse Primers (of each 8 primers) + 25 µL Maxima® Hot Start PCR Master Mix (2X) + 18 µL Nuclease Free Water) to complete total volume of 25 µL was adjusted. Then, PCR products of 16S rRNA using GeneJET™ PCR Purification Kit (Thermo K0701) were purified. PCR products were then sequenced and analyzed using ABI 3730x1 DNA sequencer via forward and reverse primers (GATC Company, Germany) by combining the traditional Sanger technology with the new 454 technology as follows:

F: 5 —— AGA GTT TGA TCC TGG CTC AG —— 3
R: 5 —— GGT TAC CTT GTT ACG ACT T —— 3

Phylogenetic analysis in MEGA6 was conducted (Tamura et al., 2013). For the phylogenetic analysis, maximum parsimony and neighbor-joining trees were constructed from 1000 bootstrap replicates.

Cultivations

As classical batch, cultivations of the selected three bacterial isolates on ammonia as a sole source of Nitrogen were carried out. Prior to the batch experiment, a studied

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11831196

substrate (ammonia, NH_3) was added to the culture through a sterile Cellulose Nitrate filter membrane of 0.45 µm (Sartorius Stedim, Biotech GmbH, 37070 Gottingen, Germany) by a syringe. All cultivations were carried out in flasks containing MSB media, with replacing NH_3 instead of $(NH_4)_2$ SO_4. The working volume was 200 ml. Cultures were supplied with 0.0, 5.0, 10.0 and 20.0 mg L^{-1} ammonia as a sole source of nitrogen for each isolate. All cultivations were carried out in three replicates. Cultures were shaking incubated on 150 rpm at 35±0.5°C (Shaking Incubator, INCUCELL–V-55, Einrichtungen GmbH, D-82166 Gräfelfing, Germany) for 25 days. After that, removing of ammonia was assayed in the incubated cultures by a spectrophotometer at 420 nm as described by APHA (2005) and substrate consumption rates at the tested substrate concentrations, pH, temperature and ammonia concentrations were determined.

Based on a material balance for substrate (ammonia) in the batch cultivation, absolute substrate consumption rate (*Rs*) can be expressed as mg L^{-1} day^{-1} according to Shalaby (2007) and the modified equation of Curtis et al. (2018) as follows:

$$\boldsymbol{rs} = \frac{dCs}{dt} \qquad \text{(Eq.1)}$$

where:
rs - ammonia consumption rate (mg L^{-1} day^{-1}),
dCs - difference between Initial ammonia and remaining ammonia concentrations (mg L^{-1}),
dt - difference between end and start incubation time (day).

Effect of pH, temperature and ammonia concentrations on the biodegradation of ammonia

To determine the effect of temperature, pH and ammonia concentrations on the biodegradation of ammonia, a volume of 200 ml MSB media containing 5.0 mg L^{-1} ammonia and inoculating with 1.0 ml bacterial cell suspension 10^5 CFU ml^{-1}. To determine the optimum pH, experiments were carried out at pH 5.5, 6.5, 7.0, 7.5 and 8.0. Cultures were incubated on a rotary shaker at 35±0.5°C and 150 rpm up to 25 days. To determine the effect of temperature, MSB media with pH 7.0 was incubated at 20, 25, 30, 32 and 35°C under 150 rpm for 25 days. To determine the effect of ammonia concentration, MSB media replaced their nitrogen source with 0.0, 5.0, 10.0 and 20.0 mg L^{-1} ammonia adjusted their pH at 7.0 and incubated at 35±0.5°C under 150 rpm for 25 days. Bioremediation of ammonia based on the absorbance measured by a spectrophotometer was determined and substrate consumption rate was calculated according to Shalaby (2007) and Curtis et al. (2018).

Bioremediation of ammonia by mixtures of the tested bacterial isolates

To test interaction behavior between them, antagonism test of the three bacterial isolates were inoculated in dual and in ternary bacterial mixtures in the same media as preliminary experiment. Nutrient agar (NA) media were liquefied, allowed to cool to about 45°C, homogenized and inoculated with the initial test organism. These were then poured into sterile petri dishes and allowed to cool at room temperature before streaking with the second bacteria in the dual mixture or with the second and third bacteria in the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11831196

ternary mixture. Observations and cultural relations were recorded 48 h after incubation of the plates at 37°C as described by Herbert et al. (2009).

Based on the observations of the antagonism test between the three isolates, applicability of the ternary bacterial mixtures in removal or degradation of ammonia was tested. To achieve the purpose mentioned, 1.0 ml bacterial cell suspension containing 10^5 CFU ml^{-1} of each isolate was cultivated immediately with 200 ml raw water from El-Bahr El-Saedy drinking water treatment plant in shake flasks containing 10.0 mg L^{-1} of ammonia. The cultures were shaking incubated under 150 rpm at 35±0.5°C for 5.0, 10.0, 15.0, 20.0 and 25 days. Un-inoculated shake flasks were acted as control. The experiment was carried out in three replicates. Bioremediation of ammonia by the bacterial mixture was determined after the incubation period based on the absorbance measured by a spectrophotometer and substrate consumption rate was calculated according to the well-known formula of Shalaby (2007) and the modified equation of Curtis et al. (2018) previously used.

Statistical analysis

The statistical results were calculated by one-way analysis using the SPSS statistical software. A *P*-value < 0.05 indicated statistical significance. The means were compared according to Duncan's multiple range test (Snedecor and Cochran, 1980).

Results and discussion

Isolation of the ammonia-removing isolates

From the microbial source (El-Bahr El-Saedy drinking water treatment plant) a total of 10 morphologically different ammonia-degrading bacterial isolates were obtained. Based on their efficiencies, three bacterial isolates designated as (M.1), (M.2) and (M.3) achieved higher ammonia consumption rates and were selected for further tests comparing with the other isolates, and the differences between treatment were significant at $P< 0.05$ (*Table 2*).

Identification of the ammonia-removing isolates

Based on their cultural, morphological and biochemical properties, M.1, M.2 and M.3 isolates were identified as *Bacillus aerius, Bacillus bingmayongensis* and *Bacillus toyonensis* (*Table 3*). They were rods in shape, white color colonies, gram-positive, motile, had positive ability to form endospores and grew on 5% NaCl. It was found also that all tested bacteria gave positive of oxidase, citrate utilization, catalase activity and starch hydrolysis. On the contrary, negative reactions of both urease and indole production were obtained.

Identification of such isolates was confirmed by using molecular genomic technique (Boye et al., 1999). According to the 16S rRNA analysis, the phylogenetic tree of the ammonia degrading *Bacillus* isolate (M.1) was done. It can be clearly seen that the M.1 *Bacillus* isolate was closely related to the species *aerius*. It showed the highest sequence similarities with *Bacillus aerius* strain 24K (76%) (*Figure 2*).

Although *Falsibacillus pallidus* strain has ident (77%), the identification confirms that the tested isolate belongs to *Bacillus aerius* (76%) based on total score of it (315) in comparison with total score of *Falsibacillus pallidus* (280). As well as, the second isolate (M.2) was found to be included in the genus *Bacillus* and closely related to the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11831196

species *bingmayogensis*. It showed the highest sequence similarities with *Bacillus bingmayongensis* strain FJAT-13831 (89%) (*Figure 3*). Although all strains have the same ident (89%), the identification confirms that the tested isolate belongs to *Bacillus bingmayongensis* based on total score of it (547) which is higher total score than that of other strains.

+ Positive; - Negative

For the third isolate (M.3), it was found that it also belonged to genus *Bacillus* and was closely related to the species *toyonensis*. It showed the highest sequence similarities with *Bacillus toyonensis* strain BCT-7112 (99%) (*Figure 4*). Although all strains have the same ident (99%), the identification confirms that the tested isolate belongs to *Bacillus toyonensis* based on total score of it (1437) which is a higher total score than in other strains.

As well as, results recorded in *Figure 5* showed that 1500 bp DNA fragment was obtained by PCR amplification of the 16S rRNA gene of the three tested *Bacillus* isolates.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11831196

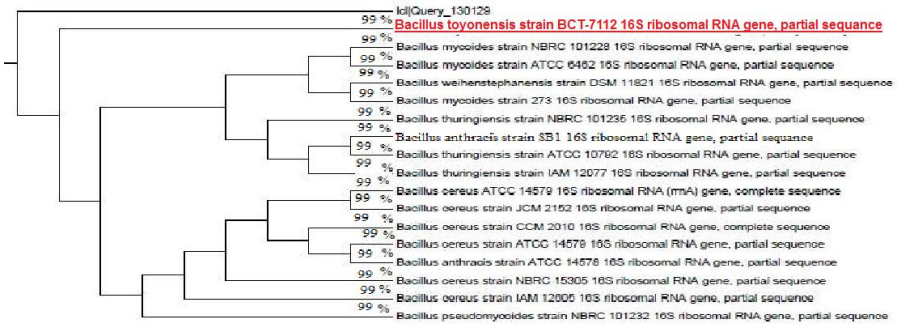

Figure 4. *The phylogenetic tree of the ammonia-degrading bacterium isolate M.3 was identified as Bacillus toyonensis (M.3)*

Isolation of such ammonia-degrading *Bacillus* isolates from the studied aquatic inlet site on Rosetta branch, River Nile indicated high capacity and variation of the microbial populations. It was in full agreement with Belal et al. (2017), who isolated *Ralstonia pickettii* (ST.1) and *Chryseobacterium gambrini* (ST.2) from River Nile during increasing ammonia concentration and identified it morphologically using enrichment technique then molecularly using 16S rDNA gene. While Kundu et al. (2014) pointed that *Chryseobacterium gambrini* is capable of simultaneous removal of organic carbon and nitrogen from wastewater.

Effect of pH and temperature on the biodegradation of ammonia

Effect of pH

Influence of pH on ammonia consumption rate in cultures inoculated separately with *B. aerius* (M.1), *B. bingmayongensis* (M.2) and *B. toyonensis* (M.3) each was obtained and presented in *Table 4*. Results indicated that pH values of 6.5 and 7.0 were the most suitable range for removing ammonia by the three tested isolates. On the other hand, no consumption of ammonia in the control cultures free from any biomass was noticed, indicating no chemical degradation. For *B. aerius* (M.1) and *B. toyonensis* (M.3), the highest consumption rates of 0.160 and 0.157 mg L^{-1} day^{-1} at pH 6.5 was achieved. in the case of *B. aerius* (M.1), the differences between treatment are significant at $P< 0.05$, as well as in the case of *B. toyonensis* (M.3) at pH values 6.5, 7.5 and 8, the differences between treatments are significant at $P< 0.05$, but at pH values 5.5 and 7, the differences between treatments are not significant.

Table 4. *Effect of different pH values on ammonia consumption rates by B. aerius (M.1), B. bingmayongensis (M.2) and B. toyonensis (M.3) under batch culture conditions*

pH	Ammonia consumption rate (mg L^{-1} day^{-1})			
	Control	*B. aerius* (M.1)	*B. bingmayongensis* (M.2)	*B. toyonensis* (M.3)
5.5	00.0	0.143 b	0.114 e	0.138 b
6.5	00.0	0.160 a	0.136 b	0.157 a

It was in full agreement with Shafi et al. (2017), who suggested that the pH value has a critical role in the production of secondary metabolites and that its maintenance at medium levels is optimal for neutrophils such as *B. aerius* and confirmed that activity achieved at range pH 4-10 and the highest activity for bioremediation was observed at

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11831196

pH 6.5. As well as, Tallur et al. (2016) confirmed that *B. toyonensis* (PNTB1) can grow at pH ranged between 5.5 – 10.0 and its optimal value at pH 7.1 was obtained. While, the highest consumption rate due to use of *B. bingmayongensis* (M.2) was achieved at pH 7.0, and the differences between treatments are significant at $P< 0.05$. Such result was given by Liu et al. (2014). They reported that *B. bingmayongensis* can grow at pH ranged between 4.0 – 10.0 and its optimal value was recorded at pH 7.0.

Effect of temperature

Influence of temperature degrees on ammonia consumption rate in cultures inoculated separately with *B. aerius* (M.1), *B. bingmayongensis* (M.2) *and B. toyonensis* (M.3) each was obtained and presented in *Table 5*. Data illustrated that temperature degrees of 30, 32 and 35ºC were the most optimal for removing ammonia by the three tested isolates. On the other hand, no consumption of ammonia in the control cultures was noticed, indicating no chemical degradation. In the case of *B. aerius* (M.1), the optimal temperature degree recorded for ammonia bioremediation was 32ºC, at which ammonia consumption rate to its maximum of 0.168 mg $L^{-1}day^{-1}$ was reached, and the differences between treatments are significant at $P< 0.05$. This result was in full agreement with Shafi et al. (2017), who confirmed that *B. aerius* can grow at temperature ranging between 8.0 and 40.0ºC and the optimal was reached at 32ºC under the experimental conditions. For *B. bingmayongensis* (M.2), the corresponding optimal temperature degree at 30ºC was done and ammonia consumption rate of 0.164 mg $L^{-1}day^{-1}$ were given, but the differences between treatments are not significant.

Table 5. *Effect of different temperature degrees on ammonia consumption rates by B. aerius (M.1), B. bingmayongensis (M.2) and B. toyonensis (M.3) under batch culture conditions*

Temp. (ºC)	Ammonia consumption rate (mg L^{-1} day^{-1})

Temp. (ºC): Temperature

Liu et al. (2014) agreed with these results and stated that *B. bingmayongensis* can be grown very well at range varied between 15.0 and 45.0ºC and 30.0ºC was the optimum. On the other hand, *B. toyonensis* (M.3) was the most thermo-tolerant isolate in comparison with the others; by its ammonia consumption rate reached to its maximum of 0.164 mg $L^{-1}day^{-1}$ at 35.0ºC, and the differences between treatments are significant at $P< 0.05$. These results agreed by Tallur et al. (2016), who confirmed that *B. toyonensis* (PNTB1) has a great ability to grow at temperature range between 10.0 and 45.0ºC and its optimum degree is 37.0ºC.

Effect of ammonia concentrations

To investigate the effect of high ammonia concentrations accumulated in the aquatic system on the microbial activity and their ability to remove the excess of its doses,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11831196

relationship between ammonia concentrations and its consumption rates by the tested isolates were recorded in *Table 6*. Results illustrated increase in ammonia consumption rates by increasing its concentration in the cultivation media due to the tested bacterial isolates, indicating growth activation and no substrate limitation. It seems to note that substrate consumption rates at both 5.0 and 10.0 mg L^{-1} ammonia were found to be identical and located at similar line for all isolates. At 20.0 mg L^{-1}, efficiencies of the three isolates in removing ammonia varied. The greatest ability to overcome and remove the excess of ammonia concentrations (20.0 mg L^{-1}) was obtained by the superior isolate *B. toyonensis* (M.3), by which its consumption rate to its maximum of 0.684 mg $L^{-1}day^{-1}$ was reached. It was followed by *B. bingmayongensis* (M.2) and *B. aerius* (M.1), by which consumption rates of ammonia to 0.635 and 0.595 mg $L^{-1}day^{-1}$ at the highest dose were obtained, respectively. On the other hand, no ammonia was consumed in control cultures, indicating no chemical degradation, and the differences between treatments are significant at $P< 0.05$. These results were in agreement with Leejeerajumnean et al. (2000), who found that bacteria particularly sensitive to ammonia (inhibited by 25 mmol l^{-1}) or specially tolerant to ammonia (growth in the presence of 300 mmol l^{-1}) included both Gram-positive and Gram-negative strains and there was no evidence for sensitivity or tolerance being associated with any specific bacterial genera.

Table 6. *Effect of different ammonia concentrations on its consumption rates by B. aerius (M.1), B. bingmayongensis (M.2) and B. toyonensis (M.3) under batch culture conditions*

Bioremediation of ammonia by mixtures of the tested bacterial isolates

One of the major problems of the biological degradation of environmental pollutants in an aquatic environment is the co-existence of substrate compounds or/and microbial mixtures. In the aquatic ecosystems, the microorganisms grow under complex conditions. Therefore, occurrence of the microbes in mixtures is an important problem, because removal or degradation of one component by a microbe can be prevented or inhibited by the other microbe in the mixture, and different conditions may be required.

Accordingly, and based on their cultural observations, growth and microbial relations, results showed no antagonistic reaction between isolates *B. aerius* (M.1), *B. bingmayongensis* (M.2) and *B. toyonensis* (M.3) in both dual and ternary culture mixtures. Microbes of the tested cultural mixtures were in their normal states without any disorders, disruption or competition between each other. Microbe may compete with another microbe for place or nutrients. Competitions often led to inhibit growth of the other microbe(s) in the same media via production of toxic metabolites, indicating antagonistic effect (Talaro et al., 2002).

Based on the results of antagonism test, efficiency of the ternary bacterial mixture composed of *B. aerius* (M.1), *B. bingmayongensis* (M.2) and *B. toyonensis* (M.3) in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11831196

removal or degradation of 10.0 mg L^{-1} ammonia in MSB media free from any other nitrogen source at 35±0.5°C for different incubation periods was evaluated (*Figure 6*).

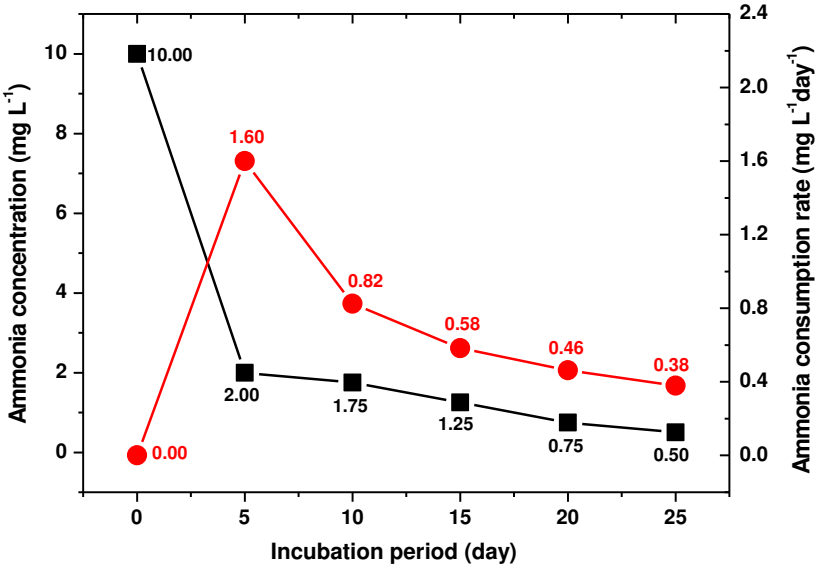

Figure 6. *Remaining ammonia concentrations and their consumption rates by ternary bacterial mixtures composed of B. aerius (M.1), B. bingmayongensis (M.2) and B. toyonensis (M.3) at 35±0.5°C for different incubation periods. Curve with different letters are significantly different at 0.05 level based on Duncan's multiple range test*

Results showed sharp reduction of ammonia concentration by the ternary bacterial mixture five days after incubation from 10.0 to 2.0 mg L^{-1}, and consumption rate to its maximum of 1.60 mg $L^{-1}day^{-1}$ was reached, and then reduced slowly. After 25 incubation days, only 0.50 mg L^{-1} of ammonia were remained and its consumption to its minimal rate of 0.38 mg $L^{-1}day^{-1}$ was given, and the differences between treatments were significant at $P< 0.05$. These results were in agreement with the findings of Hemida et al. (2018), who reported that the co-inoculation of the two selected endophytic bacteria strains *B. aerius* (M.1) and *B. toyonensis* could successfully enhance salt tolerance and nitrogen fixation, ammonia utilization, inorganic phosphate solubilization. To investigate ammonia utilization pattern by the ternary mixture (simultaneous or sequential), its consumption rates by the individual isolates were compared with those obtained by the ternary mixture. In the presence of 10 mg L^{-1} ammonia, its consumption rate reached to 0.46 mg L^{-1} day^{-1} by the ternary mixture 20.0 days after incubation, compared with 0.36, 0.35 and 0.36 mg L^{-1} day^{-1} by single isolates of *B. aerius* (M.1), *B. bingmayongensis* (M.2) and *B. toyonensis* (M.3), respectively. It means increasing efficiency of the ternary mixture in removing ammonia compared with the individual treatment. So, ammonia utilization pattern by the ternary bacterial mixture was sequential, indicating activation not antagonism between isolates in the ternary mixture.

Conclusion

From the obtained results it can be concluded that the cultivation of a ternary tested bacterial mixture of ammonia can be expressed by substrate consumption rates obtained

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11831196

from the individually cultivations. In general, it can be stated that the removal of different ammonia concentrations from the aquatic systems was successfully done via both individual and ternary mixture composed of *B. aerius* (M.1), *B. bingmayongensis* (M.2) and *B. toyonensis* (M.3) under static batch cultivation.

We must keep River Nile as a sole source of drinking water in Egypt healthy. Complete optimization of such tested bacterial isolates used successfully for removing pollutants of aquatic systems, especially at a temperature range more than 35ºC and high concentrations of ammonia more than 20 mg L^{-1} is necessary in the future.

Abstract. Using the community index of the ground beetles (IKS) the quality status of 4 habitat types in 6 localities of, Stolické vrchy and Juhoslovenská kotlina basin (The Southern Part Of Central Slovakia) were evaluated. In the 2015-2017 period we noticed 2,379 individuals (1,030 ♂, 1,349 ♀) belonging to 52 species. Friedman's test showed a significant difference in IKS values in years 2015-2017 between study areas. By calculating IKS we found a greater number of adaptable species in areas with lower habitat disturbance (quality class III) compared to higher disturbance (quality class I), where eurytopic species predominated. We predicted an increase in IKS values for 2020 and 2022 for the habitats including meadow (area 1), nitrophilous waterside vegetation (areas 2, 6) and a decrease for pasture habitat (area 3), nitrophilous waterside vegetation (area 4) and fallow field (area 5) using the regression polynomial and exponential distribution models.
Keywords: *Carabidae, Stolické vrchy, Juhoslovenská kotlina, assessment of habitats quality, bioindication classes (A,E,R)*

Introduction

For the bioindication and monitoring changes in the quality of the environment, the *Carabidae* family (Coleoptera) is the most commonly used (Nietupski et al., 2015; Burgio et al., 2015). *Carabidae* inhabit different habitat types, especially meadow, field and forest habitats (Heydeman, 1955; Hůrka, 1996). Most species have a narrow ecological valence and therefore respond sensitively to changes in habitat conditions (pH, soil moisture changes) as well as the presence of toxic substances including herbicides and insecticides. Changes in the species structure of the short-lived communities reflect various long-term environmental changes. Bioindicative use is based on assessing the impact of human economic activities (Cardamo and Spence, 1994; Porhajašová et al., 2008, 2009).

We have already conducted similar faunistic research, the results of which can be found in the following references: Langraf et al., 2016b, 2018a. We processed data of 54 species (N = 4,675 individuals) serving as an input dataset for the calculation of indexes for ellipsoid biovolume (EV), flight ability and community index of the ground beetles (IKS). Pilot results (Langraf et al., 2016a) confirm a negative anthropogenic impact on the forest ecosystem, which means the worsening of living conditions for adaptable and relict species. We found out the prevalence of eurytopic species (IKS - bioindication group E) in intensively influenced forest and meadow habitats of the Juhoslovenská kotlina basin. Langraf et al. (2017, 2018b) assessed the elipsoid biovolume (EV) and flight ability indices on 5 habitat types (forest, fallow field, meadow, pasture, nitrophilic waterside vegetation). The results confirm a decrease in EV index values and an increase in the number of flight ability (eurytopic) species on habitats with higher anthropogenic disturbance. On the contrary, with decreasing anthropic intervention, the value of the EV index and thus the number of apteric and brachypterous species increases. In the last study (Langraf et al., 2019) we evaluated all 3 bioindication methods in forest ecosystems. We confirmed the correlation of the decrease of IKS, EV index values and increase of eurytopic species due to anthropogenic disturbance of forest ecosystems by cutting.

Monitoring of gradual successive changes and the impact of management on agricultural land is also important for bioindicative evaluation. Compared to natural ecosystems, biodiversity is reduced in agricultural areas. Typical *Carabidae* bound to arable land reported Vician et al. (2010, 2011) as follows: *Amara aenea, Anchomenus dorsalis, Calathus fuscipes, Clivina fossor, Harpalus affinis, H. distinguendus* and *Pseudoophonus rufipes.* Šťastná and Bezděk (2004), Purchart and Kula (2005), Baranová et al. (2013), Lemic et al. (2017) recorded the predominance of eurytopic species over adaptable (terminology used in IKS assessment) in the agricultural areas of the family *Carabidae* as a consequence of habitat disturbance. The species represented by a high number of individuals were: *Anchomenus dorsalis, Poecilus cupreus, Pseudoophonus rufipes* and *Pterostichus melanarius*. Igondová and Majzlan (2015) confirmed the lowest IKS values at the field-meadow edge and the meadow playground. The highest IKS values were recorded in forest areas and peatbogs. The prevalence of eurytopic species over adaptable to Permanent grassland has been reported by Jaďuďová et al. (2016). Stluka (2013) investigated the *Carabidae* on three habitats: spruce forest, spruce nursery and glade.

The IKS index in the glade found a strong anthropogenic impact with a predominance of group E (see chapter Methodology) and the lowest in the spruce forest with a predominance of group A species. It is clear that the intensity of management influences the biodiversity of the forest ecosystem. Rajová (2007) found in 10 localities of Klánovice forest in 2000 and 2001 a higher proportion of adaptable species compared to eurytopic, but significant decrease of stenotopic (relict) species. This fact points to anthropogenic influence of forest and worsening of living conditions of stenotope (relict) species. The lowest value of IKS was recorded by the author at 2 marginal forest localities the remaining forest areas had higher IKS values.

The destruction of the microorganism environment due to forest cutting leads to the loss of specific forest species of *Carabidae* and their replacement by eurytopic species, which are typically found in open habitats, ruderal habitats and fields (Elek et al., 2001; Finch, 2005; Wiezik et al., 2007). According to Niemelä et al. (2002), urbanization

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11971210

causes a decrease in the biodiversity of *Carabidae* species and in most cases increases the number of small species belonging to bioindication group E towards the city center.

In this study we continue with the bioindicative evaluation of the *Carabidae* obtained during the years 2015-2017 in Stolické vrchy and Juhoslovenská kotlina basin for prediction models.

The aim of the paper is to set habitat quality using IKS on 6 study areas representing 4 habitat types with different intensity of anthropogenic activity (habitat management). We evaluated the working hypotheses: (1) IKS value decreases in the direction from anthropically less disturbed habitats to anthropically more disturbed; (2) in unstable habitats disturbed by anthropic activity, there is a predominance of species from bioindication group E; (3) in more stable habitats less disturbed by anthropic activity, the predominance of species from bioindication group A is predominant.

Material and methods

Ground beetles were collected from April to October 2015-2017 in 6 localities (*Fig. 1*) representing 4 types of biotopes, classified according to Ružičková et al. (1996). The following crops were grown in the contact area of sites 4, 5 and 6: wheat, barley, sunflower, maize and rape. We used pitfall traps (750 ml), yellow pan trap (1,500 ml) (Novák et al., 1969) which were arranged at each biotope in a trap line, and each trap line consisted of five pitfall traps (at 10 m intervals). The material was collected in eat regular three-week intervals. As a killing agent, 4% saline solution was used.

Computation community index of the ground beetles (IKS)

Ground beetles we divided into three bioindication classes according to Farkač et al. (2006):

Group R – relicts, stenotopic species, narrow ecological valence – mostly rare and endangered species of natural ecosystems.

Group A – adaptable species which colonize semi-natural habitats, they occur in secondary, good regenerating biotopes and its ecotones.

Group E – eurytopic species without special requirements on the character and quality of environment. They occur in unstable and changing biotopes with strong anthropogenic influence.

The Index of Community of ground beetles (IKS) is calculated according to Nenadál (1998) based on the division of the Carabidae into bioindication groups (A, E, R). We use the following formula:

$$IKS = 100 - (\Sigma E + 0.5 \times \Sigma A) \quad \text{(Eq.1)}$$

where E = percentage of individuals in group E (E%), A = percentage of individuals in group A (%).

The IKS index includes the values ranging from zero to 100. In cases where the index value is close to zero, we identified mostly species of group E. Conversely, when the value of index is close to 100; there are mostly species from group R. The final values included five classes according to the Nenadal's (1998) classification scale of human influence on habitat: I (0−15) strongly influenced, II (10−35) significantly influenced, III (30−50) influenced, IV (45−65) marginally influenced and V (65−100) not influenced.

Data analyses

Statistical analysis of IKS data on the study areas in years 2015-2017 using the programs Statistica Cz. Ver. 7.0 (StatSoft, 2004; Ter Brak and Šmilauer, 2002), CanoDraw 4.5 (Ter Brak and Šmilauer, 2002) and the Excel 2016 Analysis Program (Barrila et al., 2016) were evaluated.

For data assessment Detrended Correspondence Analysis (DCA), Redundancy Analysis (RDA), normality distribution (Shapiro-Willksov W test), testing of variance from mean values Friedman test (ANOVA), testing of selected correlation relations (polynomial regression, exponential distribution) were used. Statistical significance of the environment (luminance, humidity and pH) was tested by the Monte Carlo permutation test.

Results

In the study area of Stolické vrchy and Juhoslovenská kotlina basin using both methods (pitfall traps, yellow pan trap) we recorded 2,379 individuals (1,030 ♂, 1,349 ♀) belonging to 52 species. Based on the division of the *Carabidae* into bioindication groups (A, E, R) to tolerate anthropogenic effects, we calculated the *Carabidae* IKS for each area examined. We recorded the highest species distribution in the localities in group A (31 species; 66.62%). To a lesser extent, group E species (18 species; 32.45%) were represented. Group R was represented by 3 species (0.92%) (*Table 2*).

DOI: http://dx.doi.org/10.15666/aeer/1801_11971210

The lowest value of IKS was observed in the area of 3 (pastures), which shows the highest anthropogenic interference in the study areas. There were 4 species preferring arable land find in the area 1: *Amara aenea, Calathus fuscipes, Harpalus affinis* and *Pseudoophonus rufipes*, which were represented by a low number of individuals. The arable land (areas 3 and 5) species were represented by a higher number of individuals *Amara aenea, Anchomenus dorsalis, Calathus fuscipes, Harpalus affinis* and *Pseudoophonus rufipes*. Indeed, the intensive agricultural use of the landscape prevails around areas 3 and 5. Fallow field of the watercourses of the locality had different IKS values. The lowest value was recorded in area 4, where 2 species *Anchomenus dorsalis* and *Pseudoophonus rufipes* favoring arable land. Areas 2 and 6 were connected with forest fields, therefore adaptable species predominated and IKS values were higher than in area 4.

We evaluated the difference in representation of bioindication groups A, E, R and IKS values between areas from 2015 to 2017 by RDA analysis (the highest value of lengths of gradient = 2.51). The RDA analysis has values of explained variability of species data of the first ordination axis (45.3%) and the second ordination axis (68.4%). The variability of the species set explained by environmental variables represent by the ordinal axis is 46.3%, while the second axis represents 70.5% (*Fig. 3*).

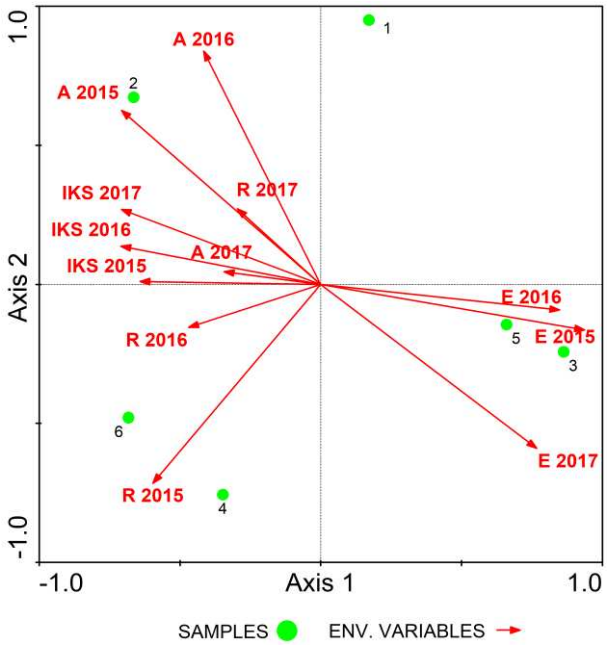

Figure 3. *Representation of groups A, E, R and IKS values 2015 - 2017. Explanatory notes: A - Group A, E - Group E, R - Group R, IKS – Carabidae Community Index*

Ordination graph showed correlation between the group A species with the nitrophilous waterside vegetation (area 2) with their highest representation. Vectors showing individual years (2015-2017) for this group did not differ significantly, suggesting only small variations in the number of species for group A. Open spaced areas 3 and 5 were abundantly represented by group E species, as illustrated by the correlation of this group over the years 2015-2017. Vectors did not differ significantly between 2015-2016, until 2017 indicating a change in the number of group E species.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11971210

The following fact indicates an intensification of agricultural land use. Area 1 (meadow) is ordained away from the vectors, indicating a slight variation in the proportion of bioindication groups and IKS values. Group R species correlated in 2015 with areas 4 and 6 (nitrophilic herbaceous vegetation) where they were recorded. In 2016 and 2017 there was a significant delay in vectors, which was influenced by the occurrence of R group species also in area 1. The vectors for IKS values did not significantly diverge in years 2015-2017. The following fact shows that there have been minor changes in IKS values over the years 2015-2017. The correlation with forest areas 2 and 6 was influenced by high IKS values during all 3 years.

For normality distribution in years 2015-2017 for all areas the Shapiro-Wilks W-test was used. We tested the hypothesis H_0: random selection comes from a set with normal distribution, if $p > p\alpha$ => we do not reject H_0 at the level of selected statistical significance $p\alpha = 0.05$. As a result, the normal distribution of IKS data across all areas in 2015-2017 was disrupted (p-value = 0.00).

A non-parametric Friedman test for testing H_0 hypothesis was used because of distribution normality data disruption, which verified the H_0 hypothesis: IKS values do not differ in areas in 2015-2017. This means if $p > p\alpha$ => do not reject H_0 at the level of statistical significance chosen by us $p\alpha = 0.05$. The result of the testing is the rejection of the H_0 hypothesis (p=0.00), which means that IKS values are significantly different in all areas in 2015-2017 (*Fig. 4*). The gradual increase in the IKS value caused by the succession and non-mowed meadow was recorded. The same increase in IKS was also observed in area 6, where waterside vegetation was not treated for 3 years and naturally overgrown with trees. Species of group R were found in the study areas, their presence indicates a low anthropic interference in the environment. In 2016, the waterside vegetation of area 2 was modified by tree and shrubs cutting and therefore the value of IKS decreased. No changes were made in the following year and the area was overgrown, which also affected the increase in the IKS value for 2017. The same progress was also recorded in the area 5, where shrubs were removed and frequent mowing during 2016 and subsequent succession in 2017. Area 3 was grazed by cattle, which was more intense in 2017 reflected in IKS 0. The waterside vegetation of area 4 was treated during all 3 years by removing shrubs and trees causing annual IKS values to fall.

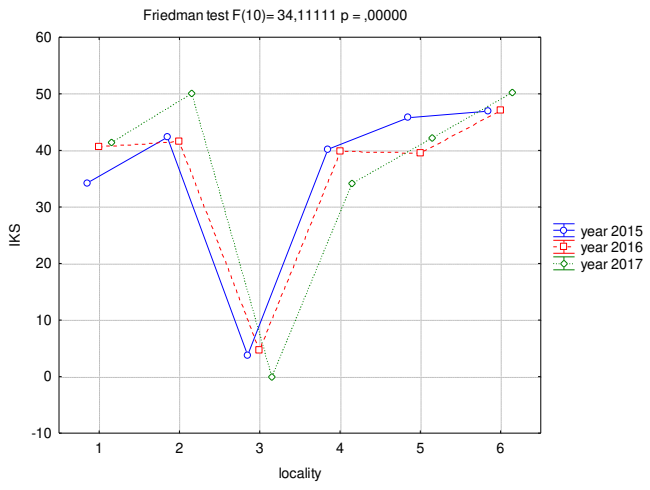

Figure 4. *Analysis of IKS variation of individual ares by Friedman test (ANOVA) from 2015 to 2017*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11971210

Polynomial regression (quadratic distribution) for evaluation of IKS change in 2015-2017 was used. Using the regression model we expressed the relationship (correlation) between IKS at the areas to the harvest years. The value of the correlation coefficient for area 1 is (r = 0.90), which indicates an almost perfect relationship. For areas 2 (r = 0.81), 3 (r = 0.75), 4 (r = 0.89) and 6 (r = 0.87) the relationship is very large. For area 5 (r = 0.56) the relationship is large. The overall suitability of the regression model is statistically significant for all areas. The results are as follow: area 1 (p-value = 0.02), 2 (p-value = 0.03), 3 (p-value = 0.04), 4 (p-value = 0.02), 5 (p-value = 0.01) and 6 (p-value = 0.03) thus confirms the effect of years on the IKS values of the study areas. Based on the regression equations shown in *Fig. 5* we can predict the IKS value of individual areas for year 2020: for area 1 (IKS = 53), area 2 (IKS = 59), area 3 (IKS = 0), area 4 (IKS = 26), area 5 (IKS = 35) and area 6 (IKS = 54). The predicted results may be fulfilled in areas 1, 2 and 6 in the case of continued spontaneous succession in which the areas are overgrown by vegetation (areas not managed). For areas 3, 4 and 5 the trend will be reversed and areas will be modified by anthropogenic activity. From the above results we can conclude, that the quality of habitats and class will change as follows. Areas 1, 2 and 6 rise from Class III (affected) to Class IV (little affected). For area 3 the quality and habitat class will remain unchanged I (very strongly affected). In areas 4 and 5 there will be a decline from Class III (affected) to Class II (heavily affected).

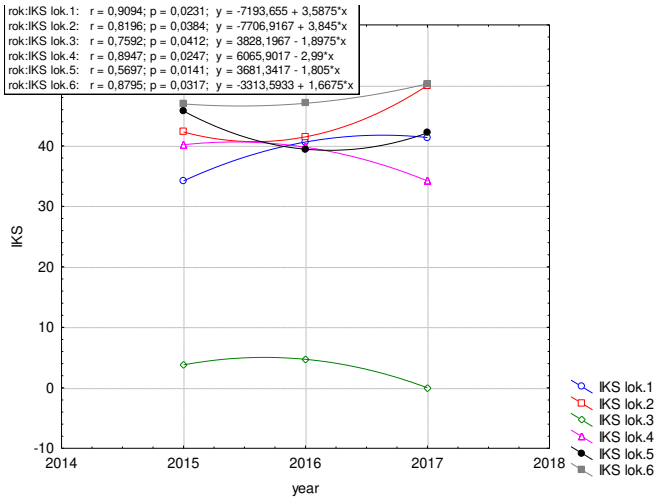

Figure 5. *Polynomial regression of IKS values 2015 - 2019*

Using the exponential distribution we predicted that IKS = 70 would be 5 years later (with 99% probability) in areas 1, 2 and 6. In the same way we predicted IKS = 10 by 5 years (with 57% probability) in areas 4 and 5.

The correlation of luminous intensity, moisture, pH was determined by redundancy analysis (RDA), which points out on values of explained variability of species data of the first ordination axis 43.7% and on the second ordination axis 64.5%. The variability of the species set explained by the environmental variables captured by the first ordinate axis 57%, the second axis captured by 84.2%. Carabidae are ordained into 4 clusters (*Fig. 6*), the first cluster (I) consisted of species correlating with luminous intensity. The second cluster (II) was represented by pH-binding species. The third (III) cluster was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11971210

represented by species correlating with moisture. The last cluster (IV) consisted of species that were not ordained in any cluster and are not influenced by the investigated factors (luminous intensity, moisture and pH). The Monte Carlo permutation test verified the H0 hypothesis: environmental factors (luminous intensity, moisture and pH) did not affect the species of the Carabidae family, if p> pα => do not reject H0 at the stated level of statistical significance pα = 0.05. As statistically significant factor (p-value = 0.002) we confirmed luminous intensity, in others we did not confirm statistical significance: moisture (p-value = 0.378) and pH (p-value = 0.268). Factors were not correlated with each other, maximum inflation factor = 4.247.

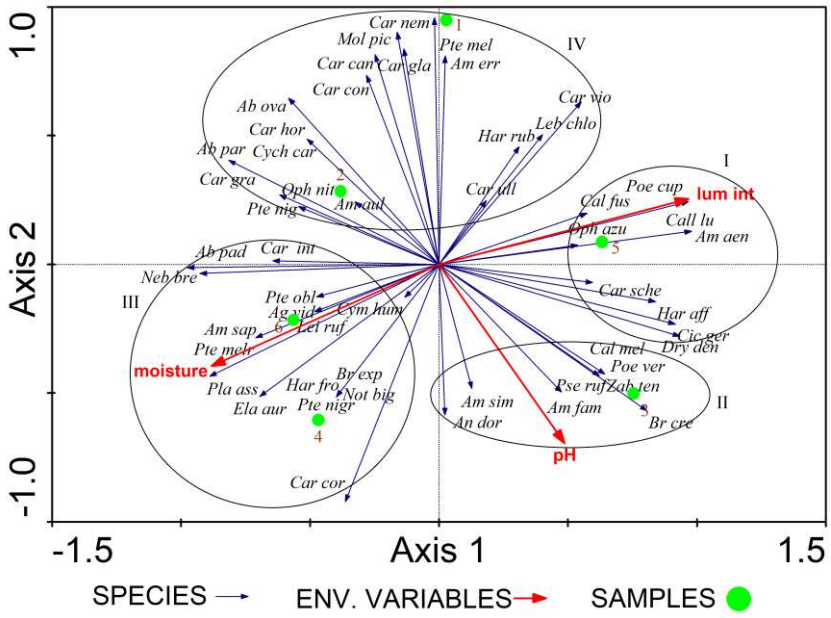

Figure 6. *RDA analysis of ground beetles and environment variables (luminous intensity, moisture, pH). Explanatory notes: lum int - luminous intensity*

Discussion

Our research evaluated the anthropogenic effect (agriculture, treatment of waterside vegetation, mowing meadows) on the *Carabidae* cenosis. The species were divided into bioindication groups according to Farkač et al. (2006) and the subsequently calculated Index of the *Carabidae* IKS according to Nenadál (1998).

The lowest IKS value was recorded in area 3 (IKS = 0) with the prevalence of eurytopic species (IKS) over adaptable (IKS). This fact confirms a very strong disruption of the area (habitat quality class I). The same fact was pointed out by Langraf et al. (2016), Igondová and Majzlan (2015), Šťastná and Bezděk (2004), Purchart and Kula (2005), Baranová et al. (2013) and Lemic et al. (2017) whose in their work have noticed the prevalence of eurytopic species (IKS) over adaptable (IKS) in agricultural areas and Jaďuďová et al. (2016) in permanent grassland. Other areas had a habitat quality class III, indicating a moderate disturbance with adaptable species predominating over eurytopic species. The same fact was noted in their works Stluka (2013), and Rajová (2007).

A gradual increase in IKS over 3 years was observed in areas 1 and 6, which was influenced by succession. Area 1 (meadow) was not mowed and area 6 (nitrophilic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11971210

waterside) had no treated waterside vegetation. Species from group R were also recorded in the areas. The decrease in IKS values over the study period was found in the areas 3 and 4 in which significant anthropic activity took place. A higher number of E group species was also recorded. Area 3 (pasture) was grazed by cattle and area 4 (nitrophilic waterside vegetation) had trimmed waterside vegetation by cutting trees and shrubs. Areas 2 (nitrophilic waterside vegetation) and 5 (fallow field) had a decrease in IKS values and an increase in group E species during 2016, in the following 2017 IKS values increased. With increasing anthropic intervention IKS values decreased and the number of eurytopic species that replaced adaptable increased. As a result of decreasing interventions IKS values increased and the number of group A and R species increased as well. The same was found by Langraf et al. (2019), Niemel et al. (2002), Elek et al. (2001), Finch (2005) and Wiezik et al. (2007).

Polynomial regression models assume the continuing trend of succession (area1, 2 and 6), where we predicted by exponential distribution 99% probability of IKS increase to 70 in 2022. For areas 3, 4 and 5 we predicted a higher impact of anthropogenic activity. Exponential distribution predicted 57% probability of reducing IKS to 10 for 2022.

Vician et al. (2010, 2011) cited as typical species mainly associated with arable land *Clivina fossor, Calathus fuscipes, Amara aenea, Anchomenus dorsalis, Harpalus affinis, H. distinguendus* and *Pseudoophonus rufipes*. The presence of these species with a higher number of individuals was recorded in areas 3 and 5 adjacent to the farmed land.

Conclusion

The different intensity of anthropogenic impacts (developed agriculture, treatment of waterside vegetation, mowing meadows) on *Carabidae* species in six study areas representing 4 habitat types was evaluated.

We confirmed statistically significant changes in values in years 2015-2017 for all study areas using the IKS index. We found a low IKS value = 0 with a predominance of eurytopic species on habitat quality class 3 = I, indicating a very strong disturbance. Other areas had habitat quality class III, indicating moderate disturbance with the prevalence of adaptable species. The above facts have confirmed our first working hypothesis.

Significant differences in the number of bioindicating species (groups A, E, R) were observed for eurytopic species in years 2016-2017, indicating a more intensive agricultural use of the landscape (cattle grazing, expansion of fields at area 5). Bioindication group R also increased in years 2016-2017, which was influenced by the spread of group R species to area 1. Species belonging to group A showed year-on-year changes, but not so significant. It follows from the above that the second and third working hypotheses are confirmed. The arable land species were represented by a higher number of individuals: *Amara aenea, Anchomenus dorsalis, Calathus fuscipes, Harpalus affinis* and *Pseudoophonus rufipes* on areas 3 and 5.

The regression models predicted the continuation of succession on areas 1, 2 and 6, where we predict a 99% probability of IKS to rise to 70 in 2022 at exponential distribution. The above facts confirm the reduction of anthropic activity in these localities. We predicted a higher impact of anthropogenic activity and a decrease in IKS

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_11971210

values by the regression polynomial model on areas 3, 4 and 5. We also pointed on the 57% probability of reducing IKS with a value of 10 in 2022 by exponential distribution.

In order to maintain the original biodiversity of the carabidae family, it is possible to adjust the management and management of the investigated sites. Verification of the success of the introduced changes during the continuation of the results in the years referring to the forecast.

(Received 15th Aug 2019; accepted 14th Nov 2019)

Abstract. This experiment was established in pots during the vegetative period of 2017, in Kalar Sulaymaniyah, Northern Iraq, to investigate the effect of seaweed extracts (Alga 600) of four concentrations (0, 2, 4, 8 $g.L^{-1}$) applied with fertigation system on growth, flowering, yield and quality properties of strawberry cv. Albion. Drip irrigation system was used in this experiment. According to the results in terms of the vegetative growth characteristics, increasing seaweed extract (Alga 600) amounts had significantly different effects on plants with a different number of crowns. The results concerning flower properties show that increasing seaweed extract applications had significant effects on the number of flowers per plant, yielding 16.55-21.77 units/plant. The results in point of fruit properties show that increasing Alga 600 amounts caused a significant increase of 11.81-17.7 units/plant in terms of fruit number, 211.74-329.37 ml in terms of fruit volume, and an increase of 191.7-295.03 g in terms of yield, compared to the control treatment. The results show that increasing seaweed extract caused a significant increase in fruit quality (TSS/TA ratio from 8.29 to 13.35) compared to the control treatment and increasing seaweed application caused a significant decrease in the TA of the fruit.
Keywords: *Fragaria x ananassa Duch, organic fertigation, cv. Albion, morphological properties, pomological properties, algae extract*

Introduction

Strawberry (*Fragaria x ananassa* Duch) is small fruit that planted in a wide range in the world, it belongs to family Rosaceae. Before the relatively modernity development of *Fragaria x ananassa*, wood strawberries (*Fragaria vesca*) and Musky strawberries (*Fragaria moschata*) were cultivated in Europe and Russia for centuries. These species were in generally supplanted by the cultivation of *Fragaria x ananassa* over the last 250 years. In the early 1700s, inter-planting of *Fragaria virginiana* (male) with *Fragaria chiloensis* (female) in France led to the production of hybrid seedlings that bring to be known as Pineapple or Pine strawberry plants, progenitors of the new cultivated strawberry plant (*Fragaria x ananassa* Duch) (Darrow, 1966). It is a rich source of vitamins and minerals with delicate flavor (Sharma, 2002).

It is one of the most delicious and refreshing temperate fruits of the world. It gives early and very high returns per unit area compared to other fruits because its crop is ready for harvesting within six months after planting (Katiyar et al., 2009). Being a non-climacteric, it matures only on the plant (Cordenunsi et al., 2003). Its fruits are appealing with a distinct, enjoyable and refreshing aroma. It also contains a higher percentage of other components including phenolic and flavonoids (Häkkinen and Törrönen, 2000). Strawberry is a perfect source of Vitamin C (30-100 mg/100 g of fruit) as well as a foliate and photochemical compound such as the Alganic acid. Consuming

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12111225

strawberries can reduce the risk of increasing cancer by 50% due to higher levels of Vitamin C can increase the flow of blood and oxygen to the muscles by 7% due to nitrates (Kumar et al., 2013). Strawberry contains 90% water and 37% calories, 0.7 grams of protein, 0.5 g of oil, 10 g of carbohydrate, 1.3 g fiber and vitamins, contain vitamin A (0.07 mg), vitamin B1, B2 (0.3 mg), niacin (28 mg) and calcium (27 mg) (Watt et al., 1963).

Strawberry can be cultivated in almost all regions from arctic to tropic regions (Hancock, 1999). Including sub-tropical areas like North of Iraq. Country's weather is favorable for the production of high quality strawberries though it is normally produced in countries having cold weather, particularly in the north. Strawberry cultivation technique is fairly new in North of Iraq whereas cultivation area is increasing bit by bit. Strawberry can be grown during the month of October to April in North of Iraq. A sustainable variety is needed for continuous production from year to year. Screening of strawberry variety is needed for a suitable variety for continuous production and some varietals screening has also done. Today, strawberries are produced in almost every country in the world, most notably, Turkey, America, and Iran. This wide distribution suggests that the strawberry plant is well adapted, and as a genus. However, a lot of individual genotypes or cultivars of strawberries are accurately adapted to local conditions, and so choosing cultivars that are proven to perform well in your specific region is important and key of the work. Strawberry reproduction, fruit quality land yield depends on a lot of factors, for example; weather conditions during the growing stage, the cultivar and all agronomic practices such as fertilization, irrigation or crop protection (Gülsoy and Yılmaz, 2004).

Cultivated strawberry (*Fragaria x ananassa*) and wild strawberry (*Fragaria virginiana*) are plants in the family of Rosaceae. The fruit of the strawberry plant is composed of several tiny fruits that together produce the whole fruit, where every small fruit has one seed called achene. Seaweed extracts are the cheap source of naturally occurring plant development regulators which have better potential as bio stimulants in horticulture. The plant growth regulators available in the seaweed extracts and concentrates is thought to be involved in the enhancing plant growth and yield. Different plant phytohormones and growth regulators available in seaweed extracts are known to promote the yield and yield attributes of crops. Because the extract contains natural plant hormones and deferent natural nutrient material, vitamins, carbohydrates such as Alganic acid, polysaccharide, trace minerals (Panda et al., 2012).

The aim of this study, to investigate the effect of seaweed extract (Alga 600) on the vegetative growth, flowering quantitative and qualitative parameter of yield on strawberry cv. Albion under Iraq ecological conditions.

Literature Review

Seaweed extract is an organic substance that is concentrated and can be found in liquid or soluble granule form. It is mixed with water and added to seeds, transplant, and plant to fertilize it. Accordingly, as it has been remarked by Aitken and Senn (1965) it can also replace nutrition deficiencies of plant development. This material is an important substance because it is safe to use. It does not have a dangerous side effect on human being, animal and land. In addition to that is reduces land pollution and the rate of soil salt inside the soil (El-Moniem and Abd-Allah, 2008). It is also economical to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12111225

use since it won't cast too much. For the above-mentioned reason, it has been a preferred fertilizer throughout centuries (Temple and Bomke, 1988).

Seaweed extract, in its different types and methods of application, has been a catalyst for plant growth and productivity. As it has been concluded in different studies, seaweed has led to the active development of plants through improving photosynthesis, activating flower, leaves, promoting shoots, leaf minerals, and carbohydrates, vegetative weights. As it has been remarked by Masny et al. (2004) in a study leaves activity improves and photosynthesis will be in better quality when seaweed (Kelpak SL and Goemar BM86®) with three treatments (0, 0.5 and 1 $ml.L^{-1}$) is sprayed on the leaves of strawberry. It also promotes an increase in the number of flowers in each plant. This experiment is done on strawberry plants cv. Elkat and Salut in 2001-2003. It is also stated it stimulates shoot growth, the area of leaves a long with the chemical components of leave such as carbohydrates and minerals of the leaf. As it is mentioned by Mansour et al. (2006) in an experiment when algae extract added to the sandy soil of thirty Anna apple trees aged 12 years on MM106 rootstock cultivated at 3.5x3.5 m. The effect of the extract is shown in other studies again remarks its positive effect on plant growth. El-Moniem and Abd-Allah (2008) in a study show the positive effect of the extract. The result of spraying green alga cells extract on the grapevine is shown in comparison with other nutrition fertilizers. The use of algae extract at 25 to 100% had improved on the growth characters, including the leaf area, shoot length and promoted leaves number in each shoot rather than check treatment.

The development and activation of leaves noticed when algae extract concentration was under 50%. But with a concentration above 50%, its effect on increasing percentage N, P, and K in the leaves is less than under 50%. Other studies also indicate the positive effect of the extract on plant production and leaf improvement. Taha (2008) in a study exposes the influence of spraying three seaweed extracts (Algren, Soluamine, Mannarine) in two types of Strawberry (Hapil and Kaiser's sampling). It is concluded that spraying cv. Kaiser's sampling with seaweed (Algren) stimulates an increase in the total chlorophyll content and obvious enhance in pollen viability ratio, whereas spraying extracts Soluamine has boosted flower in each plant more than negative controls, as for the cv. Hapil when using Algren extract, there was an increase in dry weight of shoots and leaf area and important superiority of crown diameter. However, spraying extract Soluamine there was an increase in the rate of fresh weight of shoot and dry weight of the root system.

Algae extract increases productivity in strawberry as found by Al-Hermizy (2011) in a study. That deals with the effect of sea algae extract (Alga 600) in two levels (0 and 3 $ml.L^{-1}$) on strawberry growth as far as productivity concerned. The outcome of the study shows that spraying with sea algae extract (Alga 600) caused a significant increase in all vegetative growth characteristics (crown diameter, total leaf area, fresh and dry weight of vegetative growth, number of runner and number of leaflet per plant). Accordingly, Mac et al. (2008) studied the influence of Alga Green (cold process seaweed liquid extract), as foliar fertilization on the plots of mature "Bramley's seedling" apple trees in comparison of other non-applicant trees. It is found that seaweed caused a significant increase in leaf mineral content.

Seaweed can be defined as a fertilizer that makes plant prolific in terms of quantity and quality. As it has been proved in different studies seaweed extract has helped the increase in the rate of fruit weight, size, number. It promotes them to be prolific. As affirmed by Kivijarvi et al. (2002) in a study done on strawberry (Jonsok, Ruukki, and Bounty) with different concentrations of seaweed extract that resulted in the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12111225

improvement of the rate of fruit weight and size, the quantity of yield. There is also a positive outcome of studies done by Al-Hermizy (2011) in search of the impact of seaweed (Alga 600) in two-scale (Zero, and 3 ml.L^{-1}) on yield properties of strawberry. The outcome indicated that Spraying with seaweed Alga 600 caused a significant increase in every yield characteristic (fruit weight, size, yield per plant, total yield). Again in other studies like Eshghi et al. (2013), there is a prolific result of using a foliar application of seaweed extracts including Algren at 0, 3, 6 and 9 g.L^{-1}, Drin at 0, 0.5, 1 and 2 g.L^{-1} focus on quality fruits of strawberry cv. Selva. The results show that the Algren at 9 g.L^{-1} focus produces better chlorophyll content.

Material and Methods

This study was carried out during the vegetation periods of 2016-2017 with pots in open area in Kalar, Sulaymaniyah, North of Iraq located between latitude N 34.62131°, longitude E 45.31961° and on elevation 200 m above sea level. During the vegetation period, in Kalar, the minimum temperature was -3°C; max. the temperature started to increase in the middle of April, more than 35°C. No field trials have been established to protect plants from low temperatures seen in winter due to continental climatic conditions. When the temperature dropped below zero during the experiment, a plastic sheet was drawn over the plants. Effect of high temperature was seen on strawberry fruit size and weight in our experiment at the beginning of May (it was the last harvest time) as shown in *Table 1* (Anonymous, 2017).

Table 1. *The weather of Kalar - Sulaymaniyah / Iraq, from January/2017 to June/2017.*

Date	Average temperature /month	Maximum temperature /month	Minimum temperature /month	Average relative humidity /month	Maximum relative humidity /month	Minimum relative humidity /month

Experimental Details

Albion variety was used as plant material in our experiment. Seedlings were brought at 1th January 2017 from Antalya, Turkey (*Figure 1*). The experiment was established in pots with capacity 5 kg in open area on 15 January 2017 in Kalar. Four concentrations of fertigation solutions (0, 2, 4 and 8 g.L^{-1}) were prepared from seaweed (Alga 600). The prepared solutions were applied to the plants twice with fertigation. The first application was in the flowering stage (after the formation of first fruiting) and the second application was twenty days later. The seaweed was dissolved in 22ºC of water for better fixing. Fertigation was applied in the morning. Components of seaweed are shown in *Table 2.*

Plant Growth Observations and Pomological Properties

After full flowering (15th February 2017) and two harvesting times (20th March and 12th May 2017) some vegetative growth parameters and pomological properties such as

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12111225

single leaf area, total leaf area of per plant, number of leaves per plant, vegetative fresh weight, vegetative dry weight, root dry weight, chlorophyll (total =chlorophyll A + chlorophyll B) content in the plants, strawberry runner properties (daughter plant), strawberry runner properties (stolon), strawberry crown, number of flowers per plant, flower setting percentage, number of fruits of per plant, average fruit weight, average fruit volume, average total fruit volume, yield of per plant, yield per unit area (kg/hectare), fruit total soluble solid percentage (TSS %), fruit total acidity (TA %), TSS/TA ratio (ripening index) were measured. For measurements of root weight, after second harvest time, the roots of plants were washed to remove the soil particles under tap water very well. Then roots of plants were dried at 70°C in the oven.

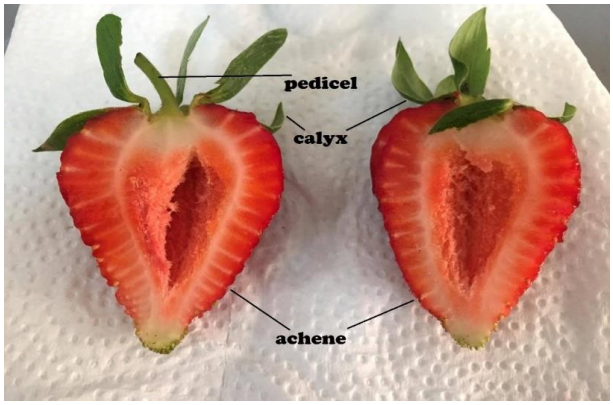

Figure 1. *Fruit of Strawberry cv. Albion.*

1	Nitrogen N	0.5-1.0%
2	Alganic acid	6-9%
3	Sulfur (S)	1.0-1.5%
4	Phosphorus pentoxide (P_2O_5)	6-9%
5	Calcium oxide (CaO)	0.4-1.6%
6	Iron (Fe)	0.15-0.3%
7	Magnesium oxide (MgO)	0.06%
8	Potassium oxide (K_2O)	21-24%
9	Amino acid	4%
10	PH	9-11
11	Organic matter	40-50%

Statistical Calculations

Data were analyzed by the analysis of variance method for randomized plot design. Four treatments (0, 2, 4, and 8 $g.L^{-1}$), with three replications and each experimental unit, contains nine plants. LSD multiple comparison test was used for determination of the differences between of the means. Significance threshold were set as $\alpha = 0.05$ and $\alpha = 0.01$. Descriptive statistics, like mean and standard errors, were presented for the investigated features. Statistical calculations of findings are presented under the tables as **: $p<0.01$, significant at 0,01 level; *: $p<0.05$, significant at 0.05 level and NS: not significant.

Results and Discussion

Plant Growth Observations and Pomological Properties

Single Leaf Area Per Plant

As shown in *Table 3*, compared to the negative control seaweed (Alga 600) showed an increase in single leaf area per plant. However, it is not a statistically significant result. Measurements gave the maximum value of the single leaf area as 127.88 cm^2 in seaweed (Alga 600) in 8 $g.L^{-1}$ treatment group. Owing to seaweed (Alga 600) including more vitamins, amino acids, and some trace elements, these results were expected. However, the past studies have demonstrated that seaweed extracts indirectly or directly, effects on the physiological performance of the plants. Previous studies were concluded to be stemming from the content properties of seaweed (Alga 600), which contains auxin and cytokines. Accordingly, cell division and elongation proposed to be affected by the content (El-Yazied et al., 2012; El-Miniawy et al., 2014; Saif Eldeen et al., 2014).

Table 3. *The effect of fertigation of seaweed on single leaf area.*

Name	Single leaf area per plant (cm^2)^{NS}
T1 (Control)	102.87
T2 (2 $g.L^{-1}$)	106.52
T3 (4 $g.L^{-1}$)	116.35
T4 (8 $g.L^{-1}$)	127.88

NS: not significantly different.

Total Leaf Area Per Plant

Data in *Table 4* shows the effect of seaweed (Alga 600) on the total leaf area per plant. There is an increase compared with control treatment yet it was not significant, and it shows the fertigation of seaweed (Alga 600) in 8 $g.L^{-1}$ give the maximum value of total leaf area per plant is (1464.44 cm^2) and lowest value recorded by control treatment (1038.21 cm^2). These results are plausibly observed because of the incentive effect of Seaweed (Alga 600) on the single leaf area as previously mentioned.

Table 4. *The effect of fertigation of seaweed on total leaf area of per plant.*

Name	Total leaf area (cm^2)^{NS}
T1 (Control)	1038.21
T2 (2 $g.L^{-1}$)	1088.56
T3 (4 $g.L^{-1}$)	1167.29
T4 (8 $g.L^{-1}$)	1464.44

NS: not significantly different.

The Number of Leaves Per Plant

The results in *Table 5* reveal fertigation levels and their combinations. There is an increasing trend in the number of leaves per plant notwithstanding there is no statistically significant difference among the groups. The highest measurement recorded by fertigation with seaweed (Alga 600) in 8 $g.L^{-1}$ (11.33 unit), and the lowest one recorded by the control group (9.48 unit).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12111225

Table 5. *The effect of fertigation of seaweed on leaves number of per plant.*

Name	Number of leaf per plant^{NS}
T1 (Control)	9.48
T2 (2 g.L^{-1})	9.74
T3 (4 g.L^{-1})	10.59
T4 (8 g.L^{-1})	11.33

NS: not significantly different.

Vegetative Fresh Weight

Table 6 shows that the effect of seaweed (Alga 600) on vegetative fresh weight. Despite there is an increasing trend on vegetative fresh weight compared with control, this increase is not significant. The fertigation of seaweed (Alga 600) in 8 g.L^{-1} gives the maximum value of vegetative fresh weight (65.95 g) and the lowest value recorded by control (53.02 g). These result can be explained by the favorable effects of seaweed for the increase in the parameters such as single leaf area and leaf number per plant (El-Miniawy et al., 2014; Saif Eldeen et al., 2014).

Table 6. *The effect of fertigation of seaweed on vegetative fresh weight.*

Name	Vegetative fresh weight (g)^{NS}
T1 (Control)	53.02
T2 (2 g.L^{-1})	58.12
T3 (4 g.L^{-1})	62.23
T4 (8 g.L^{-1})	65.95

NS: not significantly different.

Vegetative Dry Weight

As shown in *Table 7*, the effect of seaweed (Alga 600) on vegetative dry weight, there is a raise compared with control, and it shows the fertigation of seaweed (Alga 600) in 8 g.L^{-1} gives the maximum value of vegetative dry weight (23.96 g) and the lowest value read by control (17.74 g). The reason behind this observation might be caused by seaweed (Alga 600) components, as discussed before. Besides, our records revealed that there is an increasing trend for single leaf area, the number of leaves per plant and vegetative fresh weight. Previous studies reported that seaweed extracts lead to the spectacular physiological performance of the plants (El-Yazied et al., 2012; El-Miniawy et al., 2014; Saif Eldeen et al., 2014).

Table 7. *The effect of fertigation of seaweed on Vegetative dry weigh.*

DOI: http://dx.doi.org/10.15666/aeer/1801_12111225

Root Dry Weight

Data in *Table 8* shows the effect of seaweed (Alga 600) on root dry weight. The fertigation of seaweed (Alga 600) in 8 $g.L^{-1}$ give the maximum value of root dry weight (12.31 g) and the lowest value recorded by the control group (8.36 g). Again, we observed an improvement in dry root weight with seaweed (Alga 600) treatment yet it is not significant. Vitamins, minerals and some trace elements might have caused this observation. Our records are compatible with previous studies (Abdel-Mawgoud et al., 2010; Shehata et al., 2011; El-Yazied et al., 2012).

Table 8. *The effect of fertigation of seaweed on root dry weight.*

T1 (Control)	8.36
T2 (2 $g.L^{-1}$)	8.62
T3 (4 $g.L^{-1}$)	11.96
T4 (8 $g.L^{-1}$)	12.31

NS: not significantly different.

Chlorophyll Content in Plant

As shown in *Table 9*, seaweed (Alga 600) augments total chlorophyll content despite the statistically significant difference. The fertigation of seaweed (Alga 600) in 8 $g.L^{-1}$ resulted with the maximum value of total chlorophyll content in the leaf (41.09 unit) and the lowest value recorded by the control (38.41 unit). This observation can be grounded by the amino acid content of seaweed. Seaweed treatment eases amino acid accession of the plant which culminates in provoked protein synthesis and this leads to the higher amount of photosynthetic pigment production, the total chlorophyll in the leaves. Previous studies also approve this observation (Thirumaran et al., 2009; Shehata et al., 2011; El-Miniawy et al., 2014; Mohamed, 2015).

Table 9. *The effect of seaweed fertigation on total chlorophyll in leaves.*

Name	Total Chlorophyll in leaf (Unit)^{NS}
T1 (Control)	38.41
T2 (2 $g.L^{-1}$)	38.81
T3 (4 $g.L^{-1}$)	39.72
T4 (8 $g.L^{-1}$)	41.09

NS: not significantly different.

Plant Runner Properties

Data has shown in *Table 10*, the effect of seaweed (Alga 600) on number daughter plant and number of stolon that there is an increase compared with control. However, it is not significant, and it pointed that the fertigation of seaweed (Alga 600) in 8 $g.L^{-1}$ give the maximum value of number daughter plant (4.55 unit) and for number of stolon (7.29 unit) and lowest value recorded by control treatment for daughter plant (3.44 unit) and number of stolons is (5.85 unit). These results suggest that the physiological and biological activity of seaweed extract, containing high levels of auxin and cytokinins, stimulates the cell division in the plant. Another parameter can be GA_3 which causes an

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12111225

increase of the number of the runners, growth in length of the cell, and elongation of internodes. Our results are coherent with previous papers by Hytönen et al. (2009), Ragab et al. (2010), Abo Sedera et al. (2014) and Mohamed (2015).

Table 10. *The effect of fertigation of seaweed on plant runner properties.*

Name	Number of runner (daughter plant)^{NS}	Number of stolon^{NS}
T1 (Control)	3.44	5.85
T2 (2 g.L^{-1})	3.71	6.66
T3 (4 g.L^{-1})	3.70	6.70
T4 (8 g.L^{-1})	4.55	7.29

NS: not significantly different.

The Number of Crowns

Data in *Table 11* has showed that the effect of seaweed (Alga 600) on the number of crowns. We observed that there is a significant increase in the number of crowns of treatment groups compared with control. The fertigation of seaweed (Alga 600) in 4 g.L^{-1} and 8 g.L^{-1} given rise to the maximum value of the number of crowns (T3=3.64 unit) and (T4=3.5 unit) and the lowest value recorded by control (2.75 unit). These records are thought to be driven by the physiological and biological activity of seaweed extract, which is rich in terms of auxin and cytokinins. Hence, cell division on the plant must be triggered. These results are coherent with studies of Khalid et al. (2013) and Mohamed (2015).

Table 11. *The effect of seaweed fertigation on the number of crowns.*

Name	Number of crown**
T1 (Control)	2.75b
T2 (2 g.L^{-1})	2.719b
T3 (4 g.L^{-1})	3.64a
T4 (8 g.L^{-1})	3.50a

**: $p<0.01$, significant at 0.01 level.

Fruit Setting Percentage

As shown in *Table 12*, the effect of seaweed (Alga 600) on fruit setting percentage is not significant but an increasing trend is detected (T4=8 g.L^{-1}) compared with control. The fertigation of seaweed (Alga 600) in 8 g.L^{-1} culminated in the maximum value of setting percentage (T4=80%) and the lowest value recorded by control treatment (T1=70%). These results are consistent with previous studies of Khalid et al. (2013) and Mohamed (2015).

Table 12. *The effect of seaweed fertigation on fuit setting percentage.*

Name	Fruit Setting percentage^{NS}
T1 (Control)	70%
T2 (2 g.L^{-1})	74%
T3 (4 g.L^{-1})	78%
T4 (8 g.L^{-1})	80%

NS: not significantly different.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12111225

The number of fruits per plant

Records of the number of fruits per plant are shown in *Table 13*. The significant effect of seaweed (Alga 600) is observed in the number of fruits per plant. Specifically, there was a significant increase in T4 and T3 compared with control (T1). The fertigation of seaweed (Alga 600) in 8 $g.L^{-1}$ resulted in the maximum value of the number of fruits per plant (T4-17.70 unit) and the lowest value recorded by control treatment (T1-11.81 unit). Increasing the vegetative growth or the number of crowns per plant might be the cause of this finding.

Table 13. *The effect of seaweed fertigation on number of fruits per plant.*

Name	Number of fruits per plant**
T1 (Control)	11.81b
T2 (2 $g.L^{-1}$)	13.40ab
T3 (4 $g.L^{-1}$)	17.22a
T4 (8 $g.L^{-1}$)	17.70a

**: $p<0.01$, significant at 0.01 level.

The average weight of the fruit

The effect of seaweed (Alga 600) is shown in *Table 14*. Seaweed does not have a significant effect on the average weight of the fruit. On the other hand, we observed an increase in T4 compared with T3 and T2. The maximum value of the average weight of fruit (g) was T4=16.85 g and the lowest value recorded by T3=14.65 g. The seaweed extract improves some vegetative characteristics. It also stimulates production quality and quantity through the enhancement of photosynthetic process. Accordingly, Abdulraheem (2009) has affirmed that seaweed application leads to the improvement in the development of fruit diameter, strength, and length in addition to a better rate of fruit production. In spite of there is no direct correlation between treatment groups, this finding might be caused by increasing the vegetative growth or the number of the crown.

Table 14. *The effect of seaweed f fertigation on Averae weight of fruit.*

Name	Average weight of fruit (g)NS
T1 (Control)	15.80
T2 (2 $g.L^{-1}$)	15.11
T3 (4 $g.L^{-1}$)	14.65
T4 (8 $g.L^{-1}$)	16.85

NS: not significantly different.

Average and Total volume of fruit per plant

In *Table 15*, data showed the effect of seaweed (Alga 600) on the average volume of fruit (ml^3). There is no significant effect but there is an increasing trend in T4 compared with other treatments T1 and T2. The fertigation of seaweed (Alga 600) in 8 $g.L^{-1}$ gave the maximum value of the average volume of fruit (ml^3) (T4=18.88 ml^3) and total volume of fruit (ml^3) (T4=329.37 ml^3) and the lowest value recorded by control treatment. This records can be explained by the fact that seaweed application leads to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12111225

the improvement in the development of fruit diameter, strength, and length in addition to a better rate of fruit production (Abdulraheem, 2009).

Table 15. *The effect of seaweed fertigation on average and total volume of fruit.*

Name	Average volume of fruit (ml^3)^{NS}	Total volume of fruit (ml^3)*
T1 (Control)	17.50	211.74b
T2 (2 $g.L^{-1}$)	16.89	228.14b
T3 (4 $g.L^{-1}$)	16.60	285.92ab
T4 (8 $g.L^{-1}$)	18.88	329.37a

NS: not significantly different, *: $p<0.05$, significant at 0.05 level.

Plant yield and yield per area unit

The influence of seaweed (Alga 600) on yield per plant (g) and per hectare (kg/ha) are shown in *Table 16*. There is a significant increase in T4 compared with control (T1) and T2. The fertigation with seaweed (Alga 600) in and 8 $g.L^{-1}$ resulted in the maximum value of yield per plant (g) T4-295.03 g and per hectare T4-3278.18 kg/ha. The lowest value belongs to the negative control. This results can be explained as seaweed extract improves some vegetative characteristics. It also stimulates the quality and quantity of production through the augmentation of the photosynthetic process. Accordingly, Abdulraheem (2009) has affirmed that seaweed application leads to the improvement in the development of fruit diameter, strength, and length in addition to a better rate of fruit production. This increase leads to improved vegetative growth or number of the crowns.

Table 16. *The effect of seaweed fertigation on yield per plant and yield per hectare.*

Name	Yield per plant (g)*	Yield per hectare (kg/hectare)*
T1 (Control)	191.70b	2130.04b
T2 (2 $g.L^{-1}$)	204.11b	2267.90b

T4 (8 $g.L^{-1}$)	295.03a	3278.18a

*: $p<0.05$, significant at 0.05 level.

Total soluble solid (TSS)

According to the findings in *Table 17*, the effect of seaweed (Alga 600) on total soluble solid (TSS) that there is an increase compared with control. However, it was not significant and it has shown the fertigation of seaweed (Alga 600) in 8 $g.L^{-1}$ resulted in the maximum value of total soluble solid (TSS) (7.46 unit) and lowest value recorded by control (6.85 unit). These results are compatible with reports from El-Moniem and Abd-Allah (2008) and Taha (2008).

Total acidity (TA)

In *Table 18* the effect of seaweed (Alga 600) on total acidity (TA), there are significant differences among the treatment groups. Increasing of levels of seaweed extract (Alga 600) decreases the TA, control treatment has significantly different than T2 and higher than T4 but it is not significant, and it showed the maximum value in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12111225

control treatment and lowest value recorded by fertigation of seaweed (Alga 600) in 2 $g.L^{-1}$, because while TSS increase, the TA decrease.

Table 17. *The effect of seaweed fertigation on total soluble solid.*

*: $p<0.05$, significant at 0.05 level.

TSS/TA ratio (ripening index)

The findings have shown in *Table 19*, the effect of seaweed (Alga 600) on TSS/TA ratio in T4 and T2 significantly increased compared with control. It showed the fertigation of seaweed (Alga 600) in 8 $g.L^{-1}$ gave the maximum value of TSS/TA ratio (13.35 unit) and the lowest value recorded by control treatment (8.29 unit). These results are coherent with that information by El-Moniem and Abd-Allah (2008) and Taha (2008).

Conclusion

According to the results of our study the effect of seaweed (Alga 600) on the flowering, vegetative growth and fruiting of strawberry cv. Albion, the following conclusion can be drawn. The seaweed extract at 2 $g.L^{-1}$ is less effective on strawberry vegetative properties, flowering and yield properties and chemical characteristics of fruit than other treatment. The seaweed extract (Alga 600) at 4 $g.L^{-1}$ is more effective than 2 $g.L^{-1}$ and it has a significant effect on the number of the crowns, number of flowers, number of the fruits at 0.01 level, and total volume of the fruit, yield per plant, yield per hectare, TA and TSS/TA ratio at 0.05 level. The seaweed extract at a higher

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12111225

concentration (8 $g.L^{-1}$) has the more effective to increase the vegetative growth, flowering and yield properties. Organic fertigation (Alga 600) has a significant effect on the number of the crown, number of flowers, number of the fruit at 0.01 level, and total volume of fruit, yield per plant, yield per hectare, TA and TSS/TA ratio.

Seaweed fertilizers are an important alternative organic fertilizing to increase yield and to achieve a better quality product. The use of seaweed as support for fertilization in production increases the yield and quality while ensuring the sustainability of the soil due to its ecological nature. Strawberry, with high economic returns; rich in taste, aroma and antioxidant substances and no marketing problems, is a fruit. Strawberry cultivation is not common in Iraq yet. In this sense, the result of our study is a guide for those who want to cultivate strawberry in Iraq. In conclusion, as the amount of seaweed extract applied increased, vegetative growth rate and flowering rate increased in our experiment. For this reason, in particular, we believe that the application of doses above 8 $g.L^{-1}$ will significantly increase the productivity and quality of yield.

Abstract. Drought stress is a severe problem for wheat production. The purpose of the present experiment was to study the effects of the exogenous sodium selenite application at different concentrations on wheat seedlings performance under drought stress. Two wheat varieties, '*Shunmai-1718*' and '*Jintai-102*' were used as materials in this study and four selenium concentration levels were prepared from distilled water (CK), and 20 mg/L (Se1), 40 mg/L (Se2) and 60 mg/L (Se3) of sodium selenite. 7 days after the sowing, the sodium selenite solutions were foliarly applied to wheat seedlings. 9 days after the sowing, 20% PEG-6000 was used to simulate drought conditions for 7 days. The results showed that exogenous selenium significantly increased the plant height, root length, root number, fresh weight and dry weight of wheat seedlings under drought stress. Foliar application of sodium selenite under drought stress also increased antioxidant enzyme activity and the osmoprotectant contents while reducing the content of MDA and O_2^-. Furthermore, the application of sodium selenite under drought stress up-regulated the levels of transcriptional expression in some genes related to antioxidative enzymes and osmo-protectants such as Plant peroxidase, Class Ⅲ peroxidase, Glutathione S-transferase and Catalase immune-responsive.

Introduction

China is a big wheat (*Triticum aestivum* L.) planting country reaching 10.5% of the global planting area, but around 70% of it is distributed over arid and semiarid regions (Xuan et al., 2017). Many studies had showed that drought stress could severely affect the growth and development of crops (Clauw et al., 2015; Hatmi et al., 2015). The study of Hao et al. (2015) indicated that the problems of wheat yield reduction and poor grain quality caused by drought always exist in the process of wheat cultivation. Thus, effective ways to relieve the drought stress are required to achieve the goal of ensuring the stability of wheat productivity and exogenous plant growth regulators might come in handy.

Selenium (Se) is a necessary chemical element for human body. It exists in nature in two forms: inorganic Se and organic Se. Selenium has the functions of anti-cancer, anti-oxidation and improving human immunity (Broghamer et al., 1976; Scott et al., 1998). Coronary heart disease, hypertension, Kashin-Beck disease and other diseases are all related to selenium deficiency, and low selenium environment is one of the main factors for the occurrence of these diseases (Rayman, 2012). Although selenium is not an essential element in plants, it has a significant effect on the physiological characteristics of plants. A number of studies showed that Se application could enhance the crops

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12271236

performance. For example, He et al. (2019) demonstrated that foliar application of sodium selenate at low concentration could enhance the antioxidant enzymes activities and increase the chlorophyll content of rice. The study of Duan et al. (2019) revealed that exogenous Se application at heading stage could delay the senescence of rice leaves at grain filling stage. Some early studies have shown selenium can improve the drought resistance of wheat or alleviate the damage caused by drought stress (Yao et al., 2009a,b). However, the physiological and molecular basis for effects of exogenous selenium on wheat seedlings performance under drought stress remained largely unexplored.

Hence, present study was conducted with four concentration of exogenous selenite in order to explore the effect of foliar application of sodium selenite on wheat seedling under drought stress and the related physiological and molecular basis.

Materials and Methods

Plant materials and experimental details

Present experiment was conducted in the College of Agriculture with two wheat cultivars, *Yangmai9023* and *Zhengmai20*, which are widely planted in Central China. Before sowing, the selected seeds were soaked with 0.1% $HgCl_2$ for 15 minutes for sterilization, and then washed by distilled water, shade dried, the seeds were sowed into culture dish (9 cm in diameter and 50 seeds for each dish). 7 days after the sowing, the sodium selenite solutions (0 (CK), 10 (Se1), 20 (Se2), 30 (Se3) mg L^{-1} and 40 (Se4) mg L^{-1}) were foliar applied to wheat seedlings. 9 days after the sowing, 20% PEG-6000 was used to simulate drought conditions for 7 days.

Seedling quality

After 7 days of cultivation under drought stress, 15 wheat seedlings with the same growth status were selected in each dish, and their plant height, root length, root number, fresh weight and dry weight were measured.

Estimation of superoxide anion (O_2^-), malondialdehyde (MDA) and anti-oxidant responses

The MDA content and activities of peroxidase (POD), superoxide (SOD) and catalase (CAT) were detected according to the methods of Kong et al. (2017). After MDA reacted with thiobarbituric acid, the absorbance was read at the 532, 600 and 450 nm. The MDA content in the reaction solution was calculated as: MDA content (μmol/L) = 6.45 (OD532 −OD600) − 0.56OD450, and finally expressed as μmol/g FW. POD (EC 1.11.1.7) activity was estimated after the reaction in the solution including enzyme extract (50 μl), 1 ml of 0.3% H_2O_2, 0.95 ml of 0.2% guaiacol, and 1 ml of 50 $mM \cdot l^{-1}$ sodium phosphate buffer (SPB, pH 7.0). One POD unit of enzyme activity was expressed as the absorbance increase by 0.01 (U/g FW) due to guaiacol oxidation. SOD (EC 1.15.1.1) activity was measured by using nitro blue tetrazolium (NBT). In brief, 0.05 ml of an enzyme extract was added into the reaction mixture which contained 1.75 ml of SPB (pH 7.8), 0.3 ml of 130 mM methionine buffer, 0.3 ml of 750 $\mu mol \cdot L^{-1}$ NBT buffer, 0.3 ml of 100 $\mu mol \cdot L^{-1}$ ethylene diamine tetraacetic acid (EDTA)-2Na buffer and 0.3 ml of 20 $\mu mol \cdot L^{-1}$ lactoflavin. After the reaction, the absorbance was recorded at 560 nm. One unit of SOD activity was equal to the volume of the extract needed to cause 50% inhibition of the color reaction. CAT (EC 1.11.1.6) activity was estimated by adding an aliquot of enzyme

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12271236

extract (50 µl) to the reaction solution containing 1 ml of 0.3% H_2O_2 and 1.95 ml of SPB and then the absorbance was read at 240 nm. One CAT unit of enzyme activity was defined as the absorbance decrease by 0.01 (U/g FW). Ascorbate peroxidase (APX, EC 1.11.1.11) activity was estimated by using "APX determination kit" purchased from Nanjing Jiancheng Bioengineering Institute, China (Ashraf et al., 2017). The estimation of superoxide anion (O_2^-) was according to the method of Shah et al. (2001) and the content of O_2^- was expressed as nmol g^{-1} FW.

Estimation of soluble protein, proline, reduced glutathione (GSH) and ascorbic acid (AsA)

The contents of soluble protein and proline were detected according to the methods of Li et al. (2016). In brief, the reaction mixture of 2-ml proline and 4 ml of 1.25% ninhydrin in glacial acetic acid was bathed at 100°C for 30 min, and then the absorbance of the reaction mixture was recorded at 508 nm. Protein concentration was measured based on the standard curve of bovine serum albumin after reaction with Coomassie Brilliant Blue G250 Reagent. The measurement of GSH was described by Ashraf et al. (2018) and the instructions were strictly followed and the absorbance was read at 420 and 412 nm. The determination of AsA was according to Yu et al. (2017). About 0.1 g of fresh flag leaves or endosperms were homogenized in 1 mL 6% trichloroacetic acid (TCA) solution in an ice bath, and the homogenate was centrifuged at 12 000 rpm and 4°C for10 min and the supernatant was used for AsA analysis.

Real-time quantitative RT-PCR

Fresh leaves (0.03 g) were collected for total RNA extraction. Total RNA was extracted using HiPure Plant RNA Mini Kit (Magen, Guangzhou, China). The quality and quantity of RNA was assessed by Nanodrop 2000. The Hiscript II QRT SuperMix for qPCR (+gDNA wiper) (Vazyme, Nanjing, China) was used to synthesize cDNA from 500 ng of total RNA. The following mixtures were prepared in qPCR tubes: 4.4 µl cDNA, 0.2 µl each for forward and reverse primers, 5 µl 2*chamQ SYBR qPCR Master MiX and 0.2 µl ROX reference Dye 1, ddH2O to 20 µl (Vazyme, Nanjing, China). Real-time quantitative RTPCR (qRT-PCR) was conducted in CFX96 real-time PCR System (Bio-Rad, Hercules, CA, USA). Each RNA sample was performed in triplicate. A negative control without cDNA template was always included. Primers used for qRT-PCR were listed in *Table 1*. All primers were designed using the software tool Primer 5.

Statistical analysis

Data were analyzed using statistical software 'Statistix 8.1' (Analytical Software, Tallahassee, FL, USA) while differences amongst means were separated by using least significant difference (LSD) test at 5% probability level. Graphical representation was conducted via Sigma Plot 14.0 (Systat Software Inc., California, USA).

Result

Seedling quality

Analysis of variance showed that foliar application of sodium selenite treatments significantly affected the wheat seedling quality (plant height, root length, root number, fresh weight and dry weight) under drought stress (*Table 2*). Comparing CK, Se1, Se2, Se3 and Se4 treatment all significantly increased plant height of rice seedling for *Zhengmai9023* and *Yangmai20*. The higher root lengths were recorded in Se1, Se2, Se3 and Se4 than CK for both cultivars. Similar trends were also observed in fresh weight and dry weight.

MDA and O_2^- content

Analysis of variance showed that sodium selenite treatments significantly influenced the contents of MDA and O2- in wheat seedling under drought stress (*Figure 1*). For *Zhengmai9023* CK, Se1, Se2, Se3 and Se4 treatments significantly decreased the O_2^- content by 7.47, 6.68, 12.06 and 16.82% while 16.53, 16.67, 20.51 and 22.97% lower MDA contents were recorded in Se1, Se2, Se3 and Se4 than in CK. For *Yangmai20* CK, Se1, Se2, Se3 and Se4 treatments significantly decreased the O_2^- content by 12.33, 16.04, 20.75 and 27.22% while 14.74, 24.30, 26.82 and 35.56% lower MDA contents were recorded in Se1, Se2, Se3 and Se4 than in CK.

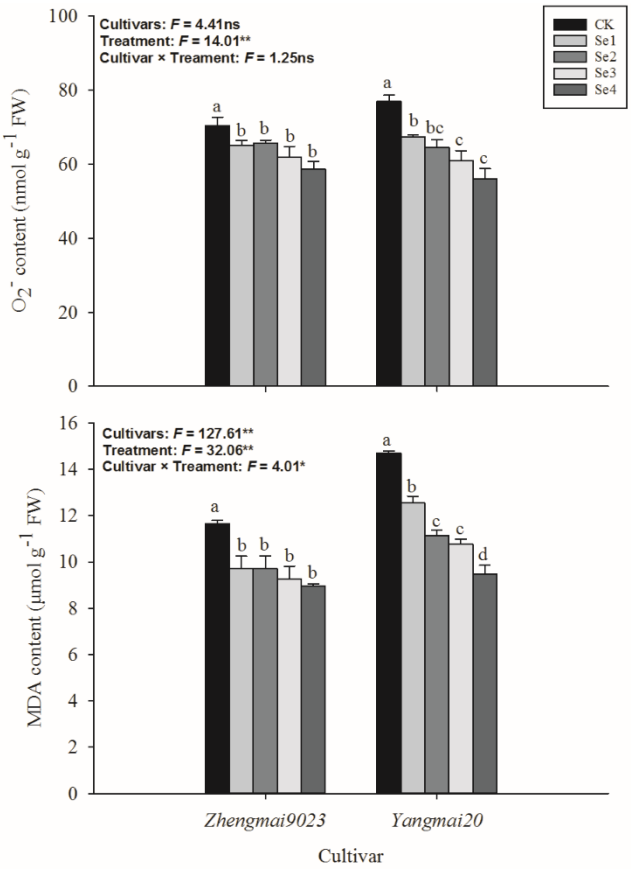

Figure 1. *Effect of exogenous sodium selenite on MDA and O_2^- content of wheat seedling under drought stress (Bars within the same cultivar followed by a different letter are significantly different at $P < 0.05$ probability level)*

Anti-oxidant enzymes activity

As shown in *Figure 2*, foliar application of sodium selenite significantly increased the anti-oxidant enzymes activities of wheat seedling under drought stress. Higher POD activities were recorded in Se1, Se2, Se3 and Se4 treatments than in CK in both cultivars and similar trends were also recorded in SOD activities. For CAT activities, Se1, Se2, Se3 and Se4 all significantly increased CAT activities compared to CK in *Yangmai20* whilst only Se3 and Se4 remarkably increased CAT activities in *Zhengmai9023*. For APX activities, comparing CK, Se2, Se3 and Se4 significantly increased APX activities were observed in Zheng9023 while for Yangmai20, higher APX activities were recorded in Se1, Se2, Se3 and Se4 treatments than in CK.

Osmo-protectants

As shown in analysis of variance, exogenous selenium induced dynamics in soluble protein, proline, GSH and AsA accumulation under drought stress (*Figure 3*). For *Zhengmai9023* CK, Se2, Se3 and Se4 treatments increased the soluble protein, proline, GSH and AsA contents by 10.22-19.93, 6.54-10.98, 13.40-24.92 and 12.32-22.82%, respectively. For *Yangmai20* CK, Se2, Se3 and Se4 treatments increased the soluble protein, proline, GSH and AsA contents by 23.70-25.16, 10.89-26.95, 23.41-23.94 and 21.28-31.15%, respectively.

Real-time PCR analyses

As depicted in *Figure 4*, compared to CK, higher levels of *Plant peroxidase*, *Class Ⅲ peroxidase*, *Glutathione S-transferase* and *Catalase immune-responsive* transcripts were found in Se2, Se3 and Se4 treatments for *Zhengmai9023* and *Yangmai20*.

Discussion

Water is the main limiting factor for wheat growth and yield formation (Li et al., 2015). In recent years, due to climate change, frequent drought weather is one of the main natural disasters affecting wheat production in China (Wang et al., 2014). The tillering and root growth of wheat were mainly carried out at seedling stage and hence, the growth and development of seedling significantly affected the formation of effective panicle and grain number per panicle which are the yield components of wheat. Previous study revealed that drought stress in wheat seedling stage will seriously affect tillering and spikelet differentiation, and ultimately lead to yield reduction (Leilah and Al-Khateeb, 2005). Present study revealed the alleviative effect of Se application on wheat seedling to drought stress in two wheat cultivars. Foliar applications of Se improved the wheat seedling quality under drought stress in terms of plant height, root length, fresh weight and dry weight. This result agreed with the study of Yao et al. (2009b) who indicated that treatments with selenium was able to promote the biomass accumulation of wheat seedlings under drought stress.

When the plant is under drought stress, it will affect the metabolism of reactive oxygen species (ROS) in the plant, leading to the increase of the content of reactive oxygen

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12271236

species in the plant (Kong et al., 2017). A large number of ROS can peroxidise the membrane lipids in plants to produce MDA which can damage the membrane structure of plant cells (Ashraf et al., 2017). Normally, plant itself has an antioxidant enzyme system to reduce the damage of cell membrane lipids in arid environment (Ashraf et al., 2018). Present study observed that foliar application of sodium selenite could regulated the anti-oxidative enzymatic activities in terms of SOD, POD, CAT and APX while reducing the oxidative damage by lowering the MDA and O_2^- production. The increase of O_2^- in plants will lead to the oxidation of polyunsaturated fatty acids, which will lead to the excessive accumulation of MDA. The anti-oxidative enzymes have significant roles in osmo-regulations and often help in maintaining cellular structures and functions under stress condition (Luo et al., 2018). For example, SOD dismutases superoxide radical whereas POD and CAT involved in scavenging H_2O_2 (Pan et al., 2013). In our study, the activities of SOD, POD, CAT and APX in wheat seedlings of two cultivars were significantly increased after applying exogenous selenium (*Figure 2*), and the contents of O_2^- and MDA were decreased (*Figure 1*) under PEG simulated drought stress. On the other hand, Se treatments also induced regulation in proline, soluble protein, GSH and AsA accumulation. Proteins and proline have significant roles in osmo-regulations and often help in maintaining cellular structures and functions while anti-oxidants help to quench ROS (Luo et al., 2018). Previous studies also indicated that both GSH and AsA are the most abundant non-enzymatic anti-oxidants in plants and also provide protection in plant cells from ROS-generated free radicals and serve as redox buffer (Ashraf et al., 2017). The regulations in anti-oxidative enzymatic activities and non-enzymatic antioxidants due to Se applications under drought stress may be attributed to higher levels of transcriptional expression of *Plant peroxidase*, *Class Ⅲ peroxidase*, *Glutathione S-transferase* and *Catalase immune-responsive* genes. Our results indicated that the foliar application of Se in the appropriate concentration could increase the activities of antioxidant enzymes in wheat seedlings, enhance the ability of scavenging active oxygen free radicals and reduce the degree of membrane lipid peroxidation to alleviate the adverse effects of drought stress on crops.

As far as sodium selenite concentration was concerned, the highest activities of antioxidative enzyme and the highest content of osmo-protectants were all recorded in Se2, Se3 and Se4 for both cultivars while the lowest MDA and O_2^- was also recorded in Se2, Se3 and Se4 treatments for both cultivars. Thus, the optimized selenium amendment for wheat seedlings under drought stress might be the foliar application of 20-40 mg L^{-1} sodium selenite.

Conclusion

Foliar application of sodium selenite under drought stress can promote root growth of wheat seedlings, maintain water content and biomass of plant tissues, increase activities of antioxidant enzymes and the contents of osmo-protectants while reducing the content of MDA and O_2^-. Furthermore, the application of sodium selenite under drought stress up-regulated the levels of transcriptional expression in some genes related to anti-oxidative enzyme and osmo-protectants such as *Plant peroxidase*, *Class Ⅲ peroxidase*, *Glutathione S-transferase* and *Catalase immune-responsive*. More field experiments should be conducted in the future.

Abstract. This research was carried out in the multiple-environment trials (MET) which one is in Bayburt (40°24'05.7"N 40°08'31.3"E) where the Black Sea geographical region located in the north of Turkey and in the Kahramanmaras (37°35'24.8"N 36°48'49.4"E) where the Mediterranean geographical region located in the south of Turkey in 2016 and 2017 years. In this investigation, 6 registered pea cultivars (Bolero, Jof, Karina, Nihal, Reyna and Utrillo) and 2 wild pea genotypes (*Pisum sativum* L. subsp. *elatius* and *P. sativum* L. subsp. *sativum*) were used. The variance analysis showed a significant difference among Location (L), genotypes (G), genotypes×locations interaction (GL), genotypes×year interaction (GY), year×location interaction (YL) (all significant at P<0.01 level) and genotype×location×year interaction (GLY) (significant at P<0.05 level) interaction in terms of seed yield. Main effect genotypes (G) is explained 24.42% of total variation. This is followed by 18.78% (L), 17.87% (YL) 7.04% (GL), 4.91% (GY), 2.71% (GLY) and 1.12% (Y), respectively. Graphs were drawn according to the results of GGE biplot analysis and yield data of genotypes were evaluated according to these graphs. In accordance with GGE biplot analysis the seed yield first principal component explained 82.81% of the total variation and second principal component explained 17.19% of the total variation.
Keywords: *multi environment (MET), stability, yield, Pisum sativum*

Introduction

Dry pea cultivation was carried out on 8.141.031 hectare area in the world and it has 16.205.448 tons production and 1990,6 kg/ha yield value. On the other hand green pea cultivation has 2.669.305 hectare area value, 20.699.736 tons production and 7754,7 kg/ha yield value worldwide (FAO, 2018).

Peas are the second most produced legumes in worldwide (FAO, 2018). The number of diploid chromosomes in pea is 14 (Murtaza et al., 2005) and it is a legume crops which origin is near east (Abbo et al., 2017). This region is also the source of wild pea subspecies (Symkal et al., 2015). On the other hand for further pea crop improvement the wild peas are important sources of genetic diversity in climate change context (Symkal et al., 2018).

It is known that Biplot concept started with Descartes. Also Ptolemy used to map cities in ancient times (Gower et al., 2011). Also "Biplot" is a term used by Gabriel (1971), but the first using of biplots in agricultural data was Bradu and Gabriel (1978), as popular versions of variables which were represented by directed vectors and Gower and Hand (1996), emphasized its advantages of biplots with calibrated axes.

DOI: http://dx.doi.org/10.15666/aeer/1801_12371251

Genotype×Environment interaction is complicate source of variation and also makes the selection of genotype(s) difficult (Magari and Kang, 1993). Genotype by environment (GE) interaction may vary according to crops and years (Milligan, 1994). When G×E interaction is statistically significant, its nature, reason and results must be carefully examined (Magari and Kang, 1993). On the other genotype environment interaction is very effective on seed yield to reveal the effectiveness of interaction; trials should have multiple years and multiple locations (Rao et al., 2011; Luo et al., 2015).

It is reported that the best method for revealing Genotype×Environment interaction is GGE-biplot analysis (Samonte et al., 2005; Fan et al., 2007). Using the graphs, GE interaction could be better understandable (Luo et al., 2015). GGE biplot technique has been used by many researchers to determine product performance such as-rapeseed (Shang et al., 2006), peanut (Chen et al., 2009), millet (Zhang et al., 2016), barley (Kendal et al., 2014; Kizilgeci, 2019), oat (Zhang et al., 2010), rice (Sharifi and Motlagh, 2011), sugarcane (Luo et al., 2015), wheat (Akbarzai et al., 2017), maize (Fan et al., 2007), bean (Kang et al., 2006), chickpea (Farshadfar, 2013).

The objectives of the study were to (1) reveal genotype, location, year values, (2) determine genotype by location interaction, (3) determine genotype by year interaction, (4) determine year×location interaction, (5) determine genotype×location×year interaction, (6) reveal the stability of wild and cultivated pea genotypes in Bayburt and Kahramanmaras locations (in northern and southern part of Turkey) via GGE biplot analysis. As a result, more compatible genotypes will be obtained in future breeding studies.

Material and Methods

Research areas

This research was carried out in the multiple-environment trials (MET). The locations were Bayburt/Turkey (Bayburt University, Food and Agriculture and Livestock Application and Research Center area) (40°24'05.7"N 40°08'31.3"E) and Kahramanmaras/Turkey (Kahramanmaras Sutcu Imam University, Field Crops Department Treatment area) (37°35'24.8"N 36°48'49.4"E). The study was conducted at the locations in 2016 and 2017 years. These locations are located in the northern and the southern of Turkey (*Table 1*). Climate data of the research areas are given in *Table 2*. In the research, each plot consists of 5 rows, the distance between rows was 50 cm and the plot length was 5 m, total plot area is determined as 12.5 m^2 and plant density was 40 plant m^{-2}.

Table 1. *Global positions and soil properties of the research areas*

Location	Soil feature	Altitude	Global position
Bayburt	Loamy soil	1650	40°24'05.7"N 40°08'31.3"E
Kahramanmaras	Loamy soil	507	37°35'24.8"N 36°48'49.4"E

Seed materials

Two wild pea genotypes (*Pisum sativum* L. subsp. *elatius* and *P. sativum* L. subsp. *sativum*) in which they were gained from natural vegetation in Turkey and six registered pea cultivars (Bolero, Jof, Karina, Nihal, Reyna and Utrillo) were used and the study

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12371251

was used in the study. The selection criterion was considered to be the genotype that can adapt to both regions.

Before the seed yield was obtained, one row on each side of the plot and 0.5 m from both ends of the plot which was evaluated as side effect were excluded from the evaluation and the central rows harvested by hand, according to Girgel (2013).

*(TSMS, 2019)

Statistical analysis

In the research, for the phenotypic variation, P = E + G + GE formula was used. In the formula, the phenotype P represents the environment, the G genotype, and GE represents the genotype×environment interaction (Yan and Kang, 2003). Also, year and location factors are within environment (E).

In addition to being a multiple-environment trials (MET), the factors could be divided because it was conducted for two years (2016 and 2017). For a more detailed variance analysis (E) is divided year (Y) and location (L) factors also all interactions between G, L and Y factors were evaluated according to Comstock and Moll (1963).

The experiment was established with 3 replications in according to randomized complete block design (RCBD). Statistical analysis was performed with GenStat Release 12.1 (VSN International Ltd.) according to Gomez and Gomez (1984) and Rao (2007). And GGE biplot graphs and analysis was performed according to Gabriel (1971), Yan et al. (2000), Yan and Tinker (2006) and Kang et al. (2006) by using GenStat software (VSNI, 2009).

Results and Discussion

Analysis of variance

In the study, genotype, locaiton, year and their interactions were examined. The variance analysis showed a significant difference among genotypes (G), locations (L), genotypes×location interaction (GL), genotypes×year interaction (GY), year×location interaction (YL) (all significant at P<0.01 level) and genotype×location×year interaction

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12371251

(GLY) (significant at P<0.05 level) in terms of seed yield (*Table 3*). Luo et al. (2015) reports that the factors of genotype, location, year, and all interactions between them were found to be statistically significant. And similar statistical results reported by Kan et al. (2010).

Table 3. *Variance analysis for seed yield of pea genotypes in two years (2016 and 2017) and two locations (Bayburt and Kahramanmaras)*

Source of Variation	DF	SS	MS	F pr.	Exlained (%)

Total	95	100941.5			

DF: Degree of freedom, SS: Sum of square, MS: Mean square, F pr.: Probability

In the investigation, variance analysis showed that the genotypes had greater effect on seed yield than the factors location or year. Genotype, environment and year factors and their interactions explain 76.85% of the total variance (*Table 3*). In here the greatest variance value is due to main effect genotypes (G) and it is explained 24.42% of total variation. This is followed by 18.78% (L), 17.87% (YL) 7.04% (GL), 4.91% (GY), 2.71% (GLY) and 1.12% (Y), respectively. On the other hand, least significant difference statistical groups (LSD) for all measurement interactions and factors were determined with the help of MSTAT-C software package program (v2.10) (MSTAT-C, 1994) (*Table 4*).

Environmental factors and primarily genetic structure are the main factors in determining the phenotype. As a result of the interactions of these factors reveals the amount of seed yield. Yan and Kang (2003) reported that phenotypic variation consists of genotype and environment and their interaction. Sabaghnia et al. (2011) reported that when there are no different locations, the year factor explained the large proportion of the total variation. On the other hand, similar results gained by Noerwijati et al. (2014).

According to GGE biplot analysis results for the seed yield first principal component explained 82.81% of the total variation and second principal component explained 17.19% of the total variation. The PCA (Principle Component Analysis) model based on the GGE biplot explains further variation (Yan and Kang, 2003).

Scatter plot results

According to the scatter plot graph for ranking of locations and genotypes, it can be said that there is almost none correlation the between Bayburt and Kahramanmaraş locations due to the acute angle value is very close to the right angle (*Fig. 1*). In the analysis, the cosine of the angle between vectors shows that correlation between vectors i.e. obtuse angles shows that negative association and acute angle indicate positive association and at right angles there is no relationship between vectors (Yan, 2014; Dallo et al., 2019).

** 1. Bolero, 2. Jof, 3. Karina, 4. Nihal, 5. Reyna, 6. ssp. sativum, 7. ssp. elatius, 8. Utrillo

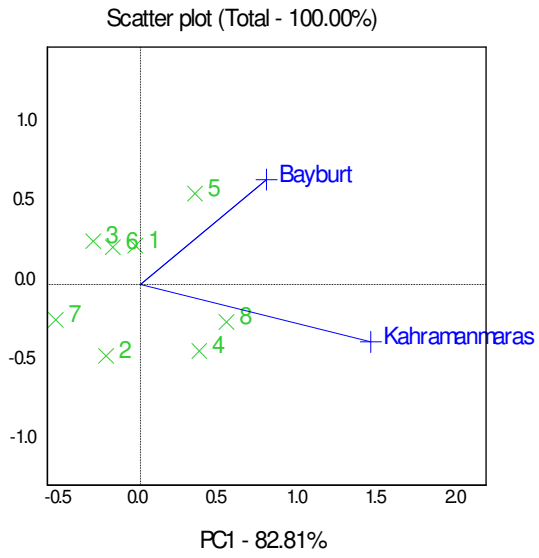

Figure 1. *GGE scatter biplot graph shows that ranking of genotypes over the environments (x: shows wild and cultivated genotype scores and +: shows environment scores) (1.Bolero, 2.Jof, 3.Karina, 4.Nihal, 5.Reyna, 6.ssp.sativum, 7.ssp.elatius, 8.Utrillo)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12371251

Narrow angle, indicates a correlation between genotypes. Similar opinions have been reported by Yan (2002) and Kang et al. (2006). Utrillo cv. was found to be most yielding genotype but *Pisum sativum* subsp. *elatius* was determined as the lowest yielding but the most stable genotype.

In terms of the years the first principal components (PC1) and second principal components (PC2) of the seed yield accounted as 87.65 and 12.35, respectively (*Fig. 2*). The years was similar to each other due to the narrow angle and there is a very small amount positive correlation. In other words, the conditions of the years are similar. It is reported that in such graphs, there is a correlation between the parameters examined when there is a narrow angle (Yan, 2002).

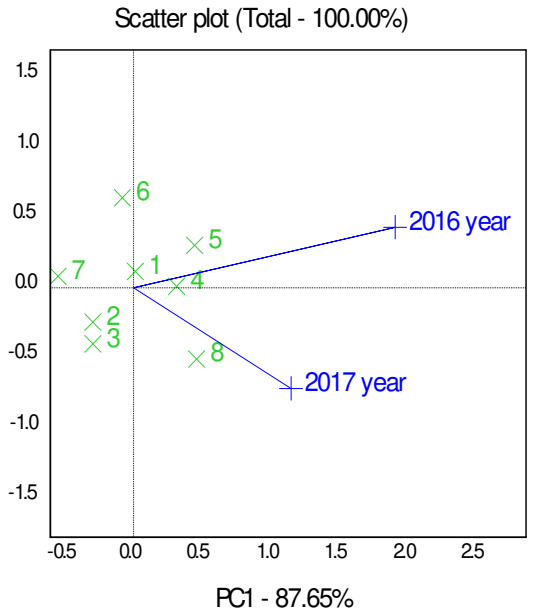

Figure 2. *GGE scatter biplot graph shows that ranking of genotypes over the years (x: shows wild and cultivated genotype scores and +: shows year scores) (1.Bolero, 2.Jof, 3.Karina, 4.Nihal, 5.Reyna, 6.ssp.sativum, 7.ssp.elatius, 8.Utrillo)*

Pea plants showed better adaptation under the first year environmental conditions and the first year point was close to the stability line than second year. On the other hand, the Nihal variety was determined as the genotype closest to the stability line (*Fig. 2*). Snoad and Arthur (1974), point out that repeated trials for many years reveal genotype-environment interaction in a more understandable way.

According to polygonal Genotype×Environment interaction scatter biplot graph, under the conditions of Kahramanmaras, Utrillo genotype is environmentally compatible and under the Bayburt conditions, Reyna and bolero genotypes are located in the same sectors and emerged as high performance varieties that are compatible with this environment (*Fig. 3*). Genotype×Environment interaction is very important for genotype selection and therefore, repeating the experiments at different years and locations provides accurate genotypic results. Similar opinions reported by Weber et al. (1996). On the other hand, Yan and Kang (2003) recommended a biplot polygon graph to better understanding the genotype environment interaction.

According to polygonal Genotype×Year interaction scatter biplot graph, in the first year Reyna and Nihal, in the second year, Utrillo and Nihal varieties appeared as the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12371251

highest performance genotypes (*Fig. 4*). In the graph, the polygon was divided into 5 parts and the years had taken place in different sections. As a rule, polygon edges and axes were at right angles to each other. If the locations are not taken into consideration, in terms of years, the cv. Bolero was located at the center of the axis in the graph and had been the least affected by the environmental conditions of that year. However, this genotype had less seed yield. On the other hand, cv. Nihal was determined to be stable regardless of locations and it had higher seed yield from cv. Bolero.

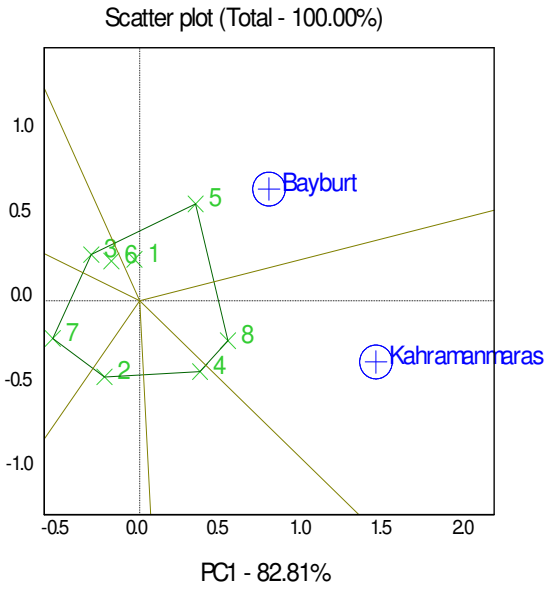

Figure 3. *Polygon graph of Genotype×Environment interaction for genotypes over the environments (x: shows wild and cultivated genotype scores and +: shows environment scores) (1.Bolero, 2.Jof, 3.Karina, 4.Nihal, 5.Reyna, 6.ssp.sativum, 7.ssp.elatius, 8.Utrillo)*

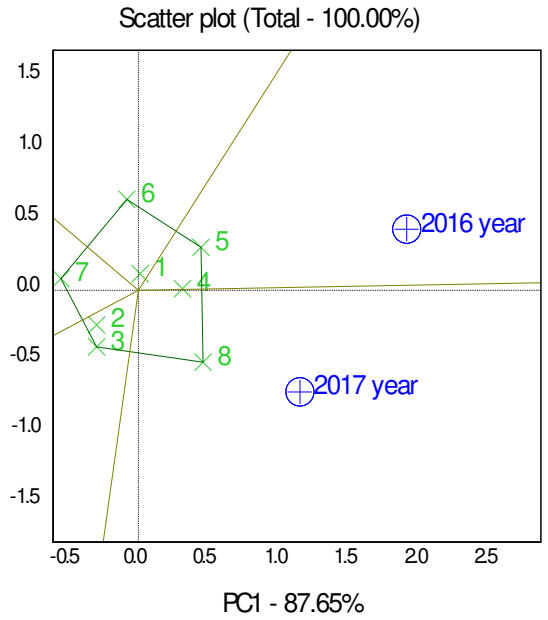

Figure 4. *Polygon graph of Genotype×Year interaction for genotypes over the years (x: shows wild and cultivated genotype scores and +: shows year scores)*

DOI: http://dx.doi.org/10.15666/aeer/1801_12371251

Ranking biplot results

GGE ranking biplot graph shows the status of genotypes by Bayburt location (*Fig. 5*). In the graph a line representing the province of Bayburt was drawn through the biplot origin and another a line perpendicular to the Bayburt axis was drawn from each genotype. The Bayburt line represented the axis for the Bayburt province. Yan and Tinker (2006) reported that the seed yield in the direction of the arrow increases and genotypes closer to the arrow line are more stable. When the GGE ranking biplot graph was examined, Reyna variety showed the highest performance in Bayburt province, followed by Utrillo variety, but it was found that Reyna, which is close to the axis in terms of stability, was more convenient (*Fig. 5*).

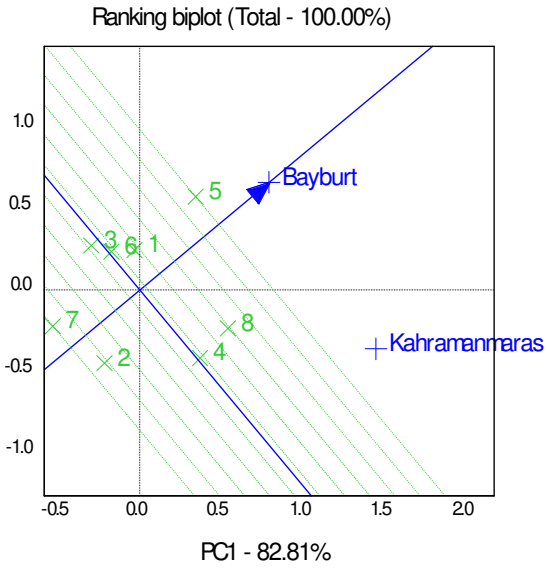

Figure 5. *GGE ranking biplot graph showed according to Bayburt province the ranking of the genotypes yield (x: shows wild and cultivated genotype scores and +: shows environment scores) (1.Bolero, 2.Jof, 3.Karina, 4.Nihal, 5.Reyna, 6.ssp.sativum, 7.ssp.elatius, 8.Utrillo)*

In the GGE ranking biplot graph the Kahramanmaras line represented the axis for the Kahramanmaras province. Yan and Tinker (2006) pointed that the seed yield in the direction of the arrow increases and genotypes closer to the arrow line are more stable. When the GGE ranking biplot graph was examined, under the Kahramanmaraş conditions, the Utrillo variety was determined as highest seed yield and the most stable genotype in terms of seed yield (*Fig. 6*).

Comparison biplot results

By using the ideal environment as the center in order to visualize the distance between Bayburt and Kahramanmaras locations concentric circles were drawn (Yan et al., 2000; Yan and Rajcan, 2002).

The comparison biplot graph assumes that the province of Bayburt has ideal environmental conditions and draws from the center towards the outer ring suitability for genotypes. Concentric circles were drawn so that the ideal environment is in the center (Yan et al., 2000; Yan and Rajcan, 2002). Bayburt ecological conditions were considered as an ideal environment; Reyna variety was found to be most suitable. In

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12371251

addition, Bolero and Utrillo varieties and wild genotype *Pisum sativum* subsp. *sativum* can be evaluated. Jof cultivar and *Pisum sativum* subsp. *elatius* wild cultivar were not suitable for the region (*Fig. 7*). Our results are in agreement with other observational study of Yihunie and Gesesse (2018).

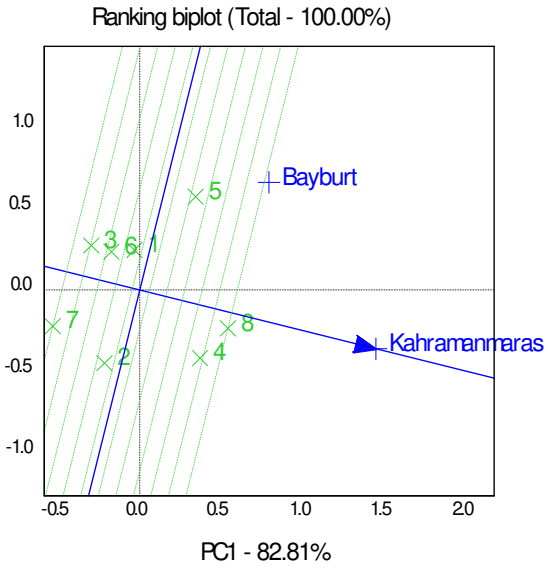

Figure 6. *GGE ranking biplot graph shows according to Kahramanmaras province the ranking of the genotypes yield (x: shows wild and cultivated genotype scores and +: shows environment scores) (1.Bolero, 2.Jof, 3.Karina, 4.Nihal, 5.Reyna, 6.ssp.sativum, 7.ssp.elatius, 8.Utrillo)*

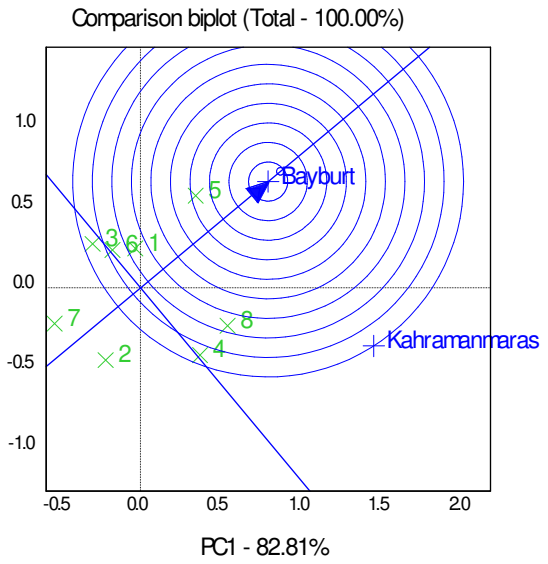

Figure 7. *GGE Comparison biplot graph shows the ranking of the genotypes as an ideal environment Bayburt province (x: shows wild and cultivated genotype scores and +: shows environment scores) (1.Bolero, 2.Jof, 3.Karina, 4.Nihal, 5.Reyna, 6.ssp.sativum, 7.ssp.elatius, 8.Utrillo)*

Kahramanmaras as the ideal environment according to the comparison biplot graph, Utrillo and Nihal varieties are found to be appropriate (*Fig. 8*). The rings moving away

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12371251

from the center of Kahramanmaras in the comparison biplot graph show that the genotype is less suitable for the province.

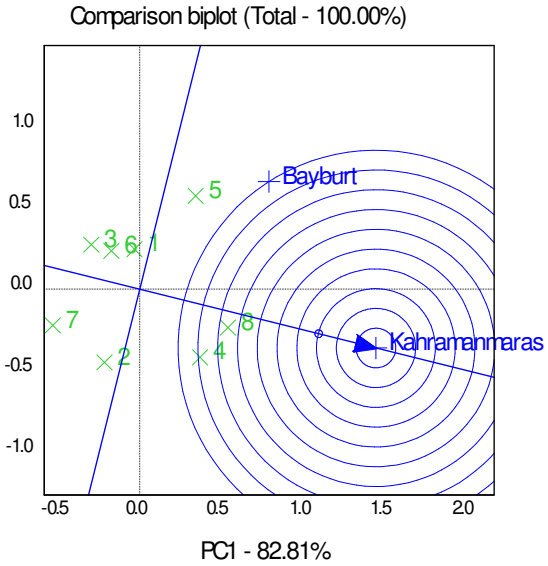

Figure 8. *GGE Comparison biplot graph shows the ranking of the genotypes as an ideal environment Kahramanmaras province (x: shows wild and cultivated genotype scores and +: shows environment scores) (1.Bolero, 2.Jof, 3.Karina, 4.Nihal, 5.Reyna, 6.ssp.sativum, 7.ssp.elatius, 8.Utrillo)*

Joint biplot results

When the provinces were evaluated together according to the joint biplot graph, it was determined that Utrillo was a more stable variety on the other hand Reyna showed higher yield differences (*Fig. 9*).

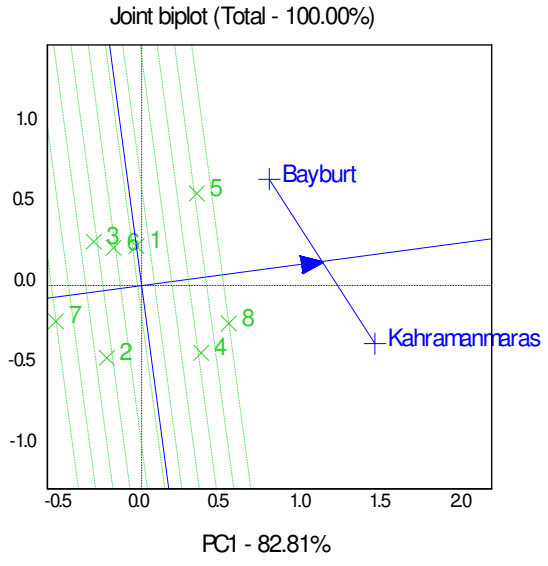

Figure 9. *GGE Joint biplot graph shows stability of genotypes according to evaluation of two provinces (x: shows wild and cultivated genotype scores and +: shows environment scores) (1.Bolero, 2.Jof, 3.Karina, 4.Nihal, 5.Reyna, 6.ssp.sativum, 7.ssp.elatius, 8.Utrillo)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12371251

Two genotype or two locations can be visually compared by connecting them with a linear line in a GGE biplot (Yan and Tinker, 2006). When the two provinces are evaluated together, the yield ranking of the varieties is as follows; Utrillo > Reyna > Nihal > Bolero > *Pisum sativum* subsp. *sativum* > Karina > Jof > *Pisum sativum* subsp. *elatius*. However, Reyna Jof and Nihal varieties were located further away from the stability line.

Considering the biplot graph based on an average of two years, genotypes showed as follows ranking; Utrillo > Reyna > Nihal > Bolero > *Pisum sativum* subsp. *sativum* > Karina > Jof > *Pisum sativum* subs. *elatius* (*Fig. 10*). Subsp. *sativum* was the closest wild species to the cultivars, so yield levels were higher than some cultivars. Nihal, *Pisum sativum* subsp *elatius* ve Bolero genotypes were determined to be highly stable, regardless of locations, according to two year averages. Repeated trials for many years reveal GEI in a more understandable way (Snoad and Arthur, 1974).

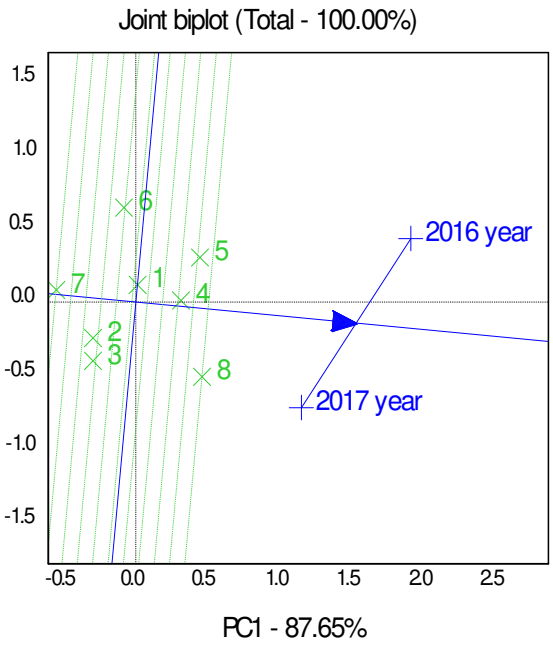

Figure 10. *GGE Joint biplot graph shows stability of genotypes according to evaluation of two years (2016 and 2017) (x: shows wild and cultivated genotype scores and +: shows year scores) (1.Bolero, 2.Jof, 3.Karina, 4.Nihal, 5.Reyna, 6.ssp.sativum, 7.ssp.elatius, 8.Utrillo)*

Environment-centered data results

According to environment-centered data graphs, when two locations were taken into consideration, Utrillo, Jof, Nihal performed better in Kahramanmaras, while Reyna, Bolero, *Pisum sativum* L. subsp. *sativum*, Karina and *Pisum sativum* L. subsp. *elatius* had better performance in Bayburt province (*Fig. 11*). Subsp.*sativum* was the closest wild species to the cultivars, so yield levels were higher than some cultivars. To select superior genotypes and increase efficiency in selection, the biplot analysis is a good method (Dallo et al., 2019).

DOI: http://dx.doi.org/10.15666/aeer/1801_12371251

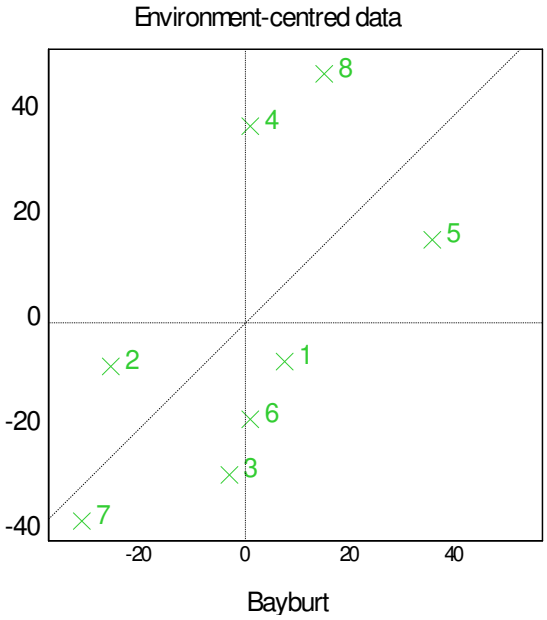

Figure 11. *Environment-centered data graph shows that sorting genotypes by environment (x: shows wild and cultivated genotype scores) (The right side of the diagonal represents Bayburt province and the left side of the diagonal represents Kahramanmaras province) (1.Bolero, 2.Jof, 3.Karina, 4.Nihal, 5.Reyna, 6.ssp.sativum, 7.ssp.elatius, 8.Utrillo)*

Conclusion

Biplot analysis is an important technique in crop improvement and agricultural research. GGE biplot is an appropriate method for genotype selection and data analysis for agronomists, geneticists and breeders of the plant.

According to variance analysis main effect genotypes (G) explained 24.42%, main effect locations 18.78% (L) and main effect year 1.12% (Y). On the other hand, year×location interaction explained 17.87% (YL) of total variation and it is followed by other interactions 7.04% (GY), 4.91% (GY), 2.71% (GLY) and respectively.

According to GGE biplot analysis results for the seed yield first principal component explained 82.81% of the total variation and second principal component explained 17.19% of the total variation.

In Bayburt province Reyna cultivar was highest yielding and most stable genotype, in Kahramanmaras province Utrillo cv. highest yielding and most stable genotype. When evaluated together for two years, ranking of the wild and cultivated pea genotypes such as Utrillo > Reyna > Nihal > Bolero > *Pisum sativum* subsp. *sativum* > Carina > Jof > subsp. *elatius*. Considering the two-year results obtained from Bayburt and Kahramanmaras, ranking of the genotypes such as Utrillo > Reyna > Nihal > Bolero > *Pisum sativum* subsp. *sativum* > Carina > Jof > *Pisum sativum* subsp. *elatius*.

According to all these results, it would be more appropriate to use Utrillo variety. On the other hand, wild genotype *Pisum sativum* subsp. *sativum* has higher seed yield from some standard varieties (Karina and Jof) and as an important result it can be used to provide gene in breeding studies.

(Received 19th Aug 2019; accepted 25th Nov 2019)

Abstract. This study investigated the distribution of heavy metals in the soil layer from 0 to 30 cm in the Yellow River beaches of Hancheng, Heyang and Tongguan section, China. The results showed that: (1) In the soil of the study area, the average Zn content was highest, and the average contents of As and Cd were lowest. Except for Ni, the coefficient of variation of other heavy metals is relatively large. (2) Pb and Cd of Hancheng beach showed significant positive correlations between Cr and Cu ($p < 0.01$). The correlations among Cr-Cd, Pb-Ni, Zn-Cr, and Zn-Cu of Tongguan beach were significant ($p < 0.01$). (3) Single factor pollution index and Nemero pollution index identified a certain degree of Zn pollution in the soil of Hancheng beach, and the overall heavy metal content of the soil of both Heyang and Tongguan beaches reached the level I safety level. (4) According to the Hakanson potential ecological hazard index, the average potential ecological risk index of the soil in the study area is 83.36 < 135. The comprehensive potential risk of soil in different river sections follows: Hancheng > Heyang > Tongguan.
Keywords: *heavy metal pollution, floodplain, pollution assessment, soil*

Introduction

Over recent years, due to the rapid development of mining and transportation industries, compound pollution of inorganic and organic pollutants has gradually intensified (Chakraborty and Das, 2016). Especially in coastal areas, soil heavy metal pollution is gradually appearing. Due to the persistence and high toxicity of heavy metals in soil, the ecotoxicological risks induced by heavy metals have been gradually received increasing attention (Mi et al., 2015; Fan et al., 2019; Li et al., 2017). The problems of soil environmental quality and soil environmental safety related to agriculture have received particular attention (Crnkovic et al., 2006; Douay et al., 2007; Tume et al., 2008). All countries conducted research on the distribution laws of heavy metals in soil, their migration characteristics, enrichment characteristics, their forms, and phytoremediation. Starting from the idea of soil organic reconstruction,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12531265

Shaanxi Land Engineering Construction Group carry out soil heavy metal repair by the means of the soil materials and soil structure, and achieved notable results. At present, research on heavy metals in soils mainly explores their migration, transformation, enrichment, morphology, and bioremediation. The study area is dominated by farmland, urban land, and mining areas; however, river beaches and wetlands have not received sufficient attention (Islam et al., 2015; Fan et al., 2008; Li et al., 2015; Cheng et al., 2012).

The Yellow River Hancheng to Tongguan section is located at the junction between central Shaanxi and southern Shanxi, and is commonly known as the Xiaobei River, with a total length of 132.5 km. It forms an important section that integrates natural resources, humanities, agriculture, water resources, and tourism resources. This study focused on the distribution of heavy metals in the Yellow River beaches, beginning at the Hancheng-Tongguan section of the Yellow River. The sampling points include three regions, they are Xiayukou of Hancheng, Bailiang of Heyang and Qindong of Tongguan, Shannxi, China. The risk and harm for the ecological protection of the Yellow River beaches and the development and utilization of the Yellow River beaches were investigated. The results of this study have practical significance for the alleviation of heavy metal pollution in this region.

Materials and methods

Description of the research area

The section between Hancheng and Tongguan in the Yellow River is located at the junction between central Shaanxi and southern Shanxi. To the west of the Yellow River, Hancheng, Heyang, and Tongguan are located, and Hejin and Yongji in Shanxi Province form the main areas to the east of the Yellow River. The project covers a total length of 132.5 km from Yumenkou to the Tongguan Railway Bridge on the west bank of the Yellow River. It includes four cities and counties, such as Hancheng, Heyang, Dali, and Tongguan in Weinan City, as well as 12 towns and 54 administrative villages with a total population of 57,500. Sampling points of Hangcheng range between 110°5’50”-108° 36’29” E and 34°36’59”-35°39’34” N; sampling points of Heyang range between 109°58′33″-110°27′00″ E and 34°59′16″-35°26′07″ N; sampling points of Tongguan range between 110°09′13″-110°25′26″ E and 34°23′38″-34°40′17″ N (*Fig. 1*).

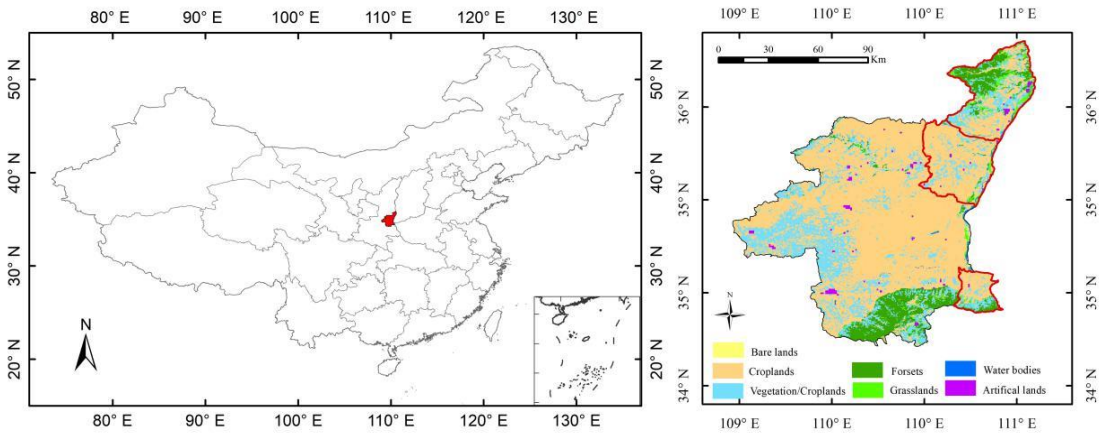

Figure 1. *The sample distribution from Hancheng to Heyang*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12531265

The study area has a warm temperate semi-humid and semi-arid monsoon climate, with four seasons. The frost-free period lasts 199-255 days, and the area has a changing spring climate, with hot and rainy summers, cool autumns, and dry and sunny winters. The average annual temperature is 12-14 °C, the annual rainfall is 600 mm, and the sun shines for 2200-2500 h annually. Climatic conditions are conducive to the development of agriculture; however, droughts, autumn floods, and dry and hot summer winds are more harmful for crops. *Figure 2* shows the average temperature and precipitation for each month. The economy of this region is mainly based on agricultural production and transportation hubs.

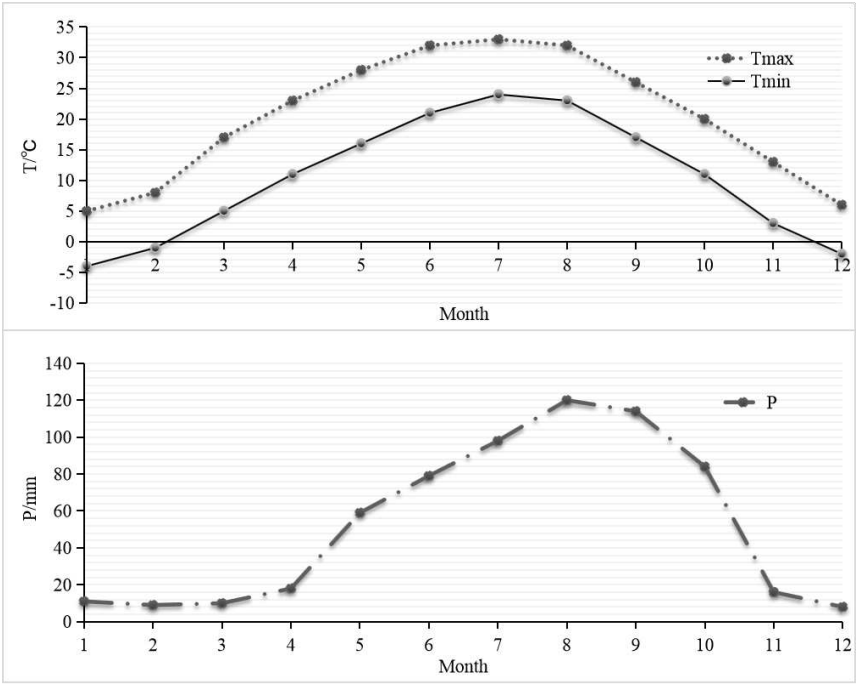

Figure 2. *An average temperature and rainfall in the study area from January to December of the year 2016 (Tmax, Tmin and P are represent the an average maximum temperature, anaverage minimum temperature and precipitation of every month)*

Sample collection

Soil samples were collected in May 2016. Sampling spots were distributed throughout Hancheng, Heyang, and Tongguan Yellow River floodplains and were collected from the Yellow River beach 0-30 cm surface soil layer. 300 samples were collected, 120 of which were collected from the Xiayukou in Hancheng section of the Yellow River. 80 samples were collected from Bailiang Town in Heyang. 100 samples were collected from Tongguan; the sampling point distribution is shown in *Figure 1*.

Each sample is a mixture of five points and consists of mixed samples. At each sampling spot, approximately 1 kg of soil was taken, stored in a sample bag, and returned to the laboratory to determine heavy metals in the soil.

Sample processing and determination

The soil samples (50 g) were air-dried, debris was removed, and samples were ground through a 0.149 mm nylon mesh (Hu et al., 2014; Xu et al., 2014). The soil total

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12531265

Pb-Zn was determined according to GB/T 17141-1997, "Determination of Pb and Cd in Soil Quality: Graphite Furnace Atomic Absorption Spectrometry" (GB/T-22105.1-2008), "Determination of Cr: Flame atomic absorption spectrophotometry" (HJ 491-2009), "Determination of soil quality Ni: Flame atomic absorption spectrophotometry" (GB/T 17139-1997), "Determination of soil quality of Cu, Zn: Flame atomic absorption spectrophotometry" (GB/T 17138-1997), "Determination of total mercury in soil quality, total As, total Pb by atomic fluorescence spectrometry Part 1: Determination of total mercury in soil" (GB/T 22105.1-2008), and "Determination of total mercury, total As and total Pb in soil quality: atomic fluorescence spectrometry Part 2: Determination of total As in soil" (GB/T 22105.2-2008). The pH was determined potentiometrically and the heavy metal contents in soils were determined by Inductively Coupled Plasma-Mass Spectrometry (ICP-MS).

Hakanson potential ecological risk index

This study used the Hakanson potential ecological risk index method (Hakanson, 1980) to evaluate the degree of heavy metal risk in the soils of Yellow River beaches. The equations are as follows:

$$C_f^i = \frac{C^i}{C_n^i} \quad \text{(Eq.1)}$$

$$E_r^i = T_r^i \times C_f^i \quad \text{(Eq.2)}$$

$$RI = \sum_{i=1}^{m} E_r^i \quad \text{(Eq.3)}$$

where C_f^i represents the individual pollution coefficient, C^i represents the actual content of pollutant i in the soil sample, and C_n^i represents the reference value of pollutant i. E_r^i represents the single potential ecological risk index of pollutant i, in which T_r^i represents the toxicity coefficient of pollutant i, and RI represents the potential ecological risk index. E_r^i and RI can be used to evaluate the degree of the potential ecological risk of single pollutants and multiple pollutants, respectively. *Tables 1, 2,* and *3* are the toxicity coefficients of pollutants, the potential ecological risk classification criteria according to Hankanson, and the grading standards, respectively.

Results

Descriptive statistics of the data

According to the national soil environmental quality standard (GB 15618-2018), the soil environmental quality was divided into three grades (Yuan et al., 2008) (*Table 4*). As an important section of the middle and lower reaches of the Yellow River, the Hancheng-Tongguan section forms an important demarcation line between Shaanxi Province and Shanxi Province. A wide range of agricultural cultivation areas are distributed throughout both sides of the Yellow River. The environmental quality of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12531265

Yellow River soil is directly related to the broad masses. In addition, the Yellow River beach area also forms a very important wetland system in this region. Therefore, this study used the soil background value of Grade I standard of the national soil environmental quality standard to evaluate the soil of the Yellow River beach land. The main evaluation index includes As, Ni, Pb, Cd, Cr, Cu, and Zn.

Descriptive statistical analysis of the heavy metals As, Hg, Pb, Cr, Cd, Cu, and Zn in soils from the Hancheng to Tongguan section of the Yellow River (*Table 5*) showed that the mean value of Zn was highest in the Yellow River beach soil, which was followed by Cr, and the average value of Cd was lowest. The average level of Cr was highest in Heyang and Tongguan, where the average Cd was lowest. Coefficients of variation of heavy metals of Hancheng exceeded 10%. Coefficients of variation for heavy metals such as Cr, Cu, Zn, and Ni were highest in Heyang and Tongguan. The sources of soil heavy metal pollution are very complex and other sources may add

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12531265

pollution based on the siltation of the Yellow River beach soil. The status of heavy metal pollution in this soil is similar in that of the section of Heyang and Tongguan. As, Pb, Cd, and other heavy metals have a small variation coefficient, which may be mainly related to the formation and deposition of soils on the Yellow River beaches. Heavy metal elements such as Cr, Cu, Zn, and Ni may be affected by other sources of pollution. Among these, the coefficient of variation of Cu was highest in all reaches. The coefficient of variation of Cu was 40.1% in the lower reaches of Hancheng, the coefficient of variation of Cu in Heyang was 49.4%, and the coefficient of variation of Cu in Tongguan was 56.9%. Although the average content of Cu met the national standard, the Cu content of several samples reached the national standard. This shows that Cu in the Yellow River beach soil is particularly affected by external disturbances. The main origin may lie in the heavy use of pesticides and the emission of smelting gases around the Yellow River. The study area is located at the junction between Shaanxi, Shanxi, and Henan provinces, where the main modes of transportation include cars and trains, especially large trucks, according to the data on the official website of 12306 (the official website of China Railway), there are more than 40 trains through this area, which introduce a significant volume of tail gases and heavy metal pollution. The main pesticides used include *butacarb*, *bensultap*, *bismerthiazol*, *bromacil*, and *2,4,5-TB*. Farmers use these pesticides about two to three times every year to reduce pests and weeds. Furthermore, this area features a large number of coal and gold mines, which also introduce severe heavy metal pollution, such as Pb, Cd, and Hg.

Table 5 and *Figure 3* show that the As content in the soils of the Yellow River Hancheng to Tongguan section ranged within 3.4-12.8 $mg \cdot kg^{-1}$, with an average content of 9.0 $mg \cdot kg^{-1}$. The As content in the soil of the floodplain in various regions follows a distribution of Heyang > Tongguan > Hancheng. The As content of the river beaches of Heyang was highest, with an average of 11.1 $mg \cdot kg^{-1}$, and lowest in Hancheng. As content in the soil of the floodplain of Tongguan is more than Hancheng significantly ($p < 0.05$). The soil As content in the estuary was 5.8 $mg \cdot kg^{-1}$. These results showed that the average As content in the floodplain of the Yellow River Hancheng to Tongguan section remained below the national soil environmental quality standard.

The Pb level in the soil of the Yellow River Hancheng to Tongguan section was 7.0-27.6 $mg \cdot kg^{-1}$, at an average content of 18.8 $mg \cdot kg^{-1}$. The average Pb content in the soil of the Yellow River beach in Hancheng was significantly lower compared with the whole area ($p < 0.05$). Here, the average content was 12.4 $mg \cdot kg^{-1}$, and the average Pb content of the soil in the Yellow River beaches of Heyang County and Tongguan County were 23.5 $mg \cdot kg^{-1}$ and 23 $mg \cdot kg^{-1}$, respectively. However, the value was lower than that of the first-level standard for soil environmental quality. These levels remain below the national first-level standard for soil environmental quality.

The Cd content in the soil of the Yellow River Hancheng to Tongguan section was 0.1-0.5 $mg \cdot kg^{-1}$, with an average of 0.2 $mg \cdot kg^{-1}$. The Cd content in the floodplains of each region can be ordered according to: Hancheng > Heyang and Tongguan. Cd content in the soil of the floodplain of Hancheng is more than Heyang and Tongguan significantly ($p < 0.05$). The average Cd content in the Yellow River beach in Hancheng was 0.3 $mg \cdot kg^{-1}$, which basically met the national secondary standard for soil environmental quality.

The Cr content in the soil of the Yellow River Hancheng to Tongguan section was 23.9-120.0 $mg \cdot kg^{-1}$, with an average of 58.4 $mg \cdot kg^{-1}$. The average content of Cr in the Yellow River beach of Hancheng was lowest at 55.8 $mg \cdot kg^{-1}$ and the Cr content in the Yellow River beach of Tongguan County was highest, with an average value of 62.5 $mg \cdot kg^{-1}$. Both levels remain far below the national first-level standard for soil environmental quality.

The Cu content in the soil of the Yellow River Hancheng to Tongguan section was 10.1-76.2 $mg \cdot kg^{-1}$, with an average of 30.3 $mg \cdot kg^{-1}$. The Cu content in the soil of Hancheng was about twice as high as that of Heyang and Tongguan ($p < 0.05$), with an average value of 43.7 $mg \cdot kg^{-1}$. This exceeds the national first-level standard for soil environmental quality.

The Zn content in the soil of the Yellow River Hancheng to Tongguan section was 32.7-307.8 $mg \cdot kg^{-1}$, with an average of 137.3 $mg \cdot kg^{-1}$. The Zn content in the soil of the Yellow River beach in Hancheng was highest, reaching 265.8 $mg \cdot kg^{-1}$, which slightly exceeded the national secondary standards for soil environmental quality.

The Ni content in the soil of the Yellow River Hancheng to Tongguan section was 17.3-52.6 $mg \cdot kg^{-1}$, with an average content of 33.2 $mg \cdot kg^{-1}$. The Ni content in the soil of each region followed: Hancheng > Tongguan > Heyang. Ni content in the soil of the floodplain of Hancheng is more than Tongguan significantly ($p < 0.05$), while Ni content of Tongguan and Heyang is not significantly ($p > 0.05$). The average Ni content in the soil of the Yellow River beach in Hancheng was 41.2 $mg \cdot kg^{-1}$, which exceeds the national first-level standard for soil environmental quality.

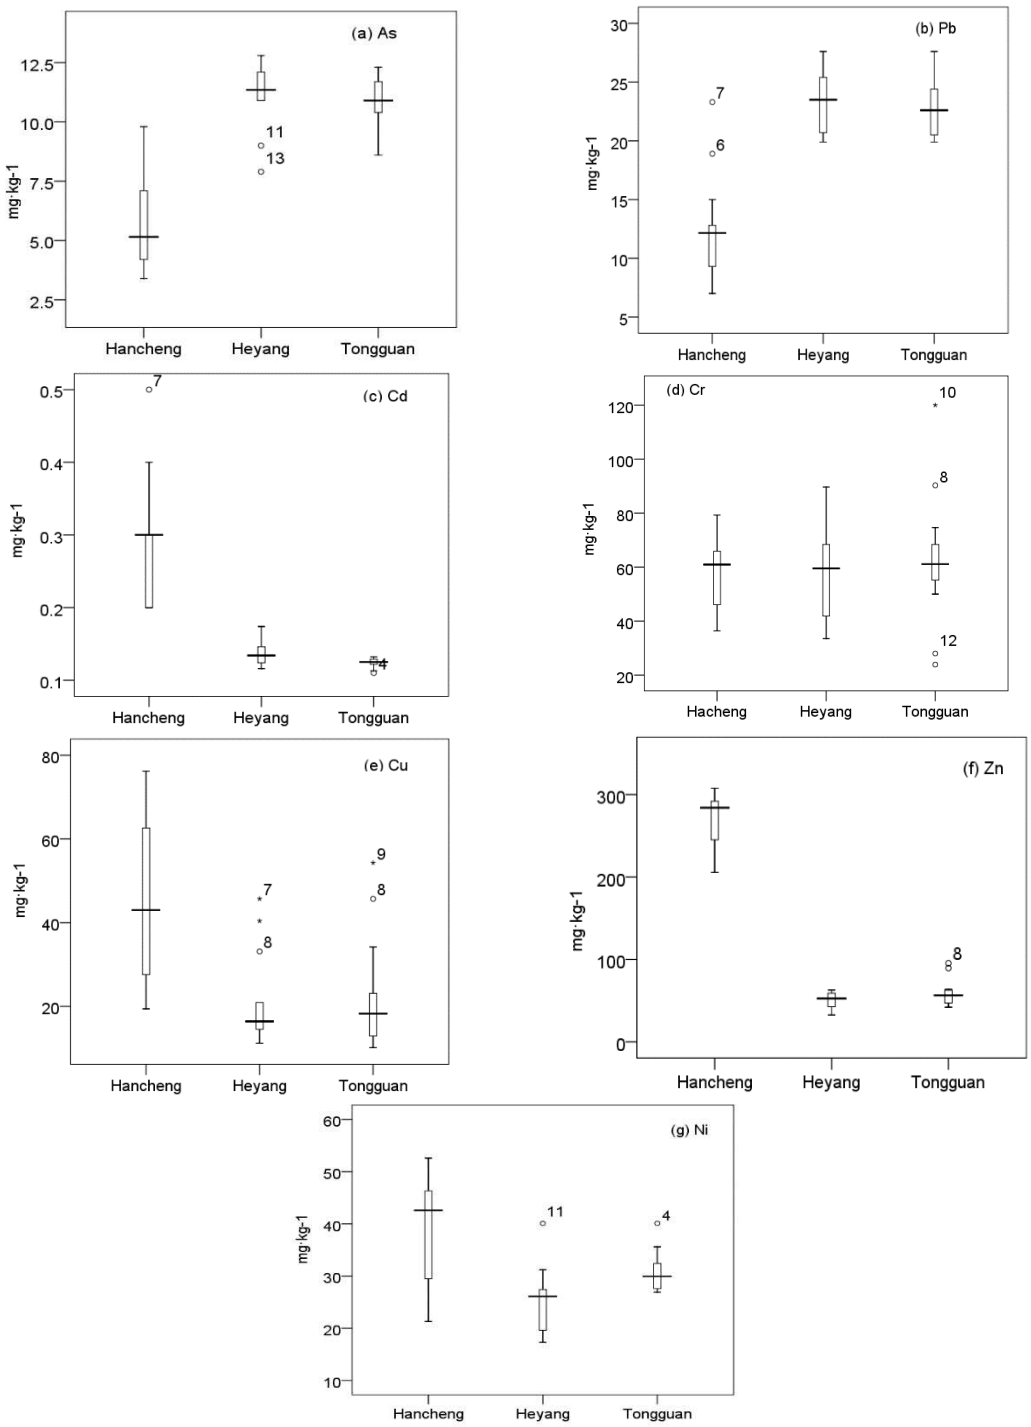

Figure 3. *Boxplots of heavy metals concentration in the Yellow River region between Hancheng to Tongguan*

Discussion

Correlation analysis of soil heavy metals

Correlation analysis of the soil heavy metal contents in the floodplain from Hancheng to Tongguan section of the Yellow River identified Pb, Cd, Cr, and Cu in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12531265

soils of the Yellow River beach at the Lower Xiayukou section of Hancheng (*Table 6*). A significant positive correlation was found between heavy metals ($p < 0.01$), indicating that these heavy metals have similar sources, which may mainly originate from the region's automobile exhaust and large-scale pesticide use. The correlation between Cr, Cd, Pb-Ni, Zn-Cr, Zn-Cu, and other heavy metals was significant ($p < 0.01$) in the Yellow River beach of Tongguan. This is likely due to the large-scale gold development in Tongguan.

Soil ecological risk assessment of heavy metals

The results of *Equations 1–3* were calculated for each heavy metal, and the values are listed in *Table 7*. With regard to the average single pollution coefficient of heavy metals, the soil of Hancheng had strong Zn pollution. Cd, Cu, and Ni caused moderate pollution, and other elements caused slight pollution. The pollution degree of the heavy metals followed Zn > Cd > Cu > Ni > Cr > As > Pb. As shown in *Table 8,* the percentage of samples with strong Zn pollution in soil reached 100%, the percentage of samples with strongly contaminated soil Cd was 11.11%, and 88.89% of samples were moderately contaminated. With regard to the single potential ecological risk index of heavy metals, the potential ecological risk of Cd in the soil of Hancheng in the Yellow River reached a strong level (=80), while the ecological potential risks of other heavy metal elements were slight. The contribution of Cd to the potential ecological risk of heavy metals reached as high as 50%, which therefore is the heavy metal with the most

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12531265

important ecological risk. This is consistent with the study of Yuan et al. (2008), Ye et al. (2010) and Davidson et al. (1994). The order of the ecological hazards of heavy metals followed Cd > Cu > Ni > As > Zn > Pb > Cr.

Table 7 shows the average individual pollution coefficients of heavy metals. Cd, As, and Pb in Heyang cause moderate pollution, and soil was slightly polluted with other heavy metals. Their degree of pollution followed Cd > As > Pb > Cr > Ni > Cu > Zn. As shown in *Table 8,* 100% of Cd reached a moderate level of pollution, and the percentages of samples with moderate pollution of As and Pb were 85.71% and 64.29%, respectively. With regard to the average single potential ecological risk index of heavy metals in soils (*Tables 7* and *8*), all heavy metals in the soils of riverside beaches in Heyang, except for medium pollution (=41.08), reached a contribution rate of Cd to soil potential ecological risk in the floodplain of Heyang of 100%.

With regard to the average individual pollution coefficient of heavy metals, the contents of Cd, As, Pb, Ni, and other elements in the soil of Yellow River beach in Tongguan caused moderate pollution. The contents of heavy metals in other soils caused slight pollution. The levels follow Cd, As, Pb > Cr > Ni > Cr > Zn > Cu. This is similar to the heavy metal pollution in the soil of the Yellow River beach in Heyang. The average single potential ecological risk index of heavy metals in Tonglian and Heyang followed a similar trend. Except for the moderate pollution (37.22), all other heavy metal elements caused slight pollution. Among these, the contribution of Cd to soil potential ecological risk of the Yellow River beach in Tongguan was 100%, which agreed with the results of Heyang.

In general, Cd was identified as the main pollutant in the Yellow River beaches of the Hancheng-Tongguan section of the Yellow River. The contribution rate of Cd to soil potential ecological risk was 82.98%, while that to the soil potential strong ecological risk was 17.02%. This study showed that the overall potential ecological risk index of soils in Hancheng-Tongguan section of Yellow River was 83.36 < 135; therefore, the

DOI: http://dx.doi.org/10.15666/aeer/1801_12531265

potential risk of soils in the Yellow River beach is slight. The comprehensive potential risks of soil in different reaches of the river follow: Hancheng > Heyang > Tongguan. The comprehensive potential ecological risk index of soils in Hancheng was 109.5 < 135, indicating slight risks.

Conclusions

(1) The contents of As, Ni, Pb, Cd, Cr, Cu, Zn in the soil samples of the Hancheng to Tongguan section of the Yellow River were assessed. The average Zn content was highest, arrived 137.3 $mg \cdot kg^{-1}$. The average As and Cd contents were smallest, and with the exception of Ni, the coefficients of variation of all other tested heavy metals were large, indicating a notable difference between these heavy metals.

(2) A significant positive correlation ($p < 0.01$) was found between heavy metals such as Pb, Cd, Cr, and Cu in the Yellow River floodplain of Hancheng ($p < 0.01$). This

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12531265

indicates that these heavy metals have similar origins and are most likely the result of car exhaust emissions and large-scale pesticide use. The correlation between Cr, Cd, Pb-Ni, Zn-Cr, Zn-Cu, and other heavy metals was significant ($p < 0.01$) in the Yellow River beach of Tongguan, which is likely due to the large-scale gold development in Tongguan.

(3) According to the Hakanson potential ecological risk index, the overall potential ecological risk index of soil in the Yellow River from Hancheng to Tongguan section is $83.36 < 135$; therefore, the potential risk of soils in the Yellow River beach is slight. The results follow: Hancheng > Heyang > Tongguan. The comprehensive potential ecological risk index of the soil of the Yellow River beach in Hancheng is $109.5 < 135$, which also indicates slight risk.

(4) The impact of human activities on heavy metal pollution in the Yellow River beaches is relatively minor; however, to avoid intensification of the potential ecological hazards in the soil, attention should be directed to the treatment of heavy metal pollution in the Yellow River beach at their source.

(Received 22nd Aug 2019; accepted 15th Nov 2019)

Abstract. This pot experiment was carried out to investigate the effects of four doses (0, 2, 4 and 8 $g.L^{-1}$) of seaweed extract (Alga 600) application with fertigation on nutrient uptake of strawberry cv. Albion during the 2016-2017 vegetation period in Kalar city located in Northern Iraq. The results of leaf analysis indicated significant ($p<0.01$) differences at the nitrogen (N), phosphorus (P), potassium (K), magnesium (Mg), calcium (Ca), manganese (Mn) and iron (Fe) concentrations between two sampling periods. In contrast, copper (Cu) and zinc (Zn) concentrations of plants leaves did not significantly differed between the sampling periods. According to the statistical analysis, the effect of seaweed doses on nutrients were statistically insignificant for all nutrients except Mn ($p>0.05$). While for the Mn element, the highest value (223.70 ± 11.59 mg kg^{-1}) obtained from T4 (8 $g.L^{-1}$) seaweed dose; the lowest one (164.91 ± 11.59 mg kg^{-1}) obtained from control dose. The effect of interaction between seaweed doses and periods on nutrients was also not found statistically significant ($p>0.05$). In general, seaweed extract of 8 $g.L^{-1}$ was more effective on macro and micro nutrient contents of strawberry leaves.
Keywords: *Fragaria x ananassa Duch, cv. Albion, organic fertigation, algae extract, plant nutrients*

Introduction

Strawberry (*Fragaria* x *ananassa* Duch) belonging to family Rosaceae, is one of the most delicious and refreshing temperate fruits of the world. It has rich source of vitamins and minerals with delicate flavor (Sharma, 2002) and gives early and very high returns per unit area compared to the other fruits because the fruits are ready for harvest within six months of the planting (Katiyar et al., 2009). Wood strawberry (*Fragaria vesca*) and musky strawberry (*Fragaria moschata*) had been cultivated in Europe and Russia for centuries before the breeding of *Fragaria x ananassa*. In the early 1700s, inter-planting of *Fragaria virginiana* (male) with *Fragaria chiloensis* (female) in France led to the production of hybrid seedlings known as Pineapple or Pine strawberry plants, which are the progenitors of the new cultivated strawberry plant (*Fragaria x ananassa* Duch) (Darrow, 1966).

Several factors constrain agricultural production by negatively affecting the plant growth. Soil characteristics determining the fertility of soils on which the plant is grown and the climatic characteristics such as temperature and humidity positively or negatively affect the crop production. Seaweed is used in many countries as liquid extract or mixing directly with the soil. The seaweed, an organic amendment regulates the soil structure when mixed directly into the soil and sustains the productivity for a long time. Some seaweeds have been used as fertilizers in the production areas for many years (Güner and Aysel, 1996). Seaweed extracts have been used extensively in organic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12671279

farming especially in developed countries due to the reducing storage losses, increasing the production, uptake of inorganic nutrients from soil, seed germination, resistance to stress conditions, diseases and pests (Blunden, 1991). Seaweed increases nutrient and water uptake by providing strong root development of plants and encourages vegetative growth by accelerating the formation of chlorophyll. In addition, yield and quality of the products are improved by increasing the balanced and long-term uptake of macro and micro nutrients from the soil; thus, the market and export value of the product are increased (Blunden et al., 1992; Hong et al., 1995). Seaweed extracts increase the uptake of micro elements by chelating the micronutrients. Side branching and fruit formation in fruit trees also have been increased with seaweed application. In addition, flower and fruit losses have been decreased and yield increased up to 30%. Seaweeds also have been reported to increase the impacts of pesticides by 25% (Blunden et al., 1992).

Seas are generally covered with various qualities and numbers of seaweeds from the surface to a depth of 1000 m. The distribution of seaweeds, whose nutritional and other economic values have been documented, in the seas vary greatly depending on the water compositions of seas and the climate characteristics of the region (Blunden, 1991). Several types of compounds such as macro and micro elements (N, Ca, Mg, Mn, B, Br, I, Zn, Cu and Co), plant growth regulators (auxin, cytokinin, gibberellin and abscisic acid) and betaines are responsible from the positive effects of seaweeds (Hong et al., 1995).

In this study, a potting experiment with four different doses of seaweed extract, including the control treatment, was carried out to investigate the effect of seaweed, an organic fertilizer, on plant growth and nutrient uptake of Albion strawberry cultivar. This is a pioneering study that will serve to expand the production of strawberry which has not yet been cultivated widespread in Iraq.

Materials and Methods

The study was carried out during the vegetation period of 2016-2017 with pots in an open area of Kalar city located at Sulaymaniyah governate in Northern Iraq. The experimental site is situated between 34.62131° north latitude and 45.31961° east longitude at 200 m above sea level. The minimum and the maximum temperatures in Kalar during the vegetation period were -3°C and 35°C (Anonymous, 2017). The temperature started to increase in the middle of the April; thus, the effects of high temperature on size and weight of strawberry fruits appeared at the beginning of May, which was the last harvest time (*Table 1*).

Experimental Details

The plant material used in the experiment was Albion variety which was registered in 2006 by the University of California and sent out to the world. Despite the low yield of the Albion variety, the farmers report from the Mid-Atlantic on fruit quality are positive. The Albion variety has firm fruits with a high marketable yield percentage due to the shape and volume of the fruits. The ideal color and acceptable flavor of strawberry fruits are obtained at maturity. The Albion variety is very strong, and produces a high number of daughter plants and stolons (Lantz et al., 2010) (*Figure 1*).

Figure 1. *Strawberry plants and fruits of cv. Albion.*

The seedlings used in the experiment were obtained on January 1st, 2017 from Antalya province, Turkey. The pot experiment laid out based on the randomized plot design with three replicates. The pots were filled with 5 kg peat moss, watered with drip system and placed to an open area on January 15th, 2017 in Kalar district. Full flowering time was on 15th February 2017, first harvesting time was on 20th March and second one was on 12th May 2017 in our experiment. Four different doses (0, 2, 4 and 8 $g.L^{-1}$) of fertigation solutions were prepared from the seaweed (Alga 600). Based on the literature information, we applied three different doses (except control) starting from 2 $g.L^{-1}$ and increasing in double doses thought to will be obtained effective results in the study. The seaweed was dissolved in 22°C water for better absorption. The prepared solutions were applied to the plants twice. First application was applied in the full flowering stage (after the formation of first fruits) and second one was applied 20 days later then previous one, in other words, after the first harvesting time. The fertigation was applied in the morning. Components of seaweed were shown in *Table 2*.

Nutrient Analysis of Strawberry Leaves

Twelve (Four seaweed applications with three repetitions) leaf sample bags (each bag contains three leaves) with two replications (two fertigation times) were prepared during the flowering stage and after the first harvest to determine the plant nutrient concentrations. Leaves were washed in tap water and rinsed with distilled water then left for drying in oven at 60°C for 48 hours. The dried samples were ground by milling and stored in pouch papers until the chemical analysis. Plant nutrient concentration of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12671279

samples was determined by using the methods reported by Kaçar and İnal (2008). Nitrogen (N) concentration was determined by Kjeldahl method. Phosphorus (P), potassium (K), magnesium (Mg), calcium (Ca), manganese (Mn) and iron (Fe) copper (Cu) and zinc (Zn) concentrations were analyzed by microwave method using an ICP-MS instrument (Thermo Scientific, ICAP Q model).

Table 2. *Chemical composition of seaweed (Alga 600) used in the experiment.*

Chemical Composition	Unit	Content
Nitrogen (N)		0.5-1.0
Alganic acid		6.0-9.0
Sulfur (S)		1.0-1.5
Phosphorus pentoxide (P_2O_5)		6.0-9.0
Calcium oxide (CaO)		0.4-1.6
Iron (Fe)	%	0.15-0.3
Magnesium oxide (MgO)		0.06
Potassium oxide (K_2O)		21-24
Amino acid		4.0
pH		9-11
Organic matter		40-50

Statistical Analysis

The effects of seaweed doses and application periods on nutrient concentrations of strawberry leaves were assessed by the two-way analysis of variance test conducted according to the randomized plot design (ANOVA). Significance threshold was set to 0.05 and 0.01 levels. Paired samples t test was used to test the difference between the periods. Descriptive statistics such as mean and standard errors of nutrient contents were presented.

Results and Discussion

According to the results obtained in our study, increasing seaweed doses (0, 2, 4 and 8 $g.L^{-1}$) were increased the yield and fruit quality of the product. There is a significant increase in T4 (8 $g.L^{-1}$) compared with control (T1) and T2 treatment. The fertigation with seaweed (Alga 600) in T4 treatment resulted in the maximum value of yield per plant (g) 295.03 g and per hectare 3278.18 kg/ha. The lowest value belongs to the control treatment. Moreover, the T4 dose (8 $g.L^{-1}$) gave the maximum value of the average volume of fruit (18.88 ml^3) and total volume of fruit (329.37 ml^3) and the lowest value recorded by control treatment. This records can be explained by the fact that seaweed application leads to the improvement in the development of fruit diameter, strength, and length in addition to a better rate of fruit production (Abdulraheem, 2009).

The essential elements are divided in two groups as macro and micro plant nutrients. Macro nutrients consist of N, P, K, Ca and Mg which are used in large quantities; therefore, macro nutrients are very important for plant growth supplied by fertilizers. Micro nutrients are Fe, Cu, Cl, Bo, Mn and Zn which are used in small quantities by the plants though are necessary for plant essential. As a result of two-way analysis of variance, the effect of seaweed doses on nutrients was statistically insignificant for all nutrients except Mn ($p>0.05$) (*Table 3*). The results of nutrient concentrations of

DOI: http://dx.doi.org/10.15666/aeer/1801_12671279

strawberry leaf samples in flowering time and after the first harvest were given in *Table 4*. The effect of interaction between seaweed doses and periods on nutrients was also not found statistically significant ($p>0.05$).

Macronutrient Contents of Strawberry Leaves

The effect of different fertigation doses of seaweed (Alga 600) treatments on N concentration of strawberry leaves were presented in *Figure 2*. The highest N concentration was obtained with T3 seaweed treatment (4 $g.L^{-1}$), while the N concentration was sharply decreased with T4 treatment (8 $g.L^{-1}$) which caused to the lowest N concentration in leaves. The N concentration of leaves in the seaweed treatments after the second harvest was lower than the control treatment (T1). Sampling time had a significant effect on N concentration of leaves (*Table 4*). The N concentration recorded in the flowering stage (3.73 ± 0.09 mg kg^{-1}) was significantly higher than that obtained after the first harvest (2.31 ± 0.09 mg kg^{-1}). The differences in N concentration between the sampling periods was related to the higher consumption of N in fruiting stage compared to the flowering stage (Rathore et al., 2009). The results indicated that seaweed was not able to supply adequate N required by strawberry plants (Schmidt et al., 2003), though it may improve the root growth of plants. The results obtained were in agreement with those reported by Shehata et al. (2011).

DOI: http://dx.doi.org/10.15666/aeer/1801_12671279

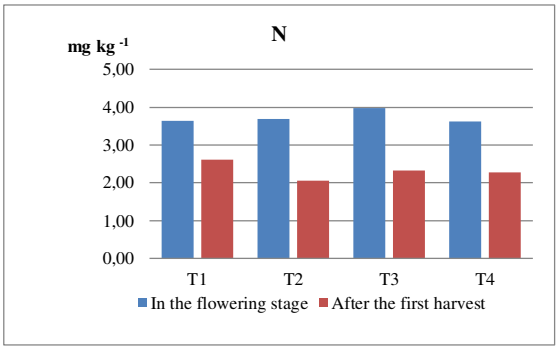

Figure 2. *Nitrogen concentrations of strawberry leaves at two different sampling times for 4 different seaweed doses.*

Phosphorus has several key plant functions, including energy transfer, photosynthesis, transformation of sugars and starches, nutrient movement within the plant and transfer of genetic characteristics between the generations (Blevins, 1999). Plants with high P content in leaves need high P supply for fruit production (Margarida et al., 2014). The effects of different doses of seaweed fertigation on P concentration of strawberry leaves were shown in *Figure 3*. The P concentration in T2, T3 and T4 treatments did not significantly differ from the control treatment. The highest P concentration of strawberry leaves was recorded in T4 treatment at flowering stage and the lowest P concentration was in T3 treatment at flowering stage. The highest P value in the second sampling period was obtained in T1, while the lowest P value was in T4 treatment. The P concentration between two sampling periods was significantly different ($p<0.01$). The concentration of P in the flowering stage was significantly higher (5657.78 ± 182.61 mg kg^{-1}) than the P concentration recorded after the first harvest (2525.63 ± 182.61 mg kg^{-1}).

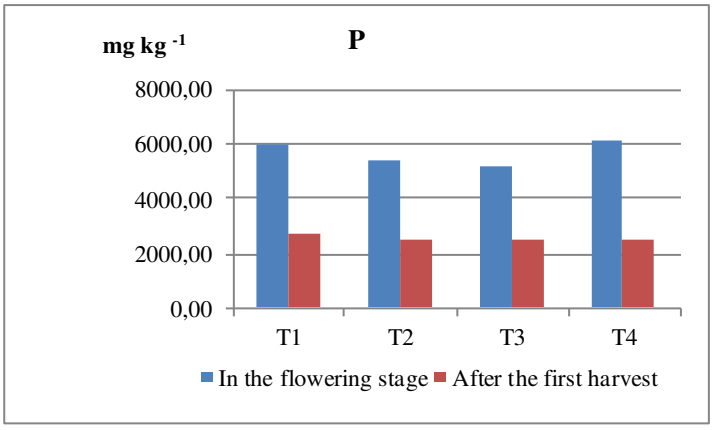

Figure 3. *Phosphorus content of strawberry leaves at two different sampling times for 4 different seaweed doses.*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12671279

Potassium is one of the major nutrients for plant survival and is involved in activation of the meristematic tissue growth, water transport and photosynthesis (Mengel and Kirkby, 1987). The results of ANOVA indicated that seaweed doses did not have significant affect on K concentrations of strawberry leaves (*Figure 4*). The highest K concentration was obtained in T4 at flowering stage and the lowest K value was in T3 treatment at flowering stage. The highest K content in the second sampling was recorded in T3, while the lowest value was in T4 treatment. The K content of strawberry leaves was significantly different ($p<0.01$) between the sampling periods. The K concentration of leaves in the flowering stage (20155.3 ± 782.19 mg kg^{-1}) was higher compared to K content recorded after the first harvest (15505.2 ± 782.19 mg kg^{-1}). Battacharyya et al. (2015), had been found similar results to our results in their experiment.

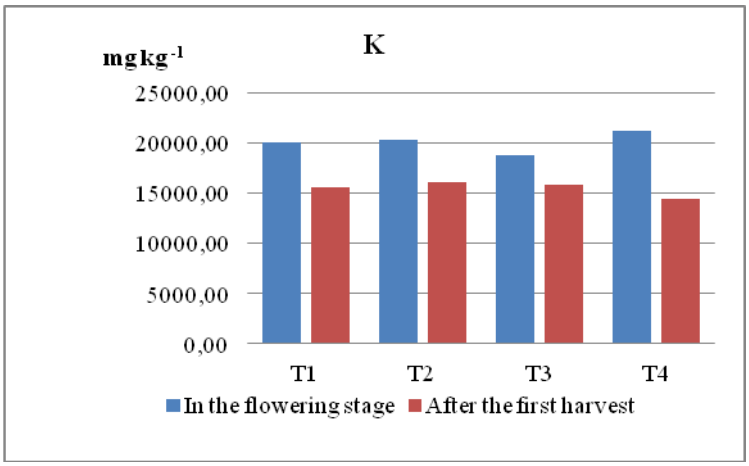

Figure 4. *Potassium content of strawberry leaves at two different sampling times for 4 different seaweed doses.*

Magnesium is the key nutrient of chlorophyll production, improves the mobility of P, increases the activity and components of some plant hormones; influences earliness and uniformity of the fruit maturity. Tavasoli et al. (2010) showed that Mg increases the fruit yield due to the influence on the intensity of photosynthesis different doses of seaweed (Alga 600) had no significant effect on Mg concentration of strawberry leaves as similar to our study in *Figure 5*. The concentration of Mg in T4 and T2 treatments were higher compared with the control, and the highest value was recorded in T4 treatment at flowering stage. The highest Mg content in the second sampling was obtained in T3 treatment while the lowest value was in T4 treatment. The concentration of Mg was significantly different ($p<0.01$) between the sampling periods (*Table 3*). The highest Mg value was recorded after the first harvest (6487.06 ± 212.56 mg kg^{-1}) and the lowest value was in the flowering stage (3380.43 ± 212.56 mg kg^{-1}).

The effects of different doses of seaweed extracts on Ca concentration of strawberry leaves was presented in *Figure 6*. The seaweed doses had no significant effect on Ca concentration of leaves. The concentration of Ca in T2 and T4 treatments was higher compared with the control. The highest Ca concentration was recorded in T4 treatment at flowering stage while the lowest value in control at flowering stage. In the second sampling, the highest value was obtained in control and the lowest value was in T2 treatment. The concentration of Ca was significantly different ($p<0.01$) between the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12671279

sampling periods. The highest Ca concentration was recorded after the first harvest (1281.56 ± 35.10 mg kg^{-1}) and the lowest value was at the flowering stage (490.88 ± 35.10 mg kg^{-1}). Rathore et al. (2009), had also been determined close results to ours in their research.

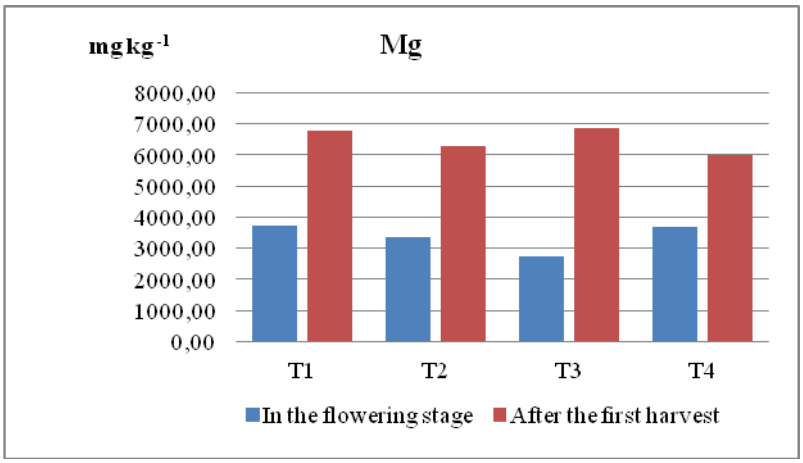

Figure 5. *Magnesium content of strawberry leaves at two different sampling times for 4 different seaweed doses.*

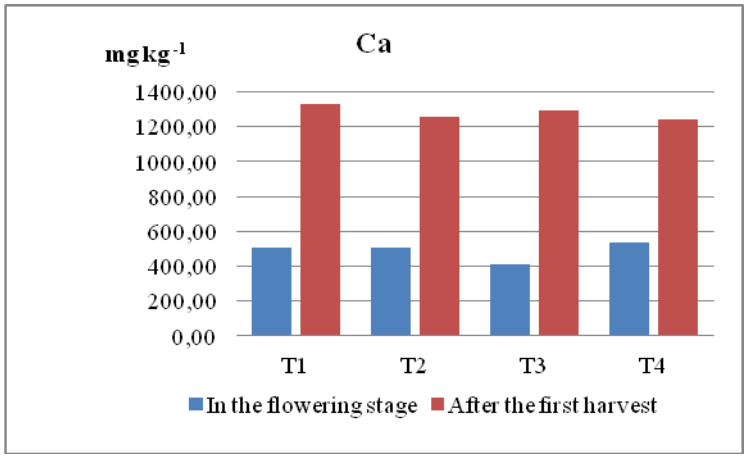

Figure 6. *Calcium content in strawberry leaves at two different sampling times for 4 different seaweed doses.*

Micronutrient Concentrations of Strawberry Leaves

The results of ANOVA test conducted to determine the effects of seaweed treatments on Mn concentration of strawberry leaves were given in *Figure 7*. The seaweed application significantly ($p<0.05$) increased the Mn concentration of leaves and the Mn concentrations of leaves increased with increasing doses of seaweed. The highest Mn value was recorded in T4 while the lowest value was in T1 at flowering stage. In the first harvest, the Mn concentration of leaves increased with higher doses of seaweed though the changes were not significant. The highest Mn content after the first harvest was obtained with T4 treatment and the lowest value was in T1 treatment. Statistically significant difference ($p<0.01$) was observed in Mn concentration of leaves between the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12671279

sampling periods. The concentration of leaves after the first harvest was significantly higher (242.09 ± 8.19 mg kg^{-1}) than the Mn concentration recorded in the flowering stage (131.30 ± 8.19 mg kg^{-1}). The increase in Mn concentration of leaves can be attributed to the high micronutrient concentration of seaweed used in this study. Fertigation of seaweed improved the Mn uptake by root system. Kumari et al. (2011) reported higher vegetative growth, yield and pest resistance with liquid spray application of seaweed. Similarly, Crouch and Staden (1992) showed that seaweed enhanced the root growth and had positive effect on nutrient uptake such as Mn.

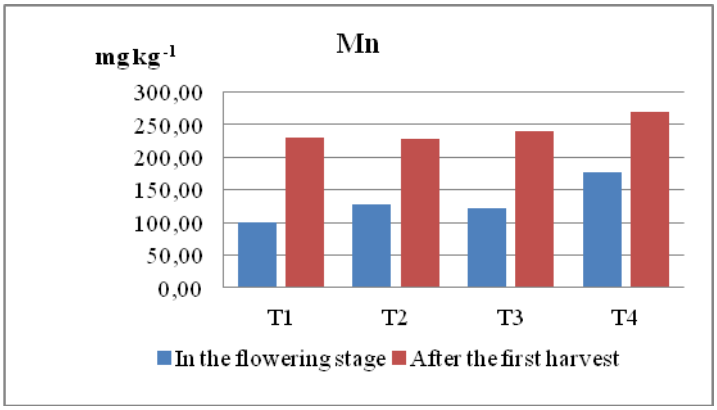

Figure 7. *Manganese content in strawberry leaves at two different sampling times for 4 different seaweed doses.*

The effect of seaweed doses on Fe concentration of strawberry plants were shown in *Figure 8*. The seaweed doses did not have a significant effect on Fe concentration of leaves. The concentration of Fe in T1 and T4 treatments were higher compare to the T2 and T3 treatments. The highest value was recorded in control at the flowering stage and the lowest value was in T2 treatment at flowering stage. In second sampling, the highest value was obtained with T4 treatment and the lowest value was in control. The concentration of Fe recorded after the first harvest (484.77 ± 13.02 mg kg^{-1}) was significantly ($p<0.01$) higher than the Fe concentration obtained in the flowering stage (267.62 ± 13.02 mg kg^{-1}). Similarly, Rathore et al. (2009), had been highlighted close results to our study.

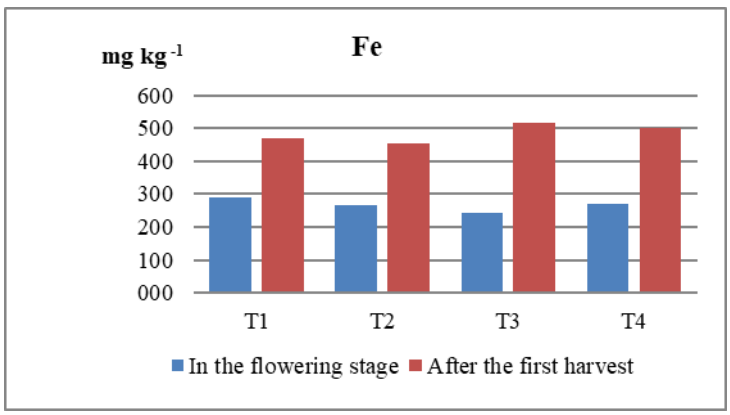

Figure 8. *Iron content in leaf of strawberry leaves at two different sampling times for 4 different seaweed doses.*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12671279

The seaweed treatments had no significant effect on Cu concentrations of strawberry leaves (*Figure 9*). The concentration of Cu in control treatment was higher than the Cu contents recorded in seaweed applications. The highest Cu concentration in flowering stage was recorded in control and the lowest value was obtained in T2 at the flowering stage. Similarly, the highest Cu concentration in the second sampling was recorded in T1 treatment. The Cu concentration of strawberry leaves recorded in flowering stage (3.17 ± 0.14 mg kg^{-1}) was slightly lower compared to the Cu concentration recorded after the first harvest (3.22 ± 0.14 mg kg^{-1}). Shehata et al. (2011), had also been found similar findings to our experiment.

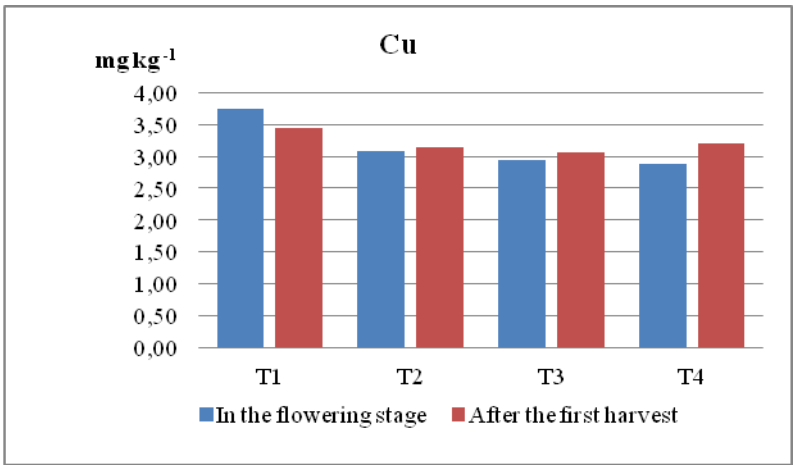

Figure 9. *Copper content in leaf of strawberry leaves at two different sampling times for 4 different seaweed doses.*

Zn has been reported causing higher fruit yield due to the positive effects on the intensity of photosynthesis (Tavasoli et al., 2010). The seaweed treatment did not significantly affect the Zn concentration of strawberry leaves. The lowest Zn concentration was obtained with T3 treatment, while the highest value was recorded in T4 at flowering stage. In contrast to the flowering stage, the highest Zn concentration after the first harvest was obtained with T3 and the lowest value was in T2 treatment. The concentration of Zn at two different sampling periods was significantly different ($p<0.01$). The Zn concentration in flowering stage (31.90 ± 1.65 mg kg^{-1}) was higher than the Zn concentration recorded after the first harvest (29.70 ± 1.65 mg kg^{-1}), though the difference was not statistically significant (*Figure 10*).

Soil quality in undeveloped and developing countries deteriorates due to the lack of proper fertilization techniques or over-fertilization. In appropriate fertilization causes losing the fertility of agricultural lands and the sustainability of soils and nature. In some cases, a lack of sufficient fertilization results in low yield in agricultural lands. Fertilization and productivity have a close relationship in agriculture. For healthy plant growth, sufficient and balanced amount of plant nutrients must be present in soils. On the other hand, the availability of nutrients for plant uptake is extremely important for the plants to benefit sufficiently from the nutrients in the soil. Several factors such as soil structure, plant type, and climate affect the ability of plants to benefit from fertilizers applied to soil (Özbek, 1970). The use of organic fertilizers such as seaweed instead of chemical inputs should be expanded to maintain a sustainable production

DOI: http://dx.doi.org/10.15666/aeer/1801_12671279

system that protects the environment and natural resources in the long term. Recent scientific studies also support these views (Khan et al., 2009; Craigie, 2011; Calvo et al., 2014; Arioli et al., 2015).

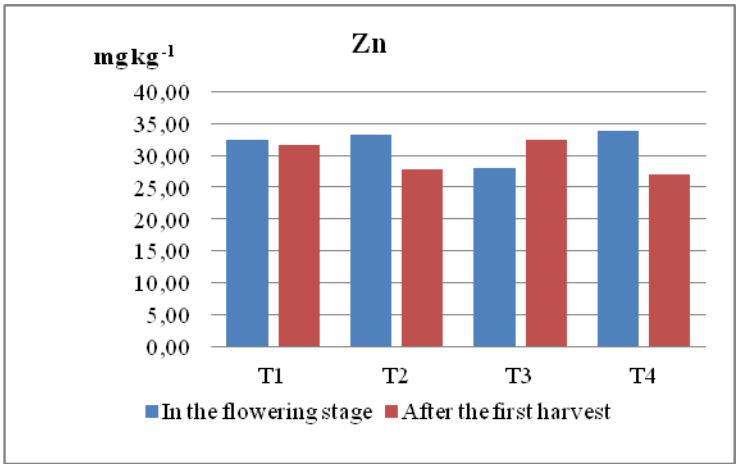

Figure 10. *Zinc content in leaf of strawberry leaves at two different sampling times for 4 different seaweed doses.*

Conclusion

This study was conducted to investigate the effects of seaweed (Alga 600) on nutrient uptake of strawberry cv. Albion. Following conclusions can be drawn from the results obtained in this study. The concentrations of N, P, K, Mg, Ca, Mn and Fe in strawberry leaves recorded in two different sampling periods (flowering and after the first harvest) were significantly different from each other. Consequently, it was pointed according to the result of the two-way analysis of variance, the effect of seaweed doses on nutrients were statistically insignificant for all nutrients except Mn ($p>0.05$) (*Table 3*). While the Mn element, the higest value (223.70 ± 11.59 mg kg^{-1}) obtained from T4 (8 $g.L^{-1}$) seaweed dose; the lowest value (164.91 ± 11.59 mg kg^{-1}) obtained from control dose. The effect of interaction between seaweed doses and periods on nutrients was also not found statistically significant ($p>0.05$). As shown in *Table 4*, the effect of fertilizer application periods on N, P, K, Mg, Ca, Mn and Fe elements were significant statistically except Cu and Zn elements. In general, the seaweed (Alga 600) do not have a significant effect on macro and micro nutrient contents of leaves. Seaweed fertigation significantly increased the Mn contents of leaves at both application periods. In general, seaweed extract of 8 $g.L^{-1}$ was more effective on macro and micro nutrient contents of strawberry leaves. Higher N, P, K, Mg, Ca, Mn and Fe concentrations were recorded respectively; 2.94 ± 0.13 mg kg^{-1}, 4277.42 ± 258.25 mg kg^{-1}, 17857.60 ± 1106.18 mg kg^{-1}, 4851.53 ± 300.60 mg kg^{-1}, 887.16 ± 49.64 mg kg^{-1}, 223.70 ± 11.59 mg kg^{-1}, 385.73 ± 18.41 mg kg^{-1} in T4 treatment after the first seaweed application.

As a result of this study carried out in Iraq, which tries to strengthen agriculture, industry, and economy after the war, is thought to lead the expanding of strawberry production in the region, improving the strawberry cultivation with superior yield and quality characteristics and adopting the environmentally friendly production techniques.

Abstract. With the rapid development of agricultural industrialization, agricultural nonpoint source pollution, which occurs when synthetic chemical additives (e.g. fertilizer, pesticides, and herbicides) runoff into rivers or lakes, has become a major concern. To explore the approaches of reducing the application of chemical additives, we conducted a field experiment to test whether the integrated farming systems would alleviate the nonpoint source pollution. Specifically, we tested whether mixed-cropping or mixed-cropping plus duck co-culture (MCDC) systems with optimized rice (*Oryza sativa* L.) cultivars could reduce nutrients runoff or leaching from paddy field. We found that compared to the mono-cropping systems, the electrical conductance (EC), oxidation-reduction potential (ORP), the contents of dissolved oxygen (DO), nitrates (NO_3^-), ammonium (NH_4^+), total nitrogen (TN), total phosphorus (TP) and total potassium (TK) of paddy water in MCDC systems all increased during the rice-growing stages. The contents of the TN, TP, and TK of paddy water in MCDC systems were 45.35%, 52.43% and 40.47% higher than those in the mono-cropping systems, respectively. Compared to the conventional mono-cropping, the mixed-cropping systems could alleviate nonpoint source pollution by decreasing the application of synthetic chemicals to rice paddies, the rice-duck co-culture system had significantly lower additions of agro-chemicals to paddy fields, which decreased the loss/runoff/leaching rates of nitrogen, phosphorus and potassium from paddy fields into the surrounding water areas by 32.73%, 8.72% and 31.88%, respectively. Considering that the MCDC systems exerted similar/even better performances as/than the rice-duck co-culture system and the rice mixed-cropping system, we deduced that the MCDC systems could also could alleviate nonpoint source pollution to a certain extent.
Keywords: *mixed-cropping, rice-duck co-culture, rice cultivars, nutrient runoff, paddy water, nonpoint source pollution*

Introduction

Nonpoint source pollution is a serious problem that degrades surface waters and aquatic ecosystems (Dodds et al., 2008). Nutrients, sediment, and other pollutants from human-altered landscapes can damage the integrity of freshwater systems (Hunsaker et

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12811300

al., 1995). Technologies and techniques to prevent and control industrial point source pollution are becoming more mature and widely implemented, but agricultural nonpoint source pollution has become the main cause of eutrophication in the world's aquatic environments (Ma et al., 2012). Water pollution has become an increasingly serious problem in China since the 1970s (Jusi, 1989). Literature reviews have highlighted concerns of agricultural nonpoint pollution in China entailing excessive inputs of fertilizers, pesticides, herbicides, and heavy metals into waters and soils (Smil, 1997; Schwarzenbach et al., 2010; Sun et al., 2012; Kale, 2013; Moldes et al., 2013).

At present, China is the largest rice growing and consuming country in the world (Thomas et al., 2011). In 2017, China accounted for 15.7% of the world's rice planting area and 28.8% of the world's total rice output. However, the area of cultivated land available for rice cultivation in China is gradually decreasing, while the population and demand for food are increasing (Cheng et al., 2007; Chen et al., 2019; Yin et al., 2019). Studies have shown that the farmers in the country currently use chemical fertilizers at very high rates (Wu, 2011; Yin et al., 2018; Wang et al., 2019). For instance, Li et al. (2019a) reported that the average rates of nitrogen (N), phosphorus (P) and potassium (K) fertilizers runoffs in orchards of major citrus producing regions of China were as high as 485 kg ha^{-1} (N), 198 kg ha^{-1} (P_2O_5), and 254 kg ha^{-1} (K_2O), respectively. Sun et al. (2019) found that more than 85% of sampled farming households used complex fertilizers in rice production, and that complex fertilizers account for more than half of the total use of chemical fertilizers. These overuse of chemical fertilizers could damage streams and rivers (Liu et al., 2018; Qiu, 2018; Reddy et al., 2018), pollute groundwater (Cui et al., 2018), and lead to declines in biodiversity (Asai et al., 2011; Sun et al., 2015). Nonpoint source pollution from rice farms is becoming particularly bad in southern China, a region with relatively high precipitation.

To reduce nonpoint source pollution and improve water quality, it is important to adopt techniques that reduce the use of synthetic chemical additives, such as chemical fertilizers, pesticides and herbicides (Saraswat et al., 2016). Ecological agriculture technologies, including livestock farming, intercropping and mixed farming, show promise for improving water quality and increasing biodiversity in rice paddy fields (Wu et al., 2013; Li et al., 2019b). Teng et al. (2019) found that rice-duck integrated organic farming protected water quality in Dianshan Lake and raised the incomes of local farmers. Another study found that hedgerow intercropping could fix nitrogen, reducing the need for chemical fertilizers, hedgerows also, prevented soil erosion, took up soil nutrients, and filtered pollutants (Zhang et al., 2008).

Rice-duck co-culture, in particular, is an integrated farming technology that helps control rice pests and weeds, and improve rice production, grain quality, and ecological sustainability (Zhang et al., 2008; Luo, 2018; Yang et al., 2018; Li et al., 2019c). Also, there is a mixed-cropping system, which cultivates multiple crop species or cultivars simultaneously in the same field for a significant part of their life cycles, using the space more efficiently and spreading risks more uniformly (Vandermeer et al., 1998; Lithourgidis et al., 2011). Numerous studies have reported that intensive integrated cropping systems, like rice-duck co-culture, have advantages over mono-cropping systems, largely due to reductions in pest incidence (Gold, 1993; Pridham et al., 2007) and more efficient use of nutrients, water, and solar radiation (Mason et al., 1988).

However, the relative effectiveness of different integrated cropping approaches for reducing nutrients loss, runoff, or leaching is still unknown. In this study, we compared the effects of rice mono-cropping system, mixed-cropping system with different rice

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12811300

cultivars, and mixed-cropping of different rice cultivars plus duck co-culture (MCDC) on paddy water nutrients in paddy fields in southern China. We hypothesized that mixed-cropping system and mixed-cropping plus duck co-culture system with optimized rice cultivars would have more ecological benefits to improve the absorption of nutrients by rice plants and reduce nutrients loss, runoff, and leaching from the paddy fields.

Material and methods

Site description

We conducted our field experiment at Zengcheng Teaching and Research Farm (23°14′N, 113°38′E), South China Agricultural University, Guangzhou, China in 2018, where subtropical monsoonal climate was characterized by warm winter and hot summer, with an annual rainfall of 1,738 mm and an average temperature of 22.75℃ (*Fig. 1*). The soil in the experimental site was sandy loam. The nutrients of the soil were determined at epipedon prior to the experiment. The soil contained organic matter of 15.62 $g \cdot kg^{-1}$, total nitrogen of 0.81 $g \cdot kg^{-1}$, total phosphorous of 0.55 $g \cdot kg^{-1}$, total potassium of 12.84 $g \cdot kg^{-1}$, available nitrogen of 61.62 $mg \cdot kg^{-1}$, available phosphorus of 39.11 $mg \cdot kg^{-1}$, and available potassium of 69.19 $mg \cdot kg^{-1}$. The soil had a pH value of 4.88.

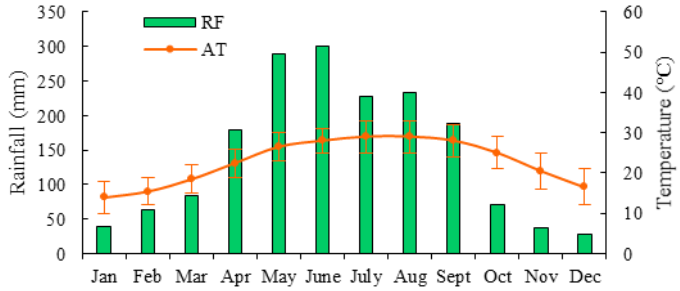

Figure 1. *Monthly rainfall (RF) and average temperature (AT) during 2018, the year of the experiment, in Zengcheng, Guangzhou, Guangdong, China.Temperature errorbars indicate the highest and lowest recorded temperatures.*

Experimental design and treatment

The experiment used completely random design with thirteen treatments and three replicates for each treatment (see Appendix *Fig. S1*). Each plot covered an area of 35 m^2 (5.0 m × 7.0 m). In this study, we used five traditional *indica* rice cultivars, including four from Rice Research Institute of Guangdong Academy of Agricultural Sciences (*Yuenongsimiao*, *Meixiangzhan 2*, *Huangguangyouzhan*, and *Huanghuazhan*) and one from National Engineering Research Centre of Plant Breeding at South China Agricultural University (*Huahang 31*) (*Table S1*), here labelled as A, B, C, D, and E, respectively. We selected four combinations of cultivars (BC, ACD, BDE, and ABDE) according to their growth period, plant height, grain yield and quality, and resistance to diseases of the five rice cultivars (*Table S1*), and also according to the screening of combinations optimized by pot experiments (Li et al., 2019b). Seeds were mixed for all combinations with the rice cultivars at equal weight ratios. Each mixed-cropping combination had six plots, three with and three without co-culture of ducks. The five

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12811300

rice cultivars were also mono-cropped in pure plots as the corresponding controls of the three replicates, but without duck co-culture.

Agronomic management

All seeds were soaked in water for 48 h at room temperature and germinated under suitable conditions. Germinated seeds of each combination were sown on 15th March 2018 in the fields of Zengcheng Teaching and Research Farm. Seedlings of all combinations were transplanted to the field plots on 21th April 2018 at the normal spacing of 20 cm × 20 cm. In each plot, we applied organic fertilizer (6,750 $kg \cdot ha^{-1}$, among which N ≥ 1.63%, P_2O_5 ≥ 3.53%, K_2O ≥ 1.92% and organic matter ≥ 46%) by broadcasting before rice transplanting.

Seven days after transplanting rice seedlings, we released ducklings into the specified plots at a density of 3 ducks per plot, based on the recommended population of Zhang et al. (2005). Each paddy field plot was surrounded by 50 cm high nylon mesh fencing to prevent ducks from escaping. The ducks were kept in the fields until rice reached its heading stage on 18th June in 2018. Water was kept at 6-8 cm deep while ducks were in the fields, but irrigation was stopped one week before the rice harvest. Photos of different growth periods in the paddy field of this study were shown in *Fig. 2*.

Figure 2. *Photos of different growth periods in the paddy field of this study. (a): Returning green stage; (b): Full heading stage*

Trait measurements

Physical and chemical parameters of paddy water, such as pH value, temperature (Temp), electrical conductivity (EC), oxidation-reduction potential (ORP), and dissolved oxygen content (DO), were analyzed using pH meter, EC meter, ORP meter (KEDIDA, Shenzhen, China), and DO meter (LEICI JPB-607A, Shanghai, China). Measurements were made at 10:00h-11:30h with three repetitions in each plot. Water samples were randomly collected as composites of 5 sub-samples from the surface water (0-5 cm) within a 2-m-diameter circular area centered in each plot on 5th April (one week before rice seedlings were transplanted), 27th May, 22nd June, and 18th July in 2018 correspondingly. The impurities of all water samples were filtrated with filter papers (d12.5 cm). We measured nitrates (NO_3^-), ammonium (NH_4^+), total nitrogen (TN), total phosphorus (TP) and total potassium (TK).

Data analyses

All data were expressed as means ± standard errors. To compare the effects of rice mono-cropping, mixed-cropping with different rice cultivars, and mixed-cropping of different rice cultivars with duck co-cultureon paddy water physical and chemical

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12811300

properties, we compared the experimental treatments using one-way ANOVA followed by Fisher's least significant difference post-hoc tests. For example, the data from B and C mono-cropping systems were pooled, and then compared with the results from BC mixed-cropping and BC mixed-cropping with duck co-culture. All statistical analyses were performed with R 3.20 (R Development Core Team 2015).

Results

Environmental background before ducklings released in paddy fields

Prior to releasing ducklings, the treatment plots did not differ significantly in water physical and chemical characteristics (pH, water temperature, electrical conductance, oxidation-reduction potential, and dissolved oxygen content) (*Fig. 3*), and also in the contents of nutrients (nitrate, ammonium, total nitrogen, total phosphorus, and total potassium) of paddy water (*Fig. 4*). These included plots for mono-cropping, mixed-cropping and MCDC systems for all combinations of rice cultivars (BC, ACD, BDE, and ABDE).

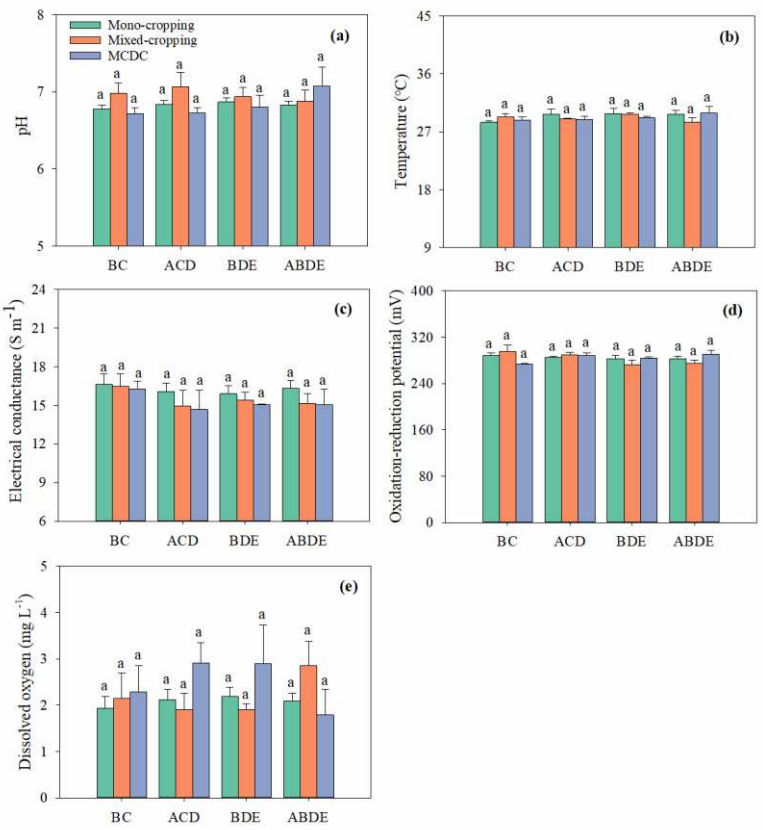

Figure 3. *pH value (a), temperature (b), electrical conductance (c), oxidation-reduction potential (d), and dissolved oxygen content (e) of paddy water for mono-cropping, mixed-cropping, and MCDC systems before ducklings were released in the paddy fields. MCDC refers to rice mixed-cropping with duck co-culture. Labels on the x-axes represent combinations of rice cultivars, with A=Yuenongsimiao, B=Meixiangzhan 2, C=Huangguangyouzhan, D=Huanghuazhan, E=Huahang 31. The error terms above bars indicates SEs. Physical and chemical properties of paddy water

According to ANOVA analyses, the pH of MCDC treatments was significantly higher than that of the mono-cropping and mixed-cropping systems on 22nd June and 18th July (*Fig. 5*). Compared to the mono-cropping and mixed-cropping systems, the MCDC treatments had lower paddy water temperatures on 22nd June and 18th July. The electrical conductance, oxidation-reduction potential, and dissolved oxygen content were all significantly higher in the MCDC systems than in the mono-cropping and mixed-cropping systems on 27th May, 22nd June and 18th July, respectively (*Fig. 5*).

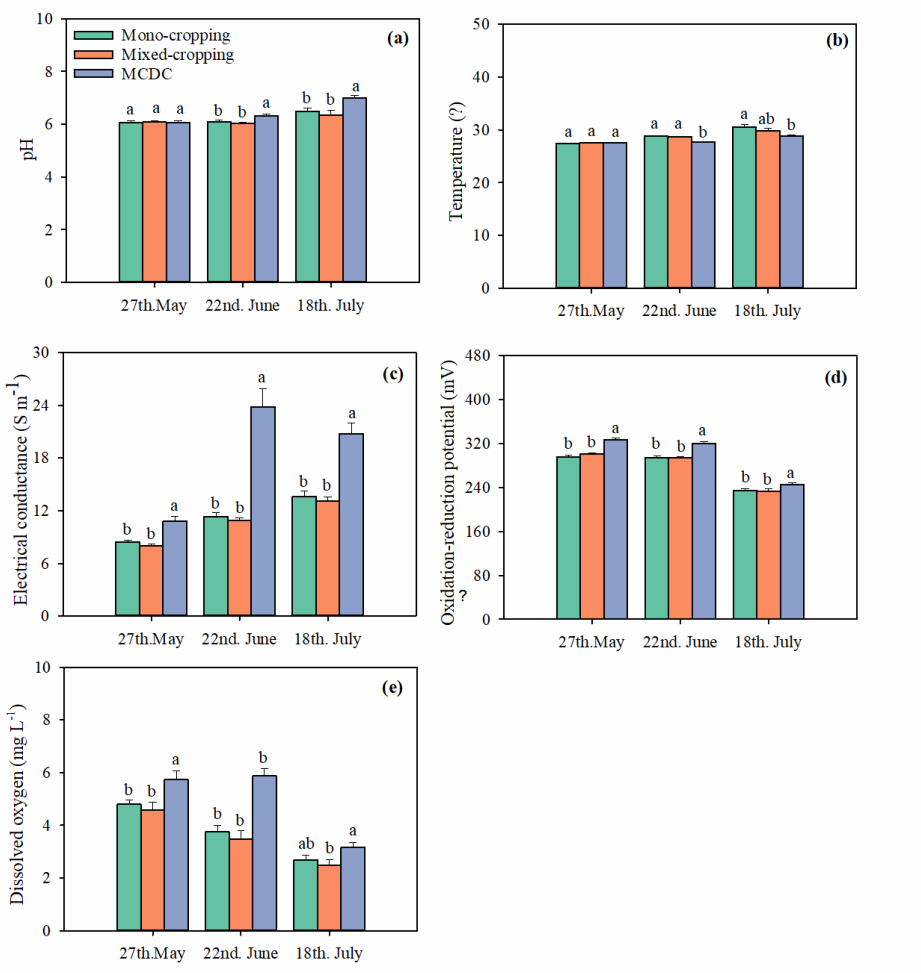

Figure 5. *Differences in the water pH value (a), water temperature (b), electrical conductance (c), oxidation-reduction potential (d), and dissolved oxygen (e) for mono-cropping, mixed-cropping, and MCDC systems after ducklings were released in the paddy fields in 2018. MCDC refers to rice mixed-cropping plus duck co-culture system. Different letters above bars indicate significant differences between the mean values of treatments (Fisher's LSD; P<0.05)*

Nutrient concentration of paddy water

Compared to the mono-cropping and mixed-cropping systems, the nitrate concentrations of paddy water in MCDC systems were higher at all stages (except 18th July) of rice growth, which exerted an increase status (from 8.67 to 33.39%, and from 6.53 to 27.97%, respectively) (*Fig. 6*). The ammonium concentration of paddy water in MCDC systems was also significantly higher than that in the other two systems. Similarly, compared to the mono-cropping systems, the concentrations of total nitrogen, total phosphorus, and total potassium of paddy water all improved (39.51-45.35%, 18.23-52.43%, 34.09-40.47%) obviously in MCDC systems. Moreover, the concentrations of total nitrogen, total phosphorus, and total potassium of paddy water all significantly increased (22.96-36.99%, 19.14-40.27%, 35.03-40.94%) in the MCDC systems than the mixed-cropping systems.

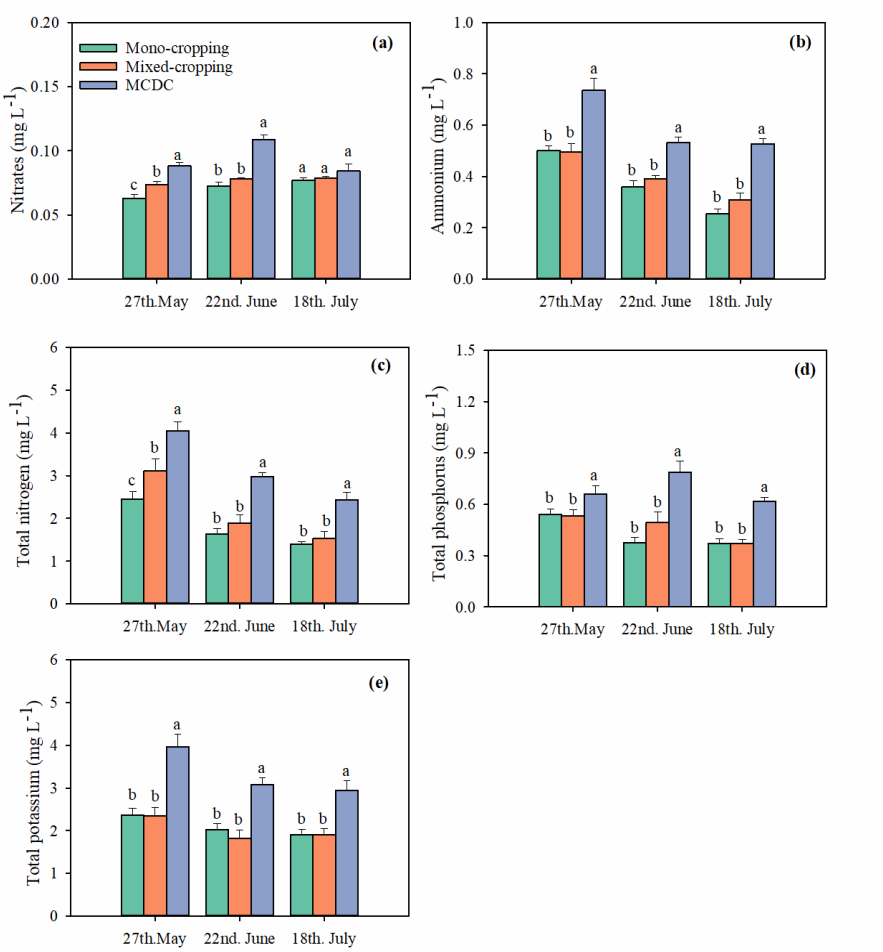

Figure 6. *Differences in concentrations of water nitrates (a), water ammonium (b), total nitrogen (c), total phosphorus (d), and total potassium (e) for mono-cropping, mixed-cropping, and MCDC systems after ducklings were released in the paddy fields in 2018. MCDC refers to rice mixed-cropping plus duck co-culture system. Different letters above bars indicate significant differences between the mean values of treatments (Fisher's LSD; P<0.05)*

Nutrients loss/runoff/leaching from paddy fields

Both the mixed-cropping and the rice-duck co-culture required almost no use of chemical fertilizers and pesticides, or other chemical additives (*Table 1*), but the conventional mono-cropping required much more application of chemical pesticides to protect the rice from being attacked by pests, and required much more compound fertilizers to increase rice production. Compared to the conventional mono-cropping rice system, the rice-duck co-culture systems showed lower rates of nitrogen, phosphorus and potassium loss, runoff, and leaching, which dropped to 32.73%, 8.72%, and 31.88%, respectively (*Table 1*).

Discussion

Few studies evaluated the effect of the mixed-cropping or mixed-cropping plus duck co-culture systems (MCDC) on nutrient leaching or runoff. In this study, we investigated whether this two new agroecosystems could reduce nonpoint source pollution. And we found that integrated rice-duck coculture in paddy fields could reduce nonpoint source pollution. In a previous study, Quan et al. (2008) illustrated that rice-duck co-culture improved the paddy water nutrient supply. Wang et al. (2004) indicated that rice-duck co-culture reduced the cardinal numbers of plant diseases and insect pests, and increased N and P uptake by rice crops. In this study, we found that the electrical conductance, oxidation-reduction potential, the contents of dissolved oxygen, nitrates, ammonium, total nitrogen, total phosphorus and total potassium in paddy water of MCDC systems were all higher than those of the mono-cropping and mixed-cropping systems, but there was no significant difference between the rice mono-cropping and mixed-cropping systems (*Fig. 4* and *Fig. 5*).

Rice-duck co-culture system is a typical farmland ecosystem, in which rice plants or weeds are producers, ducks are top consumers, bacteria and fungi are decomposers, and other animals (e.g. spiders, locusts, rice planthoppers, etc.) are consumers as well (*Fig. 7*). In this ecosystem, ducks play an important role to help rice to grow by eradicating the insect pests and weeds, trampling the paddy soil, stirring the paddy water, and excreting the feces to produce the nutrients absorbed by rice plants. This highly cycling and efficient utilization of nutrients by crops in the rice-duck co-culture system with less water drainage and without chemical pesticide and herbicide additions would help to reduce nutrients(such as TN and TP) loss and runoff and other pollutants from paddy field and hence may alleviate agricultural nonpoint source pollution (*Fig. 7*).

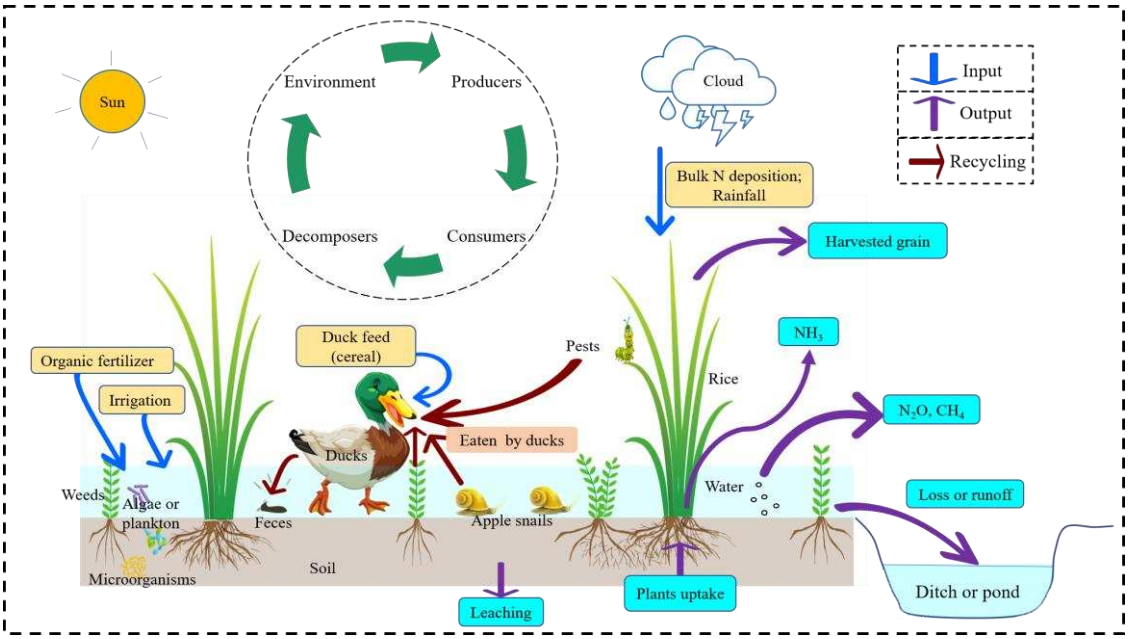

Figure 7. *Outline of nutrients flows in rice-duck co-culture paddy fields. NH_3, ammonia volatilization; N_2O, nitrous oxide; CH_4, methane*

Our study is consistent with previous researches that have shown increases in the soil nutrients, paddy water nutrients, and the efficiency with which rice plants could use nutrients under oxidation reaction by increasing dissolved oxygen, strengthening oxidation-reduction potential, and improving electrical conductance. These effects resulted from ducks activities in rice paddy fields, such as touching, pecking or shaking rice plants, eating weeds, pests, apple snails and other consumable organisms, depositing fecal matter, and agitating and stirring paddy water (Zhang, 2013; Yang et al., 2018). In this study, we kept the same irrigation or drainage in each plot. But in the rice-duck co-culture system, ducks could mix paddy water in the rice fields to play a role in evenly spreading nutrients, stirring paddy water to increase dissolved oxygen and electrical conductance, and then to activate nutrients pool of paddy water and soils for rice plants to absorb availably and greatly.

Studies reported that keeping ducks in the paddy fields all day and night until rice reached the heading stage could increase the economic value of rice grains and ducks, and reduce the loss of nutrients that could potentially lead to nonpoint source pollution (Zhang et al., 2011; Zhang, 2013; Sheng et al., 2018). Moreover, some researches indicated that rice-duck co-culture system could reduce the risk of N and P runoff and leaching, and could improve the use efficiency of N and P by the growth of rice under the ducks agitating or stirring the water in paddy fields (Li et al., 2008; Zhang et al., 2011; Yang et al., 2018; Teng et al., 2019). In addition, Zhang et al. (2008) found that emissions of heat-trapping gasses which contributed to global warming potential (CH_4 and N_2O) decreased when rice-duck co-culture was implemented.

Furthermore, rice-duck co-culture systems, especially those that use green or organic production techniques, could reduce or limit the use of chemical fertilizers, pesticides (Teng et al., 2016), and herbicides (Zhang et al., 2009; Teng et al., 2016), and then to decrease the nonpoint source pollution. Likewise, mixed-cropping systems are commonly used in marginal agroecological environments, where they fulfill a variety of functions, such as supplementing the use of growth factors (e.g. soil nutrients, light, and water), reducing pests and diseases incidence, reducing soil erosion, and improving total biomass production, yield stability, and household food security (Weltzien et al., 2017). Mixed-cropping systems, with different genetic diversity and species diversity from different crops or varieties, could alleviate pests and diseases and avoid the applications of chemical pesticides and herbicides. For example, Zhu et al. (2000) found that multiple cropping systems with different disease-susceptible rice cultivars could control rice disease effectively by genetic diversity of rice cultivars. Paulsen et al. (2006) also found that mixed-cropping systems could suppress weeds in linseed and reduce pests infestation in cereals or legumes. In our study, the concentrations of nitrates, ammonium, nitrogen, phosphorus, and potassium in paddy water were not significantly differed between the mixed-cropping and mono-cropping systems. However, the mixed-cropping systems might reduce the pests or weeds by integrating diverse characteristics possessed by different rice cultivars (e.g. growing period, height, genotype, resistance for pests and diseases, and so on) , and changing the microclimate (i.e. light, moisture, air, and temperature).

On the contrary, the conventional mono-cropping system had more applications of chemical fertilizers, pesticides and herbicides, and the nutrients were not completely absorbed by plants and then the stagnant water in rice fields could be discharged into rivers or lakes. Usually, in the rice mono-cropping systems, different kinds of chemical pesticides are overused to kill insects pests and diseases to protect crops in paddy fields,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_12811300

and they have negative impact on the environment and biodiversity (Mahmood et al., 2016; Larsen et al., 2017). Some researchers have found that only 10-20% of the chemical pesticides applied to crops remain on the plants for a long time; 1-4% directly act on target pests, and the rest go into the atmosphere, soil, and water (Nascimento et al., 2017). Mao et al. (2002) also reported that about 9.22% of pesticides are lost into water while those were applied to rice paddy fields. Our findings reinforce that mixed-cropping system which does not require synthetic chemical pesticides can reduce pollution of these chemicals.

In our study, the MCDC systems also increased electrical conductance, oxidation-reduction potential, the concentrations of dissolved oxygen, nitrates, ammonium, total nitrogen, total phosphorus and total potassium of paddy water, and reduce the external inputs of synthetic chemical additives (chemical fertilizers, pesticides and herbicides). The MCDC systems showed similar/even better performances as/than the rice-duck co-culture systems and the rice mixed-cropping systems. Based on the above comparative analysis, although we didn't measure and calculate the nutrient loss/runoff/leaching from the MCDC systems, we may estimate that the MCDC system could reduce total loss of N, P, and K, and hence decrease agricultural nonpoint source pollution, because this farming approach maintains a virtuous circle within the ecosystem and without chemical pesticide and herbicide inputs, and then ensure the ecological balance of the farmland.

However, further detailed studies are needed in the future. For example, in order to know better and more accurately about the nonpoint pollution status in the MCDC and mixed cropping systems, the water quality of large-scale paddy fields and its surrounding water bodies should be monitored, and the quantity of the nutrients loss/runoff/leaching outside the paddy fields should also be measured, finally the nutrients balance analysis in paddy ecosystem should be studied as well.

Conclusion

We found that the MCDC systems increased the electrical conductance, oxidation-reduction potential, contents of dissolved oxygen, nitrates, ammonium, total nitrogen, total phosphorus, and total potassium of paddy water. The mixed-cropping systems had no differences from the mono-cropping systems in terms of their effects on physical and chemical properties of paddy water. Nevertheless, compared to the conventional rice mono-cropping system, both of the rice-duck co-culture and mixed-cropping systems could prevent pollution of the water environment by reducing or eliminating inputs of chemical fertilizers, herbicides and pesticides that would otherwise be applied to rice paddy fields, and lower the total loss of nutrients, pesticides and herbicides from paddy fields. Moreover, we deduced and pointed out that the MCDC systems, which exerted similar/even better performances as/than the rice-duck co-culture systems and the rice mixed-cropping systems, could reduce the application and transportation of chemical fertilizers, pesticides and herbicides into the nearby rivers or lakes, and hence could also alleviate nonpoint source pollution to a certain extent from rice production.

APPENDIX

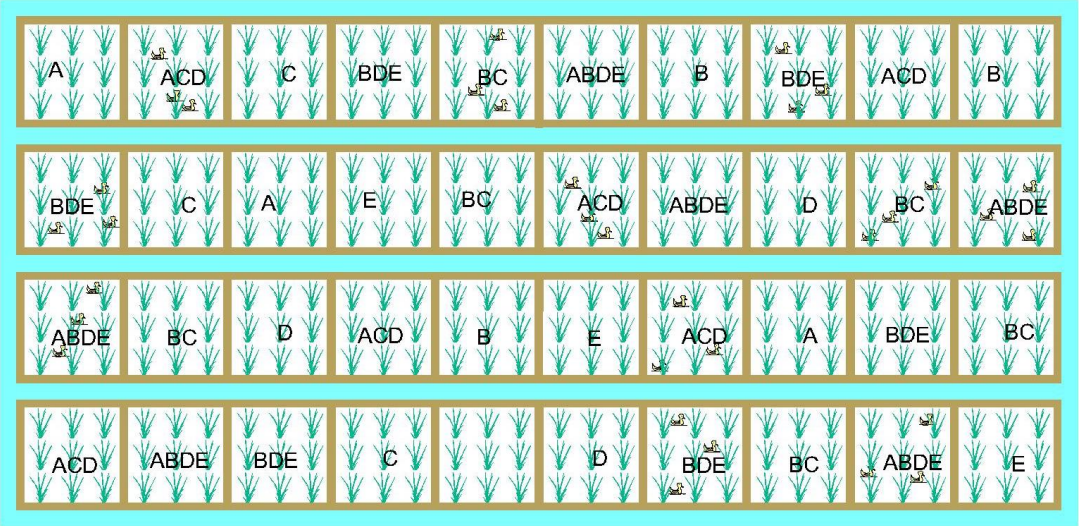

Figure S1. *Design of mono-cropping, mixed-cropping, and MCDC treatments in the paddy field. The A, B, C, D, and E stand for Yuenongsimiao, Meixiangzhan 2, Huangguangyouzhan, Huanghuazhan and Huahang31, respectively. Two or more letters indicate the treatments of mixed-cropping systems or MCDC systems (with duck in the plots). For example, BC stands for the treatment of mixed-cropping system with the rice cultivars of Meixiangzhan 2 and Huangguangyouzhan or stands for the treatments of rice-duck co-culture with different rice cultivars (MCDC) of Meixiangzhan 2 and Huangguangyouzhan. Other treatments are labelled similarly. In the figure, one plot was one replication of one treatment*

APPENDIX-1

HUMAN-GREY WOLF INTERACTION SURVEY

Enumerator Name: _____ Date: _____
Respondent Name: _____ Village Name: _____
Education: _____ Age: _____
Ethnic background: _____ Occupation_____
How many earning members are there in the household? _____
Home much agricultural land your family own? _____ HH Size _____

Predator Status:
Did you sight Grey wolf in your area in the past 1 year (Jan-Dec 2016)?

Wolf	***Response***		***Nubmer of observations***	***Status***		
Sighting/observation	*Yes*	*No*		*Common*	*Rare*	*Absent*

Population of wolf you wish to increase/maintain/reduce /eliminate from your area:
↑ / → / ↓/x

Increase	***Maintain***	***Reduce***	***Eliminate***	No response

Do you consider wolf dangerous for your livestock? Pelase rate it from not dangerou to extermly dangreous

Not dangerous	***Dangerous***	***Slightly dangerous***	***Very dangerous***	***Extremly dangerous***

Livestock
How many livestock your family own?

Livestock	**Goats**	**Sheep**	**Cattle**	**Other**
Number				
Vaccinated				

Other: Donkey, Horse etc.

Mortality due to Disease in 1 year (January – December 2016):

Livestock	Goats	Sheep	Cattle	Yak	Other
Number					

Livestock sold in 1 year:

Livestock	Goats	Sheep	Cattle	Yak	Other
Number					
Total Income in Rs					
Slaughtered for domestic consumption					

Predation Losses

Predation in 1 year:

Predator	Season/ month	Location	Prey type	Prey sex	Prey Age	Guarded (Y/N)	Circumstances

Seasons: Winter (Dec-Feb), Spring (Mar-May), Summer (Jun-Aug), Autumn (Sep-Nov)

Any other Damage by wildlife: _____

Abstract. Human-wolf conflict is a major factor contributing to the decline of grey wolf population both locally and globally. This study was carried out in December 2016 to determine the status and nature of human-wolf conflict in the study area. A total 80 locals from all walks of life were interviewed using a semi-structured questionnaire. The grey wolf was declared as a common species by 50% of the locals with an annual sighting rate of 0.3 each. During the year, a total of 256 livestock were lost to grey wolf predation and disease. Of the total, grey wolf was held responsible for a total 71 livestock losses. Goat was the most vulnerable domestic prey as it accounted for 60.5% of the total reported depredations. Out of the total economic loss (USD 27562, USD 344.525/household), grey wolf was accountable for USD 6244 (USD 78.05/household), while disease contributed USD 21318 (USD 266/household). High depredation was observed during the summer season (54%) followed by spring and autumn. The unattended livestock grazing in forest were more prone to grey wolf attack. Most of the respondents (71%) displayed a negative attitude towards grey wolf. Reported human-wolf conflict in the area can be reduced by initiating wildlife importance related awareness programs, livestock vaccination and depredation compensation schemes. Active herding technique is also recommended to reduce chances of wolf attacks on livestock.
Keywords: *human-wolf conflict, predation, diseases, economical loss, live stock*

Introduction

Generally, the large carnivores are known as keystone species in an ecosystem, due to their top position in the food chain. They are considered as the important population regulators of different species especially their prey. Therefore, they play an impactful role in maintaining the quality of a habitat and eventually of the whole ecosystem

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_129139

(Meyer and Terborgh, 2011; Ripple and Beschta, 2012). Human-wildlife conflict has its roots in the human history and it has intensified many folds over the time. Due to this conflict a large number of species especially, large carnivores have become extinct and threatened or their population is rapidly decreasing in most part of the world (Qamar et al., 2010; Ripple et al., 2014; Van et al., 2018; Jamtsho and Katel, 2019)

Human and wildlife conflict cases are represented by snow leopards (*Panthera uncia*) in the rugged mountains of central Asia (Bagchi and Mishra, 2006), grey wolf (*Canis lupus*) (Linnaeus, 1758) in the North America (Musiani et al., 2003), hyenas (*Crocuta crocuta*) and lions (*Panthera leo*) in Africa (Kolowski and Holekamp, 2006; Kissui, 2008) jaguars (*Panthera onca*) and pumas (*Puma concolor*) in South America (Mazzolli et al., 2002; Polisar et al., 2003), brown bear (*Ursus arctos*) in Tibetan Plateau of northwest China (Tsering et al., 2006) and dingoes (*Canis lupus dingo*) in Australia (Allen and Sparkes, 2001).

Human-wolf conflict is a major issue in various parts of the world (Ali &Usman, et al., 2016). Primarily, it occurs for two main reasons, first wolf predation on domestic livestock which is the primary source of income in the pastoral communities. Secondly, sometime wolf also attacks on human causing injuries or even death (Krithivasan et al., 2009). There has been 3-18% annual economic loss to the pastoral communities that holds livestock in trans-Himalaya due to snow leopard and wolf (Namgail et al., 2007). The other perception held by livestock owners that contributes to the conflict is surplus killings of livestock by wolf that is beyond its food requirement. It causes a huge economic loss in short time thus negatively influencing the opinion of livestock owners (Gipson et al., 1998; Short et al., 2002; Din et al., 2019). The grey wolf may have occasional attacks on human beings and may cause mortalities and injuries (Shahi, 1982). But these incidences are rare and often because of human interference like destroying dens, traps and persecution of pups (Linnell et al., 2002).

Wolves have traditionally inhabited much of the northern hemisphere and conflicts between them and pastoralists were common and this was primary cause of extirpation of wolves from the western world (Jhala, 2003). Although there are sanctions on wolf hunting but it is killed within its range in retaliatory killings using mostly firearms (Fritts et al., 1997). The other methods used for killing wolves include blocking or smoking out dens containing pups or adults inside them (Kumar and Rahmani, 2000; Singh and Kumara, 2006) and poisoning which is recently come in practice (Jhala, 2003).

The other issues beside retaliatory killings with wolf include habitat loss, degradation and fragmentation, disease, decrease in natural prey population and competition with other carnivore species (Irshad, 2010). Peaceful coexistence between people and wolves is very challenging due to high rate of predation of livestock (Eshete et al., 2018), most of livestock herders perceived wolves as dangerous to livestock and wanted to reduce or eliminate their population from the area. Greater number of livestock density and high predation of wolves led to negative attitude by the local communities (Din et al., 2013). The grey wolf living closer to an urbanized area where plentiful food sources, livestock and garbage are abundantly available, the chances of predation and human wolf conflict are higher (Timm et al., 2004). A recent study conducted in Karakoram suggested that livestock made about 66-75% of the diet of wolf and snow leopard (Bocci et al., 2017) while, in the Himalayas livestock constituted about 24-27% their diet (Chetri et al., 2017). Besides, spatial trend in livestock depredation by wolf can also be subjected to habitat prefercne and suitability, abundance of predator in that area (Wielgus and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_129139

Peebles, 2014), population of natural prey and competition with livestock over avilabe resources and livestock grazing pattern (Johansson et al., 2015).

Pastoralist-predator conflict is a major social-ecological concern that can affect community attitudes and tolerance towards carnivores (Din et al., 2017). The coexistence predator and livestock can be attained by incorporating livestock management into conservation planning and initiation of predation mitigation and compensation schemes in the sensitive mountain ecosystem where pastoral communities live (Tyrrell et al., 2017). A very few research studies have been conducted in Pakistan in order to evaluate the statues and magnitude of grey wolf conflict with locals. However, there was no single record of grey wolf statues, nature of conflict and perception of local communities about the species from the study area. Hence, considering the importance grey wolf ecological role, we conducted this study to explore status, magnitude and nature of grey wolf conflict with resident communities of the area.

Methodology

Field survey

Our study area named Timergara is located in District Lower Dir, Khyber Pakhtunkhwa (KP) province, Pakistan (35°10′N, 72°00′E). During 2016, we interviewed male participants from the selected villages of the study area. We interviewed only male participants because in our study area, only males are engaged in outdoor activities related to livestock grazing and selling, fodder collection and agriculture, while on the other hand females stay at home doing household jobs. These households represent about 5% of the total households within each village (Shakeel et al., 2016). The questionnaire surveys are considered as an important tool to gather information about presence, tolerance and perception of local communities towards the wildlife species present in an area (White et al., 2005). Moreover, the local people can be a valuable and a reliable source of information about the presence of wildlife species in their area (Lunney et al., 2001; Shima et al., 2019). The participants were selected based on their pre-existing knowledge about different wildlife species in general and grey wolf in specific. The main proportion of the participants included the herders, farmers, locals engaged in different businesses, school/college teachers and local hunters of the study area. The interviews were taken from the respondents in the study area (*Fig. 1*) with the help of written semi-structured questionnaires designed with open ended questions following (Dar et al., 2009; Din et al., 2013).

In addition, color printed photographs of the species (grey wolf and other carnivores) were shown to the local respondents to evaluate their level of species identification. This was helpful to get credible information during the interview. These types of surveys are considered as an important tool for evaluating attitude, tolerance and perception of local people towards the wildlife species present in an area.

The sequence of questions asked were varied in different interviews, and depended on the response flow of respondents during interviewing. The questionnaire topics mainly covered; the number of grey wolfs sighted by the respondents in one year, perceptions about the grey wolf and human attitude towards grey wolf (current). The attitudes of the respondents who wanted to increase or maintain wolf population in the study area were categorized as a positive while those who desired to decrease or eradicate wolf were grouped as a negative attitude category. Intensity of wolf danger for

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

livestock was categorized into five main categories; not dangerous, dangerous, slightly dangerous, very dangerous, and extremely dangerous (following L & Rensis 1932). Moreover, we also recorded the primary demographic respondent's data including earning members, age, agriculture land, household (HH) size, occupation, education level, numbers of livestock, and their dependency (L & Rensis 1932) on livestock. All the collected data was put and analyzed in the Microsoft Excel (2016). The map of the study area was developed using Arc Global Positioning System in (ArcGIS, 10.2)

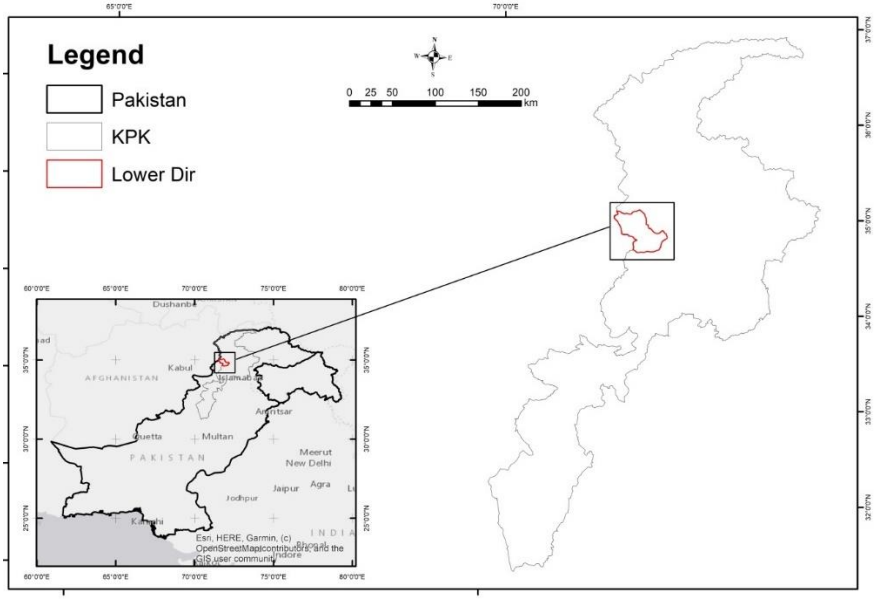

Figure 1. *Location of our study area where the questionnaire surveys were done*

Results

Demography of local people

During 2016 we interviewed 80 male respondents with an average age of 38 years (range 20-76 years). Most respondents (63.5%) were farmers and herders, followed by business men (19.3%) while the remaining (17.2%) were mainly school teachers, engineers and doctors. Most of the respondent (55.5%) in study sites were also highly dependent on livestock, 20.22% showed medium dependency and 20.22% showed low dependency on the livestock. Only 10% of interviewers poorly recognized the occurrence or absence of wolfs in the study sites (i.e., their information's about the presence or absence of wolfs was low); whereas, 35.5% of people were at average knowledge level and 54.4% were remarkably knowledgeable.

Wolf damage and people response

In the study area livestock rearing was the main source of income. In the study area, our surveyed households (n = 80) owned 1745 livestock with an average herd size of 21.8/household. Goats accounted for the largest percentage of livestock (56%), followed by sheep (24%), cattle (17%), and others (mules, horses and donkeys) (3%). We interviewed a total of 80 respondents to document sighting records of grey wolf in the study area. Respondent reported a total of 31 sighting records of grey wolf with an average sighting of 0.3 during the past one year. About the status of grey wolf in the

study area, our respondents shared mix views. Most (n = 43, 50%) of the respondents claimed that wolf is a common species in the area, while 46% and 4% respondents declared its status as a rare (n = 31) and absent (n = 6) respectively in the area (*Fig. 2*).

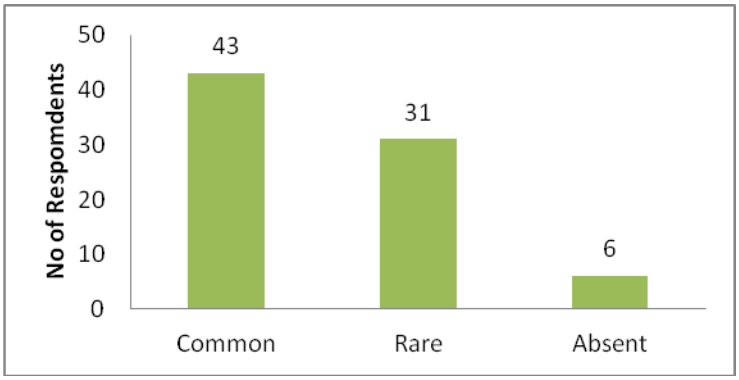

Figure 2. *Status of grey wolf in the study area*

Respondent reported a total loss of 256 livestock diseases and wolf predation and disease during the year 2016 (*Table 1*). Among the total 71 livestock losses were caused by wolves, while different disease accounted for 185 livestock losses. Goats were the largely victimized prey species, which accounted 43 (60.5%) of wolf killings, followed by sheep 23 (32.3%), cattle 2 (2.8%) and other 3 (4.2%). The reported figure of 256 livestock losses to grey wolf and diseases constitute an economic loss of USD 27562 (USD 344.525 per household).

Livestock depredation by grey wolf was reported at peak in the summer season, where more than half (54%) of the total livestock depredation occurred. Attack of wolf on the livestock was lowest in spring and winter (4% each) (*Fig. 3*). During the last year, a total of two attacks of wolf were reported on the human in the study area. The victims were attacked in nearby forest. In the attacks, the victims revived injuries that were not fatal, but it ended in the killing of wolf. Most (71%) of the respondents shared negative views about wolf (*Fig. 4*). The entire respondents declared the intensity of wolf danger as extremely high for their livestock as compared to rest of the wildlife species found in their area. Locals reported that all livestock depredation occurred inside the forest. Majority (55%) of the livestock depredation occurred when livestock were grazing in the nearby forest unattended by guard.

Table 1. *Economic losses due to grey wolf predation and diseases*

Livestock	UV ($)	Wolf		Disease		Total ($)
		No	Loss in $	No	Loss in $	
Goat	80	43	3440	95	7600	11040
Sheep	80	23	1840	59	4720	6560
Cattle	302	2	604	29	8758	9362
Other	120	3	360	2	240	600
		71	**6244**	**185**	**21318**	**27562**
			78.05		**266.475**	**344.525**

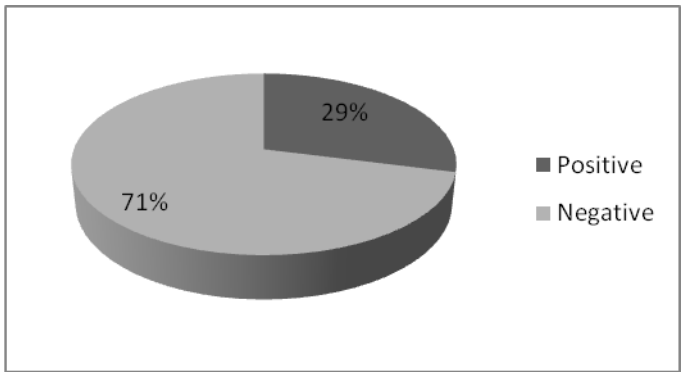

Figure 4. *Attitude of locals towards grey wolf*

Discussion

The grey wolf is known to the remote and rugged mountainous terrains of the district Lower Dir (KPK). This study was aimed to explore the statues and conflict of grey wolf with the local people of the selected villages of study area. Roberts (1977) and Dar et al. (2009) stated that the northern areas are the intrinsic habitats for the grey wolf. The human population inhibiting the study area is scattered and the presence of pastures and greenery accompanied by rugged terrains makes the area an appropriate habitat for the species. According to Divisional forest officer (Waqif, personal communication, December 27, 2016) locals were attack by an animal that resulted in the certain death of the animals and injuries to victims. The animal was thoroughly examined later one and was identified as a grey wolf.

Due to the unavailability of the veterinary service and high rate of livestock per household in the study area, a high rate of mortalities due to different diseases was observed. In the year 2016 a total of 256 livestock losses were reported by the locals. Due to diseases locals bear an economic loss of USD 21318 (USD 266 per household), that was higher than the economic loss occurred due to wolf depredation USD 6244 (USD 78.05 per household). Similar results (Ahmad et al., 2016; Dar et al., 2009) stated that the diseases in the livestock are the major cause of losses in stocks in the northern part of Pakistan. It is always argued that the carnivore predators are the prime suspects

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_129139

and responsible factor of livestock losses and paired economic losses. In a recent study, it was concluded that the disease had resulted in the economic loss twice more than the loss caused by carnivore's predators, which was higher than each household's income by selling livestock.

Moreover, a research study carried in Sanjiangyuan part of China by Li et al. (2013) showed 809 livestock mortality cases related to loss due to disease accounting for a money loss of 375,031 USD per annum, which makes 2604 UDS per family yearly. It was evident from the interviews conducted from the affected locals that these economic losses were primarily caused by the livestock disease that were easily curable but were not treated well in time due to unavailability of the veterinary services in the study area, see (*Table 1*).

Livestock depredation is one of the main causes of human-carnivores conflict, which resulted in the retaliated killings of wildlife both locally and globally. The human-wildlife conflict is prevailing in its severe form in the developing countries where locals are highly dependent on livestock rearing. In the Himalayas and Hindu Kush mountain regions the higher rate livestock depredations by large carnivores has been linked with higher population of livestock per household (Jackson and Hunter, 1996; Mishra, 1997; Hussain, 2003; Distefano, 2005). Additionally, the areas having small population of carnivore's natural prey and large livestock population have higher depredation rates (Meriggi and Lovari, 1996; Kolowski and Holekamp, 2006). In our study, the respondent's stated that a total of 71 livestock depredation were caused due to wolf predation last year.

Current study showed that medium size prey including goats and sheep were more vulnerable to grey wolf attacks. The most vulnerable livestock to depredation is the medium-sized livestock weighing 25–45 kg, because predators can easily capture and eat them with ease safety (Dar et al., 2009; Bibi et al., 2013). Similar results were concluded in studies carried out in Musk Deer National Park (Ahmad et al., 2016), Machiara National Park Azad Jammu and Kashmir (Dar et al., 2009; Kabir et al., 2014) and India (Suryawanshi et al., 2013).

Livestock depredation by wolf was found at its peak during summer season, followed by autumn, spring and winter respectively. Livestock depredation normally follows some seasonal patterns. During summer and autumn season the pasture and other grazing grounds of the study area are the suitable locations for livestock grazing. This makes the unattended livestock more vulnerable to predator attack. While during winter season locals usually keep livestock at home nourishing them with the stocked fodders (Dar et al., 2009; Sogbohossou et al., 2011)

The local respondents shared negative perception and attitude towards the grey wolf (*Fig. 4*). Due to conflict over livestock depredation most of our respondents wanted to see the grey wolf population decreases or even eliminated from their area. Usually livestock losses due to carnivores, when coupled with restricting locals from using the naturally resources found in their area like forest, develop negative and aggressive attitude among the locals towards wildlife (Conforti and de Azevedo, 2003). The interviewed locals reported that the wolves were the major predators found in their area, and they consider them the most dangerous to livestock. Moreover, it was also considered to be a threat to local people too. The species is depicted as a sign of viciousness and tyranny in the study.

Most of the depredation was reported when the livestock were grazing inside the near forest in the absence of guard. Herd guarding mechanism and active defense is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_129139

important and necessary against the carnivore's attack. Low predation rate was observed in presence of herdsman (Breitenmoser, 1998). Studies conducted in Europe, Italy and France reveal high depredation in the areas where domestic livestock graze freely or rarely guarded (Sillero-Zubiri and Laurenson, 2001; Espuno et al., 2004). Our study also helps to conclude that livestock depredation is much lower when herds were guarded, showing the effectiveness of active guarding.

Conclusion and recommendations

Most of the respondents of the area consider the grey wolf as a common carnivore found in the area. The species was blamed for a high rate of livestock depredation and faced a severe negative attitude of locals as it caused them economic loss. To ensure the grey wolf conservation and reduce the economic losses of the local communities, it is recommended to initiate a vaccination program as the area is lacking any animal care center. Livestock compensation scheme is also recommended because it will shift the negative perception of the local to positive. Proper guarding of livestock is recommended to reduce chances of wolf attacks. Moreover, intensive sign and camera trap surveys are recommended to be carried out in order to determine the abundance and habitat preference of the species in the area.

Acknowledgements. We are grateful to the locals in general and our respondents of the area for specific for giving us time and sharing their views about the species. This study was jointly supported by grants from The Ministry of Science and Technology of the People's Republic of China (research and application of key techniques on endangered species conservation and prediction of forest fire and pests in response to climate change, 2013BAC09B00) and National forestry and grassland administration, (management and improvement of monitoring in national park, 2018HWFWBHQLXF-01).

Abstract. Plant lectins are the potential proteins that specifically bound and cross linked with carbohydrates and target particular glycans present on the cell surface of viruses through a pathway termed as a lectin activation pathway. They have a role in plant defense system. In this study, we evaluated anti-*PVY* (potato virus Y) activity of plant derived lectin in in-vitro assay. A tetramer lectin was isolated from the corms of *Crocus vernus* and purified to sub fractions through ammonium sulfate precipitation, dialysis, filtration on the PD 10 column, cation exchange chromatography on SP-Sepharose gel. In-silico studies predicted stable interaction between *Crocus vernus* lectin (CVL) and targeted protein of *PVY*. Cytotoxicity tests performed on HepG2 cells indicated IC50 value for CVL was 770 µg/ml. The IC50 values indicated the safe limit and non-cytotoxic effect of the CVL extract and worth for further testing. The hemagglutination activity of CVL against the rabbit erythrocytes was revealed to be 100 µg/ml. The anti-*PVY* activity displayed in the CVL lectin was evaluated through quantitative real-time PCR assay. It was revealed that CVL was effective against targeted gene of *PVY* at 30, 60 and 90 µg/ml concentration and up to 100% inhibition of the *PVY* mRNA was achieved in all three tested concentrations in comparison with control. Our results clearly indicate the CVL gene can be a used for transformation studies in potato to control the potato virus Y as an effective tool, in the future.
Keywords: *Crocus vernus lectin (CVL), potato virus Y, real time PCR, coat protein, antiviral activity, in silico analysis*

Introduction

Mannose-binding lectins prove to be of immense importance and potency in preventing and treating virus-mediated infections as they specifically target particular glycans present on the cell surface which are required by virus for entry (Balzarini et al., 2007). A variety of lectins have already been reported from different organisms belonging to a wide range of taxonomical groups, including plants, animals, bacteria, fungus and algae (Golotin et al., 2019; Singh et al., 2018; Sreeramulu et al., 2018; Muslim et al., 2018; Zhang et al., 2017a). The structure, efficacy and specificity of these lectins may vary from source to source. Till to date, lectins have been published from different plant families, including *Alliaceae, Amaryllidaceae, Araceae, Bromeliaceae,*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13011315

Iridaceae, Liliaceae, and *Orchidaceae* and their activity has been reported against Human Immunodeficiency Virus, Simian Immunodeficiency Virus and Feline Immunodeficiency Virus (Lam and Ng, 2001; Davidson et al., 2000).

Potato virus Y (*PVY*) belongs to the genus *Potyvirus* of the *Potyviridae* family (Kitajima et al., 1997). Worldwide a number of crops are affected in a severe damaging way by this virus, especially solanaceous plants like potato (*Solanumtuberosum* L.), tobacco (*Nicotianatabacum* L.) and pepper (*Capsicum annuum* L.). *PVY* symptoms vary from barely visible mosaic patterns to an extreme necrosis and premature death of plants (Tabassum et al., 2016). *PVY* infection is difficult to control because it is vegetatively propagated, making primary viral infection more destructive and consistent generations after generations (Gargouri-Bouzid et al., 2005). In Pakistan, due to early infection of *PVY* loss is about 70% (Abbas et al., 2017). Among the crucial genes of *PVY*, capsid protein (CP) gene is involved in the encapsulation, in replication of the viral genome, movement across host cells, and transfer from infected to uninfected plants using mobile biological vectors (Callaway et al., 2001).

Several approaches have been tested to date to produce high yielding commercial varieties with advance levels of resistance, including genetic amendments of the *PVY* coat protein (CP) gene or P1 gene (Gargouri-Bouzid et al., 2005; Mäki-Valkama et al., 2000). Resistance exhibited by gene silencing is more effective as compared to protein mediated resistance (Mäki-Valkama et al., 2007).

In Pakistan, commercially offered high yielding potato lines fail to show resistance against viruses, especially the potato virus Y. In the current study, we aimed to find out the effect of mannose-binding lectin from the bulbs of *C. vernus* activity against the *PVY* coat protein gene.

Materials and methods

Sequence retrieval and modeling of CP protein

The full-length amino acid sequence of potato virus Y, coat protein (Accession # ABK13679.1) was retrieved from the NCBI database and functional domains of Coat Protein (CP) were determined using an online InterPro server (www.ebi.ac.uk/interpro/).

Crocus vernus lectin (CVL) molecular structure, coordinate information (PDB ID: 3MEZ) was downloaded from the protein database (http://www.rcsb.org/structure/3MEZ) and the CP structure was generated using the online tool (http://zhanglab.ccmb.med.umich.edu/I-TASSER/). The validity of the predicted model was checked by calculating the Ramachandran plot which was produced by online tool RAMPAGE (http://mordred.bioc.cam.ac.uk/~ rapper/rampage.php).

Refinement, evaluation, and validation of CP protein model

Using the ModRefiner online tool (https://zhanglab.ccmb.med.umich.edu/ModRefiner/), the CP model was further refined. Using Ramachandran plot and by determining the physiochemical properties of the CP protein through ProtScale, the model was evaluated and authenticated.

Protein-protein docking analysis of CP and CVL

Online server Z-DOCK (http:// zdock.umassmed.edu/) was used for docking of receptor model to fusion protein and ten coordinate files were obtained. PDBePISA

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13011315

online tool (http://www.ebi.ac.uk/pdbe/pisa/) was used to find the interactions between the CP and CVL. For the visualization of structures showing the interactions between the two proteins the PDB viewer was used.

Protein source, extraction and fractionation of extract

Crocus vernus (L.) Hill corms were kindly provided by Dr. Ahmed Akrem (Institute of Pure and Applied Biology, Bahauddin Zakariya University, Multan-Pakistan). Briefly, 10 g of corms were reduced to powder and homogenized in 0.1 M phosphate buffer (pH 6.5). The slurry was stirred continuously at 4 °C for 2 h. Further, the suspension was filtered through the muslin cloth and centrifuged at 15000 × g for 15 min at 4 °C. Supernatant was collected and subjected to 60% ammonium sulfate precipitation. The pellet was re-suspended in 20 mM phosphate buffer (pH 6.5) and dialyzed overnight by dialyzing tube (Spectra/Por RC Biotech membrane, 6-8 kDa MWCO) against 10 mM phosphate buffer (pH 6.5).

Crude protein extracts were fractionated through cation exchange chromatography where desalted protein was subjected to Hi Trap SP FF column (GE Healthcare). The column was equilibrated with 5 cv of 50 mM of phosphate buffer (pH 6.5) and then partially purified protein was loaded onto the column. Protein was eluted with 0.5 M NaCl gradient and different fractions were obtained which were analyzed by SDS-PAGE. The protein was quantified through the Bradford method (Bradford, 1976).

Construction of pCP-PVY clone

Full length coat protein (CP) gene of potato virus Y (*PVY*) was amplified from *PVY* infected potato samples. A fragment of full-length CP gene 807 bp was amplified with specific forward 5′-ATGGCAAATGACACAATCGAT-3′ and reverse primer 5′-ATCACCCTGCCACCTCTATC-3′ and the deduced sequence was submitted in NCBI database under accession # MK130988. For directional cloning in pCDNA3.1 (+) (mammalian expression vector), the amplified fragments were generated with *HindIII* and *EcoRI* restriction sites at 5 and 3 ends. The recombinant vector was named as pCP-PVY.

Cell line

The HepG2 cell line was grown and maintained in Dulbecco's modified Eagle medium (DMEM) containing 100 U/ml penicillin, 100 µg/ml streptomycin and 10% Fetal Bovine Serum (FBS) at 37 °C in 5% CO2 atmosphere at 37 °C.

Cytotoxicity assay for CVL

Cell survival and proliferation was quantified by using the MTT assay kit (Millipore, USA). Using the HepG2 cell model, Cell viability and proliferation was evaluated. HepG2 cells were cultured in 96 well plate containing DMEM supplemented with 10% FBS, 100 µg/ml streptomycin and 100 IU/ml penicillin. CVL protein was diluted in different concentration ranges (110 to 770 µg/ml, 3 wells per concentration) in 96-well plates and incubated at 37 °C in the humidified CO_2 incubator.

After incubation, the concentration range of CVL drawn from 110 to 770 µg/ml and were added to the wells of the plate in triplicates and the plate was again incubated at 37 °C for 24 h in CO_2 incubator. After incubation, the exhausted media was discarded

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13011315

and fresh media along with MTT reagent (5 mg/ml in PBS) were added to each well according to the manufacturer's instructions. The plate was then incubated at 37 °C in a CO_2 incubator for 4 h. To dissolve the formazen crystals produced after incubation, DMSO was added in the wells. To quantify the MTT formazen product, the optical density of contents of plate was analyzed through ELISA plate reader as per described protocol.

Cell viability was attained by means of following formula (Rehman et al., 2011):

Percent cell viability = (Test 570 nm – 620 nm / Control 570 nm – 620 nm) × 100.

Hemagglutinating activity

The hemagglutinating activity of the CVL was evaluated against the rabbit erythrocytes using the U-shaped bottom 96 wells microtiter plate as described by Ynalvez et al. (2015). Briefly, twofold serial dilutions of the CVL were made in phosphate buffer saline (PBS) and was incubated with 2% erythrocytes suspension in equal volume and kept at room temperature for 1 h, while control contains the PBS in spite of the CVL. Positive results indicated the red-carpet layer while negative results show the red button formation in the well.

Co-transfection

The HepG2 cells were cultured at a cell density of 1×10^6 cells per well in a 6-well plate. CVL protein extract and pCP-PVY plasmid DNA were co-transfected at 50-70% cell confluence. Lipofectamine 2000 (Invitrogen, CA) was used as transfection reagent. For the down regulation of CP-PVY mRNA, 50 ng – 1 µg construct DNA was used along with three different CVL concentrations; 30, 60 and 90 µg/ml. Experiments were carried out in triplicate.

Real-time PCR analysis

To measure the anti-PVY potential of CVL, the mRNA expression of CP gene was revealed through real time PCR assay. Post co-transfection, total RNA was isolated from HepG2 cells by using TRIzol reagent (Invitrogen) and 1 µg was used to synthesize complementary DNA (cDNA) by using the cDNA synthesis kit (Thermo Scientific, Lithuania). Specific forward 5′-TGTGGGTTTAGCGCGTTATG-3′ and reverse 5′-GTGCCTCTCTGTGTTCTCCT -3′ were used to amplify 172 bp amplicon. The assay was run in triplicate in the PikoReal™ Real-Time PCR system (Thermo Scientific). Reactions were prepared in a total volume of 10 µl containing: 1 µl cDNA, 0. 5 µl of each 10 pmoles primer, 5 µl of Maxima SYBR Green qPCR Master Mix (2X) (Thermo scientific) and 2.5 µl RNase/DNase-free sterile water. The cycle profile comprised of 30 cycles with denaturation at 94 °C for 30 s, annealing at 54 °C for 30 s and extension at 72 °C for 30 s after an initial denaturation at 94 °C for 10 min. For normalization, β-actin was used as a control. The relative gene expression analysis was measured by using Cq values in different samples. Each real-time PCR assay was performed in triplicate.

Statistical analysis

Statistical analysis was carried out using GraphPad Prism 7. Triplicate studies were performed. Descriptive statistics were used to evaluate the mean and standard deviation

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13011315

of the results. One-way ANOVA was used was to investigate a significant reduction in the cell viability and MRNA expression of the CP gene at $P \leq 0.05$.

Results

In silico modeling, refinement, evaluation, and validation of CP gene was performed with online available tools as indicated in *Figure 1A* and *B*. The verified in silico model of CP was used for docking analysis.

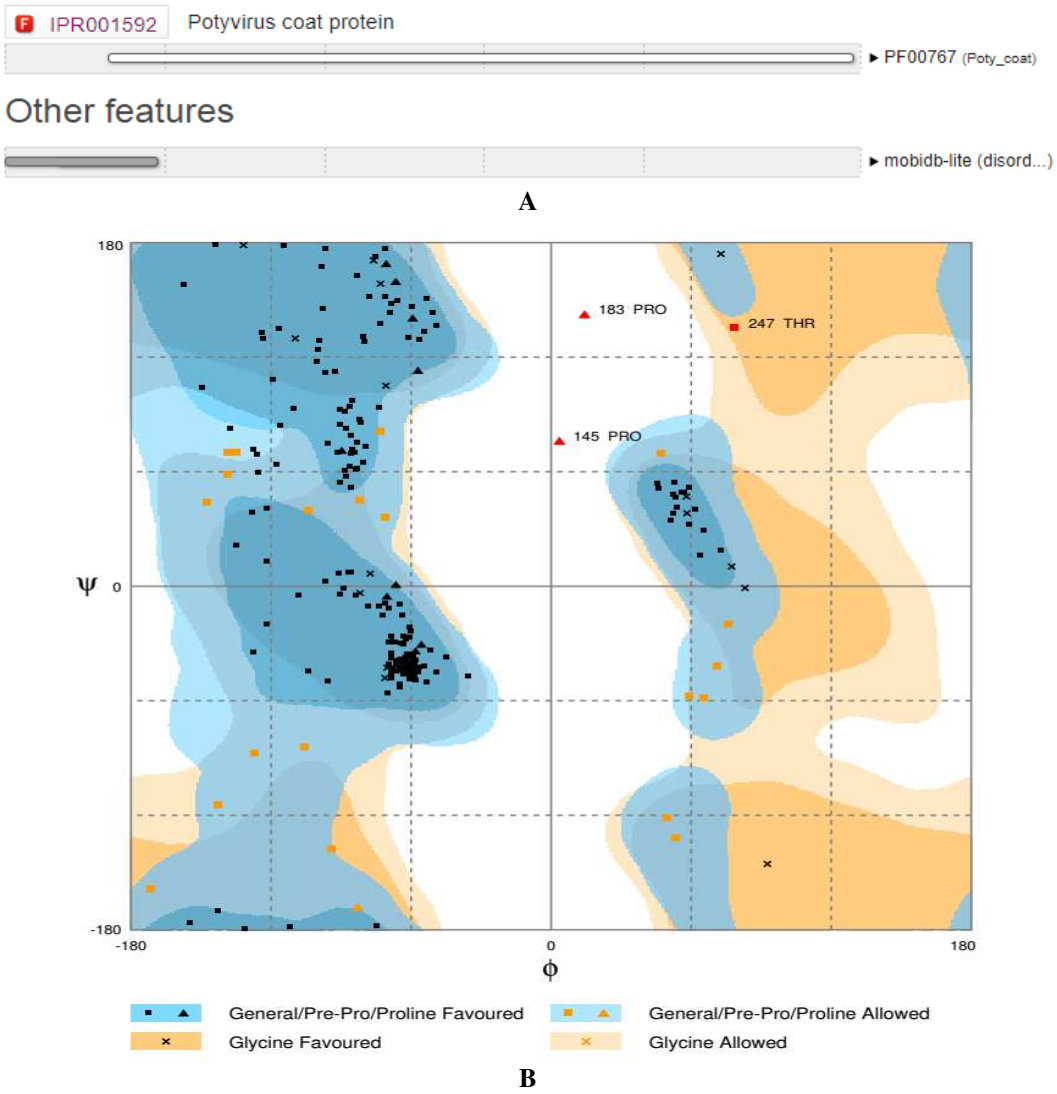

Figure 1. A *Functional domains analysis of CP sequence through InterPro is showing Potyvirus CP domain.* ***B*** *Ramachandran plot analysis of Capsid protein model to visualize dihedral angles; ϕ against ψ. Only two residues indicated with a red triangle in the figure are in the outlier region except these two, all other residues are in favored and allowed regions*

Primary structure examination of the CP model was executed utilizing Protparam (https://web.expasy.org/protparam/). It was found that the CP has an aggregate length of 267 amino acids and hypothetical *pI* of 6.61. The instability index was 43.03, ordering it

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13011315

as not steady protein. The evaluated half-life in mammalian reticulocytes was 30 h, whereas in yeast and *Escherichia coli* is over twenty and 10 h, on an individual basis (*Fig. 2A*). Similarly, the CVL protein model was taken as a PDB format from the online protein data bank. CVL protein contains four chains in which chain 1 and 3 were the same and chain 2 and 4 were same as given with the amino acid details (*Fig. 2B*).

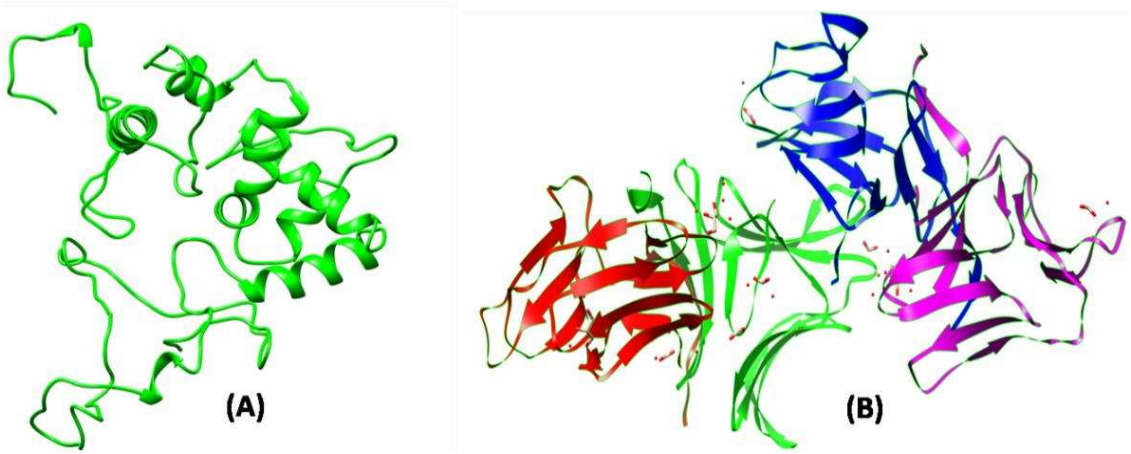

Figure 2. *Three-dimensional protein models of (**A**) PVY coat protein and (**B**) CVL protein, predicted by I-TASSER. In (B), the red color chains present A chain, green shows B, magenta C and blue presenting D chain*

Docking analysis of coat protein with CVL

The amino acids and molecules concerned in interchain H bonds, while not choosing any residue within the CP, were assessed utilizing the ZDOCK server. The interactions created through the ZDOCK server between CP and CVL protein are shown by the hydrogen bonds between the two proteins. Details of hydrogen bonds are given as in *Tables 1* and *2*.

Table 1. *Hydrogen bonds between CP and CVL (A and C domain) obtained from PDBePisa. Interactions with a value less than 3.0 were considered to have highlighted bond distances*

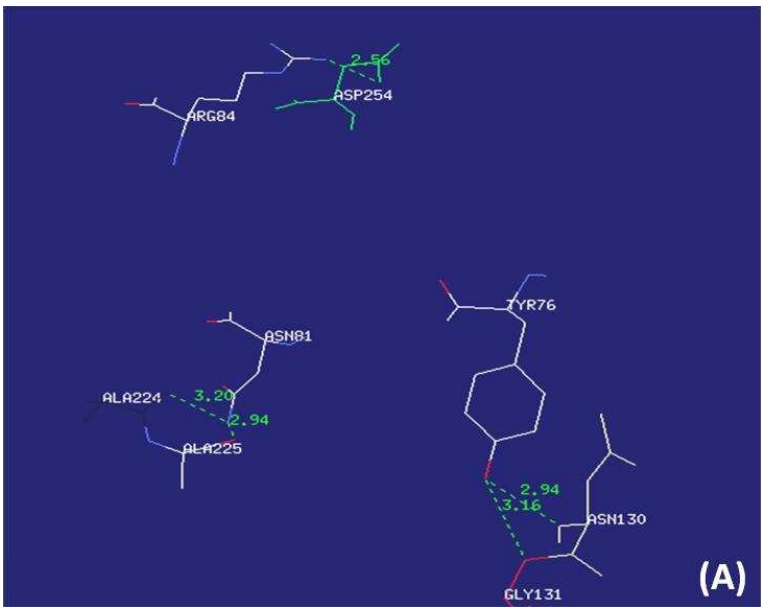
The two proteins interacted only through hydrogen bonds and no disulphide or covalent bonds were observed. The PDBePISA tool was utilized to locate the most effective interaction between coat protein and the two chains, i.e. chain A and B of CVL as mentioned before as CVL has four chains and chain 1 and 3 are same as chain 2 and 4. The outcomes demonstrated that various residues of the CP are predictable to act with the chain of CVL. In the case of A and C domain of CVL interaction with CP, totally 13 hydrogen bonds were observed from which three bonds, which are highlighted in *Table 1* has been shown in *Figure 3A*. In the case of B and D domain of CVL interacting with CP, totally 9 hydrogen bonds were observed from which two bonds, which are highlighted in *Table 2* has been shown in *Figure 3B*.

CVL protein purification and cytotoxic activity

CVL protein was purified through cation exchange chromatography using the column Hi Trap SP FF (GE Healthcare). On SDS-PAGE, two final fractions were obtained with their exchange profiles; one was of 10.5 kDa and the other fraction was about 11.5 kDa (*Fig. 4A* and *B*).



http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

The cytotoxic concentration that inhibited 50% of cell growth (CC50) showed that the CVL protein extract had the highest cytotoxicity with CC50 value of 770 µg/ml (*Fig. 4*). It was found that at 110 µg/ml CVL concentration, the cytotoxicity was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13011315

111.47%. Similarly, at 220, 330, 440, 550, 660 µg/ml CVL concentrations, the cytotoxicity was recorded as 71.87, 62.39, 65.13 and 54.00% as compared to the control (*Fig. 5*).

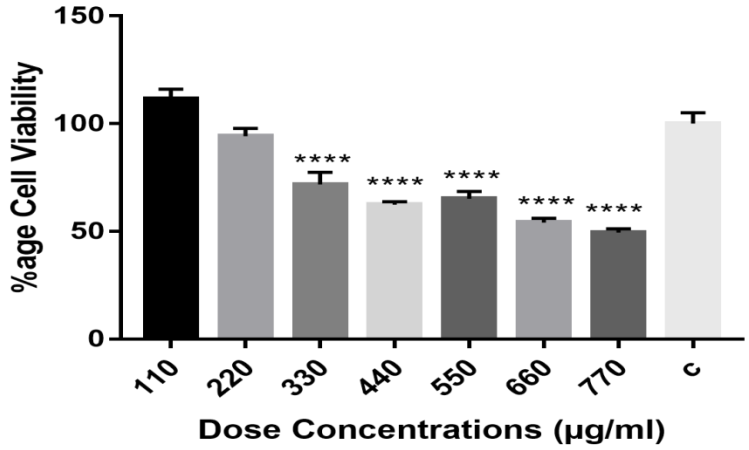

Figure 5. *Cytotoxicity of CVL to reveal a safe dose limit. The dose concentration of CVL purified protein extracts was ranging between 110 -770 µg/ml. Percentage cell survivals were calculated for each dose. Bars indicate the standard deviation. One-way ANOVA (see tables in the Appendix) shows the significant reduction of cell viability at the concentrations 330, 440, 550, 660 and 770 µg/ml at P < 0.0001. Three biological replicated were processed to obtain data*

Hemagglutination activity

The minimum concentration of purified CVL was observed at the end of the 1-h incubation period, which shows hemagglutination activity against the rabbit erythrocytes was high approximately 100 µg/ml as described by Van Dam et al. (2000).

Antiviral activity of CVL purified fractions against CP-PVY

In the antiviral screening assay, the CVL purified fractions were found to be active against the CP-PVY in in-vitro assays. Briefly, 30 µg/ml CVL displayed 98% inhibition of CP-PVY, 99% inhibition at 60 µg/ml, while up to 100% inhibition at 90 µg/ml CVL concentration (*Fig. 6*). However, the control sample did not exhibit any inhibition of CP-PVY expression.

Discussion

Potato is central crop and it is rigorously affected by Potato Virus Y (*PVY*). The essential point of the present work was to utilize CVL to effectively build firm PVY-resistance in in-vitro assays. Lectins derived from different plants have shown the antiviral activity against different plant viruses (Lusvarghi and Bewley, 2016; Liu et al., 2014). CVL is a tetrameric protein comprising of four subunits with two chains of 10.5 kDa, while other two of 11.5 kDa and is capable of agglutinating the rabbit erythrocytes. Previous studies have shown that CVL and lectin from *C. sativus* has identical N-terminal sequences and moreover, CVL showed reasonable similarity with respect to the two domain lectins of tulip and *Arum maculatum,* which reinforce that the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13011315

CVL belongs to monocot mannose-binding lectins (Van Dam et al., 2000). There are numbers of pathogens, including bacteria, fungi, viruses and parasites through, which mannose binding lectins interact and provide protection against these to the host (Kilpatrick, 2002).

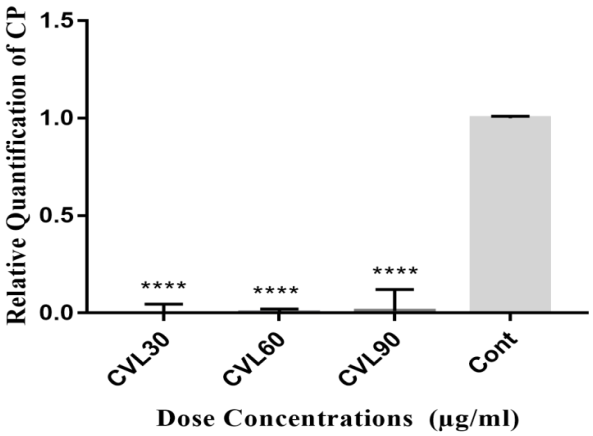

Figure 6. *Real time PCR study of down regulation of CP-PVY against CVL. Antiviral activity of CVL dose against CP-PVY. Three dose concentrations of CVL were tested; 30, 60 and 90 µg/ml. Percent inhibition of CP-PVY mRNA was measured, bars in the graph depict the standard deviation, while a significant decrease in CP gene expression was observed in 30, 60 and 90 µg/ml at P < 0.0001*

Protein docking refers to the scheming of three-dimensional (3D) structure of a protein initiating with the separate structures of protein subunits. The aim of protein docking is to know how proteins interact (Vitkup et al., 2001). Aloy and Russell stated that an estimate of 9 interaction partners are present for each protein and these interactions are one of around 10000 basic types, out of which only 2000 are known till date (Aloy and Russell, 2004) protein docking has emerged as a distinct computational field which make use of techniques and knowledge from diverse spectrum of science with the intention of formulating in silico how macromolecules like proteins act (Camacho et al., 2000). The in-silico protein-protein interaction showed that CP interact with the chain C and chain B of CVL. Our findings correlate with of Zhang et al. (2017b) who reported that Arg90 of *TMV* (tobacco mosaic virus) has a major role of interaction with the antiviral enantiomericα-aminophosphonate derivatives for the loss of virus ability to cause infection. In a similar study, mannose binding lectin from *Lycorisradiate* indicated that Gln80, Asp82, Asn84 and Tyr88 are the main residues which are involved in the interaction with mannose (Zhu et al., 2013).

We adopted in-vitro assay to reveal the antiviral effect of CVL, which is based on transient expression of the CP gene in the mammalian cell line. Several reports support the adoption of in-vitro assay to screen potential plant extracts against plant viruses like Li et al. (2012) showed that tobacco mosaic virus (*TMV*) virions were transfected into HeLa cells to generate the expression of the CP gene of *TMV*. The possibility of plant capsid uptake and release in mammalian cells has been proposed in case of clover necrotic mosaic virus (*RCNMV*) by Lockney et al. (2011). In another study, 480 bp of CP from *PVY* was transfected into CHO cells and its mRNA knockdown assay was conducted with siRNA (Tabassum et al., 2011). Furthermore, plant viral capsids have

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13011315

been used as vectors in mammalian cells for gene delivery and expression studies (Azizgolshani et al., 2013). More recently, *Arabidopsis* cryptochrome was successfully expressed in the HEK293T cells to produce a photochemically active product (Yang et al., 2016).

To reveal the activity of lectin (CVL), instead of full *PVY* virus particles, we cloned the CP gene as it is involved in the number of virus infection events like, uncoating and translation of the viral RNA, targeting the site of replication and in the transmission of potyviruses by vectors/aphids (Bol, 2008). There are some studies which clearly indicate involvement of CP transgene in creating resistance in transgenic potato crops (Bukovinszki et al., 2007; Gargouri-Bouzid et al., 2005).

The high antiviral effect of CVL protein fractions (up to 100% in our study) attributed the effectiveness of plant derived lectins in preventing notorious plant viruses like PVY. Plant lectins might show involvement in recognition of pathogenic microorganisms. Lectin from a soybean show high affinity for binding to β-glucan, which is a powerful PAMP of Phytophthorasojae (Mithöfer et al., 2000). Similarly, spread of tobacco etch virus (TEV), a single-stranded RNA plant virus belonging to the genus Potyvirus is restricted by, the *Arabidopsis thaliana* restricted TEV movement 1 (RTM1) lectin gene (Whitham et al., 2000). Moreover, a jacalin-type lectin gene exhibits resistance to potexviruses which belong to family Potexviridae. This resistance is conferred in the early stage of infection caused by plant viruses as compared to another lectinRTM1 which shows resistance at an advanced stage of viral infection, implementing the vital role of lectin-mediated resistance in a multiplicity of plant-virus relation (Yamaji et al., 2012). Conclusively, we have reported the antiviral activity of lectin derived from *C. vernus* against potato virus Y. The purified fractions of CVL exhibited the strong antiviral effect against *PVY*. To the best of our knowledge, this is the first report on the antiviral activity of CVL against *PVY*. Furthermore, as results showing the maximum down regulation of the CP gene due to CVL, which clearly indicate that efficiency of the CVL against PVY. The genetic integration of lectin in the potato genome could provide complete protection from PVY in transgenic potato plants.

Conclusion

Lectins obtained from different plants have been shown to have antiviral activity against various plant viruses. The purified *Crocus vernus* lectin exhibited the strong antiviral effect against *PVY*. This is the first study of CVL's antiviral activity against PVY, as far as we know. Genetic incorporation of lectin into the genome of potatoes could provide comprehensive defense against PVY in transgenic potato plants.

(Received 9th Sep 2019; accepted 4th Dec 2019)

Abstract. Biogenic amines and neuropeptides are important neurotransmitters and modulators in the peripheral and central nervous systems of several invertebrate species. Biogenic amines play essential roles in modulating physiological and behavioral processes as neuromodulators, neurotransmitters, and neurohormones. Biogenic amines such as octopamine, dopamine, tyramine, or even serotonin can act as slow neuromodulator or fast transmitters. In both invertebrates and vertebrates, dopamine found in the central nervous system. Dopamine receptors (D1-like family - D1, D5) and (D2-like family- D2, D3, D4) directly modulate and regulate other neurotransmitters, the release of cyclic adenosine monophosphate (cAMP), differentiation, and cell proliferation. Here, we highlighted the essential role of dopamine and dopamine receptors in the control of cognition, locomotion, attention, memory formation, and behavioral plasticity in the central nervous system (CNS). In CNS, D1-like and D2-like are the most abundant dopamine receptors. Dopamine receptors contribution in several aspects of motor function, cognition besides reinforcement/reward and complex behavior. Behavioral and mental diseases associated with major neurotransmission disruptions of dopamine as well as hyperactivity/attention-deficit disorder, schizophrenia, substance abuse, and Huntington's disease cause a major neuropsychological deficiency in attention, memory, and learning besides to other major symptoms.
Keywords: *biogenic amines, honeybee, memory, receptors, olfactory learning*

Introduction

In numerous social insects, such as bees and ants, biogenic amines perform decisive roles in the regulation of sociality. How biogenic amines (BA) and their receptors in ancestral, most of the solitary species have been chosen during the change to control different behaviors in complex social species are discussed by Kamhi et al. (2017). Biogenic amines are vital messenger elements in the central nervous system (CNS) and the peripheral area of invertebrates and vertebrates. Honeybee, *A. mellifera*, is outstandingly appropriated to reveal the biogenic amines functions in behavior, as long as it has wide-ranging behavioral capabilities, in this insect, there are a lot of biogenic amine receptors (Scheiner et al., 2006). Biogenic amines are involved in coordinating responses related to metabolic reactions, for instance, starvation. Whenever there exist starve d rate-limiting enzyme tyrosine-ß-hydroxylase mutant fruit flies, octopamine cannot be synthesized, having higher concentrations of glucose level in their hemolymph compared to controls, as revealed by Li et al. (2017). Damrau et al. (2018) investigated starvation or fat deposition resistance by using fruit flies defective in the expression of tyramine and octopamine receptors. Their tissue-specific RNAi experiments showed a very complicated interorgan transmission resulting in various

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13171327

metabolic phenotypes in tyramine and octopamine lacking fruit flies. Stocker et al. (2018) reported the comparison of the axon terminals of octopaminergic efferent ventral and dorsal median unpaired neurons in whether fruit flies or desert locusts throughout skeletal muscles, exposing numerous similarities. For both octopamine and tyramine, type11 terminals are immunopositive and dissimilarity to the type I terminals that have visible synaptic blades, and they comprise of dense-core vesicles. They revealed that hunger modulates the neuromuscular-branched morphology in a time-based manner. In this mini-review, we discuss the role of dopamine (DA) receptors to regulate the behavior in honeybee and other insects and summarize the role of dopamine, types, physiology, and genes of dopamine receptors.

Moreover, the authors confirmed that the delivery of octopamine from axonal and dendritic type II terminals applies parallel to synaptic machinery to glutamate allow from excitatory motor neurons (type I terminals). Buckemüller et al. (2017) examined changes in glucose concentration level in hemolymph, feeding, and survival behaviors after hunger and studied the role of octopamine on these pharmacological experiments. Their experiments confirmed that octopamine in honeybee performs similarly to noradrenalin and adrenalin in mammals in modulating an animal's counter-regulatory response. The study evaluates different types of octopamine and tyramine receptors that might be involved in energy homeostasis. Many neurons that mediate the release of octopamine belong to the class median dorsal unpaired neurons, and their electrical qualities in cockroaches have been widely investigated by Lapied et al. (2017). Scheiner et al. (2017) reported the role of the fat body in regulating gustatory sensitivity accomplished by tyramine signaling in many behavioral races of the honeybee. Their findings proposed that distinctive tyramine signaling in the fat body play an essential role in the adaptability of labor division by modulating gustatory responsiveness (*Fig. 1*).

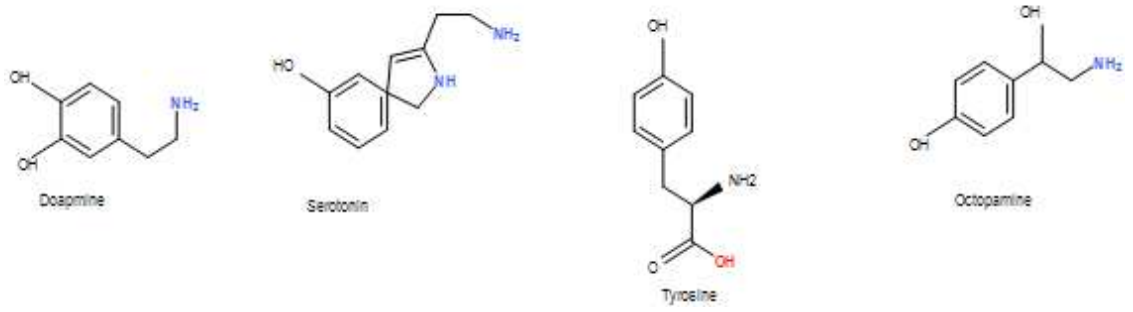

Figure 1. *Chemical structure of each monoamine*

Blenau et al. (2017) disclosed the fifth serotonin receptor in Drosophila melanogaster that is Dm5-HT2B. Besides that, three Dm5-HT7, Dm5-HT1B, and Dm5-HT1 along with the Dm5-HT2A and cyclic adenosine monophosphate (cAMP) signaling cascades directing toward Ca2 + signaling mechanism through ITP. Authors also reported that this important fifth receptor is concerned with immune system function and controlling heartbeat, and it can be aggravated by mianserin and metoclopramide. The circulation of immune reactivity for receptor molecules-AmTyr1 and tyramine has been reported by Sinakevitch et al. (2017) for the brain of the honeybee, and specific significance is positioned on neuropils related to olfactory sensation learning and memory (*Fig. 2*). They emphasized two important Ventral (Unpaired) median neurons of the suboesophageal ganglion belong to axons that arise to the bee's brain and stimulate the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13171327

antennal lobe (AL) and mushroom body (MB) calyx. Remarkably, AmTyr1 expression was initiated in pre-synaptic positions of olfactory receptor neurons (ORN) and projection neurons, maximum prospective to apply for the inhibitory mechanism of neurotransmitter (Chemical messenger) release.

There is adding confirmation that octopamine and tyramine use opposite performances in insects. Their investigation upon Drosophila melanogaster (fruit fly) flight behavior, revealed the role and importance of tyramine and an enzyme-dehydrogenase/reductase for tyramine catabolism. This enzyme is found in the specific glial cells group, which is placed near the border of motor neuropil and through continuations toward the motor neuropil of flight. Whenever RNAi knocks down this enzyme, flight time is decreased, which is distinctive for high tyramine levels and blocked octopamine. This study also explores critical signaling pathways for tyramine (Ryglewski et al., 2017).

(Source: Grünewald, 1999; Barron et al., 2015)*

Role of dopamine and dopamine receptors

Berke (2018) described that dopamine transfer's motivational significance and encourages movement activity even at seconds time scales. They also reported that, is dopamine a signal for motivation or signal for learning, or both? Our knowledge about dopamine has modulated in the previous and is fluctuating once again. One essential and distinctive is between dopamine effects on future learning behavior and current

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13171327

performance behavior. Both kinds of behavior are significant and real, but sometimes one was in favor, and other was not. DA is a critical vital learning and motivation modulator. Dopamine receptors (D1-like, D2-like) are classified into two significant subfamilies. Dopamine is a major neurotransmitter that facilitates physiological tasks in both the peripheral and central nervous system (CNS) via relating to DA cell surface receptors. Dopamine receptors (D1-like, D2-like) are classified into two significant subfamilies. Dopamine is a major neurotransmitter that facilitates physiological tasks in both the peripheral and central nervous system (CNS) via relating to DA cell surface receptors. DA receptors are G-protein coupled receptors (GPCRS) that are categorized into (D1-like, D2-like) receptors based on their physiological, pharmacological, and biochemical effects (*Fig. 3*).

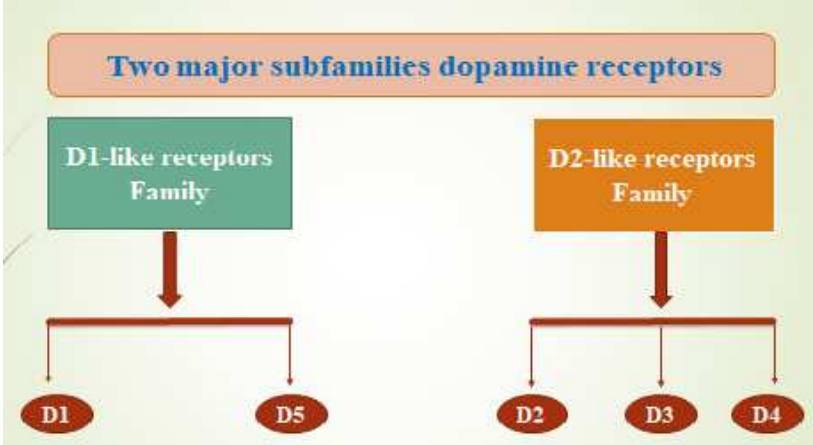

Figure 3. *Dopamine receptors are divided in to two major subfamilies: D1-like and D2-like*

Physiology of dopamine receptors

The biogenic amines (BA) of serotonin, dopamine, tyramine, and octopamine in the honeybee modify neuronal tasks in numerous ways. Serotonin and dopamine are present in the bee brain at high concentrations. Additionally, tyramine and octopamine are a small quantity. Octopamine is a critical molecule to regulate the behavior of honeybee. It usually has a stimulating effect and results in increasing the sensitivity of sensory inputs, improve learning efficacy, and better foraging behavior. Tyramine has been recommended to act as an inhibitor to octopamine, but only limited experimental data are available for this amine. Serotonin and Dopamine often have inhibitory effects in comparison with octopamine. Scheiner et al. (2006) reported the role of BA and biogenic amines receptor-mediated cellular responses regulating distinct behavior involved in learning performance and labor division. Biogenic amines (BA) bind to membrane receptors that belong primarily to big GTP-binding (G) protein gene family combined with receptors. The behavioral function, the regional brain expression, selective antagonists, selective agonists, and mechanism of action of various types of dopamine receptors are outlined in (*Table 1;* Mishra et al., 2018).

Significant differences are produced in the concentration of Inositol trisphosphate receptor (IP3), (cAMP), and Ca2 + in intracellular Second messenger levels. Besides, several honeybee (BA) receptors have been characterized and cloned recently; still, several genes remained to be recognized. The approachability of the fully sequenced *Apis mellifera* genome will make a significant contribution in bridging this gap in *Table 2*.

Types of dopamine receptors

Dopamine receptors are five distinct kinds (D1, D2, D3, D4, and D5), all receptors, coupled with G-proteins. These subtypes are categorized into two significant classes

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13171327

(D1 like receptors and D2 like receptors). D1 like receptors are excitatory and post-synaptic. D2 like receptors are inhibitory, pre-synaptic, and post-synaptic. (Rang HP, 2006) summarized the overview of activation of each receptor type, follow the comparison of kinds and function of dopamine receptors, and Under comparison of the kinds and tasks of dopamine receptors, it is possible to determine how the dopaminergic system unique built-in phyla. Ferreri et al. (2019) demonstrated that dopamine role is related to the pleasure of music experience. They orally controlled each contributor, a dopamine antagonist (risperidone), a placebo (lactose), and a dopamine precursor (levodopa) in three separate sessions, according to their results, risperidone and levodopa led to a conflicting response in trials of motivation and musical pleasure. Although the placebo compared with dopamine precursor levodopa, improved the cognitive experience and motivational responses associated with music, but risperidone result decreased in both. Shows a vital function musical pleasure of dopamine and specifies that dopaminergic transmission could play a distinct role.

In recent studies,(Beggs and Mercer (2009) found that Queen mandibular pheromone produced by the queen is used to control the physiology and behaviors of their colony individual. Homovanillyl alcohol is one of the significant components of Queen mandibular pheromone QMP in blocking aversive learning in young working bees. Homovanillyl alcohol (HVA) was found to reduce the concentration of brain dopamine and modify the intracellular cAMP concentration in the centers of the brain concerned with learning and memory. They investigated that HVA directly interacts with the bee's dopamine receptor, also HVA activates AmDOP3 (D2-like dopamine receptor) selectively. They suggested a specific molecular system through which dopamine signaling pathways can be modulated. *Apis mellifera* dopamine receptor (DOP3) induced blockage of aversive learning in worker bees is caused by HVA (Beggs and Mercer, 2009).

In a study on *Apis mellifera* brain, Lerner et al. (1995) observed that expression of amino-receptors varies significantly throughout Kenyon cell subpopulations. In present models of mushroom body function, differential expression of amine-receptor genes in neurons and plasticity that exists at this stage are mainly ignored characteristics. Their findings are consistent with confirmation that short- term and long-term sensory memories formed in distinct parts of the brain's mushroom bodies and there are efficient parts of the brain center (McQuillan et al., 2012 b). They illustrated the role of gene expression in reproductive organisms of male honeybee are throughout the sexual development and maturation. Dopamine is a distinct operator between three reproductive systems and CNS. They also suggested that in seminal vesical of honeybee brain, 20 dopamine receptors can be used to drive dopamine (DA) for reproduction and 21 receptors involved in storage and sperm transfer in the reproductive organ of males (Matsushima et al., 2019).

In these studies, they investigated specific caste development of the dopaminergic system in female honeybees during metamorphosis. Caste-specific changes by dopaminergic systems in social insects help to continue caste-specific behavior. Their findings showed that the developmental procedure of caste-specific dopaminergic systems in honey bee during metamorphosis recommends caste-specific behavior and reproduction division in this greatly eusocial species (Sasaki et al., 2018).

Mustard et al. (2010) investigated that dopamine and D1-like receptors (AmDOP2) cause regulation of motor behavior in the honeybee. Assessing the particular molecular pathways by which dopamine impacts behavior complexed by the involvement of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13171327

various subtypes of dopamine receptors linking distinct second messenger pathways. Spontaneous movements of adult bees in the field were used to explore the role of dopamine signaling in modulating the behavior of honeybee. A significant difference between control and treated bees was observed for many behaviors such as flying, grooming, fanning, stopped walking and upside down. Finally, their findings established that DA plays a significant role in modulating the motor behavior of the *Apis mellifera* (Mustard et al., 2010).

Kokay and Mercer (1997) found the developmental changes in densities of dopamine receptors and the measurement of dopamine levels in the honeybee brain. Their findings confirmed the expression of dopamine receptor subtype-specific patterns in insect brain and illustrated that D1 and D2-like receptors are not only expressed in the adult bees CNS, as well as during bee's brain developmental stages (*Fig. 4*)

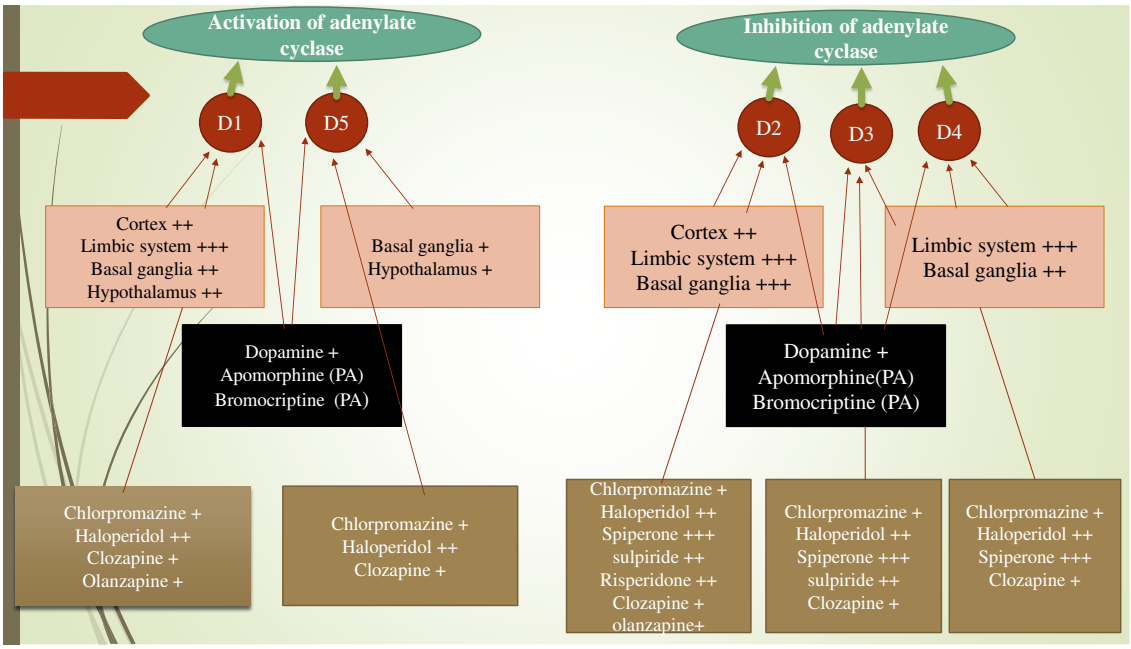

Figure 4. *Expression of dopamine receptor*

Role of dopamine in insects

Locusta migratoria (migratory locust), showed incredible phenotypic adaptability in response to the population density variation at morphological, physiological, and cognitive levels. In migratory locust, two dopamine (Dop1 and Dop2) receptors play distinct roles in developmental changes. DA and dopamine genes in metabolic pathways facilitate phase modification in *L. migratoria*. They proved that dopamine (Dop1 and Dop2) controlled locust phase variation in two various directions (Guo et al., 2015).

The significant role of dopamine being strengthening and processing is applied in a range of species varying from *Homo sapiens* to *Drosophila melanogaster*, while D1 receptors have been recognized to make a significant contribution to fruit flies' aversive odor sensitivity learning. Scholz-Kornehl and Schwartzel (2016) revealed that D2 receptors endorsed to facilitate a combined type of odor memory referred to as anesthesia-resistant learning and memory. Observing the distinct role of dopamine and dopamine receptor (D2R) in "forgetting"(retroactive role of dopamine), balancing,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13171327

acquisition of memory (the proactive task of dopamine) and dopamine release, their findings recommended D2R as the crucial player of each process (Scholz-Kornehl and Schwärzel, 2016). Ichinose et al. (2017) analyzed the function of dopaminergic neurons in the fruit fly brain, and how they influence the animal's internal condition/cognitive behavior. Dopamine might play both roles, a slow neuromodulator, a fast neurotransmitter. It depends on the postsynaptic neuron. Genetic modification of dopamine neuron activity resulted in differences in the fly's behavior. Behaviors such as learning and memory, sexual drive, sleep, and hunger were affected (Ichinose et al., 2017).

Zhukovskaya and Polyanovsky (2017) studied the effects of various amines such as octopamine, tyramine, dopamine, and serotonin on olfactory and gustatory receptor neurons in insect antennae. Many amines systemically released into the hemolymph, an open circulatory system in insects, supplied different body compartments, the dorsal or ventral cavity, the muscles, the central nervous system, and so on.. The authors suggest that the antenna may be a partially autonomous hemolymph compartment separated from other body parts. An important aspect of chemical signaling is that all transmitters, whether they be classical transmitters, neuromodulators, or hormones, can only act through their respective receptor molecules. Depending on which receptor type activated, different signaling cascades can be triggered. In this issue, some articles devoted to receptors. Niens et al. (2017) showed that in the fruit fly, imbalances between dopamine and serotonin are modeled. Like in rodents, a lack of dopamine leads to increased levels of 5-HT and arborizations in specific brain neuropils.

Conversely, increased dopamine levels lead to reduced connectivity of 5-HT neurons., both neurons, dopamine, and 5-HT play an essential role in learning behavior. Dopamine signaling is critical for mediating reinforcing properties of unconditioned stimuli during associative learning. Tedjakumala et al. (2017) characterized dopaminergic neurons in the honeybee brain by immune reactivity distribution of dopamine precursor enzyme, tyrosine-hydroxylase. They also describe new clusters of dopaminergic neurons. Sun et al. (2018) studied startle-induced locomotion and the activity of specific clusters of dopaminergic neurons afferent to the mushroom bodies.

Conclusion

Receptors of dopamine (DA) have a crucial role in a broad range of behavior, such as motor function, sensory processing, arousal, and reward. In this way, abnormal dopamine signaling is correlated with many psychiatric and neurological disorders. Comprehension of the pathways through which DA neurotransmission motivates intracellular signaling mechanisms, that behavior modulation can provide essential insights for the development of specific therapeutics. Since these general themes begin to emerge, a lot of work needs to be done to distinguish the particular signaling mechanisms of DA receptors in simple model organisms.

This mini review also contributes toward an emerging picture of the brain circuits modulating locomotor reactivity that appear to both overlaps and differ from those mediating associative learning and memory, sleep/wake state, and stress-induced hyperactivity. Furthers, requires more investigation on the molecular, pharmacological, functional, and physiological basis of dopamine receptors and functions in modulating phase change will improve our understanding of the molecular mechanism underlying phenotypic plasticity in honeybee and model insects.

Abstract. Salinization is one of the most significant environmental problems in the world. Salinity negatively affects the physicochemical properties of the soil and reduces crop production. This study aimed to investigate the potential use of *Aptenia cordifolia* L. for the phytoremediation of salt-affected soils. Three salt levels; non-saline (NS, EC: 1.38 dS m^{-1}), slightly saline (SS, EC: 3.54 dS m^{-1}) and highly saline (HS, EC: 9.58 dS m^{-1}) soils were collected from Harran Plain-Turkey and used to cultivated *A. cordifolia* in pots. To assess the salt tolerance of the plants, physiological and biochemical parameters as well as the accumulation of leaf Na^+ and Cl^- ions were determined. In the meantime, soils were evaluated in terms of electrical conductivity, pH, organic matter and soil enzymes (dehydrogenase, urease, phosphatase and protease) before and after the cultivation. A significant increase in shoot fresh weight and dry weight were obtained from *A. cordifolia* cultivated-SS soils. No significant differences were determined in terms of crop yield in NS and HS soils. A decrease in total chlorophyll content was evident only in plants growing in HS soils. Proline and malondialdehyde contents and the activity of catalase and peroxidase enzymes were found significantly higher ($P \leq 0.05$) in plants growing in HS as compared to those growing in SS and NS soils. *A. cordifolia* plants, accumulated more Na^+ and Cl^- ions in their leaves as the salinity levels increased. Soil pH levels under all soil conditions were not affected although slim increases were observed. However, soil electrical conductivity were decreased 2 and 2.5 times in SS and HS soil types, respectively. Soil organic matter were significantly increased along with the increase in the activity of soil enzymes in all soil types. We suggest that cultivation *A. cordifolia* in SS and HS soils will improve the condition of soil physicochemical properties in an environmentally-friendly manner.
Keywords: *abiotic stress, phytoremediation, soil enzymes, halophytes, ameliorate*

Introduction

Salinization is a worldwide problem in which salts gradually accumulate in the soil. In this process, water-soluble salts in the soils are dissolved via irrigation or rain and transferred to upper part of the soil and can then be accumulated when irrigation or rain ceased in semi-arid or arid environments (Panta et al., 2018). This negatively affects the crop productivity, quality and microbial community thus affects soil health (FAO, 2016). Due to soil salinization, soil infertility has been in an increasing trend (Slama et al., 2015). If serious measurements have not been taken, salt stress not only negatively affects the physical and chemical properties of the soil but also reduces the concentration of microorganisms and decrease the soil fertility. On the other hand, salinity reduces the quality and quantity of crops and in severe cases, it would not allow any seeds to germinate in which the standing point of agriculture (Yuan et al., 2007;

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13291345

Negrao et al., 2017). Salt stress also leads to the production of reactive oxygen species (ROS) in crop plants that disrupt the membrane functionality and damages protein, lipid and nucleic acids. Although plants are able to develop a series of ROS detoxification mechanisms to minimize the impact of ROS via antioxidative enzyme systems including catalase (CAT), glutathione reductase (GR), superoxide dismutase (SOD), ascorbate peroxidase (APX) and non-enzymatic metabolites (ascorbate, proline, glutathione etc.), this may not be enough for plants to function under harsh conditions. Even resistant plants may not cope with the ongoing stress such as salinity and heavy metal stress (Gill and Tuteja, 2010; Hossain et al., 2017).

In nature, plants develop various physiological and biochemical mechanisms in order to survive in soils characterized with salinity. General salt tolerance mechanisms include ion homeostasis and compartmentalization, ion transport and uptake and synthesis of osmoprotectants via compatible solutes (Gupta and Huang, 2014). Halophytes are plants that can tolerate and grow in soils characterized with high salt concentration. They, in general, are known to accumulate salts in various plant parts such as leaf, root etc. (Grigore et al., 2014; Flowers and Colmer).

Various physical, chemical and biological techniques can be used to remediate salt contaminated soils. The use of halophytes is one of the most promising and cost-effective methods for phytoremediation. It is a strategy where plants are used to remove, immobilize, degrade the soil contaminants such as salt and heavy metals (Kaushal et al., 2015). Phytoremediation has been used to manage wastes, especially petroleum hydrocarbons, polycyclic aromatic hydrocarbon, organic matter, and nutrients. So far a number of plants have been identified in use of phytoremediation purposes. Reclamation of salt-affected soils could be achieved and crop plants could grow in less stressed soils. Glycophyte plants could be grown together with the halophytes as companion plants in such soils. Also, the harvested above-ground biomass of halophytes can be used as animal feed (Ammari et al., 2013; Karakas et al., 2013).

A. cordifolia (L. f.) Schwant, also known as *Mesembryanthemum cordifolium*, is a species of succulent plant from the Aizoaceae family and has a Crassulacean acid metabolism (CAM) (Herppich and Peckmann, 1997; Tripodi and Modesta, 2003). In this study, we aimed to determine the performance of *A. cordifolia* against salt stress and to evaluate its performance under saline conditions for phytoremediation purposes. We determined the shoot fresh and dry weight, total chlorophyll, proline, malondialdehyde (MDA), Na^+ and Cl^- ions levels and catalase (CAT, E.C.1.11.1.6) and peroxidase (POX, E.C.1.11.1.7) enzyme responses of *A. cordifolia.* We also elucidated the physical and chemical properties of the soil in the vicinity of root area of *A. cordifolia* to determine the remediation capacity of the halophyte through measurement of soil electrical conductivity (EC), pH, organic matter (OM), ion (Na^+, Cl^-) contents and soil enzyme activities (dehydrogenase, urease and protease) prior to and following cultivation with *A. cordifolia.*

Materials and methods

Experimental design and plant growth

Treatments consisted of three different soil salinity levels; non-saline (NS, EC: 1.38 dS m^{-1}), slightly saline (SS, EC: 3.54 dS m^{-1}) and highly saline (HS, EC: 9.58 dS m^{-1}) soils collected from Harran Plain-Turkey. Trials were performed in a randomized block design with three replicates. Before trial, soil samples were carefully air-dried to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13291345

allow sieving with a 2-mm mesh sieve. Three-week-old *A. cordifolia* seedlings were planted into 8-L pots containing 6 kg air-dried soil from each category in greenhouse (35 °C ± 1) conditions. The seedlings were planted on (April 2016) at a rate of 6 plants per pot. Pots were irrigated with full field capacity. Plants were then harvested on (July 2016) 100 days after onset of treatments. For the plant analysis, the shoot fresh weight (FW) and shoot dry weight (DW) were determined following harvest (*Fig. 1*).

Figure 1. *Growth of A. cordifolia at three different salinity levels*

Total chlorophyll contents were determined according to the method of Arnon (1949) with slight modifications (Dikilitas, 2003). For the analysis, a 0.5 g leaf sample was homogenized in a 5 mL acetone: water (80:20% v/v) mixture. After filtration through Whatman No. 2 filter paper, a reading was made against 80% acetone blank for total chlorophyll at 652 nm using a UV spectrophotometer (UV-1700, Shimadzu). The results were then expressed as mg g^{-1} FW for total chlorophyll.

The proline measurement was conducted according to the method of Bates et al. (1973). Acid-ninhydrin was employed as a reagent, which was made by dissolving (warming and agitating) 1.25 g of ninhydrin in 30 mL of glacial acetic acid and 20 mL of 6 M phosphoric acid. A quantity of 0.5 g of leaf material was homogenized in 10 mL of 3% w/v sulphosalicylic acid then the homogenate was filtered through Whatman No. 2 filter paper. A 2-mL of filtrate was mixed in a test tube with 2 mL of acid ninhydrin reagent and boiled at 100 °C for 1 h. The reaction was terminated in an ice bath. The reaction mixture was extracted with 5 mL of toluene. Tubes were thoroughly shaken for 15-20 s and left for further 20 min in order to achieve separation of the two layers. The chromophore containing toluene was removed and allowed to warm to room temperature. Absorbance of the solution was measured at 515 nm using a toluene blank as a reference in a spectrophotometry (UV-1700, Shimadzu). The results were expressed as µmol g^{-1} fresh tissue.

The malondialdehyde (MDA) content was determined according to the method of Sairam and Sexena (2003). A 0.5 g leaf tissue sample was homogenized using 10 mL of a 0.1% trichloroacetic acid (TCA) and the homogenate was centrifuged at 10,000 *g* for 5 min. Four mL of 20% v/v TCA containing 0.5% v/v thiobarbituric acid (TBA) was added to 1 mL of the supernatant. The solution was heated at 95 °C for 30 min and then quickly cooled on ice. The mixture was centrifuged once again at 10,000 *g* for 5 min and the absorbance of the clean supernatant was determined at 532 and 600 nm. The MDA content was calculated using *Equation 1*.

$$MDA\,(nmol\ g^{-1}) = \frac{Extract\ volume\,(ml)\ \mathrm{x}\ \left[(A_{532} - A_{600})/(155\ mM^{-1}\ cm^{-1})\right]}{Sample\ amaunt\,(g)}\ \mathrm{x}\,10^{3} \quad \text{(Eq.1)}$$

DOI: http://dx.doi.org/10.15666/aeer/1801_13291345

Catalase enzyme activity (CAT, E.C.1.11.1.6) was determined by monitoring the decomposition of H_2O_2 according to the method of Aebi (1984), with slight modifications (Karakas et al., 2016). For the analysis, 0.5 g of plant material was homogenized in 10 mL of a 50 mM Na-phosphate buffer solution then 50 µL of plant extract was added to a 2.95 mL (10 mM H_2O_2, 50 mM Na-phosphate buffer and 4 mM Na_2EDTA) reaction mixture and measured for 30 s at 240 nm with a UV spectrometer (UV-1700, Shimadzu). One CAT activity unit (U) is defined as a change of 0.1 absorbance unit per minute. Activity is expressed as enzyme units per gram fresh weight.

Peroxidase enzyme activity (POX, E.C.1.11.1.7) was determined by monitoring the increase in absorbance due to the tetraguaiacol formation at 470 nm according to the method of Cvikrova et al. (1994) with slight modifications (Karakas et al., 2016). For the analysis, 100 µL of extract (obtained as above) was added to 3 mL of the reaction mixture (13 mM guaiacol, 5 mM H_2O_2, and 50 mM Na-phosphate, pH 6.5). The reaction was initiated with an H_2O_2 addition and was measured at 470 nm using a UV spectrophotometer (UV-1700, Shimadzu) at 1-min interval until 3rd minute. One unit of POX activity is defined as a change of 0.1 absorbance unit per minute at 470 nm. Activity is expressed as enzyme units per gram of fresh weight.

The Na^+ ion content of leaves was determined according to the method of Chapman and Pratt (1961). with slight modifications (Karakas et al., 2016). Samples burned at 500 °C were homogenized in 5 mL of a 2N HCl. For quantification of Na^+ ions, the homogenate obtained following filtration was analyzed via Inductively Coupled Plasma (ICP, Perkin Elmer).

Chloride determination of plant samples was made according to the Mohr method using indicator (Johnson and Ulrich, 1959; Kacar and Inal, 2008).

Soil samples electrical conductivity (EC), pH, organic matter (OM) content and soil enzymes were determined before and after the trial. Soil EC and pH were determined using a saturated soil paste extraction (Soil Conservation Service, 1972; Thomas, 1996). OM content was determined according to Walkley (1947) and FAO (1974). One gram soil, 10 mL 1 N $Cr_2O_7^-$ solution and 20 mL concentrated H_2SO_4 were poured into 500 mL beaker and mixed and allowed to stand for 30 min at room temperature. Then, 200 mL dH_2O and 10 mL concentrated orthophosphoric acid was added to the solution. The mixture was then cooled down to room temperature and 10-15 drops of diphenylamine indicator were added. The mixture was then titrated with 0.5 M $FeH_8N_2O_8S_2$ solution until the color changes from violet-blue to green. A reagent blank using the above procedure without soil was employed. The blank is used to standardize the Fe^{2+} solution daily. OM was calculated with *Equation 2*.

$$Total\ C(\%) = \left((A-S)xFe^{+2}x(0.003)x(100/B)\right) \quad \text{(Eq.2)}$$

To convert total C, the results were multiplied by 1.30 into the correction factor, OM, *Equation 3* was used.

$$OM(\%) = TotalCx1.72/0.58 \quad \text{(Eq.3)}$$

where A: blank titration ml ferrous solution, B: sample titration ml ferrous solution, 0.003: milliequivalent weight of C in g, factor of 1.72.

Dehydrogenase activity was measured using triphenyl tetrazolium chloride (TTC) colorimetric analysis according to Tabatabai (1994). The principle of dehydrogenase assay is that when metabolizing cells come in contact with an aqueous solution of 2,3,5-triphenyl tetrazolium chloride (TTC) under anaerobic conditions, it is converted into triphenylformazan (TPF) and can be measured colorimetrically. Soil sample (5 g) was taken in 70 × 150 mm screw cap tubes. To each tube, 1 ml of 3% TTC and 5 ml of deionized water were added. Then the samples were mixed on a vortex, the tubes were stoppered and incubated in the dark for 24 h at 37 °C. After incubation, 10 ml of methanol were added, the samples were shaken and and filtered Whatman filter paper No.1. After filtration, the optical reading was made at 485 nm with a UV spectrophotometer using methanol extract as the blank. The results were expressed as μmol TPF g^{-1} soil h^{-1}.

The urease activity was determined following the method of Guan (1986) with some modifications. Briefly, 0.5 ml toluene, 20 ml of 0.1 M Na-citrate buffer (pH 6.7) and 10 ml of 10 % urea were added to 5.0 g soil and then the mixture was incubated at 37 °C for 24 h. One milliliter from the filtrate was obtained and added to 9 ml dH_2O and mixed with 4 ml Na-phenolate and 3 ml NaClO. The releasing ammonium was measured with a UV spectrophotometer at 578 nm. A control without urea was prepared with each sample. The results were expressed as mg urease-N kg^{-1} h^{-1}.

Phosphatase activities were measured based on the colorimetric estimation of the *p*-nitrophenol release from *p*-nitrophenyl phosphate (Tabatabai, 1994). One gram soil was placed in a 50-mL Erlenmeyer flask and then 0.2 mL toluene, 0.1 M modified universal buffer (pH 6.5), 1 ml 0.1 M *p*-nitrophenyl phosphate (PNP) solution was added to the flask. The flask was swirled for a few seconds and incubated at 37 °C for 1 h in the incubator with a stopper. After removing the stopper, 1 ml of 0.5 M $CaCl_2$ and 4 ml of 0.5 M NaOH were added to the mixture. The soil suspension was filtered through Whatman No. 1 filter paper. The optical density of the filtrate was then measured at 420 nm in a spectrophotometer (UV-1700, Shimadzu). Blank was maintained similarly without soil. The results were expressed as mg *P*-nitrophenyl kg^{-1} h^{-1}.

Protease activity was determined according to the method of Girard and Michaud (2002). Air-dried soil (0.1 g) was placed into 1.5 mL Eppendorf tube and then 500 μL of 1% (w/v) azocasein in 50 mmol L^{-1} Tris-HCl, pH 8.8. Azocasein hydrolysis was initiated by incubating the tubes 2 h at room temperature. Proteolysis was stopped by adding 300 μl of 10 (w/v) cold trichloroacetic acid (TCA). After centrifugation for 10 min at 15000 g, 350 μl of the supernatant was collected and mixed with of 300 μl of 1 N NaOH. Protease activity was then determined by reading the optical density of the resulting solution at 440 nm using a UV spectrophotometer. A change of 0.01 units per minute in absorbance was considered to be equal to one unit protease activity, which was expressed as U (unit) mg^{-1} protein.

Data were subjected to an analysis of variance (ANOVA) at a significance level of $P \leq 0.05$ using Duncan's Multiple Range Test (DMRT) from the SPSS software program (Version 22.0). Data are presented as a mean value ± the standard error.

Results

Plant analysis of A. cordifolia under salinity levels

A. cordifolia plants were harvested after 100 days of cultivation from the soils differing in salinity levels. Growth of shoots was followed by measuring FW and DW

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13291345

of the plants. At SS soil conditions, FW and DW of the plants significantly increased. At HS soil conditions, FW and DW of the plants did not significantly differ from those of control plants cultivated in NS soil conditions (*Fig. 2A* and *B; Table 1*).

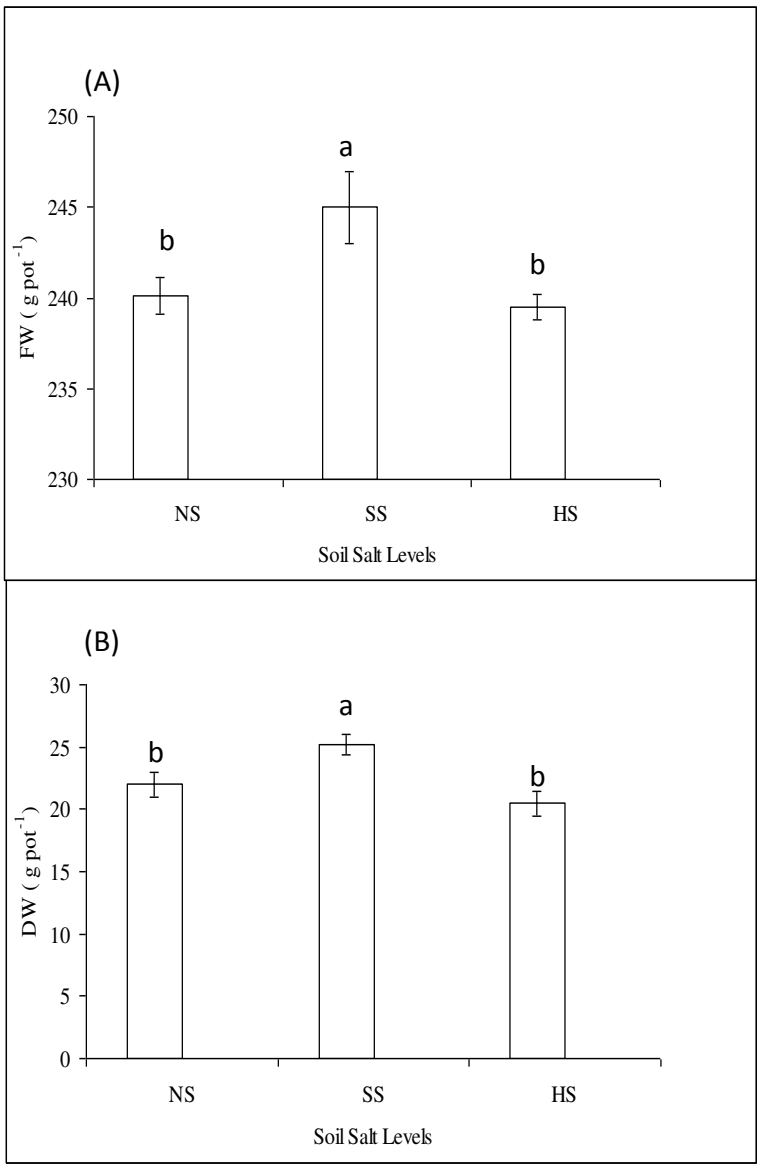

Figure 2. *A) FW, B) DW of A. cordifolia plants at three different salinity levels: non-saline (NS), slightly saline (SS), and highly saline (HS) soils. Bars indicate the means of the three replicates ± standard error. Bars with different letters indicate significant differences from one another according to Duncan's Multiple Range Test at P ≤ 0.05*

When salinity levels increased, the accumulation of NaCl ions, Na^+ and Cl^-, in leaves of A. cordifolia also increased. The accumulation of both ions was more prominent of HS soil conditions. A. cordifolia plants accumulated approximately 16 g Na^+ and 19 g Cl^-ions per kg leaf at SS soil conditions. On the other hand, A. cordifolia plants at HS soils accumulated almost 28 g kg^{-1} and 32 g kg^{-1} Na^+ and Cl^- ions, respectively their leaves (*Fig. 3A* and *B; Table 1*).

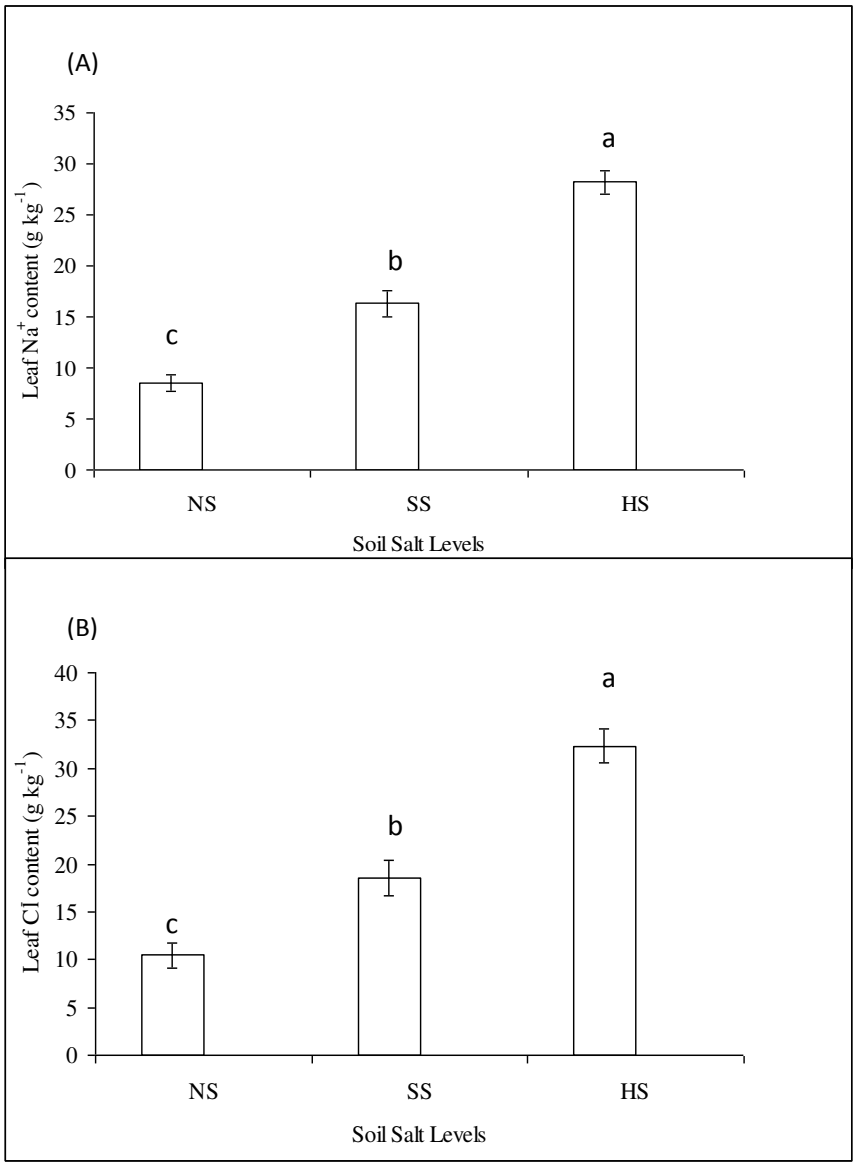

Figure 3. *A) leaf Na^+ content, B) leaf Cl^- content of A. cordifolia plants at three different salinity levels: non-saline (NS), slightly saline (SS), and highly saline (HS) soils. Bars indicate the means of the three replicates ± standard error. Bars with different letters indicate significant differences from one another according to Duncan's Multiple Range Test at $P \leq 0.05$*

When biochemical parameters were examined under saline conditions, total chlorophyll contents were not statistically significant at all saline conditions (*Fig. 3A*). Both proline and MDA contents increased in plants subjected to HS soil conditions. The proline content was 1.9 μmol g^{-1} at HS conditions doubling the levels of NS and SS soil conditions. Again, MDA contents were at the highest levels at HS conditions (*Fig. 4B* and *C*).

As a response to salinity stress, both enzymes, POX and CAT, showed increasing trend as the concentration of NaCl increased in the soil. A significant increase was evident at HS soil conditions *A. cordifolia* plants did not exhibit significant enzyme responses at SS soil conditions (*Fig. 4D* and *E; Table 1*).

Soil analysis of A. cordifolia under salinity levels

Soil characteristics such as soil pH, EC and OM contents were evaluated bare soil before (control) and after cultivation with *A. cordifolia.* To make a comprehensive evaluation, bare soil (not cultivated with any plants) was also employed when pH, EC and OM contents were measured. In this trial, physical soil parameters were determined and recorded in all soil conditions before and after 100-days cultivation with *A.*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13291345

cordifolia. The same parameters were-remeasured to see the differences in measured soil parameters. According to our findings, soil pH levels measured at different salinity conditions did not change throughout the course of the experiment. Cultivation of saline soils with *A. cordifolia* plants increased soil pH levels, however, this was not significant as compared to those of soils with no-cultivation (*Fig. 5A; Table 2*).

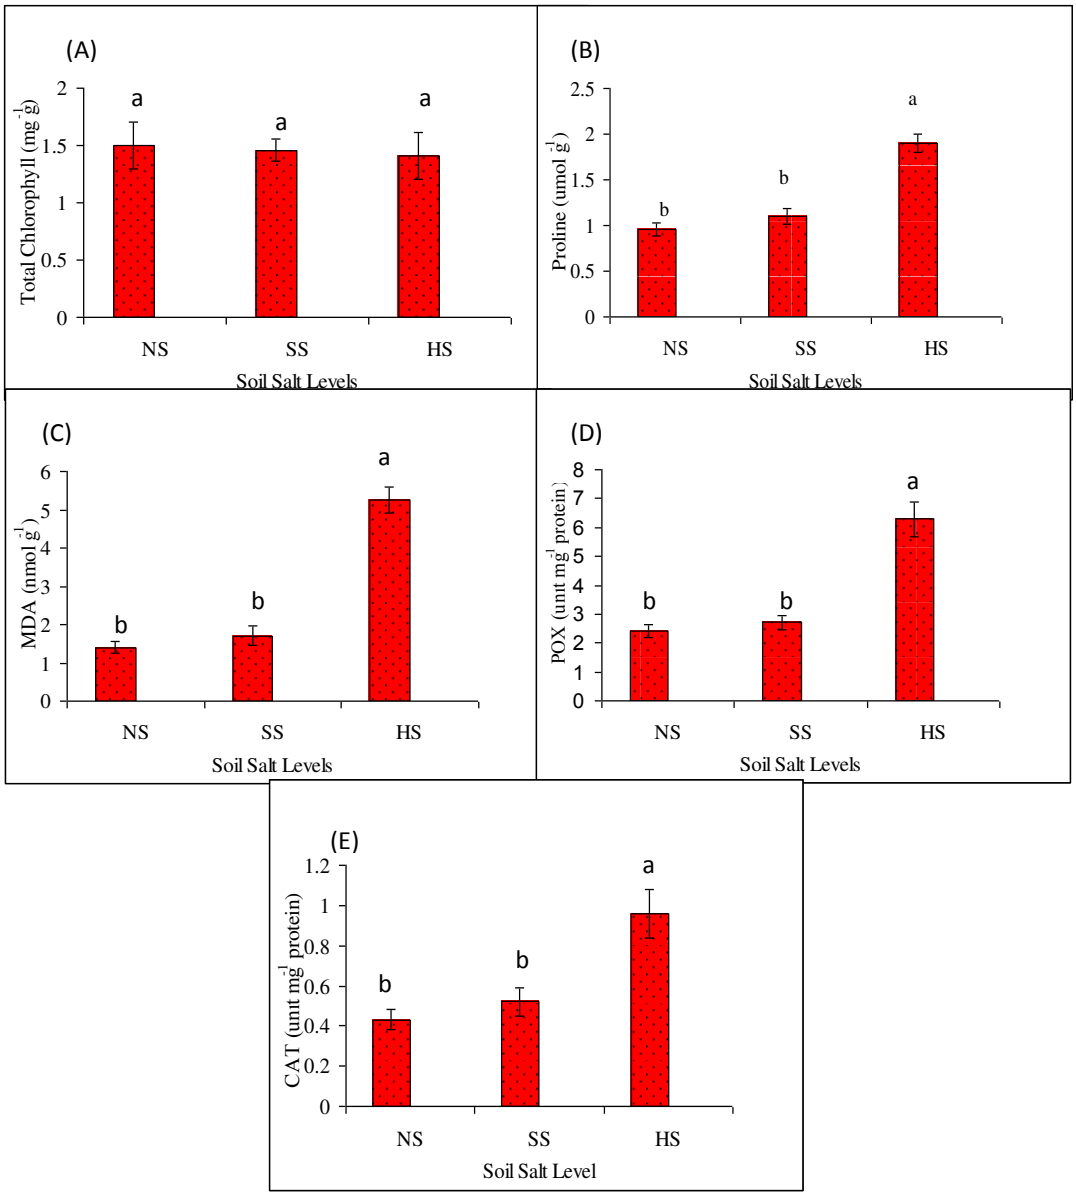

Figure 4. *A) Total chlorophyll; B) proline; C) MDA; D) POX and E) CAT of A. cordifolia plants at three different salinity levels: non-saline (NS), slightly saline (SS), and highly saline (HS) soils. Bars indicate the means of the three replicates ± standard error. Bars with different letters indicate significant differences from one another according to Duncan's Multiple Range Test at $P \leq 0.05$*

Use of *A. cordifolia* also affected the contents of OM in all soil conditions including SS soil conditions. Cultivation with *A. cordifolia* improved the soil OM significantly

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13291345

meaning that cultivation with *A. cordifolia* contributed soil OM by secreting organic materials from their root systems (*Fig. 5B; Table 2*).

When soil EC levels were measured, it was determined that soil EC levels were significantly decreased in all conditions after 100-days cultivation with *A. cordifolia* (*Fig. 5C; Table 2*). Decrease in soil EC level was more remarkable in HS soil conditions.

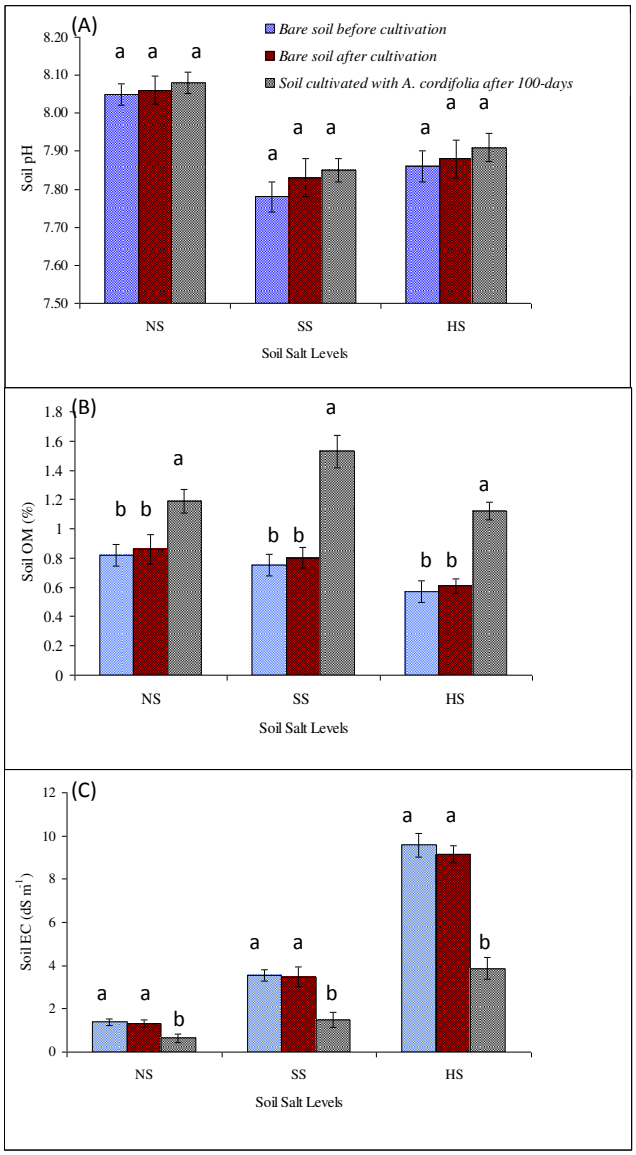

Figure 5. *A) soil pH; B) soil OM; C) soil EC values of before and after cultivation with A. cordifolia at three different salinity levels: non-saline (NS), slightly saline (SS), and highly saline (HS) soils. Bars with different letters indicate significant differences from one another according to Duncan's Multiple Range Test at $P \leq 0.05$*

Finally, soil enzymes were measured in all soil conditions to see if *A. cordifolia* plants contributed to soil health through increase in soil enzymes. Accordingly, cultivation with *A. cordifolia* significantly increased the soil enzymes such as dehydrogenase, urease, phosphatase and protease.

A. cordifolia plants contributed to soil enzyme activities in NS soil conditions an indicating that soil health could be improved via cultivation with this plant (*Figs. 6A, B, C* and *D; Table 3*). Also, *A. cordifolia* plants improved soil enzyme levels in saline conditions. For example, soil dehydrogenase activity 1.5, soil urease activity 1.4, soil phosphatase activity 1.2 and soil protease activity 1.8 times increased after cultivation with *A. cordifolia* plants in HS soil conditions when compared to control soil (bare soil before cultivated). The increase in soil enzyme levels were more prominent in SS and HS soil conditions indicating that *A. cordifolia* plants played significant roles under saline stress conditions.

Discussion

This study assessed the capacity of *A. cordifolia* to withstand salt stress. Phytoremediation and production potentials (biomass production and ion uptake) of *A. cordifolia* was evaluated at three different salinity levels in a 100-day pot experiment under controlled greenhouse conditions. Measurement was made in terms of growth, total chlorophyll, proline, malondialdehyde (MDA), mineral content, CAT and POX antioxidant enzyme changes as well as with the determination of soil EC, pH, OM, ion (Na^+, Cl^-) contents and soil enzyme activities (dehydrogenase, urease, phosphatase and protease) before and after cultivation of such soils with *A. cordifolia*.

The results of this study showed that *A. cordifolia* plant was tolerant to both slight and high salinity. Accumulation of Na^+ and Cl^- ions increased in the leaves at both salinity levels. Therefore, this plant would be promising in reducing the electrical conductivity (EC) of such soils. The plants displayed great tolerance to the deleterious influence of salinity by preserving the integrity of their cell membranes by their proline and enzyme levels. During the growth period, proline contents and enzyme activities increased in the leaves under increasing saline levels. The accumulation of organic osmolytes such as proline, glycine betaine, sugar, alcohols, polyamines and proteins plays a key role in maintaining the low intracellular osmotic potential of plants and in preventing the harmful effects of salinity stress (Hýskova and Ryslava, 2018; Dutta et al., 2018). In our study, lipid peroxidation (MDA), POX and CAT activities increased significantly in *A. cordifolia* under salt stress. Salt stress, in general, increases lipid peroxidation and induces oxidative stress in plant tissues (Kim et al., 2016; Taibi et al., 2016). However, antioxidants such as POX and CAT tend to increase in tolerant cultivars, which scavenge H_2O_2 and other reactive oxygen species (ROS). These enzymes play significant roles in preventing cellular damages. We noticed that *A. cordifolia* plants were able to increase their organic metabolites upon stress exposure. It is important to note that those parameters were measured after 100 days in saline conditions. At SS conditions, FW and DW of the plants significantly increased. It is possible that SS might exert hormonal activity on *A. cordifolia* plants. This might have increased the FW and DW contents of the plants. Similar findings were stated that by Cela and Munné-Bosch (2012) on *A. cordifolia* was able to adapt to salt stress by increasing fresh biomass production. Therefore, tolerance of this plant after relatively long time under saline conditions is quite remarkable when compared to short-time stress of glycophytes in saline conditions under salinity stress. A plant with high tolerance to salinity with high capacity to accumulate Na^+ and Cl^- ions in their leaf or other parts including fruits is a good candidate for phytoremediation purposes (Bhuiyan et al., 2017; Karakas et al., 2017). *A. cordifolia* also improved the conditions of saline soils without spoiling the physical and chemical properties of such soils. Soil enzyme levels significantly increased along with the increase of OM contents and decrease in EC levels without changing pH balance of such soils. In most cases, changes in physical and chemical properties result in changes in pH levels (Miltner et al., 2012; Shrivastava and Kumar, 2015; Yang et al., 2018).

Soil enzyme activity is closely related to the carbon inputs, crop growth stages, organic matter content, microbial community structure, soil ecology, physical and chemical properties, vegetation, fertility, soil pH, soil quality and abiotic soil environment (Jin et al., 2009; Rout et al., 2017). Microbial population and decomposition of organic matter result in increased activity of soil enzymes. For example, high urease activity was observed during the active growth of maize (Jin et al.,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13291345

2009). The present study suggests that *A. cordifolia* can be used for soil improvement in saline areas. *A. cordifolia* could remediate structure of soil where salinity is predicted to occur. Indeed, this species behaves similarly to those of halophytes that tolerate moderate and high doses of salt. The use of this species over halophytes has a great advantage since its vegetative life is longer than halophytes, therefore, it has significantly more time to improve soil conditions under saline threat. Its ecological competence via rapid colonization in soils and accumulation of toxic ions in over those of other species could be considered as a good remediative plant. Our next approach is to investigate other properties of this plant if it is to be used as a good companion plant with other glycophytes to improve the potential vegetative and fruiting performance under saline stress conditions. It is important to note that the performance of *A. cordifolia* plants under heavy metal polluted soils would increase the popularity and use of this plant.

Conclusions

Salinity is one of the most significant environmental problems in arid and semi-arid regions. One of the alternate ways is to use of arable lands efficiently and to include the marginal quality of areas or non-agricultural lands into agricultural areas. These areas should be remediated via physical, chemical and biological approaches. Phytoremediation, in this aspect, has many advantageous; its major advantages are the low cost and environmentally-friendly sites. In this respect use of one of salt-tolerant (halophyte) plants is one of the cost-effective methods. Although salt-tolerant plants are less affected than their non-salt tolerant counterparts to the effect of salinity, however, the generation of salt-tolerant plants is very difficult and not cost-effective as planned. Those plants might possess salt tolerance properties unlike exhibiting disease susceptibility, therefore, the generation of salt-tolerant plants might not be good solution as its own. However, this could be achieved via the use of halophyte plants if they are used for phytoremediation purposes. Phytoremediation process not only remediate the conditions of soil but also reduces the stress level on crop plants. This approach could be practiced in all soil types in differing soil salinity levels and in all plant species when co-cultivated. With this approach, much cheaper and faster improvements could be achieved. Instead of developing salt-tolerance mechanisms via expensive arrays directly on crop plants, use of phytoremediation in saline stressed soils would reduce the impact of salinity indirectly via much safer ways.

This study assessed salt tolerance capacity of the *A. cordifolia* in three salt levels (NS, SS and HS). Its adaptation mechanisms and performances were assessed in terms of plant growth, total chlorophyll, accumulation of osmolyte proline, MDA, and antioxidative system (POX, CAT). *A. cordifolia* significantly increased soil OM and soil enzymes (dehydrogenase, urease, phosphatase and protease). We suggest that cultivation of *A. cordifolia* in slightly and highly saline soils would improve the condition of soil physicochemical and soil enzymes properties in an environmentally-friendly manner. *A. cordifolia* could be used in phytoremediation studies.

Abstract. The selection of genotypes based on multiple traits and multiple environments is very important to improve stable varieties for breeding programs. Since climatic conditions are very variable and unpredictable, they are very effective in the selection of genotypes based on multiple traits in multiple environmental conditions. Thus, the genotype by yield*trait (GYT) biplot approach was used to determine the best barley candidate from 12 barley genotypes based on multiple (four) environment and multiple (six) traits. In this study, the strengths and weaknesses of each genotype was determined by combining yield and other target traits with GYT biplot method and it was compared with GT (genotype*trait). The stability and general adaptability of each genotype showed differences with between GYT and GT biplot techniques. According to the GT biplot method, advanced lines (3, 9, 12) and Altıkat variety were good genotypes, whereas in the GYT biplot method only Altıkat variety was the best genotype based on yield × traits combinations. In addition, it was concluded that the best genotype was not fully determined in the GT biplot method, whereas Altıkat variety was the best genotype and based on combined traits by GYT biplot. The study showed that GYT biplot is a very good technique, the ideal and stable genotypes can be detected visually with it, and it can be used to define the best candidate based on combining yield and traits selection in breeding programs.
Keywords: *physiological traits, genotype, Turkey, multiple traits, yield*

Introduction

Barley (*Hordeum vulgare* L.) is used by animal feed, malt industries, human food and biodiesel industries and it has been the fourth most produced cereal plant after corn, wheat and rice in the world. The production of barley, ranged between 5.4 and 7.4 million tons depending on the growing seasons and it is the most produced after wheat in Turkey (http://www.fao.org/faostat/en/#data/QC; Kendal et al., 2019; Oral et al., 2019). Therefore, it is very important to develop high yield varieties which are physiologically and morphologically compatible with different environmental conditions.

Barley breeders have been conducting studies in all fields for many years in order to develop high yielding varieties for multi-environments. It is very difficult to develop varieties which are high-yielding in multi-environments. In addition, many ecological and agronomic problems encountered during breeding process, limiting the success of plant breeders and so they have been struggling to develop different models to overcome these problems. The breeder process is confronted with two problems. The

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13471359

first is the negative interaction between the genotype and the environmental interaction (GEI) and the second is genotype yield traits interaction (Yan and Frégeau-Reid, 2018).

The breeders have studied for many years the first subjects (genotype x environment interactions). The candidate and new varieties have been tested under different environmental conditions by many developed methods (GE, GEI, AMMI) in order to characterize their behavior. In the breeder programs, many researchers who work with cereals in different years and environments (Dogan et al., 2016;Kendal and Tekdal, 2016; Kilic, 2014; Mohammadi et al., 2014) reported that the interaction of genotype x year x location (GYL) is very important. The second subjects is to develop varieties that can give good results (high efficiency and quality, resistant to diseases, hospitalization, and drought and temperature stress and frost risk) in different environmental conditions. It is very difficult to improve the best varieties in terms of all traits studied in different environments. Therefore, the breeder has the responsibility for identifying if a trait is positively or negatively associated with grain yield, i.e., identifying if grain yield should be multiplied or divided by a specific trait (Mohammadi, 2019). From this, indices are generated by multiplying the grain yield by the magnitudes of traits in question (positive selection) or by dividing the magnitude of traits by the grain yield (negative selection).

The value of crop cultivars for growers increases, when the breeding is done based on multiple traits. For this purpose, a genotype by yield*trait (GYT) biplot approach recently improved by different researchers (Yan and Frégeau-Reid, 2018; Mohammadi, 2019; Kendal, 2019) and this method provide useful information for genotype evaluation on multiple traits. This methodology identifies strengths and weaknesses of each genotype and provides a superiority index (SI) which allows evaluating genotypes in relation to multi-traits.

The aims of this study are to use GYT biplot and identify which traits are associated with grain yield in barley breeding materials to develop new barley cultivars determined in terms of high yielding, agronomic and physiological traits in different environmental conditions.

Materials and methods

Twelve spring barley genotypes (two checks) were evaluated in two locations in 2013-2014 and 2014-2015 growing seasons in Turkey. The information on genotypes are presented in *Table 1* and the information about locations are presented in *Table 2*. The locations and trial pictures are given in *Appendix* as *Photos 1, 2* and *3*. The standards used in the research are widely cultivated in the region. Therefore, these varieties were selected as standard. *Altıkat* cultivar is used in the study as control; because this cultivar was released in 2011 in the research area. So, it is very stable among cultivars which used in research on grain yield, because it is regional and majority barley growers prefer the 6 rows cultivar in this area. *Şahin 91* cultivar was used in the study as control; because this cultivar is a national cultivar, and it is a facultative type and used in common in the north part of the region, because it is resistant to cold damage which sometimes occur in spring time. The advanced lines used in the research are genotypes generally developed by ICARDA and recommended to the regions with moderate precipitation. These genotypes are suitable for the conditions of Southeastern Anatolia Region since the temperature values are high and average rainfall areas are suggested during the development period. For this reason, detailed studies on these genotypes will be made and registered as appropriate for the region.

Table 2. *Years, sites, codes and coordinate status of environment*

Years	Sites	Altitude (m)	Latitude	Longitude	Soil properties	Average of pers. (mm)
2013-2014	Diyarbakır	612	37° 55’ N	40°14’ E	pH = 7.30 clay-silt	483.5
2014-2015	Adiyaman	685	37° 46’ N	38° 17’ E	pH = 7.50 clay-silt	704.3

The trials were carried out in a randomized block design with four replications and sowing density was used 450 seeds per m^{-2}. Plot size was 7.2 m^{-2} in sowing time (6 m long × 1.2 m wide) spacing was 20 cm and they composed of a total of 6 rows. Sowing of trials were done in November. The fertilizing percentages were used 60 kg N ha^{-1} and 60 kg P ha^{-1} with planting and 60 kg N ha^{-1} was used to each plots at tillering time for all plots. Harvesting was done using a Hege 140 harvester in an area of 6 m^2 in each plot.

Moreover, grain yield, agronomic traits (plant height, heading time), physiological traits (canopy temperature depression, SPAD chlorophyll meter (Minolta Co. Ltd., Tokyo, Japan) morphological traits (seed number per spike and yield per spike) gathered for each genotype in each plot. The investigated traits were measured as follows.

Plant height: While the plants were yellow, they were obtained by measuring between the bottom of the plants and the peak.

Heading time: It was obtained by calculating between the period of tillering and the period in which 50 percent of the plants in the parcel were spiked.

Canopy temperature depression: Measurements were measured with Rothenbenger precision infrared thermometer when plants were in spike flowering time (50%). Measurements were performed by Fisher et al. (1998) and the measurement method and time was measured at an angle of 30° in the middle of the plot, 50 cm above the plant height, in the afternoon, in open and windless weather.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13471359

SPAD measurement: While the plants were in the grain filling period, the middle parts of the flag leaf of 10 plants which were randomly selected were determined in SPAD unit by measuring with the SPAD-502 Plus (Minolta SPAD-502, Osaka, Japan) device which is used to measure the chlorophyll amount of the plants. Measurements were measured when plants were in spike flowering time (50%).

Seed number per spike: The 10 ears randomly taken from each parcel were blended and the values were obtained by counting grains.

Yield per spike: The 10 ears randomly taken from each parcel were blended and the values were obtained by weighing grains.

Sowing and harvesting time: All test plots were sown in the fall (November), which is the optimal sowing time for barley in the trial areas. Harvesting was carried out in July, when the plants were in the harvesting period. The soil properties of the trials area, pH = 7.30 and soil is clay-silt. All agronomic application such as weed control and fertilization were practiced uniformly.

Statistical analysis (GT and GYT)

The data of twelve barley genotypes in multi-location and multi-year trials were analyzed by GT biplot method, as recommended by Yan and Thinker (2005), GYT biplot method, as recommended by Yan and Frégeau-Reid (2018) and Mohammadi (2019). A superiority index (SI) combining all yield-trait integrations were calculated based on the standardized GYT (Yan and Frégeau-Reid 2018). Biplot method was built for all scored traits of genotypes using Genstat 14 release software program. The data were graphically analyzed for interpretation of GT and GYT using the GGE biplot software. *Figure 1A-E* was produced based on the performance of each genotype for each trait (GT), *Figure 2A-E* was generated based on the performance of genotypes by yield*traits (GYT).

Results

The biplot of genotype by trait (GT) and yield trait combination (GYT)

The mean data of traits across two years in two location of 12 barley genotypes are shown in *Table 3*. The pairwise correlations among traits of 12 spring barley genotypes are shown in *Table 4*. These two table data were used to generate a GT biplot *Figure 1,* although the genotype is compatible with biplot, it represents only 69.01% of the variation. The genotype by yield*trait (GYT) data for 12 spring barley genotypes across two years in two locations are shown in (*Table 5*). The data in the GYT table (*Table 5*) was generated from the GT table (*Table 3*) and in GYT table. The data in each column consists of a combination of yield-trait. The standardized genotype by yield*trait (GYT) data and superiority index for 12 spring barley genotypes across two years in two locations are shown in *Table 6*. The genotypes are quite compatible with biplot, they represent 91.58% of the total variation (PC1 74.96%, PC2 16.60%).

Figure 1A visualize the relationships between properties and trait by genotype profiles. Considering the observations on this figure indicated that grain yield was positively correlated with (GY, CTD, SPAD, SNS and YS), while negative corelated with especially quality traits (HT and PH). However, On the other hand the explanations are confirmed by the correlation values in (*Table 2*). Based on these principles

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13471359

described in the GYT biplot technique, the following observations can be made about relationships between yield trait combinations in *Figure 2A*. Considering the observations on this figure indicated that all yield-trait combinations tend to correlate positively with each other because they have yields as a component, as shown by the triangular angles between the vectors (*Fig. 2A*). This is an important feature of the GYT biplot (*Fig. 2*) technique, in contrast to the GT biplot (*Fig. 1*); According to the yield-trait combinations (below), graphically, it provides the opportunity for genotypes to be ranking in a more meaningful way. However, as shown the strong relationships between the two traits in the GT biplot technique (*Fig. 1A*), for exam, there is a positive correlation between GY*CTD and a negative correlation between GY*HT and GY*PH (*Fig. 1A; Table 3*). In GYT biplot technique there is a positive correlation among GY and all traits. Therefore, it is better to select genotypes based on different analysis output.

Figure 1B visualizes the stability of genotypes based on trait, and in the figure, a horizontal stability axis and a vertical mean axis are created over the average values and the genotypes are evaluated according to these axes. If the genotypes are located under of vertical axis, it means that they are unpreferable if they located above vertical axis, it means that they are preferable genotypes. On the other hand; the genotypes are located near or in the center of the horizontal line it means that these genotypes are stable, and if they move away from the horizontal line, it means that they are unstable (Yan and Rajcan, 2002). Considering *Figure 1B* with this prediction;

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13471359

the advanced line (3) is quite stable because this genotype is located in the center of horizontal axis, and advanced line 12 is stable because this genotype is located near the center of the horizontal axis; Altıkat variety and advanced line 9,11 etc. are unstable, because they are located far from the center of the horizontal axis. While, Şahin 91(control), advanced line 1 and 8 are unpreferable genotypes because they are located under the vertical axis line, other genotypes (Altıkat variety, etc), which are located above the axis vertical line, are preferable genotypes based on trait profiles. The effect of GYT to stability and superiority of genotypes are presented in *Figure 2B*. The stability and superiority analysis of GYT indicated that Altıkat (control) variety is quite stable because this genotype is located in the center of the horizontal axis, and advanced line 4 is stable because this genotype is located near the center of the horizontal axis; advanced line 12, 11 etc. are unstable, because they are located far from the center of the horizontal axis. While, Şahin 91 (control), advanced line 11 and 8 are unpreferable genotypes because of they located under the vertical axis line, other genotypes (advanced line 1, etc), in which located above the vertical axis line, are preferable genotypes based on trait profiles. The result showed that we have to select different genotypes based on GT and GYT biplot analysis and GYT biplot allows us to make a much clear and more efficient selection in the breeding program.

Figure 1C visualizes the discrimination and representativeness of genotypes based traits, and it provides a representative "ideal center" over the mean values of the properties and offers the opportunity to evaluate genotypes according to their proximity or distance to this center (Yan and Tinker, 2005; Oral, 2018). If the genotypes are located in the center, they are the most ideal, if they are located on the average vertical axis, but far from the center, it means that they are ideal, if they are located below the vertical axis, it means that they are undesirable. Considering *Figure 1C* with this prediction; advanced line 9 and 12 are more ideal than 3, 11 and Altıkat variety, because it is nearest to the "ideal center", while Şahin 91(control) and advanced lines 1, 6, 8 are located under the vertical axis, and also far from the ideal center, so these genotypes are undesirable. Discrimination and representativeness of genotypes based on GYT combination are presented in *Figure 2C* and it provides a representative "ideal center" over the mean values of GYT. Considering *Figure 2C* with this prediction; Altıkat variety is the most ideal genotype, because it was located nearest to the "ideal center" and advanced lines 12, 9, 4, 7, 6, 1 and 3 are desirable for GYT combination. while Şahin 91 and advanced lines 11, 2, 8 are undesirable genotypes, because these genotypes are located under the mean values of the vertical line. The results of GYT biplot analysis were found to be more clear and stable than GT.

Figure 1D visualizes the polygon of GT biplot (which-won-where/what) based on across season data. The figure divided by thick axis from center figure, and each zone separated by two thick lines is referred to as the "sector" and is indicated by numbers 1, 2, 3 etc., starting from the lower right part of the graph, and if the genotypes and properties located the same sector it means they are closely related to each other (Yan and Tinker, 2006; Dogan et al., 2016). Considering *Figure 1D* with this prediction; figure is divided into 6 sectors and different traits are associated with different genotypes in each sector. Genotype 11 is the winner of the sector 1 correlated to PH trait, advanced line 9 is the winner of the sector 2 located in the same sector with line 12 and correlated to HT. The Altıkat variety is the winner of the sector 3 located and correlated to GY, CTD, SPAD, SNS and YS. The other genotypes (2, 3, 4, 6, 7, 8, Şahin 91variety) are located in other sectors and did not correlate with any traits. The GYT

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13471359

biplot of sector analysis "which-won-where" can be seen in *Figure 2D*. The most effective genotype associated with trait profiles in each sector is indicated by a polygon peak. In the sector analysis, the figure was divided into 6 sectors and all combinations were in the same sector. Altıkat (control) variety located in sector 1 with all combining (GY*CTD, GY*SPAD, GY*SNS, GY*YS, GY*HT, GY*PH). Other genotypes except Altıkat variety did not correlated with any combinations. The result showed that Altıkat is the best based on combining of all traits with GY. The result showed that GYT is more effective on the selection of genotypes which is the best based on all traits with grain yield than GT biplot method.

Figure 1E visualizes the group of GT based on across season data and in the figure, the traits and genotypes have relationship, they are located in the center of a circle, it means that there are positive correlation among them (Kendal and Dogan, 2016). Considering *Figure 1E* in the light of these explanations; features were separated to 3 different mega-traits. The mega-trait 1 were included only (HT) trait, the mega-trait 2 included only (PH) trait, and other traits (GY, CTD, SPAD, SNS, YS) included mega-trait 3. The mega- traits based on yield-traits combination across season data are presented in *Figure 2E*, which visualizes to yield-trait combinations, which are in a close relationship, are shown in the same circle. Considering *Figure 2E* in the light of these explanations; all yield-trait combinations (GY*CTD, GY*SPAD, GY*SNS, GY*YS, GY*HT and GY*PH) were located in only one mega-trait and Altıkat variety was located in the center of this mega-trait. It means that there is correlation among all trait with yield combination. On the other hand, the figure showed that Altıkat variety is the best genotype based on grain yield with combining traits. The results showed that in a possible selection, the GYT biplot method explained the results more clearly and formally than the GT method.

Discussion

The GT biplot technique has been used successfully by many researchers for a long time to see the relationship between genotype by trait in different plants, and effective selections were made in breeding programs according to the interaction between genotype by trait. However, GYT biplot technique was designed to complete the deficiencies encountered in the GT biplot technique and to enable more efficient selection of plant breeders. GYT biplot is used to sort genotypes according to their general advantages over yield by trait combinations and to show profiles of traits.

The result showed that the selection of genotypes is based on mega-traits, the use of GYT biplot has more advantages instead of GT biplot in breeding studies. In fact, in barley breeding studies, yield is the only trait that can determine the effectiveness of a genotype alone; other traits (agronomic, morphological and physiological characteristics) are valuable only for the breeders when combined with high yield levels, and these properties alone do not mean anything to growers. For example; a barley genotype is not valuable for breeders if it is resistant to temperature stress and the yield is low. However, if the genotype yield is high, it makes the genotype valuable if it has good agronomic and morphological and physiological characteristics as well as. Therefore, the selection of the best genotypes based on the combination effects of yield-trait are more meaningful than the effects of individual traits. In the GT biplot technique, a great value (*Table 3*; *Fig. 1B*) makes the ATC appearance insignificant in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13471359

some cases (Dehghani et al., 2006; Yan and Tinker, 2006; Kendal and Dogan, 2016; Oral et al., 2018), while in the GYT biplot technique it makes the ATC appearance a meaningful and effective tool (Yan and Frégeau Reid, 2018; Mohammadi, 2019; Kendal, 2019), because it ranks genotypes based on various yield-trait combinations and indicates the strengths and weaknesses of genotypes (*Fig. 2B; Table 5*). The GT biplot technique was used to construct *Figure 1A-E* using the data in *Table 3,* while the GYT biplot technique was used in *Figure 2A-E* using the data given in *Table 5,* and genotypes were examined with different graphs according to both techniques. The genotypes examined depend on the superiority index (SI) and yield-trait combination (GYT) and the result of *Figure 2* showed that the genotypes can be select easy than GT biplot in *Figure 1*. On the other hand, in GT biplot it is not clear which is the best genotype that is very stable for all traits, while the Altıkat is stable and advanced line 4 and 12 for all combination in GYT biplot. Therefore, it was found in this study that GYT biplot technique is a suitable method for determining the most suitable genotype for all properties in barley breeding studies. GYT biplot, in combination with the yield and any trait, is used to measure how the grain yield is combined with that trait in genotypes. When both the grain yield and the values of any trait are low or high, the values will be either low or high and the genotypes will be evaluated accordingly. On the other hand, the GYT biplot technique was developed to determine when the value of a trait of any genotype is low, grain yield is high or vice versa, whether the results are affected from the combination or is there any changing in the ranking of them. As a result, when the values of the traits and the yield values enter the combination, the data changes and the ranking of the genotypes changes. GYT biplot approach has been reported to be a comprehensive and effective method since it classifies genotypes according to their levels in combination with target characteristics and graphically rank the genotypes with their strengths and weaknesses and in different plants (Yan and Frégeau-Reid, 2018).

Conclusion

The results of this study showed that GYT approach puts too much weight on yield relative to other traits. However, this approach can be used in other crops which is studied based on multi-location, multi-years with multi-traits. The study also verified that there is a potential for simultaneous genetic improvement of the characteristics (SPAD-reading, CTD) in barley. In terms of all traits, the stability of the genotypes and the best genotype is clearly can be seen in the GYT biplot technique (Altıkat), while the best genotypes cannot be seen, because of the GT biplot technique is more complex. Therefore, GYT technique can be used in different plants and traits by researchers for breeding studies.

Abstract. Reference evapotranspiration (ETo) is an important parameter for climatological, hydrological and agricultural management. The FAO56 Penman-Monteith (FAO56-PM) model is one of the most accurate models. But it needs a detailed climate dataset from weather stations. Therefore, empirical reference evapotranspiration models (ETo) that need a reduced set of climate data can become an alternative approach. In this study, nine different evapotranspiration models were calibrated for the 1978-2000 period and validated based on the period between 2001-2017 with respect to standard FAO56-PM method based on the real climatic data obtained from Aseer metrological department, Saudi Arabia. The ranking of all the evaluated models based on the multi-criteria decision making was done in order to get the best alternative to the FAO56-PM Model. The result showed that Mahringer and Trabert models are the most appropriate with RMSE values of 2.13 mm/day and 2.47 mm/day, respectively and the value of percent error were 77.27% and 89.43%, respectively. Moreover, the values of mean bias error were found to be -2.03 mm/day and -2.35 mm/day, respectively**.** The calibration and validation of different ETo equations tend to increase their performance. Thus, the validated evapotranspiration model that used less climatic parameters could predict the ETo condition accurately for any region.

Introduction

Having an accurate estimation of crop water requirements is crucial for good planning so that water resources can be utilized efficiently (Jin et al., 2018). The most important factors for water resource planning and irrigation scheduling is the determination of reference evapotranspiration ETo (Jiang et al., 2017; Tie et al., 2018). Therefore, precise estimation of ETo is essential for net irrigation water requirement, regional water management,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13611386

environmental studies and climate change impacts (Wei et al., 2016; Gabri et al., 2019). The method of estimating the evapotranspiration is using a lysimeter. It can provide high accuracy while measuring the evapotranspiration (Hausler et al., 2018). However, these methods are very costly and require much expensive and sophisticated equipment for measurement. As a result, the FAO56-PM Model which bears the high correlation with lysimeter measurement is used for the estimation of evapotranspiration (Allen et al., 1998). Although FAO56-PM method is rigorously used in different part of the world, it still requires various climatic parameters as an input to compute the reference evapotranspiration. Hence, based on the limited climatic parameters, researchers have developed and estimated numerous ETo equations around the world (Djaman et al., 2015, 2016a). Therefore, empirical methods, including mass transfer, radiation, temperature and pan evaporation-based methods have been developed to estimate the reference crop evapotranspiration using the limited data. Although different ETo methods can provide the estimated ETo with relatively good accuracy, they fail to adapt to all the climatic conditions. As a result, the performance of these ETo equations needs to improve under various weather conditions (Li et al., 2018). During the past few years, many studies have been conducted to evaluate various evapotranspiration model but very few studies are focusing on the calibration and validation of evapotranspiration model (*Table 1*) with respect to the standard FAO56-PM model. Considerable effort has been exerted to evaluate other methods using FAO56-PM as the standard (Hu et al., 2009). Trajkovic and Kolakovic (2009) evaluated five evapotranspiration equations under the humid conditions and concluded that the Turc equation is suitable to estimate the reference evapotranspiration at humid locations, especially when the weather data are limited. Calibration and validation of six evapotranspiration model were performed in the Senegal river delta and it can be concluded that the preciseness of the result can be enhanced substantially as the error was decreased after calibration (Djaman et al., 2016a). Besides that, eleven equations to calculate the monthly ETo were calibrated (Zhai et al., 2010). After calibration, the differences of the regional suitability disappeared or even reversed. In addition, the ETo equations with lysimeter results and found radiation-based method can perform much better as compared to the temperature-based model after calibration (Xu et al., 2013). Pandey and Pandey (2018) performed the calibration and ranking of seven Valiantzas reference evapotranspiration equations for the study period of 2006-2016 under the humid climate at North India. The result showed that Valiantaz model 7 has the best performance. However, the study is lacking the validation of calibrated equation. Djaman et al. (2017a) performed the validation of Valiantzas' reference evapotranspiration equation under humid, sub-humid and semiarid conditions in Africa. The analysis showed that the Valiantzas' ETo equation could become an alternative to the FAO56-PM equation without calibration to follow the local humid, sub-humid and semiarid climatic conditions. However, the analysis is lacking evaluation of different ETo equations. Djaman et al. (2016b) performed the evaluation of the FAO56-PM model with limited data and the Valiantzas models for estimating evapotranspiration in agro-ecological zones of Burkina Faso, West Africa. The result showed that Valiantzas 2 equation with full climatic data has resulted in good ETo estimates relative to the FAO56-PM. However, the calibration and validation are not incorporated in the study. Djaman et al. (2016a) performed the calibration and validation of six ETo model in Senegal river basin, West Africa and concluded that the Valiantzas 2 equation was the best model for the Senegal river delta. However, the ranking operation is not performed in the equation. Albelewi et al. (2015) assessed six evapotranspiration models in the hyper-arid environment in Saudi Arabia. The study concluded that FAO56-PM is the most accurate ETo model to estimate crop water irrigation needs in hyper-arid environments.

DOI: http://dx.doi.org/10.15666/aeer/1801_13611386

However, the validation of the model is not incorporated in the study. Djaman et al. (2015) evaluated sixteen reference evapotranspiration methods under the sahelian conditions in the Senegal river valley. The study showed that Valiantaz is the most promising model that can be used as an alternative to the FAO56-PM model. However, the ranking of the equation is lacking in this study. Pandey et al. (2016) evaluated eighteen reference evapotranspiration methods for the northeastern region of India. The findings revealed that Irmak3 and Turc models performed equally well and are the best among the selected models for the majority of stations. However, the validation of the calibrated equation is not performed in the study. Cadro et al. (2017) performed the validation and calibration of eleven reference evapotranspiration alternative methods under the climate conditions of Bosnia and Herzegovina and concluded that Trajkovic method is the best model. Djaman et al. (2017b) evaluated eleven reference evapotranspiration models in semiarid conditions and concluded that the Abtew equation showed the best performance among the selected ETo equations but the validation and ranking are lacking in the analysis. Bogawski and Bednorz (2014) made comparison and validation of selected evapotranspiration models for conditions in Poland (Central Europe). This approach could substantially decrease the errors produced by the recommended non-calibrated equations. However, there is no ranking procedure involved in the analysis. Lang et al. (2017) make a comparative study of evapotranspiration estimation by eight methods with FAO56-PM method in Southwestern China. The result showed that the radiation-based methods performed better than temperature-based methods among the selected methods in the study area. Among the radiation-based methods, Makking performed the best while Hargreaves and Samani showed the best performance among the temperature-based methods. However, the calibration and ranking are lacking in the study.

The past studies were basically assessed different ETo models against the FAO56-PM model based on the Central and Eastern region and few in southern region of Saudi Arabia (Salih and Sendil, 1984; Saeed, 1986; Mustafa et al., 1989; Al-Omran and Shalaby, 1992; Abo-Ghobar and Mohammad, 1995; Elnesr et al., 2010; Islam et al., 2019a,b). However, in high mountain environments, such as the Abha Asir region, Saudi Arabia, meteorological monitoring is limited and high-quality data are scarce. Moreover, measurements of relative humidity by electronic sensors are commonly plagued by hysteresis, nonlinearity and calibration errors (Allen, 1996). There is no significant work related to the calibration and validation of different evapotranspiration model with respect to standard FAO56-PM in Abha city of Asia region. Based on an extensive literature review, it can be concluded that there are no comprehensive studies being conducted to evaluate the performance of empirical models in the semi-arid region, Abha Aseer, Kingdom of Saudi Arabia on the basis of calibration validation and ranking, especially on a monthly timescale. To fill in this research gap, in this study, an effort was made to estimate the evapotranspiration from a different model based on the availability of meteorological data for the period 1978-2017 and ranking has been done using multi-criteria decision making method. This can aid in recognizing the suitable method that can be used as an alternative equation to standard FAO56-PM method. The finding of the research work is helpful in reducing the error during the evapotranspiration computation. Moreover, the best-evaluated model equation the for evapotranspiration could assist in computing the evapotranspiration in future in the field of water management system, climate change studies, irrigation and water resource planning.

Material and Methods

Site Description

The research work deals with Abha mountainous region of Aseer province, Kingdom of Saudi Arabia having an area of 370 km^2 located between the latitude of 18°10′12.39″N and 18°23′33.05″N and longitude of 42°21′41.58″E and 42°39′36.09″E as shown in *Fig. 1*.

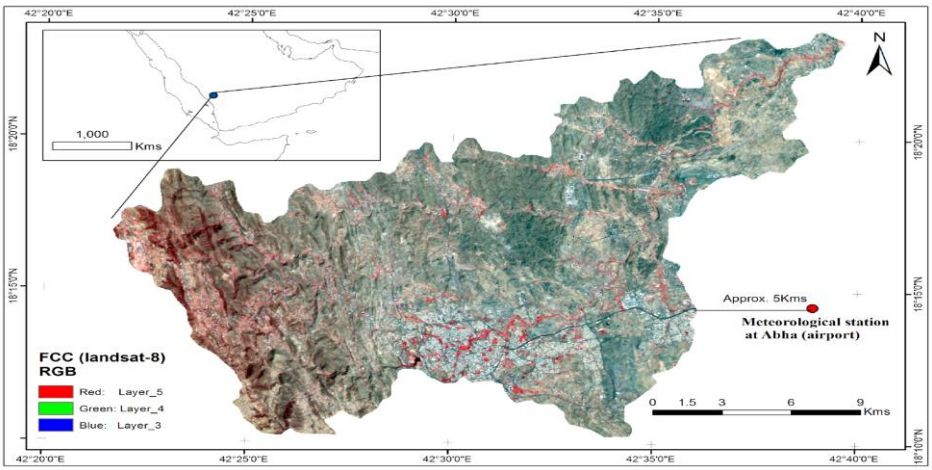

Figure 1. *Location map of Abha Asir region, Kingdom of Saudi Arabia*

The zone is prone to heavy rainfall as compared to other parts of Saudi Arabia. The elevation varies from 1951 to 2991 m (msl) with average precipitation of 355 mm which mainly occurs between June and October. According to the topographical features of the investigation region, it is found to have weak geology because of the precipitation and slope nature during the past few years. It was observed that this area is facing problem-related to the soil disintegration which influences the efficiency of agriculture, especially water characteristics of catchment zones.

Data Availibility

In this research work, primary (raw) weather parameters were collected from Abha meteorological weather station for the period between 1978–2017 (40 years) which includes wind velocity, maximum and minimum temperature, mean temperature, mean relative humidity and solar radiation as well. The data collected were checked by Allen (1996). The weather data are shown in *Table 2*.

Methodology

Various ETo estimation techniques taking into account distinctive data prerequisites are available in the literature. In this research work ETo were estimated by nine reference evapotranspiration model based on available climatic data. Among nine model four model were mass transfer based i.e., Trabert (1896), Mahringer (1970), Penman (1948), Albrecht (1950). Four model were radiation based i.e., Priestley and Taylor (1972), Turc (1961), Makkink modified (1967), Makkink (1957) and one combination based Valiantzas (2013) model. Moreover, the reference ETo values were estimated using standardized FAO56-PM. The values estimated from different equations were compared with the reference value obtained from FAO56-PM for the period between 1978-2017. Further all nine equations were calibrated for the period between 1978-2000 then validation of calibrated equation for the period between 2001-2017 with respect to FAO56-PM model. The performance of equations was evaluated by utilizing several statistical measures such as root mean square value, mean bias error, standard error of estimates, percentage error respectively and finally based on evaluation criteria the ranking was done in order to get most promising model which can be used alternative to FAO56-PM model. The flowchart as shown in *Fig. 2* described the stepwise procedure to compute most promising model among nine model to be used as alternate of FAO56-PM model.

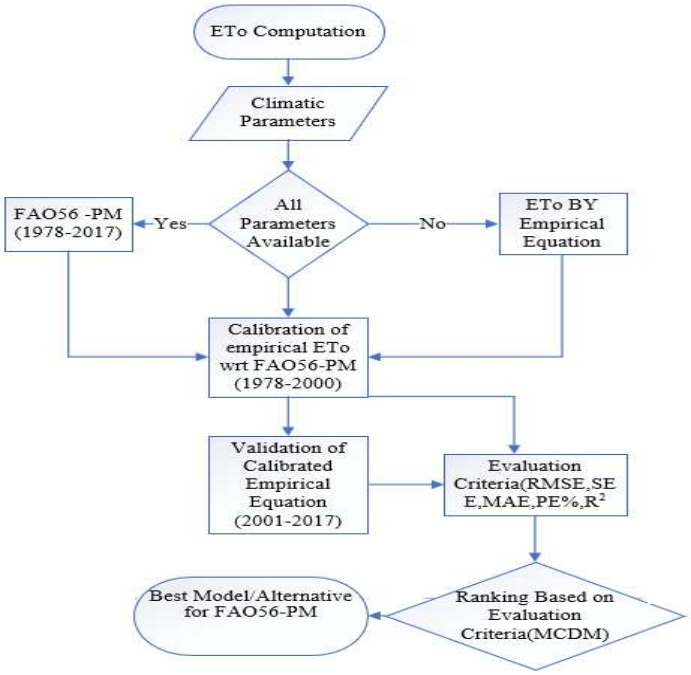

Figure 2. *Flowchart showing stepwise computation of ETo*

Reference Evapotranspiration (ETo) Model

This study work aims to analyze trends of the monthly ETo calculated by the Standard FAO56-PM model (*Eq. 1*) in the Abha Asir region, Kingdom of Saudi Arabia. However, the use of the FAO56-PM is limited by the insufficiency of climatic input parameters, and the alternative is to employ simple empirical models. The following mass transfer combination and temperature based alternative methods (*Eq. 2-11*) for estimating ETo have been chosen for this study. The selection of methods was based on their wide acceptance, simple calculation procedure and applicability in present conditions.

FAO Penman -Monteith (Allen et al., 1998)

$$ETo = \frac{0.408\times\Delta\times(Rn-G)+\gamma\times\left(\frac{900}{T+273}\right)\times u_2\times(e_s-e_a)}{\Delta+\gamma\times(1+0.34u_2)} \quad \text{(Eq.1)}$$

Trabert (1896)

$$ETo = 0.408 \times 0.3075 \times \sqrt{u_2} \times (e_s - e_a) \quad \text{(Eq.2)}$$

Mahringer (1970)

$$ETo = 0.15072 \times \sqrt{3.6u_2} \times (e_s - e_a) \quad \text{(Eq.3)}$$

Penman (1948)

$$ETo = 0.35 \times (1 + 0.24u_2) \times (e_s - e_a) \quad \text{(Eq.4)}$$

Albrecht (1950)

$$ETo = (0.1005 + 0.297u_2) \times (e_s - e_a) \quad \text{(Eq.5)}$$

Priestley and Taylor (1972)

$$ETo = 1.26 \times \left(\frac{\Delta}{\Delta+\gamma}\right) \times \left(\frac{R_n-G}{\lambda}\right) \quad \text{(Eq.6)}$$

Turc (1961)

$$ETo = 0.013 \times \left(\frac{T}{T+15}\right) \times (R_s + 50) \times \left(1 - \frac{50-RH}{70}\right) \quad RH \prec 50 \quad \text{(Eq.7)}$$

$$ET_0 = 0.013 \times \left(\frac{T}{T+15}\right) \times (R_s + 50) \quad RH \prec 50 \quad \text{(Eq.8)}$$

Makkink (1967) modified Hansen (1984)

$$ETo = 0.7 \times \left(\frac{\Delta}{\Delta+\gamma}\right) \times \left(\frac{R_s}{\lambda}\right) \quad \text{(Eq.9)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13611386

Makkink (1957)

$$ETo = 0.61 \times \left(\frac{\Delta}{\Delta + \gamma}\right) \times \left(\frac{R_s}{\lambda}\right) - 0.12 \quad \text{(Eq.10)}$$

Valiantaz (2013)

$$ETo = 0.00668 \times R_a \times (T_{mean} + 9.5) \times (T_{max} - T_{min})^{0.5} - 0.0696 \times (T_{max} - T_{min}) - 0.024 \times (T_{mean} + 20) \times \left(1 - \frac{RH}{100}\right) - 0.00455 \times R_a \times (T_{max} - T_{dew})^{0.5} + 0.0984 \times (T_{mean} + 20) \times (1.03 + 0.00055 \times (T_{max} - T_{min})^2 - (RH/100)) \quad \text{(Eq.11)}$$

where ETo = reference evapotranspiration (mm day^{-1}); Rn = net radiation at the crop surface (MJm^{-2} day^{-1}); G = soil heat flux density (MJm^{-2} day^{-1})) that is taken as zero for daily ETo estimation; u_2= wind speed at 2 m height (m s^{-1}); e_s = saturation vapor pressure (kPa); e_a = actual vapor pressure (kPa); T = temperature at 2 m height (°C); (e_s-e_a) = vapor pressure deficit (kPa); Δ =slope of vapor pressure curve (kPa °C^{-1}); and γ = psychrometric constant (kPa °C^{-1}); T_{max} = Maximum Temperature (°C); T_{min} = Minimum Temperature (°C); T_{mean} = Mean Temperature (°C); RH_{mean} = Mean Relative Humidity (%); RH_{max} = Maximum Relative Humidity (%); RH_{min} = Minimum Relative Humidity (%).

Model Validation

For the validation of FAO56-PM ETo model, the estimated result of FAO56-PM were compared with value measured from Davis Vantage Pro2 weather stations installed in Abha region. The instrument provides real-time data for weather conditions. It uses air temperature, relative humidity, average wind speed, and solar radiation data to estimate ETo, which is calculated once an hour. Validation of FAO56-PM with measured value as represented by *Fig. 3*. After evaluating FAO56-PM with measure ETo the RMSE and MBE value found to be 0.144 and 0.011 mm while coefficient of determination found to be 0.987 with slope and intercept of 1.013 and -0.032, respectively.

Calibration and Validation of ET_O Equations

The linear regression model was employed to calibrate and validate the empirical models against the FAO56-PM model (Allen et al., 1998). The specific expression is as shown in *Eq. 12*.

$$ET_{FA056-PM} = a.ET_{EMP} + b \quad \text{(Eq.12)}$$

where $ET_{FAO56\text{-}PM}$ and ET_{EMP} represent the daily reference evapotranspiration estimated by the FAO56-PM model and the nine empirical models respectively whereby and a and b are calibrated empirical coefficients. In this research work, the climatic data from 1978-2000 were used for the development of the calibrated equations and data from

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13611386

2000-2017 were applied for validation purpose. This partitioning is important as more data is required for the models' training.

The main objective of calibrating ETo was to make the slope equally inclined to both x and y axis and intercept reaching zero. For this purpose, a linear regression was done in between Standard PM-ETo and values were obtained through the nine ETo equations. To accomplish this, calibration coefficients need to be determined which can be obtained by applying product operation to the slope of a regression line between the FAO56-PM-ETo and ETo equation by inversing the slope. This will get a new slope so that the new equation will be closer to unity. Moreover, opposite sign value of the intercept was added to get a new intercept close to zero for new regression equation. The calibration and validation of ETo estimates were performed as suggested by (Xu et al., 2013).

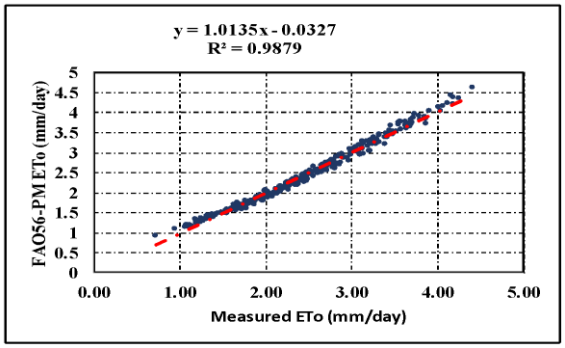

Figure 3. *Validation of Standard FAO56-PM ETo with Measured ETo*

Comparison of the Performance of Different ETo Methods

The comparative study was performed for the FAO56-PM model and the rest of the local nine ETo equations by making use of the scatter plot. The linear regression line was plotted to get the the coefficient of determination. The high value of coefficient shows the best sign of goodness of fit for the observations (Djaman et al., 2016a). Moreover, the performance indicator such as root mean squared error (RMSE) (*Eq. 13*), mean bias error (MBE) (*Eq. 14*), percent error of estimate (PE) (*Eq. 15*), the standard error of estimate (SEE) (*Eq. 16*), Correlation Coefficient (R^2) (*Eq. 17*) were used to compare the nine ETo models. A comprehensive statistical analysis was used to analyze the model results against the observed data. Moreover, it can also be employed to test the agronomical models. The significance of root mean square error is that it is an absolute measure of the overall error in the estimates relative to the observed values which are expressed in the same units and scale as the data itself. It can take any positive value with zero indicating a perfect lack of error.

Root Mean Square Error

$$RMSE = \sqrt{\sum_{i=1}^{n} \frac{(ET_{Eq} - ET_{PM-FAO})^2}{n}} \quad \text{(Eq.13)}$$

Similarly, the mean bias error (MBE) measures the extent to which the estimated value deviates from the observed value. It can take any value with negative values

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13611386

indicating the systematic under-estimation and positive values, over-estimation and zero indicating a perfect lack of bias.

Mean Bias Error

$$\mathrm{MBE} = \sum_{i=1}^{n} \frac{(\mathrm{ET_{Eq}} - \mathrm{ET_{PM-FAO}})}{n} \quad \text{(Eq.14)}$$

$$\mathrm{PE} = \left| \frac{(\mathrm{ET_{Eqav}} - \mathrm{ET_{PM-FAOav}})}{\mathrm{ET_{PM-FAOav}}} \right| \times 100 \quad \text{(Eq.15)}$$

The SEE was computed following the equation as shown below:

$$\mathrm{SEE} = \sqrt{\left(\frac{1}{n(n-2)}\right)\left[n\sum_{i=1}^{n}\mathrm{ET_{eq}}^{2} - \left(\sum_{i=1}^{n}\mathrm{ET_{eq}}\right)^{2} - \frac{\left[n\sum_{i=1}^{n}\mathrm{ET_{FAO56-PM}} \times \mathrm{ET_{eq}} - \sum_{i=1}^{n}\mathrm{ET_{FAO56-PM}} \times \sum_{i=1}^{n}\mathrm{ET_{eq}}\right]^{2}}{n\sum_{i=1}^{n}\mathrm{ET^{2}_{FAO56-PM}} - \left(\sum_{i=1}^{n}\mathrm{ET_{FAO56-PM}}\right)^{2}}\right]} \quad \text{(Eq.16)}$$

Correlation Coefficient

$$R^2 = 1 - \frac{\sum_{i=1}^{n}\left(ET_{O,Mi} - ET_{o,FAO56-PM}\right)^2}{\sum_{i=1}^{n}\left(ET_{O,Mi} - ET_{O,Mi_{av}}\right)^2} \quad \text{(Eq.17)}$$

where, $ET_{O,Mi}$ $ET_{O,Mi}$ = Reference evapotranspiration by ith model; $ET_{o,FAO56-PM}$ = Reference evapotranspiration by Standard model 1; SD = Standard Deviation.

Ranking

Many researchers employ multi-criteria decision making (MCDM) methods to cope with water-related problems in their studies (Makropoulos et al., 2008) such as river basin planning (Qin et al., 2008), water supply reservoir (e.g. Srdjevic et al., 2004), urban water management (Zarghami et al., 2008), groundwater management (Pietersen, 2006), wetland management (Janssen et al., 2005), and irrigation planning (Gupta et al., 2000). Senent-Aparicio et al. (2017) uses SWAT and Fuzzy TOPSIS to assess the Impactof Climate Change in Segura River Basin (SE Spain). The present study deals MCDM technique (Entropy for weightage and TOPSIS for performance) for ranking ETo models (alternatives) using statistical indices (criterias), coefficient of determination, standard error of estimate, mean bias error, root mean square error and percent error. The value of SEE, RMSE, MBE and PE is indirectly proportional to the rank called as non-beneficial criteria. Moreover, R^2 value is directly proportional to the rank called as beneficial criteria. The performance value (greater the value better will be the model) of different ETo models will decide the promising model in Abha region which is one of the novelty in this research work.

Entropy Method

Objective Weight

The objective weight is determined by Entropy method by making use of probability theory (Vinogradova et al., 2018).

The decision matrix A with m alternatives and n criteria is shown by *Eq. 18*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13611386

$$A = \begin{bmatrix} x_{11} & \cdots & x_{1n} \\ \vdots & \ddots & \vdots \\ x_{m1} & \cdots & x_{mn} \end{bmatrix} \quad \text{(Eq.18)}$$

where x_{ij} (i = 1, 2, . . . , m; j = 1, 2, . . . , n) shows the performance value of the i^{th} alternative to the j^{th} criteria.

The normalized decision matrix is calculated using *Eq. 19*.

$$P_{ij} = \frac{x_{ij}}{\sqrt{\sum_{i=1}^{m} x_{ij}^2}} \quad \text{(Eq.19)}$$

The entropy E_j of the jth criteria is computed by *Eq. 20*.

$$E_j = -k \sum_{i=1}^{m} P_{ij} ln(P_{ij}) \; j = 1,2, \ldots, n \quad \text{(Eq.20)}$$

A constant that ensures $0 \le E_j \le 10 \le E_j \le 1$ in the $k = 1/\ln m \, k = 1/\ln m$ where m presents the number of choices.

The degree of divergence (d_j) computed by *Eq. 21*.

$$d_j = |1 - E_j| \quad \text{(Eq.21)}$$

The jth criteria entropy weight is computed by *Eq. 22*.

$$\beta_j = \frac{d_j}{\sum_{j=1}^{n} d_j} \quad \text{(Eq.22)}$$

Topsis Method

The TOPSIS method (Alamanos et al., 2018) is expressed in a succession of six steps as follows:

Step 1: The normalized value of matrix as in *Equation 18* is calculated by *Eq. 23*.

$$\overline{X_{ij}} = \frac{X_{ij}}{\sqrt{\sum_{j=1}^{n} X_{ij}^2}} \quad \text{(Eq.23)}$$

where i = 1, 2, ..., m and j = 1, 2, ..., n.

Step 2: The weighted normalized value is computed by multiplying the normalized value by weightage of criterios obtained by *Eq. 22*.

Step 3: Determine the ideal best value (V_J^+) and ideal negative value (V_J^-) from weightage normalized value.

Step 4: The Euclidean distance of each alternative from the ideal best solution (*Eq. 24*) and the ideal worst solution (*Eq. 25*), respectively, are as follows:

$$S_i^+ = \left[\sum_{j=1}^{m} \left(V_{ij} - V_j^+ \right)^2 \right]^{0.5} \quad \text{(Eq.24)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13611386

$$S_i^- = \left[\sum_{j=1}^{m}\left(V_{ij} - V_j^-\right)^2\right]^{0.5} \quad \text{(Eq.25)}$$

Step 5: The performance score is computed by *Eq. 26*.

$$P_i = \frac{S_i^-}{S_i^+ + S_i^-} \quad \text{(Eq.26)}$$

Step 6: Rank the alternatives (greater the P_i value better will be rank).

Results

Evaluation of Reference Evapotranspiration Equations for the 1978–2017 Period

The comparative study of all reference evapotranspiration equation with Standard Penman-Monteith equation is shown in *Fig. 4a-i*. The plot clearly stated that the Evapotranspiration value from all the nine equations has a high correlation with the PM-ETo with the coefficient of determination R^2 range from 0.54 to 0.96. The highest correlation was shown by Albrecht model while the lowest correlation was Makkink method. The best fit of a model is measured by the linear regression line slope close to unity and the intercept to zero. The variation of slope and intercept of the Trabert model were found to be 0.114 and -0.053, respectively and the value of the coefficient of determination was 0.944 (*Fig. 4a*). Similarly, slope and intercept of the Mahringer model (*Fig. 4b*) were found to be 0.261 and -0.12, respectively and the value of the coefficient of determination was 0.944. Moreover, slope and intercept of the Penman model (*Fig. 4c*) were found to be 0.421 and -0.81, respectively and the value of the coefficient of determination was 0.941. Meanwhile, slope and intercept of the Albrecht model (*Fig. 4d*) were found to be 0.473 and -0.225 and the value of the coefficient of determination was 0.963. The slope and intercept of the Priestly Taylor model (*Fig. 4e*) were found to be 1.126 and 1.039, respectively and the value of the coefficient of determination was 0.733. From *Fig. 4f*, it can be seen that the slope and intercept of the Turc model were found to be 0.287 and 0.981, respectively and the value of the coefficient of determination was 0.659. In *Fig. 4g*, the slope and intercept of the Makkink Modified Hansen model were found to be 0.63 and 2.958, respectively and the value of the coefficient of determination was 0.54. The slope and intercept of the Makkink (1957) model (*Fig. 4h*) were found to be 0.549 and 2.459, respectively and the value of the coefficient of determination was 0.54. Similarly, the slope and intercept of the Valiantaz model (*Fig. 4i*) were found to be 0.457 and 0.511 and the value of the coefficient of determination was 0.673. The slope that was closer to one was observed in Priestly Taylor method. On the other hand, the intercept that was closer to zero was shown by Trabert model. The regression equation for evaluation, calibration and validation are shown in *Table 3*) The accuracy of the result was performed using evaluation criteria like RMSE, SEE, MBE and PE values as shown in *Table 4*. Statistical analysis showed that all the selected equations underestimated ETo. The RMSE values were ranging from 0.98 to 2.36 mm/day with the minimum error shown by Valiantaz model and maximum error shown by Trabert model. The MBE values were ranging from 0.78 to 2.24 mm/day with the minimum error shown by Turc model.

Calibration of the Reference Evapotranspiration Equations between 1978-2000

The main objective of the model calibration is to improve the performance of all equations. The computed result from the year 1978 to 2000 was used to calibrate the evapotranspiration equation. Based on the calibration procedure as shown in *Fig. 5a-i*, it can be observed that the coefficient for determination improved substantially with values of R^2 ranges from 0.61 to 0.99 whereby high correlation was shown by Albrecht model and lower value by Makkink method. The slope and intercept of the Trabert model were found to be 1.015 and -0.033, respectively and the value of the coefficient of determination was 0.963 (*Fig. 5a*). Similarly, the slope and intercept of the Mahringer model (*Fig. 5b*) were found to be 1.01 and -0.036, respectively and the value of the coefficient of determination was 0.963. In *Fig. 5c*, the slope and intercept of the Penman model were found to be 1.011 and -0.033, respectively and the value of the coefficient of determination was 0.961. The slope and intercept of the Albrecht model (*Fig. 5d*) were found to be 1.013 and -0.031, respectively and the value of the coefficient of determination was 0.985. In *Fig. 5e* the slope and intercept of the Priestly Taylor model were found to be 1.059 and -0.089, respectively and the value of the coefficient of determination was 0.77. Similarly, in *Fig. 5f*, the slope and intercept of the Turc model were found to be 1.059 and -0.08, respectively and the value of the coefficient of determination was 0.66. The slope and intercept of the Makkink Modified Hansen model (*Fig. 5g*) were found to be 1.096 and -0.142, respectively and the value of the coefficient of determination was 0.609. In *Fig. 5h* the slope and intercept of the Makkink (1957) model were found to be 1.096 and -0.169, respectively and the value of the coefficient of determination was 0.609. Similarly, in *Fig. 5i* the slope and intercept

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13611386

of the Valiantaz were found to be 1.048 and -0.169, respectively and the value of the coefficient of determination was 0.681. The slope that was closer to one was observed in Mahringer model while the intercept that was closer to zero was shown by Albrecht model.

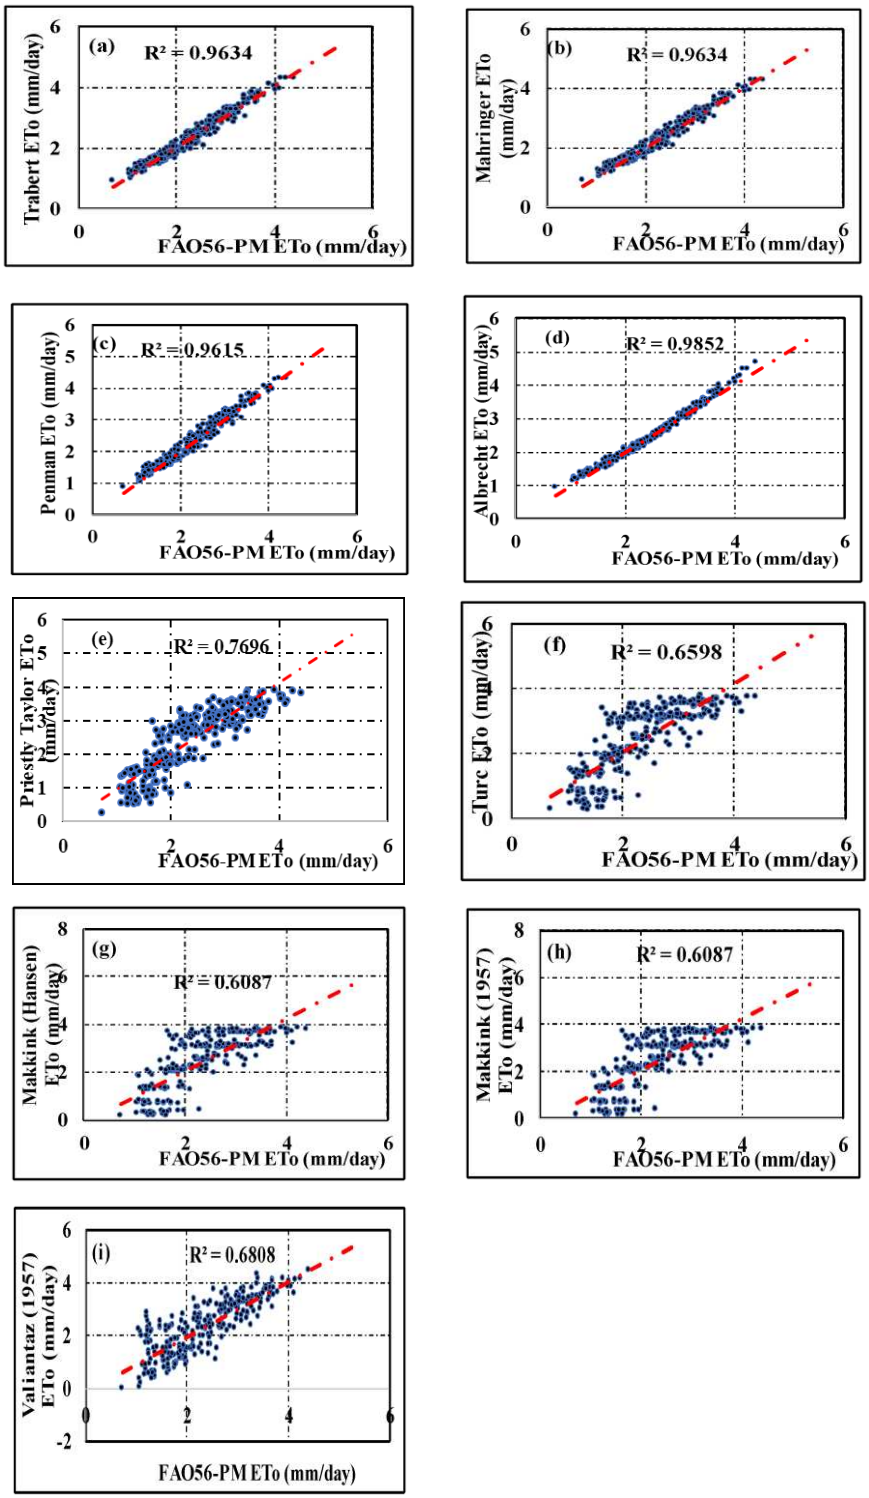

Figure 5. *Relationship between the calibrated daily ETo estimates of each method versus the FAO56-PM at Abha for the 1978-2000 period*

The RMSE values were ranging from 0.1 to 0.71 mm/day with the minimum error shown by Albrecht model and maximum error is shown by Makkink model. The MBE values were ranging from -0.14 to 0.09 mm/day with the minimum error shown by Albreht and Trabert. The SEE values were ranging from 0.1 to 0.7 with the minimum error shown by Albrecht and Maximum error shown by Makkink method. The PE% were ranging from 3.63 to 0.01 with minimum error shown by Albrecht model. There was considerable a reduction in RMSE and MBE values for all the equations after calibration as shown in *Table 5*. The percentage error also reduced significantly whereby the maximum reduction in error percentage was found to be in Trabert Model in which the error reduced from 90.70 to 0.1%. However, there was no improvement in SEE values as the error increased slightly in Priestly Taylor method whereby the error reduced from 0.57 to 0.46.

Validation of ET Model from Calibrated Equation for Period between 2001-2017

Nine calibrated evapotranspiration equations have been validated for the period of 2001–2017 in order to show which calibrated equation perform well and can be further employed as an alternative to Standard FAO Penman Monteith model.

From the validation procedure as shown in *Fig. 6a-i*, it can be observed that the coefficient of determination improved substantially with values of R^2 ranges from 0.48 to 0.936 with high correlation shown by Albrecht model and lower value by Makkink method. The slope and intercept of the Trabert model were found to be 0.111 and -0.014, respectively and the value of the coefficient of determination was 0.919 (*Fig. 6a*). Similarly, the slope and intercept of the Mahringer model (*Fig. 6b*) were found to be 0.254 and -0.07, respectively and the value of the coefficient of determination was 0.919. In *Fig. 6c* the slope and intercept of the Penman model were found to be 0.401 and -0.127, respectively and the value of the coefficient of determination was 0.916. The slope and intercept of the Albrecht model (*Fig. 6d*) were found to be 0.46 and -0.173, respectively and the value of the coefficient of determination was 0.936. In *Fig. 6e* the slope and intercept of the Priestly Taylor model were found to be 1.019 and 1.112, respectively and the value of the coefficient of determination was 0.696. In *Fig. 6f* the slope and intercept of the Turc model were found to be 0.261 and 1.007, respectively and the value of the coefficient of determination was 0.667. Similarly, in *Fig. 6g* the slope and intercept of the Makkink Modified Hansen model were found to be 0.537 and 2.86, respectively and the value of the coefficient of determination was 0.48. The slope and intercept of the Makkink (1957) model (*Fig. 6h*) were found to be 0.468 and 2.425, respectively and the value of the coefficient of determination was 0.48. In *Fig. 6i* the slope and intercept of the Valiantaz model were found to be 0.4 and 0.776,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13611386

respectively and the value of the coefficient of determination was 0.647. The slope that was closer to one was observed in the Priestly Taylor model while the intercept closer to zero was shown by Trabert model.

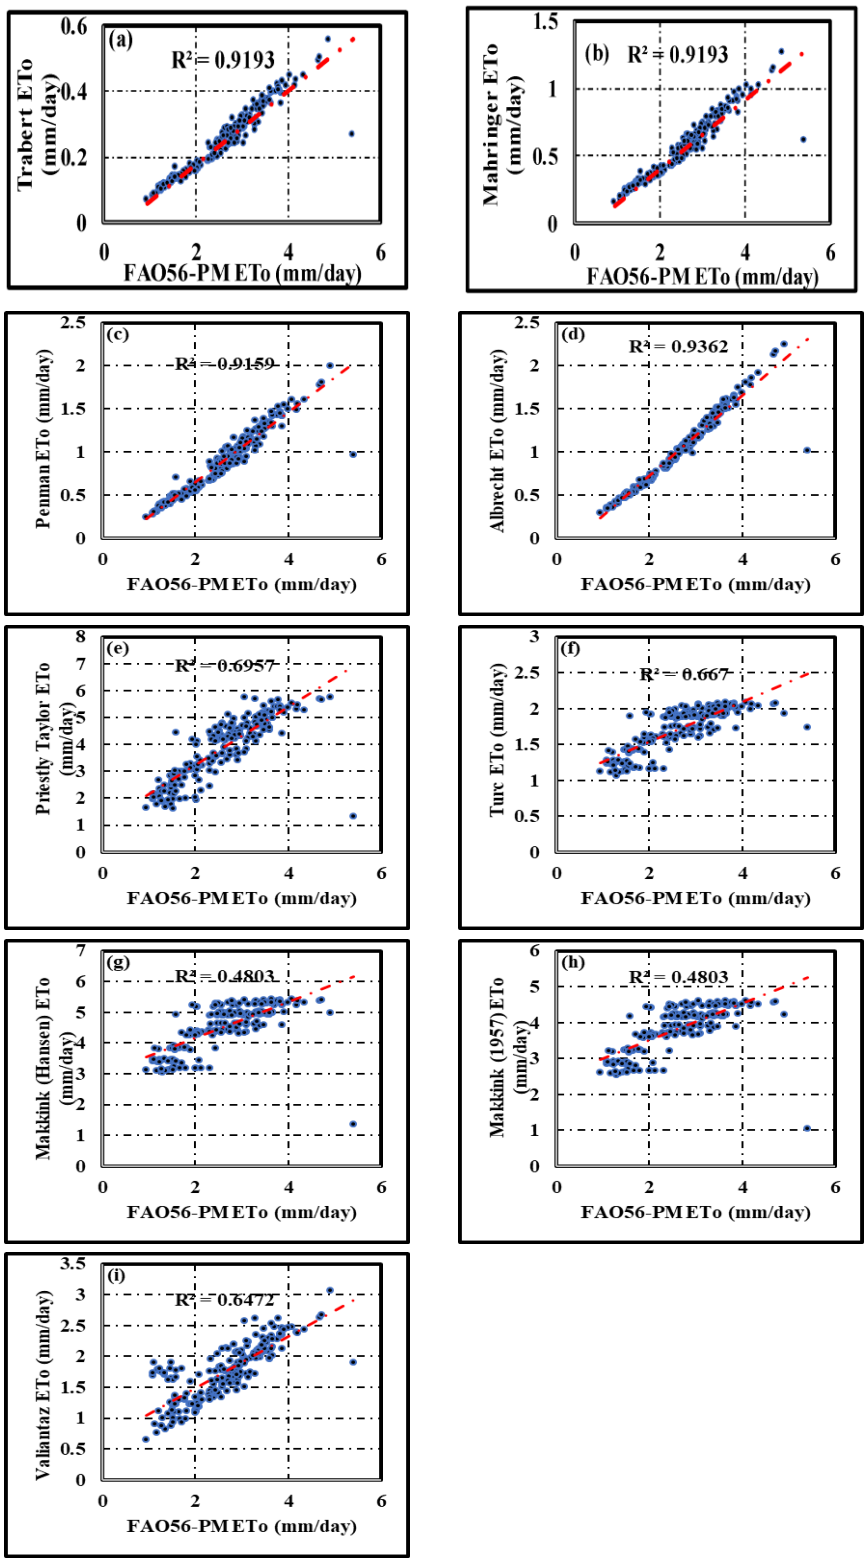

Figure 6. *Validating the calibrated equation for the period between 2001-2017*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13611386

The statistical analysis as shown in *Table 6* illustrates that there is a close relationship between the validated equation result with the Penman Monteith estimates. Similar to the output of the calibrated equation, the result obtained from SEE, RMSE, MB and PE showed a similar pattern with only slightly decrease in R^2. The value of SEE, RMSE, MBE and PE is acceptable for ETo estimation with any of the nine ETo equations at Abha station. However, Validated Valiantzas equation (R^2=0.65, the lowest RMSE 0.99 mm/day and the lowest PE of 30.32%) should be the first option to estimate ETo in the Abha Region followed by Turc then Albrecht. The worst performance was given by Makkink modified method.

Table 6. *Evaluation of criteria parameters for validating ET estimate between 2001-2017*

Method	R2	SEE	RMSE	MBE	PE
Trabert-ET0(mm)	0.92	0.03	2.47	-2.35	89.43
Mahringer-ET0(mm)	0.92	0.07	2.13	-2.03	77.27

Ranking of ETo Estimation

The primary requirement of ranking is to get weightage for statistical indices which is computed by Entropy method (*Table 7*). The values depicted as shown in *Table 8* below describes the ranking of ETo Estimate of nine models for the period between 1978-2017. It was observed that the Mahringer model ranked number 1 while Makkink Modified model was in the last position for the case of without calibrating the ETo equation. Also, the ranking of ETo Estimate of nine models after calibrating for the period between 1978-2000 are shown in *Table 9*, Albrecht model ranked number 1 and Valiantaz model was in the last position. Moreover, the ranking as shown in *Table 10* gives the ETo Estimate of nine models for Validating the Calibrated equation for the period between 2001-2017. Mahringer model ranked number 1 and Priestly Taylor was in the last position. Hence, it is quite clear that Mahringer method is the most promising model which can be used as an alternative to FAO56-PM model. The comparative study of Ranking is shown in *Fig. 7*. From the whole ranking analysis, it can be observed that the ranks' results did not exactly match with each other and in some cases considerably differs from the other.

Table 7. *Weightage by Entropy Method*

Criteria	R^2	SEE	RMSE	MBE	PE	Sum
Weightage Evaluation	0.05	0.67	0.08	0.11	0.10	1.00
Weightage Calibration	0.01	0.13	0.13	0.44	0.29	1.00
Weightage Validation	0.06	0.62	0.08	0.12	0.12	1.00

Discussions

Different ETo models were used around the world to compute the reference evapotranspiration by using the climatic parameters such as mean temperature, relative humidity, solar radiation and wind speed. FAO56-PM model recommended by the Food and Agricultural Organization (FAO) has been recognized as the most accurate model for estimating the ETo over the past few decades. But due to the constraint of limited climatic parameters, FAO56-PM is not suitable to be implemented. Thus, to find an alternative technique of accurate prediction of ETo, the performance of the nine empirical models were evaluated against the FAO56-PM model by using the four common statistical approaches: root-mean-square error (RMSE), mean bias error (MBE), standard error of estimates (SEE) and percent error (PE). Additionally, a linear regression model was adopted to calibrate and validate the performance of the empirical models during the 1978–2000 and 2001–2017 time periods, respectively. The current study compared four mass transfer methods (Trabert, Mahringer, Penman and Albrecht), four radiation-based methods (Priestly Taylor, Turc, Makkink and Makkink Modified) and one combination-based method against the FAO56-PM method.

The result evaluated from 1978-2017 showed that the mass transfer method performed better without calibration with the highest the coefficient of determination was the Albrecht (R^2=0.96) followed by the combined method and lastly was the radiation method. The statistical output showed that the combined model (Valiantzas equation) performed better as compared to the other model with an RMSE value of 0.98 mm/day, MBE=0.83, PE%=33.53 and SEE=0.268 mm/day. The higher precision of the combined models might be due to the combination of the most suitable and important meteorological parameters being incorporated. Similar results were also obtained previously after evaluating six ETo equations (Trabert, Mahringer, Penman (1948), Albrecht, Valiantzas1 and Valiantzas2) for the Senegal River Delta (Djaman et al., 2016a). The result is in agreement with the present work with $R^2 > 0.60$ for the daily ETo estimates. The Valiantzas2 equation was the best model for the Senegal River Delta and had the lowest root mean squared difference (RMSE) of 0.45 mm/day and the lowest percent error of estimate (PE) about 7.1%. The findings of the research are in agreement with the study conducted by other researchers (Djaman et al., 2015) after evaluating the sixteen reference evapotranspiration methods under sahelian conditions in the Senegal River Valley. However, Valiantzas equation was found to be the promising equations that could be used for the reference evapotranspiration estimation in the Senegal River Valley. After calibrating the empirical equation from (1978-2000), it was observed that there was a remarkable improvement in the performance of these nine equations. Additionally, the findings revealed that the calibration improved the reliability and consistency of different ETo equations. The correlation value significantly increased. Moreover, the statistical measures such as RMSE, SEE, MBE and PE significantly reduced for all the models but both the Albrect and Makkink models gave the least correlation. However, no improvement was seen in Turc model with its SEE. But, there was a remarkable improvement in the performance of equations. Additionally, the findings revealed that calibration improved the reliability and consistency of different Valiantzas equations. Valipour (2015) reported that there was an improvement in the calibrated Trabert and Mahringer equations in Iran with MBE as low as 0.02 mm/day. He indicated that the Trabert model can skip the calibration process to generate the best performance in Iran. Meanwhile, Valiantzas equations were suitable for ETo estimation as compared to PM-ETo in the Pilbara

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13611386

region of Western Australia. But, their performance can be further improved through calibration (Ahooghalandari et al., 2017).

The calibrated Valiantzas equation showed the best performance using the limited data in Guizhou Province, China (Gao et al., 2015). This phenomenon was similar to the performance's results of the calibrated Valiantzas equation at Adana Station in Turkey (Kisi and Zounemat-Kermani, 2014). The calibrated Trabert, Albrecht and the Mahringer equations showed different performance relative to the PM-ETo, depending on the region. But, the better performance was observed at Ndiaye 35 km inland than Saint-Louis at the coast. The dependency of mass transfer equation on the vapor pressure was too small. It was reported that better performance of the Trabert and Mahringer equations were in inland area than at the coastal area in the Senegal River Valley (Djaman et al., 2015). The climate variables in a coastal area like Saint-Louis located near the mouth of the Senegal river might be influenced by surrounding water (Hargreaves, 1994). These results were contradicted with the findings of Valipour (2015) who reported that the calibrated mass transfer ETo equation had better performance near the Caspian Sea and the Persian Gulf in Iran with RH higher than 65% than the other area. The validation of the nine ETo equations for the 2001–2017 shows a strong correlation between the calibrated equations to the PM estimates. Similar RMSE, MBE and PE were obtained from the calibration and validation with only slightly decrease in R^2. The magnitude of RMSE, MBE and PE were acceptable for ETo estimation for any nine ETo equation at Abha.

From the ranking of evaluated model and during validation of calibrating ETo model, it was observed that Mahringer ranked number 1 and Makkink modified gives worst performance during evaluation and Priestly Taylor was in the last position during the validation of the calibrated equation. Hence, Mahringer method is the most promising model which can be used as an alternative to the FAO Penman-Monteith method. Moreover, during calibration the Albrecht model is found to be best one and Valiantaz shows the worst result. The overall improvement result after calibration and during validation against the evaluated evapotranspiration for the first three rank model is as shown in *Fig. 8*. It clearly shows that the evaluation criteria significantly improved with respect to the evaluated equation after calibration and validation. However, there is no considerable improvement in the coefficient of determination in some cases. The outcomes of the study will provide meaningful guidance for agricultural production, hydrological planning and management in the vital region as well as other regions with similar climates.

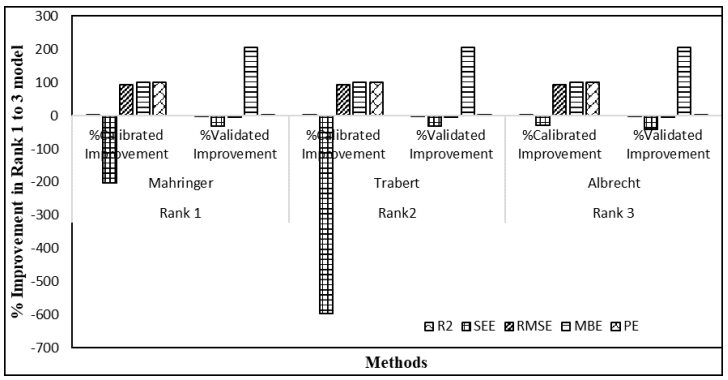

Figure 8. *Comparative study of rank 1 to 3 evaluation criteria*

Conclusions

The current study was performed with an aim to evaluate the nine reference evapotranspiration models with respect to standard FAO56-PM model in the semi-arid region of Kingdom of Saudi Arabia. The nine evapotranspiration models have been successfully evaluated (period: 1978-2017), calibrated (period: 1978-2000) and further validated (period: 2001-2017). Based on the statistical indices as criteria, the ranking was performed using multi criteria decision making (weightage by Entropy and performance score by TOPSIS) in order to observe the performance against the FAO56-PM equation under the available climatic conditions in Abha city. Based on the analysis result following inference can be made

- There was a remarkable improvement in the performance of calibrated equation. Moreover, the calibration approach improves the reliability and consistency of different evapotranspiration equation.
- The ranking of evaluated evapotranspiration models (1978-2017) and during validation (2001-2017) shows that the Mahringer model performed very well. While during calibration (1978-2000), Albrecht model shows better performance. Hence Mahringer model was the most promising model and can be used as an alternative approach to Standard FAO56-PM model.
- In the case of data limitations, the equations calibrated in this study are recommended for ETo estimation in the Abha region.
- The Use of multiple criterion decision-making methods (MCDM) allows a researcher to choose the best alternative out of a number of the considered alternatives.
- The findings, are likely to help in diminishing the error associated with ETo estimation, and the recognized models in this study could be utilized as part of further examinations in the related field.
- To some extent, it is expected that the conclusions of this study can be used in regions with similar topography and climatic conditions in the world.
- The results of this study could be used by the water management system, crop cultivators, crop advisors, researchers and students from universities and research centres. Moreover, it is beneficial for the decision maker in the vast field of agriculture, hydrology and environment.
- Further research is required in order to assess the effect of using reduced set of data for daily hourly ETo estmation. Moreover, the seasonal changes in ETo is also need to be investigated in future.

Acknowledgments. The authors extend their appreciation to the Deanship of Scientific Research at King Khalid University for funding this work through research group program under grant number (R.G.P.1/85/40). The authors of current work wish to thank Universiti Tecknologi Malaysia, Johor Bahru for their facilities and Lab support. The outcome of this research paper is based on the excerpts of current ongoing Ph.D research study. We would also like to thank general authority of the meteorological department, Abha, Asir region, Saudi Arabia for providing the weather data.

Conflict of interests. The authors declare no conflict of interests.

Abstract. One of the most serious problems of the environment is heavy metal toxicity originating from the industrial activities even in traces which harm the ecosystems. Initially a total of 30 isolates were screened on nutrient agar medium containing heavy metals: zinc, iron, cobalt, cadmium, copper and lead at four different concentrations (25, 50, 75 and 100 µg/mL in their salt form). Three isolates of Bacillus sp. were isolated from effluent industrial wastewater of Abu Kerqas Sugar Factory (27°55' 28.8" N 30°49' 00.4" E), identified by using 16S rRNA gene and documented in GenBank as Bacillus spp. SMMAA-1 (LC472522), Bacillus cereus SMMAA-3 (LC472523), Bacillus altitudinis SMMAA-4 (LC472524). The bacterial isolates were selected based on their growth curve; IAA reaction and antibiosis effect were identified based on their morphological, biochemical characterization and utilization of carbohydrates as carbon sources. These isolates were evaluated for their abilities to bio-remediate the toxic heavy metals. Results showed that bacteria present resistance to six heavy metals. B. cereus is more effective concerning its removal efficiency percentage for six heavy metals (Zn^{+2}, Fe^{+2}, Co^{+2}, Cd^{+2}, Cu^{+2} and Pb^{+2}) (94.77%) from Industrial Wastewater than Bacillus spp. (83.19%) and B. altitudinis (83.21%). The highest removal efficiencies by Bacterial isolates were found with Co^{+2}, Cd^{+2} and Cu^{+2} and the lowest removal biosorption were recorded with Fe^{+2}.
Keywords: *Bacillus spp., Bacillus cereus, Bacillus altitudinis, bioremediation, effluent wastewater, 16S rRNA gene, GenBank*

Introduction

Many organizations and scientists from various disciplines mentioned that the bioremediation can be used to break down the metal availability below the permissible limit. Most of them are in their advanced stages of developing different protocols and identifying a plethora of bacterial species to solve the issue (Kielak et al., 2017; Sardar et al., 2018). Exceedingly higher concentrations of heavy metals are a menace to human health due to their harmful effects such as genotoxicity towards the DNA and immunotoxicity as they are major irritants to the body. The genomic instability by these metals induces cancer (Leonard et al., 2004).

Heavy metals toxicity is significant environmental pollutants problem of increased significance for ecological, evolutionary, nutritional and environmental reasons (Nagajyoti et al., 2010; Jaishankar et al., 2014). Heavy metals water pollution one of serious important problems in world and Egypt. Heavy metals accumulations were observed in Egyptian

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13871406

cultivated such as soil, Nile River and air (Abbas and Kamel, 2004). Today, the quality of Nile water is a matter of serious concern due to exposure to increasing at an alarming rate multiple sources of heavy metals pollution including industrial, agricultural and domestic effluents. Effluent industrial wastewater is the main source of Nile pollution by heavy metals. The most commonly found heavy metals in wastewater include arsenic, cobalt, iron, cadmium, chromium, copper, lead, nickel, and zinc, all of which cause risks for human health and the environment (Lambert et al., 2000).

So, quick and easy removal and recovery of heavy metals from industrial wastewater at low cost are needed. Several conventional methods include precipitation, membrane filtration, ion exchange, electrochemical recovery; biological separation and adsorption are used to remove heavy metals from wastewater. Nevertheless, these methods unfriendly environmental, long processing times and high costs (Carolin et al., 2017). Nowadays, in light of this necessary for attractive alternative strategies low-cost, efficient and environmentally friendly methods instead of traditional to recover heavy metals from wastewater are needed (Moradi et al., 2015). The growing industrialization has spread worldwide and has left persistent toxic heavy metals, like chromium, nickel, lead, zinc, cadmium and copper in our ecosystem. These heavy metals tend to accumulate and deteriorate the environment. This is especially true for developing countries like China and India (Raja et al., 2008; Chauhan et al., 2017).

The bioremediation methods for reducing more of heavy metals in the environment have attracted importance. Living organisms were reported to able to absorb pollutants and remove heavy metals from the environment. Plants, fungi and microorganisms such as yeasts, bacteria, algae, and cyanobacteria are usually used for the bioremediation of heavy metals and recorded to be the best acceptable ones because they are easier to work with (Massoud et al., 2018). Several studies reported that bioremediation is the most effective management tool to manage the polluted environment and recover contaminated environment (Ahemad, 2012). Since heavy metals are ubiquitously present in our environment, microorganisms such as bacteria, yeast or fungi have developed mechanisms to removal contaminated soil and water via heavy metals (Kumar et al., 2011). Bioremediation includes some methods such as phytoremediation, biodegradation, bioventing (Dupont, 1993).

Assessment of microbes for their remediation potential in dealing with industrial pollutants is another point of interest where a bacterium or a fungus produces metabolites as their weapon of degradation (Pathak et al., 2017). Many bacterial strains contain genetic determinants of resistance to heavy metals such as Hg^{2+}, Ag^{2+}, $Cu^{2+,}$ Ni^{2+}, Cd^{2+} and others (Karelova et al., 2011; Chauhan et al., 2017).

Several investigators have used different bacterial strains like Bacillus sp., Bacillus licheniformis, Bacillus thuringiensis, Pseudomonas sp., Staphylococcus aureus to for the biosorption as well as bioaccumulation of various metal ions like Cr(VI), Ni(II), Zn(II), Pb(II) etc. (Şahin and Ozturk, 2005; Tunali et al., 2006; Zhou et al., 2007; Ziagova et al., 2007; Wang et al., 2010; Akhter et al., 2017). Thus, the overall objective of the study is to enhance production of bacterial strains with high ability to uptake of heavy metals by different concentrations to helping in the reduction of Industrial wastewater effluent pollution of heavy metal. This emphasizes the importance and needs of carrying out extended testing for the compatibility of biosorption to heavy metals toxicity. It is more effective, cheap than traditional technologies of treating contaminated water with heavy metals, including precipitation, ion exchange or reverse osmosis still generate too large costs.

This study aimed to isolation and identification of bacterial isolates that have ability to heavy metals biosorption and the role of bioremediation as technological method for uptake of six heavy metal ions from industrial wastewater effluent in Egypt to reduce the environmental pollutions.

Materials and methods

This study was conducted at both of Laboratory of Microbiology, Mallawy Agric. Res. Station, Dept. of Agric. Microbiology., Soil, Water and Environmental Research Institute, Agric. Res. Center, Giza, Egypt, and Central Lab., Faculty of Postgraduate Studies for Advanced Sciences, Beni Suef University. Molecular identification of the bacterial isolates was done in Microbiological Laboratory, Faculty of Agriculture, Zhejiang University, Hangzhou City, and East China during the period of 2017-2018.

Industrial wastewater samples collection and preparation

In this study, effluent industrial wastewater samples were collected from the site of the main drain of Abu Kerqas Sugar Factory (27°55' 28.8" N 30°49' 00.4" E) (*Fig. 1*), El-Minia Governorate, March, 2017. Three samples of wastewater each 10 L per sample were collected in plastic jerry cans. Cans were previously sterilized by 75% ethanol, washed three times with wastewater to remove the residual effect of ethanol, and filled with the samples and then transferred immediately to the Microbiology Lab of Mallawy Agric. Res. Station. The three samples were mixed gently to obtain the main sample and kept in the refrigerator (6 ± 2 °C) for the further studies.

Figure 1. *The main drain of Abu Kerqas Sugar Factory (27°55' 28.8" N30°49' 00.4" E)*

Determination of heavy metal concentrations in the wastewater samples

Samples were taken from the main sample and sent to the Central Lab., Faculty of Postgraduate Studies for Advanced Sciences, Beni Suef University. The concentrations of heavy metals (Zn^{+2}, Fe^{+2}, Co^{+2}, Cd^{+2}, Cu^{+2} and Pb^{+2}) in samples were analyzed and determined by the Atomic Absorption Spectroscopy (Model: Agilent Technologies 200 series AA System) according to the method of EPA (2005).

Bacteria isolation via streak plate technique

Three dilutions (1.00, 0.50 and 0.25) of each of the main sample and collected samples containing heavy metals, was done as described by Azad et al. (2013) to isolate

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13871406

the desired bacteria that have more tolerance to high concentration of heavy metals. This technique was applied to isolate some bacterial colonies able to grow in the presence of heavy metals. Two loops from the best dilution of the wastewater samples was taken and streaked onto sterile petri plates containing nutrient agar medium (NAM) as recorded by Marzan et al. (2017). Single colonies were selected, picked, purified and inoculated on NAM slant and coded as T1 up to T30. These single colonies were purified on NAM, and preserved on different plates or slants for further experiments.

Tolerance of bacterial isolates to six heavy metals

Six heavy metals: zinc (Zn^{+2}), iron (Fe^{+2}), cobalt (Co^{+2}), cadmium (Cd^{+2}), copper (Cu^{+2}) and lead (Pb^{+2}) were used in their salt structures as: $ZnSO_4$, $FeSO_4•7H_2O$, $COCl_2$, $CdSO_4•3H2O$, $CuSO_4•5H_2O$ and $PbSO_4$. According to the method of Vijayadeep and Sastry (2014) heavy metals salt solutions (25, 50, 75, 100 µg/mL) were prepared in distilled water to obtain concentrations and sterilized by 0.2 µm pore-size Millipore sterile filters. The bacterial isolates (T1, T2 and T3……T30) were checked for the heavy metals tolerance using the agar well diffusion method as reported by Collins et al. (1985) in sterile NAM plates. On incubation of plates at 35-37 °C for 72 h, the inhibition zones (the distance between the end of the zone and the edge of the well, mm) were measured. Isolates showing a clear zone of 1 mm or less was considered as resistance (R) isolate according to Rani and Moreira (2010). The bacterial isolates which appeared resistance to the heavy metal ions at the all tested concentrations were recorded as (T1, T2, T3, T4, T5, T6, T7, T8, T10 and T18).

Effect of industrial wastewater (IWW) toxicity on each of bacterial growth and indole acetic acid (IAA) production (color change) by the ten bacterial isolates

The effects of IWW on the growth of the selected isolates (T1, T2, T3, T4, T5, T6, T7, T8, T10 and T18) were determined by growing the bacteria in nutrient broth medium (NBM) supplemented with sterile IWW (SIWW). IWW was sterilized by 0.2 µm pore-size Millipore sterile filters. The cultures of bacterial isolates were grown in the presence of SIWW, and as a blank SIWW were taken out. One loop from each isolate culture was taken and inoculated in 100 mL NBM and incubated under shaking condition (180 rpm) for 24 h at 30 °C as described by Priyadharshini and Kumar (2016). Then, 3.0 mL of the bacterial culture were added to each flask contained 100 mL of SIWW, mixed well and incubated as mentioned before. Bacterial growth was measured using a spectrophotometer (Spectronic 20 BauTchandLomp) at 620 nm as optical density (OD). The recorded data were taken after 1, 2, 3, 4, 5, 6 and 7 days from the incubation.

In case of effect of IWW on IAA produced by the bacterial isolates under investigation, the ten bacterial isolates were grown overnight in sterilized NB medium at 30 °C for 24 h, and then 2.0 mL from each isolate were taken and inoculated with 5 mL SIWW to determine the degree of IAA by change of color visually as described by Glickmann and Dessaux (1995).

Methods to determine the antibiosis activities of the ten bacterial isolates

The antagonism of the bacterial isolates against F. solani, S. rolfsii and E. coli was performed using well diffusion method of Nedialkova and Naidenova (2005). The filtrate of E. coli was dropped (1-2 mL) in prepared holes of the NAM inoculated with

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13871406

ten bacterial isolates and incubated at 30 °C for 24-48 h. Concerning to the antagonistic effect against F. solani and S. rolfsii, disc from each fungus growing on potato dextrose agar medium (PDA) was taken, and inoculated with the tested bacterial isolates. Three petri dishes per each of isolate and pathogen were used as replicates. The plates were incubated at 28 °C for 6 days, and the antagonistic activities were then recorded.

Biological and molecular identification of the selected bacterial isolates

The three bacterial isolates (T1, T3, and T4) which selected based on their tolerance to heavy metals; growth curve, IAA production and antagonistic effects were identified according to the methods described by Juni (1986) reported in Bergey's Manual of Systematic Bacteriology (1986, 2012).

Using 16S rRNA gene the identification of the three bacterial isolates was confirmed. NAM slants of the isolates were sent to Microbiology Laboratory, Faculty of Agriculture, Zhejiang University, Hangzhou City and East China. The genomic DNA of isolates was extracted using a Gene JET extraction kit (Thermo K0721) according to the Manufacturer's instructions.16S rRNA region was amplified with the following bacterial primers (F: 5'AGA GTT TGA TCC TGG CTC AG3' and R: 5'GGT TAC CTT GTT ACG ACTT3'). Thermal cycling consisted of initial denaturation at 94 °C for 2-5 min, followed by a cycle of denaturation at 95°C for 30 s, annealing at 55-60 °C for 1 min and elongation at 72 °C for 60 s, and finally, at 72 °C for 5-10 min for completion. The PCR amplification was performed using Gene JET Gel Extraction (ThermoK0701). Sequencing was performed using the ABI PRISM BigDyeTM Terminator Cycle Sequencing Kits, ABI PRISM 3730XL Analyzer (96 capillary type) sequencer (Applied Biosystems), MJ Research PTC-225 Peltier Thermal Cycler, DNA polymerase (FS enzyme) (Applied Biosystems). The DNA sequences of the PCR product of the 16S rRNA gene of the three bacterial isolates were through the BLAST P program which available on the National Center for Biotechnology Information website http://blast.ncbi.nlm.nih.gov/Blastcgi? PROGRAM=blast p and PAGE – TYPE=BLAST Search and LINK – LOC=blast home (Altschul et al., 1990).

Selected bacterial isolates (T1) Bacillus spp., (T3) B. cereus and (T4) B. altitudinis effects

The effects of the selected isolates (Bacillus spp., B. cereus and B. altitudinis) were tested for their ability to alleviate or eliminate the heavy metal concentrations for industrial wastewater effluent.

1 ml from each bacterial isolate that growing in nutrient broth medium was inoculated to flasks contained 100 ml of sterilized industrial wastewater (SIWW). The flasks were incubated in a shaker for 24 h at 30 ± 2 °C under static conditions as mentioned by Priyadharshini and Kumar (2016). The flasks were filtered (Whatman filter paper No.1) then the samples were received to the Central Lab., Faculty of Postgraduate Studies for Advanced Sciences, Beni Suef University to determinate the heavy metals concentrations for each sample. The percentage of removal heavy metals (Zn^{+2}, Fe^{+2}, Co^{+2}, Cd^{+2}, Cu^{+2} and Pb^{+2}) was calculated as *Equation 1* and that recoded by Bakar et al. (2013) as follows:

$$\text{Removal efficiency\%} = \frac{\text{Initial metal conc.} - \text{Final metal conc.}}{\text{Initial metal conc.}} \times 100 \qquad \text{(Eq.1)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13871406

Statistical analysis

The data were prepared by mean ± standard deviation (n = 3) and carried out as a randomized complete design (Snedecor and Cochran, 1980) using LSD test to compare means of treatments in investigation. Statistical significance was defined as $P < 0.05$. Mean values of three replicates followed by the same letters in each column are not significantly different ($P > 0.05$) (Duncan multiple range test).

Results and discussion

This study was designed to isolate some promising bacteria able to tolerant the high levels of heavy metals in EIWW in a trail to decrease or remove the heavy metals present in the EIWW. Therefore, determination of heavy metals concentration in EIWW samples was conducted for the six heavy metal ions (Zn^{+2}, Fe^{+2}, Co^{+2}, Cd^{+2}, Cu^{+2} and Pb^{+2}) that threatening the environments, human, plants and animals.

Heavy metal concentrations in the EIWW samples

Data illustrated in *Table 1,* showed that the concentrations of the six selected heavy metal ions in EIWW samples. The concentrations were ranged from 6 ppm (Zn^{+2}) to 1.4 ppm (Co^{+2}). It was noted that all tested heavy metals presented in high concentration compared to permissible limits excepted for Fe^{+2} ion which was the lowest one (2.1 ppm) compared to permissible rate (3.0 ppm). Also, the concentrations of Co^{+2}, Cd^{+2} and Pb^{+2} heavy metals were more folds than the guidelines and standers of WHO, therefore, these ions were considered as the highest toxic ions. This notes in harmony with that reported by Rajendran and Gunasekaran (2007) and Murthy et al. (2012).

Table 1. *Heavy metals concentrations in the main EIWW sample collected from Abu Kerqas Sugar Factory, El-Minia, Egypt, compared to permissible rate (ppm) according the guidelines and standers of WHO*

Metals	Conc. (ppm)	Permissible rate (ppm)	References
Zn^{+2}	6.0	5.000	WHO (1984)
Fe^{+2}	2.1	3.000	WHO (2006)
Co^{+2}	1.4	0.010	WHO (2003)
Cd^{+2}	1.8	0.005	WHO (1984)
		0.003	WHO (2003)
Cu^{+2}	1.5	1.000	WHO (1984, 2003)
		1.300	WHO (2006)
pb^{+2}	1.9	0.050	WHO (1984, 2003)

WHO = World Health Organization

Bacteria isolation via streak plate technique using NA media supplemented with different dilutions of EIWW

Data represented in *Figure 2* show the presence of single colonies exhibited Bacillus-like species cultural properties grown on NAM inoculated with different dilutions of EIWW. The lowest concentration (0.25 mL) from (EIWW) have purified single separated colonies compared that of 0.50 and 1.00 mL. The last two dilutions showed crowded, compacted and irregular colonies on the NAM which are not easily

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13871406

distinguished. Therefore, it has been observed that of the dilution of 0.25 mL was considered the best dilution to obtain the single separated colonies which were easily selected, picked, purified and easily distinguished. A number of 30 isolates were picked, purified and coded symbols of T1, T2, T3 and T4 …to T30.

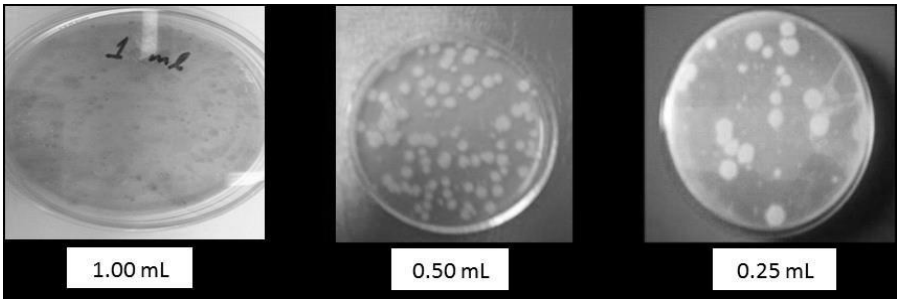

Figure 2. *Cultural properties of the isolated bacteria grown on different dilutions of EIWW*

Tolerance of bacterial isolates to six heavy metals

The bacterial isolates were coded as T1 up to T30, and evaluated for their abilities to tolerant a number of six heavy metals (Zn^{+2}, Fe^{+2}, Co^{+2}, Cd^{+2}, Cu^{+2} and Pb^{+2}) at four concentrations (25, 50, 75 and 100 µg/mL) as shown in *Table 2*. Based on the diameter of inhibition zones, the isolates were classified as sensitive or tolerant to each heavy metal ion and its concentration. The isolates were varied in their abilities to tolerant the heavy metal concentrations. The isolates that able to grow at concentrations of metal ions at 25, 50, 75 and 100 (µg/mL) were considered as tolerant as they showed a clear inhibition zone of 1 mm (*Fig. 3*) or less according to (Rani et al., 2010). Data in *Table 2,* showed that T10 isolate appeared tolerance to Cd^{+2}, Cu^{+2} and Pb^{+2}, while T18 isolate were tolerant to Zn^{+2}, Fe^{+2} and Co^{+2}. Results also showed that the highest tolerant bacterial isolates to the four concentrations of the six for heavy metal ions were T1, T2, T3, T4, T5, T6, T7, and T8. On the other direction, T23 isolate appeared sensitivity to all tested heavy metal ions except for with Pb, as it was tolerant (*Table 2*).

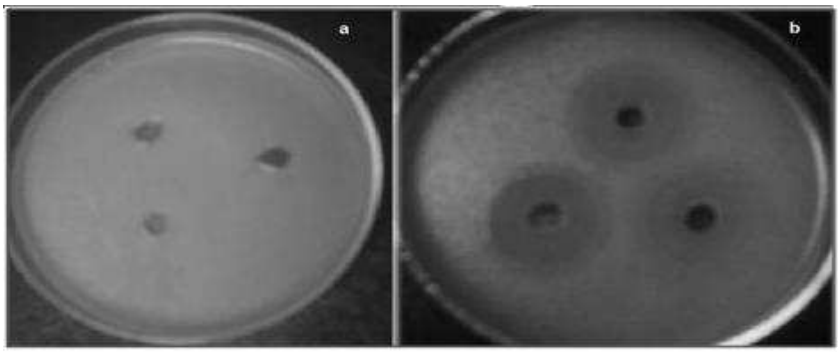

Figure 3. *Tolerance of the bacterial isolate to heavy metals [resistant (a) and clear of inhibition zone as sensitive (b)]*

At the lowest concentration (25 µg/mL) of all six heavy metal ions, all bacterial isolates were tolerant except for the heavy metal ion (Pb^{+2}). These results are in agreed with that reported by Malik and Jaiswal (2000), who showed that acceptable

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13871406

concentration of metal ions, which could be used for distinguishing metal tolerant and metal-sensitive bacteria, strains able to grow at concentrations of metal ions at and above 1.0 mM were considered resistant. Based on the experimental findings, the heavy metal-tolerant bacteria could be selected as especially promising microorganisms for bioremediation application of heavy metals polluted places.

Effect of EIWW toxicity on each of bacterial growth and indole acetic acid (IAA) produced by bacterial isolates

Effects of SIWW on bacterial growth, representing in each of growth curve [expressed as optical density (OD) (λ = 620 nm) as recommended by Priyadharshini and Kumar (2016), and bacterial growth periods [1, 2, 3, 4, 5, 6 and 7 days] of ten isolates (T1, T2, T3, T4, T5, T6, T7, T8, T10 and T18) was carried out.

ICs: Isolate codes. R: Resistance. S: sensitive. *: Inhibition zone dimension

Results in *Figures 4* and *5* revealed that the lag phase growth started in the 1st day of bacterial isolates (T1, T2, T3, T4 and T5) and in the 2nd day for the isolates (T6, T7, T8, T10 and T18). Four recognizable phases are seen when the increase in cell number was determined in relation to time by lag phase, log phase, stationary phase and decline phase (Priyadharshini and Kumar, 2016).

The lag phase continuously in the growth for the 3rd day and the highest OD (0.61 nm) was recorded with isolates T10 and T18. Regarding to the log phase, the three isolates coded T1, T3 and T4 registered the highest values (0.41, 0.40 and 0.46 nm) respectively. The stationary phase was observed in the 5th day and the high value was recorded for T3 isolate (0.42 nm) and T6 isolate (0.41 nm). From the 6th day all the tested bacterial isolates started in the decline phase. The obtained data indicated that the selected bacterial isolates (T1, T3 and T4) were continuously to the growth from the 1st day until the 5th day and the optimum growth period was registered in the 4th day. These

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13871406

results considering that the selected bacterial isolates (T1, T3 and T4) are promising bacteria for up taking the heavy metal ions from EIWW.

Effect of EIWW toxicity on the abilities of the selected bacterial isolates to produce IAA was studied. Results in *Table 3* (illustrated by *Fig. 6*) showed that the selected bacterial isolates were varied in their production of IAA affected by EIWW.

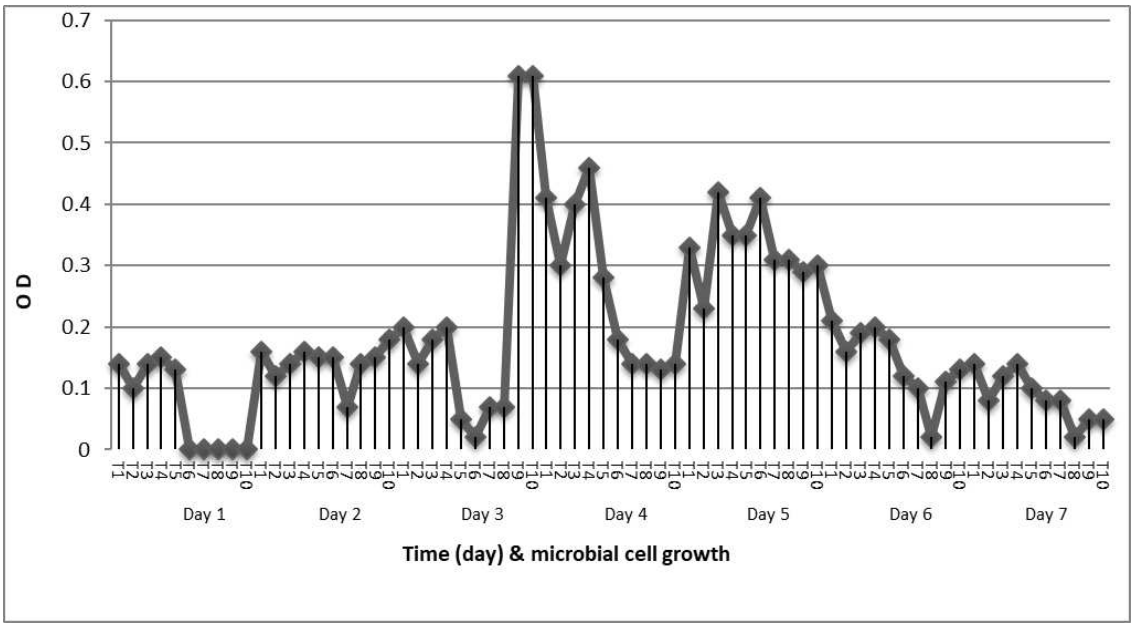

Figure 4. *Optical density (λ = 620 nm) of ten selected bacterial isolates (T1, T2, T3, T4, T5, T6, T7, T8, T10 and T18) as affected by growth periods*

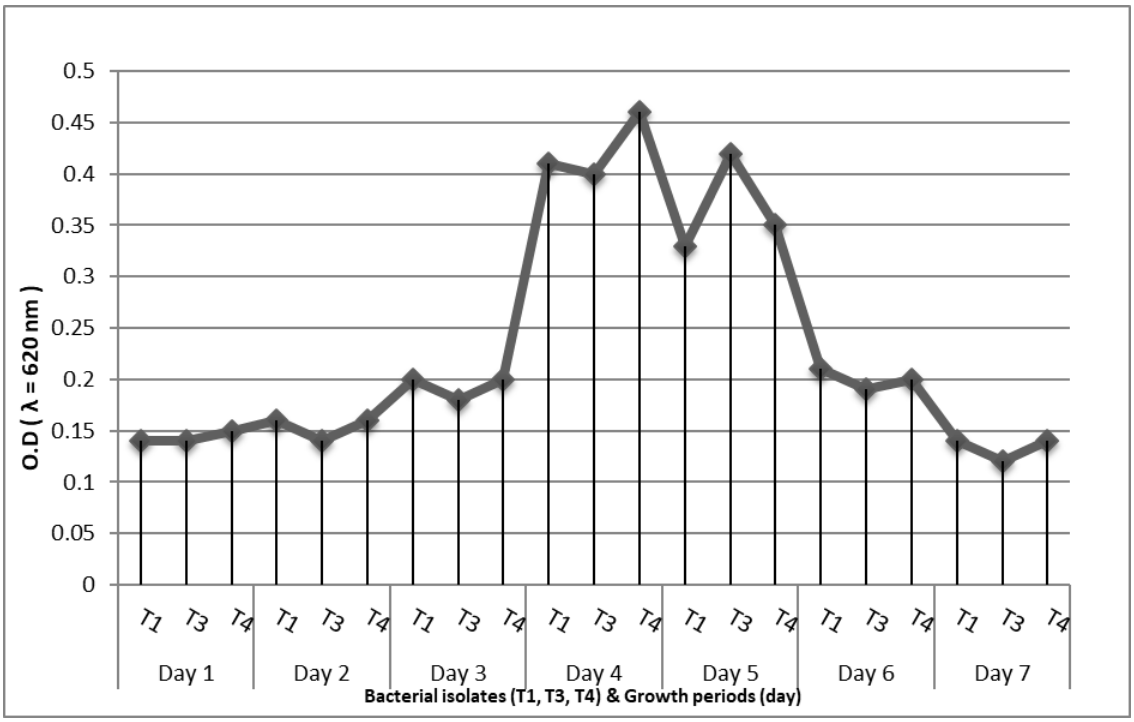

Figure 5. *Optical density (λ = 620 nm) of three selected bacterial isolates (T1, T3, and T4) as affected by growth periods*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13871406

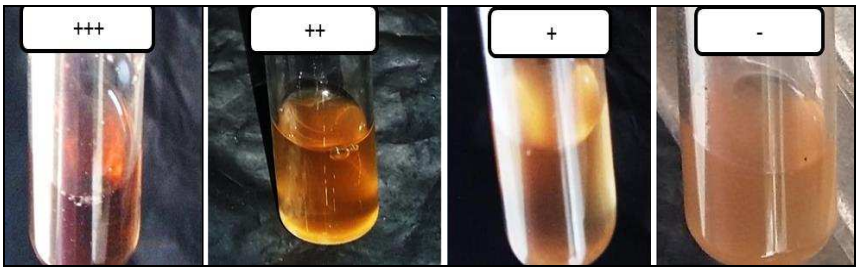

Figure 6. *Photos shows the IAA visual reaction degrees of a bacterial isolate for IAA production, [high (+++), moderate (++), low (+), no reaction (-)]*

Table 3. *Degree of color changes of bacterial isolates (T1, T2, T3, T4, T5, T6, T7, T8, T10 and T18) to producing IAA on NBM containing SIWW, and L-tryptophan (0.1%, v/w)*

Bacterial isolates code	IAA visual reaction degrees
T1	Moderate
T2	High
T3	Moderate
T4	Moderate
T5	Moderate
T6	Moderate
T7	Low
T8	Low
T10	Low
T18	Low

These results are harmony with that reported by Özdal et al. (2016) who reported that the production of IAA dependence on the Bacillus spp. isolates and fermentation time. Isolate (T2) gave the highest degree of color change that evidence on its high ability for the consumption of L-tryptophan and IAA production, while, the T1, T3, T4, T5 and T6 isolates gave the moderate degree of color change. The lowest degree for color change was noticed by T7, T8, T10 and T18 isolates. From these results three bacterial isolates coded T1, T3 and T4 were selected and subjected to biological and molecular identification.

Determination of antibiosis activities of the ten bacterial isolates

Data presented in *Table 4* and *Figure* 7 revealed that the all tested bacterial isolates gave antibiosis reaction against *E. coli* when growing on NAM. Similar results were obtained by Yilmaz et al. (2006), who mentioned that *B. cereus* has inhibitory affect both against Gram-positive and Gram-negative bacteria. Negative reaction was recorded with T2 and T6 isolates against *F. solani* and *S. relfsii*. The rest of bacterial isolates, T1, T3, T4, T5, T7, T8, T10 and T18 have positive reaction against the three tested pathogens (*F. solani*, *S. relfsii* and *E. coli*).

These results are in harmony with that of Kim et al. (2015), who showed that the Bacillus spp. had broad-spectrum antifungal activity against *F. solani* and *F. oxysporum*. Results of Ghai et al. (2007) also supported this study, as they recorded that the more strains of Bacillus spp. had antagonistic activities against some fungal

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13871406

pathogens, e.g. *Clerotium rolfsii*, *Fusarium oxysporum* and *Rhizoctonia solani*. Based on these results it has been observed that, three isolates coded T1, T3 and T4 were selected and subjected to biological and molecular identification.

Table 4. *Antibiosis activities of bacterial isolates (T1, T2, T3, T4, T5, T6, T7, T8, T10 and T18) against F. solani, S. relfsii and E. coli*

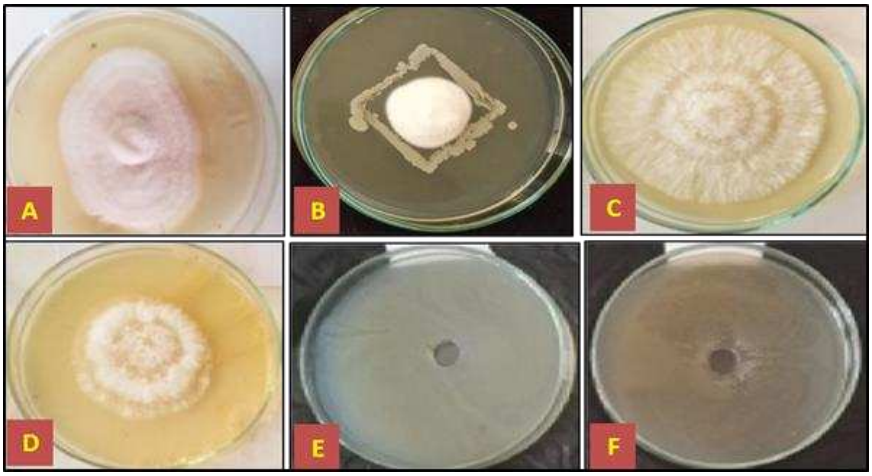

Figure 7. *Antibiosis activities of abacterial isolate against F. solani (A), S. rolfsii (C) and E. coli (E) compared to the growth alone to every one (B, D and F), respectively*

Biological identification of the selected bacterial isolates

The bacterial isolates which were selected based on their growth curve; IAA reaction (color change) and antibiosis effect were identified according to (Juni 1986) mentioned in Bergey's Manual of Systematic Bacteriology (1986, 2012) and Barrow and Fellthan (1993).

Morphological, biochemical characterization and utilization of carbohydrates as carbon sources via the bacterial isolates which coded with T1, T3 and T4 are presented in *Table 5*. On NAM, all 48 h-old cultures of tested isolates were positive to Gram stain, motile, rod shaped with white colony for T3, T4 isolates and yellowish colony for T1

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13871406

isolate. Furthermore, all bacterial isolates were positive effect on both catalase and Indole tests. The coded isolates T1 and T3 were negative with oxidase, Methyl-red and citrate tests. All isolates utilized sucrose and lactose as carbon sources, while, T1 failed to utilize glucose, maltose and xylose. From the obtained data and classifying bacterial isolates in accordance to Claus and Berkeley (1986) that identified the coded (T1, T3 and T4) as *Bacillus spp.*, *Bacillus cereus* and *Bacillus altitudinis*, respectively.

Molecular identification of the selected bacterial isolates

Biological identification of the three bacterial isolates alone was not completely enough, and these tests consume a lot of time and chemicals. Due to the advanced technology such as 16SrRNA gene, primers had been developed by investigators to target specifically the 16S rRNA sequence of the bacteria. In this search, the three bacterial isolates obtained from EIWW samples were also identified using primers targeting their 16S rRNA sequence (Jeffrey, 2008). The nucleotide sequences of 16S rRNA gene were partially determined using the DNA template of the three bacterial isolates (T1, T3, and T4). Results showed that partial sequences of 985, 997 and 983 nts were obtained for the three isolates, respectively. These sequences were compared with four universal bacterial isolates as mentioned in *Table 5*. These bacteria were classified as Bacillus sp. SMMAA-1, Bacillus cereus SMMAA-3 and Bacillus altitudinis SMMAA-4 and documented in GenBank under the accession numbers of LC472522, LC472523 and LC472524, respectively. Results in *Table 6* showed that the percent

identities between the three bacterial strains and those similar strains recorded in GenBank ranged from 84.85% to 100.00%. Phylogenetic trees of the three bacterial strains compared to that similar strain in GenBank confirmed the biological identification of these strains as illustrated in *Figure 8*.

Role of selected bacterial isolates (Bacillus spp., B. cereus and B. altitudinis) on the biosorption of six heavy metals (Zn^{+2}, Fe^{+2}, Co^{+2}, Cd^{+2}, Cu^{+2} and Pb^{+2}) from industrial wastewater (IWW)

Biosorption efficiency of heavy metals from SIWW by Bacillus spp., B. cereus and B. altitudinis is depicted in *Table 7* and *Figure 9*. Data showed that the initial values of six heavy metals (ppm) were founded by diversity in IWW and wide ranged from 1.4 ppm to 6 ppm. The maximum conc. was found with Zn^{+2} (6 ppm) while, the minimum conc. was found with Co^{+2} (1.4 ppm). The values of final metal conc. of heavy metals in SIWW were reduced as result of biosorption occurred by bacteria and ranged from 0.109 ppm to 0.409 ppm compared to the initial metal conc. (2.450 ppm). The ability of bacterial isolates tested (Bacillus spp., B. cereus and B. altitudinis) for biosorption of the six heavy metals were differed among them.

Table 7. *Initial and residual values of heavy metals (ppm) in IWW as affected by SIWW inoculated with the selected bacteria (Bacillus spp., B. cereus and B. altitudinis)*

Heavy metals	Initial metal conc.(ppm)	Residual values of heavy metals (ppm)			Mean
		SIWW + Bacillus spp.	SIWW + B. cereus	SIWW + B. altitudinis	
Zn	6.000	0.551	0.016	0.490	0.352
Fe	2.100	1.782	0.552	1.782	1.372
Co	1.400	0.002	0.004	0.008	0.004
Cd	1.800	0.017	0.016	0.019	0.017
Cu	1.500	0.017	0.004	0.014	0.011
Pb	1.900	0.087	0.063	0.097	0.082
Mean	2.450	0.409	0.109	0.401	

IWW = Industrial Wastewater, SIWW = Sterile Industrial Wastewater

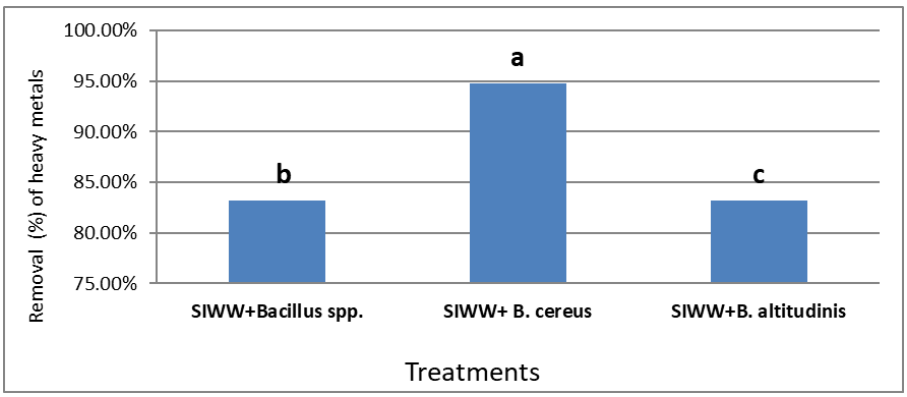

Figure 9. *Average of the mean values (A) of the heavy metals removal % of IWW as affected by SIWW inoculated with the selected bacteria (Bacillus spp, B. cereus and B. altitudinis). Values having the same alphabetical letter within each column are not significantly different at the 0.05 level according to (Duncan multiple range test)*

Data exhibited that B. cereus was more effected than *B. altitudinis* and *Bacillus spp.* for biosorption final metal conc. (0.109, 0.401 and 0.409 ppm) respectively. Also, the data indicated that (Co^{+2}) ion was more biosorption by the three bacterial isolates and gave the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13871406

little values compared to (Fe^{+2}) which gave the highest values in IWW. The ions (Co^{+2} and Cu^{+2}) recorded the highest biosorption by the three bacterial isolates followed by the (Zn^{+2}, $Pb^{+2}$and Cd^{+2}) but the lowest biosorption recorded with Fe^{+2} metal.

From the obtained result data revealed that the all bacterial isolates play an important role in detoxification of heavy metals founded in the IWW of Abu-kerqas sugar factory-El-Minia, Egypt. The all studied bacteria were more effective for the biosorption of the heavy metal contents in SIWW. Co^{+2} ion was more absorbed by *Bacillus spp.* (0.002 ppm) followed by *B. cereus* (0.004 ppm) and *B. altitudinis* (0.008 ppm).

The results presented in *Table 8* and *Figure 9* show the biosorption ability of *B. cereus* is significantly effective for removal efficiency percentage of six heavy metals (Zn^{+2}, Fe^{+2}, Co^{+2}, Cd^{+2}, Cu^{+2} and Pb^{+2}) (94.77%) from IWW. However, the removal efficiency % of it is heavy metals using *Bacillus spp.* and *B. altitudinis* recorded 83.19%and 83.21% with insignificant difference between them. This indicted that *B. cereus* has a higher capability of biosorption potentiality of heavy metals compared to the others. Similar results are recorded by Huang et al. (2013).

Regarding to the effects of the different heavy metals tested for the removal efficiency %, the results in *Table 8* and *Figure 10* show significant effects. Available data revealed that higher removal efficiencies of 99.66% for Co^{+2}, 99.22% for Cu^{+2} and 99.03% for Cd^{+2} and lower removal efficiencies 34.66% for Fe^{+2} were recorded as Mullen et al. (1989).

Table 8. *Removal efficiency % of heavy metals from IWWas affected by SIWW inoculated with the selected bacteria (Bacillus spp., B. cereus and B. altitudinis)*

Treatments	Removal efficiency % of heavy metals						
	Zn^{+2}	Fe^{+2}	Co^{+2}	Cd^{+2}	Cu^{+2}	Pb^{+2}	Mean of A
Bacillus spp. + SIWW	90.83 d	15.14 f	99.86 a	99.06 a	98.87 a	95.42 bc	83.19 b
B. cereus + SIWW	99.73 a	73.71 e	99.71 a	99.11 a	99.73 a	96.68 b	94.77 a
B. altitudinis + SIWW	91.83 c	15.14 f	99.42 a	98.94 a	99.06 a	94.89 bc	83.21 b
Mean of B	94.13 b	34.66 c	99.66 a	99.03 a	99.22 a	95.66 b	

Mean values of three replicates followed by the same letters in each column are not significantly different (P > 0.05) (Duncan multiple range test). LSD at (0.05%) for A = 0.0715, B = 1.012, AB = 1.753

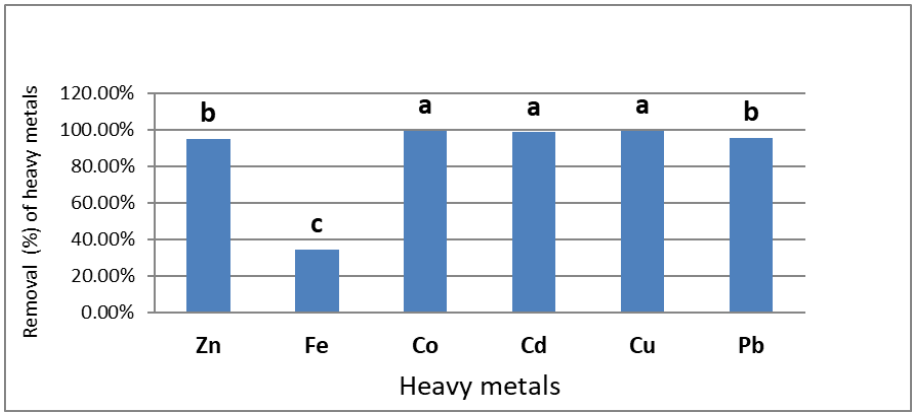

Figure 10. *Average of the mean values (B) of the different six heavy metals removal % from IWW). Values having the same alphabetical letter within each column are not significantly different at the 0.05 level according to (Duncan multiple range test)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_13871406

Also, similar data in *Table 8* and *Figure 11* revealed that a significantly higher removal efficiencies for Co^{+2}, Cd^{+2} and Cu^{+2} when combined with bacterial isolates (*Bacillus spp.*, *B. cereus* and *B. altitudinis*) without significant differences among them. The highest residual values and the lowest removal biosorption by bacterial isolates were recorded with Fe^{+2} similar results are recorded by Tuzen et al. (2007).

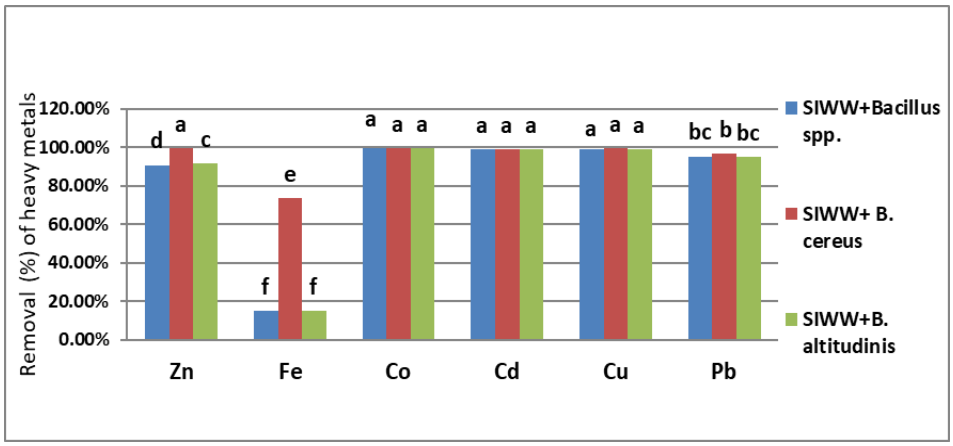

Figure 11. *The interaction (AB) effect between the treatments (SIWW + Bacillus spp., SIWW + B. cereus, SIWW + B. altitudinis) and six heavy metals removal % of IWW. Values having the same alphabetical letter within each column are not significantly different at the 0.05 level according to (Duncan multiple range test). IWW = Industrial Wastewater, SIWW = Sterile Industrial Wastewater*

Conclusion

The isolation and identification of tolerant bacteria against six heavy metals (Zn^{+2}, Fe^{+2}, Co^{+2}, Cd^{+2}, Cu^{+2} and Pb^{+2}) give the new technology of bioremediation method. Among 30 isolates of Bacillus spp., 3 isolates exhibited more resistance effect against 6 heavy metals. These isolates were identified by morphological, biochemical characterization, molecular identification by using 16S rRNA gene and documented in GenBank as Bacillus sp. SMMAA-1 (LC472522), Bacillus cereus SMMAA-3 (LC472523), and Bacillus altitudinis SMMAA-4 (LC472524). These isolates are promising for further studies and can be used in bioremediation. The findings showed that bacteria present resistance of six heavy metals. B. cereus is more effective for removal efficiency percentage of six heavy metals (Zn^{+2}, Fe^{+2}, Co^{+2}, Cd^{+2}, Cu^{+2} and Pb^{+2}) (94.77%) from IWW than Bacillus spp. (83.19%) and B. altitudinis (83.21%). The highest removal efficiencies by Bacterial isolates were found with Co^{+2}, Cd^{+2} and Cu^{+2} and the lowest removal biosorption were recorded with Fe^{+2}. Data recommended to using of Bacillus cereus in bioremediation of heavy metals from industrial wastewater effluent especially with Co^{+2}, Cd^{+2} and Cu^{+2} metals.

Acknowledgements. A special thank is paid to Prof. Dr. Nasser Sayed Youssef professor of Vegetables, Horticulture Research Institute, Agriculture Research Centre for his valuable continuous helpful, discussing the results, fruitful discussions, encouragement and necessary guidance during the long tenure of my study.

(Received 14th Sep 2019; accepted 8th Jan 2020)

Abstract. A multidrug resistant, an enteric pathogen, *Salmonella enterica* is the most frequent cause of food poisoning. They are gram negative, aerobic or facultative anaerobic bacteria belonging to the family *Enterobacteriacae.* Migratory birds serve as key factor, may disseminate *Salmonella* to the susceptible people through shared environment, fecal shedding and by mean of direct contact. The aim of present study was to investigate the occurrence of beta-lactamase genes (CTX-M and TEM) within antibiotic resistant strains *of Salmonella enterica* isolated from migratory birds. Present study incorporated isolation of 60 samples of *Salmonella enterica* from saliva, intestinal fluid and blood of different migratory birds. They are catalase positive, oxidase negative and H_2S gas producer. The antibiotic resistance of all isolated strains (29) was tested against 10 antibiotics by Kirby-Bauer disc diffusion method. The antibiotics that were used include ciprofloxacin (5 µg), ceftriaxone (30 µg), meropenam (10 µg), aztreonam (30 µg), penicillin (10 µg), erythromycin (15 µg), streptomycin (10 µg), gentamycin (10 µg), vancomycin (10 µg) and imipenem (10 µg). These strains indicated more resistance towards penicillin (93%), streptomycin (100%), erythromycin (93%), aztreonam (62%) and vancomycin (90%) and low resistance towards ciprofloxacin (21%), ceftriaxone (54%) and imepenam (45%). For the detection of CTX-M and TEM gene in ciprofloxacin and ceftriaxone resistant strains, DNA was obtained through chemical method. These strains were further checked for the presence of CTX-M and TEM gene by polymerase chain reaction (PCR). PCR results demonstrated that all the strains contain TEM gene but CTX-M gene was not identified in any of these strains. PCR amplified product was sequenced, followed by BLAST, which confirmed the presence of TEM gene giving resistance to beta-lactam antibiotics.
Keywords: *Salmonella enterica, TEM gene, antimicrobial resistance, CTX-M gene, polymerase chain reaction (PCR), BLAST*

Introduction

The bacterial genus *Salmonella* which is an enteric pathogen causes a wide spectrum of disease (Acheson and Hohmann, 2001). *Salmonella enterica* is mostly responsible for food poisoning (Herikstad et al., 2002). *Salmonella* is an exceptionally assorted family,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14071418

which contain two species that are *S. bongori* and *S. enterica* (Tindall et al., 2005). *S. bongori* infects mostly ectotherms and unusually humans while *S. enterica* incorporates around 2500 serovars (Brenner et al., 2000). It is subdivided into 6 subspecies *enterica, arizonae, diarizonae, salamae, indica and houtenae* dependent on biochemistry and genomics (Malorny et al., 2011). The normal characteristic environment for subspecies *enterica* is endotherms while for the subspecies *salamae, arizonae, diari zonae, houtenae*, *indica* and S. *bongori* is ectotherms and environment. Migratory birds may serve as vehicle for the transmission of various extrinsic microorganisms (Maeda et al., 2001). *Salmonella* have been isolated from wildlife including exotic birds (Refsum et al., 2002). Gourmelon et al. (2010) have also observed that aquatic system gets polluted by fecal material of these exotic species can lead to human infection. During annual migration, migratory birds move from one place to another in search of suitable weather and food and play an important role in causing infections in humans and animals (Foti et al., 2011). They can easily be transmitted through contaminated food and water, improper hygienic conditions and improper disposal of sewage. Antimicrobial resistance in *Salmonella* takes place due to horizontal and vertical transference of antimicrobial gene, inappropriate self-medication which leads to resistance in microorganisms against chemical, therapeutic agents (White et al., 2002). The excessive use of antimicrobials has brought about a development of antibiotic resistance in humans, animals and environment (Berendonk et al., 2015; Radhouani et al., 2014). Majority of ceftriaxone and ciprofloxacin resistance was because of the action of β-lactamase gene. The horizontal gene transfer plays an important part in expanding ceftriaxone and ciprofloxacin resistance.

The main objective of present study was to isolate different strains of *Salmonella* from oral, intestinal and blood samples of migratory birds and to investigate the occurrence of beta-lactamase genes (CTX-M and TEM) which give antibiotic resistance against beta-lactam antibiotics (ciprofloxacin and ceftriaxone).

Material and methods

Study design

This study involved biochemical identification of *Salmonella enterica* from blood, nasal and intestinal fluid of migratory birds and molecular characterization and PCR detection of β-lactamase (CTX-M and TEM) genes.

Sample collection

Oral, intestinal and blood samples were collected from different seasonal avian species at watery sites of Hazara division (Tarbela Lake, Chakai, Siran Valley, and Khanpur). During period from September 2018 till February 2019, migratory birds were captured for study by licensed hunters from different watery sites of Hazara division. A sterile culturette was used to collect samples. A total of 60 samples were collected by rubbing swabs to oral, intestine and blood of different migratory birds. 47 blood samples were obtained through sterile syringes while 6 swabs from saliva and 7 swabs from intestinal fluid were obtained. After sampling, the culturettes were placed in their plastic sheath having nutrient broth and kept in refrigerator at 4 ℃. Then the samples were enriched by adding peptone water and incubated at 37 ℃ for 24 h. After incubation, the pre-enriched samples were examined for the presence of *Salmonella.*

DOI: http://dx.doi.org/10.15666/aeer/1801_14071418

Isolation and identification

The samples were inoculated on sterile petri plates containing *Salmonella Shigella* agar and incubated at 37 ℃ for 24 h. The isolated colonies were picked up and again streaked on *SS* agar medium to obtain a pure culture. Purified bacterial colonies were exposed to cultural, colony morphology and biochemical identification by using catalase, oxidase and citrate test.

Antibiotic sensitivity

Antibiotic Sensitivity of 29 positive isolates of *Salmonella enterica* to 10 antibiotics was checked on Muller Hinton agar by Kirby-Bauer disc diffusion method. A fresh colony of *Salmonella* was picked up from the culture plate and spread over the entire petri plate containing Muller Hinton agar by using sterile cotton swab. Ten antibiotics with different concentrations were used which included ciprofloxacin, ceftriaxone, penicillin, erythromycin, streptomycin, vancomycin, gentamicin, imipenem, meropenam and aztreonam. The antimicrobial disks were placed on the surface of agar with the help of forceps and plates were incubated overnight at a temperature of 37 ℃. After incubation, the zone diameters were measured to nearest millimeter and classified as sensitive (S), intermediate (I) and resistant (R) according to European Committee on Antimicrobial Susceptibility Testing (EUCAST) (*Table 1*).

Table 1. *Concentration (µg) and breakpoints (mm) of antibiotics*

Antibiotics	Disc code	Potency (µg)	Zone diameter breakpoint (mm)	
			S ≥	R <
Ciprofloxacin	CIP	5	22	19
Ceftriaxone	CRO	30	23	20
Penicillin	P	10	14	15
Erythromycin	E	15	21	15
Streptomycin	S	10	15	11
Vancomycin	VA	10	17	14
Gentamicin	CN	10	17	14
Imipenem	IPM	10	22	16
Meropenam	MEM	10	22	16
Aztreonam	ATM	30	24	21

DNA extraction

DNA was extracted by chemical method (Ausubel et al., 1994). The 1 ml growth culture of bacterial suspension was incubated overnight and centrifuged at 8000 g for 2 min. Supernatant was removed. 400 µl STE buffer was added twice and cells were centrifuged at 8000 g for 2 min. Supernatant was discarded again and 200 µl TE buffer was added to the pellets. Then, 100 µl Tris-saturated phenol was added and tubes were vortexed for 1 min. Samples were centrifuged at 13,000 g for 5 min at 4 °C so that the aqueous phase is separated from organic phase. Then 40 µl TE buffer was added to 160 µl upper aqueous phase and mixed with 100 µl chloroform and centrifuged at 13,000 g for 5 min at 4 °C. 150 µl upper aqueous phase was taken into clean eppendorf tube and that contained the required purified DNA.

DOI: http://dx.doi.org/10.15666/aeer/1801_14071418

Polymerase chain reaction (PCR)

PCR was performed for DNA amplification on thermocycler (Multigene Optimax, USA). Two sets of primer pairs specific for TEM and CTX-M gene were used (*Table 2*). The reactions were performed in final volume of 25 µL that involved 3 µL of DNA template, 1 µL of forward primer, 1 µL of reverse primer, 10 µL of 5X FIREPol® master mix (FIREPol® DNA Polymerase, 5X reaction buffer B (0.4 M Tris-HCl, 0.1 M $(NH_4)_2SO_4$, 0.1% w/v Tween 20), 7.5 mM $MgCl_2$, 1 mM dNTPs of each dATP, dGTP, dCTP, dTTP) (Solis BioDyne) and 10 µL of distilled water. Amplification was carried out using optimum conditions as follows: 1 cycle of 5 min for initial denaturation at 94 °C, 35 cycles of 45 s for final denaturation at 94 °C, 45 s for annealing at 54 °C, 1 min for initial extension at 72 °C and 1 cycle of 10 min for final extension at 72 °C in case of CTX-M gene. TEM gene was amplified using the same thermocycler with the exception of annealing at 52 °C for 45 s.

The amplification products were interpreted by gel electrophoresis. The samples were loaded in 1.2% gel stained with ethidium bromide (2 µg/mL) with the help of micro pipette and run at 90 V for 45 min. A 100-bp ladder (Solis BioDyne) was used as molecular weight marker. Gel was placed in Cleaver Scientific UV transilluminator (CSLUVTL312) to visualize the DNA bands under UV light for the presence of target gene.

Table 2. *Primers sequence of CTX-M and TEM gene*

Primers	Target gene	Length	Sequence (5′-3′)	References
TEM F_5 TEM R_5	TEM	20 20	5′ TTGGGTGCACGAGTGGGTTA 3′ 5′ TAATTGTTGCCGGGAAGCTA 3′	Gangoue-Pieboji et al., 2005
CTX-M F_5 CTX-M R_5	CTX-M	20 22	5′ ACCGCCGATAATTCGCAGAT 3′ 5′ GATATCGTTGGTGGTGCCATAA 3′	Kaftandzieva et al., 2011

Statistical analysis

The Vassar Stats.net was used for *Chi Square* test *(x^2)* to estimate significance level between sources of *S. enterica* isolates.

Genome sequencing and BLAST

Identification of resistant gene was confirmed by genome sequencing. The DNA of isolated strains was sequenced by Sanger sequencing method. The nucleotide sequence was analyzed and compared with sequences available on databases by using Basic Local Alignment Search Tool (BLAST).

Results

For the isolation of *Salmonella enterica, Salmonella Shigella* agar was used. Out of 60 samples 29 samples were positive for different serovars of *Salmonella enterica* and 31 samples were negative. Total isolation frequency of Salmonella enterica was found to be 29/60 (48%) (*Fig. 1*).

Out of these 29 samples, 22 (30%) samples were positive from blood, 3 (27%) from intestinal fluid and 4 (43%) from saliva (*Fig. 2*).

DOI: http://dx.doi.org/10.15666/aeer/1801_14071418

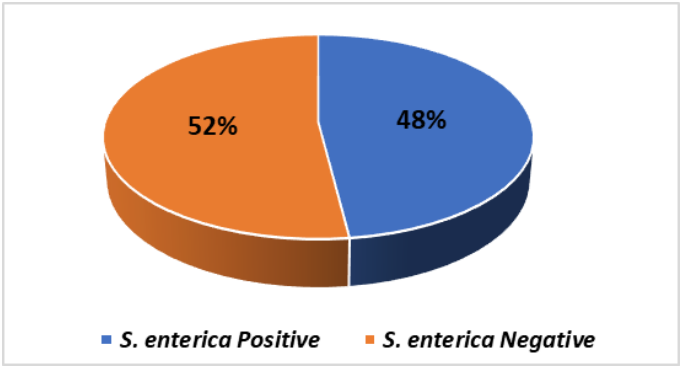

Figure 1. *Isolation frequency of Salmonella enterica from migratory birds*

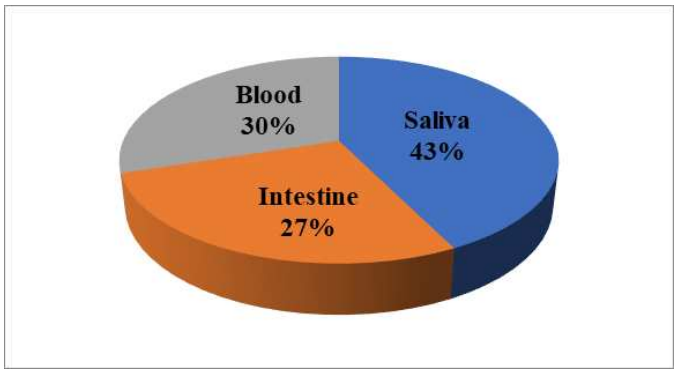

Figure 2. *Percentage comparison of migratory birds positive for S. enterica*

The chi square test (x) revealed a non-significant difference between sources of *S. enterica* for all antibiotics tested except meropenem where a significant difference was observed ($p < 0.3$) (*Table 3*). The pink or yellow with black centered, flat and irregular/smooth colonies were observed on *SS* agar. The isolated colonies were stained with Gram's stain and appeared as rod shaped and pink in color under microscope (100X) (*Fig. 3*).

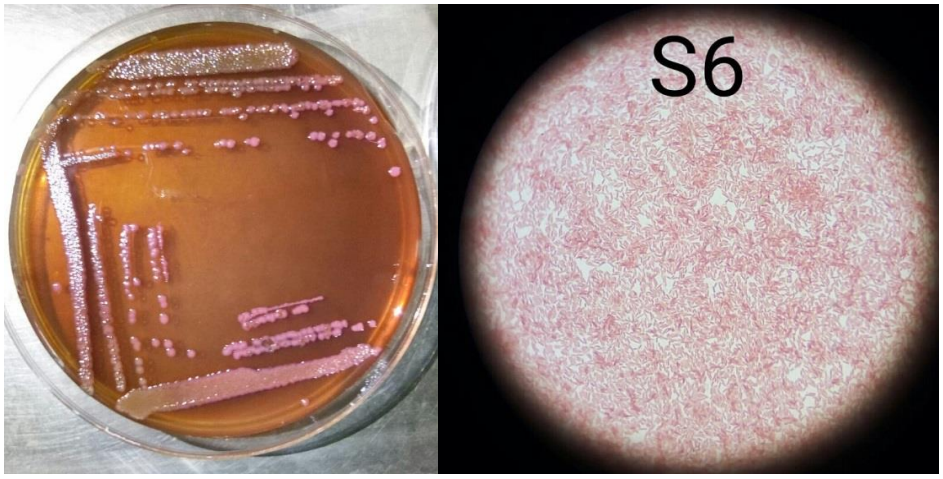

Figure 3. *Cultural and microscopic (100X) identification of S. enterica isolated from migratory birds*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14071418

All the positive isolates were catalase positive and oxidase negative (*Fig. 4*).

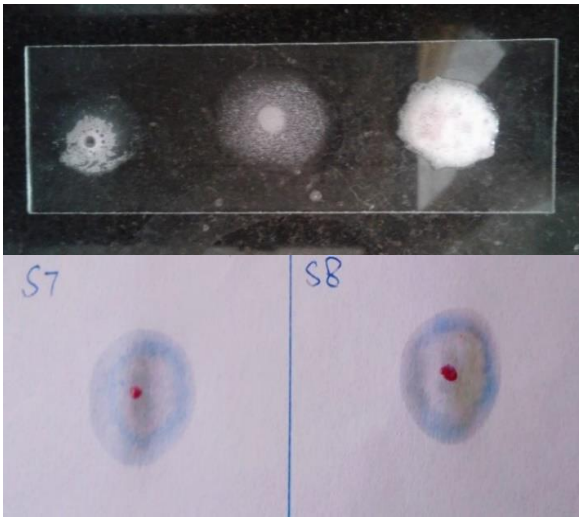

Figure 4. *Biochemical identification of Salmonella enterica isolated from migratory birds*

The *Salmonella enterica* serotypes were confirmed by citrate test. *Salmonella enterica* is citrate positive except *S. typhimurium* (*Fig. 5*).

Figure 5. *Citrate test for the detection of Salmonella enteric*

Antibiotic sensitivity of 29 isolates of *Salmonella enterica* obtained from saliva (n = 4), intestine (n = 3) and blood (n = 22) was checked against the ten antibiotics. In this study, *Salmonella enterica* showed resistance towards most antibiotics. The isolated strains showed more resistance against penicillin (93%), streptomycin (100%), erythromycin (93%), vancomycin (90%), aztreonam (59%) and meropenam (59%). They showed low resistance against ciprofloxacin (21%), ceftriaxone (52%), imipenem (45%) and gentamycin (55%). 25% (1/4) resistance was observed against ciprofloxacin and ceftriaxone in saliva samples, 33% (1/3) resistance against ciprofloxacin and 100% (3/3) resistance against ceftriaxone was noticed in intestinal fluid and 18% (4/22) resistance against ciprofloxacin and 50% (11/22) resistance against ceftriaxone were recognized in blood samples of migratory birds (*Figs. 6, 7* and *8*).

Statistical analysis was performed by chi-square test (Vassarstats.net) with P values for the comparison of difference between resistance rates of *S. enterica* to different antibiotics among the three sample sources (blood, intestine, saliva) (*Table 3*). The P values showed that there were no significant differences in antibiotic prescription patterns between blood, intestine and saliva sample except meropenam (0.03) (P value < 0.05 = significantly different).

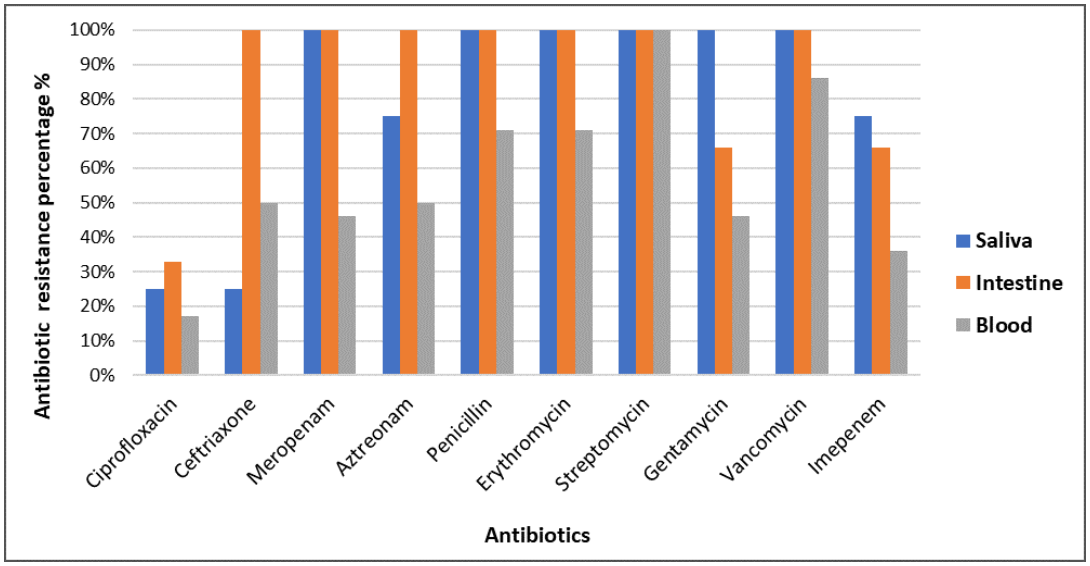

Figure 8. *Antibiotic resistance pattern of isolates obtained from migratory birds*

The extracted DNA of isolated strains was visualized by using gel electrophoresis (*Fig. 9*).

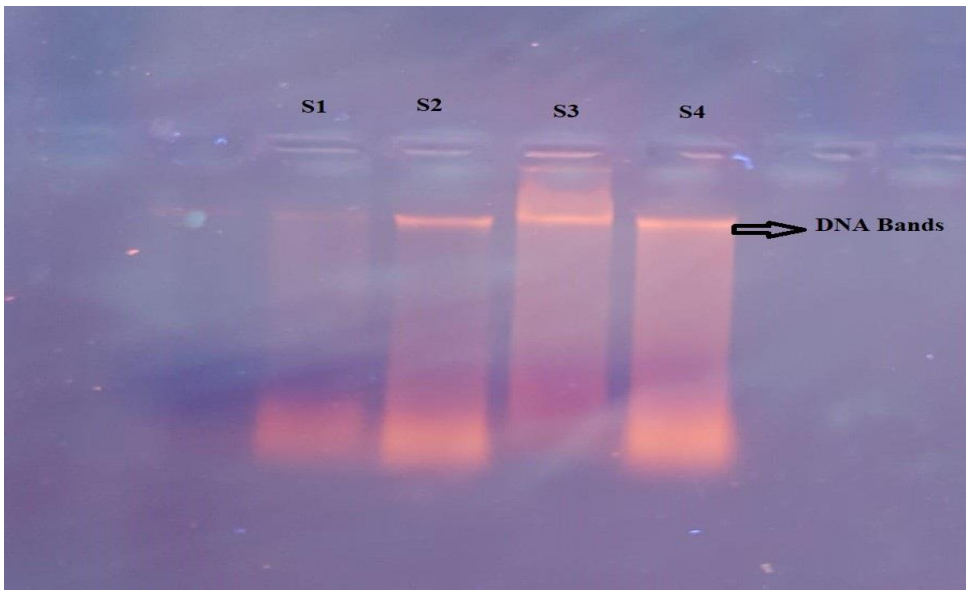

Figure 9. *Gel electrophoresis of extracted DNA of isolated strains*

Amplified PCR samples were analyzed by using gel electrophoresis. TEM gene was amplified in 100% strains of *S. enterica* tested for the presence of antibiotic resistant gene, yielding a strong band as dictated by correlation with size markers keep running on similar gel while no one isolates have CTX-M gene and its presence is 0% (*Fig. 10*).

Sample numbers S1, S2, S3, S4 and S5 showed a 508 bp fragment of TEM gene and L (Ladder) showed a 100 bp DNA size marker. Genome sequencing, followed by BLAST, confirmed the presence of TEM gene. The BLAST analysis showed highest similarity (88% identity) with *Klebsiella oxytoca*, which also harbors TEM gene (*Fig. 11*).

Discussion

The S. enterica was found higher in oral cavity (43%) followed by blood (30%) and intestinal fluid (27%). The different isolation frequency of *Salmonella* was due to reason that it was found in oral cavity by eating contaminated food and its presence in blood indicates bacteremia. Experimental studies have demonstrated that gastrointestinal carriages of *Salmonella* take place in wild birds after disease; hence it is conceivable that healthy birds could be persisting carriers. Samad (2011) declared that *Salmonella* was transmitted through birds which obtain this infection from their surrounding environment. Present data was identical to the findings of Samad that

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14071418

infected birds can play a main role in the transmission of diseases in humans and animals. In current study, among the ten antibiotics used a high rate of antibiotic resistance was observed against penicillin (93%), streptomycin (100%), erythromycin (93%) and vancomycin (90%). Thung et al. (2018) have also discovered comparable outcomes, who found higher prevalance of *Salmonella* in retail beef meat from different retail markets of Selangor, Malaysia. Antibiotic susceptibility was checked against 15 antibiotics. They also found that all the isolates showed resistance towards penicillin, erythromycin and vancomycin but sensitivity was observed for tetracycline, gentamicin and amoxicillin/clavulanic acid.

TEM gene was present in all positive strains (100%) tested for the presence of antibiotic resistant gene but CTX-M was absent in these strains and its presence is (0%). The presence of TEM gene was further confirmed by genome sequencing which showed 88% similarity with database sequence of *Klebsiella oxytoca* by using BLAST. This indicates that *S. enterica* might have acquired TEM gene from *K. oxytoca.* Threfall et al. (2002) reported *Salmonella* from India and different locations of Asia. They presumed that one of the primary factors of failure of treating *Salmonella* is because of resistance to ciprofloxacin. Majority of ceftriaxone and ciprofloxacin resistance was the result of activity of β-lactamase gene which includes CTX-M and TEM gene (Elumalai et al., 2014). Beta-lactamases producing *Enterobacteriaceae* have progressively developed because of widespread utilization of cephalosporin and represent a major challenge in disease control (Chong et al., 2018). The horizontal gene transfer through wild birds plays an important role in expanding ciprofloxacin and ceftriaxone resistance.

CTX-M gene was not amplified in any *S. enterica* isolate. This is due to the reason that the universal CTX-M primer used in current study was unable to recognize all positive strains even though showing positive results of resistance to beta lactam drugs. The primers for one group of CTX-M gene were unable to recognize the other groups of CTX-M gene, which results in no amplification of DNA. Pitout et al. (2004) also demonstrated a high level of specificity for the group specific primers.

Wild migratory birds have been recommended as reservoir of beta-lactamase producing pathogenic bacteria in various studies around the world (Bonnedahl et al., 2015; Atterby et al., 2016). Mohsin et al. (2017) indicated beta-lactamase producing *E. coli* in migratory birds along the Indus migration in Pakistan. He revealed that all ESBL-producing *E. coli* have CTX-M gene as the most prevailing genotype. Study carried out in Korea by Kang et al. (2015) declared that *Salmonella enterica* subsp. were the infectious agent mostly found in wild birds and brings about mortality in certain species of birds.

Conclusion

The increase in antimicrobial resistance has turned into a serious issue around the world. It has also been found that migratory birds are playing a main role in the transmission of multidrug resistant pathogens from one place to another. It presents potential risk around the world since these species can easily be utilized as expected and unexpected agents of serious foodborne disease. To avoid the occurrence of antibiotic resistance and MDR *Salmonella,* it is basic to keep up the continuous checking of antimicrobial resistance and pursue an objective remedy of antimicrobials dependent on local antimicrobial pattern.

(Received 19th Jul 2019; accepted 15th Nov 2019)

Abstract. The study was conducted on ACLSV (Apple Chlorotic Leafspot Virus) isolates found in samples collected from temperate zone fruit orchards in Adana and Mersin provinces and districts in the Eastern Mediterranean region of Turkey. Reported as a natural host, Styrax officinalis bush was included in the study as a different host isolate (Kayseri). Leaf and cortical samples have been tested with commercial ELISA kits for the presence of common viruses. In order to verify DAS-ELISA results, the total RNAs were used in RT-PCR test and only positive responses were obtained from ACLSV-specific antiserum and primers. ACLSV isolates obtained from different hosts in the Eastern Mediterranean region were subjected to molecular variation analyses. Possible recombination sites of ACLSV were identified in the partial sequences of coat protein genes via comparison of ACLSV sequences from the GenBank database. As a result, for the first time recombinat or variant ACLSV isolates were reported in the region. Coat Protein Nucleotide sequences based on phylogenetic trees showed that these isolates were grouped and conserved signatures of type B6 clusters. This paper confirmed that *Styrax officinalis* as a natural ACLSV reservoir.
Keywords: *ACLSV, Rosacea and wild hosts, genetic variability, CP, East Mediterranean region of Turkey,*

Introduction

ACLSV, found in the morphological subgroup A in the trichovirus group of family Betaflexiviridae, is a member of the stone and pome fruit infecting virus species leading to significant losses (Dunez, 1988; Martelli et al., 1994). ACLSV is known to have a convoluted filamentous particle of 600-740 × 12 nm, and the RNA of the virus is known to be single-helical and one-part (Lister, 1970; German et al., 1990). Many strains of ACLSV are reported to have changed due to a high proportion of virus strains in their emerging symptoms; many of the strains are able to infect all hosts, but some Apple strains are difficult to transmit to stone fruits (Chairez and Lister, 1973; Smith et al., 1998; Brunt et al., 1996). ACLSV's hosts are found all over the world where they are grown and the virus is often carried without symptoms in pome fruit trees, while stone-core fruit trees suffer from very serious diseases (Nemeth, 1986; Poul and Dunez, 1988; Smith et al., 1998; Brunt et al., 1996). ACLSV, in cherry and sour cherry, are also found as latent in many varieties (Dosba et al., 1986; Desvignes and Boye, 1989). Martelli et al. (1994) thought that ACLSV was one of the most economically dangerous viruses and ACLSV is transmitted by mechanically and grafting. Flegg and Clark (1979) noted that ELISA (Enzyme Linked Immuno Sorbent Assay) is a very convenient method for diagnosing viruses in broad indexing programs and epidemiological studies, and that the classical DAS (Double Antibody Sandwich)-ELISA method can identify ACLSV from time to time, and they have developed a different procedure. Barba and Clark (1986)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_141157

stated that the virus dispersed irregularly in trees, in a way that the leaves at the bottom of the tree contained more viruses, and that bark tissues were the most suitable material for ELISA, especially towards the end of the vegetation period. However, because of the low concentration problem of the virus is known to infect plants even with ELISA negative results.

Candresse et al. (1995) reported variability in nucleotide sequences between different isolates despite being of the same plant origin. In addition, Niu et al. (2012) underlined that ACLSV genomes are relatively variable. They analyzed ten complete genome sequences from different hosts and reported a variation percentage between 67.2 and 95.1%. Moreover, Kuzmitskaya et al. (2016) when they compared ACLSV isolates in Belarus, Apple interpreted divergence levels of chlorotic leaf spot virus that varied in different genomic regions.

The presence of ACLSV in stone fruit trees grown in Turkey was first identified in Yalova by Yürektürk (1984) with biological indexing using GF305 peach rootstocks. The agent has been reported by different researchers in stone and pome fruits of different species, varieties and geographical origin (Dunez, 1986; Çağlayan and Çalı, 1994; Elibüyük, 1998; Fidan and Özdemir, 1998; Sipahioğlu et al., 1999; Ulubaş and Ertunç, 2004; Ulubas Serce and Rosner, 2006; Koç and Bakoglu, 2007; Koç et al., 2008; Öztürk, 2012; Değirmenci and Akbaş, 2013). But the background about the genetic variability of Apple Chlorotic Leaf Spot Virus in the East Mediterranean region and Turkey, still has influence. Therefore, we have investigated molecular variability of ACLSV isolates in Pome and Stone fruit orchard isolates from the East Mediterranean Region of Turkey (EMT) to forecast genetic relationships by analysing the nucleotide sequences of ACLSV genome via BootScan and Sisscan pro.

Materials and methods

Sources of ACLSV isolates

Temperate zone fruit orchards in the East Mediterranean region of Turkey (EMT) is generally maintained between low and high altitude (50 to 1360 m) in two different condition levels. Five ACLSV isolates from samples of different plant species have been collected from commercial gardens in the area to establish genbank accession numbers.

The isolates compared in the study were selected according to host type and geographical differences and distances. In addition, these isolates originated from the samples that have been collected and tested by the same investigator team during the surveys conducted in the region in the last fifteen years. The studied isolates represent 379 samples collected from the surveys followed in the region between 2005 and 2019 (*Fig. 1*).

Therefore, five isolates were stepped forward as representative for the virus comparison and the region. A nectarine isolate of ACLSV was collected from Yenice/Adana (2019) and an apple isolate from Fındıklı/Adana (2011), a pear isolate from Kamışlı/Adana (2006), a sweet cherry isolate from Çamardı/Nigde (2013) and an *Strax officinalis* isolate supplied from Kayseri (by Dr. H. Fidan; 2018), Fresh shoots of systemically infected isolates were used as samples within nucleic acid extraction and RT-PCR assays. Collected plantlets were stored at 4 °C before when DAS-ELISA tests and nucleic acid extractions were run. All positive samples were eradicated according to national interests, internal quarantine rules and sanctions. Studies were only carried out on isolated nucleic acids.

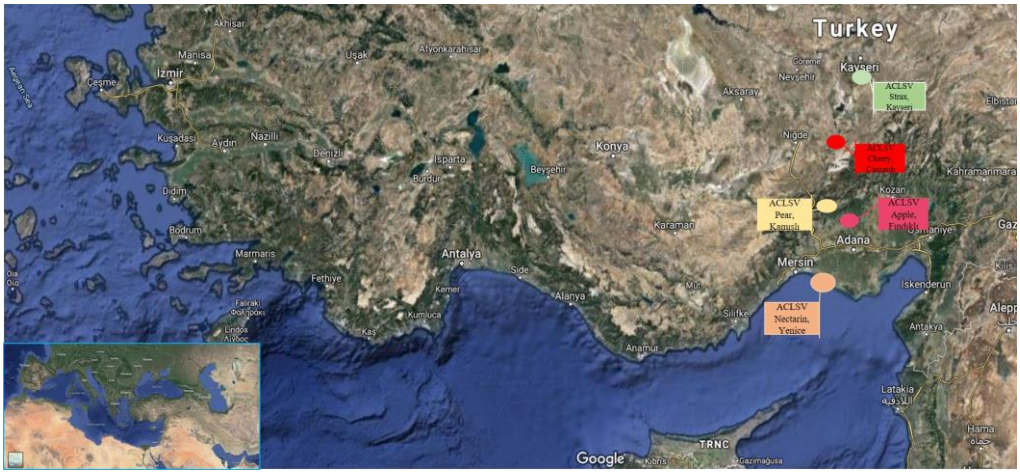

Figure 1. *Isolate sources and locations of ACLSV in the East Mediterranean region of Turkey. (https://www.google.com/maps/@37.5034496,33.2747851,395256m/data=!3m1!1e3)*

Serological tests

The plantlets were labelled and placed in isolated transparent bags, which were put in ice pail and transported to the virology laboratory and maintained at 4 °C. All samples were tested within a day.

Enzyme linked immunosorbent assay (ELISA)

To distinguish their infection in the specimens, the leaves were tested through ELISA using polyclonal antiserum against various virus species that could possibly be found in temperate zone plants given in *Table 1*. Antiserums provided by Agdia (USA) and Bioreba AG, (Switzerland) were diluted in accordance with suppliers' instructions and tested according to Clark and Adams (1977). PNRSV, PDV, PPV and other possible mixed infections common in Pome and Prunus were tested by ELISA with virus-specific antibodies.

Results were made by photometric measurement of absorption values at 405 nm wavelength and yellow color formation in ELISA reader. At photometric absorbance values read at a wavelength of 405 nm, samples that yielded at least twice the healthy control value and a higher reading value were considered positive or contaminated.

Nucleic acid based assays, total RNA extraction and RT-PCR

Samples with serologically positive results with ACLSV specific antibodies (Bioreba) were concentrated in molecular studies. Moreover, Nucleic acid isolations, RT-PCR and sequence analyses were performed to detect possible recombinations or variations of ACLSV isolates from the East Mediterranean in Turkey (EMT). In Molecular Studies, a pair of primers specific to the conserved regions containing some or all of the CP genes belonging to ACLSV, and identified as a result of DAS-ELISA and RT-PCR, were used.

Total nucleic acid extraction (NAE) and reverse transcription polymerase chain reaction (RT-PCR)

Extracted Nucleic Acid (NA) from infected plants were processed in Dellaporta et al. (1983). RT-PCR Assay; The cDNAs were generated by sense primer

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_141157

5'TTCATGGAAAGACAGGGGCAA 3' and antisense primer 5'AAGTCTACAGGCTATTTATTATAAGTCTAA3' which were described before by Menzel et al. (2002), to obtain 677 bp fragment related to the partial CP for screening of ACLSV isolates. cDNAs were obtained from ACLSV NAs with Thermo Science Verso 1 Step RT-PCR Kit package in accordance with manufacturer's manual. The amplification process and conditions were described at Menzel et al. (2002). Therefore, ACLSV thermal cycling parameters were, reverse transcription at 42 °C for 30 min; one cycle for activation of *Taq* polymerase at 95 °C for 15 min chained by 34 cycles of denaturation at 94 °C for 30 s, annealing at 62 °C for 30 s, and extension at 72 °C for 1 min. The final extension step was carried out at 72 °C for 7 min.

The amplified PCR products were run in 1.5% agarose gel, stained with ethidium bromide and visualized under UV illumination.

RT-PCR products analysis

10 ul of PCR item was used with gel loading buffer and analyzed on a 1.5% agarose gel containing 0.5 mg/ml of ethidium bromide (Sambrook et al., 1989). 100 bp DNA ladder (thermo) was used on each gel to analyze PCR items.

Phylogenetic analysis

The ACLSV RT-PCR products obtained according to Menzel et al. (2002) primers, were sequenced by a commercial sequencing company and dnasp5 program was conducted. Phylogeny and evolutionary analyses were made by MEGA 7 (Molecular Evolutionary Genetics Analysis) software and neighbour joining process, according to convention analysis. Occurred sequences were compared with different isolates of ACLSV originated by host and geographical locations from gen bank (NCBI, National

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_141157

Center for Biotechnology Information). Sequences from the accessions (*Table 2*) had been considered. Sequence alignment of the ACLSV isolates and homology between sequences were acted in accordance with to Thompson et al. (1994). The present ACLSV isolates in the study compared with those of 23 ACLSV isolates were available in the NCBI GenBank. A sequence identity matrix of the partial CP gene of the ACLSV isolates were configured using the BIOEDIT with worldwide ACLSV sequences obtained in the GenBank.

Recombination event analysis

The Recombination Detection Program v4.16 (RDP4) was performed (Martin et al., 2010), by utilizing the RDP, GENECONV, Chimaera, MaxChi, BOOTSCAN, SISCAN and 3SEQ methods implemented in the RDP 4 program with default settings. These

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_141157

recombination determinations have been accepted if determined as "clear" recombination by more than four methods with a p-value > 1×10-6 (Martin and Rybicki, 2000).

Genetic diversity analysis for ACLSV population of EMR

The estimate of nucleotide diversity values of EMR ACLSV isolates is structured by DNASP version 5.0 (Librado and Rozas, 2009).

The Pi value, including nucleotide diversity, was estimated by Tajima, [1983), with the average number of nucleotide differences between two random sequences in a population.

The frequency and number of haplotypes in a population of haplotype diversity (Hd) was conducted by Watterson (1975) according to the θ Estimator from the number of segregated sites (S), while the average ratio of non-synonymous and synonym substitutes (Tajima's d'si) was conducted by Tajima (1989), and the D and F analyses of Fu and Li were conducted by Fu and Li (1993) neutrality tests.

Results and discussion

Serology (DAS-ELISA)

Commercially available ELISA kits have been used to serologically detect virus diseases that are harmful in stone fruit trees. ACLSV, ApMV, PPV, PNRSV, PDV and other important temperate zone fruit viruses (*Table 1*) commercially available kits have been used in accordance with the procedures reported by the companies. As a result of the ELISA tests, mostly non-mixed infections were determined from samples collected from important temperate climate fruits such as quince, pear, apple, cherry, apricot, cherry peach and nectarine. Only one example showed multiple mixed infections. The number of viral infections detected is summarized in *Table 1* according to fruit species. Accordingly, it was also tested for verification of previous serological studies, one Nectarine isolate of ACLSV was collected from Yenice/Adana (2019) and one Apple isolate from Fındıklı/Adana (2011), one Pear isolate from Kamışlı/Adana (2006), one Sweet cherry isolate from Çamardı/Nigde (2013) and one *Strax officinalis* isolate supplied from Kayseri (by Dr. H. Fidan; 2018) in the samples, ACLSV infection was confirmed by giving at least twice the healthy control value and a higher reading value. Only *Strax officinalis* has been identified with a triple mixed viral infection. This mixed infection was found to be caused by ACLSV, PDV and ApMV.

In contrast to having positive results against to ACLSV, ApMV and PDV, ELISA did not give positive results for all samples for the rest of among all 12 tested different viruses (*Table 1*).

However, serological techniques, although very widely used costs are high, each phenological period of plants and different organs of the delicate results can not stand as techniques. For these reasons, molecular techniques are applied to verify the results. In particular, low costs, high sensitivity and detailed characterization possibilities can be provided in part, as well as an easy-to-implement technique can be considered as an advantage.

RT-PCR, sequence analysis and phylogenetic analysis

In addition, reverse transcription-polymerase chain reaction (RT-PCR) method was used to obtain the complementary DNA (cDNA) from the RNAs obtained as a result of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_141157

Total RNA isolation. In the next stage, approximately 677 bp-sized compounds containing conserved regions associated with the ACLSV CP gene parts by means of forward and reverse primers were observed in 1.5% agarose gel containing 0.5 mg/ml of ethidium bromide (*Fig. 2*).

DAS-ELISA positive results of isolates obtained from different production areas of the Eastern Mediterranean region were confirmed in this way. Phylogenetic tree was created based on sequence analyses of amplicons or RT-PCR products obtained.

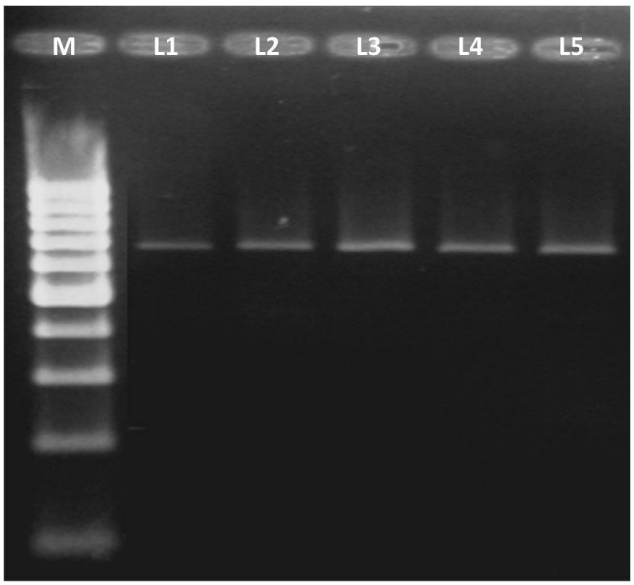

Figure 2. *First lane M DNA ladder; RT-PCR products of 677 bp of ACLSV CP on agarose gel (1.5%) (Lane1 nectarine isolate of ACLSV; Lane2 apple isolate; Lane3 pear isolate; Lane4 Strax officinalis isolate; Lane5 sweet cherry isolate from Mediterranean Cost in Turkey*

Phylogenetic analysis

Designated sequences have been compared with different isolates' sequences of ACLSV from the accessions (*Table 2*). Phylogeny was conducted by Mega7, as indicated by entered ACLSV sequences (*Fig. 3*). The evolutionary history was inferred using the Neighbor-Joining method. The optimal tree with the sum of branch length = 22,06180530 is shown. The percentage of replicate trees in which the associated taxa clustered together in the bootstrap test (1000 replicates) are shown next to the branches.

The Phylogenetic tree is drawn to scale, with branch lengths in the same units as those of the evolutionary distances used to infer the phylogenetic tree. The computed evolutionary distances using the Maximum Composite Likelihood method, are in the units of the number of base substitutions per site. The analysis had been involved 28 nucleotide sequences. All positions containing gaps and missing data were eliminated. There were a total of 237 positions in the final dataset. Evolutionary analyses were conducted in MEGA7. The *Stone Ansd Pome Fruit* Samples from East Mediterranean of Turkey in Genbank with accession Number (*Table 2*) MK986792 Nectarine, MK986793 Cherry, MK986794 Pear, MK986795 Apple and MK986796 Strax officinalis were accessed as to NCBI system (*Fig. 3*) and listed below with other isolates from worldwide in *Table 2* and matrixed in *Table 3*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_141157

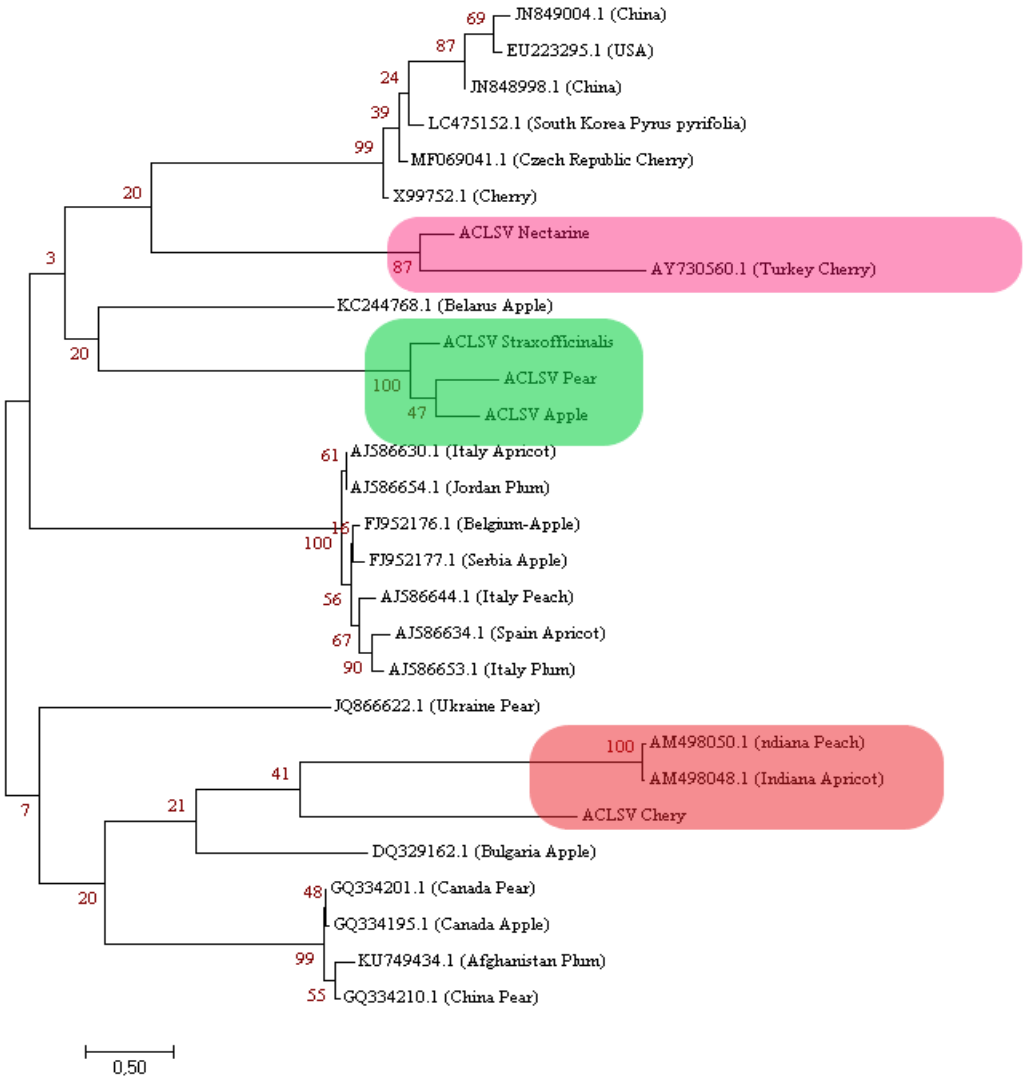

Figure 3. *Phylogenetic tree of five different ACLSV isolates from Mediterranean coast of Turkey and 23 of gene bank, were clustered within the GenBank database*

Despite of having approximately 97.09 %similarity with each other isolates from Turkey there are three clades among *Stone and Pome Fruit* isolates from East Mediterranean Turkey (EMT). It may be caused by material origin. The sequences were clarified with Accession Num. MK986792 Nectarine isolates (96.12%) from EMT have similar homology with Accession Num. AY730560.1 Sweet Cherry isolate (83.19%) from Turkey (in pink cloud at tree). While Accession Num. MK986794 Pear (96.92%), Accession Num. MK986795 Apple (97.09%) and Accession Num. MK986796 *Strax officinalis (*96.77%*)* from EMT were in cluster with Accession Num. KC244768.1 Malus X Domestica from Belarus isolate (86.22%) (in green cloud at tree).

The third cluster which is covering Accession Num. MK986793 ACLSV Cherry (96.61%) (in coral orange cloud at tree) has two more isolates, with Accession Num. AM498048.1 Wild Apricot (Chuli) (86.01%) from India: Kullu and Accession Num. AM498050.1 Peach from India: Solan (97.42%). This cluster next to other branch, has Accession Num. DQ329162.1 Apple isolates (86.24%) from Bulgaria (*Tables 2* and *3; Fig. 3*).

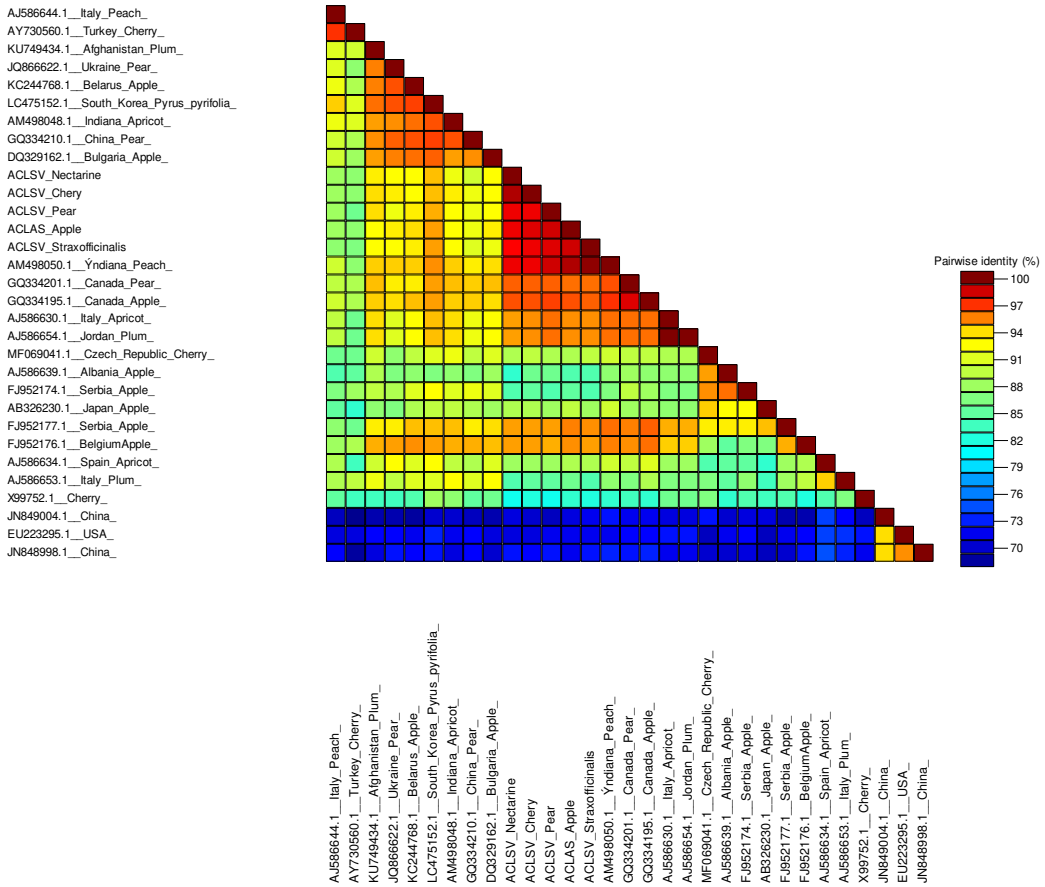
Table 3. *Pairwise distances have matrixed according to the accession numbers (also in Table 2), of ACLSV isolates which are MK986792 Nectarine, MK986793 Cherry, MK986794 Pear, MK986795 Apple and MK986796 Strax officinalis in this study for molecular comparisons analysis (1-5) from EMT. It compares the degree of proximity between red and blue*



Dark Red indicates the closest kinship level. While Dark Blue is the opposite

According to Liu et al. (2014) specifications, isolates P205, B6 and Ta Tao 5 can be determined based on some amino acid points on the Capsid protein. According to this analysis, ACLSV-Pear, ACLSV-Nectarine, ACLSV-Apple, ACLSV-Cherry, ACLSV-*Strax officinalis* isolates from Turkey all have amino acid alignment within the B6 group isolates (*Table 4*). In our result CP based classification for ACLSV was proposed likely on the covariation analysis of the five amino acids at positions 40, 59, 75, 130 and 184, which are highly conserved within two clusters recently described by Yaegashi et al. [2007). The Amino acid clusters of East Mediterranean ACLSV isolates were designated as 'B6 type' due to the isolates containing Ser40, Leu59, Tyr75, Ala86, Thr130 and Leu184 series.

Table 4. *Protein-based amino acid sequence of ACLSV isolates*

Group name	40	59	75	86	130	184
Group I P205	Ala	Val	Phe	Ile	Ser	Met
Group II B6	Ser	Leu	Tyr	Ala	Thr	Leu

Recombination analysis by RPD4

In order to determine recombination events with each other of the 5 isolates used in the phylogenetic tree, "the Recombination Detection Program v4.16 RDP4" was used. RPD 4 (Martin et al., 2010) according to the program given 7 algorithms; recombination events were analyzed.

The presence of recombination signal on ACSLV_Pear isolate was determined according to BootScan and SisCan algorithms from 7 algorithms used. When the RDP4 program data was examined, the ACSLV_pear isolate was determined to be a potential recombinant (*Table 5*). Because the nucleotide variation value ($p > 0.1$) was determined in two algorithms.

In analyses performed using RDP4, recombinations must be determined by at least three of the methods in the program (Martin and Rybicki, 2000; Martin et al., 2010). However, in this study the discovery of recombination signals in only two algorithms established the general belief that recombination events were not detected in the 5 isolates in the study (*Table 5; Figs 4* and *5*).

Population diversity data according to DNASp6

ACSLV isolates obtained from different regions were subjected to recombination analysis using the DNSp6 program. According to this analysis, S:41 fields were

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_141157

identified in Segregession (polymorphic). According to Hudson (1987) data, recombination parameters have been estimated. The distribution variance of the samples was determined as Kij, Sk^2: 72,838. Theta estimate data for each gene: 18,800, functional data g(C,n) 0.1798, estimated value of R for each gene: 368 was determined.

The number of minimum recombination events was determined according to Hudsan and Kaplan (1985). According to this analysis, the number of binary comparisons analyzed was determined as 820. The number of minimum recombination activity was found to be at (54.61) (61,407) points as Rm:2 (*Table 6*).

Table 6. *Population diversity data according to DNASp6 of the ACLSV pear isolate*

Region	**Population statics**								**Tests of neutrality**	
CP	n	S	Hd	Pi:	dS	dN	**dN/dS**	Tajima's D	Fu & Li's D	Fu & Li's F
	5	41	1.000	0.03072	0.59633	-0.17175	**0.288**	-0.6543	-0.3364	-0.3364

n: Number of sequences; S: number of segregating sites; Hd: haplotype diversity; Pi: Nucleotid diversity; dS: rate of synonymous substitutions per site; dN: rate of non-synonymous substitutions per site

Conclusion

The East Mediterranean region is a unique area for many varieties of plants grown in Turkey. The viruses similarly with the other plant diseases can restrict the production via reducing fruitfulness all through the Mediterranean region of Turkey. But in practice, there is no chemical suggestion to control virus diseases unlike the others. Consequently, their epidemiology and molecular bases have to be well decoded to apply control measures. Additionally, resistant cultivars and sanitation should be used for controlling the many viruses in practices.

Natural distribution and occurrence of Temperate Zone viruses in the studied area have determined in Turkey. Our results showed as it has already mentioned above that sanitary situations in stone and pome fruits growing regions are very vitally important in Turkey.

Therefore, molecular epidemiology of ACLSV should be well understood for the prevention. The insufficient of ecologically more important agrochemical disease management strategy, has been increased the jeopardy of infection spread. As well, it can also originate progressively from different annual species and occurs after infection with infected saplings or contamination sources (herbaceous and woody plants) if the insufficient level is suppressed. This is the first preliminarily recombination event report of ACLSV pear isolate among the other isolates from different hosts in the Mediterranean region of Turkey. Our results have shown that reliable laboratory molecular methods with immunological ELISA and molecular RT-PCR analyses have to be used. Further advanced statistical techniques such as RPD4 etc. could be used to confirm our results and other possible recombination events. Because the new recombinant isolates, may become economically dangerous in time, it can cause aggressive breeds to form. Likewise, Fidan (2016) has reported new TSWV isolates that break down the durability of peppers.

Presumably it may more easy transmitted by infected material and cuttings. In response to this "Certified plant materials, destruction of the source of disease and prevention of vectors" are powerful strategies to overcome the disease. Recognition of new strains or isolates will help sustain disease management on the right track. Genetic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_141157

changes due to recombination events can be very important for RNA viruses. Isolate due to point mutations in virus structures are changing so that the emergence of new isolates is realized (Fidan and Sari, 2019). Cultural methods used for preventing virus infections are not enough. Virus vectors and host weeds need to be managed.

Durable/tolerant as possible varieties should be preferred (Öztürk Keleş and Baloğlu, 2019). It is possible that the new isolates may cause severe virus diseases even in mixed or different isolates in the host plants. It is not possible to predict this without observing or experiencing the negative effects and epidemiology of recombinants in agricultural ecology and natural ecology (Fidan et al., 2019).

This paper might additionally indicate that broaded distribution of infected host species between countries and regions will allow the spread of plant's viruses. In the present paper RT-PCR was used as a standardized method for reliable detection of local ACLSV isolates. The analyses performed in this study revealed the variability between ACLSV pear and other isolates in the Eastern Mediterranean region. Molecular variability analysis of 5 ACLSV isolates in the Eastern Mediterranean region, were detected comparable. The phylogenetic tree separated the 5 ACLSV isolates into only 3 subgroups (but not the main group). In addition, our results highlighted possible relationships between ACLSV clusters and host resources. Viruses with large host sequences such as ACLSV are highly likely to undergo recombination.

In addition, isolates resulting from mutation and recombination with high adaptation or adaptability will be able to reach a wider host sequence. This may have severe ecological consequences. In order to detect and identify measures, race and isolate variations should be better analyzed with detailed research. Vertical transmission of ACLSV and many viral agents among different plant species may be the result of recombination or mutation delivery.

Variation analysis will be better understood over time as more advanced technologies emerge and the analysis width of these methods increases. Applicable and facilitated algorithms will be able to reveal wider host sequences and variations in geographic area. Thus, threat risks on agricultural and environmental ecologies will have the potential to be proactively resolved. Moreover, full and true decoding of recombination may open new accessions to the management against ACLSV and others. Deep impacts on the ecological environment can be prevented by well understanding of virus relationships. As well, the detailed and multidisciplinary projects should be acted. All isolates in the study were eradicated on behalf of the country's interests.

(Received 16th Sep 2019; accepted 15th Nov 2019)

Abstract. Giant ragweed (*Ambrosia trifida* L.) and Common ragweed (*Ambrosia artemisifolia* L.) are well known species native to North America and can now be found in China. These weeds are ecologically important and have the ability to spread into agricultural areas and can create future risks. This study is an attempt to investigate the control potential of the root, a pathogen and a gall forming stem insect herbivore for *Ambrosia* species at different locations of Liaoning Province in Northeast China. Significantly ($P<0.05$) high pathogen herbivore (*Puccinia xanthii*) abundance was investigated in sites IV and II (16.76%; 14.04%) with 58-66% humidity at site temperature ranges between minimum-maximum (20-30°C). Significant abundance ($P<0.05$) in stem gall insect herbivore (*Epiblema strenuana*) were recorded in site IV (12.49%) and site I (12.34%). This herbivore displayed a steep asymptotic curve decrease significantly from upper to lower position gave positive relationship. The value of co-efficient of determination ($R^2 = 0.52$) as depicted gave the indication of model fitness. Pathogen herbivore displayed also a steep asymptotic curve investigated moderate positive relationship with $R^2 = 0.45$ followed by site I ($R^2 = 0.36$) form parabola curve. Stem galling insect and pathogen herbivores were diversified significantly with Simpson's index of diversity (SID). Similarly, root herbivore (fire ant) demonstrated its biological control potential on invasive *Ambrosia artemisifolia* at site I recorded significant ($P<0.05$) reduction in plant height (30.62%); diameter (43.21%) and number of leave (73.60%) compared to gall forming stem herbivore.
Keywords: *damage level, Epiblema strenuana, invasiveness, potential, Puccinia xanthii, Solenopsis invicta*

Introduction

Invasive alien species (IAS) create hazard and develop a key pressure on biodiversity of the world that alter ecosystem, reduce native species abundance and cause economic loss (Butchart et al., 2010; Vilà et al., 2011; Hejda et al., 2009; Buttenschøn et al., 2010). However, there is a dire need to react and develop strategies against this hazard should be a basic goal (Lambertini et al., 2011).

Common ragweed (*Ambrosia artemisifolia* L.) is an annual invasive weed belongs to family asteraceae native to North America and Mexico present all over the world (*Fig. 1*) and also in China (Zhou et al., 2017). This weed unintentionally introduced in south east coastal areas in China in 1930's (Chen et al., 2007; Wan et al., 1995). Invasive weeds can affect ecosystem processes, alter community structure and resulting in loss of native weeds populations (Hejda et al., 2009; Powell et al., 2011). *Ambrosia* species introduced as noxious invasive weed in southern area of European Russia, Europe that extends into Georgia and westwards into Ukraine (Moskalenko, 2002; Reznik, 2009; Bullock et al., 2012; Essl et al., 2015; Protopopova et al., 2006; Ustinova and Sizovenko, 2006). This weed infested on agricultural crops (oilseed, rapeseed crop,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14191436

sunflower and soybean) as well as on fallow land resulted significant yield losses (Kazinczi et al., 2008; Buttenschøn et al., 2010; Tóth et al., 2004; Kőmíves et al., 2006; Chollet, 1999; Moskalenko, 2002).

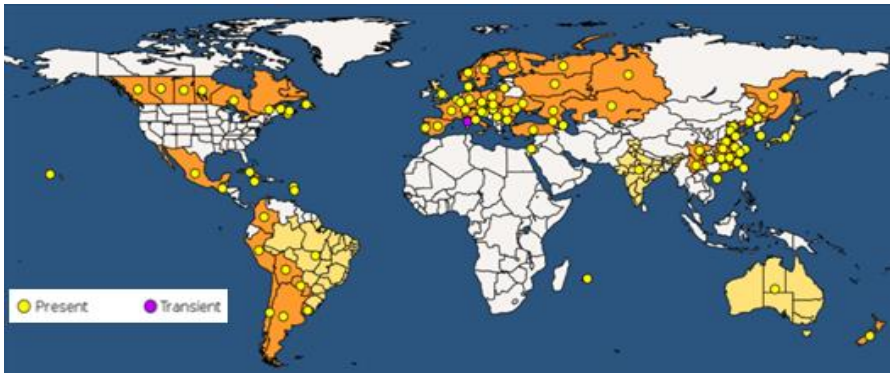

Figure 1. *Distributional map and invasion status of Common ragweed (Ambrosia artemisifolia) around the globe (EPPO, 2008)*

Giant ragweed (*Ambrosia trifida* L.) is an annual herb with branched, erect stems with 30 - 150 cm in height which prolong up to 400 cm. Their leaves were mostly opposite, slightly scabrous, elliptical, 3-5 lobes, margins usually dentate, petioles with 10-30 mm in size (Strother, 2006). This is the most competitive weed in row crops which evolved resistance against multiple herbicides (Goplen et al., 2016). *Ambrosia* species dispersed in 21 provinces in eastern part of China including Jiangxi, Hunan, Hubei, Anhui, Fujian, Zhejiang, Nanjing, Jiangsu (Zhou et al., 2014; Zhou et al., 2010; Meng and Li, 2005) and this weed is polymorphism in nature (Bassett and Crompton, 1975). There is extensive history of biological control against *Ambrosia* species in Eastern Europe, Australia, China and Kazakhstan (*Fig. 2*).

Figure 2. *Distributional map and invasion status of Giant ragweed (Ambrosia trifida) around the globe (GBIF, 2018; Committee, 2011)*

Epiblema strenuana (Walker) (Lepidoptera: Tortricidae) is an endemic and widely distributed in North America, Canada, Mexico and USA, Arkansas, California, Colorado, Connecticut, Columbia, Florida, Illinois, Maryland, New Jersey, New York, North Carolina, Ohio, Pennsylvania, Tennessee, Virginia (Heinrich, 1923), Iowa, Mississippi, Dakota (Brown, 1973) and Israel (Yaacoby and Seplyarsky, 2011).

DOI: http://dx.doi.org/10.15666/aeer/1801_14191436

Rust is a pathogen herbivore (*Puccinia xanthii*), the most promising candidate for biological control of *Ambrosia* species (Hennen et al., 2005). *P. xanthii* collected on *A. trifida* in North America recorded high level of specificity to its original host named *P. xanthii* f. sp. *ambrosiae-trifidae* (Batra, 1981), however, this pathogen did not show its infection on *A. artemisiifolia* (Kiss, 2007; Morin et al., 1993). The significant impact of *P. xanthii* having its host documented in China on *Ambrosia trifida* caused serious die-back of infected plants (Lu et al., 2004a).

Fire ants (Formicidae: Hymenoptera) are social insects reside in colonies that habitually fabricate hills/mounds/tunnels within the soil like pastures and arable lands. Their nests are present within the soil, under stones, or in trees.

The stem galling insect herbivore (*Epiblema strenuana*) was introduced from Australia to China and host specificity tests were conducted on sunflower crops (Zhao et al., 2014; Wan et al., 1995), however, insect herbivore was introduced in 1990 to control *A. artemisifolia*. The insect release in a small-scale in Hunan Province, and later the insect established its population and began to spread. Host specificity and feeding studies indicated that there are four host plants (*A. artemisifolia*, *A. trifida*, *Xanthium sibiricum* and *Parthenium hysterophorus*) were discovered in China (Ma et al., 2003).

There is an intensive need to locate and develop eco-friendly solutions regarding biological control agents (BCA's) for the proper management of invasive weeds (McFadyen, 1998). These weeds produced allergic pollens that cause pollution and considered significant possible hazard to human beings and the natural diversity (Qureshi et al., 2014). The most important key provoking strategies to control these invasive weeds are chemicals. The chemical industry of China has taken one of the most re-known positions in global village. Many broad, narrow and sedges type of invasive and non invasive weeds were controlled by herbicides. These chemical herbicides create negative impacts on the natural ecosystem may cause toxicity to human beings (Bastiaans et al., 2008; Wilson and Tisdell, 2001; Zhang et al., 2011b).

To overcome the problem of excessive usage of chemicals; biological control agents are the best option without posing contamination to environment and naturally growing populations. The study hypothesis is that the damage level of pathogen herbivore (*Puccinia xanthii*) may vary with locations depend upon the prevailing environmental conditions and to find out insects having biological control efficiency against invasive weeds. The study comprised the relationship between root and stem galling insect herbivores against *Ambrosia artemisifolia* in relation to plant growth parameters. However, the survey was conducted to point out coefficient of determination (R^2) of natural herbivores associated with *Ambrosia trifida* and to study diversity of natural herbivores with Ecological Indices on *Ambrosia trifida* at four locations. This survey was planned under Liaoning Key Laboratory for Biological Invasions and Global Changes, College of Bioscience and Biotechnology, Shenyang Agricultural University (SYAU), Shenyang, Liaoning Province, People Republic of China during 2018.

Materials and Methods

The field survey was conducted to evaluate root herbivore fire ant (*Solenopsis invicta*); gall forming stem herbivore (*Epiblema strenuana*) and pathogen herbivore (*Puccinia xanthii*) studied as biological control agents (BCA's) on invasive ragweed species (*Ambrosia artemisifolia* and *A. trifida*) at different sites. However, minimum and maximum temperature was recorded on the spot site having site I (22-31°C & 69% humidity); site II (21-30°C &

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14191436

66% humidity); site III (21-34°C with 62% RH) and site IV (20-30°C with 58% RH) as shown (*Fig. 3*). The study was conducted in peak season keeping in view the pressure of the herbivores are maximum in July-August during 2018 (*Fig. 4*).

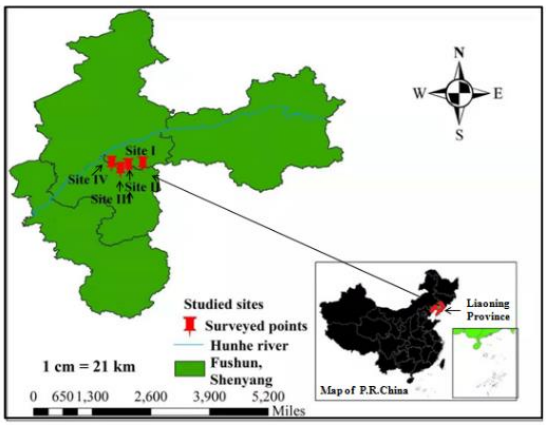

Figure 3. *Mapping location of biological control agents (Epiblema, Puccinia and Solenopsis) using ArcGIS software (Kumar et al., 2014)*

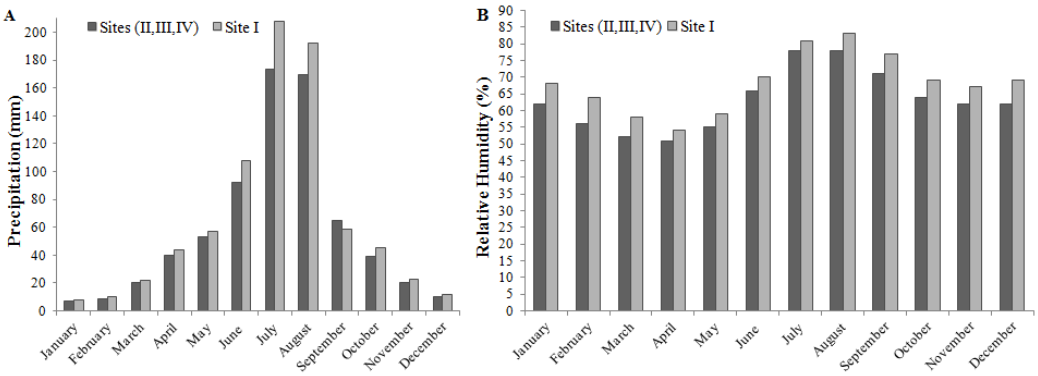

Figure 4. *The climatic data showing mean monthly precipitation (A); Monthly mean Relative Humidity (B) of four sites (data sourced from Chinese meteorological data base)*

The studied area is a northeastern part in China having hilly area at the boarder of South Korea. The average annual rainfall of site I was recorded 786.8 mm with range of annual relative humidity 54-83%. However, the site II, III, IV having annual rainfall were recorded 698.5 mm with range of annual relative humidity 51-78% (*Fig. 4A,B*).

The approach used was a simple random sampling technique designed through extensive field survey (Iqbal et al., 2019). The transect line was eighty meter long parallel to the roadside or riverside; however, we collected four different points twenty meters in one side of transect and data were recorded using quadratic ring (Murphy et al., 2015; Riaz and Javaid, 2011; Zereen et al., 2018; Iqbal et al., 2019) having (100 x 100 cm) following standard protocol (Andersen et al., 2015). Our sampling focused on stem galling insect and pathogen herbivores consumed directly on the leave and stem on *Ambroia trifida* at four locations. The data of root with gall forming herbivore were recorded in site I on *Ambrosia artemisifolia* due to the availability of both herbivores at this site. The root herbivore of common ragweed plants present in each quadratic ring

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14191436

was collected and same procedure was adopted for control for proper comparison. The nine damaged leaves collected randomly from the upper, middle and lower portions of *A. trifida*, and repeat this procedure three times. The insect galled stems in *A. artemisifolia* were also collected in a quadratic ring counted the number of galls and repeated thrice. The *A. trifida* leave spread fully on the hardboard with white background and cover it by transparent flexible plastic cover for digital image analysis. We evaluated and quantify herbivore damage on *A. trifida* leaves by Adobe Photoshop and ImageJ at maximum entropy (MaxEnt) threshold (Moles and Westoby, 2000; Lowman, 1984; Goodwin and Hsiang, 2010; O'Neal et al., 2002). Then leaf area fed/consumed (%) by natural herbivores were assessed (Balami and Thapa, 2017).

At the end, total number of healthy and damaged leave were counted for the calculation of damage percentage (Balami and Thapa, 2017). Simpson index of Diversity (SID), evenness and abundance values were calculated (Magurran, 1988; Qureshi et al., 2018; Mahajan and Fatima, 2017; Chao et al., 2005; Letourneau et al., 2009; Kilewa and Rashid, 2014; El-Azazi et al., 2013).

The consumed area by *Puccinia xanthii* recorded on *A. trifida* leaves collected from these locations and examined under microscope (Iqbal et al., 2019) with 40 µm and 100 µm magnifications. The root, stem and pathogen herbivore were identified by morphometric characteristics (McClay, 1987; Bincheng, 1994; Yaacoby and Seplyarsky, 2011; Wahyuno, 2012; Batra, 1981).

Re-modification of the evolving model

The regression-type relationship carried out for developing the model comparison between mean of natural herbivore fed sites with root mean square error (RMSE). The regression model was set out to determine the effect natural herbivores consumed plant/leave parts investigated different parameters, gave the information about how far away the predicted line is from the observed line. The researchers previously exposed how scattered the observed points around the predicted line, which alternatively revealed about the validity of the model fitness (Hossain et al., 2017; Debaeke et al., 1997; Ahmed et al., 2019). RMSE gave magnitude of the characteristic variation between predicted and observed data (Mayer and Butler, 1993) resulted to assess the precision of the model (Royo-Esnal et al., 2010; Iqbal et al., 2019).

Statistical analysis

The growth parameter analyzed by one-way analysis of variance with Tukey's HSD test keeping in view $P>0.05$; however, coefficients of determinations (R^2) were calculated by means of respective sites. The geographic coordinates during survey site was recorded using GPS navigator (GPS-Hollox, Taiwan) and map was drawn on ArcGIS version 10.2 software (ESRI) (ArcGis, 2013).

Results

Response of natural herbivores on Giant Ragweed (Ambrosia trifida L.)

Validation of the model fitness

The gall forming stem herbivore (*Epiblema strenuana*) after emergence fed on *A. trifida* leave at four different sites gave indication that site II and IV displayed a steep asymptotic curve decrease significantly from upper to lower position. This curvature

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14191436

went in upward direction investigated moderate strength of the variables that gave positive relationship. However, *coefficient of determination* was recorded in site II (R^2 = 0.52) followed by site I (R^2 = 0.49) showed linear line. In site IV, *coefficient of determination* (R^2 = 0.43) was recorded polynomial positive interactions of the model fitness as depicted (*Fig. 5A,B*) compared to site III (R^2 = 0.02) having line parallel to x-axis recorded no relationship of herbivore with its calculated consumed leave (%).

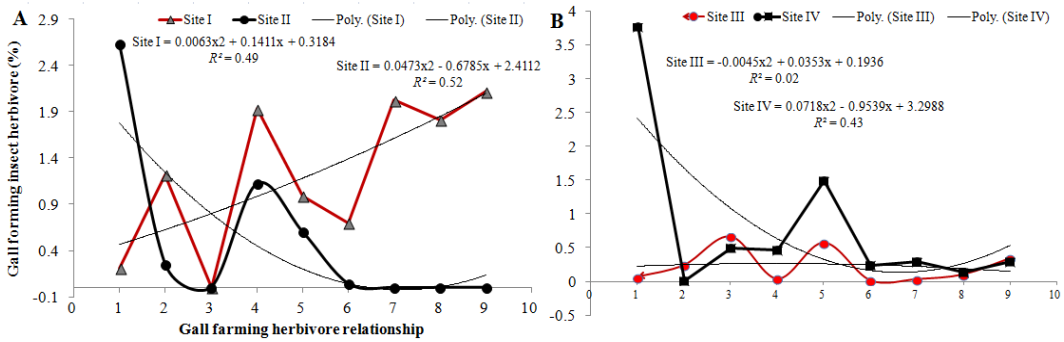

Figure 5. *Power relationship of gall forming stem herbivores feeding (%) on A. trifida leave with different sites; whereas Site I and II (A); III and IV (B); R^2 = Co-efficient of determinations; Poly means Polynomial*

The affect of natural insect herbivore feeding (%) on *A. trifida* leaves were investigated non significant (P>0.05) relationship at all four sites, therefore the value of root mean square error (RMSE) <5 recorded in our experiment gave the indication of model fitness (*Table 1*). The pathogen herbivore recorded significant (P<0.05) effect in site II on *A. trifida* leave with the leave feeding rate (7.78%) with RMSE (3.15) compared to the rest of the studied sites.

Table 1. *Relationship of RMSE with affect of natural stem galling and pathogen herbivore (%) on A. trifida leave at different locations during 2018*

Locations	GFSH±SE	RMSE	PH±SE	RMSE
Site I	1.22±0.27*	0.30	3.25±1.89	3.13
Site II	0.52±0.29*	0.27	7.78±1.55*	3.15
Site III	0.23±0.08*	0.25	1.17±0.20	3.12
Site IV	0.80±0.40*	0.28	5.98±1.27	3.14

Whereas level of significance was P<0.05, RMSE – root mean square error; GFSH – means gall forming stem insect herbivore (%); PH – means pathogen herbivore (%); SE – standard error

The pathogen herbivore investigated on *A. trifida* leave described that site II and I displayed a steep asymptotic curve decrease significantly from upper to lower side. At the end of the streak curvature went in upward direction investigated moderate positive relationship with the value of *coefficient of determination* (R^2 = 0.45) followed by site I (R^2 = 0.36) and falls this polynomial curve on the ground like parabola. Same trend line was recorded in Site IV with R^2 = 0.14 described polynomial positive weak interactions of the studied model soundness as illustrated (*Fig. 6A,B*) compared to site III (R^2 = 0.03) have no significant relationship with herbivore feeding or consumed (%).

Ecological indices

Maximum evenness of gall forming insect (*Epiblema strenuana*) herbivore was investigated on site I & IV (0.15 & 0.15) recorded more stable in the community followed by site II (0.13) and site III (0.08). Similarly this herbivore was also more diversified in site I and IV (0.86 and 0.85) compared to other sites.

Maximum evenness of pathogen herbivore was investigated on site II & IV (0.15 & 0.15) recorded maximum stability in the community followed by site I (0.13) and site III (0.12). Pathogen herbivore was more diversified in site II and IV produced simpson's index of diversity 0.91 and 0.88 respectively (*Fig. 7*) .

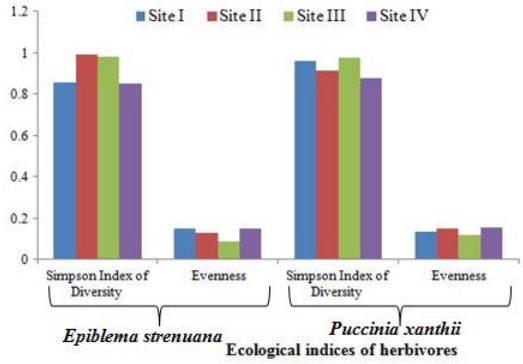

Figure 7. *Ecological indices of gall forming insect and pathogen herbivores on A. trifida*

The maximum pathogen herbivore abundance (%) per plant recorded in site IV (16.76%) followed by site II (14.04%). Similarly, highly significant (P<0.05) abundance in leave consumed was determined by gall forming stem herbivore at site IV (12.49%) followed by site I (12.34%) which was comparable to the other sites (*Fig. 8A*). Further more high number of leaves (12.22 and 14.56) consumed by gall forming insect and *Puccinia xanthii* herbivores respectively at location IV which differed significantly (P<0.01) compared to all other sites (*Fig. 8B*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

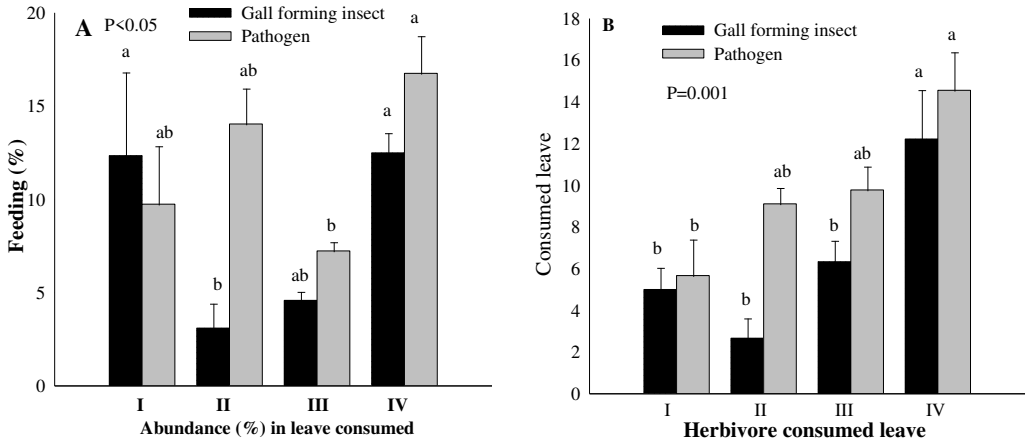

Figure 8. *Comparison of abundance (%) in leave consumed/plant by gall forming insect (Epiblema strenuana) and pathogen (Puccinia xanthii) herbivores (A), number of leave consumed by herbivores (B) at four locations during 2018. Whereas level of significance was P<0.05 by Tukey's HSD test for each response variable; the mean having different lettering differ statistically from each other*

Response of natural herbivores on common ragweed (Ambrosia artemisifolia L.)

Plant growth parameters

The result of this study recorded significant (P<0.05) increase in total number of leaves (74.70%) with F = 138.416; SS = 9202.722 in control treatment comparable to the root herbivore in quadratic rings. However, significant (P<0.05) increase in plant height (cm) with (F = 74.729 and SS = 4461.976); diameter (mm) were (34.16%) with (F = 55.106; SS = 26.451) and (33.90%) with in control compared to root herbivore (*Fig. 9A,B,C*).

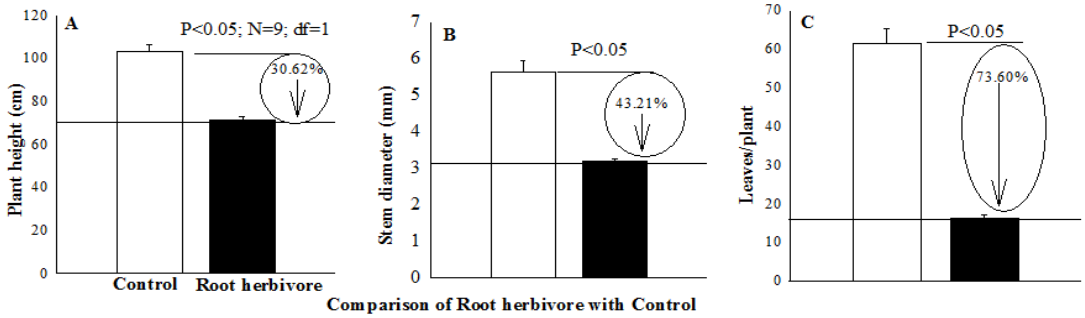

Figure 9. *Comparative efficiency of root herbivore affected on growth parameters of Ambrosia artemisifolia L. during 2018 whereas (A) plant height (cm), (B) stem diameter (mm), (C) total number of leaves per plant. Whereas level of significance was P<0.05 by Tukey's HSD test*

The analysis showed that root herbivore distributed at site I showed its biological control potential against common ragweed. These results suggested that the trend of plant height (30.62%), stem diameter (43.21%) and the number of leaves (73.60%) of *A. artemisifolia* decreased significantly due to biting behavior of root herbivores on the roots zone compared to control.

DOI: http://dx.doi.org/10.15666/aeer/1801_14191436

Comparative efficacy of herbivores

The data regarding root herbivore showed non significant (P>0.05) result on replicated plots at three different sub locations in site I with each other but recorded significant (P<0.05) result with gall forming stem herbivore. The data described that root herbivore reduced the plant height significantly (P<0.05) of the invasive *A. artemisifolia* compared to stem feeding herbivore (*Fig. 10A*). Furthermore, the same significant (P<0.05) trend was investigated in case of stem diameter (mm) to control *A. artemisifolia* (*Fig. 10B*). Multivariate analysis suggested that biological control herbivores recorded significant (P<0.05) reduction in growth parameters of invasive weed compared to control.

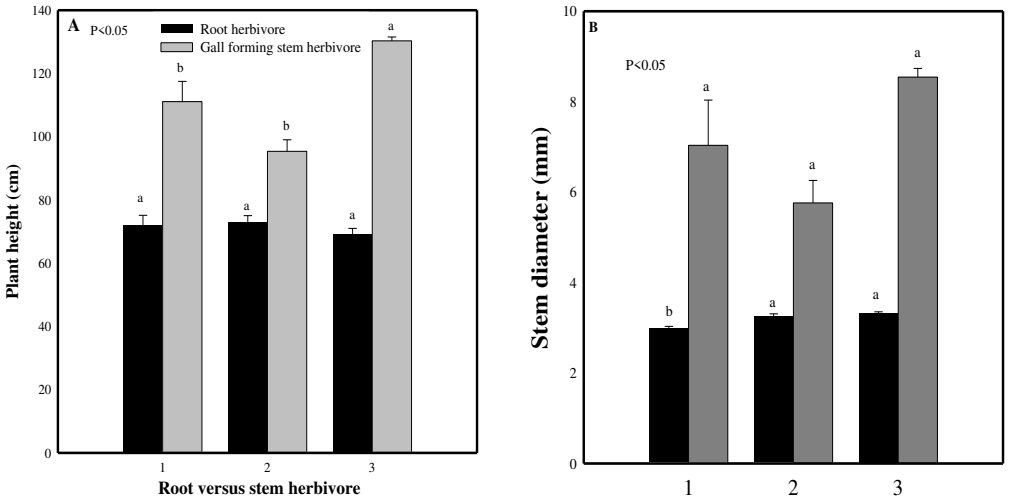

Figure 10. *Comparative efficacy of root and gall forming stem herbivore on plant height (A); stem diameter (B) of Ambrosia artemisifolia at α= 0.05 (Tukey's HSD test), for each response variable at site I; the mean having different lettering differed statistically from each other*

Discussion

Relationship of gall forming herbivore with Ambrosia trifida L.

The infestation of gall forming insect herbivore used as biological control agent on *A. trifida* displayed a steep asymptotic curve decrease significantly gave polynomial positive and moderate relationship of coefficient of determination (R^2) indicated model fitness as depicted. This insect herbivore fed on leaf tissues (%) was produced statistically non significant (P>0.05) relationship (*Table 1*) with root mean square error (RMSE = 0.30). These results were supported to the researchers who reported that the value of RMSE investigated less than 5 gave the indication of awesome model fitness (Royo-Esnal et al., 2010; Iqbal et al., 2019).

Significant evenness was recorded by gall insect herbivore investigated on site I & IV (0.15 & 0.15). This herbivore was more diversified in site I and IV (0.86, 0.85) compareable to the other sites. These results are inaccordance to the researchers who reported that *A. trifida* L. occured in Northeast China, in heavily infested areas, ragweeds were often found in dense monospecific communities with an average diversity index of 0.19 (Wan et al., 1995). *Ambrosia* species an annual weed plant present almost everywhere in China and prefers open and sunny habitats where its

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14191436

competition with other native weed is comparatively low. *Ambrosia* species reduced the natural species abundance in arable land and thus it investigated negative impacts on the agriculture and biodiversity (Pinke et al., 2011; Pál, 2004). The present investigation stated that stem insect herbivore larvae after hatching fed initially on *Ambrosia trifida* leave. After that the larvae enter on the terminal meristem, thickens the stem thus creating elongated galls in plants live there until it pupates. Highly significant ($P<0.05$) abundance in leave consumed by stem gall forming herbivore investigated 12.49% and 12.34% in plant. Gall forming stem herbivore consumed high number of leaves 12.22 per plant at site IV differed significantly ($P<0.01$) with all other rest of the sites. These results are agreed with the scientists who reported that gall herbivore is a nocturnal moth, with a life span of 7-11 days that feed on the invasive weed (Bincheng, 1994; McFadyen, 1992; Dhileepan and McFadyen, 2001; Dhileepan et al., 2018).

Biological characteristics of gall forming stem herbivore

The stem-galling herbivore (*Epiblema strenuana* Walker; Lepidoptera: Tortricidae) lay very small pale color eggs on the leaves (Dhileepan et al., 2018). After hatching eggs, the larvae emerged and fed directly on leave. The length of the larva is about 10 mm straight, but the length of 3rd instar larva is 14 mm, yellow or creamy, with brown heads with light brown ganitalia. The larva of this herbivore make small hole on the top meristem and branches, enter into plant tissues. The developmental stages completed within the gall and pupate. The color of the pupa is brown, 8-9 mm long. Pupal stage converted into adult moth under favorable environmental conditions within 5-7 days, however this period prolonged upto 13 days under unfavorable environmental conditions. The open wing span of caterpiller was 15-18 mm in male and 12-15 mm wide in females. Adult moths have 10-8 mm (male-female) long grayish wings with pale glitery wingtips (*Fig. 11*). There are 3-4 generations of this herbivore that start from the end of April to early October in Southern China and each generation prolong upto 30–40 days (Feng-feng et al., 2002) and the survival time of the adult was 3-5 days under natural environmental conditions at Shenyang.

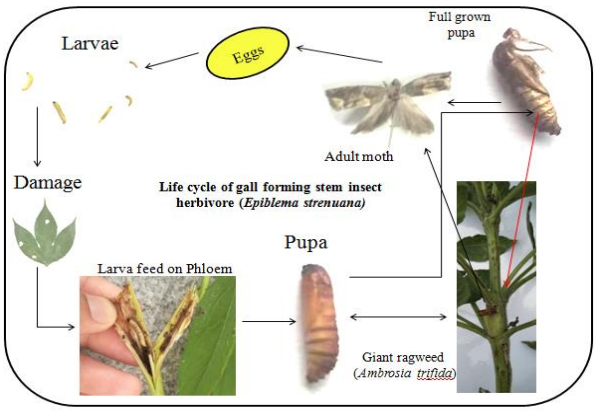

Figure 11. *Biological characteristics of gall forming stem herbivore on Ambrosia trifida plant*

Relationship of pathogen herbivore with Ambrosia trifida L.

The pathogen herbivore described moderate positive co-efficient of determinations (R^2) in site II (0.45) and site I (0.36), however, weak relationship was recorded in site

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14191436

IV and no relationship was determined in site III having its almost line parralel to X-axis. Maximum evenness of pathogen herbivore (*Puccinia xanthii*) was investigated on site II & IV (0.15 & 0.15) and more diversified in site II (0.91) and IV (0.88) compared to site I and III, respectively. These results are in line with the previously studied field investigations in Liaoning and Jilin provinces reported that pathogen herbivore caused considerable destruction to giant ragweed. The fungus of pathogen herbivore feed on the leaves cause plant death on a large scale and may serve as an effective biological control agent of *A. trifida* (Zhang et al., 2011a; Lu et al., 2004b).

Significantly ($P<0.05$) high pathogen herbivore (*Puccinia xanthii*) abundance was investigated in sites IV and II (16.76%; 14.04%) with 58-66% humidity at site temperature ranges minimum 20°C and maximum 30°C. These results are in accordance to the researchers who reported that this pathogen herbivore (giant ragweed rust) significantly favored high humidity and high temperature for its development. This pathogen was flourished in June-September in Shenyang area (Liaoning Province), so due to its obligate parasitic behavior and strong pathogenicity, this herbivore expected as biocontrol agent for the control of *Ambrosia trifida* (Qu et al., 2009; Guozhong et al., 2018). *Puccinia xanthii* herbivore consumed high number of leaves (14.56/plant) at location IV differed significantly ($P<0.01$) with all other sites. These results gave the indications that favorable humidity played a significant positive role for spread of pathogen herbivore pressure. These findings support our hypothesis that significant infection of rust herbivore (*Puccinia xanthii*) on invasive weed may vary with locations depending upon the favorable environmental conditions. The favorable temperature for the germination of teliospore was 20-30°C and optimum temperature for the production and germination of basidiospores was 20°C but the temperature required for high infection was 20-25°C (Morin et al., 1992). The researchers reported in their field experiment that pathogen herbivore (*Puccinia xanthii* Schwein. f. sp. *Ambrosiae-trifidae* S.W.T. Batra) is an obligate parasitic rust fungus recorded an effective biocontrol agent against giant ragweed (Zhang et al., 2011a; Lu et al., 2004c; Seier et al., 2009; Batra, 1981) used as mycoherbicides against *Ambrosia* species (Wilson, 1969; Hasan, 1974; Barreto and Evans, 1995).

Life stages of pathogen herbivore

The pathogen herbivore (*Puccinia xanthii*) is an obligate parasite overwinters in the form of yellow powder of spores in dead plants at high humidity (Dhileepan, 2001; Qu et al., 2009). Its initial symptoms are clearly identified on leaves and its infection causes reduced plant growth rates and, dark brown telia appears clearly, easily identified on the whole leaves (*Fig. 12*).

Response of root herbivore on common ragweed (Ambrosia artemisifolia L.)

The present study suggested that root herbivore (Fire ants) is a biological control agent on common ragweed (*A. artemisifolia*) present in site I at 26ºC (22-31ºC) near Hanhe River. These results are in line with the researchers who reported that environmental conditions played a vital role for the development of root herbivore, however optimum temperature required for its foraging was between 25–35°C (Drees et al., 2007). Multivariate analysis suggested that biological control herbivores recorded significant ($P<0.05$) reduction in growth parameters of invasive weed compared to control treatment. This herbivore affected root portion resulted in significant ($P<0.05$) reduction of growth parameters of invasive weed compared to control. The experiment

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14191436

suggested that the trend of plant height (30.62%), stem diameter (43.21%) and number of leaves (73.60%) of the *A. artemisifolia* decreased significantly (P<0.05) due to biting behaviour of root herbivores compared to control. Scientists studied plant mortality up to 12.5-17.2% in grooves (Smittle et al., 1988), calyx feeding resulted in reduction of 50% flowers (Adams, 1986) due to root herbivores. Root herbivores constructed furrows/holes in the stem, hypocotyls portion and reduced plants height. The results of this study are in line with the researchers who reported that root herbivore reduced plant height significantly (P<0.05) having potential to feed on carbohydrates and polysaccharides from the root tissues (Stewart and Vinson, 1991).

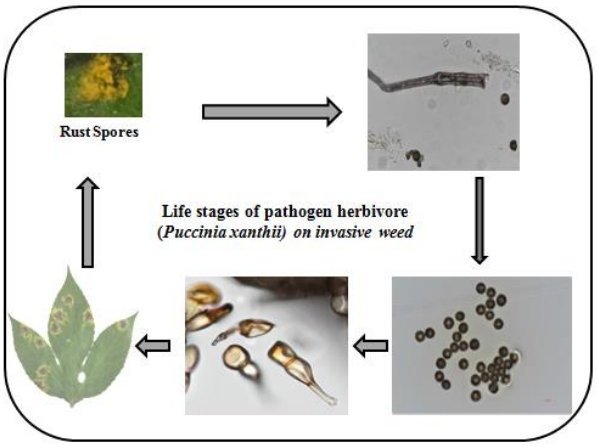

Figure 12. *Life stages of pathogen herbivore completed on Ambrosia trifida leaves identified with 40 µm and 100 µm magnification under microscope*

Our results are also in accordance with the researchers who reported that polyphagous ant (Hymenoptera: Formicidae) thinning the root collars that interrupt nutrient supply between shoots and roots (Niu et al., 2010; Vörös and Gallé, 2002) recorded significant damage to the plants. Root herbivores have high reproductive and distribution capabilities, toxic and non-toxic belongings of stings and forceful scavenging performance (Allen et al., 2004; Parris et al., 2002). Root herbivores store small portion of food material to the nest but also assist to crash bigger food item along its transportation (Tschinkel, 2006). These results are in accordance to the researchers who reported that growth and plant height reduced significantly by feeding of fire ant root herbivore (Adams, 1983). Oil contents and carbohydrates (polysaccharides, glucose, and fructose) are necessary ingredients in the diet of ants (root herbivores). Therefore, these herbivores scratch the sap from root portion may be associated with their necessary nutritional carbohydrates (Vander Meer et al., 1995) from plant tissues. The researchers investigated that root herbivore feed on the bark and cambium to obtain sap resulting the death of orange and grapefruit plants in Florida (Banks et al., 1991). Root herbivore (ants) attack on the stems of sunflower at ground level, removed phloem tissue leaving the woody cortex however, 40–50% of the crop was infested (Stewart and Vinson, 1991). In our experiment root herbivore significantly (P<0.05) reduced the plant growth characteristics of *A. artemisifolia* compared to gall forming stem herbivore. The hypothesis was proved that root herbivore having capability to injure the roots of invasive *A. artemisifolia* resulting in significant reduction in plant growth characteristics.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14191436

This study shows that gall forming stem insect and pathogen herbivores have potential biological control agent against *Ambrosia trifida* recorded significant abundance (%) regarding leave area consumption. During filed survey it had observed that plant hoppers suck the cell sap from the basal portions of stem tissues of *A. Artemisifolia* plant. In future, it may become a biological control agent (BCA's) of this invasive weed. The study also described that root herbivore significantly reduced the growth characteristics of *A. artemisifolia* may become a promising candidate for BCA's in future.

Conclusion

The present study concluded that pathogen herbivores deliberated and caused significant effect on giant ragweed (*Ambrosia trifida* L.). The root, stem galling insect and pathogen herbivores having biologically effective and helpful in reducing the growth characteristics of the *Ambrosia* species in natural ecosystems. In future, there is a dire need to find out more natural enemies having biologically control efficiency against invasive weeds. In the light of our study, we encouraged the entomologists, plant pathologists and ecologists to explore the mode of action of these herbivores along with phyto-chemical screening and their interactions mechanism on invasive weeds. However, reciprocal relationship of root herbivores with roots of the invasive weeds would be studied in future.

Abstract. The additive main effects and multiplicative interaction (AMMI) model and genotype main effects and genotype-by-environment interaction (GGE) biplot are commonly used to analyze multi environmental trial data. This study adopted the AMMI model and GGE biplot to comprehensively analyze the data on genotypes tested in the 2016–2017 Zhongcheng combined regional maize trial in China. Results showed that the traits highly and significantly differed across different genotypes (G) and environments (E). Significant or very significant genotype-by-environment interactions (GEI) were also found. With the exception of 100-kernel weight, the ratio of GEI for the remaining three traits was lower than that of E and higher than that of G. GEI was decomposed, and the interaction information of PCA1 and PCA2 in the interaction of four traits was significant. Hengyu1587 and Shiyu 1503 performed better than the other hybrids and were identified as excellent varieties across locations because of their outstanding performances according to a 2-year observation. The comprehensive utilization of the AMMI model and GGE biplot can enable the scientific and objective judgment of the high yield, stability, and adaptability of tested maize hybrids and provides theoretical support for the rational layout of maize hybrids in the environments of Hebei Province.
Keywords: *yield, stability, adaptability, AMMI model, GGE biplot*

Introduction

Maize (*Zea mays* L.) is an important industrial, feed, and food crop in China and plays an important role in the national economy (Yue et al., 2018a). The three major maize-producing areas in China are northeast spring, southwest mountainous, and Huanghuaihai summer, which has the largest maize concentration. The wheat–maize double cropping system is the planting mode in this region which accounts for approximately 1/3 of the planting area and output of the country and frequently experiences natural disasters, such as high winds, heavy rainfall, drought, mites, high temperatures, and low temperatures during the filling period (Zhang et al., 2015; Zhao and Yang, 2018). In addition, the continued occurrence of maize pests and diseases destabilizes the production from this area and results in a massive difference between the actual field yield and genetic yield potential of maize hybrids (Yue et al., 2018b). These problems have seriously hindered the healthy development of the maize industry. Breeding high-yielding and stable hybrids suitable for environmental conditions in various regions is necessary to achieve high and stable maize yields.

The combined regional trial of crop varieties is an important form of national and provincial regional trial that has emerged in the past 2 years and is an inevitable outcome of the modern seed industry. The combined regional trial of maize hybrids is the comprehensive evaluation of the yield, adaptability, stress resistance, quality, and representativeness of newly cultivated hybrids according to standard specifications (Bao et al., 2017; Zhao et al., 2018). Combined regional trials are performed to screen out genotypes with excellent performance, determine the best adaptation areas for the tested varieties, and maximize the yield potential in accordance with local conditions. Discriminative analysis between locations is an important aspect of combined regional trials. The scientific and effective selection of locations and the improvement of screening services for new hybrids are difficult problems encountered by agricultural researchers (Zhang et al., 2016; Blanche and Myers, 2016).

Yield and other important agronomic traits of maize hybrids are represented by genotype (G), environment (E), and genotype main effects and genotype–environment interaction effects (GEI). The GEI effect occurs when different hybrids face different Es. E affects G because of the GEI effect, which in turn causes changes in different hybrids (Ma'ali, 2008; Abakemal et al., 2016). A high interaction effect degrades the stability of maize hybrids. In general, maize hybrids that exhibit high and stable yields under different environmental conditions have good adaptability, a large promotion value, and an outstanding productivity but poor stability in local areas. Genotypes with special adaptability also have a high production promotion. Therefore, understanding the connotation and essence of the interaction effect is helpful for studying the stability of maize yields and agronomic traits under different environmental conditions.

Agricultural researchers have proposed numerous research methods, including ANOVA (Lin et al., 1992), principal component analysis (Perkins, 1972), high stability coefficient (Berzsenyi and Dang, 2008), coefficient of variation (Döring and Reckling, 2018), additive main effects and multiplicative interaction (AMMI model) (Zobel et al., 1988), and genotype main effects and GEI effect (GGE) biplot (Yan et al., 2000), for the analysis of crop genotype and environment interaction. The AMMI model and the GGE biplot have been commonly used for GEI analysis. The AMMI model, also known as the additive main effect product interaction model, is the combination of ANOVA and principal component analysis for maximizing the interaction between G and E and separating the sum of product terms with different values from additive model interactions. This technique can also maximize assessment accuracy (Thillainathan and Fernandez, 2001; Dehghani et al., 2016). The results of AMMI model analysis can be intuitively and concisely expressed and interpreted, thus aiding the stability analysis of varieties and the screening of G with special GEI effects and providing valuable information for the breeding of special varieties adapted for a particular environment (Lal, 2012). Several scholars have used the AMMI model for the GEI analysis of crops, such as maize (Ndhlela et al., 2014), wheat (Sareen et al., 2012), rice (Suwaero and Nasrullah, 2011), millet (Bashir et al., 2014), barley (Bocianowski et al., 2019) and potato (Thiyagu et al., 2012). The genotype main effect plus GEI (GGE) biplotl method was first proposed by Yan to analyze the regional test data of wheat varieties (Yan et al., 2000). This method analyzes the data in the regional experiment in a 2D map, and the results only show the G effect and GEI related to variety evaluation. This technique has become an ideal tool for studying crop genotype stability and location discrimination (Kaya et al., 2006; Baxevanos et al., 2008; Laurie and Booyse, 2015; Rea et al., 2016; Dehghani et al., 2017). Nevertheless, any analytical method is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14371458

imperfect and has its own shortcomings. The AMMI model mainly considers the interaction between G and E. Comprehensively evaluating the G effect in the breeding and promotion of genotypes is necessary. Analysis results often focus on genotypes that are stable and high yielding or stable and low yielding while ignoring genotypes with high yields but poor stability and thus are subjected to certain restrictions during application (Akinwale et al., 2014). The GGE biplot reveals the GEI information in the form of maps and reflects the cultivar's environmental adaptability. Relying only on 2D plane mapping in the analysis will lead to a loss of a part of the GE's mutation information. Therefore, this approach has a certain risk. The AMMI model and the GGE biplot method can be combined for the regional trials of crop genotypes, to screen out genotypes with good yield and poor stability and apply them in specific regions, thus greatly improving the accuracy of results (Muthoni, 2015; Erdemci, 2018).

Here, the AMMI model and the GGE biplot were used to comprehensively evaluate the stability, adaptability, and discrimination in the Zhongcheng combined regional maize trial in Hebei province from 2016 to 2017. This work aims to provide a theoretical basis for the selection and utilization of maize hybrids in the Huanghuaihai summer maize area of China.

Materials and methods

Experimental data were derived from the Zhongcheng combined regional maize trial of Hebei Province, China. Thirteen hybrids from private and public companies were tested in 2016 and 2017, and Zhengdan 958 was used as a control hybrid. Information on the tested hybrids is shown in *Table 1*. The numbers of locations in 2016 and 2017 were 13 and 16, respectively. The latitude, longitude, altitude, and annual rainfall differed between locations as shown in *Table 2*.

Experimental design

Each location was designed by randomized complete block design (RCBD) with three repetitions. Each experimental plot contained 5 rows with dimensions of 6.7 m for each genotype, 6–8 rows were surrounded by protected areas, and 3 rows of each plot were harvested on time. The field management of each plot was slightly more intense than the field level and involved timely chemical weeding and pest control. Field management and measurements were completed on the same day in case of special weather. Integrated pest management methods, including the use of bait to trap rats. Thrips and armyworm are the most important pests in maize seedling stage, and the control measure is to use 4.5% high efficiency cypermethrin 15000 times liquid spray per hectare. The control of weeds is carried out in two stages. In the first stage, weeds are controlled by chemical agents (methalamin 3000 ml/ha plus 450 kg/ha) at pre-emergence stage. The second stage is to use 225 ml/ha of nitrocellulose at a concentration of 225 kg/ha of nitrocellulose in the 3-5 leaves of the post-emergence stage. Both pre-emergence and post-emergence weeding are directed sprayed under windless conditions. The sowing date was carried out on 10^{th}-20^{th} of June of each location, and the harvest period was controlled from 1^{th} to 10^{th} of October during 2016-2017. Each location was reasonably arranged for fertilizer application according to the respective soil measurement conditions, 150-200 kg N ha^{-1} and 100-130 kg P_2O_5 ha^{-1} were applied at the time of sowing date. The plant height and ear position of the hybrid were investigated during the milk maturity period, and lodging and folding were

DOI: http://dx.doi.org/10.15666/aeer/1801_14371458

investigated during the waxy stage. The traits of 100-grain weight, ear length, and kernel weight were investigated after harvest and the grain yield has been corrected for 14% moisture at each location.

Data analysis

AMMI model

The formula for the AMMI model is as follows:

$$y_{ge} = \mu + \alpha_g + \beta_e + \sum_{n=1}^{N} \lambda_n \gamma_{gn} \delta_{en} + \theta_{ge} \quad \text{(Eq.1)}$$

where y_{ge} represents the yield of genotype (g) in the environment (e), μ is the grand mean, α_g represents the average deviation of g from μ, β_e represents the average deviation of e from μ, λ_n is the nth eigenvalue of interaction effect principal component axis, γ_{gn} is the G principal component score representing the nth principal component, δ_{en} represents the environmental principal component score of the nth principal component, and θ_{ge} is the error term.

GGE biplot method

The yield and ear trait data in the regional trials of the Zhongcheng combined regional maize trial were compiled into a two-way table with G and E. Each test value was the average value of each hybrid in the corresponding location, and the calculation formula is as follows:

$$Y_{ge} - y_e = \lambda_1 \xi_{g1} \eta_{e1} + \lambda_2 \xi_{g2} \eta_{e2} + \varepsilon_{ge} \quad \text{(Eq.2)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14371458

where Y_{ge} is the yield of genotype *g* in environment *e*; y_e is the yield performance of all varieties in environment *e*; $\lambda_1\xi_{g1}\eta_{e1}$ and $\lambda_2\xi_{g2}\eta_{e2}$ represent the first and second principal component scores of genotype *g* in the environment *e*, respectively; λ_1 and λ_2 are the eigenvectors of the first and second principal components, respectively; ξ_{g1} and ξ_{g2} are the first and second eigenvector scores of environment *e*, respectively; and ε_{ge} represents the residuals in the model (Balestre et al., 2009). AMMI model and GGE biplot analyses were performed using DPSV18.0 edition (Tang and Zhao, 2013).

Results

Ear traits and yield performance of maize hybrids

100 kernel weight

As shown in *Figure 1,* in 2016, the average 100-kernel weight was 39.03 g for Xingyu 26 and 38.85 g for Hengyu 12. These values were significantly higher than that of the control hybrid Zhengdan 958. The 100-kernel weight of Shiyu 1501 had a minimum value of 31.89, which was significantly lower than that of Zhengdan 958.

In the 2017 Zhongcheng combined regional maize trial, the average 100-kernel weights of Xingyu 1799, Jiyu 7176, Hengyu 6084, Tangyu 6925 and Hengyu 1587 were 39.21, 39.20, 37.38, 35.99, and 35.89 g, respectively. These values were significantly higher than that of Zhengdan 958. The average of 100-kernel weights of Jiyu 906, Jiyu 202, and RT3321 were lower than those of Zhengdan 958, but the differences between these values were not significant. The 100-kernel weights of other varieties were significantly lower than that of Zhengdan 958.

Grain yield

In the 2016 Zhongcheng combined regional maize trial, the highest average grain yield of Shiyu 1501 was 10.44 t ha^{-1}. The average grain yields of Shiyu 1502 and Hengyu 1587 were 10.41 and 10.33 t ha^{-1}, respectively, which ranked second and third, respectively. The highest average grain yields of Xingyu 26 and Jiyu 906 were 10.10 and 10.01 t ha^{-1}, respectively. The average grain yields of the above hybrids increased significantly compared with those of the control hybrid Zhegndan 958. JL658 and the control Zhengdan 958 had the same yield, and the average grain yields of other hybrids were significantly reduced compared with those of the control.

In the 2017 Zhongcheng combined regional maize trial, the grain yields of Hengyu 1587, Shiyu 1503, Tangyu 6925 and Jiyu 906 were higher than those of Zhegndan 958 and were 10.53, 10.50, 10.40, and 10.26 t ha^{-1}, respectively. No significant differences existed between these varieties and Zhengdan 958. The yields of Hengyu 6084, Jiyu 202 and Xingyu 1511 were 10.14, 10.12, and 10.06 t ha^{-1}, respectively, and were insignificantly lower than those of the control. The grain yield of the other varieties was significantly lower than that of Zhengdan 958.

Grain weight per ear

In 2016, Jiyu 974 had the highest average grain weight per ear of 167.96 g, followed by Xingyu 375 (164.53 g) and Hengyu 1587. The average grain weight per ear of Xing yu 26 and Shiyu 1503 was 164.48 g. The average grain weights per ear of JL658 and Shiyu 1501 ranked fourth and seventh, respectively, and were insignificantly higher

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14371458

than those of the control. The average grain weights per ear of Jiyu 906, Hengyu 12, Tangyu 5115, and Cangkeyu 1 were lower than those of control hybrid. The average grain weight per ear of Cangkeyu 1 was the lowest (141.59 g) and was significantly different from that of Zhengdan 958.

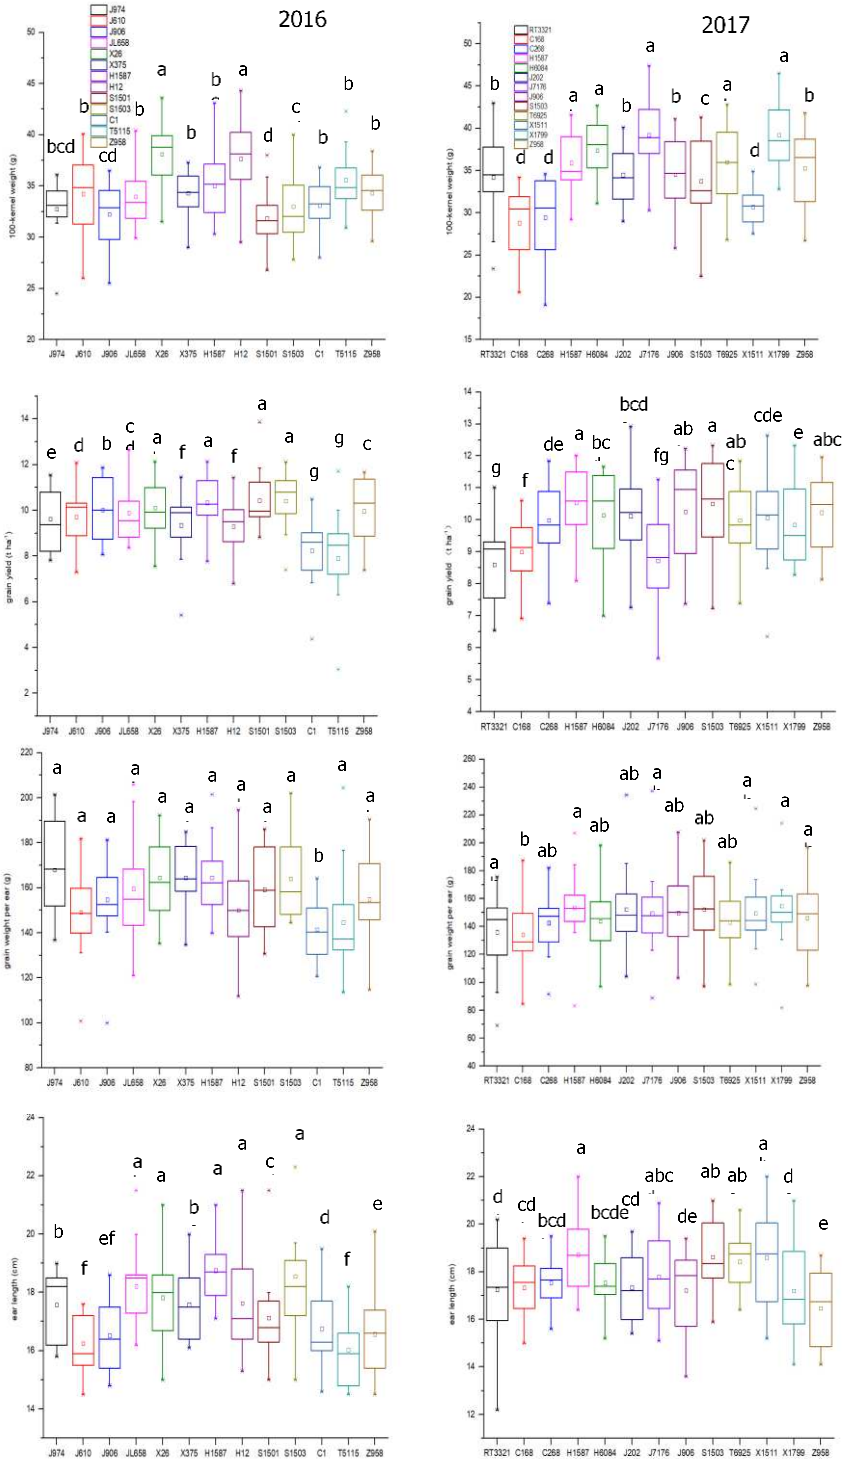

Figure 1. *Traits average performance of maize hybrids in 2016-2017. The lowercase letters indicate significant difference at the 0.05 level*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14371458

In the 2017 test, Xingyu 1799 had the highest average grain weight per ear of 154.96 g, followed by Hengyu 1587 at 153.58 g and Jiyu 202 at 152.53 g. The average grain weights per ear of Hengyu 6084, Tangyu 6925, Cangyu 268, RT3321, and Cangyu 168 were lower than that of the control hybrid Zhengdan 958.

Ear length

In 2016, Hengyu 1587 had the highest average ear length of 18.75 cm, followed by Shiyu 1503 and JL 658. The average ear lengths of Xingyu 26, Hengyu 12, Shiyu 1501, and Cangkeyu 1 ranked fourth, fifth, sixth, and seventh, respectively, and were significantly higher than that of the control. The average ear lengths of Jiyu 906, Jiyu 610, and Tangyu 5115 were lower than that of the control. Significant difference was found between Jiyu 906 and Zhegndan 958 but not between the two hybrids and the control hybrid Zhengdan 958.

In 2017, the average ear length of all tested hybrids was higher than that of the control. Among them, Hengyu 1587 had the highest with 18.72 cm, followed by Shiyu 1503, Xingyu 1511, and Jiyu 7176 with 18.62, 18.61, and 17.78 cm, respectively. The differences between the above hybrids and the control were significant. The values for other hybrids did not reach significant levels.

Analysis of AMMI model for various traits of maize hybrids

100-kernel weight

Variance analysis for 100-kernel weight in 2016 showed that G, E, and GEI were extremely significant (*Table 3*). The squared sum of G accounted for 39.39% of the sum of squares. The square of the GEI had a total squared sum of 36.40%. The ratio of square sum to the sum of squares for E was the smallest at 24.21%. The interaction between G and GEI had a greater impact on 100-kernel weight than E. GEI was 1.5 times higher than E, indicating that the former is crucial for the reasonable evaluation of 100-kernel weight. GEI was decomposed by the AMMI model, and the interaction effects of the first two principal component axes (PCA1 and PCA2) reached extremely significant levels. The square sums of PCA1 and PCA2 accounted for 33.01% and 21.34% of the sum of the interaction effects, respectively.

Variance analysis for 100-grain weight in the 2017 trial showed that the squared sum of G and E accounted for 36.19% and 35.66% of the sum of squares, respectively (*Table 4*). GEI squared accounted for 28.15% of the sum of squares, and G effects and E effects reached extremely significant levels. However, GEI effect was not significant. AMMI model analysis showed that the *P*-value of the GEI effect expressed by PCA1 and PCA2 was less than 0.01 and reached a very significant level, and the sum of the squares accounted for 31.02% and 20.77% of the square of the interaction effect.

Grain yield

Variance analysis of grain yield in the 2016 regional trial showed that the square sum of the E accounted for 46.67% of the total squared sum, that of GEI accounted for 31.06%, and the square of G accounted for 22.26%. G, E, and GEI effects reached a very significant level. E effect accounted for the largest proportion of the total effect. The variations of E and GEI were 2.10 times and 1.40 times that of genotype variation,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14371458

respectively. Therefore, analyzing the stability of grain yield was necessary. PCA1 and PCA2 accounted for 41.04% and 23.55% of the sum of the GEI effects, respectively, and both reached extremely significant levels.

Variance analysis for 2017 showed that G, E, and GEI accounted for 18.41%, 48.17% and 33.43% of the total squared sum, respectively, and all of them reached extremely significant levels. The variations in E and GEI were 2.62 and 1.82 times

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14371458

higher than those of G. GEI was decomposed by the AMMI model, and the interaction information between PCA1 and PCA2 reached a very significant level. PCA1 and PCA2 accounted for 40.39% and 22.87% of the sum of square effects, respectively.

Grain weight ear

Variance analysis of regional trials in 2016 and 2017 showed that G and E differences reached extremely significant levels. GEI did not reach significant levels in 2016 but was significantly different in 2017. Environmental variation accounted for the majority of the variation in the 2-year regional trial. In 2016 and 2017, the sum of the squared environmental variances accounted for 46.17% and 64.59% of the total squared sum, respectively. The variations in GE and GEI were 2.72 and 5.55 times those of G effects, respectively. In 2016, PCA1 and PCA2 explained 44.77% and 52.61% of the square of the interaction effect. In 2016, the PCA1 interaction information reached a significant level, and PCA2 did not reach a significant level. PCA1 and PCA2 reached a very significant level in 2017.

The ear length

The variance analysis of ear length in 2016 showed that the squared sums of G, E, and GEI accounted for 26.72%, 37.62%, and 35.67%, respectively. G and E reached extremely significant differences. GEI effect reached a significant difference. AMMI model analysis showed that the square sum of PCA1 and PCA2 accounted for 33.25% and 23.03% of the sum of the square effects of the interaction, respectively. Both reached extremely significant levels. The AMMI model provided a thorough analysis of GEI effects.

Variance analysis revealed a significant difference between G and E in 2017. The sum of the squares accounted for 15.86% and 50.97% of the total squared sum, respectively, and the square of the interactions accounted for 33.17% of the total square but did not reach a significant level. The results of AMMI model analysis showed that PCA1 and PCA2 accounted for 50.44% of the sum of squares of interactions and reached extremely significant differences.

Adaptability analysis of tested varieties based on GGE biplot

The GGE biplot visually represents the varieties with outstanding performance in different environments with different traits. Each of the "vertex" hybrid in the biplot is sequentially connected by a straight line to form a polygon, which is divided into a plurality of sectors from its origin. Each test environment is embedded in the sector. The "top angle" hybrid in each sector is the best-performing genotype in a certain environment (Yue et al., 2019a).

100-kernel weight

Adaptive analysis showed that the biplot map for 100-kernel weight in 2016 was divided into six sectors (*Fig. 2-A1*). Shenzhou, Fengnan, and Renxian were in the first sector. Xingyu 26 performed best in this sector. The remaining locations were divided into the second sector, and Hengyu 12 was the best performing hybrid. Adaptive analysis showed that the biplot map for 100-kernel weight in 2017, and the biplot map was divided into four sectors (*Fig. 2-B1*). The first sector included three locations in Shenzhou, Gaocheng, and Dingxing. Tangyu 6925 performed best in this sector. Hengyu 6084 had

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14371458

good adaptability in Zhaoxian, Botou, Qixian, and Luquan, and Hengyu 6084 showed the best performance in the second sector. The remaining locations were distributed in the third sector, wherein Xingyu 1799 and Jiyu 7176 showed the best performance. The fourth sector did not show a location, indicating that Cangyu 168, Cangyu 268, and Xingyu 1511 in this sector were not satisfactory in all locations.

Grain yield

The 13 locations of the 2016 regional trial were divided into three sectors (*Fig. 2-A2*). Only Botou was located in the first sector, and Cangkeyu 1 showed the best performance. Zhaoxian, Longyao, Luquan, Mancheng, Dingxing, Cangzhou, Shenzhou, Gaocheng, Fengnan, and Qingxian were located in the second sector. Hengyu 1587 and Shiyu 1501 performed well in these locations. The third sector did not contain a location and included only Tangyu 5115. This result showed that Tangyu 5115 performed poorly in all locations. In 2017, the 16 plots of regional trial were divided into four sectors (*Fig. 2-B2*). Jiyu 202 exhibited outstanding performance in Botou, Shenzhou, Qianying, Gaocheng, Dingxing, and Longyao. Shiyu 1503 performed best in the remaining locations, and Hengyu 1587, Xingyu 1511, and Xingyu 1799 had strong adaptability.

Grain weight per ear

In 2016, 13 plots were divided into five sectors (*Fig. 2-A3*). Luquan, Cangzhou, Shenzhou, Qingxian, and Fengnan were classified as the first sector, and Hengyu 1587 had good adaptability in the above locations. The second sector had four locations, namely, Handan, Gaocheng, Mancheng, and Longyao. Jiyu 974 performed best in this sector. Renxian, Zhaoxian, and Botou were located in the third sector, and Xingyu 26 performed best. The fourth sector had only one location, and Cangkeyu 1 and Hengyu12 performed well in the Dingxing location. A location drop was not observed in the fifth sector, indicating that Tangyu 5115 and Jiyu 610 in this sector did not perform well in all locations. In 2017, 16 plots of the regional trial were divided into four sectors (*Fig. 2-B3*). The first sector only had one location in Zhaoxian, and RT3321 performed best in this sector. Botou, Dingxing, Langfang, Fengnan, Houying, and Luquan belonged to the second sector, and Xingyu 1799 had good adaptability in these locations. Mancheng, Yucheng, and Qianying belonged to the third sector, and Jiyu 7176 performed best. The remaining locations belonged to the fourth sector, and Jiyu 202 performed best.

Ear length

The adaptation analysis of the 2016 regional trial based on ear length showed that Shiyu 1503 performed best in the locations of Dingxing, Qingxian, Handan, and Zhaoxian. Hengyu 1587 had strong adaptability in Luquan, Zhangzhou, Yucheng, Shenzhou, Botou, Mancheng, and Renxian. Jiyu 974, Jiyu 906, Jiyu 610, Tangyu 5115, Shiyu 1501, and Cangkeyu 1 had unsatisfactory performances in all locations (*Fig. 2-A4*). The results of the adaptation analysis of the 2017 regional trial based on ear length were obtained (*Fig. 2-B4*). Xingyu 1511 showed good adaptability in Langfang, Longyan, Renxian, Zhaoxian, Qixian, Shenzhou, Luquan, and Botou locations. Shiyu 1503 and Hengyu 1587 had good adaptability in different locations, such as Gaocheng, Dingxing, Handan, Mancheng, Houying, and Yongnian. The performance of all varieties in Qianying was not satisfactory, and the performances of Zhengdan 958 and Xingyu 1799 were not satisfactory in all the locations.

Analysis of the high yield and stability of the tested varieties based on GGE biplot

The small diamond in *Figure 3* represents the average environment, and the central straight line represents the average environmental axis. The genotypes in the double plot is perpendicular to the average environmental axis, and the high yield of the hybrids can be determined in accordance with the position and length of the vertical line. Vertical lines close to the average environment indicate that traits have high average values and are superior. Short vertical lines are indicative of small deviations from the average environmental axis and high trait stability (Sujay et al., 2012).

100-kernel weight

The analysis of 100-kernel weight and stability in the 2016 Zhongcheng combined regional maize trial revealed that Hengyu 12 had the highest weight, followed by Xingyu 26, Tangyu 5115, and Jiyu 610. Jiyu 906, Shiyu 1503, and Shiyu 1501 had poor performances in terms of 100-kernel weight. Hengyu 12, Zhengdan 958, Jiyu 974, Hengyu 1587, and Cangkeyu 1 had good stability, and Tangyu 5115, Xingyu 375, and Shiyu 1503 had poor performances (*Fig. 3-A1*). In the 2017 regional trial, Jiyu 7176 and Xingyu 1799 were closer to the average environment than other varieties. These two varieties had good 100-kernel weight performance. The performances of these varieties were followed by those of Hengyu 6084, Tangyu 6925, and Hengyu 1587. Xingyu 1511, Cangyu 268, and Cangyu 168 had low average 100-kernel weight. The stabilities of the 100-kernel weights of Jiyu 7176, Xingyu 1799, and Tangyu 6925 were poor, and those of the 100-kernel weights of Jiyu 202, Hengyu 6084, and Hengyu 1587 were good (*Fig. 3-B1*).

Grain yield

The grain yield in 2016 was analyzed (*Fig. 3-A2*). The yields of Shiyu 1501, Shiyu 1503, Hengyu 1587, and Xingyu 26 exceeded those of the control Zhengdan 958, Tang 5115, Cangkeyu 1, and Shiyu 1501, and the stability of the three varieties was significantly lower than that of the remaining varieties. In the 2017 regional trial, the yields of Shiyu 1503, Hengyu 1587, and Jiyu 906 were superior to those of Zhengdan 958. Cangyu 168, Cangyu 268, Hengyu 1587, and Shiyu 1503 had good stability (*Fig. 3-B2*).

Grain weight per ear

In the 2016 regional trial, the average grain weights per ear of Jiyu 974 were the highest, followed by those of Xingyu 26, Shiyu 1503, Xingyu 375, and Hengyu 1587. Cangkeyu1 had the lowest average grain weight per ear. The grain weight stabilities of Jiyu 974, Shiyu 1501, Shiyu 1503, and Zhengdan 958 were high, and those of other varieties were low (*Fig. 3-A3*). In the 2017 regional trial, the average grain weights of Jiyu 7176 were the highest, followed by those of Hengyu 1587, Xingyu 1799, Xingyu 1511, Jiyu 202, Jiyu 906, and Shiyu 1503. The average grain weights of the remaining varieties were lower than those of the control variety Zhengdan 958. The grain weight stabilities of Tangyu 6925, Xingyu 1511, Cangyu 268, and Hengyu 6084 were high, and those of Jiyu 202, Xingyu 1799, and Shiyu 1503 were poor (*Fig. 3-B3*).

DOI: http://dx.doi.org/10.15666/aeer/1801_14371458

Ear length

In the 2016 regional trial, the average ear length of Hengyu 1587 was the highest, and those of Shiyu 1503 and JL658 were ranked second and third, respectively. Those of Cangkeyu 1, Jiyu 906, Jiyu 610, and Tang 5115 were lower than those of the control. The ear lengths of Jiyu 658, Xingyu 375, Hengyu 12, Hengyu 1587, Tangyu 5115, and Zhengdan 958 were stable, and those of other varieties were unstable (*Fig. 3-A4*). In the 2017 regional trial, the average ear lengths of Xingyu 1511, Hengyu 1587, Shiyu 1503, and Tangyu 6925 were high, and Zhengdan 958 had the lowest average ear length. Zhengdan 958, Jiyu 202, Cangyu 168, and Hengyu 1587 had high stability, and Shiyu 1503, Jiyu 7176, Xingyu 1511, and Xingyu 1799 had poor stability (*Fig. 3-B4*).

Analysis of ideal varieties based on GGE biplot

The GGE biplot can be used to visually and clearly determine the position of an ideal genotype. The ideal hybrid is the genotype with the highest average yield and the best stability in all test environments. The ideal hybrid is presented as the center of a multilayered concentric circle, and the pros and cons of the tested hybrids are judged on the basis of their distance from the ideal hybrid. Genotypes close to the center of the concentric circle have good performance, and those far from the center of the circle have poor performance (Kendal and Tekdal, 2019).

100-kernel weight

As shown in *Figure 4-A1*, Hengyu 12 and Xingyu 26 were closer to the center of the concentric circle than other hybrids. These two hybrids had high 100-kernel weights and were stable. Jiyu 906, Shiyu 1503, and Shiyu 1501 were far from the center of the concentric circle and had low 100-kernel weights and poor stability. As shown in *Figure 4-B1*, Xingyu 1799 was closest to the center of the concentric circle, indicating that this hybrid had a high kernel weight and good stability. Xingyu 1511, Cangyu 268, and Cangyu 168 were far from the center of the concentric circle and had low 100-grain weights and poor stability.

Grain yield

As illustrated in *Figure 4-A2,* Shiyu 1501, Shiyu 1503, and Hengyu 1587 were close to the center of the concentric circle, indicating that these genotypes had good yield and stability. Cangkeyu 1 and Tangyu 5115 were far from the center of the circle and had low yield and poor stability. *Figure 4-B2* shows that Shiyu 1503, Jiyu 906, and Hengyu 1587 were closest to the center, indicating that these three varieties were high yielding and stable. Jiyu 202, Xingyu 1799, Cangyu 168, RT3321, and Xingyu 7176 were far from the center and had poor yield and stability.

Grain weight per ear

In 2016, Jiyu 974 was the closest to the center of concentric circles, indicating that its grain weight per ear was the highest and its stability was the best. The grain weight per ear of Cangkeyu 1 was opposite to that of Jiyu 974 and was the worst (*Fig. 4-A3*). In the 2017 regional trial, the grain weight per ear of Jiyu 7176 was the closest to the ideal value. Jiyu 7176 was a genotype with high grain weight per ear and good stability. The

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14371458

grain weights per ear of Hengyu 1587, Xingyu 1511, and Xingyu 1799 were ideal, and the comprehensive performances of Cangyu 168 and RT3321 were poor (*Fig. 4-B3*).

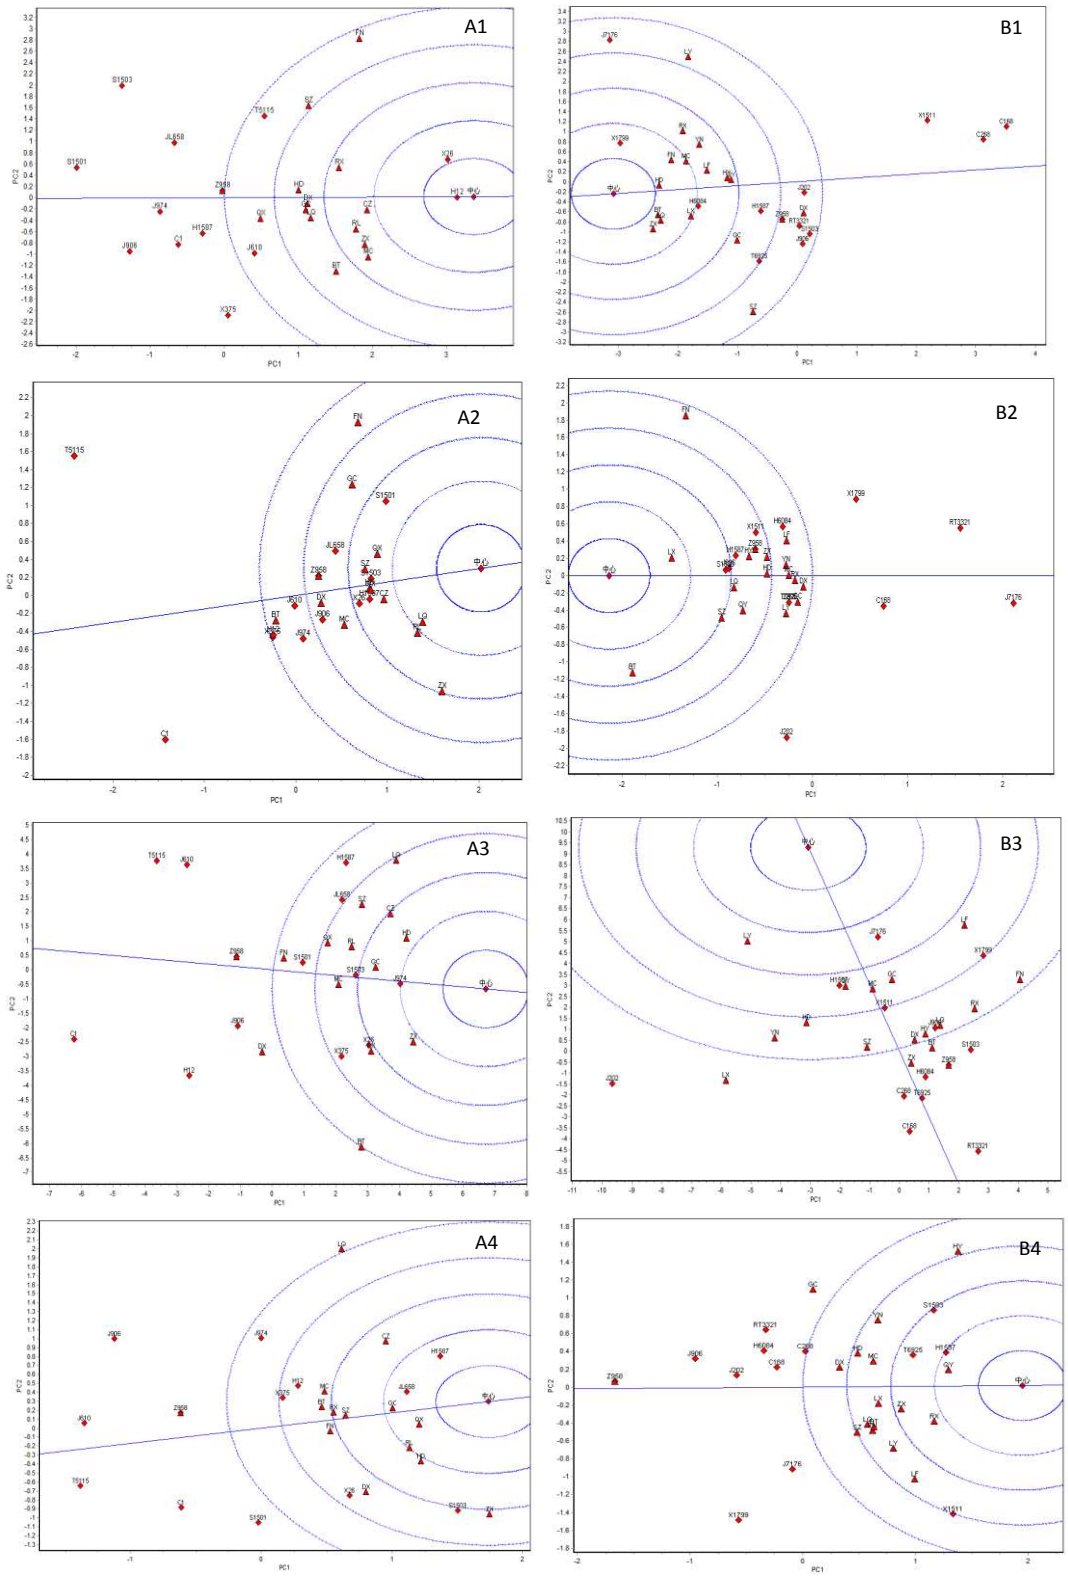

Figure 4. *Comparisons of maize tested varieties with the ideal cultivar for each trait based on GGE biplot*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14371458

Ear length

It can be seen from *Figure 4-A4* that the closest ideal genotypes in 2016 were Hengyu 1587 and JL 658, and the overall performance of the ear length was better. Genotypes such as Shiyu 1501, Cangkeyu 1, Zhengdan 958, Jiyu 906, Jiyu 610 and Tang 5115 had poor overall performance and are not ideal genotype. In the 2017 regional trial, Hengyu 1587 was the closest to the center of concentric circles, indicating that its overall ear length was excellent and belongs to the ideal genotype. Jiyu 202, Xingyu 1799, Jiyu 906 and Zhengdan 958 were far away from the center of concentric circles. Among them, Zhengdan 958 was the farthest from the center, and the overall performance of ear length was the worst (*Fig. 4-B4*).

Discussion

The traits of crop varieties are the results of G, E, and GEI. GEI directly affects the stability of varietal traits (Tekdal and Kendal, 2018). This study showed that in addition to 100-kernel weight, the effects of GEI on three agronomic traits were less than those of E, but had significant effects on traits that were greater than those of G. The GEI effect of three traits, such as grain yield, grain weight per ear, and ear length in 2016–2017 was 1.3-5.5 times that of G (Balestre et al., 2009; Badu-Apraku et al., 2012; Yue et al., 2019b). This result is consistent with previous results. Trait differences caused by crop G changes and GEI effects must be considered in the regional trial analysis of crop varieties. Only by fully studying and utilizing the effects of GEI can breeding efficiency be considerably improved. This requires us to promote corn production and rationally distribute of varieties. First, the appropriate promotion area must be selected in accordance with local light and heat resources. Then, suitable varieties must be screened on the basis of characteristics. The influence of GEI on varietal traits must be emphasized (Kandus et al., 2010). The 2-year analysis of variance showed that the 100-kernel weight of the tested varieties was less affected by external E and GEI. This indicates that 100-kernel weight is an inherent characteristic of the hybrid and is not easily affected by environmental changes. The expression of this trait is dominated by genotype effects.

The research and mastery of the variation in maize panicle traits are important bases for the breeding of high-yielding and stable maize hybrids and developing supporting cultivation techniques. Therefore, the stability analysis of important panicle traits and grain yield of maize genotypes can help fully understand the variation factors of varietal traits. The AMMI model can be used to calculate the AMMI stability value of the tested varieties in the form of a table and judge whether a genotye is high yielding and stable. The model focuses on GEI and enables the stability analysis of the genotypes. However, it fails to fully describe the adaptability of the varieties. The GGE biplot analysis compensates for this shortcoming. The GGE biplot map is a visual representation of the adapted area of the tested genotypes in a polygonal manner. This method focuses on the evaluation of varietal adaptability and yield (Erdemci, 2018; Malik et al., 2019). The GGE biplot analysis of the 2016 regional trial showed the adaptability of varieties on the basis of 100-kernel weight performance. Xingyu 26 and Hengyu 12 showed wide adaptability. The analysis of grain yield revealed that Hengyu 1587 and Shiyu 1501 had wide adaptability in 10 locations. The analysis of grain weight per ear revealed that Hengyu 1587, Jiyu 974, and Xingyu 26 had good adaptability in their respective regions. The analysis of ear length performance indicated that Shiyu 1503 and Hengyu

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14371458

1587 had wide adaptability. According to the 100-kernel weight adaptation analysis of the GGE biplot of the regional trial in 2017, Tangyu 6925, Hengyu 6084, Xingyu 199 and Jiyu 7176 had strong adaptability. The analysis of grain yield showed that Jiyu 202, Shiyu 1503, Hengyu 1587, Xingyu 1511, and Xingyu 1799 were widely adaptable. The analysis of grain weight per ear indicated that Xingyu 1799, Jiyu 7176, and Jiyu 202 had wide adaptability. Ear length analysis revealed that Shiyu 1503 and Xingyu 1511 had wide adaptability.

Ideal genotypes have high yield, stability, and wide adaptability in different environments. In fact, this is an ideal assumption and is rare in actual agricultural production. The high yield, stability, and adaptability of crop varieties are important indicators in breeding. Breeders tend to focus on genotypes with good yield stability but often overlook varieties with high yield and outstanding stability but limited adaptability (Jain et al., 2019). The rational use of maize hybrids should be based on the premise of high yield, and some varieties with good stability and adaptability should be selected. Selecting hybrids with good stability and adaptability from genotypes with poor yield is inadvisable. The stability of maize hybrids must be based on the premise of high yield. The regional trials of maize hybrids revealed that some genotypes are suitable for specific regions. For example, in 2016, Cangkeyu 1 exhibited the best grain yield in the environment of Botou but showed general performance at other locations. It had the highest grain weight per ear in the Dingxing environment. In 2017, the grain yield of Jiyu 202 ranked first in the environments of Botou, Shenzhou, Qianying, Gaocheng, Dingxing, and Longyao but had general overall performance in the remaining locations. Cangkeyu 1 and Jiyu 202 had special adaptability and can be planted in suitable areas. Therefore, we should not only pay attention to genotypes with perfect characteristics, but also to the identification and utilization of special adaptive hybrids in production practice (Rakshit et al., 2012; Yue et al., 2019). Through the analysis of the results of AMMI and GGE in this study, the two analytical methods had similar results considering the specific adaptability to environmental conditions. Due to the GEI, both AMMI and GGE can effectively explore the variability in multi environmental trials (Mets) data, and both methods have been shown to be approximately equivalent, thus screening for genotypes with the highest yield and high stability (Neisse et al., 2018; Kendal et al., 2019).

Conclusion

Multi environmental trials are an effective means to identify good or bad maize hybrids. The scientific evaluation of the stability, yield, and adaptability of maize genotypes is an important link before the promotion of hybrids. We evaluated important agronomic traits, such as 100-kernel weight, grain yield, grain weight per ear and ear length of maize hybrids using the AMMI model and GGE biplot analysis. We observed significant differences in agronomic traits between different genotypes and environments and significant or extremely significant GEIs. Combined with the performance of 2 years of experiments, Hengyu 1587 and Shiyu 1503 presented good comprehensive performance, while Cangkeyu 1 and Jiyu 202 showed special adaptability. The comprehensive application of AMMI and GGE biplot can more accurately and intuitively evaluate the high yield, stability and adaptability of each hybrid as well as the resolution and representativeness of each location. This research can provide valuable theoretical reference for the identification and promotion of new maize hybrids.

Abstract. Tree height growth assessment is important to understand forest dynamics that can reflect the health, productivity, and sustainability of a forest. Tree growth models are important tools to provide a reliable set of information for forest management. Accurate prediction of plant height from time is important for estimating future production. In this study, we used 80 native Moso bamboo and fit 9 models to predict bamboo height as a function of time since sprouting. Our results showed that Logistic growth model was the most suitable for predicting bamboo height (r=0.969), and can be used for predicting the growth and yield of mature native Moso bamboo, and provide a basis for the calculating biomass and carbon storage.
Keywords: *Phyllostachys heterocycla, tree growth, height, growth time, optimal model*

Introduction

Forest ecosystems account for 30% of the global terrestrial ecosystem. It is the most biologically and genetically diverse ecosystem providing not only habitat to more than 50% of the world's flora and fauna (Aerts and Honnay, 2011; Keenan et al., 2015; Miura et al., 2015), but also served human all through human history by providing food, water resources and other valuable timber products (Morales et al., 2015; Miura et al., 2015). Forest ecosystems also play an irreplaceable role in curbing global climate change, carbon cycle, soil and water conservation, and sustainable supply and regulation of forest products (Piao et al., 2018). The research and development of the forest growth model can timely and accurately understand the quantity, quality and dynamic changes of forest resources, and provide a basis for the analysis and assessment of forest growth, biomass and forest yield (Köhl et al., 2015).

Tree growth is an important facet of forest dynamics and can reflect the health, productivity, and sustainability of the forest (Zhang et al., 2019), therefore, it is very important to measure it on a regular basis. Tree growth models are important tools in providing reliable information for decision making regarding forest management (Liu et al., 2017). Many tree growth models that can effectively project changes in forest resources have been developed (Cortini et al., 2011; McCullagh et al., 2017). Tree height is the most important factor in forest resource inventory surveys, production and management of forest resources and for research on forest ecosystems (Vargas-Larreta et al., 2009; Xuan et al., 2016). Accurate estimation of tree height is important in the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14591470

development of forest growth models and can be used to estimate stock volume, biomass and carbon stocks (Li et al., 2015).

Tree growth is a complex process that depends on multiple and interacting factors. It is influenced by site conditions (Lévesque et al., 2016), climatic variables (Zell, 2018), and management (Biging and Dobbertin, 1995). Observation of tree height (H) from the ground is usually affected by the complexity of the distribution of understory vegetation, forest density and topography of the terrain (Temesgen et al., 2014). Moreover, the procedure to measure H is both time and cost expansive. Due to these reasons estimation of H is relatively more tricky and difficult that DBH (D) measurement. Because of this difficulty and to reduce the costs associated with field inventories, it is common practice to fit tree models based on D to predict H (Saunders and Wagner, 2008; Paulo et al., 2011). Further, an improved understanding of the H–D relationship is needed for reliable regional and global estimates of forest biomass and carbon storage. An allometric power relationship between H and D is often assumed in estimating H, although this approach neglects the possible large deviation in estimating biomass by allometry (Feldpausch et al., 2011; Stark et al., 2013). Besides this, non-linear theoretical functions are often used, such as the Chapman-Richards (Song et al., 2011), Hossfeld (Yen et al., 2010), Logistic, and Gompertz (Richards, 1959; Huang et al., 1992; Zeide, 1993; Cieszewski, 2001).

Bamboo is an important forest resources in many parts of the world. There are more than 70 genera of bamboo that are mainly distributed in tropical and subtropical regions (Zhou, 1992). Bamboo is particularly import in China, which is known as the "kingdom of bamboo". There are more than 40 genera and 400 species of bamboo in China. The Chinese bamboo forest covers 6.01 million ha, mainly distributed in Fujian, Jiangxi, Zhejiang, Hunan, Sichuan, Guangdong, Guangxi, and Anhui provinces (State Forestry Administration, 2014).

Bamboo is the main food for giant pandas, which are a unique and protected species in China (Mertens et al., 2008). Bamboo provides food for humans too. Further, it is a green material that can be used as a substitute and supplement for wood where it is widely used in construction, transportation, papermaking, furniture, and handicraft manufacturing (Tang et al., 2016). *Phyllostachys heterocycla* (Moso bamboo), which is characterized by its fast growth and rapid biomass accumulation is an important forest type in Southern China (Zhao et al., 2016). These forests cover 4.43 million ha in China, accounting for about 70% of the national bamboo forest area. The main forest products from Moso bamboo forests are timber and shoots for human consumption. Moso bamboo can reach a height of 20 m when mature and can grow between 30 and 100 cm per day during the growing season (Jiang et al., 2002; Chen, 2011). Thus, it has a higher annual carbon sequestration than other common timber trees (Song et al., 2011), suggesting a high potential for carbon storage (Yen et al., 2010).

For these reasons, there is a need to monitor and accurately estimate the biomass of Moso bamboo forests in China. The growth patterns of bamboo are different from trees; its unique characteristics include fast growth, high production and rapid maturation from shoot to culm (Scurlock et al., 2000). Few researchers have addressed the H–D relationship of bamboo using an allometric power equation (Inoue et al., 2011). The H-D relationship of Moso bamboo has only been studied by Inoue (2013), who used reduced major axis regression. Previous studies have mostly focused on biomass and carbon storage, and did not systematically study bamboo height. In this paper we use the bamboo height data to develop a growth model for Moso bamboo. Such an equation is useful for quantifying bamboo biomass and carbon storage.

Materials and methods

Study area

The study area is located near Yixing City and Wuxi City in southwest Jiangsu Province, adjacent to the Zhuhai Scenic Area (N 31°25′and E 119°73′). The area has a higher elevation and mountainous in the south and lower in elevation and relatively flat in the north, the range of the DEM is -137~614 m (*Fig. 1*). The area called "the ocean of bamboo" in Chinese. The area falls within the subtropical monsoon climate region, with abundant rainfall all year round. The average annual number of rainy days is 136.6, and the annual average precipitation is 1177 mm (Wu and Ming, 2007). The rainfall is concentrated in spring and summer, although it is warm and humid throughout much of the year. The annual average temperature is 15.7°C, the average frost-free period is more than 240 days, and the growth period is up to 250 days. The rivers cris-cross the study area and the average annual precipitation is 1177 mm. The soil is mainly yellow in colour with abundant organic matter providing excellent conditions for the growth of bamboo (Peng and Zou, 2011).

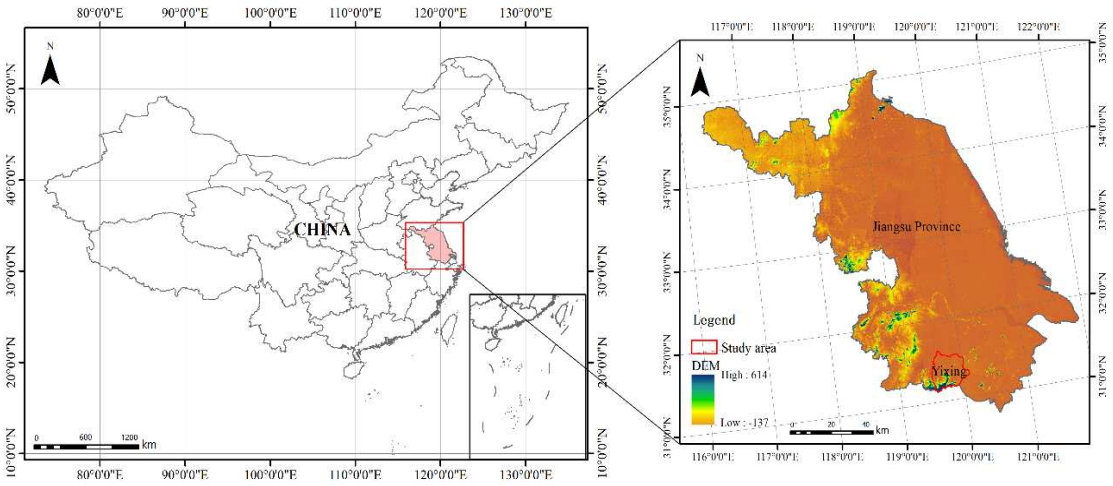

Figure 1. *Location and digital elevation model (DEM) of the study area*

Data acquisition

Five plots (15*15 m) were set up in the study area, and 20 bamboo shoots were randomly selected from each sample plots. Shoots that died or which were damaged by animal foraging or vandalism were removed from the data set, eighty bamboo shoots were left from sample plots in the study area as measurement samples, shoots were identified for measurement on March 26, 2015, and visited at regular intervals. By May 22, the shoots began to grow in height. Height growth was completed after 56 days. When the shoot height was less than 2 m, height was measured by a tape; when the shoot height exceeded 2 m, the height references were accurately measured by total station (Leica Flexline TS06plus Total Station) with accuracy to the millimetre level. The complete height recorded after the growth ranged from 10.71m to 16.06 m.

The models used were nonlinear and fit using the statistical package SPSS 20.0 (SPSS for Windows version 20.0) and the Levenberg-Marquardt (LM) method.

Tree height models assessment

We selected nonlinear models such as tree growth empirical equations and theoretical equations to compare the performance of the model. All model formulas refer to the reference (Meng, 2006). The model formulas were shown in *Table 1*.

Table 1. *Selected tree height models*

Number	Model	Formula
Model 1	Logistic	$h = \frac{A}{1+\mathrm{be}^{-ct}}$
Model 2	Richard	$h = A(1-e^{-bt})^c$
Model 3	Gompertz	$h = Ae^{-be^{-rt}}$
Model 4	Schumacher	$h = Ae^{-b/t}$
Model 5	Sloboda	$h = Ae^{-be^{-ct^d}}$
Model 6	Роляср	$h = At^b e^{-ct}$
Model 7	Weibull	$h = A(1-e^{-bt})^c$
Model 8	Power function	$h = At^b$
Model 9	Korf	$h = Ae^{-bt^{-c}}$

H: Moso bamboo's height, m; t: time, day; a-d are parameters

Model evaluation

In order to verify the accuracy of the forecasting accuracy of the above methods, we validated the models. Usually the model is validated by independent data sets, which is the best way to validate the model at present (Zhang et al., 2019). The majority of the data (80%) was used for model calibration, and the remaining (20%) data was used for verifying the consistency of the models. At present, this method of model validation has been applied in many model validation, such as the biomass model, DBH growth model and carbon storage model (Zhang et al., 2019). Model evaluation mainly used the following indicators: root mean squared error (RMSE), adjusted coefficient of determination (R^2_{adj}), and other criteria (Montgomery, 2013). RMSE combines the variation of mean deviation and deviation, and can directly and clearly evaluate the accuracy of the model. RMSE and R^2 are important evaluation factors in this paper. The closer the R^2 value is to 1, the better the fitness of the model is (Peng et al., 2001). However, Cameron and Windmeijer (1997) suggested that the coefficient of determination (R^2) is not suitable for model evaluation of non-linear functions. Therefore, this paper uses six indicators to evaluate it comprehensively (Burnham and Anderson, 2002) including: root of mean square error (RMSE), coefficient of determination (R^2) and adjusted coefficient of determination (R^2_{adj}), bias (BIAS) and relative bias ($BIAS_{rel}$), residual sum of squares (RSS), Akaike's Information Criterion (AIC). The smaller the RMSE value, the higher the predicted accuracy. The large of R^2 and R^2_{adj} value, and correlation is stronger. AIC is an information standard commonly used to choose the best model. The expressions of the statistics are shown as follows:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14591470

$$RMSE = \sqrt{\frac{\sum_{i=1}^{n}(h_i - \hat{h}_i)}{n-p-1}} \quad \text{(Eq.1)}$$

$$R^2 = 1 - \frac{\sum_{i=1}^{n}(h_i - \hat{h}_i)^2}{\sum_{i=1}^{n}(h_i - \bar{h}_i)^2} \quad \text{(Eq.2)}$$

$$R^2_{\text{adj}} = 1 - (1 - R^2) \times \frac{n-1}{n-p-1} \quad \text{(Eq.3)}$$

$$Bias = \frac{\sum_{i=1}^{n}(\hat{h}_i - h_i)}{n} \quad \text{(Eq.4)}$$

$$Bias_{\text{rel}} = \frac{\sum_{i=1}^{n}(\hat{h}_i - h_i)/h_i}{n} \times 100 \quad \text{(Eq.5)}$$

$$RSS = \sum_{i=1}^{n}(h_i - \hat{h}_i)^2 \quad \text{(Eq.6)}$$

$$AIC = n\ln(RSS) + 2(p+1) - n\ln(n) \quad \text{(Eq.7)}$$

where h_i is the observation value; $\hat{h}_i$ is the forecast value and $\bar{h}_i$ is the average value; n is the total number of data used to the fitted model; and p is the number of independent variables.

Results

Non-linear regression analysis was performed by SPSS. The model estimated all the parameters by using the calibration data, and obtained the parameters and R^2 values of each model (*Table 2*). Except for model 9, all of them showed relatively satisfying results. Therefore, it can be seen that model 9 is not suitable for this data. As shown in *Table 2*, Model 1-8 uses all the data to estimate the parameters by nonlinear regression. All parameters are significant ($p < 0.05$), and the parameters of each model are easily obtained by calculation except model 9.

Table 2. *Parameter estimates and fitting statistics of the models using all data*

Parameter	a	b	c	d	R^2
Model 1	1553.94	142.43	0.135		0.969
Model 2	1946.97	7.73	0.06		0.964
Model 3	1891.38	10.05	0.066		0.965
Model 4	5506.07	72.04			0.961
Model 5	2181.55	51.33	0.596	0.523	0.963

Model fitting and evaluation

Using the Origin8.1, the growth model was fitted by the Levenberg-Marquardt (LM) method. The fitting effects of Model 1, Model 2, Model 3, Model 4 and Model 8 were good (*Fig. 2*). Other models adopt nonlinear regression, and the fitting results werenon-convergence, which was not suitable for the prediction of this data. In the subsequent statistics, the statistical results of the unconverging model were removed.

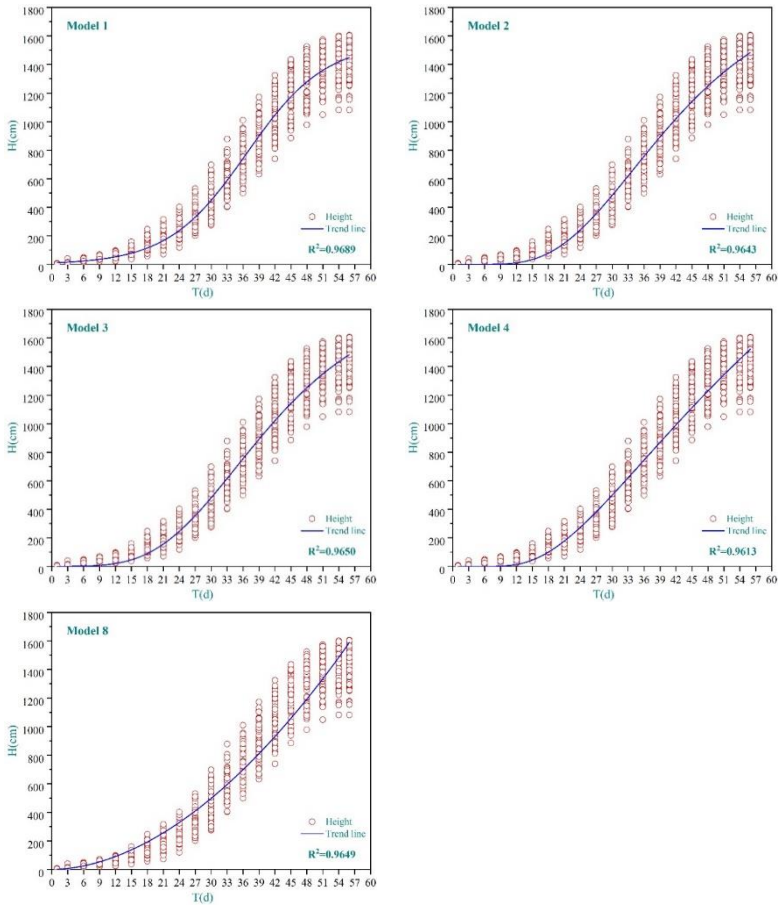

Figure 2. *Models fitting trend line*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14591470

It can be seen from the above trend graph that bamboo's height and the growth time have a high correlation, and models 1, 2, 3, 4 and 8 have higher R^2 values: 0.9689, 0.9643, 0.9650, 0.9613 and 0.9649, respectively. The correlation coefficient of Model 1 was the highest observed, and the result obtained in the fitting of the calibration data has the highest precision, which is suitable for the estimation of bamboo's height growth and conforms to the law of tree growth curve.

As shown in *Fig. 3*, the models 1, 2, 3, 4, and 8, respectively, use the calibration data to obtain the residual of the predicted height, and most of the data points are distributed around y=0. These models show the full uniformity of the predicted values and the independence of the residuals. The residual distribution of model 1 in the figure is relatively small, which reveals model 1 is the best model in the study.

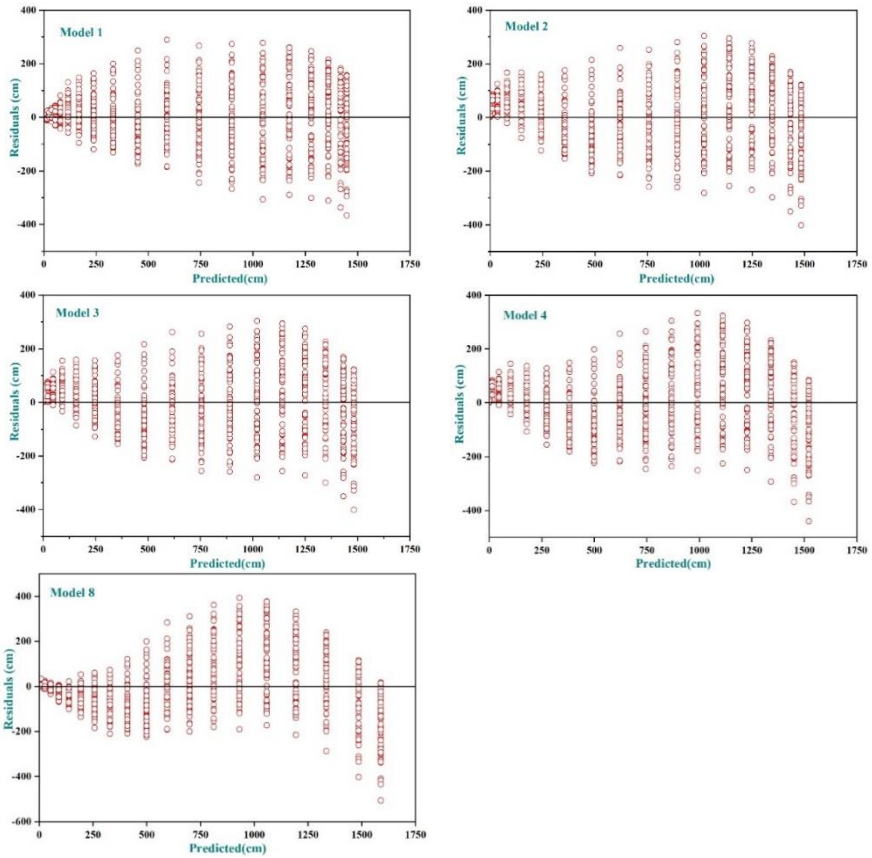

Figure 3. *Residual plots in the calibration dataset for the models (Model 1; Model 2; Model 3; Model 4; Model 8)*

As shown in *Fig. 4*, the models 1, 2, 3, 4, and 8 use the verification data to obtain the average deviation value and RMSE of the bamboo height through the growth period. The standard deviations of models 1, 2, 3, 4 and 8 are mainly distributed around y=0, in which the standard deviation of model 8 is 1.61 m, and deviations of most model are less than 1 m, accounting for 93% of all deviations. The RMSE values of models 1, 2, 3, 4 and 8 are between 0.049-1.86, the RMSE of model 8 varies greatly, the RMSE value of model 1 changes little, and the model is relatively stable. According to the above analysis, the model 1 is the most suitable model in the calibration data and the verification data among the five models.

Discussion

In this study, based on the tree-based growth model, a model suitable for bamboo height and time was selected, which is very important for predicting the change of bamboo growth height with time. Tree growth is an important manifestation of the dynamic changes of forests, which can provide a basis for forest productivity and temporal and spatial changes in forests. The tree height and DBH models are the most basic and effective models in the growth model. The choice of models should be based on the arrangement of the expression of models with calibration data and validation data (the adjusted R^2, R^2, RMSE, the absolute deviation, the relative deviation and the AIC). The model with the adjusted R^2, R^2 value closest to the highest value and a deviation (absolute and relative deviation) closest to zero is thought to be the best. The lower the value of RMSE and AIC, the higher the ranking of the model. For each model, its final ranking is the sum of the statistics of the five evaluation values. The model with the minimum sum (i.e., the highest ranking) is considered to be the functional model that is most suitable for estimating the growth of Moso bamboo. According to this analysis, the calibration data and the validation data show that model 1 is the most suitable for estimatingthe growth rate.

In comparison with previous studies, Huang et al., 1992) developed the HT-DBH functional model of the main tree species from 20 weighted nonlinear equations. It was observed that Weibull, Modified Logistic, Chapman-Richards and Schnute functions generally provided the most satisfactory results. Zhang (1997) concluded that the Schnute, Weibull and Chapman-Richards models provided the best predictive performance for 10 conifer species in the inland regions of the United States in the six nonlinear growth functions selected for HT-DBH. Peng et al. (2001) and Sharma and Parton (2007) recommended Chapman-Richards, Weibull, and Schnute nonlinear growth functions as the most satisfactory models in total height predictions in Canada. Ahmadi et al. (2013) reported that Chapman-Richards, Weibull and Schnute functions in predicting accurate total height predictions in Iranian Hyrcanian forests have shown excellent predictive performance, based on mathematical features, biological interpretation of parameters.

Furthermore, Lumbres et al. (2013) reported that the Modified Logistic nonlinear growth function was the best model for the Pinus kesiya Royle ex Gordon of Benguet in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14591470

Philippines. Based on the result of the researchers, nonlinear growth functions are reliable in the prediction of total height of trees. In the latest study of Lumbres et al. (2015) entitled DBH-height modeling and validation for Acacia mangium and Eucalyptus pellita, the Weibull and Chapman-Richards models were observed as the best nonlinear growth functions for Acacia mangium. However, the result of our study suggested that the Logistic regression model has the highest accuracy in predicting the growth of bamboo among the nine models we selected, which is obviously different from the previous research results.

Conclusion

In this study, the bamboo was used as the object, and the measured data of the fixed sample plots were used. The nonlinear regression method was used to model 80 bamboo shoots randomly seletected in five different study plots. Considering the interrelation between the growth time of bamboo and bamboo's height, the tree growth and empirical equations were used to establish a height growth model of bamboo. From the modeling results, the conclusions are showed as follow. Using the models 1, 2, 3, 4 and 8 to predict the bamboo height, the majority of the bamboo height determination coefficient R^2 can reach 0.9 or more, and in terms of accuracy the model 1 performance was the best. The methods and the models recommended in this study are based on statistics, which provide a reliable basis for the estimation of forest growth and survival and planting management for Chinese native Moso bamboo.

Abstract. In order to compare the ecological characteristics of non-marine ostracods with different reproductive modes, 68 sites including 11 different habitat types were examined in the province of Muğla during July of 2014. A total of 28 taxa were found and 11 of them were new reports for Muğla. Sexual populations of *Psychrodromus olivaceus* and *P. fontinalis* were encountered from the same sampling site. Males of the latter species were reported for the first time from Turkey. The female/male ratio of these species was higher at low altitudes while it was about the same at medium altitudes. Numbers of species in sexual and/or parthenogenetic populations with/without swimming setae and individuals in natural and artificial habitats did not show significant difference ($P > 0.05$). Troughs were described as the richest habitats for ostracods. The first two axes of Canonical Correspondence Analysis explained 66.2% of the relationships between species and environmental variables when the water temperature was the most effective factor on species composition ($P < 0.01$). Results suggest that type of reproductive modes did not show significant relationship with species distribution among different water bodies. Hence, it seems distribution of species is most probably affected by several biotic and abiotic factors.
Keywords: *non-marine species, distribution, natural-artificial habitats, altitudes, swimming ability*

Introduction

Although, freshwater habitats occupy only small parts of the Earth's surface with a ratio of 0.8%, they host approximately 6% of species known in the world (Dudgeon et al., 2006). In this respect, freshwaters are considered to be one of the main sources of biological diversity on the Earth. However, these habitats are known to be affected at global (e.g. climate changes) and local (e.g. species invasion, habitat degradation, water pollution) scales by a variety of biotic and abiotic factors (Dudgeon et al., 2006). Thus, different kinds of habitat destruction lead to changes in species composition, their geographic distribution, and also cause a decrease in species diversity (Finlayson et al., 2013). However, some features of the organisms including (i) morphological characteristics (e.g., to occupy different ecological niches with different movement types (Wiens, 2011), (ii) phenotypic plasticity (e.g., fitting ability of the size and shape

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14711487

as a response to the changes in environmental conditions (Carbonel et al., 1988)), (iii) biological characteristics (e.g., to tolerate rapid or great environmental changes with different reproductive modes (Cohuo et al., 2015)), and (iv) ecological characteristics (e.g., to endure unpredictable environmental conditions with high ecological tolerance levels (Külköylüoğlu, 2004)) allow species to cope with the changes and elevate their survival chances in a variety of habitats. These biological and ecological features of the species also determine the degree of their distribution and abundance at spatiotemporal scale in relation to habitat conditions (Heino and Tolonen, 2018).

Ostracods, small bivalved crustaceans, are an important part of biological diversity in freshwater habitats with approximately 2330 extant species (Meisch et al., 2019). They can be fossilized due to their carapace (two valves) which consists of low Mg-calcite. The first record of fossil ostracods dates back to Early Ordovician (ca. 485 Ma), and thus ostracods are known as one of the oldest groups in microfauna (Williams et al., 2008). Besides, they have different reproductive modes of sexual, parthenogenetic (asexual) and/or mixed populations, and exhibit specific ecological requirements and species-specific tolerance levels. The different types of reproductive modes of the ostracods can be related to taxonomic and ecological features of particular species (Gülen, 1985a; Cohen and Morin, 1990; Martens et al., 2008) and may depend on geographical and/or ecological isolation (Mayr and Ashlock, 1991). All these features contribute to their widespread geographic distribution and high species diversity and also make them a particularly valuable group for a number of purposes in palaeo- and neoenvironmental studies. If the ostracod species' morphological features and ecological preferences are known, they can be used to estimate water quality conditions and rate of environmental changes (Wagner, 1964; Mezquita et al., 1999; Külköylüoğlu, 2004). In addition, the knowledge of the present-day distributional patterns of ostracods according to their reproductive modes in different region and/or environmental conditions can also be used as an informative marker for non-marine ostracods in the ecological sense.

Studies on ostracods in Turkey exhibited that distribution of both parthenogenetic and sexual populations were widespread throughout the country (Külköylüoğlu et al., 2015; Yavuzatmaca et al., 2017). Nevertheless, the distributional pattern and habitat preferences of species according to their reproductive modes have not been discussed and explained the Muğla province in the south-western part of Anatolia. Therefore, the main aim of the study is to investigate ecological preferences and distribution of species with different reproductive modes among the different aquatic bodies of the region.

Materials and methods

Site description

The province of Muğla, which is located on the south-west corner of Turkey, was chosen as a research area because of the possibility to find a variety of aquatic habitats and the lack of extensive studies on ostracods in this area. It represents typical Mediterranean climatic conditions where summers are very hot, long and dry, winters are cool and rainy. In total, 68 sites containing 11 habitat types (lake, reservoir, pond, pool, ditch, canal, creek, stream, spring water, trough, and waterfall) were randomly chosen from sea level to 1093 m of altitude between the 12 and 15 of July 2014 (*Fig. 1*).

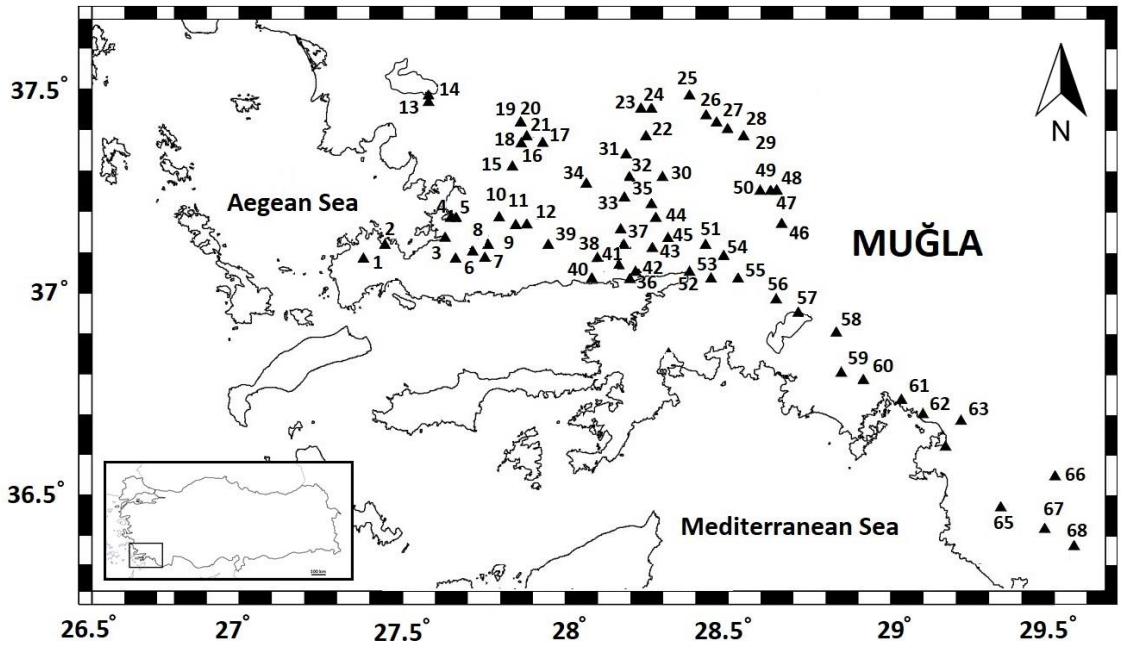

Figure 1. *Distribution of the 68 sampling sites in the Muğla province*

Sampling and measurements

Ostracod samples were collected with a standard sized hand net (200 µm mesh size) from the surface of sediments within an area of approximately 100 cm^2 and a depth of up to 100 cm. At each site, approximately 100 g of sediments were gathered and fixed with 70% ethanol in 250 ml plastic containers *in situ*. In the laboratory, sediments including ostracods were washed and filtered through 4 standard sized sieves (1.00, 0.25, 0.16, 0.08 mm mesh size) under tap water and fixed in 70% ethanol for long term storage. Ostracod samples were sorted from sediments by using fine needles and Pasteur pipettes under a stereo microscope (Meiji-Techno). Soft body parts of ostracods were separated from the carapace and dissected in Lactophenol – Orange G solution. The carapace and valves were preserved in micropaleontological slides. Subsequently, species identification was carried out under a binocular microscope (Olympus-CX41) based on the dissected soft body parts and carapace structures by using the standard taxonomic works of Broodbaker and Danielopol (1982), Gonzalez Mozo et al. (1996), Meisch (2000) and Karanovic (2012). However, some species were identified at the genus-level because of damaged individuals, lack of soft body parts or only the presence of juveniles.

Environmental variables were measured *in situ* before sampling to avoid possible results of Pseudoreplication (Hurlbert, 1984). Dissolved oxygen (DO, mg L^{-1}), oxygen saturation (S, %), electrical conductivity (EC, µS cm^{-1}), water temperature (Tw, °C), salinity (Sal, ppt) and total dissolved solids (TDS, mg L^{-1}) of aquatic habitats were measured with a YSI professional plus device (*Table A1* in the *Appendix*). Geographical data (latitude, longitude, elevation) from each sampling site were determined with a Garmin GPS 45 XL (*Fig. 1*) while air temperature (Ta, °C), moisture (Moi, %), wind (m s^{-1}) and atmospheric pressure (Atm, mmHg) were measured with a Testo 410-2 anemometer (*Table A1* in the *Appendix*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14711487

A 100 ml of water was taken from each sampling site in plastic bottles and preserved in a container at 4 °C for the analyses of cations (sodium (Na^{+1}), potassium (K^{+1}), magnesium (Mg^{+2}), calcium (Ca^{+2})), and anions (fluoride (F^{-1}), chloride (Cl^{-1}), sulphate (SO_4^{-2})). Analyses of these major ions were conducted in the laboratory of the Engineering Department of Bolu Abant İzzet Baysal University. The standard method no: 4110 using Ion Chromatography (Dionex 1100) was followed during the analyses. Also, sediment samples were collected from each site in eppendorf tubes for in/organic phosphate and total phosphate (mg kg^{-1}) analyses. In the laboratory, sediment samples were dried in oven at 40 °C (at least 24 h) and were subsequently analyzed according to Ruban et al. (1999) with a sequential extraction procedure (*Table A1* in the *Appendix*).

Statistical analyses

A Detrended Correspondence Analysis (DCA) was applied to confirm the suitability of the data for Canonical Correspondence Analysis (CCA) (ter Braak, 1986). The length of gradient in DCA was calculated as 3.64 referring the suitability of our data for CCA. CCA was performed to estimate most effective environmental variable(s) on species composition by using the CANOCO version 5 program (ter Braak and Šmilauer, 2012). The significance of the environmental variables used in CCA was tested by Monte Carlo permutation test (499 permutations). To eliminate possible multicollinearity, rare species were not used during the analyses. Shannon-Wiener (or Shannon, H') index values were calculated by using a Species Diversity and Richness 4 software (Seaby and Henderson, 2006) to determine the species diversity in different habitat types where the values of H' (1.5 and 3.5) for ecological data suggest poor to rich diversity, respectively. In order to understand possible correlations among species and environmental variables measured here, Spearman Correlation Analyses were conducted in the SPSS program version 6.0. The C2 Software was used to measure ecological tolerance (t_k) and optimum (u_k) estimates of individual species along with Hill's coefficient (measure of effective number of occurrences) (Juggins, 2003). The chi-square test was used to determine whether there was a significant difference between the numbers/abundances of species in sexual and parthenogenetic populations with or without swimming setae in natural and artificial habitats. During the analyses, only adult individuals, occurred at least three or more times in different habitats, were used. The ostracod materials were deposited at the Limnology Laboratory of the Department of Biology, Bolu Abant İzzet Baysal University, Bolu, Turkey. Additional information about the sampling sites and species reported here can be available upon request from the authors.

Results

During this study, a total of 28 taxa (24 living and 4 sub-fossil) were reported among 11 habitat types while 11 of the living species (*Candona weltneri*, *Psychrodromus fontinalis*, *Heterocypris barbara*, *Ilyocypris gibba*, *I. hartmanni*, *Limnocythere inopinata*, *Potamocypris arcuata*, *P. producta*, *P. unicaudata*, *P. villosa* and *Trajancypris leavis*) were new for Muğla. The sexual population of *P. fontinalis* was found for the first time, while *P. producta* was recorded for the second time in Turkey.

The first two axes of the CCA explained about 66.2% of the relationship between 12 species and 5 environmental variables (F = 2.9, P = 0.04) (*Table 1*). According to CCA,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14711487

the water temperature ($P = 0.008$, F = 1.8) showed a significant effect on the ordination of species (*Fig. 2*). Except *L. inopinata,* four species (*C. neglecta, I. bradyi* and *P. olivaceus, P. fontinalis)* without (reduced or short) swimming setae on A2 were located on the left side of the CCA diagram, while species with swimming setae were situated on the right side of the diagram. However, one of the species with reduced swimming setae, *Cyprideis torosa,* was placed separately from other species on the CCA diagram (*Fig. 2*).

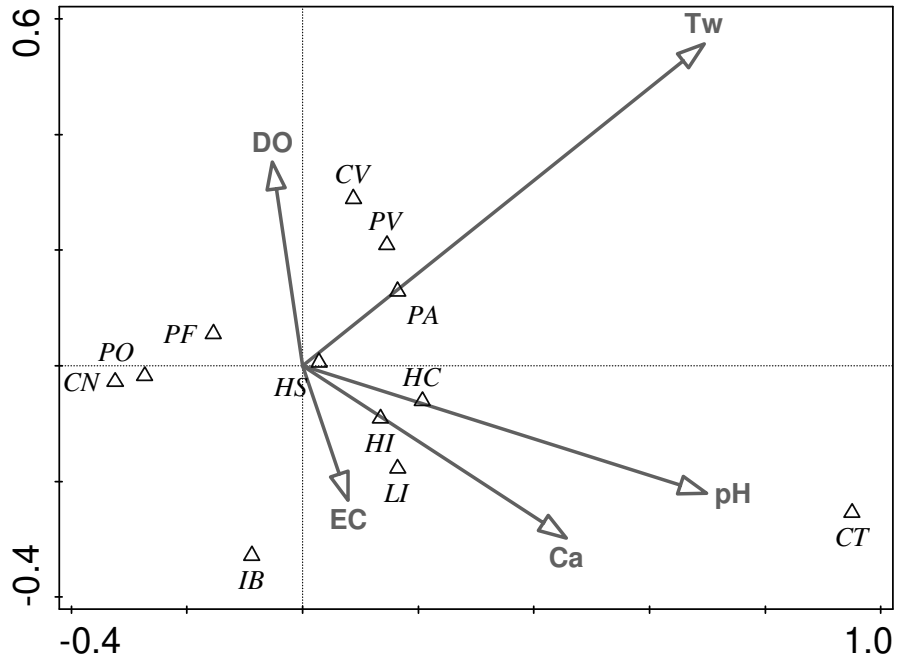

Figure 2. *CCA diagram of five environmental variables (arrows) and 12 species (triangle). Abbreviations are given in Tables 4 and A1 in the Appendix*

According to the results of Spearman Correlation Analyses, *H. salina* showed negatively significant correlations with *P. olivaceus* and *P. fontinalis* while the correlation was positive with *I. bradyi* ($P < 0.01$). *P. fontinalis* exhibited a negative correlation with *L. inopinata* ($P < 0.01$). Among the species, *C. torosa* indicated strong

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14711487

and significant positive correlations with Ca^{+2} and Mg^{+2} values of the water bodies, when *P. variegata* showed negative correlation to Ca^{+2} and electrical conductivity ($P < 0.01$). *Potamocypris variegata* displayed low ecological tolerance values for dissolved oxygen, electrical conductivity, Na^{+}, Mg^{+2}, and Ca^{+2} when *C. torosa* showed the highest tolerances for total phosphates in the sediment, and several other major ions of the water bodies. Also, *I. bradyi* had the lowest tolerance levels for pH but the highest tolerances for conductivity and water temperature. *Heterocypris salina* displayed the highest tolerance levels for dissolved oxygen and pH (for more details see *Table 2*).

Abbreviations: Count, numbers of species occurrence; Max, maximum numbers of individuals; N2, Hill's coefficient (measure of effective number of occurrences); u_k, optimum values; t_k, ecological tolerance values. See *Tables 4* and *A1* in the *Appendix* for the other abbreviations

Numbers of species with (17 spp.) and without (20 spp.) swimming setae on A2 were not significantly different ($P > 0.05$) between artificial (e.g., trough, reservoir, canal etc.) and natural (e.g., lake, spring, creek etc.) habitats (*Table 3*). Among the species, 13 species were commonly found in both natural and artificial habitats. Parthenogenetic populations herein were encountered from all of the habitat types, while only five sexual populations (*Candona neglecta, C. weltneri, N. monacha, P. olivaceus* and *P. fontinalis*) were obtained from four natural habitats (spring water, pool, ditch, waterfall), and one artificial habitat (trough). A total of 17 species were represented with parthenogenetic populations but bisexual populations of two (*P. olivaceus* and *P. fontinalis*) of them were also reported in artificial habitats. 12 of 17 species carried swimming setae when five species had reduced setae. All of the obtained specimens of *Potamocypris* spp. have long swimming setae and three of them (*P. producta, P. unicaudata* and *P. villosa*) were reported only from the artificial habitats (troughs) with an accompanying swimming species (*Heterocypris barbara*). In contrast, 4 sexual and 17 parthenogenetic species were encountered in natural habitats. Among them, 11 and 9 species were with and without swimming setae, respectively. The species *C. neglecta, C. weltneri, C. torosa,* and *P. zenkeri* are non-swimmers while *I. decipiens, N. monacho* and *T. leavis* are known as swimmers established solely in natural habitats (*Table 3*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14711487

Table 3. *Species occurrences based on their swimming ability and types of reproduction in artificial and natural habitats. Note that sexual and parthenogenetic populations of P. olivaceus, also parthenogenetic populations of P. fontinalis were found in artificial and natural habitats. On the other hand, sexual population of P. fontinalis was found in only artificial habitats. This situation was taken into consideration for total numbers of species*

		Artificial habitat	**Natural habitat**	**Total**
Sexual species	Without swimming setae	2	3	4
	With swimming setae	-	1	1
Parthenogenetic species	Without swimming setae	5	7	7
	With swimming setae	12	10	14
	Numbers of species	17	20	24
	Numbers of individuals	2388	2081	4469

According to Shannon-Wiener index results, among the habitat types, troughs were shown as the richest habitats with regards to species diversity (up to 14 spp.) (*Table 4*) and numbers of individuals (2147 of 4469 ind.). On the other hand, numbers of species per site (ca. 0.54) were almost the lowest in troughs in comparison to the other habitats. In addition, although the number of troughs (26) was significantly higher than the creeks (12) and ponds (9), Shannon-Wiener (H') values for troughs (H' = 2.34), creeks (H' = 2.33) and ponds (H' = 2.11) were very close to each other (*Table 4*). H' values of the other habitats were relatively low and close to or less than 1.5 degree, which implies to be poor in diversity.

Although sexual populations of *P. olivaceus* and *P. fontinalis* are less-known in the literature, sexual population of them were found herein from a trough (Site 37) but individual populations of both species with different reproductive modes were also found from other habitats (*Table 5*). The dominance of females against males (female-biased sex ratio) was especially remarkable at low altitudes (Sites 15, 16, 33) while the ratio was almost equal at medium altitudes (*Table 5*).

Discussion

Along with the 28 ostracod taxa herein, the number of recent freshwater ostracod species of the Muğla province is now increased to 49 with the addition of previous reports (e.g. Gülen, 1985a; Aygen et al., 2004).

According to CCA and Spearman correlation analyses, the water temperature was the most effective factor on species occurrences and composition (*Fig. 2*). Especially, the ecological tolerance and optimum values of the commonly occurring species were found relatively higher than the other species. For example, common occurrences of *P. olivaceus* in many aquatic habitats (with 15 independent occurrences) agree with the literature (Meisch, 2000) that pinpointed the relatively high ecological tolerance levels of this species for many ecological variables. Also, Külköylüoğlu and Yılmaz (2006) suggested that *P. olivaceus* have a broader geographical distribution as long as habitat conditions are suitable.

In the present study, there was no statistical difference between the population density or the number of species in the natural or the artificial habitats. On the other hand, while the number of the swimming and non-swimming species were close to each other in the natural habitats with 11 and 10 spp., respectively, the number of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14711487

swimming species (12 spp.) was higher than the numbers of non-swimmers (7 spp.) in the artificial habitats (*Table 3*). Species in such habitats can alter their location faster in active way (using swimming setae) than passive one due to unpredictable ecological conditions of artificial habitats (e.g., troughs). Thus, such ability of active movement may increase their survival chances by finding new location. Along with these movement abilities, the importance of ecological fitting abilities of species and habitat suitability should not be ignored for the survival success of species in different niches or wider range of habitats.

Among habitats, troughs are generally located in/near villages to provide water for drinking, cleaning and/or irrigation purposes and they are used as microhabitats by ostracods (Külköylüoğlu et al., 2013). Such kind of artificial habitats (e.g., troughs) can open new possibilities for other species, although the establishment of troughs from natural sources can cause irreversible changes in species diversity and habitats. Because, waters of troughs come from underground sources, springs and/or surface waters, and these connections with those of natural habitats may influence species diversity (Külköylüoğlu et al., 2013). Except these water connections, different transportation vectors (e.g., air, insect, fish, birds, humans) may enrich species diversity

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14711487

since ostracods can be distributed passively between different aquatic habitats by such kind of vectors (Mezquita et al., 1999). All of these explain the high Shannon-Wiener index value of troughs among habitats.

Potamocypris producta was commonly found in Africa (see e.g., Sars, 1924; Martens, 1984) but it was also reported from Europe (Macedonia, Petkovski, 1964), Japan (Okubo, 1976), and Turkey. Males of the species were only reported from South Africa by Sars (1924). 48 female individuals of *P. producta* in a trough along with *P. olivaceus* and *H. Barbara* were found. This record of *P. producta* herein makes an important contribution to the distribution and ecological preferences of species. This indicates that the species can also be found in artificial habitats.

The occurrence of parthenogenetic and sexual populations of *P. olivaceus* and *P. fontinalis* in troughs (*Table 5*) contribute to the knowledge of the habitat preferences of these species with different reproduction modes. This situation probably signals to a passive dispersal of them by subaquatic/nearby springs or underground waters, since these two species are known to prefer spring waters, flowing waters and pond fed by springs (Meisch, 2000). Fox (1965) claimed that males of *P. fontinalis* were found in northern Italy but later, Baltanás et al. (1993) stated that these specimens belong to another species, *P. betharrami,* collected from a subterranean stream in the Cave of Betharram (France). Sexual populations of *P. fontinalis* were described for the first time

DOI: http://dx.doi.org/10.15666/aeer/1801_14711487

in Macedonia by Petkovski and Meisch (1995). Until now, there is no any report of the sexual populations of these species from Turkey. Therefore, the sexual population of *P. fontinalis* herein is the first report from Turkey. However, males of *P. olivaceus* are already known from different countries of Europe (Petkovski, 1959, 1966; Järvekülg, 1959; Petkovski and Meisch, 1995). In Turkey, the male of *P. olivaceus* was found for the first time by Gülen (1985b) in the Lake Karamık (Afyon) and followed by other studies (Külköylüoğlu and Yılmaz, 2006; Rasouli et al., 2014; Külköylüoğlu et al., 2015; the present study).

Among these records, similar distribution patterns of *P. producta* and *P. fontinalis* were recorded from Macedonia and Turkey, and this may be explained with different passive dispersion ways. For instance, it is well known that Anatolia is an important migration route and works as a bridge between the Balkans and Africa for some migratory birds (Deinet et al., 2013). Ostracods can attach to the external surface of the birds, and so they are transported passively among the different geographic regions. Additionally, the record of *P. producta* from Japan is an interesting finding and might signal a human-mediated dispersal. Considering that the success of the species transported is related to the habitat suitability, and the ecological and biological features of the species, these records show the fitting ability under suitable environmental conditions of these two species.

Although troughs have relatively high ostracod diversity, the numbers of species per trough is not the highest among habitats (*Table 4*). Comparing to other sites, this situation may be explained with more samplings from these artificial habitats. However, another interesting point here is that although the number of individuals in troughs was prominently high, most of the individuals (1111 of 2147) collected from troughs belonged to two well-known cosmopolitan species (*H. incongruens* and *H. salina*). Moreover, finding at least two other species (e.g., *P. olivaceus, Potamocypris unicaudata)* with high densities in these habitats suggests that such artificial habitats can provide some chance of survival mainly for species with relatively high ecological tolerance ranges. Actually, troughs are routinely cleaned out and emptied by local people. Eventually, such process can cause a huge impact on the populations. In such case, ostracods may leave their desiccation resistant eggs until troughs are filled by water again. It means that the species with their cosmopolitan features as well as their adaptive values to harsh environmental conditions can easily colonize in the troughs. If troughs are accepted as newly development habitat after habitat degradation, in the case of recolonization, high ostracod richness and strong dominance of cosmopolitan species in troughs are inevitable. Therefore, this situation indicates the “primer succession” of species with high ecological tolerance levels as transitional and/or opportunistic populations. Additionally, most of the species found from troughs were parthenogens, even though some species were represented with sexual populations in a trough. A similar case observed in a newly developed spring in Turkey (Külköylüoğlu, 2009) supports this previous statement. The dominance of the parthenogens in following colonization may be the sign of the transition to stability or predictability in the environmental conditions, because it is known that if environmental deterioration continues as a result of stochastic and drastic changes, such kind of habitats can be established by sexual populations (Hewitt, 1999; Horne and Martens, 1999). Thus, it can be argued that the different reproduction modes of species can be effective as well as their relatively wide ecological tolerance levels for the initial colonization of the habitats.

As seen in *Table 5,* sexual populations of *P. olivaceus* and *P. fontinalis* co-occurred in a trough (St. 37) and there is a difference in the sex ratio of the individuals of both species. Generally, one of the reasons of female-biased sex ratio can be explained by the presence of the females of species with both reproductive modes from the same sampling site. On the other hand, although it is not the scope of this study, some genetic factors can play a role such as the greater longevity of females that lead to the skewed sex ratio in the population (Butlin et al., 1998). Thus, the possible reasons of the skewed sex ratio can be better understood by means of genetic data to determine the proportion of the fully sexual and parthenogenetic females.

In contrast to Gülen (1985b) who reported the sex ratio of *P. olivaceus* as about 1/2 favoring males (16 females and 33 males), the ratio in our study was almost about 1/8 favoring the females. The dominance of females against males (female-biased sex ratio) was especially remarkable at low altitudes (e.g., cf. stations 15, 16, 33) where the population densities were high. However, both the numbers of female and male became close to each other, and population densities were low at medium altitude (st. 37, 1093 m). In addition, the first record of the sexual forms of *P. olivaceus* was given by Petkovski (1959) from the moderately medium altitudes (1300 m) to high altitudes (ca. 2200 m) favoring the females. In the present study, a sexual population of *P. olivaceus* was found from two spring waters and one trough located at different altitudes that put into the previously known altitudinal ranges. Unlike *P. olivaceus*, the sexual populations of *P. fontinalis* were only found from a trough at 1093 m in Muğla. Males of *P. fontinalis* were also known from a small mountain spring water at 1600 m a.s.l (Petkovski and Meisch, 1995). The ranges of altitude (312-1262 m, Külköylüoğlu et al., (2012b) where species occur in literature reinforce the statement of Külköylüoğlu et al. (2012a) as parthenogenetic populations of *P. fontinalis* had the highest tolerance values for altitude. Similarly, parthenogenetic populations of *P. fontinalis* were found at various altitudes ranging from 114 m to 1093 m a.s.l. in the present study.

Parthenogenetic populations of the species were found from sea level to 1093 m, while sexual populations were obtained in a limited number of habitats located between 327 and 1093 m a.s.l. Külköylüoğlu et al. (2012b) showed no relationship between occurrence of sexual and parthenogenetic forms at different altitudes, although Peck et al. (1998) suggested that population densities of parthenogens exhibited the tendency to occur in northern areas at high altitudes.

According to the hypotheses of the distributional patterns of ostracods in terms of reproduction modes, both circum-Mediterranean shelters staying after the Pleistocene glaciation, and the fluctuating environmental conditions of the early Holocene, persisted some sexual populations in southern regions (i.e., post glacial invasion/re-colonization hypothesis). The following Holocene climatic stability provided more common dispersion and increase of frequencies of the parthenogens (Holocene stability hypothesis) (Horne and Martens, 1999). Similarly (but not in the same way), during this glaciation period, Anatolia played a critical role for the survival of both sexual and parthenogens providing opportunity to recolonize species in the other regions (Gülen, 1985a; Hewitt, 1999; Külköylüoğlu et al., 2012b). Additionally, as stated above, since Anatolia is an important route for the migration of birds, the ostracods species can be transported via passive dispersion from different regions to Anatolia. Then, other factors, such as different climatic conditions, latitudes in Anatolia, allow the colonization of the species in new locations. Thus, finding the males of *P. fontinalis*

DOI: http://dx.doi.org/10.15666/aeer/1801_14711487

along with *P. olivaceus* supports the idea that "there are so many sexual populations in Turkey" (Külköylüoğlu et al., 2012b).

Conclusion

Overall, along with ecological preferences and tolerance levels of the species, if it is created the distributional patterns of ostracods according to their reproductive modes, ostracods can be used as an informative marker for monitoring environmental changes for the neo-studies. On the other hand, to know (i) how species diversity is affected when species faced with changes in habitat degradation, (ii) which species are the first members of the new colonization or (iii) that there is any remarkable alteration favoring the parthenogens or sexual in time after the dramatic environmental changes provides useful information for invisible environmental shifts (e.g. volcanic eruptions, drought) in the palaeo-studies. Due to short sampling time, our results, however, cannot be generalized at the moment but they support the idea that parthenogenetic species (and populations as well) clearly show a much wider geographical distribution than their sexual counterparts. Therefore, different factors and/or combination of them that affect this distribution (ecological, historical, and biological) should be investigated comprehensively.

(Received 23rd Sep 2019; accepted 8th Jan 2020)

Abstract. The paper presents the characteristics of slaughter efficiency and chemical composition of carcasses, the course of spermatogenesis processes as well as epizootic and epidemiological threats of male mallard ducks (*Anas platyrhynchos* L.). Tests and analyses carried out indicate a high slaughter output of 64.5% and a decrease in body weight during the winter months and the subsequent turning period. Muscles of male crosses were characterized by high protein content (23.54-23.58%) and low fat content (0.65-0.84%). In addition, a high level of unsaturated fatty acids, including those in the C 20 group, and a favorable UFA to SFA ratio of 1.5 were found. Organoleptic and bacteriological evaluation showed the presence of intestinal parasites of the *Hymenolepididae* family and muscle parasites of the *Sarcocystis* genus, as well as *E. coli* and *Staphylococcus aureus*, which were mostly resistant to the antibiotics used. The assessment of the advancement of the spermatogenesis process during the reproductive season showed the correct development of reproductive capacity in drakes. In addition, it has been shown that fully developed sperm capable of fertilization is produced at the turn of March and April, despite the fact that pairing occurs much earlier. The described composition of fatty acids indicates high pro-health values of mallard meat. At the same time, the parasites and bacteria found indicate that mallard duck meat may pose a risk to human health, and therefore carcasses must be tested before being intended for consumption.
Keywords: *mallard duck, body mass, venision, slaughter efficiency, natural selection, bacterial diseases, Lublin Upland*

Introduction

Mallard duck (*Anas platyrhynchos* L.) is one of the most common species of wild duck in many European, Asian and North American countries. They are also the ancestor of most domestic duck breeds. Can also be found in Australia and New Zealand (Tracey et al., 2008; Söderquist, 2012). In the United States, breeding crosses settled hunting grounds for hunting (Smith and Rohwer, 1997). In Poland, the mallard is the most huntable species among the four huntable of wild ducks that can be hunted and has been one of the most important game birds for many years. Despite the continuing downward trend over the past decade, approximately 100,000 wild ducks are acquired annually, of which around 95% are mallards (Książkiewicz, 2006; List of hunting reporting data, 2018). As the reason for the decline in the population, the most frequently mentioned are transformations in aquatic ecosystems and the related reproduction processes of these birds. Therefore, an important element of knowledge about the population is to learn the principles of natural selection during the mating

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14891507

season and the timeliness of its course. It is also important to learn about male spermatogenesis processes, which directly affect breeding success, and thus natural growth. Although climate change and improvement of habitat conditions affect the increase of duck weight and survival in winter, it is not known whether these changes cannot have a negative effect on the spermatogenesis process and reproduction rates of mallard ducks (Guillemain et al., 2010). Guillemain et al. (2013) reported that climate change may have an impact on the course of many population processes such as: migration distance, mortality rates as well as reproductive distribution and success. In addition, climate change significantly affects the shift towards the north of the optimal winter refuges, as well as earlier migrations to the southern areas. Climate change also leads to the impoverishment of habitat and hence breeding areas. Consequently, the described elements may affect the course of reproductive processes as well as the raising of chicks, and thus the complete reproductive success (Gaston et al., 2009).

Hunting is one of the areas of social activity that is quite important in terms of culture and recreation. In addition, they allow the regulation of the size of individual populations on the principles of sustainable development. By hunting, it is possible to regulate the population structures of individual species that affect reproduction and survival rates, while optimizing the functioning of the population (Borman and Mattson, 2012). Not without significance is the fact that high-quality meat is provided, commonly referred to as venison, which is characterized by both taste and health benefits. Despite the fact that the global production of poultry meat shows an upward trend, many consumers are looking for an alternative in terms of meat quality, hence there is an increasing interest in meat from wild animals, in particular from wild game (Hoffman and Wiklund, 2006; Górecka and Szmańko, 2010; Nuernberg et al., 2011; Siminska et al., 2011; Kasprzyk, 2013; Ljung et al., 2015; Żmijewski et al., 2018; Flis et al., 2019).

On average in Europe, in total meat production, venison accounts for a small percentage of 0.2-0.4% (Siminska et al., 2011; Popczyk, 2012). According to research carried out in Sweden, venison consumption also depends on the social perception of hunting in a given region and is characterized by quite considerable variation. Nevertheless, only 2% of the total consumption of this type of meat comes from sales in shops, while the remaining consumption is conditioned by the fact of hunting or the purchase of it is related to social networks (Ljung et al., 2015).

Among game meat from game birds, pheasant meat definitely prevails, which has very high taste and dietary values (Kuźniacka et al., 2007; Biesiada-Drzazga et al., 2011; Kokoszyński et al., 2014; Flis et al., 2019), nevertheless meat from mallard ducks is most often considered a culinary delicacy, but it is most often consumed in hunters' environment. This is conditioned by its periodic supply related to the hunting season, as well as the limited accessibility resulting from meat trade regulations, and thus the lack of companies distributing this type of game (Bertolini et al., 2005; Nuernberg et al., 2011; Popczyk, 2012; Janiszewski et al., 2018).

In the nutritional aspect, a fairly important element is the fatty acid profile, in particular the share of polyunsaturated acids. Meat from wild birds is usually characterized by an increased share of these acids, mainly omega-3, which is why it is referred to as dietary and health-promoting. The taste characteristics, high digestibility and quality of meat deserve emphasis, which is also largely determined by the content of polyunsaturated acids - n-3 and n-6 PUFA in an appropriate proportion (Mishra et al., 1993; Cobos et al., 2000; Janiszewski et al., 2018; Flis et al., 2019). In addition, meat

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14891507

from wild ducks is a valuable source of iron, zinc, copper and manganese (Lorenzo et al., 2011).

At the same time, one of the consumers' concerns about the possibility of consuming venison is the fact related to the common opinion about the possibility of contracting diseases (Nagalska and Rejman, 2014; Kwiecińska et al., 2016). Avian influenza is mentioned as the most dangerous in the mallard, which is a migratory species (Gunnarsson et al., 2012; Wille et al., 2018), however, other viral or bacterial diseases and quite often parasitic diseases, as well as mycoses are also found (Betlejewska et al., 2002; Żbikowski et al., 2006; Haščík et al., 2010; Dynowska et al., 2013; Flis and Grela, 2018).

Despite the fact that when consuming meat derived from carcasses of small animals, as a rule no research is carried out in terms of epidemiological risk, organoleptic assessment of carcasses and internal organs is carried out during post-mortem inspection and preparation of meat for consumption.

The aim of the study was to evaluate the composition of the carcasses, their slaughter performance and the chemical composition of the pectoral muscles in the aspect of healthy properties of wild duck meat. In addition, bacteriological and macroscopic evaluation (presence of sarcocysts) of carcasses was aimed at determining a possible threat to human health. The aim was also to assess the correct development of male reproduction capacity of male mallard ducks during the breeding period in terms of climate change.

Materials and metods

Material

The materials for work were male mallard ducks obtained by hunting, in accordance with applicable law in the hunting season in Poland, from October to December 2017 years. In addition, with the consent of the Minister of the Environment (decision DL-III.6713.21.2017.JC), five drakes were shot per month in the period from January to April 2018 years, i.e. during the protection period, in order to determine possible changes in the winter and spring, when the birds are exposed to increased pressure of environmental factors, and furthermore a leking site is taking place. Thus, seven periods of one month were identified in which the material for research was obtained. In total, 35 subjects constituted the research material. Male mallard ducks were shot in water reservoirs (fish ponds, small ponds and rivers) in the south-western part of the Lublin region (*Figure 1*).

Preparation of tests

In each case, after obtaining the birds, they were cooled down. Then, after being transported to the laboratory, each of them was weighed. The next weighing was performed after decapitation of the head. The next step was to nibble and weigh the carcass without feathers and lower legs. Then the birds were gutted and weighed again. Weighing also included edible intestines (heart, liver and muscle stomach after cleansing of gastrointestinal content). Each weighing was carried out on a laboratory scale with an accuracy of 1 gram. The entrails were stored in a refrigerator at 4°C for 24 hours, after which they were sent for bacteriological and parasitological tests.

Figure 1. *Location of the research area*

Then the pectoral muscle (*m. pectoralis*) of the birds was prepared, minced and stored one day at 4°C, after which the crude fat content was determined according to the method of Folch et al. (1957). The fatty acid profile was determined by gas chromatography in the obtained fat. Fatty acid methyl esters were determined in a Varian CP 3800 gas chromatograph under the following assay conditions: CP WAX 52CB DF 0.25 UM capillary column, 100 m long, carrier gas - helium, flow - 1.4 ml/min, column operating temperature - 120ºC with a gradual increase of 2ºC/min. up to 210ºC, determination time - 157 min, dispenser temperature - 160ºC, detector temperature - 160ºC, supporting gases - hydrogen and air.

Also after evisceration, the testicles were dissected, which were stored in string bags for a period of 24 hours also at 4ºC, after which they were transferred to laboratory tests covering the course of spermatogenesis processes.

Organoleptical, bacteriological research

The macroscopic evaluation included the examination of each bird directly after shooting, plucking the carcass and skinning it. Its purpose was to capture possible lesions or occurrence of parasites.

Various multiplication and differentiation media were used to identify individual microbial species. The solid medium was agar with the addition of 5% sheep blood to multiply aerobic microorganisms and possibly determine hemolysis. As a liquid medium, sugar broth was used to propagate aerobic bacteria. Other media, including Chapman, MacConkey, and Sabouard media were also used to identify possibly occurring organ mycoses. The cetrymid medium for the identification of Pseudomonas microorganisms and the D-coccosel medium for the identification of fecal bacteria were also used for the tests. Further identification of individual types of bacteria was carried out using bioMerieux API (Analytical Profile Index) biochemical tests. Media fertility control was carried out using standard strains. After determining the bacterial strain, the growth rate of bacterial flora was assessed using the criteria of fairly low (+), intesive

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14891507

(++) and very intensive (+++). An analysis of the sensitivity of isolated bacterial strains to 7 commonly used antibiotics was also carried out. The analysis was performed using the diffusion-disk method (Kirby-Bauer) based on the diffusion of the antibiotic in the disk into the medium using the created concentration gradient. Based on the size of the bacterial inhibition zone, its sensitivity to a given antibiotic is determined by defining it as sensitive, moderately sensitive and resistant (Borowska et al., 2014). The sensitivity scale was determined on the basis of the tables of the "European Committee on Antimicrobial Susceptibility Testing" (EUCAST).

The following antibiotics were used for the analyzes in doses: Doxycycline DO30 - 30µg, Amoxycilin AML25/AX25 - 25µg, Ampicillin AMP10/AM10 - 10µg, Amoxicillin/clavulanic acid Synulox AMC30 - 30µg, Lincomycin/Spectinomycin LS109 - 5µg, Colistin CT50 - 50µg.

Spermatogenesis process

The prepared nuclei were weighed on a laboratory scale with an accuracy of 0.001 gram. Then microscopic preparations were made. The epididymis and testes were incised with a scalpel, followed by several imprint preparations on microscope slides. The preparations were dried, fixed and stained by several methods to obtain the best-quality microscopic image. The best preparations were obtained using the Hemacolor rapid staining method (Merck KGaA, Darmstadt, Germany). After preparation, the slides were evaluated on an Olympus CX4 light microscope with an attached Bassler A312 camera (Olympus Corporation, Japan) at 1000-fold magnification, under immersion. The image from the camera was read on a computer monitor, which facilitated the work and significantly improved the accuracy of the examination and allowed documentation of the preparations.

Statistical analysis

To determine the differences between the average values of the analyzed slaughter performance traits and testicles weight analyzed, between test periods, a one-way analysis of variance was performed. Considering equal sample sizes (n = 5/period), in order to verify the possible occurrence of differences between the means, calculations were made using the Newman Keuls test in Statistica 10.0. The impact of the study period was considered significant at a significance level of $P \leq 0.05$. The value and significance of correlation coefficients between the weight of internal organs and the body weight and weight of duck carcasses were also calculated.

Results

Body weight and characteristics of carcasses

During the study period, despite slight fluctuations, weight loss occurred (*Table 1*). Between October and April this decrease was 10.3% (y =-25.643x+1316.9). This indicates a high impact of environmental factors on the body weight of birds, which is confirmed by the value of the determination coefficient of $R^2 = 0.7303$. The average weight of drakes during the study period was 1214.3 grams. The carcass weight decrease was slightly larger and amounted to 11.4% (y =-19.771x+865.03), which indicates the utilization of fat reserves in the winter period. The average carcass weight was 785.9 grams.

a, b, c - means denoted by the same letter between individual study periods do not differ statistically significantly ($p \leq 0.05$)

In the analyzed period, slaughter performance was at an average level of 64.5% with a differentiation from 60.4 to 69.1% in individual study periods. In terms of body weight, the heart was 1.0%, the liver 2.1% and the muscle stomach 2.9%. The remaining part (29%) were inedible guts (*Figure 2*). A statistically significant relationship between the mass of internal organs (heart, liver, stomach) and the body weight of birds was shown (*Table 2*). The relationship between the mass of organs described and the carcass weight was significant only for the heart and stomach.

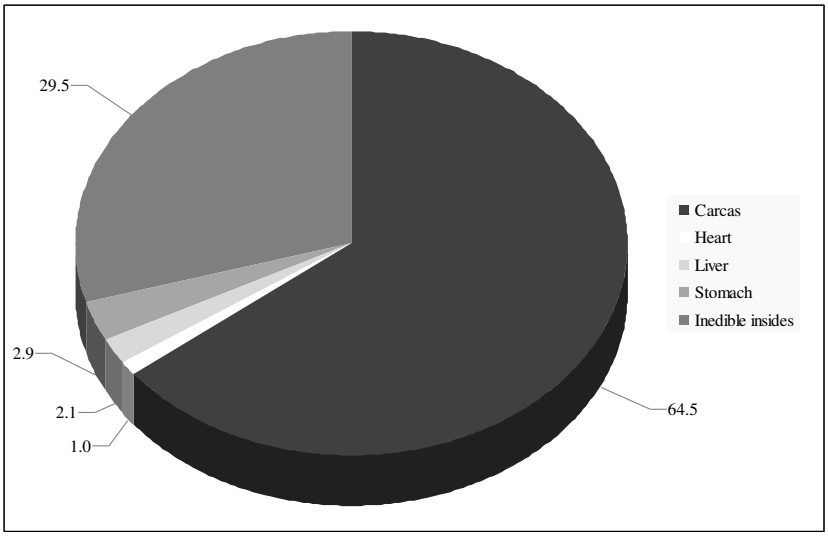

Figure 2. *Percentage shares of carcass components in the total body weight male mallard*

The chemical composition of the pectoral muscle showed slight variation in individual periods of the study (*Table 3*). Muscles contained 23.54 to 23.58% protein. The fat content showed a downward trend from 0.84 to 0.65% but these differences were not statistically significant ($p > 0.05$). The highest heart weight (12.6 g) was found

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14891507

in drakes obtained in October. In the following months, until February, the mass of this body decreased, but in the last two study periods it increased to 11.8 grams in the last study period. The mean values of individual components of the breast muscle chemical composition did not differ statistically significantly between the study periods ($p>0.05$). In contrast, the average values of the mass of internal organs showed differentiation between some periods of the study and some differences proved to be statistically significant ($p\leq0.05$). During the seven-month study period, liver mass showed quite significant variations. The drakes shot in December had the highest average weight of this organ, while the lightest livers were found in drakes obtained in April. The average values of this trait between some periods of research were statistically significantly different ($p\leq0.05$). Ducks from the first study period had the highest and statistically significantly different ($p\leq0.05$) muscle mass.

a, b, c - means denoted by the same letter between individual study periods do not differ statistically significantly ($p\leq0.05$)

In the next four periods, the mass was similar, while in the last two it dropped to an average level of 25.5 grams and these values differed significantly ($p\leq0.05$) from the average for this feature from all other periods.

Analysis of the fatty acid profile indicates that the pectoral muscles of the crosses had an average of 38.28% content of saturated SFA fatty acids (*Table 4*). There were no significant differences during the study period. The share of MUFA monounsaturated acids was 17.24%, and polyunsaturated at the average level of 40.35%. In both cases, no significant differences were found between study periods ($p\leq0.05$). The share of unsaturated acids in total accounted for over 57%, while their ratio to saturated acids was at the level of 1.5. On the other hand, the ratio of omega 6 to omega 3 polyunsaturated acids was not very differentiated in particular periods of the study and averaged 4.40.

Organoleptic and bacteriological analysis

The organoleptic analyzes carried out showed the presence of four drakees in the breast muscles of Sarcocystis protozoan cysts (*Table 5*). One case occurred in a drake shot in November, another case was shot in March, and two cases were found in drake obtained in April. In the case of one drake, the invasion was defined as very numerous (*Figure 3*), while in the remaining three cases the occurrence was less numerous.

Bacteriological analyzes of internal organs showed the presence of three groups of bacteria. Escherichia coli were found to be abundant in three drakes in the stomach and liver. They were specimens obtained in February and March, in the same complex of water reservoirs. One drake obtained in December and one in January found numerous occurrences of *Aeromonas veronii*. In one case, the bacterium was found in all internal organs, while in the other only in the liver. *Staphylococcus aureus* has also been found to be quite abundant in the livers of two drakes. In the small intestines of the individuals examined both organoleptically and using a stereoscopic microscope, tapeworms from the *Hymenolepididae* family were found. These parasites were found in all drakes with varying degrees of severity, from a few to several animals.

Resistance to antibiotics

As part of the study, an assessment of the sensitivity of isolated bacterial strains to antibiotics in vitro was performed (*Table 6*). The isolated *Escherichia coli* strain was found to be resistant to most of the antibiotics used, moderately sensitive to one and sensitive to Colistin and Doxicicline. The *Aeromonas veronii* strain was resistant to 4 antibiotics and sensitive to Colistin, Doxicicline and Enrofloxacine. In turn, the *Staphylococcus aureus* strain was also resistant to 4 of the antibiotics used, moderately sensitive to Enrofloxacine, and sensitive to Doxicicline and Lincomycin/Spectinomycin.

Table 6. *Sensitivity of isolated bacterial strains to antibiotics*

Antibiotic used	**Type of bacterial strain**		
	Escherichia coli	*Aeromonas veronii*	*Staphylococcus aureus*
Doxycycline **DO30**	W	W	W
Amoxycilin **AML25/AX25**	O	O	O
Ampicillin **AMP10/AM10**	O	O	O

Colistin **CT50**	W	W	O

Description: W - sensitive; ŚW - moderately sensitive; O - resistant

Spermatogenesis process

The analysis of the spermatogenesis process was carried out based on the mass of the testicles and epididymis and the cytological evaluation of testicular and epididymal imprints. The analysis was carried out until the presence of correctly formed sperm was observed. During the seven-month period of research for the period from October to January, the testicular mass was quite stable and ranged from 0.205 to 0.414 grams (*Figure 4*). In duck shot in February, testis weight was 0.712 g, and this value did not differ significantly from those of previous months. In drakes obtained in March, the average testis weight was 2,572 g and was significantly higher than the values obtained in previous months, and lower than the last test ($p \leq 0.05$). The average mass of drake

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14891507

testicles shot in April was 14.140 g and was significantly higher ($p \leq 0.05$) than the values obtained in all earlier months of the study. The correlation coefficient between body weight and testicular weight was negative and statistically insignificant, r_{xy}=-0.400.

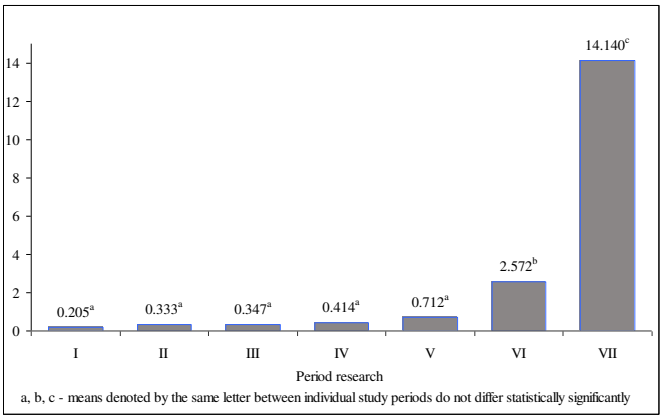

Figure 4. *Shaping the weight of testes (g) drakes during the study period*

In the evaluated microscopic preparations, in the initial period of research, i.e. October, proper germ cells were not shown, but only sperm-forming epithelial cells difficult to identify, in the initial period of development presumably spermatogonies (*Figure 5*). Later, from November to the end of February, characteristic cells were observed in the preparations - oval with a wide, clear layer of cytoplasm and the nucleus in the central part of the cell, reminiscent of spermatocytes. It was observed that the shape of the cell changed from oval to round with time, and the shape of the nucleus from cylindrical to oval (*Figure 6*). From the first half of March, correctly formed spermatozoa were visible in the preparations, but spermatocytes were also visible (*Figure 7*). In addition, spermatides in the less advanced - early spermatid (WS) and the more advanced - late spermatid (PS) stage of transformation into mature germ cells - spermatozoa were also seen in preparations from this period (*Figure 8*). Duck sperm had a very large head in the shape of an elongated cone and a thinly visible thin withe, reminiscent of hot pepper Peperoni (*Figure 9*).

Discussion

The obtained weight results of mallard ducks, despite the differences in the 7-month research cycle, indicate that it was higher than that in studies conducted in north-eastern Poland, despite the fact that these studies covered the winter period and matings, which is associated with more than 10% decrease in body weight compared to the initial weight (Janiszewski et al., 2018). The average value of this trait is similar to that of research conducted in Hungary and in the case of males it is only less than 14 grams lower (Szász et al., 2006), while compared to the results of research from north-eastern France, it was 49 grams lower (Boos et al., 2002). The carcass weight was also higher than that in research conducted in north-eastern Poland, which resulted in slaughter efficiency higher by 7.7%. On the other hand, the share of heart and liver weight was similar, and the stomach weight was significantly lower compared to ducks from north-eastern Poland (Janiszewski et al., 2018). Also the chemical composition of the carcass was similar to that of research conducted in north-eastern Poland, and slight differences were due to the date of hunting and the habitat from which the birds came. At the same time, the pectoral muscles were characterized by a high protein content, with a low fat content, whose share decreased with the time of shooting (Lorenzo et al., 2011; Janiszewski et al., 2018). In turn, the results of other authors indicate lower protein content and definitely higher fat in meat from mallard ducks (Cobos et al., 2000).

The content of 14 fatty acids was found in the pectoral muscles of male crosses. The occurrence of saturated fatty acids (SFA) as well as monounsaturated (MUFA) and polyunsaturated (PUFA) was similar to that of other authors. However, the content of individual acids showed slight variation, which may be due to the composition of the diet of birds from different environments and the date of their shooting (Cobos et al., 2000; Nuernberg et al., 2011; Janiszewski et al., 2018). Quite a high level of C 20 PUFA acids, especially C 20:4, was conditioned by the diet of birds, because these acids come only from exogenous sources and cannot be synthesized in the body of birds. High levels of these acids in mallard meat have also been confirmed in studies by other authors (Mishra et al., 1993; Nuernberg et al., 2011). Such a high level of PUFA acids, as well as the UFA to SFA ratio of 1.50 means that the meat of the crosses has enormous health benefits,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14891507

especially for people suffering from hypertension, which has been confirmed in experimental and clinical studies (Appel et al., 1993).

The demonstrated occurrence of protozoan cysts of the *Sarcocystis* genus in 4 ducks, with varying severity, indicates that there is a fairly serious threat from this pathogen. Based on the data obtained, it can be assumed that every 5 ducks may have sarcocysts. Until now, reports of sarcocystosis in ducks have been few, which were explained by the fact that duck hunters did not pay attention especially to the rare sarcocysts (Stenzel and Koncicki, 2007; Śmiałek et al., 2014; Flis and Grela, 2018). Intestinal parasites, including those found in the *Hymenolepididae* family, are quite common in both wild and domestic ducks, and although they have a destabilizing effect on the host organism, they do not affect the meat's utility (Raś-Noryńska et al., 2016; Sokół et al., 2016). Studies conducted in three different places in Poland have shown the occurrence of 22 nematode species from the family *Hymenolepididae* (Nowak et al., 2012). Also Ukrainian studies indicate the presence of parasites of this family with varying severity (Syrota et al., 2018).

The finding in some internal organs of *Escherichia coli* indicates that the crossbreeds can be an important reservoir of zoonotic strains of this bacterium, as well as a bioindicator of the state of the environment, mainly of the water reservoirs in which they reside. This is confirmed by studies of other authors indicating that crosses can be an important source of *E. coli* strains capable of causing intestinal diseases (Ewers et al., 2009). Slovak studies have shown that in fresh meat of crosses no *E. Coli* bacteria were found, and they were found after a 7-day meat maturation period (Haščík et al., 2010). Gram negative rods of the genus *Aeromonas* are widespread in the aquatic environment, thus they are quite common in birds inhabiting these habitats. They may also be responsible for infection in humans (Mencacci et al., 2003). The finding of two cases of *Staphylococcus aureus* is a confirmation that this highly widespread bacterium can also occur in mallards, and thus may be a potential source of infection for people who have contact with hunted ducks as well as eating meat derived from them. In addition, duck droppings can also be a source of infection, as well as a vector of the spread of bacteria in the natural environment, and thus may pose a threat to public health (Adegunloye and Adejumo, 2014).

Our own research shows that reproductive processes in male mallard ducks are normal. Outside of the October and November breeding season, inhibition of sexual activity in drakes was observed. This is evidenced by both the very low testicular mass and the presence in the cytological preparations of the testicles from this period, only the basic germ cells - spermatogonia. Although the ducks are already mating at this time of year, the spermatogenesis process is still stopped. Bonding of both sexes in pairs is dictated, as Davis studies (2002) show, by a periodic increase in testosterone levels in drakes. After pairing, the level of this hormone decreases, and during the reproductive period it gradually increases again and also gradually stimulates the process of spermatogenesis. A slight increase in testosterone levels causes mating of ducks and mating behavior, but it is too low to activate spermatogenesis. That is why, in the initial studies, no increase in testicular mass and germ cell development was demonstrated. Similar relationships were observed in guinea fowls (Numida meleagris), which also show seasonal reproduction (Abdul-Rahman et al., 2016). In the following months of December, January and February, the spermatogenesis process, which was already beginning, was observed, since the first and second order spermatocytes and second order spermatocytes were visible in the preparations. Although the testicular mass was still low, it increased steadily (from October to February it increased more than threefold). Similar increase in testicular

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_14891507

weight and development of reproductive cells in the beginning reproductive season was demonstrated by other authors in drakes and pheasants (Bauchinger et al., 2007; Górska et al., 2015). In March, the process of spermatogenesis was already developed; fully developed spermatozoa appeared in cytological preparations. However, it seems that the drakes obtained full fertility at the beginning of April, which is visible both in the highest testis mass obtained (increase 69 times since the beginning of the study) and the presence of a large number of spermatozoa in cytological preparations. The proper intensification of the spermatogenesis process is a very important factor in the reproduction of ducks, but equally important is the shift associated with global warming during the breeding period in wild birds (Virkkala and Lehikoinen, 2017). Research carried out on the capercaillie and the black grouse has shown acceleration of the breeding period, but for the benefit of reproduction rates in these bird species (Wegge and Rolstad, 2017). It is not known, however, whether this effect can also be expected in ducks.

Conclusions

The conducted research authorizes to formulate the following statements and conclusions:

Body weight and cross carcass weight were similar to the results of other authors, and its 10% decrease occurred only in the winter and spring months, which should be associated with the climatic conditions and course of mating in this species. The crosswords were characterized by high slaughter efficiency at the level of 64.5%. A statistically significant relationship between the mass of internal organs (heart, liver, stomach) and the body weight of birds was demonstrated.

The chemical composition of cross carcasses was characterized by high protein content and low fat content. At the same time, the fatty acid profile indicates a high content of unsaturated fatty acids, including those from the C 20 group, which can only come from exogenous sources. The high content of the described acids in connection with the favorable ratio of UFA to SFA at 1.5, confirms the high health benefits of these birds, which should be an important component of the diet, especially for people with hypertension.

Organoleptic and bacteriological evaluation of carcasses showed the occurrence of protozoan cysts of the *Sarcocystis* genus and intestinal parasites of the *Hymenolepididae* family. These groups of parasites, despite having an impact on the host, do not play a major epidemiological significance. At the same time, it should be emphasized that the presence of *E. coli* and *Staphylococcus* aureus in some internal organs is of some concern, especially since these bacteria showed sensitivity to only two of the seven antibiotics used. This is due to the fact that crosswords can be a potential source of human infection as well as a reservoir, and also a vector for the spread of these bacteria, and thus pose a threat to public health.

Assessment of both testicular weight and cytological imprints made of testicles and epididymis allows confirmation of the correct development of the spermatogenesis process in mallard ducks during the breeding season. Despite the fact that pairing takes place already in winter, the fullness of matings, and thus the fertilization of females, takes place in April, which is confirmed by the results obtained. However, it is not possible to determine from conducted studies whether there were shifts during the breeding season, this requires furthermore focused research.

Abstract. Traditional medicine has a great contribution to the treatment of many chronic diseases. Therefore, the main purpose of this study was to evaluate the antioxidant and antidiabetic values and the α-amylase and α-glucosidase inhibiting potential of *Farsetia jacquemontii* in Bannu district, Pakistan. Antioxidant activity was assessed by using reagents; 1, 1-diphenyl-2-picrylhydrazyl (DPPH) stable free radicals, 2, 2′- azino-bis (3-ethylbenzthiazoline-6-sulfonic acid) (ABTS) radical cation, hydrogen peroxide (H_2O_2) and sodium molybdate (Na_2MoO_4). The antidiabetic activity was analyzed through the inhibition of α-amylase and α-galactosidase with IC_{50} values of 290 µg/ml and 240 µg/ml respectively. The extract was found to possess antioxidant potential depending on concentration in a cell-free system. Antioxidant potential was highest against ABTS with 98 µg/mL IC_{50}, followed by MoO_4 100 µg/mL, DPPH 149 µg/mL and H_2O_2 250 µg/mL respectively. The antidiabetic activity was a result of the inhibition of α-amylase and α-galactosidase with IC_{50} values of 290 µg/ml and 240 µg/ml respectively. The methanolic extract possessed electron donating ability and reduced the free radicals in a cell free system. *F. jacquemontii* exhibited highest antioxidant potential against ABTS with IC_{50} 98 µg/mL IC_{50} > MoO_4 100 µg/mL > DPPH 149 µg/mL > H_2O_2 250 µg/mL. Based on the results, it can be concluded that *Farsetia jacquemontii* has antioxidant and antidiabetic potential as it contains vital phytochemicals with aforementioned properties.
Keywords: *DPPH, ABTS, H_2O_2, Na_2MoO_4, α-amylase*

Introduction

Antioxidants are substances that possess free radical chain reaction breaking properties (Pourmorad et al., 2006). The reactive derivatives of O_2 recognized as reactive oxygen species (ROS) are constantly produced in the human body that encourages oxidative damage of many biomolecules (Farber, 1994). Oxidative stress is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_15091521

a common factor of many chronic diseases such as cardiovascular disease, diabetes, cancer, liver diseases, Alzheimer's disease and cataracts (Lü et al., 2010). Nowadays, research is focused on natural antioxidants used in food for health promotion and disease prevention (Finkel and Holbrook, 2000; Gorinstein et al., 2003; Valko et al., 2007; Pham-Huy et al., 2008). Many plants species have been recognized for their antioxidant activities and their consumption is recommended (Tiwari, 2001; Lee et al., 2003; Alali et al., 2007; Gan et al., 2010; Spiridon et al., 2011). Phenols are mostly found in plants and heaving antioxidant activity (Foti, 2007). Their antioxidant activity is mainly due to the fact that they can act as a reducing agent and hydrogen donators. Several studies had been conducted in order to correlate the number of compounds in plants and antioxidant activity (Alali et al., 2007; Gan et al., 2010; Spiridon et al., 2011).

Diabetes mellitus is a chronic disease attributed by hyperglycemia, glycosuria, negative nitrogen balance and insufficient production of insulin hormone. Three types of diabetes mellitus have been recognized; insulin dependent, noninsulin-dependent and gestational diabetes (Devi et al., 2016). It is the prevailing disorder throughout the globe affecting about 25% world population (Grover et al., 2002). According to WHO report in 2012, 1.5 million deceases worldwide were due to diabetes mellitus and 80% of deaths occurred in poor countries due to these diseases (WHO, 2012). Statistics show that this disease will affect more people, which will increase the death ratio up to 347 million in 2030 (Boyle et al., 2001; Shaw et al., 2010). In the world, Pakistan is considered among the top ten countries in which diabetes occur with high frequency. There were 5.2 million people in 2000 that would increase to 13.9 million in 2030 (Wild et al., 2004).

Presently, type II diabetes mellitus is a common type of diabetes, which is managed by a combination of diet, exercise, oral hypoglycemic drugs and sometimes insulin injections. However, these drugs have adverse side effect and high secondary failure rate (Bailey, 2000; Dormandy et al., 2005; Colhoun et al., 2012). In these patients, there is the main focus on blood glucose level (Stratton et al., 2000). Herbal drugs play important role in traditional medicine with many plant species showing antidiabetic activity (Arulrayan et al., 2007).

F. jacquemontii (Hook.f. & Thoms.) Jafri belongs to family Brassicaceae, a small shrub usually with a woody base. Ethnobotanical studies conducted indicate that this plant possesses medicinal properties i.e. root of the plant is used as carminative, colic, heartburns, dyspepsia (Ullah et al., 2014), anti-rheumatic agent (Ajaib et al., 2014), in piles, abdominal/stomach problems and pain (Shaheen et al., 2014). Ethnomedicinal information of this plant was collected from district Bannu, Pakistan (*Fig. 1*), where inhabitants use this plant as a household remedy for diabetes, ulcer, febrifuge, antidropsical, diuretic, in piles, and dyspepsia. Even though the plant is used for medicinal purposes but lacks pharmacological indication. From this perspective, the current study was conducted; to assess the antioxidant and antidiabetic potential of *F. jacquemontii* and their potential of inhibiting α-amylase and α-glucosidase.

Materials Methods

Identification and extraction

F. jacquemontii plant was collected in March, 2018 from Bannu District, union council Asperka, (Pakistan) and identified with the help of available literature (Ali and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_15091521

Qaisar, 1995-2009; Nasir and Ali, 1971-2007), assigned with herbarium voucher number no# Bot. 20131(PUP) and placed in herbarium, Department of Botany, University of Peshawar.

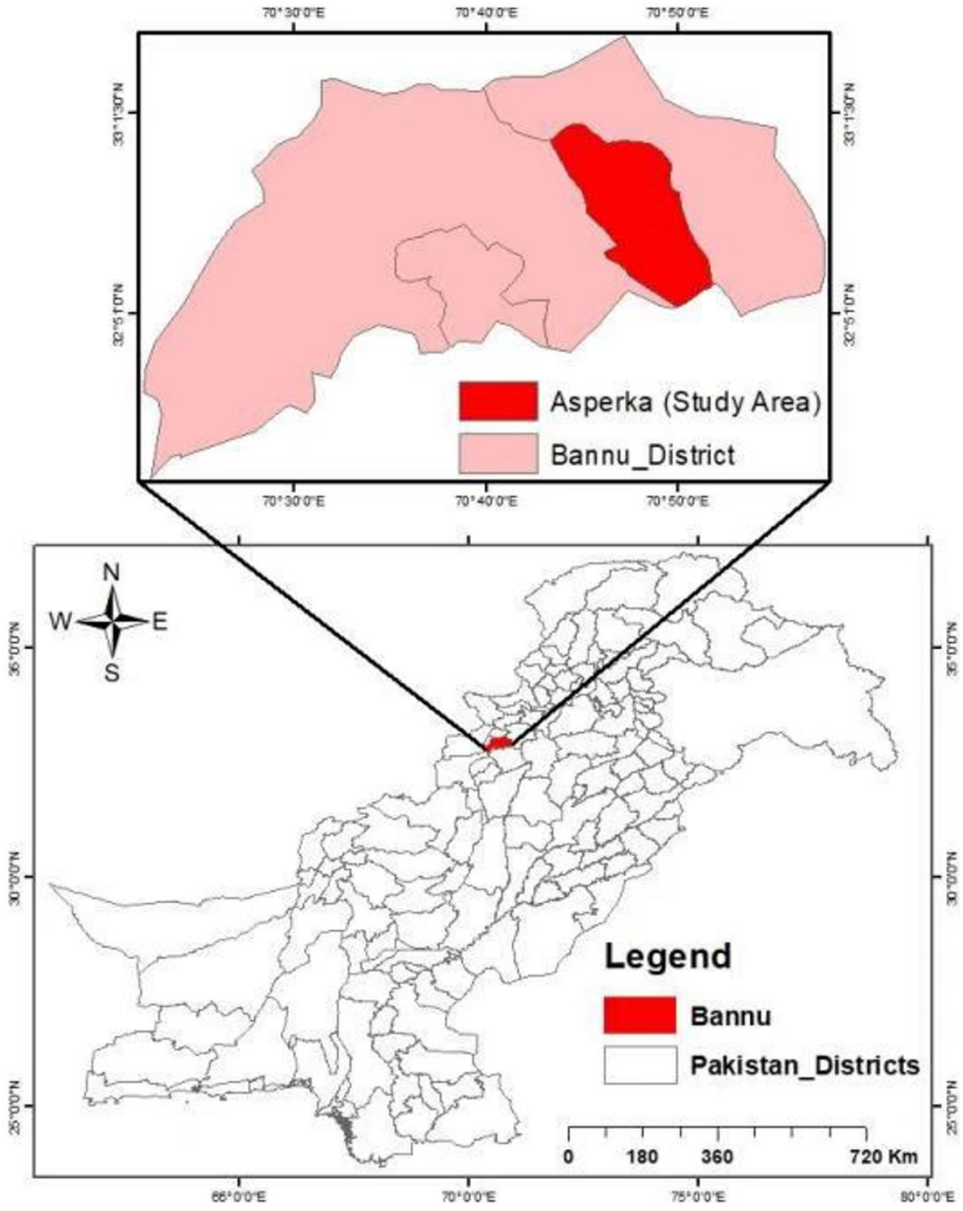

Figure 1. *Map of the study area*

The plant was washed with distilled water and the material was dried in shade, mechanically grounded into fine powder using Digitran grinder. The extract was provided gentle agitation through magnetic stirrer (Utech-Schenectady, USA) for 12 h then the extract of 100 g powder was obtained by keeping for 7 days in methanol (Ahmad et al., 2100). The extract was then filtered by Whatman no. 1 filter paper (125 mm) (Whatman Ltd., England). Phytochemical analysis of the extract for saponins, flavonoids, phenols, tannins and phlobatannins were made according to Trease and Evans (1989) with some amendments accordingly.

DOI: http://dx.doi.org/10.15666/aeer/1801_15091521

Screening procedure

Test for tannins and phenols

An extract of 5 mg was dissolved in 5 ml distilled water and then filtered. The filtrate was mixed with the $FeCl_3$ solution. A greenish-black precipitate was an indicator of tannins and phenols in the extract.

Test for saponins

An extract of 5 mg was mixed with distilled water and shake gently. Then the mixture was kept on heating Wisd Lab and foaming appearance was the indication of saponins.

Test for terpenoids

Chloroform (2 ml) was added with 5 ml methanolic extract and then added a small amount of H_2SO_4. The solution color was changed to blue-green with ring formation that confirmed terpenoids in the extract.

Test for flavonoids

Plant powder was boiled using Wiseven in 5 ml ethanol and an insufficient amount of concentrated HCl with a combination of magnesium. Then the solution color was changed to red that indicated the flavonoids.

Antioxidant activity

In this study, four procedures of antioxidant evaluation, ABTS, DPPH, H_2O_2 and Na_2MoO_4 were carried out to check the antioxidant potential of methanolic extract of *F. jacquemontii* (Hook.f. & Thoms.) Jafri.

Standard and sample solutions

An extract of 3 mg was dissolved in 3 ml methanol as a stock solution. Further dilutions were prepared by dissolving stock in methanol i.e. 50-500 µg/ml concentration (M1V1 = M2V2). Ascorbic acid served as a control and prepared accordingly as mentioned above i.e. 4 mg/1000 mL.

Diphenyl picrylhydrazyl radical scavenging activity

The DPPH (1, 1-diphenyl-2-picrylhydrazyl) assay was carried according to the method described by Gyamfi et al. (1999) with some amendments. The absorbance of DPPH was measured via spectrophotometer (UV-1602 BMS) at 517 nm which was 0.854 (<1). The reaction was performed at 37 °C in darkness. 200 µL extract from each sample solution and 800 µL DPPH were mixed and allowed to react at 25 °C for 30 min in darkness and checked its absorbance. The same procedure was repeated with an ascorbic acid solution. The potential of methanolic extract scavenging free radicals was articulated as IC_{50}. Ascorbic acid served as a control. The experiment was repeated three times. Extract potential was calculated on the basis of % DPPH radicals scavenged:

$$\%\ DPPH\ scavenging = 1 - \frac{Abs\ of\ DPPH - Abs\ of\ sample}{DPPH\ Abs} \times 100 \quad \text{(Eq.1)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_15091521

where: Abs of DPPH means an absorbance of 1, 1-diphenyl-2-picrylhydrazyl.

$ABTS^{+}$ radical cation (potassium persulfate) bioassay

Arnao et al. (2001) procedure with modification was betrothed for $ABTS^{+}$ radical cation (potassium persulfate) bioassay. The basic theme of ABTS bioassay was the capability of extract to scavenge 2, 2′- azino-bis (3-ethylbenzthiazoline-6-sulfonic acid) radical cation. Seven millimolar ABTS were mixed with 2.45 mM potassium persulfate and allowed to react for 30 min. Next 0.2 mL extract was added to 1.8 mL $ABTS^{+}$ potassium persulfate solution. Absorbance ($ABTS^{\cdot +}$ Potassium persulfate) were taken in comparison to control (ascorbic acid) at 745 nm using (UV-1602 BMS). The scavenging potential of the extract was calculated at various concentrations:

$$\%\ antioxidant\ capacity = 1 - \frac{Abs\ of\ test\ sample}{Abs\ of\ ascorbic\ acid} \times 100 \qquad \text{(Eq.2)}$$

where Abs means absorbance.

Hydrogen peroxide scavenging activity

Dehpour method with some modification was employed to determine extract scavenging activity of hydrogen peroxide radical (Ruch et al., 1989). Forty millimolar hydrogen peroxide solution in phosphate buffer of pH 7.4 was measured at 230 nm to determine its concentration. Methanolic extract of 200 µL extract from each concentration (50-500 µg/ml) was added to 1.8 mL of hydrogen peroxide solution, incubated for 10 min at room temperature and the measured absorbance at 230 nm against a blank, with phosphate buffer only. Scavenging of hydrogen peroxide radical was calculated:

$$\%\ antioxidant\ capacity = 1 - \frac{Abs\ of\ test\ sample}{Abs\ of\ ascorbic\ acid} \times 100 \qquad \text{(Eq.3)}$$

where Abs means absorbance.

Sodium molybdate reduction assay

The methanolic extract antioxidant ability against sodium molybdate radical was determined by mixing 3 mL solution (0.6 M sulphuric acid, 28 mM sodium phosphate and 4 mM sodium molybdate) with various concentrations of extract. The mixture was incubated (DAIHAN Scientific) (Ahmad et al., 2011) at 95 °C for 90 min. The mixture was cool down and measured its absorbance at 765 nm via digital spectrophotometer against a blank containing methanol. Ascorbic acid served as standard. Reduction power of the extract was calculated as the number of the equivalent of ascorbic acid. The comparative antioxidant capacity of *F. jacquemontii* (Hook.f. & Thoms.) Jafri extract was calculated:

$$\%\ Sodium\ molidate\ reduction = \frac{Abs\ of\ test\ sample}{Abs\ of\ ascorbic\ acid} \times 100 \qquad \text{(Eq.4)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_15091521

where Abs means absorbance.

Anti-diabetic assay

Test for alpha-amylase

0.1 g of potato starch and 100 mL of sodium acetate buffer were taken and mixed them to obtain a solution of starch (0.1% w/v). 27.5 mg of α–amylase was dissolved in 100 mL distilled water to prepare enzyme solution. 96 mM of 3, 5 di-nitro salicylic acid solution was prepared and mixed with sodium potassium Tartarate to obtain colorimetric reagent. Plant extract was mixed with the starch solution and then added α–amylase and left for some time. The condition was basic for reaction and temperature was 25 °C. The measurement was taken after 3 min. The maltoses generated were calculated by the production of 3-amino-5-nitro salicylic acid which was formed from the reduction of 3, 5 dinitro salicylic acid. The absorbance was measured at 540 nm with the help of spectrophotometer.

Test for alpha-glucosidase

The inhibitory activity of alpha-glucosidase was performed by taking starch solution as a substrate (2% w/v). The starch used in this assay was sucrose. 0.2 M Tris buffer (pH 8.0) was prepared. Plant extracts (200-800 µg/ml)), starch solution and Tris buffer were incubated at 37 °C for 5 min and 1mL of α-glucosidase (1 U/mL) was then added and incubated for 40 min at 35 °C using (DAIHAN Scientific) and then 2 ml of 6N HCl was added to the solution to stop the reaction. The color intensity was measured at 540 nm with the help of spectrophotometer.

Calculation of IC_{50}

The concentration of *F. jacquemontii* (Hook.f. & Thoms.) Jafri extracts required for 50% inhibition of the activity of the enzyme (IC_{50}) was calculated by using % inhibition at five different concentrations of the extract. Percentage inhibition (I %) was calculated:

$$\% \ Inhibition = \frac{Ac - As}{Ac} \times 100 \qquad \text{(Eq.5)}$$

where: Ac means absorbance of the control and As means absorbance of the sample.

Statistical analysis

All calculations and art work presentation were performed in ORIGIN Pro 8. Percentages of inhibition were expressed as Mean ± Standard deviation from three observations in each case.

Results

DPPH

The methanolic extract of *F. jacquemontii* scavenges the DPPH (1, 1-diphenyl-2-picrylhydrazyl) radicals at all tested concentrations (50-500 µg/ml). Extract declared

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_15091521

highest scavenging potential at 500 µg/ml (70%). The IC_{50} calculated in this case was 147 µg/ml. The effect was detected with reduced scavenging activity. The antioxidant effect of FJME against DPPH free radicals presented is in *Figure 2*.

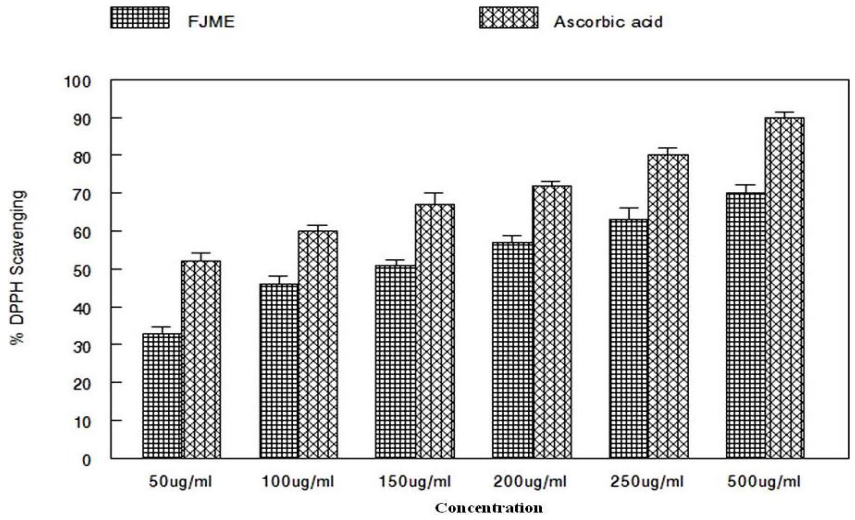

Figure 2. *1, 1- diphenyl-2-picrylhydrazyl stable free radicals (DPPH) scavenging at various concentrations by Farsetia jacquemontii. Error bars show the standard deviation. FJME is Farsetia jacquemontii methanolic extract (n = 3)*

ABTS

Scavenging capacities of tested samples were measured spectrophotometrically with ABTS (2, 2′- azino-bis ethylbenzthiazoline-6-sulfonic acid) free radical. The extract showed the highest scavenging at 500 µg/ml (85%), while at the same concentration, control exhibited (92%) antioxidant property. IC_{50} calculated in this case was 80 µg/mL (*Fig. 3*).

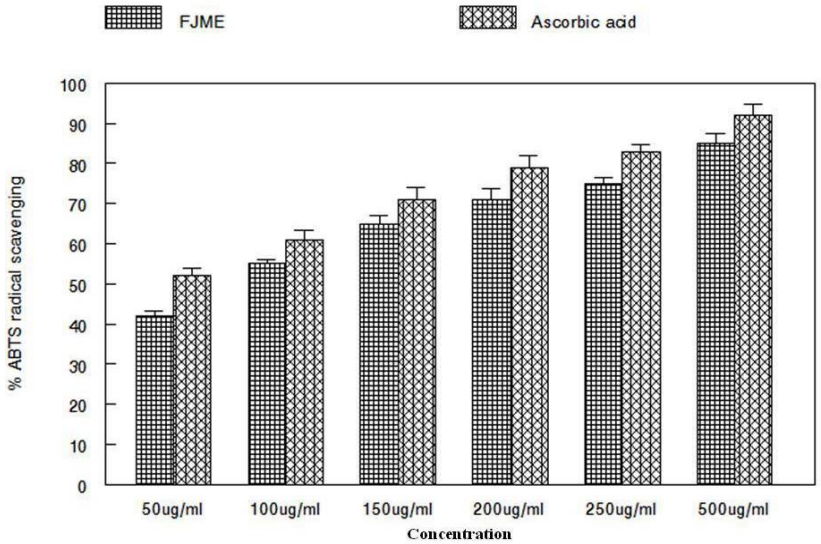

Figure 3. *Interaction of Farsetia jacquemontii with 2'- azino-bis ethylbenzthiazoline-6-sulfonic acid (ABTS) radical cation. Error bars show the standard deviation. FJME is Farsetia jacquemontii methanolic extract (n = 3)*

DOI: http://dx.doi.org/10.15666/aeer/1801_15091521

H_2O_2 reducing activity

H_2O_2 radicals reducing the power of FJME was tested at various concentrations (50-500 µg/ml). The extract showed significant radical scavenging activity (61%) at 500 µg/mL and declined with the decrease in extract concentration. While control showed the highest antioxidant activity (90%) at 500 µg/ml. IC_{50} in this case was 215 µg/mL (*Fig. 4*).

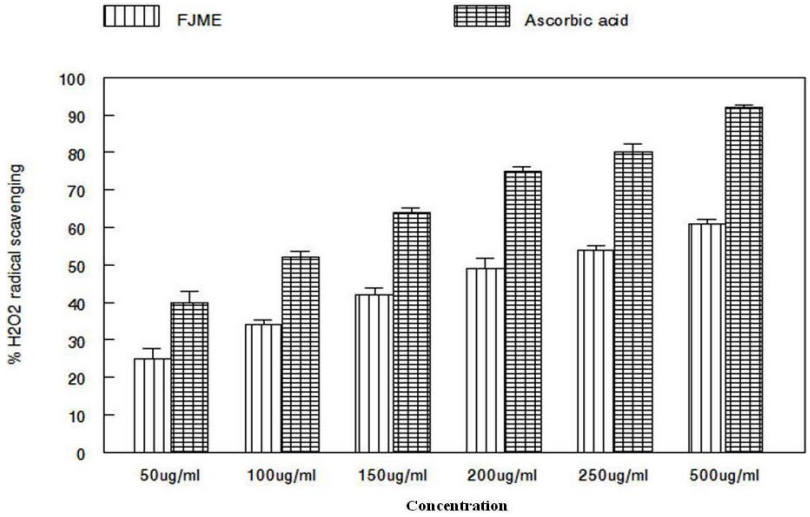

Figure 4. *Reduction of hydrogen peroxide (H_2O_2) by Farsetia jacquemontii methanolic extract. Error bars show the standard deviation. FJME is Farsetia jacquemontii methanolic extract (n = 3)*

Sodium molybdate reduction activity

It was found that FJME reduced molybdate radicals in a concentration-dependent manner. Results indicate that 78% molybdate radicals were reduced at 500 µg/ml comparative to control 95% at the same concentration, shown in *Figure 5*. IC_{50} for molybdate activity was 101 µg/ml.

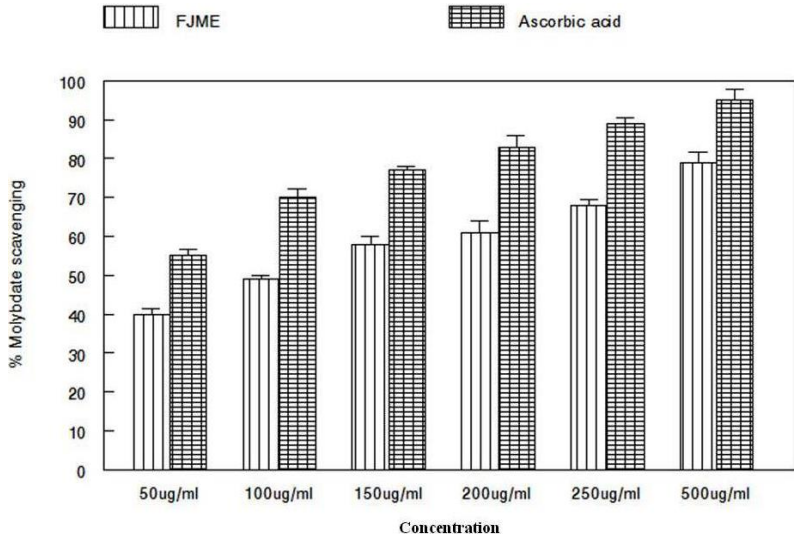

Figure 5. *Reduction potential of Farsetia jacquemontii methanolic extract (FJME) against sodium molybdate free-radicals. Error bars show the standard deviation (n = 3)*

α-amylase inhibitor effectiveness of FJME

Various concentrations (200-1000 µg/ml) of FJME were analyzed for α-amylase inhibitory activity. Fair increase in the percentage of α-amylase inhibition was observed. IC_{50} was 520 µg/mL for α-amylase. Among the extracts tested, 1000 µg/ml revealed the highest percentage of inhibition (82%). The concentration of Glimepiride (reference standard antidiabetic) employed in the test was similar to that of extract. Glimepiride (10 µg/mL) showed 98% inhibition with IC_{50} of 1.3 µg/ml (*Table 1*).

Table 1. *Inhibition of α-amylase enzyme activity by FJME*

Sample	Concentrations (µg/ml)	α-amylase inhibition (%)	IC_{50}
FJME	200	41 ± 1.45	290 µg/ml
	400	60 ± 0.88	
	600	67 ± 1.26	
	800	76 ± 2.02	
	1000	82 ± 1.71	
Glimepiride	2	75 ± 0.74	1.3 µg/ml
	4	81 ± 2.91	
	6	89 ± 0.97	
	8	95 ± 1.86	
	10	98 ± 1.50	

FJME is *Farsetia jacquemontii* methanolic extract. Percentages of inhibition expressed as mean ± standard deviation, IC_{50} is the half maximal inhibitory concentration

α-glucosidase inhibitor effectiveness of FJME

A dose-dependent and gradual increase in the percentage inhibition of α-glucosidase was observed with FJME. Highest percentage inhibition (87%) was observed at 1000 µg/ml. The IC_{50} values were found to be 250 µg/ml. Glimepiride at a concentration of 2 to 10 µg/ml was employed and served as reference standard drug for α-glucosidase inhibitory activity. The lowest dose (2 µg/ml) produced an inhibitory percentage of (60%) and the highest dose (10 µg/ml) produced 96% inhibition with IC_{50} of 1.7 µg/ml. Like FJME, a dose-dependent increase in the percentage of inhibition was observed (*Table 2*).

Table 2. *Inhibition of α-glucosidase enzyme activity by FJME*

Sample	Concentrations (µg/ml)	α -glucosidase inhibition (%)	IC_{50}
FJME	200	40 ± 0.92	240 µg/ml
	400	62 ± 1.83	
	600	74 ± 2.80	
	800	82 ± 2.67	
	1000	87 ± 1.73	
Glimepiride	2	60 ± 0.74	1.7 µg/ml
	4	74 ± 2.91	
	6	84 ± 0.97	
	8	91 ± 1.86	
	10	96 ± 1.50	

FJME is *Farsetia jacquemontii* methanolic extract. Percentages of inhibition expressed as mean ± standard deviation, IC_{50} is the half maximal inhibitory concentration

Discussion

Free radicals have been focused on notable concern amongst researchers due to their potential role in human diseases (Maxwell, 1995; Finkel and Holbrook, 2000). They are atoms or group of atoms with free electrons while antioxidants neutralize these toxins by providing electron (Jovanovic and M.G, 2000). These include mitochondrial radicals that initiate series of reaction in a living organism. In normal conditions, the production of pro-oxidants in the form of reactive oxygen species is efficiently checked and maintained by various levels of antioxidant defense mechanism like enzymes. Our dietary supplement contains antioxidants that effectively neutralizing these ROS during various disease conditions. Oxidative stress has been concerned with the consequence of free radical that attacks lipids, proteins and DNA. To investigate the characteristics of phenolic and anthocyanin as an antioxidant, MoO_4, DPPH and H_2O_2 radicals were used as a model in this study.

Mostly plants are investigated for their antioxidant effects that conventionally used in folk medicine. For the evaluation of antioxidant activity, various methods and modifications have been used (Aksoy et al., 2013). Our study revealed the presence of bioactive polyphenolic flavonoids, which might play an important role in improving of oxidative stress. Other studies documented the presence of phytochemicals during chemical characterization of medicinal plants (Aksoy et al., 2013). The data of the present study concluded that FJME contained good amount of phenolic compounds gifted with high antioxidant. The results provide a good pharmacological proof for this plant in diabetes, ulcer, febrifuge, antidropsical, and anti-rheumatic as well as its use in traditional medicine in Pakistan.

Phenolic compounds with one cyclic ring along with one or more OH functional moiety are the major group of phytochemicals in plants. Antioxidant activity which is one of the valuable activity among biological function exists in different phenolic compounds. Phenolic compounds have a unique structure and high affinity for metal chelating. Their electron donating/accepting ability let them play various potential roles to scavenge free radicals (Huang et al., 2009; Huda-Faujan et al., 2009; Bhatt and Negi, 2012; Khoddami et al., 2013). They are well predicted on the basis of their involvement in a large number of pathogenic diseases. Effective scavenger of free radicals acts as a potential antioxidant candidate (Ebrahimzadeh et al., 2008).

In the current research work, FJME in all cases showed equivalent scavenging ability to the standard compounds. Its phytochemical forage stable radicals and may exercise a defensive protection against oxidative damage to DNA, proteins etc. *F. jacquemontii* (Hook.f. & Thoms.) Jafri is a rich source of phenolic compounds and therefore strongly showed antioxidant properties in each case. So in food industries and other pharmaceutical planning *F. jacquemontii* (Hook.f. & Thoms.) Jafri is the best candidate because of its effective antioxidant properties.

On the other hand, diabetes results in huge oxidative damage by means of the creation of reactive oxygen free radicals, which leads to the pathogenesis of various diabetic complications. Insulin is a foremost participant in the management of glucose concentration. Deficiency or absence of insulin indicates very low or no carbohydrate metabolism (Gandhi and Sasikumar, 2012). Diabetes management still challenges the medical community. It was documented that inhibition of α-amylase and α-glucosidase would defer carbohydrate breakdown, which in turn results in reduced absorption of glucose, as a consequence blood glucose level becomes reduced (Chiasson and Rabasa-Lhoret, 2004).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_15091521

Current research has been conducted to assess FJME in inhibiting α-amylase and α-glucosidase. The inhibitory effectiveness indicates that FJME acquires the potential to inhibit the gastrointestinal enzymes α-amylase and α-glucosidase. Possible inhibition mechanism disclosed that FJME exerts action on carbohydrate linking sites in starch and glycogen, delayed their breakdown to oligosaccharides and considered targets for inhibition of postprandial hyperglycemia. Dietary starch is hydrolyzed into maltose which in turn breaks down to glucose by the action of amylase. Since delayed and even weakened starch digestion, such inhibitors in foodstuff could be accountable to play a significant role in the starch breakdown (Jaffé and Vega Lette, 1968; Marshal, 1975). For the first time, we have explored FJME as a potent antidiabetic agent against gastrointestinal enzymes that are mainly accountable for hyperglycemia in diabetes and hope that this study will help researchers for further investigation in isolating the target compounds.

Conclusion

In the present study *Farsetia jacquemontii* methanolic extract showed the presence of various phytochemicals. These bioactive constituents are considered the medicinal efficacy of *F. jacquemontii*. Furthermore, the phenols and flavonoids of *F. jacquemontii* methanolic extract might be able to manage oxidative stress.

Abstract. The aim of this research was to understand some physiological and agronomical behaviors of the Merlot grapevine subjected to different canopy management practices under the climatic conditions of different growing seasons in Tekirdag, Turkey. The resulting must composition and berry maturation were also determined. Adult vines of *Vitis vinifera* L. cv. Merlot, grafted onto 5BB were applied to different leaf areas (various levels of leaf removal from main and lateral shoots) during the growing season. Leaf photosynthesis (A) and transpiration (E), stomatal conductance (g_s), yield parameters, maturation indices and berry composition at harvest were analyzed over a period of three consecutive years between 2013 and 2015. In the vegetation periods of 2013 and 2015 when there is less precipitation, proportional humidity is relatively low and temperatures are high, positive results were obtained in terms of quality criteria in half lateral shoots (3-4 leaves= HLS) application. Under extreme rainfall and high relative humidity conditions as in 2014, none lateral shoots (NLS) application increased physiological activity and relative quality. The main factor controlling the physiological behavior and grape ripening in Merlot vines was largely dependent on the meso-climatic conditions during the growing season. However, the total effect of small differences in the canopy microclimates created by different leaf area reduction applications affected the indicators of industrial maturity at the end of vegetation. Planning of canopy management practices should be done by taking into consideration long- and medium-term meteorological evaluations, and short-term planning within vegetation should be considered by weighing weekly and monthly meteorological risks.
Keywords: *canopy management, green pruning, climate, leaf gas exchange, quality*

Introduction

Climate, especially temperature is the major component of wine grape terroirs, with a number of other factors including soil characteristics and soil water reserves, grape variety and rootstock, cultivation techniques such as cover crops and leaf fruit ratio. Grape berry maturation is generally associated with all of these factors.

The negative effects of the current climate crisis are getting worse every year. Early and accelerated berry ripening (Petrie and Sadras, 2008; Keller, 2010a), changing of usual wine styles due to unexpected seasonal precipitation (Mira de Orduña, 2010; Schultz and Stoll, 2010), problems like higher alcohol ratios with lower acidity and reduced varietal aroma compounds due to high sugar in berries (Keller, 2010a) are the troubles that stand out to be solved by winemakers. It is very important for the wine industry to adapt to alternative viticulture and winemaking methods to get used to these new climatic conditions (Clingeleffer, 2010). As Carbonneau and Bahar (2009) stated global warming is inevitable, a couple of new strategies should be tried like breeding of new varieties and rootstocks, soil management and more important for short term vine

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_15231538

canopy management for sustainable viticulture. Canopy management treatments, such as pruning, trimming and leaf removal, can be certainly utilize to organize vine source-sink balance (Santesteban et al., 2011; Moran et al., 2017). There are a lot of researches indicating that the early maturation or postponement of the industrial maturity may occur when the leaf removal is applied in the proper style and time (Poni et al., 2013; Caccavello et al., 2017).

Another factor which is as effective as the climate in determining berry maturity is the genetic infrastructure of the variety that determines the physiological activity. Young leaves generally start to produce excess photo assimilates, translocated afterwards to the other parts of the vine after they reach one third of their full sizes, approximately 5 or 6 weeks after leaf unfolding (Keller, 2010b). As the leaves age, their photosynthetic capacity and their contribution to organic matter production increase to some point, then fall. Depending on leaf age, regardless of whether they come from the lateral or main shoot, individual photosynthetic activities are effective in berry ripening and in sugar accumulation in grape juice (Hirano et al., 1994). Due to this phenomenon it is important to point out the role of leaf removal practices about ripening processes. The lack of proper canopy management promotes the occurrence of unbalanced vineyards with intense vegetative growth (Zalamena et al., 2013; Bem et al., 2016) and results unbalanced wines.

The aim of the study was to have a better understanding about the impact of leaf removal practices on physiological activities and berry maturation of grapes under the monitored climate conditions.

Materials and Methods

Location, vine material and experimental set-up

The experimental study was conducted in 2013, 2014 and 2015 in an experimental vineyard, in Tekirdağ Viticulture Research Institute, Turkey (40.96 °N-40.97 °N latitudes, 27.46 °E-27.47 °E longitudes) with *Vitis vinifera* cv. Merlot which is grown in large quantities in the Thrace region and preferred because it has high adaptability to the region climate and gives high wine quality. However, Merlot which showed more anisohydric characters (Collins and Loveys, 2010).

The grapevines, grafted on 5BB rootstock were 14 years old. Double Guyot training vines loaded 16-18 buds per vine, with distances of 2.5 m between rows and 1.5 m between plants. The vineyard is planted on North-South at 40 m altitude on a high groundwater and, flat land with no significant soil variations. Analyses in 0-90 cm soil depth observed that in the clay-loam structure, slightly alkaline and calcareous, in at a depth of 60-90 cm highly calcareous with no salinity problem. Agrotechnical applications were done 3 consecutive years which were given *Table 1*. All plant protection procedures were done routinely in vineyard.

Different leaf areas of vines were created by the limitations of main shoot lengths 1 m, 1.25 m and 1.5 m while they reached 170-180 cm (EL 31-33). Lateral shoots also limited as full lateral shoots (6-7 leaves: FLS), half lateral shoots (3-4 leaves: HLS) and none lateral shoots (no leaf: NLS) performed in veraison (Eichhorn-Lorenz growing stages 35) according to Lorenz et al. (1995). Both applications were kept at the same length until the harvest period.

Descriptive meso-climatic weather data such as temperature, relative humidity, light intensity, wind speed and total precipitation at two meters high from ground were

Despite the equal number of (16) buds left in the winter pruning, the plants that disrupt homogeneity in the number of shoots and bunches were balanced when the shoots reached an average length of 30-40 cm (EL 15-17) or excluded from the trial. Standard cultural practices in the region were applied to all treatments during research. The vines data taken were selected from the same development period and with the approximate charge and those without spaces.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_15231538

Total leaf area and leaf area per kg of grapes

Leaf areas of each application were calculated by, multiplying the number of shoots per vine and the number of leaves per shoot which were scanned with CI-202 Portable Laser Leaf Area Meter (CID Bio-Science, Washington, USA), from four shoots in each vine of every application.

Ratio of total leaf area (m^2 $vine^{-1}$) to yield (kg $vine^{-1}$) was calculated for determining leaf area per kg of grapes according to Sanchez-de-Miguel et al. (2010).

Leaf gas exchange measurements

Leaf gas exchange [net photosynthesis (A, μmol CO_2 m^{-2} s^{-1}) and transpiration (E, mmol H_2O m^{-2} s^{-1})], stomatal conductance (g_s, μmol m^{-2} s^{-1}) were measured on healthy, fully expanded, mature and non-senescent leaves by using LI-6400XT (Li-Cor Inc., Nebraska, USA) portable photosynthesis system, between 10:00-12:00 AM. During the measurements, the device was calibrated to 400 μmol CO_2 m^{-2} s^{-1} atmospheric CO_2 and 25°C block temperature. In each application, 10 measurements were performed on one leaf of each of the four grapevines, and these measurements were used as the average of repetitions.

Must composition and berry maturation

At harvest, two hundred berries per replicate were selected to determine primary juice compounds as total soluble solids (%, TSS; °Brix) with handheld refractometer (ATAGO Co. Ltd., Tokyo, Japan), pH with digital pH meter (Mettler Toledo FE20. Switzerland), total acidity (g L^{-1} of tartaric acid) in must at the harvest date using the official methods of the Organisation Internationale de la Vigne et du Vin (OIV, 2012).

In addition, the amount of sugar per gram of grapes (mg g-$berry^{-1}$) was calculated by dividing the amount of sugar in the berry by the fresh weight (Ferrer et al., 2014). Maturity indicators; °Brix/titratable acid, and pH^2 × °Brix values were calculated and evaluated according to Blouin and Guimberteau (2000).

Statistical analysis

Results were subjected to variance analysis with JMP 13.2.0 statistical software according to split-plots trail design for determining of differences in applications and years. LSD test was used at 5% significance level to identify differences between significant means.

Results and Discussion

Climatic conditions and grapevine phenology

In the 3 years that the study was carried out, 2014 was distinguished from 2013 and 2015 in terms of temperature and especially precipitation amount, as well as climatic characteristics such as light intensity, relative humidity and wind speed. While the mean of total annual precipitation for the 1939-2018 period is 582.90 mm; the total precipitation was 443.80 mm in 2013, 770.50 mm in 2014 and 507.90 mm in 2015 (*Table 2*).

As a result of the phenological observations made throughout the trial, the day green shoot tips seen clearly in the buds was 05.04.2013 in 2013 (94^{th} calendar day),

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_15231538

02.04.2014 (91st calendar day) for the year 2014, for 2015 it was observed as 12.04.2015 (101st calendar day). The date of the veraison was determined as 22.07.2013 (202th calendar day) for the year 2013, 30.07.2014 (210th calendar day) for the year 2014 and 01.08.2015 (212th calendar day) for the year 2015. Harvest was done at %22-23 TSS excluding 2014. It was held on 26.08.2013 (237th calendar day) in 2013, 16.09.2014 (258th calendar day) in 2014 and 05.10.2015 (277th calendar day) in 2015.

Climatic data were also recorded on the days of physiological activity measurement at 10.00-12.00 during the experiment (*Table 3*).

Table 3. *The climatic data of physiological activity measurement days in years of 2013, 2014 and 2015*

Yield (kg vine^{-1})

In both years, 16 buds per vine were left in winter pruning, and shoots and clusters were equalized when the shoots reached 30-40 cm length. Thus, the differences between the yield values were not statistically significant. Yield values were seen the lowest for NLS application with 4.60 kg vine^{-1} and highest for FLS application with 5.00 kg vine^{-1}.

Due to 16 buds per vine were left in winter pruning and the equalization of shoots and clusters, in every three years the differences between the yield values were not statistically significant and ranged between 5.20 kg vine^{-1} and 5.43 kg vine^{-1}. The lowest yield was seen for 1 m main shoot length and the highest were seen for 1.5 m main shoot length treatment for the mean of years.

Total leaf area and leaf area per kg of grapes (m^2 vine^{-1})

In accordance with the method, different total leaf areas and different canopy microclimates were tried to be created in each year. The result that the interventions on

DOI: http://dx.doi.org/10.15666/aeer/1801_15231538

the total leaf areas per vine were found to be statistically significant when the mean of the three years and were each year individually, showed that the desired different canopy architecture and differentiation of the canopies were achieved (*Table 4*).

TLA and LA represent total leaf area (m^2 per vine) and leaf area (m^2 per kg grape). NLS, HLS, and FLS represent none lateral shoots (no leaf), half lateral shoots (3-4 leaves) full lateral shoots (6-7 leaves), MSME means main shoot main effect, LSME means lateral shoot main effect and YME means year main effect. Different lowercase superscript letters in same column and uppercase letters in same line represent statistically significant differences between means at $p < 0.05$ according to least significant difference test. n.s. means not significant

Values for leaf area per kg of grapes resulting from unusually low yields in 2014, due to severe *Plasmopara viticola* epidemic caused extraordinary rainfall, increased average values for both lateral and main shoot treatments. When the year 2014 is ignored, it is seen that 0.73 m^2 leaf area for kg $grape^{-1}$ of vine for 1 m main shoot length for 2013 year is sufficient and statistically significant. Also, lateral shoot treatments were found statistically significant in terms of each year and mean of years (*Table 4*).

In our study, it is seen that the targeted yield can be achieved, without quality loss, with some delay in industrial maturity even when the leaf areas are reduced more than regional standards. Therefore, it is considered that the decrease in leaf areas can be compensated for in terms of yield by arrangements in the internal metabolism of the vine. This shows that unusual canopy management practices that can be applied against unusual climatic conditions (high relative humidity, high temperature fluctuations, extreme rainy periods, etc.) can be used in certain periods, but not every year. However, to obtain the quality and optimum yield without excessive vegetative growth, interventions to the clusters and canopy should be considered carefully in order to optimize the leaf/crop ratio at different stages of development.

Net photosynthesis (A). transpiration (E) and stomatal conductance (g_s) measurements

When the measurement days are examined one by one in 2013; it is seen that photosynthesis (A) values vary between 18.03 - 7.62 µmol CO_2 m^{-2} s^{-1}. HLS showed the highest rate of photosynthesis (A) in 4 of 7 days. In terms of main shoot lengths, 1.25 m treatment showed the highest rates of photosynthesis in 4 of 7 days. As can be seen in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_15231538

Figure 1 transpiration (E) measurements also show parallelism with photosynthesis (A) rates. In general, the highest transpiration rates were observed in the measurements performed in July. Although there were no significant differences between the applications, highest transpiration values were measured in NLS and 1.25 m applications after the completion of the lateral shoot applications and the creation of the desired leaf area formations.

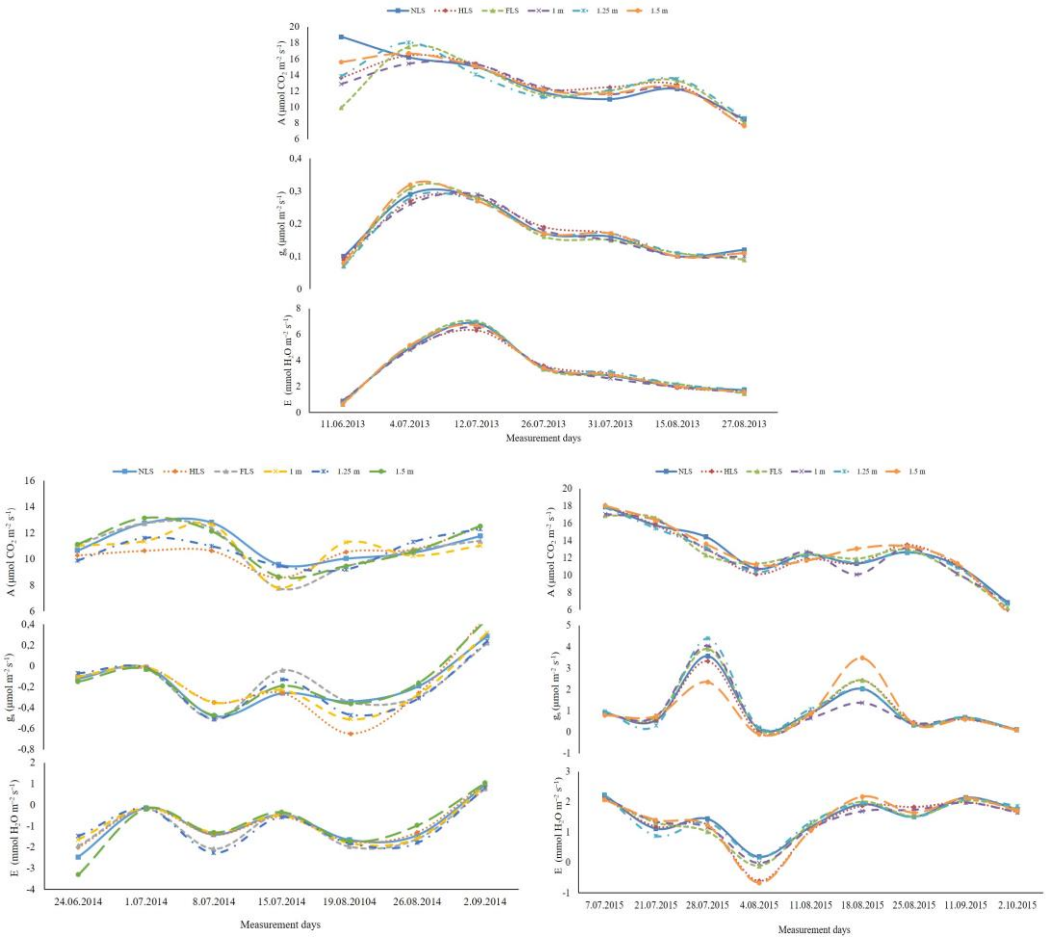

Figure 1. *Net photosynthesis (A), transpiration (E) and stomatal conductance (g_s) measurements in years of 2013, 2014 and 2015. NLS, HLS, and FLS represent none lateral shoots (no leaf), half lateral shoots (3-4 leaves) full lateral shoots (6-7 leaves). 1 m, 1.25 m and 1.5 m also represent main shoot lengths*

In many literature examining the relationship between photosynthesis (A), transpiration (E), stoma conductivity (g_s) (Motzer et al., 2005; Miyashita et al., 2005; Greer, 2012) and in the previous year measurements at the same vineyard (Candar et al., 2017), high correlation between stoma conductivity (g_s), photosynthesis (A) and transpiration (E) in other varieties and grapevines was also observed in 2013 measurements. The highest values in the measurements made after completion of canopy interventions were seen in NLS and 1.25 m applications.

In 2014 when the photosynthesis averages of the measurement days are evaluated as a whole without leaving the treatments, it is seen that the measurements taken on 181st calendar day of 2014 have a higher rate of photosynthesis than the other days with

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_15231538

12.05 μmol CO_2 m^{-2} s^{-1} ratio. In the meso-climatic measurements made between 10:00-12:00 on the same day, the average temperature was 23.30ºC, the highest temperature was 26.50ºC and the lowest temperature was 18.20ºC. The average wind speed was 2.10 m sec^{-1} and relative humidity was 78%, while the light intensity was 723.24 μmol m² / sec. The lowest photosynthesis rate for all days in 2014 was measured as 7.76 μmol CO_2 m^{-2} s^{-1} on 195th calendar day of 2014. On 195th calendar day of 2014 the maximum air temperature was 30.20ºC and the relative humidity 73.00%. Light intensity recorded at 725.67 μmol m² sec^{-1}. The lowest photosynthesis rate for all days was measured as 7.76 μmol CO_2 m^{-2} s^{-1} on 195th calendar day of 2014. On the same calendar day maximum air temperature was 30.20ºC and the relative humidity 73.00%. Light intensity recorded at 725.67 μmol m² / sec^{-1}.

In 2014, NLS was the first in 3 of 7 days and in 4 days, it was seen that the second place. When the measurement days are evaluated together. NLS application stands out with the highest photosynthesis rate with the average of 11.16 μmol CO_2 m^{-2} s^{-1}.

Transpiration (E) measurements in 2014 recorded less than zero results in six of the seven measurement days. Although this situation is not encountered in the literature in terms of vine varieties, it is seen in the studies made for perennial woody plants (Vesala et al., 2017).

In terms of the monitored climate characteristics, the average, low and high temperature values at 2 m level for 2014 and 2015 are very close to each other; the relative humidity is 72.33% in 2014 and 73.36% in 2015; It can be said that the sub-zero transpiration values in 2014 were due to the average wind speed of 2.78 m s^{-1} and the light intensity values measured as 1191.955 mol m² s^{-1} which is slow than 2015.

Escalona et al. (2013) reported that water vapor can condense on the leaf surface and enter through the stoma openings, especially on humid nights where the vapor pressure difference is very low in coastal areas. This prevents transpiration at night and therefore reduces water loss and increases the water usage efficiency of the next day.

As expected, stoma conductivity (g_s) values are also largely negative measurements. When stoma conductivity (g_s) measurements are examined by subjects, it is seen that there are no significant differences between applications. However, the variation between the measurements is higher than the transpiration (E) values.

Both transpiration (E) and stoma conductivity (g_s) produce similar curves. In terms of shoot length applications, 1.25 m application showed high values in vegetation average, albeit with very small differences. The main factor controlling these physiological variables appears to be meso-climatic conditions rather than applications. However, the cumulative effect of small canopy management manipulations becomes more significant when evaluated throughout phenological periods or when the all vegetation period is evaluated as whole.

When photosynthesis (A), transpiration (E) and stoma conductance (g_s) measurements were evaluated on the basis of applications, although there were no significant differences between the applications, the removal of the entire lateral shoots in 2014 positively affected the vine microclimate in terms of these criteria.

Figure 1 shows the measurement values of 2015 photosynthesis (A). When the averages of the measurement days are evaluated as a whole without separating the applications, it is seen that the measurements made on 187th calendar day of 2015 have a higher rate of photosynthesis than the other days with a ratio of 17.63 μmol CO_2 $m^{-2}s^{-1}$. On the same calendar day between 10:00-14:00 meso-climatic measurements mean temperature of 24.60ºC; The highest temperature was 29.50ºC and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_15231538

the lowest temperature was 18.40ºC. The average wind speed was 2.30 m sec^{-1} and relative humidity was recorded as 70.10%, while the illumination intensity is 1902.26 µmol m^2 s^{-1}. The lowest photosynthesis rate for all days on 02.10.2015 was measured as 6.40 µmol CO_2 m^{-2} s^{-1}. On 274th calendar day of 2015, the maximum air temperature was 19.90ºC and the relative humidity was 77.30%. Light intensity was recorded as 44.37 µmol m^2 s^{-1}.

In terms of photosynthesis values, HLS was in the first place in 5 of 9 days in 2015; and in the second place in 2 days. When all measurement days average is evaluated together, this time. FLS application has the highest photosynthesis rate, with a small difference of 12.70 µmol CO_2 m^{-2} s^{-1}.

The highest transpiration (E) value in all days in 2015 was measured as 2.15 mmol m^{-2} s^{-1} under the average temperature of 24.60ºC, average wind speed of 2.30 m s^{-1}, 70.10% relative humidity and 1902.26 µmol m^2 s^{-1} light intensity conditions.

Furthermore, the lowest transpiration (E) value was measured as -0.18 mmol m^{-2} s^{-1} on 215th calendar day of 2015. Today's average temperature was 30.20ºC and the relative humidity was 76.20%. The average wind speed was recorded as 2.20 m s^{-1}.

Although some researchers report that transpiration decreases due to wind speed (Kuiper, 1961; Drake et al., 1970; Dixon and Grace, 1984). General acceptance, evaporation also increased due to the increasing wind speed that increased atmospheric evaporative demand (Mcvicar et al., 2012; Ben Neriah et al., 2014; Schymanski and Or, 2015).

In terms of general application averages, the highest transpiration rate was 1.49 mmol m^{-2} s^{-1} with NLS application which all lateral leaves were taken.

When stoma conductivity (g_s) measurements of 2015 are examined according to the subjects, it is seen that there are no significant differences between the applications and create similar curves with transpiration (E).

Greer (2012) reported that transpiration is strongly related to temperature. It is stated that the rates increase exponentially, especially at temperatures above 35°C, and it is 4 times more than 20°C at 45°C. In our study, when the data for 3 years are examined, it can be said that the relative humidity above 75% decreases the transpiration and increases between 65-70% the relative humidity.

Many studies on grapevine have focused on seeking answers to questions about water use efficiency through photosynthesis (A), transpiration (E), and stoma conductivity (g_s) by different levels of drought stress (Bota et al., 2001; Flexas et al., 2002; Souza et al., 2003; Pou et al., 2008; Zsófi et al., 2009), variety differences (Gibberd et al., 2001; Gaudillère et al., 2002; Tomás et al., 2012) and the effects of rootstocks (Satisha et al., 2006). However, attempting to interpret results over total biomass is problematic due to measurements made from a single leaf.

Photosynthesis is the source of carbohydrate gain in plants; transpiration is also the biggest source of water losses under normal conditions. Discrepancies between WUE leaf and WUE plant may occur due to water losses during the night and daily carbon losses through respiration (Flexas et al., 2010; Schultz and Stoll, 2010).

Must composition and berry maturation

In terms of total soluble solids (TSS) content NLS treatment differs from other lateral shoot applications every 3 years. While the lowest data were obtained from this application with 21.18% in 2013 and 22.42% in 2015, the highest TSS content was observed in 2014 with 21.31% (*Table 5*).

NLS, HLS, and FLS represent none lateral shoots (no leaf), half lateral shoots (3-4 leaves) full lateral shoots (6-7 leaves), MSME means main shoot main effect, LSME means lateral shoot main effect and YME means year main effect. Different lowercase superscript letters in same column and uppercase letters in same line represent statistically significant differences between means at $p < 0.05$ according to least significant difference test. n.s. means not significant

As NLS application stands out with the highest photosynthesis rate in 2014, during the vegetation period, excessive precipitation and high proportional humidity conditions positively affected the physiological activity of the NLS application and accelerated the photosynthetic efficiency and thus the accumulation of dry matter. Therefore, it was seen that the effects of negative climate characteristics can be reduced by manipulations on the canopy at the right time and in the right way.

The results obtained in 2013 and 2015 suggest that increased photosynthesis rates in HLS application also increase the accumulation of TSS.

Korkutal et al. (2017) reported that the complete removal of the lateral leaves increases the total acidity. In our study, the same results were observed in NLS application in 2013, but it was seen in 2014 and 2015 and the mean of all years caused lower total acidity (*Table 5*).

One of the most significant relationships between temperature and berry quality is that high temperatures reduce the concentration of organic acid in the berry (Kliewer, 1973). Organic acid accumulation and degradation at different stages of berry development also show different characteristics (Ford, 2012). Tartaric and malic acids are predominant organic acids in all stages of berry maturation and cause significant effects on must acidity and pH (Morris et al., 1983). In particular, malate is deposited in the berry until the veraison and stored as a potential source for the carbon requirement that occurs during the ripening process (Ruffner, 1982). During this period, the reduction of total acidity due to consumed malic acid balances sugar and acid ratios (Kliewer, 1965).

A similar situation was observed in 2013, NLS application reduced the usefulness of photosynthesis, thus reducing the use of malic acid as a carbon source and the total acidity remained high. Apart from this, no statistical significance was found between the applications and total acidity level for the mean of years. On the other hand, the increase in the length of the main shoot caused an increase of titratable acid in the average of years, but not statistically. Likewise, according to Yasasin et al. (2018), the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_15231538

increase in main shoot length causes a decrease in total acidity, although this is not statistically significant.

pH is a measure of active acidity in must and wine. Therefore. there is a dynamic relationship between pH and acidity. The pH of grape must be one of the critical determinants of wine quality. The exchange of tartaric acid compounds with potassium cations produces water-insoluble potassium bi-tartrates. This leads to a reduction of free acids and tartaric/malic acid ratios and an increase in pH (Kodur, 2011).

In our study, pH values increased in 2013 and 2014 with the decrease of leaf area under the main effect of lateral shoot applications. This change in 2014 is also statistically significant. Although this relationship between manipulations and pH did not occur in the mean of years, it is important to reflect the relationship between variables such as titratable acidity, potassium and the amount of precipitation to which they depend. Lateral shoot manipulations have a statistically significant effect on the amount of sugar per gram every 3 years. The NLS application reached its highest value in 2014 and took the last place in the other years (*Table 6*).

Table 6. *Effects of main shoot and lateral shoot treatments on pH and sugar*

The ideal °Brix/titratable acid ratio range was expressed as 3-4 g L^{-1} by Blouin and Guimberteau (2000). Except for 2014, these values were observed in other years and in different main and lateral shoot applications. 2013 and 2015 were the years with the highest °Brix/titratable acid ratios of 3.87 g L^{-1} and 3.82 g L^{-1}. In 2014 °Brix/titratable acid ratio was calculated as 2.79 g L^{-1}. The mean of years was statistically significant at LSD level of 5%. The main effects of lateral and main shoot applications were not statistically significant except for 2014. In 2014, the NLS application differs from HLS and FLS (*Table 7*).

The mean of years was statistically significant at LSD level of 5% for $pH^2 \times$ °Brix, maturity index. However, the main effects of the applications in 2014 were statistically significant and it is seen that NLS application has brought maturity to an early stage when compared to other two. In 2014, the $pH^2 \times$ °Brix was calculated as 262.98.

According to the maturity index of $pH^2 \times$ °Brix, berries over 260 reach full maturity (Blouin and Guimberteau, 2000). According to this indicator, maturity was reached

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_15231538

every three years and in all applications. The difference between the applications is low and statistically insignificant, but it is determined that small changes in maturity level can be created with different canopy management techniques.

Conclusion

When photosynthesis (A), transpiration (E) and stoma conductivity (g_s) measurements were evaluated together with the climatic conditions of lateral shoot applications; It can be said that the significant differences between the applications are mostly seen in the criteria of average light intensity, relative humidity and average wind speed on some days.

In this sense, the main factor controlling these physiological variables appears to be the meso-climatic climatic conditions. However, the cumulative effect of small microclimatic differences becomes more significant when compared to phenological periods or when the vegetation period is evaluated as a whole.

Relative humidity is more effective than temperature in terms of physiological activity. It can be said that proportional humidity above 75% decreases transpiration and increases proportional humidity between 65-70%. The potential importance of night-time transpiration and the interaction of water use efficiency with regard to plant quality are emerging as new research topics.

It can be said that keeping the leaf areas under control in order to provide sufficient yield/quality balance under the conditions which the experiment is carried out may be a solution. Even in cases where leaf areas are reduced more than normal, there is no shortage of the desired yield with delay in industrial maturity.

Therefore, it is considered that the decrease in leaf areas can be compensated for in terms of yield by arrangements in the internal metabolism of the vine. This shows that unusual canopy management practices that can be performed against unusual climatic conditions (high proportional humidity, high temperature fluctuations, heavy rainy periods, etc.) can be used at certain periods even if not every year.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_15231538

It is seen that NLS application is separated from the others in total soluble solids content every 3 years. While the lowest data were obtained from this application with 21.18% in 2013 and 22.42%. In 2015, the highest TSS was observed in 2014 with 21.31%. In 2014, excessive rainfall and high proportional humidity during the vegetation period positively affected the physiological activity of NLS vines, accelerating the efficiency of photosynthesis and thus the accumulation of dry matter throughout the vine.

In terms of the main shoot lengths, as the shoot length increases, stress and some quality criteria tend to increase, but these effects are generally not statistically significant. Even when the main shoot length is kept at 1m, leaf areas can reach a sufficient level in terms of yield and quality.

Although the applications are effective in terms of quality and physiological activity, seasonal effects of each vegetation period are the main determining factors.

Abstract. Sex identification and composition analysis is an important research topic in fish population ecology, and the results have important implications concerning the conservation of wild fish resources and artificial propagation. However, since the individual morphological differences between male and female spotted steed (*Hemibarbus maculates*) are not obvious, it is usually difficult to identify sex by direct observation. Thus, it is usually done by observing the reproductive system after dissection. However, this method results in the death of the identified fish and cannot be used for later reproduction. To establish a method for sex identification of *H. maculates* by morphological quantitative indicators, 36 directly measured traits and 35 standardized traits from 68 *H. maculates* individuals collected from the Yuanzhou section of the Yuanhe River, China, were measured and analyzed. Based on the data, 13 personalities were screened from the 35 standardized traits by stepwise discriminant method and used to establish discriminant equations. The rate of correctly identifying the male and female individuals was 92.65%. In addition, the condition factor, $D_{7\text{-}9}$, the dorsal fin long-throned length, the post-orbital length, $D_{7\text{-}10}$, the head length, and the body length were significantly different between male and female *H. maculates* (t-test, $P<0.05$). These results implied that the male and female individuals of *H. maculates* could be identified using our established discriminant equations.
Keywords: *aquaculture, artificial propagation, fish, multivariate analysis, morphological discrimination*

Introduction

Sex identification and composition analysis is an important research content in fish population ecology, and the results have important guidance to conservation of wild fish resources and artificial propagation (Chang et al., 2015; Lombardi-Carlson and Andrews, 2015; An et al., 2017). Sex can be distinguished by the differences of body size and secondary sexual characteristics for fish with obvious heteromorphism. However, it is very hard to distinguish the sex for fish that do not have obvious heteromorphism, such as *Acrossocheilus wenchowensis* (Xu et al., 2006), Khanka spiny bitterling (*Acanthorhodeus chankaensi* Dybowsky) (Chen et al., 2013a), and top-mouth culter (*Eryghroculter ilishaeformis*) (Chen et al., 2013b). There are a lot of limitations in the use of anatomical and other sex identification methods, which are not conducive to the protection of studied fish and the implementation of artificial reproduction. Methods that identify male and female individuals by quantitative indicators of body shape characteristics has been successfully applied in many fish, such as elongate ilisha (*Ilisha elongata*) (Ni and Chen, 2003), Japanese eel (*Aniguilla japonica*) (Guo et al., 2011) and spotted scat (*Scatophagus argus*) (Wu et al., 2014). Though the application of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_15391550

discriminant equation that is established according to fish morphological indexes, the accuracy of sex identification can be as high as 85%.

Spotted steed (*Hemibarbus maculatus* Bleeker) is a small freshwater Cyprinidae fish, which is an endemic fish in China. Morphology and population ecology of *H. maculatus* living in different rivers have been studied (Wu et al., 1979; Miao and Yin, 1983; Xie et al., 1988; Fu and Qiao, 2008; Li et al., 2012; Tuo, 2012, 2013; Sun et al., 2014). Lin et al. (2005) report that there is no significant difference in individual size between male and female *H. maculatus* in the Oujiang River. Our previous investigation to *H. maculatus* in the Ganjiang River also shows that there is no obvious difference in individual size between male and female individuals of wild *H. maculatus*. Sexual maturity of male and female *H. maculatus* is not synchronous. Generally, the male fish reach sexual maturity in March, while the female fish reach sexual maturity in April or May. The parasexual characteristics of mature male fish lasted for a short time, and were obvious in March, but not in April and May. In addition, the abdominal bulge of the male fish is similar to that of females due to a large amount of food intake. Therefore, sex of *H. maculatus* cannot be identified directly from its morphological characteristics, which is not conducive to carrying out population ecology investigation and artificial reproduction. Therefore, to solve the problem of sex identification and provide reference for the study of population ecology and artificial reproduction of *H. maculatus*, in the present study, we systematically analyzed the morphological indexes of *H. maculatus* in the Ganjiang River, and established a sex identification model of *H. maculatus*.

Materials and Methods

Sample collection

H. maculatus samples were collected from the Yuanzhou section of the Yuanhe River using screen meshes and floor cages from December 2010 to June 2012 (113°54′-114°37′ E, 27°33′-28°05′ N; *Fig. 1*). The Yuanhe River is a breach of the Ganjiang River. Fresh samples were placed in containers with oxygen pump, which can continuously oxygenate, and were quickly transport to the laboratory. The fish samples were anaesthetized using anesthetic MS-222 (50 mg/L) for 3-5 min before morphological measure and dissecting for sex identification. All experiments were carried out in accordance with the Animal Ethics Committee of Hunan Agricultural University.

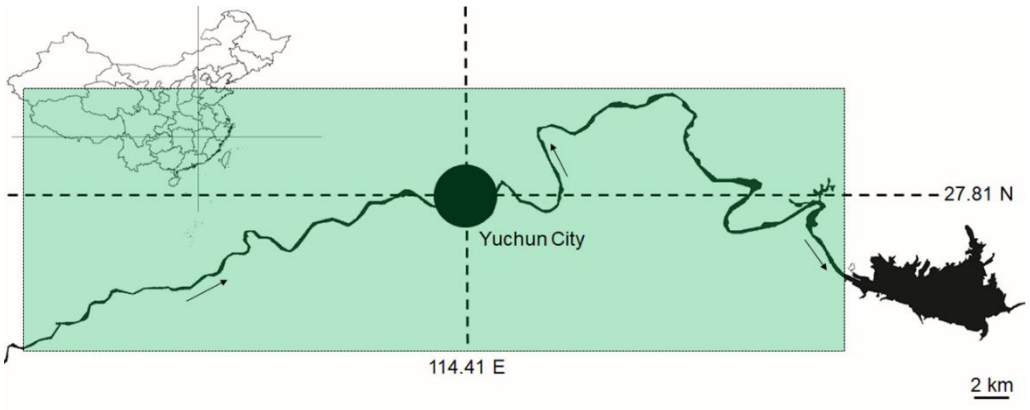

Figure 1. *Map shows sampling area. The green rectangular area shows the range of sampling section of the river. The black arrows indicate the direction of water flow*

DOI: http://dx.doi.org/10.15666/aeer/1801_15391550

Measurement of morphological indicators

Body length *(BL)*, head length (*HL*), head width (*HW*), head height (*HH*), snout length (*SL*), post-orbital length (*PL*), eye diameter (*ED*), interorbital width (*IW*), mouth width (*MW*), mouth length (*ML*), body highness (*BH*), pectoral fin length (*PFL*), Caudal fin length (*CFL*), distance between pelvic fin and anal fin (*PAFD*), and dorsal fin long-throned length (*DFL*) were measured using rulers and vernier calipers according to previous description (Fish Research Laboratory of Hubei Institute of Hydrobiology, 1976; Lin et al., 2005). The lengths were accurate to two decimal places. Sex glands were dissected and sex was identified by naked eyes. Fish body weight (*W*), gonad weight (W_g), and shell weight (W_0) were weighed by an electronic balance. The weights were accurate to two decimal places. The condition factor (*K*) was calculated as follows,

$$K = 100 \times (W/BL^3) \quad \text{(Eq.1)}$$

where *W* was body weight, and *BL* was body length.

Ten coordinate points were set up on the surface of fish based on the truss network theory (*Fig. 2A*), according to previous reports (Strauss and Bookstein, 1982; Corti et al., 1988; Bookstein, 1997). A total of 21 truss network measurement traits were measured, including $D_{1\text{-}2}$, …, and $D_{9\text{-}10}$. The measured distance of truss network structure was the straight-line distance between two points (*Fig. 2B*).

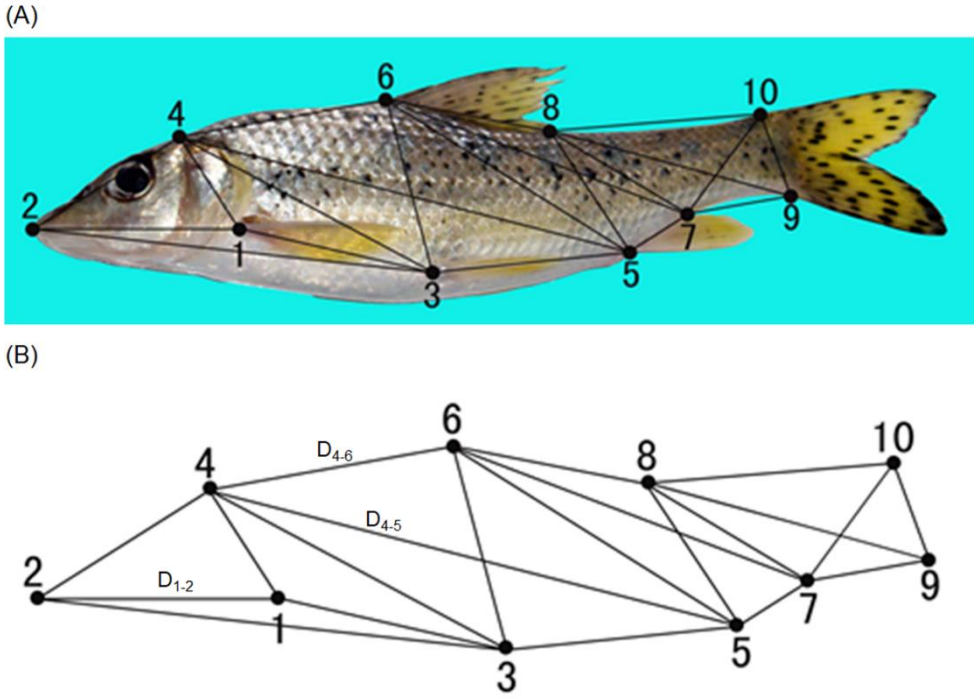

Figure 2. *Schematic measuring points based on the truss network (A) and representation examples of the distances between points (B)*

Data analysis

Data were recorded using Excel 2003 and analyzed using Statistica 10. Date are expressed as mean ± standard deviation (S.D.). In the present study, we analyzed three

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_15391550

types of data, i.e. (1) data from traditional morphological indices, (2) data from truss network indices, and (3) data combing traditional morphological indices with truss network indices. Considering fish size is influenced by the age of fish, we also analyzed the traditional morphological data and truss network indices using three data transformed modes, i.e., ratio:

$$M_{adj} = M/SL \quad \text{(Eq.2)}$$

logarithmic ratio:

$$M_{adj} = logM/logSL \quad \text{(Eq.3)}$$

and logarithmic heterocorrelation index (*ALLOM*):

$$M_{adj} = logM - b(logSL - logSL_{mean}) \quad \text{(Eq.4)}$$

according to previous reports (Turan, 1999; Turan et al., 2004; Pinheiro et al., 2005). Where M is the local characteristic measurements of each specimen, SL is the body length of each specimen, SL_{mean} is the mean body length of male or female fish, and b is the slope of linear regression of $log_{10}M$ and $log_{10}SL$.

Index of sexual heteromorphism (I_{sh}) was calculated as follows (Gibbons and Lovich, 1990; Shou et al., 2005),

$$I_{sh} = 1 - BL_{mean.sbs}/BL_{mean.lbs} \quad \text{(Eq.5)}$$

where I_{sh} is the index of sexual heteromorphism, $BL_{mean.sbs}$ is mean body length of the gender with smaller body size, and $BL_{mean.lbs}$ is mean body length of the gender with larger body size. *Student's t* test was used to compare the body length and 35 morphological parameters of male and female individuals. The significant level was set to $p = 0.05$.

A comprehensive index with the largest eigenvalue vector was selected from 35 directly measured characteristic parameters, and the principal component with a larger contribution rate was determined, then the principal component analysis (PCA) profile was drawn. R-cluster analysis was conducted based on the Pearson correlation coefficient. Stepwise regression method was used to further analyze and screen the characteristics with significant differences between male and female individuals, and the discriminant equations of male and female *H. maculatus* were established.

Results

Heteromorphism of male and female H. maculatus

A total of 68 *H. maculatus* samples were collected. The *BL*s of female *H. maculatus* were range from 11.00 to 26.90 cm (17.88 ± 3.91 cm), which were larger than those of male *H. maculatus* (range from 11.60 to 21.60 cm, 15.82±3.25 cm; *Table 1*). The I_{sh} was 0.126. The individual size of male and female *H. maculatus* samples were significantly different (t-test, t = -2.36, P=0.021; *Table 1*). The morphological parameters were positively correlated with the body length (*Appendix 1*). The correlation coefficients were range from 0.278 to 0.903. After logarithmic heterodyne transformation according to the

DOI: http://dx.doi.org/10.15666/aeer/1801_15391550

equation *Eq.4*, the $D_{7\text{-}9}$, and $D_{7\text{-}10}$ of males were significantly higher than those of females (t-test, $P < 0.05$). The *K*, *HL*, *PL*, and *DFL* of females were significantly higher than those of males (t-test, $P < 0.05$). There was no significant difference in other local characteristics between the sexes (*Table 1*).

Except BL, other morphological parameters were logarithmically heterodyne transformed. Date are expressed as mean ± S.D. (cm). Transformation variables are compared with t-test. BL, body length; HL, head length; ED, eye diameter; PL, post-orbital length; DFL, dorsal fin long-throned length; K, condition factor; HH, head height; HW, head width; SL, snout length; IW, interorbital width; BH, body highness; ML, mouth length; PFL, pectoral fin length; CFL, caudal fin length; PAFD, Distance between pelvic fin and anal fin

Correlations between morphological characteristic variables of H. maculatus

The first three principal components of 35 morphological characteristics of *H. maculatus* explained 85.17% of variation (*Table 2*). *BL*, $D_{1\text{-}2}$, $D_{1\text{-}3}$, $D_{2\text{-}3}$, $D_{5\text{-}6}$, $D_{9\text{-}10}$, $D_{4\text{-}6}$, $D_{6\text{-}7}$, and *HL* had higher positive load coefficients in the first principal component (explaining 75.93% of variation). *K* had a higher positive load coefficient in the second principal component (explaining 6.40% of variation). *HL* had a higher positive load

Variables with major contributions from each principal component are indicated in bold. BL, body length; HL, head length; ED, eye diameter; PL, post-orbital length; DFL, dorsal fin long-throned length; K, condition factor; HH, head height; HW, head width; SL, snout length; IW, interorbital width; BH, body highness; ML, mouth length; PFL, pectoral fin length; CFL, caudal fin length; PAFD, Distance between pelvic fin and anal fin

The results of R-cluster analysis of 35 morphological parameters by heterocorrelation transformation showed that the standardized relative traits were divided into two branches. The first branch contained D_{1-2}, …, D_{9-10}, and *K*, which represented body shape and lean characteristic parameters; and the second branch contained *HL*, *HH*, *HW*, *SL*, *IW*, *ED*, and *IDL*, which mainly represented the head traits of *H. maculatus* (*Fig. 3B*).

Sex discrimination based on quantitatively morphological characteristics

The comprehensive discriminant rate based on the traditionally morphological data was 83.82%. (Male: 88.57%; Female: 78.79%). The comprehensive discriminant rate based on the truss network data was 91.18% (Male: 97.14%; Female: 84.85%). The comprehensive discriminant rate based on the integrated data of traditionally morphological characteristics and truss network characteristics was 98.53% (Male: 100%; Female: 96.97%). The comprehensive discriminant rates based on the three data transfer methods of the integrated data of traditionally morphological characteristics and truss network characteristics was 82.35% for ratio (Male: 80%; Female: 84.85%), 88.24% for logarithmic ratio (Male: 94.29%; Female: 81.82%), and 92.65% for ALLOM (Male: 1.43%; Female: 93.94%), respectively.

The discriminant formulas for male and female of *H. maculatus* were constructed as follows based on the 13 morphological parameters (i.e. *K*, *DFL*, $D_{7\text{-}9}$, *IW*, $D_{3\text{-}6}$, $D_{4\text{-}6}$, *BH*, *HL*, $D_{8\text{-}9}$, $D_{6\text{-}8}$, $D_{3\text{-}4}$, $D_{5\text{-}8}$, and $D_{3\text{-}5}$) after the logarithmic heterocorrelation transformation that were screened by stepwise regression,

$$\begin{aligned} Y_1 = {} & -1857.66 - 27.39K - 320.14DFL + 860.03D_{7-9} \\ & - 385.12\,IW + 235.83D_{3-6} - 436.43D_{4-6} \\ & - 21.39BH + 3527.74\,HL + 582.19D_{8-9} \\ & - 1391.47D_{6-8} + 1491.79D_{3-4} + 717.05D_{5-8} \\ & - 232.48D_{3-5} \end{aligned} \quad \text{(Eq.6)}$$

$$\begin{aligned} Y_2 = {} & -1960.26 - 33.16K - 355.13DFL + 904.87D_{7-9} \\ & - 350.58IW + 258.83D_{3-6} - 474.59D_{4-6} \\ & - 58.20BH + 3644.81HL + 603.11D_{8-9} \\ & - 1446.06D_{6-8} + 1538.12D_{3-4} + 757.36D_{5-8} \\ & - 246.62D_{3-5} \end{aligned} \quad \text{(Eq.7)}$$

DOI: http://dx.doi.org/10.15666/aeer/1801_15391550

If $Y_1 > Y_2$, the fish was male, otherwise it was female. The significance test of the discriminant function shows that the discriminant function has reached the extremely significant level ($F_{(13, 54)} = 9.2441$, $P < 0.001$). The frequency distribution of each individual's discriminant scores also showed that the model could distinguish male and female *H. maculates* (*Fig. 4*). The sixty-eight individuals were judged by the sex discrimination equations (*Eq.6* and *Eq.7*), and anatomical verification, only 5 (7.35%) fish individuals had misjudged sex by the sex discrimination equations. The accuracy rate was 92.65% (*Table 3*).

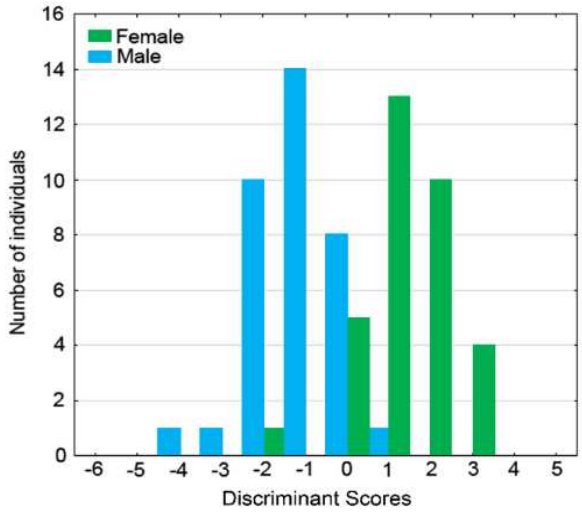

Figure 4. *Frequency distribution of discriminant scores of male and female H. maculatus*

Table 3. *Discriminant analysis results of the stepwise discriminant function analysis based on the standardized morphological data of H. maculatus*

Sex	Histologic identification	Predicted result		Accuracy of discrimination (%)	Total discrimination accuracy (%)	Transformations*
		Male	Female			
Male	35	28	7	80	82.35	*M* / *SL*
Female	33	5	28	84.85		
Male	35	33	2	94.29	88.24	*logM* / *logSL*
Female	33	6	27	81.82		
Male	35	32	3	91.43	92.65	*logM* - *b*(*logSL* - $logSL_{mean}$)
Female	33	2	31	93.94		

* M is the local characteristic measurements of each specimen, SL is the body length of each specimen, SL_{mean} is the mean body length of male or female fish, and b is the slope of linear regression of $\log_{10}M$ and $\log_{10}SL$

Discussion

Sexual heteromorphism of individuals is generally interpreted as the result of a combination of sexual selection, fertility selection, and ecological selection (Emlen and Oring, 1977; Lande, 1980; Hedrick and Temeles, 1989). There are three main types of sexual heteromorphism of fish individual size, i.e. female adult is larger than male adult, female adult is smaller than male adult, and the size of male and female individuals is similar (Parker, 1992; Pyron, 1996; Erlandsson and Ribbink, 1997). Lin et al. (2005)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1801_15391550

report that the individual size of *H. maculatus* in the Oujiang River is no significant difference between male and female individuals, while female adults of *H. maculatus* in the Yuanhe River are significantly larger than male adults. This result indicates that the ecological factors from different habitats could influence the heteromorphism of individual size of *H. maculatus*. The difference of local morphological characteristics between males and females showed that the male of *H. maculatus* in the Yuanhe River had larger tail stalk than female, in consistent with eleotrid goby (*Odontobutis obscurus*) (Fan et al., 2009), and catfish (*Clarias fuscus*) (Fan et al., 2014).

The results of PCA and R-cluster analysis showed that the morphologic differences of male and female *H. maculatus* in the Yuanhe River mainly concentrated in three aspects: fish body shape, *K*, and head shape, which was basically consistent with the results of *I. Elongata* (Ni and Chen, 2003) and *S. argus* (Wu et al., 2014).

Integration of the traditionally morphological indicators and the truss network data could significantly improve the accuracy of sex discrimination of *H. maculatus*, which was consistent with the reports of blunt snout bream (*Megalobrama amblycephala*) (Li et al., 1991). The *ALLOM* data transformation method has the highest accuracy for male and female discrimination of *H. maculatus* in Yuanhe River, with a comprehensive recognition rate of 92.65%. It should be further verified whether the transformation method could improve the accuracy in other fish.

Conclusion

In conclusion, a quantitatively morphological discriminant model for identifying male and female *H. maculates* was established in the present study. The accuracy rate of *H. maculates* discrimination between male and female was 92.65% using logarithmic heterocorrelation method to transform the quantitatively morphological data. However, automatic identification system based on the model needs to further develop to speed up the identification of male and female *H. machlates*. The best sex ration for artificial propagation of *H. machlates* also needs to further study.
